In the future, several optimization algorithms can be employed to enhance the performance of the proposed deepfake video detection method. Furthermore, a huge multimodal video dataset may be utilized to improve the detection method's performance.

# Three on Three Optimizer: A New Metaheuristic with Three Guided Searches and Three Random Searches

Purba Daru Kusuma, Ashri Dinimaharawati  
Computer Engineering, Telkom University, Bandung, Indonesia

**Abstract**—This paper presents a new swarm intelligence-based metaheuristic called a three-on-three optimizer (TOTO). This name is chosen based on its novel mechanism in adopting multiple searches into a single metaheuristic. These multiple searches consist of three guided searches and three random searches. These three guided searches are searching toward the global best solution, searching for the global best solution to avoid the corresponding agent, and searching based on the interaction between the corresponding agent and a randomly selected agent. The three random searches are the local search of the corresponding agent, the local search of the global best solution, and the global search within the entire search space. TOTO is challenged to solve the classic 23 functions as a theoretical optimization problem and the portfolio optimization problem as a real-world optimization problem. There are 13 bank stocks from Kompas 100 index that should be optimized. The result indicates that TOTO performs well in solving the classic 23 functions. TOTO can find the global optimal solution of eleven functions. TOTO is superior to five new metaheuristics in solving 17 functions. These metaheuristics are grey wolf optimizer (GWO), marine predator algorithm (MPA), mixed leader-based optimizer (MLBO), golden search optimizer (GSO), and guided pelican algorithm (GPA). TOTO is better than GWO, MPA, MLBO, GSO, and GPA in solving 22, 21, 21, 19, and 15 functions, respectively. It means TOTO is powerful to solve high-dimension unimodal, multimodal, and fixed-dimension multimodal problems. TOTO performs as the second-best metaheuristic in solving a portfolio optimization problem.

**Keywords**—*Optimization; metaheuristic; swarm intelligence; portfolio optimization; Kompas 100; bank*

## I. INTRODUCTION

Many real-world problems can be seen as optimization problems. This circumstance comes from the nature of human behavior or activity in achieving their objective most efficiently. Ironically, people always find certain limitations or constraints. This consideration is the same as the optimization work. In general, optimization is constructed by two elements: objective and constraint. In the optimization problem, many solutions can be chosen in the solution space. However, some solutions are better than others. One solution that is the best one is called the optimal global solution.

The objective of optimization can be minimization or maximization. In the minimization, the optimal global solution is the solution with the lowest value. Some experimental parameters in the minimization, such as delay [1], total order completion time [2], idle time [2], tardiness cost and maintenance [3], project duration [4], energy consumption [5], transmission losses [6], and so on. On the other hand, in

maximization, the optimal global solution is the solution with the highest value. Some parameters in the maximization are profit [7], voltage stability [6], revenue [8], service level [9], and so on.

Two ways can be chosen to solve the optimization problem. These methods are a mathematical method and a metaheuristic [10]. The mathematical method is robust in solving a simple optimization problem. It guarantees finding the optimal global solution. However, the mathematical or deterministic method often fails to solve a complex optimization problem, such as a non-convex or multimodal problem. Moreover, the mathematical method is less flexible in facing various real-world optimization problems [11].

On the other hand, metaheuristic is widely used in many optimizations. Metaheuristics have several advantages. First, it is flexible enough to be implemented in various problems because it focuses on the objectives and constraints [10]. Second, it can be implemented in an environment with limited computational resources because of its approximate approach so that not all possible solutions are traced [12]. This approximate approach comes with the consequence that metaheuristic does not guarantee finding the optimal global solution.

There are hundreds of metaheuristics developed in recent decades. Moreover, many metaheuristics have been developed in recent years. Many of them used metaphors for their name. Many of these shortcoming metaheuristics were inspired by animal behavior, such as the butterfly optimization algorithm (BOA) [13], chameleon swam algorithm (CSA) [14], coati optimization algorithm (COA) [15], Komodo mlipir algorithm (KMA) [16], northern goshawk optimizer (NGO) [17], raccoon optimization algorithm (ROA) [18], marine predator algorithm (MPA) [19], Tasmanian devil optimizer (TDO) [11], snake optimizer (SO) [10], white shark optimizer (WSO) [20], guided pelican algorithm (GPA) [21], and so on. Some metaheuristics were inspired by the mechanics of plants, such as the tunicate swarm algorithm (TSA) [22], flower pollination algorithm (FPA) [23], and so on. Some metaheuristics are named based on their references in their guided search, such as three influential member-based optimizers (TIMBO) [24], mixed leader-based optimizers (MLBO) [25], multi-leader optimizers (MLO) [26], random selected leader-based optimizer (RLSBO) [27], and so on. Some metaheuristics were inspired by human activities, such as stochastic paint optimizer (SPO) [28], modified social forces algorithm (MSFA) [29], driving training-based optimizer (DTBO) [30], and so on. Some metaheuristics were free from metaphor and named based on

their central concept, such as average subtraction-based optimizer (ASBO) [31], golden search optimizer (GSO) [32], total interaction algorithm (TIA) [33], and so on.

Many early metaheuristics depend on a single strategy to find the optimal solution to problems. Unfortunately, as mentioned in the no-free-lunch theory, no metaheuristics can solve all optimization problems [34]. A search may be excellent for solving some optimization problems [34]. Meanwhile, the performance of this search may need to improve in solving other optimization problems. This circumstance gives strong motivation to develop multi search-based metaheuristic. Many shortcomings in metaheuristics were built by accommodating multiple searches in every iteration. Moreover, this multiple search strategy is proven better in solving an optimization problem. However, adding more searches in a single metaheuristic can increase the algorithm complexity and, in the end, the computational resources.

Many existing swarm-based metaheuristics depend more on the guided search than the random one. In some metaheuristics like KMA [16] or COA [15], segregation of roles is implemented in the population. It means that some agents implement segregation of roles while some other agents do not implement segregation of roles. A more guided search is deployed in many swarm-based metaheuristics with multiple searches. Some metaheuristic deploys neighborhood search only or does not implement any random search. Meanwhile, random search is essential in tackling the local optimal entrapment often found in multimodal problems.

Based on this problem and motivated by the no-free-lunch theory, this paper is aimed to propose a new swarm-based metaheuristic with multiple searches where there is a balance between the guided search and the random search. This proposed metaheuristic is named a three-on-three optimizer (TOTO). This name represents the six searches adopted in this metaheuristic. Three searches are guided searches, while three other searches are random.

The scientific contributions of this paper are listed as follows.

- 1) This paper proposes a new swarm-based metaheuristic with multiple searches within this metaheuristic.
- 2) This paper proposes a balanced proportion between the guided search and random search in every iteration.
- 3) The evaluation is performed by benchmarking the performance of the proposed TOTO with five shortcoming metaheuristics: GWO, MPA, MLBO, GSO, and GPA.
- 4) The benchmark test to evaluate the proposed metaheuristic in solving the classic 23 functions and the comparison with other shortcoming metaheuristics is carried out as a proof of concept regarding the significant performance of TOTO.
- 5) The stock optimization problem is chosen as evaluation of the proposed TOTO in solving real-world optimization problem in financial sector and comparison with other metaheuristics.

The remainder of this paper is arranged as follows. The investigation of several shortcomings of metaheuristics is carried out in section two. This investigation includes the mechanics adopted in these metaheuristics and the position of this work to make the novelty and contribution of this work clear. A detailed presentation of the proposed metaheuristic can be found in section three. This presentation includes the concept, algorithm, mathematical model, and algorithm complexity. The test carried out in this work regarding the evaluation of the proposed metaheuristic is presented in section four. The investigation of the result and findings are explored in section five. Finally, the conclusion and the opportunity for future works are summarized in section six.

## II. RELATED WORKS

Metaheuristics have been evolving for decades. Early metaheuristics are simple with a single strategy. In general, they deploy neighborhood search with some strategy to avoid the local optimal. Simulated annealing (SA) and tabu search (TS) are examples of metaheuristics that adopt a simple neighborhood search with a distinct approach to tackling the optimal local problem. In simulated annealing, some probabilistic calculations can still accept a worse solution, where the acceptance becomes more difficult as the iteration goes [35]. Meanwhile, tabu search uses some list to avoid old solutions will be revisited for a certain period [36].

The evolution goes with the development of population-based metaheuristics. Genetic algorithm (GA) and invasive weed optimizer (IWO) are clear examples of these metaheuristics. Population-based metaheuristics give two main advantages. First, they improve the solution faster than the single solution-based metaheuristics. Second, they give broader tracing within the search space. GA has a simple solution in improving the solution by implementing a crossover strategy between two solutions and mutation for exploration [37]. In IWO, multiple new solutions are generated around every existing solution based on normal distribution [38]. Then, all solutions are ranked, and the worse ones are eliminated [38].

The evolution continues with the introduction of a swarm-based metaheuristic. A particle swarm optimizer (PSO) is an example of an early swarm-based metaheuristic. In the swarm-based metaheuristic, each solution can be seen as an autonomous agent that does not have centralized coordination. However, specific interaction and collective intelligence are conducted to help the improvement. As a member of the swarm, each agent conducts a guided search. It means each agent moves in a specific direction, called a guided search toward some references. As an early swarm-based metaheuristic, PSO deploys a simple strategy. In PSO, each agent moves toward the reference at a certain speed [39]. Its references are the combination between the local best solution and the global best solution [39].

In recent decades, the development of swarm-based metaheuristics is more extensive. Various aspects can be used as a baseline for developing new swarm-based metaheuristics. These aspects include reference, stochastic movement, acceptance rejection, segregation of roles, etc. Moreover, many shortcomings of metaheuristics deploy multiple strategies rather than a single strategy to improve its quality in achieving

a better final solution or achieving the objective faster. This multiple strategy/search approach is carried out in a single or multiple phases. Some metaheuristics are also equipped with random search to avoid the convergence achieved faster and

trapped in the local optimal. A detailed review of shortcoming swarm-based metaheuristics is presented in Table I. The mechanics of the proposed metaheuristic is presented in the last row to make a clear position and contribution of this work.

TABLE I. DETAIL SUMMARY OF SEVERAL SHORTCOMING METAHEURISTIC

No	Metaheuristic	Number of Phases	Number of Searches	Guided Searches	Random Searches	Segregation of Roles
1	COA [15]	2	3	searching toward the best solution in the current iteration; searching toward a randomly solution within the search space	searching around the local search space	yes
2	MSFA [29]	1	2	searching toward a target where the target is a random solution within the search space	searching around the local search	no
3	CSA [14]	3	4	searching toward the gap between the local best solution and global best solution; searching toward the mixture between the global best solution and local best solution	searching within the search space; searching within the local search space;	yes
4	KMA [16]	1	4	searching toward the resultant of several best solutions; searching toward the resultant of several better best solutions and avoiding the resultant of several worse best solutions; and searching toward the best solution in the current iteration.	searching within the search space	yes
5	SO [10]	2	4	searching of the best solution to avoid the corresponding solution; searching toward the best solution in different group; searching toward a solution outside the group with same index	searching within the search space	yes
6	ASBO [31]	3	3	searching relative to the average between the best and worst solutions in the current iteration; search toward the gap between the best and worst solutions in the current iteration; searching toward the gap between the corresponding solution and the best solution	-	no
7	TIA [33]	1	1	searching relative to all other solutions in the population	-	no
8	WSO [20]	2	3	searching toward the mixture between the global best solution and local best solution; searching of the best solution to avoid the corresponding solution.	searching between the previous solution and its new guided search.	yes
9	GSO [32]	1	1	searching toward the mixture between the local best solution and the global best solution	-	no
10	NGO [17]	2	2	searching toward a randomly selected solution	search within the local search space.	no
11	GPA [21]	1	2	searching toward the global best solution	searching within the local search space	no
12	MLBO [25]	1	1	searching toward the mixture between the best solution in the current iteration and a randomly selected solution	-	no
13	TIMBO [24]	3	3	searching toward the best solution in the current iteration; searching to avoid the worst solution in the current iteration; and searching relative to the mean member in the current iteration	-	no
14	SPO [28]	1	4	searching toward adjacent solutions; searching toward the gap between a solution from the primary group and a solution from the tertiary group; searching toward the average among a solution from each group; and searching toward the average of a solution from each group plus a randomly selected solution	-	no
15	RSLBO [27]	1	1	searching toward a randomly selected solution	-	no
16	this work	1	6	searching toward the global best solution; searching of the global best solution to avoid the corresponding solution; searching relative to a randomly selected solution;	searching within the local search space of the corresponding solution; searching within the local search space of the global best solution; searching within the search space	no

Table I indicates the limitations of the existing swarm-based metaheuristics. First, many swarm based metaheuristics prioritize guided search rather than random search. Second, some swarm-based metaheuristics deploys only one random search while some others do not deploy any random search. Third, searching methods implemented in every metaheuristic are still less than five methods. Fourth, these multiple searches are performed in the multiple phase process. Based on this circumstance, there is a room in developing swarm-based metaheuristic that deploys multiple searches and puts the balance between guided search and random search as in this work.

### III. PROPOSED MODEL

TOTO is a swarm-based metaheuristic with multiple strategies in every iteration. The multiple-strategy approach aims to cover each strategy's disadvantages because each has its strengths and weaknesses. The multiple strategy approach is interpreted by conducting six searches by each agent in every iteration. It means that these searches are mandatory for each agent. In other words, TOTO does not implement segregation of roles. It differs from other metaheuristics, such as RDA, KMA, or SKA, where the segregation of roles is implemented among the population. These searches are three guided searches and three random searches. Each search generates a candidate. Then, the best candidate among these six candidates is chosen as the selected candidate to be compared with the corresponding agent. If this candidate is better than the current solution of the corresponding agent, this candidate becomes the replacement as a new solution for the corresponding agent. This mechanism is also different from some metaheuristics, such as DTBO, GPA, NGO, and so on, where the searches are conducted sequentially. This new solution is then compared with the current global best solution. If this new solution is better than the global best solution, then the global best solution is updated.

The global best solution and a randomly selected agent become the reference in these three guided searches. In the first guided search, a candidate is generated based on the movement of the corresponding agent toward the best global solution. In

the second guided search, a candidate is generated based on the movement of the global best solution avoiding the corresponding solution. In the third guided search, a candidate is generated based on the movement of the corresponding agent relative to a randomly selected agent. If the randomly selected agent is better than the corresponding agent, then the third candidate is generated based on the movement of the corresponding agent toward the randomly selected agent. Otherwise, the third candidate is generated based on the movement of the corresponding agent, avoiding the randomly selected agent.

The local search space is used for the first and second random searches. On the other hand, local search space is not needed in the third random search. The local search space width declines linearly due to the increase in the iteration. In the first random search, a candidate is generated within the local search space of the corresponding agent. In the second search space, a candidate is generated within the local search space of the global best solution. A candidate is generated within the search space in the third random search. The illustration of these six searches is presented in Fig. 1.

Based on the previous explanation, the rationale of the proposed strategy is highlighted and summarized as follows.

- The multiple searches are proven better than single search as the multiple search approach is adopted in various shortcoming metaheuristics.
- The balance between the guided searches and random searches is designed to give balance between exploration capability and exploitation capability.
- Multiple references are adopted to expand the searching capability because searching process cannot depend on only single reference.
- The strict acceptance-rejection approach is adopted to avoid the searching process moves to the worse solution or area.

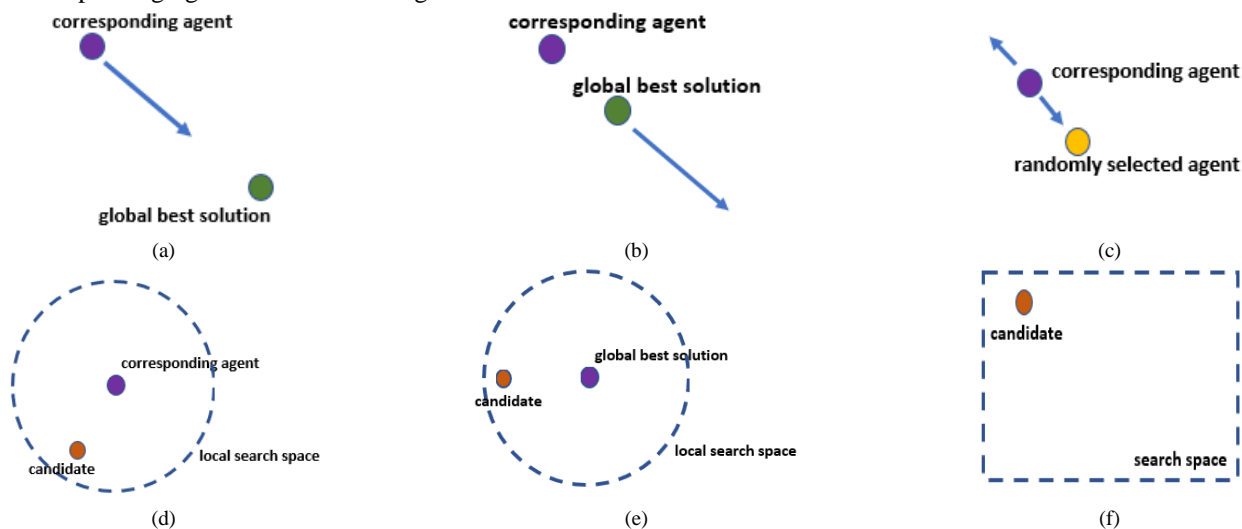

Fig. 1. Illustration of six searches in TOTO: (a) First guided search, (b) Second guided search, (c) Third guided search, (d) First random search, (e) Second random search, and (f) Third random search.

The algorithm of TOTO is then constructed based on its main concept as the formalization of this metaheuristic. This algorithm is presented in algorithm 1. Equation (1) to (11) is used as formalization of the related process. The annotations used in this paper are as follows.

$a$	agent
$A$	set of agents
$a_{best}$	global best agent
$a_{sel}$	randomly selected agent
$a_l$	lower boundary
$a_u$	upper boundary
$c_1$	first candidate
$c_2$	second candidate
$c_3$	third candidate
$c_4$	fourth candidate
$c_5$	fifth candidate
$c_6$	sixth candidate
$c_{sel}$	selected candidate
$f$	fitness function
$r_1$	real uniform random number between 0 and 1
$r_2$	integer uniform random number between 1 and 2
$r_3$	real uniform random number between -1 and 1
$t$	iteration
$t_{max}$	maximum iteration
$u$	uniform random

**algorithm 1:** main algorithm of TOTO

```

1  Begin
2  for all  $a$  in  $A$ 
3    generate  $a$  using (1)
4    update  $a_{best}$  using (2)
5  end for
6  for  $t = 1$  to  $t_{max}$ 
7    for all  $a$  in  $A$ 
8      first guided search using (3)
9      second guided search using (4)
10     third guided search using (5) and (6)
11     first random search using (7)
12     second random search using (8)
13     third random search using (9)
14     choose  $c_{sel}$  using (10)
15     update  $a$  using (11)
16     update  $a_{best}$  using (2)
17   end for
18 end for
19 end

```

$$a = U(a_l, a_u) \quad (1)$$

$$a_{best}' = \begin{cases} a, & f(a) < f(a_{best}) \\ a_{best}, & \text{else} \end{cases} \quad (2)$$

$$c_1 = a + r_1(a_{best} - r_2a) \quad (3)$$

$$c_2 = a_{best} + r_1(a_{best} - r_2a) \quad (4)$$

$$a_{sel} = U(A) \quad (5)$$

$$c_3 = \begin{cases} a + r_1(a_{sel} - r_2a), & f(a_{sel}) < f(a) \\ a + r_1(a - r_2a_{sel}), & \text{else} \end{cases} \quad (6)$$

$$c_4 = a + r_3 \left(1 - \frac{t}{t_m}\right) (a_u - a_l) \quad (7)$$

$$c_5 = a_{best} + r_3 \left(1 - \frac{t}{t_m}\right) (a_u - a_l) \quad (8)$$

$$c_6 = a_l + r_1(a_u - a_l) \quad (9)$$

$$c_{sel} = c \in C, \min(f(c)) \quad (10)$$

$$a' = \begin{cases} c_{sel}, & f(c_{sel}) < f(a) \\ a, & \text{else} \end{cases} \quad (11)$$

The explanation of (1) to (11) is as follows. Equation (1) states that the initial solution is randomized within the search space. Equation (2) states that the global best solution is updated by comparing the current value of the global best solution and the new value of the corresponding agent. If the corresponding agent is better than the global best solution, then the corresponding agent replaces the current global best solution. Equation (3) states that the candidate of the first guided search is generated based on the movement of the corresponding agent toward the global best solution. Equation (4) states that the candidate of the second guided search is generated based on the movement of the global best solution avoiding the corresponding agent. Equation (5) states that an agent is randomly selected among the population. Equation (6) states that the candidate of the third guided search is generated based on the movement of the corresponding agent relative to a randomly selected agent. Equation (7) states that the candidate of the first random search is generated based on the neighborhood search around the corresponding agent. Equation (8) states that the candidate of the second random search is generated based on the neighborhood search around the global best solution. Equation (9) states that the candidate of the third random search is generated based on the constant random search within the search space. Equation (10) states that the best candidate among these six candidates is selected to be compared with the corresponding solution. Equation (11) states that this candidate replaces the corresponding solution if this candidate is better than the corresponding solution.

The algorithm complexity of TOTO is presented as  $O(6t_{max}.n(A))$ . Based on this presentation, the complexity of TOTO is affected by two parameters: maximum iteration and population size. Each parameter has a linear proportion to the complexity.

#### IV. SIMULATION AND RESULT

This section discusses the performance analysis regarding the proposed metaheuristic. Some optimization tests are carried out due to provide the performance data. The first test is carried out to evaluate the performance of TOTO in solving classic 23 functions. These functions are standard as benchmark tests in many works proposing new metaheuristics. These functions consist of seven high dimension unimodal functions (Sphere, Schwefel 2.22, Schwefel 1.2, Schwefel 2.21, Rosenbrock, Step, and Quartic), six high-dimension multimodal functions (Schwefel, Rastrigin, Ackley, Griewank, Penalized, and Penalized 2), and ten fixed dimension multimodal functions (Shekel Foxholes, Kowalik, Six Hump Camel, Branin, Goldstein-Price, Hartman 3, Hartman 6, Shekel 5, Shekel 7, and Shekel 10). The second test is carried out to analyze the

hyperparameters of TOTO. The third test is carried out to evaluate the performance of TOTO in solving the practical optimization problem. The third test is carried out to evaluate the performance of TOTO in solving a real-world optimization problem. The portfolio optimization problem is chosen as the use case in this work.

The first test compares TOTO with five shortcoming swarm-based metaheuristics: GWO, MPA, MLBO, GSO, and GPA. GWO and MPA are older than the others but widely used in various optimization works. On the other hand, MLBO, GSO, and GPA are newer, but the use of these metaheuristics is still rare.

Several parameters regarding the first test are set as follows. The population size is 10. The maximum iteration is 50. The problem dimension is 50. The fishing aggregate devices for MPA are 0.5. The number of candidates for GPA is 5. The result is presented in Table II. The average fitness score, less than  $10^{-4}$ , is rounded to the nearest  $10^{-4}$  value. The best score in every function is presented in bold font. The cluster-based comparison is presented in Table III.

Table II indicates the excellent performance of TOTO in solving the 23 classic functions and competing with five other metaheuristics. The result presents that TOTO can find the

optimal global solution of eight functions (Sphere, Schwefel 2.22, Schwefel 2.21, Rastrigin, Ackley, Six Hump Camel, and Goldstein-Price). Moreover, TOTO also performs as the best metaheuristics in solving 17 functions. Seven high-dimension unimodal functions (Sphere, Schwefel 2.22, Schwefel 1.2, Schwefel 2.21, Rosenbrock, Step, and Quartic), five high-dimension multimodal functions (Rastrigin, Ackley, Griewank, Penalized, and Penalized 2), and five fixed dimension multimodal functions (Kowalik, Six Hump Camel, Branin, Goldstein-Price, and Shekel 7). But other metaheuristics also find the optimal global solutions in solving three functions (Schwefel 2.22, Six Hump Camel, and Branin).

Table III strengthens the superiority of TOTO. TOTO is better than GWO, MPA, MLBO, GSO, and GPA in solving 22, 21, 21, 19, and 15 functions, respectively. GWO becomes the easiest metaheuristic to beat. On the other hand, GPA becomes the most challenging metaheuristic to beat. Compared to GPA, TOTO is superior in solving high-dimension functions. On the other hand, GPA is superior in solving fixed-dimension functions.

In the second test, the performance of TOTO is evaluated due to the increase in the maximum iteration. This test has three maximum iterations: 100, 150, and 200. The result is presented in Table IV.

Shekel 10	-8.5191	-8.4954	-9.0716

Table IV indicates that the increase in maximum iteration does not improve the performance of TOTO in most functions. There are two possible reasons for this circumstance. The first reason is the optimal global solution has been found when the maximum iteration is still low. The second reason is TOTO fails to improve, although the optimal global solution has yet to be found. In some functions, the increase of maximum iteration improves the performance of TOTO but is less significant. Fortunately, when the maximum iteration increases, TOTO can find the optimal global solution of Schwefel 1.2, Griewank, and Shekel Foxholes.

In the third test, the performance of TOTO is evaluated due to the increase of population size. There are three values of population size: 20, 30, and 40. The result is presented in Table V.

TABLE V. RELATION BETWEEN POPULATION SIZE AND AVERAGE FITNESS SCORE

Function	Average Fitness Score		
	$n(S) = 20$	$n(S) = 30$	$n(S) = 40$
Sphere	0.0000	0.0000	0.0000
Schwefel 2.22	0.0000	0.0000	0.0000
Schwefel 1.2	0.0003	0.0000	0.0000
Schwefel 2.21	0.0000	0.0000	0.0000
Rosenbrock	$4.8806 \times 10^1$	$4.8727 \times 10^1$	$4.8723 \times 10^1$
Step	8.0915	7.7506	7.2435
Quartic	0.0027	0.0012	0.0011
Schwefel	$-6.0975 \times 10^3$	$-6.746 \times 10^1$	$-6.8492 \times 10^3$
Rastrigin	0.0000	0.0000	0.0000
Ackley	0.0000	0.0000	0.0000
Griewank	0.0006	0.0000	0.0000
Penalized	0.5811	0.5286	0.4791
Penalized 2	2.8680	2.7882	2.8189
Shekel Foxholes	0.9980	0.9980	0.9980
Kowalik	0.0015	0.0006	0.0009
Six Hump Camel	-1.0316	-1.0316	-1.0316
Branin	0.3981	0.3981	0.3981
Goldstein-Price	3.0000	3.0000	3.0000
Hartman 3	-0.0495	-0.0495	-0.0495
Hartman 6	-3.2551	-3.2150	-3.2796
Shekel 5	-7.8440	-8.1561	-8.0214
Shekel 7	-8.1235	-8.7475	-9.3842
Shekel 10	-7.4649	-9.1384	-9.4117

Table V indicates there are also two circumstances regarding the increase in the population size. First, the performance of TOTO needs to improve the increase in population size. Like in the second test, this circumstance happens because the optimal global solution has been found or TOTO fails to improve, although the optimal global solution has yet to be found. Like in the first test, the population size increase also makes TOTO find the optimal global solution of three more functions: Schwefel 1.2, Griewank, and Shekel Foxholes. Meanwhile, in some other functions, TOTO can improve its performance.

In the fourth test, TOTO is challenged to solve the portfolio optimization problem as a real-world problem. In this work, the optimization determines the stocks the investor should buy. The stocks selected in this work are stocks from the banking sector in Indonesia, which are listed in Kompas 100 index. Kompas 100 is a list that consists of preferred stocks in Indonesia. 13 stocks in the banking sector are listed in Kompas 100. Detailed information regarding these stocks is presented in Table VI. In Table VI, the second column represents the stock index, the third column represents the stock price taken on 11 November 2022, and the third column represents the six-month capital gain of these stocks. The price and capital gain are presented in rupiah per share.

TABLE VI. STOCK INFORMATION

No	Stock Index	Price	Capital Gain
1	AGRO	525	-410
2	AMAR	366	42
3	ARTO	5,700	-2,100
4	BACA	136	-23
5	BBCA	8,725	1,350
6	BBHI	2,380	-2,450
7	BBNI	9,175	325
8	BBRI	4,590	260
9	BTPN	2,620	90
10	BMRI	10,100	2,225
11	BNBA	1,530	-310
12	BRIS	1,360	-55
13	BTPS	3,060	110

The objective of this portfolio optimization is to maximize the total capital gain. The total capital gain is calculated by accumulating the capital gain from the stocks. Two constraints limit this optimization. The first constraint is that the investor can purchase stock from 100 to 1,000 lots for each stock. One lot means 100 shares. The second constraint is that the maximum investment is 4,000,000,000 rupiah. This work benchmarked TOTO with GPA, GSO, MLBO, MPA, and GWO. The population size is ten, and the maximum iteration is 50. The result is presented in Table VII.

TABLE VII. PORTFOLIO OPTIMIZATION RESULT

No	Metaheuristic	Total Capital Gain
1	TOTO	382,157,681
2	GPA	384,955,295
3	GSO	289,744,968
4	MLBO	361,041,190
5	MPA	188,953,890
6	GWO	-16,222,768

Table VII indicates the good performance of TOTO. It is shown that TOTO outperforms GSO, MLBO, MPA, and GWO. Meanwhile, GPA is better than TOTO with very narrow gap. GWO becomes the metaheuristic with the poorest performance because it produces negative total capital gain which means loss.

## V. DISCUSSION

This fifth section will discuss the more profound analysis of the result and findings. This discussion consists of four parts. The first part is the discussion regarding the performance of TOTO in solving the 23 classic functions. The second part is the discussion regarding hyperparameters. The third part is the discussion regarding the performance of TOTO in solving the portfolio optimization problem. The fourth part is the discussion regarding the limitation of this work, especially the proposed metaheuristic.

The first discussion is about the performance of TOTO. TOTO performs well in solving the classic 23 functions and benchmarking with five other metaheuristics. As mentioned previously, TOTO performs as the best metaheuristic in solving 17 functions in the low population size and low maximum iteration circumstances. Meanwhile, TOTO can find the optimal global solution of eight functions in these circumstances. Moreover, TOTO can find the optimal global solution of three additional functions in the high maximum iteration or population size circumstances. Comparing metaheuristics, TOTO is better than GWO, MPA, MLBO, and GSO in almost all functions. Meanwhile, TOTO is better than GPA in 15 functions.

In general, the superiority of TOTO occurs in all three groups of these 23 functions. It means that TOTO can tackle various problems indicated in these functions. Due to the consideration that multimodal functions are used to test the exploration capability while unimodal functions are used to test the exploitation capability [40], the proposed TOTO is proven in having superior exploration and exploitation capabilities. Meanwhile, the inferiority of TOTO in solving the fixed dimension multimodal functions compared to GPA is that GPA performs very well in solving the fixed dimension multimodal problems. But the superiority of GPA in solving these functions comes with the consequence that the complexity of GPA is higher than TOTO. GPA generates several candidates in its searches, whether it's guided search toward the global best solution or its local search [21]. On the other hand, the tournament of six searches adopted in TOTO is proven better than the multiple candidate strategy adopted in GPA [21]. The result also proves that the sorting mechanism at the beginning of the iteration, as adopted in GWO [41], is unimportant.

The second discussion is related to hyperparameter analysis. Theoretically, the population size and maximum iteration positively affect the performance of metaheuristics. Meanwhile, the result in Table III and Table IV indicates that after some level, the increase of maximum iteration or population size remains the same. In the low maximum iteration or population size, the increase of one of these two parameters may improve the result. But, increasing one of these parameters does not produce a better result in the high maximum iteration and population size. In almost all functions, the acceptable solution, whether globally optimal or sub-optimal, has been found in the low maximum iteration and population size.

The third discussion is related to the performance of TOTO in solving the portfolio optimization problem. The result indicates that TOTO performs well in solving this problem by producing the second-best total capital gain. On the other hand, GPA becomes the best one. Fortunately, the performance gap between GPA and TOTO is very narrow. This test also indicates that real-world optimization problems should be used to test all metaheuristics. This result shows that the performance gap in the portfolio optimization problem is narrow compared with the classic 23 functions. It is also indicated that gaining significant improvement in the real-world optimization problem is much more complicated than in the theoretical optimization problem, primarily when the solution is based on an integer number.

The fourth discussion is regarding the limitation of this work and the proposed metaheuristic. This paper has presented that metaheuristics with multiple strategies generally perform better than other metaheuristics with one or two strategies. Meanwhile, TOTO adopts only six strategies (three guided and three random searches). On the other hand, there are a lot of other guided searches, and random searches can be chosen. It means TOTO can be improved by embedding more searches into this metaheuristic. But there are also limitations in embedding new searches. The first limitation is that it can only accommodate some searches into a single metaheuristic. The second limitation is that accommodating various searches into a single metaheuristic is also not wise because some may be less effective than other searches. The question is which searches are better than others. In other words, in which condition is some searches better than others.

The limitation that has been previously discussed makes the development of a new metaheuristic still possible. Although the references used in the guided search converge to the best or randomly selected solution, the selection of these references is still various. For example, many metaheuristics choose the best solution so far like in GPA [21], the best solution in the current iteration like in COA [15], or some best solutions as the leader. In many metaheuristics, for example in RLSBO [27], a randomly selected solution or some randomly selected solutions are uniformly selected among the population. On the hand, like in SO [10], some solutions from some fixed-size groups are randomly chosen to reduce dependency on the best solution that may come with convergence too early.

The second opportunity comes from the motive to minimize the maximum iteration or population size. This work demonstrated that TOTO could perform well in low population sizes and maximum iteration. Theoretically, the performance of any metaheuristic can be improved by increasing the population size or maximum iteration to a very high number. Meanwhile, this work has demonstrated that choosing an appropriate strategy can be a better option than just scaling up the maximum iteration or population size, which is closer to the greedy approach.

The third opportunity comes from the scalability aspect. For example, large-scale problems with very high dimensions can be found easily in many real-world optimization problems, such as optimizing the purchase order of a supermarket with hundreds of stock-keeping units or optimizing the investor's portfolio with hundreds of stocks can be chosen. Large-scale optimization problems consume more computational resources, whether from increasing the maximum iteration or population size so that a sub-optimal solution can be found. It is still challenging to develop a new metaheuristic that does not need excessive computational resources in handling the large-scale problems.

## VI. CONCLUSION

A new swarm-based metaheuristic, namely TOTO, with its superior performance, has been presented in this paper. This paper also has presented a novel mechanism for adopting three guided and three random searches in a competition to find a better solution. The test result indicates that TOTO and precisely the strategy adopted in this metaheuristic perform

better not just in beating some previous metaheuristics but also finding acceptable solutions in the low maximum iteration and low population size circumstances. This work presents that TOTO can find the optimal global solution of eleven functions. Moreover, TOTO is better than GWO, MPA, MLBO, GSO, and GPA in solving 22, 21, 21, 19, and 15 functions, respectively. It means TOTO can tackle problems faced in the three groups of functions. In the test related to a portfolio optimization problem, TOTO is better than GWO, MPA, MLBO, and GSO by producing better total capital gain.

Due to the limitations of this work, this work and especially the proposed metaheuristic can become the baseline for future studies. These future studies can be carried out by improving TOTO or implementing TOTO to solve various real-world optimization problems.

**Abstract**—This paper aims to investigate the main factors that have an impact on the adoption of cloud-based enterprise resource planning (ERP) among small- and medium-sized enterprises (SMEs) in the Republic of Iraq using TOE, DOI, and HOT-fit as a theoretical framework. Data was collected from 136 decision maker senior executives, and IT managers in SMEs in the Republic of Iraq. A web-based survey questionnaire was used for data collection processes. The research model and the derived hypotheses were tested using SPSS and SmartPLS. The findings indicate several specific factors have a significant effect on the adoption of cloud-based ERP. This conclusion can be utilized in enhancing the strategies for approaching cloud-based ERP by pinpointing the reasons why some SMEs choose to adopt this technology and success during the adoption phase, while others still do not go forward with the adoption. This study provides an overview and empirically shows the main determinants logistical factors that might face SMEs in the Republic of Iraq. The findings also help SMEs consider their information technologies investments when they think to adopt cloud-based ERP.

**Keywords**—SMEs; TOE; DOI and HOT-fit frameworks; Cloud-based ERP; ICT; SmartPLS; SPSS

## I. INTRODUCTION

Business competitiveness can be improved and can provide a significant benefit for businesses when using information and communication technologies (ICTs) [1]. One of the types of businesses are small and medium sized enterprises (SMEs) [2]. SMEs are an important part of every country's economy because they provide most new jobs and drive technical advancement. SMEs account for a more significant proportion of all businesses and GDP than any other sector<sup>1</sup>. SMEs have historically played an essential role in contributing to the economic development of many countries worldwide. SMEs are playing a critical role and considered essential in the world's economies, providing jobs, adding value, and stimulating innovation<sup>1</sup>.

However, SMEs face various logistical challenges and determinants compared to large corporations. They have less

budget allocated and fewer staff [3], making their computing environment less complex than equivalent large enterprises. Moreover, SMEs face requirements similar to those experienced by larger companies. Therefore, SMEs need to improve their service level to achieve the targeted goals of the company. According to [2], SMEs will be expected to modify various logistics to suit the needs of their information technology (IT) departments. Thus, SMEs need to use IT technologies to achieve a higher level of competence and efficiency. The use of enterprise resource planning (ERP) systems offers SMEs numerous tangible benefits. Improving competitive organizational position in the market is considered the most interesting benefit when implementing ERP systems. According to [4], ERP provides a real-time infrastructure for a company's back-end systems, including (purchasing, marketing, sales and inventory, procurement, finance, and human resources) (p.1). However, utilizing standard ERP has several disadvantages for businesses; for instance, on-premise ERP require excessive expenses in terms of initial investments [5]. The author in [6] believed that one of the criteria for SMEs to select ERP systems is to check the affordability. Therefore, there was a need for cloud ERP systems that were lower in cost and less time consuming than traditional ERP systems, and that is where ICT can be an asset.

Due to dramatic business changes, there has been globally widespread use of ICTs among various size enterprises, specifically SMEs. The author in [1] found the use of ICTs by SMEs impacts livelihoods and reduces vulnerabilities. Moreover, applying ICT innovatively in SMEs within most developing countries will increase the opportunity to create jobs. Cloud computing technology is an ICT that helps organizations leverage new IT development at an affordable cost. It has grown in importance as a source of new business service innovations. SMEs will better utilize their limited IT resources by using cloud computing to increase IT system stability and scalability. Therefore, SMEs have been identified as the main beneficiaries of cloud computing [7].

<sup>1</sup><https://www.oecd.org/industry/C-MIN-2017-8-EN.pdf>

In this regard, the field of ERP has seen an evolution through the development of cloud-based ERP systems [2]. Cloud ERP system enables users to transfer and share information in real-time due to its three-layer architecture [4]. Moreover, cloud ERP can be used without IT infrastructure requirements; all updates are reported and processed immediately by the providers [8]. Thereby, cloud-based ERP is a cost-effective alternative to traditional ERPs. As a result, adopting these solutions would be highly beneficial to SMEs.

Cloud-based ERP solutions offer various significant benefits to SMEs due to their cost and time effectiveness. Cloud services enable SMEs to save money by extending the flexibility and agility of internal and external operations while also lowering manufacturing costs. Additionally, the ERP market has expanded with the advent of cloud-based ERP solutions [2]. Cloud ERP systems in past few years are gaining more attention in the market, especially among SMEs, however, it has been recognized that SMEs have low motivation toward the adoption of this technology [9] due to failure of implementation after the adoption of cloud ERP system. The author in [10] stated that SMEs' decision makers face failure after cloud ERP implementation due to lack of knowledge and experience. Therefore, it is critical to identify the factors and recognize the issues leading to implementation failure through the adoption stage. To have a successful adoption, decision makers are required to understand and evaluate the factors affecting the adoption of cloud ERP.

Although several studies have attempted in the past to assist decision-makers in addressing their worries about cloud ERP adoption, it's worth noting that most of these proposed frameworks and models have several limitations. Because present models and frameworks primarily focus on the operational and tactical levels, the frameworks and models themselves are limited (that is, they do not encompass many perspectives). Moreover, there was a lack of research and studies on the factors that affect the use of cloud-based ERP in developing Middle East countries [11]. Additionally, most past studies have been undertaken in developed countries and the North Asia Pacific region [12]. Very few studies have been conducted to study the factors affecting cloud ERP adoption in developing nations, notably among SMEs in the Republic of Iraq. The adoption of cloud ERP systems in the Republic of Iraq is still at an early stage. To the best of the author's knowledge, no previous study has investigated the factors that may influence an SME's decision to adopt a cloud ERP system in the private sector in Iraqi SMEs. Therefore, this study aims to address the abovementioned gap by examining the factors influencing the adoption of cloud ERP in Iraqi SMEs from the perspective of decision-makers. The study addresses the following research questions:

- What are the critical factors leading to the adoption of cloud-based ERP system in Iraqi SMEs?
- How can the relationships between the factors and the adoption of cloud-based ERP can be modelled?

The study integrates three relevant frameworks, which were the Diffusion of innovation (DOI), the technology organization environment (TOE) framework and technology, human, and organization (HOT-fit) framework. Based on

these frameworks and due to the dynamic nature of cloud ERP, a multidisciplinary approach is required to explain the decision-making aspects impacting cloud ERP adoption. This study proposes an integrated model to identify the main factors that will encourage or prevent SME decision-makers in Iraq from moving on to cloud-based ERP systems, using web-based survey system for data gathering. This paper is organised as follows. The literature review of the cloud-based ERP and the problem area following by prior research studies are presented in Section II. In Section III we present our research model and the theoretical frameworks that has been used. The research hypothesis of the research model is presented in Section IV. The Methodology of the study is located in Section V. In Section VI, the findings of our study are presented. Section VII and Section VIII contain the discussion and the contribution. We conclude the paper in Section IX with a conclusion, limitations and future work.

## II. LITERATURE REVIEW

### A. Cloud-based ERP

Cloud computing's popularity has accelerated in recent years [13]. Additionally, the concept of ERP adoption (particularly for on-premise systems) has been extensively investigated. Nevertheless, over the last six years, cloud-based ERP (also known as cloud ERP) has gained popularity [14]. Cloud ERP is defined in this section as software applications that integrate business processes and transaction-oriented data across an organization via a model that enables ubiquitous, convenient, on-demand network access with minimal management effort or service provider response. For decades, ERP systems have been adopted as industry-standard software that satisfies business requirements. With the advent of cloud infrastructure, ERP software vendors are aggressively investing in cloud-based ERP systems, and this deployment model is gaining traction as a practical method of delivering ERP software [15]. Cloud-based ERP systems enable businesses to rent their whole ERP system landscape from various service providers, including software and infrastructure providers.

Future SME growth was significantly correlated with (Internet of Things) implementation. Investments in technology could help SMEs develop more rapidly than previously anticipated. SMEs must use technical innovations and e-commerce products to increase their competitive advantage [2]. With regard to SMEs, similar studies supporting the usage of radio-frequency identification technology to address the idea of technical advancements within SMEs. As a result, technical innovations in relation to the adoption of cloud-ERP systems would be extremely beneficial in accelerating the growth of SMEs.

Cloud-based ERP systems arose in the mid-2000s as an alternative to on-premise ERP systems, particularly for handling upgrades and maintenance operations [16]. Cost pressures on enterprises have led to an increase in the use of cloud computing solutions [17]. The use of cloud services is growing as the cost of these systems falls. Cloud-based ERP system is broadly classified into three categories: SaaS (software-as-a-service), IaaS (Infrastructure-as-a-server) and Hybrid cloud ERP [8].

### B. Prior Research Studies in Cloud ERP Adoption

The use of cloud-based ERP systems by SMEs would contribute to their growth by addressing issues and enhancing their competitiveness [2]. Because cloud ERP would increase productivity and efficiency while also lowering electricity costs, it is a more cost-effective option [10].

Numerous studies have been undertaken to evaluate the benefits and challenges that businesses encounter when implementing cloud ERP in their businesses [9] [18]. Some researchers have concentrated on cloud ERP adoption in various locations such as Europe, the United States, Australia, and Asia [19] [20]. Others have concentrated on the acceptance of cloud ERP in various industries such as banking, healthcare, and manufacturing [11] [21] [22].

The author in [2] investigated the key logistical determinants of cloud ERP adoption in SMES in developing Middle Eastern countries in order to improve cloud ERP approach strategies by examining why some SMEs embrace this technology while others do not. The DOI and TOE theoretical frameworks were used to investigate 14 variables in this study. Although the study contributes to the adoption of cloud ERP, the study model did not include the human context. The author in [23] investigated the difficulties of cloud ERP implementation. They also investigated the primary advantages of issues encountered during cloud-ERP installation. However, their study was not focused on the adoption phase. The author in [24] examined the factors influencing cloud ERP adoption by manufacturing SMEs in Nigeria. The TOE framework and the DOI theory was used to develop a theoretical model and validated the factors using quantitative analysis. Their findings indicated that cost savings, compatibility, and data privacy are the primary and most significant elements influencing the technological background for cloud ERP adoption. However, they ignore decision makers factors. The author in [25] investigated the reasons for SMEs in developing countries' unwillingness to use Cloud ERP. The study has examined several factors that lead to the reluctance of Cloud ERP based on individual, innovation and organizational characteristics from twenty SMEs in Namibia. This study has some limitations regarding the number of data collected. Moreover, the study covered the SMEs during the implementation phase.

The author in [26] conducted a study that incorporated the TOE framework. He tried to ascertain the variations in TOE characteristics between firms that implemented Cloud ERP systems and those that did not. However, the study had no intention of researching any organization's size, and the responders to the results were not decision-makers within the firm. The author in [19] created a theoretical model utilizing the TOE framework and hypothesized the effect of critical factors on the intention of SMEs in Malaysia, to use cloud-based ERP systems. However, their findings have no noticeable effect on cloud-based ERP adoption. Their findings are ambiguous and have limitations when it comes to decision makers' characteristic determinants. The author in [11] combined the TOE and DOI frameworks to construct a model for examining the factors driving cloud ERP system adoption in Saudi Arabian organizations. Their study had limitations that it did not consider critical variables such as security and

privacy, nor did it take into account the characteristics of decision-makers that could influence cloud adoption. The author in [18] explored the challenges to cloud ERP adoption in Pakistani SMEs using a qualitative methodology in association with unstructured interviews. According to the study, ten potential barriers to the adoption were identified the primary issues to determine whether to accept or reject cloud ERP solutions. However, their analysis excluded human features and relied entirely on qualitative data.

Furthermore, while most of previous studies emphasize the technological aspects of cloud ERP, they overlook the human and organizational aspects [12]. Even though some concepts of cloud computing technology are universal, others will differ due to different contexts and country requirements. Cloud ERP adoption also varies by country and industry. Although the researchers identify cloud ERP as a global IT phenomenon, they also emphasize that the factors influencing the adoption of cloud ERP play different roles in different economic environments. Human factors such as the characteristics of decision makers differ from country to country, even if the countries are located in the same region. Despite the importance of cloud-based ERP usage and its role to enhance the company's performance, there was a lack of research and studies on the factors that affect the use of cloud-based ERP in developing Middle East countries [11].

In summary, this study found that the preceding research on cloud-ERP adoption and its factors is twofold. First, the majority of the research has focused on the benefits and limitations of cloud ERP adoption, the development of cloud ERP frameworks, and the variables influencing cloud ERP implementation from a service's perspective in developed countries. However, few studies have been conducted on organizational perspectives, notably those of decision-makers or end-users, which are crucial for business cloud ERP adoption. As a result, numerous research uses the TOE paradigm to investigate the cloud-ERP implementation issue. Secondly, prior studies have emphasized the significance of technological, organizational, and environmental factors in cloud ERP adoption. The adoption of cloud ERP, however, varies depending on the human factors across industrial sectors. For instance, factors that may affect SME adoption decisions made by decision-makers have not been sufficiently examined in conjunction with other aspects in prior studies.

## III. THEORETICAL FRAMEWORK

### A. Research Model

There is a tendency toward merging several frameworks or theories. In order to better explain adoption in the context of cloud-based ERP, the majority of academics combine two or more theories. The complementarity of various existing theories on technology adoption makes this approach applicable. DOI, TOE, and HOT fit theories complement one another to thoroughly understand the major determinants of technologies [22]. The TOE, DOI, and HOT-fit frameworks are the most influential theories in cloud service adoption studies in organizations [22]. The TOE framework is based on the organizational level theory, which provides a multi-perspective framework by incorporating internal and external elements [27]. They also identified three institutional contexts

of the TOE framework, including the technological, organizational, and environmental contexts, which impact the adoption of technological innovations. The author in [28] defined DOI as a process for decreasing uncertainty, and he provided attributes that aid in reducing uncertainties about a technological invention. They are the following: Relative Advantage, Compatibility, Complexity, Trialability, and Observability. The author in [29] presented HOT-fit as an

evaluation paradigm for health information systems. HOT-fit evaluates HIS systems on three dimensions (technology, human, and organization), arguing that user attitude and competence also affect technology adoption.

The present study comprises four dimensions that influence cloud-ERP adoption: Technological context, Organizational contexts, Environmental context, and Human context. Fig. 1 illustrates the research model.

Fig. 1. Research model.

#### IV. RESEARCH HYPOTHESIS

##### A. Technological Context

The technological context in the original TOE framework referred to both internal and external technologies critical to a company [30]. The technological context has been developed by combining the DOI attributes and the technology dimension of TOE framework.

The most influential factors in the innovation adoption have been adopted to create the technological contexts, include: relative advantage, compatibility, complexity, trialability, security and privacy, and cost saving.

The Relative Advantage (RA) factor relates to determining if cloud ERP systems will benefit the indicated SME more than other technologies. This factor is a substantial and favorable influence in the choice to use cloud ERP [13]. According to [31], a company is more likely to adopt cloud ERP in its operations if it recognizes the potential benefits of cloud ERP over other traditional types of ERP. Moreover, RA has been identified as a significant element and is wholly associated with adopting IT innovations [32]. It was discovered that relative advantage has a considerable and beneficial effect on cloud service adoption in Lebanese SMEs [33].

Compatibility (CAT) is defined as the degree to which new technology is compatible with an organization's principles, current demands, and historical traditions. The

author in [9] identified compatibility as a critical aspect in adopting innovation in cloud ERPs. While CAT was identified as a critical factor in the adoption of cloud services by SMEs [34]. However, it was not shown to affect cloud service adoption in Saudi Arabian higher education institutions [35].

Complexity (CEX) is a term that refers to how difficult innovation is to learn, use, and adopt. The more easily a business can integrate with technology, the more rapidly it may be accepted when innovation is primarily intended to add value to the business. Adopting new technology, such as cloud ERP Services, may present obstacles for SMEs, such as the need to modify current processes [36].

Trialability (TRA) has been viewed as a crucial necessary element of adopting new technology [7] [37] [38]. TRA is essential for early adopters than late adopters, as the latter can profit from the previous experience as a benchmark of the innovation's performance.

Security and Privacy (SP) are described as (the extent to which cloud computing is seen as more secure than other computer ideas) [34]. The SP of an organization's data are significant obstacles to shifting data to the cloud. One of the most frequently mentioned concerns concerning cloud-based services is the cloud's security and privacy. The term (cloud security and privacy) relates to various issues, including the cloud's confidentiality and integrity [39].

The Cost Saving (CT) of cloud ERP is defined as (the extent to which decision-makers view the entire cost of employing cloud ERP to be less than the cost of on-premise ERP). Cloud services support innovation by lowering IT investment costs and total IT capital expenditure [33]. The cost was shown to be a significant factor in determining whether to utilize cloud services by Australian SME's [38]. These considerations lead to the following hypotheses:

- H1: Relative advantage (RA) will positively influence the decision to adopt Cloud ERP within SMEs.
- H2: Compatibility (CAT) will positively influence the decision to adopt Cloud ERP within SMEs.
- H3: Complexity (CEX) will negatively influence the decision to adopt Cloud ERP within SMEs.
- H4: Trialability (TRA) will positively influence the decision to adopt Cloud ERP within SMEs.
- H5: Security (SP) and Privacy concerns will positively influence the decision to adopt Cloud ERP within SMEs.
- H6: Cost Saving (CT) will positively influence the decision to adopt Cloud ERP within SMEs.

#### B. Organizational Context

The organizational context relates to the organization's properties and the resources available to foster innovation. In the context of cloud ERP, successful cloud ERP adoption requires the organization to endure both technical and organizational changes. The organizational context in this study includes firm size, employee's cloud knowledge, and information intensity.

The Firm Size (FS) has a significant impact on how quickly a technology innovation is being adopted. Numerous studies have demonstrated that an organization's size can positively influence its adoption of cloud services [7] [37]. The author in [37] demonstrated that the effect of certain variables varied according to organization size.

Numerous studies have discovered that employee's cloud knowledge (ECK) play a significant role in technology adoption decisions [7] [33]. Employees' understanding of similar prior experiences can be viewed as showing the similarity between current practice and prior experience. As a result, an organization's employees' cloud knowledge and experience could be referred to as its technological capability. To use the ERP system through the cloud, staff must acquire both cloud-related expertise and prior ERP system experience.

Information Intensity (INI) is defined as the degree to which a business's product or service contains information. The term (information intensity) relates to the amount of information available within a business service. Businesses in various areas require varying levels of information; for example, financial brokers require access to the most up-to-date information. According to [40], INI positively affects the adoption of cloud services because the cloud can provide up-to-date and appropriate information. According to [41], information intensity increases innovation adoption. Based on

the discussion above, the following hypotheses are proposed for this study:

- H7: Firm size (FS) will positively influence the decision to adopt Cloud ERP within SMEs.
- H8: Employee's knowledge/Experience (ECK) will positively influence the decision to adopt Cloud ERP within SMEs.
- H9: Information Intensity (INI) will positively influence the decision to adopt Cloud ERP within SMEs.

#### C. Environmental Context

The environmental context refers to the location of the firm as indicated by the industry type. The researcher found several factors, including competitive pressure, industry type, and supplier effort and external support that might influence an organization's decision to adopt cloud ERP.

Competitive Pressure (CP) refers to the degree to which an enterprise is under pressure from other external partners, such as competitors within the market [2]. Numerous studies have demonstrated the effect of competitive pressure on technology adoption, such as cloud ERP, in SMEs [26] [42], while other empirical studies have revealed no relationship between competitive pressure and technology adoption [7] [11].

The organization's industry sector (IN) has a significant impact on whether or not it decides to implement new technology [7]. Since firms in different sectors have varying business needs, those that depend on technology are much more willing to adopt a technology invention such as cloud ERP. It has been claimed that the industry in which a business operates affects the information processing requirements of the business, which in turn affects the firm's decision to adopt new technology.

Supplier effort and External support (ES) is described as the amount of assistance in integrating an information system [7]. In the context of cloud ERP, external support refers to assistance provided by cloud server providers, government policies, and legal safeguards to assist SME decision-makers in adopting cloud ERP. Because cloud ERP is seen as new in developing countries, there is a lack of information and existing work on cloud ERP engaging SMEs [11]. Thus, the following hypotheses are proposed:

- H10: Competitive pressure (CP) will positively influence the decision to adopt Cloud ERP within SMEs.
- H11: Industry sector (IN) which SME operate will positively influence the decision to adopt Cloud ERP within SMEs.
- H12: Supplier efforts and external computing support (ES) will positively influence the decision to adopt Cloud ERP within SMEs.

#### D. Human Context

Before adopting any IT project, the human factors should be considered since it affects the successful acceptance of innovative technology [29]. According to [22], the human

context was selected as the most crucial context for adopting cloud services. The following human factors are:

Decision Maker's Innovativeness (DMI) is defined as the degree to which decision-makers are willing to experiment with innovative and perhaps risky solutions [43]. The innovativeness of decision-makers is measured by their willingness and ability to experiment with new technologies that have not yet been thoroughly explored in their industry [44]. Previous studies have found the innovativeness of decision-makers to be a positive factor for cloud services adoption [7] [22] [44]. Studies highlighted that if the individuals are critical decision-makers in the company, personal innovativeness can help identify who will adopt an innovation first [7].

Possessing sufficient knowledge about new technology is the first stage in adopting. According to [45], the CEO's knowledge of information systems (DMC) has a beneficial effect on IS/IT adoption. The technological knowledge and skills of the decision-maker will influence the decision to adopt an IT innovation. SME will have more trust if the decision-maker has proper knowledge and skills on cloud ERP. As a result, the following hypothesis is generated:

- H13: Decision Makers' innovativeness (DMI) will positively influence the decision to adopt Cloud ERP within SMEs.
- H14: Decision Makers' cloud knowledge (DMC) will positively influence the decision to adopt Cloud ERP within SMEs.

## V. METHODOLOGY

### A. Scope, Sampling and Measurement Instrument

The purpose of this study is to investigate the primary determinants and variables impacting a SME's decision makers to adopt cloud ERPs in Republic of Iraq. This study's target respondents were composed of the decision-makers (Owners, CIOs, CEOs, IT executives, and IT managers) belonging to SMEs. The participants who are either (Owners, CIOs, CEOs) or heading departments (IT executives and IT managers), directly involved and responsible for technology acquisition and policy decisions for their SMEs. Managers are presumed to be the decision-makers or contributors to decision-making for adopting new technologies in their enterprises. Although the researchers were able to gain a list of private enterprises from the Ministry of planning website in the Republic of Iraq, several issues were encountered when validating the frame, such as the list not being up to date, the list not specifying the location of the SMEs, a larger number of these enterprises being already closed, inactive numbers, duplication of firms or duplicated phone numbers, and these enterprises not specifying if the enterprises were small or medium-sized. After several iterations and cleaning of this list, 300 unique and validated phone numbers of enterprises were identified, which were considered the core of the sample frame. Each SME in the sample met the following criteria: must be in Baghdad governorate; and must not have more than 30 employees. SMEs in Baghdad government were chosen because they are in a better position to understand current IT

operations, increase in growth rates and future trends for their enterprises [11]. The questionnaire was prepared in English and subsequently translated into Arabic, as the study was conducted in Iraq, where Arabic is the official language. A web-based survey was utilized due to various benefits, including quicker distribution, a more professionalism, affordability, and an improvement in response rate.

Pilot study was necessary to revise the wording, structure, content, arrangement, layout, simplicity, and clarity of the survey instrument [46]. 50 samples from the total sample frame were conducted for the purpose of pilot study. The feedback from the pilot study was necessary to enhance the questions and test respondents' comprehension and clarity before administering the actual survey.

Since the data was analyzed using SEM, this research has determined the sample size according to [47] rule, which indicate the sample size in SEM must equal the larger 10 times the largest number of formative indicators used to measure a single construct. The number of leading indicators utilized for measuring a single construct is 12 for RA; therefore, the sample size is 120 ( $10 \times 12$ ).

Since the sample size of 120 is required for this study, 180 questionnaires were given to respondents to eliminate a questionnaire shortage caused by various factors (missing, ignoring, and incomplete). One hundred fifty-five (155) decision-makers responded to our email and completed the survey, representing an 86.1 percent response rate. Thus, it was acceptable for a web survey that was sent via e-mail/internet [48].

Eleven (11) of 155 respondents were rejected because significant areas of the questionnaires were incomplete. Moreover, eight (8) responses were eliminated since they were ineligible to participate in the survey due to not meeting the criteria. 136 completed surveys were left for the study.

An email was sent to every decision-maker contained a link to the online survey, which was conducted using Google Forms, as well as a cover letter describing the study's aim. The survey contained a definition and description of various terms used in the questionnaire to enhance the validity of the response. A first and second reminder was given to all decision-makers interested in participating in this research study, both by email and separated by a few weeks to ensure the completion of the survey. In total, 75 items for 14 constructs in the survey came from prior studies and literature which was modified by the researcher to fit the context of cloud-based ERP adoption. The survey is divided into two main parts. Part one seeks the demographic information from the respondents; this part also relates demographic information to the respondent's organization as shown in Table I. This part of the questionnaire was related to fundamental questions about the firm, such as whether the SME has adopted on-premise ERP or cloud ERP. Also, questions regarding businesses size, industry, and market scope were included. Part two was about the core constructs developed in the proposed model, which contained the questions used for studying the four contexts, namely technological, organizational, environmental, and human, assessed by five Likert-type items.

TABLE I. DEMOGRAPHIC INFORMATION

Variable	Frequency	Percentage	Variable	Frequency	Percentage
<b>Position</b>			<b>Cloud ERP awareness</b>		
Owner	44	32.4	High awareness	77	56.6

+21	9	6.6			

**B. Data Analysis**

The partial least squares (PLS) path modelling approach was used for this work because it is more appropriate for predictive and exploratory research [48]. PLS-SEM is chosen as the most acceptable approach because this study was designed to predict the influencing factors among the specified variables and to analyze their impacts on adoption within the proposed model.

To analyse the data, SmartPLS software was used, which is one of the most well-known software applications for PLS-SEM [49]. Statistical Package for the Social Science (SPSS) software was used to analyze demographic and institutional data, such as industry and market size. In addition, the instrument's reliability was also tested using Cronbach's alpha technique.

**VI. FINDINGS**

**A. Reliability and Validity**

The reliability and validity were measured first. The reliability of data was evaluated using composite reliability and the alpha coefficient. The composite reliability (CR) values ranged from 0.860 to 0.957 and Cronbach's Alpha values ranged from 0.757 to 0.951. Table II shows that all constructs are regarded to have adequate internal consistency reliability were above the acceptable 0.7 threshold.

Validity was measured by considering convergent and discriminant validity. The author in [47] defined convergent validity as the degree of correlation between two measures of the same construct. This study assessed the convergent validity using the AVE [50]. Convergent validity is permitted when AVE is at least 0.5. The study's measuring approach has good convergent validity since all AVE values meet the minimum requirement of 0.50 as shown in Table II [50].

TABLE II. CONSTRUCT CONSISTENCY AND RELIABILITY

Constructs	AVE	CR	CA
AD	0.875	0.934	0.859
RA	0.649	0.957	0.951
CEX	0.747	0.898	0.832
CAT	0.653	0.917	0.888
TRA	0.776	0.932	0.904
SP	0.686	0.945	0.933
CT	0.666	0.952	0.944
IN	0.741	0.895	0.824
ES	0.755	0.939	0.919
CP	0.793	0.920	0.871
ECK	0.831	0.951	0.933
INI	0.720	0.885	0.810
FS	0.786	0.917	0.866
DMI	0.673	0.860	0.757
DMC	0.875	0.934	0.859

The author in [51] defines discriminant validity as the degree of difference between two notions. The discriminant validity of constructs is assessed by the [52] criterion, HTMT and cross-loadings of construct items. The discriminant validity of a construct is supported when the square root of its AVE is greater than its correlation with other constructs [52]. The discriminant validity of a measurement model is determined by the item loadings and the square root of the construct's AVE. The square roots of AVE, shown in Table III, were larger than their corresponding correlation, showing that our data had good discriminant validity.

The HTMT is a new technique for determining discriminative validity in contrast-based SEM. HTMT is the average of all correlations of indicators across combinations that measure different structures relative to each other. The author in [53] suggested that HTMT values below 0.85 indicated distinct combinations. Table IV shows all HTMT values below 0.85. As a result, discriminatory structures were provided.

### B. Hypothesis Testing

Bootstrapping is a statistical approach used in SmartPLS to evaluate the correlations (paths) between dependent and independent variables. The structural model was constructed to identify the path relationship among the variables. The study tests the relationship between endogenous and exogenous variables via the path coefficient ( $\beta$ ) and t-statistics.

The study found that RA ( $\beta=0.100$ ,  $p=0.005$ ,  $t=2.853$ ), CAT ( $\beta=0.106$ ,  $p=0.036$ ,  $t=2.100$ ), TRA ( $\beta=0.138$ ,  $p=0.005$ ,  $t=2.835$ ), SP ( $\beta=0.166$ ,  $p=0.004$ ,  $t=2.893$ ), CT ( $\beta=0.137$ ,  $p=0.001$ ,  $t=3.236$ ), FS ( $\beta=0.152$ ,  $p=0.037$ ,  $t=2.561$ ), ECK ( $\beta=0.105$ ,  $p=0.034$ ,  $t=2.125$ ), IN ( $\beta=0.185$ ,  $p=0.016$ ,  $t=2.411$ ), ES ( $\beta=0.116$ ,  $p=0.025$ ,  $t=2.255$ ), DMI ( $\beta=0.113$ ,  $p=0.032$ ,  $t=2.147$ ), and DMC ( $\beta=0.125$ ,  $p<0.001$ ,  $t=3.611$ ) have a significant impact on the Adoption Decision (AD) of cloud ERP. However, CEX ( $\beta= -0.003$ ,  $p=0.949$ ,  $t=0.064$ ), INI ( $\beta= -0.016$ ,  $p=0.823$ ,  $t=0.224$ ), and CP ( $\beta= -0.034$ ,  $p=0.432$ ,  $t=0.787$ ) have no significant impact on the Adoption Decision (AD) of cloud ERP. Table V indicated the result of the hypothesis.

The T-statistic was used to determine the contribution of independent constructs to the predictor of the dependent construct, AD. The items' t-values ranged from 0.224 to 3.611, reaching the level of significance. All structural model relationships were statistically significant when the p-value  $<0.05$  and the t-value  $>1.96$ . Except for the paths between (CEX, INI, and CP) and AD, where the CEX ( $t=0.064$ ,  $p=0.949$ ), INI ( $t=0.224$ ,  $p=0.823$ ), and CP ( $t=0.787$ ,  $p=0.432$ ), all of which did not meet the recommended value; thus, these paths this path were not significant.

## VII. DISCUSSION

The purpose of the first study question was to identify the factors that influence an SME's decision to adopt a cloud-based ERP system in Iraqi SMEs. This research question was answered based on the literature review related to the adoption of cloud-based ERP. A comprehensive literature review on cloud ERP system, SMEs, trends, strategies, and frameworks for cloud-based ERP system in different sectors was conducted. Moreover, the cloud-based ERP system was critically reviewed the existing and the use of cloud-based ERP system in the SME sector. Literature deeply emphasizes the importance of technological, organizational, environmental, and human characteristics while conducting technology adoption studies. To identify and confirm the critical factors affecting the adoption of the cloud ERP system, data was collected and examined quantitatively. Based on the analysis, eleven factors out of fourteen were found to influence the adoption in SMEs. The findings in each context are discussed as follows:

### A. Technological Context

Regarding RA, CAT, TRA, SP and CT the findings indicate they are significantly influence cloud-ERP adoption in SMEs. The findings are consistent with some previous studies [11] [24] [34] [38] [54]. Conversely, this finding was inconsistent with that obtained by [2]. These results may strongly contribute to the adoption of cloud ERP in SMEs

through utilizing these factors of influence. In regard of CEX, the findings indicate it was not significant to the adoption of cloud-ERP. The result of CEX was consistent with the result from [2].

### B. Organisational Context

In regard to FS and ECK, the results were consistent with several previous findings from cloud ERP adoption studies which report the significant positive influence the adoption [11] [24] [54]. Contrary to expectations, this study did not find a significant relationship between INI and cloud-ERP adoption. The findings of INI were inconsistent with [40], which indicates that cloud services can make the best use of information intensity and thus influence positively.

### C. Environmental Context

Unexpectedly, CP did not significantly affect cloud-ERP adoption. This result was consistent with previous studies [2] [22]. In contrast, [24] and [11] found that CP has a significant impact in association with cloud-ERP adoption.

IN and ES were statistically significant for cloud-ERP adoption in SMEs in Iraq. In terms of IN, the finding of this study is consistent with the finding of some previous studies [7] [54]. However, it is inconsistent with those of [38], which indicates that cloud services can be understood in the context of an overall business's strategy based on agility and responsiveness. In terms of ES, the result is consistent with those of [26] [38] [42], which they found that the factor was positively associated with adoption in SME. In addition, [26] implied that the availability of vendor (external) support could be a vital factor that encourages SMEs' adoption of the cloud ERP system.

### D. Human Context

Interestingly, two predictors in the form of DMI and DMC were found as statistically significant influences in ERP adoption decisions. The findings of DMI and DMC are consistent and similar to the findings of some previous studies [21] [22] [24], which found that the factor was positively associated with adoption in SME.

TABLE V. RESULTS OF HYPOTHESES AND RELATIVE PATHS

Path	$\beta$	t-values	p-values
RA→AD	0.100	2.853	0.005
CAT→AD	0.106	2.100	0.036
CEX→AD	-0.003	0.064	0.949
TRA→AD	0.138	2.835	0.005
SP→AD	0.166	2.893	0.004
CT→AD	0.137	3.236	0.001
FS→AD	0.152	2.561	0.037
ECK→AD	0.105	2.125	0.034
INI→AD	-0.016	0.224	0.823
CP→AD	-0.034	0.787	0.432
IN→AD	0.185	2.411	0.016
ES→AD	0.116	2.255	0.025
DMI→AD	0.113	2.147	0.032
DMC→AD	0.125	3.611	0.000

Following the second study question and to meet the study's objective, the research proposed an integrated model to identify the main factors that could encourage or prevent SME decision-makers from moving on to cloud-based ERP systems. The initial model integrates the critical factors from the literature review as the main factors that may impact the SME's intention to adopt cloud-based ERP. This research integrates three theoretical frameworks (DOI theory, TOE framework, and HOF-fit framework) to develop the conceptual research model. To refine and confirm the factors in the cloud-based ERP adoption model, the study utilized quantitative methods. A questionnaire survey was used to test the proposed model and confirm the identified factors for the cloud-based ERP adoption. Eleven of the fourteen hypotheses were eventually supported. Both study questions were answered, and study objectives were achieved.

## VIII. CONTRIBUTION

### A. Theoretical Contribution

Based on a review of the literature and to the best of the researchers' knowledge, this study is the first exploratory study that combines DOI, TOE and HOF-fit in identifying the determinants that will affect the adoption of cloud ERP in a developing Middle Eastern nation, particularly, the Republic of Iraq. It aimed to determine the significant link between technological, organizational, environmental, and human context; and the adoption decision of cloud-based ERP in Iraqi SMEs. The effect of several factors, such as relative advantage, compatibility, complexity, trialability, security and privacy, cost saving, firm size, employee's cloud knowledge, information intensity, supplier efforts and external computing support, competitive pressure, industry, decision maker's innovativeness, and decision maker's cloud knowledge towards cloud ERP adoption is an important topic that should be considered further in the future. The results also provide further support for the utility of the TOE, DOI and HOF-fit in technology adoption such as cloud ERP.

### B. Practical Contribution

For SMEs' decision-maker and cloud service providers, the outcomes of this study can be effectively applied. Cloud service providers can use the research model to improve their knowledge about why certain SMEs decide to adopt new technologies while others in the SME sector do not, since cloud service providers need to be aware of typical issues experienced in SMEs when deciding on a new adoption of cloud services. This will be a guide to assess the cloud-based ERP system, providing the SMEs' decision-makers the opportunity to trial this solution before the actual implementation and thus improve the awareness of cloud services. Moreover, SMEs (decision-makers) will evaluate the cloud services (cloud-based ERP systems) before their actual use, allowing them to check the level of compatibility and complexity with their existing system. This study exposes that the decision-makers of some enterprises in the private sector still lack enough knowledge to make an informed choice. Therefore, the decision to adopt this technology depends not only on the decision-maker's lack of innovation, and the adoption requires both innovativeness and knowledge to adopt technological innovations. As a result, the outcomes of this

study will give practical instructions for the effective adoption of cloud ERP in Iraq, as well as help other emerging economies in similar situations prepare for and implement cloud ERP services.

### C. Academic Contribution

Compared with other models of the adoption decision study, the proposed model is intended to be more comprehensive where it falls in the adoption decision phase of the cloud ERP life cycle by assessing the decision to adopt the system by identifying the factors that influence the decision to adopt cloud ERP. This study will open opportunities for more research and enhance the constructs further to clarify the adoption of cloud-based ERP systems in SMEs. The results confirmed that the proposed model fitted the situation well with the data. Therefore, the developed model is seen as valid and can contribute significantly to explaining the adoption of the cloud ERP system. Additionally, the study contributes to the Iraqi innovations technology and enterprises literature by identifying the significant variables that affect SME adoption of the cloud-based ERP systems. A long-ignored decision-makers characteristic is introduced that integrates variables pertinent to a human context.

## IX. CONCLUSION

Enterprises facing business issues have demonstrated a significant desire for cloud ERP. Yet, research on the variables impacting the adoption of cloud ERP, particularly in the growing Middle Eastern nations, is scarce. This report sheds light on the variables that SMEs' decision makers must consider before adopting cloud ERP, with a focus on the challenges faced by decision makers of Iraqi SMEs from different business scopes. The literature review served as the foundation for this study's integrated conceptual model, which was then developed and put to the test, utilizing quantitative research. Therefore, it is anticipated that this research will advance theory, methodology, and practice. The researchers studied the body of literature on the adoption of cloud ERP, the TOE framework, the theory of innovation characteristics (DOI) and HOF-fit framework. The study also provided an in-depth analysis of the present relevant theories and indicated the initial (technological, organizational, environmental, and human) influences on the adoption of cloud ERP. The TOE framework, DOI theory and HOF-fit framework were specifically cited as the best suitable theories for creating a conceptual model for SMEs adopting cloud ERP. Eleven factors (RA, CAT, TRA, CT, SP, FS, ECK, IN, ES, DMI, AND DMC) were found to be significant determinants factors of cloud-ERP adoption. Three factors (CEX, INI, and CP) were insignificant. The findings of this study will enhance the adoption of cloud ERP in the Republic of Iraq and other developing middle Eastern countries. The cloud vendors and SMEs' decision maker will benefit from the findings in overcoming obstacles and effectively adopt cloud ERP.

This study endeavoured to investigate the impact of the most notable factors in the adoption of cloud ERP rather than including a complete list of all possible influencing factors. Future studies could examine at more variables and see how they affect the adoption of cloud ERP. Second, this study was conducted in the Republic of Iraq, the findings of which

cannot represent the overall situation of a developing country. Moreover, data were obtained in a specific governorate, SMEs in Baghdad, limiting the generalizability of the findings. Further research should be done to collect data from different developing countries and additional research could expand the scope of the study by examining another governorate within the Republic of Iraq. Third, the decision makers answered questions based on their observations, work experiences, and ICT understanding. Thus, the data collected may not be sufficiently objective. However, due to the nature of this study (exploratory research), the quality of the collected data is acceptable. Finally, the sample selection was quite limited and must be expanded in future work.

#### ACKNOWLEDGMENT

The authors would like to thank BIOCORE Research Group, Center of Advanced Computing Technology (C-ACT), Fakulti Teknologi Maklumat dan Komunikasi (FTMK) and Centre for Research and Innovation Management (CRIM), Universiti Teknikal Malaysia Melaka (UTeM) for providing the facilities and support for this research.

**Abstract**—In epidemiological research on spine surgery, machine learning represents a promising new area. It is made up of several algorithms that work together to identify patterns in the data. Machine learning provides many benefits over traditional regression techniques, including a lower necessity for a priori predictor information and a higher capacity for managing huge datasets. Recent research has made significant progress toward using machine learning more effectively in spinal cord injury (SCI). Machine learning algorithms are employed to analyze non-traumatic and traumatic spinal cord injuries. Non-traumatic spinal cord injuries often reflect degenerative spine conditions that cause spinal cord compression, such as degenerative cervical myelopathy. This article proposes a novel correlated graph model (CGM) that adopts correlated learning to predict various outcomes published in traumatic and non-traumatic SCI. In the studies mentioned, machine learning is used for several purposes, including imaging analysis and epidemiological data set prediction. We discuss how these clinical predictive models are based on machine learning compared to traditional statistical prediction models. Finally, we outline the actions that must be taken in the future for machine learning to be a more prevalent statistical analysis method in SCI.

**Keywords**—Spinal cord injury; regression; machine learning; graph model

## I. INTRODUCTION

Movement and sensory impulses from the spinal cord, peripheral nerve system, and brain (SC) are key conducts. The nervous system is made of SC and the brain. It has a tubular structure and grey and white matter, including spinal tracks (the bodies of neurons) [1]. SCI is due to the damage in the spinal tracks while carrying information, and damage in the motor and nervous systems results in [2]. Patients may experience paralysis or have their organs cease working properly due to an SCI. We can evaluate SCI patients more precisely because of the motor and sensory ratings provided by the International Standards for Neurological Classification of Spinal Cord Injury (ISNCSCI). American Spinal Injury Association (ASIA) created these scores, which have since been modified multiple times [3]. They are crucial for determining a patient's SCI sufferer's prognosis in a therapeutic rehabilitation program since they are connected with functional status [4]. For a reliable diagnosis of SCIs, clinical evaluation based on ISNCSCI scores has limitations.

It relies on the patient's input, which is subjective and ambiguous when there is concurrent damage to other organs [5].

For the diagnosis of SCI, conventional MRI is frequently employed. A medical imaging technique called MRI creates detailed macroscopic images of organs and tissues. It uses a striking image (black & white) to discriminate between hard and soft tissues [6]. Modern technology called Diffusion Tensor Imaging (DTI) employs echo-planar MRI data. Using the tissue's architecture and structure, it monitors the movement via the SC and brain tissue, water molecules [7]. DTI is used to study pathological conditions and disorders such as multiple sclerosis, hypertensive encephalopathy, and brain tumours. It gives quantitative data on the size and placement of a three-dimensional (3D) space containing each tissue. Diffusion anisotropy is the word used for this. Numerous floating diffusion ellipsoids make up the diffusion tensor [8]. Each diffusion ellipsoid's orientation is specified by a group of vectors that indicate orientation, often called eigenvectors. A distinct outcome matching an eigenvalue is produced when an eigenvector's length or direction is altered. DTI allows for the expression of diffusion anisotropy as fractional anisotropy (FA) [9]. FA, which has a scale from 0 to 1, is frequently used to determine the degree of fibre integrity since it is sensitive to the number of directionally directed fibres per voxel. Water diffusion anisotropy is measured by the FA value, with a higher degree indicated by a higher FA value [10]. In this research, we provide a brand-new Machine learning-based SC analysis technique. One of the main professionals in diagnosing SCI is [11]. Currently, choices are made using human specialists' analysis of FA values and DTI pictures. If we can provide them with more factual data, they will be able to diagnose more precisely. Classification systems are used in machine learning to make predictions or diagnose problems [12] – [13]. However, classification jobs call for training data. We create a training dataset for our method utilizing four FA values from patient and healthy control slice images. The base dataset is then expanded to 15 features present in a dataset with more dimensions, and the intended dataset is abstracted to increase classification precision [14]. Prediction accuracy for the generated dataset is higher than 90%. Our two contributions are using a classification technique to predict SCIs and creating a training set of images produced by the DTI. The data connected to a specific person

is more than 200 MB [15]. There is a huge challenging factor to employ in computer-aided diagnosis; raw data is large. The major research challenge is the complexity in accurate prediction of spinal cord injury using least sample dataset. Some existing machine learning approaches fail to give better accuracy due to lesser number of samples. However, this can be resolved using the advanced learning approaches. This motivates to adopt a novel learning approach for predicting accurate spinal cord injury and to enhance the accuracy with available samples. In our plan, we take the raw DTI data and extract meaningful numerical information that we subsequently use for diagnosis. Any field in which DTI is used for diagnosis can use our method. This work intends to validate the efficiency of the anticipated CGM and explores the prediction ability with the construction of SCI-based functional connectivity. Here, the behavioural relationship between the injury regions is analyzed from the available online dataset. The proposed CGM constructs the connectivity pattern among the injured region to predict the differences from other regions. The experimental outcomes demonstrate that the anticipated CGM-based prediction model outperforms the overall approach significantly. The model is more reliable and stronger in its prediction nature.

The work is organized as follows: Section II offers a comprehensive analysis of prevailing approaches; Section III gives a detailed analysis of the proposed graph-based model and correlation analysis. In Section IV, the numerical analysis of the anticipated model is provided, and the results are discussed. The summary is provided in Section V.

## II. RELATED WORKS

Machine learning is a broad field that primarily applies computing models to many real-world situations. The primary objective of machine learning relies on the development of algorithms using information from a database. Recognition, diagnostics, planning, robot control, and prediction are tasks that can be accomplished when it is employed. Additionally, it can use machine learning to analyze neuroimaging data and predict tissue toxicity [16]. Both tasks use pattern recognition which requires the identification of numerous important variables. Nowadays, enormous data is employed by the researchers that must be managed, analyzed and used. Large amounts of data may conceal significant linkages and correlations that are uncovered via machine learning. It enhances the effectiveness of systems and machine design. Medical image analysis, lesion segmentation, and computer-aided diagnosis have turned as key application areas for machine learning.

In biological studies, classification is a major task where machine learning is crucial to the classification process. With well-known dataset, unknown sample data can be predicted using machine learning. It can distinguish two or more disparate items, combine related objects, or divide different objects. During the classification process, objects are categorized based on their unique characteristics and each item is given a class name to indicate the specific category to which it belongs ("patient," "normal") [17]. Predictions are made using training and testing of unlabelled data. Test dataset contains unidentified sample that are required to

establish the class label and the performance of the training dataset is evaluated. Two popular categorization methods are k-NN and SVM). K-NN is based on instances of feature-space classifiers that select the most nearby data points for classification choices.

The numbers of characteristics are redundant and irrelevant while classification accuracy is preserved by feature selection. Statistical ML is widely utilized before classification and creates a powerful and stable predictor. In addition to noisy data, feature selection manages exceedingly big datasets. Feature selection makes classification faster and efficient by reducing the dimensions of the data. Feature selection methods like Clearness-Based Feature Selection (CBFS), Features selection based on a distance discriminant (FSDD), R-value-based Feature Selection (RFS), ReliefF, and CBFS are some examples of feature selection. R-value [18], is a statistic for measuring the region of overlap between classes in a feature. Identifying traits that promote effective class separability across classes and maximizing the proximity of samples within the same classes form the basis of the FSDD method. ReliefF is one of the most effective feature selection methods. The concept is to estimate feature weights iteratively based on how well they can distinguish between nearby examples. Based on "CScore" metrics, CBFS is an excellent feature selection technique. Many samples were located in the right class region was determined by the score presents an alternative feature selection approach based on the Lasso. This method establishes a scoring system to determine the "quality" of each distinct feature. Several samples are created using training data and then high-relevance feature orderings are chosen for each sample. Finally, highly relevant properties are integrated. This study use selection of features to assess each feature's discriminative power and identify the most distinct feature subset [19] – [20].

Sagittal and axial panels have undergone T1- and T2-weighted imaging to assess SCI separately. Clinical evaluation is performed to gauge neurological damage and its seriousness was measured using MRI technology. The signal change level and clinical outcomes were linked [21]. We automatically applied classification technique to distinguish patient image slices. The system quickly and accurately produces outcomes and integrates algorithms easily. A key indicator of a prediction quality is classification accuracy. Many academics have tried to increase classification accuracy through algorithm or dataset improvements. Obtaining FA values from DTI is to help people find the impacted area. Human experts heavily rely on the personal knowledge they have gained from earlier assessments of T1- or T2-weighted pictures, even though FA value validates SCI. An automated system can identify SCI to diagnose the condition of the affected area and offer pertinent data would be beneficial [22].

Since there is currently no cure for SCI, individuals with motor-related injuries have little chance of sustaining voluntary movement recovery over the long term (more than a year after the injury) [23]. There is growing evidence that neuro-modulation may be viable for chronic and persistent SCI based on recent reports of effective partial functional recovery. [24]. Even with these positive case studies and series, there are still a lot of problems to be fixed before a

conclusive clinical trial. The ability to customize each patient's spatial and temporal neuro-modulation has increased with the technological advancements in implantable neuro-modulation platforms. However, large, high dimensional flexibility necessitates effective algorithmic optimization customized to each patient's unique pathologies and underlying physiologic system.

Based on simulation conditions, research using animal models has shown huge responses in voluntary movement. Further evidence of this variance was found in human models, necessitating the spatiotemporal adjustment of eSCS-customized patient-specific characteristics [25]. It is crucial to find the optimal parameters because the heterogeneity of SCIs may cause the observed variation in response to the stimulation parameters. A reliable system for choosing the best settings must be created for electrical stimulation therapy because there are trillions of potential configurations for 16-lead paddle. Some studies are currently available on eSCS optimization techniques for causing volitional movement after cSCI. The majority of research uses animal models, and various teams make use of various optimization strategies. To identify the spinal circuits and fibres drawn by eSCS, the author developed computer model that merged 3D finite element approach with rat spinal cord model. The ideal parameters for standing and walking rats are predicted using different electrode configurations. Specific muscle responses to be evaluated by electromyography (EMG) in spinally transected rats were chosen by bipolar stimuli based on Bayesian optimization [26]. Another animal experiment focused on enhancing stepping by adjusting stimulus intensity, the time between pulses and strength. Some staff members determined the ideal frequency and intensity subjectively. Then, kinematic data, EMG, and various stimulation pulse intervals were used to re-evaluate these parameters. To find the best parameter combinations, one study used 3D kinematic data recorders and quantitative gait characteristics [27] – [28].

Even less research has been done on enhancing stimulation in human model systems than in animal models. Various optimization goals and techniques have been tested in various investigations. A map of each participant's motor neuron activation was produced to identify where the spinal cord was engaged during particular muscle movements. Using computerized model, the best electrode combinations were identified through simulations [29]. EMG mapping data has also chosen [30]. The limitations of current optimization approaches make it evident that all-encompassing strategy for choosing the best model for SCI prediction. The major research gap is a lack of proper methodology for feature selection and classification even with small datasets. This may leads to poor prediction outcomes. Therefore, this research concentrates on modelling an efficient approach for prediction.

### III. METHODOLOGY

This section gives a detailed explanation of the proposed model for soft tissue prediction using learning concepts. We initially provide a brief overview of a few terminologies, and there are some definitions of graphs and graph signals. Using SVR, it is then determined how the FC patterns relate to the

appropriate behavioural measure; refer to the framework in Fig. 1. Next, we build FC patterns using the spinal image and our correlated graph model (CGM). Finally, we use simulated data to validate the proposed CGM.

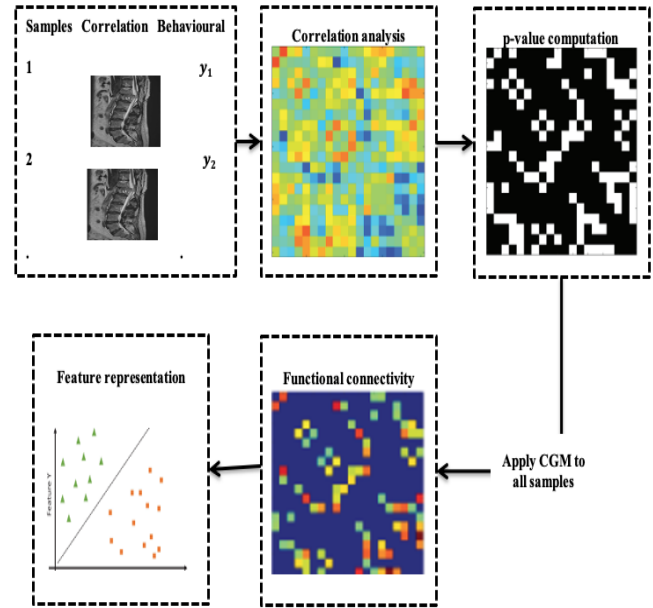

Fig. 1. Framework on a predictive model.

#### A. Graph model

Consider the FCN to be an undirected, linked, weighted graph. Let's build a graph with  $G = \{V, W\}$  where  $V = \{v_1, v_2, v_N\}$  is a collection of  $N$  nodes (ROIs) and  $W = [W_{ij}]_{i,j=1}^N \in R^{N \times N}$  is a weighted adjacency matrix that is symmetric (and frequently sparse), with  $W_{ij} \geq 0$  representing the degree of similarity between the nodes. The degree matrix generated by the diagonal matrix with its diagonal  $D \in R^{N \times N}$ ,  $L \in R^{N \times N}$  member  $D_{ii} = \sum_{j=1}^N W_{ij}$  is referred to as the "Laplacian matrix."

$$L = D - W \quad (1)$$

As a result, we use either the Laplacian matrix,  $L$  or the weighted adjacency matrix of graph  $W$ , which may uniquely describe the underlying graph, to define the  $FC$  pattern quantitatively. With  $f = [f_1, f_2, f_3, \dots, f_N]^T \in R^N$ ,  $f$  be a signal on the graph  $G$  that links value-based feature selection and features selected using a distance discriminant, overall variability about the Laplacian matrix  $L$  as depicted in Eq. (2):

$$f^T L f = \frac{1}{2} \sum_{i \neq j} W_{ij} (f_i - f_j)^2 \quad (2)$$

The smoothness of the graph-wide variation of a graph signal measures the size of the change. Given that nodes with high edge weights are densely coupled, it makes sense that when  $W_{ij}$  is sizable, the gap between  $f_i$  and  $f_j$  will also be narrow. As a result, many machine learning methods like graph regularization and transductive learning have successfully used this graph smoothness notation. According to the perspective of graph signal processing, by utilizing the

graph frequencies provided by the eigenvalues to define different degrees of graph signal smoothness, the eigenvectors of  $L$  offer Fourier transform for graph signals. The  $FC$  pattern in this work was different from the  $FC$  pattern predicted by our CGM due to the magnitude of squared spectral coherences among the time courses of paired ROIs and the examination of brain signals related to diverse graph frequencies.

### B. Correlation Analysis

Consider that  $M$  training subjects are present. In the image courses, let  $X^{(i)} = [x_1^{(i)}, x_2^{(i)}, \dots, x_N^{(i)}]^T \in R^{N \times K}$ . Assume there are  $M$  training participants with  $i^{th}$  subject  $1 \leq i \leq M$  where  $x_j^{(i)} \in R^k$  specifies the ROI in the  $i^{th}$  subject and  $N$  represents the number of ROI. Let  $y_i, 1 \leq i, = M$  specify the subjects' measure. Consider  $X^{(i)}$  is normalized to pose zero mean and unit normalization. The Pearson's correlation matrices  $R^{(i)} \in R^{N \times N}, 1 \leq i \leq M$  for all individuals,  $R_{ijk}^{(i)}$  specifies correlation coefficient among  $j^{th}$  and  $k^{th}$  ROI in the  $i^{th}$  individual, i.e.

$$R_{jk}^{(i)} = corr(x_j^{(i)}, x_k^{(i)}) \quad (3)$$

The behavioural measure is then coupled with Pearson correlation matrices; correlation matrices  $Q \in R^{N \times N}$  and  $P \in R^{N \times N}$  correspond to each between-ROI correlation coefficient.

$$Q_{jk} = corr(r_{jk}, y) \quad (4)$$

Where  $h$  refers correlation coefficient across all people,  $r_{jk} = [R_{jk}^{(1)}, R_{jk}^{(2)}, \dots, R_{jk}^{(M)}]^T \in R^M$  is the  $(j, k)^{th}$  among ROI correlation coefficient and  $y = [y_1, y_2, \dots, y_M]^T \in R^M$  is the behavioural measure. Then, we choose the significant correlation coefficients in  $Q$  from the  $p$ -value matrix  $P$  that are associated with the behavioural measure using a certain threshold. Thus, the matrix  $C \in R^{N \times N}$  is expressed as:

$$C_{jk} = \begin{cases} 1 & \text{if } P_{jk} < \tau \\ 0 & \text{else} \end{cases} \quad (5)$$

With the label information of the subjects, we can drastically reduce the amount of redundant or irrelevant  $FC$  characteristics by employing matrix  $C$  as a guide for learning the  $FC$  pattern. To estimate the  $FC$  pattern, the CGM technique, in addition to the conventional following, is the graph learning technique:

$$\min_{\tilde{L} \in R^{N \times N}} tr \left( (X^{(i)})^T (\tilde{L}^{(i)} \odot C) X^{(i)} \right) + \beta \left\| \tilde{L}^{(i)} \odot C \right\|_F^2 \quad (6)$$

$$tr(\tilde{L}^{(i)} \odot C) = N \quad (7)$$

$$(\tilde{L}^{(i)} \odot C)_{jk} = \left( (\tilde{L}^{(i)} \odot C)_{kj} \right) \leq 0, j \neq k \quad (8)$$

$$\left( (\tilde{L}^{(i)} \odot C) \right) \cdot I_N = 0_N \quad (9)$$

Here,  $L(i) = \tilde{L}^{(i)} \odot C$  and  $C$  refer graph's Laplacian matrix ( $FC$  pattern), where  $C$  is computed with Eq. (5),  $\beta > 0$  refers to the positive regularization parameter and  $\|\cdot\|$  and  $\odot$  specifies matrix norm and element-wise product respectively. The CGM transforms into the conventional graph

learning methodology when the threshold is 1 or there is no correlation guidance, as in Eq. (6), where the matrix  $C = 1_{N \times N}$ .

It is important to note that by minimizing their fluctuations on the learnt graph, the first component of the goal of Eq. (6) is to match the observed spinal cord injury image with the learned graph. The second term helps to further eliminate duplicate  $FC$  characteristics by regulating the sparsity of  $L^{(i)}$  as denser as is greater and vice versa. Additionally, the second and third conditions are included to guarantee that the first restriction is imposed as normalization and learned  $L^{(i)}$  refers to a legitimate positive semidefinite Laplacian matrix. There is a safeguard against trivial solutions. Cross-validation will be utilized to identify the hyper-parameter  $\beta > 0$ .

To create subject-specific  $FC$  patterns that reflect a common template matrix  $C$ , the CGM was constructed in Eq. (6) for both the link between ROIs and the graph organization between ROIs. Specifically, by obtaining the  $1 \leq (i) \leq M$  learned Laplacian  $L^{(i)}$  matrices, we use graph-weighted matrices  $W(i)$  for  $1 \leq (i) \leq M$  to reflect  $FC$  patterns of  $M$  individuals by applying the convex optimization. The vector length  $N(N-1)/2$  represents the  $FC$  features of the  $i$ -th individual produced by triangle  $W$ 's symmetric section.

From these results, the CGM successfully recovers  $FC$  patterns that have more power to discriminate between people, as they are intrinsically relevant to the targeted behavioural measure suggesting the superior performance of behavioural prediction. Therefore, we do a regression analysis to determine how the generated  $FC$  patterns relate to each other using linear SVR with default settings and the behavioural measure in this work to verify the efficacy of the suggested CGM. Fig. 1 is used to train a prediction model. To further clarify how subjects are split into training and test sets, see 1 for more information. After the test subjects' generated  $FC$  patterns are created, the training set's framework is fed into the trained predictive model to provide projected behavioural measures. Although there are many other regression models, the higher effectiveness of the recommended CGM for the optimal  $FC$  pattern prediction is the focus of this study rather than the best regression model schemes.

Concerning the simulated data ( $K = 100$ ) on  $N = 12$  node random weighted network, we verified the CGM made two processes to create the random graph. First, the graph's structure was created with 0.5 probability connections between each pair of nodes, giving the linked edge between the two nodes a uniformly distributed random weight between 0 and 1. Then, a random multiplication of the  $C$  matrix of the  $N \times N$  zero-one template. With edge weights, the graph-weighted matrix  $W$  was produced by linearly coupling the first four eigenvectors of Laplacian matrix  $L$ . Here,  $K = 100$  graph signals are then produced as linear combinations of the eigenvectors (first four) of the graph Laplacian matrix  $L$ .

$$x = 3 \sum_{i=1}^4 \alpha_i f_i \quad (10)$$

Where  $f_i$  refers to an  $i^{th}$  eigenvector of  $L$  and  $\alpha_i$  refers uniform random variable with  $[0, 1]$  range. We inferred the graph structure from these graph signals regarding the

different values of  $\beta$ , specifically the values of  $\beta \in \{0.5, 1, 5, 10, 50, \text{ and } 80\}$ . We discovered that  $\beta = 10$  produced the highest level of performance as determined by the graph Laplacian matrix and Normalized Mutual Information (NMI) discovered during signal processing and the ground truth. The learned graph Laplacian matrices are shown in Fig. 2 for  $\beta = 1, 10, \text{ and } 80$ , respectively. We used a separate zero-one template matrix  $C_b$ , which had 40 randomly generated  $C$  elements to emphasize the significance of ensuring a CGM-acceptable zero-one template matrix. Comparing the NMI performance of the CGM with  $C$  and  $\hat{C}$ , we varied, as shown in Table I.

TABLE I. TEMPLATE MATRIX

	$\beta = 0.5$	$\beta = 1$	$\beta = 5$	$\beta = 10$	$\beta = 50$	$\beta = 80$
$C$	0.50	0.37	0.61	0.71	0.51	0.48
$\hat{C}$	0.23	0.23	0.23	0.15	0.048	0.03

Fig. 2. Matrix evaluation.

#### IV. EXPERIMENTAL SETTINGS

In our trials, we used state SCI data to predict various measures. Using a 5-fold CV, five times using SVR was used to predict individuals' behaviour using FC patterns derived from the CGM (with LIBSVM). The entire group of patients was divided into five roughly equal-sized disjoint subsets by chance; chose one subset at random as the test set, and the training set was used with the other four. 20 rounds of this process were performed to reduce how sample bias affects cross-validation (CV). The prediction performance (average) over all 20 iterations was reported using a 5-fold CV. The hyper-parameter  $\beta$  was found by employing the grid search ranges from  $[0.05, 2.5]$  and the inner CV of the training set. The correlation between the anticipated and observed behavioural variables among people in the test set and Root Mean Square Error (RMSE) were used to evaluate the prediction performance. The template matrix  $C$  was generated at a random significance level. To find the optimal threshold, with values of 0.01, 0.05, 0.1, 0.15, and 0.25, we repeatedly examined five distinct  $p$ -value criteria.

#### A. Dataset

The significance of MRI is to provide superior discriminate soft tissues, along with its capability to acquire heterogeneity and tumour changes. The available online dataset known as Cancer Imaging Archive is used in this research. The dataset comprises CT/PET/MRI scans of 51 patients. Another dataset with 21 patients is also considered. Here, 11 pathologically verified Liposarcomas arise with the soft tissue, and 10 Leiomyosarcomas influence muscle cells. The cohort is composed of 9 females and 12 males with a duration of 31 months. Ground truth discriminating histopathological subtypes is definite. Tumours are localized in the pelvis, biceps, and thigh. Here, three different types of MRI are utilized for training T1-, T2-weighted fat-saturated, and short tau inversion recovery (STIR). With the T1 sequences, the data acquisition is made of the axial plane, while STIR and T2FS are acquired in diverse orientations (coronal, sagittal, and axial). MRI scan with slice thickness is 5.5 mm for T1 and 5 mm for T2-weighted fat saturated. The plane resolution is  $0.63mm^2, 0.74mm^2, \text{ and } 0.86mm^2$  for T2FS, T1, and STIR scans.

#### B. Result Analysis

It's important to remember that in the proposed CGM, the graph model is used to evaluate and identify functional linkages that we need to assess. A significance test is then performed on the degree to which these chosen linkages are connected and the between ROI correlation coefficients with the participant-wide behavioural measure of interest as in Fig. 3. Each behavioural measure shows the mean SCI functional network patterns among patients employing the related techniques separately. The PC-based FC patterns are clear to see based on graph learning and are significantly denser than the FC patterns based on the graph model. The proposed model generates FC patterns that are substantially less dense than those generated by the correlated graph model. The CGM-based FC patterns show greater variability in multiple functional connections, further reinforcing connectivity with high functionality strength and vice versa. It highlights CGM's usefulness and combines pair-wise correlation and graph learning. It assesses the prediction performance of the suggested model for each behavioural indicator in Table II and Table III. The recommended CGM had the best  $cc$  and  $RMSE$ -based prediction performance. By contrasting these outcomes, we may demonstrate the suggested CGM's efficacy and efficiency based on its superior performance. To extract more discriminative FC patterns for building SCI-behavior linkages, it may be advantageous to merge temporal correlation among ROIs with the graph structure across ROIs (GL) of CGM.

We also looked into how the parameters in the suggested CGM affected the accuracy of behavioural prediction. First, the  $p$ -value threshold used in the overall results of the CGM for each behavioural measure is impacted by the method used to construct the template matrix. The  $p$ -value threshold determines how many functional connections in the CGM must be learned. With a lower  $p$ -value threshold, The CGM's graph learning stage will accept fewer connections, indicating a more rigorous connection selection process. Except for

WRAT prediction, the  $p$ -value threshold selection affects how well other predictions. Second, we directly computed the prediction results using a fixed and carefully chosen  $p$ -value cutoff for creating the template matrix and 20 iterations of the 5-fold cross-validation with various hyper-parameter values. It was done to investigate the CGM's sensitivity to the relevant regularization parameter  $\beta$ . Fig. 4 presents the  $cc$  results. We discovered that the results varied depending on the regularization parameter's value and obtained the best performance in each case.

Finally, we evaluated the most distinctive biologically significant functional relationships that may be linked to these three behavioural characteristics using the FC patterns produced by the proposed CGM. As imaging biomarkers affect a person's variance in the mentioned behavioural assessments, the identified connections may be a supervised learning technique called the SVR assigns distinct attributes distinct weights to most closely mimic the response values in the training set. In this investigation, we emphasized the linkages to which the trained SVR gave more weight. Finally, using the FC patterns produced by the proposed CGM, we independently explored the most discriminative functional links with hypothesized biological values associated with these three behavioural traits. Imaging biomarkers, which influence the individual variation, the relationships found may be employed in the aforementioned behavioural tests. Fig. 5 and Fig. 6 depict the performance comparison of the proposed model.

### C. Discussion and Analysis

In this study, we presented the CGM, which builds by considering the graph structure between ROIs, the relationship between ROIs at different times, more discriminating FC patterns, and constructing brain-behaviour correlations that have been discovered. The CGGL was then used to individually predict three behavioural measures of SCI data from the resting state using the publically available PNC

datasets. In prediction performance, this method outperformed competing FC pattern estimating techniques. The CGM offers a potentially reliable and efficient solution for examining the connections between the brain and behaviour to estimate FC patterns.

Fig. 6. Accuracy comparison.

The FC pattern generation methods based on deep learning have drawn more attention recently, largely because of the incredibly high prediction performance. Fundamentally, layer-by-layer learning from SCI courses is the basis for deep learning-based FC patterns, which typically have more complicated hidden information. On the other hand, deep learning techniques inevitably entail several variables. Substantial training datasets are frequently required to account for the weights and biases of the various layers and expensive computing power to optimize these parameters. However, with fewer parameters, our suggested technique can produce discriminative FC patterns. In the case of small samples, this reduces the over-fitting issue and increases generalization capacity and effectiveness. Gaining an anatomical understanding of which functional relationships result in individual variation in the relevant behavioural measure was another goal of this investigation.

## V. CONCLUSION

In this study, we introduced the CGM, a novel technique for creating spinal cord injury FC pattern patterns. The recommended CGM combines two widely utilized FC pattern analyses with graph learning and Pearson's correlation. Both the graph structure across ROIs and the relationship between ROI points and time were considered. As a result, the suggested CGM has a lot of promise for improving the generated FC patterns' prediction ability for establishing SC injury correlations and collecting insightful knowledge about the biological processes involved in the behavioural measures of interest. By independently predicting three behavioural variables, we assessed the effectiveness and efficiency of our

suggested CGM using available data from the available sources. The experiment's findings supported the proposed CGM's superiority over other FC pattern estimating techniques which have broad implications in brain network analysis. In future, this study can be further extended with adoption of a novel optimization approach for attaining the global outcomes in terms of accuracy and prediction. Also, with the adoption of pre-trained model, the time complexity can be reduced effectually.

# The Practices of Online Assessment in a Digital Device in the Context of University Training: The Case of Hassan II University

## How to Evaluate Online Learning in the Context of University Training?

**Abstract**—This research presents online assessment in a digital device in the context of university training, aimed at improving their practices with emerging technologies based on an experiment with students from Hassan II University. Or, online assessment is a systematic process that helps measure the knowledge and skills of learners through multiple technological tools in a digital device. Indeed, digital devices intend to revolutionize higher education with the use of Information and Communication Technologies (ICT). Nevertheless, digital devices pose the problem of student identity verification during online assessment. In reality, automated online assessment systems are extremely vulnerable to cheating. So, our aim of this research is to explore, firstly, the types of online assessment that could be implemented in a digital device and secondly, how to verify the identity of the student during an online course on a digital device? The sample of our experiment consists of (N = 108) students from the Hassan II University of Casablanca, divided into two classes of the ITEF and MIMPA Masters and, our study was based on an online questionnaire for (N = 37) teachers at Hassan II University in Casablanca. The results obtained is to put into practice in digital devices diagnostic evaluations and formative evaluations using biometric methods for identity verification with a limited number. However, biometrics is inapplicable in summative assessments due to the problem of massiveness and hindrances in the online exam. For this reason, measures must be put in place to promote the smooth running of the online assessment.

### I. INTRODUCTION

Since March 2020 and due to the measures taken by the Moroccan authorities to combat the spread of COVID-19 such as the suspension of all activities involving a gathering of people, education in Morocco has undergone a remarkable evolution with the replacement of face-to-face courses by distance education. However, distance education allows students and all those who wish to train online and interact with others, particularly in the health crisis that has affected our country [1]. As well as classroom exams have been replaced by online assessments.

First of all, online assessment is a crucial step in distance learning in order to measure the degree of student acquisition through different assessment methods and in different fields (education, economics, engineering ...). This section aims to describe the theories from the literature review related to online assessment. Indeed, online evaluation should not simply invent new technologies that recycle our inefficient practices [2]. For example, the issue of assessing student learning in an online course has not been fully addressed [3]. And that assessment is at the heart of the teaching-learning process. What is assessed defines what is taught and how it is learned. The assessment process, in turn, shapes practice and affects the learner's view of the value of engaging in learning [4] and that online assessment remains an emerging new practice for most educators and trainers [5]. Furthermore, in professional settings and training institutions, assessment practices are numerous and diverse. Their most often stated purpose is to improve production processes and/or to certify the achievement of objectives [6]. Because of these observations, the authors underline the interest in online evaluation and the growth in its use, which is based on social, technological and economic factors. Assessment practices (diagnostic, formative, summative), whether face-to-face or online, can therefore be a mobilizing lever in an initial or continuing university education institution. These practices aim to achieve learning objectives through various authentic or collaborative activities in order to improve the development of students' skills [7].

Although Morocco is returning to its normal state thanks to the gradual decrease of the COVID-19 pandemic, distance learning retains a particular importance as it meets the growing and diversified needs of Generation Z learners, such as developing their skills and that they prefer to learn through digital resources and create their own personal learning environment [8,9]. It is now seen as a solution to ensure pedagogical continuity with learners in particular, those who cannot always be present. Hassan II University of Casablanca has developed several digital services grouped together at the Digital Workspace <https://ent.univh2c.ma>. This has allowed all the actors to have a simplified access to many institutional tools: electronic mail, e-portfolio, software, electronic books and magazines, e-learning platform. The digital resources of

the UH2C allow its students to regularly follow their courses in direct broadcast mode or in deferred access on the Moodle platform. The teachers of the Hassan II University of Casablanca use several digital devices in their teaching practice. Through these devices, teachers will be able to make their courses available online. However, it is difficult for the teacher to really practice summative evaluation online because on the day of the online exam, the learner can use any excuse to justify his absence or non-participation in the course.

According to previous research, students have been very satisfied with taking courses on online learning platforms and assessment methods [10]. Moreover, online and peer assessment plays a key factor in students' engagement during their learning and leads to learning performance [11]. The development of online assessment based on a standardized model helps to improve or enhance students' online learning [12]. Furthermore, the importance of integrating online assessment activities such as online knowledge surveys, online closed or open-ended questions, and peer review [13]. However, assessment activities should measure the degree to which students acquire learning objects with the same online opportunities and conditions [14].

It is for this reason that we are going to carry out this experiment, at the level of the Hassan II University of Casablanca, which will focus on formative evaluation practices. In this regard, the purpose of this research is to present the online assessment in a digital device in the context of university training, aiming to improve their practices with emerging technologies based on an experience with students of Hassan II University. In this context, we posed the following questions:

- What are the types of online assessment that could be implemented as part of a digital system?
- How to verify the identity of the student in the context of online assessments?
- What measures should be put in place to promote online assessment?

## II. THEORETICAL FRAMEWORK

This part aims to describe the theories resulting from the bibliographical review in relation to the types of online evaluation and the phenomena of cheating that could be seen during online evaluation.

### A. Online Assessment Practices

Generally, there are three types of evaluation, which can have different purposes. Most often, we distinguish:

1) *Diagnostic assessment or pre-test*: done before or at the start of a course or program to determine the prerequisites or knowledge required. A distinction is sometimes made between diagnostic and prognostic evaluation. The first concerns first of all the learner, allowing him to adapt his path or to take remedial measures and, the second serves rather the evaluator aims to produce information which makes it possible to orient or train or to adjust the training to his profile [15]. It makes it

possible to determine the profile of the learner in order to guide the course that adapts to his knowledge path.

2) *Formative assessment*: done during a course or program to support or enhance learning and foster learner motivation based on observed needs. It insists on the value of consolidation and feedback on error in order to support learning [16]. Its purpose is to check whether the learner is progressing and approaching the chosen educational objective of the established program. It promotes integrated motivation and encourages the learner to adopt a more effective approach to learning [17]. [18] Describe five functions of formative assessment: explaining goals, tasks and assessment, seeking evidence of understanding, seeking evidence of progress of the task, feedback anticipating future steps and empowerment of learners. However, the feedback therefore plays a central role. It is often more continuous or repeated at regular intervals during training.

These functions can be put to good use in the current situation of pedagogical changeover for the benefit of student learning.

3) *Summative assessment*: done after a course or program or during exams. This terminal practice aims to categorize, certify and validate practices, behaviors or knowledge [19], and to report. Its purpose is to say if such a learner is worthy of such a grade or if he can access the higher class. Consequently, it makes it possible to provide a balance sheet and to allow a decision (does he access the upper class or not?)

### B. Cheating

Cheating or copying<sup>1</sup> would therefore be associated with unauthorized mutual assistance, particularly with cheating in real time, often during exams. [7] For (CCA<sup>2</sup>, 2010), in the context of online assessment, for example:

Swap answers during an exam:

- By computer (instant messaging, email, etc.).
- By mobile phone.
- By text messaging.

And, according to [20] it gives the example of a student who “connects with the same username and the same password as another student to steal information or work” or, more simply, the one who obtains from a colleague the questions of a previous examination; “to consult non-admissible notes during an exam”. For example, his or her own notes or the web, when it is not allowed to:

- Submit work done in whole or in part by another person.
- Submit the same work, which may be an exam, for various courses without having obtained permission, where the work may be an exam.

<sup>1</sup> Defined by the great terminology dictionary of the Office of the French language as: “Fraud of a pupil who copies, during an examination or a test, the duty of a comrade, a book or course notes”.

<sup>2</sup> The Canadian Council on Learning.

However, cheating mostly targets contexts where external sources are not allowed. Additionally, plagiarism or copying generally applies in the context of a work where the use of other sources is permitted, but on condition that credit should be clearly attributed to the original author. What are the cheating detection tools that can be implemented in a digital device?

### III. METHODOLOGY

#### A. Measuring Instrument

To answer the above questions, we opted for a quantitative methodology through a questionnaire. We drafted a questionnaire for teachers and then administered it to 37 teachers at Hassan II University in order to enrich our problematic.

#### B. Methods of Experimentation

Therefore, we searched for suitable tools and methods to address the aforementioned issue. So, we have chosen to integrate the biometric method which makes it possible to specify the automatic identification of a student during online evaluations. The latter measures the uniqueness of an individual from the unchangeable parts of his body. This method is based on two methods: Behavioral modalities and, morphological modalities. In addition, we decided to work with a morphological modality through the recognition of the student's face and the other behavioral modality through the recognition of the student's voice. Then, we set up a system with emerging technologies. Next, we opted for the latest version of the moodle platform because it is more suitable for the implementation of a real digital device than the Open edx platform. In addition, we installed the moodle platform online with the xamp server, by integrating two plugins: one to block the search browser window during the online assessment. And the other which is based on the camera and the microphone to ensure the online identification of the students.

#### C. Echontillon

To answer the research questions above, we carried out an experiment with the students of the Master class of Engineering and Technologies for Education and the Master class Instrumentation and Physico-Chemical Methods of Analysis in second semester of the quality module: Management and tools at Hassan II University. The number of our sample was (N=108) and our experiment on the digital device [www.digitaloftkill.net](http://www.digitaloftkill.net) (Fig. 1) which was in the form of a questionnaire of 20 multiple-choices questions. Each question with four answer choices in a period of 15 min.

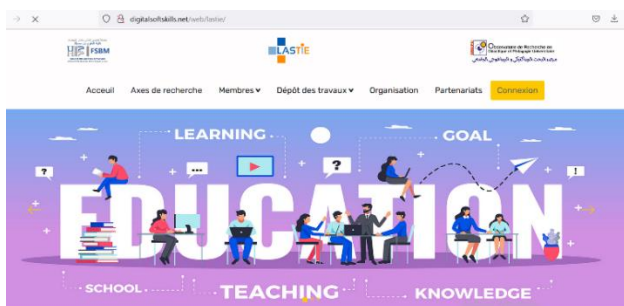

Fig. 1. Overview of the platform [www.digitaloftkill.net](http://www.digitaloftkill.net).

We have created an account for each student that contains a username and password in order to take the online assessment. Each student must follow the instructions below before starting the evaluation, respecting the period of time determined and the number of possible attempts (Table I).

TABLE I. TABLE OF INSTRUCTIONS

Instructions
1. Install Safe exam browser version 3.1.1 on your desktop.
2. Inform people around you not to enter the place where you are doing the MCQ.
3. Download the QCM SEB file.
4. Click on the meeting link.
5. Activate your camera and sound.
6. Click on the test file (for example: mock test).
7. Click on no.
8. Enter your following username and password: Username: student2 Password: Student2 @ 21
9. Click on continue the attempt (to start the test).
10. Answer the exam questions.
11. Click on end test.
12. Click on send all and finish.
13. Click on quit Safe exam browser.

### IV. RESULTS ANALYSIS

#### A. Results of the Questionnaire

To answer the questions above, we wrote a questionnaire for the teachers then, we administered these questionnaires for 37 teachers of the university Hassan II in order to enrich our problem. Based on this teacher questionnaire, we present some of the following results:

In the situation of the COVID-19 pandemic, we noticed that there are 60% of teachers preferred online courses; on the other hand, there are 40% of teachers preferred face-to-face courses (Fig. 2).

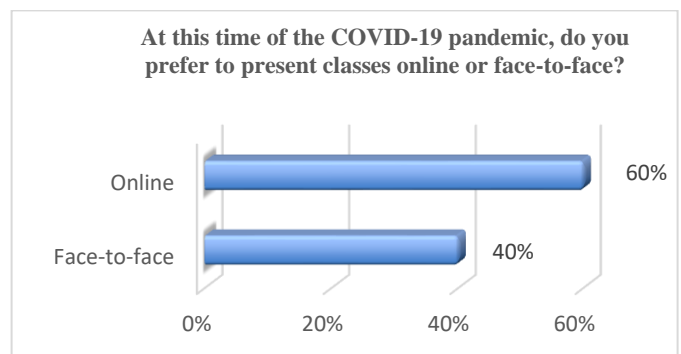

Fig. 2. The choice of online and face-to-face teaching.

From this diagram, we found that 38% of teachers prefer online assessment and 62% of teachers prefer face-to-face assessment (Fig. 3).

We noticed that there are 65% of teachers do not trust students during online assessment and 35% of teachers trust students (Fig. 4). Hence the question: What measures should be put in place to promote online assessment?

Fig. 3. The choice between in-class and online assessment.

Fig. 4. Teacher confidence in online assessment.

### B. Experimental Results

We present below the results of this experiment: these are general data relating to the gender questionnaire, average scores, number of attempts and the constraints (or obstacles) that hinder online assessment practices, in order to determine the measures to promote the establishment of an online assessment.

Regarding the percentage of students, we have 60% of female respondents and 40% of student respondents, which shows that female respondents are more numerous than male one (Table II).

Regarding the average pass mark, we have 14.57 for female students and 13.63 for male students and 14.16 for the general average of the two classes. So, we can deduce that the majority of students have good grades and have not found any difficulties in the MCQ. Although it is necessary to take into consideration the students who failed and those who could not pass the MCQ (Table III).

TABLE II. CHARACTERISTICS OF THE SAMPLE BY GENDER

Gender	Percentage	Number of participants
Female	60 %	64
Male	40 %	44
Total	100%	108

TABLE III. THE AVERAGE SCORES ON A PASSAGE TEST

The average score	
Female	14.57
Male	13.63
General average	14.16

Regarding the success rate of the students, we have 86.11% of the students who passed and, 5.56% of the students failed in the assessment as well as, 8.33% of the students could not pass the assessment. So, we can deduce that most students have succeeded in this online assessment, but we must try to understand the difficulties (or the obstacles) encountered by other students in online assessment practices (Table IV).

TABLE IV. THE STUDENT SUCCESS RATE

Success rate	Percentage	Number of participants
Passed	86,11%	62
Failed	5,56%	6
Did not pass the assessment	8,33%	9
Total	100%	108

Among the 99 students who passed the MCQ, we find that 48.49% of the students who answered on the first attempt while we have 51.51% of the students who answered after the 2nd attempt because they encountered obstacles during the 1st attempt (Table V).

TABLE V. THE NUMBER OF STUDENT RESPONSES ACCORDING TO ATTEMPTS

Responses by attempts	Percentage	Number of participants
Student responses after the 1st attempt	44,44%	48
Student responses after the 2nd attempt	47,22%	51
No answer	8,33%	8
Total	100%	108

### C. Obstacles Encountered

According to this experiment, we find that 5.56% of students who did not follow the instructions requested. We also have 2.78% of the students who encountered hardware problems; they didn't have cameras in their computers. We also note that 19.44% of the students found problems installing the Safe exam browser because this software requires a more recent operating system whereas the students had an older version on their computers (windows 7, windows XP, etc.). We also have 5.56% of students who found constraints in the quality of the internet connection as the quality of the internet network is low or limited because, the connection which is consumed during the evaluation. Then, we have 13.89% of the students received error messages indicating that the server becomes slow when it is loaded because of a large number of users. On the other hand, we see that 44.44% of the students did not find any problems during the online evaluation on the first attempt (Table VI).

TABLE VI. THE CONSTRAINTS EXPERIENCED

Constraints	Percentage	Number of participants
Problem of following requested instructions	5,56%	6
Material problem: Camera	2,78%	3
Connection quality problem	5,56%	6
Problem installation of the browser secure exam due of the update operating system (Windows 7 and Windows XP)	19,44%	21
Server load problem	19,44%	21
Didn't find any problem	44,44%	48
Total	100%	108

## V. DISCUSSION

For the question “What types of online assessment could be implemented in the context of a digital device?”, we always advise teachers to implement diagnostic assessments and formative assessments on digital devices. However, it is not recommended to set up summative evaluations there because of the obstacles that can be encountered during online exams such as: (the loss of light, the poor quality of the Internet network, the overload of the server quality or the error messages that occur following the overload of the server, malfunction of the hardware equipment for example: the camera, the microphone, etc.).

For the question, "How to verify the identity of the learner in the context of online assessments?", we can verify the identity of the student with the biometric methods in front of the camera and by voice recognition with the microphone within the framework of diagnostic and/or formative assessments with a limited number of students. However, biometrics is inapplicable in summative assessments due to the problem of massiveness and the constraints that hinder online assessment. Regarding the measures to be put in place to promote the smooth running of the online assessment, we can mention:

### D. Verification of Student Identity during Online Assessment on a Digital Device

Among the 99 students who responded at to the 1st attempt or the 2nd attempt, the identity of 75.76% of the students was verified whereas we could not verify the identity of 24.24% of them (Table VII).

Among the 24.24% of students whose identity could not be verified, 21.21% of them were not verified by the Safe exam browser tool and 3.03% of other has not been verified by camera and microphone (Table VII).

Regarding the verification of the identity of the student by face and voice recognition, we verified with 96.97% students who have the camera and the microphone through the Google meet tool. But, we could not verify with 3.03% who do not have the camera and the microphone (Table VIII).

For the phenomenon of electronic cheating, we found the SEB tool (which allows to block the search browser window) to be feasible with 78.79% of students who were able to install SEB but, is not feasible with 21.21% students (Table IX).

- Design very clear instructions to guide students in preference, to be given before the day of the assessment or to take a practical test.
- Ask the learners to prepare the appropriate equipment for the smooth running of the assessment (a good camera, a good microphone).
- Require students to have good internet quality (a speed that allows the assessment to be taken without internet interruption) or to provide a good internet network to all students at the time of the online assessment.
- Ask students to update their operating system at the beginning of the module.
- For teachers, it is recommended to use online servers and avoid using local servers.
- Declare the time and period of the online assessment and, make more than one attempt to overcome all obstacles during the online assessment. For teachers, it is recommended to use online servers to avoid error messages from overloading local servers.

TABLE VII. VERIFICATION USING TECHNOLOGICAL TOOLS

Verification by technologiques tools	Percentage	Number of participants
Couldn't verify by biometric modalities (camera, microphone)	3,03%	1
Couldn't verify by Safe exam browser tool	21,21%	7
Total	24,24%	8

TABLE VIII. VERIFICATION BY FACE AND VOICE RECOGNITION

Verification by face and voice recognition	Percentage	Number of participants
Don't have a camera and microphone	3,03%	1
Have camera and microphone	96,97%	32
Total	100%	33

TABLE IX. ASSESSMENT BY THE SAFE EXAM BROWSER TOOL

Assessment by the Safe Exam Browser tool	Percentage	Number of participants
Couldn't install SEB	21,21%	7
Were able to install SEB	78,79%	26
Total	100%	33

## VI. CONCLUSION AND FUTURE WORKS

This research aims to present the online assessment in a digital device in the context of university training, aiming to improve their practices with emerging technologies based on an experience with students of Hassan II University. Our discussion to the results that we recommend teachers to

implement diagnostic assessments and formative assessments on digital devices and to avoid implementing summative assessments on them. Thus, we can verify the identity of the student with biometric methods in front of the camera and by voice recognition with the microphone in diagnostic and/or formative assessments with a limited number of students. But biometrics is not applicable in summative evaluations.

As a follow-up to this study, we plan to analyze students' and teachers' attitudes about the use of biometrics on learning platforms during the learning of a given module and with a focus on passing assessments.

#### ACKNOWLEDGMENT

The corresponding author would like to thank the Faculty of Sciences Ben M'sick, Hassan II University, for their support in experimenting with this research, as well as all the teachers and the students who participated in this study. This research received no external funding. The authors would like to thank the editor and reviewers for their insightful comments on the first draft of the article.

**Abstract**—This paper presents the study to differentiate between normal and anomaly conditions detected by humanoid robots using comparative statistics. The study has been conducted in robotic software as a platform to examine the scenario and evaluate between the anomalies and normal behaviour in different conditions. This study employed a machine vision technique to run an image segmentation process and carry out semi-supervised object training within a controlled environment. The robot is trained by differentiating the measurement size of the target object, its location, and the object's visibility within three different frames. The effect is measured by extracting the positive predictive value (PPV) value, mean and standard deviation value from the captured image using statistical techniques in machine vision. The results showed that the mean value decreased by around 50% from the normal scenario when an anomaly occurred. Aside from that, the standard deviation values were more than twofold compared to the common scenario, especially after the object's size grew. In contrast, the deviation value is remarkably small when the target is situated in the middle of adjacent frames, compared to the value when the entire shape is positioned in the frame. Simultaneously, the mean values from the processed image produced a minor difference.

**Keywords**—Anomaly detection; humanoid robot; vision system; statistical analysis; robot recognition

## I. INTRODUCTION

Over time, the application and comprehension of machine vision and robotics research have become increasingly valuable and helpful, especially for humans. Among the numerous studies, one that has piqued researchers' interest is applying picture segmentation approaches for spotting objects and people in various settings and orientations. Hence, it is scientifically referred to as anomaly detection. Anomaly is also defined as a low likelihood or probability of occurrence in a given setting. To put it simply, anomalies occur when the item's state deviates from the standard or customary order [1,2]. Certain anomaly detection studies generally implemented computational intelligence knowledge, including fuzzy logic-based outlier identification and neural networks.

Moreover, this detection algorithm employs machine learning and statistical detection methods, as the subject's previous behaviour or trends need to be learned and interpreted [3,4]. It may also be utilized for practical purposes in product quality control, enhancing national security, and

military purposes. Anomaly detection might also be used for mobile robots and unmanned aerial vehicles (UAV). These robots can detect anomalous behaviour and sceneries in various environments. Among them, the humanoid robot is a type of mobile robot. The robot can be programmed to use picture segmentation and processing techniques to determine the output pixel value and identify anomalous behaviour.

In anomaly detection, there are several issues that need to be considered, such as objects' features and illumination circumstances [5], dense 3D shape models, image resolution, objects in different frames, and many other things [5-7]. Although some of the methodologies and procedures worked well under specific conditions or requirements, the accuracy for distinguishing anomalous behaviour has significant degradation due to different issues. Anomaly detection is perhaps one of the promising and fascinating fields to study.

Among the issues, the issue of recognizing static objects when located in different positions is addressed in this study. Apparently, the issue occurs when there is confusion regarding the identical frames and variable object sizes. Besides that, the issue also arises when an object is placed at the boundary or when the object is located in a different position or corner in the frame. The object may not appear identical to its predecessor as it holds the corresponding pixel value in every scenario. Mean values and deviation of pixels value also vary between photos. Hence, this research focuses on utilizing humanoid robots by integrating machine vision studies to detect any irregularities in their view and classify them using statistical techniques. This project was created using the CoppeliaSim and Python (x,y) programming to demonstrate the method and simulation of how the work functions.

The next section will delve into the broad idea of machine vision with the theories of robotics vision and humanoid vision as part of the component with the block diagram of necessary processes in the system, including techniques for learning in anomaly conditions. Then in the methodology part, the procedures and methodologies performed on each experiment are presented in detail. In the following section, all recorded data and information observed from every single experiment are tallied and illustrated in graph form. Next, Section V will discuss and evaluate the outcome after the simulation of each experiment to support the hypothesis and proposed method. Meanwhile, Section VI summarizes the key

findings and conveys realistic recommendations for improvements in future works.

## II. LITERATURE REVIEW

### A. Machine Vision

Visual exploration in unknown settings is a common and crucial job for intelligent automation in the present day. One of the most compelling aims for machine vision applications is for robots to be able to search for identifiable things in an unknown environment; even though some robots have a deficiency in visual skills because of unable to compete with human ability, particularly in brains and eyesight [8]. Regardless, it may still be explored and improved regularly with various concepts and theories, especially with the continuation of innovative technology.

Machine Vision is a “simple” processing system that captures visual information by processing, analyzing and measuring the image attributes using a combination of hardware and software. This is used to extract the information utilized in decision-making in order to generate the required result. The application of vision has been developed into a software platform to make people unnecessary spending an extended time developing algorithms for image processing [9].

Furthermore, the platform is user-friendly and allows for a simple extraction and modification of image information. Some of the examples are HALCON from MVTec Software, IMAQ from National Instruments, Visilog from Norpix, and PatMAX from Cognex Corporation [10]. It may sometimes surpass humans in specialized tasks. As shown in Fig. 1, the practical strategy for recognizing objects in vision systems mainly uses local characteristics as a primary tool to match scene material to models of recognized items.

### B. Robotics Vision

Robots are growing increasingly capable in line with the decade’s developments because they can execute a growing number of activities that would be too risky or difficult for humans. Flexibility has been required as job complexity has risen. The need for adaptability has grown in tandem with the complexity of modern jobs. The creation of humanoid robots gives way to the establishment of societies of robots that collaborate with humans as humanoid robot technology advances [9,10]. The evolution of robots goes from single and tiny robots to the establishment of humanoid and gigantic robots that can work together with humans.

The application of vision is becoming a critical element in robotics and machine automation. Hence, the studies have been implemented in robotics advancement, known as robotic vision. In standard function, robot vision is utilized for part identification and navigation. In advanced function, the vision enables to lead and guide the robots or other automated machines to recognize, think and perform the task, resembling a human [11,12]. By controlling the special machine vision software, it can make the part identification and replace or complement manual inspections, navigation and measurements with digital cameras and imaging processes. Then the controller will automate and coordinate a necessary

process to perform the task. The general process can be seen in Fig. 2.

### C. Humanoid Vision

Ideally, the vision has been applied to many types of robotics and machines, not being left behind in humanoid robots. With the intelligent vision system used in humanoids, the robot can interpret images in terms of colour, size, shape, and position of the object on the scene. In addition, both sights of a humanoid robot can recognize various objects with different traits. The image will undergo pre-processing and image segmentation stage before continuing with object matching and tracking [13, 14]. An intelligent system is also able to perform a high-level recognition task. Some of the essential elements in the automated analysis and extraction of the required information are shown in Fig. 3.

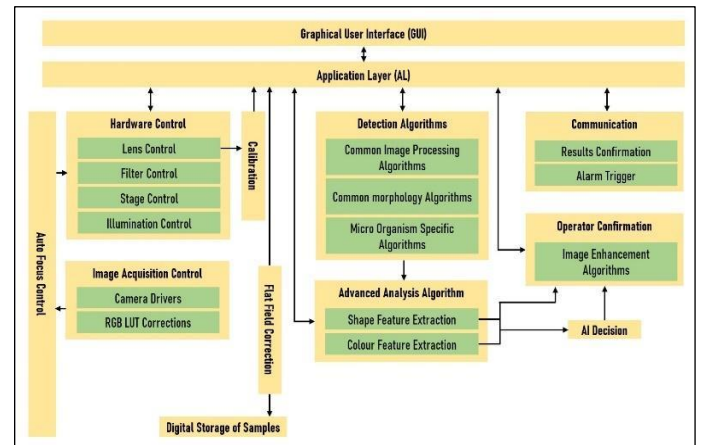

Fig. 1. Machine vision software architecture.

Fig. 2. Machine vision process with three important components.

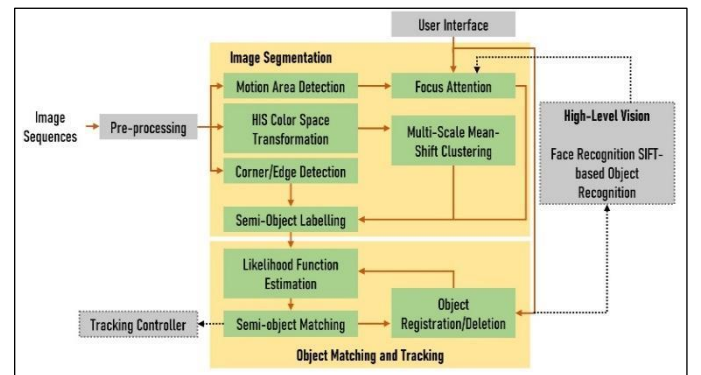

Fig. 3. Structure of the robotic vision system.

#### D. Methodology Used

Anomaly detection can occur in different surroundings and circumstances, depending on what abnormal behaviour are set. Therefore, anomaly detection methods are classified according to their input type, output type, learning method and the type of target anomaly. There are three types of learning methods in anomaly detection, which are supervised, semi-supervised and unsupervised [9,10].

For supervised learning, data sets labelled with normal or anomalous are used for training the model. While for semi-supervised, the model is trained with only normal data. The data points that do not match normal behaviour are considered anomalous during the detection. Differ for unsupervised learning case, no training data required. The input data is expected to contain a high ratio of normal to anomalous points.

Alternatively, the model will consider frequent anomalous behaviour as a common condition [15]. As mentioned earlier, the main objective of this research is to detect an anomaly behavior of non-motion objects via a humanoid robot. Besides that, the anomaly behavior in different frames is also observed using the single camera attached to the robot. The experiment is handled in a roomy space in which all the variables are controlled, fixed and not moving.

Thus, the method highlighted earlier is reasonable and much more apposite to be carried out in this project for anomaly behaviour as it can detect objects even though in a different position of a frame. First, this method is tested on the same base background and light intensity with different object sizes. After that, the outcome from each experiment and observation is turned into the percentage of accuracy, precision, and limitations. Finally, the data is discussed in the analysis and result section.

### III. METHODOLOGY

Generally, this study aims to let the humanoid robot learn to detect and identify objects in anomaly behavior. In order to observe and evaluate the performance of object identification and anomalies cases, a series of experiments is conducted to prove the object's behaviour in different cases. Primarily, specific aspects and parameters need to be determined and controlled to maintain the accuracy of the experiments. As an example, lighting and frame background. Originally, the methodology to conduct the experiment was broken down into two stages. The first one is the system design phase which discusses about the software and type of simulation used to run the experiment. The other stage explains how the methodology is implemented, where the details on how experiments are handled to get reliable results.

#### A. System Designation

The experimental platform to work for this project is Python (x,y) for Windows and CoppeliaSim software. This study is developed and runs through the simulation process by these two softwares. The coding code for the programming is developed in Python. At the same time, the environment scene and robot used for the experiment are built in a robotic simulator, CoppeliaSim. These two softwares are linked to

each other and act as terminals to show the overall simulation and experiment process.

In overall, this project undergoes four different types of experiments. The experiments are semi-structured scenes, calculating the mean and the standard deviation values based on different sizes of the object, determining the location and position of the object from the robot and lastly, collecting the mean and standard deviation values based on the different positions of an object in one frame.

#### B. Stereo segmentation

Interest points that are matching in the left picture are divided into groups based on their location and discrepancy. Then, a greedy clustering approach is applied, starting with a single interest point. After that, if the x-position, y-position, and disparity are within the 5-pixel threshold of any neighbouring cluster member, it is supplemented with new ones. The segmentation usually occurs at a comparable depth but in a different spatial position or at a nearby spatial location but at a different depth. Fig. 4(a) and 4(b) showed the pattern of the process.

To enhance the segmentation step, feature locations are divided into on-object and outside-object groups (white vs other colours). According to the above image in Fig. 4(a) and 4(b), every bit of outside-object locations and any image pixels outside the bounding region are considered outside-object pixels. This region is emphasized in black colour after the segmentation process. Following that, the location for the on-object is highlighted in grey colour. To indicate that the particular shade is an anomaly, an image's pixel value is generated in histogram form so that it is easier to compare between the normal and abnormal or determine the different cases for every anomaly.

#### C. Anomaly Criterion

While learning the object samples, two sorts of anomalies can be identified; For starters, the event patterns that never have been seen before and employed as variable for classification. The flow is shown in Fig. 5 below. The anomaly scenario is defined as samples that deviate significantly (in terms of distance) from other clusters in the model [16]. Secondly, the model contains exemplars of other sorts of anomalies. It does, however, have a minimum frequency this time. As a result, it might also be characterized as a false positive. Both forms of abnormalities may be discovered by taking distance and frequency into account to classify.

Fig. 4. Image segmentation, where the feature for matching exists, is clustered and plotted into the histogram.

According to equation (1), an intra-class distance  $Dist(C_i)$  in each cluster is defined as the greatest distance between any cluster member and the cluster centre.

$$Dist(C_i) = jmax\|f(e_j^{C_i}) - f(C_i)\|_2 \quad (1)$$

Thus, as long as the abnormal grid event is detected, the frame triggered the condition as abnormal, either in significant or small deviations [16]. The deviation is calculated by using a simple formula. In this study, the deviation is extracted using the plug-in Open CV and Numpy Software in Python (x,y).

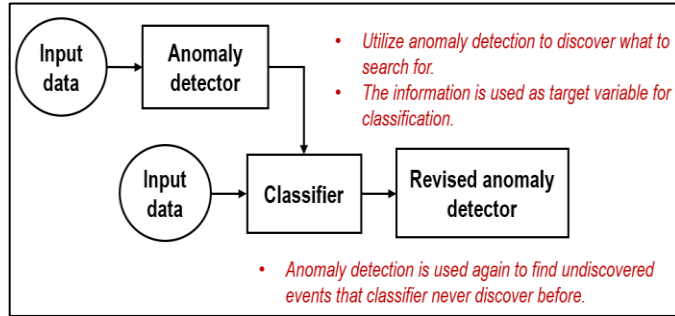

Fig. 5. Example of flow process of anomaly behavior for classification.

#### D. Research Procedure

1) *Experiment A: Semi-supervised Scene:* This experiment investigates the object's behaviour and the pixel number when it is located at a different position in the same black background frame. The object is fixed in a triangular shape and red colour. The output results were positive predictive value (PPV), which is technically the pixel data extracted from the image captured. In addition, intra class-distance is calculated manually to find the percentage of anomaly that can happen. Finally, the value is compared with the smallest distance value to identify true-positive and false-positive anomalies.

2) *Experiment B: influence on the object size:* This experiment measures the performance and effect of the variant size of an object on the system. The object that has been used is a cuboid with the same colour as the previous experiment. The frame background is fixed to a grey colour to differentiate it from black. Black is the default colour for the surroundings, as seen on the vision sensor recorded in the CoppeliaSim. There are three 50 cm-width and 80 cm-high walls labelled as Frame 1, Frame 2 and Frame 3. Frame 1 is set at the origin at  $180^\circ$ . All frames have the same surface, colour and size.

Fig. 6. The top view of the experimental setup is placed ahead of the NAO robot.

Meanwhile, Frame 2 is located at  $-40^\circ$  and deviates from the horizontal axis. Meanwhile, Frame 3 has deviated as much as  $40^\circ$  from the horizontal axis. The setup can be seen in Fig. 6 above. The parameter for the object's size is set from 0.4 cm x 0.4 cm up to 45 cm x 45 cm. This dimension is for Frame 1. However, for Frame 2 and Frame 3, the object size added an extra size of 50 cm x 50 cm. This is because both frames need a larger cuboid surface to cover up all areas of the wall frame.

3) *Experiment C: detection of object's location:* This experiment is conducted to locate the anomaly by calculating the distance and angle between the robot and the wall screen. The experiment scene setup is still the same, as shown in Fig. 6. In this experiment, the cuboid's maximum size was not identical to the cuboid in Experiment B. The maximum size of the cuboid for Frame 1 and Frame 3 is 20 cm x 20 cm, while for Frame 2 is 25 cm x 25 cm, depending on all cuboid sides that are possible to be fitted in a frame. Using the formula of Pythagoras' Theorem and Sine Rule, the location of the cuboid in each frame can be ascertained. The experiment is continued with the same procedure in each particular frame.

4) *Experiment D: impact on various placement:* From the result obtained in experiment B, only one size of a cuboid is selected as a fixed parameter in each frame. The cuboid size is picked based on the output mean and standard deviation difference between normal and abnormal conditions. For this time, the middle range of difference is selected. The cuboid is placed independently from 0 cm to 50 cm along the wall. Then, the effect of object position on the system is measured from the data attained in the mean and standard deviation of the pixel value. The experiment is continued with the same procedure in each particular frame. The difference between the normal and anomaly condition is observed based on the data outcomes.

## IV. RESULTS AND DISCUSSION

### A. Semi-Structured Scenes (Semi-Supervised)

For the early experiment, only one frame is used despite the different positions of the target. The reason for this is to observe the performance of the target object. In this case, a triangular object is placed on the screen. The black background colour is chosen to make the number of pixels easy to calculate, as this experiment has not yet applied the image segmentation process. The object has been used as the target and labelled by 'A'. Even though the object is in different positions on the frame, 'A' is successfully recognised and marked as normal behavior. The series of the captured image by the robot vision is shown in Fig. 7.

Normal scenes are classified whenever the object is still inside the frame range, not at the edge or outside the boundary. From the early hypothesis, a subject is marked as an anomaly when it is located at the frame's edge. The reason for this is that the frame's pixel value is counted differently than it is supposed to be. However, depending on the situation and output data, it can be categorized as a false positive or a true positive.

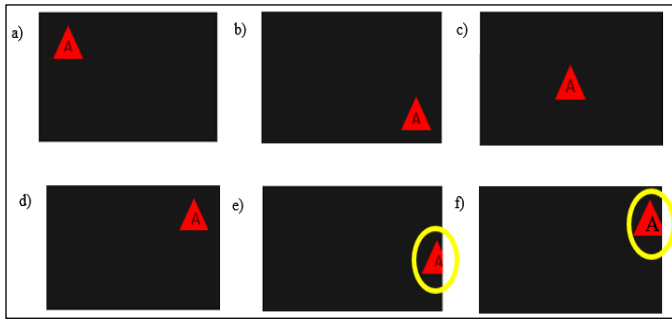

Fig. 7. A collection of object samples observed by the camera in a particular circumstance. Images (a)-(d) depict normal behaviour, whereas images (e)-(f) depict anomalous behaviour.

Precision or positive predictive value (PPV) is the ratio of the number of object pixels that are correctly recognized object pixels to the number of detected object pixels. When the ratio computation is near one, the performance is good. It is also known as the True Positive Rate (TPR), where the ratio of the number of object pixels correctly acknowledged to the number of object pixels in the ground truth. These quantitative analyses can be seen in Table I.

TABLE I. PPV VALUE OF OBJECT SAMPLES IN DIFFERENT POSITIONS

Sample	1st	2nd	3rd	4th	5th	Average PPV Value
a	0.95	0.96	0.97	0.96	0.96	0.96
b	0.94	0.95	0.94	0.94	0.94	0.94
c	0.98	0.99	0.98	0.99	0.98	0.98
d	0.95	0.94	0.95	0.95	0.95	0.95
e	0.67	0.67	0.67	0.67	0.67	0.67
f	0.87	0.88	0.89	0.89	0.89	0.89

$$PPV = \frac{\text{number of object pixels is correctly identified}}{\text{number of object pixels detected}} \quad (2)$$

By calculating the mean, variance and standard deviation using the formula follows:

1) Mean,  $\mu$

$$\mu = \frac{\sum x}{N} \quad (3)$$

$$\mu = \frac{0.96+0.94+0.98+0.95+0.67+0.89}{6} = 0.8983$$

2) Variance,  $\sigma^2$

$$\sigma^2 = \frac{1}{N} \sum_{i=1}^N (x_i - \mu)^2 \quad (4)$$

$$\sigma^2 = \frac{1}{6} [(0.96 - 0.8983)^2 + (0.94 - 0.8983)^2 + (0.98 - 0.8983)^2 + (0.95 - 0.8983)^2 + (0.67 - 0.8983)^2 + (0.89 - 0.8983)^2] = 0.0112$$

3) Standard Deviation,  $\sigma$

$$\sigma = \sqrt{\frac{1}{N} \sum_{i=1}^N (x_i - \mu)^2} \quad (5)$$

$$\sigma = \sqrt{0.0112} = 0.106$$

4) Intra - class distance,  $Dist(C_i)$

$$Dist(C_i) = jmax \|f(e_j^{C_i}) - f(C_i)\|^2 \quad (6)$$

$$Dist(C_i) = \|0.67 - 0.945\|^2 = 0.0756 \approx 0.08 \quad (\text{for case } e)$$

$$Dist(C_i) = \|0.89 - 0.945\|^2 = 0.0030 \quad (\text{for case } f)$$

5) Smallest distance between  $f(e_x)$  and  $f(C_x)$

$$d(e_x, C_x) = 0.98 - 0.945 = 0.0035$$

The parameters that have been calculated above show that the value of standard deviation,  $\sigma \approx 0.1$  and intraclass distance is 0.08. Thus, it shows that the percentage of anomalies that can be occurred is very low. To prove the anomaly in Experiment 1, the calculated value from  $d(e_x, C_x)$  is less than  $Dist(C_x)$ , which shows that abnormality in Fig. 7(e) has happened. However, the value of  $Dist(C_x)$  and  $d(e_x, C_x)$  in Fig. 7(f) is much alike. Therefore from Fig. 7(e) and Fig. 7(f), two out of six cases are abnormal. Fig. 7(f) can be labelled as a false positive as the PPV value is very near to the PPV reading of ordinary cases. Meanwhile, the image in Fig. 7(e) is quite distant from the mean value and other ordinary cases. Thus, Fig. 7(e) can be labelled as true-positive.

Aside from that, the shape in Fig. 7(e) showed a bigger proportion surpassing the boundary of the frame compared to the smaller proportion of the object in Fig. 7(f). The percentage of the whole object in Fig. 8(f) is about 90%, but in Fig. 7(e) is almost 60%. Data that does not match normal behavior in semi-structured scenes is considered anomalous during the detection.

Based on experiment A that has been done, the pixel values are close to 1 despite the object's different position on a frame. The PPV value is significant when the object is at the edge of a frame. This value is categorised as an anomaly, whether false-positive or true-positive. False-positive is when the condition is an anomaly. Still, the output data is near the normal condition. At the same time, true-positive can be labelled when the condition is obviously an anomaly and slightly far from the deviation. Somehow, a false-positive can still be described as an anomaly. However, the percentage and accuracy are not much likeable and noticeable. For instance, the PPV value of Fig. 8(f) in the semi-structured experiment is 0.89. It has the lowest difference, with an overall mean value of 0.8983. Hence, the percentage of the object positively identified in Fig. 8(f) is almost 90%. Still, the image captured in Fig. 8(e) shows that the object has surpassed the frame edge at almost 40%. Based on the standard deviation calculation,  $\sigma$  the value is approximately 0.1, which is quite good for anomaly detection. It is because the range or frequency for an anomaly to happen is less and close to 0.

Fig. 8. True-positive anomaly versus False-Positive anomaly.

**B. Object Size**

The main objective of this experiment is to observe the pattern of mean and standard deviation values of each image taken from the vision sensor humanoid robot. With the pattern, it can be deduced on what condition the frames can be labelled as abnormal or normal. First, the colour and shape of the object are fixed throughout the experiment to ensure the output result is clear and easy to analyse. The object chosen is a cuboid and red. To control the experiment and for comparison, the mean and standard deviation value for the normal frame is recorded first. The recorded values are tabulated in Table II below. A normal scene is when no object is placed in the corresponding frame area.

TABLE II. MEAN AND STANDARD DEVIATION VALUES IN A NORMAL BEHAVIOR

Frame Number	Data	Value
Frame 1 (Center)	Mean ( $\times 10^2$ )	$2.02 \times 10^2$
	Std. Deviation ( $\times 10^1$ )	$4.06 \times 10^1$
Frame 2 (Left)	Mean ( $\times 10^2$ )	$2.20 \times 10^2$
	Std. Deviation ( $\times 10^1$ )	$3.68 \times 10^1$
Frame 3 (Right)	Mean ( $\times 10^2$ )	$2.06 \times 10^2$
	Std. Deviation ( $\times 10^1$ )	$3.94 \times 10^1$

Fig. 9. Graph for mean and std. deviation average versus object size (Frame 1).

Fig. 10. Graph for mean and std. deviation average versus object size (frame 2).

Fig. 11. Graph for mean and std. deviation average versus object size (Frame 3).

In Experiment B, only the object's size is manipulated. Other than that, the colour, shape and position are controlled during the experiment. The output data are plotted in the graph version, as shown in Fig. 9 to Fig. 11. The graphs show that the anomaly is identified when the cuboid size gets bigger than the typical size. The differences between the normal mean value and normal standard deviation value are very apparent too, with the biggest difference is recorded in Frame 3. The size for the cuboid reaches up to 50 cm x 50 cm and covers the whole frame wall. Moreover, anomalies also can be identified on the smaller object as long as the standard deviation value passes the threshold value. From the plotted graph above, cuboid size 1 cm x 1 cm is the minimum size detected as an anomaly in Frame 1. For Frame 2 and Frame 3, the smallest size is 0.8 cm x 0.8 cm. It is because when the object is smaller, the pixel value for the coloured object has no differences from the normal condition. Technically, it is considered normal behaviour, although the object is inside the frame. Therefore, it is known as a false-positive anomaly. More simply, pixel levels in the output image are too small and do not pass the normal frame value to be labelled as abnormal.

As for the bigger size, the pixel values for the coloured object are different from the plain frame as pixel intensity for the red colour is much higher than the grey one. This is also known as a true-positive anomaly.

**C. Location of Object**

In this experiment, the shape and colour of the cuboid are set not to change. However, the size is still different from the smallest to the biggest, which makes it possible to fit the cuboid size and calculate its position. The main objective of this experiment is to observe the location and position of the red cuboid image in a particular frame. With the pattern, it can be deduced which size of cuboid and position is suitable for humanoid robots to detect the anomalies. As stated earlier, the colour and shape of the object are fixed throughout the experiment to ensure the output result is clear and easy to analyze. For example, Frame 1 is still at the centre at 0° while Frame 2 is +40° and Frame 3 is -40°.

Here, Fig. 12 below shows the accomplished segmentation process to locate only the inside region of the object (dark grey colour) and eliminate the rest of the outer region (black colour).

Fig. 12. Images captured by vision sensor for 5 cm x 5 cm, 20 cm x 20 cm and 35 cm x 35cm surface area.

Based on the calculation from each frame, it proves that the object's location from the humanoid robot is about  $8^{\circ}31'$  on the left side of the frame wall. The value is calculated based on Pythagoras' Theorem and Sine Rule.

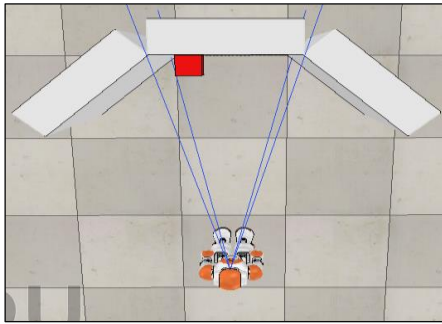

Fig. 13. Setting from the upper view between the wall frame and the robot to measure the angle.

The wall frame is 0.5 m in length. Starting from the centre until the left edge of the frame is 0.25 m. Then, the cuboid is set to be 0.1 m from the left side of the frame edge. So, the value of  $a = 0.15$  m. Value  $b$ , the distance between the robot and the frame, is fixed at 1 m. To calculate  $c$  and  $x$ :

$$c = \sqrt{b^2 + a^2} \quad (7)$$

$$c = \sqrt{1^2 + 0.15^2}$$

$$c = 1.01\text{m} \quad \text{and,}$$

$$\frac{\sin X}{0.15\text{m}} = \frac{\sin 90}{1.01\text{m}} \quad (8)$$

$$1.01\text{m} \times \sin X = 0.15\text{m} \times \sin 90$$

$$X = 8^{\circ}31'$$

So, the cuboid is located  $8^{\circ}31'$  between the centre and left of the robot. The outline can be seen in Fig. 13. Different situation with experiment C, the robot needs to locate the actual size and location of the anomalies on the frame wall after the anomaly behavior can be distinguished. Similar to Experiment B, the cuboid's colour, shape and position are fixed during the experiment. However, in this experiment, the

robot could spot the cuboid size location up to 20 cm x 20 cm for Frame 1 and Frame 3 and 25 cm x 25 cm for Frame 2. When the object is bigger than the limit size, the centre and edges of the object are not fully fitted in a particular frame. Therefore, the centre and edges of the cuboid are located differently and over the limit; even the standard deviation value differs from the normal behavior. This condition can be considered a true-negative anomaly. To make the robot detect bigger object than the limits, the size of the wall need to be bigger and extended. Using Pythagoras Theorem and Sine Rule, the actual location, right side and distance of the abnormal can be calculated. With this ability, anomaly detection can be improved as the robot can locate the object's location as long as it is still within the frame boundaries.

#### D. Position of Object

The main objective of this experiment is to observe the pattern of mean and standard deviation values in a particular frame despite the position not being fixed while the size is constant. With the pattern, it can be assumed that the best position is suitable for a humanoid robot to detect anomalies. From the results, the surface area of a 10 cm x 10 cm cuboid is chosen as the best measurement to get the median value. It also fits the normal frame and the other two slanted frames, regardless of various positions. As stated earlier, for making a comparison, the mean and standard deviation value for the normal frame is recorded first.

Fig. 14. Graph of mean and std. deviation average vs object position (frame 1).

Fig. 15. Graph of mean and std. deviation average vs object position (frame 2).

Fig. 16. Graph of mean and std. deviation average vs object position (frame 3).

In general, experiment D is quite similar to Experiment B. The changes in the scenario where the cuboid is placed at the halfway point but varies along different lengths on the frame. This experiment uses the output result in mean and standard deviation values to distinguish the anomaly pattern. A 10 cm x 10 cm cuboid was fixed during the experiment. The reason for using the mentioned size area is that it can be fitted on the surfaces of all kinds of frames. As mentioned in the prior subchapter, Frame 2 and Frame 3 were tilted ( $\pm 40^\circ$ ) from their original axis ( $\pm 0^\circ$ ). It also gives the best output image after being detected by robot vision. It has a median value with the highest and lowest mean and standard deviation pixels recorded from the previous experiment. The result shows that an anomaly can still be identified and evaluated, even though the standard deviation value has fluctuated in all frames. Because of the fixed size, the mean graph shown in Fig. 14 to Fig. 16 for each frame does not change critically. Their differences were at least 0.01 until 0.04 from the normal mean value.

## V. DISCUSSION

With all the observations, the calculated mean,  $\mu$  and standard deviation,  $\sigma$  for the initial and final point of the object in all three frames were recorded as the lowest. The biggest difference in  $\sigma$  value showed when the object moved nearer to the middle. It is because, at 0 cm and 50 cm, the cuboid is captured half of its actual size in frame boundaries. Thus the pixel intensity of the background value is the highest compared to the object colour value, making the standard deviation value drops significantly. The image pixel also shows the highest grey intensity when the object is located by the edge of any frame. All performance data in Experiments B, C and D are categorized as quantitative results.

Based on the graph trends corresponding to the tabulated data recorded in Experiment B, the  $\sigma$  curve ascends and achieves the highest peak when the object is 35 cm x 35 cm. In contrast, the mean line decreases slightly until its minimum value. It is because the pixel intensity for the red value surpasses the grey value, which gives great differences in deviation reading compared to the normal deviation data. However, it started to decline slightly after the highest peak as the pixel value for grey is untraceable inside the frame. It also happens when the object size is smaller. For example, when the measurement size is 1 cm x 1 cm, the line for standard deviation approaches the line for the normal value. The

changes happened in the mean line too. This can be explained as the pixel value for red being untraceable and considered a normal condition. This situation also applies in Frame 2 and Frame 3. Observing through each graph in Experiment D, the pattern for mean in anomaly and common condition shows little differences and is fixed horizontally. However, a different outlook is observed in the standard deviation pattern. The graph is up and down compared to the normal standard deviation line. The outcome shows that the standard deviation value is the best parameter to be observed when examining anomaly behavior and comparing them with the normal state.

Meanwhile, the camera on the humanoid robot followed the object no matter the target object's position in image segmentation. From the concept, the distance between the object on the frame and the NAO robot is always the same. Both images in the left and right eye are matched so that only the image of the target object is recognized, pinpointed and shaded in the bounding area. Interest points are grouped according to respective image position and disparity. Each of them carries a different pixel number.

However, the mean pixel number of a particular object is much alike, although it is located in various positions. To access each image's pixel value and calculate the mean and standard deviation, Open CV and Numpy plug-in library functions need to be explored. In this project, every image is set to produce only 3-bit pixel values. The pixels are red, green and blue intensity. The pixel value detected differed from what it was supposed to be whenever the object's position was between the edges of two frames, or the object surpassed the frame edge.

As a consequence, the segmented image produced different values of pixels. As stated earlier, anomaly behavior happens when there is unlike frequency happening at a time. Thus, when the mean, standard deviation, or PPV value produced differs from the normal state, it can be categorized as an anomaly, as stated by a study in [17, 18].

The proposition that can be made from Experiments A, B and D is that both  $\mu$  and  $\sigma$  values are reliable. The difference between normal and anomaly is comparable and can be proved based on the physical data and recorded image. To validate, each experiment is repeated five times to get accurate results, and the average value is calculated and recorded in tables. However, minor errors happen when the head yaw of the humanoid robot is rotated  $30^\circ$  to the left and right during detecting and scanning the frames repeatedly. Sometimes, the robot turned less than  $30^\circ$  or more than  $30^\circ$  from what it was supposed to. The effect of this the captured image is not similar as expected because the frame and point of vision are visibly not parallel because of the few internal factors such as joint errors and kinematic errors [19]. Because of that, the simulation must stop and take a break for 5 to 6 seconds. Then, it resumed again to get a precise result and eliminate the insignificant error that might change the results, as proposed by [20].

## VI. CONCLUSION AND RECOMMENDATIONS

In a nutshell, the main objectives of this project are successfully achieved using the semi-supervised approach to

learn the anomalies. PPV value, overall mean value, variance and standard deviation have been calculated to prove the anomaly statistically in that scenario. It also can be concluded that an object's positions greatly vary the standard deviation values. The location of the abnormal condition also has been proved during the experiment. It is proved by observing the maximum size of the object that can fit in the captured frame by ensuring all surfaces are within the range. Data obtained from Frame 2 differs from the data in Frame 3, although both slanted 40° from the horizontal. The setting for the frames and light tuning needs to be customized in the future. Besides that, a shadow effect is formed from different angles even though the light intensity for the surrounding has been set to default in the early setup. Furthermore, the calculation for mean and standard deviation pixel value can be made to access every bit image rather than only 3-bit colour to improve the study result. And lastly, the improvement could be focused on when there are ambient environmental changes in terms of illumination intensity, object colour and quantity of objects to be detected. The control system of the robot could also be improved by using closed loop estimation system [21] or by adaptive technique called disturbance observer [22].

#### ACKNOWLEDGMENT

The authors would like to acknowledge the funding supplied by Universiti Teknikal Malaysia Melaka (UTeM) under the Zamalah scheme to perform the study. The authors would also like to convey our credits and gratitude to the Robotics and Industrial Automation research group within the Faculty of Electrical Engineering.

# Queueing Model based Dynamic Scalability for Containerized Cloud

Ankita Srivastava\*, Narander Kumar

Department of Computer Science, Babasaheb Bhimrao Ambedkar University, Lucknow, India

**Abstract**—Cloud computing has become a growing technology and has received wide acceptance in the scientific community and large organizations like government and industry. Due to the highly complex nature of VM virtualization, lightweight containers have gained wide popularity, and techniques to provision the resources to these containers have drawn researchers towards themselves. The models or algorithms that provide dynamic scalability which meets the demand of high performance and QoS utilizing the minimum number of resources for the containerized cloud have been lacking in the literature. The dynamic scalability facilitates the cloud services in offering timely, on-demand, and computing resources having the characteristic of dynamic adjustment to the end users. The manuscript has presented a technique which has exploited the queuing model to perform the dynamic scalability and scale the virtual resources of the containers while reducing the finances and meeting up the user's Service Level Agreement (SLA). The paper aims in improving the usage of virtual resources and satisfy the SLA requirements in terms of response time, drop rate, system throughput, and the number of containers. The work has been simulated using Cloudsim and has been compared with the existing work and the analysis has shown that the proposed work has performed better.

**Keywords**—Cloud computing; scalability; containers; containerized cloud models; queueing model

## I. INTRODUCTION

Cloud computing has evolved into a highly dynamic computing model. It has gained attraction from various organizations due to its cost, availability, scalability, and security. It is an internet-based computing technology that provides higher-end computation and a shared pool of resources which are accessible on demand [1]. It has revolutionized the internet world through its hosting services and computational ability. Its unique technology has facilitated the user to pay for only those services and resources which have been demanded by them and further these resources can be increased and decreased depending upon the requirement. The potential and high capabilities have led to amplified productivity with reduced costs and flexibility as against the other IT industries [2]. The prime technology working behind the cloud is virtualization which enabled the cloud to instantiate various Virtual Machines (VMs) on one single physical machine (PM). Virtualization can occur at various levels like desktop, network, storage, and application [3]. It can affirm high performance, confidentiality, reliability, and security among VMs. One VM is isolated from the other VM on the same PM making it securely isolated. Despite various benefits exhibited through virtualization, applications demanding less isolation and maximum flexibility at runtime,

VM virtualization may not be sufficient enough to satisfy all the QoS standards [4]. The container-based virtualization is gaining more popularity these days because of the more dynamic and flexible nature of the workload which varies highly with time. It expedites the seamless movement of applications from one architecture to another as against the VMs virtualization. Container executes on a kernel with the equivalent performance as VMs but with lesser cost than expensive VM runtime management overhead [5]. Containers provide a good platform to execute microservices on the cloud and they provide good support for the technologies such as fog computing, and the Internet of Things (IoT) [6]. As container technology gained popularity various large-scale IT industries providing cloud services have come up with their container-based cloud services.

The most renowned service models available in the cloud are Infrastructure as a Service (IaaS), Platform as a Service (PaaS), and Software as a Service (SaaS) with various energy efficient datacenters (DC) which are solely responsible for managing the scalability through resource management and load optimization [7]. With the PaaS service, the users can deploy any applications on the cloud. This model encapsulates the underlying infrastructure and facilitates the user to deploy the applications anywhere without giving a single thought about infrastructure management. One of the components of the PaaS service is containers and they are its enablers [8]. So, a user application can be deployed on a single cloud infrastructure as a unique block or deployed separately in different cloud infrastructures.

The key characteristic of the cloud to scale up has attracted a lot of users. The variation and fluctuation in workload have compelled the cloud providers to scale up the resources (VMs or containers) dynamically as per the requirement. The cloud has eased the process of obtaining and releasing resources but it can be challenging to decide how many resources are needed to handle a fluctuating workload. There is an urgent demand for a model which can provision and de-provision the resources dynamically at the burst of demands. Despite the development of container technology and harnessing its potential, there is still room for the improvement in dynamic scaling of cloud resources. Insufficient scalability which is not competent enough to confront the variation in the workload intensity may lead to under-provisioning (UP) or over-provisioning (OP) of the resources. In the UP scenario, the performance of the cloud degrades and SLA is violated. While in OP there is low consumption of resources that are allocated resulting in a higher cost for the providers. As a result, in response to dynamic changes in the global arrival rate during

\*Corresponding Author.

runtime, adaptation mechanisms are covered for polished dynamic scalability. Appropriate dynamic scalability is the demand of the time and it affirms the performance of the SLA while making the cost low. An efficient technique for dynamic scalability is required for fulfilling the requirement of both the users and CSP.

This work has proposed a dynamic scaling approach for the containerized cloud. The approach enables us to acquire the dynamic and scalable nature of cloud computing and analyze its efficaciousness. The model tries to estimate the future resource demand and provision the resources in a dynamic way for mitigating the SLA violation and reducing the cost incurred by the system. The work is simulated in Cloudsim and the work is evaluated under the various quantity of workload. The main contribution of the paper goes as:

- A queuing model is proposed to estimate and acquire the behavior of containerized DC.
- The load balancer model and container model are discussed.
- The mathematical formulation has been derived from the analytical model for various QoS measures.
- Simulation of the work is performed on Cloudsim.

The remaining paper is compiled as follows: the literature study associated with the work is done in Section II. The proposed work is discussed in Section III. Section IV performs the results and discussion and lastly, the work is concluded in Section V.

## II. RELATED WORK

Containerization is not a novice concept of computer science. It was existing back in 1972 on Linux or Unix systems in different ways [9]. It aided the developer in providing an efficacious programming environment which has a quite reduced operational cost. Docker has adopted container technology and led to the start of open containers in the industries like Google, Microsoft, and many more and it is getting popularity day by day due to its isolation strategy. Fig. 1 describes the container in the cloud system with its private OS, interface, and file system. Cloud containers provide a thin encapsulation over the application so its deployment is relatively easier and faster. Initially, it started with the VMs which are light. These technologies possessed an isolated OS on which the application can be deployed [10]. Containers have several benefits over VMs [11]. Firstly, compared to virtual machines, containers use host system resources far more efficiently. Second, starting and stopping the containers only takes a minute time. Next, the mobility container prevents inter-system dependency conflict and guarantees its separate functioning from the system on which it is hosted. Fourth, unlike VMs, which are frequently not distributed production environments, containers possess the feature of being exceedingly lightweight, enabling end users to operate dozens or more of them simultaneously. Fifth, instead of having to go through hours-long installation and configuration hassles, end users of apps can instantly download and run sophisticated software. Additionally, unlike virtual machines (VMs), which strive to virtualize an external

environment, a container's primary goal is to make an application fully portable and independent [12].

The containerized cloud is emerging as one of the most challenging issues over the past few years and a lot of work has been published in this regard. This section studies the relevant work associated with the scalability and performance of container-based cloud models. Some study is associated with scalability to provide better insight into scalability and some shows the scalability in container clouds.

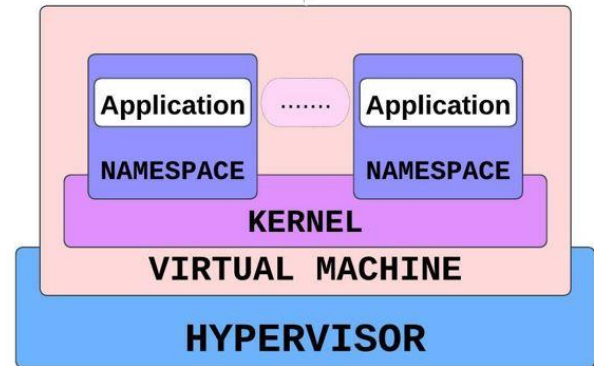

Fig. 1. Container structure.

Scalability has once been qualified as the key feature contributing to the efficient working of cloud-based services. A deep scaling methodology has been introduced in [13] where three components have been included for effective resource utilization. First, it forecasted the workload then it mapped the workload intensity to the approximated CPU utilization and lastly, an auto scale method is developed for maximizing the CPU utilization. A proactive elastic model was defined in [14] which resolved the scalability issues in cloud-based IoT systems. It utilizes the ant colony optimization technique along with the Markov chain for scheduling the resources efficiently which enhances the performance and maintains the QoS measures. It improved the response time and request throughput. A benchmarking method is proposed that defined a framework for scalability benchmarking tools for quantifying the scalability. It included the scalability metrics and measurement methods to specify the achievement of the given service level objectives. It also provided the facility for configuring the scalability parameters for getting an efficient response [15]. The author in [16] proposed a container-based autoscaling procedure that used a heuristic technique for utilizing the resources efficiently. It improved the execution time, throughput, response time, and the minimum number of containers. The author in [17] addresses the two major scalability metrics volume scalability and quality scalability. Volume scalability is highly influenced by the scaling of service volume while quality scalability is affected by the service quality provisioned. These parameters quantify the technical scalability and helped in assessing the impact of demand on the service. Besides, they also aided in designing and performing scalability testing with the motive of the identification of the components that affect the scalability performance.

Scalability in container clouds has made the processing of cloud applications lightweight and efficient. An automatic scaling method is discussed in [18] where it reduces the response time, energy consumption, and better CPU utilization. An analytical model based on the stochastic technique for the container-based DC has been discussed in [19]. It studied and analyzed the performance of the cloud system with respect to mean job delay and job rejection probability. It created a framework for container emulation and assessed the same against the suggested stochastic technique. Through experimental development, the suggested model is validated using actual data. Insight into DC planning is provided to system designers by numerical verification. Another approach is introduced in [20] in which AWS autoscaling is implemented which facilitate estimating the future workload. It applied a future prediction algorithm using Prophet API. It studied the CPU utilization and the creation of new EC2 instances when the workload is heavy. An auto-scaler-based model has been discussed in [21] which provide the architecture for the container-based application. It has included a monitoring mechanism, prediction model, time series model, and decision mechanism. The prediction utilized the time series to predict the future workload. It has provided better provisioning and speedy elasticity. The author in [22] introduced a framework for auto-scaled containerized applications which is governed by workload demand. It offered both reactive and proactive scaling. Reactive scaling was implemented using the threshold rules and proactive scaling utilized a neural network. It ensured the requirement of QoS. Another container-based module was developed in [23] which provided efficient provisioning. It used an adaptive function tree for scalable container provisioning. It mitigated the provisioning cost further by using a fetching mechanism showing the quality of on-demand and I/O efficiency. It turned out to be providing better scaling, response time, and provisioning. A horizontal scaling technique is discussed in [24] which configured the services in a docker container while the workload was balanced using the load balancer. It calibrated the infrastructures depending on the number of predicted users. It expanded the infrastructure and processing capability in a short duration and offered a fault-tolerant system for medium and small-scale industries. Another technique for resource utilization in a cloud-based application is discussed in [25] for container clouds leveraging the vertical elasticity of Docker. The resource coordinator and monitoring policies are implemented during the execution of tasks. Scalability parameters are the configurable parameters in the procedure.

To the greatest of our knowledge and as of this time, there hasn't been any research available for the effectiveness and dynamic scalability of containers published in the literature. The existing work does not consider the dynamic scalability in the containers which has provided a cost-effective solution to the virtualization. It is of utmost importance to identify the number of containers required to cope with the highly dynamic workload to satisfy the SLA and QoS requirements. Dynamic scalability is attained only when there is neither overprovisioning nor under-provisioning. Overprovisioning may result in higher costs as more containers will be

engrossed while under-provisioning leads to SLA violation. Therefore, the main distinction between our study and the studies listed above is that in addition to forecasting workload, we also forecast the future need for computing resources. Furthermore, in contrast to most techniques that focus on only one factor (CPU utilization), our model provides cloud providers with more information about the timely scaling and descaling of containers' and VMs' volume. This not only decreases the cost incurred by the users but also improves the user's experience and also mitigates the financial burden of service provider and infrastructure cost due to the efficient and wise usage of the resources.

### III. PROPOSED WORK

#### A. Problem Formulation

A model consisting of DC consists of PMs which has the capability of holding various VMs which are further profound enough to hold various containers representing the real practical scenario of current existing cloud services. A hypervisor is held responsible for allocating various VMs to a PM while multiple containers can be allocated to a VM. The task execution request raised from the different users is being sent to the load balancer (LB). This LB routes the traffic to the PMs for execution. These requests are sent to a buffer system which is linked to the LB queue from where it is sent to the containers for the allocation of the resources and their execution. The tasks from the queue are allocated to the containers as per the availability of the resources. Whenever the user demands a new container with a particular requirement of the resources, the establishment of SLA between the final users and the CSP is agreed upon by the delivery of the requested QoS. If the breach in the agreed SLA happens the CSP is supposed to pay the penalty to consumers. The flow of the tasks happens as end users put in the request and it is sent to the LB. This LB receives the requests and distributes the tasks to the PMs as per the allocation policy utilized. Each task is allocated a unique container. As the task request increases the VM scales up the through the addition of the container for the execution of the request. Mostly the companies utilizing the features of the famous company Docker [26], use at least 18 containers simultaneously. Let us consider the  $m$  PMs which are represented as  $P = \{P_1, P_2, P_3, \dots, P_m\}$  which can hold a maximum of up to  $n$  VMs represented as  $V = \{V_1, V_2, V_3, \dots, V_n\}$ . A VM can contain maximum  $l$  containers represented as  $C = \{C_1, C_2, C_3, \dots, C_l\}$ . So, a PM can be scaled maximum to  $n$  VMs which can accommodate a maximum of  $n \times c$  containers.

#### B. Queuing Model

The PMs undertaken in the DC have a similar configuration. The requests generated by the end users are sent to the queue and are served at each node in the DC based on a first come first serve basis. When the requests are executed and served well then they exit from the system. This paper has assumed that each request is served in only one container and one container will serve only one request. The DC is modeled using the open Jackson queuing model represented in Fig. 2.

Fig. 2. Queuing model.

### C. Load Balancer Model

The LB is held responsible for managing the huge load which comes with cloud computing in the form of an ample number of requests from the end users. To serve the requests well the LB is modeled as an M/M/1 queuing model having the provision of the infinite capacity task requests buffer and the arrival of requests is supposed to be one by one [27]. The Markov chain with the continuous time of the LB model, and state  $t$  depicts the task number which means  $t - 1$  tasks are waiting to get allocated in the queue. The arrival of the tasks happens at the  $\gamma$  rate similar to that of the Poisson procedure in which the arrival duration of two immediate tasks is independent and the distribution is exponential according to the rate  $1/\gamma$ . The serving time to the task at the PM in the LB is exponentially distributed over the  $\vartheta$  rate and  $1/\vartheta$  is the mean serving time. If  $\alpha < 1$  the M/M/1 is assumed to be stationary, where  $\alpha = \frac{\gamma}{\vartheta}$ . Let the probability be  $\pi_t$  be for the  $t^{th}$  state. The following equations can be summated utilizing the balanced equation [28]:

$$\gamma\pi_0 = \vartheta\pi_1 \quad (1)$$

$$(\gamma + \vartheta)\pi_t = \gamma\pi_{t-1} + \vartheta\pi_{t+1}, \quad t \geq 1 \quad (2)$$

From equation 1 and 2, it can be written

$$\pi_t = \alpha^t \pi_0, \quad t \geq 1 \quad (3)$$

According to the normalized equation,

$$\sum_{t=0}^{\infty} \pi_t = 1 \quad (4)$$

One can deduce that,

$$\pi_0 = 1 - \alpha \quad (5)$$

And then the steady-state probability of  $t$  tasks in the queue can be given as:

$$\pi_t = (1 - \alpha)\alpha^t, \quad t \geq 0 \quad (6)$$

The number of tasks on an average queued in LB can be deduced as:

$$U_{lb} = \sum_{t=0}^{\infty} t\pi_t = \alpha(1 - \alpha) \sum_{t=0}^{\infty} t\alpha^{t-1} = \frac{\alpha}{1 - \alpha} = \frac{\gamma}{\vartheta - \gamma} \quad (7)$$

The average response time that the tasks in the queue obtained can be evaluated through Little's law [29] given as:

$$R_{lb} = \frac{U}{\gamma} = \frac{1}{\vartheta - \gamma} \quad (8)$$

### D. Container Model

The paper has considered a DC containing various PMs having various VMs designated to hold one or more container instances executing on it. The local Scheduler (LS) and the runtime component (VMs) are the two major holdings of a PM. Fig. 3 demonstrate the placement of VMs and containers and LS in a PM. The container is executed on these VMs as an isolated thread in a similar namespace with a guest OS shared among other containers in the same VM. The hypervisor performs the operations that include resource management for placing the containers in the pool of VMs in accordance with the workload being requested from the users.

Fig. 3. PM structure.

Let's consider CDC contains  $m$  PMs with LS modeled as M/M/1/C model [30] with  $n$  VMs and  $l$  containers  $\eta = n \times l$  and thus making the queue full. This implies that PM is exhausted with the resources and is not in a condition to accept any new task until it gets finished up with the tasks previously allotted to it. So, it will reject the incoming new tasks. According to Burke [31], the departure procedure in the queue M/M/1 follows the Poisson process with the same rate  $\gamma$ . Thus, the tasks arriving at each PM follow the Poisson rate with  $\gamma_1 = \gamma/m$  and each task is served with a service time exponentially distributed with an average  $1/\vartheta_1$ . As the queue is finite in size so, for all the values of  $\gamma_1$  and  $\vartheta_1$  the system is stable. The  $i^{th}$  PM with  $t$  tasks in the queue has an equilibrium probability that can be defined as:

$$\pi_i^t = \begin{cases} \frac{(1-\omega)\omega^t}{(1-\omega^{\eta+1})}, & \omega \neq 1 \\ \frac{1}{\eta+1}, & \omega = 1 \end{cases} \quad (9)$$

The rate at which tasks are lost at the  $i^{th}$  PM at the LS queue can be obtained as:

$$L_i = \gamma_1 \pi_i^\eta = \gamma_1 \frac{(1-\omega)\omega^\eta}{(1-\omega^{\eta+1})} \quad (10)$$

The LS queue has  $i^{th}$  PM whose throughput is given as:

$$N_i = \gamma_1(1 - L_i) = \gamma_1 \frac{1-\omega^\eta}{1-\omega^{\eta+1}}, \quad \omega \neq 1 \quad (11)$$

Similarly, the volume of tasks available in  $i^{th}$  PM at the queue is:

$$D_i = \sum_t^\eta t\pi_i^t = \begin{cases} \frac{\omega}{1-\omega} \times \frac{1-(\eta+1)\omega^\eta + \eta\omega^{\eta+1}}{1-\omega^{\eta+1}}, & \omega \neq 1 \\ \frac{\eta}{2}, & \omega = 1 \end{cases} \quad (12)$$

The number of tasks undergoing the service is:

$$S_i = 1 - \frac{1-\omega}{1-\omega^{\eta+1}}, \omega \neq 1 \quad (13)$$

So, the tasks waiting in the queue can be given as:

$$W_i = D_i - S_i \quad (14)$$

The CPU utilization can be given as:

$$U = \frac{N_i}{\vartheta_1} \quad (15)$$

The waiting time for the tasks at  $i^{th}$  PM is:

$$WT_j = \frac{W_i}{\gamma_1} \quad (16)$$

Thus, the response time at  $i^{th}$  PM is evaluated as:

$$R_i = \frac{D_i}{N_i} = \frac{1}{\vartheta_1 - 1} - \frac{\eta\gamma_1^\eta}{\vartheta_1^{\eta+1} - \gamma_1^\eta}, \omega \neq 1 \quad (17)$$

For the later part of PM, each VM is modeled as the servers with  $l$  servers and the queue is not available with these servers i.e., M/M/1 [32] where  $l$  depicts the volume of containers available with each VM. As stated in [31], each virtual machine's incoming tasks follow a Poisson process with a rate of  $\gamma_2$ , indicating that each container receives an equal amount of requests. Since there are  $n$  VMs so each will get the tasks with an arrival rate  $\gamma_2 = \gamma_1/n$ . This will provide a balance system as each VM has a similar configuration. The service rate of each container can be taken as  $\vartheta_2$ . The task incoming at the VM can be visualized as a birth and death process. In a state  $a < l$ , the rate of the incoming task is  $\gamma_a = \gamma_2$  where  $\gamma_l = 0$ . While in the state  $a = 0, 1, 2 \dots l$ , the death rate  $\vartheta_a = a\vartheta_2$ . Let  $s_a$  be the stationary probability with  $a$  tasks in the  $a^{th}$  VM. It is observed:  $\gamma_2 s_{a-1} = a\mu_2 s_a$ , ( $0 \leq a \leq l$ ), from the local balance equation. With  $\delta = \gamma_2/\vartheta_2$ , it can be written as:

$$s_a = s_{a-1} \frac{\delta}{a} = s_0 \frac{\delta^a}{a!}, 0 \leq a \leq l \quad (18)$$

After the application of standardization condition [33],  $s_0$  can be generalized as:

$$s_0 = \frac{1}{\sum_{a=0}^l \frac{\delta^a}{a!}} \quad (19)$$

It can be further deduced:

$$s_a = \frac{\delta^a}{a!} \frac{1}{\sum_{a=0}^l \frac{\delta^a}{a!}}, 0 \leq a \leq l \quad (20)$$

The loss probability  $L_a$  for the tasks lost at  $a^{th}$  VM, as the VM was full, is recognized as:

$$L_a = \frac{\frac{\delta^l}{l!}}{\sum_{a=0}^l \frac{\delta^a}{a!}} \quad (21)$$

As there is no queue for the VM, so the tasks' volume in the VM

$$D_a = \delta(1 - s_a^{loss}) \quad (22)$$

As earlier, the response time is evaluated as:

$$R_a = \frac{1}{\vartheta_2} \quad (23)$$

As it is already known, when the LB sends the request, a job can only be carried out by one PM and in one VM by a container. Thus, the response time of the tasks before they went for execution can be summed as:

$$R = R_{lb} + R_i + R_a \quad (24)$$

With a similar analysis, the task being rejected in DC is:

$$L = L_a + L_i \quad (25)$$

#### IV. RESULTS AND DISCUSSION

The model proposed above is simulated through a series of experiments to analyze its effectiveness. The simulation has been performed on a personal computer with a 2.30 GHz Intel Core i3 processor and 4GB of RAM. The simulation tool used is Cloudsim. Initially, the DC is configured with 5 PMs and each PM is capable of supporting 10 VMs which varies to 50 VMs while each VM can accommodate a maximum of up to 18 containers. The arrival rate of the task varies from 1000 to 10,000 tasks per second. The task in the queue requests for execution which is serviced in 0.0001 seconds. The maximum capacity of the queue is 300. The LS service the request on an average of 0.001 seconds. The experiment is performed with 100 repetitions for efficient analysis.

##### A. Response Time

The response time of the system is very much affected by the volume of VMs which is analyzed with the varied task arrival rate. Fig. 4 illustrates the same. Here, the capacity of each VM to hold containers is 20. From the figure, it can be observed that the increment in response time to the task arrival is quite proportional. It is analyzed, for all the given scales of VMs, there are no substantial change in the response time when the arrival rate of the task varies from 5500 tasks per second to 9500 tasks per second. As the tasks arrival rate increases from 9500 tasks/second the response time increase exponentially for all the scales of containers. The response time 0.41second is observed in the 20 VMs scenario when the arrival rate is 10,000. The proper configuration of the VM can be chosen if the minimum response time is one of the QoS targets to be achieved for SLA.

Fig. 4. Response time.

**B. Drop Rate**

The drop rate of the system is defined as the rate at which the tasks are dropped or rejected because of either lack of space in the LS queue or a lack of capacity in DC. Fig. 5 depicts the drop rate against the task arrival rate with the varied number of containers. Each VM has 18 containers. It can be observed from the figure that initially there is not much drop in the tasks but as the task rate increases the drop rate increases. This increase varies differently with a different configuration. In the case of 20 VMs, the loss starts after the 2000 task arrival rate is reached while in the 50 VMs case this loss starts after 5000 tasks/sec. Until the rate reaches 5000 the 50VMs configuration doesn't show any loss while the 3015 tasks/s are lost in the same task arrival rate as the 20VMs configuration. It can be deduced with the increased number of containers there is less loss of tasks.

Fig. 5. Drop rate.

**C. Throughput**

The system throughput is being analyzed against the task arrival rate with all four configurations of the containers. Fig. 6 shows the variation of the system throughput measured in tasks per second. As it can be observed that in all four cases the system throughput is similar till 2000 tasks/sec. The impact of the different configurations of containers can be

seen beyond 2000 tasks/sec. The system performs better with a large number of containers. There is not much variation that can be seen when the rate of the task reaches 2000 tasks/sec in the first case, 3000 tasks/sec in the second case, 4000 tasks/sec in the third case, and 5000 tasks/sec in the last case. After a certain threshold, the throughput has become quite fixed. The requirement of predefined system throughput in SLA can be resolved using the selection of the best configuration of containers by the service providers.

**D. Number of Containers**

To study the effects of the number of containers on response time and drop rate the tasks arrival rate has been fixed at 9000 tasks/sec. The number of containers has been increased from 8 to 18 containers. Table I represents the response time. It is observed from the table as the number of containers increases the response time decreases. A dramatic decrease can be seen after the 16<sup>th</sup> container. The response time of the system is highly dependent on the volume of containers. The system drop rate is also getting highly influenced by the number of containers. It can be analyzed that as the containers increase the drop rate decreases. It shows that to keep the drop rate below 3010 tasks/sec the minimum number of VMs and containers is 50 and 8 respectively.

Fig. 6. System throughput.

TABLE I. SYSTEM RESPONSE TIME AND DROP RATE WITH RESPECT TO THE NUMBER OF CONTAINERS

No. of Containers	System Response Time				System Drop Rate			
	20	30	40	50	20	30	40	50
8	0.317	0.311	0.293	0.284	6135	5147	4087	3010
9	0.316	0.308	0.289	0.282	5948	5084	3942	2985
10	0.3149	0.304	0.286	0.2815	5827	4972	3875	2875
11	0.315	0.3037	0.288	0.281	5773	4864	3751	2870
12	0.3157	0.3021	0.287	0.2807	5648	4784	3617	2861
13	0.3154	0.2998	0.285	0.2794	5584	4743	3561	2756
14	0.3148	0.2994	0.283	0.279	5538	4476	3548	2641
15	0.297	0.287	0.277	0.274	5416	4507	3472	2571
16	0.283	0.278	0.264	0.258	5386	4459	3378	2468
17	0.257	0.246	0.238	0.2334	5258	4319	3307	2402
18	0.226	0.218	0.210	0.204	5156	4238	3193	2354

### E. Comparison with other Algorithms

The response time and system drop rate are compared with the existing work [11] and [16] for the 50VMs with 18 containers each. From Fig. 7, it can be observed that till the 4000 tasks/sec there is not much variation among the algorithms. As the rate increases the proposed shows better results. With 10000 tasks/sec, the response rate is 0.3301sec and that of [11a] is 0.601 sec. From Fig. 8., it can be deduced that till the task rate is 4000 all the algorithms show the same drop rate but as the task rate increases there is an exponential increment in the drop rate. With 10000 tasks/sec, the drop rate of the proposed algorithm is 4859 tasks/sec and while that of others is 5338 and 5812 respectively. The suggested method is significantly more effective than others.

The results obtained above have demonstrated that the increment in task arrival rate affects the QoS measures depending on the containers available in the DC. So, it's very essential to scale up or scale down the container instances depending upon the rate of the incoming task. In addition to this, the number of containers available has to fulfill the SLA requirements. Besides, in the DC the workload is very dynamic and to provision, the minimum containers dynamically which can fully satisfy the SLA requisite which monitors the usage of virtual resources and modify the number of resources to be used is of utmost importance. Therefore, the main challenge that needs to be worked upon is the engagement of the minimal number of containers for fulfilling the SLA exigencies. Allocation of a greater number of containers than required may lead to the OP which increases the cost. Deploying a lesser volume of containers than expected may result in UP leading to more SLA violations. Therefore, dynamic scalability is the requirement of the time to avoid the situation of under and over-provisioning. The proposed algorithm facilitates the service provider to identify the minimal containers required while the rate of the task fluctuates helping in scaling up and down the resources and maintaining the SLA.

Fig. 7. Comparative analysis of system response rate.

Fig. 8. Comparative analysis of system drop rate.

Further, the resources are allocated to the tasks in the order of their arrival. It may not consider the priority tasks which can be handled in further study. Since the arrival rate of the tasks is considered fixed which may differ in real life scenario as the arrival rate can vary with the state and thus making the potential customer to switch other service due to long waiting queue and thus it may affect the efficiency of the system.

### V. CONCLUSION

This paper has proposed a queuing model for dynamic scalability in containerized clouds to analyze the workload and the effects of scaling on the QoS parameters. It also suggests the number of containers is scaled up or down for the requirement of a particular given SLA. A mathematical model is developed for identifying the key performance metrics. The model predicts and approximates the resource request for future requirements to mitigate the SLA violations and provide cost-effective solutions. The proposed methodology can also be used to scale the DC containers to guarantee the QoS parameters. The model is proficient enough in deciding the number of containers required for the provision or deprovisioned as per the given workload situation to meet up the SLA demand and QoS metrics. The proposed model is tested against some existing work and has turned out to be performing better. In future work, the model can be implemented in a real working environment and more SLA parameters can be included for the analysis. Further, clustering technique can be included and the model can have queue classified according to the requirements of the tasks like some tasks may require more processing units while some require more storage unit.

**Abstract**—The goal of this research is to create a machine learning (ML) classifier that can improve breast cancer (BC) diagnosis and prediction. The principle components analysis (PCA) technique is used in this work to minimize the dimensions of the BC dataset and achieve better classification metrics. The developed classifier outperformed others in terms of F1 score and accuracy score. Using the original BC dataset, four different classifiers are applied to determine the best classifier in terms of performance metrics. The used classifiers were RandomForest, DecisionTree, AdaBoost, and GradientBoosting. The RandomForest classifier obtained (95.7%) f1 score and (94.5%) accuracy score, the DecisionTree classifier obtained (93%) f1 score and (91%) accuracy score, the GradientBoosting classifier obtained (95%) f1 score and (93.5%) accuracy score, and the AdaBoost classifier obtained (95.8%) f1 score and (94.5%). The AdaBoost classifier was utilized to create the final model using the reduced PCA dataset because it scored the highest performance metrics. The developed classifier is named as “pcaAdaBoost”. The optimized pcaAdaBoost achieved higher performance metrics in terms of f1 score (99%) and accuracy score (98.8%). The results reveal that the optimized pcaAdaBoost scored highest performance measures in terms of cross-validation and testing outcomes, with an overall accuracy of (99%). The improved results justify the use of dimensionality reduction in high-dimension datasets to reduce complexity and improve performance measures.

**Keywords**—Breast cancer; diagnosis; prediction; AdaBoost, RandomForest; PCA

## I. INTRODUCTION

Several studies and technologies have been conducted worldwide to screen for and investigate the risk of Breast Cancer (BC). Despite significant advances in screening and patient management, BC represents one of the common malignancies in women worldwide and it was ranked as the second most likely cause of cancer mortality. Statistically, there were 268,600 new cases of BC diagnosed in American women in 2019, with 41,760 deaths [1-3]. BC is a very diverse illness with numerous forms and subtypes. Approximately 95 % of BCs responded to endocrine and targeted therapy, and their prognosis and survival rates are generally favorable. However, the widely used screening instrument is a two-dimensional mammography, which can detect tumors that are too small to perceive. The breast is compressed between two rigid plates in a conventional mammogram, and X-rays have been used to capture images of the breast tissue. Such techniques are invasive, costly, and tedious to conduct. With the advent of new computational power in terms of big data, machine

learning (ML), and data science (DS), scholars have attempted to apply such new computation techniques to the analysis of BC datasets, as well as to develop new promising low cost and fast BC classification techniques. However, to reduce processing time and to increase prediction performance, data reduction techniques are used. Removing irrelevant input data and get rid of redundant inputs would probably enhance classifier's capability in terms of performance measures. In this study, the PCA technique is used in this work to minimize the dimensions of the BC dataset and achieve better classification metrics. The generated classifier outperformed others in terms of F1 score and accuracy score. Using the original BC dataset, four different classifiers are applied to determine the best classifier in terms of performance metrics. Therefore, the following classifiers, RandomForest, DecisionTree, AdaBoost, and GradientBoosting, are used and evaluated. This work utilized the PCA method to reduce features from the original BC dataset. This method improved the performance of the ML model on hand and enabled better data visualization. In this way, the PCA is used to reduce the dimensions of the BC dataset, making it less sparse and more statistically significant.

## II. LITERATURE REVIEWS

Scholars defined ML as a subset of artificial intelligence (AI). It denotes a mathematical model that is used to make decisions or predictions using a training dataset. It is frequently referred to as an evolving prediction model that will improve classification capabilities in a variety of fields including disease diagnosis and screening as in medical industry [4]. It is necessity to reduce the danger of diseases, infections, disorders, or pandemics using a proactive ML model [5-6]. To deal with the increasing complexity of the vast data and convert it into meaningful scientific knowledge for the benefit of humanity, new bioinformatics methods must be developed [7-8]. The use of ML classification techniques in medical diagnosis applications is highly valued [6]. However, traditional classification may not have performed as well as planned, raising the necessity of such investigations that could improve the current classification technologies in medical sectors. The goal of medical AI and ML research is to create applications that use AI technologies to aid practitioners in providing treatment based on better decision making [9-10]. Some research has been conducted on comprehensible AI in order to solve the downfalls of AI analysis tools being black boxes. In comparison to AI systems such as deep learning, XAI can present model's explanations and decision-making

\*Corresponding Author.

capabilities [11]. Many traditional ML approaches for classification problems are used like logistic regression (LR), support vector machine (SVM), decision tree (DT), and RandomForest (RF). The RF is a ML classification method that comprised of several decision trees in an ensemble. The outcome of these DT elections symbolizes the RF decision. Regardless of the used ML algorithm, several evaluation methods such as F1\_score, accuracy\_score, precision, recall, AUC, and ROC have been commonly used to assess the effectiveness of each proposed method [12]. One of the most important areas of medical based ML applications is BC classification. BC has now surpassed lung cancer as being the most prevalent malignancy afflicted in women worldwide [13]. For the prognosis and diagnosis of BC disease, researchers developed a SVMs based classifier in contrast to Bayesian classifiers and ANN. However, they gave implementation summary for the findings of the evaluated classifiers [14]. Another study [15] used the BC dataset to classify BC disease using several ML methods: Knn, RF, SVM, DT, and LR. They evaluate the results of each method and concluded that the SVM algorithm outperformed the others with a performance accuracy of (97.2%). Another study [16] tried to examine the findings and to analyze several ML approaches for the detecting of BC using the same dataset. Another study [17] proposed an efficient recursive neural network (RNN) approach for BC classification using RNN and “Keras-Tuner” enhancement method in which they claimed that, the developed model achieved high performance accuracy. However, the study in [16] showed that Logistic regression classifier beats the other classifiers in predicting BC disease using BC Wisconsin (Diagnostic) data set (BCWD).

### III. RESEARCH METHODS

The current study attempts to minimize the dimensionality

of the dataset before selecting the optimal features to be fed to the classifier. The proposed method employs the simplest model that meets the performance requirements of the complicated models. Accordingly, the dataset shall be dimensionally reduced in order to improve model performance and eliminate extraneous features. Therefore, the proposed model begins with data preprocessing, followed by feature selection, dimensionality reduction, and classification (Fig. 1). In this methodology, four different supervised classification algorithms are used, RandomForest, AdaBoost, GradientBoost, and DecisionTree respectively. For this study, the classifier that obtained the best performance measure (Accuracy\_score, and F1\_score) is selected to perform classification process. However, after selecting the best classifier, the principle components analysis (PCA) procedure is taken place to perform dimensionality reduction. The reduced dataset is then fed to the chosen classifier to implement BC classification. The developed model is then validated using k-fold cross validation, tested using a subset of the original dataset (30%), and lastly, performance measures are evaluated.

#### A. Dataset Description

In this study, BCWD data is being utilized for model development purposes. The data include 31 features along with the class feature (target). The cell nuclei detected in the breast image clip are represented by the independent indices. Moreover, the dependent index contains binary outcome: zero indicates benign, and one describes malignant. The output will be classified as being benign or malignant. However, the shape of the used dataset is (569,31), and its descriptive analysis is shown in Fig. 2. Additionally, the bar chart (Fig. 3) depicts the count of the target variable to be malignant (M) or benign (B).

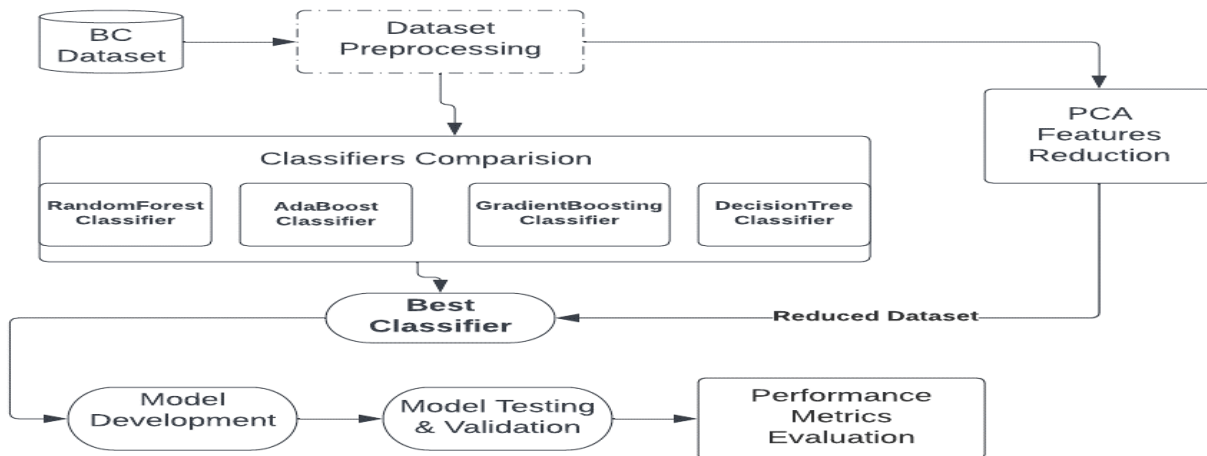

Fig. 1. An enhanced methodology for BC classification using PCA.

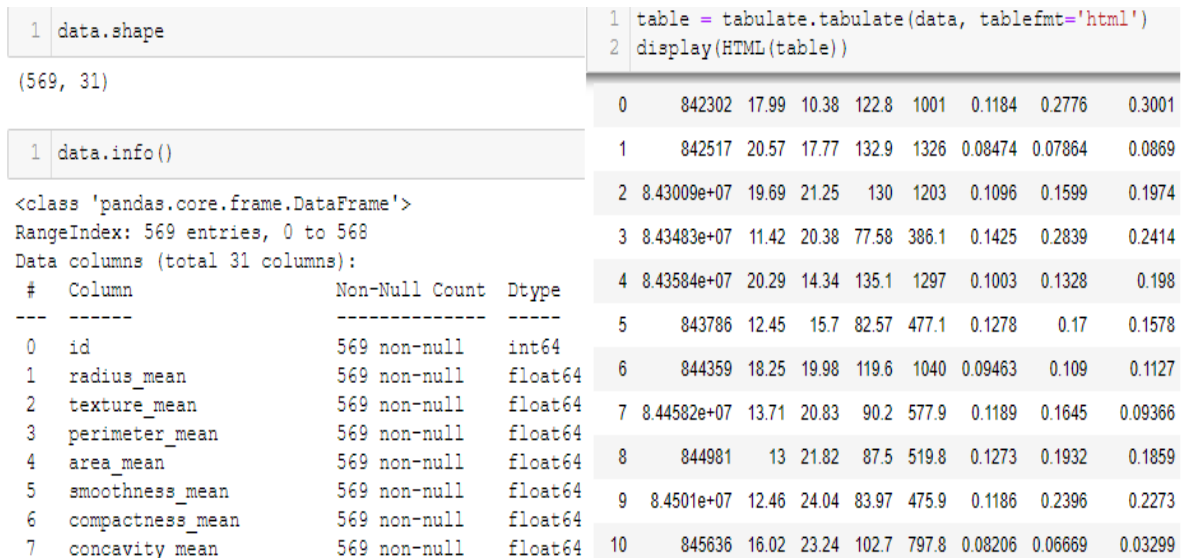

Fig. 2. Descriptive analysis of BC dataset.

Fig. 3. Count for class variable (diagnosis).

### B. Dimensionality Reduction

Features reduction represents a very important preprocessing stage that eliminates redundancy, inconsistent, and unimportant features to optimize learning, classification accuracy, and minimize training cost [18]. One of the its approaches that diminishes computation cost for the learning process is called “Principal Component Analysis (PCA)”. Moreover, features reduction is useful in several realms because it reduces the computational burden as well as other unfavorable characteristics of high-dimensional areas. Many scholars recommended the utilization of features reduction techniques to improve computational power and to enhance performance accuracy [5]. Therefore, the literature has several uses of dimensionality reduction techniques such as, Zhao and Du [19] in which they advocated for the use of the “feature\_based” spectral-spatial” classification (SSFC) structure. Another study by Xu. Y et. al [20] proposed spontaneous removal of piece picture from side to side deep learning. However, the PCA is commonly used method for features reduction.

### C. Classification

Classification represents the most important task in supervised learning techniques [21-23]. It normally utilized to separate the dataset into a unique class as per the values in the dependent variable [24-25]. To select the best classifier that provides the optimal performance metrics based on BC dataset, four different classifiers are used, namely, RandomForest, Adaboost, Gradientboost, and DecisionTree are used. A brief detail-on each classifier is shown below:

1) *Random forest classifier*: Because of its ease of implementation and high versatility, it is one of the most often used supervised learning algorithms. It is a collection of prediction trees capable of handling large datasets.

2) *Adaboost classifier*: AdaBoost was among the first applications to employ the boosting technology. It accomplishes this by integrating numerous weak classifiers into a single strong classification method.

3) *Gradientboost classifier*: It is an ensemble, functional gradient iterative approach that reduces a “loss function” by repeatedly selecting a function who points towards the negative slope.

4) *Decision tree classifier*: The decision tree can be defined as a supervised learning technique in which it is commonly implemented for solving binary classification problems. However, such a technique bases its decision on some rules.

## IV. RESULTS

In this study, initially four different classifiers were employed to get performance metrics using BC dataset. The established approaches were assessed using accuracy score and F1 score metrics. However, the model with the best metrics was used to develop the enhanced model. After data preprocessing and visualization, the dataset is reduced into two main components namely, first principal component and second principal component. Fig. 4 illustrates the reduced PCA components.

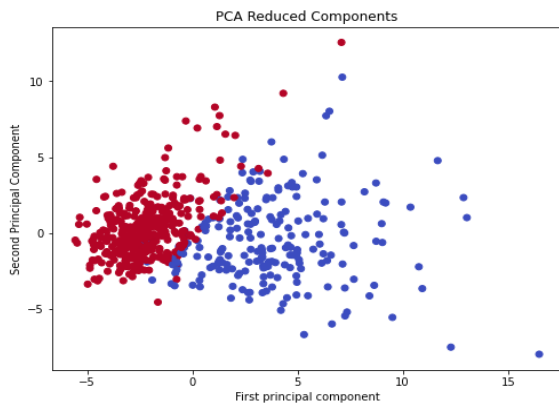

Fig. 4. The reduced PCA components (first & second principal components).

Fig. 5. Heatmap of the reduced PCA features.

As it can be seen in Fig. 4, the reduced dataset consists of two principal components in which they can represent the original dataset with no loss of information. It can be noticed that the reduced dataset can be used to clearly discriminate between the two classes of the target variable ('diagnosis'). The reduced dataset represents a dumpy matrix array in its rows represents the principal components and each column in it relates back to the original indices. Such relationship can be visualized as heatmap (Fig. 5).

The classifier that obtained the higher performance metrics is selected to implement the final model using the reduced PCA dataset. The RandomForest classifier obtained (95.7%) f1\_score and (94.5%) accuracy\_score in which it occupied position number two among the selected classifiers. The DecisionTree classifier obtained (93%) f1\_score and (91%) accuracy\_score. The GradientBoosting classifier obtained (95%) f1\_score and (93.5%) accuracy\_score. Eventually, the AdaBoost classifier obtained (95.8%) f1\_score and (94.5%) accuracy\_score (Table I).

TABLE I. CLASSIFIERS PERFORMANCE METRICS

Classifier	F1-Score	Accuracy-Score
Random Forest	95.7%	94.5%
Decision Tree	93%	91%
Ada-Boost	95.8%	94.5%
Gradient-Boosting	95%	93.5%

## V. DISCUSSIONS

The obtained results showed that AdaBoost classifier outperforms other used classifiers in terms of f1\_score and accuracy\_score. Thereby, it was used to implement the final enhanced model. On other hand, the RandomForest classifier achieved a very similar performance metrics to the AdaBoost classifier in terms of accuracy\_score, but the AdaBoost classifiers achieved higher F1\_score. Hence, the reduced PCA components were fed again to AdaBoost classifier to validate the enhancement made by the reduced dataset features using PCA components. Fig. 6 showed the enhanced performance metrics in which it achieved an overall accuracy of (99%). The new enhanced model is used to make predictions on a new dataset to validate its performance. The developed classifier was able to correctly classify the new data into its correct classes where they were 'Malignant' or 'Benign'. The final accuracy\_score and F1\_score is depicted in Fig. 7. The model obtained a noticeable higher f1\_score (99%) and noticeable higher accuracy\_score (98.8%).

Fig. 7. The improved performance metrics using AdaBoost and PCA.

As shown in Fig. 7, the developed model obtained higher accuracy score and higher F1 score. Therefore, it can be concluded that, the reduced dataset using PCA components analysis can enhance classification performance in high-dimensions datasets. Furthermore, dimensionality reduction simplifies the classification process in ML, resulting in a better fit to the constructed classifier.

## VI. CONCLUSIONS

This research utilized PCA technique to minimize the input features in the BC dataset seeking better enhancement of BC classification in terms of F1\_score and accuracy\_score. The developed model started with a performance metrics comparison between four supervised classification techniques namely, RandomForest, DecisionTree, AdaBoost, and GradientBoosting. The RandomForest classifier showed (95.7%) f1\_score and (94.5%) accuracy\_score, DecisionTree classifier obtained (93%) f1\_score and (91%) accuracy\_score, GradientBoosting classifier obtained (95%) f1\_score and (93.5%) accuracy\_score, and finally, AdaBoost classifier obtained (95.8%) f1\_score and (94.5%) accuracy\_score. Since the AdaBoost classifier scored the highest performance metrics, it used to implement the final model using the reduced PCA dataset. The developed classifier is named "pcaAdaBoost". The optimized pcaAdaBoost achieved higher performance metrics in terms of F1\_Score (99%) and accuracy\_score (98.8%). The results show that the optimized pcaAdaBoost has delivered the best results in terms of cross-validation and testing. with an overall accuracy of (99%). However, as per future works, the developed classifier should be trained and tested using different datasets to validate its ability to enhance performance metrics. Finally, the developed model is hoped to introduce a predictive tool for early diagnosis and classification of BC in our large society.

## VII. DATA AVAILABILITY

The used data in the development of this model and that is used to support the findings of this research can be accessed online at:

UCI Machine Learning Repository: Breast Cancer Wisconsin (Diagnostic) Data Set.

YOUSSEF QAWQZEH received the PhD. degree in systems engineering from UKM University, Bangi, Kuala Lumpur, Malaysia, in 2011, where he is currently working as an associate professor in the college of information technology, Fujairah University. He is currently working on several projects in the fields of machine learning, data science, and bioinformatics. He has several publications in international journal and conferences. His research interest includes the early prediction of cardiovascular diseases using the photoplethysmography technique, the development of computer-aided diagnosis systems for early diagnosis of breast cancer using artificial intelligence and machine learning techniques, and the detection and prediction of high-risk diabetics using machine learning and artificial intelligence techniques.

ABDULLAH ALOURANI is an assistant professor at the Department of Computer Science and Information, Majmaah University, Saudi Arabia. He received his Ph.D. in computer science from the University of Illinois at Chicago, United States, his Master's degree in computer science from DePaul University in Chicago, United States, and his Bachelor's degree in computer science from Qassim University, Saudi Arabia. His current research interests are in the areas of software engineering, security, and artificial intelligence. He is a member of ACM and IEEE.

SAMEH GHWANMEH a full Professor of Computer Science and Engineering, and ICT. Obtained his PhD and MS in Computer Engineering from UK, in 1996 and 1993 respectively, and BS degree in Computer Engineering from Jordan, in 1985. More than 24 years of leadership experience in HE institutions. Was and still involved in many administrative and academic positions: University Chancellor (current), Registrar Director, Dean of Faculty of Information Technology, Director of Accreditation, Associate Dean, Program Chair, Academic Adviser to the Minister of Education and Higher Education in Jordan. The published work exceeds 50 international journal papers, and was an invited speaker in different international conferences and workshops. Received many national and international awards. Was involved in curriculum development for a number of undergraduate and graduate programs. Managed and coordinated several research projects that are funded by regional and international agencies such as European Commission.

# Efficient Multimedia Content Transmission Model for Disaster Management using Delay Tolerant Mobile Adhoc Networks

Sushant Mangasuli, Mahesh Kaluti

Dept. of Computer Science and Engineering, PES College of Engineering, Mandya, India

**Abstract**—Natural and manmade disasters such as earthquakes, floods, unprecedented rainfall, etc. pose several threats to our society. The citizens upload disaster information in the form of multimedia content such as pictures, audio, and videos. Efficient information and communication framework are critical for disaster management. Mobile Adhoc Networks (MANET) have been used effectively for disaster management. However, Disaster management prerequisites following Quality of Service (QoS) requirements such as bandwidth, high delivery ratio, low overhead, and minimal latency; however, the existing data transmission scheme induces high latency and overhead among intermediate devices; In order to meet the QoS requirement of disaster management applications in this paper, High Delivery Efficiency and Low Latency Multimedia Content Transmission (HDELL-MCT) scheme for MANETs is presented. Then, an improved buffer management scheme is presented for meeting disaster management performance and latency prerequisites. The experiment is conducted using ONE Simulator, the outcome shows the HDELL-MCT scheme achieves very good performance considering different QoS metrics such as improving delivery ratio by 38.02%, reducing latency by 7.53% and minimizing hop communication overhead by 65.1% in comparison with existing multimedia content transmission model.

**Keywords**—Buffer management; disaster management; Mobile Adhoc Network; opportunistic routing; Quality of Service

## I. INTRODUCTION

Disaster management is unpredictable as the disasters can be caused by humans or can be a natural calamity. In the disaster, many man-made things are damaged or destroyed such as buildings, cellular towers, power grids, network infrastructure, etc. [1], [2]. Due to these damages, there is no proper communication if a person is stuck in a disaster. Moreover, there is congestion in the communication channel due to the data traffic as the people try to contact their family or friends seeking help. The disaster management teams are deployed to rescue the people, and resources and many people use an online platform to share the condition of that area by posting videos and pictures [3]. Due to this, there is more traffic and congestion in the communication networks [4]. Despite having massive technologies, there are many communication problems which include system overload, system failure, and incompatibility between communication systems used by different agencies. These communication problems can be resolved by providing a redundant

communication channel or by providing a separate communication network for disaster management [5], [6].

In disaster management, the Mobile Ad-hoc Networks (MANETs) can play an important role by providing the person's information when the rescue team cannot find the person who is stuck in a disaster [7], [8]. The MANETs contain various mobile nodes that are deployed randomly which can join or leave the given network when it moves. The mobile nodes can communicate opportunistically [9] with other nodes using the wireless link to share the information. Mobile Ad-hoc Networks can add various new devices rapidly. All the devices which are in the network can move freely in any direction. Some examples of MANETs that are currently being used are in military operations, a small conference room, rescue operations on the battlefield, ad-hoc networks, and emergency operations [9].

During the transmission of the nodes from the source to the destination, many challenges are faced by the MANETs [10], [11], & [12]. Some of the challenges include the delivery ratio, multihop, congestion control, and latency. Thus, designing a network in MANETs is a challenging task as there are many problems in its design. Every node in the network acts like a router that can send the packets (i.e., images, videos, etc.) from the source to the destination in an opportunistic manner [13]. The nodes can be of any device like mobiles, laptops, personal computers, etc. Mobile Ad-hoc Networks can range from small networks to very large dynamic networks for provisioning multimedia applications [14]. The nodes communicate with the other nodes in a multihop manner. When the transmitter sends a packet to a given destination node, an intermediate node is used for communication in the network. Hence, every node plays a vital role in sending the packets from the source to the destination [3], [15], [16]. An extensive survey shows existing data transmission scheme induces memory overhead among intermediate for provisioning disaster management applications; thus, inducing poor delivery ratio and latency. This motivated the research to develop an improved multimedia content delivery model namely HDELL-MCT for provisioning disaster management applications. The HDELL-MCT incorporates the location feature into the actual packet and predicts whether the current device will go toward destined groups or not; further, each packet is composed of time validity within which the data has to be delivered to the destined group. Then, an improved buffer management scheme is presented for

meeting disaster management performance and latency prerequisites. The significance of HDELL-MCT is as follows.

- The HDELL-MCT employs a two-level multimedia data transmission model for MANETs.
- The HDELL-MCT model can meet the delivery ratio and latency requirement of disaster management applications.
- The HDELL-MCT improves delivery ratio, and intermediate hop overhead, and reduces latency in comparison with the existing multimedia data transmission model.

The manuscript is arranged as follows. In section II, various existing data transmission model for wireless and Mobile Adhoc networks is discussed, and also identified research issues for developing an improved multimedia content transmission model. In section III, the proposed high delivery efficiency and low latency multimedia content transmission model have been presented for disaster management using Mobile Adhoc networks. In section IV, the simulation outcome of HDELL-MCT and existing MCT through The One simulator is validated. In the last section, the result is concluded with a future research direction.

## II. LITERATURE SURVEY

Here are various existing data transmission schemes for provisioning disaster management applications for wireless and Mobile Adhoc networks. In [5], a routing protocol, TA-AOMDV has been proposed which can adjust to the movement of the node at high speed to achieve a good quality of service. In this protocol, an algorithm is used which takes the node resources for the selection of the path and also to connect the stability probability between any two nodes. This protocol uses a technique that constantly brings up-to-date routing strategies using the evaluation of the link stability of the nodes. In [6], a routing scheme known as BARS has been presented which can avoid the overcrowding of the bandwidth problems in network paths and make space in the queues to store the information in the cache. The available storage of the cache must be evaluated before the transmission of the data takes place. This model uses a technique of feedback through which it can identify the traffic source to adjust the data rate using the bandwidth and hold the data in a queue so it can be sent to the routing path. In [7], a study on MANET has been evaluated using the AODV protocol, which evaluates the outcome of the route requesting parameters. This protocol was compared with the OLSR protocol using the performance metrics such as energy consumption, latency, and other metrics. The comparison tells that the OLSR model has some latency when compared with the AODV model.

In [8], a routing protocol has been proposed using the delay-tolerant MANET, in which the virtual nodes are carefully chosen based on the delivery to the destination node, only if the node is not delivered using the MANET protocol. The transmission of the node is done from the source node to the destination node. In [10], a routing protocol has been proposed opportunistic network, which generates a data forwarding model in the communication of the data where it

evaluates the rules of transferring data in a partition scheme for node activity. To achieve the trade-off between the transmission efficiency and system overhead a different approach has been used. A free movement degree model is developed depending on which a utility capacity is concluded to pick nodes for transmission of the information [11]. In [12], focused on addressing the congestion at the node and link-level adopting reactive routing mechanism using random early detection and expanding ring searching models to improve packet delivery ratio with minimal latency. In [13], an energy-efficient version of the FCSG, EFCSG has been proposed for the OppNets. This protocol uses the fuzzy controller with fuzzy features to check the nodes that can be considered for the routing process.

In [15], a technique, TBSMR is used to improve the Quality of Service in MANETs performance. This technique uses different factors like malicious detection of nodes, control of congestion, packet loss reduction, etc. to strengthen the Mobile Ad-hoc Networks quality of service. In [3], a method, namely MMDSR (multipath multimedia dynamic source routing) has been modified from the previous version to include the tie strength in the decision which is done using the forwarding algorithm; where the model finds a trade-off between the QoS and the reputation between the users who arrange the path in the MANET. This method increases the reputation metric without affecting the QoS. However, the major drawback of the existing data transmission scheme is that they achieve poor data delivery ratio and induce memory management overhead considering delay-tolerant disaster management application; For overcoming research issues an improved multimedia data transmission scheme for provisioning disaster management through Mobile Adhoc Network.

## III. HIGH DELIVERY EFFICIENCY AND LOW LATENCY MULTIMEDIA CONTENT TRANSMISSION MODEL FOR DISASTER MANAGEMENT USING MOBILE ADHOC NETWORKS

This section presents high delivery efficiency and low latency multimedia content transmission model for disaster management using Mobile Adhoc networks. In traditional MANETs, the messages are generally broadcasted to every neighboring device available leading to high congestion in the network. In addressing this work employ group-casting-based communication where groups represent a location that can provide services; Any MANET device that resides within a group will become a possible receiver. In group-casting, all information's are addressed to a respective group and each MANET device that resides within that group will receive the data packets; thus, it is important to outline groups in MANETs. Further, information should incorporate the group's information; thus, every MANET device that resides within groups will receive packets.

### A. MANET Device Group Classification

Here we define the groups for MANETs considering delay-tolerant prerequisite of disaster management applications. The groups define MANET devices that reside in the same region and have coverage to communicate the data packets. In disaster management applications the groups are represented through two-dimensional geographical coordinates. Here the MANET

devices randomly transmit information to destined groups; thus, aiding in reducing broadcasting overhead by preventing unwanted message transmission. Most of the existing group-casting-based data transmission scheme assumes groups through circular pair, these models generally increase their circular radius for reaching faraway MANET devices; thus, resulting in bandwidth wastage. In a standard group-casting-based data transmission model the groups must be predefined; however, in this work, the message carries coordinates information which is the address of the destined device. In MANETs, the device is highly mobile and is aware of adjacent device locations; however, each device can share information among them through intermediate nodes. Therefore, every information must have information about destined groups. Along with the data transmission scheme must be in a position to communicate information to a destined group. The data transmission scheme should be in a position to establish MANET device is within the group or not in a reliable manner. The step involved in establishing whether a destined MANET device is within-group or not is described in Algorithm 1.

**Algorithm 1. MANET Device Group Classification**

Step 1	<b>For each</b> collected data with respective MANETs, the device <b>do</b>
Step 2	<b>Obtain</b> the MANETs device location $(x, y)$
Step 3	<b>Compute</b> vertical segment of network with $x$ - coordinate of respective MANETs device's location
Step 4	<b>Establish</b> intersected array among the vertical segment and the receiver's group of MANETs.
Step 5	<b>For each</b> intersected region within the array <b>do</b>
Step 6	<b>If</b> $y$ -coordinate of the intersected region is lesser when compared with $y$ -coordinate of the destination's region <b>then</b>
Step 7	<b>Eliminate it</b> within the array
Step 8	<b>End if</b>
Step 9	<b>End for each</b>
Step 10	<b>If</b> the intersected number is not odd, <b>then</b>
Step 11	<b>get</b> 0 (i.e., MANETs device is not the receiver of corresponding data and is outside the group)
Step 12	<b>Else</b>
Step 13	<b>get</b> 1 (i.e., the current MANETs device is the receiver of corresponding data)
Step 14	<b>End if</b>
Step 15	<b>End for each</b>

**B. Multimedia Data Transmission Scheme**

The objective of HDELL-MCT is to effectively convey the group-casting information to all the MANET nodes that reside within the destined group considering a certain session period. As the MANET device are mobile, they frequently dynamically change groups, thus, incorporating session information is very important. As a result, the HDELL-MCT model delivers to the device that can reach the destination group within the stipulated time. On the other side, the existing routing strategy delivers the packet to detained group according to the device ID defined. However, group association is dependent on MANET device coordinates which vary according to their mobility. Thus, every MANET device must obtain session validity and group address information for routing to be successful to deliver to the intended destination. The main challenge of incorporating session validity into HDELL-MCT, here the session validity is obtained based on

message creation time and its maximum time limit i.e., content validity (CV).

The HDELL-MCT model is composed of two-level. In level 1, an effective carry-forward mechanism toward the destined group. In level 2, message delivery to all MANET device that resides within the region/group. The graphical representation of the two-level HDELL-MCT model is shown in Fig. 1.

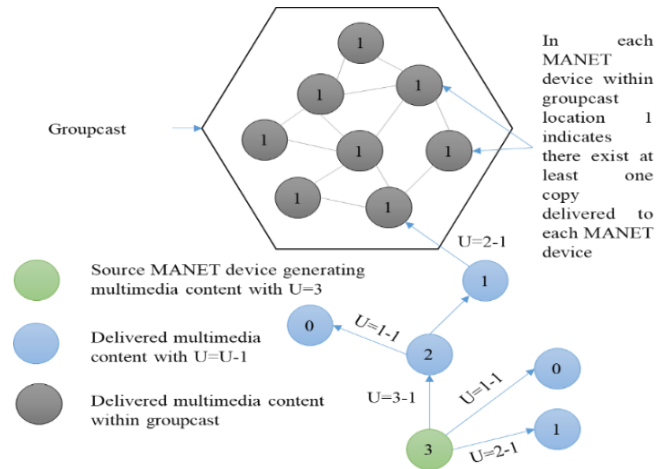

Fig. 1. Graphical representation of HDELL-MDC scheme.

1) *Level 1- Forwarding Multimedia Content toward the destination group:* In this work, a similar multi-copy spray and wait (MCSW) technique [17] is used. The adoption of MCSW aid in reducing communication overhead and improves message delivery; thus, aids in providing an efficient manner of reaching the destination group. Here every time a message is created a token  $U$  is attested to the message. The parameter  $U$  will act as an identifier for representing the size of message replication considered. The parameter  $U$  will be reduced by 1 every time it encounters a MANET device. Once  $U$  reaches to 0, the message will be no longer communicated defining the message as expired, and the message will be deleted from the local memory.

2) *Level 2- Deliver Multimedia Content to all MANET devices within the group:* Here the message is communicated to all the MANET devices within the group by employing an efficient flooding mechanism. The HDELL-MCT model first flood the information to all MANET device and every device keep a copy of the content (as described in line 14-16 and line 21-24 of Algorithm 2). In HDELL-MCT, if a replicated multimedia content goes beyond the destined group, the multimedia content is forwarded back to the MANET device that resides within the group (this step is described in line 20 of HDELL-MCT Algorithm 2); until  $U$  becomes 0 i.e., expires. Finally, the message is removed from the memory (as described in line number 4 of HDELL-MCT Algorithm 2). This aids in reducing memory and network overhead by preventing information exchange beyond the destined group. The two-level HDELL-MCT is described in Algorithm 2. In HDELL-MCT the value of  $U$  can be pre-configured according

to disaster and safety-related application prerequisites such as operating environment, mobility, density, and so on. However, in this work, the U is configured dynamically and device density impacting delivery ratio and latency is a major focus for HDELL-MCT.

**Algorithm 2. Multimedia Data Transmission Scheme**

```

Step 1 For each interaction among two MANET devices
       within the network do
Step 2   One device becomes the sender  $T_1$  and other becomes
       the receiver  $T_2$ 
Step 3 If the MANET device is the sender  $T_1$  then
Step 4   Remove valid multimedia content from the memory
Step 5   Apply memory optimization scheme
Step 6 For each multimedia content within the memory do
Step 7 If multimedia content is already present within  $T_2$ 
       memory
Step 8   Move on to the next multimedia content present within
       the for loop
Step 9 End if
Step 10 If ( $U > 0$ ) then
Step 11  $U \leftarrow U - 1$ 
Step 12 Send a replicated multimedia content to  $T_2$ 
Step 13 Else if ( $U = 0$ ) then
Step 14 If  $T_1$  is within the receiver group (see algorithm 1) then
Step 15 Send a replicated multimedia content to  $T_2$ 
Step 16 End if
Step 17 End if
Step 18 End for each
Step 19 Else if the MANET device is the receiver  $T_1$  then
Step 20 For each received content do
Step 21 If  $T_2$  is within the receiver group (use algorithm 1) then
Step 22 Transmit the multimedia content to the application
       layer
Step 23 Keep a replicated multimedia content in the memory
Step 24  $U \leftarrow 0$ 
Step 25 Else if  $T_2$  is outside the receiver group (use algorithm
       1) then
Step 26 Keep multimedia content in the memory
Step 27  $U \leftarrow U - 1$ 
Step 28 End if
Step 29 End for each
Step 30 End if
Step 31 Change scenario (sender  $T_1$  and receiver  $T_2$ ) and return
       to step 3 at least once
Step 32 End for each

```

**C. Memory Optimization Model**

Algorithm 2 encompasses the memory optimization problem in line 5. The parameter U has been used for delivery efficiency considering limited bandwidth availability, the memory optimization is done using priority optimization. Here we route the packet based on First Come First Serve (FCFS) with Minimal Content Validity (MCV). The HDELL-MCT scheme uses very less resources with a high delivery ratio and less latency when compared with the recent standard data transmission scheme which is experimentally proven next section below.

**IV. SIMULATION RESULT AND ANALYSIS**

Here experiment is conducted for validating the performance of the proposed High Delivery efficiency and low latencies multimedia content transmission (HDELL-MCT)

scheme and standard data transmission [3]. The delivery ratio, intermedia hop forwarding overhead, and latencies by varying network density size are performance metrics considered for validating models. To validate the performance of HDELL-MCT over existing MCT schemes, simulation is conducted using real-time scenarios through The One simulator [18]. This work uses QSMVM (QoS-based Socio-Aware Multi-metric) routing scheme as an existing MCT scheme for comparison because it performed significantly well with better packet delivery and reasonable latency in comparison with various existing baseline data transmission models such as Social aware Content-based Opportunistic Routing Protocol (SCORP) [19], Prophet [20], Epidemic [21], and other data transmission protocol [11].

**A. Simulation Parameter Configuration**

The scenario namely, Helsinki comprised of synthetic traces, is based on the one presented in [3], where nodes are placed on the map of Helsinki city (see Fig. 2). We considered a variable number of MANET devices (i.e., 20, 40, and 80), to assess the performance for different densities. During the simulated 12 h time-period, the MANET device moves on the map roads at an average speed of 50 km/h, between random locations, and with random pause times between 5 and 15 minutes. Each MANET device randomly generates many posts (i.e., to grant the participation of all the MANET devices in the network, every MANET device generates at least one message per day) and generates a message depending on its location at that moment. The parameters taken in this work are based on [3] and Table I shows the main parameters used in the simulated safety-related (disaster management) application scenarios.

Fig. 2. The traffic pattern of devices placed across the map of Helsinki [8].

TABLE I. SIMULATION PARAMETER CONSIDERED

Parameters	Configured
Message Generation Rate	1000 messages per simulation
Message Size	[12] MB
TTL	12 h
Network Interface	IEEE 802.11 a, b, g, n, p
Transmission Range	200 meters

**B. Latency Performance**

Fig. 3 shows the latency induced for transmitting data in the network using QSMVM and HDELL\_MCT scheme considering varied MANET device sizes of 20, 40, and 80. From the result, we can see the HDELL\_MCT model achieves much lesser latency for transmitting packets when compared with the QSMVM scheme. A latency reduction of 7.53% is achieved using HDELL\_MCT over the QSMVM multimedia data transmission scheme.

Fig. 3. Multimedia content transmission latency performance for varied MANETs devices.

**C. Delivery Ratio Performance**

Fig. 4 shows the delivery ratio performance for transmitting data in the network using QSMVM and HDELL\_MCT scheme considering varied MANET device sizes of 20, 40, and 80. From the result, we can see the HDELL\_MCT model achieves much superior delivery ratio performance when compared with the QSMVM scheme. A delivery ratio performance improvement of 38.02% is achieved using HDELL\_MCT over the QSMVM multimedia data transmission scheme.

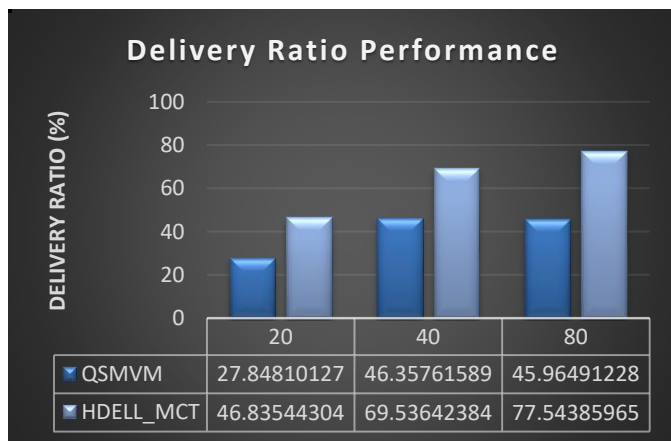

Fig. 4. Multimedia content transmission delivery ratio performance for varied MANETs devices.

**D. Number of Hop-Count Performance**

Fig. 5 shows the hop count performance for transmitting data in the network using QSMVM and HDELL\_MCT scheme considering varied MANET device sizes of 20, 40, and 80. From the result, we can see the HDELL\_MCT model uses less

number of a forwarder for transmitting packets when compared with the QSMVM scheme; thus reducing the control channel computation overhead of the network. A computation overhead reduction of 65.19% is achieved using HDELL\_MCT over the QSMVM multimedia data transmission scheme.

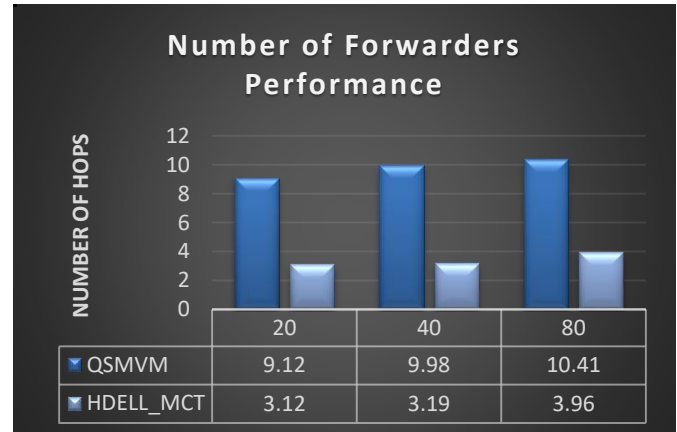

Fig. 5. Multimedia content transmission Hop count performance for varied MANETs devices.

From the overall result attained it can be seen the HDELL\_MCT scheme achieves superior packet delivery ratio performance with fewer latencies and computation overhead under varied density; thus, are suitable for provisioning safety-related (disaster management) applications.

**V. CONCLUSION**

In this paper an effective MCT model namely the HDELL-MCT model is presented for provisioning disaster management applications. The MCT is designed considering improving delivery ratio and reducing latency. In order to meet the QoS requirement of disaster management applications in this paper, High Delivery Efficiency and Low Latency Multimedia Content Transmission (HDELL-MCT) scheme for MANETs is presented. Then, an improved buffer management scheme is presented for meeting disaster management performance and latency prerequisites. The HDELL-MCT employed a two-level multimedia content transmission algorithm for meeting the prerequisite of disaster management applications. Further, HDELL-MCT uses the location-aware feature, group-casting-based efficient flooding, and using priority-based memory optimization scheme balancing delivery ratio and latency reduction performance. The experiment is conducted using ONE Simulator, the outcome shows the HDELL-MCT scheme achieves very good performance considering different QoS metrics such as improving delivery ratio by 38.02%, reducing latency by 7.53% and minimizing hop communication overhead by 65.1% in comparison with existing multimedia content transmission model. Experiment outcome shows the HDELL-MCT model improves delivery ratio, uses less number of intermediate hop MANET devices, and reduces latency in transmitting multimedia data in comparison with the existing data transmission scheme for MANETs.

Future work would consider designing an adaptive propagation model for MCT considering diverse mobility patterns and the presence of obstacles in the line of sight along

with, constructing an effective video encoding technique for improving storage and bandwidth efficiency of delay-tolerant MANETs.

#### ACKNOWLEDGMENT

The authors declare that no funds, grants, or other support were received during the preparation of this manuscript. On behalf of all authors, the corresponding author states that there is no conflict of interest. I would like to thank Dr. Mahesh Kaluti for his valuable and constructive suggestions during all the aspects of our study and for their help in writing the manuscript.

**Abstract**—Radiofrequency ablation (RFA) is the treatment of choice for certain types of cancers, especially liver cancer. However, the main issue with RFA is that the larger the tumor volume, the longer the ablation period. That causes more pain for the patient, so the surgeons perform a larger number of ablation sessions or surgeries. The current commonly used electrode material, nickel-titanium alloy, used in RFA is characterized by low thermal and electrical conductivities. Using an electrode material with higher electrical conductivity and thermal conductivity provides more thermal energy to tumors. In this paper, we design two models: a cool-tip RF electrode and a multi-hook RF electrode, which aim to study the effect of the thermal and electrical conductivities of the electrode material on ablation volume. Gold, silver, and platinum have higher thermal and electrical conductivity than nickel and titanium alloy, and therefore we studied the effect of these materials on the ablation volume using two different designs, which are the RF cooling tip electrode and the multi-hook electrode. The proposed model reduces the ablation time and damages healthy tissue while increasing the ablation volume with values ranging from 2.6 cm<sup>3</sup> to 15.4 cm<sup>3</sup>. The results show ablation volume increasing with materials characterized by higher thermal and electrical conductivities and thus reducing patient pain.

## I. INTRODUCTION

Cancer is one of the leading causes of death in both men and women, with 11.3 million deaths in 2020 [1]. The second most common cause of death in Egypt [2]. Liver cancer is the fourth most common type of cancer worldwide [3] and the second most common cancer in Egypt [2]. The most common way to treat liver tumors is resection (RES), microwave ablation (MWA), and radiofrequency ablation (RFA) [4]. RFA is based on passing high-frequency (400-500 kHz) electric currents through the tissue between two excitation electrodes, causing the tissues to heat up, which results in tissue ablation [5, 6]. The main limitation with RFA is that as tumor volume increases the whole-tumor ablation duration increases, which the patient's pain. Therefore, RFA is effective for small tumors (i.e., tumors with a diameter of 3 cm), but still not very effective for large tumors [7, 8]. Radiofrequency (RF) electrode materials should be biocompatible with the human body and have low relative permittivity to be compatible with

any device [9, 10]. Fang et al., suggested several factors contribute to increased ablation volume with reduced ablation time, such as electrode design and the material of the electrode [11]. Electrodes made of materials with high thermal conductivity and high electrical conductivity can contribute to increased ablation volume and reduced time of ablation [12, 13]. Current electrode materials used in RFA are characterized by low thermal and electrical conductivity, such as nickel-titanium alloy [14].

The finite element model (FEM) is a numerical technique used to perform finite element analysis (FEA) of any given physical phenomenon [15]. Alemayehu, et al., have simulated a medical problem about bones and joints using FEM to solve the problems of cartilage erosion [16]. In [17], the authors have used FEM in various fields of dentistry for calculating the strength and behavior of structures and have succeeded in calculating deflection, stress, vibration, and buckling behavior. While on the other side, the authors simulated FEM to ablate breast cancer by using RFA and succeeded in abating 80% of the tumor [18]. In [19], the authors designed FEM to ablate liver tumors by using cool-tip RF electrodes.

Many studies are conducted in ex-vivo studies [20, 21] and clinical studies [22, 23] on the effect of electrode materials on volume ablation due to their electrical and thermal properties. Thermal conductivity gets high attention for researchers in theory because, as the thermal conductivity of the material increases, so the thermal emission capacity of the material does [24, 25]. Several theoretical studies compared materials that have high thermal conductivity with those of low thermal conductivity [26, 27], while other several studies compared materials that have high electrical conductivity with those that have low electrical conductivity [28-30]. These studies found that the use of materials of high thermal and electrical conductivities helps to increase the ablation volume while reducing the ablation time.

The aim of this paper is to study the effect of different materials having high thermal conductivity and high electrical conductivity for RF electrodes on the ablation volume using a FEM. Although our results are specific to the case of RFA of the liver, they may also be important for other ablation applications, such as kidney cancer. In this paper, we design two models based on the cool tip RF electrode and the multi-hook RF electrode.

The two models are based on a numerical finite element analysis to compute the distribution of heat and electric potential inside the damaged and surrounding tissue during an RF ablation. These two models simulate the ablation of large tumors while trying to reduce the damage to healthy cells in less time. This paper is organized as follows: First, an explanation of the methodology of the proposed model, including its equations. Second, the results and discussions of the proposed model show the differences in results between our model and others, and finally, the conclusions.

## II. METHODS

We used COMSOL 5.4 software [31] to implement FEM to develop two models (cool-tip and multi-hook RF electrode models). Each model is included within a cylindrical domain that contains both the liver domain and an electrode domain. The radius of the base of the cylinder is 5 cm, and the height is 12 cm.

### A. FEM Modeling

1) *Liver domain*: The liver tissue is the main tissue capable of generating glucose from lactate, glycerol, and amino acids (mainly alanine from muscle). It is located in the right upper quadrant of the abdominal cavity, rests just below the diaphragm, to the right of the stomach, and overlies the gallbladder. The liver domain includes everything surrounding the electrode: blood, blood vessels, and liver tissues.

#### 2) Electrode domains

a) *A cool-tip RF electrode domain*: It is distinguished by its excellent resistance to rust and corrosion as well as by its high flexibility, which avoids breakage or distortion, both of which pose risks to the patient's safety. The proposed model disregards the inner tube for brine injection responsible for cooling.

The cool tip RF electrode domain, consists of an electrode domain and a trocar domain as shown in Fig. 1 [32].

The RF electrode consists of:

- An insulated stainless-steel trocar with a diameter of 0.73 mm and a height of 12 cm.
- A nickel-titanium alloy (nitinol) electrode with a height of 3 cm and a diameter of 0.73 mm with a tip in a cone.

Fig. 1. A simplified model shows the design of the electrode [32].

Fig. 2. A simple model that shows how a RF electrode works to ablate the tumor.

Fig. 2 explains the issue, where the tissue area is modelled as a cylindrical volume with the active electrode inserted into the tissue. The tissue area consists of the tumor in a spherical shape surrounded by healthy tissue inside the cylinder.

In our study, we set the power equal to 15 watts and assumed that the tumor was spherical, as 56% of liver cancer patients had spherical tumors [33]. We also assumed that the tumor size was 16 cm<sup>3</sup>, which is the largest volume that has been recorded for a liver tumor in Egypt in the last ten years [34].

#### a) A multi-hook RF electrode domain

Fig. 3 shows the design of multi-hook electrodes.

Fig. 3. Simplified model shows design of the electrode.

The multi-hook RF electrode consists of:

- Insulated stainless steel trocar with a height of 10 cm and a diameter of 2 mm.
- A stainless-steel electrode measures 1 cm in height and 2 mm in diameter, with a nickel-titanium alloy with a 1.5 cm major diameter and 0.5 mm minor diameter tip in a hook.

In our model, the initial conditions and boundary conditions of the simulation model are defined. We set the multi-hook RF electrode as the voltage source and set power equal to 15 watts, while we defined the liver boundary as the ground.

3) *Thermal and electrical properties:* Table I lists the different properties at 500 kHz used in our model to describe the gold (Au), the silver (Ag), the platinum (Pt), the nickel-titanium alloy (Nitinol), artery wall, and blood. The table shows the relative permittivity, density, and melting point values of the materials in the table are close. On the other hand, the table shows a clear variance in thermal and electrical conductivity values. So, we chose these two characteristics to study their effect on the ablation volume. During the ablation process, the tissue temperature increases. Changes in temperature lead to changes in the electrical conductivity of biological tissues [35]. The changes that occurred in the electrical conductivity of the tissues within the model are described as follows:

$$\delta(T) = \delta_0[1 + k_1\Delta T] \quad (1)$$

where:

$\delta_0$  is the initial electrical conductivity at the reference temperature (30°C),  $k_1$  is the temperature coefficient,  $\Delta T$  [°C] is the temperature difference from the initial reference temperature.

The linear electrical conductivity of the model is determined by.

$$\delta(T) = 0.155[1 + 0.0265\Delta T] \quad (2)$$

Expect the artery wall, and the equation is.

$$\delta(T) = 0.221[1 + 0.0265\Delta T] \quad (3)$$

Both equations are bounded at 30–80°C.

#### 4) Mathematical equations

a) *Electric field:* The electro-magnetic problem has been solved using a simplified version of Maxwell's equation that uses the quasistatic approximation because the displacement current is so minimal relative to the resistive current at the frequency range employed in the RFA technique (450–550 kHz). As a result, the generalized Laplace equation has been used to calculate the electric field.

$$\nabla \cdot (\sigma \Delta V) = 0 \quad (4)$$

Where:

$\sigma$  is (S/m) the electrical conductivity and V is the electric potential (V). The current study takes into account the tissue's electrical conductivity, which is temperature-dependent and increases linearly (10% per °C).

In the model tissues, the losses due to heat contact with the tissues are not significant, so we neglected the losses in our model [39]. The electric field E (V/m) is calculated from the equation.

$$E = -\nabla V \quad (5)$$

where  $\nabla$  is the operating factor. Then, current density J (A/m<sup>2</sup>) is calculated from

$$J = E/\rho e \quad (6)$$

where  $\rho e$  is the electrical resistivity of the material ( $\Omega$  m)

b) *Bioheat equation:* Calculations of the temperature distributions were made using FEM. By resolving the heat transfer equation (Equation 7), where we ignored the metabolic heat production  $Q_m$  and blood perfusion heat loss  $Q_b$  due to their comparatively small magnitudes, we were able to determine the temperature distribution throughout the tissue:

Bioheat transfer due to RF current can be mathematically explained by the following Pennes equation [40].

$$\rho c \partial T / \partial t = \nabla \cdot (k \nabla T) - \rho_b c_b \omega_b (T - T_b) + Q_m + JE + Q_b \quad (7)$$

$$JE = \sigma |\nabla V|^2 \quad (8)$$

$$Q_b = \omega_b c_b (T_b - T) \quad (9)$$

where  $\rho$  is the density of tissue (kg/m<sup>3</sup>),  $c$  is the specific heat capacity of the tissue (J/kg/K),  $k$  is the tissue thermal conductivity (W/m/K),  $\omega_b$  is the blood perfusion rate (1/s),  $Q_m$  is the volumetric heat produced by the metabolism (W/m<sup>3</sup>),  $JE$  is joule heating that represents heat generated from RF, where  $\sigma$  is the conductivity with a unit of  $S m^{-1}$ ,  $V$  is the voltage impressed on the electrode,  $Q_b$  is the volumetric heat produced by radiofrequency heating (Wm<sup>-3</sup>) calculated using Equation (2),  $T_b$  is the core blood temperature (supposed to be 37°C), because the blood vessels effect was discarded in this study then we can assume  $T_b$  and T are equal then  $Q_b$  was set to zero Wm<sup>-3</sup>

#### c) Boundary conditions

The boundary conditions are:

temp = normal body temperature (37 °C)

voltage = 0 V.

TABLE I. DIFFERENT PROPERTIES OF THE MODEL [36-38]

Material	Electrical conductivity $\sigma$ (S/m)	Thermal conductivity (W/ m. K)	Relative permittivity ( $\epsilon_r$ )	Density (kg/m3)	Melting point (°C)
Gold (Au)	44.2×10 <sup>6</sup>	315	1.143	1060	1064
Silver (Ag)	62.1×10 <sup>6</sup>	429	1.2	999	961.8
Platinum (Pt)	9.3×10 <sup>6</sup>	69.1	2.7	2190	1768
Nickel-titanium alloy (Nitinol)	2.4×10 <sup>6</sup>	18	86	6450	1650
Normal liver tissues	0.333	0.512	44.9	1060	-
Normal tumor tissues	0.1168	0.552	60.2	999	-

The complete FEM model's initial voltage and temperature have been taken into account to be 0 V and 37°C, respectively. The cylinder domain's bottom surface has been adjusted to 0 V to mimic a dispersive ground pad.

In the FEM model, an RF generator-controlled variable voltage source has been added to the electrode borders. All of the FEM model's remaining outside boundaries has been subjected to an electrical insulation boundary condition. For ten minutes, all of the numerical simulations of temperature-controlled RFA in various tissues were run. Furthermore, multiple temperature values were ranging from 50°C to 60°C.

d) *Ablated tissue*: The ablation area (i.e., where cell death occurs), it depends on the following factors:

- Damage time is the amount of time required to destroy the tumor-infected, damaged cell, equaling 10 minutes.
- The ablated temperature, equal to 50 °C, is the temperature required to destroy tumor-infected, damaged cells.
- Enthalpy change is the amount of heat evolved or absorbed in liver tissues (0 J/kg).

### III. RESULTS AND DISCUSSION

Cool-tip RF electrodes and multi-hook electrode ablation in our study depended on three materials: gold, silver, and platinum. This study analyzed these materials to provide guidance in clinical practice.

#### A. Cool-tip RF Electrode

Table II shows the ablation volumes due to the used electrode materials at different ablation durations.

TABLE II. RESULTS FROM SIMULATION WITH A COOL-TIP RF ELECTRODE

Time (min)	Electrode material	Ablation volume(cm <sup>3</sup> )
1	Nitinol	2.5
	Pt	4.7
	Ag	6.4
	Au	7.6
2.5	Nitinol	3.7
	Pt	6.8
	Ag	8.4
	Au	9.5
5	Nitinol	5.1
	Pt	8.4
	Ag	10.1
	Au	11.3
7.5	Nitinol	6.2
	Pt	10.3
	Ag	12
	Au	13.3
10	Nitinol	7.4
	Pt	12.2
	Ag	13.9
	Au	15.2

The ablation volume of tumor results output from gold, silver, platinum, nickel-titanium alloys, and electrodes respectively is shown in Fig. 4, 5, 6, and 7, respectively.

Fig. 4. View of the fraction of damage and the ablation volume resulting from using a cool-tip RF electrode made of Gold after ten minutes.

Fig. 5. View of the fraction of damage and the ablation volume resulting from using a cool-tip RF electrode made of Silver after ten minutes.

Fig. 6. View of the fraction of damage and the ablation volume resulting from using a cool-tip RF electrode made of Platinum after ten minutes.

Fig. 7. View of the fraction of damage and the ablation volume resulting from using a cool-tip RF electrode made of Nickel-Titanium alloy after ten minutes.

Fig. 8. Comparison of percentage of ablation volume for cool-tip RF electrodes made of Gold, Silver, Platinum, and Nickel-Titanium alloy.

The simulation results and the percentage of ablation achieved from gold, silver, platinum, and nickel-titanium alloy are shown graphically in Fig. 8.

### B. Multi-hook RF Electrode

Table III shows the results for the simulations with the new design of multi-hook RF electrode shown in Table III. At the same time and with the same power, there was an appreciable difference in the ablation volume between the different electrode materials.

TABLE III. SIMULATION RESULTS WITH A MULTI-HOOK RF ELECTRODE

Time (min)	Electrode material	Ablation volume(cm <sup>3</sup> )
1	Nitinol	2.6
	Pt	4.8
	Ag	6.5
	Au	7.8
2.5	Nitinol	4
	Pt	6.9
	Ag	8.5
	Au	9.8
5	Nitinol	5.3
	Pt	8.5
	Ag	10.2
	Au	11.7
7.5	Nitinol	6.5
	Pt	10.6
	Ag	12.4
	Au	13.5
10	Nitinol	7.9
	Pt	12.3

	Au	15.4

The ablation volume of tumor results output from gold, silver, platinum, and nickel-titanium alloy RF electrodes, respectively, is shown in Fig. 9, 10, 11, and 12, respectively.

Fig. 9. View of temperature distribution and the ablation volume resulting from using a multi-hook RF electrode made of Gold after ten minutes.

Fig. 11. View of temperature distribution and the ablation volume resulting from using a multi-hook RF electrode made of Platinum after ten minutes.

Fig. 10. View of temperature distribution and the ablation volume resulting from using a multi-hook RF electrode made of Silver after ten minutes.

Fig. 12. View of temperature distribution and the ablation volume resulting from using a multi-hook electrode made of Nickel-Titanium alloy after ten minutes.

The simulation results and the percentage of ablation achieved from gold, silver, platinum, and nickel-titanium alloy are shown graphically in Fig. 13.

Fig. 13. Comparison of percentage of ablation volume for multi-hook RF electrodes made of Gold, Silver, Platinum, and Nickel-Titanium alloy.

In this paper, we designed a computer model to investigate whether gold, silver, and platinum RF electrodes create larger volume ablation than nickel-titanium alloy electrodes using the same conditions. As shown from the results, for RF and multi-hook electrodes, there is a difference in the percentage of ablation using RF electrodes made of gold, silver, and platinum materials compared to using an electrode made of a nickel-titanium alloy by an amount ranging from five percent to ten percent after a minute, while the difference in the percentage of ablation ranged from 14% to 30%. On the other hand, the ablation rate with the multi-hook electrode is 2% greater than the ablation rate with the cool-tip RF electrode in all kinds of materials used as the multi-hook electrode covers a larger area due to the design difference between the two electrodes.

Previous theoretical research looked into the impacts of using Pt, Ag, and Au as the electrode material for RF ablation rather than nitinol since these metals have higher thermal and electrical conductivities. According to the results, a different amount of ablation was produced, with each of the four electrode materials. Using varied powers at various intervals, we investigated in this study whether Pt, Ag, and Au electrodes produced thermal ablation more successfully than nitinol electrodes. In all simulations, we proved that as the temperature rose, more power was given via the Pt, Ag, and Au electrodes, leading to greater maximum tissue temperatures and a larger ablation volume, as depicted in Fig. 14, 15, and 16. We discovered that the four electrodes' ablation volumes varied.

Therefore, differences in the thermal and electrical conductivities of RF electrode material offer solutions in certain clinical situations. Our modelling succeeded in reducing time and reducing patient pain.

#### IV. CONCLUSION

The results show that using gamma titanium instead of nickel-titanium achieved an increase in the ablation volume because it has higher electrical and thermal conductivity than nickel-titanium alloy. Also, the results show the effect of tuning parameters (ablation power, ablation time and design of the electrode) on increasing the ablation volume and decreasing the ablation time. The results show that the electrode design is the most important tuning parameter because with the change of design from the reference model to our developed model, the effect and success of the rest of the tuning parameters appeared. That helps to reduce the patient's pain and increase the accuracy. Future work can study the effect of the RF multi-hooks electrodes on large tumors by using the same tuning parameters and compare it with a RF cool-tip electrode.

# A Light-weight Authentication Scheme in the Internet of Things using the Enhanced Bloom Filter

Xiaoyan Huo

Information Construction and Management Center, Jiaozuo University, Jiaozuo, Henan, 454003, China

**Abstract**—Authenticated key exchange mechanisms are critical for security-sensitive Internet of Things (IoT) and Wireless Sensor Networks (WSNs). In this area, the Bloom Filter (BF) plays a crucial role directly and indirectly, which has a significant advantage in space and time. Light-weight input authentication is one of the most challenging tasks in IoT. Weak or inefficient defense algorithms can allow fake information to enter the system, share information, send unnecessary messages, and reduce network efficiency. The utilization of an augmented Bloom filter for creating an authentication prominent called En-route Authentication Bitmap (EAB) has a substantial advantage over traditional methods that involve direct usage of Message Authentication Codes (MAC). This effective method of EAB picks the fake information almost accurately, thereby reducing the feeding attacks within not more than two steps taken by the attacker. EAB necessarily needs only a few bytes of bandwidth for efficient defense against at least ten forward steps of the adversary. Without hesitation, the Augmented Bloom filter and its components are becoming more common in network defense mechanisms.

**Keywords**—En-route authentication bitmap; message authentication codes; internet of things; bloom filter

## I. INTRODUCTION

As the Internet of Things (IoT) expands, it is poised to transform human lifestyles and release several monetary benefits [1, 2]. Security and trust issues present significant adoption limitations for the IoT [3]. Blockchain, a distributed and tamper-resistant ledger, maintains regular statistics data at only places and can deal with the information protection situation in IoT networks [4]. The IoT is an entirely novel paradigm combining technologies and elements that come from different strategies [5]. The real and virtual worlds constantly interact through embedded devices, communication technology, sensing technology, Internet protocol, pervasive computing, and ubiquitous computing [6]. The IoT vision relies on smart objects. Putting intelligence into everyday objects enables them to collect environmental data, interact with the physical world, and interconnect via the Internet with alternate facts and records [7]. New business opportunities will arise as devices become increasingly connected and records become increasingly plentiful. This enables delivering tangible advantages to individual residents, the economy, the environment, and society [8].

Designers are primarily concerned with the trade-off between cost, computation, and security [9]. Although end-to-end authentication can be validated by sharing keys between the source and target, accuracy is complicated halfway, where intermediate nodes cannot determine authenticity without

additional information [10]. In wireless broadcasting, promotional messages should be eliminated as much as possible [11]. Data passes through a node route every time. The relative nodes are instructed to remain still and observe the information even though those nodes are neither the target nor the transporters. Making things worse, the transfer packet data does not make use only the way where the neighbor nodes are present but also the neighbor region [12].

There is competition between the two-hop nodes for communication channels, similar to the hidden ones problem [13]. Hop-by-hop routing easily identifies entryways for the attackers to feed and take the system information [14]. The endpoint cannot be made to believe the take information by the adversary unless the two-end key is weak or unsafe [15]. Providing false messages in the pathway, redundant traffic creation, waste usage of computation power of the route, and retarding the efficiency of the network can usually be made simple by the attacker [16]. Using a network-wide authentication key is a natural way to solve this problem. However, the adjustment of one node can lead to the adjustment of the whole arrangement. It can be seen as the most effective way to follow  $\mu$ Tesla, in which the authentication key is updated frequently. Nevertheless, this method has its advantage in that network synchronization with standard timing error should be present. Synchronizing the timing is complicated if the route is extensive. Moreover, these approaches are suitable for central nodes, like base stations [17].

Attaching all Message Authentication Codes (MACs) with the source node to the payload for every router is another effective solution [18]. As the number of route nodes increases, the volume of the message gradually increases. These problems necessitate the need for lightweight en-route authentication schemes in multi-hop networks. This paper discusses a statistical way to solve the hop-by-hop message authentication problem between two ends. We efficiently examine data filtration in a routing way for bandwidth mitigation. En-route Authentication Route Bitmap (EAB) is a structure of the bloom filter method that is appended to appropriate messages as extra data. We propose a method for protecting the system from attack by injecting bogus data since the damage is contained in its immediate area. Slight numerical adjustments can improve efficiency and protection.

The challenges of IoT security are securing restrained devices, empowering devices, validating devices, updating devices, ensuring the confidentiality and reliability of data, managing web, mobile, and cloud functions, guaranteeing high availability, detecting vulnerabilities and incidents, handling

vulnerabilities, and forecasting security issues. To overcome the constraints in the IoT, we propose a system that can defend the Internet of Things from attack and implement a lightweight authentication. Bloom filters are primarily responsible for authentication. This paper implements an Augmented Bloom Filter. The EAB is inaccurate for mapping multiple MACs. EAB classifies false data during the first constrained hop instead of being dropped at the first sign. Therefore, the false negative rate adjacent to the adversary is satisfactory, but it quickly rises with increasing bound counts. This swapping drastically reduces authentication communication overhead.

Multihop wireless networks face challenges with lightweight en-route authentication. False data can be injected into a system in the absence of an efficient defense mechanism, causing redundant message forwarding and consuming node power. We create an authentication manifest using EAB, which differs from conventional approaches that directly use MACs. By filtering out false data with a high success rate, EAB makes injection attacks less likely to spread beyond one or two hops. While EAB spends a few bytes of bandwidth, it can effectively protect tens of hops along the forwarding path.

The rest of the paper is organized in the following manner. Preliminaries are presented in Section II. Basis design of the mechanism is discussed in Section III. A discussion of random padding improvements is presented in Section IV. Section V concludes the paper.

## II. RELATED WORK

Nianmin, Haifeng [19] proposed a method for ensuring data integrity. This one-level hash structure has three advantages over traditional hash trees: a lower computation overhead, a lower space overhead, and the ability to adjust the security level. The proposed method was compared with an efficient integrity checking scheme for its overhead and security. According to the evaluation results, the method has a lower overhead for most benchmarks.

Saravanan and Senthilkumar [20] present an enhanced bloom filter technique to represent large sets of data in a secure manner and apply it to distributed applications such as web caching and peer networks. Also, to limit the possibility of unauthorized access to the dataset by unauthorized intruders, the enhanced bloom filter is applied with an upper bound on the false-positive probability by increasing its capacity as the packet data size increases. As compared to the existing dynamic bloom filter approach, the experimental results show a 42.5% improvement in packet data security.

A scheme based on an improved counting bloom filter was developed by Wang, Wang [21] for securing authentication keys in heterogeneous sensor networks. By applying the Set theory to heterogeneous sensor networks, the counting bloom filter algorithm is improved to address the authentication key agreement problem. As demonstrated by experimental results, the proposed scheme has greater network scalability, lower communication costs, and can resist brute force attacks during a node capture.

Malhi and Batra [22] proposed an authentication framework based on pseudonyms that preserves privacy. An ID-based signature scheme is used for vehicle-to-RSU

communication, and a new digital signature scheme is designed for vehicular communications. The identity of the vehicle is revealed by multiple authorities in the event of revocation. Bloom filters are used to improve the signature verification scheme, which was implemented on a simulated environment to evaluate the results.

Mbarek, Sahli [23] developed an efficient authentication method to authenticate sensors utilizing the Bloom Filter. DoS attacks can be mitigated by using multiple MACs along with a Bloom filter in delayed key disclosure schemes. A set of scenarios was used to assess the feasibility of the protocol. Authentication protocol reduces false positives in Bloom Filters, according to the results.

By derived from the cryptographic permutation Xoodoo, Sateesan, Vliegen [24] proposed a new noncryptographic hash function, called Xoodoo-NC, for developing ultra-high-speed Bloom filters on FPGAs. The Xoodoo-NC hash function inherits the desired avalanche properties of Xoodoo and the low logical depth, resulting in an ultra-low-latency non-cryptographic hash function.

## III. PRELIMINARIES

### A. System Model

There are several computing nodes in IoT. These nodes can pick the links between themselves and their adjacent nodes and set up a connection with nodes that are far away by implementing a path through the nodes in the way. There may be several server nodes in existence containing effective resources that may include cloud computing and fog computing. Node A and Node B can be considered fellow nodes if the authentication key is shared. These authentications between fellow nodes that are end-to-end are certified with contributed keys through some systems. To share information between two end nodes, both nodes should possess a common key, or the sender should appoint the information to be delivered to both end nodes. The division of the path is considered a series of transmission systems. Using step-by-step verification as a benefit of end-to-end information sharing is mainly discussed here. Considering the routing paths to be constant, we assume it to be sensed by the node from the origin.

### B. Threat Model

End-to-end authentication usually assures the security and purity of the information. This security can be breached by exposing the pairwise key among the source and target nodes. Imposing false traffic and message authentication on the nodes' path and diminishing the network's efficiency is the attacker's main aim in this case. Here the adversary creates upstream packets or forge packets and spreads them in the route path. These can falsely act as the origin or pathway of some other fake data. Rejection of messages that come across the path is an alternative attack technique of the adversary. This type of attack naturally does not have the right solution until there is an effective connection between the relative nodes.

### C. Bloom Filters

Bloom Filters are probabilistic data structures with some errors. It is a simple hashing algorithm that requires very little

memory. Various research areas have been applied by Bloom Filter to boost performance. As a membership filter, it returns either "true" or "false". The term "true" can, however, refer to either a false positive or true positive. In the same way, a "false" can also be a true negative or a false negative. False positives and false negatives are errors of the Bloom Filter. However, the error is negligible and tolerable. Nevertheless, Bloom Filter is not suitable for many systems, such as real-time systems.

A very less false positive and null false negative is effectively obtained through the Bloom filter, which is greatly useful in representing a pack of inputs to fulfill the above criteria. Firstly, every bit used in the Bloom filter remains unmarked, and  $k$  is set to be stochastic hash functions.  $H = \{H^1, \dots, H^k\}$  where the range is from  $\{0, \dots, m-1\}$ . Representation of the set  $S = \{s_1, \dots, s_n\}$  of a number of inputs ( $n$ ),  $n$  and  $H_i(s_j)$  are set to 1 where  $1 \leq j \leq n$  and  $1 \leq i \leq k$ . Where every input  $s_i$  are set to 1 to the bitmap, the chances for a particular bit to be marked is  $p = 1 - (1 - 1/m)^{kn}$ . It results in nearly  $mp = (1 - (1 - 1/m)^{kn})$  bits in the map being marked averagely. The discussed method is effectively used to create a Bloom filter, where  $Bitmap^{bloom} \leftarrow H, S$ .

In order to evaluate a new input  $x$  in  $S$ , a mark for every  $hi(x)$  bit is considered. If everything is marked, then it can be definite that  $x$  is input in  $S$ . Here, the only flow along with the small false positive chance  $f = (1-p)^k$  is probable, based on the value of  $m/n$  and  $k$ . If anything is left unmarked,  $x$  is definitely not present in  $S$ .

Border and Mitzenmacher coined the Bloom filter. Using a list or sets at premium spaces, using the Bloom filter is relevant, where it is possible to lower the severity of false positives. Augmented Bloom filters are more efficient when compared to other set representation data structures such as hash tables, binary search trees, linked lists, or simple arrays. Here we use a bloom filter array for a defense mechanism. The augmented bloom filter proceeded with two main steps, insertion operation and membership testing. Firstly, the elements in the set  $S$  should be inserted into the bloom filter array of  $m$  bits. Let the elements be  $x_1, x_2, x_3, \dots, x_n$ , where  $n$  is the number of elements. This makes it easier for members to test whether the element is present in the set or not.

#### D. Insertion Operation

The elements in the set  $S$  are added to the bloom filter array after yielding corresponding hash keys of individual elements using hash functions such as MD5. Here we are using a hash function named MD5 algorithm. The usage of the hash function greatly reduces the occurrence of false positives. In contrast, using a single hash function to insert elements in the bloom filter array leads to a high possibility of false positives. There will be no false negative outputs either by multiple hash functions or by implementing the hash function differently into the bloom filter.

Usually, the bloom filter implements three hash function algorithms to obtain three different key values. Here we will utilize a single hash function, but a slightly different method is preferred. Initially, divide the input value into three parts and then hashed by using the MD5 algorithm individually, which

can be represented as  $hk_1(x_1), hk_2(x_2), hk_3(x_3)$ , where  $k_1, k_2,$  and  $k_3$  are the hash functions. In order to generate hexadecimal values using the MD5 algorithm, the following steps must be sequentially applied.

1) *Appending padding bits:* In the first step, the element  $x$ , initially a URL, is converted to bits. By adding a single '1' bit at the end of the 'b' bit message, the message becomes divisible by 448 or 512.

2) *Appending length:* By adding a 64-bit representation, an output multiple of 448 can be converted into a multiple of 512.

3) *Buffer initialization:* This step divides the b-bit result from the preceding step into four 32-bit registers (A, B, C, D). A 128-bit message digest is derived using these registers.

4) *Processing the message:* Four auxiliary functions are applied to the message, and various processing steps produce the required output. The plain text is then converted into cipher text, resulting in the message digest.

We convert the obtained hexadecimal values into binary values, which can finally be inserted into the bloom filter, where the bits are initially zero. After adding the elements in the set, those '0' bits on the corresponding positions will eventually become '1' based on the inserted element.

#### E. Membership Testing

We check their similarity, ensuring it is already present in the array. Hence the bits need not be stored in the Augmented Bloom filter array. If not, we should add those bits to the Augmented Bloom filter array after checking whether the current bit is 1. If the relevant Augmented Bloom filter array is 0, it changes to 1. Otherwise, nothing is changed in membership testing.

1) *Augmented bloom filter array:* The Bloom filter is a space-efficient probabilistic statistics structure for determining whether elements belong to sets or not. They are astonishingly honest: take an array of  $k, n, m,$  and  $p$ . Both are examined for the use of hash features. By setting all bits, the element possibly now exists via a false positive rate of  $p$ ; if the number of the bits is not specified, the element genuinely does not exist. Bloom filters locate an in-depth type of usage, counting and tracking articles that one has to examine, accelerating Bitcoin clients, detecting malicious links, and improving cache performance. This will help us select the most reliable size for our filter. Fig. 1 to 3 show graphs among  $p$  versus  $n, m,$  and  $k$ .  $n$  refers to the number of items within the filter,  $p$  stands for the probability of false positives, the fraction between zero and one or various representing 1-in- $p$ ,  $m$  signifies the number of bits in the filter out, and  $k$  shows the number of hash functions. These values are computed by Eq. 1-4.

Fig. 1. Dynamic bloom filter.

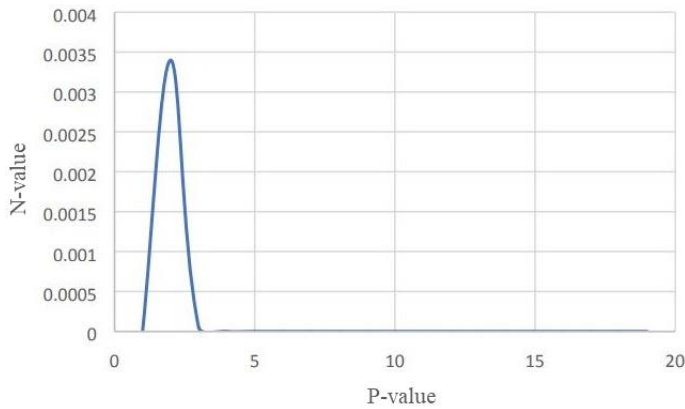

Fig. 2. Graph p vs. n.

Fig. 3. Graph p vs. m.

Consider the Bloom Filter in which P and Q are two input elements. In Bloom Filter, k represents the number of hash functions of a key or element. In Figure 2, P and Q occupy 3 cells if  $k = 3$ . P is hashed into three different places in the array. In some Bloom filters, fingerprints are stored, while in others, only '1' or '0' are stored. Also, Q is hashed three times in the array. A positive answer of the Bloom Filter requires those three positions to be set (true) when checking the membership of P or Q.

#### F. Overall Work

In situations where non-symmetrical methods such as digital signatures are barely suitable, message authentication codes are commonly implemented in end-to-end authentication. They are most commonly provided in HMAC format. This step-by-step authentication is greatly relevant to broadcast authentication as a privacy enhancer. Hence, WSNs in cellular networks are mostly supplied with this system. Here this system mainly aims to send information to a particular target. Broadcast authentication is very good for securing hop transactions, as every cellular network depends on the broadcast. Delivers a method of hop-by-hop authentication that greatly assures the detection of any imparted false messages by the sink node, where ignoring nodes never crosses the limit. The target should contact adjustment nodes to connect their message authentication codes. Borgia [25] provides a key chain method for LHAP [26], where another keychain is generated to evaluate information from adjacent nodes. Here, consistency

assurance among neighbors is essential. In the case of HEAP [27], every node gets message authentication codes connected, which would increase the band in turn. It is compulsory when ALPHA [28] is concerned with good relations between the source and the target. Even though Curtain [29] becomes the first want to use the bloom filter, authentication of broadcast from the origin is the authors' concern. We have successfully connected the message authentication codes of neighbor nodes with the help of Bloom filters, which can be as efficient as theirs.

$$k = \text{round}((m/n) * \log(2)) \quad (1)$$

$$m = \text{ceil}((n * \log(p)) / \log(1 / \text{pow}(2, \log(2)))) \quad (2)$$

$$p = \text{pow}(1 - \exp(-k / (m/n)), k) \quad (3)$$

$$n = \text{ceil}(m / \log(1 - \exp(\log(p)/k))) \quad (4)$$

#### IV. BASIC DESIGN OF THE MECHANISM

All the route nodes that lie in the band are assumed to be friends because the source has contributed its authentication key with all those nodes. The information M is shared through the routing path  $R_T = \{R_1, R_2, \dots, R_n\}$  to the target node T by the source S. Initially, a fundamental system with an issue is presented, and then we propose a further greater creation is shown inside the subsequent phase. To simplify this, we pass over by using what manner the networks come to a selection and provide routing paths.

##### A. Basic Technique

The construction of the MAC manifest using the Bloom filter is considered the entire working system for step-by-step recognition. En-route authentication with a map is the output obtained by applying the above technique. While other methods use a particular receiver to evaluate the genuineness of information en route authentication, the bitmap uses one or more receivers. En-route authentication code is much smaller than the message authentication code. Thus, EAB utilizes a lower amount of bandwidth for transmitting. Hence it becomes fitter to travel through the routing path. When an en-route authentication code is employed, every router in between is insisted to allow only false information of less liability. Hence, it becomes compulsory for the foe to breach an authorized EAB to impart a false message to a node where each router allows only less liable false messages.

##### B. Protocol Description

1) *Source node*: Firstly, the validation parameters are determined by the source node based on its privacy needs. There begins the multi-hop routing along S, R, and T. The source node initially creates a signature that is responsible for the start of end-to-end authentication. To generate the signature, either message authentication uses a public key code. Only the source node has the message authentication code key. There is no threat to the security by the adversary since M is in the encrypted state. Here the message by S is  $M' \leftarrow \{S | T | M | \text{sig}\}$ .

Every route  $H_i$  gets validated by  $S$  with the help of an en-route authentication bitmap. Using this source node pare wise key, the message authentication code is generated by Eq. 5.

$$EAB[x] = \begin{cases} 1 & \exists_i \exists_j, x = H_j(MAC(KS, R_i, M')) \\ 0 & otherwise \end{cases} \quad (5)$$

When including  $H_i$ , the message authentication code is interlinked with the  $m$ -bit filter; hence, the en-route authentication code is generated when the particular message, as well as its path, is concerned. At last, the initial root node receives the combination of information and its en-route authentication code. Algorithm 1 explains the source node procedure.

2) *Destination node*: The best authentication method for sigS or TM is to authenticate  $M$  at the destination.

3) *Route node*:  $R_i$  gets a message with the EAB BFS,  $R(M')$  for each routing node, which makes certain of the following situations. The number of marked bits in EAB falls within the variety according to Eq. 6.

$$\begin{aligned} & [[mp - \delta], [mp + \delta]] \quad (6) \\ & \delta = \sqrt{mp(1-p)} \\ & p = 1 - (1 - 1/m) k_n \end{aligned}$$

We will make clear the effect of  $\delta$  in the element deferred. If each situation is contented,  $R_i$  will course the message at the side of the filter out to the subsequent router  $R_{i+1}$ . Afterward, it separates the message and reports some false facts. Algorithm 2 describes the procedure in detail.

For instance, as shown in Fig. 4, the source node shapes an augmented Bloom filter of size  $m = 32$  for the diffusion over  $N = 8$  path nodes. Every MAC ( $KS, R_i, M'$ ) maps to  $k = 3$  marked bits in EAB. The ultimate EAB is the bit-wise AND of all plotting. On routine, the EAB will incorporate about 15 marked bits. According to Fig. 5 and 6, the mapped bits in EAB are segmented by MAC.

Fig. 4. Graph p vs. k.

### C. Accomplishment of Hash Set

Generally, it is not necessary for  $S$  to implement a new hash set  $h$  to work on every message authentication code. In case cryptographic hash functions are used in message authentication code, the marked bits are automatically defined by the output gained. When the image is fragmented to 160/5, that is 32 pieces. The initial three pieces are selected by  $S$  as a reference to the market bits in the En authentication code. It greatly adds an advantage when the cost is concerned, where the root node must implement only one hash function to validate the information.

### D. Security Analysis

As the message authentication codes are directly involved in the development of en-route authentication code, the MAC keys are confidential; the breach system mainly aims to break through en-route authentication, aiming its false messages, where breaking in maximum probable route nodes is planned. Here, en-route authentication consists of hash functions generated by the message authentication code of various route nodes, in which the attacker has individual distributions. So, ignoring any node on the way could cause the attacker's intentions to fail.

1) *Probability of bypass*: With the usage of a 32-bit en-route authentication bitmap and  $k=3$  hash by the source node, the attack of the adversary reduces up to 81 percent before the completion of two steps. Security increases as the size of the en-route authentication bit increase, but the bandwidth also increases. This attack probability further decreases when 64-bit Android authentication bitmap and  $k=6$  hash function. The adversary must inject a maximum of 1400 information to breach at least the third step node even with half chances. The probability is given by Eq. 7.

$$P_{bypass} = (1 - (\frac{1}{m})^{nk})^t \quad (7)$$

2) *The parameter k*: To calibrate the bloom filter, the amount of hash function is to be calibrated. If  $k = \ln 2m/n$ , the en-route authentication bitmap would contain the maximum false positive.

The parameter  $\delta$ : The attacker can produce fewer Mark bits by optimizing this parameter. This makes the en-route authentication bitmap to be a binomial distribution. It is not necessary e for the mark bit to be  $mp$  always. The common number of marked bits can be between  $\delta = 2\sqrt{mp(1-p)}$  whose chances is higher than 90%. It would be very easy for the attacker to break all the barriers easily without this parameter. There are some disadvantages. The attacker sets the largest possible number of Marked bits instead of the optimum amount to increase the winning chances. In some cases,  $S$  would create an en-route authentication map.

**Algorithm 1.** Source node procedure

---

```

compute M' ← {S | T | M | sigs,T(M)}
clean EAB
for i=1 to n do
    Bitmap  $\xleftarrow{\text{bloom}} H, MAC(K_{S,R_i}, M')$ 
    EAB ⊕ bitmapi
end for
Send out { M'|EAB }

```

---

**Algorithm 2.** Route node R<sub>i</sub> procedure

---

```

Receive packet { M'|EAB } from router Ri-1
If (⌊mp - δ⌋ ≤ count(EAB) ≤ ⌊mp + δ⌋) then
    for j = 1 to k do
        compute x'_j ← H_j(MACS,R_i(M'))
        if (EAB[x'_j] = 0) then
            drop the packet
        end if
    end for
    forward the packet to the next route Ri+1
else
    drop the packet
end if
return

```

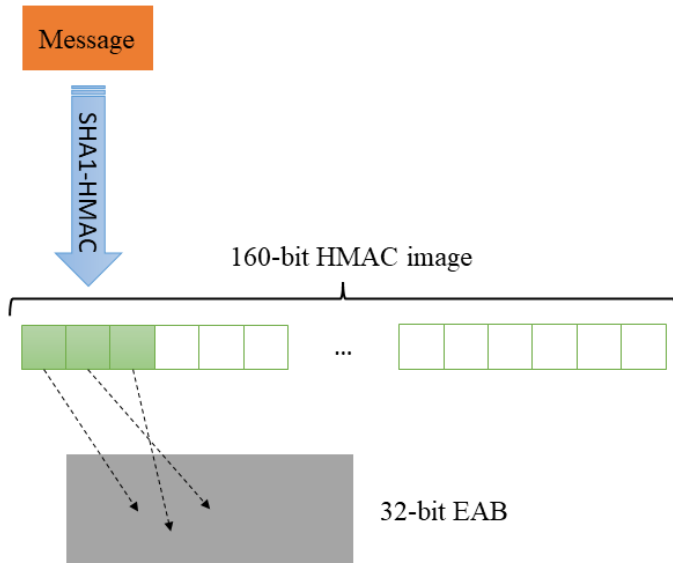

Fig. 6. The segmentation of MAC.

### V. IMPROVEMENT WITH RANDOM PADDING

We have proposed an easy remedy for this problem. This can increase privacy to the next level. The information is as follows when source node  $S$  is supposed to possess two pots.

$$M' \leftarrow \{S|T|M|padding|sig_{S,T}(M|padding)\} \quad (8)$$

Less size of stochastic string that is chosen by  $S$  is said to be a wedding. Hence, the en-route authentication bitmap depends on the number of marked bits. Till the information  $m$  gives an output en-route authentication bitmap with marked bits less than  $\beta$ , the source node sets the padding stochastically until the message is sent. The value of beta is a common and accepted value by each routing node. This helps  $S$  to check different en-route authentication bitmaps for constant information. Hence, it would be easy for the source node to discard insecure en-route authentication bitmaps. However, this checking time method should be reduced if successful results come in series. There is no need for the padding to be larger to succeed in every aspect. In line 2 of algorithm 2,  $S$  changes its characteristics as follows.

$$count(EAB) \leq \beta \quad (9)$$

The approximate number of times of testing the good en-route authentication bitmap as Eq. 8 is as follows.

$$\frac{1}{\sum_{i=1}^{\beta} \binom{m}{i} p^i (1-p)^{m-i}} \quad (9)$$

For example, according to Fig. 7, when  $M$  is 32,  $n$  is 8, and  $k$  is 2, the source node generates an en-route authentication bitmap with marked bits with bits below 13, and this can reduce the injection of false data up to 94.73% in the first and second steps it further gets reduced to 99.72%. When a 4-bit is padded, this probability goes down to  $3.8 \times 10^{21}$ .

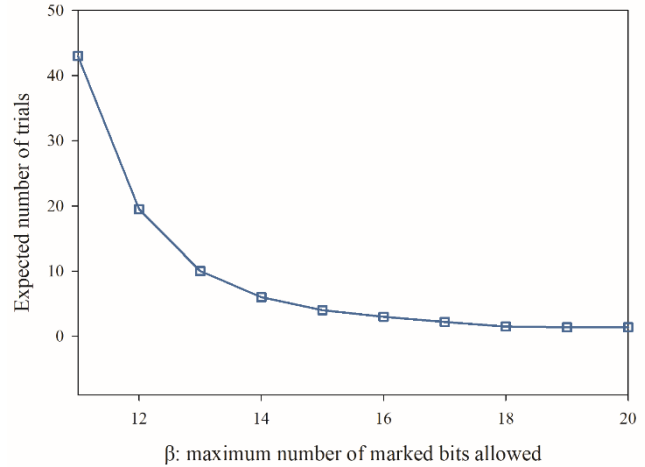

Fig. 7. The expected number of trials to find the desired EAB.

As shown in Fig. 8, for Bloom filters with  $m = 32$  and  $n = 8$ , the optimal  $k$  value should be 3, which will increase the probability of passing through route nodes. The well-selected EAB of  $\beta = 15$  under  $k = 4$  may have superior performance compared to smaller  $\beta$  under smaller  $k$ . Nevertheless, more padding tests or even greater padding will be needed if the number of hashes increases. According to Eq. 10, the parameters depend on the network requirements.

The number of route nodes through which the false injection aims to pass

Fig. 8. The probability of bypass in fine-tuned EAB.

$$\frac{1}{n^S} \leq \left(\frac{\beta}{m}\right)^k \leq P_b \quad (10)$$

### VI. CONCLUSION

This paper proposed a lightweight answer for step-by-step authentication in IoT. Low computational cost, high accuracy, and low communication overhead characterize our shape. Authentication is performed by combining Augmented Bloom filters with bitmaps from en-route authentication. The Augmented bloom filter utilizes a single hash function named Message Digest (MD5). Its main intention is to thoroughly remove the false negative rate and highly lessen the false positive rate. Single hash function usage results from more

false positive rates, but we impuse the MD5 here. We split the input into three and applied the MD5 hash function to each of them separately to collect three different key values. This idea works great on it and successfully results in a less false positive rate. The most important goal of EAB is to categorize false records inside the first limited steps as a substitute for dropping them at the beginning sign. Thus, we admit an adequate false-negative rate adjoining the adversary, but the false-negative rates quickly come together as the next count increases. This interchange significantly diminishes the communique overhead received through authentication. We declare that such remedy can be retained similarly to light-weight authentication outlines in cooperative environments.

**Abstract**—In recent years, the electroencephalography (EEG) signal identification of epileptic seizures has developed into a routine procedure to determine epilepsy. Since physically identifying epileptic seizures by expert neurologists becomes a labor-intensive, time-consuming procedure that also produces several errors. Thus, efficient, and computerized detection of epileptic seizures is required. The disordered brain function that causes epileptic seizures can have an impact on a patient's condition. Epileptic seizures can be prevented by medicine with great success if they are predicted before they start. Electroencephalogram (EEG) signals are utilized to predict epileptic seizures by using machine learning algorithms and complex computational methodologies. Furthermore, two significant challenges that affect both expectancy time and genuine positive forecast rate are feature extraction from EEG signals and noise removal from EEG signals. As a result, we suggest a model that offers trustworthy preprocessing and feature extraction techniques. To automatically identify epileptic seizures, a variety of ensemble learning-based classifiers were utilized to extract frequency-based features from the EEG signal. Our algorithm offers a higher true positive rate and diagnoses epileptic episodes with enough foresight before they begin. On the scalp EEG CHB-MIT dataset on 24 subjects, this suggested framework detects the beginning of the preictal state, the state that occurs before a few minutes of the onset of the detention, resulting in an elevated true positive rate of (91%) than conventional methods and an optimum estimation time of 33 minutes and an average time of prediction is 23 minutes and 36 seconds. Depending on the experimental findings' The maximum accuracy, sensitivity, and specificity rates in this research were 91%, 98%, and 84%.

## I. INTRODUCTION

A set of neurological illnesses known as epilepsy can afflict people of any age and are defined by a persistent propensity to cause repeated seizures. The progressive neurobiological process known as "epileptogenic" causes epilepsy [1]. The aberrant synchronized electrical activity of brain neurons is the primary cause of epilepsy, a persistent, non-communicable condition [2, 3]. The oldest and most prevalent neurological condition in the globe is epilepsy [4, 5]. Epilepsy is the third most prevalent neurological condition in the world, affecting 50 million individuals worldwide, based on a World Health Organization (WHO) study from June 2019 [6]-[10]. An abnormality of the brain characterized by recurrent seizures is called Epilepsy. Typically, a seizure is described as a sudden (abrupt) shift in behavior because of an

abnormal disturbance in the electrical activity of the human brain [11]. Some minute electrical impulses are continuously produced by the brain resulting in a consistent pattern. Neurotransmitters are the chemical signals which carry electrical signals along with neurons, and neural networks in the brain and throughout the entire body [12].

Fig. 1 illustrates how epilepsy causes the brain's electrical cycles to become unbalanced and cause recurring seizures. Individuals having seizures must face synchronized electrical energy bursts that may alter their cognition, movements, or perceptions and disturb the regular brain electrical sequence for a period. The main symptoms of epilepsy are varied and complex due to variations in the beginning location and method of propagation of aberrant electrical activity in the brain [13]. Recurrent seizures can have a long-lasting severe impact on a patient's psychological and cognitive abilities and pose a serious risk to their lives [14]. Investigation into the treatment and diagnosis of epilepsy, therefore, has huge therapeutic implications.

Epileptic seizures can be prevented by medication if they are predicted early, giving ample time before they happen. Four distinct states occur during epileptic seizures. The first state that emerges before the beginning of the seizure is the prodromal (pre-ictal) state, the second state i.e., the ictal state, starts with the exact beginning of the seizure and completes leaving a threat, after the ending of the ictal state comes the third state i.e., postictal state, and last is an interictal state, that begins after the postictal state of the first seizure and is finished before the begin of the preictal state of the subsequent seizure. The various input conditions for three distinct channels are depicted in Fig. 2. Additionally, the onset of the preictal state can be used to anticipate seizures [15].

Fig. 1. Epilepsy hotspot.

\*Corresponding Author.

Fig. 2. Different input states of epileptic seizure [15].

The remainder of the essay has been structured as follows: The complaints are covered in Section II, the background of epilepsy seizures is covered in Section III, and the proposed technique is covered in Section IV. The experimental results are reported in Section V. Section VI brings the essay to a close and discusses unfinished business.

## II. TYPES AND SYMPTOMS OF EPILEPTIC SEIZURE

Neurologically epilepsy is characterized by abnormal activity of the brain that results in seizures resulting in strange behavior, emotional sensations, and most of the time total loss of conscious [16]. When a person experiences at least 2 seizures that are not related to another established medical problem, such as opiate withdrawal or exceptionally low blood sugar, an epilepsy diagnosis is typically made [17]. That part of the brain from which the seizure frequently originates in early phases causes disturbance in functions of the affected part. The right side of the body is governed by the left half of the brain, while the left side of the body is governed by the right half of the brain. Typically, Doctors determine seizure as either generalized or focal depending on where and how the abnormal activity of the brain starts [18]. Focal seizures are caused by the aberrant activity of the brain in a specific part of the brain, while Generalized seizures appear to be involved in the entire brain [19]. Neuro-experts have divided seizures into two main groups, partial and generalized, depending on the signs, as depicted in Fig. 3 [20, 21]. The symptoms of a partial seizure, which are mostly brought on by damage to the cerebral hemisphere, can be utilized to define it. Additionally, there are two basic categories of partial seizures: simple-partial and complex-partial. In simple-partial, the person appears cognizant and can typically speak, whereas, in complex-partial, patients behave erratically, become disoriented, and frequently mumble and chew. A generalized seizure comprises two main components as well. While definitive seizures are challenging to detect because they lack motor signals, non-conclusive seizures can be identified by their clear motor symptoms. The person is unable to move or say anything other than to gaze [22, 23].

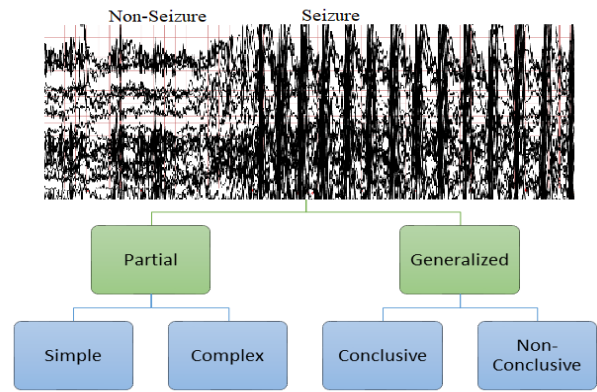

Fig. 3. Types of epileptic seizures.

Fig. 4. Symptoms of epileptic seizure [23].

Fig. 4 illustrates the wide range of seizure signs. Throughout a seizure, some patients just stare aimlessly for a specific period, while others continuously jerk their limbs or legs. One seizure may not necessarily indicate epilepsy. For an epileptic classification, at least 2 unprovoked seizures (seizures caused by unknown reasons) must be occurred within 24 hours away [24, 25]. Any brain-coordinated process can be disturbed by seizures since aberrant brain activity causes Epilepsy. Some specific symptoms determine the epilepsy type. Some of the below-mentioned sensations will be realized from time to time while others become consistent. Most of the time, an individual having epilepsy experiences the same type of seizure every other time. Symbols and Seizure indications may contain [26]:

- Brief uncertainty (confusion).
- Steady Eye spell.
- Rigid Body Movement.
- Uncontrollable spasmodic motion.
- Unawareness and incognizance.
- Spiritual indications such as fear or nervousness.

### III. RELATED WORK

Early studies on Epilepsy prediction were conducted in the 1970s utilizing feature extraction methods that were linear [27]. Because of the non-linear character of EEG signals in the 1980s, researchers were able to apply these approaches for feature extraction thanks to the advent of non-linear methods [28, 29]. The utilization of the pre-ictal phase for epilepsy identification was also implemented in this decade with the diagnosis of the EEG patterns associated with epilepsy, including preictal, ictal, and interictal patterns. Salant et al. conducted early ES prediction almost 6 seconds before the seizure began in 1998 [30], and Drogenlen et al. 2003 expanded on this work [31]. They employed a feature called Kolmogorov entropy to forecast epilepsy 2 – 40 minutes before it began. The very first worldwide session on epilepsy forecasting took place in 2002, and several epilepsy facilities contributed a database of multi-day EEG recordings. Eventually, this database was the subject of other investigations [32]. Mormann et al. discovered in 2003 that the periodic synchronization of various EEG channels diminishes before seizure onset [33] using this theory that the hyper-synchronous discharge of the brain's neurons causes ES. Research studies on substantial EEG data have cast doubt on the accuracy of metrics computed in the past century during the first 10 years of the ongoing century. Some researchers discovered that these findings belonging to past studies were based on a limited number of carefully chosen data that could not be replicated on a large amount of previously unreported data. In worldwide workshops held on the subject, it was determined to hold contests on seizure prediction. These contests were created to make it easier to compare the effectiveness of algorithms that had been trained on the same dataset [34, 35]. The International Workshop on Seizure Prediction 3 (IWSP3) and the International Workshop on Seizure Prediction 4 (IWSP4) collaborated on the inaugural seizure prediction competition, which took place in 2007. The participants in both events received continuous iEEG recordings from 3 epilepsy patients. The algorithms' results obtained, however, fell short of expectations.

The 2014 American Epilepsy Society Seizure Forecasting Trial used long-term iEEG recordings of epileptic canines as well as short-term human iEEG containing 942 seizures acquired over more than 500 days. The same training and testing data, lasting 10 minutes, was given to each contestant. An evaluation metric for effectiveness was the Area Under the Curve (AUC). Another competition by Melbourne University with a similar format comprised long-term iEEG recording with 1139 seizures [36]. Any algorithm estimating the fundamental properties of EEG signals for epilepsy predictions or machine learning algorithms based on these basic properties was eligible for the competition. In any scenario, we are still unsure of the ideal characteristics or techniques. People entered algorithms that were excessively complex in the competitions. Therefore, it is challenging to determine which attribute or ML method was better. A novel solution presented by Maturana et al. [37] may be effective for a variety of patients. They determined that the crucial slowing of neural activity served as an ES prediction indication. Fig. 5 shows a timeline for the evolution of EEG data measurements. Readers who are interested in learning more about the

background of these advances should consult [38] for additional details. Fig. 6 from Natu et al. [39] discussion on the development of technology for epileptic seizure detection.

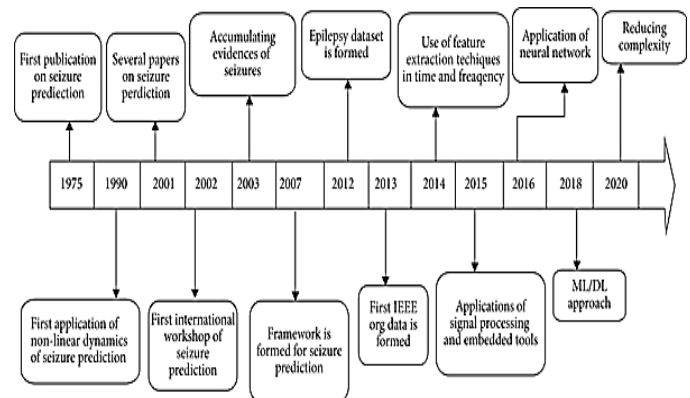

Fig. 6. Machine learning for generalized epileptic seizure prediction.

#### IV. MACHINE LEARNING FOR GENERALIZED EPILEPTIC SEIZURE PREDICTION

Since the turn of the century, scientists have been trying to get past the difficulties in diagnosing and predicting epilepsy. The initial emphasis of the ES forecast study was mainly on the evaluation of EEG recordings because EEG data are an important source to observe brain function before, throughout, and after epilepsy. Eye rotations, blinks, heart signals, and muscular noise contaminate EEG signals. To lessen the impact of these numerous sources of interference and distortions, a variety of filtration and noise reduction techniques are employed [40]. Substantial features are required for developing Machine learning models for the classification and identification of interictal and pre-ictal phases once artifacts have been removed. Fig. 7 illustrates the traditional Machine learning approach for epilepsy forecasting and emphasizes the key distinction between the application of Machine learning and Deep Learning methods.

##### A. Signal Processing

One important step in the analysis of raw biological signals is the identification of noise and artifacts. Filtering of these artifacts is required to lessen their impact on feature extraction. For filtering, a variety of methods have been used, including many filters such as Wavelet, Band-Pass, Finite Impulse response, and adaptive filters. Additionally, such processing is done to make the data standardized so that it may be compared to the records of other patients.

##### B. Feature Extraction and Collection

Reliable features are a requirement for all prediction models. These features can be divided into unilateral (steps undertaken on each EEG channel independently) and multimodal (measurements taken on two or more EEG channels) categories according to the quantity of EEG channels. Numerous techniques recommended in the literature were used to do the EEG study. As shown in Fig. 8, these methods were widely divided into 4 categories: frequency domain, time domain, nonlinear approaches, and time-frequency domain.

##### C. Classification

Artificial neural networks (ANN), fuzzy logic, k-means clustering, support vector machines (SVM), and decision trees are used to ensure the identification of epileptic seizures from provided EEG data. Most of the time, feature values with thresholds are used to draw inferences.

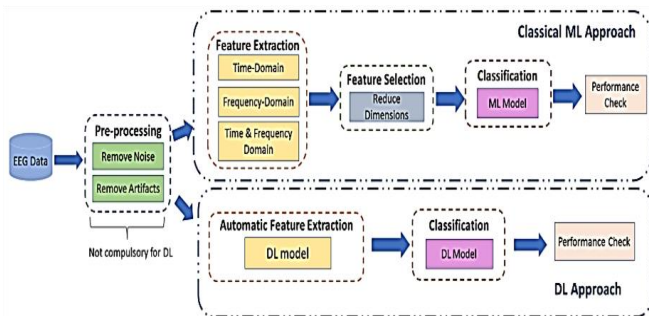

Fig. 7. Different input states of epileptic seizure [15].

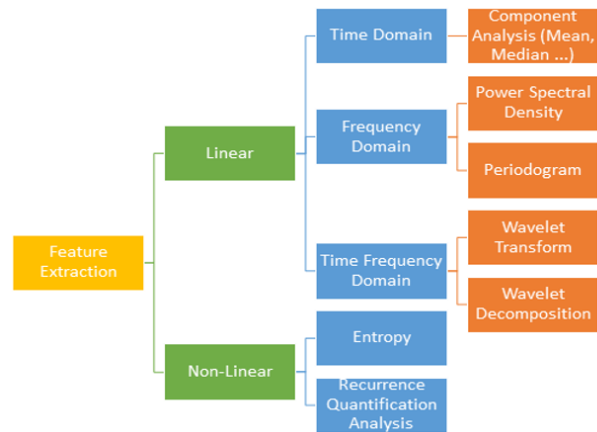

Fig. 8. Classification of feature extraction approaches [42].

#### V. GENERALIZED EPILEPSY PREDICTION USING ML METHOD EXPERIMENTAL DETAILS

The primary goal of this research is to use computer vision algorithms to classify EEG signals as epileptic signals (pre-ictal phase) or non-epileptic signals for the diagnosis of epilepsy. The signals in this are centered on ictal release for epileptic signals, whereas non-epileptic signals are consisting of both normal and pathological inter-ictal discharges for non-epileptic signals. The technique utilized to accomplish this is as follows:

- 1) EEG signal normalization and signal extraction.
- 2) To generate a feature collection, extract statistical features.
- 3) Apply wavelet decomposition to the signal to break it down.
- 4) To reduce the runtime, using k-means clustering for reducing the number of features in the feature set.
- 5) Training of the Support Vector Machine using the condensed feature set.
- 6) On a test data set, compare how well the SVM is based on the entire and modified feature set performed in separating epileptic from non-epileptic signals.

Fig. 9. Machine learning proposed model.

Fig. 9 displays the suggested method's block diagram. The gathering of EEG datasets, the pre-processing of these signals, feature extraction, and classification are the four primary stages of this approach. Below is a detailed explanation of these actions.

**D. EEG Dataset Collection**

The CHB-MIT database, which contains EEG recordings, was used in this investigation. All signals were captured and made accessible to the public by Boston Children's Hospital. Many recordings last an hour, but others go on for two or four hours. 24 portions of an EEG recording are separated and recorded in the EDF database schema. An EEG recording is represented by each EDF file. The CHB-MIT dataset signals include 686 EEG recordings from 23 people ranging in age from 1.5 to 17 years old. Each participant is represented by several EEG signals from various channels, and the dataset's sample frequency is 256 Hz. The Chb01 (1st subject) and Chb21 (second subject) in this database are the same individuals who were enrolled over 1.5 years. Information from the CHB-MIT dataset is shown in Table I.

Fig. 10 depicts a sample EEG signal from a person experiencing an epileptic seizure. In this image, the Seizure time window is indicated by red lines. Instances of (a) non-seizure records and (b) seizure records from the CHB-MIT database are shown in Fig. 11 [41]. Dataset information from EEGLAB executing in MATLAB is shown in Fig. 12.

**E. Pre-Processing of EEG Signals**

Preprocessing is the procedure of transforming raw data into a format that is more suitable for further analysis and interpretable for the user. In the case of EEG data, preprocessing usually refers to removing noise from the data to get closer to the true neural signals.

There are several reasons for preprocessing of EEG data is necessary. First, the signals that are picked up from the scalp are not necessarily an accurate representation of the signals originating from the brain, as the spatial information gets lost.

Secondly, EEG data tends to contain a lot of noise which can obscure weaker EEG signals. Artifacts such as blinking, or muscle movement can contaminate the data and distort the picture. Finally, we want to separate the relevant neural signals from random neural activity that occurs during EEG recordings. Fig. 13 represents the preprocessing pipeline that is followed in this research.

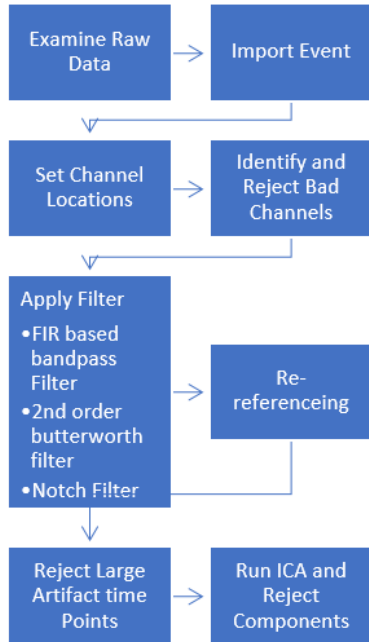

Fig. 13. Preprocessing pipeline.

After following the preprocessing pipeline, we reduce the 23 channels into 8 channels which are:

- 1) FP1-F7
- 2) P3-O1
- 3) P4-O2
- 4) FP2-F8
- 5) P8-O2
- 6) FZ-CZ
- 7) CZ-PZ
- 8) P7-T7

The results of these 8 channels are shown in Fig. 14. The dataset with the following setting is shown in Fig. 15. Save the dataset as a '.set' file extension for the next step which is feature extraction.

Fig. 14. Visualization of 8-selected channels.

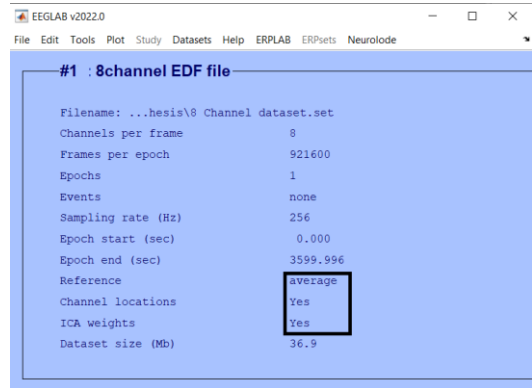

Fig. 15. Data of 8 selected channels.

### F. Feature Extraction

To collect the abstract information required for the classification procedure at this point, feature extraction was used to remove the duplicate information from the EEG signals. When analyzing signals using wavelet transform, it's crucial to choose the right wavelets and the right number of layers of decomposition. The signal's prominent frequency components are used to determine the number of decomposition levels. The amount of decay is selected so that the wavelet coefficients preserve the frequencies necessary for the identification of the signal. The MATLAB software program was used to calculate the wavelet coefficients. In this study, we extract several features including the Fast Fourier transform, wavelet transforms, Mean, and Standard Deviation for alpha, beta, theta, delta, and gamma frequencies as shown in Fig. 16. 12 Features value extracted and saved as '.mat' for normal and epilepsy as shown in Fig. 17.

Fig. 16. Alpha, beta, and gamma features.

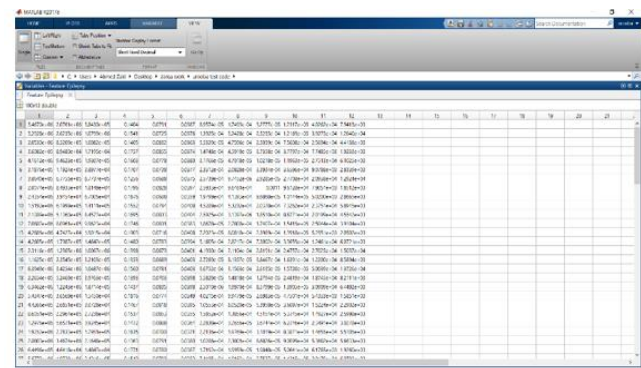

Fig. 17. Feature extraction.

### G. Classification

The goal of the model was to determine the most effective dimensionality reduction method that, when combined with SVM, would provide the maximum degree of sensitivity and validity for gathering statistics as either epileptic or not. In a high-dimensional space, the support vector machine (SVM) creates a hyperplane or series of hyperplanes that can be utilized for classification. SVM has been demonstrated to be a useful supervised model based on a statistical learning tool with high generalization. The principle underlying SVM is the separation of two data sets. This separation can be linear or non-linear. In the case of linear separation, SVM uses a discriminant hyperplane to distinguish classes. However, in the case of nonlinear separation, SVM uses the kernel function to identify decision boundaries. Compared with that of other supervised algorithms, such as ANNs [42, 43] and KNN, the computational complexity of SVM is low [44]-[46].

In this study, the model of all data of 23 people is used for training each time, and data of the remaining 1 subject is used for the test. We explore multiple training, validation, and testing divisions of the dataset to see the effect on the performance achieved on these subsets. With an increase in training data as compared to testing data, an increase in performance for accuracy and sensitivity is observed. In our experimentation, a train-validation-test ratio of (70%-20%-10%) is followed. This ratio resulted in a total of 50 epochs for training. Fig. 18 shows the Epileptic seizure detection training, validation, and testing of 24 patients.

Fig. 18. Epileptic seizure detection training, validation, and testing.

## VI. RESULTS

The clinical employment of ES prediction methods requires a sufficient performance and quality check and different evaluation metrics have been discussed in this section. Our end goal is to classify data into two classes non-seizure and seizure. To measure the performance of the proposed method, a confusion matrix, shown in Fig. 19 is obtained. In this table, (TP) represents true positive (epileptic region predicted as epileptic), TN represents true negative (non-epileptic region predicted as non-epileptic), FP represents false positive (non-epileptic region predicted as epileptic), and FN represents false negative (epileptic region predicted as non-epileptic).

One main challenge in classifying seizure data is the imbalance of the dataset. This comes from the fact that seizures (and so preictal data) do not occur frequently and the size of the interictal class is much larger than the preictal class. This may cause naive classification, which means that the classifier labels all the data as interictal and completely ignores the other class, and still reports a good precision. To avoid this, we propose a few contingency plans. First, we do not rely only on accuracy as the main factor to choose the best classifier. More informative factors can be sensitivity and specificity. Here, accuracy is the correct classification rate, sensitivity is the proportion of the epileptic regions that are correctly classified and specificity is the proportion of the non-epileptic regions that are correctly classified. Sensitivity is defined as the ratio of the total number of true positives (TP) to the sum of the total number of true positives and false negatives (FN). True positive is defined as the detection of a seizure in a segment which is also identified as a seizure segment by experts. Whereas false negatives represent a seizure segment not being classified as so by the algorithm, while the segment is identified as a seizure segment by experts. Specificity is defined as the ratio of the total number of true negatives (TN) to the sum of the total number of true negatives and false positives (FP). True negative is defined as the detection of a non-seizure segment which is also identified as a non-seizure segment by experts. Whereas false positives represent a seizure segment being classified by the algorithm, while the segment is identified to be a non-seizure segment by experts. Accuracy is defined as the ratio of the sum of TP and TN to the sum of TP, TN, FP, and FN. Hence, the higher the value, the better the performance is achieved. Classification results are shown in Table II.

TABLE II. CLASSIFICATION RESULTS

Measure	Value	Derivations
<b>Sensitivity</b>	0.980	$TPR = TP / (TP + FN)$
<b>Specificity</b>	0.840	$SPC = TN / (FP + TN)$
<b>Precision</b>	0.859	$PPV = TP / (TP + FP)$
<b>Negative Predictive Value</b>	0.976	$NPV = TN / (TN + FN)$
<b>False Positive Rate</b>	0.160	$FPR = FP / (FP + TN)$
<b>False Discovery Rate</b>	0.140	$FDR = FP / (FP + TP)$
<b>False Negative Rate</b>	0.020	$FNR = FN / (FN + TP)$
<b>Accuracy</b>	0.910	$ACC = (TP + TN) / (P + N)$
<b>F1 Score</b>	0.915	$F1 = 2TP / (2TP + FP + FN)$

In Fig. 19, the first two diagonal cells show the number and percentage of correct classifications by the trained network. For example, 98 recordings are correctly classified as benign. This corresponds to 49.0% of all 200 recordings. Similarly, 84 cases are correctly classified as malignant. This corresponds to 42.0% of all recordings. 16 of the malignant recordings are incorrectly classified as benign and this corresponds to 8.0% of all 200 recordings in the data. Similarly, 2 of the benign recordings are incorrectly classified as malignant and this corresponds to 1.0% of all data. Out of 114 benign predictions, 86.0% are correct and 14.0% are wrong. Out of 86 malignant predictions, 97.7% are correct and 2.3% are wrong. Out of 100 benign cases, 98.0% are correctly

predicted as benign and 2.0% are predicted as malignant. Out of 100 malignant cases, 84.0% are correctly classified as malignant and 16.0% are classified as benign. Overall, 91.0% of the predictions are correct and 9.0% are wrong. Considering the proposed approach system's specificity (SP), sensitivity (SN), and accuracy (AC) allows for an evaluation of its performance. The proportion of the total number of true positives (TP) to the total number of false negatives and true positives is known as the sensitivity (FN). True positive is the identification of a seizure in a part that is also recognized by professionals as a seizure section. False negatives, on the other hand, refer to a seizure segment that is recognized as a seizure segment by specialists but is not classified as such by the algorithm. Therefore, better performance is obtained as the greater the value. The classification time of SVM is shown in Table III.

Fig. 19. Confusion matrix.

TABLE III. CLASSIFICATION TIME

Classifier	Training Time (Sec)	Testing Time (Sec)
Support Vector Machine (SVM)	0.150	0.050

## VII. CONCLUSION

The automatic approaches for detecting epileptic seizures have been suggested in this paper. Data from CHB MIT were utilized to detect seizure events. An SVM classifier was used for classification, and maximum accuracy of 90.7% was attained. Training of the classification algorithm was carried out across patients to assess the effectiveness of the suggested method, and the experimental findings were as a result. The maximum accuracy, sensitivity, and specificity rates in this research were 91.0%, 98%, and 84% correspondingly as shown in Fig. 20.

# The Impact of COVID-19 on Digital Competence

## A Case Study of Preservice Teacher Education Students in the Sultanate of Oman

Syerina Syahrin<sup>1</sup>, Khalid Almashiki<sup>2</sup>, Eman Alzaanin<sup>3</sup>

College of Arts and Applied Sciences, Dhofar University, Sultanate of Oman<sup>1,2</sup>

Faculty of Languages and Translation, King Khalid University, Saudi Arabia<sup>3</sup>

**Abstract**— The study looked into how COVID-19 affected the digital competence of a group of preservice teacher education students at a higher education institution in the Sultanate of Oman. The paper examined students' digital profile in five areas namely information and data literacy, communication and collaboration, digital content creation, safety and problem solving. Data from 32 undergraduate students was collected by utilizing DigComp, a European Commission digital skills self-assessment tool and findings from a survey. The digital competence framework measures the set of skills, knowledge and attitudes that describes what it means to be digitally competent. These skills are important for students to be effective global citizens in the 21<sup>st</sup> century. The results of the study revealed that the majority of the students scored Level 3 (Intermediate) in their self-assessment competency test score. The majority of the students perceived that their digital competence improved significantly as the result of online learning which was accelerated by the COVID-19 pandemic. The rationale of this investigation is that it helps educators understand the students' level of digital competence and the students' perspectives on ICT skills. In turn, it informs us the ways to monitor the students' digital progress and the next steps in developing their digital competency.

**Keywords**—Digital competence; digital skills; digital profile; ICT skills; preservice teacher education

### I. INTRODUCTION

Oman's National Education Strategy 2040 aims to align the country's education system with the changing needs of the economy and society, with a focus on developing the skills and knowledge that student need to be successful in a rapidly changing world. This includes a focus on critical thinking, digital literacy, as well as the promotion of values such as creativity, innovation, and entrepreneurship [58]. The Education Council explained that twenty-first century skills are the "global currency" (p.17) for local and international workplaces [52]. Developing digital competencies can help students in Oman to develop skills and competencies that are in line with the needs of international labor markets. Digital competencies such as proficiency in technology, digital literacy, and digital communication are becoming increasingly important in today's global economy. By developing these skills, students in Oman can better prepare themselves for jobs in various fields, including technology, business, and communication. Additionally, digital competencies can also help students to become more adaptable and resilient in an ever-changing job market [2]. Many jobs today need digital skills [28]. To that end, the Education Council [52] described:

Oman's movement towards a knowledge-based economy requires reform of the current education system. [It] should consider improving the information technology infrastructure in educational institutions [and] supporting the use of cutting-edge technology, e-learning, capacity building and infrastructure improvement in schools and higher education (p.33).

The COVID-19 pandemic led to a rapid shift towards digital learning as universities were forced to close and shift to remote learning. This included the use of online learning platforms, video conferencing tools, and virtual classrooms. In a recent report, the Ministry of Transport, Communications, and Information Technology has set-up plans and strategies to equip 10,000 young Omanis with digital skills by 2025 [4]. The task of learning new digital skills is not new in Oman. Prior to the pandemic, students in the higher education institutions in Oman has somewhat experienced using electronic databases and e-learning platforms, as well as engaging with their peers in formal learning context online [38]. However, students often cited internet speed and internet coverage as factors that limit their online experience [50]. However, the internet speed, bandwidth and coverage in the Sultanate of Oman dramatically increased after the pandemic [41]. As a result, universities, such in the case of this study, Dhofar University, were able to adapt to the challenges posed by the pandemic and continue providing education to students through online learning [49]. As the result of that, the instructors at the university were able to utilize synchronous and asynchronous classroom instructions during online learning. Dhofar University is a private higher education institution located in the southern region of Oman. The Methodology section of a study provides a detailed explanation of the research design and methods used to conduct the study.

The COVID-19 crisis has led to the discovery of new and creative ways to utilize technology for teaching, learning, and analysis. The research aims to investigate the effect of post-pandemic online learning on the digital competence of a group of students in preservice teacher education. The study is framed by the following research questions:

1) How do the preservice teacher students evaluate their digital competencies?

2) How do the preservice teacher students perceive their competencies in Information and Communications Technology (ICT) post-pandemic?

3) What is the relationship between the number of years the preservice teacher students report to actively use ICT in their everyday lives to their digital assessment score?

The present study is significant as it documents the preservice teacher students' digital profile and sought the students' perspectives on their ICT skills. The individuals examined in the study were students preparing to become teachers. Currently, there is a lack of knowledge about the digital abilities of these student teachers within the context of Oman. The World Bank reported two important findings that set the backdrop of this study. First, the majority of Omani teachers have less than a decade of teaching experience. Second, the majority of the teachers do not know how to incorporate technology in the classroom. The lack of digital competence among the new teachers is a cause for concern. As Oman shifts its focus to hiring local talent through its Omanization policy, it is crucial to ensure that preservice teachers, like the participants in this study, are proficient in digital skills. Omanization is the national initiative to increase the employment of local citizens in the workforce [2]. Oman Vision 2040 has placed the education sector at the center of the country's development. In order to ensure that the country produces highly competent teachers, it is evident that teacher education programs need to be scrutinized.

The study aimed to gather information on the students' digital profiles and their views on their ICT skills before and after the online learning during the COVID-19 pandemic, using a survey method. The main idea behind the research was that online learning would result in an improvement in self-perceived digital proficiency.

## II. BACKGROUND OF STUDY

### A. Digital Competence in Higher Education

The widespread use of information and communication technology (ICT) has made digital competence a commonly discussed topic in academic literature and policy documents [60] [7]. The rise of digitalization has also led to new expectations in higher education [60]. The heavy influence of digitalization can be seen in the way it has impacted the knowledge development process and the performance of both teachers and students.

Digital competence is a clear priority in European policies [47], hence the common references to European Union policy documents when defining the concept in academic publications [60]. In the context of higher education, digital competence is poorly defined, and most scholars use definitions from policy papers [60]. A viable explanation is the future-oriented nature of digital competence, as it focuses on the skills required to become a professional and citizen [47]. Higher educational institutions are responsible for the development of these skills among students [47]. This view is echoed in the United Nation's 2030 Agenda for Sustainable Development [57], which endorsed that ICT skills and competencies must be harnessed by young people, and that digital technologies enable rethinking teaching and learning processes. There is a growing place for ICT and digital competence in and out of the HE classroom to support teaching and learning [44].

### B. Teachers' Digital Competencies in Higher Education

Digital competence is among the key challenges that teachers in higher education face [8]. However, there is no established definition for professional digital competence, nor is it an established practice [9]. Although digital competence is becoming essential for citizens in general, teachers in higher education specifically hold a responsibility to master it. Digital transformation and improvement of education very much depend on teachers' actions [8]. Professional digital competence in education settings is highly contextual, as teachers need to manage complexity and master decision-making for the optimal use of ICT to meet learning outcomes [9] [53]. Moreover, studies recognize that teachers are role models for students, who need to be digitally confident to inspire the class to make the best use of ICT [5] [26].

A popular conceptualization of teachers' digital competence is the layered approach levels [26]. The macro level is concerned with generic skills. At the meso level is didactic digital competence and how classrooms are affected and afforded by ICT. The micro level is connected to teachers' enactment of digital competence to design courses, communicate with audiences and stakeholders manage digitally-rich classrooms [22]. A fourth dimension, suggesting that educators should possess transformative agency [9]. The term captures the notion that teachers are not passive recipients of frameworks and tools. Instead, they take the initiative to transform practices and engage in problem-solving by implementing ICT, depending on the classroom situations they face [9] [1].

### C. Impact of the COVID-19 Pandemic on Preservice Teachers' Digital Competence

It was against this backdrop when the COVID-19 pandemic abruptly replaced most face-to-face teacher education courses with online lectures [42] [45]. The pandemic pushed the importance of digital competence in higher education to a new height [60]. Pre-service teachers had to go through their training online [25]. It is not that they were not familiar with technology like Google Classroom, Zoom or WhatsApp. However, some of them were not ready for extensively using it [6]. Moreover, student teachers also had to deliver online lectures as a part of their practicum [6] [10].

On the one hand, the coronavirus outbreak encouraged teachers in higher education to quickly change their practices to allow for learning continuity from distance [8]. On the other hand, teachers' urgent response to the crisis involved little time for preparation [25] [35]. A few studies posed the question of whether the digital competence of pre-service teachers increased during the pandemic or not [24] [29]. A study found that during the first year of the pandemic prospective teachers at a German university made enormous changes towards digital technology adoption [24]. Despite this, the researchers did not report a significant impact on their digital competencies, probably because they were seeing the pandemic as a temporary event and were planning to go back to their pre-pandemic behaviour. Another study surveyed 147 pre-service teachers to reveal their self-reported digital literacy pre-university, or before the pandemic, and during

distance education after the COVID-19 outbreak [43]. Findings show that pre-university evaluations were more positive, while the emergency highlighted some weaknesses that resulted in lowered evaluations of digital literacy. Much of the issue stems from widespread the use of smartphones to attend online classes, which causes distractions. Nevertheless, 27% of participants reported improvement in digital communication skills [43]. Another report looked at the written reflections of 51 student teachers in Norway [25]. Their findings demonstrate an overall reluctance to integrate digital technology during teaching practicum due to some difficulties related to digital competence. The scholars highlight the need for continuous development of ICT skills, as the pandemic has demonstrated their critical significance for teachers' education.

The Background section addresses issues that support the need for a research design that allows preservice teacher education students to evaluate their digital competence and ICT skills before and after the pandemic.

### III. METHODOLOGY

#### A. Context of the Study

The Sultanate of Oman is situated in the southeast portion of the Arabian Peninsula and shares borders with Saudi Arabia, the United Arab Emirates, and the Republic of Yemen. The latest census shows that the population of Oman is slightly above 4.5 million, with Omani citizens making up 62% of the population and expatriates comprising 38% [37]. The majority of the study participants come from the Dhofar region, which is located in the southern part of the country and borders the Republic of Yemen.

The Sultanate of Oman generates most of its revenue from oil resources and it has been the source of the country's development [46]. After oil, the fisheries account for the majority of the country's trade export. The government identified other sectors as means to diversify the country's economy. The sectors are tourism, fisheries, mining, logistics and manufacturing. The Sultanate also aimed to make the ports in the country into regional maritime hubs [46]. The traditional economic activities in Oman, in particular the Dhofar region, are production of honey, frankincense, fisheries, and agriculture which includes raising animal livestock such as camels and cows [37]. While a proportion of the population still maintain the traditional economic activities, some moved and worked in the cities to take up jobs in various government and private sectors [37]. The government is also pushing the agenda for the growth of entrepreneurship and Small-Medium Enterprises (SME) for wider socio-economic goals, as part of the country's Vision 2040 [27]. The national policy also outlined digitization and technological innovation in transforming the country's economy [37].

In the education sector, the ministry is rolling-up the plans for digital transformation. This included training teachers with skills and technology [38], developing IT infrastructure [40], and equipping students with digital skills for their future careers [4]. Being digitally competent in all areas of work, in

particular, the education sector is crucial in the development of the Sultanate of Oman.

#### B. Participants of the Study

The study recruited 32 undergraduate students (28 female, 4 male) from Dhofar University in Oman, using a systematic sampling method. These participants were all enrolled in a preservice teacher course and had prior experience with online learning due to the pandemic. The participants were at the second, third, or fourth year level of their undergraduate studies and had the intention to become teachers after graduation.

#### C. Data Collection

The participants of the study are 32 undergraduate preservice teacher education students at Dhofar University. Dhofar University students who participated in the research experienced remote learning during the restricted movement as part of the country's initiatives to minimize the spread of COVID-19 pandemic from March 2020 to July 2021. Although some of the students had experienced some aspects of technology in the classroom prior to the pandemic, the abrupt move towards online learning forced the students to acquire new skills without sufficient training and in a ramp-up time [59].

Dhofar University's learning management system is Moodle. Through Moodle, the students received synchronous and asynchronous instructions. The instructors at Dhofar University, at least some of them, used video conferencing tools to deliver their classes virtually. There were also several instructors who used game-based learning tools. The students who participated in the research returned to campus for face-to-face learning beginning September 2021. Although the majority of the courses are delivered face-to-face, some instructors continued to incorporate some aspects of technology in their classroom teaching and learning.

The data was gathered and analyzed using the following steps. First, the students were invited to evaluate their digital competence in the form of an online test. The testing tool that was used, as further explained in the Research Instruments section, is DigComp. The data gathered from the test were recorded as their digital profiles in five areas namely, information and data literacy, communication and collaboration, digital content creation, safety and problem solving. All items were averaged respectively. The data was then interpreted using Dimension 3 Proficiency Level from the European Digital Competence Framework for Citizens. Second, the students were invited to self-assess their ICT competencies pre- and post- pandemic through an online survey. The survey items were adapted from the DiCTE project [15]. The hypothesis being tested was that participating in online learning during the pandemic would result in a rise in self-reported digital proficiency. The statistical analysis was carried out using SPSS (Version 27). To evaluate the hypothesis, a Paired-Samples test was applied to the mean of responses to all items ( $p < .05$  significance level). Additionally, the open-ended responses were analyzed, coded and grouped according to themes.

#### D. Research Instruments

The investigation utilizes two research instruments. The first is the testing instrument called the DigCom. The instrument is developed from the European Digital Competence Framework for Citizens DigComp 2.1. [19]. The digital competence framework measures the set of skills, knowledge and attitudes that describes what it means to be digitally competent. These skills are important for students to be effective global citizens in the 21st century. The test covers five competence areas namely information and data literacy, communication and collaboration, digital content creation, safety and problem solving [20]. When completing the test, the participants will receive overall results per competence area and an average level for all competences (Foundation, Intermediate or Advanced). The test allows participants to evaluate their own digital competence level, from 1 to 6. Levels 7 and 8 of DigComp 2.1 are not taken into consideration as they are reserved for highly specialized careers [20]. DigCom has been used and tested in many countries in Europe as part of their Digital Education Plan, as well as countries outside of Europe and this can be traced in the report by the Council of European Professional Informatics Societies (CEPIS) [11] [51]. In this study, the DigComp test results are used as a reference to define and assess digital profiles for the preservice teacher education students.

The online survey serves as the second research tool. It enables students to assess their proficiency in ICT, from “not at all” to “very high degree”, both pre- and post-pandemic. The survey was adapted from the DiCTE project, which stands for Developing ICT in Teacher Education and is funded by the European Commission. The survey created by the DiCTE project aims to determine the digital competence of student teachers at the start of their education [15] [31].

#### IV. RESULTS

DigCom test covers five competence areas namely information and data literacy, communication and collaboration, digital content creation, safety and problem solving, as indicated in Table I below. The data are then interpreted using Dimension 3 of the European Digital Competence Framework.

TABLE I. DIGCOM MEAN SCORE

Competencies	Mean score
Information and data literacy	2.451612903
Communication and collaboration	2.709677419
Digital content creation	3.387096774
Safety	2.290323
Problem-solving	2.193548387
Overall	2.606452

The results from Table I revealed the mean score of the participants’ digital profile is as follows:

- 1) Information and data literacy at the mean score of 2.45

- 2) Communication and collaboration at the mean score of 2.7
- 3) Digital content creation at the mean score of 3.38
- 4) Safety at the mean score of 2.29
- 5) Problem-solving at the mean score of 2.19

The overall mean score of the students’ digital competence in all five areas is at 2.6. Each of the mean score is interpreted using Dimension 3 of the European Digital Competence Framework. Each of the competency is explained in turns.

##### A. Information and Data Literacy

The students’ competency in Information and Data Literacy is based on their ability in the following categories:

- 1) Browsing, searching, and filtering data
- 2) Evaluating data
- 3) Managing data, information, and digital content

The preservice teacher education students who participated in this study scored an average of 2.45 for Information and Data Literacy. According to the Dimension 3 of the European Digital Competence Framework, the students’ competence in Information and Data Literacy is in the Foundation 2 category. This means, the students are able to do a simple search on their own or with guidance. They can identify their information needs, detect the credibility and reliability of data sources, and organize information in structured environments.

##### B. Communication and Collaboration

The participants’ competence in Communication and Collaboration is at the mean score of 2.7. The students’ competency in Communication and Collaboration is based on their ability in the following categories:

- 1) Interacting through digital technologies
- 2) Sharing through digital technologies
- 3) Engaging citizenship
- 4) Collaborating through digital technologies
- 5) Netiquette
- 6) Managing digital identity

The students’ proficiency in Communication and Collaboration is categorized at the level of Intermediate 3. Dimension 3 of the DigComp 2.1 framework described the students’ competence at Intermediate 3 Communication and Collaboration as the ability to perform interactions with digital technologies, select appropriate digital communication to participate in society, to empower oneself and to collaborate with others. At this level too, students are able to explain know-how while using technologies, express communication strategies adapted to an audience, and ways to protect one’s reputation online.

##### C. Digital Content Creation

The participants’ digital competence in Digital Content Creation is at the mean score of 3.38. Out of the five digital competence areas, this area is the highest mean score. When interpreted against Dimension 3 of the European Digital Competence Framework, the score can be categorized as Intermediate 3 level.

The participants' digital competence in Digital Content Creation Literacy is based on their ability in the following categories:

- 1) Developing digital content
- 2) Integrating and re-elaborating digital content
- 3) Copyright and licenses
- 4) Programming

According to Dimension 3 of the DigComp 2.1 framework, at Intermediate 3 Digital Content Creation, the students are able to create and edit routine content, express oneself through the digital content creation, indicate rules of copyright and licenses, as well as to list instructions for a computing system to solve routine problems.

#### D. Safety

The participants' digital competence in Safety is at the mean score of 2.29. When interpreted against Dimension 3 of the European Digital Competence Framework, the score can be categorized at the Foundation 2 level. The students' digital competency in Safety is based on their ability in the following categories:

- 1) Protecting devices
- 2) Protecting personal data and privacy
- 3) Protecting health and well-being
- 4) Protecting the environment

At the Foundation 2 level, students are able to identify simple ways to protect their devices and digital content, differentiate simple risks and threats, follow simple safety and security measures, and have due regard to reliability and privacy. They can also select simple ways to protect their personal data and privacy in digital environments, use and share personally identifiable information while protecting themselves and others from damages, differentiate simple ways to avoid health risks and threats to physical and psychological well-being while using digital technologies, and select simple ways to protect themselves from possible dangers in digital environments [20].

#### E. Problem-Solving

Lastly, the participants' digital competence in Problem-Solving is at the mean score of 2.19. Out of the five digital competence areas, this is the lowest mean score. When interpreted against Dimension 3 of the European Digital Competence Framework, the score can be categorized at the Foundation 2 level. The students' digital competency in Problem-Solving is based on their ability in the following categories:

- 1) Solving technical problems
- 2) Identifying needs and technological responses
- 3) Creatively using digital technology
- 4) Identifying digital competence gaps

At the Foundation 2 level, students can recognize basic technical issues while using devices, propose basic solutions, identify needs, and understand basic digital tools and how they can be used to address those needs. They can also identify digital tools and technologies that can be used to generate new knowledge and improve processes and products. Additionally, they are able to address basic problems in digital

environments, recognize areas where their own digital skills need improvement or updating, and identify opportunities for self-development and staying current with digital advancements [20].

#### F. Overall Digital Competence Score

The overall mean score of the participants' digital competence is at 2.6. When interpreted against the Dimension 3 of the European Digital Competence Framework, we can round-up the mean score and conclude that the students' digital competence can be categorized as Intermediate 3 level.

#### G. ICT Competencies Pre- and Post- Online Learning COVID-19 Pandemic

The results for the next section are presented based on the statistical tests outlined in the Data Collection section. Significance levels are indicated by \* for  $p < .05$ , \*\* for  $p < .01$ , and \*\*\* for  $p < .001$ .

The students self-assessed their ICT competencies pre- and post- pandemic in regard to the following areas:

- 1) Competence in using word processor
- 2) Competence in using spreadsheet
- 3) Competence in using Presentation tools
- 4) Competence in using photo and video editing applications and tools
- 5) Competence in using Learning Management System
- 6) Competence in using educational games

The research utilized paired samples test to measure the differences in the way the students perceived the impact of online learning on their digital competencies, pre- and post-pandemic. The following hypotheses guided the statistical analysis of the study:

The null hypothesis ( $H_0$ ):  $\mu =$  there is no association of the students' participation in online learning to an increase in self-assessed digital competence

The alternative hypothesis: ( $H_a$ ):  $\mu =$  there is an association of the students' participation in online learning to an increase in self-assessed digital competence

The data suggests that the students perceived an increase in ICT competence post- pandemic, as they participated in online learning. Utilizing a 0.05 level of significance, the p-values are of 0.001, 0.000 and 0.002 are less than the significance level of 0.05. Thus, it rejects the null hypothesis.

The common themes emerged from the open-ended responses to, "as a preservice teacher education student, I should be digitally competent because ..." are coded and categorized as follows:

- 1) Learning approach for present and future times
- 2) Prepare students with skills for the workplace
- 3) Prepare students for the global society

Finally, the findings measured the correlation between the participants' digital competency overall score (DigCom) to the number of years they reported to actively use ICT in their everyday lives. The Pearson correlation coefficient for the number of years and score is .893, which is significant ( $p < .01$  for a two-tailed test). There is a significant relationship

between years of experience and competency score. It demonstrates that the student's experience in utilizing technology in their everyday lives has a significant impact on their competency score, as illustrated in Table II below.

TABLE II. CORRELATION BETWEEN NUMBER OF YEARS ACTIVELY USE ICT AND DIGITAL COMPETENCY SCORE

		Score	Number of years
Score	Pearson Correlation	1	.893**
	Sig. (2-tailed)		.000
	N	32	32
Number of years	Pearson Correlation	.893**	1
	Sig. (2-tailed)	.000	
	N	32	32

\*\* . Correlation is significant at the 0.01 level (2-tailed).

## V. DISCUSSION

The paper investigated the perspectives of a group of preservice teacher education students on their digital competence by assessing their digital competence before and after the online learning resulted from the pandemic. In regards to the first research question, the findings show the students' overall proficiency in digital skills is at Intermediate 3. This finding is similar with the result with undergraduate Chilean students, with a sample size of 817 participants [48]. Although the overall score is similar, the Chilean report differs when it comes to the five digital areas. The Chilean students scored highest for Safety/Network Security and lowest for Digital Content Creation. The students participated in this research on the other hand, scored highest for Digital Content Creation. In both countries, Chile and the Sultanate of Oman, the low mean score for Problem-Solving is a cause for concern. In current scholarship, particularly in the context of the Sultanate of Oman, the inability of graduates in solving problems is viewed as one of the major educational challenges [36]. The educational policy makers and curriculum developers in the country were tasked to ensure that soft skills, such as problem-solving are integrated in the curriculum. Previous investigations addressed different ways problem-solving skills may be incorporated in the classroom teaching and learning [55] [3].

An area that needs to be addressed is the participants' increased competency in Digital Content Creation, particularly when it comes to developing and integrating digital content. One possible explanation is that the participants are active and frequent users of Web 2.0. Web 2.0 refers to the current state of the internet technology that allows users to generate content for other end users [13]. The earlier version of the internet, Web 1.0 had fewer content creators and the majority of the internet users were only consumers [13]. Web 2.0 gave rise to various social media platforms. The skills associated with the active and frequent use of social media may contribute to the reported level of skills in creating digital contents. With the population of slightly above 4.5 million [39], social media applications in the country are Facebook and Instagram. Facebook has 1.6 million users while Instagram has 1.2 million users [39]. The popularity of the social media

applications depends on the active participation of the users in producing, sharing, and interacting about digital contents.

In regards to the second line of inquiry, the research measured the differences in the perceived ICT competence pre- and post- pandemic. The finding rejected the null hypothesis and unveiled that there was an association of the students' participation in online learning to an increase in self-assessed digital competence. In their self-assessment, the participants reported to have increased ICT competence in using word processor, spreadsheet, presentation tools, photo and video editing tools, Learning Management System and educational games post- pandemic, resulted from online learning. Similar finding was traced in previous studies [16] [18]. The study found that the preservice teachers' competence and online teaching readiness was enhanced post-pandemic. Although the findings favored online learning as it has positively impacted the students' ICT skills, we cannot assume that the students are prepared with pedagogical practices to teach online. In a study in the US, the authors found that even though most teachers perceived readiness, they did not use the appropriate digital tools when teaching in the classroom [16].

Another consideration is regarding the survey instrument. The survey' results represent the students' belief about their ICT competence rather than their actual level of competence. This latter should be measured by performance tasks [21]. Previous research explained that one of the weaknesses of survey instruments is the respondents themselves [30]. The participants may respond to the survey items with social-desirability bias such as the desire to please the instructor or bias in self-perception. The previous study addressed the need for the validation of the survey instruments, particularly when it is used as the yardstick in measuring one's competence [54].

The open-ended item in the survey sought the participants' perspectives on the importance of equipping oneself with digital skills. The common themes that emerged from the responses can be summarized and categorized as follows:

- The participants linked equipping oneself with digital skills to the ability to approach classroom teaching and learning that is relevant for present day and for the future
- The participants linked the importance of equipping oneself with digital skills to prepare students for the workplace and global society.

An excerpt from one of the responses states,

"It's important for me to be digitally competent so that I can impart my knowledge to my students in a new way. We are no longer living in a traditional way- to learn from books. Students today learn from YouTube and Google". (S11)

The excerpt above is one of the examples the participants gave in which the student linked the importance of preservice teacher education students equipping themselves with ICT skills to the ability to approach the classroom that fit current and future times. In other words, digitally competent teachers are able to make classroom teaching and learning relevant.

Other excerpts state,

“I don’t see how we can teach without having some ideas about technology. Maybe we are not IT experts, but we should have some ideas. In future, our students need IT skills for their work too. It starts with us”. (S8)

“Oman is no longer a traditional society. We interact with people from different countries through studies, work, government and so on. Being good with technology is important for us as future teachers so that we can show the younger Omani children how to use technology to connect with people from other countries”. (S3)

The excerpts above are examples the participants gave in which the students linked the importance of preservice teacher education students equipping themselves with ICT skills to preparing students for the workplace and the global society. Being competent in ICT is an unarguably an essential part of teacher education [23]. In a study with preservice teacher education in Ireland, Norway and Spain, the authors found that despite the different ways the education policies developed, the participants had a similar and shared view of the importance of digital skills [32]. Another study found that preservice teacher education students in an Irish University had a favorable positive attitude toward using technology in the classroom [33]. Both of the studies utilized the DiCTE project survey as their instrument of study.

Finally, this paper investigated the relationship between the participants’ digital competency score, which was derived from DigComp digital profile to the participants’ reported active use of ICT in their daily lives. The active use of ICT is narrowed into the following: the use of word processor, spreadsheet, presentation tools, photo and video editing tools, Learning Management System and educational games. The results found there is a strong correlation between the number of years the participants reported to actively use ICT in their lives to their digital competence score. In other words, the duration of exposure and active use of ICT has a significant impact on their digital competencies. This discovery aligns with previous research that found teachers who feel confident in their ability to use educational technology and see it as beneficial for teaching and learning are more likely to incorporate digital tools in their teaching. Similarly, providing preservice student teachers with more opportunities to work with digital tools has been found to improve their ability to use technology in their classrooms in the future [12] [14].

## VI. CONCLUSION

The study examined the effects of COVID-19 on the digital skills of preservice teacher education students at Dhofar University in Oman, focusing on the students’ level of digital competence, their views on their ICT abilities post-pandemic, and the correlation between their reported years of active ICT use and their digital competency scores.

The study utilized two instruments that were DigCom, a digital skills self-assessment tool which was produced by the European Commission and a survey which was adapted from the DiCTE project. Both of the research instruments have been validated by studies around the world, as explained in the Discussion section.

In summary, the findings first revealed that the majority of the students scored Level 3 (Intermediate) in their self-assessment competency test score. The results of the study also showed that among the five areas tested, namely information and data literacy, communication and collaboration, digital content creation, safety and problem solving, the students scored the highest for digital content creation and the lowest for problem-solving. Second, the findings showed that the majority of the students perceived that their digital competence improved significantly as the result of online learning which was accelerated by the COVID-19 pandemic. Finally, the study demonstrated that the duration of active use of ICT has a significant impact on the students’ digital competency score.

The rationale of this investigation is that it helps educators understand the preservice teacher students’ level of digital competence. It also gave us an insight on the ways the students perceived their ICT skills before and after the pandemic. In turn, the data informs us the ways we could identify their strengths and weaknesses, monitor their progress and identify ways in supporting and developing their digital skills.

An avenue for future research, is to consider measuring the students’ digital competency based on performance tasks. The present study is based on the students’ self-assessment, which reflect their belief about their digital competence. Another consideration to make is to have digital assessment that is more relevant to the Arab region. The expression of survey result may differ, as the participants respond to statements that are more contextually relevant to them.

The implication that can be drawn from the findings of the study is that, if the students were given more time and opportunities to engage with various forms of ICT, the more they would perceive themselves to be digitally competent. This belief would then influence the way they conduct their classes. The more positive the belief is, the more effectively they would incorporate aspects of technology in their classroom. As future teachers, the students have a greater responsibility to empower their students with important skills for work and participation in the society through the use of technology. As the DiCTE project [15] explains,

“Formal education has an important role to play in this regard and none more so than in teacher education. From a perspective of equity, it is crucial for teacher education to equip future teachers with the required professional digital competence so that they can prepare children to grow up in a digital society” (para.2).

The growing importance of technology in education is without a doubt, transforming the ways learning takes place. In the Sultanate of Oman, there have been suggestions for hybrid education in which combine the aspects of face-to-face and online learning in classroom teaching and learning [34]. Reimagine Education, an initiative pioneered by the UNICEF explained that technology could bring about change in delivering learning opportunities to children and young people “anywhere, at any time” [56]. The growth of technology requires innovative pedagogies, which could only take place if the future teachers are digitally competent. As these students

would be future teachers, they would be given a greater responsibility in designing instructional strategies that align with the country's Vision 2040, the implications of this study are immediate to them.

**Abstract**—Mobile Edge Computing (MEC) uses to perform computation operations at the edge of a network for mobile devices. This allows the deployment of more powerful and efficient computing resources in a cost-effective, lightweight and scalable manner. MEC can optimize mobile device performance, enhance security and privacy, improve battery life, provide increased bandwidth, and reduce latency across wireless networks. Cloudlets are a new concept of computations that can perform at the edge of the networks. The service provider can deploy cloudlets services in a MEC environment with the ability for mobile devices to offload their tasks to cloudlets. In the MEC environment, the offloading problem depends on cloudlets' availability of computation resources. Also, the deployment method of cloudlets in the environment will affect the task offloading. This paper investigates the approach to the cloudlet deployment and task offloading problem in the MEC environment. First demonstrate that the problem has to be considered a Multi-objective optimization problem since it needs more than one objective to be optimized. Then prove that the problem is NP-completeness, give an overview of existing solutions using the meta-heuristic algorithms, and suggest future solutions for this problem. Finally, explain the advantages of using Variable-length of solution space with meta-heuristic algorithms for this problem.

**Keywords**—Mobile edge computing, cloudlet deployment; task offloading; mobile device; multi-objective optimization; meta-heuristics; variable-length

## I. INTRODUCTION

Mobile Edge Computing (MEC) is a technology that enables computation and storage capabilities at the edge of a mobile network, closer to the end-users [1]. It extends cloud computing to the network's edge, allowing for delivering low-latency and high-bandwidth services to mobile users [2]. The end-users typically execute the applications on their resource-constrained mobile devices for current internet-enabled applications requiring fast processing and less response time [3]. MEC is designed to address the challenges of providing low-latency and high-bandwidth services to mobile users, such as those required for augmented reality, virtual reality, and Internet of Things (IoT) applications [4]. Furthermore, the mobile devices at the edge of the network offload their computation tasks to the ( edge-server, edge-cloud, sometimes

referred to as Cloudlet) instead of the remote cloud, which will decrease the response time for offloaded tasks (low latency) and reduce overcrowding in the back-haul networks [5].

Cloudlet is a new computing paradigm introduced to the Mobile Edge Computing (MEC) service framework. It allows computing resources to be closer to mobile devices. The cloudlets location is essential to the delay tolerance of mobile devices, primarily in a large-scale Wireless Metropolitan Area Network (WMAN) that consists of hundred Base Stations (BSs) [6], where mobile devices can access the cloudlets. The capacity of cloudlet is much smaller than cloud computing as edge computing is supplied with one or a few servers due to the limitation of space and cooling requirements [7]. MEC has been adopted to allow mobile devices to offload their tasks to the cloudlets because of the limited processing, small storage and low computational capabilities of mobile devices [8]. The high quality of service (QoS) requirements for the highly interactive applications, which include low latency and high throughput, are computationally demanding [9]. Mobile computing has recently experienced a paradigm change from mobile central cloud computing to MEC, fueled by hopes for 5G and 6G IoT connectivity [10]. In order to support latency-intensive computing applications and critical latency for mobile devices with limited resources, MEC's main purpose is to push mobile computing, network control and storage to the network's edges [11]. In the MEC environment, cloudlets are usually deployed collocated with cellular base stations so that the mobile devices can offload tasks to the nearby cloudlets.

Offloading is a technique used in the MEC environment to increase the effectiveness of mobile device applications by moving resource-intensive activities to nearby cloudlets [12]. Offloading in MEC mostly refers to running resource-intensive applications on behalf of local mobile devices to minimize workloads, overhead, and processing costs compared to local computing. To perform compute offloading, mobile devices and cloudlets must operate offloading frameworks [13]. Many technical articles view the topic as incredibly important to provide new ways of reaching the objectives in the offloading criteria. Most of the strategies presented in these technical publications were based on mathematics, model-based, machine learning, game theory,

heuristic-based, meta-heuristic, or a combination of the abovementioned techniques. In the MEC context, computation offloading problems are a very difficult challenge [14]. The primary drawback of offloading work to a remote cloud is the latency, which disrupts user experiences in interactive applications like mobile gaming [15]. Cloudlets get around this problem by giving users low-latency access to network-edge computing resources, which significantly boosts the efficiency of mobile applications [16]. The primary issue with WMAN is the deployment of fewer cloudlets with good services to end user. From the perspective of network management, it is costly to place a cloudlet at each BS to service end users [17].

Multi-objective optimization techniques are an excellent approach in this situation. In multi-objective optimization, as opposed to single-objective optimization, the search is for a collection of non-dominated solutions known as the Pareto optimal set rather than a single optimal solution, which must be optimized [18]. The non-dominated objective solutions are the ones that provide the best potential compromises between the many objectives of the problem (i.e., these solutions cannot enhance one objective without affecting another). The decision-makers, in this case, the service providers, are given access to such non-dominated solutions so that they may choose the one that caters to their specific demands and requirements in the most effective manner. The computational methods that are currently available to solve multi-objective optimization problems include meta-heuristics and high-level strategies governing underlying techniques. Additionally, in contrast to the conventional mathematical programming approaches used to solve multi-objective optimization problems, meta-heuristics can create many members of the Pareto optimal set in a single iteration [19]. Most researchers consider the problem as a Single Objective Optimization in the related works, while a few deal with it as a Multi-Objective Optimization problem.

A meta-heuristic optimization has shown its effectiveness in tackling several NP-hard problems. Computer science, networking, communication, robotics, and manufacturing, are just a few areas where this mechanism has been used in the real world. The literature on meta-heuristic optimization has yet to adequately address the multi-objective optimization component, despite its prevalence in many problems. The meta-heuristic algorithms have a substantial impact on solving cloudlet deployment and task offloading optimization issues. Consequently, this paper provides a survey of published articles about cloudlet deployment and task offloading to summarize the problems that need solving for future research. First discuss the challenges addressed partially or entirely for the problem and suggest several promising directions for future research to minimize time, reduce cost, and save energy. Second, demonstrate that the problem is multi-objective optimization since it deals with more than one objective to be optimized and proves it is an NP-completeness. Third, explain the diverse current, well-known traditional heuristic and meta-heuristic algorithms for cloudlet

deployment and task offloading problems in the MEC environment, emphasizing meta-heuristics. Fourth present the capabilities of using the variable-length searching approach within meta-heuristic optimization algorithms for solving this type of problem, especially with the constant change in the required number of cloudlets to deploy in MEC based on computing requirements. This work can be helpful for academia and companies regarding service provisioning in the mobile edge computing environment.

The rest of this paper is organized as follows: Section II presents a background and an overview of the relevant literature, which helps to understand the rest of the article. Sections III introduce the optimization technique. Section IV demonstrates the multi-objective optimization and the meta-heuristics algorithms. Section V Provides the Variable-length approach for solution space and its benefits for future research, and finally, the conclusion are provided in Section VI.

## II. BACKGROUND

This section presents an overview of the relevant works, which assists in understanding the rest of the article. Cloudlet deployment and task-offloading (for simple CDTO) have been fertile research ground for several years. Thus, many papers on solutions related to this area are in the literature.

### A. Mobile Edge Computing

One of the essential fields on the technology scene today is Cloud Computing, which is one of the elements preparing for the future. Thanks to advancements in wireless communication and mobile computing, in the last decade, new smartphone device services have prospered in diverse fields such as transportation, mobile payment, and social media [20]. The spread of mobile devices and their constant presence in daily life has generated massive traffic between end users and remote clouds [21]. To plan for the increasing data traffic in the following years and the need for low-latency computation resources near the users, network service providers are gradually turning to "Mobile Edge Computing" to bring cloud computing capabilities to the edge of the network [22]. Users at the edge of the network offload their computation tasks to the ( edge-server, edge-cloud, sometimes referred to as Cloudlet) instead of remote clouds, which will decrease the response time for offloaded tasks (low latency) and reduce overcrowding in the back-haul network [20].

Due to the limitations of the cloud environment (i.e., long-distance from mobile devices and limited geographical distribution), mobile devices with hungry applications for computation resources need to offload tasks to the nearby clouds closer to the end-devices through newer computing paradigms, such as cloudlets in Mobile Edge Computing environment (MECE) [23]. Cloudlets are a distributed decentralized infrastructure with nearby mobile devices that can leverage the computing and storage resources of the cloudlets. Table I presents the comparative summary of Cloud and Cloudlet.

TABLE I. COMPARISON BETWEEN CLOUD AND CLOUDLET

Feature	Cloud	Cloudlet
Cost	High	Low
End-to-end latency	High	Low
Infrastructure	Centralized	Decentralized
Deployment Environment	Large Data Center	Can be deployed anywhere
Bandwidth for end-user	Low	High
Offline Availability	Not available	Available
Computing Power	High	Low
Resource Elasticity	High	High
Availability	High	High
Access to resources	through core network	typically via 1-hop wireless gateway
Resources at individual locations	Many	Few
Geo-distribution of computing resources	locally clustered	widespread
Offloading granularity	mostly entire applications	computationally intensive and latency-critical parts
User Experience	Satisfactory QoE	Excellent QoE
Network resource sharing at individual locations	Large number of users	Limited number of users

### B. Wireless Metropolitan Area Networks

The wireless metropolitan area networks (WMANs) have emerged in recent years as a public network that enables mobile devices to easily access the abundant computing resources in urban cities as the number of mobile devices continues to grow [24]. In addition, wireless broadband connectivity requirements are growing (i.e., 5G and 6G), and the technology continues to evolve to meet these requirements [25]. It is currently evolving as a public network to expand mobile device performance, covering the metropolis and enabling mobile devices to access abundant computing resources [26]. Compared to Wireless Local Area Networks (WLANs), Wireless Metropolitan Area Networks (WMANs) offer wireless communications over significantly broader geographic regions. The problem of CDTO gets significantly worse when considering the deployment of cloudlets in WMANs because of the size of the WMANs [27]. Due to the high population density in urban regions, many users will have access to cloudlets. As a result, cloudlets will be more cost-effective since they will be less likely to stay idle. Furthermore, due to the population in WMANs, service providers can take advantage of economies by deploying a small number of cloudlets to provide services through the WMANs [20] and making cloudlets accessible to the general public.

### C. Cloudlet-deployment and Task-offloading (CDTO)

Cloudlets deployment is the first step in implementing mobile edge computing. Service providers always hope to provide services to as many users as possible under limited funds. The idea of treating cloudlets as a separate “data center in a box” must be scrapped. There are obvious benefits of connecting several cloudlets to form a network of cloudlets that can be distributed in the wireless metropolitan area networks, collocated with the base stations [20]. Cloudlet can be a single server or a cluster of servers, collocated with base stations, and mobile devices can access cloudlets close to the

range [28]. Cloudlets can also be considered as offloading mobile device destinations, aiming to save energy [29] and reduce the latency between the remote clouds and mobile devices [30]. The close physical proximity between cloudlets and mobile devices is a significant benefit of cloudlets over the remote cloud. So that allows for low latency in communication, thus improving the QoS and the user experience of interactive applications [31]. To overcome the restrictions of mobile devices in the offloading process technique, mobile devices offload their tasks to the MECE [32]. Task-offloading improves the computing efficiency of mobile devices while reducing latency and overall spent energy if adequately designed and planned [5]. There are four types of delays in task-offloading from mobile devices to cloudlets: uploading, queuing, execution, and downloading the result. A typical process flow of task-offloading in WMAN is illustrated in Fig. 1.

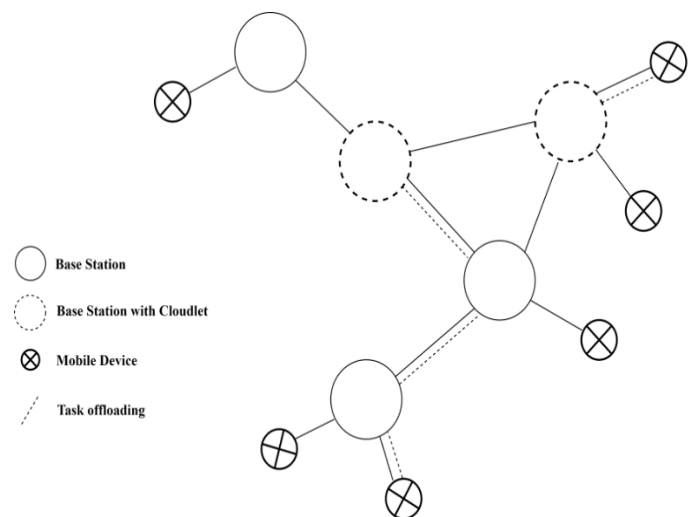

Fig. 1. Process flow of the task-offloading in WMAN.

In related works, there are mainly three metrics expressing system requirements that can be optimized, the task response time [33], the cost of service for service provider and user side [34], and the energy consumption (the energy consumed by the device while task-offloading and the power needed by cloudlet to process tasks) [35]. In addition, some issues have been partially addressed in previous works, which are reliability, load balancing, cache content, task migration, user mobility, and cloudlet mobility. The exciting issues for related works that dealt with the problem as a single objective optimization are shown in Table II.

### 1) Response Time

The QoS metric in the design of offloading methods is the response time, which is the time between offloading the task from a mobile device to a cloudlet, processing it, and receiving the result back [36]. Furthermore, the response time is also defined as the delay [37], or latency [38] in some related works. Many aspects influence the response time of a task as followings:

- The communication delay between the mobile device and the base station while offloading the task to the cloudlet.
- The communication delay between the base station and the attached cloudlet, which is always minimal while using fiber optics cables.
- The communication delay while routing the offloaded task from overloaded to under-loaded cloudlet.
- The queuing time before processing in the cloudlet.
- The processing time on the cloudlet.
- The communication delay between the base station and mobile device while receiving the result.

Fig. 2 shows the task lifetime, from the mobile device to cloudlet, which is an uplink delay, queuing and execution at cloudlet, which is a processing delay, and from cloudlet to mobile device, which is a downlink delay.

Fig. 2. Task service delay.

### 2) Cost

The cost can be categorized into two sides: service providers and users. For the service provider, the cost of deploying cloudlets is related to two factors [21], which are site rentals and computations needs. The former means that the more locations are selected to deploy cloudlets, the higher the cost. The latter aspect tells us that the greater the computation needs, the greater the number of cloudlets, resulting in higher costs. On the other hand, users look for the best service at a reasonable price. The service price (the

amount user have to pay) mainly specifies the willingness of users to pay for services [39].

### 3) Energy

Most existing works on MECE mainly focus on saving energy for mobile devices by offloading tasks to the cloudlets. Due to the battery life limitation for various mobile devices, the energy consumed by the mobile device processing the tasks is one of the most significant issues [40]. The energy is mainly consumed by mobile device data processing and transmission. Due to the limitation of processing in a mobile device [39], it is better to offload tasks from mobile devices to nearby cloudlets for energy-saving. The offloading of a task can decrease the processing energy by reducing the processed data size but increases the transmission energy by increasing the size of transmitted data [35]. On the other hand, service providers are looking for energy savings for cloudlets, reducing power costs.

### 4) Reliability

Reliability is a significant component that influences user QoS and service provider profit [41]. The significant causes of reliability decreases are failures or errors in the mobile edge computing environments. Failures and errors in the system can occur during task-offloading, processing, routing tasks from one cloudlet to the other, and receiving the result back [42]. Improving the reliability of task-offloading under the resource capabilities of the cloudlets and the dynamic network is an important challenge in the MECE.

### 5) Load Balancing

The cloudlets contain single or multiple servers to process the offloaded tasks. The load inequality in these cloudlets leads to different response times for offloaded tasks. Therefore, the load balancing between cloudlets for task-offloading becomes essential [22]. Increasing the number of servers in the cloudlet makes balancing user workload less critical as the cloudlets can handle higher loads [43]. On the other hand, increasing the number of users will increase the task waiting time. Once the cloudlet reaches its maximum workload, it must route its overflow users' requests to the other cloudlets for better performance [44]. This means that a better strategy is to assign user tasks to under-loaded cloudlets rather than keeping them in an overloaded cloudlet [22]. Hence, it is clear that balancing the workload between cloudlets is necessary by mapping the tasks of users to different cloudlets.

### 6) Cache Content

When a task is offloaded to a cloudlet, the critical impact on task execution performance is data transmission delay. One of the most successful solutions is to cache data for the offloaded task in advance. Furthermore, because user data access patterns in WMANs are challenging to forecast [45], creating an adequate data caching technique with high access hit ratio is challenging. The number of content cached at cloudlet increases with the number of offloaded tasks increasing [46]. Content cache performance significantly impacts delay and bandwidth [47]. For example, the popular cached content in cloudlet can reduce the delay and the bandwidth usage of subsequent access to the same content.

7) Task Migration

In the MECE, the inter-flow between cloudlets is essential to make a load-balancing and support user mobility. In the network of cloudlets, to make load-balancing, tasks have to be forwarded from the overloaded cloudlet to the under-loaded cloudlet, so there will be no idle cloudlet in the system [48]. Hence, as shown in Fig. 3, to support user mobility in the system, tasks must route from one cloudlet to another cloudlet so that the task will be close to the mobile user for result download [49].

8) User Mobility

To support user mobility, edge computing requires the flexible and scalable deployment of cloudlets for the inherent dynamism of the operating environment and various applications, some of which require real-time response [50]. In related works, WMAN's user mobility pattern has attracted very little attention. A mobile user may move around the area covered by WMAN with specific transmission patterns, but different movement patterns may change the traffic size of the network. The cloudlet placement and task offloading strategy should reflect the mobility pattern better to meet the requirements of mobile devices to access network resources [51]. The mobility pattern is reflected by the connection possibilities between mobile devices and BS. Furthermore, the mobility pattern of mobile devices is highly correlated with service access delay. Connection failures may happen during user mobility with the poor quality of the wireless connection between mobile devices and BSs [52]. However, the next generation of cellular communication has overcome this issue. The excellent service would necessitate frequent wireless handover between multiple BSs to guarantee user QoS during

movement. For constant QoS, mobile devices may be serviced by many cloudlets. Because of user mobility, wireless handover and service migration may be performed frequently, putting a heavy load on the other network entities [53].

To support user mobility, task migrations have to perform when a mobile user moves from the service region of one cloudlet to another. As mentioned four types of task service delay; there will also be a delay in task migration during user movement. Fig. 3 illustrates the task migration during user movement. To provide QoS for users, mobility management should make a wireless handover decision to select optimum BSs and cloudlets [54]. The primary goal of mobility management is to provide mobile computing services to continuous and uninterrupted customers during user movements.

Fig. 3. Task migration while user movement.

### 9) Cloudlet Mobility

The cloudlet in the MECE can be static or mobile [12]. In mobile cloudlet networks, it is crucial to figure out how to make load-balancing between all mobile cloudlets so that all resources are utilized and tasks can be processed concurrently and sustainably by different cloudlets, therefore, reducing the average task response time and energy [61]. Cloudlet mobility is essential in MECE to provide good services for users, especially when the population moves (e.g. festivals, sporting events, etc.).

In Table II, all researchers consider the problem as a single-objective optimization. Most of them take the problem on one side (cloudlet-deployment or task-offloading), while very few consider both themes. Furthermore, most existing works mainly focus on minimizing time, reducing cost, saving energy, and load balancing, while the others take little attention. In Table II, various algorithms and methods were employed to address the issues, including greedy algorithms, clustering algorithms, heuristics, meta-heuristics, reinforcement learning, and mathematical programming. Comparisons were made between meta-heuristic and heuristic algorithms, meta-heuristic and greedy algorithms, reinforcement learning and mathematical programming. In addition, research studies such as [44] have compared meta-heuristic and unsupervised learning algorithms, while [65] has compared meta-heuristic and mathematical programming, with results consistently demonstrating the superiority of meta-heuristic algorithms.

### D. Related Survey Works

CDTO has been a fertile study area in recent years. As a result, many surveys and studies in the literature on solutions related to this area. In the work of [67], the problems of mobile cloud computing are presented and provide the most recent mobile cloudlet architecture. Furthermore, propose a hierarchical taxonomy to classify the most recent cloudlet solutions and discover the cloudlet application areas. In addition, it presents the aspects of cloudlet management, like cloudlet discovery, resource management, data security, mobility, and application offloading. The work of [68], studied the fundamental concepts of cloud and edge computing. Presented the application domain classified the state-of-the-art edge computing (Mobile Edge Computing, Cloudlet, and Fog) and the application domain area services such as real-time applications, resource management, data analytics, and security. Furthermore, state the essential requirements that must be achieved for edge computing to be enabled. The work of [69] proposes a taxonomy of task-offloading in edge-cloud environments to examine and categorize related research papers and outline the challenges that still need to be studied before using edge-cloud computing to improve services. To identify the modern processes, the work of [70] provides a review of the machine learning-based computation offloading strategies in the MECE in classical taxonomy. Furthermore, it investigated various strategies and novel approaches related to machine learning-based offloading mechanisms in the MECE ecosystem. Also, taxonomy for classifying various principles of machine learning-based offloading mechanisms was proposed.

Finally, there are many other surveys, each considering a particular aspect of Mobile Edge Computing, which also lacks considering the Multi-objective optimization approach for the problem of CDTO.

## III. OPTIMIZATION

Optimization is a method of finding and comparing appropriate solutions until cannot find any better solutions. Optimization often involves minimizing or maximizing the objective functions. Optimization, in other terms, refers to a collection of methods that may be applied to a mathematical model of the problem. The optimization algorithm provides systematic and efficient methods for producing and comparing new solutions to achieve the optimal solution [71]. Optimization is experimenting with various input-output combinations to find the resulting outputs. Its methods are far more advanced than those used in the computation. Optimization theory has custom-made algorithms to identify the best solution with little processing by utilizing model information. Optimum selection evaluations, suitable trade-offs, and non-intuitive analysis of optimization techniques are utilized to develop a better and faster optimal design [72]. The role of modeling in optimization involves testing out many different combinations of inputs to determine what the output (i.e., the number you are trying to minimize or maximize) will be under each of those circumstances, with many inputs, it is usually not practical to guess and check on an existing system [73], optimization requires a mathematical model of the system, which is just the math that relates the inputs to the outputs. By using a system model to iterate, there is no limit to the number of combinations you can try (maybe just computational limitations). Optimization algorithms are much more sophisticated than guessing and checking a range of varieties (a process known as enumeration) [74]. Fig. 4 outlines the steps usually involved in an optimal design formulation.

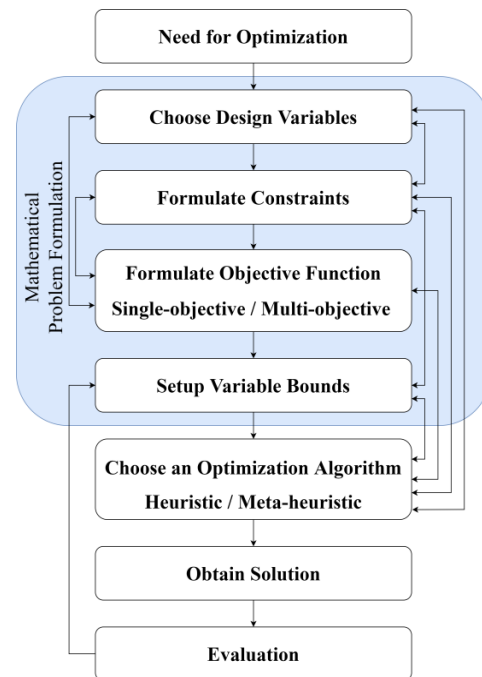

Fig. 4. Steps of problem optimization.

In the Mobile Edge Computing environment, users and the service provider have various requirements. The deployment of a small number of cloudlets in the WMANs to serve many users is significant for service providers. In addition, user satisfaction is one of the most important quality-of-experience (QoE) evaluation measures, especially affecting the service provider's profit due to the penalty when there is any infringement of the Service Level Agreement (SLA), which establishes an agreement between service providers and their users [75]. It significantly influences users' willingness to pay for services in the future. Thus, when offering services, user requirements must be considered and satisfied [40]. Furthermore, in the problem of CDTO, most existing works consider single-objective optimization, while very few consider it a Multi-objective optimization. The relationship "better than" between two solutions is insignificant when dealing with single-objective optimization problems. Whether a function has to be maximized or minimized, the one with the lower or higher fitness value is preferred. The relationship "better than" has to be redefined while dealing with the Multi-objective optimizations. Furthermore, when two non-dominated solutions are compared, there is only one way to rate the best if enforcing specific user preferences. As a result, a new kind of fitness measurement is required [74].

#### IV. MULTI-OBJECTIVE OPTIMIZATION

Problems involve more than one objective in the real world, and conflict naturally leads to trade-off solutions. It is hard for the mobile edge computing service provider to determine the constraints. A feasible solution cannot be found if the constraints are not appropriate. Only one objective is confirmed, and only one solution may be generated if a constrained single-objective optimization problem is considered rather than a multi-objective optimization problem which may not result in a satisfactory trade-off between all objectives [76]. Most researchers in related works dealt with the problem as a single-objective optimization. In contrast, few researchers are dealt with the problem as multi-objective optimization, as shown in Table III.

For the Multi-objective optimization problem arising from Cloudlet-deployment and Task-offloading (for simple MO-CDTO) in MECE, not only the minimization of task completion time and the energy consumption is required, but also the minimization of cloudlet-deployment cost is demanded [60]. In Table III, researchers consider the problem

as multi-objective optimization. Most of them take the problem on one side, which is task offloading. Furthermore, time, cost, energy, and task migration have more extensive attention than others. The algorithms and methods were employed to address the multi-objective optimization problems, including meta-heuristic algorithms, a hybrid of meta-heuristic algorithms, machine learning and reinforcement learning. The results consistently demonstrate the superiority of the hybrid of meta-heuristic algorithms to address the multi-objective optimization problems.

##### A. The NP-Completeness of MO-CDTO Problem

The NP-complete problem is the hardest to solve. It is a problem that if there is an algorithm that can solve any of these problems, then it can solve all of them. Nobody has been able to prove that NP-complete problems are intractable. To prove that the MO-CDTO is an NP-completeness, first must explain that the problem belongs to the NP class and then show it is NP-hardness. When presenting a solution for the problem of MO-CDTO, the problem takes  $O(ML)$  time to evaluate if the total task-offloading probability for each user is no more than one and the maximum workload restriction for each cloudlet. Furthermore,  $O(L)$  time is required to verify that the number of deployed cloudlets at each base station is not greater than one. As a result, verifying a solution for MO-CDTO takes polynomial time. Therefore, MO-CDTO is under the class of NP problems. Based on the explanation of the p-median problem in [81]. When  $\forall 1 \leq i \leq$  the number of users, the computing capacity of user  $i$  is zero, the computing capacity of each cloudlet is infinity, the cost of each cloudlet is equal to zero, the energy consumption of users is constant, the cloudlet deployment cost can be neglected, and the maximum number of cloudlets that may be deployed must be deployed to reduce user task response time. Therefore, the problem of MO-CDTO becomes selecting BSs to deploy the number of cloudlets and assigning each user to a cloudlet so that the sum of the connection delay is minimized from all users to the cloudlets they are assigned. To that end, each user must be assigned to a cloudlet with the smallest communication delay so that the MO-CDTO problem is NP-hard. Furthermore, based on the definition of NP-complete in [82] and [83] "If the problem  $X \in$  NP class and  $X$  is NP-hard so  $X$  is NP-complete", while the problem of MO-CDTO belongs to the NP class and it is NP-hard, so it is NP-complete.

**B. Meta-heuristic Algorithms**

The meta-heuristic algorithms are a class of local search algorithms used to solve multi-objective optimization problems. The main objective of these algorithms is to find the optimal solution for the given set of problems based on a given set of constraints. The main idea behind this method is that it considers all the constraints and variables that affect the solution. Users can specify these constraints or automatically generate them by the algorithm. In mathematical programming, heuristic algorithms are used to design solutions to problems as quickly as possible. It may not produce the best solution, but it will give a near-optimal solution in a short time [71]. Some trade-off conditions give an initial idea of whether a heuristic algorithm is a good fit or not for a given problem. One of these conditions is the

completeness of the problem. If several solutions exist for a given problem, it is better to use a meta-heuristic algorithm [74]. A heuristic algorithm generally provides one solution that may not be the best among all the available solutions. Furthermore, meta-heuristic-based optimization has proved effective in solving many NP-hard problems. This method has been used in various real-world applications, including computer science, networking, communication, robotics, and manufacturing [84]. The main difference is that heuristic is the problem-specific method, while meta-heuristic is the problem-independent method that can be applied to many problems. Table IV classifies the heuristic and meta-heuristic algorithms. Meta-heuristic algorithms are divided into nature-inspired and non-nature-inspired.

TABLE IV. CLASSIFICATION OF HEURISTICS AND META-HEURISTICS ALGORITHMS

Heuristics	Meta-heuristics	
	Nature-inspired	Non-nature-inspired
<ul style="list-style-type: none"> <li>• Greedy Algorithms</li> <li>• Best-First Search</li> <li>• Brute-force Search</li> <li>• A* Search</li> <li>• Hill Climbing</li> <li>• Bidirectional Search</li> <li>• Beam Search</li> </ul>	<ul style="list-style-type: none"> <li>• Swarm Intelligence                             <ul style="list-style-type: none"> <li>• Whale Optimization (WO)</li> <li>• Cuckoo search algorithm (CSA)</li> <li>• Particle Swarm Optimization (PSO)</li> <li>• Ant Colony Optimization (ACO)</li> </ul> </li> <li>• Estimation of Distribution Algorithm (EDA)</li> <li>• Simulated annealing (SA)</li> <li>• Evolutionary Computation (EC)                             <ul style="list-style-type: none"> <li>• Differential Evolution (DE)</li> <li>• Evolution Strategy (ES)</li> <li>• Genetic Algorithm (GA)</li> <li>• Genetic Programming (GP)</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• Guided Local Search (GLS)</li> <li>• Greedy Randomized Adaptive Search Procedure (GRASP)</li> <li>• Iterated Local Search (ILS)</li> <li>• Path Relinking (PR)</li> <li>• Scatter Search (SS)</li> <li>• Tabu Search (TS)</li> <li>• Variable Neighborhood Search (VNS)</li> </ul>

Meta-heuristic algorithms are generated based on the mathematical models of different biological processes [3] and activities [85] that appear in nature, modified and applied according to a specific problem so that the result statistical data can be analyzed. Meta-heuristic algorithms can be used for CDTO performance metrics, such as cost, time and energy consumption, to reach the optimal solutions for the problem of MO-CDTO. The frameworks and procedures for the different evolutionary, swarm and hybrid algorithms are comparable [86]. However, the methods for population initiating, evaluating the initial fitness (the quality of the solution), the strategies for coming up with new solutions, and the iterative procedures are often different [3]. Because of their success in solving complex and important computing problems, meta-heuristic algorithms have achieved widespread during the last two decades [87]. Due to their applicable independence in problem-solving, meta-heuristic algorithms are useful and well respected for solving problems in different fields with highly acceptable performance. Meta-heuristic algorithms are frequently exploited as an efficient way to address NP-hard optimization problems [88]. The most well-known and extensively used under meta-heuristics are evolutionary algorithms (EAs). Individuals, or potential solutions in EAs, are made up of a chromosome (a representation of the problem's variables) and fitness (the quality of solutions) [89]. Individuals are grouped to form populations. Every time a new solution is developed, it is examined to determine its fitness value. A generation occurs when a new one replaces the

present population [90]. Evolution is iterating through consecutive generations that end when a termination condition is met. The most meta-heuristic algorithms used in the related works are the following:

*1) Genetic Algorithm (GA)*

Genetic Algorithms are natural search algorithms inspired by Darwin's theory of evolution. JH Holland first introduced it in 1973. Genetic algorithms can create high-quality solutions for various problems, including search and optimization, by imitating the processes of natural selection, reproduction, and mutation [91]. The population is updated using the traditional GA update approach, which includes binary tournament selection, a two-point crossover operator, and a mutation operator. Furthermore, the elite individuals (those with the highest fitness values in the population) are entirely replicated in the next generation using the elitist preservation mechanism of this algorithm [8].

*2) Simulated Annealing (SA)*

Simulated annealing is a technique for addressing unconstrained and bound-constrained optimization problems. It was first introduced by [92] in 1983. Simulated annealing investigates alternative configurations to produce better solutions to the massive combinatorial problem. The configurations are updated and compared at each iteration, allowing the best configuration to be chosen [93]. Furthermore, a simulated annealing algorithm initially allows other random movements in the neighboring search space, but

the activities are reduced over time. The algorithm chooses neighboring states with a cost lower than the current state or the exact cost [94].

### 3) Whale Optimization (WO)

Whale Optimization is a new nature-inspired meta-heuristic optimization algorithm that simulates humpback whale social behavior. The bubble-net hunting approach inspired the algorithm. Mirjalili and Lewis, two Australian researchers, introduced the Whale Optimization Algorithm in 2016 [95]. The WOA offers a lot of potential benefits. It is unaffected by early solutions, which can considerably impact some traditional algorithms. It also contains adaptive mechanisms to balance explorative and exploitative behaviors appropriately. It is widely used in various domains, including engineering optimization, feature selection, and parameter extraction [96].

### 4) Particle Swarm Optimization (PSO)

The particle swarm optimization algorithm is based on the study of bird predation behavior. Its straightforward premise is to discover the best solution through collaboration and sharing information between individuals in the swarm. The PSO is one of the meta-heuristic algorithms proposed by [97] in 1995 based on the social swarm evolving notion. According to experimental studies and applications, the PSO is highly competitive in optimization. The essential idea of particle swarms is the social interaction that results in collective intelligent behavior. Both the set of entities and the swarm of birds move with two velocity components. The first one attracts them to the best global entity, and the second attracts them to the best local entity [84].

### 5) Ant Colony Optimization (ACO)

In the ACO technique, natural ant behavior is crucial in determining the optimum route between colonies and food sources. This concept was first presented as the "ant system" [98] in 1992. As they go forward, the ants expel the pheromones. Pheromones form the shortest paths over time, and the intensity of the pheromone helps to identify the quickest route to the food source. Indeed, the ACO was inspired by the ant behavior to determine the shortest path between anthill and the location of the food supply [99].

### 6) Cuckoo Search Algorithm (CSA)

Cuckoo Search is a meta-heuristic optimization algorithm used to solve optimization problems. Yang and Deb invented it in 2009 [100]. The CSA is a nature-inspired meta-heuristic algorithm based on cuckoo brood parasitism, and Levy flights random walks. The CSA is based on the parasitism of the offspring of a bird species known as the cuckoo. The CSA algorithm implements the Lévy flights [100]. Usually, the parameters of the cuckoo search are kept constant for a particular duration; this results in a decrease in the algorithm's efficiency.

### 7) Differential Evolution (DE)

Differential evolution (DE) is one of the most well-known generation EAs, developed by Storn and Price [101] in 1997 and effective for constrained optimization problems in nonlinear and multimodal environments. Differential Evolution is a generic Nature-inspired population-based

global-search meta-heuristic optimization algorithm. Therefore, it is largely suited for numerical optimization problems based on vector differences.

### 8) Tabu Search (TS)

Tabu search (TS) is a heuristic method proposed initially by Glover in 1986 [102]. Tabu search is a potential tool to discover a feasible optimal solution from a limited set of solutions. In other words, it is an optimization approach that uses a guided local search procedure that avoids local optimum and denies moves to points already visited in the search space using the so-called tabu list [102].

The common trend of EAs is hybrids of different evolutionary algorithms. These hybrids are relatively easy since most EAs can use the same population table and gene presentation. Hybrids are mainly accomplished to avoid the shortcomings of one algorithm; for example, using a hybrid of two algorithms, one for a local search and the other for a global search.

## V. VARIABLE-LENGTH

While there is no proper definition for a vector of a variable-length searching of solution space, therefore, most optimization theories depend on the fixed-length assumption to represent solutions [73]. There are several cases of variable-length approaches in which the number of variables is not fixed. One of these cases is CDTO. Standard optimization procedures may be used by considering a fixed number of variables. However, a sub-optimal length will result in a sub-optimal solution [86]. The algorithms can be executed iteratively and change the given length until an optimal solution is found. However, this is inefficient and impractical if there is an extensive range of possible lengths. For other fields of study, Table V shows the algorithms developed in meta-heuristic optimization with the variable length features. Variable-length algorithms are better since their solution vectors can vary in length [103].

Overall, as shown in Table V of the reviewed algorithms, the majority of them were developed to support a single objective except for the work of [89], which is based on an evolutionary algorithm and was applied only to a Bi-objectives problem without investigating the proposed algorithm and the work of [84], which suffers from weak interaction between solutions.

The traditional meta-heuristic optimization algorithms consider a fixed length of solution space, but these solutions do not apply to many real-world problems. The specific values of some decision variables might generate another or disable others, which cause the variable-length nature of solution space because of the different lengths of solutions. Multi-objective nature comes from having more than one objective to be optimized, e.g., delay, cost, and energy. Hence, MO-CDTO is a multi-objective variable-length optimization problem; the variable-length nature comes from the different number of cloudlets to deploy according to the computing requirements. Furthermore, the related works for the problem of MO-CDTO lack a single or multi-objective optimization algorithm with the variable-length feature.

TABLE V. THE PRESENT VARIABLE-LENGTH OPTIMIZATION FOR DIFFERENT FIELDS

Article	Application	Decision space	Algorithm	Limitation	Number Of objectives

## VI. CONCLUSION

Mobile edge computing has become an important technology to overcome some of the inherent constraints of mobile devices. Service providers are looking to provide excellent and cheap service to the MECE end-users. Furthermore, researchers focus on three main things in the MECE, which are minimizing time, reducing cost, and saving energy while solving different issues. Hence, the issues are related to each other. In contrast, the reliability and load-balancing affect time and energy, the cached content affects time, and the task migration and cloudlet mobility support the user mobility for good service and reducing time. The problem of CDTO has become an exciting research area. It has to be considered a multi-objective optimization problem since it needs more than one objective to be optimized. The problem of MO-CDTO is NP-complete because it belongs to the NP class and is NP-hard. The Meta-Heuristic algorithms have to be used for this type of problem as it is practical to solve MOO problems. For feature works, variable length of solution space is an appropriate approach for the problem of MO-CDTO because of the variation in the number of cloudlets to be deployed. A hybrid of two meta-heuristic algorithms with the variable-length aspect may generate powerful solutions. Many issues still need to address in the MECE, like reliability, user mobility, and load-balancing between cloudlets. This study is excellent material for future researchers to have an overview of the problem and take the research forward to resolve the unaddressed issues.

**Abstract**—With the advent of wearable devices and smart health care, the wearable health care technology for obtaining Patient Centric Data (PCD) has gained popularity in recent years. To establish access control over encrypted data in health records, Ciphertext Policy-Attribute Based Encryption (CP-ABE), is used. The most critical element is granting secure access to the generated information. However, with growing complexity of access policy, computational overhead of encryption and decryption process also increases. As a result, ensuring data access control as well as efficiency in PCD collected by wearables is crucial and challenging. This paper proposes and demonstrates a proof-of-work for the Merkle-based access tree using notion of hiding the sensitive access policy attributes.

**Keywords**—Merkle tree; hashing; CP-ABE; access policy; PCD

## I. INTRODUCTION

In order to manage access to important or valuable resources, access control is governed in computer security, according to Di Francesco Maesa et al. [1]. When access requests are made, access control policies are matched to the existing access context to determine subjects' permissions to resources. Many access control methods have been established in research to prevent unauthorized access to vital assets that are more centralized than distributed, such as healthcare records. According to Hong-Ning Dai et al. [2], Healthcare frameworks will inevitably undergo a digital change. The Internet of Medical Things (IoMT) is critical, but inherent security and privacy concerns limit mainstream use. According to Vincent Hu et al., [3], Blockchain has provided new insights into the security of clinical information, with the highlights of distributed, trustless data storage, peer-to-peer transmission, and encryption algorithms, and it may overcome the inconsistency between information sharing and privacy with suitable security measures. Using EHR raises issues regarding the confidentiality, protection, and dependability of medical information, according to Liang Huang et al. [4]. According to Buket Yüksel et al., [5] the combination of Blockchain with cloud has drawn a lot of attention recently for ensuring effectiveness, transparency, security, and providing better cloud administrations. To maximize the capability of the Blockchain-cloud mix, a full understanding of the present initiatives in this field is essential. Since healthcare applications are a good example of dispersed environments and depend on servers for storage and processing, CP-ABE is one of the most promising security mechanisms in this area. One-to-many communication [6] is supported by CP-ABE, and the owner defines the access policy, such that only

approved decryptor can access the data. An encrypted storage system is a use case for CP-ABE. One encryption key cannot encrypt many sets of data, preventing the implementation of fine-grained access control. The CP-ABE approach may provide access control without increasing the amount of keys by indicating the set of properties of the decryptor, such as affiliation. Enhanced schemes of ABE include broadcast encryption, multi-authority provisioning, and anonymous user or decryptor. Additionally, the number of attributes and pairing computations are inversely related. On the other hand, Merkle trees are designed to authenticate messages with a distinctive signature while also enabling an intended validator to confirm the authenticity of one message without exposing the validity of others.

## A. Research Problem

One of the main challenges in managing access to sensitive patient information is the attribute disclosure problem. Traditional access control methods, such as role-based access control (RBAC) and access control lists (ACLs), are not well-suited to the attribute disclosure problem, as they do not provide fine-grained control over access to sensitive patient information based on the user's attributes. CPABE is one of the few models that can provide this type of access control, but the attribute disclosure problem still persists as the access policy is exposed. To overcome this issue, a novel approach of attribute hiding through Merkle tree is proposed for PCD while preserving privacy. The Proof-of-work ensures that the decryption is performed by an authorized user and not an attacker.

## B. Research Questions

- 1) What are the main challenges in managing access to sensitive patient information?
- 2) How does the proposed Merkle tree based access structure for sensitive attributes of PCD in CPABE avoid unauthorized access and preserve privacy?
- 3) How can cryptographic techniques be used to ensure that the Merkle tree-based CPABE system is verifiable?
- 4) What are the benefits of a verifiable Merkle tree-based CPABE system in terms of in security and privacy?

## C. Research Objectives

The research objective of this study is to address the main challenges in managing access to sensitive patient information by proposing a Merkle tree based access structure for sensitive attributes of PCD in CPABE, and examining how this

structure can be used to avoid unauthorized access and preserve privacy. Additionally, the objective is to investigate the use of cryptographic techniques to ensure that the Merkle tree-based CPABE system is verifiable and to explore the benefits of such a system in terms of security and privacy.

#### D. Research Significance

The Proof-of-work proposed in the article provides a secure method for managing sensitive attributes in a patient-centric approach. It enhances security and integrity for both users and providers in healthcare associations. The proposed scheme uses a monotonic access structure for policy transmission, and is resistant to chosen-ciphertext attacks (CCA) even when an attacker acquires multiple private keys. Additionally, it can handle large volumes of data and provide quick integrity proof. This model contributes new knowledge in the domain of secure access control for sensitive patient information.

## II. LITERATURE REVIEW

By 2025, the worldwide IoT healthcare industry is anticipated to grow to 534.3 billion US Dollars. Carminati B, et al., [7] wearable health care is a popular and convenient technology that enables users to access medical services. Wearable medical data needs rapid and accurate information sharing from any place for better healthcare choices. However, the security and confidentiality of such patient information will become a major issue while sharing. When unauthorized access to information is unavoidable in medical settings, the security of patients' data is crucial. Siti Dhalila et al., [8] to overcome these challenges, new systems must be created with protected electronic health data, efficient storage, and a properly verified retrieval mechanism. Clauson et al., [9] aside from the patient-provider interaction and access-sharing, such a provision must also protect the patient's privacy with a greater focus on patient-centric health data management. Shan Jiang et al., [10] presented an access control mechanism based on smart contracts for access verification to get EHRs sharing by integrating data dumping and sharing processes for providing e-medical services through cloud and Blockchain. The medical information obtained by IoT devices is forwarded to nearest edge workers for information management while providing security. The data is then shared via Blockchain exchange.

According to C. Nguyen et al., [11], a framework-proposed fast CP-ABE model can assign costly computing jobs to semi-trusted third parties while keeping consistent number of simple calculations. To validate the validity of the decryption output, a Boneh-Lynn-Shacham signature model is utilized. Wang et al., [12] the approach creates a privacy schema for clinical data that is based on Blockchain and the cloud. It can perform safe insurance and clinical information integrity verification, as well as handle computation, information sharing, and security challenges. Wang et al., [13] offer a patient-driven PCD sharing system to preserve patients' privacy and provide them control over their PCDs. Prior to reevaluating, all PCDs in this structure are encrypted with multi-authority and ABE, addressing the key facilitation issue and achieving fine-grained access control. Additionally, anonymous authentication between the cloud and the user is

advised to preserve integrity while concealing the patient during validation. Leyou Zhang et al., [14] demonstrate a successful character identity-based distributed decryption technique for a medical records sharing framework. It allows them to share their data with different people without having to recreate the decryption of their private key. ABE was proposed [15] in order for the user to decode; there must be at least  $n$  attributes that match between the ciphertext and the user. V Goyal et al., [16] design extended the expressiveness of access structure by tying a ciphertext to a set of attributes, which they dubbed KP-ABE. Bethencourt et al., [17] introduced CP-ABE, which employs attributes to reflect the credentials of a user. Healthcare data that is sent in real-time or kept on a third-party cloud server is susceptible to a number of threats. A patient's life might be severely affected by the unauthorized access to sensitive medical information. Communication between multiple devices is one of the criteria for an IoT healthcare system. CP-ABE is a method that has promise for providing role-based access control in this situation. A type of public key cryptosystem called CP-ABE uses a collection of attributes to establish the user roles. In this case, the decryption key is linked to the receiver's attribute set and the access policy is contained with ciphertext. If and only if, the recipient's attribute set complies with the access structure/policy used for encryption, a successful decryption will take place. The data owners established the access policy. According to Hui Cui et al., [18] the decryption keys were only a collection of attributes with no tree structure. In a CP-ABE system, an access structure is included in the ciphertext, which may leak sensitive information about the underlying plaintext and the privileged receivers since anybody who views the ciphertext may learn the privileged recipients' attributes from the associated access structure.

Patients can encrypt data in a variety of methods to tighten access control in healthcare, such that anybody who reads the encrypted text can only comprehend the patient's publicly known qualities and the sensitive information stays hidden. This is according to Vijayan, V et al., [19]. Use of CP-ABE to encrypt the whole access policy with attributes or only the portion of the policy that has to be concealed is one or more solutions. However, the system cannot determine if the end user has the necessary authorization to access it because the ciphertext can only be retrieved by authorized end users, according to Nishide, T et al., [20]. This method's inability to outsource the decryption costs is its second drawback. The system will not be protected by CP-ABE encryption if the policies are wholly or partially obscured. Data must be patient-centric in a healthcare setting since it may be shared across several domains. This may be accomplished by hiding the access policy property using CP-ABE's different degrees of hashing, which supports fine-grained access control. It must also be done efficiently and securely to confirm the existence of the attributes used in the formulation of the access policy without disclosing the content at the time of decryption.

## III. PRELIMINARIES

The access tree is a list of all stakeholders who have access. The proposed approach's major purpose is to prove the existence of attributes in the access structure without revealing the sensitive attributes to the decryptor.

A. System Model

CP-ABE, according to Wang, Shulan, et al. [12], can enable privacy preserving and safe data sharing in public environment. The policy is embedded in the ciphertext, and each user's private key is based on attributes set and successful decryption can occur, iff the ciphertext or attributes satisfy the access key. Fig. 1 shows the Architecture for CP-ABE policy.

B. Access Tree for PCD

The CP-ABE access policy with attributes like hospital,

physician, Insurance company and department is defined for accessing PCD as in figure 2 is (“Physician” AND “Hospital X”) OR (“Insurance company X” AND “Insurance Department”). The proposed algorithm has five phases:

Phase 1: Initial Setup phase -  $S_c(\lambda, S) \rightarrow (PU_K, MS_K)$

The  $K_{GC}$  generates  $PU_K$  and  $MS_K$ , respectively, given by a  $\lambda$  and  $S$ .

Phase 2: Key Generation phase -  $K_G(PU_K, MS_K, S) \rightarrow S_K$

For  $M$ .  $PU_K$ ,  $MS_K$  and  $S$ , the  $K_{GC}$  generates  $S_K$ .

Fig. 1. Traditional CP-ABE architecture.

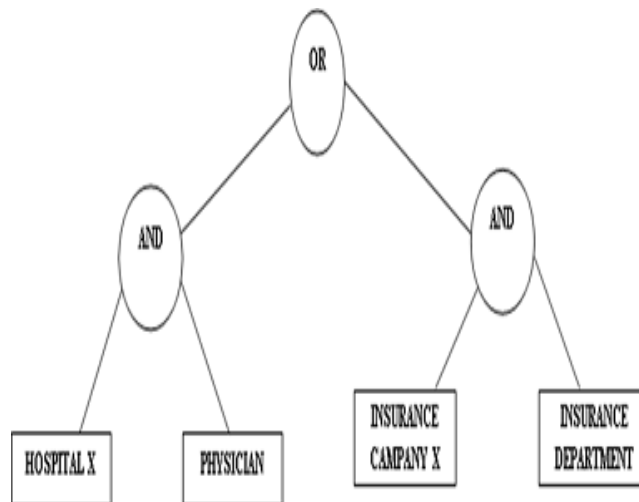

Fig. 2. The access tree generated for PCD.

Phase 3: Access Tree Construction phase

Given a collection of messages,  $M = \{m_1, m_2, \dots, m_n\}$  creates a Merkle tree whose interior nodes include the concatenation of the hash values corresponding to its leaf nodes and whose leaves include the hash value of each message  $m$  in  $M$ . In the Fig. 3 below, shows the Merkle tree construction through attributes set,  $A = \{a_1, a_2, a_3, a_4\}$ .  $H_R$  represents the root hash value also called Merkle Root.

Phase 4: Encryption phase -  $E(PU_K, S_T, NS_T, M) \rightarrow C_T$

The sender outputs the CT with input PUK, trees ST, NST, and M, where ST is a sensitive Merkle tree and

NST is a non-sensitive public tree.

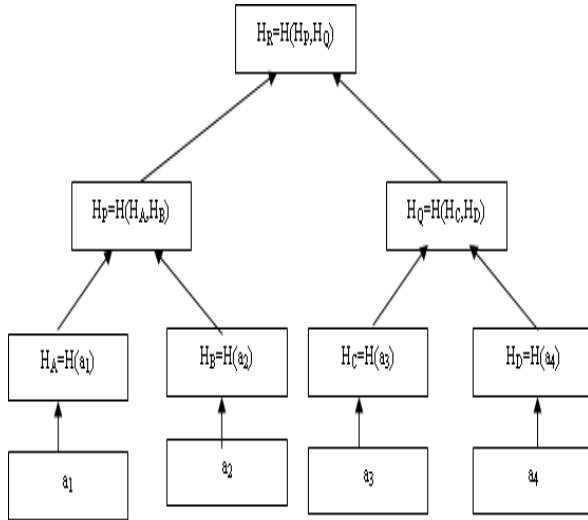

Fig. 3. The sensitive attribute Merkle tree  $S_T$ .

Phase 5: Decryption phase -  $D(C_T, S_K) \rightarrow M$

The decryptor then decrypts  $C_T$  with  $S_K$  and outputs message  $M$ . By moving up the tree  $T_S$  from a specific transaction node to root node, Merkle proofs can demonstrate that a specific attribute is present during decryption. The decryptor examines the public tree  $T_{NS}$  and discovers the Merkle proof for  $S_T$  to verify the integrity of hidden attributes.

Consider  $a_3$  from the attribute set  $A$  and  $H_C$  the hash of  $a_3$  to be verified, represented by bolded rectangle. Given  $H_P$  from other sub tree and  $H_D$ , the adjacent node hash value, represented by dashed rectangles. The  $H_R$  value can be calculated. If  $H_R = H_R$ , the hash root value of the tree when generated as in Fig. 4, the attributes are considered to be secure.

C. Data Set

The tree was designed for use in experiments using the IBM-Clinical Hub [21] data set, which was stated in [23]. This data set contains clinical data elements that, when paired with patient identification data, allow for the storage, production, and access of longitudinal patient records. The IBM-Clinical Hub is a more comprehensive workbench paradigm that offers access to consuming systems and processes as well as patient and clinical data. An ongoing stream of HL7 events and messages is used to construct the longitudinal patient record.

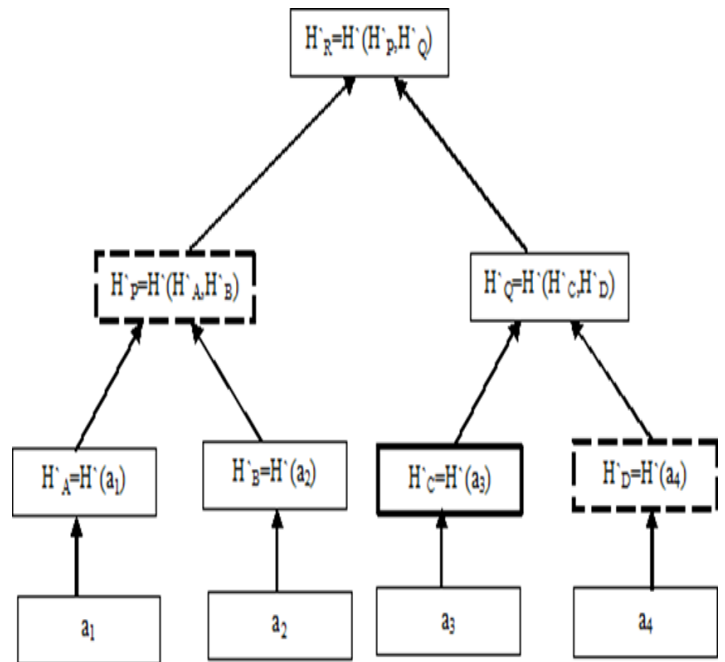

Fig. 4. The proposed sensitive attributes Merkle tree with verifiable nodes.

IV. PROPOSED VERIFIABLE MERKLE PROOF MODEL FOR SENSITIVE ATTRIBUTES

Merkle proof is a type of selective disclosure and is a useful strategy for protecting users' privacy by hiding unwanted sections of certificates or other documents and only offering partial disclosure for evidence. A Merkle proof validates specific transactions represented by a Merkle hash root's leaf or branch hash. Table II represents the list of PCD sensitive attributes for which the tree is generated with the root,  $r$ . The decryptor in the proposed Merkle tree based CP-ABE sensitive attribute access structure scheme will verify the integrity of the non-public attributes by selecting one attribute at random and by giving its hash value as input for the proof. In turn the decryptor will be given few other branch nodes hash values at random. Based on these multiple available hash values, the decryptor constructs the tree resulting to root hash. If the final hash value matches Merkle tree root, it means the attribute exists and the transaction can be processed.

Algorithm for Proposed Model

Step 1:

Consider the access tree [20] ST with root R. Hence,  $ST == TR$ . Where SsT represents the subtree of sensitive attributes tree ST rooted at the node ST.

Step 2:

If  $A(\beta) \in SsT$ , Then denote [15] it as  $SsT(\beta) = 1$ .

Step 3:

Compute  $SsT(\beta)$  recursively as follows.

if(ST  $\neq$  leaf)

Evaluate  $SsT(\beta) = 1 \forall$  children ST' of node ST.

$SsT(\beta) == 1$

iff  $\geq k_s$  with children 1.

if(ST == leaf),

Then  $SsT(\beta) = 1$

iff  $A(ST) \in \beta$ .

V. RESULTS AND DISCUSSION

The proposed Merkle tree based sensitive attribute access structure in CPABE is implemented using the pymerkle package[22], and its performance is evaluated by measuring the time taken to generate the Merkle tree as in Table I and Merkle proof for varying numbers of sensitive attributes using the SHA-256 algorithm. As the number of sensitive attributes increases, the size of the tree and its height also increases, resulting in longer generation times. Additionally, the results show that the Merkle proof computational time increases with the number of sensitive attributes. However, the time taken to generate the tree and Merkle proof decreases as the key size for the SHA-256 algorithm increases. These results demonstrate that the proposed scheme as in Figure 5 is efficient in terms of computational time and can be effectively implemented in real-world scenarios.

A. Comparison with other Frameworks

The Table II represents the comparison of the proposed model with other schemes, covering CPU load, data integrity, proof-of-work, efficiency and privacy. By creating a Merkle tree proof, guaranteeing integrity via a hash and providing effective data access control, the proposed CP-ABE scheme is capable to implement hidden sensitive attribute access policies with less computation load

B. Security Analysis

1) Chosen-ciphertext attack: The proposed Merkle tree model is secure against chosen-ciphertext attack is through the collision-resistant scheme. This means that it is computationally infeasible for an attacker to find two different sets of data blocks that have the same Merkle root.

Let  $H(x)$  be a cryptographic hash function that takes in input  $x$  and produces a fixed-length output. We can construct a Merkle tree with  $n$  leaf nodes, where each leaf node  $i$  is a hash of a data block  $D_i$ , represented as  $H(D_i)$ . The non-leaf nodes in the tree are the hash of their children nodes, represented as  $H(L_i, R_i)$  where  $L_i$  and  $R_i$  are the left and right child nodes respectively.

The Merkle root of the tree, represented as  $R$ , is the hash of the root node and it is computed as  $R = H(H(L_1, R_1), H(L_2, R_2) \dots H(L_{n/2}, R_{n/2}))$ . To show that the tree is collision-resistant, assume that there exists an attacker who can find two different sets of data blocks,  $D_1$  and  $D_2$ , such that  $H(D_1) = H(D_2)$  for all  $i$ . Therefore, the attacker can

construct two different Merkle trees,  $T_1$  and  $T_2$ , with the same Merkle root.

However, since  $H(x)$  is a collision-resistant hash function, it is computationally infeasible for the attacker to find two different inputs  $x_1$  and  $x_2$  such that  $H(x_1) = H(x_2)$ . Therefore, it is also computationally infeasible for the attacker to find two different sets of data blocks that have the same Merkle root, and the Merkle tree structure provides a secure method for verifying the integrity of the sensitive attributes in the access structure. Additionally, the use of a one-way hash function in the construction of the Merkle tree ensures that it is computationally infeasible for an attacker to obtain the original sensitive attributes from the hash values stored in the tree, providing further security against chosen-ciphertext attacks.

TABLE I. TREE GENERATION TIME VS PROOF COMPUTATIONAL TIME

S.No.	Number of Sensitive Attributes	Size/ Total nodes	Tree Height	Merkle Tree generation time (in seconds)*10 <sup>-2</sup>	Merkle Proof computational time (in seconds) *10 <sup>-2</sup>
1.	24	47	5	97.6	23.4
2.	90	179	7	33.0	30.1

Fig. 5. The sensitive attributes vs tree generation and proof.

TABLE II. COMPARISON OF PROPOSED MODEL WITH OTHER FRAMEWORKS

S.No.	Model	CPU Load	Integrity	Efficiency	Proof of work	Privacy
1.	Siti Dhalila et al., [6]	Moderate	Yes	Improved	No	Through fully hiding Full Policy/ file hiding through one-way Hashing
2.	John Bethencourt et al.,[15]	Moderate	No	Nominal	No	The model applicable to large universe of attributes. Policy and Attribute are exposed to unauthorized
3.	Proposed model	Less	Yes	High	Yes	Partial sensitive attribute hiding

2) *Replay attack*: In order to protect against replay attacks, one approach is to include a timestamp or nonce in the data block that is hashed to create the leaf node of the Merkle tree. When a user requests access to a sensitive attribute, the system will re-compute the hash value of the leaf node using the current timestamp or nonce. This ensures that each request is unique and cannot be replayed at a later time.

For example, consider a user requests access to a sensitive attribute at time  $t_1$ , the system will compute the hash of the data block with the timestamp  $t_1$ . If the same user tries to access the same attribute again at time  $t_2$ , the system will compute the hash of the data block with the timestamp  $t_2$ , which will be different than the previous hash computed at time  $t_1$ , hence it will prevent replay attack as the hash values are different.

## VI. CONCLUSION

The Merkle tree based access structure in CPABE addresses the attribute disclosure problem in managing access to sensitive patient information by providing fine-grained control and preserving privacy through attribute hiding. The proposed model, a proof-of-work algorithm, enhances security and integrity for both users and providers in healthcare organizations by using a monotonic access structure for policy transmission and being resistant to chosen-ciphertext attacks and replay attacks. It can also handle large volumes of data and provide quick integrity proof. While the model addresses limitations of existing solutions and provides a secure solution for healthcare organizations, further research is needed to explore its potential in addressing other security challenges and improving its efficiency. Overall, this study makes a significant contribution to the field of secure access control for sensitive patient information.

STMIK Sinar, Nusantara, Surakarta<sup>5</sup>

**Abstract**—Manual water faucets, which are commonly used in mosques and homes, cannot control water use, resulting in a variety of issues, including water waste when the user forgets to close the water faucet, resulting in water continuously coming out. In addition to filling the water tank, which is also an important factor in saving water, the water reserve in the tank must be properly controlled so that its availability is maintained. Based on the existing problems, a water faucet system was made for abluion and monitoring water tanks using Arduino and Telegram. An automatic abluion water faucet system that can drain water automatically with an ultrasonic sensor as a body movement reader and a solenoid valve as a substitute for a faucet. The water pump can help fill the water tank automatically and know how much water is in the tank using an ultrasonic sensor; liquid crystal display and Telegram as recipients of text messages from the results of the condition of water faucets, water pumps, and water levels.

**Keywords**—Arduino; solenoid valves; ultrasonic sensor; pump water

## I. INTRODUCTION

Water is one of the things that is very influential in human life and is needed in everyday life [1]+ because water is a source of life for humans in this world [2]. In human life, clean water is one of the natural resources used by humans for consumption or in carrying out their daily activities and the existence of water sources should be maintained [3][14]. One of them is the abluion used by Muslims to worship before worship, which requires cleanliness and sanctity [4]. One of the abluion activities is to use clean water that flows over certain limbs, namely the face, hands, head, and feet [5].

In places of worship such as mosques, there are rooms used for abluion, and the faucets used are mostly still manually operated to regulate the size of the water output [6]. To adjust the size and volume of water output, the user must turn the faucet lever manually, and the faucet is easily damaged because the faucet lever is often rotated. so that it becomes one of the factors contributing to excessive water expenditure or wasteful water use [7]. Places of worship, such as mosques, must have tanks or water containers to store clean water [8]. The water reservoir is not only a storage area but also maintains the smoothness and availability of water for the needs of the mosque [9][15]. Filling water and monitoring water tanks in mosques is still done manually, so it often causes waste due to negligence in turning off the water pump when the tank is full [10].

From the problems above, it can be formulated how to regulate the expenditure of water used during abluion so that there is no waste of spending water and the use of water can be controlled, and how to find out the water level in the water tank [11]. For this reason, an open-source electronic platform is needed that is easy to use, namely Arduino. Arduino technology can assist in making things automatic, so they no longer need to be controlled [12]. One way to overcome this problem is to build an automatic abluion water faucet as a regulator of water expenditure by using an ultrasonic sensor as a distance reader and a solenoid valve as a substitute for a manual faucet. In addition, the controller built using ultrasonic sensors can also work in real time, so it is suitable for controlling abluion water in mosques. The use of the microcontroller on Arduino, which is designed by adding the HC-SR04 ultrasonic sensor, solenoid valve, and water pump, is made into a system that works under the control of the user interface and can adjust the opening and closing of water faucets automatically [13] and aims to control the expenditure of water so that it is not excessive and to make it easier for mosque guards to know the contents of the tank.

## II. RESEARCH METHODS

The method in this study is used to carry out a planning stage or describe a workflow in compiling an idea with many stages. The stages used in this research method are as follows:

Fig. 1. Research stages

### A. Identification

At this early stage, identification of the requirements that will be needed to design a system is carried out. At this initial stage what is done is to analyze why this research was carried

out. This identification stage is divided into two things, namely needs analysis and work method analysis.

- 1) Identification of needs
- 2) Identify How It Works

### B. Design

The design of this study contains the development of the system work analysis stages, which are changed to block diagrams so that researchers can understand the flow and function of the design that will be made. The following are the stages of this research design. The design of the hardware used in the research is carried out; the design is made in the form of a block diagram to illustrate interconnected diagrams.

### C. Implementation

The implementation phase implements everything that has been well designed, such as hardware design. The hardware implementation stage includes the implementation of connecting modules and the implementation of Telegram.

### D. Function Testing

At this stage, various kinds of tests will be carried out that have been implemented in the previous stage. This stage is carried out by:

- 1) HC-SR04 Ultrasonic Sensor Function Testing
- 2) Relay Function Testing
- 3) Solenoid Valve Function Testing
- 4) Waterpump Function Testing
- 5) Ethernet Shield Testing
- 6) Telegram function testing

## III. RESULT

At this point, the findings of this study, titled "Design of the Ablution Water Faucet System and Monitoring the Water Tank Using Arduino and Telegram," will be discussed.

### A. Identification

Based on the existing problems, it can be concluded from several system requirements regarding the implementation of the design of the abluion water faucet system and monitoring the water tank using Arduino and Telegram, as previously explained, that several needs were needed, including

1) *Identification of needs:* At the stage of identifying the needs that will be carried out, there are several hardware devices to support the implementation of research on the design of the abluion water faucet system and monitoring the water tank using Arduino and telegram, as shown in the following table:

TABLE I. IDENTIFICATION OF REQUIREMENTS (HARDWARE)

No.	Identification of requirements (hardware)
1	Arduino Uno
2	Solenoid Valves
3	Ultrasonic Sensor HC-SR04
4	Water Pump
5	5v Relays
6	Liquid Crystal Display
7	Ethernet Shield
8	Jumper Cables
9	Telegram

In Table I, No. 1, Arduino Uno is a system controller and an electronic prototyping platform that is open-source hardware based on hardware and software that is flexible and easy to use [13]. In Table I, No. 2, Solenoid Valve is a valve that is driven by electrical energy which has a coil as its driving force. In addition, the solenoid valve also has a fast opening and closing response [16]. At No. 3, "The HC-SR04 type ultrasonic sensor is a device used to measure the distance from an object and as an object reader" [17]. In Table I, No. 4, the Water Pump is a water pump motor used for aquariums, fish ponds, hydroponics, robotics, or projects making microcontroller-based applications [18]. In Table I, No. 5, Relays are on-and-off switches that are operated electrically and are electromechanical components [19]. In Table I, No. 6, the Liquid Crystal Display can function to display a sensor result value, display text, or display a menu on the microcontroller [20]. In Table I, No. 7, the Ethernet Shield is a module that is used to connect Arduino to the internet [21]. In Table I, No. 8, Jumper Cables are used to connect all components in the circuit on the breadboard [22]. In Table I, No. 9, Telegram is a cloud-based application, which makes it easier for users to access a Telegram account from different devices and simultaneously [23]. Telegram Messenger is a cross-platform messaging application that allows us to exchange messages without SMS fees because Telegram uses the same internet data package for email, web browsing, and so on [24].

2) *Identify how it works:* In the process of working assistance, it will be explained how the working system works. The following image will explain the analysis of how this system works:

Fig. 2. Working notes

In Fig. 2, explains how the system works, we need to know whether the system we have created is in line with expectations or not. Ultrasonic sensors will be used as input in this research, and data from ultrasonic sensors will be sent to Arduino upon receipt. The relay functions as a limiter on/off the water pump and solenoid valve, while the solenoid valve controls the opening and closing of the faucet. Arduino will process the data and send data output to the LCD in the form of text and numbers. Next, the system will pass the information to telegram via the Ethernet shield network, and then send the information to the server, where the information will be forwarded to a pre-arranged telegram bot, which will automatically route the phone via the telegram messenger.

**B. Design**

The hardware design stages used in the creation of a system are carried out during this design stage. The design is made in the form of a block diagram to illustrate a connected diagram. The following are several design stages in this study:

1) *Hardware design:* Based on the functional block diagram contained in Fig. 3, the system is divided into several parts. Sensors as inputs, Arduino as receivers and senders, relays as on/off switches that act as power regulators that enter the solenoid valve, and solenoid valves as the opening and closing of water faucets, LCD (liquid crystal display) as output that displays data in the form of letters and numbers; Ethernet shield as output, i.e., connecting a telegram to the internet.

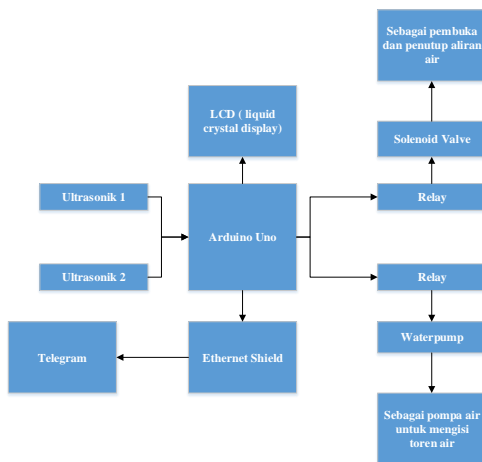

Fig. 3. Block diagram

a) *Series of ultrasonic sensors HC-SR04:* The type of sensor used is an ultrasonic sensor, type HC-SR04. The sensor used to measure the distance of an object is based on the working principle of sound (ultrasonic). The HC-SR04 Ultrasonic Sensor works by shooting sound (ultrasonic) towards objects in front of it. Then the sound is reflected by the object back towards the sensor. The time taken from the sound of the shot until it is received again is used as a parameter to determine the distance between the object and the sensor.

Fig. 4. Ultrasonic sensor circuit

In Fig. 4, this ultrasonic sensor circuit has 4 pins, namely, the GND pin is connected to the GND pin, the VCC pin is connected to the 5V pin, the echo pin is connected to pin 9, and the triangle pin is connected to pin 10.

b) *Relay circuit:* The relay functions as a switch that is operated electrically and carries out the logic functions of the Arduino Uno. The relay is made up of four different components: an electromagnetic coil, an armature, switch contact points (switches), and a spring. The switches located at the contact points themselves are grouped into two types: normally closed (NC) and normally open (NO). What is meant by "normally closed" is the closed position in the initial state when the relay has not been activated. Whereas what is meant by "normally open" is the open position in the initial state when the relay has not been activated.

Fig. 5. Series of relay

In Fig. 5, the relay circuit shows that the relay module has 6 pinouts, namely, GND, VCC, IN, NO, NC, and COM. Then the pin is connected to the Arduino, which serves as a connector. Then the GND pin is connected to the GND pin, the VCC pin is connected to the 5 volt pin, and the IN pin is connected to pin 12.

c) *I2C LCD circuit:* The I2C LCD layer is used as an output to display data controlled by Arduino and has a size of 16x2. Because it produces a good display of characters and a lot, LCD is the easiest display medium to observe. On a 16x2 LCD, it can display 32 characters: 16 characters on the top line and 16 characters on the bottom line. Lcd16x2 employs a special driver that allows the 16x2 lcd to be controlled via I2C lines. Through i2c, the LCD can be controlled using only 2 pins, namely SDA and SCL.

Fig. 6. I2C LCD (liquid crystal display)

Fig. 6 shows that the i2c LCD has 4 pins, namely, the GND pin connected to GND, the VCC pin connected to the 5 volt pin, the SDA pin connected to pin A4, and the SCL pin connected to pin A5.

d) *Relay circuit with solenoid valve and waterpump:* The relay module connects the solenoid valve and water pump to the Arduino. The Arduino's 5 volt pin is connected to the relay module's VCC pin, and the Arduino's GND pin is connected to the relay module's GND pin. Connect the relay module to the positive lead of the 12 volt DC supply and the positive lead of the solenoid valve, and attach the negative lead of the 12 volt DC supply to the negative lead of the solenoid valve. It's the same with the solenoid—how to connect the relay module with the water pump is also the same as with the solenoid. That is the only difference between them and their respective functions.

Fig. 7. Relay circuit with solenoid valve and water pump

In Fig. 7, the function of the relay module with the solenoid is to act as a valve control switch on the solenoid. The function of the relay module with the water pump is the on/off switch for the pump controller.

e) *Arduino circuit with Ethernet shield:* In Fig. 8, the last output component is the Ethernet shield. This board is installed directly on the Arduino Uno by stacking it on top. The SPI.h and Ethernet.h libraries manage communication between the Arduino Uno Board and the Ethernet Shield.

Fig. 8. Arduino uno circuit with Ethernet shield

2) *Network topology design:* The network topology design shows that the Ethernet shield connected to the switch has, of course, been programmed according to the programming instructions that have been made.

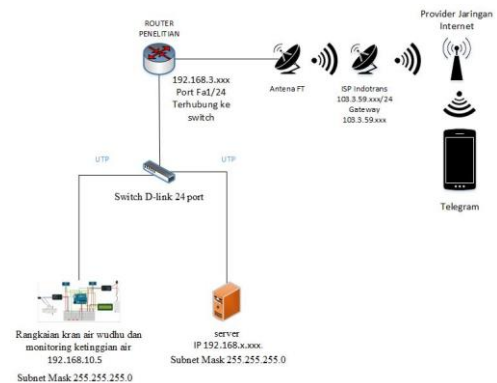

Fig. 9. Network topology design

Fig. 9 is a network design that will be made with a series of tools. To connect the Arduino Uno to the Cisco switch, given the IP address 192.168.x.x./24, use a UTP cable. The CISCO switch is connected to the Mikrotik router with the IP address 192.168.x.xxx/24. Mikrotik router with public IP 103.3.59.xxx connected to ISP Indotrans.

### C. Implementation

In Fig. 10 and 11 at the implementation stage, includes the assembly or installation of all components that are carried out before being implemented in a real system. In addition, the following hardware combinations are implemented in series: HC-SR04 ultrasonic sensor, 5V relay, solenoid valve, water pump, I2C LCD, 12V adapter, Ethernet shield. The following implementation stages will be carried out using a workflow system.

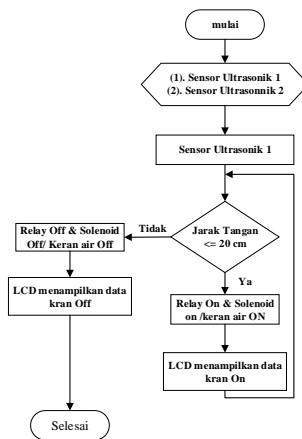

Fig. 10. Water faucet system workflow

Fig. 11. Water level monitoring system workflow

#### D. Function Testing

At this function-testing stage, namely testing the function of the design tool for the ablation water tap system and monitoring the water tank using Arduino and Telegram, This test is carried out so that the tool is made in accordance with the expected goals.

The following are the stages of testing the function of the design circuit for automatic ablation faucets and water monitoring using Arduino Uno and ultrasonic sensors.

1) *Ultrasonik sensor function testing:* In Fig. 12, at the testing stage of the ultrasonic sensor function, the faucet is a test of the ultrasonic sensor when it detects an object approaching. When the sensor detects an object nearby, the relay will be on, and when the solenoid valve is also on, water will flow.

Fig. 12. Ultrasonik sensor testing

2) *Relay function testing:* In Fig. 13 at this stage, testing the function of the relay is carried out when the relay functions as an on and off switch for the solenoid valve and water pump. When relay one is on, the solenoid valve is on; when relay one is off, the solenoid valve is off; and if relay two is on, the water pump is on; when relay two is off, the water pump is also off.

Fig. 13. Relay function testing

3) *Solenoid fungsi solenoid valve:* In Fig. 14, at this stage of testing the function of the solenoid valve, the solenoid valve functions when the relay is on and the solenoid valve is also on. Then, when the relay is off, the solenoid valve is closed. A solenoid valve functions as a substitute for a faucet, whose function is to open and close the flow of water automatically.

Fig. 14. Solenoid valve testing

4) *Waterpump testing:* In Fig. 15, at this stage of testing the function of the water pump, the water pump functions as an increase in water pressure and also as a water filler for the tower. The water pump will turn on if the ultrasonic sensor

detects the water in the tank is low or is about to run out. And the water pump is dead if the water in the tank is full.

Fig. 15. Water pump testing

5) *Ethernet shield testing:* In Fig. 16, this Ethernet shield test, it is done to find out whether the Ethernet shield is connected or not to the internet network so that it can send water level data and control faucets and pumps to see it with the serial monitor on Arduino.

Fig. 16. Ethernet shield function testing

6) *Telegram testing:* In Fig. 17, this stage is carried out to test the function on Telegram. This test is conducted as a notification. This system will send a telegram message in the form of a text on the state of the water tap, water pump, and water level data obtained and will be saved in the database using the abluation water faucet to find out how much content is in the water tank that has been used. The system will send telegram messages in the form of text on the state of the water taps, water pumps, and water level data so that the data obtained will be saved in the database that has been created and can be viewed.

Fig. 17. Telegram testing

7) *Overall tool test results:* The image depicts the state of the abluation water faucet and the monitoring of the water tank with Arduino and Telegram. The ultrasonic sensor that is right at the water faucet functions as a gesture reader. When the hand is under the water faucet with a distance of 20 cm, the relay will be on and the solenoid valve will open the valve so that water comes out automatically when the hand is right under the water faucet. If the distance between the hand and the ultrasonic sensor is greater than or equal to 20 cm, the relay will be off and the solenoid valve will be closed. Furthermore, the ultrasonic sensor located above the water tank functions as a reader of the water level contained in the tank. If the water level in the water tank is less than 5 cm, then the relay is on and the water pump will turn on to fill the water tower. If the water level rises above 30 cm, the water pump will shut down. Then, in the next stage, the system will send a message to the LCD and a telegram in the form of a text of water taps, water pumps, and water level data.

Fig. 18. Overall tool test results

#### IV. CONCLUSION

The conclusions that can be drawn from the results of the tests and discussions that have been carried out regarding the design of the abluation water faucet system and monitoring the water tank using Arduino and telegram. A system has been designed for the application of automatic abluation water taps that can automatically dispense water with the HC-SR04 ultrasonic sensor as a body motion reader and a solenoid valve as a substitute for a faucet that functions as the opening and closing of the water flow. Monitoring the water level in the water tower with the HC-SR04 ultrasonic sensor as a water tap can detect when the contents of the tower are about to run out and alert the level reader in the water tank and a water pump as a water filler can find out the water level in the tank via telegram. After conducting research with the abluation water faucet system and monitoring the water tank using Arduino and telegram, suggestions were made for better development, including 1) In conducting further research, it is expected to be possible to use more than one solenoid valve. 2) It is hoped that further research will monitor via the web and have a database for storing water level data in the tank. 3) For further research, you can expect to use a buzzer when the water in the tank has run out.

Department of Science and Technology, Philippines<sup>5, 6, 7</sup>

**Abstract**—The City of Cauayan Isabela is known as one of the first smart cities and leading agro-industrial centers in the Philippines. Since the center of the economy is in urban areas like Cauayan City, there is a tendency for people and businesses to converge when development and activity take place, with that, a risk analysis was done to analyze hazards for urban water infrastructures in the City of Cauayan. This paper includes an Inventory of the existing urban water infrastructure, with the aid of Geographic Information system Software and gathered data, maps were generated for flood hazards with 5, 25, and 100 yr. return period, liquefaction, ground shaking, and drought of urban water infrastructures. These maps were generated to help the people of Cauayan City, Isabela. The main goal of the paper is to assess the potential prone areas where water infrastructures are located, and monitor areas that are suitable for building such water infrastructures. Problems encountered by the people in utilizing urban water infrastructure can be able to minimize by proper installation of water infrastructures in suitable places which can help the people of the city in water utilization. Since Storm water can cause wide flooding in low elevated areas, to utilize the storm water and to address such problems, an urban water infrastructure with decision support systems intervention can be able to help the city in times of scarcity of water. In addition, the analysis can be used by the local government of the city for proper planning and to project the extent of the hazards.

**Keywords**—Water infrastructure; risk analysis; geographic information systems; decision support systems; storm water

## I. INTRODUCTION

Urban places like Cauayan City in the province of Isabela have a growing population which is a sign that the water demand will increase in future years. Building water infrastructures in places that are prone to hazards like flood, drought, liquefaction, and ground shaking will cause trouble in water utilization which leads to limited sources of water. Thoroughly hazards like flood, drought, liquefaction, and ground shaking will affect the growing economy of the City, and to mitigate the effects of future hazards, a risk analysis can be able to help people to assess the areas where water infrastructures can be installed and for proper planning.

Risk analysis is the process of identifying and assessing potential issues that could negatively impact important business initiatives and operations [1]. This process is utilized in mitigating or reducing certain risks. When performing a risk analysis, adverse events are taken into account, caused by either natural phenomenon, such as severe storms, earthquakes, or floods, or undesirable occurrences brought

about by intentional or unintentional human activities. In addition, the process of a risk analysis helps determine the potential harm from these occurrences, as well as the probability of its occurrences [2].

One of the most frequent types of natural disasters is floods, occurring when an overflow of water submerges land that is usually dry [3]. Floods brought by heavy rainfall can result in a wide range of devastation of critical public health infrastructure, damage of personal property, agricultural sector, and loss of life. From 1998-2017, 2 (two) billion people worldwide were affected by floods [4]. The most vulnerable to floods were the people who live in floodplains or non-resistant buildings, places that are not aware of flooding hazards, or lack warning systems. In this case, a flood risk assessment (FRA) can be done, reviewing the development of documents for its proposal form to consider the possibility of flooding from rivers or groundwater, surface water from sewer sources, estuaries, or even the coast. It must also consider the community and whether a flood risk exists with the development risk to adjacent areas.

Historically, saturated soils have been primarily linked to liquefaction in soils. Unsaturated soils may also be prone to liquefaction in the presence of seismic activity. The consequences of not prioritizing unsaturated soils that are close to saturation as the first rule for liquefaction assessment can be dangerous and disastrous.

Ground shaking is the second main risk for earthquakes due to rapid ground acceleration [5]. There are various levels of ground shaking in one region depending on aspects like topography, type of bedrock, and location and orientation of the fault rupture, all of these have an impact on how seismic waves travel through the ground. Suppose an earthquake is strong enough to cause significant damage to established structures, and sloped terrain may become unstable temporarily or permanently. In a wider extent of earthquakes, districts can be completely destroyed by the effects of ground shaking.

In the natural climate cycle, a drought is a protracted dry period that can happen anywhere. The lack of precipitation makes it a disaster with a slow onset that causes in a shortage of water. Drought can seriously affect agriculture, health, energy, economies, and the environment [6]. Drought affects an estimated 55 million people worldwide every year, and they are the greatest threat to livestock and crops almost everywhere in the world [7]. Due to drought, the livelihood of

individuals is at high risk of disease, death risks are increased and mass migration is fueled. In addition, 40% of the world's population suffers from water scarcity [8], and as a result, the probability of 700 million people being uprooted due to droughts is high by 2030 [7]. On the other hand, regions that are already dry are becoming drier due to rising temperatures brought on by climate change, and wet areas getting wetter. This means that as temperature rises in arid areas, water evaporates more quickly, increasing the possibility of drought or extending the period of drought. Approximately 80-90% of all reported disasters caused by natural calamities over the last ten years have been devastated by floods, drought, tropical cyclones, heat waves, and extreme weather [7].

## II. RELATED WORKS

The identification of locations susceptible to floods and flash floods is an important component of risk management. Floods are natural risk occurrences that vary in severity and cause considerable economic and human losses. They are caused by the interaction of various distinct anthropogenic and natural variables that are particular to a place and have varied impacts on the formation of these events [9]. Around one billion individuals live in flood-prone regions, and floods are regarded as one of the world's most damaging dangers. Under anticipated climate change scenarios, the risks of extreme hydrological events and floods are especially expected to be high and to rise over time [10].

Flash floods are one of the most severe natural disasters, threatening human lives and property in many countries around the world [11] [12]. Floods destroy a large number of people and animals and create catastrophic financial and property damages. They have massive socioeconomic consequences, infrastructural devastation, and environmental disturbance [13]. One of the solutions to solve this is through flood suitability and flood hazard maps that would be useful in assisting local governments, national and international organizations with flood disaster risk reduction and flood shelter design and building [14].

On the other hand, liquefaction is a soil behavior in which strength is reduced and arises due to an increase in pore pressure during earthquake ground shaking on saturated soil [15]. One of the most prevalent seismic consequences that frequently leads to major structure damage during earthquakes is soil liquefaction. Various locations of the world have previously reported liquefaction-induced ground and structure damage in loose, saturated sands and other granular soils [16].

Mapping broad territories for earthquake-induced soil liquefaction danger may appear to be an oxymoron, given that soil liquefaction is a spatially highly limited phenomena in and of itself [17]. In a recent study, they developed combined velocity and fault model that paved the way for further research into seismic segmentation, ground shaking, and rupture modeling [18]. Following the current national earthquake hazard models, the a newly constructed seismogenic source model was established in a paper which includes completely harmonized and cross-border seismogenic sources [19]. In addition, a seismic hazard analysis was also done based from the geologic and geomorphic data [20]. In this study, it includes current and future challenges. Another

study was conducted to develop a region-specific soil behavior type index corrections for evaluating liquefaction hazards [21].

Drought is also considered for assessment in this study. Drought catastrophes endanger agricultural productivity and are projected to worsen as a result of global climate change [22]. Drought analysis was studied that resulted in the identification of key dry periods based on the analyzed drought features, as well as the development of geographic maps of magnitude, length, and intensity for each index for each dry period [23]. Authors have also identified that the standardized precipitation index is used to estimate the drought hazard (SPI) while drought susceptibility is assessed using a variety of indicators, including meteorological conditions, soil characteristics, and irrigation factors [24]. Several models for drought hazards were established like novel hybridized models [25] and MODIS-based Evaporative Stress Index (ESI) and ROC Analysis [26] that offer the spatial resolution required to evaluate regional drought hazard assessment and small-scale agriculture area.

## III. MATERIALS AND METHODS

### A. Flood Hazard

Techniques for assessing the risk of flooding are based on a variety of factors, including meteorological, hydrological, and socioeconomic factors. There are 4 (four) significant phases that are involved in the assessment of flood risk, which include describing the location, estimating the amount of danger, and evaluation of sensitivity and risk as well as intensity. A base map of Cauayan City was obtained from the Local Government Unit of Cauayan, also, secondary data from LiDAR Distribution for Archiving was requested, Using Quantum GIS, this data was processed to determine the extent of flooding. LiDAR flood data includes 5, 25, and 100-yr return periods.

### B. Liquefaction and Ground Shaking Hazard

A base map of Cauayan City was obtained from the Local Government Unit of Cauayan City, also, Secondary data from GEORISK.PH was requested regarding liquefaction and ground shaking, using quantum GIS, this data was processed to determine the extent of liquefaction and ground shaking within the vicinity of Cauayan City.

### C. Drought Hazard

A widely used measure for describing precipitation is the standard precipitation index (SPI) using a variety of timescales for meteorological drought. The SPI is closely related to soil moisture on short time periods, while on longer time scales, it can be related to groundwater and reservoir storage. Regional comparisons of the SPI can be made with climates that differ significantly. It calculates observed precipitation using a consistent scale. Deviation from a chosen probability distribution function represents the raw data on precipitation. Typically, raw precipitation data are fitted to a Pearson type III distribution and then transformed into a normal distribution. SPI values can be interpreted as the number of standard deviations associated with the observed anomaly that deviates from the long-term average. The SPI can be generated using monthly input data for various time periods

ranging from 1 to 36 months.

Rainfall data from PAG-ASA were gathered and served as input to compute the SPI of consecutive months which was analyzed through QGIS. This open-source software was used to analyze and generate a drought hazard map of different existing water infrastructures of Poblacion Cauayan City, Isabela. Existing water infrastructures are: water elevated infrastructures, drainage networks, flood control, and irrigation infrastructures. The principle of the Standardized Precipitation Index was used to analyze and generate maps that include 1, 3, 6, 9 and 12-month SPI through Interpolation. This method requires precipitation data then a calculation of the SPI values out of rainfall data gathered from PAG-ASA was performed to categorize the current level of drought occurring in the City.

#### IV. RESULTS AND DISCUSSION

##### A. Flood Hazard

Flood Hazard data from the LiDAR portal for archiving and distribution was gathered. The local government could use the created map for the Cauayan City government for proper land use planning in flood-prone cones and to identify places at high risk of disaster and manage disaster risk, such as effective and immediate evacuation plans and flooding.

A flood Hazard map with a 5, 25, and 100-year return period was created. Based on the 5-year Flood Hazard Map (see Fig. 1) the Analysis shows that the different Existing water Infrastructures were Classified as Low hazard and Medium Hazard(See Appendix Summary Table for Flood Hazard Map 5-year return period) While on the 25-year Flood Hazard Map (see Fig. 2) the analysis revealed that among the water Infrastructures 9 are classified as medium Hazard, 3 are high risk and the rest are Low Hazard (see Appendix Summary Table for Flood Hazard Map ,25-year return period) and for the 100-year flood hazard Map (see Fig. 3) the analysis shows that among the water Infrastructures, 12 are classified as Medium Hazard, 4 are high risk and the rest of the water infrastructures were low hazard (See Appendix Summary Table for Flood Hazard Map 100-year return period).

##### B. Liquefaction and Ground Shaking Hazard

The assessment was based on the geology and seismic source zone, historical reports of liquefaction, geomorphology, hydrology, and preliminary data from the microtremor survey is used to confirm the type of underlying materials. A semi-detailed map has been developed that can be utilized for land use, emergency response, and mitigation planning but shouldn't be utilized for site-specific evaluation. In addition, no construction is prohibited by liquefaction and ground shaking hazard maps, buildings, and construction in places prone to liquefaction and ground shaking are still possible for as long as the appropriate engineering factors are considered.

Based on the Liquefaction Hazard Map (see Fig. 4) the Analysis shows that the different Existing water Infrastructures were Classified as Low Susceptible, Not Susceptible, and Moderate Susceptible. Among the Water

Infrastructures, 14 are Low Susceptible, 1 – is Moderate Susceptible, and 16 water infrastructures are not Susceptible (see the Appendix Summary Table for Liquefaction Map). In Addition, based on the Ground Shaking Hazard Map (see Fig. 5) based on the revealed analysis it shows that the different Existing water Infrastructures were Classified as Destructive Ground Shaking, labeled as PEIS\* Intensity VII (see Appendix Summary Table for Ground Shaking Hazard Map).

##### C. Drought Hazard

According to the generated 1-month SPI Map (see Fig. 6), among the existing water infrastructures in the different barangays of Poblacion it reflects that it is categorized as near normal which ranges from 0.99 to -0.99 (see Appendix Summary Table of water infrastructures for 1-month SPI Drought Map). The 1-month SPI map depicts a map showing the 30-day period's usual precipitation percentage. However, the generated SPI represents monthly precipitation more accurately because the distribution has been made normal. Based on the generated 3-month SPI map (see Fig. 7) it reflects that all water infrastructures at Poblacion are categorized as near normal which ranges from 0.99 to -0.99. In addition, it appears that some of the barangays were categorized as moderately dry ranging from -1.0 to -1.49 which includes barangay Gappal, Dianao, Manaoag, Linglingay and Buyon (see Appendix Summary Table of water infrastructures for 3-month SPI Drought Map). The 3-month SPI offers a comparison between the precipitation over a certain three-month period and the sum of the 3-month totals of precipitation for each of the years included in the historical records. For the 6-month SPI drought map (see Fig. 8) it reflects that 22 barangays were categorized as moderately dry ranges from -1.0 to -1.49 which includes barangays where water infrastructures located and the rest of barangays in the City were categorized as near normal ranges from 0.99 to -0.99 (see Appendix Summary Table of water infrastructures for 6-month SPI Drought Map). A six-month SPI compares the rainfall for that time frame with the corresponding six-month period over the historical data and can be very effective in showing the precipitation over distinct seasons, While on the generated 9-month SPI map (see Fig. 9), it reflects that existing water infrastructures within the vicinity of Poblacion area of the City were categorized as near normal ranges from 0.99 to -0.99 but based on the map generated (see Fig. 9) there are 9 barangays categorized as moderately dry ranges from -1.0 to -1.49 (See Appendix Summary Table of water infrastructures for 9-month SPI Drought Map). The 9-month SPI shows inter-seasonal precipitation patterns over a medium-term duration, typically, it takes a season or longer for a drought to emerge.

The SPI value below -1.5 for these periods is a good sign that dryness has a major effect on agriculture and might also be having an impact on other sectors. For the 12-month SPI map (see Fig. 10), it also reflects that existing water infrastructures within the Poblacion area were considered as near normal ranges from 0.99 to -0.99 while 17 barangays were categorized as moderately dry ranges from -1.0 to -1.49 (see Appendix Summary Table of water infrastructures for 12-month SPI Drought Map). Long-term precipitation trends are

reflected in the SPI at these timescales. A comparison of the precipitation over 12 consecutive months is referred to as a 12-month SPI which is reported in the same 12 months in a row in every previous year for which data is available. Due to the fact that these timeframes represent the sum of potentially shorter timelines, higher or lower than usual, the longer the SPIs typically converge to zero unless a noticeable dry or wet tendency is present.

## V. CONCLUSION AND RECOMMENDATIONS

Risk analysis was done to analyze and identify areas that are prone to different hazards such as flood, Liquefaction, ground shaking, and drought. Based on the flood analysis of existing urban water infrastructures it appears that these infrastructures were at high risk.

The local government would be able to use the generated

hazard maps for identifying flood-prone areas and perform hazard risk reduction and management measures, such as establishing an effective evacuation strategy. In addition, liquefaction, ground shaking, and drought hazard maps also appear the potential areas that are prone to hazards.

## ACKNOWLEDGMENT

**Abstract**—Software-Defined Networking (SDN) is a recent trend that is combined with Internet of Things (IoT) in wireless network applications. SDN focus entirely on the upper-level network management and IoT enables monitoring the physical activity of the real-time environment via internet network connectivity. The IoT clusters with SDN often undergoes challenges like network security concerns like getting attacked by a Distributed Denial of Service (DDoS). The mitigation of network management issues is carried out by the frequent software update of SDN. On other hand, the security enhancement is needed to all alleviate the mitigation of security attacks in the network. With such motivation, the research uses machine learning based intrusion detection system to mitigate the DDoS attack in SDN-IoT network. The control layer in the SDN is responsible for the prevention of attacks in IoT network using a strong Intrusion Detection System (IDS) framework. The IDS enables a higher-level attack resistance to the DDoS attack as the framework involves feature selection-based classification model. The simulation is conducted to test the efficacy of the model against various levels of DDoS attacks. The results of simulation show that the proposed method achieves better classification of attacks in the network than other methods.

**Keywords**—DDoS; SDN; IoT; machine learning

## I. INTRODUCTION

As the frequency of cyberattacks on governments and corporations across the world rises, academics like have been working feverishly to develop effective network intrusion detection systems (NIDS) [1].

Web-based platform attacks, DoS attacks, and malicious insiders are among the most severe forms of cybercrime [2]. Businesses risk having their intellectual property stolen, and governments risk having interruptions to their key national infrastructure if malicious software is permitted to infiltrate the system. Companies use security measures like firewalls, antivirus programs, and NIDS to keep hackers out of their networks [3].

A new architecture, the software-defined network (SDN) [4] divides the network control functions from its forwarding functions. By physically separating the control plane from the data plane, it is feasible to facilitate uncomplicated management of the network [5]. This component of SDN makes it easier to create new types of applications, which in turn promotes the need for a new sort of networking paradigm

that can handle NIDS. Using SDN, developers may quickly and easily design innovative software. SDN controllers have the capacity to incorporate machine learning and deep learning (ML/DL) methodologies [6]. This facilitates better network visibility and security when IoT is interfaced with SDN.

Earlier attempts to deploy NIDS utilizing SDN controllers and deep learning techniques have met with mixed success. In [6], the authors implement a controller based on an anomalous algorithm. They constructed a deep neural network in order to cut down on the number of distinguishing criteria that may be used to discern regular traffic from abnormal traffic. In addition to this, they utilized deep learning strategies in order to evaluate their model [7].

From the problems stated above, it is found that there exists a gap of concurrent processing that effectively retain the level of accuracy while mitigating the attacks in the network.

The selection of a lightweight attack mitigation mechanism using a machine learning (ML) can pose a lighter load to the network and may not affect the network in terms of its computational burden.

In this paper, the research uses machine learning based intrusion detection system to mitigate the Distributed Denial of Service (DDoS) attack in SDN-IoT network. The Intrusion Detection System (IDS) enables a higher-level attack resistance to the DDoS attack as the framework involves feature selection-based classification model.

## II. RELATED WORKS

In order to defend the control and data planes from DDoS attacks, Shoeb and Chithralekha [8] established a controller process priorities are set according to the node trust level, which is configured based on the node behaviour during regular business hours. The node worth is calculated based on its activity. In high-demand situations, the controller is set up to ignore requests from some nodes if the sum of their requests has already reached a predetermined maximum. The controller makes a rule change to one with a shorter timeout, prompting a response from the standard nodes as well.

Support vector machine (SVM) classifiers are proposed by Kokila et al. [9] for detecting DDoS attacks. The SVM must be trained with historical data before it can reliably predict the behaviour of unobserved traffic samples. When compared to

other simulated methods, the SVM has superior accuracy and fewer false positives. However, SVM is very dependent on the accuracy of the data used to train the model.

Xiao et al. [10] suggest a concept that employs a bloom filter in the SDN to detect link flooding attack. When the collector detects a deviation in link use, it checks the switch flow table to determine whether any aberrant flows can be deduced from the data. The detector can perform packet sniffing thanks to a controller that watches the network in real time. Seeing as the Bloom filter retains crucial IP features, it can be used to determine if the packet current classification is anomalous. However, neither a definition of anomalous link consumption nor the controller detection mechanisms are provided.

Lim et al. [11] suggest that changing one IP address is one way to lessen the impact of distributed denial of service attacks. If a host changes its IP address but then continues to send more than some threshold number of packets to the old address, the host will be marked as a bot and banned. It appears from the simulation results that bot-driven DDoS attacks can be countered. The question of what metric or threshold should be used to initiate defensive measures and withdrawal from a conflict remains unclear.

Similar to SVM and Self Organising Machine (SOM), the method for categorizing DDoS attacks described by Phan et al. [12] combines the two models. Both SVM and SOM models can be trained and tested using pre-existing data sets. Each protocol employs its own distinct set of SVMs to filter control-plane communications. If the SVM determines that data from a certain flow could be associated with the attack region, it will forward that data to the classifier. The SOM must decide if the current is appropriate for the current style era. Simulations show that when SVM and SOM are used together, better results are achieved than when using either approach alone.

An approach to detecting distributed denial of service (DDoS) attacks is presented by Chin et al. [13], which makes use of the interplay between a monitor, a correlater, and a controller. The Monitor component alerts the IDS whenever it finds something out of the ordinary on the network. Once the IDS has confirmed the existence of an attack, it will send the relevant data to the correlater.

Hameed and Khan [14] developed a secure protocol using a cooperative DDoS mitigation technique. The exchange of messages, certificates, and signatures are the fundamental

building blocks of the C-to-C protocol. While the signature component is responsible for ensuring the accuracy and integrity of the data, the certificate component is responsible for establishing a trust connection between authenticating controllers. When a controller detects a DDoS attack, it warns its surrounding controllers as soon as possible by transmitting a list of malicious IP addresses and by modifying the policy on the data plane. As a result, access to these packets is being prohibited across the network in a number of different locations. The results of the simulation illustrate how rapidly this method may warn neighbouring controllers and thwart attacks.

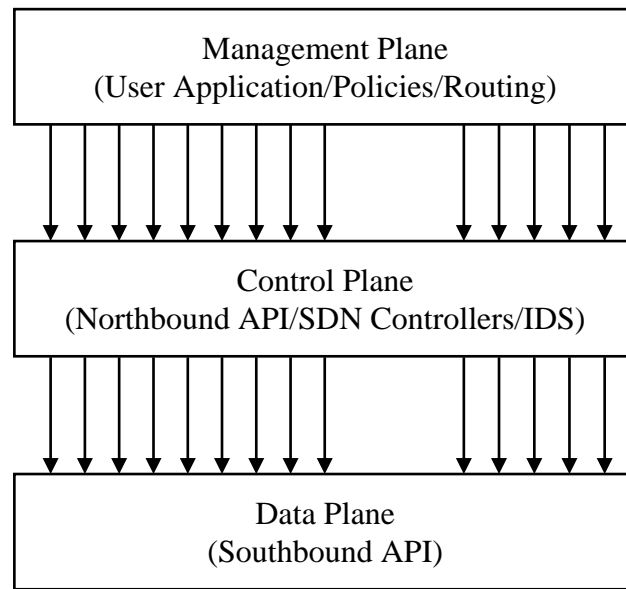

Macedo et al. [15] came up with the idea of a multi-controller cluster when they were developing The DDoS Attack Mitigation in SDN Networks is comprised of these three stages: (i) identifying the overloaded controller by using control message latency or stability; (ii) selecting the controller with the highest performance for coordinated mitigation; and (iii) reducing the impact of attacks. The model identifies the overloaded controller by using control message latency or stability.

A DDoS security architecture was introduced by Sahay et al. [16]. Its primary goal is to reduce the amount of destructive Internet traffic. In order to identify network flows, and the customer end detection engine is the one that determines whether or not the traffic flow is malicious. The status of the connection is communicated from the controller belonging to the customer to the controller belonging to the service provider. A determination made by the ISP controller directs that the harmful flow be sent to the filter so that it can be examined in further detail. Nevertheless, the communication between controllers also needs to be secure.

### III. PROPOSED METHOD

The research makes use of an intrusion detection system that is founded on machine learning in order to mitigate the impact that DDoS attacks have on SDN-IoT networks. The layers of SDN are provided in Fig. 1(a) and when the IoT network connected with SDN layers under attacks is illustrated in Fig. 1(b).

In Fig. 1(a) and 1(b), the control plane in SDN is responsible for mitigating the attacks in IoT network as it is embedded with a strong IDS framework that reads the network logs and classifies the traffic, and mitigates the attacks based on the anomalies present.

(a)

(b)

Fig. 1. SDN layered architecture b) IoT network with SDN architecture

It employs a feature selection-based classification methodology, the IDS is able to withstand more complex varieties of DDoS attack. A simulation is carried out in order to check that the model is capable of withstanding DDoS attacks of varying degrees of severity. The findings of the simulation reveal that the suggested strategy works better than competing alternatives when it comes to classifying network intrusions.

In Fig. 2, a variety of strategies and processes are illustrated for the purpose of putting an intrusion detection system into action. A number of methods have been created, and they can be roughly categorized as statistical approaches, data mining techniques, and machine learning-based methods. These methods were designed to identify anomalies in the data.

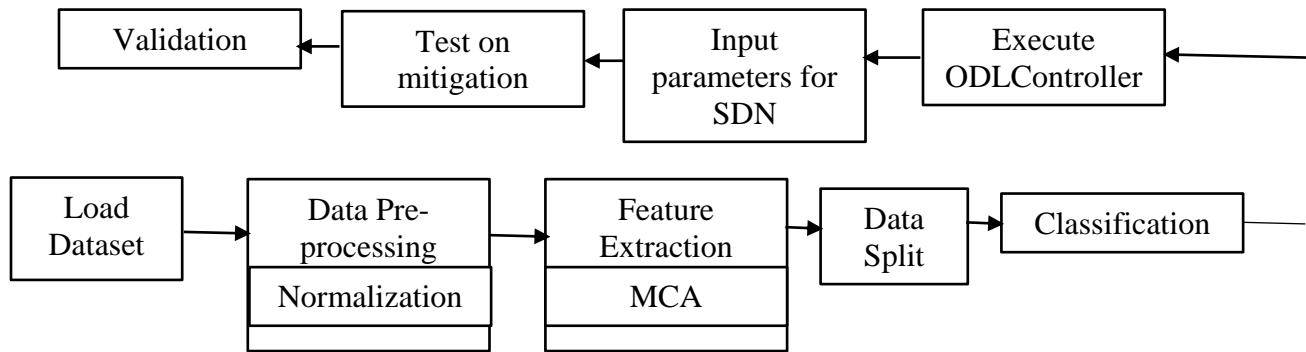

Fig. 2. Proposed IDS framework in SDN controller

A NIDS that relies on signatures can only detect previously discovered strains of malicious software. The detection system makes use of a set of rules that are derived from a combination of packet header and packet content inspection utilizing a present signature in order to identify potentially malicious network activity.

An ML/DL-based SDN-based intrusion detection system excels in a number of different areas, including security enforcement, virtual management, and QoS. SDN provides us with the opportunity to enhance the security of our networks by doing away with the requirement for specialist hardware, providing us with greater creative leeway in the manner in which we build our networks, and making it simpler for us to put into action new security measures.

A SDN can be constructed with fully adjustable features and software implementations of switches by making use of platforms that simulate and emulate real-world conditions. When it comes to putting the ideas of SDN into practice, Open Flow is one of the protocol standards that have been embraced by the largest number of organizations.

The SDN controller, also referred to as a network operating system, is an essential component of SDN networks. The SDN controller is responsible for presenting a consolidated image of the network as well as coordinating interactions with all programmable network components. In addition, there are already a variety of alternative SDN controllers that can be utilized. Fig. 4 is a representation of a network intrusion detection system that is based on SDN.

When compared to NIDS, machine learning makes it abundantly evident that researchers have started applying deep learning techniques. Deep learning is a potential strategy for the next generation of intrusion detection methods, as it can automatically uncover a correlation in the data. When applied to a wide variety of categorization difficulties in SDN networks, methodologies based on ML performed significantly better than state-of-art methods.

Classification problems appear to be where supervised machine learning systems shine the brightest. ML-based approaches performed far better than classic machine learning methods did. Due to the fact that the characteristics of attacks are unknown, unsupervised learning algorithms such as stacked autoencoders, RNNs, and hybrid-based algorithms will prove to be the most successful algorithms for implementing NIDS on an SDN platform.

### A. Pre-Processing

The technique begins with the normalization of the dataset. The raw data is processed so it is standardized for the subsequent processing steps. This makes the entire thing simpler to design and more effective to put into practice. The first normalization of both the training/testing data set happens during the pre-processing step of the procedure.

The degree to which the underlying data are standardized determines a significant portion of the success of the weight coefficients selection approach. The standardization strategy does not incorporate any approaches that can be used to manipulate the detection rate in any way. Normalization of the measured values on a separate scale is conceptually shared scale before averaging the results of the measurements. There are many different kinds of normalization, and some of them require a rescaling technique in order to obtain values that are associated with an entirely new variable. The equation for the normalization of the mean and standard deviation is given as below:

$$\sigma_i^2 = -\frac{1}{(1-m-n)} \sum_{j=1}^n \varepsilon_j^2 \quad (1)$$

where

$\sigma$  - standard deviation

$m, n$  - parameter.

When the errors can be distinguished from one another, they can be formulated as follows:

$$g_i \sim \frac{T\sqrt{O}}{\sqrt{O+T^2-1}} \quad (2)$$

where

$T, O$  – initialized datasets and

$g$  - random variable.

The standard deviation is employed to analyze the change in the variable.

$$K = \frac{\mu^k}{O^k} \quad (3)$$

where

k - moment scale,

$\mu$  - normally ordered distribution

$$\mu^k = S(X - \mu)^k \quad (4)$$

where

X - random variable and

s - expected value

$$O^k = \left( \sqrt{s(X - \mu)^k} \right)^a \quad (5)$$

The scaling is used to normalize the normalizing the variable's distribution,

$$s_v = \frac{S}{X} \quad (6)$$

where

$s_v$  - coefficient of variance.

The study determines the adjusted new normalized value. When applied in mapping fashion, the resulting value can take on values between 0 and 1. Standardization helps give a better training instance since it ensures that all of the training data shares the same field, which could range between 0 and 1. The normalizing formula is represented as below:

$$Ss = (S - S_{min}) / (S_{max} - S_{min}) \quad (7)$$

where

$S_s$  - output of the normalization procedure and S - initial value.

$S_{max}$  and  $S_{min}$  - maximum and minimum attribute values, respectively.

The main aim of the pre-processing involves the data standardization to eliminate the restrict the duplicate information and missing statements.

During this stage of pre-processing, both the input IDS datasets and the dataset itself are standardized, and the dataset is also normalized using the missing data.

1) *Feature extraction:* Multilinear Component Analysis (MCA) is widely used for the extraction of most relevant feature. This is because MCA is able to extract the most nuanced features through the incorporation of these search methods. The MCA places a high value on both the redundancy that exists between features and the unique extrapolative potential that each one possesses. There are many different ways to obtain attribute information.

$$Y = V\Sigma U^T \quad (8)$$

where

$V \in R^{S \times S}$  - column orthogonal matrices of Y,

$U \in R^{M \times M}$  - row orthogonal matrices of Y.

$\Sigma$  - diagonal matrix

Thus an attribute obtained using the attribute function (Y) is the combination of orthogonal matrix of both rows and columns and a diagonal matrix.

The capacity of a component to supply information for the data it is believed that the image is mirrored in the variation of the projection. The following equation can be used to evaluate the performance of feature extraction:

$$C_{xc} = \frac{tc_x^j}{\sqrt{t + t(t-1)c_j^j}} \quad (9)$$

where

$C_{xc}$  - correlation between the variables and subsets,

n - attributes.

$c_x^j$  - correlation between the variable and attributes.

$c_j^j$  - average inter-correlation between the attributes.

The ratio of principal components is defined as below:

$$C = \frac{\sum_{n=1}^P \eta_n^2}{\sum_{n=1}^N \eta_n^2} \quad (10)$$

A few principal components can preserve more than 90% of the overall variance of the Y data. This is the case even though the CCV ratio is calculated using only the variables.

### B. Attack Detection

A model distinguishes between a huge volume of normal traffic in order to protect itself from a decentralized attack. The specified input is utilized by the attack in order to perform an estimation of the discrete scalable memory-based attack vector probability approach. Estimating the value of a random variable requires taking its distribution into account as the starting point of the process. The primary goals are to discover context and keep a close eye on relevant data as it emerges by chance. Only by persistent, day-to-day effort will it be possible to realize the goal. It is possible to have a look at the user tendencies as well as the value that is at risk. Using SVM, one may determine the likelihood of a vector value being one of several possible values. It is found by multiplying the value of the standard deviation by the constant that is used in the calculation.

$$P\left(\frac{\emptyset}{x}\right) = \frac{\left(\frac{x}{\emptyset}\right)P(\emptyset)}{P(x)} \quad (11)$$

where

$P(\emptyset)$  - probability distribution function,

$P(x|\emptyset)$  - likelihood function.

$P(\emptyset/x)$  - evidence function.

The probability distribution provides the value of both likelihood and evidence function to find the rate at which the vector value changes.

A direct connection may be made between the likelihood and the posterior probability. The likelihood of the probability is defined as below:

$$F(x) = \frac{f(x)L\left(\frac{x}{y} = y(x)\right)}{\int_{-\infty}^{\infty} f(x)(u)L\left(\frac{x}{y} = y(x)\right)(u)+u} \quad (12)$$

where

$F(x)$  - prior density function.

$f(x)L\left(\frac{x}{y} = y(x)\right)$  - likelihood function.

$f(x)(u)L\left(\frac{x}{y} = y(x)\right)$  - normalizing constant.

Using the probability equation, we were able to essentially create a map of the function irregularity. Following the computation of the attack baseline probability, the results were presented. After that one is able to evaluate the significance of the attack path.

$$A = \min_{i=1:M} OS_i^* \quad (13)$$

After determining the extent of the damage caused by an attack, it is possible to classify the attack. The vector technique might make use of convolutional layers as a crucial layer in order to acquire knowledge more effectively from the input data. It does what its job title implies and reduces low-level features (kernels). However, the convolutional operator lacks rotation invariance as a property of its own. In addition, additional layers in the stack are pooling layers, which result in a reduction in the amount of data. In fact, neural networks and other fully connected structures form the core of the suggested classifier architecture. The first stage of training a classifier is called the feed phase, and the second stage is called the reverse propagation phase.

The network error is what is utilized to generate the parameter gradient, and with that, the weight matrices are updated as part of the process of context propagation. This is

all done by utilizing the network error. Classifier-trained systems must be governed by large amounts of data in order to successfully accomplish classification jobs. Because the classification error is reduced in proportion to the depth of the classifier, which it is carried out.

The target is given a score based on the probabilities that are calculated for it. It is possible to calculate the difference between a single variable and a number of other variables by employing a technique known as the SVM. The recommended method can initially read and reorganize the data and then evaluate the identified technique based on the likelihood that it belongs to each class.

$$F = \Delta M - k(A(M))^2 \quad (14)$$

where

$F$  - feature,

$M$  - pointed feature,

$\lambda_1\lambda_2$  - classified features.

$$\Delta M = \lambda_1\lambda_2$$

$$A(M) = \lambda_1 + \lambda_2$$

The classification based on the scalable memory is defined as below:

$$F = \lambda_1\lambda_2 - K(\lambda_1 + \lambda_2)^2 \quad (15)$$

where

$K$  - empirical constant.

### C. Attack Mitigation

The SDN controllers are able to instruct switches regarding the destination to which packets should be sent when they make use of the Open Flow Protocol Specification. Researchers are able to conduct experiments on real-world networks thanks to a protocol standard known as Open Flow. This protocol standard details the message formats that are utilized by each controller.

This technique needs the establishment of a robust network in addition to the expensive acquisition of various assets so that it can withstand an attack. In the event of a serious DDoS, the upstream network resources need to be severed in order to preclude any reliable local response. Before subscribing to a DDoS mitigation service, there are a number of elements that need to be taken into consideration. Some of these factors include scalability, endurance, stability, and network traffic. This is only a passing phase that will resolve itself when some time has passed. The modified attack device packets will be transmitted to an analysis service at some point in time.

#### IV. RESULTS AND DISCUSSIONS

In this section, setting up the cloud with the necessary conditions exist is part of the system model configuration. Using the deep learning model, we report the results obtained from the CTU-13 botnet and the ISCX 2012 IDS datasets. Ninety per cent of the total sample size is split evenly between the training and testing stages. To clarify, this means that 90% of the sample is used for training, while the remaining 10% is split evenly between validation and test data. Our group used a 10-cross validation technique to ensure the accuracy of the results. The current plan is to use 9 partitions from the total data samples as training samples and 1 partition as a testing sample. Each of them will be selected at random. The procedure is repeated ten times, and the final result is the mean of these ten separate estimates.

The proposed method is compared with existing machine learning methods like ANN, SVM and SOM.

TABLE I. SIMULATION PARAMETERS

Parameters	Values
Packet Size	1442byte
Bandwidth	10 Mbps
Monitoring Time	20 s
Forwarding Method	Fitness route

The 99.12% accuracy achieved on the training data sample is matched by the 98.88% accuracy achieved on the test sample using Table I.

Fig. 3 shows the results of accuracy in detecting the attacks with the conventional NIDS models. The results show that the proposed NIDS has a higher rate of accuracy than the other methods. The range of accuracy using the proposed SVM classifier along with the feature extraction and pre-processing information is between the range of 95-96% and this is higher than the existing methods.

Fig. 5. Recall

Fig. 4 shows the results of precision in detecting the attacks with the conventional NIDS models. The results show that the proposed NIDS has a higher rate of precision than the other methods.

Fig. 5 shows the results of recall in detecting the attacks with the conventional NIDS models. The results show that the proposed NIDS has a higher rate of recall than the other methods.

Fig. 6. F-measure

Fig. 6 shows the results of f-measure in detecting the attacks with the conventional NIDS models. The results show that the proposed NIDS has a higher rate of f-measure than the other methods.

Fig. 7. MAE

Fig. 7 shows the results of mean absolute error (MAE) in detecting the attacks with the conventional NIDS models. The results show that the proposed NIDS has a reduced error than the other methods. From the results of simulation, it is seen that the proposed SVM has reduced error rate than the existing methods.

## V. CONCLUSION

In this paper, we employ a machine learning-based IDS to protect the SDN-IoT networks from DDoS attacks. The framework involves feature selection-based classification allows the IDS to offer better defence against DDoS attacks. The resilience of the model to DDoS attacks of varied severities is tested via simulation. The simulation results show that the proposed approach is superior to other options for identifying and categorizing network intrusions. In future, the attacks on large scale network can be mitigated using multi-

SDN controllers which reduce single point of failure and this cannot pose a serious computational burden on the networks.

**Abstract**—Customer reviews of products and services play a key role in the customers' decision to buy a product or use a service. Customers' preferences and choices are influenced by the opinions of others online; on blogs or social networks. New customers are faced with many views on the web, but they can't make the right decision. Hence, the need for sentiment analysis is to clarify whether opinions are positive, negative or neutral. This paper suggests using the Aspect-Based Sentiment Analysis approach on reviews extracted from tourism websites such as TripAdvisor and Booking. This approach is based on two main steps namely aspect extraction and sentiment classification related to each aspect. For aspect extraction, an approach based on topic modeling is proposed using the semi-supervised CorEx (Correlation Explanation) method for labeling word sequences into entities. As for sentiment classification, various supervised machine learning techniques are used to associate a sentiment (positive, negative or neutral) to a given aspect expression. Experiments on opinion corpora have shown very encouraging performances.

**Keywords**—Topic modeling; aspect-based sentiments analysis; aspect extraction; sentiment classification; machine learning

## I. INTRODUCTION

In the last few years, the use of the internet and online interactions has grown tremendously. A significant quantity of data are generated daily via social media, forums, chats, and other sources that is primarily displayed as natural language text[1]. The way internet users behave online has also changed how the internet works. For instance, rather than being merely content consumers, internet users are becoming content creators[2]. One significant piece of information that is produced daily within the wide range of content produced by internet users is opinions[2].

Internet users have the ability to criticize or popularize a service or a product with a simple comment or review on the internet and in different fields[3]. Numerous enterprises and businesses have taken advantage of this pertinent data to offer the greatest services or goods for their clients. Among these areas, tourism which is a continuously developing industry and an important key industry for many regions and countries[4]. The opinions and reviews of tourists who visit touristic places every year are shared on various sites such as TripAdvisor, Booking and Yelp...etc[5][6]. Internet users do not have the ability to read, understand and summarize the large number of reviews available for a specific hotel. It is challenging for a simple user to make use of the information at hand to choose a comfortable hotel for his/her trip. The principle on which this

work is based is to carry out an analysis of customers' opinions on hotels located in Marrakech in order to allow them to improve their services and focus more on the main obstacles that have an impact on the attractiveness of these hotels. In this article, a study and application of Aspect-Based Sentiment Analysis are carried out in the hotel and tourism industry. Specifically, opinions will be analyzed so as to determine the sentiment that is expressed towards certain characteristics of the hotel and the service delivered by its employees. The main goal is to produce results whose conclusions can provide directions that lead to improve the performance in sentiment analysis[7]. To achieve this goal, several objectives will be accomplished. The first objective is to use the various preprocessing steps available for text preprocessing. The second objective is using existing libraries like, TextBlob or Vader to label the dataset. The third aim is to use and compare multiple classification methods to classify the views so as to correct aspects and sentiments, i.e., classification of online comments into polarity (negative, positive, and neutral), and finally apply an Aspect-Based Sentiment Analysis on the product (hotel) features identified. In order to achieve these objectives through a clear and logical progression, this work will be presented according to the following structure. Section II will be devoted to the different related works linked to the Aspect-Based Sentiment Analysis. As for Section III, it will expose a background of Topic Modeling and Machine Learning model. The construction of the DataFrame, the methodology and the experimental results will be presented in Section IV. A summary of the experiment's results will be shown in Section V. Last but not least, Section VI will be devoted to the conclusion and future work.

## II. RELATED WORKS

For aspect-based opinion classification, aspect extraction is a crucial task. The vast bulk of extractions techniques have recently been put forth for the tourism industry. These methods have employed a variety of mechanisms and techniques to extract crucial information from tourism reviews. These methods can be split into three primary groups: methods based on rules, seeds, and topic models. There are several works in the field of hotels and tourism that concern Aspect-Based Sentiment Analysis which will be described as the following:

"Pekar et al." [8] utilized TermExtractor to divide hotel reviews into terms. The terms were then trained in a lexicon. Finally, they manually extracted from the term lexicon the six most obvious characteristics (single nouns and multi-word

nouns). This proposed method is based on rules that allow to extract aspects from hotel reviews using aspect appearance on every review.

Similar preprocessing steps were used by "Muangon et al." [9] and were supported by LexToPus. These steps are used to categorize all hotel reviews into features. These characteristics include polar words as well as aspects. They extracted all of the top-rated aspects using a prioritized method.

"Marrese taylor et al." [10] have suggested an algorithm with the goal of extracting aspects. Aspects from restaurant reviews can be extracted thanks to this algorithm. The authors converted the reviews into sentences and then used Part-Of-Speech tagger to extract nouns from the sentences.

A different method for aspect extraction was proposed by "Hai et al." [11]. According to two criteria—domain specific and domain independent—the authors extracted aspects. They created a list of candidate aspects by first using syntactic dependency rules. Then, they determined the intrinsic domain relevance score (IDR) and extrinsic domain relevance score (EDR) for each specific domain and independent domain of each extracted candidate feature, respectively. And at the end, these candidate features are extracted from the list of candidates that have low IDR score and high EDR score.

An algorithm based on a bootstrapping approach, which has been proposed by "Wang et al." [12], extracts the main aspects of the review. In this algorithm, each sentence was initially given an aspect based on the maximum of overlap between its words and the aspect. Then, to examine the relationship between the allocated aspect and the sentence words, they determine the basic dependencies between them. Finally, sentence words that have a strong relationship with the assigned aspect are added to the list of aspect keywords and are considered to be aspects.

BESAHOT, which is a system that has been presented by "Walter Kasper et al." [13], performs analyzed comment processing for text segmentation, statistical polarity detection of text segments, and extraction of linguistic information from review topics and their aspects. It is a quality control support system for hoteliers that provide them with complete overviews and summaries of their hotel and how it is rated and commented by users on the web.

### III. ASPECT-BASED SENTIMENT ANALYSIS

An essential task in the field of Sentiment Analysis is Aspect-Based Sentiment Analysis (ABSA) [14]. It involves assigning a polarity (positive, negative or neutral) to each aspect evoked in an opinion sentence. Aspect extraction and aspect-level sentiment analysis are often the two main tasks used to accomplish this.

Although traditional Sentiment Analysis is done using document and sentence level Sentiment Analysis techniques, the current trend is to move to a deeper level which is presented as ABSA (features). This latter [15] performs a deeper and a better analysis, as it directly examines the opinion itself. This domain is a deeper end in Natural Language Processing (NLP) [16] where it presents a richer problem for researchers.

One of the main features of NLP is Topic Modeling. Topic Modeling can be applied to any form of text: emails, tickets, feedbacks, etc. in order to have a global vision of customers' concerns.

#### A. Topic Modeling

Natural Language Processing (NLP) [17] includes Topic Modeling, which is used to train Machine Learning models. It entails identifying from a document or corpus of data the words of themes that are associated with a particular topic.

Topic Modeling is an unsupervised Machine Learning approach to discover topics in various text documents. It can find patterns of words and phrases and automatically cluster groups of words and associated phrases that best represent the whole [18]. It also provides a useful view of a large corpus in terms of the relationships between them and individual documents.

The figure above (Fig. 1) represents the ordinary workflow of the thematic modeling process. A set of text documents is introduced into the black box of the thematic modeling algorithm and the following results are obtained:

List of Topics: Topics are the key themes representing the entire collection of documents. Each topic consists of several words that occur at the same time. A word can belong to more than one topic because a word can have a different meaning in a different context.

Topic Definition: A topic is represented by the weighted frequency of words. Each topic can be interpreted as a theme.

Topic Distribution of Document: Each document is represented as a topic distribution where the weight of a topic defines the part of the document covered by that topic. In a way, it provides a "soft grouping" of the document.

Topic modeling is a method for selecting a set of topics from a group of documents that best summarizes the information in the group. To create topic models, numerous techniques are employed. One of the areas of interest is in: LDA, LSA, NMF, and Corex which will be discussed later on in this section.

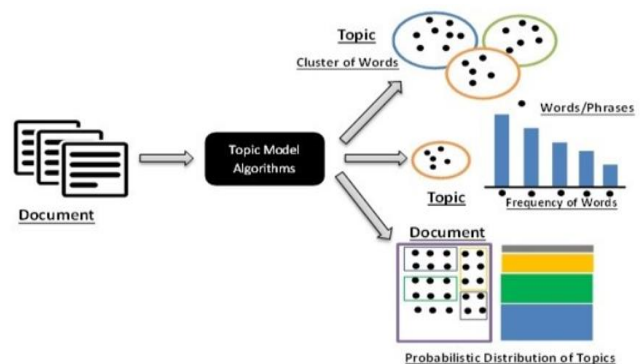

Fig. 1. Topic models process

1) LDA: Latent Dirichlet Allocation, [19] is a powerful learning algorithm for automatically and jointly classifying words in documents in mixtures of contexts. It has been successfully applied to model changes in scientific domains

over time. LDA is a probabilistic generative model. Based on the assumption that the order of documents in the collection and the order of words in a text are indifferent, LDA defines finite mixture models on sets of underlying topics to generate the collection. Each topic is being modeled as an infinite mixture on probabilities of the underlying topics. In an iterative procedure, these probabilities are computed several times, until the algorithm converges.

Advantages: Among the advantages of using the LDA method, the following are worth mentioning:

- LDA is easy to implement, understand and use.
- It maximizes inter-class scattering.
- It reduces intra-class scattering.

Disadvantages: Despite these advantages, a set of negative points still exist such as:

- LDA is costly in computation time.
- It is also costly in memory space.
- It renders poor results when the number of training images is large.
- It is hard to know when LDA is working. Metrics like perplexity are acceptable to check if learning is working, but there is a very poor indicators of overall model quality. For example, you could have a model with very low perplexity, but whose topics are not very informative.
- The topics are predicated on the multinomial distribution, while the words are predicated on a different multinomial distribution formed specifically for this topic. The structure may not be properly adjusted if the real structure is more complex than a multinomial distribution or if the data needed to construct the structure are insufficient.
- The user specifies the total number of subjects in the dataset (or bases it on a certain distribution using sampling), which is subjective and may not always reflect the true distribution of subjects.

2) *LSA*: Latent Semantic Analysis [20], or *LSI* (Latent Semantic Index), employs a bag-of-words (BoW) model, creating a term-document matrix (occurrence of terms in a document) [21]. Terms are represented in rows, and documents are represented in columns. By applying singular value decomposition to the term-document matrix, LSA can identify latent subjects. It is typically applied as a technique for noise or dimension reduction. In this method, document analysis is done by machines using Term Frequency-Inverse Document Frequency (TF-IDF). TF-IDF is a metric that quantifies the significance of a word for a corpus of documents.

Advantages:

- Easy to understand and implement.

- In comparison to the vector space model, it shows improved outcomes.
- Only involves the decomposition of document term matrix which makes it faster than other available algorithms.

Disadvantages:

- In general, LSI is very slow on large corpora and not very accurate compared to LDA.
- The dimension of the latent subject depends on the rank of the matrix.
- The decomposed LSA matrix is extremely dense, making it challenging to index the individual dimension.
- Polysemy cannot be captured by LSA (multiple meanings of a word).
- It provides less accuracy than LDA.

3) *NMF*: Since the non-negative matrix factorization [22] is an unsupervised method, the subjects on which the model will be trained are not labeled. NMF factors or decomposes high-dimensional vectors into a representation that has a lower dimension. Since the coefficients of these lower-dimensional vectors are nonnegative, they are likewise nonnegative vectors. Consider the general scenario where there is an input matrix  $V$  with the form  $m \times n$ . This approach divides  $V$  into two matrices,  $W$  and  $H$ , whose dimensions are  $m \times k$  and  $n \times k$ , respectively. In this case,  $V$  stands for the term document matrix,  $H$  stands for an embedded word in each row, and  $W$  stands for the weight of each word found in each sentence.

Advantages:

- NMF can handle missing values naturally and this property leads to a new method to determine the rank hyper parameter.

Disadvantages:

- NMF cannot be applied to several real-world issues where the domain limited knowledge of experts is available
- It sometimes provides semantically incorrect results

4) *CorEx*: Contrary to LDA and NMF, the semi-supervised topic model Correlation Explanation [23] allows to give the model "anchor words" which exemplified potential topics that the model might be looking for. CorEx also allows to provide the model with a confidence score for the anchors. If this choice is less certain, the model may forgo the target recommendations if they don't sufficiently match the data. This new capability is strong in guiding a thematic model with the chosen domain expertise. CorEx provides a flexible framework for learning topics that are maximally informative about a text corpus. The CorEx topic model makes few assumptions about the LDA structure and flexibly incorporates domain knowledge through user-specified

"anchor words". With anchor words, one can guide the topic model to topics of substantial interest, interact with the topics, and refine them in ways not possible with traditional topic models.

Advantages: CorEx competes with LDA in terms of producing semantically consistent topics that aid in document classification. By citing above some advantages of this model [23]:

- The CorEx's modeling algorithm is rapid.
- It searches for topics that are "maximally informative" about a set of documents rather than assuming a specific model of data generation.
- Word-level domain knowledge can be flexibly integrated into the CorEx thematic model.
- It consistently creates document clusters with higher homogeneity than LDA in terms of clustering.
- The CorEx anchor steers the thematic model toward topics that don't naturally arise and frequently results in topics that are more coherent and predictable.

Disadvantages: Despite the number of advantages of the CorEx thematic model over LDA, there are some drawbacks[23]:

- The sparse implementation necessitates that every word appears in just one topic. It is not a matter of fundamental theoretical limitations, but rather of computer efficiency.
- CorEx relies on binary accounting data for its parcel-level optimization rather than the usual accounting data that are input into LDA and other theoretical models.

Despite binary number limitations, CorEx nonetheless discovers a reliable and competitive structure in the data.

### B. Machine Learning Model

The determination of the direction of the opinions in a text divided into two or more classes on certain features is known as classification of opinions by aspect. The classification of opinions has been done into several categories, such as binary, ternary, etc.

Typically, the classification task is defined as the task of predicting the label that is to say, assigning each given object to a group based on a classification rule. The primary goal at work entails classifying aspect opinions, thus training a classifier to predict the label for each input text is needed. There are three kinds of polarities (positive, negative, or neutral). In this section, the most common employed algorithm shall be outlined. [24].

1) *Logistic regression (LR)*: This is an analytical technique key in the social and scientific sciences [25]. Logistic regression, which also closely resembles neural networks, is the standard supervised Machine Learning approach for classification in natural language processing. A logistic function is used in logistic regression to create discrete dependent variables from a series of data points.

2) *Support vector machines (SVM)* [26]: This can be applied to both regression and classification tasks. SVM methods aim to partition linearly separable data into two classes with the maximum distance between them. In the high-dimensional space, SVM identifies an ideal hyperplane that separates the input data with the greatest possible margin between it and the point(s) that are closest to it. The points for which the margin is reached are called support vectors. A kernel function can be used to map the data into a higher dimensional space in order to make them linearly separable if the input data are not linearly separable. The polynomial kernel, Gaussian radial basis function, and sigmoid kernel are the three most widely used nonlinear kernels.

3) *K-nearest neighbour (K-NN)*: This is one of the simplest Machine Learning algorithms used for classification and regression problems[27]. The information is subsequently allocated to the class with the closest neighbor based on the nearest measures.

4) *Naïve bayes (NB)* [28]: This Machine Learning algorithm can be used to divide objects into two or more classes, such as text documents. It is founded on the Bayes theorem, which uses conditional probabilities as its foundation.

5) *Decision tree (DT)*: This is part of the supervised algorithms in the field of Machine Learning [29]. Their principle is to divide learning data into groups whose content becomes increasingly homogeneous until pure data are obtained (belonging to the same class) or a maximum number of partitions is reached. The resulting model is a tree composed of several decision rules and is easily interpretable. As with any supervised learning method, decision trees make use of examples. Building a decision tree by category is necessary if one has to categorize the documents. In order to determine to what extent a category a new document belongs to, the Decision Tree will be used for each category in which the classified document is submitted. Each tree responds with yes or no.

6) *Random forest (RF)* [30]: This is a prediction method that Ho developed in 1995. In 2001, scientists Leo Breiman and Adele Cutler formally proposed the algorithm. It is made up of various decision trees that each focus on a different aspect of the problem independently. Multiple decision trees are produced by this classifier using a subset of the training data that is randomly chosen. The final class of test objects is then decided by aggregating the votes from various decision trees.

7) *ExtraTrees (ET)*: Extremely Randomized Trees [31] is an ensemble-supervised Machine Learning technique that makes use of decision trees. It builds multiple trees and divides the nodes using random subsets of features, but the sampling for each tree is without replacement. As such, the most important and unique feature of the algorithm is the random selection of a splitting value for a feature, which makes the trees diverse and uncorrelated.

8) *AdaBoost (AB)* [32]: This is a widely used boosting algorithm. It builds a majority vote iteratively. Over the iterations, it maintains a weight distribution on the training examples so that poorly classified examples see their weight increase and well classified examples see their weight decrease. At each iteration, the weak learning algorithm is trained with the set of weighted examples and the resulting classifier is added to the majority vote.

9) *GradientBoost (GB)*: A meta estimator that fits a series of weak learners is gradient boosting [33]. It is a powerful Machine Learning algorithm used to solve regression and classification problems. It creates a prediction model in the form of a collection of weak prediction models, typically decision trees. It builds the model incrementally, much like other boosting techniques do, and generalizes them by enabling the optimization of an arbitrarily differentiable loss function.

#### IV. BUILDING THE DATAFRAME

The workflow and the subtasks for each phase are shown in Fig. 2. The learning phase and the testing phase are the two steps that make up this workflow.

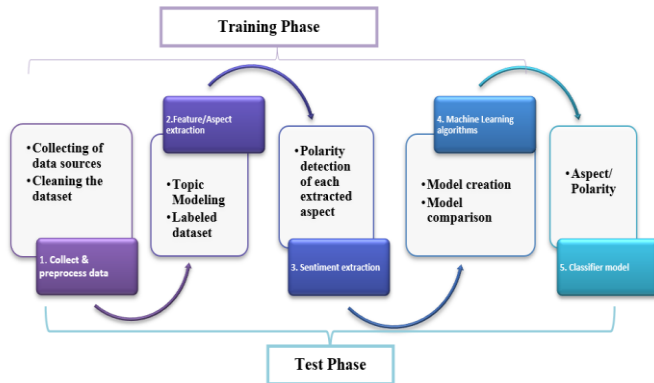

Fig. 2. Aspect-based sentiment analysis workflow

##### A. Training Phase

Fig. 3 gives an overview of this process namely the collection, the data sources and the pre-processing of the datasets. The main tasks of each step are described in the paragraphs that follow.

1) *Data sources*: User opinions are the main criterion for enhancing the quality of the services provided and improving the value of the products delivered. These opinions can be found in different data sources namely review sites, blogs and micro-blogs.

a) *Review sites*: Opinions have the role of decision makers for any user during the purchase phase. User generated reviews of products and services are widely available on the

internet. Sentiment ratings or texts use reviewer data collected from websites such as TripAdvisor and Booking (hotel reviews). These sites host millions of visitors' hotel reviews.

Fig. 3. Sentiment analysis process at aspect level

b) *Blogs and micro-blogs*: Blogs and micro-blogs are among the most popular communication tools of internet users. Millions of messages are posted every day on well-known microblogging platforms including Twitter, Tumblr, and Facebook. Sometimes Twitter messages express opinions that are used as a source of data to classify sentiments.

2) *Data collection*: The data acquisition or collection phase consists of obtaining the corpus to be analyzed. The "web scraping" method [34] is used to collect the reviews, since the goal is to collect reviews from various hotels in Marrakech. As shown in Fig. 4, each entry in this dataset is structured as follows:

- *Hotel\_name*: designates the name of the establishment (Hotel)
- *Title\_review*: refers to the title written by the client to give a general summary
- *Reviews\_hotel*: contains reviews (text), written in English
- *Rating\_date*: indicates the date of publication of a journal
- *Score\_rating*: the evaluation given by each customer between 10 and 50

The reviews for 10 different hotels in the city of Marrakech are obtained from two websites (booking and TripAdvisor). The dataset consists of 21619 reviews in English, but only 14356 reviews are used for this study. Table I represents a summary of the dataset used:

TABLE I. SUMMARY OF THE DATASET

Domain	Numbers of reviewers	Words average
Hotels	14356	7.06

	Hotel_Name	Title_review	reviews_hotel	Score_rating	Rating_Date

4	Radisson Blu Hotel, Marrakech Carre Eden	Refund Refused despite the Pandemic	I was an expat living in Marrakech. Four of us...	10	19 November 2020

Fig. 4. Example of datasets

3) *Review pre-processing*: The pre-processing procedure followed in this work aims to clean up the notices and to make them as close as possible to a formal language. First, the notices were filtered considering only those written in English. Because a corpus of different languages is a corpus that contains noise. To do this, a Python library called Langdetect is used and then proceeded to a pre-processing that follows the following steps:

Split the text into several rows: As represented in Fig. 5, this task consists of splitting the text contained in each cell of the "Reviews\_hotel" column into several rows by the '.' delimiter, for example:

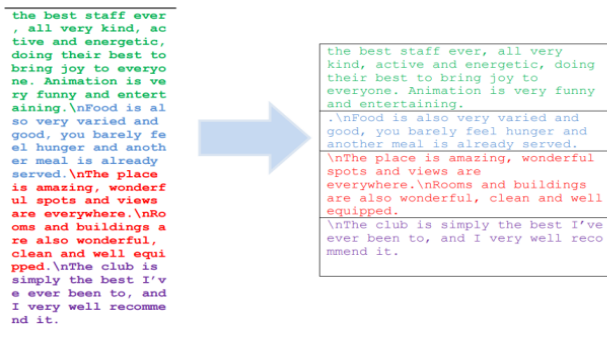

Fig. 5. Example of paragraph splitting into multiple lines

Noise cleaning - spacing, special characters, lowercasing: In a text you can find various characters such as numbers, free white spaces, all kinds of punctuation and some terms are put in random capital letters. This form of noise cleaning takes care of the spacing and special characters. Turning all words into lower case is also a very common pre-processing step. Next, all punctuation and special characters will be removed since they serve no purpose once analyzing the data begins.

Eliminate emoji: One cannot ignore the content of the notices full of emoticons, symbols and pictographs as well as a set of flags. So, this task concerns the elimination of these characters.

Tokenization / eliminating words below three letters: First, separating the corpus into a vocabulary of single terms is essential, which is called tokenization. Individual terms and overwrite all words below three letters can be tokenized.

Delete Stop Words: Some words in English, while necessary, do not contribute much to the meaning of a sentence. These words, such as "when", "had" or "before", are called stop words and should be filtered out.

Stemming and lemmatization of the text: The process of turning a word into its Racine form is known as racinization.

Rooting can create non-real words. Lemmatization, as opposed to racinization, aims to obtain the canonical (grammatically correct) word forms, or lemmas. In terms of calculation, lemmatization is much more difficult and computationally expensive than racinization. In actual practice, the two methods have little impact on the performance of text classification.

4) *Aspect terms extraction*: To accomplish the Machine Learning task, the aspect or category detection of each review must be first tackled. This can be done according to different tools described in Section III. Topic Modeling has been tested using LDA techniques as well as CorEx and NMF.

For this experimentation, 9 Aspects are predefined: Rooms/Cleanliness, Location, Staff, Food/Restaurant, Experience/Value, Price/Quality, Service, Amenities/Activities, and Hotel/Property.

5) *Topic modeling*: In this section, the steps as well as the result of the three topic modeling methods have been presented, namely, LDA, NMF and CorEx. The steps followed using LDA are: corpus vectorization which allows to create the term matrix document using Counvectorizer which is an excellent tool provided by Scikit-learn library in Python. It is used to transform a given text into a vector based on the frequency (number) of each word that occurs in the whole text. Then, the LDA model will be built, to evaluate this performance with perplexity and log probability. Gridsearch was used to choose the "right" number of topics for the LDA model, then two hyper parameters (learning decay and number of topics) were tested. And finally, the labeled topics joined the original text.

In Non-negative Matrix Factorization (NMF), the first step is to convert the document into a term-document matrix which is a collection of all the words in the given document using the TfidfVectorizer. Then, build the NMF model with Scikit-learn and view the original topics. And as far as CorEx is concerned, the first step is the corpus vectorization which converts the document into a document-Terms-matrix using the TfidfVectorizer by creating a vocabulary containing the topics. The second step is the creation of the model, starting with the identification of the Anchors (anchored words) and then creating the model that allows to generate the set of topics. In each of these models, topics related to four distinct themes for LDA and NMF can clearly be seen. But it is also clear that these topics contain words that can apply to multiple contexts and cause problems in certain circumstances. The following table (Table II) illustrates the comparison between these techniques:

TABLE II. COMPARISON OF THE THREE EXTRACTION METHODS

	LDA	NMF	CorEx

While topic models can be rapidly run, they are not necessarily as accurate in their classification decisions as the more complicated supervised learning models, and occasionally their outputs can even be outright false. Semi supervised topic modeling will be utilized to determine the main topics of these documents in order to prevent ambiguities between topics. This most recent development gave a middle ground between supervised classification modeling and unsupervised topic modeling.

From the comparison table, CorEx provides more specification of aspects than the others, CorEx is chosen as the best, as the grouping of each aspect seems better. Fig. 6 shows what the dataset looks like at this point.

	review_text_clean	Score_rating	dominant_topic	Categorie_Aspect
0	nice experience hotel amaze view	50	4.0	Experience/Value

14354	food	30	3.0	Food/Restaurant
14355	price pay overall happy	30	5.0	Price/Quality

14356 rows x 4 columns

Fig. 6. Datasets after aspect extraction

6) *Annotation of journals:* For review annotation, reviews were labeled using two tools VADER (Valence aware Dictionary and Sentiment Reasoner) and TextBlob. There are three types of sentiments in this dataset: positive, negative, and neutral. To pursue the supervised learning approach, the type of sentiment (polarity) of each review should be known.

VADER has been chosen since it provides a better classification and more negative feelings than the other (Fig. 7).

	review_text_clean	Score_rating	dominant_topic	Categorie_Aspect	scores compound	Sentiment_Vader
0	nice experience hotel amaze view	50	4.0	Experience/Value	{'neg': 0.0, 'neu': 0.323, 'pos': 0.677, 'compound...}	0.7430 Positive
1	netflix amaze	50	7.0	Amenities/Activities	{'neg': 0.0, 'neu': 0.222, 'pos': 0.778, 'compound...}	0.5423 Positive
2	peaceful hotel completely love enjoyed beginning	50	4.0	Experience/Value	{'neg': 0.0, 'neu': 0.21, 'pos': 0.79, 'compound...}	0.9056 Positive

Fig. 7. Datasets after polarity detection

7) *Multi-target classification (aspect/sentiment):* In order to use machine learning algorithms in the textual data, there is a need to represent the text in the document as a vector of fixed size and this in order to plunge the data in a metric space. Among the vectorization techniques the TF-IDF and CountVectorizer are two ways to convert text into numbers.

a) *Count vectorizer:* Count Vectorizer offers a straightforward method for tokenizing a group of text documents, creating a vocabulary of recognized words, and encoding new documents using that vocabulary.

b) *TF-IDF vectorizer:* TF-IDF, which stands for Term Frequency - Inverse Document Frequency, is a statistic which is based on a word's frequency in the corpus. It also gives a numerical representation of a word's importance for statistical analysis.

### B. Testing and Evaluation Phase

In this experiment, the most commonly used classifiers in the sentiment analysis literature are applied. "Documents x Terms" vectorization method will be evaluated using nine supervised classification models: Bayesian Naive, SVM, Logistic Regression, K-nearest Neighbor, Decision Trees, Random Forests, Extratrees, Adaboost and Gardient Boost. The performance of the selected models will be compared using their Accuracy, Precision, Recall and F1-scores to determine the best decision model.

1) *Description datasets*: The sentiment analysis as well as the aspect analysis were performed on a dataset that contains 14356 English dialect reviews from TripAdvisor and Booking websites and labeled as follows: 4337 positive texts, 397 negative texts and 8647 neutral, still 2822 texts labeled with the aspect Room, 386 with Service, 1952 with Food/Restaurant, 2118 with Staff, 1352 labeled with Location, 2833 with Experience/Value, as well as 992 are labeled with the aspect Amenities/Activities and 420 reviews are with Price/Quality.

2) *Performance measure*: The choice of classifier for the current data is based on the performance measures [35]. The evaluation of the optimal solution in classification training can be defined based on the confusion matrix. From the given confusion matrix one can determine, the number of positive and negative that are correctly classified. Meanwhile, the number of negative and positive cases are misclassified respectively. The performance measure of the various classifiers is evaluated using the accuracy, precision, recall and F1-scores.

The Accuracy metric: indicates the percentage of correct predictions. It refers to the ratio of the number of correct predictions to the total number of input samples or observations, which is shown in eq. (1).

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (1)$$

Precision: is the number of correct positive results divided by the number of positive results predicted by the classifier. The result is a value between 0.0 for no precision and 1.0 for total or perfect precision.

$$Precision = \frac{TP}{TP+FP} \quad (2)$$

Recall: In order to complete the accuracy, the recall is also calculated, which is the fraction of true positives to real positives, which is shown in eq. (3), i.e., the proportion of positives that were correctly identified.

$$Recall = \frac{TP}{TP+FN} \quad (3)$$

F1-Score: The calculated average harmony of precision and recall is used to assess how well these two metrics—rappel and precision—compromise. This unique score ranges from 0 to 1, with 0 being the worst possible outcome and 1 being the best possible outcome. It can be calculated as follows.

$$F1 = \frac{2*(Precision*Recall)}{Precision+Recall} \quad (4)$$

3) *Results*: The learning phase will be followed by the testing phase in order to evaluate the classifier. For performance validation, 80/20% rules is used to check the model, the corpus is divided into two parts, 80% for the training phase and 20% for the testing phase. Several tests, whose results are presented in the following tables, were made:

#### a) CountVectorizer embeddings classification

- Aspect Classification

TABLE III. RESULTS OBTAINED FROM ALL CLASSIFIERS IN COUNTVECTORIZER WEIGHTING METHOD FOR ASPECT CLASSIFICATION

Metrics \ Classifiers	Accuracy %	Recall%	Precision %	F1-Score %
LR	83.25	73.01	75.56	73.42
RF	<b>84.26</b>	<b>74</b>	<b>77.14</b>	<b>75</b>
NB	76	55.78	67.68	56.29
DT	48.70	28.12	43.75	26.53
KNN	71.59	63.71	67.22	64.95
SVM	83.51	70.91	86.84	72.88
ET	81.67	71.41	74.66	72.49
AB	69.83	59.33	65	60.44
GB	76.13	61.07	69	62.72

The results of aspect extraction are reported in Table III. The latter shows that the best performances are obtained in: Accuracy (84.26%), Recall (74%), Precision (77.14%) and F1-Score (75%) with the RandomForest + CountVectorizer configuration.

- Sentiment classification

TABLE IV. RESULTS OBTAINED FROM ALL CLASSIFIERS IN COUNTVECTORIZER WEIGHTING METHOD FOR SENTIMENT CLASSIFICATION

Metrics \ Classifiers	Accuracy %	Recall%	Precision %	F1-Score %
LR	<b>91</b>	<b>69.59</b>	<b>82</b>	<b>73.27</b>
RF	<b>88.87</b>	67.16	85	<b>72</b>
NB	83.28	60.43	67.26	61.58
DT	74.40	43.55	56.09	43.52
KNN	74.03	44.86	77.84	46.24
SVM	87.86	62.48	80.02	65.76
ET	88.53	68.19	82	72.59
AB	84.52	61.07	77.02	65.24
GB	87.03	57.64	58.58	57.85

The sentiment classification results are reported in Table IV. The latter shows that the best performances are obtained in precision (82%), recall (69.59%), accuracy (91%) and F1-score (73.27%) with the LogisticRegression + CountVectorizer configuration.

b) *TF-IDF Vectorizer embeddings classification*: Both Tables V and VI show the results of the classifier using the TF-IDF weighting model for sentiment classification.

- Aspect classification

TABLE V. RESULTS OBTAINED FROM ALL CLASSIFIERS IN TF-IDF WEIGHTING METHOD AOR ASPECT CLASSIFICATION

Metrics Classifiers	Accuracy %	Recall%	Precision %	F1-Score %
LR	83	70.01	78	72
RF	<b>86</b>	<b>74.78</b>	<b>81.01</b>	<b>76.59</b>
NB	76.59	72.08	50.55	51
DT	48.70	28.13	44.15	27
KNN	63.73	52.46	59.63	54.58
SVM	82.76	70.69	76.14	71.75
ET	82.80	72	76.04	73
AB	70	59.43	64.01	60.58
GB	71.63	52.04	52.42	51.44

The results of aspect classification with the TF-IDF vectorization method are presented in Table V. This latter shows that using the RandomForest + TF-IDF parameter provides the best performance in terms of precision (81.01%), recall (74.78%), accuracy (86%) and F1-score (76.59%).

- Sentiment classification

TABLE VI. RESULTS OBTAINED FROM ALL CLASSIFIERS IN TF-IDF WEIGHTING METHOD FOR SENTIMENT CLASSIFICATION

Metrics Classifiers	Accuracy %	Recall%	Precision %	F1-Score %
LR	87.37	60.73	83.84	64.04
RF	<b>89</b>	<b>66.19</b>	<b>84.51</b>	<b>70.55</b>
NB	82.87	53.17	57	54.02
DT	74.44	43.57	56.20	43.53
KNN	75.87	50.25	80	54.16
SVM	<b>87.63</b>	62.39	82.41	66.54
ET	<b>87.29</b>	76.26	78.37	71.10
AB	<b>84.82</b>	61.30	76.64	65.58
GB	<b>87.11</b>	57.50	59	57.89

The results of the sentiment classification are presented in Table VI. The latter shows that the use of the RandomForest + TF-IDF parameter allows to obtain the best performances in terms of accuracy (89%), Recall (66.19%), precision (84.51%) and F1-Score (70.55%).

## V. DISCUSSION

Traditional Sentiment Analysis is done through Sentiment Analysis techniques[36] on documents and sentences which assesses the overall polarity of the feelings of the given opinion target. Nevertheless, if the opinion target contains various aspects with a conflicting sentiment, using a single sentiment label to represent it could be incorrect[37]. The current trend is to move to a deeper level that presents itself as Aspect-Based Sentiment Analysis. ABSA is the sub-field of NLP that essentially breaks the data into aspects and finally extracts the sentiment information[38]. It performs a more advanced and higher quality analysis because it directly examines the sentiment itself. Neither document analysis nor sentence analysis find out what exactly people like and dislike. Specifically, the idea behind this work is to collect customer reviews on tourism sites such as: Booking or TripAdvisor, and assign a sentiment analysis that allows to extract the most relevant characteristics in the review of most customers. Hence the realization of a sentiment analysis as well as an aspect analysis on a dataset that contains customer reviews of hotels located in Marrakech. The results of this research were presented as follows:

The best result in all the tests for the classification of aspects is 86%, it was obtained by the RF with the use of TF-IDF, similarly the classifier GradientBoost, NB and AdaBoost reached their maximum measure (76.13%, 77%, 70% respectively), on the other hand for LR, SVM and KNN, their best results were with CountVectorizer (83.25%, 83.51%, 71.59%) respectively. Moreover, the DT classifier obtained the same result in both tests with TFIDF and CountVectorizer (48.70%). On the other hand, for sentiment classification the best result of Accuracy is 91% in CountVectorizer weighting method, achieved by LR classifier, also NB and SVM classifiers their excellent outcome were with the same method (83.28%, 87.86% respectively), also the DT classifier score is similar for both vectorization techniques with 74%, and both RF, GB, AdaBoost, and KNN classifiers got their excellent score with TF-IDF (89%, 87.11%, 84.82% and 75.87% respectively). Analyzing the results of the confusion matrices the RF+TFIDF that gave as results 2232 True Positives for the classification of the aspects, besides the best classifier for the analysis of the feelings is the LR+CountVectorizer that allows to reach a number of True Positives equal to 3158. These results show that RF is generally considered a better classifier for the aspect extraction task; in return LR is the good classifier for the sentiment classification task. As long as a good measurement is achieved, the model has permitted to perform correct results. These results are listed in Fig. 8 and 9.

Fig. 8. Sentiment per single aspect

Fig. 9. Data analysis interface

## VI. CONCLUSION

Given the increasing importance placed on online reviews and the evidence that these reviews influence customer behaviors, it is clear that companies are beginning to look at technologies that could automatically analyze what customers are saying about their product or service. In this article, the analysis of the feelings has been performed on the level of aspects in the field of hotels. The hotel reviews that were studied are comments on the service provided, written in English on the rating site TripAdvisor. The preprocessing and vectorization methods are evaluated using nine supervised classification models. The results obtained are very encouraging, and the experimentation conducted on the dataset reveals that a better accuracy score of 92% and 3158 True Positives were achieved when using the LR+ CountVectorizer

classifier for sentiment analysis as well as a good Accuracy score of 86% and a number of True Positives equal to 2232 when using RF + TF-IDF Vectorizer for aspect classification. For future work, enriching the dataset with other reviews from other languages such as French and Arabic will be highly recommended and that is by making comparisons between these languages in order to get a broader view on the aspects that are most noticed by travelers from other countries; thus, the use of the mixed class analysis rather than the positive, negative and neutral classes.

# Performance Comparison of the Kernels of Support Vector Machine Algorithm for Diabetes Mellitus Classification

Dimas Aryo Anggoro, Dian Permatasari

Informatics Engineering Department, Universitas Muhammadiyah Surakarta, Surakarta, Indonesia

**Abstract**—Diabetes Mellitus is a disease where the body cannot use insulin properly, so this disease is one of the health problems in various countries. Diabetes Mellitus can be fatal and can cause other diseases and even lead to death. Based on this, it is important to have prediction activities to find out a disease. The SVM algorithm is used in classifying Diabetes Mellitus diseases. The purpose of this study was to compare the accuracy, precision, recall, and F1-Score values of the SVM algorithm with various kernels and data preprocessing. The data preprocessing used included data splitting, data normalization, and data oversampling. This research has the benefit of solving health problems based on the percentage of Diabetes Mellitus and can be used as material for accurate information. The results of this study are that the highest accuracy was obtained by 80% obtained from the polynomial kernel, the highest precision was obtained by 65% which was also obtained from the polynomial kernel, and the highest recall was obtained by 79% obtained from the RBF kernel and the highest f1-score was obtained by 70% obtained from RBF kernel.

**Keywords**—Diabetes mellitus; kernel; normalization; oversampling; SVM

## I. INTRODUCTION

Diabetes Mellitus is a disease where blood sugar levels are overly high because the body cannot use insulin properly. Currently, Diabetes Mellitus becomes a serious health problem in various countries, including Indonesia [1]. The International Diabetes Federation (IDF) explained that in 2021 the number of people with Diabetes Mellitus in Indonesia reached 19.5 million people, while in 2019 the figure was 10.7 million. This means that there has been an increase of nearly 9 million cases in just 2 years, or just during the COVID-19 pandemic. With almost 2 times the addition, makes Indonesia ranked fifth in the world. Not only in Indonesia, but this upward trend in cases also occurs in the world. According to IDF data, currently, at least 1 in 10 people or as many as 537 million people in the world live with Diabetes Mellitus. If not treated properly immediately, Diabetes Mellitus can be fatal and can cause other diseases and even lead to death. Based on this, it is important to have prediction activities to find out a disease. This activity is carried out so that a disease can be detected quickly and can be treated immediately.

Activities in predicting various diseases have been carried out in various scientific fields, one of which is the field of computer science. Along with the development of information and communication technology, it can be used to improve the

ability of the system to help detect Diabetes Mellitus disease[2]. Data mining is part of the Knowledge Discovery in Database (KDD) process that can classify, predict, and get a lot of information from large data sets[3]. Classification is an important stage in data mining; classification is carried out by looking at variables from existing data groups and aims to predict the class of an object that was not previously known [4].

## II. LITERATURE REVIEW

Previous research conducted by Andi Maulida Argina regarding the application of the K-Nearest Neighbour classification model to the diabetes patient dataset explained that the study had the highest accuracy of 39%[5]. Another study conducted by Noviandi on the implementation of the Decision Tree C4.5 algorithm for diabetes prediction resulted in a prediction model that had the highest accuracy of 70.32% [6]. The shortcoming of the previous study is that the accuracy of the prediction model is still below 80%, so there is a need to improve accuracy performance. In research [7] that compared accuracy, recall, and precision classification on the C4.5 algorithm, Random Forest, Support Vector Machine (SVM), and Naïve Bayes resulted in the C4.5 algorithm obtaining accuracy of 86.67%, the Random Forest algorithm obtained accuracy of 83.33%, the SVM algorithm obtained accuracy by 95%, and the Naive Bayes algorithm obtained an accuracy of 86.67%. The highest accuracy algorithm is the SVM algorithm, therefore in this study applying the SVM algorithm for the classification of Diabetes Mellitus disease. This research is expected to provide accuracy results reaching 80%, so that it can improve deficiencies in previous studies.

The SVM algorithm was chosen because it is reliable in processing large amounts of data by optimizing hyperplanes in high-dimensional space that maximizes margins between data [8]. The use of the kernel in SVM is carried out to determine kernel parameters and produce the best accuracy in the classification process. Linear kernels are used when classified data can be easily separated by a hyperplane, while non-linear kernels are used when the data used is separated using curved lines or a plane in space that has high dimensions [9].

This study aims to compare the accuracy, precision, recall, and F1-Score values of the SVM algorithm with various kernels and preprocessing data in the classification of Diabetes Mellitus disease. It has the benefit of solving health problems based on the percentage of Diabetes Mellitus and can be an accurate information material. The output of this study is to

imply that the SVM algorithm is expected to show better performance values than previous studies.

### III. METHODOLOGY

#### A. Data Collection

The first stage in this study is the collection of Diabetes Mellitus datasets. The dataset used is the Pima Indian diabetes dataset obtained from the UCI Machine Learning Repository. Several variables and attributes can facilitate the research process in data mining. The Pima Indian diabetes dataset consists of 768 data and 9 attributes. The variables and attributes used are shown in Table I.

TABLE I. VARIABLES AND ATTRIBUTES OF PEOPLE WITH DIABETES MELLITUS

Variable	Attribute
X1	<i>Pregnancies</i> , the number of pregnancies during life in the range of 0-17 times.
X2	<i>Glucose</i> , glucose/blood sugar levels. Normal blood sugar levels are below 120 mg/dL, while the sugar levels of diabetics are more than 120 mg/dL. The data range in the dataset is 0-199 mg/dL.
X3	<i>Blood Pressure</i> , blood pressure with mmHg units, the data range in the dataset is 0-112 mmHg.
X4	<i>Skin Thickness</i> , skin fold thickness with a data range of 0-99 mm. The norm is about 12.5 mm.
X5	<i>Insulin</i> , insulin levels in the blood with a data range of 0-846 U / ml.
X6	<i>BMI</i> , body mass weight with a data range of 0-67.1 BMI
X7	<i>Diabetes Pedigree Function</i> , History of diabetes Mellitus disease in the family with a data range of 1.001-2.42.
X8	<i>Age</i> , age of the patient (years) with a data range of 21-81 years.
Y	<i>Outcome</i> , negative and positive class variables (0 and 1). 0 are indicators of non-diabetics while 1 is an indicator of diagnosed diabetics.

#### B. Data Preprocessing

1) *Data splitting*: The next stage is the data splitting stage which is carried out by separating training data and testing data. Training data is used to create models that are applied to testing data [10] and testing data cannot be used for the training process, so that the model really learns from the new data [11]. The determination of training data and testing data is carried out randomly, so that the proportion between categories remains balanced [12]. In this study, splitting data was divided into 80% training data and 20% testing data.

2) *Normalization data*: Normalization of data in datasets aims to create data in the same range of values [13]. This study used the min-max and z-score normalization methods.

a) *Min-max normalization*: Normalization of min-max can overcome non-uniform data forms with a range of values greater than 0-1 [14]. Min-max normalization was chosen because it has the advantage that the data is balanced between before and after normalization [15]. The normalization of min-max is presented in (1).

$$x_{new} = \frac{x_{old} - x_{min}}{x_{max} - x_{min}} \quad (1)$$

$x_{new}$  represents the min-max value,  $x_{old}$  is the value to be normalized,  $x_{min}$  is the lowest value of the overall data and  $x_{max}$  is the highest value of the entire data.

b) *Z-Score normalization*: Z-Score normalization is used to compare the performance or quality of data goals with the average distribution of data across groups based on standard deviation values [16]. Z-score normalization was chosen because it is a good normalization method for balancing data scale [17]. (2) is a formula for knowing the z-score.

$$x_{new} = \frac{x_{old} - \mu}{\sigma} \quad (2)$$

$x_{new}$  is the z-score value,  $x_{old}$  is the value to be normalized,  $\mu$  is the average value of the whole data and  $\sigma$  is the standard deviation value.

#### 3) Oversampling

a) *SMOTE (Synthetic Minority Over-sampling Technique)*: The SMOTE method can handle dataset class imbalances by working to make data replication of minor classes to be equivalent to major classes [18]. The diabetes dataset used in this study had a total of 268 positive classes and 500 negative classes so that there was an imbalance between the positive class and the negative class. Therefore, the SMOTE method was used in this study to balance between positive classes and negative classes. (3) is the formula for SMOTE.

$$x_{syn} = x_i + (x_{knn} - x_i)\gamma \quad (3)$$

$x_{syn}$  is the resulting new class data,  $x_i$  is the approach to i,  $x_{knn}$  is the x closest to  $x_i$  and  $\gamma$  is a random number between 0-1.

#### C. Data Processing

1) *Support Vector Machine (SVM)*: SVM is a good algorithm for data classification [19] with the principle of finding the best hyperplane that serves as a separator of two data classes [20]. The best hyperplane is determined by measuring the hyperplane margin and finding its maximum point, margin is the distance between the hyperplane and the nearest point of each class and this closest point is called the support vector [21]. The following is a description of SVM, there is data  $\vec{x}_i \in (\vec{x}_1, \vec{x}_2, \vec{x}_3, \dots, \vec{x}_n)$   $x_i$  is data consisting of n attributes and two classes  $y_i \in +1, -1$ . Suppose that the two classes can be perfectly separated by a d-dimensional hyperplane defined by (4).

$$\vec{w} \cdot \vec{x}_i + b = 0 \quad (4)$$

Data  $\vec{x}_i$  which belonging to the positive class (+1) are shown in (5).

$$\vec{w} \cdot \vec{x}_i + b \geq -1 \quad (5)$$

Meanwhile, data  $\vec{x}_i$  belonging to the negative class (-1) are shown in (6).

$$\vec{w} \cdot \vec{x}_i + b \leq +1 \quad (6)$$

The maximum margin can be obtained by maximizing the value of the distance between the hyperplane and its closest point or support vector which  $\frac{1}{\|\bar{w}\|}$  [22]. It is formulated as Quadratic Programming (QP) by looking for a minimum point based on (7).

$$\min \tau(w) = \frac{1}{2} \|\bar{w}\|^2 \quad (7)$$

By paying attention to the constraints on (8).

$$y_i(\bar{x}_i, \bar{w} + b) - 1 \geq 0 \quad (8)$$

$y_i$  is the target class to  $i$ ,  $\bar{x}_i$  is the input data to  $i$ ,  $\bar{w}$  is the weight, and  $b$  is the relative field position.

2) *Kernel SVM*: To work around high-dimensional data can use a kernel that transforms the input space into a feature space [23]. Kernel functions commonly used in SVM are Linear [24], Radial Basic Function (RBF) and Polynomial [25]. The parameters possessed by kernel functions are used in the testing process [26]. There is no definite conclusion about the best kernel, therefore this study will compare 4 kernel functions, namely linear, RBF, polynomial and sigmoid.

a) *Kernel linear*: The Linear kernel was chosen because it is the simplest kernel and is used when the data is linearly overstretched.

$$K(x, y) = x \cdot y \quad (9)$$

b) *Kernel polynomial*: The Polynomial kernel was chosen because it can be used when the data is not linearly separated and is suitable for use in solving classification problems in all training data that has been normalized.

$$K(x, y) = (\gamma(x \cdot y) + C)^d \quad (10)$$

3) *Kernel Radial Basic Function (RBF)*: The RBF kernel is used when the data is not linearly separated, it is chosen because it performs well with certain parameters, and the result of the training has a small error value.

$$K(x, y) = \exp(-\gamma|x - y|^2) \quad (11)$$

a) *Kernel sigmoid*: This sigmoid kernel was chosen because it is similar to the two-layer perceptron model of the neural network, which works as an activation function for neurons.

$$K(x, y) = \tanh(\gamma(x \cdot y) + C) \quad (12)$$

4) *Evaluation*: Confusion matrix is an evaluation method that provides information comparing the classification of prediction results with the actual classification [27]. There are 4 terms of value from the confusion matrix, namely True Positive (TP), True Negative (TN), False Positive (FP), and False Negative (FN). Based on these values, accuracy, precision, recall, and F1-Score values can be generated. Accuracy is the ratio of predicted correct values of all data [28].

$$Accuracy = \frac{TP+TN}{TP+FP+FN+TN} \quad (13)$$

Precision indicates a correctly classified prediction of positive values divided across positive classified data [28].

$$Precision = \frac{TP}{TP+FP} \quad (14)$$

Recall shows the comparison of the positive correct predicted value with the entire positive correct value [29].

$$Recall = \frac{TP}{TP+FN} \quad (15)$$

The F1-Score shows the average comparison of precision and recall values [29].

$$F1 - Score = \frac{2 \times Precision \times Recall}{Precision + Recall} \quad (16)$$

## IV. RESULTS AND DISCUSSIONS

This stage is a decipherment of the research obtained and its explanation.

### A. Data Preprocessing

The dataset used is the Pima Indian diabetes dataset which consists of 768 data and 9 attributes. The initial stage carried out in this study is the process of collecting and processing datasets. In this study, data preprocessing was divided into three steps. The first step is the data splitting process, where the Diabetes Mellitus dataset will be divided into training data and testing data. The second step is the data normalization process to create data in the same range. The third step is an oversampling process to balance the dataset class by using the SMOTE method. Data processing in the study uses the Python programming language in the Google colab application.

1) *Data splitting results*: After getting the dataset, the next step is to divide the dataset into training data and testing data. The Diabetes Mellitus dataset totaled 768 data consisting of 8 variables and one target/class. Then the dataset is divided into 80% training data, totaling 614 data and 20% testing data, totaling 154 data. The diagnosis of Diabetes Mellitus is divided into two, namely non-diabetics who are denoted by 0 and diabetics who are denoted by 1. Obtained diabetics totaled 268 data and non-diabetics amounted to 500 data.

2) *Data normalization results*: The normalization methods used are min-max and z-score.

Fig. 1 shows the comparison of variables in the dataset, variables compared to 2, namely, pregnancies and insulin, the data has a fairly high range of values. For example, in the insulin variable, where the range of values is between 0 to above 200, this is considered unbalanced. The min-max normalization method is used to process values into the range of 0-1. Fig. 2 shows the results after normalization of min-max, where the range of values in the insulin variable becomes smaller, namely, 0-1.

In addition to using the min-max method, data normalization is also carried out using the z-score method. Z-score is performed by processing the mean and standard deviation from the values of its attributes. Fig. 3 shows the results after normalizing the z-score.

Fig. 1. Before normalization.

Fig. 2. After min-max normalization.

Fig. 3. After z-score normalization.

3) *Oversampling results:* In the dataset there is a difference between the number of positive classes and negative classes, therefore there is a need for class balancing. Class balancing is done by oversampling using the SMOTE method and is carried out on training data only. Oversampling is carried out after splitting data so that data replication does not appear in data training and data testing [30]. It can be seen in Fig. 4, before oversampling the number of positive classes was 221 and the number of negative classes was 393. Meanwhile, after oversampling, the number between the positive class and the negative class becomes the same, which is 393 so that it becomes balanced.

### B. Data Preprocessing and Evaluation

This study compared the performance of the SVM algorithm kernels for the classification of Diabetes Mellitus diseases. SVM kernels used include linear kernels, polynomial kernels, RBF kernels, and sigmoid kernels. Evaluation is carried out using the confusion matrix method to calculate the values of accuracy, precision, recall, and f1-score by optimizing the best parameters for each kernel. Each kernel on SVM has a specific parameter, the cost parameter (C) being the most commonly used value for all kernels. The gamma ( $\gamma$ )

parameter is used to determine the degree of proximity between 2 points to make it easier to find  $\gamma$  hyperplanes that are consistent with the data. The gamma parameter is used by polynomial, RBF, and sigmoid kernels. Next is the degree (d) parameter used to map data from the input space to the higher dimension space in the feature space, only the polynomial kernel uses this parameter [31]. Determination of the best parameters on the kernel is carried out by trial and error. Table II is the result of evaluating the classification models of various SVM kernels before various data preprocessing is carried out.

For this experiment in Table II, all parameter values in each kernel use auto parameters from python. The highest accuracy is obtained from the polynomial and RBF kernels, which is 77%. The highest precision was obtained from the RBF kernel, which was 69%, the highest recall was obtained from the linear kernel, which was 57% and the highest f1-score was obtained from linear and polynomial kernels, which was 61%. Table III is the result of evaluating the classification models of various SVM kernels after preprocessing data with min-max normalization and SMOTE oversampling. Meanwhile, Table IV is the result of evaluating the classification models of various SVM kernels after preprocessing data with normalization of z-score and oversampling SMOTE.

Fig. 4. (a) Data before oversampling, (b) Data after oversampling.

TABLE II. RESULTS OF EVALUATION OF VARIOUS SVM KERNELS BEFORE DATA PREPROCESSING

	Kernel			
	Linear	Polynomial	RBF	Sigmoid
Accuracy	76%	77%	77%	51%
Precision	66%	68%	69%	12%
Recall	57%	55%	53%	8%
F1-Score	61%	61%	60%	10%

TABLE III. RESULTS OF EVALUATION WITH MIN-MAX AND SMOTE

	Kernel			
	Linear	Polynomial	RBF	Sigmoid
Accuracy	77%	79%	79%	76%
Precision	61%	64%	63%	59%
Recall	72%	72%	79%	68%
F1-Score	66%	68%	70%	63%

TABLE IV. RESULTS OF VALUATION WITH Z-SCORE AND SMOTE

	Kernel			
	Linear	Polynomial	RBF	Sigmoid
Accuracy	79%	80%	77%	78%
Precision	62%	65%	61%	62%
Recall	74%	74%	72%	72%
F1-Score	68%	69%	66%	67%

Based on Tables III and IV, it can be seen that the highest accuracy is obtained by applying z-score normalization and SMOTE oversampling, which is obtained by 80% using a polynomial kernel. The polynomial kernel using the parameter value  $C=1$   $\gamma=0.1$   $d=1.5$  is obtained through trial and error so that it can produce margin optimization values that are used to maximize the hyperplane by mapping the data into higher dimensions. The highest precision is also obtained from the polynomial kernel, which is 65%. This shows that the higher the accuracy value, the higher the precision value will be. The highest recall was obtained at 79% which is from the RBF kernel shown in Table III. The RBF kernel uses the parameter value  $C=2.5$   $\gamma=1.5$ . The highest F1-score is also obtained from the RBF kernel shown in Table III which is 70%. The values in the parameters C,  $\gamma$ , and d are the most optimal values in order to get the maximum accuracy value. If the value is increased or decreased, the accuracy value will decrease.

## V. CONCLUSION AND FUTURE WORK

This research produces the highest accuracy of up to 80% which is obtained from polynomial kernels. So that the shortcomings of previous research have been resolved in this study. By optimizing the use of the kernel on the SVM algorithm it is proven to be able to maximize performance. So it can be concluded that the SVM algorithm shows a better performance value in classifying Diabetes Mellitus. Where in this study it was found that the performance of the SVM algorithm kernel to produce the highest accuracy was obtained from the polynomial kernel. The accuracy produced in this study can be used as an accurate and useful information material for overcoming health problems based on the percentage of Diabetes Mellitus.

For further research, you can use other datasets that have more data and also use other algorithms such as Xgboost, Bayesian Classification and other algorithms to get better accuracy. In addition, the results of this study can also be used in making applications to detect Diabetes Mellitus which can be web-based or mobile.

**Abstract**—The intestinal polyp is one of the common intestinal diseases, which is characterized by protruding lining tissue of the colon or rectum. Considering that they may become cancerous, they should be removed by surgery as soon as possible. In the past, it took a lot of manpower and time to identify and diagnose intestinal polyps, which greatly affected the treatment efficiency of medical staff. Because the polyp part looks similar to the normal structure of the human body, the probability of human eye misjudgment is high. Therefore, it is necessary to use advanced computer technology to segment the intestinal polyp image. In the model established in this paper, an image segmentation method based on convolution neural network is proposed. The Har-DNet backbone network is used as the encoder in the model, and its feature processing results are converted into three feature images of different sizes, which are input to the decoding module. In the decoding process, each output first expands the receptive field module and then fuses the feature image processed by the attention mechanism. The fusion results are input to the density aggregation module for processing to improve the operation efficiency and accuracy of the model. The experimental results show that compared with the previous Pra-Net model and Har-DNet MSEG model, the accuracy and precision of this method are greatly improved, and can be applied to the actual medical image recognition process, thus improving the treatment efficiency of patients.

**Keywords**—Image segmentation; intestinal polyps; block convolutional attention mechanism; Har DNet

## I INTRODUCTION

Rectal polyps generally refer to the tissues protruding from the surface of the rectal mucosa to the intestinal cavity, which is also a high-risk factor for rectal cancer. Studies have pointed out that 95% of rectal cancer is caused by colorectal adenocarcinoma. To effectively avoid the incidence of rectal cancer, regular colonoscopy or resection of rectal polyps are effective means. During these years, with medical knowledge popularization and publicity about the causes of rectal cancer and rectal polyps, more and more people are aware of the importance of regular colonoscopy. This medical examination also depends on the doctor's own experience and competence, so it is a very arduous task for mankind. As an item of physical examination, a manual colonoscopy is a great test for doctors' clinical experience and ability. Most doctors need a lot of time to identify intestinal polyps, and also need a lot of experience to ensure the correctness of the results. Therefore, manual examination of intestinal polyp images by medical personnel is

very time-consuming work and depends on some experienced doctors. Therefore, people begin to use computers to process images instead of human to identify and segment intestinal polyps by combining image processing technology in the computer field to develop its application in the medical field.

In the medical science field, image segmentation technology is the basis of image processing in the relevant area of computers. Medical imaging (radiology) is a field where medical staff recreates images for diagnosis and treatment purposes. In order to improve the efficiency and accuracy of judging the pathological position, some valuable methods for information processing in the computer science area are adopted. After the computer processes the image and then crops the images with the elements such as brightness and texture in the image as the standard for segmenting, the model of image segmentation through a neural network has been more clearly established. Moreover, as the model is constantly improved with the algorithm, together with the adopting of a convolution neural network to process the image, the quality of the outcome has been greatly improved.

This model also applies the method of image segmentation in computer science. The core is the joint action of the convolution Neural Network (CNN) and Convolutional Block Attention Module (CBAM). The selected intestinal polyp data set is the actual medical image of the human intestinal cavity, and the polyp part has similar surface characteristics to the normal structure of the human body, which is not easy to distinguish. Therefore, segmentation of intestinal polyp images demands both the accuracy and precision of computer image processing. This model chooses to enhance the feature extraction ability to strengthen the feature of the intestinal polyp feature different from the normal intestinal cavity tissue of the human body. This model reduces the possibility of misdiagnosis in the process of computer processing by enhancing the feature extraction ability, and reduces the time of feature processing by feature enhancement, so as to jointly improve the performance of the model in terms of time cost and accuracy. The choice of CBAM mainly depends on the difficulty of intestinal polyp image processing. Through the joint processing of the attention mechanism and receptive field expansion module, the intestinal polyp features of the image are effectively enhanced, which provides excellent pre-processing for feature extraction and image segmentation.

\*Corresponding Author.

In the part of image feature extraction, this model selects the Har DNet convolution network with perfect function as the backbone network in the encoder stage. However, due to the full integration of upper and lower image features by Har DNet, the amount of calculation required to output the feature image is large. Although the accuracy and effectiveness of segmented image features are retained to a great extent, there is still room for improvement in processing speed. This model improves the processing speed based on Har DNet. Through the expansion of the receptive field and the addition of an attention mechanism, it not only improves the accuracy of feature processing but also accelerates the processing, so as to effectively improve the performance of overall image processing.

A more rapid and precise processing of the images of intestine polyps has a huge and profound impact on the medical world. In an age when computers were not used to help with medical images processing, homeopathy had to invest in a number of people in the determination of the images of intestine polyps. This does not only require the abilities of doctors, but also the time and effort of the medical personnel. This paper proposes and uses an image-processing model that can free therapeutic staff in a maximum degree. With the aid of computer technology, medical personnel do not have to spend much time identifying the pathological tissue that is very close to normal tissue. The doctor can devote more energy to the treatment of the follow up. In addition, considering the high accuracy of the model, when small colonic polyps are encountered, the model can still accurately distinguish to achieve the effect of early warning.

This paper will start with the evolution of various neural network models, emphasize the performance improvement of numerous models over time, and lead to the optimization of subsequent models in this paper. After that, the main structure of the model is the core content of the article, which is described in combination with the structure diagram. Finally, this paper will list the results of relevant experiments for readers to intuitively experience the performance improvement of this model.

## II RELATED WORK

CNN has achieved great success in the field of medical image segmentation because of its excellent feature extraction ability and good feature expression ability [1,7], and it does not need manual extraction or much pre-processing work. The U-Net neural network [2-5] is one of the earliest adopted models in the semantic segmentation network [26]. Due to the data augmentation by elastic distortions, it only needs very few annotated images. However, since each pixel needs to take an image block [17] centered on itself, two adjacent pixels are highly similar in their block information, which causes much redundancy and slow network training. Therefore, on this basis, the U-Net++ network [14-15] is developed. Through the effective integration of U-Net in different depths, that is, these U-Net parts share an encoder, and effectively recover the fine-grained details of the target object under complex background utilizing in-depth supervision and joint learning. In short, U-Net++ is equivalent to splicing four U-Net networks with different depths through multiple skip connections. The first

advantage is the improvement of accuracy, which should be brought by integrating the characteristics of different levels. The second is the flexible network structure combined with deep supervision so that the deep network with huge parameters can greatly reduce the parameters within the acceptable accuracy range, which has been developed to more advanced models [27].

The ResUNet model [18-19] performs better in-depth and avoids the degradation of the network through residual learning. The main idea of this model is to add a direct channel in the network and control the neural network of the receiving layer by allowing the original input information to be directly transmitted to the later layer. Instead of learning all the outputs after complete calculation, it can learn the residual of the output of the previous network [19]. This kind of information processing protects the integrity of information. The whole network only needs to learn the part of the difference between input and output, simplify the learning objectives and difficulties, and significantly improve the output results.

The PraNet model [9], which draws reverse attention, can effectively improve the style progress and accurate characterization of the results by mining boundary clues through the reverse attention module and establishing the connections between regions and boundaries. This model also gives inspiration for our model: the establishment of the attention module helps to build the relationship between the actual image pixels. The attention mechanism can be used as a weighting module to basically process the features in the image before processing the image so that the features in the image have a judgment similar to "important" or "unimportant". This judgment has high accuracy because of the strong correlation of the information around the attention mechanism's domain. As a kind of attention mechanism, the block attention mechanism proposed in this model can help the model give different weights to each part of the input and extract the more critical information so that the model can make a more accurate judgment. It is a lightweight attention mechanism module, so it will not bring more overhead to the calculation and storage of the model and improves the accuracy and calculation speed of the model from multiple layers.

HarDNet, as an improved model of L2-Net, measures the amount of data accessing memory through convolution input-output (CIO) [10-11]. The amount of data in storage that can be accessed through HarDNet can improve the density of calculation. Compared with the previous convolutional neural network [6,8], it has a very significant improvement in the accuracy and speed of calculation.

In recent years, the HSNet [28] model has emerged as a new neural network model for image segmentation. The model uses a convolutional neural network (CNN) to predict the 3D model of the human body, thus avoiding the limitations of handmade features and postures. At the same time, it is applied in virtual fitting and human body size measurement. In the paper on the HSNet model, four possible situations are analyzed as the input of the network: (a) The single binary contour of a human is scaled to a fixed size to prevent the loss of camera calibration information; (b) The human shadow image is scaled to a fixed size because the shadow will retain

the information complementary to the contour; (c) Assume the front profile of known camera parameters; (d) Assume that the front and side profiles of the camera parameters are known. HSNNet [28] uses CNN to accurately predict 3D human models from contour or shadow images and tries to find the global mapping of deformation parameters from 2D images to 3D models. The model has been widely evaluated and tested on thousands of people and real people. In addition, this model has been proved by comprehensive experiments that better prediction results can be obtained if there is shadow information. The model further assumes that humans wear tight clothes. Applying the proposed method to people wearing other clothes will increase the error. The limitation of the method of this model is that in the current training, it cannot deal with the posture that is obviously different from the neutral posture and contains self-occlusion [20-23]. This can be solved by generating a larger training set (including more prominent poses).

The encoder-decoder mechanism is often used in the CNN model. CNN encoder can basically be regarded as the feature extraction network, while the decoder interprets the received information and enlarges the received image features to the size of the original image through the decoded part [16,24], which greatly facilitates the prediction of the part of the image segmentation area and simplifies many subsequent calculation processes.

Considering the calculation speed and accuracy of the above models, based on the Har DNet convolution neural network, a segmentation model of intestinal polyp image with a block convolution attention mechanism is proposed in this paper. The model uses Har DNet as the basic network structure, and the image processing results obtained after passing through the backbone network are augmented to varying degrees and input into the subsequent decoder. Firstly, the decoder uses the Convolutional Block Attention Module and RFB module [25] to process the image features, so that the model can improve the feature extraction ability of the network by simulating the human receptive field. At the same time, the input feature information is weighted through the block attention mechanism, combined with the low-level and high-level feature input combination representation, so that the overall accuracy and speed of feature extraction of the model are greatly improved.

In the paper "An Imperial Study on Ensemble of Segmentation Approvals" [29], it is proposed that many machine learning models cannot be continuously learned especially neural networks. When they receive new training tasks, they will forget what they have learned before. This phenomenon is often called catastrophic amnesia. One of the reasons for the assumption of catastrophic forgetting in neural networks is the change of input distribution in different tasks [12], for example, the lack of common factors or structures may cause the optimization method to converge to completely different results each time. This paper studies the catastrophic forgetting phenomenon that occurs when the model is learning the same task. The author tries to understand the optimization

process in depth by analyzing the interaction between samples during learning. The first goal is whether to continue compressing data sets based on some forgotten data, so as to improve the efficiency of data training without affecting the generalization accuracy. The second goal is to identify "important" samples, outliers and other special data by forgetting statistical data. The model used in this paper also has the defect of unsustainable learning. In the future improvement, we will consider the method of using statistical forgetting data to identify "important samples", combined with the attention mechanism module to extract special data for image processing.[13]

### III METHODS

#### A. HarDNet

Compared with the traditional CNN, Har DNet optimizes its sampling strategy and loss function based on L2-Net, reduces the inference time, and improves the accuracy of the results by using 1 convolution. Taking sampling in a batch as an example, Har DNet's sampling strategy selects the nearest negative sample by comparing the distance between the descriptors of the corresponding patch in the batch, so as to improve the inference speed of the network by reducing shortcuts. At the same time, Har DNet also optimizes its loss function based on this idea: the distance between matching pairs is less than the distance of unmatched patch time, which reduces unnecessary calculation and improves the inference speed of the network. Compared with the speed of the optimized network, the accuracy of the optimized network is better than that of the optimized network. Therefore, Har DNet is selected as the basic network structure of this model. Fig. 1 shows the network structure of Har DNet.

#### B. Decoder

The decoder generates more accurate mapping by combining low-resolution, high-level features, and high-resolution, low-level features, and refines deep features by cascade connection. However, this method has the following two disadvantages. First, the low-level features contribute less to the network performance than the high-level features. Secondly, the use of high-resolution low-level features makes the computation more complex.

According to the above two shortcomings, it is proposed to refine the deep-seated features to improve the representation ability and abandon the shallow features to reduce the computational complexity, that is, the cascaded partial decoder is used. By cascading, the original modules are connected across to improve the expression ability and reduce the computational complexity.

#### C. Convolution Block Attention Mechanism

The decoder, CBAM is also adopted to improve the computing power of the network. The visual attention mechanism of the human visual system can assist the brain in signal processing. The CBAM works similarly: the ultimate goal is to select the information that is more critical to the current task goal from a large amount of information.

Fig. 1. HarDNet.

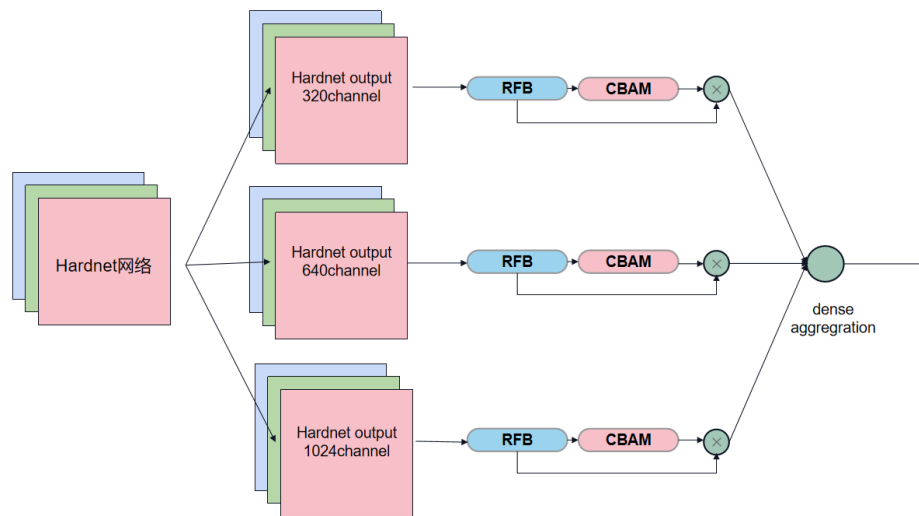

Fig. 2. Elaborate of convolutional block attention module.

The human visual attention mechanism receives the location of focal regions by quickly scanning all image information that needs to be processed by the brain and then pays more attention to these focal regions to obtain the detailed information needed by the brain. Through the judgment and selection of the focus of attention, the human eye pays more attention to the image information worth attention to rather than the non-focal, unimportant information. This attention mechanism of human vision greatly improves the information-processing efficiency of the human eye. At the same time, by investing more attention resources in the focus, the visual information obtained also has higher accuracy. Fig. 2 shows the action mechanism of the attention mechanism CBAM in the model.

The process of using the attention mechanism to improve the computing power of the network is similar to the human eye attention mechanism. Its core idea is to introduce specific weights into the input information in order to give priority to

the location of relevant information. This part of processing refers to the content of the Convolutional Block Attention Module (CBAM), and the input information is weighted through channel attention convolution and spatial attention convolution to enhance the useful features and suppress the useless features.

The channel attention model mainly focuses on the meaningful part of the input characteristic diagram, calculates the internal relationship between each channel, and finally uses the channel attention diagram to represent the internal relationship between each channel in the input characteristic diagram, and confirms the corresponding weighting of different channels to determine which channels should be ignored. The spatial attention model mainly focuses on the internal relationship of the feature map at the spatial level, that is, the weighting corresponding to different regions, which is complementary to the processing results of the channel attention model at the spatial level.

Fig. 3. Convolutional block attention module.

Fig. 3 shows the implementation mechanism of the channel attention mechanism in the model. It mainly processes the results obtained by the RFB model through a channel attention mechanism to generate the characteristic results of the channel attention mechanism and then takes it as the input characteristic diagram of the spatial attention mechanism to obtain the final results of the attention mechanism processing. The input features of RFB pass through the two pooling layers of Max pooling and average pooling respectively and then pass through MLP respectively. The output features are added based on element-wise and sigmoid activation to generate the final channel attention feature map. Then the feature map is multiplied by the input feature map, and the output feature map is used as the input feature of the spatial attention mechanism.

Similar operations are carried out in the part of the spatial attention mechanism. The feature map obtained through the channel attention mechanism passes through the two pooling layers of max pooling and average pooling, respectively. The two results are combined based on the channel, and then the feature map of the spatial attention mechanism is generated through the sigmoid operation. Finally, the feature map is multiplied with the input feature map to obtain the final

feature, which can be input into the subsequent calculation of the density aggregation part.

As Fig. 4 implies, the receptive field module network is composed of the convolutional layer with different expansion rates and convolution kernels of different sizes. By integrating the deep and shallow feature maps, the feature recognition effect can be equivalent to that of human vision. Through this method, the features are processed to achieve the effect of expanding the receptive field.

The decoder of this model enhances or suppresses the target features by adding a convolution block attention mechanism, which effectively improves the operation efficiency and feature expression ability of the model, and generally improves the performance of the model.

When processing the input image, rich feature representations is required. Combining these feature representations can improve the inference effect of category and location. Therefore, deep aggregation is used to enhance the network structure in order to better integrate information. The bottom stage is connected to the high level by jumping to fuse the size and resolution, to achieve the effect of combined expression of feature representation.

Fig. 4. Receptive field module network.

#### D. Algorithm Flow

Based on the HarDNet network, this model improved the processing speed and accuracy of the model by adding a

receptive field and block convolution attention mechanism. The overall algorithm flow is shown in Fig. 5.

### IV EXPERIMENT

Based on the results of previous data processing in related polyp experiments, five polyp segmentation data sets were taken as the experimental data sets. At the same time, the network structure used in this experiment was compared with the previous network structure, and the reasoning speed and the accuracy of the results are compared.

#### A. Datasets

In this experiment, five polyp segmentation data sets mentioned earlier were used: Kvasir-SEG, CVC-ColonDB, EndoScene, ETIS-Larib Polyp DB, and CVC-ClinicDB. This section also compared the results obtained this time with the results obtained from several previous models: U-Net, U-Net++, ResUNet, SFA, and PraNet. Table I shows the experimental results of these models on CVC-T Data Sets.

#### B. Segmentation Results of Intestinal Polyp Image

The CVC-T data set mentioned earlier in the experiment is the largest publicly released gastrointestinal image data set, which includes images of pathological tissues and images of normal phenomena. According to the needs of this experiment, 1,000 pictures of intestinal polyps were selected for the experiment (polyps of different sizes, pathological positions, and different qualities), which can reflect the more

comprehensive learning ability of this model to a certain extent. At the same time, this experimental result was the calculation result of the above-mentioned evaluation index. Each column in the table below corresponds to an evaluation index respectively. Each behavior is different and used to compare the model. The model result of the last behavior experimental design, and n/a means that the result cannot be obtained.

In the above experiment, 512×512 training input size and 1e-2 learning rate were adopted. There were 100 epochs used to test the model. It can be seen that the reasoning speed with the attention mechanism is much faster than that of other models.

In addition, according to the above calculation results, the two evaluation indexes of mDice and mIoU are improved, in which the average intersection and union ratio is increased from 0.834 to 0.851, up to 0.17, and the accuracy and processing speed are improved. It shows that the experimental model can effectively segment the meat in the actual pathological picture. However, the SM index is 0.02 lower than that of the HarDNet model, because in the process of adding attention mechanism, the image is weighted and the processing weight of some pixels is reduced, which makes this experiment lack the similarity with the actual image.

TABLE 1. COMPARISON OF EXPERIMENTAL RESULTS OF DIFFERENT MODELS ON CVC-T DATA SETS

Models	mDice	mIoU	$F_{\beta}^{\omega}$	$S_m$	MAE	$E_m^{\max}$
U-Net	0.818	0.746	0.794	0.858	0.055	0.893
U-Net++	0.821	0.743	0.808	0.862	0.048	0.91
ResUNet-mod	0.791	n/a	n/a	n/a	n/a	n/a
ResUNet++	0.813	0.793	n/a	n/a	n/a	n/a
SFA	0.723	0.611	0.67	0.782	0.075	0.849
PraNet	0.898	0.84	0.885	0.915	0.03	0.948
HarDNet-MSEG	0.901	0.834	0.871	0.935	0.008	0.974
HarDNet-CBAM	0.902	0.836	0.881	0.933	0.03	0.978

TABLE 2. EXPERIMENTAL RESULTS ON DIFFERENT DATA SETS

Models	Clinicdb		ColonDB		ETIS		Kvasir	
	mDice	mIoU	mDice	mIoU	mDice	mIoU	mDice	mIoU
U-Net	0.823	0.755	0.512	0.444	0.398	0.335	0.71	0.627
U-Net++	0.794	0.729	0.483	0.41	0.401	0.344	0.707	0.624
Res UNet-mod	0.779	n/a	n/a	n/a	n/a	n/a	n/a	n/a
Res UNet++	0.796	0.796	n/a	n/a	n/a	n/a	n/a	n/a
SFA	0.700	0.607	0.469	0.347	0.297	0.217	0.467	0.329
Pra Net	0.899	0.849	0.709	0.640	0.628	0.567	0.871	0.797
Har DNet-MSEG	0.909	0.864	0.721	0.641	0.678	0.605	0.891	0.824
Har DNet-CBAM	0.926	0.879	0.756	0.677	0.735	0.661	0.897	0.841

On the basis of the above experiments, four other data sets are used to test the results of the model, namely, ETIS, CVC-ClinicDB, Kvasir-SEG, and CVC-ColonDB. Table II shows the quantitative results of these data sets.

The four data sets used in the experiment have different characteristics. CVC-ClinicDB and CVC-ColonDB are both small-scale data sets, so they are all used in the test experiments; In addition, ETIS is a data set for early diagnosis of colorectal cancer, containing 196 images that are also used in test experiments. In this experiment, the Endosece dataset is divided into three subsets (training, verification, and test) as the previous ones did. This experiment mainly adopted the kvasir subset as the test set.

It can be seen from Table II that the results of the model with attention mechanism under the two indicators of mDice and mIoU show higher accuracy and better performance.

C. Evaluation Index

In the training, this experiment employed 900 images in kvasir SEG and 550 images in CVC-ClinicDB, a total of 1450 images as training images. The 80% of the pictures in the five datasets mentioned above (Kvasir-SEG, CVC-ColonDB, EndoScene, ETIS-Larib Polyp DB, and CVC-ClinicDB) are randomly selected as the training set, and 10% for validation, 10% for the testing set. In addition, meanDice and meanIoU were used to evaluate the accuracy and correlation of image-cutting results. The calculation method of the index is as follows:

$$\text{MeanDice} = \frac{2 \bullet \text{tp}}{2 \bullet \text{tp} + \text{fp} + \text{fn}} \quad (1)$$

$$\text{mIoU} = \frac{\text{tp}}{\text{tp} + \text{fp} + \text{fn}} \quad (2)$$

In addition, in order to further evaluate the network model, the experiment also took into account other metrics for evaluation:  $F_{\beta}^{\omega}$ ,  $S_m$ , MAE,  $E_m^{\max}$  and FPS. Among them,  $F_{\beta}^{\omega}$  is used to modify the Dice process to avoid the deviation of the results when the samples are relatively balanced. MAE is used to evaluate the accuracy of the result, and the size is at the pixel level. Because the above two metrics are pixel-level evaluation indicators, they lack the relationship between macro and global structure and ignore the evaluation of the similarity between them. Therefore, another evaluation index  $S_m$  is used as the evaluation standard of the similarity between the prediction result and the actual image, so as to make up for the defect of only pixel-level evaluation. The alignment measure for enhancement is also used  $E_m^{\max}$  to evaluate the similarity between the image processing at the pixel level and the global image.

Fig. 6 is an exemplificative picture of the segmentation in the processing test data set. The masked part is the display part of the intestinal polyps after image segmentation, and the white part is the judgment position of the trained intestinal polyps. After comparison, we can roughly feel the approximate accuracy of the experimental results.

Fig. 6. Sample of model image segmentation results.

## V SUMMARY

In this paper, a segmentation model structure of intestinal polyp image based on attention mechanism was proposed. This model added Convolutional Block Attention Module (CBAM) and RFB module based on the HarDNet backbone to optimize the feature extraction ability. By enhancing or suppressing the target features in the computer operation process, the operation efficiency of the model and the expression ability of features were effectively improved. The fusion of the CBAM module and RFB module in the calculation details not only increases the receptive field of the model through RFB model processing but also makes the result of the final feature map more prominent through the attention mechanism, which greatly improves the ability of the model to extract image features and improves the processing speed and accuracy of the model.

The HarDNet-CBAM model has also obtained very good experimental results through experiments. The average precision and processing speed of four test data sets have been greatly improved, indicating that this model has been greatly improved in feature extraction. At the same time, the HarDNet-CBAM model has been tested in different data sets. Compared with other models, this model has higher accuracy and greater advantages in a variety of test sets. In a word, the HarDNet-CBAM model has excellent learning ability and universality in polyp image segmentation. At the same time, it also reflects its advantages in feature extraction performance and accuracy of results.

## VI FUNDING STATEMENT

The research is funded by the National Key R&D Program (2018YFB1307004); Supported by the National Natural Science Foundation of China (61873008).

**Abstract**—The recognition of printed Arabic words remains an open area for research since Arabic is among the most complex languages. Prior research has shown that few efforts have been made to develop models of accurate Arabic recognition, as most of these models have faced the increasing complexity of the performance and lack of benchmark Arabic datasets. Meanwhile, Deep learning models, such as Convolutional Neural Networks (CNNs), have been shown to be beneficial in reducing the error rate and enhancing accuracy in Arabic character recognition systems. The reliability of these models increases with the depth of layers. Still, the essential condition for more layers is an extensive amount of data. Since CNN generates features by analysing large amounts of data, its performance is directly proportional to the volume of data, as DL models are considered data-hungry algorithms. Nevertheless, this technique suffers from poor generalisation ability and overfitting issues, which affect the Arabic recognition models' accuracy. These issues are due to the limited availability of Arabic databases in terms of accessibility and size, which led to a central problem facing the Arabic language nowadays. Therefore, the Arabic character recognition models still have gaps that need to be bridged. The Deep Learning techniques are also to be improved to increase the accuracy by manipulating the strength of technique in a neural network for handling the lack of datasets and the generalisation ability of the neural network in model building. To solve these problems, this study proposes a hybrid model for Arabic word recognition by adapting a deep convolutional neural network (DCNN) to work as a classifier based on a generative adversarial network (GAN) work as a data augmentation technique to develop a robust hybrid model for improving the accuracy and generalisation ability. Each proposed model is separately evaluated and compared with other state-of-the-art models. These models are tested on the Arabic printed text image dataset (APTII). The proposed hybrid deep learning model shows excellent performance regarding the accuracy, with a score of 99.76% compared to 94.81% for the proposed DCNN model on the APTII dataset. The proposed model indicates highly competitive performance and enhanced accuracy compared to the existing state-of-the-art Arabic printed word recognition models. The results demonstrate that the generalisation of networks and the handling of overfitting have also improved. This study output is comparable to other competitive models and contributes an enhanced Arabic recognition model to the body of knowledge.

**Keywords**—Deep learning; convolutional neural network; generative adversarial network; arabic recognition; image processing

## I. INTRODUCTION

Text recognition is among the fundamental computer science technologies, especially in pattern recognition, computer vision, and image processing. Furthermore, in the field of pattern recognition, text recognition is intended to compete against the human capacity to read written text in terms of speed and accuracy by correlating character codes (e.g., Unicode) with characters images (i.e., graphemes). The recognition process is defined as the process in which characters in images of a text are recognised and detected, which are then converted into data and coded that can be understood by the machine [1].

Arabic is known to be in a complex form of characters. Therefore, developing a novel and accurate Arabic printed word recognition model is still available for study. This is primarily due to the Arabic language characteristics, such as typing from right to left, diacritical marks, cursive characters and overlapping. Moreover, several Arabic letters contain dots, Hamza, Madda, and diacritics, which are markings placed above or below the Arabic letters; any misrecognition of these dots may result in the incorrect representation of the character and, hence, the entire word [2], [3]. Furthermore, multidimensional challenges (language-independent) are faced in developing systems for the Arabic language, which include the lack and absence of Arabic text databases, low-scanning resolution images, font variations, and the complex layout of scanned images. These limitations above contribute to the failure to apply the techniques developed for other types of languages to the Arabic language.

On the other hand, the term "deep learning" refers to a specific kind of machine learning based on an artificial neural network inspired by the structure and function of the human brain [4]. It was established to assist machine learning in achieving one of its primary intentions, which is artificial intelligence. It relies on imitating or mimicking the process in which the human brain processes data and extracting patterns to learn and perform intelligent decisions. Furthermore, deep learning is about learning several levels of representation and abstraction that aid in understanding data like images, sound, and text. Deep learning architectures are based on automated learning from features with no extraction or prior knowledge by using several layers to extract the final and needed information from raw data. Deep learning approaches have widespread use in various fields, including computer sciences, bioinformatics, image and pattern recognition, face and voice

\*Corresponding Author.

recognition, medical image analysis, drug discovery, and health risk evaluation [5]–[8].

Meanwhile, deep learning models such as CNNs have been shown to be beneficial in reducing the error rate and enhancing accuracy in Arabic printed word recognition systems [9]. In contrast, these models have several drawbacks when dealing with Arabic printed word recognition, including poor generalisation ability [2][10], overfitting [11][12] and low reliability [9]. These drawbacks are due to the reliability of Deep learning models, which increases with the depth of layers, but the essential condition for more layers is an extensive amount of data. Since CNN generates features by analysing large amounts of data, its performance is directly proportional to the volume of data, as DL models are considered data-hungry algorithms. The number of trainable parameters in deep learning models runs into millions; thus, appropriate training can only be executed by utilising a large amount of data, meaning that as the number of data increases, the model's performance becomes better behaved. Meanwhile, the lack of training data leads to overfitting, which will generate faulty or inaccurate predictions and decreased reliability. Furthermore, the accuracy rate for Arabic printed word recognition systems stated by the majority of studies using deep learning models has reached very high levels, even though the suggested solutions might not be scaled to other problems of a similar type, where most of these systems were tested on small datasets created privately for a particular task, each with its own evaluation protocols and metrics, making direct comparison and objective benchmarking impractical and not fair. Additionally, some proposed systems prevented other researchers from comparing their findings by making the tested dataset inaccessible to the public. Thus, these comparisons are considered to have low reliability. These issues are due to the limited availability of Arabic databases in terms of accessibility and size, which led to a central problem facing the Arabic language nowadays [13], [14]. Therefore, the availability of large and benchmark datasets is crucial for Arabic printed word recognition.

Overall, the accuracy of Arabic printed word recognition remains a problem in the field of pattern recognition, given that it is still at an infant stage for the Arabic language compared to Latin-based languages. These challenges are attributed to the fact that most Arabic recognition research continues to face the increasing complexity of the system's performance, where few efforts have been made to enhance models of recognising Arabic printed words. This depicts that there is still vast room for enhancements [15] [16].

Using novel deep learning techniques can revolutionise the interest and surge in the field of character recognition. Recently, GANs have been shown to be incredibly effective in various image-processing applications. Concurrently, GANs can be utilised in numerous fields, such as generating high-definition images from low-definition images, producing photo-realistic images of objects, and transforming images across domains [17].

Few studies related to Arabic recognition using GAN have been developed. The adoption of the Convolutional Neural Networks (CNNs) and Generative Adversarial Networks

(GANs) in the proposed research comes from their unintuitive generalisation behaviours and their ability to adapt to the new unseen data that arise from the same distribution as that used when the model was learned. In this paper, we investigate the potential of GANs algorithms in generating text to synthesise a result that could be used to estimate the prospect of the research topic. To build an Arabic printed word recognition model, the proposed methodology focused on enhancing the accuracy and reducing error rates for all possible reasons by covering the most critical phases of Arabic recognition (classification phase and training phase), and this was accomplished by utilising deep learning neural network models (DNN); two GAN models, and one DCNN model.

## II. RELATED WORK

Recent advances in deep learning algorithms, as well as the outstanding results obtained from CNN in image classification and prediction [6], paved the way for researchers to apply them in the classification and recognition of Arabic printed words [18].

In [19], a model is proposed for recognising offline Arabic printed documents to resolve the issue of segmentation for the Arabic text. A pipeline of three neural networks is proposed; the first network model predicted the Arabic words' font size, which is then employed in training the subsequent two models upon normalising the word of 18 points font size. Then words are segmented into characters by the second network model. Meanwhile, the Arabic characters are recognised by CNN by utilising the segmented characters as its input. The significant features are then automatically extracted. To enhance the model's generalisation ability and decrease the overfitting problem, the authors increased the training data size by applying data augmentation techniques. An accuracy rate of 94.3% is achieved when assessed on the APTI dataset.

A deep hybrid learning model is proposed in [20] to recognise printed Arabic text in a variety of font types and fonts that imitate Arabic handwritten scripts. Two bi-directional short long term memory networks (BDLSTM) and five convolution neural networks (CNNs) are employed. The proposed model functioned end-to-end and segmentation free. The proposed model was tested on the APTI database and reached an accuracy of 94.32%.

Recently, research on deep learning for Arabic text recognition has gained more attention, even though available Arabic databases remain limited in accessibility and size. In contrast, researchers have now begun to see artificial data as a safe and practical alternative to overcoming the obstacles to data access. Although generative models have received a lot of attention in the field of machine learning, they had a limited influence before the development of GANs, which provide an alternate data source for the current Arabic recognition systems that use machine learning, allowing the addition of artificial samples to training data to enhance model generalisation. Several GAN variants have been suggested after its advent in various fields, such as image processing and picture super-resolution. Despite this, only a few works based on GANs have been applied to the Arabic language [21]–[24].

According to [24], GANs are a merging technique to learn deep representation without much-annotated training data. The GAN model comprises a pair of deep neural nets aimed at training two adversarial networks by using a form of a min-max game. These adversarial networks include an expert known as a discriminator and a forger known as a generator. Additionally, the generative model receives random noise vectors as input and strives to generate an output (fake images) similar to genuine images (real images). The generator (forger) aims to generate forgeries realistic images that can trick the discriminator.

Meanwhile, the discriminator or expert strives to differentiate between fake and genuine images by classifying forged images generated by the generator as fake and genuine images from the original sample as real. On the other hand, the generator tries to reduce (minimise) its loss by optimising the objective function while the discriminator seeks to increase (maximise) it. A scalar likelihood that the input belongs to real data distribution is what it produces as an output [22], [25]–[27].

GANs are proposed to address the shortcomings of other deep learning algorithms. As mentioned early, the basic principle of GANs is the ability of the generator to generate as realistic samples as possible to deceive the discriminator. In contrast, the discriminator seeks to discern between fake and real examples. Through adversarial learning, the generator and discriminator both get better [27], [28]. Therefore, this adversarial process gives GANs a notable stand out among other generative algorithms. More precisely, GANs are superior to further deep learning algorithms because they can parallelise the generation, which is not achievable with other deep learning techniques like PixelCNN, and the generator design has few restrictions.

On the other hand, GANs are an effective subclass of generative models, which can generate entirely new valid data without requiring mathematical assumptions or the knowledge of explicit true data distribution. These benefits make GANs ideal for numerous astounding implementations that provide unexpected and unseen results; most of these implementations concern image processing [29], [30].

Furthermore, generative modelling is regarded as a strategy for data augmentation, also known as GAN-based data augmentation, and that refers to constructing artificial instances from a dataset that preserves comparable features to the original set. The main objective is to expand the dataset to address the overfitting issue and enhance the generalisation ability [22], [31].

In [22], a SentiGAN model is proposed to address the lack of dialectal Arabic datasets by augmenting low-size datasets and producing a variety of high-quality sentences for five different dialects of Arabic. Five generators and one discriminator are utilised in the dialectal Arabic generating process for a particular dialect, i.e., one generator for each dialect. The generator is used to produce new samples (text), and the discriminator assesses those samples (text), along with a dynamic update, to ensure that the process operates automatically and unsupervised. Before enriching the desired datasets, two metrics; novelty and diversity, are utilised to

check the consistency and the quality of the produced dialectal Arabic text. The MADAR dataset is used, and more sentences are generated than in the original dataset. Experimental results show that the created datasets are reliable and valuable.

The conditional deep convolutional generative adversarial network is the model suggested by the study in [23], it used for the generation of Arabic handwritten isolated characters. The suggested model consists of two CNNs, a discriminator and a generator, and competing to learn. The discriminator is a DCNN architecture composed of four convolutional layers, followed by an FC layer. Each convolutional layer involves batch normalisation and dropout with Leaky ReLU activation. The sequence of convolutions' high-level output is flattened, joined to the one-hot encoded conditional formation, and sent to a dense (FC) layer before being output. The generator is a generative algorithm that attempts to predict each pixel value of an image; the width and height of the input have to be increased to achieve the required shape. The first layer's output is modified and sent through three further layers of transposed/fractionally strode convolutions to predict a single-channelled 32×32 image. Batch normalisation with ReLU activation is performed on each transposed convolutional layer. The proposed model is trained on the AHCD dataset. Experimental results showed the effectiveness of the proposed model. Qualitative and quantitative data demonstrate that the produced samples are relatively equivalent to the genuine ones in terms of diversity and quality. Thus, the proposed model provides an easy substitute for the restricted Arabic handwritten characters database.

GANs have a wide range of types, such as BasicGAN, WGAN, DCGAN, VanillaGAN and BiGAN. These types share a discriminator and generator as standard GAN components, but their architectural designs vary. Consequently, different GANs generate various outputs. These types of GANs are used by [32] to generate different Arabic handwritten characters. The researchers split the proposed approach into two parts, one for generating an image and the other for evaluating the quality of the generated images by assessing how realistic and fake the generated images are. Fréchet inception distance (FID) and native-Arabic human evaluations are utilised. Each GAN is trained separately and generates different outputs due to the differences in their architectures. A total of 40,485 Arabic handwritten characters are generated. According to experimental findings, WGAN performed better in FID, with an accuracy of 96%. In contrast, DCGAN performs better in native-Arabic human evaluation, with an accuracy of 35%.

Furthermore, GANs have shown outstanding results in automatically synthesising high-resolution, realistic images from text representations. In [33], DF-GAN and AraBERT architectures are combined to generate images conditioned with Arabic text descriptions. The initial step is to translate the instruments from English to Arabic on CUB and Oxford-102 flowers datasets and recreate a new dataset that fits utilising the Arabic text-to-image generation operation by using the DeepL-Translator on text descriptions. Secondly, the AraBERT-generated sentence vector dimension was decreased to match the input shape of the FD-GAN. Thirdly, AraBERT is merged with DF-GAN by feeding the sentence embedding

vector to both the DF-GAN generator and discriminator. The proposed approach is evaluated with FID and IS. According to experimental results, the proposed model obtained an accuracy of 3.21% and 3.01% on SI and an accuracy of 60.96% and 65.45% on the FID score in the CUB and Oxford-102 datasets, respectively.

In [24], a novel GAN-based adaptive data augmentation model is proposed to recognise Arabic offline handwritten text. The proposed model is divided into two parts; in the first part, the authors employed an adaptive data augmentation method to generate a balanced dataset. Then, a GAN-based words synthesiser was trained in the new dataset to create images of Arabic words that look like they were written by humans, thereby boosting class diversity. The recurrent neural network library (RNNLIB) is used to develop the experimental models. The proposed model is evaluated on the IFN/ENIT and AHDB datasets and achieved an accuracy of 97.15% and 99.30%, respectively.

Based on the studies mentioned above, only a few of them are conducted on recognising the Arabic language by exploiting GANs to improve the recognition models and enhance accuracy rates, with generally satisfying results. Nevertheless, this is a worthwhile observation about the research in this field. Motivated by these research opportunities, the scarcity of studies and research motivated us to explore the strength of GAN to use it to recognise Arabic printed words to achieve promising results, as this study is considered among the first attempts in this field.

### III. MATERIALS AND METHOD

This section presents the proposed methodology of two deep learning-based models for Arabic printed word recognition; the DCNN model and the hybrid deep learning model based on GAN as a data augmentation technique. Also, it discusses the framework design of the proposed models.

#### A. Dataset

The training datasets are very crucial in the proposed approach since it is a straightforward way to get started with deep learning, and without having a good and sufficient training dataset, the system would never produce results with a high accuracy level. This study utilised the Arabic printed text image (APTI) dataset for testing and training. The APTI dataset is a collection of images of Arabic printed words. It was recently published by [34] for large-scale benchmarking of open-vocabulary, multi-font, multi-size and multi-style text recognition systems in Arabic. There are a total of 113284 different single words in the APTI dataset, each available in 10 diverse fonts: Andalus, Advertising Bold, Arabic Transparent, DecoType Thuluth, Tahoma, Traditional Arabic, Simplified Arabic, M Unicode Sara, and DecoType Naskh. It also comes with 10 different font sizes and four different styles: font sizes (6-18 and 24 points) and styles (plain, italic, bold, and a combination of italic and bold). For the present study, the dataset was split into training, validation and testing sets based on a ratio of 80%, 10%, and 10%, respectively.

#### B. Pre-processing Step

The success of classification for any DNN might be impacted by the pre-processing of the dataset images [35], affecting the final findings' recognition accuracy rate. In this work, both the DCNN model and the hybrid GAN-based model share the same pre-processing step, which involves dataset image resizing and image grey-scaling.

The training dataset images are comprised of various sizes. Therefore, this requires standardising the height and width of these images to cope with a dataset of images that could differ in size (height and width in pixels) throughout the stages of developing DNN layers. The size of the images should adjust before being used as input to the model. Therefore, images were resized to the size of 32×32 pixels.

On the other hand, the issue with images possessing multiple colour channels is that machine learning algorithms, or DNNs, have to function with three different data (R-G-B) values in order to extract the images' features and categorise them. This increases the computational complexity of the operation. DCNNs are responsible for transforming complex images into simpler ones for faster processing without missing pertinent features that are crucial to making an accurate prediction. Consequently, images are transformed into grayscale.

#### C. Proposed DCNN Model

The proposed DCNN model is based on two consequent convolutional layers, each possessing 64 filters, 3×3 kernel size and stride 1. Each layer is followed by a batch normalisation layer and a pooling layer of 2×2. Then the output of these layers is flattened by a flatten layer and squashed into two consequent fully connected dense layers, each possessing 256 neurons. Excluding the last layer, which used the softmax activation function, all other convolutional and dense layers in the proposed DCNN model employed the Leaky ReLU activation function. Lastly, the output of the two dense layers is keyed into the output layer – a fully connected dense layer that uses the softmax activation function to produce the results. The last layer comprises  $n$  neurons that represent the number of output classes. Fig. 1 depicts the overall architecture of the proposed DCNN model. For the optimisation process in the DCNN model, the Adam optimiser is adopted.

Moreover, the sparse categorical cross-entropy function is utilised for a loss function. To achieve the enhancement of the DCNN model, three significant modifications were made to the DCNN architecture. First, the DCCN model is modified by adding a batch normalisation layer after each max pooling layer in the model to catalyse and speed up training while utilising higher learning rates, which simplifies the learning process. Second, the Leaky ReLU activation function is adopted to replace the regular ReLU function in the dense and convolutional layers of the DCNN model to catalyse and faster the training duration, excluding the output layer, which utilises the softmax activation function. The final modification step is applying the sparse Categorical cross-entropy as a loss function to solve the problem of conversion long time.

Fig. 1. DCNN architecture

The proposed DCNN model consists of ten layers. Fig. 2 shows the general framework flow of the adopted DCNN model.

Fig. 2. DCNN model framework flow

As shown in Fig. 2, the proposed DCNN model layers are listed in Table I.

TABLE I. DCNN MODEL LAYERS

Layer no.	Layer Description
i	First layer is a 2D convolution layer (Conv2D). It uses 64 filters with a 3x3 kernel size. The training phase is catalysed and sped up by utilizing the Leaky ReLU as the activation function while preventing consistent predictions for negative input values.
ii	The second layer is a max polling layer with a 2x2 pool size. A pooling layer is a new layer added after the convolutional layer, particularly after nonlinearity, for instance, following applying Relu on the feature maps output by a convolutional layer. The dimensions of the feature maps can be reduced by using the pooling layers. Hence, the number of parameters required to learn and the amount of computation performed in the network are reduced.
iii	The third layer is the Batch Normalization layer. In each iteration, it normalizes the inputs by subtracting their mean and dividing by their standard deviation, and then it applies a scaling coefficient and a scale offset. After applying standardization, the resulting mini-batch has zero mean and unit variance.
iv	A 2D convolution layer (Conv2D) comprising a 3x3 kernel size and 64 filters makes up the Fourth layer. The layer's training was sped up by applying the Leaky ReLU as an activation function.
v	The fifth Layer is another max polling layer with a 2x2 pool size.
vi	The sixth layer is another Batch Normalisation layer.
vii	The seventh Layer is a Flatten layer, which is utilized to map the output of the previous Conv2D layer. After that, the Conv2D layer is flattened to be applied in the Dense layer as input. Some Neural Network implementations might not be able to map a spatial structure directly into a dense layer; thus, a flatten layer is necessary in between. Therefore, if the rank is higher, like with convolutions, the layer is implicitly flattened at first. So, the Flatten layer moves from convolution 2D to the Dense layer.
viii	The eighth layer is a fully connected dense layer using 256 filers and implementing Leaky Relu as an activation function.
ix	The ninth layer is a fully connected dense layer using 256 filers and implementing Leaky Relu as an activation function, which comprises a fully connected layer to transition from feature maps to an output prediction for the model.
x	The tenth layer is the output layer for the enhanced DCNN model. This layer uses the dense layer with the number of N+1 classes, and it implements the Softmax as an activation function.

Overfitting is one of the core difficulties that occur in multilayer NN learning, especially in deep neural networks. Overfitting generally happens once the DNN model performs effectively on the training dataset but fares badly on the testing dataset. Batch normalisation and dropout are two well-known approaches to overcoming this obstacle. Despite the fact that the two approaches share overlapping design fundamentals, multiple study findings have proven that they each offer particular advantages for enhancing deep learning.

However, several recent works have shown that the dropout technique is ineffective or even detrimental to CNNs training, which has proven that there are drawbacks to use in convolutional layers and sometimes its inefficiency. In

contrast, the training duration is typically increased upon applying dropout to a neural network, given that dropout increases the size of the network, which eliminates units during the training phase, and reduces the network capacity [11], [12].

On the other hand, adding batch normalisation in DNN architecture significantly improves the accuracy. Furthermore, batch normalisation substantially reduces training time and permits the utilisation of high learning rates. As a result, the training steps that are needed for network convergence are reduced [36].

According to [37], adding batch normalisation layers after the non-linear layers improves accuracy. Before introducing batch normalisation (BN), the network's training time was substantially dependent on the precise hyperparameters initialisation, including the adoption of modest learning rates, thereby increasing the time of training. During DNN training, each layer's input value distribution is influenced by the layers which came before it. Because this variation slows training, BN was developed to address it and accelerate the process of learning. The process of BN involves adjusting the unit value of every batch, and since batches are generated at random throughout training, additional noise is introduced into the training process. The noise works as a regulariser, and its effects are like that generated by dropout. Resultantly, dropout can be removed from the deep neural network.

According to [36], the addition of batch normalisation layers should be among the initial steps in optimising a CNN, not just for handling overfitting but also for its ability to improve accuracy significantly. To overcome the overfitting problem in the proposed enhanced DCNN Model, the batch normalisation layers are adopted and used after each convolutional layer in the network model.

#### D. Hybrid Model Based on GANs

This section presents the procedures applied to develop the proposed hybrid GAN-based model. The proposed hybrid GAN-based model combines the generative adversarial networks and the DCNN. The architecture of the proposed hybrid model consists of a GAN model that is used as a data augmentation technique and a DCNN model as a classifier employed for printed word recognition.

First, the GAN model is built, which comprises two deep neural networks; the discriminator network and the generator network. The generator generates new images, whereas the discriminator determines the originality of the generated images. The discriminator evaluates each produced image to decide if it is part of the training set or not. Nevertheless, the generator attempts to generate an additional fake instance in order to convince the discriminator that the image generated corresponds to the training set. During the training process, the discriminator and generator models compete with one another. While the generator strives to fool the discriminator, the discriminator attempts hard to avoid being deceived.

As a result, this competition between the two models encourages both to enhance their capabilities. The skills of these neural networks are sharpened as they undergo more training, thus increasing the ability of the generator to generate

real-like images which indistinguishable from that observed in the real world. Concurrently, the discriminator is more effective in detecting fake images. The accuracy of the final results will improve as the size of the training dataset increases. The training for the dataset will align with the level of the Arabic printed words. Fig. 3 shows the overall research framework for the proposed hybrid GAN-based model.

The second step entailed the classifier DCNN model development. The proposed DCNN is utilised to classify the images of Arabic printed words, which is the last step in the proposed hybrid GAN-based mode. The DCNN is employed, given that it is a typical multiclass classification NN. The classifier DCNN accepts the new dataset as input and captures various perspectives on features via the convolutional operation. The resulting feature maps produced from each convolution layer are passed to the following convolution layers with extra kernels. The reason for the pass is to extract a higher level of features of the input image. The pooling layer then summarises the feature map features generated by the convolution layers to reduce the dimensionality of the feature maps, hence minimising the amount of computation performed in the network. The classifier DCNN in the proposed hybrid GAN-based model shares the same architecture as the proposed DCNN model introduced previously. Fig. 1 shows the shared architecture used for both the stand-alone enhanced DCNN model and the classifier DCNN in the proposed hybrid GAN-based model. The DCNN model classifier uses the newly generated collection of images. This way, generative adversarial modelling is used as an alternative to data augmentation techniques in the proposed hybrid GAN-based model.

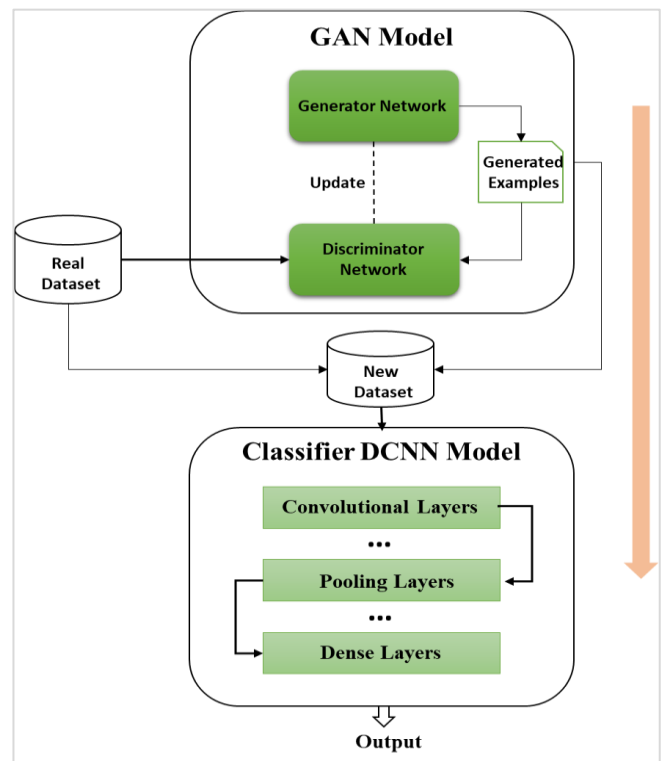

Fig. 3. Hybrid GAN-Based model design

1) *Generator neural network:* The proposed hybrid GAN-based model employs a generator neural network with ten layers. Two of the proposed enhancements for the proposed DCNN model are adopted in the generator neural network, the first one is the addition of adding batch normalisation layers, while the second one is adopting the Leaky ReLU as an activation function. The generator neural network layers are listed in Table II.

TABLE II. GENERATOR NEURAL NETWORK LAYERS

Layer no.	Layer Description
i	A sequential neural network of 10 layers is built with 8 layers as the hidden layers.
ii	The first layer is the input layer – a fully-connected dense layer with 32*32*256 filters, 32*32 for the width and height and 256 neurons.
iii	Second layer is a batch normalisation layer.
iv	Third layer is a reshape layer to convert the shape of data into two-dimensional representation.
v	Fourth layer is a transposed convolution layer with 256 filters and (3*3) kernel size.
vi	Fifth layer is another batch normalisation layer.
vii	Sixth layer is transposed convolution layer with 128 filters and (3*3) kernel size.
viii	Seventh layer is another batch normalisation layer.
ix	Eighth layer is another transposed convolution layer with 64 filters and (3*3) kernel size.
x	Ninth is the last batch normalisation layer in the network.
xi	The last layer is the output layer, which is another transposed convolution layer with (3*3) kernel size.
xii	The generator neural network is compiled using Adam Optimizer.
xiii	The loss in the generator neural network can be found with cross-entropy loss function.

2) *Discriminator neural network:* The discriminator neural network for the proposed hybrid GAN-based model consists of nine layers. For the additional enhancements, the batch normalisation layers are added after each convolution layer, and Leaky ReLU is adopted as an activation function. The discriminator neural network layers are listed in Table III.

TABLE III. DISCRIMINATOR NEURAL NETWORK LAYERS

Layer no.	Layer Description
i	A sequential neural network of 9-layers is built with 7 layers as the hidden layers.
ii	First layer is a convolution layer that has 64 filters and 3*3 kernel size with input shape 32*32*1 for height, width and one-color channel.
iii	Second layer is another convolution layer that has 128 filters and 3*3 kernel size
iv	Third layer is layer is another batch normalisation layer.
v	Fourth layer is another convolution layer with 256 filters and (3*3) kernel size.
vi	Fifth layer is another batch normalisation layer.
vii	Sixth layer is known as the flatten layer, this layer used to resize and flatten the data.
viii	Seventh layer is fully connected dense layer with 128 neurons (filters).
ix	Eighth layer (the last hidden layer) is another fully connected dense layer with 128 neurons (filters).
x	Ninth is the last batch normalisation layer in the

	network.
xi	The final layer is the output layer, a fully-connected dense layer with n+1 neurons (n = the number of classes).
xii	The discriminator neural network is compiled using Adam Optimiser.
xiii	The loss in the discriminator NN can be found with cross-entropy loss function.

3) *Deep CNN classifier:* The DCNN classifier in the proposed hybrid GAN-based model has the same architecture as the proposed DCNN model that introduced in section C. As mentioned previously, the DCNN classifier for the proposed hybrid GAN-based model consists of ten layers in total, and it has the same additional enhancements as the proposed DCNN model. The additional enhancements were the batch normalisation Layers, adopting the Leaky ReLU as the activation function and using sparse categorical cross-entropy as a loss function.

4) *Handling Overfitting for The Hybrid GAN-Based Model:* Since the proposed model consists of two parts; the GAN and the classifier DCNN part, two techniques were adopted to handle the possibility of overfitting in any of the two parts:

a) *Handling overfitting for the Generative Adversarial Part:* To avoid overfitting, generative and discriminative algorithms are used. The training dataset is fed to the discriminator; hence, the generator lacks any information on the training dataset while it creates new data instances. The generator is fed only from the discriminator, which decides whether each instance of data reviewed belongs to the actual training dataset or not. The proposed model is designed in a way that the generator never sees the genuine data; it must learn to create realistic information by receiving feedback from the discriminator. This process is called adversarial loss and works surprisingly well when implemented correctly.

b) *Handling overfitting for the Classifier Deep Convolutional Neural Network Part:* The significance of the proposed models in using GANs is to produce more realistic images to increase the dataset size for training the classifier deep CNN network. Among the techniques to handle overfitting is having more training datasets. Algorithms can be supported to detect signals effectively by training with more datasets. However, the technique would not be helpful if just noisier data were added to the training data. Thus, it should ensure that the newly generated dataset of images is clean and relevant in the GAN model. Actually, this technique works, such as data augmentation techniques, which can apply to increase the dataset's size artificially. Data augmentation refers to increasing the data size, which is increasing the number of images available in the dataset. As a result, in this way, generative adversarial modelling is utilised as an alternative to data augmentation techniques in the proposed hybrid GAN-based model. The use of generative adversarial modelling as a data augmentation technique offers a more domain-specific way to increase the number of training images with new high-quality generated images in domains with limited data. This approach enables the model to address the overfitting problem.

In addition to the previous solution, batch normalisation layers are adopted and added to the classifier DCCN part to tackle the overfitting problem in the proposed model. Since the DCNN classifier shares the same architecture as the DCNN model that proposed, a batch normalisation layer was added after each convolutional layer in the classifier DCNN to make an additional step in overfitting handling for the overall proposed hybrid GAN-based model.

#### IV. EXPERIMENTAL RESULTS AND DISCUSSION

Two models have been conducted in this study. The first model conducted is the DCNN model. Then the second model is a hybrid deep learning model based on GAN. In addition, this experimental design discusses the aim of the experiments, as well as how they may be attained. The two proposed models are evaluated using the Arabic printed text image database (APTI). The dataset is split into three sets (training, validation, and testing) using a ratio of 80%, 10%, and 10%, respectively. The implementation part of the proposed approach is a program written in Python using TensorFlow 2.0 and Keras.

##### A. DCNN Model

To evaluate the accuracy of the proposed DCNN model and to compare it with other approaches, the model is analysed through a number of evaluation scenarios using APTI datasets. The proposed DCNN is tested on the dataset before and after the additional enhancements. The results obtained from each experiment for the proposed DCNN model were compared before and after the enhancements.

Regarding the testing results, the proposed enhanced DCNN model achieved high (WRR) accuracy scores on the APTI dataset, which corresponded to an average overall test set and validation accuracy of 94.81% and 94.96%, respectively. On the other hand, the DCNN model without enhancements achieved an average accuracy of 93.67% and 94.17% for validation. The differences in results are shown in Fig. 5. The enhanced model on the APTI dataset starts learning with fast steps from the first epoch to the 20<sup>th</sup> epoch in a continuous increase in the accuracy until it attained an accuracy of 91%. Then, the training process started to slow down after the 20<sup>th</sup> epoch to the 40<sup>th</sup>. After that, the model reached stability in the training accuracy at epoch number 40. The model shows the accuracy results in ascending values and achieves the best accuracy in the 40 epochs with training accuracy.

From Fig. 4, the enhanced DCNN model learns better than the original DCNN model in the training phase. CNN models learn better if the training process is better; that means the enhancements of adding batch normalisation Layers, adopting the leaky ReLU as an activation function, and using sparse categorical cross-entropy as a loss function helped to make the model training process faster and more accurate in the Arabic printed words recognition and classification phase. Furthermore, the inclusion of batch normalisation layers facilitates the usage of higher learning rates during the training process. This explains why the enhanced DCNN model performed better in testing and validation results of the

enhanced DCNN model than the standard DCNN model without enhancements.

On the other hand, the proposed enhanced DCNN model for Arabic printed word recognition achieved high recognition accuracy (WRR) of 94.81%, outperforming other state-of-art models. Compared to the recognition accuracy obtained by the hybrid deep learning model based on CNN and BDLSTM to recognise printed Arabic text proposed by [15], where the enhanced DCNN model outperformed the hybrid CNN and BDLSTM Model by a small margin and achieved a recognition accuracy of 94.32%. In addition, the work by [14] proposed three neural networks pipeline model to recognise printed text images of the APTI dataset of words that contains over two-million-word samples, which uses data augmentation techniques and was able to score a recognition accuracy of 94.30%. The detailed comparison between the two-word recognition models is illustrated in Fig. 5.

Fig. 4. Testing and Validation Accuracy for the DCNN Model with and without the enhancements

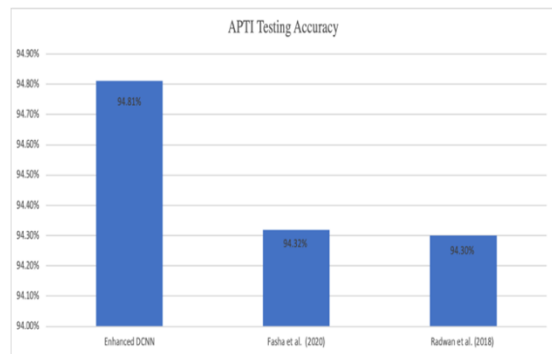

Fig. 5. Testing Results for the Enhanced DCNN against State-of-Art Models

##### B. Hybrid DL Model based On GAN

The performance of the proposed hybrid GAN-based model is evaluated by introducing the GAN phase into the proposed enhanced DCNN model to generate a new dataset of clean and relevant images. This occurs using GAN as a data Augmentation technique by artificially increasing the dataset size. The experimental testing for the proposed hybrid GAN-Based model is conducted in APTI datasets. Firstly, the results obtained from the proposed hybrid GAN-Based model were compared to those from the enhanced DCNN model to determine the impact of using the GAN phase, then compared

the proposed hybrid GAN-Based model with the state-of-the-art studies.

In terms of the testing results, very high accuracy scores (WRR) are achieved by the full proposed hybrid GAN-Based model with generative adversarial step on the APTI dataset. The overall test set accuracy is 99.76%, and 99.85% is achieved for the validation accuracy, while the corresponding values for the proposed enhanced DCNN model without the generative adversarial step as data augmentation technique was 94.81% and 94.96%, respectively. The discrepancies in results are presented in Fig. 6.

Fig. 6 illustrates that the proposed hybrid GAN-Based model achieved a higher success rate on the APTI dataset with higher testing accuracy results compared to the enhanced DCNN model. Thus, the hybrid GAN-based recognition model learnt better than the Enhanced DCNN model in the training phase.

Fig. 6. Testing and Validation Accuracy for the proposed Hybrid GAN-Based model with the Enhanced DCNN model

Furthermore, as depicted in Fig. 7, the proposed hybrid GAN-Based model also achieved promising validation scores over the enhanced DCNN model. The proposed hybrid model that based on using the generative adversarial networks as a data augmentation technique achieved higher validation accuracy than the enhanced DCNN model. The overall validation and testing results of the hybrid GAN-Based model and the enhanced DCNN model on the APTI dataset are presented in Table IV below.

TABLE IV. APTI TESTING AND VALIDATION ACCURACY RESULTS

Implementation	Validation Accuracy %	Test Accuracy %
Hybrid GAN-Based model	99.85	99.76
Enhanced DCNN model	94.96	94.81

From the previous Fig. 6 and Table IV, it is notable that the hybrid GAN-based model that is based on using the GANs as a data augmentation technique outperformed the regular enhanced DCNN model in the APTI dataset, producing higher validation and test accuracy results. Adding GANs to the classifier DCNN model and using it as a data augmentation technique assisted in making the model training process more accurate in Arabic printed word recognition and classification.

As observed in the experiments, the hybrid GAN-based model commenced learning with fast steps from the first epoch to the 20<sup>th</sup> epoch with continuously increasing accuracy until a

value of approximately 93% is attained. Then, the training process started to slow down after the 20<sup>th</sup> epoch to the 40<sup>th</sup> one. After that, the model reached stability in the training accuracy at epoch number 40. The hybrid GAN-based model shows the result of accuracy in ascending values, achieving the best accuracy in the 40 epochs with training accuracy. The testing and validation accuracy measures utilise the word recognition rate (WRR) as a measurement unit on the APTI dataset.

On the other hand, the hybrid GAN-based model for Arabic printed word recognition achieved high recognition accuracy of 99.76%, thereby outperforming other the best state-of-the-art models. The proposed hybrid GAN-based model outperformed the recognition accuracy values obtained by the hybrid CNN and BDLSTM model proposed by [20] on 18 fonts and duplicate words across fonts types in the APTI dataset with a very good margin (99.76% vs. 94.32%), as well as the three NN pipeline model proposed by [19], that used traditional data augmentation techniques regarding recognition accuracy on the Printed Text Images of the APTI dataset and achieved recognition accuracy of 94.30%. The detailed comparison between the printed word recognition models is illustrated in Fig. 7.

The experimental results for the proposed hybrid GAN-based model demonstrated that the proposed model achieved very high accuracy (WRR) scores on the APTI dataset. Specifically, the proposed hybrid GAN-based model achieved average overall testing and validation accuracy of 99.76% and 99.85%, respectively. Meanwhile, the proposed enhanced DCNN model, without using any additional data augmentation techniques, achieved an average overall test set accuracy of 94.81% and 94.96% for the validation accuracy. The proposed hybrid GAN-based benefits from all the additional enhancements that are added to the enhanced DCNN model, batch normalisation layers were added to the proposed hybrid GAN-based model networks after each convolutional layer. The leaky ReLU was also utilised as an activation function, and the sparse categorical cross-entropy was employed in the classifier DCNN part of the proposed hybrid GAN-based model as the loss function.

Fig. 7. APTI Testing Results of the proposed Hybrid GAN-Based model and other state-of-the-art models

From an analytical point of view, Fig. 6 and Fig. 7 depict the highly competitive testing accuracy results achieved by the proposed hybrid GAN-Based model, which outperformed other state-of-the-art models. The result proves that the proposed hybrid GAN-Based model could learn more and better during the training phase than the other machine learning-based models. The bigger training data generated from the generative adversarial model assisted the proposed hybrid GAN-based model in scoring higher recognition accuracy. This explains why the proposed hybrid GAN-based model outperformed other CNN models in the state-of-the-art models for Arabic printed word recognition on the APTI dataset.

## V. CONCLUSION

This study is considered one of the first to successfully develop a novel framework model based on DL techniques using DCNN and GAN to recognise Arabic words. The proposed model included two kinds of deep neural networks; GAN and DCNN, to enhance the training and classification phase of the printed word recognition model. The generative adversarial neural networks were designed to work as a data augmentation technique that is applied to artificially increase the size of the dataset by generating a new set of images and adding it to the original dataset to tackle the lack of Arabic datasets, the more extensive dataset will enhance the training accuracy for the Arabic text recognition classifier DCNN model. Additionally, solutions for the overfitting problem were introduced, such as having more data to train by employing the GAN as a data augmentation technique. More data training can assist models in avoiding overfitting issues. The experimental results showed the strength of the proposed approach of using the GAN model as a data augmentation technique.

The impressive testing accuracy results for printed word recognition prove that generative adversarial models can be used as a very good alternative data augmentation technique that can be applied to artificially increase the size of the dataset by new high-quality and real-like images indistinguishable from the real dataset images. Such new images can be crucial in boosting the training accuracy for the DCNN models. The results of the proposed model are promising, where the accuracy of the proposed model was 99.76%. These results prove the potential of the proposed model to develop an Arabic language recognition field. In future, we will test the proposed model on several languages to evaluate the proposed hybrid GAN-based model in terms of generalisation and token independency.

**Abstract**—The study of quantum cryptography is one of the great interest. A straightforward and reliable quantum experiment is provided in this paper. A half wave plate in linearly polarized light makes up a simplified polarization rotator. The polarization rotates twice as much as the half wave plate's fast axis' angle with the polarization plane when the half wave plate is rotated. Here, an experiment of message sharing is conducted to demonstrate quantum communication between parties. The unitary transformation is performed step by step using half-wave plates represented by the Mueller matrix. A simulation created using Python programming has been used to test the proposed protocol's implementation. Python was chosen because it can mathematically imitate the quantum state of superposition.

**Keywords**—Half-wave plate; polarizer; photon beam splitter; Stoke Vector

## I. INTRODUCTION

Numerous organizations, including those in the industrial and academic areas, have shown a great deal of interest in quantum cryptography. Numerous productive research projects over the past few years have demonstrated a great advancement in optical equipment development and quantum cryptography [1]. The term "flying quantum bits" is frequently used to describe photons, emphasizing both their quantum nature and their capacity to transport quantum information over long distances [2]. Light can be thought of as a transverse electromagnetic wave, as has already been established. So far, it only discussed light that is linearly polarized or plane-polarized, meaning that the electric field's orientation is constant despite changes in its amplitude and sign over time.

An optical filter known as a polarizer or polarizer is used to block light waves of certain polarizations while allowing light waves of others to flow through. A polarizer is also an optical device that uses natural light as its input and produces some kind of polarized light as its output [3]. This means that it may convert an undefined or mixed polarization light beam into polarized light by filtering it through a well-defined polarization beam. For instance, consider the superposition of two equal-amplitude, incoherent, orthogonal p-states as a possible representation of unpolarized light. A linear polarizer is a device that separates these two elements, discarding one and keeping the other [4]. In fact, the BB84 protocol, the very first quantum key distribution approach, was put forth using the polarization of photons.

Normally, light is free to oscillate at an angle to its path in any direction. When light passes through a polarizing filter, it becomes polarized. But how can be telling experimentally whether a device is a linear polarizer or not? Only light in a p-states will be transmitted if light is incident on a perfect linear polarizer. The orientation of that p-state will be parallel to the transmission axis of the polarizer, which is a specific direction. Only the part of the optical field that is parallel to the transmitting axis will effectively pass through the device unchanged. Due to the full symmetry of unpolarized light, the reading from the detector will not change if the polarizer is rotated about the z-axis. Based on the output beam's intensity, the polarizer determines the polarization states.

Now take a look at a type of optical components called retarders or also known as wave plate, which are used to modify the polarization of incident waves. Half-wave plates ( $\lambda/2$  plates) are the most common types of waveplates. Half wave plate is described as having  $\frac{\theta}{2}$  phase shift [5]. Linearly polarized light can be rotated by half wave retarders to an angle that is double the angle between the fast axis of the retarder and the plane of polarization. The polarization rotates  $90^\circ$  when the fast axis of a half wave plate is positioned at  $45^\circ$  from the polarization plane.

Continuously adjusting the energy with a half-wave plate and polarizer is another effective strategy. The polarizer can select the polarization direction of light, whereas the half-wave plate can rotate the polarization direction of light, and the two together may provide continuous light energy adjustment. The half-wave plate may continually change the polarization orientation. Assume that the slow axis is at an angle,  $\theta$  to the polarisation direction. The phase of the fast axis is incremented by one after passing through the polarizer, and the polarisation direction is rotated by an angle,  $\theta$ . Light passes into the polarizer through the half-wave plate. The transmitted energy for the polarizer is determined by Malus' law (Eq. 1).

The optical beam splitter is a crucial component in determining the statistical properties of light. The beam splitter has been used in many different areas of optics. For instance, in the field of quantum information, the beam splitter is fundamental for teleportation, bell measurements, entanglement, and basic research on photons. A beam splitter is a tool that splits an input beam into two beams travelling in different directions [6].

The rest of this paper is organized as follows: Section II reviews the related works of quantum cryptography that use optical devices. Section III presents the experiment environment. Section IV describes the principle of operation with schematic. Section V discusses hardware implementation. The experiment setup is discussed in Section VI. Section VII describes the experiment simulation. Pseudo code explained in Section VIII. Finally, Section IX concludes this paper.

In this study, presented a straightforward method for polarization alignment in which a half-wave plate is used to rotate the polarization of incoming light with respect to the fiber axis.

## II. RELATED WORK

In the last few years, several quantum experiment protocols using optical devices have been proposed. The main objective of those experiments was to ensure that the messages are delivered well among the parties involved. This section reviews several quantum experiments that use optical devices such as polarizer and half-wave plate for stimulation how the sharing message operation happens in quantum network, discussing their basic concepts, and describing their advantages and drawbacks. Fig. 1 shows the example implementation of polarizer, which when light passes through a polarizing filter, and it becomes polarized.

Fig. 1. Polarisation of light [7]

According to prior research, the quantum gate offers a number of advantages, including being simple to operate because parties do not always share information about the operators, requiring less precision than arbitrary rotational devices like half-wave plates (HWP) which enables precise measuring [8]. In 2019, Harun *et al.* proposed Hybrid M-ary in a braided single stage (HMBSS) [9]. The unitary transformation is performed step by step utilizing half-wave plates represented by the Mueller matrix. Five HWP was implemented in this protocol. For the purpose of authentication, the half wave plate's update angle or rotation is updated every 8 bits. The level of security has been raised at each stage due to the quick polarization changes, although it takes longer to send the information. The time required for message transmission and half-wave plate rotation is represented by the total transmission time. One can compute the transmission time as follows [9]:

$$\text{Transmission Time} = T_{msg} + T_{HWP} \quad (1)$$

where  $T_{msg}$  is the message transfer time and  $T_{HWP}$  is the half wave plate's time to update its angle during the encryption phase. The more the number of half wave plate implemented, the more time needed to encode each bit [10]. For example, the IV three-stage technique takes a long time because a single bit must exchange 3 times over the channel when using the three-stage protocol. The IV three-stage protocol requires Alice and Bob to use seven HWP for the polarization of bits in order to ensure the message's confidentiality, which lengthens the time it takes to encode each bit [11].

In 2021, with the use of single qubit unitary operations, Kang *et al.* have created a quantum message authentication mechanism that ensures the authenticity and integrity of the original message [12]. This protocol is made up of two parts: quantum encryption and a consistency check. Linear combinations of wave plates are used to implement the quantum encryption component. Assume that the secret key sequences have already been disclosed to Alice and Bob. This protocol implemented quantum encryption using half wave plates on Alice's side for the message authentication step.

Riggs *et al.* proposed Multi-Wavelength Quantum Key Distribution Emulation [13]. Multi-wavelength QKD can enable ternary and quaternary data transfer while removing the requirement to share a portion of the final key for eavesdropper detection. The half-wave plates were rotated before the laser pulse is sent in order to polarize the laser and measure it appropriately. In order for a half-wave plate to function, linearly polarized light must be rotated for the resulting polarization is twice as large as the angle between the optical axis and the incident polarized light [13]. In data transmission phase, through Alice's half-wave plate and Bob's half-wave plate, the laser beam is polarized. Bob's half-wave plate serves as the beam's measurement. At this point, the laser beam should only be vertically or horizontally polarized if Alice and Bob employed matching bases. If the resulting polarization is diagonal, the horizontally polarized light is transmitted while the vertically polarized light is reflected at the polarizing photon beam splitter cube. Just one of the detectors should experience the full intensity of the beam and light up if Alice and Bob employ matching bases.

## III. EXPERIMENT ENVIRONMENT

In order to fully examine the performance of the proposed method, numerous parameter values must be determined. The quantum network simulation photon generation, encoding, decoding stage and schematic diagram utilized in this paper are described in this section.

### A. Quantum Network Simulation

Quantum networks including hardware components such as optical devices are costly to deploy since expert configuration is required and real-time experiments take a long time to complete. As a result, quantum communication protocols are tested and evaluated using simulation.

Because it can describe quantum states in mathematical form, the Python software was used to simulate the function of hardware components in a quantum communication

environment. The Python software is also used to simulate the impact of light polarization in the implementation.

### B. Photon Generation

A sender turns the original message into a binary string, which is then converted into a qubit via photon polarization. Multiple photons were created for each encoded bit [14], referring to one bit of information for the production of multiphoton, let's say three photons for each bit. The operation begins with the laser generating a laser beam, which is then passed over the quantum channel and transmitted through a beam splitter, which splits the beam into two channels, one with a 0° polarizer and the other with a 90° polarizer. The mirror then assembles the laser beam before combining it with a beam combiner.

### C. Encoding and Decoding

For encoding stage, the beam is directed towards the HWP at this point in order to modify the polarization of the beam using a secret polarization angle. While for decoding stage, the detector will detect whether the bit is 0 or 1 after go through beam.

### D. Schematic Diagram

The basic polarization of light as one of the strategies to encode the photons is required by the laser that emitted numerous photons through a multi-stage process. The Stokes parameter, which is a value of a linear polarization angle, is used to determine the polarization state of light [15]. The Stokes vector is used to determine light polarization as it passes through an optical system. The following vector form can be used to represent the four Stokes parameters [16]:

$$s = \begin{bmatrix} s_0 \\ s_1 \\ s_2 \\ s_3 \end{bmatrix} \quad (2)$$

where  $s_0$  indicates total optical beam intensity,  $s_1$  indicates linear horizontal or vertical polarised light,  $s_2$  indicates +45° or -45° polarised light, and  $s_3$  indicates right circular or left circular polarised light.  $s_1$  and  $s_2$  will be affected by the simple rotation operator, but  $s_3$  will stay unaffected.

The polarizer determines the polarization states based on the intensity of the output beam. The intensity output can be determined using Malus's law, given as [17]–[19]:

$$I_o = I_i \cos^2(\theta) \quad (3)$$

where  $\theta$  is the secret polarization angle for the bits,  $I_o$  is the output intensity,  $I_i$  is the input intensity.

$$\frac{1}{2} \times [1 \cos(2\theta) \sin(\theta) 0] \times = \frac{1}{2} \times [1 + \cos(2\theta)] \quad (4)$$

where  $S$  is the input bit, Equation 2's condensed form is obtained as below:

$$\frac{1 + \cos(2\theta)}{2} = \cos^2 \theta \quad (5)$$

In this study, 90° of linearly polarized light represents bit 1 and 0° of linearly polarized light represents bit 0 in matrices, as shown in Table I.

TABLE I. STOKES VECTOR AND STATE OF POLARIZATION

Stokes Vector	State of polarization	Bit representation
$s: \begin{bmatrix} 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$	Light that isn't polarized	-
$s: \begin{bmatrix} 1 \\ 1 \\ 0 \\ 0 \end{bmatrix}$	Linearly polarized light at 0°	0
$s: \begin{bmatrix} 1 \\ -1 \\ 0 \\ 0 \end{bmatrix}$	Linearly polarized light at 90°	1

## IV. PRINCIPLE OF OPERATION WITH SCHEMATIC

Following is a detailed explanation of the full experimental process for the hardware over free space optics (FSO) illustrated in Fig. 3. The protocol's implementation was divided into three different phases which are encoding, rotation transformation and decoding phase.

### A. Encoding

Alice generates a state with a 0 linear polarization at the start of the protocol using a 0° polarizer. The polarization of light is accomplished by Alice and Bob using two sets of polarizers to change a bit into a quantum state referred as a qubit, described by a Mueller matrix [10].

$$M_{pol} = \frac{1}{2} \begin{bmatrix} 1 & \cos(2\theta) & \sin(2\theta) & 0 \\ \cos(2\theta) & \cos^2(2\theta) & \cos(2\theta) \sin(2\theta) & 0 \\ \sin(2\theta) & \cos(2\theta) \sin(2\theta) & \sin^2(2\theta) & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix} \quad (6)$$

where  $\theta$  is the degree of polarisation angle that is set from 0° to 180° and  $M_{pol}$  is the polarizer's rotation.

The beam is directed towards the HWP at this point in order to modify the polarization of the beam using a secret polarization angle. The HWP is angled at a certain angle and is updated for each batch of bits.

### B. Rotation Transformations Stage

This section discusses the configuration of the unitary transformations used with half wave plates as well as the selection of the half wave plates' rotation angle ( $\theta$ ) with regard to the horizontal axis. This decision relies on the Mueller matrix formalism to guarantee that the half wave plate setup's input and output polarisation angles are equivalent.

1) *Half wave plate operation:* Fig. 2 shows the implementation of both polarizer and half wave plate. A half wave plate generates a 180° polarization shift between the fast and slow axes of a wave plate. A HWP that is installed on a rotator and will be rotating at a random angle decided upon by Alice and Bob is also included. Given that the Stokes vector has four dimensions, Mueller matrices, as shown by [20], can be used to characterize the optical components of the HWP device as four by four matrices. The HWP operation's rotation is shown as [21]:

Fig. 2. Polarizer and half wave plate are employed [7]

$$M_{HWP} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & \cos(4\theta) & \sin(4\theta) & 0 \\ 0 & \sin(4\theta) & -\cos(4\theta) & 0 \\ 0 & 0 & 0 & -1 \end{bmatrix} \quad (7)$$

Where

$$0^\circ < \theta < 180^\circ \quad (8)$$

### C. Decoding Stage

A beam combiner is used to combine the signals that come out of the channel. When the beam goes through the  $0^\circ$  and  $90^\circ$  polarizers, the detector will detect whether the bit is 0 or 1.

## V. HARDWARE IMPLEMENTATION

Table II lists the hardware components utilized in the simulation experiments, along with their descriptions. The schematic diagram is explained in the next section.

The hardware components listed in Table II are deployed into the simulation environment at this point. Depending on the requirements of the experiment, the hardware can be put in fiber optic or free space optic.

TABLE II. HARDWARE COMPONENT [15]

Components	Description
Laser	Light intensity detector
Beam Splitter	A 50/50 beam splitter is used to split a laser beam into equal-intensity beams.
Polarizer	Filter the laser beam to produce a $0^\circ$ or $90^\circ$ polarized light beam that indicates bit 0 or 1.
Half wave plate	Encrypt the laser's data and generate superposition states based on angles.
Light intensity detector	Check whether the photons are 0 or 1.

## VI. EXPERIMENTAL SETUP

Fig. 3 shows the implementation of HWP in message sharing procedure. Alice will have two half-wave plates (HWPs), whereas Bob will have one HWP. In our implementation, a linearly polarized laser serves as the photon source. Depending on whether the input bit is 0 or 1, polarizers are used to filter a beam of light to pass a  $0^\circ$  or  $90^\circ$  degree polarized beam [8]. Alice generates a state with a 0 linear polarization at the start of the protocol using a  $0^\circ$  polarizer.

The polarization technique generates a quantum bit (qubit) by encrypting the classical bits with photons. After encrypting the classical bits to the photons, Alice will use HWP-1 to execute a transformation at the angle  $\theta_A$ , this produces the superposition state,  $|\psi\rangle$ . The superposition states hold the secret message that Alice and Bob will communicate in quantum ways.

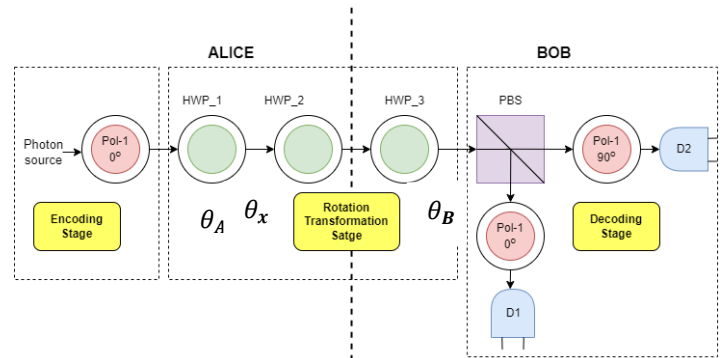

Fig. 3. Schematic of the experimental set-up over free space optics

In order to increase the security of the protocol, it is noted that HWP-1 at the angle  $\theta_A$  is the authentication key specified from  $0^\circ$  to  $45^\circ$ . The transformation coupled with the encoded bit is then applied by Alice using HWP-3, which will be set at an angle  $\theta_x = 0$  for bit 0 or  $\theta_x = 45$  for bit 1.

$$\text{Message } X \Rightarrow \text{bits} \in \{0,1\}$$

$$\{0,1\}^n \Rightarrow \begin{cases} |0\rangle, S_{out} = M_{HWP}(0^\circ) \times S_{in} \\ |1\rangle, S_{out} = M_{HWP}(45^\circ) \times S_{in} \end{cases} \quad (9)$$

where  $S_{in}$  is the input light's input state comes from the polarizer Stokes parameter sequence, which is represented as

$$S_{in} = \begin{bmatrix} S_0 \\ S_1 \\ S_2 \\ S_3 \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \\ 0 \\ 0 \end{bmatrix} \quad (10)$$

and  $S_{out}$  is the output light's input state from the polarizer Stokes parameter sequence:

$$S_{out} = \begin{bmatrix} S'_0 \\ S'_1 \\ S'_2 \\ S'_3 \end{bmatrix} \quad (11)$$

The input for this study is a  $0^\circ$  state. Consequently, the Stokes parameter's output is described by

$$S_{out} = M_{HWP}(\theta_x) \times S_{in} \quad (12)$$

After passing through the HWP, the light's polarization angle may be calculated [28,29] by:

$$\theta = \cos^{-1} \frac{S_{in}[1:3] \cdot S_{out}[1:3]}{\|S_{in}[1:3]\| \times \|S_{out}[1:3]\|} \quad (13)$$

where "." represents the multiplication operator and  $\|\cdot\|$  represents the norm operator.

Bob receives the optical beam from Alice that contains the message, and uses a HWP-3 set at an angle  $\theta_A$  to remove his transformation. After passing it via a polarization beam splitter,

Bob will receive in a beam polarizer at either  $0^0$  or  $90^0$  degrees. Accordingly, if  $\theta_x = 45$ , the output light will be vertically polarized and if  $\theta_x = 0$ , the output light will be horizontally polarized. Detectors will determine if the bit is 0 or 1.

### VII. EXPERIMENTAL SIMULATION

In this section, the proposed protocol's basic description is covered. First of all, the message that has been converted to binary code is encrypted into a quantum bit or also known as qubit. The proposed protocol is then used to communicate the qubit from Alice to Bob as follows.

1) *Let's say Alice gets a photon ready:* The first qubit,  $|0\rangle$  is what Alice wishes to transmit, and it is encrypted to the photons using the first defined angle from the first method,  $\theta_A = 30^0$ . Alice prepares photons according to Equation (10) and encrypts them by rotating HWP according to Equation (7):

$$\varphi_1 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & \cos(4(30)) & \sin(4(30)) & 0 \\ 0 & \sin(4(30)) & -\cos(4(30)) & 0 \\ 0 & 0 & 0 & -1 \end{bmatrix} \times \begin{bmatrix} 1 \\ 1 \\ 0 \\ 0 \end{bmatrix} = \begin{bmatrix} 1 \\ -0.5 \\ 0.8660254 \\ 0 \end{bmatrix} \quad (14)$$

2) Alice then performs the transformation corresponding with the encoded bit. The angle is set to  $\theta_x = 0^0$  if bit 0 is being transmitted or  $\theta_x = 45^0$  if bit 1 is being sent.

$$\varphi_2 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & \cos(4(0)) & \sin(4(0)) & 0 \\ 0 & \sin(4(0)) & -\cos(4(0)) & 0 \\ 0 & 0 & 0 & -1 \end{bmatrix} \times \begin{bmatrix} 1 \\ 1 \\ 0 \\ 0 \end{bmatrix} = \begin{bmatrix} 1 \\ -0.5 \\ -0.8660254 \\ 0 \end{bmatrix} \quad (15)$$

3) When Bob gets  $\varphi_2$ , he rotates it using the angle of the authentication key,  $\theta_A = -30^0$ , to decode it. The original message is delivered to Bob. The result of the  $\varphi_2$  represents the state  $|0\rangle$  that Alice sent.

$$\varphi_3 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & \cos(4(-30)) & \sin(4(-30)) & 0 \\ 0 & \sin(4(-30)) & -\cos(4(-30)) & 0 \\ 0 & 0 & 0 & -1 \end{bmatrix} \times \begin{bmatrix} 1 \\ -0.5 \\ -0.8660254 \\ 0 \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \\ 0 \\ 0 \end{bmatrix} \quad (16)$$

### VIII. PSEUDO CODE

The algorithms in this work serve as an exact list of instructions that carry out the steps in the process of transmitting messages via optical devices. The steps include encoding, rotation of HWP and decoding stage. The pseudo-code of the protocol is detailed in Algorithm 1.

#### Algorithm 1

1. Notation:
2.  $R(\theta) \leftarrow$  is the rotation of HWP using Equation (6)
3.  $\theta_A \leftarrow$  Angle of HWP at Alice
4.  $\theta_x \leftarrow$  Angle of HWP at Alice either  $0^0$  or  $45^0$
5.  $\theta_B \leftarrow$  Angle of HWP at Bob
6. Alice prepares a photon using Equation (9)
7. Encoding Stage: Generate a photon to represent a qubit after the laser beam passed through a linear polarizer:
8. Alice generates a state with a  $0^0$  linear polarization using a  $0^0$  polarizer.
9. Rotation of HWP Stage
10.  $R(\theta_A) |\varphi_0\rangle = |\varphi_1\rangle$
11.  $R(\theta_x) |\varphi_1\rangle = |\varphi_2\rangle$
12. **if** bit 0 is being transmitted **then**
13.      $\theta_x = 0^0$
14. **else if** bit 1 is being sent **then**
15.      $\theta_x = 45^0$
16. **end if**
17.  $R(\theta_B) |\varphi_2\rangle = |\varphi_3\rangle$
18. Decoding Stage: The polarizer detects the photon's polarization states
19. Bob receives beam polarizer at either  $0^0$  or  $90^0$  degrees
20. **if**  $\theta_x = 0^0$  **then**
21.     the output light will be horizontally polarised
22. **else if**  $\theta_x = 45^0$  **then**
23.     the output light will be vertically polarised
24. **end if**
25. Detectors will determine if the bit is 0 or 1

### IX. CONCLUSION

Photonic polarization qubits are frequently employed in quantum computation and quantum communication due to their robustness in transmission and ease of manipulation. But the usage of optical devices such as half wave plate and polarizer might high costs. The more the number of half-wave plates implemented in an experiment, the more times needed to transmit the message. This is because of changing the polarization angle of an optical device for encoding purposes, more time is required. These circumstances have led to an increase in source redundancy, which in turn causes a rise in transmission time. After consideration, this experiment implements three half-wave plates only. Bear in mind that this experiment is to help to stimulate how was the quantum cryptography works on message sharing among the parties since it can describe quantum states in mathematical form. This study was written to explain that quantum experiments can be carried out using optical devices. And the stimulation shown can be used as a guideline for other researchers. This paper also contributes an alternative way through Python software to

simulate the function of each hardware component and uses the polarization of the quantum state to encrypt messages in a quantum communication environment.

#### ACKNOWLEDGMENT

This research was supported by Ministry of Higher Education (MOHE) through Fundamental Research Grant Scheme (FRGS/1/2021/ICT11/UTHM/03/1). We also want to thank to the Government of Malaysia which provide MyBrain15 programme for sponsoring this work under the self-funded research grant and L00022 from Ministry of Science, Technology and Innovation (MOSTI).

**Abstract**—Today, with the advancement of science and technology, artificial intelligence evolves and grows along with human beings. Clinical specialists rely only on their knowledge and experience, as well as the results of complex and time-consuming clinical trials, despite the inevitable human errors of diagnosis work. Performing malignant and dangerous diseases, the use of machine learning makes it clear that the ability and capacity of these techniques are beneficial to help correctly diagnose diseases, reduce human error, improve diagnosis, and start treatment as soon as possible. In diseases, image processing and artificial intelligence is widely used in medicine and applied in stereological, histopathology. One of the essential activities for diagnosing the disease using artificial intelligence and machine learning is the fragmentation of images and classification of medical images, which is used to diagnose the disease with the help of images of the patient obtained from medical devices. In this article, we have worked on classifying medical histopathological images of brain tissue. The images are not of good quality due to sampling with standard equipment, and an attempt is made to improve the quality of the images by operating. Also, all images are segmented using the U-NET algorithm. In order to improve performance in classification, segmented images are used to classify images into two classes, normal and abnormal, instead of the images themselves. The images in the data set used in this study have a small number of images. Due to the use of a convolutional neural network algorithm to extract the feature and classify the images, more images are needed. Therefore, the data amplification technique to overcome this problem is used. Finally, the convolutional neural network has been used to extract features from images and classify fragmented images. Experimental results shown that the proposed method presented better performance compared to other existing methods.

**Keywords**—Image processing; fragmentation of images; machine learning; image classification; stereological; histopathology

## I. INTRODUCTION

Today, with advances in various fields such as engineering and medicine, organizations produce and collect large amounts of data every day. Hence, the need for data analysis to improve

an organization's processes, advance goals, speed things up, and reduce possible errors is felt. With the development of technology, there are significant advances in medicine that have increased data and information, so one of the topics in data analysis is to improve the quality-of-life process and community health, which is medical data. Machine learning can be used to improve performance and conclusions in medicine and reduce diagnostic errors. There are different types of medical data. Data can be text, image, video, and audio. In this article, the data used are medical images of the brain area taken from slides. In this way, brain cells are placed on a slide, one of the accessories of laboratory equipment, as an example for observation under a microscope. Then, microscopic observations are taken, and these images are used as data in this study.

One method of data analysis for medical images (brain area) is machine learning. Machine learning is the scientific study of algorithms and statistical models that computer systems use to perform a particular task without explicit instructions, patterns, and inference. This is known as a subset of artificial intelligence. Machine learning algorithms create a mathematical model based on sample data, known as "training data," to make predictions or decisions without explicitly planning for the task [1-4]. Using the built model, the machine learns that if new data enters the machine, the machine can use the built model to predict the new data and specify the desired label for each data. The purpose of this paper is to identify image tags using a machine [5-7].

The purpose of this study is to develop a method to perform malignant and dangerous diseases using machine learning techniques which the ability and capacity of these techniques are beneficial to help correctly diagnose diseases, reduce human error, improve diagnosis, and start treatment as soon as possible. In diseases, image processing and artificial intelligence is widely used in medicine and applied in stereological, histopathology. One of the essential activities for diagnosing the disease using artificial intelligence and machine learning is the fragmentation of images and classification of

medical images, which is used to diagnose the disease with the help of images of the patient obtained from medical devices.

Types of machine learning methods include supervised learning, semi-supervised learning, and unsupervised learning [8,9]. The data that will be used in this study are images of brain cells, all of which are labeled. So, learning that can be used for them has supervised learning. On the other hand, these data have two types of labels (normal and abnormal). As a result, the type of problem will be a binary classification problem. To learn, the machine must be able to extract features from photographs. An essential part of this study is the extraction of features from photographs and the fragmentation of photographs to examine microscopically the changes made by cerebellar cortex images in which the body changes [10,11]. The cellular neurons are comparable in different groups. The data used is raw and real, so that they will have some inconsistencies and problems. Most images are not of good quality and will confuse the machine. So, these problems must be fixed to improve performance and efficiency. On the other hand, it is necessary to prepare the data according to the conditions and the problem to the appropriate data to be injected into the desired algorithms. In general, it means that the data should be transformed in a way that the algorithm is acceptable and permissible for the implementation of algorithms, and the data should be cleared of any unnecessary errors and information to have the desired output. Data processing needs to be preprocessed. That will be the first step in this study. The most critical data preprocessing techniques include data cleansing, data integration, data reduction, and data transformation [12-15].

The next step is to segment the images. Fragmentation is a very related task in the analysis of medical images. Automatic separation of organs and structures of interest is often necessary to perform tasks such as visual augmentation, computer-aided detection, interventions, and the extraction of quantitative indicators from images [16-18]. Image segmentation, also called tagging, is the process of dividing an individual element of an image into a set of groups so that all the elements in a group have a common feature. In medicine, this common feature is usually that the elements belong to the same type of tissue or organ [19-23]. Different algorithms and methods can be used for segmentation. The purpose of segmentation is to simplify and change the representation of an image into something more understandable and easier to analyze. By segmenting the images, the borders and lines of the images will be determined, leading to better performance for the next step, which is to extract the features.

After preprocessing and segmentation, the feature extraction operation is performed on the data. Feature extraction is a process in which, by performing operations on data, it is obvious and determining features are determined. Feature extraction is done on the data used in this article to extract the features that are in the images. The machine is trained in these features, and based on the learning it has from these features, any other image except these images is provided to the machine so that the machine can correctly predict the label of the image without the label. There are different algorithms for feature extraction, which in this research will use a convolutional neural network algorithm. Deep learning

algorithms, especially convolutional neural networks, have quickly become a method for analyzing medical images. Deep network learning algorithms consist of many layers that input data while learning higher-level features. For example, it converts images to output (for example, the type of disease).

The most successful models for image analysis to date are convolutional neural networks [24-26]. In deep learning or hierarchy, several different layers are used to learn features. The more (deeper) this hierarchy of layers is, the more nonlinear properties are obtained. For this reason, this article has tried to use more layers. Of course, this statement has its limitations. After a certain number of layers, the system's performance does not improve, and new and more features are not trained. On the other hand, it is impossible to work directly on the input image to obtain or produce features containing more information. For this reason, deep learning with layers and hierarchies has been used.

Most dangerous diseases, such as cancer and the presence of tumors in the body's organs, are well diagnosed by examining and analyzing images obtained from sampled tissue samples. Therefore, it is possible to prevent the disease's progression and treat it as soon as possible by diagnosing it as quickly and accurately as possible. Therefore, a better and more accurate analysis of histological images can be beneficial to doctors and patients and can even be said to reduce the risk of death. Generally, histology specimens obtained in the operating room are processed by formalin and then embedded in paraffin to diagnose the disease. The tissue is then cut with a high-precision device and mounted on glass slides. The slides are stained with hematoxylin and eosin (H&E) to see the nucleus and cytoplasm. Finally, pathologists complete the diagnosis by visually examining histological slides under a microscope. However, in breast cancer diagnosis, histologists agree in 75% of cases and disagree in other cases [27-29]. Therefore, due to the complex nature of visible structures, traditional manual detection of tissue microstructure and general organization of nuclei in histological images is very time-consuming and can be subjective. As a result, computer-aided automation systems are essential to reduce specialists' workload by improving diagnostic efficiency and reducing the mentality of disease classification [30-33].

In this article, images of cerebellar tissue are used, the images used are of low quality, and the quality of the images should be normalized and then analyzed. In addition to the low quality of the images, when coloring the images, unfortunately, some color deposits are created in the image, which is quite similar to the cells in the texture and distorts the process. The color of the cells, on the other hand, is very similar to the background color of the tissue, slowing down the analysis. The challenges for segmentation and image classification are that the number of images is about 91, which is a minimal number and not enough to use deep learning to analyze images, and solutions had to be devised. On the other hand, an algorithm for segmentation should be selected that can perform well on histopathological images and has acceptable and good accuracy with low images. Regarding the classification algorithm, an algorithm that works well for histopathological medical images should be selected. It is expected that the quality of the images can be increased and the accuracy of the work can be

improved, and also that the images can be segmented with high accuracy. Most importantly, the results obtained by extracting features from the images using machine learning are better and more accurate than the physicians' manual method. The classification error can also be significantly reduced until new data or a histological image of the new patient can be presented. Correctly predict whether the new image has a normal or unnormal texture.

## II. PROPOSED ALGORITHM

Fig. 1 shows a flowchart of the general process and the proposed algorithm. In the first step, the image quality is improved, including two parts: color change and removing color deposits. Then, the images are divided into two training sets and experiments in the second step. In the third step, the images are segmented by the U-net algorithm. In the fourth step, due to the lack of images, data amplification technique training is applied to the images. In the fifth step, all images are pre-processed. Finally, feature extraction is performed on fragmented and amplified images using the convolution neural network algorithm and using these features. The convolution neural network classifies the images. In the following, each of these sections is examined.

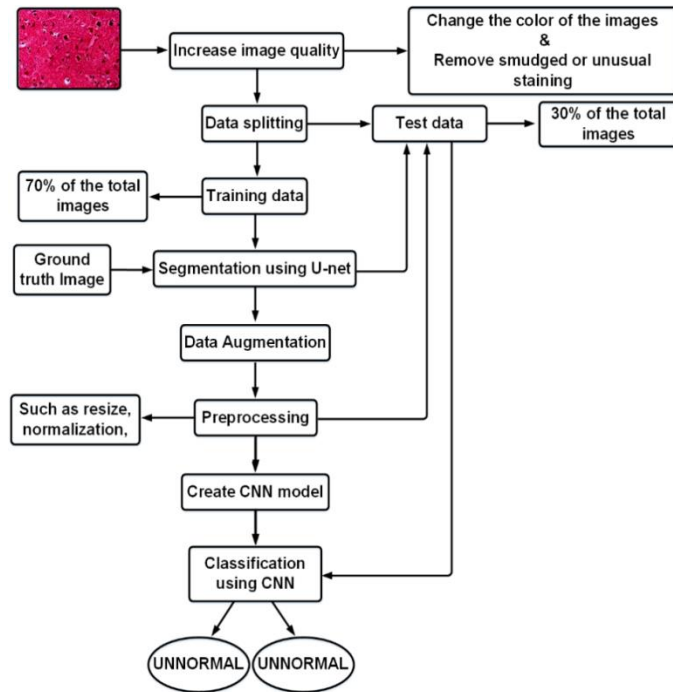

Fig. 1. The proposed algorithm

## III. PROPOSED PROCESS

In this section, the solution of the article is described in detail. According to the explanations in the previous chapters, the primary purpose of this article is to present a process for improvement in the classification of histopathological images of brain tissue using deep learning. Also, the following is a general introduction to the data set to understand the process better.

### A. Data Set

The data used in this article are brain tissue images. This dataset contains 91 histological images. All available images have labels, and there are two types of labels that are normal and abnormal. Each available image is only a member of one of these two tag classes. Class images do not overlap, meaning that an image can be a normal and non-normal class member and belongs to only one class. On the other hand, the number of images in these two classes is balanced, i.e., the number of images in the two classes is not much different from each other and is relatively evenly distributed in the two classes. For more familiarity with the available data, normal and unnormal image samples are shown in Fig. 2 and 3, respectively. As shown in the figures above, both images are very similar, and it will not be easy to distinguish between them. In histological images, in order to analyze the images, the cells in the histological images should be analyzed. These images have been used for the first time in this article, and no analysis has been done on these images before. Brain tissue is first sampled to image the data, then placed on a slide, a laboratory device, then stained by specialists to identify the cells better, and placed under a microscope and photographed. All the equipment used for sampling and photography is standard laboratory equipment, and no advanced and high-quality equipment is used because this sampling and imaging are done in a simple laboratory in the university. For this reason, the images are not of good quality.

Fig. 2. Sample normal image

Fig. 3. Sample unnormal image

### B. Improve Image Quality

As shown in the previous images in Fig. 1 and 2, the background colors and the cells in the images are very similar. This may confuse the process, so to avoid this problem to increase the images' transparency and better distinguish the cells from the background, the color of the images has been changed using the Icy program. Fig. 4 shows an example of an image before and after a color change. The sediments in the

images are very similar to the actual cells. This causes many errors in the work process. For this purpose, the colored deposits in the images must be removed. To remove these sediments, Icy software and a paint program are used, and the

sediments are removed. Fig. 5 shows an example of images (a) before and (b) after sediment removal.

Due to a large number of images, all the steps performed in this step are applied to all images in the data set.

Fig. 4. Sample images, (a) before applying the color change, (b) after applying the color change

Fig. 5. Sample images, (a) before sediment removal, (b) after sediment removal

### C. Data Separation

After changing the color and removing color deposits, the images should be divided into two parts: training and testing. In all processes, the ratio of the number of training to the test is about 7 to 3, i.e., 70% of the normal data and 70% of the unnormal data are related to the training section, and the remaining 30% are related to the test section. The following is the number of data assigned to each class. The total images are equal to 91 images, of which 50 images belong to the normal class, and 41 images belong to the unnormal class. Out of a total of 91 images, 64 images are allocated to the training set and 27 images to the test set. Out of 64 images related to the training set, 34 are for normal class, and 30 are for unnormal class. Also, out of 27 images assigned to the test set, 16 are for normal class, and 11 are for unnormal class. As it turns out, there is a balance between the number of images in both classes, meaning that the distribution of images in the classes is relatively equal.

$$\text{Overall Image} \rightarrow 91 \begin{cases} \text{Normal} \rightarrow 50 \\ \text{Unnormal} \rightarrow 41 \end{cases}$$

$$\text{Training Data} \rightarrow 64 \begin{cases} \text{Normal} \rightarrow 34 \\ \text{Unnormal} \rightarrow 30 \end{cases}$$

$$\text{Teste Data} \rightarrow 27 \begin{cases} \text{Normal} \rightarrow 16 \\ \text{Unnormal} \rightarrow 11 \end{cases}$$

### D. U-Net Algorithm

This algorithm has a specific architecture, which is used in this article. The architecture is briefly described below. In 2015, Ronberberger et al. Proposed architecture for the segmentation of biomedical images [34]. This architecture is called U-net because of its U-shape. It is also called hourglass architecture. Convolution neural networks and deep learning techniques are not yet widely used because they have limitations due to the need for large amounts of data to teach complex models. However, the U-Net architecture does not require a large number of images due to the beneficial use of

data amplification techniques. Fig. 6 shows the architecture of this algorithm. This architecture has two contracting paths on the left and a Symmetric expanding path on the right. The contracting path is to extract the feature, and the expansion path is symmetrical to obtain the feature map. In general, this architecture has 23 layers of convolution. The contraction path follows the typical architecture of a convolutional network. This path involves repeated use of two 3×3 convulsions, each modified using a linear function (ReLU) and a maximum aggregation operation of 2×2 max using step 2 for downsampling. At each step of the descent, the number of feature channels doubles. Each step in the symmetric expansion path involves a mapping of the feature map, followed by 2×2 up sampling that halves the number of

channels and two 3×3 convulsions with the ReLU linear function for correction. Also, at each stage, the feature maps are concatenated in the opposite stage of the contraction path. Cutting at any stage is necessary due to the loss of boundary pixels in each convolution. In the last layer, a 1×1 convolution is used to map all 64 attribute vector components to the number of available classes. Data reinforcement is essential when the amount of data is small. Since there is often little data in medicine, the need for data reinforcement becomes sensitive in these cases. This is present in the U-Net architecture itself, and this has made U-Net work well for low-data datasets. All images are fragmented using this algorithm, and then the images generated by the output of the U-Net algorithm will be used.

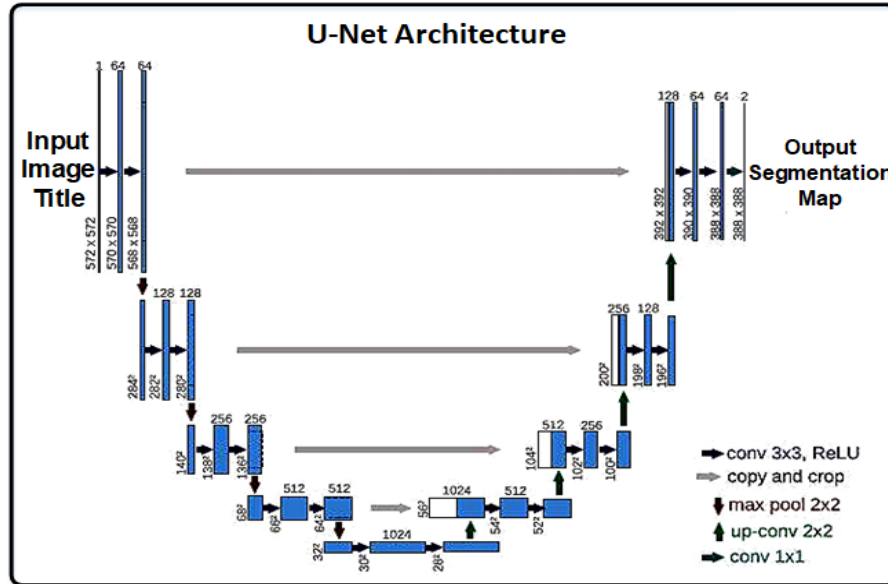

Fig. 6. U-Net architecture [34]

### E. Generate Mask Images

In order to segment images, there must be a tag for the images. The label in the segmentation is different from the label in the classification. In segmentation for system training, the system must be told which goal in the main image is to select and segment which part of the images. In image segmentation with the U-Net algorithm, the required tags are images called masks, which are given to the system to compare

the image and the mask corresponding to determine the purpose, segmentation, and selection. The real and mask sample images extracted by the excerpt are shown in Fig. 7.

As mentioned, these tags did not exist for this dataset. In this study, mask images are extracted using Icy software, a mask extraction program. This is done under the supervision of an expert so that the selection of essential areas would not be mistaken and the system could be properly trained.

Fig. 7. Sample image (a) real, (b) mask

#### F. Data Augmentation

Improving the performance of deep neural networks is often directly related to the data available for training. In convulsive neural networks, if the amount of data is small, the system learning operation will not work well. More data is needed to improve the network. On the other hand, due to the lack of data in medical imaging, especially tissue imaging, due to complex sampling and imaging, and not much data collection is possible, the image enhancement technique will be beneficial. This technique allows the data to be amplified and the data set to be strengthened without requiring new images. This data will be based on the images in the current data set. By learning new properties from those images and the original images, the network gains the power to understand a broader range of each object and becomes so-called Generalized.

Therefore, it is clear that the selection of settings for the data amplification technique must be made carefully and follow the content of the data and the type of problem. Applicable trial and error enhance data enhancements for selected images. In this way, new images are generated by the

data amplification technique using different settings. Then the convolutional neural network is trained, and user settings in the data amplification technique are selected according to the improvement or non-improvement of the network. Modern deep-learning algorithms, such as convolutional neural networks, can learn features independent of their location in the image. However, amplifying and adding data by changing rotation, light, and color can further aid in learning independent features in the image. Eventually, the grid learns to recognize the object correctly if it is turned from left to right in the image or has little light and clarity. The critical point here is that data amplification should only be applied to training images, not test data, as this would compromise network performance. Fig. 8 shows the main figure. Fig. 9 also shows (a) the vertical flip and (b) the horizontal flip.

By applying the above changes to the entire tutorial images, about 50 images are added to each of the normal and unnormal image groups. The above changes do not pose a problem histologically because histologists can analyze images from any angle and direction.

Fig. 8. The main figure

Fig. 9. Shows (a) the horizontal flip, (b) the vertical flip

#### IV. CONVOLUTION NEURAL NETWORK ARCHITECTURE

When a computer receives an image as input, it sees it as an array of numbers. The number of arrays depends on the size of the image (in pixels). For example, suppose a color image in JPG format with a size of 1280×960 pixels is given to the computer. In that case, its replacement array will have

3×1280×960 cells. The number 3 goes back to RGB and means that the image is in color. Each of these houses also has a number between 0 ~ 255. This number indicates the pixel intensity. The only available tools in the category of images using convolutional neural networks are such numbers. To understand and recognize complex images, such as the image

of a cell, the computer first recognizes the simpler features of that image, such as edges and curves.

The design of network layers can be different for each data, depending on the purpose pursued. The architecture designed in this article gave the best results for the data at hand. This architecture has 6 layers of convolution, and 5 layers of aggregation applied between the layers of convolution. In the last layer, a fully connected layer is used. The fully connected layer is responsible for calculating the score of categories (classes) to classify images. The filters used for the convolution layer have dimensions of  $5 \times 5$ , which include weights. The ReLU activator function is also used for the activator function. ReLU applies an activation function to each neuron, such as  $\max(0, x)$ , which sets the threshold at 0 (i.e., values  $x$  for negative values and 0 for negative values). This does not change the mass size from the previous step, i.e., the size of the output in this layer equals the output dimensions of the previous layer. This function does not change the dimensions of the output. The input layer is  $3 \times 224 \times 224$  images. The value of  $3 \times 224 \times 224$  are the dimensions of the images, and 3 also refers to the fact that the images are 3 channels, i.e., color images. Images enter the convolution neural network through the feed-forward stage. In the feed-forward stage, each filter is slid along the inlet's width and height, creating an Activation Map for that filter. As the filter slides across the inlet width, multiplying the point between the filter inputs by A stream is also performed. The result is passed through an activation function, and output is generated. In other words, at this stage, the input is multiplied by the weights, added to the bias, and entered into an activation function. This process continues until the end.

The initial weight of the grid is randomly weighted. Then Adam's reverse optimization algorithm is used to update the weights. The reverse algorithm is used to adjust the parameters based on their impact on the final result. This algorithm

calculates the error from the last layer. In order, layer by layer, the parameters are adjusted based on that error. That is, the weights and deviations are changed in such a way as to produce a result closer to the actual output with less error in the next iteration. CROSS ENTROPY is used as a loss function to determine the amount of error in the reverse algorithm, which aims to minimize the error. Optimizers and other activators can be used, each of which can be tried and tested. If each of these items is accurate, that item will be selected for use, but in most cases, they are not much different. In this study, it is concluded by trial and error to use the ReLU activator function and Adam optimizer. Fig. 10 shows the general structure of the architecture used.

As shown in the architecture shown in Figure 10, the first  $224 \times 224$  images enter the network. In the first layer, a convolution layer with a  $5 \times 5$  filter is applied to the image. The ReLU activator function is used, and the output is given to the aggregation layer with a  $2 \times 2$  filter and step 2, in which the dimensions of the images are halved. Then the output from the first aggregation layer is given to the second convolution layer again, and the same cycle continues. In designing convolutional neural network architecture, an important question is how many layers and what kind of sex is needed. Because the performance of architectures and layers is different for different data, like the other stages, trial and error have been used in this stage. Increasing the number of layers to a range improves neural network performance. After a range, increasing the number of layers reduces performance. This point can only be found by trial and error. The number of layers is also increased by trial and error. After this number of layers, as shown in Fig. 10, it is observed that the network performance does not improve. Even after the following few layers, it reduces the network performance. That is why the network is trained with 6 layers of convolution and ReLU, 5 layers of aggregation, and one fully connected layer.

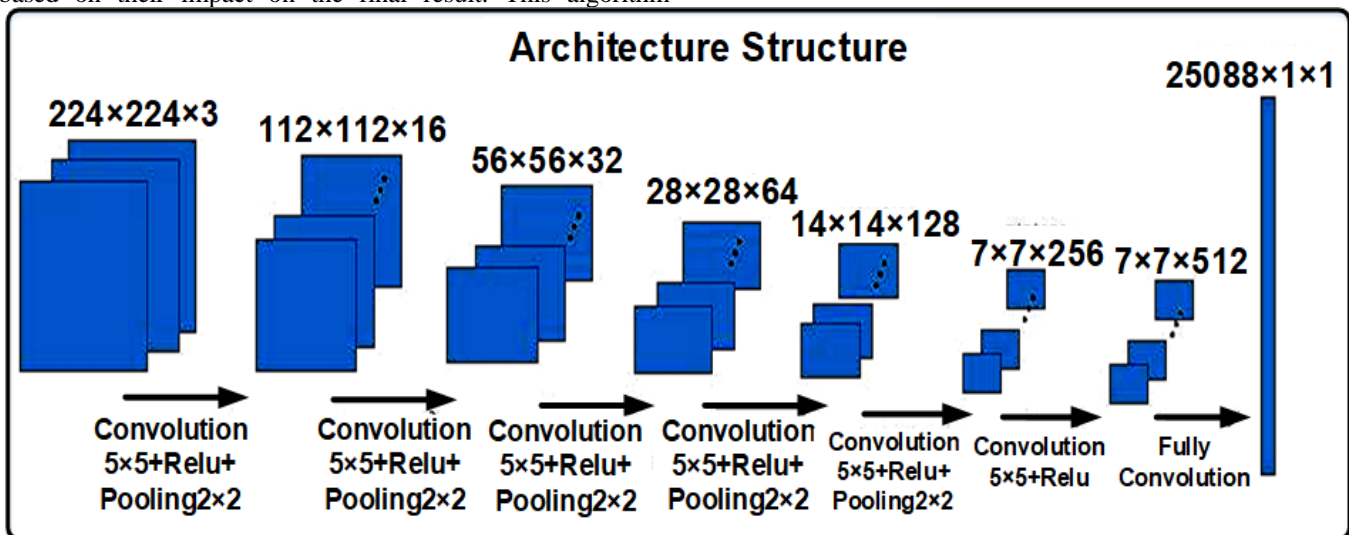

Fig. 10. General structure of architecture

## VI. RESULTS AND EVALUATION

In this section, evaluations and comparisons are provided to prove the efficiency of the proposed algorithm. For this purpose and to provide comprehensive results, the proposed method is reviewed in stages. In the following, the obtained results are discussed using evaluation criteria to measure the performance of the proposed process. The knowledge generated in the model learning stage should be analyzed in the evaluation stage to determine its value and then determine the efficiency of the model learning algorithm. These criteria can be calculated for the educational data set in the learning phase and the set of experimental records in the assessment phase. Evaluation of experimental data is often used because it shows the performance of the process. So, one of the most critical steps after designing and building a model or an algorithm is to evaluate its performance. Different evaluation criteria are used based on the existing algorithm and purpose. In this dissertation, two essential algorithms have been used, each with a separate evaluation. First, a brief description of the evaluation criteria used is given.

The results of the convolution neural network are described. In most previous works, the images entered the convolutional neural network directly after initial preprocessing. Alternatively, extracted through the neural network and then classified by another algorithm. The images are classified in several stages using a convolutional neural network, and the classification results are evaluated. All the results of these several stages are compared. The last step is related to the proposed process. The goal is to raise the standards of accuracy and reminder; the more these three criteria, the better the network performance. The criterion of accuracy obtained in all stages is in percentage.

On the other hand, the criteria of accuracy and numerical recall are between 0 and 1, which is closer to 1, i.e., the better the performance of that class. The data are randomly isolated six times for evaluation, and then all steps are performed. Finally, the results obtained from the repetition of six steps are averaged.

### A. Evaluation of Convolution Neural Network with Raw Images

In a reference study [24], the images entered the convolutional neural network for further analysis after applying techniques to reduce the number of images and select images. Because the data set, they used to have a lot of similar images. This study does not need to reduce the number of images because the data set used has few images. According to the reference, the images then entered the convolutional neural network [35]. First, the raw images entered the convolution neural network without any changes. Raw images are primary images without applying the segmentation algorithm and without applying the sediment removal and color change steps. The evaluation is performed 6 times on random data. Table I shows the accuracy, precision, and recall obtained in all these six steps. Also, in the end, the average of six steps will be considered.

In this table, the rows represent the evaluation steps, and the columns represent the evaluation criteria, which is the same

as the overall accuracy of the convolution neural network. Precision and Recall are also provided for each normal and abnormal class. Because both classes are equally important. Convulsive neural network in these conditions has an accuracy of about 76.14%. The normal class has a Precision of approximately 0.739 and a Recall of approximately 0.76. Also, the unnormal class has a Precision of approximately 0.76 and a Recall of approximately 0.73.

### B. Evaluation of Convolutional Neural Network with Fragmented Image

As mentioned before, in previous works, most images are classified using a convolutional neural network after a series of preprocessing to classify the images, especially histopathological images. In the solution proposed in this article, all images are segmented before the images are classified. Then, fragmented images are classified using a convolutional neural network. This step discusses the results obtained from the classification of fragmented images. The results for this process are according to Table II, in which also in this step, 6 random data are evaluated and finally averaged.

In this process, the accuracy is equal to 87.61%. Also, the precision and Recall of the normal class are equal to 0.871 and 0.91, respectively, and the precision and Recall of the unnormal class are equal to 0.915 and 0.846, respectively. As it is known, all the evaluation criteria in this process have improved compared to the previous process.

### C. Figures and Tables Evaluation of Convolution Neural Network with Segmented Image and Use of Data Amplification

In this series of evaluations, the quality of the images is first improved using the scale removal step and color change. The improved images are then segmented using the U-Net algorithm. Due to the lack of several images and in order to improve the performance of the convulsive neural network, the data amplification technique is used. The results obtained from the classification of this step of the images are according to Table III, also this step is repeated 6 times, and the average is taken.

The accuracy of this process is equal to 93.825%. Also, the precision and recall of the normal class are 0.912 and 0.978, respectively. On the other hand, the precision and recall of the unnormal class are equal to 0.979 and 0.9.

### D. Overall Evaluation Results

The following Table IV shows all the results of the evaluated steps. There is also a comparison chart in Fig. 11 to measure the accuracy of all steps.

Fig. 12 also provides a comparison chart for all steps and precision and recall criteria for each normal and abnormal class.

According to the diagram in Fig. 12 and Table IV, it can be seen that the accuracy obtained from the classification stage of fragmented images and the use of the data amplification technique has the highest percentage, approximately 93.82%. Also, according to Fig. 12 and Table IV, it is clear that the precision and recall of both normal and unnormal classes in the

classification of fragmented images and the use of data amplification are more than the other steps. Therefore, using the segmentation and data amplification technique in

histological medical images will have a good performance on the convolutional neural network.

TABLE I. RESULTS FROM THE CLASSIFICATION OF PRIMARY RAW IMAGES

-	Accuracy (%)	Precision (n)	Recall(n)	Precision(un)	Recall(un)

## VII. DISCUSSION

The accuracy, precision, and recall attained over the course of six steps are shown in this study's experimental results. To show the convolution neural network's overall accuracy, the evaluation process and evaluation standards are represented. Precision and Recall are also supplied for each normal and abnormal class. Because both classes are equally important. In these circumstances, the accuracy of the convulsive neural network is roughly 76.14%. Precision and Recall for the typical class are respectively 0.739 and 0.76. Also, the Abnormal class has a Precision of roughly 0.76 and a Recall of approximately 0.73.

According to the presented results, it can be seen that the accuracy obtained from the classification stage of fragmented images and the use of the data amplification technique has the highest percentage, approximately 93.82%. Moreover, the results of performance measurements indicates that the precision and recall of both normal and unnormal classes in the classification of fragmented images and the use of data amplification are more than the other steps. Therefore, using the segmentation and data amplification technique in histological medical images will have a good performance on the convolutional neural network.

## VIII. CONCLUSION

Today, deep learning has become one of the main techniques in the field of machine learning. They have solved many problems by using deep learning, and the use of deep learning has helped to improve the performance of many problems. For example, they use in-depth learning to diagnose various diseases, process medical images, social networking issues, etc. In this paper, deep learning is used to classify histological images. Images in different stages are classified using a neural network, as is clear from the results of the implementations. Improved image quality improved the performance of the U-Net segmentation algorithm. The U-Net algorithm also performed well for histopathological imaging.

On the other hand, the U-Net algorithm for small medical data sets can produce satisfactory results. The results obtained from the classification of fragmented images show that the segmentation of histological images improves the function of the convolutional neural network. The data amplification technique is also effective in this study because the number of images for training convolutional neural networks is minimal. Using the data amplification technique has led to better network learning. More images will ultimately help the process perform better. So, in general, it can be concluded that using segmented images and data amplification technique is helpful for histological images and causes better performance of the convolution neural network.

**Abstract**—Analytical reading is a necessary cognitive skill for advancing to other skills required in the digital age. Thailand is focused on the instructional development and use of digital media to enhance the digital natives' analytical reading skills, which will assist learners of all ages in effectively and quickly adapting to changes in the digital environment. After the COVID-19 pandemic situation, educational institutions in Thailand have begun to embrace a hybrid learning approach like never before. The limitations of the existing learning process for boosting digital natives' analytical reading skills are the lack of integration between reading techniques, hybrid pedagogies, and emerging learning technologies to enhance learners' seamless learning experiences. Thus, this study aims to propose the Cloud-powered Hybrid Learning process (Cp-HL process) to enhance digital natives' analytical reading skills. This study consisted of two main stages in the research methodology: 1) learning process development; and 2) learning process evaluation. The developed Cp-HL process had four main learning phases: (1) preparation for hybrid learning; (2) presentation for interactive learning; (3) practice with analytical reading; and (4) progress reports on analytical reading skills. All the experts agreed that the newly developed Cp-HL process performed extremely well in terms of overall suitability.

**Keywords**—Hybrid learning; cloud-powered learning tools; learning process; analytical reading skills; digital natives

## I. INTRODUCTION

Thailand's Key National Strategies for Human Capital Development and Strengthening focused on innovative-based instructional development and the use of digital media to help the Thai people become more moral, skilled, disciplined, kind, analytical readers, and able to "know, get, and adapt" to new technology, so that no one was left behind [1].

Analytical reading skills are high-level cognitive skills that allow a person to break down an intellectual or conceptual whole into parts for their individual study. This helps a person think, seek information, analyze information, solve problems based on that information, and make decisions in everyday life with more clarity [2–4]. The cooperative integrated reading and composition (CIRC) technique based on cooperative learning, which is intended to develop reading, writing, and other language skills, is one way to develop analytical reading abilities [5–7].

Digital natives become acquainted with digital media, digital technologies, and cloud computing at a youthful age and regard digital devices as an integral and necessary part of their lives. Many teenagers and children in developed countries are considered "digital natives" because they communicate and learn primarily through computers, social networking sites, and instant messaging. Thus, digital natives think, learn, and understand the world differently than people who have not been exposed to digital technologies [8–10].

Previous studies found that Hybrid Learning (HL) strategies are more successful than conventional learning strategies [11–13]. The success of implementing the HL strategy (experimental class) demonstrates that the hybrid strategy is appropriate for millennial students (generation Z as digital natives), or students born between 1995 and 2010. This supports several previous studies [14–15]. The HL strategy is superior to the typical classroom or face-to-face class in terms of active learning, student learning results, and learning satisfaction [13–15].

The limitations of the existing learning model for boosting digital natives' analytical reading skills are the lack of integration between characteristics of digital learners, digital reading techniques, hybrid pedagogies, and emerging learning technologies in a hybrid learning mode to enhance learners' seamless learning experiences [2, 16].

Thus, this study aims to propose the Cloud-powered Hybrid Learning process (Cp-HL process) to enhance digital natives' analytical reading skills. This article presents the research objectives, literature review on hybrid learning, cloud-powered learning tools, the CIRC technique, digital natives' analytical reading skills, the developed conceptual framework, research methodology, key findings, conclusions, and discussions.

## II. RESEARCH OBJECTIVES

- 1) To develop the Cp-HL process in order to enhance digital natives' analytical reading skills.
- 2) To evaluate the suitability of the Cp-HL process to enhance digital natives' analytical reading skills.

\*Corresponding Author.

### III. LITERATURE REVIEW

#### A. Hybrid Learning (HL)

After the COVID-19 pandemic, the one new normal in instructional design is Hybrid Learning (HL) [13, 17–18, 32]. HL, also known as blended learning or flipped learning, may vary widely in instructional design, execution, and learning support. "Face-to-face (F2F)" instruction includes those courses in which 0 to 29% of the content is delivered online, which includes both traditional and web-facilitated courses [13, 19–20]. The remaining alternative online courses are defined as having at least 80% of the course content delivered online. Whereas HL is defined as having 30 to 79% of the course content delivered online via F2F [13, 20]. This pedagogy combines the best components of both traditional classroom instruction and online classroom instruction, creating a flexible and dynamic learning environment. In a hybrid learning setting, students have the opportunity to attend classes in person, participate in online learning activities, and access digital resources and tools [19–20, 32–33].

#### B. Cloud-powered Learning Tools

Cloud-powered learning tools enable instructors to set up hybrid learning spaces where students can communicate and work together from anywhere using their digital devices, both in online learning mode and in on-site learning mode. These tools can be divided into four categories [13, 17–18, 21–29]: 1) social communication tools, such as Facebook®, LINE®, Telegram®, and Discord®; 2) browsing and seeking tools, such as Google Chrome®, Firefox®, Microsoft Edge®, and Safari®; 3) interactive presentation tools, such as Zoom®, Google Meet®, Microsoft Teams®, and ClassPoint®; 4) analytics and evaluative tools, such as ClassDojo®, Kahoot!®, Google Forms®, and Google Analytics®

#### C. CIRC Technique

The cooperative integrated reading and composition (CIRC) technique is the most effective and relevant technique for teaching students to read. CIRC derives from cooperative learning, which facilitates students' comprehension of the assigned reading material. Students are instructed to work in groups to achieve the objective of reading descriptive text and photos [5–7, 30].

#### D. Digital Natives' Analytical Reading Skills

Digital natives' analytical reading skills are rooted in the principles of analytical reading described in Dechant (1982) [31]. Previous studies about the level of understanding learners have of texts (reading) can be summarized into three components discussed as follows: 1) Comprehension reading is the level at which the reader can clearly explain, remember, and recall the idea or the details of the readable information. 2) Interpretative reading is a level of insight that is deeper than understanding the meaning of a word. Readers must be able to interpret or understand what the author does not directly address. 3) Analytical reading can reveal the latent meaning, understanding, aims, opinions, attitudes, and language level that the author has available. When they summarized what they read, they said what they liked and didn't like about it. When they retold a story, they used the information from their writing to make a conceptual schema.

Thus, digital natives' analytical reading should start with reaching and comprehending the elements of the media symbol systems, especially digital media, and then considering their validity and analyzing the message of the story in digital media by checking the elements to see how those elements make sense in terms of being intelligible, justifiable, or practicable or not. Digital natives' analytical reading essentially disassembles the entire intrinsic elements of the story under specific media symbol systems and examines how the elements relate to one another to respond to the story via interacting digital media symbol systems [2–4, 8–10]. Elements of analytical reading for digital natives can be put into five main categories [2–10]: 1) the media symbol system; 2) content; 3) language; 4) purpose; and 5) structure.

### IV. CONCEPTUAL FRAMEWORK

As shown in Fig. 1, the conceptual framework of this research used three ideas to come up with the Cp-HL process to help digital natives become better at analytical reading.

Fig. 1. Conceptual framework

Fig. 1 shows the main concepts and variables of the study to enhance the analytical reading skills of digital natives. The conceptual framework is made up of three parts:

(1) The basics of novel concept formation were divided into three concepts: *a*) Cloud-powered learning tools, which have four types: *i*) social communication tools; *ii*) browsing and seeking tools; *iii*) interactive presentation tools; *iv*) analytics and evaluative tools. *b*) Hybrid learning, which has two main learning modes: *i*) online learning mode; and *ii*) on-site learning mode. *c*) The CIRC technique, which has four main learning steps: *i*) instructor presentation; *ii*) team practice; *iii*) reading testing; *iv*) team recognition.

(2) The manipulated variable was the Cp-HL process to enhance digital natives' analytical reading skills into four main learning phases: *a*) preparation for hybrid learning (online learning mode); *b*) presentation for interactive learning (online learning mode); *c*) practice with analytical reading (on-site learning mode); *d*) progress reports in analytical reading skills (on-site learning mode)

(3) The dependent variable was digital natives' analytical reading skills, which had three components: *a*) identifying the intrinsic elements of the story and media symbol systems; *b*) analyzing the message of the story and media symbol systems; *c*) responding to the story and media symbol systems.

### V. RESEARCH METHODOLOGY

#### A. Phase I: Development of the Cp-HL Process in Order to Enhance Analytical Reading Skills for Digital Natives

In the first phase, we conducted research in the following steps: 1) a scoping review on the development of the Cp-HL process to enhance digital natives' analytical reading skills (i.e., hybrid learning, cloud-powered learning tools, CIRC

technique, analytical reading skills, and digital natives) in Thai Journals Online (ThaiJO), Education Resources Information Center (ERIC), and Scopus online databases published between 2017 and 2022 using content analysis of the research article's texts; 2) synthesis and construction of the conceptual framework; and 3) development of the Cp-HL process to enhance digital natives' analytical reading skills according to the Sloan Consortium's HL guidelines [20], which specifies a proportion of program content delivered online ranging from 30 to 79% as the most widely accepted and popular in Thailand.

### B. Phase II: Evaluation of the Suitability of the Cp-HL Process to Enhance Analytical Reading Skills for Digital Natives

In the second phase, we conducted research in the following steps: 1) creating research tools for evaluating the

suitability of the Cp-HL process; 2) proposing the Cp-HL process to nine experts in educational technology, Thai language, and instructional system design (three experts per side), each of whom holds a PhD or its equivalent and has at least three years of relevant experience; and 3) analyzing the results of the validation and evaluation of the Cp-HL process by the mean and standard deviation (S.D.). The suitability evaluation questionnaire was built on a five-point Likert scale (5 = strongly agree; 4 = agree; 3 = neither agree nor disagree; 2 = disagree; 1 = strongly disagree).

## VI. RESEARCH FINDINGS

### A. The Developed Cp-HL Process to Enhance Digital Natives' Analytical Reading Skills

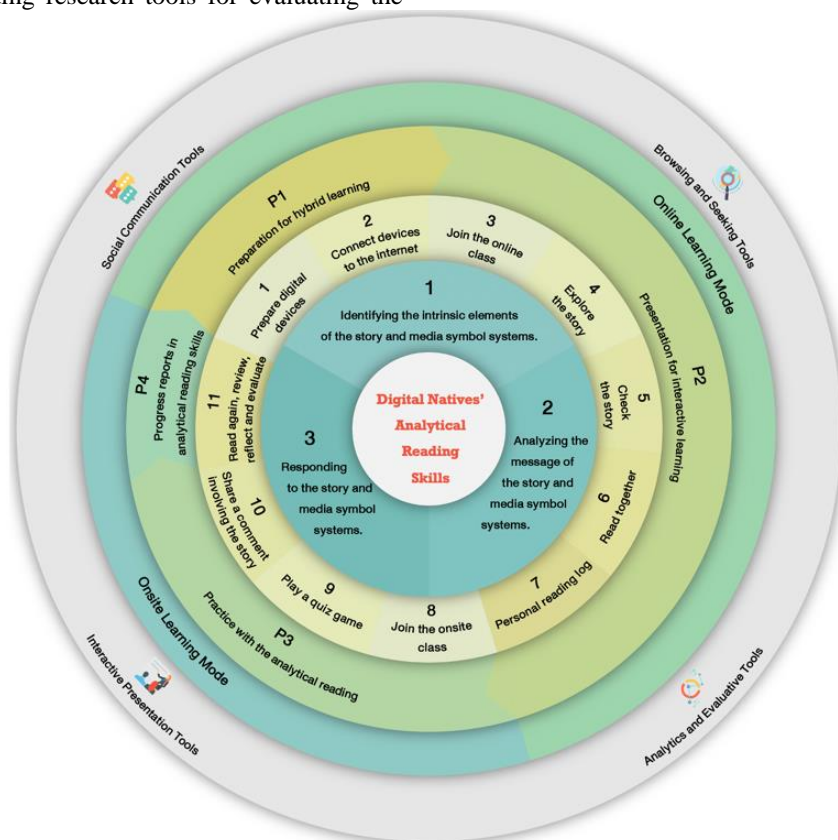

Fig. 2. The Cloud-powered Hybrid Learning process (Cp-HL process) to enhance digital natives' analytical reading skills

The developed Cp-HL process to enhance digital natives' analytical reading skills is illustrated in Fig. 2. This learning process consists of four main processes (4Ps) and 11 learning steps, as follows:

1) *P1: Preparation for hybrid learning*: In the first phase of the learning process, learners play an important role in self-directed learning; this phase has two learning stages under the online learning mode: a) Prepare digital devices (e.g., desktop, laptop, tablet, smartphone, and wearables); b) Connect devices to the Internet over a 3G, 4G, 5G, or Wi-Fi connection.

Thus, at this stage, the role of the instructor in hybrid learning management, as follows: a) Set up learning objectives, learning experiences (e.g., learning contents, pedagogies, and learning technologies), and learning assessments (e.g., formative assessment, summative assessment) that directly address the desired learning outcome, which is digital natives' analytical reading skills; and b) Encourage informal and formal communications using a variety of social communication tools (e.g., Facebook®, LINE®, Telegram®, and Discord®) and keep their frequency with learner groups in preparation for hybrid learning so instructors can open the learning cycles.

2) *P2: Presentation for interactive learning:* In the second phase of the learning process, learners play an important role in active learning; this phase has five learning stages under the online learning mode: *a)* Join the online class via browsing and seeking tools (e.g., Google Chrome®, Firefox®, Microsoft Edge®, and Safari); *b)* Explore the story on the interface display of interactive presentation tools (e.g., Zoom®, Google Meet®, Microsoft Teams®, and ClassPoint®); *c)* Check the story to identify the story's intrinsic elements and media symbol systems; *d)* Read together to analyze the story's message and media symbol systems; *e)* Personal reading log via browsing and seeking tools.

Thus, at this stage, the role of the instructor in an interactive presentation, as follows: *a)* Make it clear that instructors have high expectations for learning outcomes, that there are requirements for learning tasks and activities, and that there are rules for how to talk and interact in the classroom, both in online and on-site learning modes; and *b)* Respect diverse student abilities and learning styles to create a safe and engaging hybrid learning environment that allows for multiple responses. This will help make the classes more engaging (cognitively, socially, and emotionally) for both online and on-site learning.

3) *P3: Practice with the analytical reading:* In the third phase of the learning process, learners play an important role in collaborative learning; this phase has three learning stages under the on-site learning mode: *a)* Join the onsite class via analytics and evaluative tools (e.g., ClassDojo®, Kahoot!®, Google Forms®, and Google Analytics®); *b)* Play a quiz game via analytics and evaluative tools; *c)* Share a comment involving the story using the Think-Pair-Share (TPS) technique.

Thus, at this stage, the role of the instructor in practice with the analytical reading is very important, as follows: *a)* Respect diverse student opinions and thinking styles to create a safe and engaging hybrid learning environment that allows for multiple responses; *b)* Employ student peer assessment to promote collaborative learning skills; *c)* Develop reciprocity and cooperation among students to enhance peer support and collaboration.

4) *P4: Progress reports in analytical reading skills:* In the fourth phase of the learning process, learners play an important role in reflective learning under the on-site learning mode. This step emphasizes that the students read again, review, reflect, and evaluate the digital media for identifying the intrinsic elements of the story and media symbol systems, analyzing the message of the story and media symbol systems, and responding to the story and media symbol systems. Thus, at this stage, the role of the instructor in the progress reports of analytical reading skills, as follows: *a)* Employ student self-assessment to promote self-regulated learning skills, such as time management and learning progress monitoring; *b)* Give them quick feedback, and encourage them when they need it; *c)* Always end each lesson with a summary of what was learned and a look at what will be taught in the next lesson.

## B. The Suitability of the Cp-HL Process to Enhance Digital Natives' Analytical Reading Skills

TABLE I. THE EVALUATION OF THE SUITABILITY OF THE CP-HL PROCESS TO ENHANCE DIGITAL NATIVES' ANALYTICAL READING SKILLS

Items of evaluation	Result		Suitability Level
	Mean	S.D.	
<b>1. P1: Preparation for hybrid learning</b>			
1.1 Prepare digital devices	5.00	0.00	Strongly agree
1.2 Connect devices to the Internet	4.66	0.50	Strongly agree
<b>2. P2: Presentation for interactive learning</b>			
2.1 Join the online class	5.00	0.00	Strongly agree
2.2 Explore the story	5.00	0.00	Strongly agree
2.3 Check the story	4.66	0.50	Strongly agree
2.4 Read together	5.00	0.00	Strongly agree
2.5 Personal reading log	4.44	0.73	Agree
<b>3. P3: Practice with the analytical reading</b>			
3.1 Join the onsite class	5.00	0.00	Strongly agree
3.2 Play a quiz game	4.44	0.73	Agree
3.3 Share a comment involving the story	4.66	0.50	Strongly agree
<b>4. P4: Progress reports in analytical reading skills</b>			
4.1 Read again, review, reflect and evaluate	5.00	0.00	Strongly agree
<b>Overall</b>	4.81	0.27	Strongly agree

From Table I, the suitability of the Cp-HL process to enhance digital natives' analytical reading skills was overall the most suitable, with a mean of 4.81 and a standard deviation of 0.27.

## VII. CONCLUSIONS AND DISCUSSION

In this article, we propose the “Cloud-powered Hybrid Learning Process” (Cp-HL process) as an instructional process involving the use of cloud-powered learning tools in hybrid learning for the purpose of enhancing digital natives' analytical reading skills by providing access to a wide range of digital resources and tools in both online and on-site learning modes according to the Sloan Consortium's HL guidelines [20], which specifies the proportion of program content delivered online from 30 to 79% as the most widely accepted and popular in Thailand. The Cp-HL process to enhance digital natives' analytical reading skills. This process consisted of four major learning phases and 11 learning steps, as follows:

1) *P1: Preparation for hybrid learning:* There were two learning steps under the online learning mode: *a)* Prepare digital devices; and *b)* Connect devices to the Internet. Cloud-powered learning tools used in this process include social communication tools (e.g., Facebook®, LINE®, Telegram®, and Discord®).

2) *P2: Presentation for interactive learning:* There were five learning steps in the online learning mode: *a)* Join the online class; *b)* Explore the story; *c)* Check the story; *d)* Read together; and *e)* Personal reading log. Cloud-powered learning

tools used in this process include: i) browsing and seeking tools (e.g., Google Chrome®, Firefox®, Microsoft Edge®, and Safari®); and ii) interactive presentation tools (e.g., Zoom®, Google Meet®, Microsoft Teams®, and ClassPoint®).

3) P3: *Practice with the analytical reading*: Under the onsite learning mode, there were three learning steps: a) Join the on-site class; b) play a quiz game; and c) Share a comment involving the story using the Think-Pair-Share (TPS) technique. Cloud-powered learning tools used in this process include analytics and evaluative tools (e.g., ClassDojo®, Kahoot!®, Google Forms®, and Google Analytics®).

4) P4: *Progress reports in analytical reading skills*: There was a critical learning step under the on-site learning mode: read again, review, reflect, and evaluate the digital media. Progress reports represent the expected learning outcomes, which are digital natives' analytical reading skills, which have three components: a) identifying the intrinsic elements of the story and media symbol systems; b) analyzing the message of the story and media symbol systems; and c) responding to the story and media symbol systems. Cloud-powered learning tools used in this process include analytics and evaluative tools.

According to nine experts' evaluations of the suitability of the developed Cp-HL process, all experts agreed that the Cp-HL process was the most suitable overall for improving digital natives' analytical reading skills, with a mean of 4.81 and a standard deviation of 0.27. Based on these findings, we anticipate that our CP-HL process will be implemented in both online and onsite learning modes that integrate digital reading techniques, hybrid pedagogies, and cloud-powered learning tools to promote digital natives' analytical reading skills, which align with the characteristics of digital learners.

In the future directions of hybrid learning research [17, 32], it will still be challenging to integrate pedagogical strategies with new learning technologies to help learners of all ages gain access to learning, help people learn, and achieve the learning outcomes that society needs in lifelong learning, including those with certain barriers to learning, whether they are in formal education, non-formal education, or alternative education.

#### ACKNOWLEDGMENT

The Division of Learning Innovation and Technology, Faculty of Industrial Education and Technology, King Mongkut's University of Technology Thonburi (KMUTT) supported the research, and the research team would like to thank Dr Kridsanapong Lertbumroongchai for advice on the preparation of illustrations for the research.

# A Model for Detecting Fungal Diseases in Cotton Cultivation using Segmentation and Machine Learning Approaches

Odukoya O.H.<sup>1</sup>, Aina S.<sup>2</sup>, Dégbéssé F.W.<sup>3</sup>

Computer Science and Engineering Department, Obafemi Awolowo University, Ile-Ife, Nigeria<sup>1,2,3</sup>

**Abstract**— This research detailed a model for detecting fungal diseases via techniques for processing images of cotton leaves. The work allowed to develop a model based on the set of preprocessed data, to formulate the developed model, to simulate and evaluate the model. It is about detecting fungal diseases in cotton cultivation. The image data records were collected in an online data repository consisting of images of cotton leaves infected with fungal diseases and normal leaf images. In addition, other images of infected and uninfected cotton leaves were collected in cotton production fields in the Ségbana region in Benin Republic. The model was formulated based on watershed segmentation technique by applying Edge Detection algorithm and K-Means Clustering; and Support Vector Machine (SVM) for classification. The simulation was done using MATLAB with Image Processing Toolbox 9.4. The results gave an accuracy of 99.05%, specificity 90%, misclassification rate 0.95%, recall rate 99.5% and precision 99.5%. In addition, with less computational effort and in less than a minute, the best results were obtained, showing the efficiency of the image processing technique for the detection and classification of infected and uninfected leaves. It was concluded that this approach was applied to detect fungal diseases on cotton leaves to promote the production and harvest of good quality cotton and valuable cotton products.

**Keywords**—Fungal diseases; watershed segmentation; SVM; K-means; Edge Detection algorithm

## I. INTRODUCTION

Cotton is a soft fibrous substance, usually white, composed of the hairs encompassing the seeds of various tropical plants with free branches (genus *Gossypium*) of the mauve family [1][2]. The ordinary cotton name comes from the Arabic "quon" and generally refers to plants that produce spinnable (plush) fibers on their integument [3].

Cotton cultivation improved the living conditions of rural and urban populations. It contributed to the economic development of the CFA franc zone countries in Africa. Production of cotton has quadrupled in the last two decades, making the region the world's second largest cotton exporter, accounting for 15% of global exports. As a result, generating the most extensive receipts in various regional countries being the main cash crop for government revenues. Cotton cultivation has impacted the poverty rate positively by employing above two million rural households [4].

Due to fungal disease problems in cotton growing, agricultural industries face economic losses and a qualitative and quantitative decline in annual production. Nowadays,

modern cotton industries are trying to ensure the quality and safety of products to provide healthy cotton to consumers.

Africa is an agricultural zone where most of the population is based on cotton farming. Farmers have a wide selection of diversity to pick appropriate cotton crops. However, the growth of these plants for greatest yield and quality products is very technical. It can be enhanced with the support of technology. The management of cotton crops needs careful observation, particularly to treat diseases that will affect production and, consequently, the life after harvest.

A disease is an alteration of one or more physiological processes caused by irritation from some factors or agents resulting (pests) in loss of coordination in plants. Plant disease(s) is a hurtful modification from the traditional functioning of the process related to physiology in a particular plant. Plant diseases generally can be classified into three major parts: Classification based on the localization area, classification based on the occurrence, classification based on the causal agent [5].

Plant disease problems have arisen as a result of a considerable drop in the quality and quantity of agricultural output. Plant disease losses in Georgia (United States) in 2007 were estimated to be over \$539.74 million. Approximately \$185 million of this total was spent on disease control, with the remainder being the result of disease damage [6]. Several pests, including bacteria, aphids, insects, fungi, and others, cause serious plant diseases, but fungi are responsible for the majority of global losses [7].

FUNGI are microorganisms that exist in the planet and are responsible for nearly 75% of all diseases. They are threadlike organisms known as HYPHAE. Anthracnose, Ascochyta blight, Black root rot, Boll rot, Charcoal rot, Leaf spot, Escobilla, Fusarium wilt, Lint contamination Rust, Phymatotrichum root rot, Powdery mildew, Sclerotium stem and root rot or southern blight, Stem canker, Seedling disease complex, and Verticillium wilt are some of the diseases that can affect your plants.

Observations by experts with the naked eye are the most available method for detecting and identifying diseases in practice. However, this requires the constant supervision of professionals, which may be unaffordable on large farms. Furthermore, in certain poor nations, farmers must travel considerable distances to reach specialists, making consultants prohibitively expensive and time-consuming.

The automatic diagnosis of plant diseases is a crucial area of research. It could be useful for large-scale surveillance cultures, allowing for the automatic detection of symptoms of the disease as soon as they emerge on the plant's leaves. As a result, seeking a rapid, automatic, less expensive, and more accurate method will be a distinct advantage for the quality and development of agricultural products and derivatives, particularly when concentrating on a certain plant and disease category. This paper aims to develop a model that can detect Fungal Diseases for cotton crops only based on quality in image (of cotton leaf) processing.

In summary, the paper's contributions can be summarized as follows:

- 1) Fungal diseases Image Acquisition was done using digital camera or any other device and it was loaded and saved using Matrox Imaging Library (MIL) software and semistructured interviews and questionnaires were also administered to gather the requirements of the model.
- 2) A classification model of fungal diseases detection was formulated based on the watershed segmentation technique using K-Means Clustering and Edge Detection algorithm and Support Vector Machine (SVM) was used for classification.
- 3) Simulation of the classification model of fungal diseases detection using Matlab's Image Processing Toolbox 9.4.
- 4) Assessing the performance of the model using accuracy, efficiency, and specificity as parameters.

This paper is organized as follows. Section II illustrates relevant literature on image processing based on plant diseases and specifically fungal diseases on cotton cultivation. Section III discusses the model design approach and methodologies adopted in the course of the research. Section IV discusses an overview of the results of the simulation of the model designed and analysis of the results emanating from the simulation. Section V recaps the research work and conclusion and future work is suggested.

## II. RELATED WORKS

There are numerous literature studies on plant disease detection and image processing technologies. According to Anju [8], the watershed transformation was a good tool for image segmentation in mathematical morphology. Marker-controlled segmentation was used for watershed transformation-based segmentation. A powerful tool for image segmentation, the Prewitt Edge Detection Operator was used to demonstrate another image segmentation technique that included image enhancing and noise removal strategies. The new method was evaluated and compared to the current one. However, this work has to be improved, particularly in terms of evaluating the method's performance.

Rani and Mahip [9] published an article on the use of machine learning to detect various plant diseases using various image processing techniques. Today, the technical processing of images becomes an essential technique for diagnosing different plant diseases during cultivation. Any part of the gold harvesting area can be affected by the disease. This paper focused on detecting various diseases of cotton

cultivation and classifying them. There is as much technical classification as k-Nearest Neighbor Classifier, genetic algorithm, k-means classifier, probabilistic Neural Network, , vector support artificial analysis of the machine and main components neural network, fuzzy logic. Choosing a classification was a tedious task because the quality of the result may be different for various input data. This document provided an overview of various technical classifications used to classify plant leaf diseases.

Thikjarathi and Abirami [10] proposed an Application of Image Processing in Diagnosing Guava Leaf Diseases. In this study, scaled leaf images with improved contrasts are subjected to region expanding segmentation, color transformation (YCbCr, CIELAB), and Scale Invariant Feature Transform (SIFT). Support Vector Machines (SVM) and K-nearest Neighbor (k-NN) classifiers were investigated for disease-wise classification accuracy. While both SVM and k-NN perform well, the former has a little accuracy advantage. However, in the future, this methodology for evaluating classifiers for large datasets can be improved.

Zhang et al. [11] used a natural situation to test an artificial image segmentation algorithm for damaged cotton leaves. The authors employed a segmented monotone decreasing edge composite function, energy function guidance information, the Heaviside function, and the t penalty function to create their model  $\phi(x)$ . The results indicated that a model of a cotton leaf edge profile curve could be constructed from a model of a cotton leaf coated in bare soil, straw mulching, and plastic film mulching, and that even with non-uniformity of light, the optimal edge of the ROI could be achieved. In a complex background, the model can classify cotton leaves with uneven illumination, shadow, and weed backdrop, and it is preferable to realize the perfect extraction of the blade's edge. However, this task is restricted by the length of time it takes to complete the Segmentation (problem of efficiency). Pre-treatment, feature extraction, and picture categorization are among the other image processing processes that are bypassed.

"Detection and Identification of Rice Leaf Diseases Using Multiclass SVM and Particle Swarm Optimization Technique," by [12], for example, "By combining K-means, SVM, and multiple classifications, the author presented a new approach for detecting and identifying rice leaf illnesses." The gray level co-occurrence matrix (GLCM) was utilized to extract features. An SVM classifier was used to categorize the diseases, and Particle Swarm Optimization was used to improve detection accuracy (PSO). According to testing results, the proposed methodology was 97.91 percent accurate in terms of disease identification. Furthermore, the Feed Forward (FFNN) and SVM neuron networks accounted for 77.96 percent, 85.64 percent, and 90.56 percent, respectively, of the closest neighbour (KNN) networks.

Kumari et al. [13] suggested an automatic disease detection system for three fungal diseases in cotton crops: Alternaria leaf spot fungal disease (ALSFD), Rust Folar Fungal Disease (RFFD), and Grey Mildew Cotton Disease (GMCD). For disease segmentation on cotton leaves, the k-means clustering approach was utilized, and the results were

transferred for disease categorization to Artificial Neural Network (ANN) and Support Vector Machine (SVM) classifiers. On a Cotton plant leaf, Khalmar and Khan [14] worked on automatic early leaf spot disease segmentation. Image processing and machine learning are used in this project. The image is captured with a digital camera, and the contaminated region is segmented using a k-means clustering technique after pre-processing. The study only discovered bacterial leaf infections and did not categorize the leaves of cotton plants.

Carderia et al. [15] proposed that Deep Learning Techniques be used to identify Cotton leaf defects. This study proposes a deep learning-based method for cotton leaf screening in order to monitor the health of the leaves. In this work segmentation was not performed on the leaves, features of the leaves were identified and used for classification.

Statement of Problem Existing techniques used in detecting diseases in cotton cultivation suffer several setbacks

such as: a confusion in detection of two different diseases but having the same apparent symptoms, stages of disease detection are often incomplete and lack performance. As such, this leads to improper management of the cotton crops and causes low productivity. Therefore, there is a need for a classification model for diseases detection that will focus on specific class of the diseases (fungal diseases) to improve cotton cultivation; To fill this gap, the proposed study will provide a model that can accurately and automatically provide the right detection for fungal diseases in cotton cultivation. The outcome of this research will ensure the quality of cotton and provide healthy cotton to the consumers.

### III. PROPOSED MODEL

This section describes the developed model. This proposed model architecture depicted in Fig. 1 is an improvement of Zhang et al. [11] automation of Segmentation of infected cotton leaves under a natural environment.

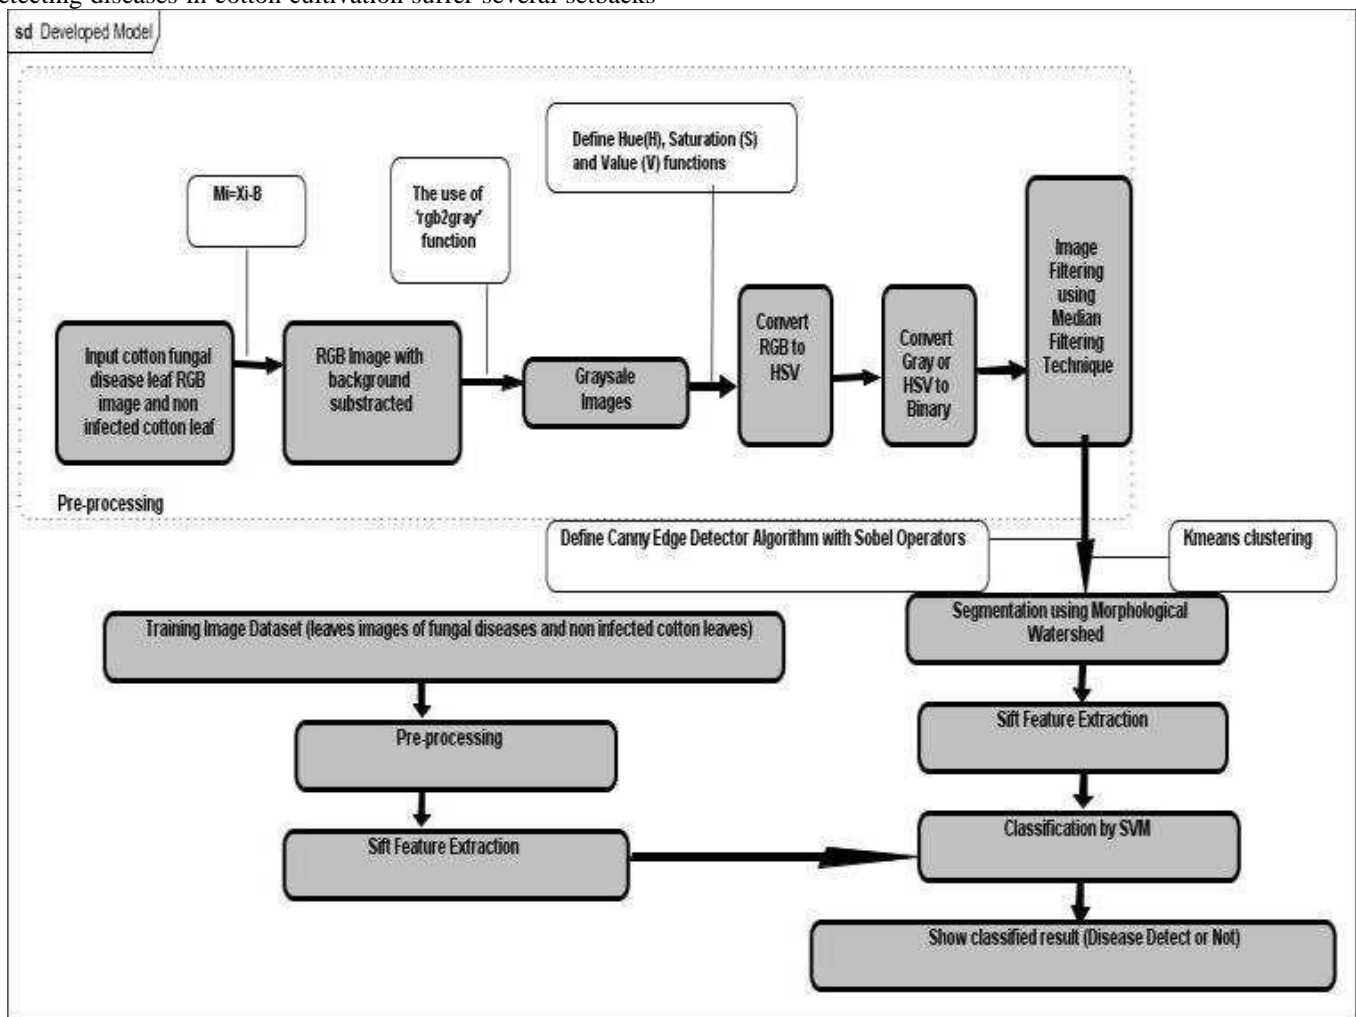

Fig. 1. Developed model.

#### A. Steps for Pre-processing

The preprocessing steps are Input picture; Subtraction of background; Converting RGB image to grayscale and HSV

image; Converting grayscale image to binary image; Filtering. Fig. 2 shows the different stages of image preprocessing.

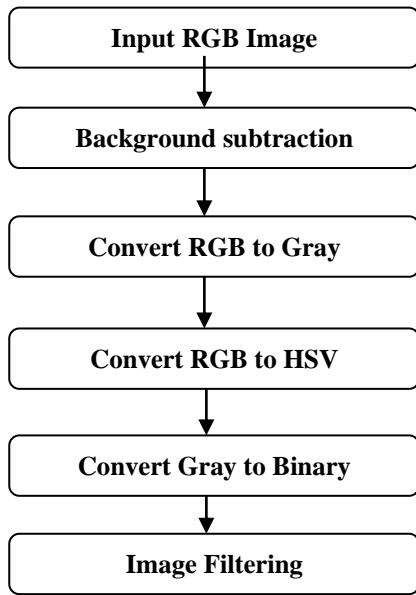

Fig. 2. Architecture flow.

### B. Development of a Formula for RGB to Grayscale

The formula of RGB to grayscale is generally expressed with a small variation of the coefficients of R, G, and B according to many papers including:

- i.  $I=0.2989R+0.5870G+0.1140B$  (1)  
according to Padmarathi and Thangadurai [16]
- ii.  $I=0.299R+0.5870G+0.1140B$  (2)  
according to Saravanan [17]
- iii.  $I= 0.3R+0.59G+0.11B$  (3)  
according to Kanan and Cottrell [18]
- iv.  $I=0.21R+0.71G+0.07B$  (4)  
according to Samuel et al. [19]

From i, ii, iii and iv luminance,

$$I=(r\%R) +(g\%G) +(b\%B) \quad (5)$$

Where

- (a) Red has contributed r%, Green has contributed g% and Blue has contributed b%;
- (b)  $r\%+g\%+b\%=100\%$  (6)

### C. Binary Image

A Binary Picture is a numeric picture. It is also considered as bi-level or two level because each pixel of this image can require a single bit 0 or 1. Generally, 0 shows the black color, and 1 shows the white color, which has two assigned pixel values. In the numeric treatment of a picture, a binary picture is used like masks or as the result of some frequent operations such as Segmentation, thresholding, and dithering, etc. Fig. 3 illustrates an example of transforming an RGB image to a grayscale image and a binary image. Fig. 4 also shows another example of transforming an RGB image to grayscale, binary and HSV image.

Fig. 3. Illustrates an example of converting an RGB image to a grayscale image and a binary image.

### D. Characteristic of Hue, Saturation, and Value(HSV)

$$H = \begin{cases} 0 & \text{if } \max = \min \\ \frac{(60^\circ \times g - b + 360^\circ)}{\max - \min} \text{ mod } 360^\circ & \text{if } \max = r \\ \frac{(60^\circ \times b - r + 120^\circ)}{\max - \min} & \text{if } \max = g \\ \frac{(60^\circ \times r - g + 240^\circ)}{\max - \min} & \text{if } \max = b \end{cases} \quad (7)$$

$$S = \begin{cases} 0 & \text{if } \max = 0 \\ \frac{\max - \min}{\max} = 1 - \frac{\min}{\max} & \text{otherwise} \end{cases} \quad (8)$$

$$V = \text{Max} = \frac{1(r+g+b)}{3} \quad (9)$$

Where r, g, and b stands for red, green and blue normalized in value [0, 1] [20].

Fig. 4. illustrates an example of converting an RGB image to a grayscale image a binary image, and an HSV image.

### E. Image Filtering

In image pre-processing, filtering is an important step to use to reduce image noise and improve the visual quality of an image. Basically, image filtering is useful in various applications such as smoothing, sharpening, noise suppression, and edge detection. There are several types of image filtering techniques, such as Laplacian filtering, low-pass filtering, high-pass filtering, and so on. However, in this study, the median filtering technique was used. The image

filtering technique is used in an image pre-processing step to reduce noise to improve the result of subsequent processing such as an edge detection example of an image. The median filter is called a nonlinear digital filtering process in image processing. The median filtering technique is used in the image to suppress the noise of the image. Fig. 5 shows an example of obtaining a filtered image from an original image.

Fig. 5. Obtaining a filtered image from an original image.

**K-means Clustering:** The K-mean is frequently used to define the natural grouping of pixels in a photograph. It is a simple and quick method that attracts a significant number of consumers. For the purpose of creating vector spaces, a clustering approach is useful. The objects are grouped together at the centroids. With luminosity layer 'L\*', chromaticity-layer 'a\*' indicating where the color falls along the red-green axis, and chromaticity-layer 'b\*' representing where the color falls along the blue-yellow axis, K-Means clustering uses the L\*a\*b color format. The 'a\*' and 'b\*' layers contain all color information. The generalized pseudocode of the traditional k-means algorithm and the traditional k-means method according to Oyelade et al. [21] are shown in Algorithm 1 and Algorithm 2, respectively.

---

**Algorithm 1:** Generalized pseudocode of the traditional k-means

1. Accept the number of clusters to group data into and the clusters as input values.
  2. Initialize the first k clusters
    - 2.1 Take the first k instances or
    - 2.2 Take Random Sampling of k elements
  3. Calculate the arithmetic mean of each cluster
  4. K-means assigns each record in the dataset to only one of the initial clusters.
    - 4.1 Each record is assigned to the nearest cluster using a measure of Distance (e.g Euclidean distance).
  5. K-means re-assigns each record in the dataset to the most similar cluster and re-calculates the arithmetic mean of all the clusters in the dataset.
- 

---

**Algorithm 2:** Traditional k-means algorithm

**INPUT:** Dataset of n data points  $x_1, x_2, \dots, x_n$

**OUTPUT:**  $m_j (j = 1, 2, \dots, k)$  = Cluster centroids

MSE (Mean Square Error) = Large Number

Select Initial Cluster centroid  $m_j$ ;

While (MSE < OldMSE) do

OldMSE = MSE;

MSE1 = 0;

For (j = 1 to k)

$m_j = 0; n_j = 0;$

endfor

For (j = 1 to k)

Compute Squared Euclidean Distance  $d^2(x_i, m_j)$ ;

endfor

For (j = 1 to k)

Find the closest centroid  $m_j$  to  $x_i$ ;

$m_j = m_j + x_i; n_j = n_j + 1;$

$MSE1 = MSE1 + d^2(x_i, m_j)$ ;

endfor

For (j = 1 to k)

$m_j = m_j + x_i;$

$n_j = n_j + 1;$

$MSE1 = MSE1 + d^2(x_i, m_j)$ ;

$n_j = \max(n_j, 1)$ ;

$m_j = m_j / n_j;$

endfor

MSE = MSE1;

---

**F. Edge Detection**

The identification of edge is employed in image analysis to determine the region's boundaries. In human vision, and probably in many other biological vision systems as well, edges and contours play a significant role. It is not just the sides that catch the eye; a few essential lines can frequently be used to describe or reconstruct an entire figure. Edges are considerable local changes of intensity in a picture. The reasons for intensity include events of geometry (orientation of surface (boundary) discontinuities, discontinuities of depth, discontinuities of color and texture) and non-geometric events (changes of illumination, specularities, inter-reflections of shadows).

There are many techniques for the recognition of edges on a picture. In this study, an appropriate estimate of the first derivative determined by two operators of Sobel will be used. As the derivatives heighten noise; the smoothing aspect is an interesting feature of operators of Sobel. Firstly, the derivatives are executed with the use of gradient amplitude. For a function  $f(x, y)$ , the gradient  $f$  at the coordinate  $(x, y)$  is determined as the two-dimensional column vector. Fig. 6 shows the edge detection with the use of Sobel operators in segmentation.

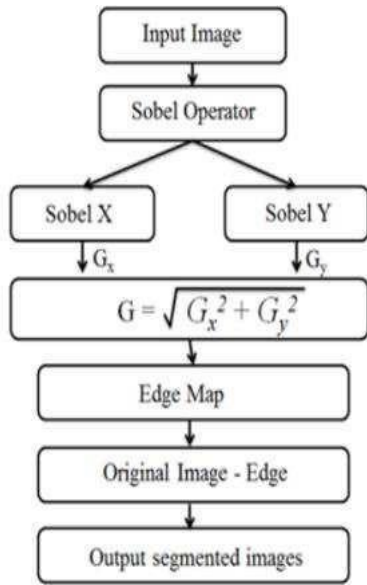

Fig. 6. The edge detection using Sobel Operators in Segmentation.

$$\Delta f = \begin{bmatrix} G_x \\ G_y \end{bmatrix} = \begin{bmatrix} \partial f / \partial x \\ \partial f / \partial y \end{bmatrix} \quad (10)$$

$$\begin{aligned} \Delta f = \text{mag}(\Delta f) &= [G_x^2 + G_y^2]^{1/2} \\ &= \left[ \left( \partial f / \partial x \right)^2 + \left( \partial f / \partial y \right)^2 \right]^{1/2} \\ &\cong [G_x + G_y] \quad (11) \end{aligned}$$

Where

$G_x$  is the gradient along the x direction

$G_y$  is the gradient along the y direction

Sandiya and Patial [22].

### G. Image Segmentation

The process of segmenting image is breaking down a numeric image to form many segments. Segmentation is a technique for giving meaning to a picture or making an analysis more intelligible. The Segmentation of the picture is used to localize the limits and objects as curves, lines, etc. Literally, in image segmentation operation, all pixels in a picture have been assigned a label where the same label allots the same visual features. The outcomes of image segmentation are multiple segments that a set of contours extracted from the picture or collectively cover the whole image. In a region, each pixel is a computed property or similar with respect to some feature, such as color, texture, or intensity.

### H. Morphological Watershed Segmentded Images

The key to using the watershed transform for segmentation is to change your image into one with catchment basins that match to the objects you wish to recognize. Infected and non-infected leaves are shown in Fig. 7 as a Morphological Watershed Segmented Image.

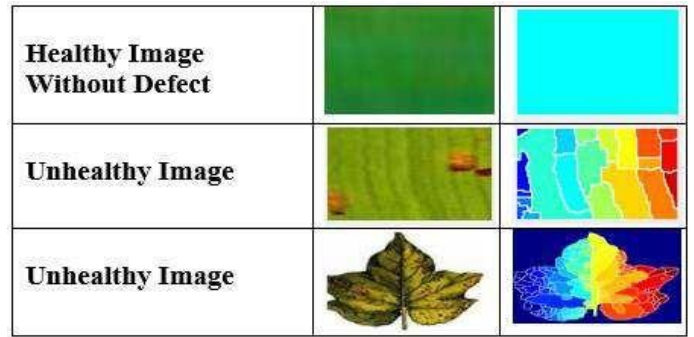

Fig. 7. Infected versus non-infected leaves in a morphological watershed image.

### I. Watershed Approach

#### 1) The Algorithm

The possibilities of the algorithm are as follows: assume that a hole is drilled at least in each regional neighborhood and that all geology is submerged from below, allowing the water to climb at a constant rate through the perforations. Flooded pixels are those that are under the water level at any given time. As the water level increases, the size of the flooded areas increases. Water will reach a level where two sites immersed in separate catchment basins will mix in the long term. When this occurs, the algorithm constructs a one-pixel thick barrier between the two sections. This overflow continues till the entire image is divided into numerous different basins separated by watershed edge lines or ridgelines.

### J. Feature Extraction: Sift-Scale Invariant Feature Transform

Any object can have various features and important details that can be accessed to produce a description. This layout is used to identify an element in an image that contains a lot of other things. The SIFT method converts a picture into a large set of local feature vectors in order to generate image characteristics. The image's size, translation, or rotation have no effect on any of these feature vectors. The SIFT algorithm uses a four-stage filtering approach to help in the extraction of these properties:

- 1) Detection of Extremes in Scale and Space
- 2) Keypoint Location
- 3) Assignment of Orientation
- 4) Descriptor of a Keypoint

### K. Development of Formula for Difference of Gaussians

Calculation  $D(x, y, \sigma)$

$$D(x, y, \sigma) \text{ if } L(x, y, \sigma) = I(x, y) * G(x, y, \sigma)$$

$$\text{Then } L(x, y, k\sigma) = I(x, y) * G(x, y, k\sigma)$$

$$\text{Therefore } D(x, y, \sigma) = L(x, y, k\sigma) - L(x, y, \sigma)$$

$$= I(x, y) * G(x, y, k\sigma) - I(x, y) * G(x, y, \sigma)$$

$$= I(x, y) * [G(x, y, k\sigma) - G(x, y, \sigma)]$$

$$\text{If } G(x, y, \sigma) = \frac{1}{2\pi e^2} e^{-\frac{(x^2+y^2)}{2e^2}} \text{ then}$$

$$D(x, y, \sigma) = I(x, y) * [G(x, y, k\sigma) - G(x, y, \sigma)]$$

$$= I(x, y) * \left[ \frac{1}{2\pi k e^2} e^{-\frac{(x^2+y^2)}{2ke^2}} - \frac{1}{2\pi e^2} e^{-\frac{(x^2+y^2)}{2e^2}} \right]$$

$$= \frac{1(xy)}{2\pi e^2} * \left[ \frac{1}{k^2} e^{-\frac{(x^2+y^2)}{2e^2}} \right]^{1/k^2} - e^{-\frac{(x^2+y^2)}{2e^2}} \right]$$

But with  $A = \frac{I(xy)}{2\pi e^2}$  and  $B = e^{-\frac{(x^2+y^2)}{2e^2}}$

$$D(x, y, \sigma) = A \times B^{\frac{(B)^{1/k-B}}{k^2}} \quad (12)$$

Where:

The difference of Gaussians calculation is  $D(x, y, \sigma)$ .

\* Denotes the convolution operator.

$I(x, y)$  is the input picture.

Then the scale space is calculated by the function:

$$L(x, y, \sigma) = I(x, y) * G(x, y, \sigma)$$

with  $G(x, y, \sigma) = \frac{1}{2\pi e^2} e^{-\frac{(x^2+y^2)}{2e^2}}$

#### L. Support Vector Machine (SVM) Classification

SVM is a technique for data analysis and recognition. It is used to do things like regression analysis and categorization. The SVM algorithm takes a set of input data and predicts classes for each individual input. SVM is a linear model-based trainer that uses extracted features to build a hyper plane that translates a piece of data into the separation between the hyperplane and the nearest training points.

### IV. RESULTS

#### a) Contrast

The intensity difference between a pixel as well as its adjacent for the entire image is returned by this function. Range=[0(size(GLCM, 1) - 1)2]. There's no difference in a continuous image.

$$Contrast = \sum_{i,j=0}^{N-1} (i, j)^2 \quad (13)$$

#### b) Energy

The GLCM Range = [0 1] returns the total of squared elements. A continual image necessitates the use of energy.

$$Energy = \sum_{i,j=0}^{N-1} C(i, j)^2 \quad (14)$$

#### c) Homogeneity

Returns a value that indicates how near an element's GLCM distribution is to the GLCM diagonal. [0 1] is the range. For a diagonal GLCM, homogeneity is 1

$$Homogeneity = \frac{\sum_{i,j=0}^{N-1} C(i, j)}{(1+(i-j))^2} \quad (15)$$

According to the results of Table I, the normal leaves of cotton have the following features: the contrast of different leaves is between 0 to 0.09; homogeneity is between 0.98 to 1.0; energy is between 0.98 to 1.0. According to the results of Table II, the disease leaves of cotton have the following features: the contrast of different leaves is between 0.1400 to 0.3; homogeneity is between 0.2000 to 0.97; energy is

between 0.3 to 0.97. The above result analysis concludes that diseased leaf image contrast is more than the normal leaf. On the other hand, diseased leaf image homogeneity and energy are less than the normal leaf. Hence, we conclude that images are defective.

TABLE I. NORMAL LEAF IMAGE ANALYSIS

Normal	Leaf1	Leaf2	Leaf3
CONTRAST	0.0898	0.0501	0.0
ENERGY	0.9879	0.9897	1.0
HOMOGENITY	0.9807	0.9759	1.0

TABLE II. DISEASED LEAF IMAGE ANALYSIS

Diseased	Leaf1	Leaf2	Leaf3
CONTRAST	0.2644	0.1628	0.1591
ENERGY	0.4889	0.5737	0.6834
HOMOGENITY	0.9725	0.9617	0.9343

#### A. Classification Results and Somecomparisons with the Existing Model

As the first manifestations and symptoms of the fungal disease appear on the leaves of the plant, detection techniques and classification are developed. The characteristics of color, texture, and form are widely used in detecting and classifying plant infections. Following segmentation, the texture, pigment, and form properties of the diseased areas are removed or separated and used as input to the SVM classifier.

According to Table III relating to the achievement of the preprocessing and image processing steps, only the image segmentation step is performed with the existing model while the preprocessing, segmentation, extraction, and classification of images are done with the developed model.

Table IV provides information on the number of infected and uninfected leaves, size, and types of images in the SVM Learning database.

TABLE III. ACHIEVEMENT OF IMAGE PREPROCESSING AND PROCESSING STEPS

Leaf Type	Number of Images	Size(pixels)	Image Type
Healthy	10	193x228	JPG
Disease	500	193x228	JPG

TABLE IV. SVM LEARNING DATABASE

S/N	Steps	Existing Model [22]	Developed Model
1	Stages in image preparation	-	+
2	Categorization of image	+	+
3	Feature Extraction	-	+
4	Classification	-	+

Achieved (+).

Not achieved (-).

B. Distribution of Images

A set of 500 images of infected cotton leaves was used to validate the detection approach of the disease. In this sample of 500 images, 300 (60%) were used for the training of the system and 200(40%) for the tests. Table V illustrates the distribution of images.

TABLE V. IMAGE DISTRIBUTION

Disease	Images	Training Sample	Testing Sample
			Diseases Detection
Fungal Disease	500	300	200
Percentage	100%	60%	40%

C. Evaluation of the Model for Fungal Diseases Detection in Cotton Cultivation

The evaluation of the proposed approach was achieved based on precision and recall, and the images are grouped in accordance with the generated results. Based on the system’s results, these images were categorized as TP (rule matched and disease present), FP (rule matched and no disease present), TN(no rule matched and no disease present), and FN (no rule matched and disease present) based on results generated by the system.

- 1) *TP (true positive)*: The infected images are predicted to have a fungal disease.
  - 2) *TN (true negative)*: Images not infected by fungal disease and are predicted to be negative of infection.
  - 3) *FP (false positives)*: No fungal diseases present in the image but predicted to be present by the system.
  - 4) *FN (false negatives)*: Presence of fungal disease in the image but the system predicted its absence.
  - 5) *GT (ground truth)*: It displays the number of comparisons made during the testing process.
  - 6) *TC (total cases)*: The total number of comparisons made during the testing process.
  - 7) *RM (result of method)*: This shows the overall number of false-positive and true positive system predictions.
  - 8) *Accuracy*: The performance of the system as a percentage of correct prediction.
  - 9) *Misclassification*: The percentage of times the system has predicted incorrectly.
  - 10) *Recall*: Represents the percentage of affirmative cases discovered by the system represented.
  - 11) *Precision*: It shows the percentage of the positive predictions made by the system.
- These results are presented in Tables VI and VII.

TABLE VI. THE CONFUSION MATRIX BASED ON FUNGAL DISEASES

Fungal Diseases	TP	TN	FP	FN
200	199	9	1	1

TABLE VII. SUMMARY OF THE RESULTS

Cases	Predicted: Negative	Predicted: Positive
Negative Cases	TN:9	FP:1
Positive Cases	FN:1	TP:199

TABLE VIII. EVALUATION OF THE PROPOSED METHODOLOGY BASED ON CLASSIFICATION RESULTS

Feature	Formula	Resulted Value	Accuracy (%)
GT	Actual Positive Images	200	-
TC	TP+TN+FP+FN	210	-
RM	FP+TP	200	-
Accuracy	(TN+TP)/TC	0.9905	99.05
Misclassification	(FP+FN)/TC	0.0095	0.95
Recall	TP/GT	0.995	99.5
Precision	TP/RM	0.995	99.5
Specificity	TN/(TN+FP)	0.90	90%

The evaluation results in Table VIII showed that the proposed technique gives 99.05% accuracy with a 0.95% misclassification rate. Furthermore, the recall rate is 99.5%, Specificity is 90% and precision is 99.5%. The system's efficiency is justified by reducing processing time and expertise costs. For example, under a 3.0 GHz Pentium IV PC with 1 GB of integrated RAM, the average processing time between preprocessing the image and the classification of the improved method was 49.6 seconds. The time required to obtain a result has been considerably reduced. This allows farmers to save time (a few seconds for a result) and resources (the cost of the expertise is considerably reduced, and it is not necessary to make an appointment with an expert in the hope of defining the quality of cotton).

Table IX represents the performance comparison between different cotton leaf disease identification and classification Systems.

TABLE IX. PERFORMANCE COMPARISON BETWEEN DIFFERENT COTTON LEAF IDENTIFICATION AND CLASSIFICATION MODELS

Reference	Technique	Disease affected Plant	Accuracy
Proposed System	Proposed Method with SVM Classifier	Cotton	99.5%
N. R. Bhimte and V. R. Thool [23]	Image Processing with SVM Classifier	Cotton	98.46%

## V. CONCLUSION AND FUTURE WORKS

In this research, cotton plant disease detection of infected leaves and classification of infected and uninfected leaves is done using image-based processing and machine learning approaches to assist farmers during their struggle against disease outbreaks by making the right decision to increase productivity and collect pure cotton. The results proved that the proposed model has the ability to accurately distinguish between infected and uninfected cotton leaves. However, the model is limited to only detecting fungal diseases in cotton leaves. For future research, this work could be extended to consider other categories of cotton plant diseases such as bacterial, seedling, and boll rots and also implement the system as a mobile and web application to eradicate the manual identification of plant defects, which has become a long and costly process.

In general, the use of image processing to detect diseases and classification does not apply to a specific area. For sustainable agriculture, this work can be applied to identify diseases or the quality of vegetables with great accuracy. This work will contribute significantly to the development of agricultural research.

## ACKNOWLEDGMENT

This Research was funded by the TEDFUND Research Fund and Africa Center of Excellence OAK-Park, Obafemi Awolowo University, Ile-Ife, Nigeria.

# Deep Learning Models for the Detection of Monkeypox Skin Lesion on Digital Skin Images

Othman A. Alrusaini

Department of Engineering and Applied Sciences  
Applied College, Umm Al-Qura University  
Makkah 24382, Saudi Arabia

**Abstract**—The study is an investigation testing the accuracy of deep learning models in the detection of Monkeypox. The disease is relatively new and difficult for physicians to detect. Data for the skins were obtained from Google via web-scraping with Python's BeautifulSoup, SERP API, and requests libraries. The images underwent scrutiny by professional physicians to determine their validity and classification. The researcher extracted the images' features using two CNN models - GoogLeNet and ResNet50. Feature selection from the images involved conducting principal component analysis. Classification employed Support Vector Machines, ResNet50, VGG-16, SqueezeNet, and InceptionV3 models. The results showed that all the models performed relatively the same. However, the most effective model was VGG-16 (accuracy = 0.96, F1-score = 0.92). It is an affirmation of the usefulness of artificial intelligence in the detection of the Monkeypox disease. Subject to the approval of national health authorities, the technology can be used to help detect the disease faster and more conveniently. If integrated into a mobile application, it can be members of the public to self-diagnose before seeking official diagnoses from approved hospitals. The researcher recommends further research into the models and building bigger image databases that will power more reliable analyses.

**Keywords**—Monkeypox; digital skin images; artificial intelligence; deep learning; convoluted neural networks; VGG-16

## I. INTRODUCTION

In the recent past, the world has experienced a pandemic and is still recovering from its adverse effects. Unfortunately, as COVID-19 diminishes in incidence and prevalence, other infectious diseases, such as Monkeypox and Ebola, have sprung up. As of July 2022, 77 countries had reported at least one case of Monkeypox disease [1]. It raises questions on whether another pandemic is in the offing. Whether Monkeypox prevalence will worsen to become a pandemic or not, the disease has made a significant mark on life and livelihoods across the globe. While the virus is endemic to Central and West Africa [2, 3], the United States is the most affected, which has reported around 27,000 cases. The Center for Disease Control and Prevention (CDC) had to raise the alert level by declaring the disease a public health emergency [4, 5]. The connectivity the US has with other parts of the world socially and economically implies that it may be a matter of time before the disease spreads even further. The most challenging factor in curbing its spread is that the virus is relatively new, and physicians are still grappling with its signs and symptoms [5].

The use of artificial intelligence in the medical field is an ongoing experiment that has been recording milestones of success. The most recent accomplishment was diagnosing COVID-19 from chest X-ray images, as studies have registered close to 100% accuracy in their predictions [6-8]. It begs the question of whether Artificial Intelligence (AI) scientists can extrapolate this methodology and apply it to the Monkeypox scourge. According to [9], the most significant signs of the disease are evident on a patient's skin. The study reports that such patients bear a rash on their skin. It is one of the many signs an individual experiences when infected with the disease [10]. Since it is a visible mark on a patient's skin, one would argue that physicians should be able to diagnose using their highly experienced eyes. However, the biggest problem with this assumption is that most physicians encounter these cases for the first time in their careers [11]. Another problem is that no scientifically proven lab tests can accurately diagnose the disease, especially in its early stages [9].

Another problem is that the rashes exhibited by Monkeypox are almost similar to those experienced by patients suffering from measles, chickenpox, smallpox, and cowpox. One would have to compare and contrast the patients' skins to tell one from the other. Such a process requires that a physician has access to patients with all other similar diseases, which is untenable [12]. Additionally, the chances of committing errors of judgment are high. Artificial intelligence can rid the diagnosis process of these bottlenecks because of its high accuracy and proven reliability in the past. Researchers are continuously creating databases of Monkeypox and other pox images to aid in the classification and isolation of the virus to curb its spread [13]. Hence, this paper tests the accuracy of machine learning models in classifying digital skin images to detect Monkeypox. A high F1-score, accuracy rate, and convincing confusion matrices should be sufficient to provide evidence that artificial intelligence is applicable in this situation. Therefore, this study investigates and testing the accuracy of deep learning models in the detection of Monkeypox on digital skin images by using different models: Support Vector Machines, ResNet50, VGG-16, SqueezeNet, and InceptionV3.

The literature review section examines existing evidence on the topic where the researcher discusses what other studies have accomplished or failed to do so. The methodology section formulates the study's data collection, feature extraction, selection, classification, and evaluation plan. In

results section, the paper compares different models in detecting Monkeypox. Afterwards, the researcher discusses these findings alongside what other studies have reported. The conclusion section explains the implications of the research and makes recommendations based on the findings.

## II. LITERATURE REVIEW

Several studies have investigated the reliability of artificial intelligence in diagnosing Monkeypox using digital skin images. The study by [14] decries the rarity of Monkeypox as the cause of the knowledge gap, which inspired the investigation. The source employed deep machine learning techniques in sourcing, preparing, and testing the image data. Findings from the research indicated AI's precision of 0.85 and a mean accuracy score of 0.83. The confusion matrices developed in the study affirm the reliability of these tests to produce accurate results. Another study on this topic is by [15], which evaluates a modified VGG-16 model. The researchers also sourced digital images from online sources and were keen only to select those with licenses. The results from the research indicate that the modified model can detect Monkeypox with an accuracy of 0.97 in the first study and 0.88 in the second study [15]. The findings present a case for using AI techniques to diagnose potential Monkeypox patients.

Some studies have utilized transfer learning techniques for feature extraction. The study by [16] employed transfer learning and GoogLeNet deep network to handle its feature extraction procedures. The paper utilized publicly available datasets to evaluate hybrid classification algorithms. Results showed that, on average, the test accuracy was 0.99. The study by [1] examined the differences between warts caused by HPV and Monkeypox. In the investigation, the researchers used DNA mapping to determine whether an individual has Monkeypox, HPV, or is healthy. Findings established that the classification algorithm managed an F1-score of 0.99 and an average accuracy score of 0.96. Similarly, the investigation by [13] used MATLAB and TensorFlow to classify skin lesion images in the detection of Monkeypox. Moreover, the mention study was particularly unique in that it created a new mobile application that would be used to scan new digital images and report the classification results. The goal was to provide a preliminary system that people with skin anomalies can use in determining whether they have a reason to worry. The results establish an accuracy score of 0.91. Even with this accuracy, the researchers still encourage people to visit hospitals for check-ups regardless of the results from the mobile application.

Some studies first built their image databases before attempting to run the analysis. An excellent example of such a study is [17]. The paper is elaborate in its approach to classifying skin lesion images to detect Monkeypox. The researchers first developed the Monkeypox Skin Lesion Dataset to include two other pox diseases, namely Measles and Chickenpox. They sourced the images from websites, case reports, and news portals. They were careful only to include publicly accessible and non-commercial images. In selecting the experimental set-up, the study adopted the 3-fold cross-validation method. Similar to the approach by [18], the

researchers then augmented this data using various techniques to create a broader database. Augmentation enhanced the dataset's size by increasing the number of images from 228 to 3,192. Classification accuracy was 0.83 for the ResNet50 model and 0.79 for the InceptionV3 model. The VGG-16 model scored 0.81 accuracy.

## III. METHODOLOGY

This section explains the methodological steps taken by the researcher in obtaining and analyzing data. The first subsection outlines the researcher's data collection plan, which is a critical part of the project. The other subsections explain the steps taken by the study in feature extraction, feature selection, image classification, and model evaluation. The flowchart for the experiment is shown by Fig. 1.

Fig. 1. Flowchart of the experiment

### A. Data Collection

The study is a research paper testing the accuracy of machine learning models in classifying digital skin images to detect Monkeypox disease. Pictorial data on the disease is still scanty. Many studies, such as [14, 15], have constructed databases of Monkeypox images that the researcher could have used. Nevertheless, the researcher was interested in conducting primary research, and contributing to the discourse by giving an independent opinion about the viability of machine learning models in detecting the disease. However, the researcher established that there are several images on the web that could become potential candidates for this analysis. Hence, the study used a web-scraping tool to search Google for Monkeypox, Measles, Smallpox, and healthy skin images. Using the requests, SERP API, and BeautifulSoup, the researcher obtained images from the search engine. The three libraries mentioned above are not the only ones employed but are the most crucial in web scraping for images on Google [19]. While there were many other images, the study confined itself to common license images to avoid unnecessary copyright infringements.

The study also hired one expert physician to screen the data to confirm its validity. The researcher targeted to have an equal number of images for each class. By the end of this screening exercise, the number of Monkeypox, Measles, Smallpox, and healthy skin images was 200 (50 for each class). While some classes had more images than others, the researcher only picked 50 so that he could maintain an equal distribution of items across the classes. Most images needed further processing, which involved cropping and removing any marks that anyone could use to identify the person in the image. Furthermore, the data was augmented by adjusting brightness, rotating, modifying sharpness, zooming, and shearing. In the end, the five augmentation techniques produced 1000 images out of the 200 original images [14]. Fig. 2 shows examples of Monkeypox, Measles, Smallpox, and healthy skin images.

Fig. 2. Example skin images of monkeypox, measles, smallpox, and healthy cases

### B. Feature Extraction

The next step succeeding the pre-processing stage is feature extraction. It is important in machine learning because it significantly reduces the noise during analysis [20, 21]. In this case, only the most critical features will end up as potential input items. The accuracy of learned models may be improved by extracting features from input data. The process eliminates duplicate data to diminish the objects' dimensions [22]. The outcome is that the time a model takes to learn the data substantially reduces. It involves technical procedures in the background, such as combinations and transformations [23]. This study considered CNN techniques in extracting features from the images. While CNN models are primarily used in classification, they also have powerful extracting capabilities. The specific CNN models used to extract features in this study were GoogLeNet and ResNet50. GoogLeNet is a 22-layer CNN with a pretrained version that can readily images into more than 1000 object categories. ResNet50 is also a CNN but has 50 layers to it and is more computational stronger than GoogLeNet [24]. The two were used in conjunction with each other to extract features from the image dataset.

### C. Feature Selection

The researcher settled for the principal component analysis technique as the feature selection method. It involves obtaining the eigenvectors of a covariance matrix with the most significant eigenvalues and then using their respective eigenvectors [25]. These values then form the basis of feature selection. In this study, the researcher squared the standard deviations of the variables to obtain their variances. Variables with the highest variances were then retained, while those with lower variances were discarded. The PCA is used as a matrix dimension reducer because it examines components and selects only those that meet a specific criterion [25]. This procedure makes the modeling process more efficient by reducing the time needed to run the machine learning procedures due to many unimportant variables.

### D. Classification

The classification phase is the stage at which the detection actually occurs. Several models can be used to classify the image data into different groups depending on their features. The researcher settled five models, namely Support Vector Machines (SVM), ResNet50, SqueezeNet, VGG-16, and InceptionV3. SVM is a deep learning technique that adopts a supervised learning approach with associated learning algorithms to classify or regress items [26]. It creates a hyperplane, which is also the decision boundary and the basis of the classification [27]. ResNet50 is a 50-layered CNN [17]. It is a robust algorithm for image classification, as it won the ImageNet challenge in 2015. VGG-16 is also a convolutional neural network that is 16 layers deep [23]. Its strength is in its implementation in that it is simple to use. InceptionV3 is a convolutional neural network primarily used in image classification and object detection [18]. It is highly applicable and is one of the modules used in GoogLeNet. SqueezeNet is an 18-layer CNN mostly used for computer vision. The model was developed and is maintained by researcher resident at the University of California. A pretrained SqueezeNet model is capable of classifying several categories of items including most common objects and animals.

### E. Evaluation

In evaluating the models, the researcher's interest is in their accuracy, precision, recall, and F1-scores. Accuracy is the ratio of all correct predictions against all possible predictions. The precision metric measures the ratio of truly positive predictions against the number of the actual positives in a dataset. The recall metric is almost similar to precision, as it measures the proportion of cases predicted as positive that are, in fact, positives. The F1-score is the harmonic mean of the true positive rate (recall) and the precision. Hence, this study will consider the accuracy and F1-score as the most critical metric in determining the reliability of the models in detecting Monkeypox from digital skin images. According to [28], the F1-score should be at least 0.90 for a machine learning modeling process to be effective in carrying out predictive analysis. The F1-score is used as the basis of determination because it combines the usefulness of two competing metrics (recall and precision). Nevertheless, all other metrics will be reported and analyzed. The following equations were utilized to compute these metrics [15]:

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (1)$$

$$Precision = \frac{TP}{TP+FP} \quad (2)$$

$$Recall = \frac{TP}{TP+FN} \quad (3)$$

$$F1 - score = \frac{2 \times Precision \times Recall}{Precision + Recall} \quad (4)$$

Where TP is the true positives, TN is the true negatives, FP is the false positives, and FN is the false negatives.

## IV. RESULTS

This section presents and analyzes the findings in training and testing the five models to detect Monkeypox disease from digital skin images dataabse explained in detail in the data

collection section. The models used in this analysis are SVM, ResNet50, VGG-16, SqueezeNet, and InceptionV3. The researcher considered a 5-fold cross-validation in enhancing the models' predictive capability since the data was not expansive enough to utilize train, validation, and splitting operations. Results in Table I show the mean metrics from the five folds. The model with the highest quality score across the five folds is VGG-16, which obtained a mean accuracy of 0.96 and a mean F1-score of 0.92. The overall performance of the five models (SVM, ResNet50, SqueezeNet, VGG-16, and InceptionV3) was reasonably close to each other. The least effective classifier model was SqueezeNet, which had an accuracy of 0.86 and an F1-score of 0.74. Other metrics

(precision, recall, and individual F1-scores) are also presented in the Table I below.

In the analysis involved attempting to make predictions using the models examined above. The outcome is presented as confusion matrices for the most effective model (VGG-16) as shown in Fig. 3 below. It is also noteworthy that there were no instances that the model reported a healthy person as being infected by Monkeypox. This fact is exemplified by healthy skin row of the confusion matrices below, where no healthy skin was detected as having Monkeypox. It adds to its reliability as a detector for the disease. Appendix A shows the matrices for the other models.

TABLE I. MODEL RESULTS ACROSS 5-FOLD CROSS-VALIDATION INSTANCES

Models	Metrics	Fold #1	Fold #2	Fold #3	Fold #4	Fold #5	Mean
SVM	Precision	0.79	0.85	0.74	0.77	0.80	0.79
	Recall	0.84	0.82	0.70	0.88	0.78	0.80
	F1-score	0.82	0.84	0.72	0.82	0.79	0.80
	Accuracy	0.91	0.92	0.87	0.91	0.90	0.90
ResNet50	Precision	0.79	0.82	0.72	0.77	0.81	0.78
	Recall	0.88	0.84	0.76	0.80	0.88	0.83

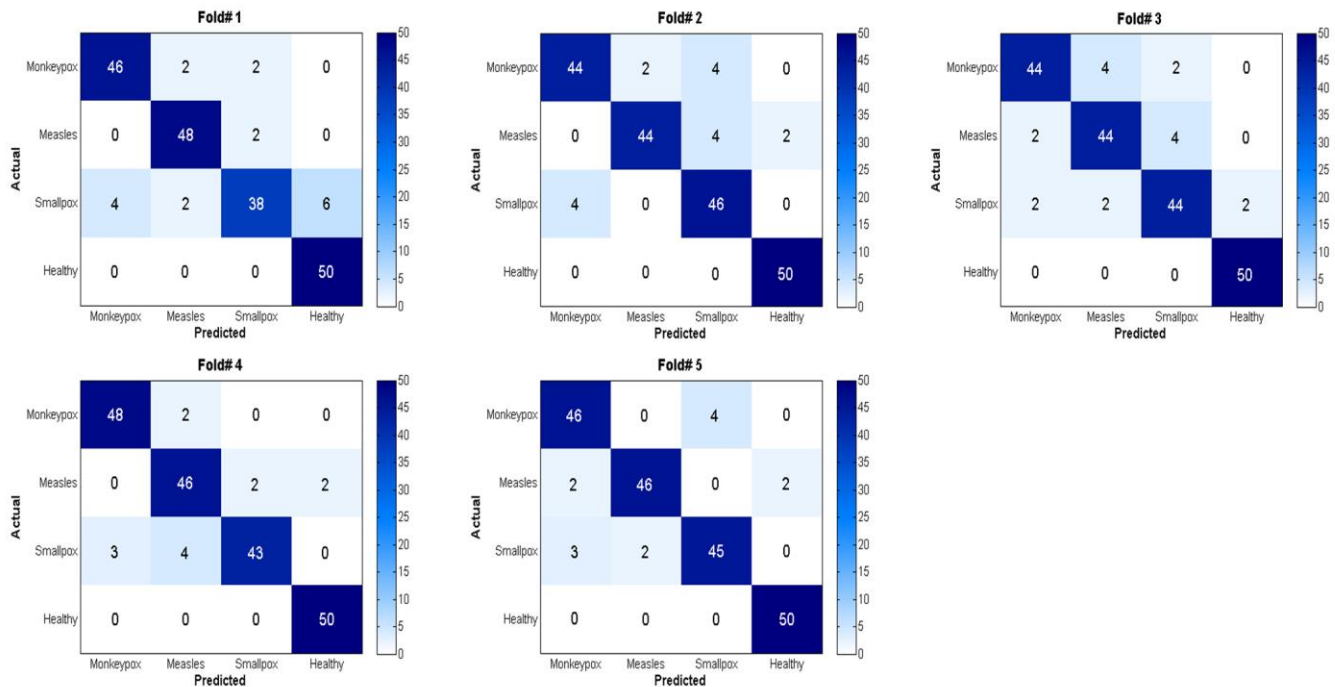

Fig. 3. Confusion matrices for VGG-16 model 5-Fold instances.

Table II below summarizes the computation of true and false positives and negatives. It shows that the model was consistent in minimizing false negatives and positives. True positives are the images correctly identified as having Monkeypox, while true negatives are the images correctly identified as having no Monkeypox. On the other hand, false positives are the images wrongly identified as having Monkeypox, while false negatives are the images wrongly identified as not infected by Monkeypox. The information is organization for each of the five cross-folds. The researcher has done the analysis using 200 images in each fold. The analysis in Table II shows that false positives and false negatives were minimal. These metrics contribute largely to the computation of recall and precision scores. For this reason, the model achieved high recall (0.91) and precision (0.92) values.

TABLE II. TRUE, FALSE POSITIVES AND NEGATIVES ANALYSIS

	FOLD #1	FOLD #2	FOLD #3	FOLD #4	FOLD #5	Sum
TP	46	44	44	48	46	228

FN	4	6	6	2	4	22
TOTAL	200	200	200	200	200	1000

### V. DISCUSSION

The study has established that the selected models are reasonably effective in detecting Monkeypox from digital skin images. However, the model with the highest metrics is VGG-16. It is an affirmation of the findings made in [15], where the

researchers found the VGG-16 model highly effective in detecting the disease by obtaining an F1-score of 0.97, higher than the current study’s findings. This study adds to their findings by comparing the model with similar CNN and SVM models to ascertain that the selected model gives good results. Nevertheless, there are remarkable differences between the studies. The cited source used only the VGG-16 model, while the one in focus applied five models. The approach taken by this investigation is similar to what [17] undertook. The researchers in the cited study compared VGG-16, ResNet50, InceptionV3, and Ensemble. The researchers in [17] found that ResNet50 is a better model for detecting Monkeypox because of its high F1-score (0.84) and accuracy (0.83) scores. Nevertheless, the same study found that VGG-16 is slightly lower than ResNet50 in its prediction accuracy, as it scored an F1-score of 0.83 and accuracy of 0.81. The data used by the study is dissimilar, and it may be the cause of the slight differences in the outcomes.

The researcher in this study opted for the multi-label approach because it is sometimes not enough to distinguish Monkeypox from healthy skin. Most people looking to determine their Monkeypox status usually suspect that they may have the disease because of the changes in their skin. Hence, it is important to differentiate it from other similar diseases that manifest as skin lesions. While this study dealt with four labels, other studies have dealt with even more. The investigation by [14] worked with six labels, namely chickenpox, cowpox, healthy, measles, and Monkeypox. The study also conducted 5-fold cross-validation to classify the digital skin images. It also engaged several other CNN models, which were ResNet50, InceptionV3, DenseNet121, MnasNet-A1, MobileNet-V2, ShuffleNet-V2, and SqueezeNet. The point of coincidence between [14] and the current study is that they both used ResNet50, InceptionV3,

and SqueezeNet. ShuffleNet-V2 was the most effective model, scoring the highest accuracy (0.79) and F1-score (0.67) metrics. However, the cited study did not model using SVM or VGG-16.

The ‘many models’ approach has also been evident in detecting other diseases aside from Monkeypox. The benefit of using these many models is that it allows the researcher to compare them and establish which is the most effective [6]. The paper established in the confusion matrix that the VGG-16 network did not report any false positives on persons with healthy skin, which would suggest that persons with healthy skins had Monkeypox. The author in [14] also established similar findings. In all the folds the researchers ran, there was no instance of healthy skin detected as having Monkeypox. The authors in [6] and [14] suggest that healthy skin differs significantly from that which has contracted Monkeypox. Hence, so long as one does not spot any lesions, chances are that they are safe from the disease. The lack of enough skin

images decried in [14, 15] seems to have affected accuracy scores obtained in this study. Obtaining and processing Monkeypox images may be difficult currently because of their rarity. Some of the images on Google may not be of the disease but some websites post them as Monkeypox. It is crucial that researchers hire a microbiologist to examine the skin images before using them in model training and prediction. This approach was used in [14] in creating a Monkeypox skin image database. The researcher in this investigation also shared the results with the consulted microbiologist to help in propagating the news about the technology in the profession.

Based on F1 scores, Table III below compares the performance of different deep learning models from the articles used in this paper. The table also shows the number of classifications that the model deals with, which in turn affects the accuracy of the results.

TABLE III. COMPARATIVE RESULTS WITH OTHER STUDIES

Publication	Model									Number of classifications
	VGG-16	ResNet50	InceptionV3	SVM	SqueezeNet	DenseNet121	GoogLeNet	MobileNet-V2	ShuffleNet-V2	
[13]								0.90		2
[14]		0.55	0.61			0.61		0.67	0.67	6
[15]	0.97									4
[16]		0.72					0.74			2
[17]	0.83	0.84	0.78							2
[18]	0.92	0.96					0.96	0.98	0.92	2
[23]	0.79	0.83	0.82			0.82		0.81		4
This study	0.92	0.81	0.78	0.80	0.74					4

## VI. CONCLUSION AND FUTURE RESEARCH

The current research is testing the accuracy of machine-learning models in detecting Monkeypox from digital skin images. Its findings have established that the consulted models manifested an almost similar performance. However, the outstanding model was VGG-16, whose accuracy and F1-scores were significantly higher than the rest. The detection of healthy skin was remarkably accurate because none of the healthy skin was classified as having Monkeypox. AI can be a reliable tool for physicians to differentiate between healthy skin and skin infected with the disease. Nevertheless, the accuracy in telling the difference in lesions caused by Monkeypox, measles, and smallpox still needs further analysis. The study’s F1-score of 0.92 meets the threshold of 0.90 proposed in [28], which is a vindication of the usefulness of AI in predicting the Monkeypox disease from skin images. While the achieved scores are reasonably high to suggest

proper classification, the researcher does not recommend that physicians use the technology until national health regulatory bodies further affirm the results. Other researchers should consider creating bigger databases that, when augmented, will validate the findings established in this investigation. The focus of future studies should only compare Monkeypox skin with diseases that cause lesions, such as Chickenpox, Measles, Smallpox, and Cowpox. With more research modeling the detection of Monkeypox, the researcher believes that artificial intelligence will add value to the detection process by making it quicker and more convenient. Once one has been tested, they can seek medical help and avoid contact with healthy individuals. If integrated into a mobile application, the technology can help in the detection of the disease in remote places where health facilities are fairly distant. It also provides a basis for additional research into the use of artificial intelligence in the detection of Monkeypox.

# Upgraded Very Fast Decision Tree: Energy Conservative Algorithm for Data Stream Classification

Mai Lefa<sup>1</sup>, Hatem Abd-Elkader<sup>2</sup>, Rashed Salem<sup>2</sup>

Department of Information System, Sadat Academy for Management Science, Cairo, Egypt<sup>1</sup>

Department of Information Systems-Faculty of Computers and Information, Minoufia University, Egypt<sup>2</sup>

**Abstract**—Traditional machine learning (ML) techniques model knowledge using static datasets. With the increased use of the Internet in today's digital world, a massive amount of data is generated at an accelerated rate that must be handled. This data must be handled as soon as it arrives because it is continuous, and cannot be kept for a long period of time. Various methods exist for mining data from streams. When developing methods like these, the machine learning community put accuracy and execution time first. Numerous sorts of studies take energy consumption into consideration while evaluating data mining methods. However, this work concentrates on Very Fast Decision Tree, which is the most often used technique in data flow classification, despite the fact that it wastes a huge amount of energy on trivial calculations. The research presents a proposed mechanism for upgrading the algorithm's energy usage and restricts computational resources, without compromising the algorithm's efficiency. The mechanism has two stages: the first is to eliminate a set of bad features that increase computational complexity and waste energy, and the second is to group the good features into a candidate group that will be used instead of using all of the attributes in the next iteration. Experiments were conducted on real-world benchmark and synthetic datasets to compare the proposed method to state-of-the-art algorithms in previous works. The proposed algorithm works considerably better and faster with less energy while maintaining accuracy.

**Keywords**—Classification; energy consumption; Hoeffding bound; Information gain; massive online analysis; stream data; very fast decision tree

## I. INTRODUCTION

In recent years, the amount of generated data is growing significantly. This data is made up of  $n$  ( $n \rightarrow \infty$ ) data samples, and it is described as a series of ordered data sequences, with starting and stopping bytes. Data stream (DS) =  $\{x_1, x_2, \dots, x_i, \dots, x_n\}$ , where  $x_n$  denotes the most recently visible data object in a stream of data [1]. Because the samples arrive in the form of continuous data flow at a great speed, the traditional classifiers cannot access the data instances in real-time [2]. The instances can only be scanned once or stored for a short period of time, so an ideal data stream classifier must be well prepared to deal with a large number of instances in real-time for better classification performance [1,3]. Data stream mining is a subset of machine learning that involves examining data flows that are continuously expanding as time series and developing a classification algorithm based on them. It is highly different from traditional data mining in

terms of processing the mining operation, but it is similar to it in terms of purpose [2].

Machine Learning (ML) techniques consist of three types: unsupervised, semi-supervised, and supervised. Unsupervised algorithms can operate with unlabeled data; the data is clustered into groups with similar characteristics. Semi-supervised algorithms partially work with labeled data [4]. Supervised algorithms require data to be labeled, which they can categorize the data according to a distinct pattern for each class based on the label, such as data stream classification algorithms [5].

Very Fast Decision Tree (VFDT) is an effective classification technique for DS classification, and it has a high level of classification accuracy. It builds the decision tree by learning examples in real-time at a reasonable cost, and its sequential feature can match the data stream's timeliness requirement. To dynamically generate the decision tree, it is based on the enhancement of the Hoeffding tree. The Hoeffding bound ( $\epsilon$ ) is used to make sure that the data utilized to build each sub tree contains enough information [6,7].

The algorithm determines the information gain ( $G$ ) for all noticed attributes after reading the minimum number of examples ( $n_{min}$ ) at that leaf. The two top features are received through using the function *Best Split Suggestion()*. The difference between these features is compared with the  $\epsilon$ , which was calculated previously. As a result, if the difference exceeds the  $\epsilon$ , there will be a split on the tree by changing the leaf with a new internal node. This function is considered among the functions with the highest energy in the algorithm [8,9]. This point is considered the main problem that the paper solves. Therefore, the proposed mechanism focuses on working to reduce bad features that take a lot of energy when calculating their  $G$ , without impacting on the performance of algorithm. These are the motivations and objectives for our mechanism:

- 1) Decrease the amount of calculations by reducing undesirable features on each leaf.
- 2) Maintain the same level of accuracy by deleting just the computations that aren't necessary.

The rest of this paper is structured as follows: Section II clarifies related work. Section III introduces the background. Our algorithm and the corresponding theoretical derivation are explained in Section IV. Experiments and results are covered

in Section V. Finally, the paper is concluded with the conclusions and the future work in Section VI.

## II. RELATED WORK

Many works have gone into improving the VFDT in various ways. The Random Forest algorithm was created by Dong Zhenjiang and Li Lingjuan [10], it is a combinational classifier that performs well in terms of classification. It is made up of multiple decision trees, and it can compensate for the lack of a single decision tree. This technique upgrades the Random Forest algorithm by sliding the time window to match the unlimited data streams, and introduces the criterion of constructing decision trees in the random forest classifier. The limitation of this study is that it improves the accuracy levels without trying to improve other evaluation criteria.

R. J. Lyon et al. proposed the GH-VFDT, a novel classification technique for unbalanced data flows. The Hellinger distance was combined with a stream classifier depending on the Hoeffding bound in an empirical study. They can be combined to create a skew-insensitive decision tree split criterion that enhances minority class recall rates significantly. On unbalanced data, the algorithm can successfully enhance minority class recall rates, with same performance levels [11].

In the research [12], Ariyam Das et al. presented a memory-efficient bootstrap simulation heuristic (Mem-ES) that effectively accelerates the learning process. Experiments show that performing resampling techniques efficiently speeds up node splits for online decision tree learning.

Victor Guilherme Turrisi da Costa et al. proposed two versions of a novel VFDT-based algorithm, SVFDTs were developed to minimize the size of VFDT-induced trees, resulting in a memory-conserving decision tree. Both SVFDTs produce trees that are substantially smaller than those produced by the VFDT, while it doesn't reduce prediction performance statistically [13].

Gayathiri Kathiresan and Krishna Mohanta [14] present the compact method that uses the adaptive reservoir sampling methodology. It helps to reduce memory usage, and handle unbalanced stream data by restricting the information gain deviation based on the improved splitting metric in the information gain measurement. The limitation of this study is that it applied the proposed method to only one dataset, neglecting the other types of datasets with different characteristics, in order to determine the reliability of the findings.

Liang, Chunquan et al. use the Hoeffding bound theory and the Uncertain Naive Bayes classifier (UNB) to improve the speed of construction and classification performance. They use gradual pruning and an adaptive tie-breaking criterion [15]. In a different study, Eva Garcia et al. proposed the *nmin* adaptation approach to enhance parameter adaptation in Hoeffding trees. They dynamically adjust the total amount of examples needed to make a split, this approach saves energy. The limitation of this study is that the *nmin* adaption method adjusts to the best *nmin* parameter based on the assumption, that newly received data would maintain the same distribution as previously seen data [16].

## III. BACKGROUND

### A. Hoeffding Tree

There are several types of supervised classification techniques: k-Nearest Neighbor (kNN), Neural Network, Support Vector Machine (SVM), Naïve Bayes (NB) and Decision Tree (DT). Hoeffding tree algorithm is an extension of the decision tree algorithm for performing DS classification. It reads data in a single pass, and builds model  $b = f(a)$  that maps test example  $a$  to class  $b$ . Every node represents a class feature, and each leaf represents the forecasted class label for that node. Beginning from the root node, the DT grows by exchanging leaf nodes with newly arrived test attributes. It would be the most efficient way of classification [17,18]. VFDT extends the Hoeffding tree algorithm by separating the current best features based on a user-specified threshold value [5].

### B. VFDT

VFDT is a tree-based ML technique for DS based on the Hoeffding bound ( $\epsilon$ ) principles. The nodes represent the features of the dataset. The edges indicate the different possible outcomes for each attribute, and the leaf nodes represent the dataset's class labels. Once the model is complete, test data passes through it, and the decision tree will determine the class label. Each instance is read one by one, it is then sorted into the appropriate leaf, and the statistics are updated [5,19].

At the leaf node, denote  $G(X_i)$  as the heuristic measure of attribute  $X_i$ . The algorithm is used to determine the heuristic measure (information gain ( $G$ )) for all observed features after reading the minimum number of instances (*nmin*) at that leaf. Assume that  $X_a$  and  $X_b$  are the attributes with the best and second-best  $G$  after seeing  $n$  pieces of data. The difference in  $G$  between both the best and second best features ( $\Delta G$ ),  $\Delta G = G(X_a) - G(X_b)$ , is compared to the  $\epsilon$  after calculating it according to Eq. 1. If  $\Delta G > \epsilon$ , then the attribute  $X_a$  is the best attribute of the current leaf node with a probability of  $1 - \delta$ . A node will replace that leaf, and there is a split on the best feature  $X_a$ .

$$\epsilon = \sqrt{\frac{R^2 \ln(\frac{1}{\delta})}{2n}} \quad (1)$$

The feature  $X_a$  is removed from the list of all features  $x$  when calculating the tested attributes in next iterations  $X_m$  as shown in Eq. (2), then the information gain for  $X_m$  must be calculated [20].

$$X_m = x - X_a. \quad (2)$$

The statistics required for attribute splitting are stored in each node. When two discrete attributes have similar split gains  $G$  or the highest and second-highest  $G$  are not significantly different, a tiebreak hyper parameter ( $\tau$ ) is introduced to enable tree growth. This is done by ignoring the Hoeffding bound condition and checking if  $G(X_a) - G(X_b) < \epsilon < \tau$  is true [18]. Because the two top attributes have extremely comparable  $G$  values, the algorithm can split into either of them [21].

The algorithm contains a set of fixed parameters that are determined before the work of the algorithm begins. The  $nmin$  parameter defines the minimum number of samples that the algorithm must observe before computing. If there are sufficient statistics for a good split; the default value is 200. The parameter  $\tau$  is utilized to break a tie in the event of a tie. When the difference between the two features is tiny enough, it suggests that both are equally as good. Therefore, waiting a long time for more instances to make a split is pointless. The  $\delta$  parameter denotes one minus the likelihood of selecting the correct feature to split on. The researchers' default split criterion is information gain or the Gini index [6].

### C. Energy Consumption for VFDT Functions

It is necessary to identify the energy consumption at each function level of the VFDT. The specific functions of the VFDT are four key functions: *homogeneous()*, *label()*, *split()* and *bestSplit()*. If all of the tree's instances can be labeled with a single class, the *homogeneous()* function returns true. The leaf node's label is returned by the *label()* function. The *split()* function encompasses all of the functions involved in splitting an internal node into several children. The best attribute to split on is returned by the *Split()* function. This can be accomplished in a variety of ways, including by utilizing the information gain function [17].

## IV. THEORETICAL MODEL OF UPGRADED U-VFDT

In this paper, U-VFDT is proposed to enhance the VFDT and improve its overall performance, which VFDT is one of the most well-known methods for handling data streams. The splitting is performed based on the current best attributes, whereas the algorithm determines the  $G$  from all noticed attributes after reading the  $nmin$  at that leaf. This process is considered one of the most energy-consuming processes in the algorithm. In this case, the *bestSplit()* function performs unnecessary operations that increase the wasted energy in the algorithm.

The difference in  $G$  between the top and the second-top feature ( $\Delta G$ ) is compared with the Hoeffding Bound ( $\epsilon$ ). If  $\Delta G > \epsilon$ , the leaf is replaced by a node, and there is a split on the best feature. That feature is deleted from the list of features available to split on that branch. This method requires a periodic check because the best attributes are prone to change. The proposed method is introduced to limit the number of checked attributes which are noticed at the leaf. Because the  $G$  of all features is calculated in each split, and it leads to leveling up the algorithm's energy usage. The proposed method introduces a dynamic mechanism for appropriate features group through two basic steps.

*The first step* is adaptive appropriate features.

At this step, the performance of all attributes is analyzed to exclude the attributes with small  $G$ , through calculating the  $G$  for all attributes. If the  $G$  for a specific attribute  $X_i$  is less than the  $G$  of the best attribute  $X_a$  by more than a difference of  $\epsilon$   $G(X_a) - G(X_i) \geq \epsilon$ , this attribute is ignored for that leaf. If  $G(X_a) - G(X_i) \leq \epsilon$ , then the attribute is regarded as top feature.

*The second step* is appropriate features group.

At this step, the appropriate features group ( $P$ ) is used in each leaf node, which stores the top  $X$  features selected at the previous step, and excludes the bad ones. Therefore, the  $P$  surely has captured the true split attribute [19]. This method leads to a reduction of the energy usage, because only appropriate features information gain will be evaluated in each split.

To implement this method, we assumed  $X_a$  is the attribute with highest  $G$ , for any other attribute  $X_i$ .  $X_i$  is said to be appropriate if  $G(X_a) - G(X_i) \leq \epsilon$  and  $X_i$  is shown in the appropriate group  $P$  ( $X_i \in P$ ), other features are removed. After making a split on the best attribute  $X_a$ , the algorithm removes  $X_a$  from the list of features in  $P$  available to split on that branch. In the next iteration, when algorithm calculates  $G$  for all tested attributes in next iterations  $X_m$ , only the list of attributes in the appropriate group will be recalculated, with the deletion of  $X_a$  as shown in Eq. 3.

$$X_m = p - X_a. \quad (3)$$

In theory, this approach should improve accuracy, reduce the number of calculations, and decrease the energy usage. It will be shown during the practical application. In Algorithm 1, a pseudo code displays the implementation of the U-VFDT with appropriate features group.

### Algorithm 1: The U-VFDT with appropriate features group mechanism

#### Require:

- S : the stream of instances
- $\epsilon$  : Hoeffding bound
- $\delta$  : the error probability
- HT: Tree with a single leaf (the root)
- X: set of attributes
- $G(\cdot)$ : split evaluation function
- P : Appropriate features group
- $\tau$ : the tiebreak parameter set by the user

#### Ensure:

- Enhanced Very Fast Decision Tree
- 1. While stream is not empty do
- 2.   Read instance  $I_i$  from S
- 3.   Sort  $I_i$  to corresponding leaf  $l$  using  $\epsilon$
- 4.   Update statistics at leaf  $l$
- 5.   Increment  $n_i$ : instances seen at leaf  $l$
- 6.   If  $n_i \geq nmin$  then
- 7.     Compute  $\epsilon$
- 8.     Compute  $G(X_i)$  for each attribute  $X_i$
- 9.     If  $G(X_a) - G(X_i) \leq \epsilon$  then
- 10.        $X_i \in p$
- 11.       Calculate  $\Delta G(\cdot) \leftarrow G(X_a) - G(X_b)$
- 12.       If  $\Delta G(\cdot) > \epsilon$
- 13.         Split on best attribute  $X_a$  and Replace  $l$  with a node.
- 14.         For each branch of the split do
- 15.           Update new leaves,
- 16.           Add New Leaf  $L_m$  with empty  $p_m$
- 17.           Let  $X_m \leftarrow p - X_a$
- 18.         End for
- 19.       End if
- 20.     End if
- 21.   Else

- |     |                  |
|-----|------------------|
| 22. | Do not split     |
| 23. | Do not update HT |
| 24. | End if           |
| 25. | End while        |

## V. EXPERIMENTS AND RESULTS

In this section, the mechanism is analyzed using reliable datasets that have been utilized in previous researches, with the goal of determining how big of an influence of our algorithm; using the results of its prior efforts as a benchmark, and comparing it with the results of proposed mechanism.

### A. Datasets

The experiment was conducted on several different types of datasets to see the impact of the proposed mechanism on each of those data. There are real-world dataset, synthetic dataset and real-world benchmarks datasets. These datasets were chosen as a baseline for the standard behavior of the algorithm. We obtained the real-world datasets from <https://archive.ics.uci.edu/theml/datasets.php>.

The airlines dataset is the real-world dataset. This classification dataset divides flights into two categories: delayed and not delayed, based on the flight's path and departure and arrival airports. It has eight attributes. The random tree dataset is a synthetic dataset that was created using MOA (Massive Online Analysis).

The synthetic generator generated one million cases. The last two datasets consist of real-world benchmarks, the first one is abalone dataset and this study includes predicting the age of abalone from physical measurements. The second one is adult dataset, which predicts whether income exceeds fifty thousand dollars per year based on census data. Their main characteristics can be seen in Table I.

TABLE I. DATASETS SUMMARY

Datasets	Name	Type	Instances	Numeric features	Binary features
1	airlines	Real-world	539,383	3	5
2	random tree	Artificial	1,000,000	5	5
3	abalone	Real-world benchmark	4177	2	6
4	adult	Real-world benchmark	48842	6	8

### B. Tools

Massive Online Analysis (MOA) is a well-known framework for developing algorithms and conducting experiments. It has a number of ML methods, such as classification, regression, clustering, concept drift detection, and a recommender system. It also includes a number of evaluation tools.

MOA can be employed with WEKA's many classification and clustering approaches. It is used for online real-time stream data, while WEKA is used for offline data [6,22]. The

MOA framework is running in parallel with IPPET (Intel(R) Platform Power Estimation Tool) which can measure how much power different processes are consuming.

A set of specifications for the device utilized in this experiment is also included in the environment for practical application, which impacts energy-related calculations such as the operating system: Windows 7 professional 64-bit (6.1, Build 7601), the processor: Intel(R) core(TM) i3-2350M CPU @ 2.30GHz (4 CPUs), ~ 2.3GHz, and memory: 4096MB RAM.

### C. Experimental Design

The primary goal of the model is to increase the efficiency of VFDT. It focuses on understanding and developing the functions of the algorithm that consume the most energy. An efficient method has been proposed for selecting best attributes which are used to perform splitting. It avoids the calculation of the heuristic measure for unnecessary attributes that consumes high energy.

To the best of our knowledge, there are no previous works that have limited the energy consumption of the VFDT except the reference [16]. It has set  $\epsilon = \Delta G$  in the  $\epsilon$  equation as shown in Eq. (4) to ensure that  $\Delta G \geq \epsilon$  is satisfied during the next iterations, resulting in a split.

$$nmin = \left\lceil \frac{R^2 \ln\left(\frac{1}{\delta}\right)}{2 \cdot \Delta G^2} \right\rceil \quad (4)$$

The following is a comparative study of the practical experiment between the performance of our method U-VFDT, the standard algorithm VFDT, and this previous modification on algorithm P-FVDT. Run-time, power, memory usage, accuracy and energy are measured using four different datasets.

1) *Run-time of VFDT algorithms:* There is a convergence of execution time in our algorithm and other two algorithms as shown in Fig. 1. The increase of examples in random tree dataset leads to an increase in times of the heuristic measure for all attributes; thus, increases the running time. The U-VFDT achieves less time to reach the highest efficiency in random tree dataset. The reason of this result is that U-VFDT works on reducing those attributes that waste time. Also, adult dataset contains a large number of features, so the proposed method is effective in working to reduce these features.

U-VFDT does not achieve effective results in the other two datasets due to two reasons. The first reason is the small airlines dataset features, and the other reason is the few examples of abalone dataset. Thus, our method is not efficient, because it depends on reducing the number of features, where time is wasted. Unlike the VFDT, the time increases dramatically as soon as it receives new examples, whereas heuristic measure is counted for each attribute of a new example when it is received.

Fig. 1. Run time of VFDT algorithms for all datasets.

2) *Power consumption of VFDT algorithms:* As shown in Fig. 2, lower power values of U-VFDT in some datasets, and other higher values in other datasets. The power levels differ in each algorithm, due to the difference in the nature of the dataset in terms of its examples and features.

U-VFDT does not achieve an effective result in the abalone dataset, because this dataset contains a small number

of examples. U-VFDT proves more efficiency than other two algorithms for other datasets due to two reasons. The first reason is the large number of examples for airlines and random tree datasets, and the other reason is the large number of features for adult dataset. Thus, our method is efficient, because it depends on reducing the number of features.

Fig. 2. Power consumption of VFDT algorithms for all datasets.

3) Energy consumption of VFDT algorithms for all datasets: U-VFDT succeeded in saving the extra time wasted, which helped in saving energy significantly, based on the Eq. (5). It saves energy only in datasets that contains many examples and attributes, by ignoring the bad features that have no chance of splitting.

$$\text{Energy} = \text{Power} \times \text{Time} \quad (5)$$

VFDT makes high computations because of the heuristic measure calculations for unnecessary attributes that is required to make a split as shown in Fig. 3.

(a)

(b)

(c)

(d)

Fig. 3. Energy consumption of VFDT algorithms for all datasets.

4) Accuracy of VFDT algorithms: As shown in Fig. 4, U-VFDT is maintaining the performance of the algorithm with light impact on accuracy; this is for data with few features and examples such as airlines and abalone datasets. On the contrary, U-VFDT significantly affects the accuracy of the algorithm, but in a greater proportion in the case of data containing a large number of examples and features, such as random tree and adult datasets, which is considered a drawback in our method.

(a)

(b)

(c)

(b)

(d)

(c)

Fig. 4. Accuracy of VFDT algorithms for all datasets Accuracy (%).

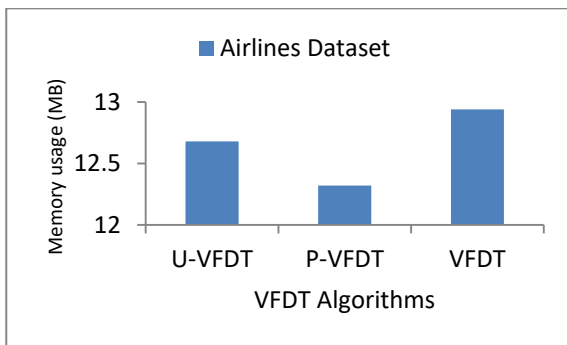

5) *Memory usage of VFDT algorithms:* For memory usage, an adult dataset contains a large number of attributes. U-VFDT proves more efficiency than other two algorithms. It achieves the least required memory for making a split as shown in Fig. 5, which it excludes bad features, thus does not perform any unnecessary operations.

In the random tree dataset, despite the large number of its instances, U-VFDT does not achieve an effective result for it, because this dataset contains noise and concept drift that wastes memory. In the other two small datasets, our method does not achieve an effective result, because it depends on reducing the features.

(d)

Fig. 5. Memory usage of VFDT algorithms for all datasets.

(a)

The experiments clarify that U-VFDT has a better performance than other two algorithms. The proposed algorithm was limited to the heuristic measure of only the good attributes, through which the split could take place. It was excluded of bad attributes that are consuming massive levels of memory, and energy as well as a large run-time. Accordingly, the energy is decreased and the processes are speed up, because of the reduction in both running time and the memory usage. The limitation of this work is that it consumes less energy only in the dataset with a large number of instances and attributes. Also, it does not achieve an effective result for the datasets with noise and concept drift.

The total computational complexity of the VFDT is  $O(n)$ . The computational complexity of the U-VFDT does not exceed its value in the original algorithm, and still retains the same value after modification, since it was  $O(n)$ .

## VI. CONCLUSIONS

This research developed a new technique to improve the VFDT, which allows for an energy conservative algorithm to construct Hoeffding trees without affecting their predictive performance, resulting in lower energy consumption and minor accuracy loss. In VFDT, after the splitting occurred, and the leaf turned into a node, all of features are recalculated to determine which splitting will occur through.

The proposed mechanism recalculates information gain for only the list of attributes in the appropriate group, with the deletion of the feature used for the previous split. It leads to the reduction of unnecessary calculations of bad attributes. Thus, an evolution occurred in the performance of the algorithm in terms of saving time and memory and reducing wasted energy consumption with maintaining the accuracy of the algorithm.

Finally, the mentioned algorithms are compared in different datasets with standard algorithm, and the previous modification work. The U-VFDT used less energy than the VFDT and the P-VFDT only in the datasets with large number instances and attributes. It does not achieve effective results in data that is small in size and has few features. The main work is based on limiting the useless features, thus reducing the number of unnecessary operations that increase running time, energy and memory usage.

Further methods are offered for future work in order to enable an energy-efficient method to build Hoeffding trees for datasets with noise and concept drift without compromising their predictive effectiveness.

**Abstract**—Diabetes mellitus is a disease characterized by abnormal glucose homeostasis resulting in an increase in blood sugar. According to data from the International Diabetes Federation (IDF), Indonesia ranks 7th out of 10 countries with the highest number of diabetes mellitus patients in the world. The prevalence of patients with diabetes mellitus in Indonesia reaches 11.3 percent or there are 10.7 million sufferers in 2019. Prevention, risk analysis and early diagnosis of diabetes mellitus are necessary to reduce the impact of diabetes mellitus and its complications. The clustering algorithm is one of methods that can be used to diagnose and analyze the risk of diabetes mellitus. The K-mean Clustering Algorithm is the most commonly used clustering algorithm because it is easy to implement and run, computation time is fast and easy to adapt. However, this method often gets to be stuck at the local optima. The problem of the K-means Clustering Algorithm can be solved by combining the K-means Clustering algorithm with the global optimization algorithm. This algorithm has the ability to find the global optimum from many local optimums, does not require derivatives, is robust, easy to implement. The Bat Algorithm (BA) is one of global optimization methods in swarm intelligence class. BA uses automated enlargement techniques into a solution and it's accompanied by a shift from exploration mode to local intensive exploitation. Based on the background that has been explained, this article proposes the development of a classification model for diagnosing diabetes mellitus based on the K-means clustering algorithm optimized with BA. The experimental results show that the K-means clustering optimized by BA has better performance than K-means clustering in all metrics evaluations, but the computational time of the K-means clustering optimized by BA is higher than K-means clustering.

**Keywords**—Diabetes mellitus; disease diagnosis methods; k-means clustering algorithm; optimization; bat algorithm

## I. INTRODUCTION

Diabetes mellitus is a disease characterized by abnormal glucose homeostasis resulting in an increase in blood sugar. According to data from the International Diabetes Federation (IDF), Indonesia ranks 7th out of 10 countries with the highest number of diabetes mellitus in the world. The prevalence of patients with diabetes mellitus in Indonesia reaches 11.3 percent or there are 10.7 million sufferers in 2019 [1]. Diabetes mellitus causes various complications such as cardiovascular disease, atherosclerotic disease, peripheral neuropathy, diabetic retinopathy, severe foot infections, kidney failure, and sexual dysfunction [2, 3].

Early diagnosis of diabetes mellitus is necessary to reduce the impact of diabetes mellitus and its complications. Clustering algorithms have been used to diagnose and analyze the risk of diabetes mellitus [4-6]. In general, clustering is divided into four categories of use, namely data reduction, hypothesis formation, hypothesis testing, and prediction based on groups [7]. Algorithm clustering is automatically able to recognize patterns in the data so that it can analyze the collected data without the label [8].

The K-mean Clustering Algorithm is the most commonly used clustering algorithm because it is easy to implement and run, the computation time is fast, and easy to adapt [9]. This algorithm has been used in various applications including diagnosis of diabetes mellitus [5], segmentation of diseases in plant leaves [10], heart disease prediction and classification [11, 12] and prediction of diabetes mellitus [13]. However, this method has a drawback, namely random centroid initialization causing, the algorithm to be stuck at the local optima [14]. The clustering result of the K-means algorithm becomes worse because the cluster center is stuck at the local optima. Therefore, the robust initialization of centroid is needed to obtain the good clustering result.

Problems of the K-means Clustering Algorithm can be overcome by combining the K-means Clustering with global optimization algorithms, e.g., swarm intelligence algorithm. This algorithm is able to find the global optimum from many local optimums, does not require derivatives, robust, and easy to implement [15]. Anam et al. have used a swarm intelligence-based algorithm (Particle Swarm Optimization) to segment disease in tomato leaves [16]. One of the swarm intelligence methods is Bat Algorithm, with a faster convergence rate than Genetic Algorithm and Particle Swarm Optimization [17]. This is because BA uses automated enlargement techniques into a promising solution. This enlargement is accompanied by a shift from exploration mode to local intensive exploitation. BA also has been used for many applications, for example travelling salesman problem [18, 19], resource scheduling [20, 21], customer churn [22, 23], brain tumor recognition [24, 25], estimating state of health of lithium-ion batteries [26], detection of myocardial infarction [27] and features selection [28, 29].

TABLE I. ATTRIBUTES DESCRIPTION OF DATA SET

No.	Attribute Name	Attribute Description
1	HighBP	Respondent has high blood pressure which is decided by health professional.
2	HighChol	Respondent has ever had high blood cholesterol which is decided by health professional.
3	CholCheck	Cholesterol check in the last five years
4	BMI	Body Mass Index (BMI)
5	Smoker	Respondent has smoked at least 100 cigarettes in his/her lifetime.
6	Stroke	Respondent has a stroke.
7	HeartDiseaseorAttack	Respondent who had reported suffering from coronary heart disease or myocardial infarction.
8	PhysActivity	Respondent who reported engaging in physical activity or sports during the last 30 days apart from their regular job.
9	Fruits	Respondent consumes fruit 1 time or more per day
10	Veggies	Respondent consumes vegetable 1 time or more per day
11	HeavyAlcoholConsumption	Heavy drinking or not (adult men drink more than 14 drinks per week and adult women drink more than 7 drinks per week)
12	AnyHealthcare	Possession of any health care coverage, including health insurance, prepaid plans, or government plans.
13	NoDoctorCost	Was there a time in the last 12 months when you needed to see a doctor but couldn't because of costs?
14	GeneralHealth	General health score. [from 1 to 5]
15	MentalHealth	Mental health which includes stress, depression and emotional problems, for how many days during the last 30 days your mental health was not good. [from 1 to 30]
16	PhysicalHealth	Physical health including physical illness and injury, for how many days during the last 30 days your physical health was not good. [from 1 to 30]
17	DiffWalking	Has serious difficulty walking/climbing stairs or not
18	Sex	Indicates the gender of the respondent. [Female: 0, Male: 1]
19	Age	Age category fourteen levels [from 1 to 14]
20	Education	The completed level of education. [from 1 to 6]
21	Income	The household's annual income from all sources: (If the respondent declines at any income level, code "Refuse.")
22	Diabetes	0 is no diabetes, 1 is pre-diabetes or diabetes

Based on the background described, this article proposes the development of a method for diagnosing diabetes mellitus based on the K-means clustering algorithm optimized by BA. The purpose of this research is to develop a rapid method for diagnosing diabetes mellitus using the K-means and BA algorithms. In this article, the K-means algorithm is improved by using the BA algorithm to overcome the problem of the K-means algorithm which is often stuck in the local optima. This research is useful for the prevention and reduction of the impact of diabetes mellitus through a rapid and inexpensive diagnosis of diabetes mellitus by utilizing information technology (machine learning).

## II. PROPOSED METHOD

This sub-chapter will explain the dataset which are used, research stages, stages of the proposed method and evaluation tools used.

### A. Data Set

The dataset used in this study was taken from the web at <https://www.kaggle.com/datasets/alexteboul/diabetes-health-indicators-dataset>. The dataset was taken from the Behavioral Risk Factor Surveillance System (BRFSS), which is a health-related telephone survey that is collected annually in America.

The dataset consists of several predictor variables, both medical and non-medical, and one target variable (diabetes mellitus sufferers and not diabetes mellitus sufferers). Description of the attributes of the dataset used can be seen in Table I. Class 1 means people with diabetes mellitus or prediabetes while class 0 means not people with diabetes mellitus. This dataset is used for the training process and for evaluation of the built diabetes mellitus prediction model.

Fig. 1. Flowchart of the proposed method.

### B. Classification Model for Diabetes Mellitus Diagnosis Based on K-Means Clustering Algorithm and Bat Algorithm

This section describes the steps of the Classification Model for Diabetes Mellitus Diagnosis Based on K-Means Clustering Algorithm and Bat Algorithm. The steps or stages of the Classification Model for Diabetes Mellitus Diagnosis Based on the K-Means Clustering Algorithm and the Swarm Intelligence Algorithm can be seen in Fig. 1. The method has several steps which are input dataset and method parameters, preprocess dataset, split data (training data and testing data),

develop a Classification Model for Diabetes Mellitus Diagnosis Based on the K-Means Clustering Algorithm and Bat Algorithm, and use Classification Models for Diabetes Mellitus Diagnosis Based on the K-Means Clustering Algorithm and the Bat Algorithm.

### C. Parameters Setting

Before the Classification Model for Diabetes Mellitus Diagnosis Based on the K-Means Clustering Algorithm and Bat Algorithm is used, there are several parameters that must be set. Some of these parameters include:

- The number of bats used is  $n = 20$ ,
- Maximum number of iterations  $t_{max} = 1000$ ,
- An initial loudness (constant or decreasing)  $A = 1$ ,
- An initial pulse rate (constant or decreasing)  $r_0 = 1$ ,
- Alpha ( $\alpha$ ) = 0.97,
- Gamma ( $\gamma$ ) = 0.1,
- A minimum frequency ( $f_{min}$ ) = 0, and
- A maximum frequency ( $f_{max}$ ) = 2.

These parameters are taken from [17].

### D. Data Preprocessing

Data preprocessing is an initial step in the data mining technique to convert raw data into data that is more efficient and in accordance with the data mining model to be used. Raw data taken from various sources often experience errors, missing values, and are inconsistent, so that the raw data need to be formatted so that data mining results are precise and accurate. In addition, raw data also need to be transformed to change data from its original form into data that is ready to be mined. Data transformation can facilitate the process of extracting data to find new knowledge. One of the data transformation techniques is normalization. Normalization is the process of scaling the attribute values of the data so that they can lie in a certain range. This study uses the Min-Max Normalization Method. The Min-Max Normalization is a normalization method by carrying out a linear transformation of the original data so as to produce a balance of comparison values between the data.

### E. Data Splitting

After preprocessing, dataset is divided into two parts for training and testing. The proportion of training and testing data is 80% and 20%. The training data in this study is used to train the model so as to get a clustering model. Data testing is used to test and evaluate the model, as a simulation of using the model in the real world. Data testing should never be used in model training before to make model validation.

### F. Develop a the Classification Model for Diabetes Mellitus Diagnosis Based on K-Means Clustering Algorithm and Bat Algorithm

The next step is to build the Classification Model for Diabetes Mellitus Diagnosis Based on K-Means Clustering Algorithm and Bat Algorithm. The diagnostic model is built

based on the Clustering Method based on the K-Means Clustering Algorithm and the Bat Algorithm. The first step is to build a K-Means Clustering algorithm that is optimized with the Bat Algorithm. The position of the bat in the Bat Algorithm represents the center of the cluster (centroid). The optimized function in the Bat Algorithm is the objective function of K-means Clustering. After the algorithm is built, the next step is to implement the program with the Python programming language.

The next step is to input the training data, the parameters of the Bat Algorithm and the number of clusters. The training data that will be included in the clustering model training process is the predictor variables of the training data. While the response variable will be used later when evaluating the clustering model after the training phase is complete. Algorithm 1 states the K-means Clustering Algorithm-Based Clustering Method and the Bat Algorithm. Algorithm 2 is used for the association of cluster centers to data classes, while Algorithm 3 is used for the testing process.

### Algorithm 1 Clustering Method Based on K-Means Clustering Algorithm and Bat Algorithm

#### Input:

The training data ( $X_{rain}$ ) with size of  $n \times m$   
The number of cluster ( $K$ )  
The parameters of Bat Algorithm

#### Output:

Best ( $x_*$ ) is the best solution produced

a. Initialize the bat positions and velocities  $x_i^0$  and  $v_i^0$ , ( $i = 1, 2, \dots, N$ ). Each  $x_i$  represents a candidate from the centroid or cluster center. For example, matrix  $C_i$  is the  $i$ -th centroid candidate represented in equation (1).

$$C_i = \begin{bmatrix} c_{1,1} & \dots & c_{1,m} \\ \dots & \dots & \dots \\ c_{K,1} & \dots & c_{K,m} \end{bmatrix} \quad (1)$$

Therefore,  $C_i$  is reshaped to get a matrix of size  $1 \times (m.K)$  and saved in  $x_i^0 = (x_{i,1}, \dots, x_{i,m.K}) = (c_{i,1}, \dots, c_{1,m}, \dots, c_{K,1}, \dots, c_{K,m})$ . It aims to facilitate the calculation process on the Bat Algorithm.  $v_i$  also sized  $1 \times (m.K)$ .

b. Initialize a frequency  $f_i$ , a pulse rate  $r_i$ , and a loudness  $A_i$

c.  $t=0$

d. **while** ( $t < \text{Maximum Iteration}$ ) **do**

1. **for**  $i = 1: N$  **do**

i. Generate the new solutions by adjusting the frequency, updating the velocity and the position of bats using equations (2), (3), and (4).

$$f_i = f_{min} + (f_{max} - f_{min})\beta, \quad (2)$$

$$v_i^{t+1} = v_i^t + (x_i^t - x_*)f_i, \quad (3)$$

$$x_i^{t+1} = x_i^t + v_i^{t+1}. \quad (4)$$

ii. **if** ( $rand < r_i$ ) **then**

Generate the local solutions randomly by

using equation (5),

$$\mathbf{x}_{new} = \mathbf{x}_{old} + \sigma \epsilon_t A^{(t)} \quad (5)$$

where  $\epsilon_t$  is random numbers obtained from the normal Gaussian distribution  $N(0,1)$ ,  $A^{(t)}$  is the average loudness of all bats over time  $t$ , and  $\sigma$  is the scale factor, for simplification, can be used  $\sigma = 0.01$ .

**end if**

- iii. Evaluate the fitness using the objective function of K-means clustering which is stated in equation (6),

$$J = \sum_{j=1}^K \sum_{i=1}^{a_j} \|\mathbf{x}_{train}^j - \mathbf{c}_j\|^2 \quad (6)$$

where  $\mathbf{c}_j$  represents centroid  $j$  of  $K$  centroid.  $\mathbf{c}_j$  reshaping results were obtained  $\mathbf{x}_i$  of size  $1 \times K$ ,  $m$  to matrix  $\mathbf{C}_i$  of size  $K \times m$ .

- iv. **if** ( $rand > A_i$  and  $f(\mathbf{x}_i) < \mathcal{F}(\mathbf{x}_*)$ ) **then**

Update the current solution using one of the solutions from step (i) or (ii)

**end if**

- v. Increase  $r_i$  and reduce  $A_i$  by using Equations (7) and (8),

$$A_i^{t+1} = \alpha A_i^t, \quad (7)$$

$$r_i^{t+1} = r_i^0 [1 - \exp(-\gamma t)], \quad (8)$$

where  $0 < \alpha < 1$ , and  $\gamma > 0$ . According to Yang (2014), to facilitate the search process  $A_i$  and  $r_i$  can equate the value of  $\alpha$  and  $\gamma$ , with value  $\alpha = \gamma = 0.9$ .

- vi. Sort the bats and determine the best solution ( $\mathbf{x}_*$ )

**end for**

**end while**

e. Do a reshape on Best ( $\mathbf{x}_*$ ) to get centroid  $\mathbf{C}$ .

The testing data

The centroids

$y_{testing}$  (class labels of each testing data)

**Output:**

Accuracy, Recall, Precision, *F1 Score*.

1. Calculate the label prediction  $y_{pred}$  based on centroid cluster.
2. Calculate Accuracy, Recall, Precision and *F1 Score*.

### G. Evaluation Metrics

The performance of the proposed method is evaluated by using accuracy, recall, precision and *F1 Score*. The performance of the proposed method is compared to the previous method, namely the K-means Clustering method. If the proposed method is better than the standard method, it can be said that the performance of this method can be improved. The evaluation metrics used are:

- 1) Classification Rate / Accuracy which is calculated using the formulation in equation (9),

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (9)$$

where TP states that diabetics and is detected as a diabetic. TN stated that healthy person and is detected as a healthy person. FN is the healthy person but detected as diabetics. FP stated that diabetics but detected as a healthy person. Accuracy is used to measure the ratio of correct predictions to the total number of instances evaluated.

- 2) Recall is calculated by the formulation in equation (10). Recall is used to measure the fraction of a correctly classified positive pattern.

$$Recall = \frac{TP}{TP+FN} \quad (10)$$

- 3) Precision is calculated by the formula in equation (11). Precision is used to measure the correctly predicted positive pattern from the total predicted pattern in the positive class.

$$Precision = \frac{TP}{TP+FP} \quad (11)$$

- 4) *F1 Score* is calculated by the formula in equation (12). *F1 Score* is harmonic mean of precision and recall.

$$F1\ Score = 2 \cdot \frac{Precision \cdot Recall}{Precision + Recall} \quad (12)$$

After the evaluation metrics are calculated, the experimental results are analyzed to obtain conclusions.

## III. RESULTS AND DISCUSSIONS

The dataset has different scale on each feature/variable; therefore the algorithm cannot work well. So that, the dataset is needed to be pre-processed to solve this problem by using normalization technique. Furthermore, the data are normalized by using the minmax normalization method. This process will make data that has the same range, namely between values 0 and 1. The normalized data is then divided into two parts, namely, 80% of the data is used for training and the remaining 20% is used for testing. After the data is appropriate with the model to be used, the data can be input for the algorithm to be executed.

### Algorithm 2 Centroid analysis on K-Means Clustering Algorithm-Based Clustering Method and Bat Algorithm

**Input:**

The training data ( $\mathbf{X}_{train}$ ) with size of  $n \times m$

The centroids

$y_{train}$  (class label of each training data)

**Output:**

Accuracy, Recall, Precision, *F1 Score*.

1. Determine which centroid represents the target class based on the majority value of the labels in each cluster.
2. Calculate the label prediction  $y_{pred}$  based on centroid cluster.
3. Calculate Accuracy, Recall, Precision and *F1 Score*.

### Algorithm 3 Testing Algorithm of Classification model of Diabetes Mellitus Diagnosis Based Clustering Method K-Means Clustering and Bat Algorithm

**Input:**

The evaluation tools used to measure the quality of each algorithm are the objective function ( $f_{\min}$ ), accuracy, precision, recall, *F1 score*, and the computational time. The accuracy, precision, recall and *F1 score* are calculated for both training data and testing data. The evaluation tool will reach the optimum value when the objective function is minimum, the accuracy, precision, recall and *F1 score* are maximum, and the computation time is not too long.

The first algorithm to run is the standard K-means Algorithm. The parameters used are the number of clusters of 2 which correspond to the expected number of targets. The iterations are carried out until one of stopping conditions is reached. The parameters used in the Bat Algorithm are initialized with the parameters described in sub-section II.C. This algorithm uses two stopping conditions which are the maximum iteration and convergence condition. The maximum iteration is 1000 times. The algorithm is assumed convergence if the global best doesn't have improvement in 100 iteration. The experiments in this study were repeated 25 times, because the Bat Algorithm and the K-means Algorithm used in the Classification Model for Diabetes Mellitus Diagnosis Based on the K-Means Clustering Algorithm and the Bat Algorithm involve random numbers in obtaining the optimum value of the objective function. Then the average and standard deviation of the evaluation tool used are calculated. The standard deviation is used to measure the spread of recall, accuracy, precision and *F1 scores*, as well as objective function values. While the average value is used to concentrate the results of recall, accuracy, precision and *F1 scores*, as well as objective function values.

Table II shows the comparison of objective function value of Classification Model for Diabetes Mellitus Diagnosis based on the K-means Clustering Algorithm and the Bat Algorithm (training data). It can be shown that the Classification Model for Diabetes Mellitus Diagnosis based on the K-means Clustering Algorithm and the Bat Algorithm has better performance than K-means Clustering Method. It results the smaller the objective values.

TABLE II. COMPARISON OF OBJECTIVE FUNCTION VALUE OF CLASSIFICATION MODEL FOR DIABETES MELLITUS DIAGNOSIS BASED ON THE K-MEANS CLUSTERING ALGORITHM AND THE BAT ALGORITHM (TRAINING DATA)

Method	Average	Deviation Standard
K-means	6389.589	82.41
K-means + Bat Algorithm, $n=10$	6341.573	3.9882
K-means + Bat Algorithm, $n=20$	<b>6340.507</b>	<b>0.0291</b>

TABLE III. MEAN OF EVALUATION METRICS FOR CLASSIFICATION MODEL FOR DIABETES MELLITUS DIAGNOSIS BASED ON THE K-MEANS CLUSTERING ALGORITHM AND THE BAT ALGORITHM (TRAINING DATA)

Method	Accuracy	Precision	Recall	F1 Score	Time (s)
K-means	0.7009	0.70797	0.71500	0.70498	<b>0.02856</b>
K-means + Bat Algorithm, $n=10$	0.72427	<b>0.73632</b>	0.69402	0.71443	1008.645
K-means + Bat Algorithm, $n=20$	<b>0.72431</b>	0.73459	<b>0.69744</b>	<b>0.71553</b>	2794.129

TABLE IV. DEVIATION STANDARD OF EVALUATION METRICS FOR CLASSIFICATION MODEL FOR DIABETES MELLITUS DIAGNOSIS BASED ON THE K-MEANS CLUSTERING ALGORITHM AND THE BAT ALGORITHM (TRAINING DATA)

Method	Accuracy	Precision	Recall	F1 Score	Time (s)
K-means	0.06834	0.07391	0.09370	0.04588	0.00927
K-means + Bat Algorithm, $n=10$	0.002607	0.003948	0.014368	0.006265	544.6731

TABLE V. MEANS OF EVALUATION METRICS FOR CLASSIFICATION MODEL FOR DIABETES MELLITUS DIAGNOSIS BASED ON THE K-MEANS CLUSTERING ALGORITHM AND THE BAT ALGORITHM (TESTING DATA)

Method	Accuracy	Precision	Recall	F1 Score
K-means	0.6956	0.7010	0.6550	0.6764
K-means + Bat Algorithm, $n=10$	0.7155	<b>0.7311</b>	0.6938	<b>0.7118</b>
K-means + Bat Algorithm, $n=20$	<b>0.7156</b>	0.7128	<b>0.6971</b>	0.70471

TABLE VI. DEVIATION STANDARD OF EVALUATION METRICS FOR CLASSIFICATION MODEL FOR DIABETES MELLITUS DIAGNOSIS BASED ON THE K-MEANS CLUSTERING ALGORITHM AND THE BAT ALGORITHM (TESTING DATA)

Method	Accuracy	Recall	Precision	F1 Score
K-means	0.06068	0.06819	0.04169	0.04988
K-means + Bat Algorithm, $n=10$	0.00146	0.02574	0.01117	0.01363
K-means + Bat Algorithm, $n=20$	0.00083	0.02778	0.00276	0.0136

Table III shows the mean of evaluation metrics for Classification Model for Diabetes Mellitus Diagnosis based on the K-means Clustering Algorithm and the Bat Algorithm (training data), while Table IV shows the deviation standard of evaluation metrics for Classification Model for Diabetes Mellitus Diagnosis based on the K-means Clustering Algorithm and the Bat Algorithm (training data). The experimental results show that the that the Model for Diabetes Mellitus Diagnosis based on the K-means Clustering Algorithm and the Bat Algorithm are superior to the standard K-means method. that the Model for Diabetes Mellitus Diagnosis based on the K-means Clustering Algorithm and the Bat Algorithm are superior in all evaluation tools (accuracy, recall, precision and *F1 Score*). The standard deviation of the accuracy, recall, precision and *F1 score* of the Diabetes Mellitus Diagnostic Model Based on the K-Means Clustering Algorithm and the Swarm Intelligence Algorithm is very small. This means that this method results in low variation. The computational time required for training the Model for Diabetes Mellitus Diagnosis based on the K-means Clustering Algorithm and the Bat Algorithm is much longer than the standard K-means method.

Table V shows the results of the classification model evaluation for data testing. The experimental results show that the Classification Model for Diabetes Mellitus Diagnosis based on the K-means Clustering Algorithm and the Bat Algorithm yields much better results compared to the standard K-means method for accuracy, recall, precision and *F1 Score values*. Tables V and VI also show the accuracy, recall, precision and *F1 scores* produced by the Model for Diabetes

Mellitus Diagnosis based on the K-means Clustering Algorithm and the Bat Algorithm are not much different between training and testing data. This shows that the proposed method has good performance and neither overfitting nor underfitting occurs.

Fig. 2. Graph of iteration and global best relationships of the diabetes mellitus diagnostic method based on the K-Means clustering algorithm and the swarm intelligence algorithm with 20 particles (global best fitness value 6340.499).

Fig. 3. Graph of iteration and global best relationships of the diabetes mellitus diagnostic method based on the K-Means clustering algorithm and the swarm intelligence algorithm with 10 particles (global best fitness value = 6340.497).

Fig. 2 and 3 show graphs of the iteration and global best relationships of the Classification Model for Diabetes Mellitus Diagnosis based on the K-means Clustering Algorithm and the Bat Algorithm with 20, and 10 Particles. The figures show the method converges less than 600 iterations for the number of particles 20 and 10. The global best convergent fitness value is around 6340.5.

#### IV. CONCLUSIONS

Based on the experimental results and analysis of the experimental results, several conclusions were obtained. that the Model for Diabetes Mellitus Diagnosis based on the K-means Clustering Algorithm and the Bat Algorithm developed from the K-Means Clustering Algorithm by adding the Bat Algorithm optimizer to determine the centroid of the cluster. The experimental results revealed that the number of bats has an effect on the method's convergence speed and processing time. The experimental results reveal that the Model for Diabetes Mellitus Diagnosis based on the K-means Clustering Algorithm and the Bat Algorithm are able to diagnose diabetes

mellitus quite well. The accuracy obtained is around 72.4% and the *F1 score* is 71.4% for training data, and the accuracy obtained is around 71.55% and the *F1 score* is 71.18% for data testing. The evaluation results show that the performance of the Model for Diabetes Mellitus Diagnosis based on the K-means Clustering Algorithm and the Bat Algorithm is better than the standard K-means for evaluating accuracy, precision, recovery, f1 score, but the recovery time is quite large.

#### ACKNOWLEDGMENT

We would like to thank Brawijaya University for funding this research through the Hibah Penelitian Pemula (HPP) research grant.

**Abstract**—Providing universities with high technology-enabled automation tools to support the administrative decision-making processes will enable them to achieve their objectives. For an institution to succeed in its everyday tasks, it should come up with the emerging and modernized management services constituted, among others, by cloud, mobile, and business analytics technology. With this, the institution's operations and management efficiency are ensured. This study aims to develop a system with descriptive analytics named as MET Online Services that will automate and optimize the monitoring of extension services key performance indicators (KPIs) in order to help the institution in making better, data-driven decisions. The dashboards and interactive visualizations of the developed system will provide quick access to real-time progress of the extension services programs, projects, and activities. Results interpretation depicted that the developed system is indeed feasible for implementation, proven to be fully-functional and passed the quality software standards of a Certified Software Quality Assurance Specialist. As the developed system satisfied the users' expectations and requirements, it would be an effective tool for the institution, extension services unit, and community, to make better strategic decisions and continuously deliver quality services to the community.

**Keywords**—Business analytics; descriptive analytics; dashboards; interactive visualizations; extension services; monitoring; key performance indicators; KPIs; community

## I. INTRODUCTION

Managing an institution and bringing together departments and campuses to achieve the vision and quality objectives are always a big challenge for the university management. Providing universities with high technology-enabled automation tools to support the administrative decision-making processes enable them to achieve their objectives. And for an institution to succeed in its everyday tasks, it should cope up with the emerging and modernized management services [1] constituted, among others, by cloud, mobile, and business analytics technology. It is supported by [2, 3], that Higher education institutions are expanding ICT-driven projects in both developed and developing nations to improve quality services in education and increase efficiency and effectiveness. With this, the institutions' operations and management efficiency are ensured.

An effective management system can help an organization use its resources more efficiently and improve its financial performance, risk management, protection of people and the environment, and ability to provide consistent and better services and products. This makes the organization more valuable to its customers and other stakeholders [4]. And to facilitate better flow of information, management system with the use of data analytics within an organization can aid in decision-making that is more strategically oriented, more effective, and maximizes performance [5, 6].

According to [7], management system is the process through which a company oversees the interdependent elements of its operations in order to achieve its goals. These goals may have to do with a variety of things, such as the continuous improvement of the products or services, operational effectiveness, performance, health and safety at work. In the Philippines, State, Universities, and Colleges are expected to extend their academic and community services to the community in accordance with the Commission on Higher Education's (CHED) directives along with instruction, research and production [8]. The office's main goal is to establish a sustainable partnership with public and private organizations with the purpose of reducing poverty. As [9] explicates that there are concerns about implementing extension programs where academic institutions must closely monitor and assess the results of their grassroots community engagement in order to attain development goals.

In this study, a monitoring system with descriptive analytics was developed and will serve as a tool in providing the users with beneficial information to do the extension activities effectively and efficiently that will allow the extension services unit team plan, implement, analyze (at both tactical and strategic levels) and administer all extension services procedure as a mechanized system in the operational level. It will automate and optimize the monitoring of extension services key performance indicators (KPIs) in order to help the institution in making better, data-driven decisions through dashboards, interactive visualizations, and reports. The study also aims to pass in the technical evaluation of a Certified Software Quality Assurance Specialist and determine the level of satisfaction and acceptance of the end-users towards the developed system.

## II. RELATED WORK

### A. Extension Services

According to [10], extension is a relatively new phenomenon and is defined as the intentional transfer of skills and the organized exchange of information. Extension service is a community-based educational opportunity offered by academic institutions [11], with the primary objective of establishing long-term partnerships with both public and private organizations working toward poverty alleviation. The office is in charge of carrying out the university's program for outreach and community development. It makes it simpler to put into action policies and programs that are intended to empower communities, especially those who have been underserved. As [12] stated that the educators from various universities came together and developed community and extension programs in the university. Serving the community is one of an organization's key principles.

The Philippine Higher Education system's objectives include improving the quality of life for Filipinos, adapting effectively to changing societal requirements and circumstances, and offering answers to issues at the local, regional, and national levels, according to [13]. As a core responsibility of universities and colleges, Extension services have been measured or evaluated in several state, universities, and colleges' assessments, including SUC Levelling, the Annual Major Final Outputs of SUCs, CHED's Institutional Sustainability Assessment, and the Accrediting Agency of Chartered Universities and Colleges (AACUP) Institutional and Program Accreditation [14].

According to [15], extension services unit should encourage, motivate, and elevate beneficiary awareness, participation, and satisfaction, especially for low-rated program services. By developing and improving its extension services to be more responsive to the community, the Philippine Higher Education Institutions (HEIs) participated in the discussion of the 2017-2022 Philippine Development Agenda (PDA). [16] explains that the government will create a strong national environment for innovation and knowledge creation, which is necessary for the nation's engagement in the global knowledge economy. It will make investments in: (a) improving the research capabilities of college and university faculty, research staff, and graduate students; (b) building the capital and institutional infrastructure needed for knowledge production and innovation; and (c) building up, retraining, and retaining a sustainable stream of new researchers.

Similar to this, the government will support formal collaborations between HEIs and community, commercial, and industry stakeholders. The intention is to integrate "informal" community-based learning and innovation with "formal" academic research and innovation as a means of accomplishing this goal. Policies and procedures will be developed for the operationalization of extension as part of applied research engagement as well as for the normative and appropriate distribution of hours for teaching and research.

### B. Key Performance Indicators (KPIs)

A performance indicator, also known as key performance indicator (KPI) is an approach of measuring performance [17].

It examines the extent to which an organization was successful in carrying out a program, a project, a product, or some other initiative in which it was involved [18].

There have been many companies that have used inappropriate measurements; as a result, metrics of this kind should not be labeled performance indicators. According to [19], the majority of businesses that are regarded as having a genuine control system make use of key performance indicators. This is the reason why there are accountants, company executives, and consultants who have appropriate knowledge and experience regarding Key Performance Indicators.

One simply cannot place an adequate amount of emphasis on the significance of key performance indicators (KPIs) to the overall success of an organization. Key performance indicators (KPIs) are metrics that evaluate how well a firm is currently doing in relation to its overall goals [20].

Key performance indicators focus on the improvement of strategic and operational levels, which provide an analytical framework for decision-making, and raise knowledge and interest in many areas [21]. KPI plays an important role because it receives timely and accurate information by comparing current performance to a goal that is necessary to satisfy business needs and goals. This allows KPI to play an instrumental role in ensuring that business needs and goals are met. Alignment with corporate goals, active monitoring, report accuracy, and timeliness are all recommended KPI selection techniques [22]. KPI reporting and dashboards are automated to keep all stakeholders on the same page.

The process of managing utilizing key performance indicators also includes the steps of establishing goals (the expected level of performance) and evaluating progress toward those goals. According to [23], to have good KPIs the organization should perform the following, (a) provide objective evidence of progress towards achieving a desired result; (b) measure what is intended to be measured to help inform better decision making; (c) offer a comparison that gauges the degree of performance change over time, (d) track efficiency, effectiveness, quality, timeliness, governance, compliance, behaviors, economics, project performance, personnel performance or resource utilization; and (e) balance the leading and lagging indicators.

Key performance indicators serve to specify a predetermined set of values that have been established. The author in [24] refers to these unprocessed groups of numbers as indicators since they can be used to feed data aggregation systems. Measuring key performance indicators (KPI) can take either a quantitative or qualitative approach. A quantitative measurement compares facts to a standard and uses facts that have a specific objective numerical value. While the qualitative, denoting conformity to a standard that is not quantifiable or an interpretation of one's own feelings, preferences, beliefs, or experiences

### C. Descriptive Analytics

Business analytics finds patterns and trends in massive data sets to improve decision-making and performance. In corporate reports and dashboards, descriptive analytics is used to produce

key performance indicators (KPIs) and metrics. Among the various sorts of analytics, descriptive analytics was recognized as the one that was the most fundamental and the one that was utilized the most [25]. Reports, key performance indicators (KPIs), and other business measures that allow businesses to monitor performance and other trends can be generated using descriptive analytics.

Four categories are frequently used to classify analytics technologies [26]: (i) descriptive (what happened), (ii) diagnostic (why did it happen), (iii) predictive (what will happen next), and (iv) prescriptive (what should be done about it). Academic institutions usually place a strong emphasis on the potential benefits of technology that makes use of sophisticated modeling in order to be either prescriptive or predictive [27, 28, 29, 30]. The majority of adopting companies' sales and marketing teams frequently employ descriptive analytics and straightforward dashboards for key performance indicators (KPIs) [31, 32, 33].

Descriptive analytics are utilized in numerous facets of a business by companies in order to assess the quality of their operations and determine whether or not they are on track to achieve their organizational objectives and used in various ways, particularly in reports, visualizations, and dashboards.

#### D. Reports

Management Information System Report is an umbrella phrase that describes a group of reports that give a picture of what goes on in an organization on a daily basis, which enables the functions of your firm to be studied. MIS Report is an acronym that stands for Management Information System [Futrlı]. They are a great tool for evaluating the performance of a firm and making decisions that are based on accurate and up-to-date information. They comprise of numerous separate reports that cover various areas of a business.

#### E. Visualizations

According to [34], The visualization of data through the use of charts, graphs, and maps, which can indicate trends in data as well as dips and spikes in a fashion that is obvious and easily accessible to the audience, is an excellent choice for providing a suitable outlet for presenting descriptive analysis. It is supported by [35] make information easier to perceive and understand. Data visualization involves the process of incorporating facts or information into a pictorial or graphical environment, like charts, maps, or other visual formats.

#### F. Dashboards

On a consistent basis, dashboards provide a quick overview of key performance indicators (KPIs) that are pertinent to a certain objective or organizational system (e.g., income, marketing, human resources, or production). In real-world usage, the terms "progress report" and "report" can sometimes be referred to as "dashboard" [36].

Regularly, the "dashboard" is shown on an internet page that is connected to a database. This connection makes it

possible for the document to be continuously updated. The term "dashboard" originated from the instrument panel seen in automobiles, where the driver can see, at a glance, the most critical functions displayed on the instrument cluster [37].

Managers can monitor the contributions of varied departments using digital dashboards. Digital dashboards can catch and record distinct information points from every department to provide a "snapshot" of overall performance. Benefits of using digital dashboards include visual presentation of overall performance measures, ability to identify and correct negative tendencies, degree efficiencies/inefficiencies, ability to generate precise reports showing new traits, ability to make more informed decisions based on accumulated business intelligence, align techniques and organizational goals, save time compared to walking a couple of reviews, and benefit total visibility of all measures.

#### G. Classification of Dashboards

Dashboards can be broken down according to position, and they combine strategic analysis with informational, analytical, and operational perspectives according to [38]. Strategic dashboards are a useful tool for managers at any level in an organization, and they give the concise evaluation that decision makers require in order to monitor the health of the business as well as its potential opportunities. These kinds of dashboards focus on high-level measurements of overall performance as well as forecasts. Static snapshots of data (daily, weekly, monthly, and quarterly) that are not constantly changing from one moment to the next are an advantage for strategic dashboards [39].

Dashboards for analytical purposes frequently include greater context, comparisons, and records, along with subtler overall performance evaluators. Analytical dashboards usually assist interactions with the data, along with drilling down into the underlying information. When dashboards were first introduced, its primary function was monitoring; but, as technology has advanced, their use has expanded to include more analytical tasks. Dashboards are currently being used in a way that incorporates scenario analysis, drill down capabilities, and flexible presentation format options [40].

### III. METHODOLOGY

This section highlights the technical system architecture and explains the composition of the developed system as well as the roles involved for the utilization of the system functionality.

#### A. MET Online Services Technical System Architecture

Fig. 1 shows the technical system architecture of the developed system, which consists of the roles of the actors, business services, business processes, application services, technology services, and technology components.

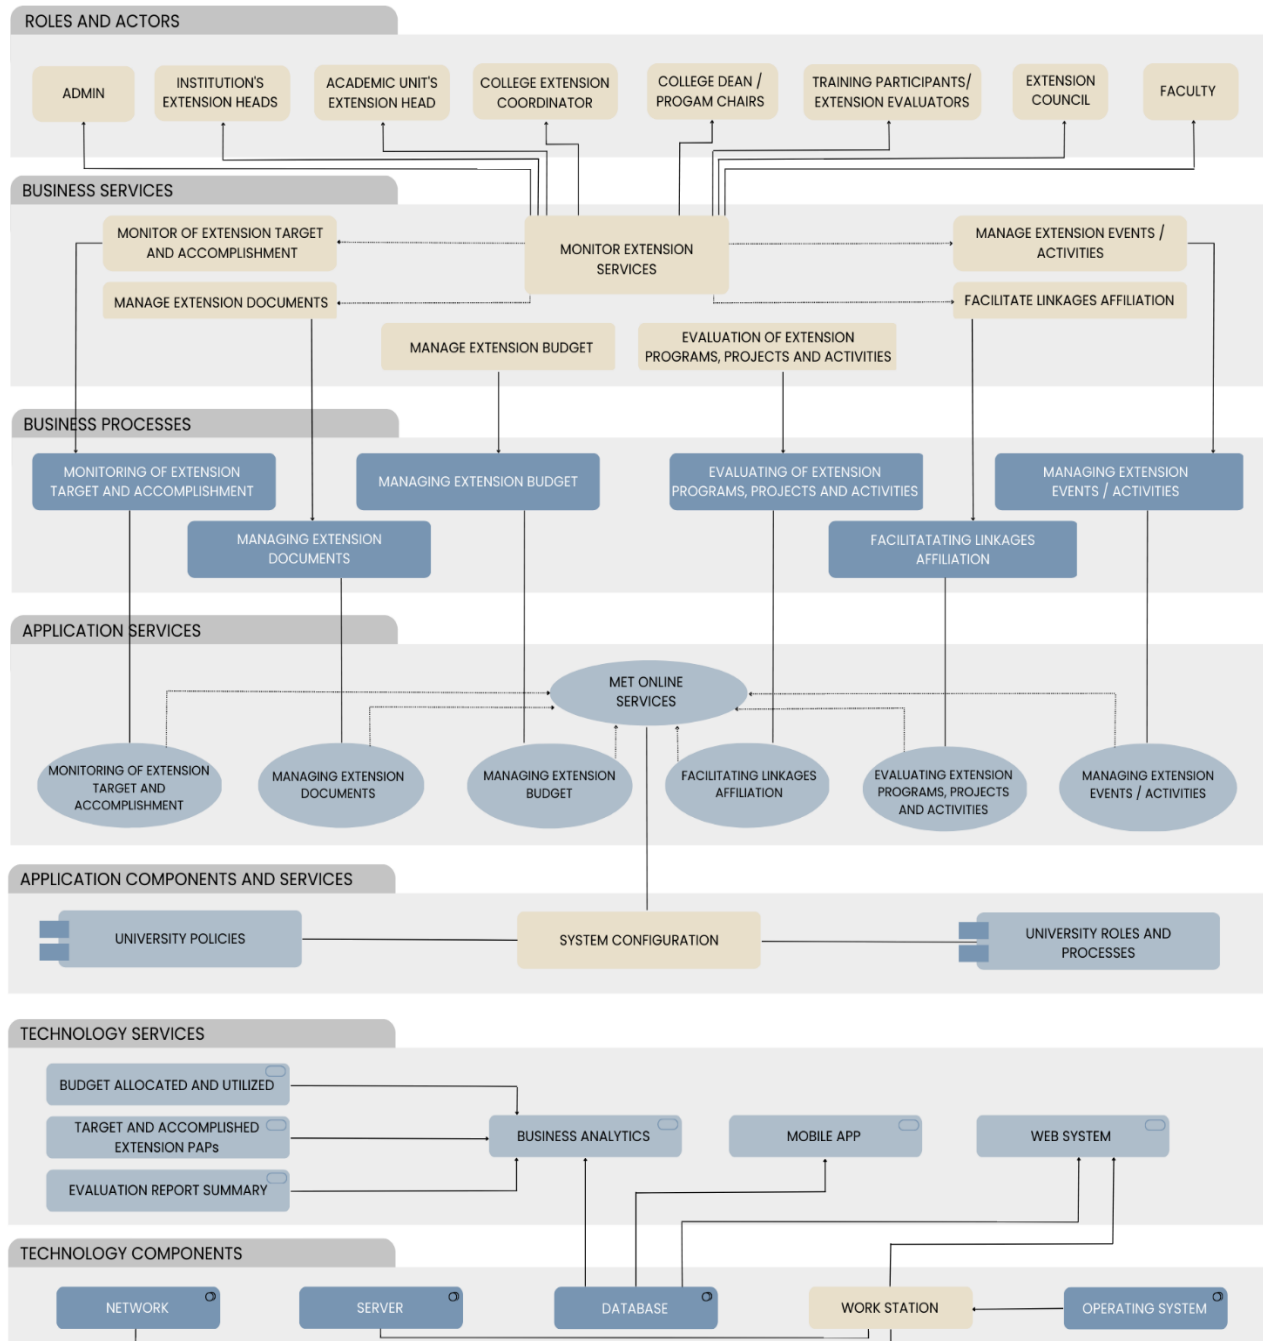

Fig. 1. Technical system architecture

### B. Roles and Actors

In order to make the most of and maximize the usability of the system, it displays its contents and components that are employed. MET Online Services is composed of eight (8) major roles and actors to wit: System Administrator, Institution's Extension Head, Academic Unit's Extension Head, College Extension Coordinators, College Dean / Program Chairpersons, Training Participants, Extension Council, and Faculty. The following users have a corresponding role in order to utilize the system.

### C. Business and Application Services

The business services / processes; and application services of MET Online Services has six (6) major components embedded in the extension services unit, these are as follows: (a) monitoring of extension programs, projects, and activities (PPAs) target and accomplishment, (b) managing extension services documents, (c) managing extension budget, (d) evaluating the extension programs, projects, and activities, (e) facilitating linkages affiliation, and (f) managing extension events / activities.

#### D. Technology Services and Components

For the technology services, the developed system is supported by business analytics, mobile application and web service. The business analytics is comprised of target and accomplished extension PPAs, budget allocated and utilized and evaluation report summary, where in technology services of the developed system it is the main feature along with the mobile application and web service.

In order to utilize the functionality of the developed system, the management must provide a secured network, normalized database, and an operating system that is suitable for the system.

### IV. RESULTS AND DISCUSSIONS

This study developed a system with descriptive analytics named as “MET Online Services” that will automate and optimize the monitoring of extension services key performance indicators (KPIs) in order to help the institution in making better, data-driven decisions. The dashboards and interactive visualizations of the developed system will provide quick access to the extension activities’ real-time progress. The study is mainly focused on the business analytics of different operations and activities in extension services unit to systematize decision-making in order to upkeep real-time responses. During the development phase, it follows the dashboard development process [41].

The system employs a configurable Key Performance Indicators (Fig. 2) in developing the executive dashboards and interactive visualizations where extension services unit track and monitor their actual accomplishments on annually and quarterly basis. Since the system can be configured for all Philippine Association of State Universities and Colleges (PASUC) institutions, the researchers adopted the standard Major Final Output (MFO) for Extension Services of [42], particularly the key performance indicators, such as: (a) Number of trainees trained; (b) Number of trainees weighted by the length of training; (c) Number of extension programs organized and supported consistent with the SUC’s mandated and priority programs; (d) Percentage of beneficiaries who rate the training course/s and advisory services as satisfactory or higher in terms of quality and relevance; and (e) Percentage of persons who receive training or advisory services who rate timeliness of service delivery as good or better.

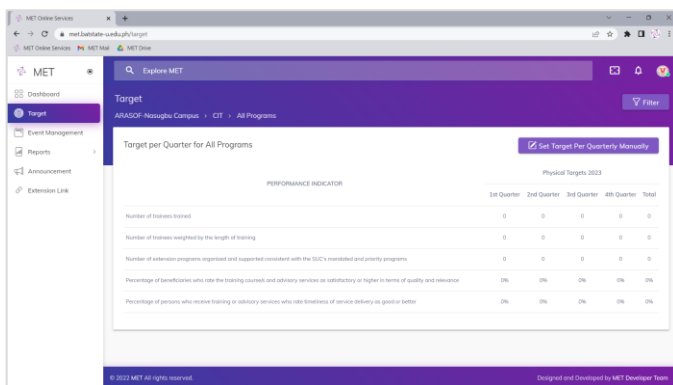

Fig. 2. Configurable key performance indicators

The executive dashboard and visualization features with filtering function [43] as shown in Fig. 3 to Fig. 5, provides the Extension Council, Institution and Academic Unit Heads along with the College Deans and Program Chairpersons with a high-level overview of the state of the extension services in their respective institutions/units/sectors. The system also generates beneficial reports on the extension services indicators which serve as a useful reference for the Office/Individual Performance Commitment Rating (OPCR/IPCR), Performance Based Bonus (PBB) and SUC leveling of the university.

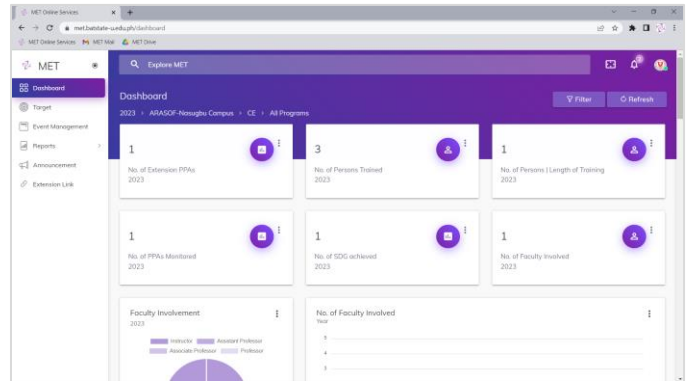

Fig. 3. Dashboards and interactive visualization (scorecards of extension key performance indicators)

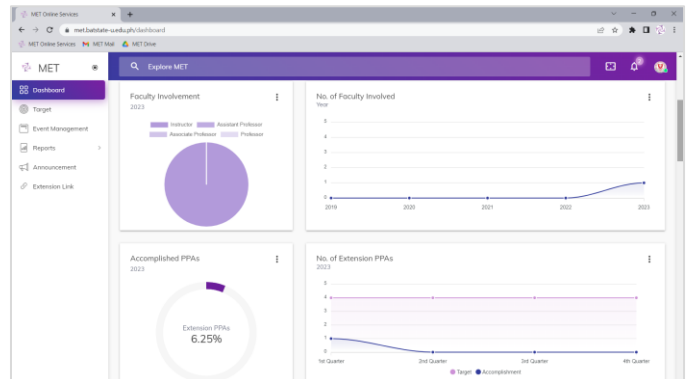

Fig. 4. Dashboards and interactive visualization (charts and graphs of faculty involvement and accomplished PPAs)

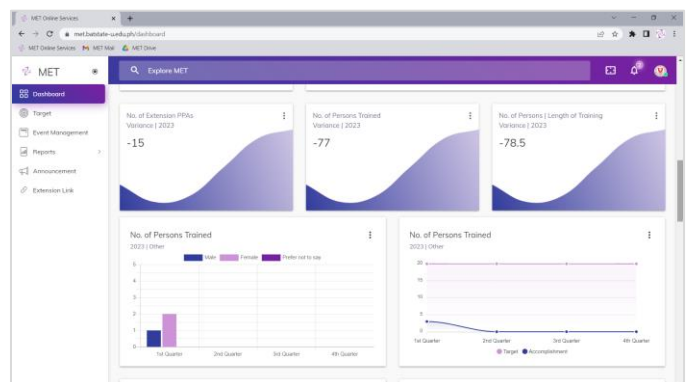

Fig. 5. Dashboards and interactive visualization (charts and graphs of variances and number of persons trained)

In addition to analytics part of the developed system, the following modules are incorporated to simplify the operations in the extension service unit: account management, target monitoring, event management, reports, announcement and extension links.

### A. Account Management

The Account Management module grants authorized users the rights to use the various services of the developed system by dividing them into groups and defining their privileges. The administration part of this module not only refers to the administration of the management system but also the administration tasks and information of the extension services unit task force.

Since MET Online Services is applicable also to other extension services unit of any State Universities and Colleges, the administration part of this module as shown in Fig. 6, is capable of configuring the following: information of the extension services unit, name of university with logo, campus/es, college/s, program/s, designation, employment status and academic rank of designated extension service task force, sustainable development goal, and type of community extension service.

Key Performance Indicators and evaluation questions and other settings are also configurable through the system administrator account. This is to fully utilize and accommodate different State Universities and Colleges (SUCs) with an end goal of improving their extension services, operations and transactions.

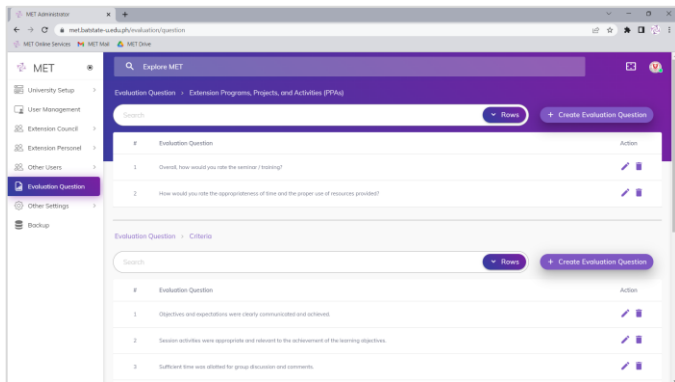

Fig. 6. Administrator account management.

### B. Target Monitoring

The Target Monitoring module involves managing and setting performance indicator targets. These transactions are processed by the institution and academic unit's extension heads along with designated college extension coordinators. The system provides a tool for the computation of key performance indicator in setting the target for the number of persons trained weighted by length of training with the corresponding legend for the weights of training (1) and percentage of beneficiaries who rate the training course/s and advisory services as satisfactory or higher in terms of quality and relevance, and timeliness (2).

$$a = b \times d \quad (1)$$

where,  $a$  is the number of persons trained weighted by length of training;  $b$  is the number of persons trained; and  $d$  is the weight of training.

Weights:

Length of Training	Weight
< 8 hours	0.50
8 hours (1 day)	1.00
2 days	1.25
3-4 days	1.50
5 days or more	2.00

$$y = (m/n) \times 100 \quad (2)$$

where,  $y$  is the percentage of beneficiaries who rate the training course/s and advisory services as satisfactory or higher in terms of quality and relevance, and timeliness;  $m$  is the number of trainees who rate the training course/s and advisory services as satisfactory or higher; and  $n$  is the total number of trainees surveyed.

### C. Event Management

The Event Management allows the institution and academic unit's extension heads as well as the college extension coordinators to manage all the extension services events / projects or activities. It includes electronic scheduling and task management of different extension activities. The status of each extension projects is automated and accessible on the web and mobile. There will be three (3) projects' status to wit: (a) For Implementation, (b) Ongoing, and (c) Implemented. These stages/statuses are dependent on the duration of the extension projects. It must be noted that once the project is implemented, it will be automatically added to the actual accomplishment. Different forms relevant to the extension services unit processes can be generated from this module, particularly the extension proposal, narrative report, monitoring proposal, and progress monitoring report.

### D. Reports

The Reports module is capable of generating monitoring and evaluation reports from the data entered from all the modules of the system including the android application used by the extension participants that evaluates the extension project. This module can be accessed and downloaded by the extension council, institution's extension head and academic unit's extension head, college dean / program chairperson and college extension coordinators (Fig. 7).

### E. Announcement and Extension Links

The announcement and extension links page will all the institution and academic unit heads to post and disseminate information to all extension services task forces relative to their regular functions and operations.

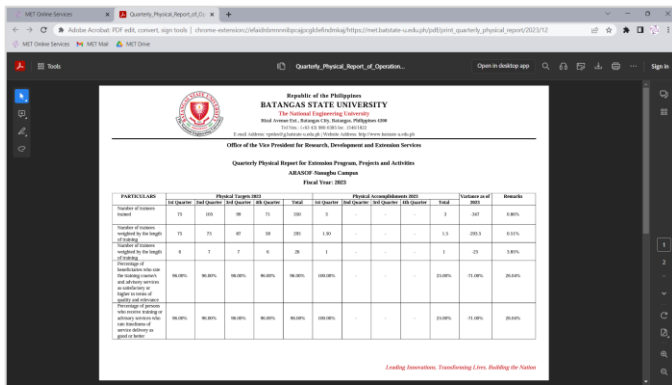

Fig. 7. Sample generated report using the prescribed template of the university

After the system development, a series of test cases and technical evaluations were carried out by a Certified Software Quality Assurance Specialist in order to ascertain, whether the developed system complies with the specified requirements. Software quality assurance (SQA) employs a methodical approach to identify trends and the necessary steps to enhance development processes. Unintended effects might result from finding and resolving coding problems; it is possible to solve one issue while also breaking other features and functions [44]. It can be gleaned from the test cases and technical evaluations as shown in Table I that the developed system is indeed feasible for implementation, proven to be fully-functional and passed the quality software standards set by the software quality assurance specialist.

TABLE I. TEST CASE AND TECHNICAL EVALUATION OF THE DEVELOPED SYSTEM

<p><b>Test Run Information:</b>                  Tester Name/s:                  A.Z. Leynes and J.R.M. Ruiz                  Date(s) of Test:                  September 9-13, 2022                  Location/server being used: N/A</p>	<p><b>Software Versions:</b>                  Application: MET Online Services                  Browser [used &amp; those COTS supports]: Google Chrome version 76.0.3809.132 (64-bit)                  Database: mySQL                  Operating System: Windows 10</p>
<p><b>Notes and Results:</b>                  Overall, we can say that this is a big help for all the extension coordinator. In this module you can monitor all the extension services key performance indicators with ease through dashboards and interactive visualizations. The user can also provide the status of each extension services what is the upcoming services, the on-going and implemented. The system can also provide reliable and consistent reports if each college coordinator hit the target accomplishment. On the other hand, the head of the extension services can also monitor all the college coordinator which is hassle free, the head of the extension coordinator will just login filter what college he/she can monitor what is the status of each college coordinator. And for reports the system provides printable reports that can use for documentation.</p>	
<b>Modules</b>	<b>Passed / Failed</b>
Account Management	Passed
Dashboard	Passed
Target Monitoring	Passed
Event Management	Passed
Reports	Passed
<b>Overall Evaluation</b>	<b>Passed</b>

As the system passed the software quality assurance, it is also clear as reflected from Table II that the developed system highly satisfied the users' expectations and requirements in terms of efficiency, functionality, reliability, usability, and security. The satisfaction of the end-users determines that the developed system is acceptable [45] and indeed feasible for implementation. It is also an indicator that the information system is effective when the users are satisfied with its functions and requirements [46, 47].

TABLE II. LEVEL OF SATISFACTION OF THE RESPONDENTS ON THE DEVELOPED SYSTEM

	Criteria	Weighted Mean	Verbal Interpretation
1	Efficiency	4.32	Highly Satisfied
2	Functionality	4.43	Highly Satisfied
3	Reliability	4.30	Highly Satisfied
4	Usability	4.57	Highly Satisfied
5	Security	4.32	Highly Satisfied
	<b>Overall Weighted Mean</b>	<b>4.39</b>	<b>Highly Satisfied</b>

The developed system automates the process of evaluation of the Extension Programs, Projects, and Activities (PPAs) as shown in Fig. 8. By using their mobile devices, the extension participants can evaluate online and raise their suggestions and comments based on the performance of the extension program conducted. It can be gleaned from Table III that the mobile application was highly accepted by the end-users in evaluating the extension programs, projects, and activities.

TABLE III. LEVEL OF ACCEPTANCE OF THE RESPONDENTS IN THE MOBILE APPLICATION OF EVALUATING THE EXTENSION ACTIVITIES

	Criteria	Weighted Mean	Verbal Interpretation
1	Ease of Use	4.30	Highly Acceptable
2	Usefulness	4.32	Highly Acceptable
	<b>Overall Weighted Mean</b>	<b>4.31</b>	<b>Highly Acceptable</b>

In case that the participants don't have mobile devices, the designated college extension coordinators and staff will be tasked to provide and assist the participants in evaluating the extension PPAs using the university's mobile devices or laptop provided by a unique evaluation code which is system generated. Another concern is the Internet connection, since the said developed information system required internet access for the evaluation, the researchers recommend that extension service office assisted by the Information and Communication Technology (ICT) office to provide laptop computers during the activity for the computerized evaluation and once there is already internet connection, the designated college extension coordinators will be the one responsible to sync the encoded evaluation answers to generate the evaluation results and update it online. Hence, there will be a fast and accurate evaluation results immediately after the online evaluation done by the extension participants.

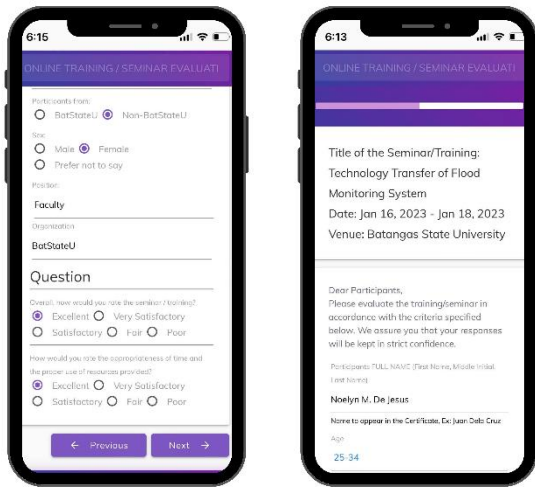

Fig. 8. Mobile evaluation of extensions activities.

## V. CONCLUSION

Most Extension Services Unit of SUCs used the manual process of managing, monitoring and evaluating their extension projects. This, most of the time, results in problems related to documents handling/archiving, timely monitoring and evaluation reports, poor management of budget allocation and utilization. The significance of this study is resolving those issues and challenges encountered in the extension services unit of the university by automating its operations and providing quick access to real-time progress of its activities through dashboards, interactive visualization, and reports.

The developed system is indeed feasible for implementation, proven to be fully-functional and passed the quality software standards of a Certified Software Quality Assurance Specialist. As the developed system satisfied the users' expectations and requirements, it would be an effective tool for the institution, extension services unit, and community, to make better strategic decisions and continuously deliver quality services to the community.

## VI. FUTURE WORK

It is suggested that future research should incorporate the evaluation for faculty involvement in extension which can be significant in the evaluation and promotion of faculty using the Qualitative Contribution Evaluation (QCE) instrument of the National Budget Circular (NBC) No. 461.

## ACKNOWLEDGMENTS

The authors would like to extend their profound gratitude and sincere appreciation to the Research, Development, and Extension Services Office, Batangas State University for supporting and funding this research. Also, to the Editors and anonymous reviewers for their valuable and constructive feedbacks to further improve the study.

# Arabic Stock-News Sentiments and Economic Aspects using BERT Model

Eman Alasmari<sup>1</sup>, Mohamed Hamdy<sup>2</sup>, Khaled H. Alyoubi<sup>3</sup>, Fahd Saleh Alotaibi<sup>4</sup>,

The Faculty of Computing and Information Technology, King Abdulaziz University, Jeddah 21589, Saudi Arabia<sup>1,3,4</sup>  
The Faculty of Computer and Information Sciences, Ain Shams University, 11566 Cairo, Egypt<sup>2</sup>

**Abstract**—Stock-market news sentiment analysis (SA) aims to identify the attitudes of the news of the stock on the official platforms toward companies' stocks. It supports making the right decision in investing or analysts' evaluation. However, the research on Arabic SA is limited compared to that on English SA due to the complexity and limited corpora of the Arabic language. This paper develops a model of sentiments to predict the polarity of Arabic stock news in microblogs based on Machine Learning and Deep Learning approaches. Also, it aims to extract the reasons which lead to polarity categorization as the main economic causes or aspects based on semantic unity. Therefore, this paper presents an Arabic SA approach based on the logistic regression model and the Bidirectional Encoder Representations from Transformers (BERT) model. The proposed model is used to classify articles as positive, negative, or neutral. It was trained based on data collected from an official Saudi stock-market article platform that was later preprocessed and labeled. Moreover, the economic reasons for the articles based on semantic unit, divided into seven economic aspects to highlight the polarity, were investigated. The supervised BERT model obtained 88% article classification accuracy based on SA, and the unsupervised mean Word2Vec encoder obtained 80% economic-aspect clustering accuracy.

**Keywords**—Machine learning; deep learning; classification; prediction; statements

## I. INTRODUCTION

Stock price decline is a concern for stock market investors and an exciting issue for stock analysts. Stock market news sentiment analysis (SA) allows investors to make the correct investment decision through thorough and thoughtful deliberation. Whereas knowing the best time to buy or sell stocks is the main aim of stock market prediction as there are various factors that may affect stock prices, these factors depend on stock market news indicators, which economists take advantage of to analyze the factors that may affect the market, such as public news sentiment [1]. Undoubtedly, everyone is familiar with sharing news with others in social communities either individually or as a company [2]. Currently, online microblogs' news makes vast amounts of news moods available. At the same time, microblogs may contain large amounts of data about companies that share their information, such as that about their stocks and the stock market, through their microblogs. The articles on these microblogs are used to classify their stocks' orientations and the economic causes of these.

Analysts and investors still have difficulty predicting the future price of a company's stocks. The sentiment of news

regarding a company's stocks is a vital interest of financial analysts, investors, and other competitors [3, 4]. SA aims at sentiment recognition and public-opinion checking, which are considered text-mining research fields [5]. Although there are many types of research for analyzing individuals' behaviors in social microblogs, few studies have analyzed the classification of stock news in financial-market microblogs [6]. These microblogs allow investors and analysts to share financial news and opinions with other investors. The SA of microblog posts helps investors perceive the risks related to companies' stocks, which assists them in their investment decision-making investor sentiment shown in microblogs has a significant impact on stock prices relative to growth stocks [7]. Therefore, the prediction of stock market behavior depends on the polarity prediction classification of microblogs' news sentiments. Such news can be categorized as positive, negative, or neutral for the polarity prediction of SA, which affects the prediction of stock news classification [3, 4, 8, 9]. Using companies' information from microblogs can therefore improve the accuracy of polarity prediction. Thus, there is a need for SA of companies' stock market articles for stock price prediction.

The previous studies on SA in deep learning (DL) and machine learning (ML) heavily focused on analyzing several features and ignored the sentences' structures and the relations between words in any targeted language, such as the Arabic language [10, 11]. Also, the recent studies have focused on applying DL in SA for multiple tasks based on the Arabic language [11]. However, to the best of the authors' knowledge, few of the previous DL studies were on the Arabic SA in the stock market fields. Moreover, there has been no study that bridges the gaps in Arabic SA by using DL with modern standard Arabic (MSA) features in the Arabic sentiments mirrored in stock news even though DL SA approaches such as the Bidirectional Encoder Representations from Transformers (BERT) model currently offer the best performance for Arabic stock news [12, 13]. Besides, no study on the extraction of the main economic aspects of the reasons for the sentiment polarity depending on Arabic news features has yet been conducted. Thus, there is a need to develop ML and DL models that can classify stock news sentiments and determine their polarity on the basis of labeled data, and that can extract the economic causes of such sentiments. The current study focused on the prediction and classification of Arabic stock market news sentiments and their main economic causes. It sought to develop a supervised model based on logistic regression and the BERT classifier for labeled Arabic data, and an unsupervised model based on k-means clustering.

## II. RELATED WORK

### A. Arabic Sentiment Analysis Techniques for Microblog News

The Arabic SA models and techniques consist of steps such as preprocessing and analysis of linguistic, part-of-speech (POS), semantic, and lexicon-derived features [14].

Preprocessing is often the first step in a text-processing system. It consists of steps for facilitating classification. For instance, in Arabic text preprocessing, the text is tokenized; the letters at the beginning of names (e.g., “ال”) are removed; the letters are normalized, such as by converting “أ” (“Hamza”) to “ا” (“Alef”); and then the stop words, such as “كان, في, إن” (“was, that, in”), are removed [15]. Thus, preprocessing cleans the textual data by removing the undesirable elements therefrom to increase the accuracy of the future SA results. Ignoring preprocessing such as spelling corrections will make systems disregard the main words [14, 16, 17], but overdoing preprocessing will make systems lose important data.

Preprocessing of microblogs increases the sentiment prediction accuracy in any field. It considers the variations of letters, such as the basic Arabic letter “Alef” or “أ,” which includes the derivative letter “Alef Maksoura” or “آ” often confused with the other basic Arabic letter “Ya” or “ي.” Also, there is usually confusion in writing the basic Arabic letters “Ta marbota” or “ة” and “Ha” or “ه.” Moreover, the letter “Hamza” is an interchangeable letter based on its word and position, which include “أ”, “ؤ”, and “ئ.” However, additional preprocessing approaches need to be used for some microblog data. These additional techniques involve several tasks, such as the elimination of hashtags, mentions, URLs, and special characters and reposting after the elimination of these elements [14]. Thus, it is essential to handle the Arabic dialects or to provide an MSA alternative.

Linguistic-feature analysis, the second step in the Arabic SA models and techniques, is divided into two techniques: analysis of n-grams and analysis of the POS features. N-gram is a chain of n-elements from some textual data, such as words, letters, and syllables. The frequently used n-gram elements are words, which are categorized into three types: unigrams (one word), bigrams (two sequential words), and trigrams (three sequential words) [14, 16, 17]. In Arabic SA, unigrams lead to a high prediction performance, along with the syntactic features. Syntactic features such as word roots, word n-grams, and punctuation impact SA. The variations in the Arabic syntactic features lead to the use of the word roots because although Arabic words have many forms, they all originate from the same root. For instance, all the Arabic words “سلمت”, “يسلم”, and “سلام” come from the root word “سلم.” Thus, there are two configuration settings for extracting the roots of Arabic words: lexeme (LEX) and lemma (LEM). LEX is a configuration setting of all word forms containing the same meaning through tokenization and morphotactics. LEM, on the other hand, is the exact form selected to represent LEX [14]; thus, the Arabic noun is the masculine singular default form but the verb is the third-person masculine singular perfective.

POS tagging consists of dividing a word into grammatical categories: nouns, pronouns, verbs, adverbs, adjectives, conjunctions, interjections, and prepositions. The POS tags in Arabic-text analysis include information about the morphology of the word. As for the semantic features, they contain contextual features that point to the semantic orientation of the surrounding textual data. Grammatical features have annotation approaches that add a polarity score to phrases or words by measuring the overall correlation of a multilabel of elements. This semantic orientation is based on various concepts of elements with a given sentiment polarity. Hence, if this element did not appear in the prior dataset with the association of the larger group of elements, polarity can be detected. Some researchers have found that semantic features outperform the unigram and POS-tagging features. Finally, the lexicon-derived features of the Arabic language are lexicons automatically created from some microblogs. However, Arabic lexicons are different from English lexicons as the Arabic language has various dialects and various word forms originating from a single root word [14].

### B. Targeted News Data

1) *Importance of the news data in microblogs:* Microblogs have become essential channels for news dissemination. An increasing number of users are expressing their feelings and sharing other information about the social news in microblogs [18]. Therefore, microblogs allow investors to share financial news and opinions with other investors. SA of microblog posts helps investors perceive the risks involved in buying a company’s stocks and make a decision regarding whether to invest in a company or not to. Hence, stock market microblog news SA has a significant impact on the stock price relative to growth stocks and is associated with stock price movement [7, 10, 16]. The decision-making regarding buying/selling orders is based on the market mood determined by technical indicators, which are measurements based on stock prices’ time series [19]. Also, unexpected events related to companies affect their performance in a positive or negative direction, such as their stock prices [10]. Consequently, for investment purposes, stock price forecasting has attracted increasing attention in recent years [20], and microblog news data may be among the essential inputs for such forecasting [21]. Thus, stock market prediction values have a significant impact on the financial sector.

Stock price prediction is important due to the high volatility of stock market prices [22]. Therefore, to minimize the risk of stock market investment, an accurate stock market price prediction model is needed. The investor sentiment index has been used for stock market prediction in recent years. It is based on stock market news, which some vendors provide as a service. To avoid buying overrated or high-risk stocks, investors decide whether to buy or sell stocks depending on the main stock news. Stock prices and their movements are thus forecasted by analyzing the related news, which outperforms an investor’s forecasting of the upcoming short-term trends [10, 23, 24]. Thus, automated decision-making supports the prediction of the upcoming stock price trends.

2) *Challenge of obtaining news data:* The primary challenge faced by researchers with regard to data collection from microblogs is the recent changing of some microblogs' terms of service, disallowing public hosting of old textual data or blogs and public extraction of these [16]. Besides, microblogs have increased the number of orders on API to retrieve specific data, such as on Twitter, as they can no longer directly obtain many data resources. Thus, microblog crawling tools are used to obtain many data resources. There are specific crawling processes: (1) selecting the number of microblogs with particular features, such as language; (2) crawling for a specific type of microblog data and filtering the textual microblog after obtaining each piece of data; (3) archiving the data obtained from crawling on the basis of the ID of each microblog in a specific period; and (4) processing the microblog texts by removing the miscellaneous elements, extracting the themes and feelings, segmenting the words, analyzing the syntax, and processing the text [18]. Accordingly, the Arabic microblogs of some news websites that use a crawler to extract data contain many labels within a specific period [15].

The user-written textual dataset is usually a massive volume of noisy and unstructured data. These data make SA a difficult and challenging task; thus, there is a need to process the unstructured data computationally to extract and determine the sentiments embedded in them [24]. Each language used to write microblog contents has a unique form or word structure [18]. The sentiment of the microblog is affected by the word sequence features, textual-language features, and grammatical-relation features [18]. These challenges can be dealt with through feature filtering (by analyzing some feature sets, such as n-grams) and by replacing certain words and processing the text, which become more significant as the data increase [16].

The processing of textual data involves removing any word that is irrelevant to the text's sentiment. Therefore, the preprocessing of such textual data involves scoring the text's sentiment after excluding the noise therein caused by the aforementioned words. Text processing is done using Python's Natural Language Toolkit on the basis of two methods: tokenization and removing stop words and symbols. Tokenization involves dividing texts by spaces to make a list of individual words per word package. Each word is then used as a feature to train or learn the classifier. Stop words are removed from the list of words because they have neutral meanings and are inappropriate for SA in the targeted language, according to its dictionary. Stop words may include prepositions, symbols such as "@" and URLs [16], and other words that have no sentiment value.

Unigrams are one-word n-grams for each unique tokenized word made for the classifier. For instance, a microblog can be classified according to whether it contains the word "bad" or does not. As this unigram is associated with a negative microblog, the classifier will classify microblogs containing the word "bad" as negative. Bigrams (two-word n-grams) and trigrams (three-word n-grams) can also be classifiers; they classify microblogs on the basis of whether they contain two or three words, respectively, or do not [16, 17]. For example,

if a microblog contains the bigram "not bad," which is associated with a positive microblog, it will be classified as a positive microblog.

Finally, word replacement involves replacing a company's stock symbols and positive and negative words.  $N$  most similar words according to a cosine similarity can be used to replace negative and positive words. Stock symbols can be replaced with a common word and can be removed from the textual blog [17], (e.g., \$AAPL can be replaced with "company").

### 3) *Sentiment classification approaches*

a) *Neural network models:* The artificial neural network (ANN) models have achieved high performance in Arabic classification and prediction on the basis of the related work chapter. The ANN has neurons in each layer. Each neuron calculates each input and the sum of the weights, adds the bias, and performs the activation function (e.g., the sigmoid function). The ANN model develops algorithms to solve complex problems such as prediction problems. Neural network models can be generalized by learning from the inputs' relationships to predict the unseen relationships on new data. This enables the model to predict and make generalizations regarding the unseen data. Neural-network prediction approaches perform better with high-volatility data by learning the unobserved relationships in the data without setting any specific relationships in the data. Thus, neural-network models are useful in financial time series prediction [25, 26], such as in the prediction of stock prices, which contain high-volatility data.

b) *Deep-learning model:* The DL techniques are used in SA because of their high performance in prediction [27]. They can yield a high result in financial applications. Their impact depends on training complex nonlinear models on the basis of massive datasets [19]. There have been studies on SA approaches based on DL for accuracy improvement, but some DL techniques ignore the words' meanings and order. Therefore, recurrent neural networks (RNNs) such as long short-term memory (LSTM), gated recurrent unit, and BERT are used to train models with solid architectures. The RNNs' architectures extract features in sequential and non-sequential data [28, 29]. The DL approaches obtain the highest results in the binary-data strategies. Thus, the previous studies' continuous-data outcomes showed that RNN and LSTM have the best classification performance [30]. Also, the sentiment classification by Bidirectional Encoder Representations Transformer-Bidirectional models such as BERT and BERT-BiLSTM [31], are superior in accuracy to other classifiers.

The BERT model takes advantage of bidirectionality and adds a masked language model (LM) to hide the word predicted and for next-sentence prediction (NSP) [32, 33]. Using such model addresses the limitations of the previous LMs, which work from left to right and do not capture the bidirectional contexts. Also, such model generalizes LM for easy fine tuning for any downstream task. The BERT model mainly performs two steps in its framework: pre-training and fine tuning. Pre-training is done through a couple of unsupervised tasks: masked LM and NSP. The BERT model

adds two tokens: Class (CSL) and two Separation Sentences (SEPs) for the input sequences as a separate structure feature and target [33], to be used in one or two sequences.

### III. MATERIALS AND METHODS

The proposed model determines the classification polarity of data and the economic-reason polarity through data gathering, data preparation, and data splitting. Then the supervised and unsupervised models are applied.

#### A. Data Gathering

The data that were used in the present study were collected from the Saudi stock market platform Tadawul, containing the Corporate Articles and Historical Data Stocks datasets. The total dataset covered articles published within nine years (2011–2019). It had 34,386 rows of news and 16 columns of variables: sector, investor name, investor ID, date, time, article title, full article, opening value, highest price, lowest price, closing value, change %, change value, quantity handled value, total price, and total of deals.

#### B. Data Preparation and Annotation

In the proposed approach, there are multiple phases of data preparation: data evaluation, data cleaning, and data validation. Some issues (e.g., noisy, incorrect data and differentiated data formats) are fixed in the data evaluation stage. The data-cleaning stage handles these issues. Noisy and incorrect data are filtered and erased manually and by Pandas DataFrame. Arabic tokenization is performed to fix the differentiated data formats and to standardize all the data sections. In the end, a manual test is performed to validate the whole dataset by testing 30,089 observations.

The polarity annotation adopts the multi-class classification system, which includes the neutral class to increase the model's prediction accuracy [34, 35]. Stock news polarity is annotated manually as negative, positive, or neutral by native Arabic speakers associated with the stock market field.

#### C. Data Splitting

Some data-splitting methods, such as k-fold, grid search, and cross-validation, split the dataset into a couple of sets. These methods are correct but take a long time to train and evaluate each hyperparameter value, which is ineffective in DL models. Therefore, splitting the dataset into three subsets (train-validation-test splitting) increases the training and evaluation speed. Train-validation-test splitting chooses the best hyperparameters by evaluating the validation set outcomes after the training level. Then it re-evaluates the test set outcomes after passing the validation level [36]. Thus, train-validation-test splitting allows selecting the best model, features, and hyperparameters on the validation and test levels. It decreases the mistake cost and performs DL fast for long-time training and evaluation, to the best of the authors' knowledge.

#### D.

#### The Applied Models

Two models were applied in the current study: the supervised DL model of SA classification and the unsupervised DL model of economic-aspect clustering. Stock news sentiment classification was performed using the BERT model; the articles were classified as positive, negative, or neutral. The unsupervised cluster was improved by performing semantic k-means clustering to categorize the articles into main economic aspects. Thus, these models classify the stock news polarity on the basis of labeled data and extract the economic reason for each stock news article's sentiment.

4) *Supervised model*: Two models were applied to the polarity classification, as shown below.

- Baseline model (BL): Logistic regression
- DL model: BERT

a) *Logistic regression model*: Starting with a simple BL such as the logistic regression model before the complex models helps test the data quality, estimate the primary result, and determine the problem dimensions. The logistic model works effectively with multi-class classification and can be generalized [37]. Also, it performs better with a massive amount of data, such as the dataset used in the present study [38]. The steps below are applied to obtain the best prediction result.

- The data are lemmatized to remove the noisy features.
- Trigrams add the important features.
- The term-frequency-inverse document frequency (TFIDF) vectorizer is used to give the essential words more weight and vice versa.
- The maximum number of features is limited according to the best result.

Weight balancing can be learned using the stochastic gradient descent (SGD) algorithm; thus, the alpha value equals 0.0001 because the TFIDF is the one that controls the importance of features to give proper weights to the important words. The logistic regression model's performance is tested on the basis of the max\_features value, by changing the size of the vocabulary. Therefore, many values are tried, and the results decrease at 20,000. Thus, 25,000 is the best choice, with the best result and the fewest maximum features. The maximum number of features is limited using the argument "max\_feature" by the fewer features and best result simultaneously. The multi-classes in the training stage are balanced using the argument "class weight" to prevent the imbalanced-learning effects on the classification performance. Table I shows the parameters' values which are setted to perform logistic regression on multi-class classification, by tuning the best result.

TABLE I. THE LOGISTIC REGRESSION MODEL MULTI-CLASS CLASSIFICATION PARAMETERS

Model	Parameter	Value
Logistic Regression	“CountVectorizer ngram_range”	1, 2
	“CountVectorizer max_features”	250,000
	“SGDClassifier __loss”	“log”
	“SGDClassifier __n_jobs”	-1
	“SGDClassifier __class_weight”	“balanced”
	“SGDClassifier __alpha”	0.00001
	“SGDClassifier __random_state”	1

b) *The bidirectional encoder representations from transformers model:* BERT comes up with a general understanding to be used in a downstream task for text classification. It trains a strong model language and then adds an output layer in each downstream task of such language. This output layer is suitable for the downstream task, allowing the fine tuning of this layer and of the other layers [33]. Using the BERT model along with WordPiece embedding will solve this problem. WordPiece takes care of the embedding for the whole token, and the embedding also divides pieces of it. Thus, the model does not discard the newly faced word in the test data but takes the embeddings of the token pieces in the training data [33, 39]. An example is if the model faced the term “going” in the training data. In the previous models, the word “going” is a full token that has only one embedding. Thus, if the previous models faced the new tokens “go” and “ing” in the test data, they would discard such tokens.

However, WordPiece gives embeddings for “go” as the first piece and “ing” as the second piece. Thus, with WordPiece, when new tokens like “go” and “ing” are faced in the test data, both will be predictable on the basis of the set embeddings’ values, and there is no need to discard them.

Table II shows the fine tuning of the optimal hyperparameter values is task specific. Still, the ranges of possible values for the following are studded to work well across all tasks on the basis of the BERT study [33]: batch size, learning rate, and number of epochs, where the best epoch equals 4 in the tests and experiments. The maximum length of documents is chosen on the basis of the quantile value, which equals 0.9; that is, 90% of the documents are less than or equal to 425 words, as the articles’ maximum length (see Fig. 1). The Max\_features value equals 30,000 based on the previous experiments, and BERT model authors [33]. The wall time of training equals 1 minute and 3 seconds.

TABLE II. FINE-TUNING PROCEDURE OF THE BIDIRECTIONAL ENCODER REPRESENTATIONS FROM TRANSFORMERS MODEL

Model	Parameter	Value
BERT	Batch size	16, 32
	Learning rate (Adam)	5e-5, 3e-5, 2e-5
	Number of epochs	2, 3, 4
	Classifier (Dense)	2,307
	Quantile	0.9
	Best_epoch	4
	Max-features	30,000

Fig. 1. Maximum length of documents based on the quantile value

BERT prediction of multi-class classification was applied to compare the results of the validation set with the actual target data. Table III shows the evaluation outcomes of the data whose classifications were predicted.

TABLE III. MULTI-CLASS CLASSIFICATION PREDICTION RESULTS OF THE BIDIRECTIONAL ENCODER REPRESENTATIONS FROM TRANSFORMERS MODEL

	Negative	Neutral	Positive
Negative	0.8842	0.0450	0.0707
Neutral	0.0218	0.8667	0.1115
Positive	0.0277	0.0748	0.8975

5) *Unsupervised model*: As shown in the previous sections, the BERT model was trained to predict the correct polarity of stock market news articles. However, although this is useful by itself, it misses some parts of the needed picture. The preceding section showed how the polarity of an article is determined but does not elaborate on why the article carries such polarity. For example, the BERT classifier classifies an article as positive, but the reason for its classification of the article as positive is unknown. The reasons for polarity can include the company profits and the fact that the company is to start a new project or production line, increase its capital, or embark on a merger or acquisition. Such assessment is invaluable to the investors, the company owners, and the company's board of directors. The determination of the economic reason for an article's polarity in the literature is called aspect-based SA, which is performed through the procedure described below.

- Annotating each article according to the aspect involved and the underlying sentiment
- Training a supervised ML or DL model on the annotated data
- Using the trained model to predict the aspect and sentiment of new articles

The aforementioned procedure, however, is extremely time consuming and costly. Therefore, the approach proposed herein is a novel and universal approach that significantly reduces both time and cost by reformulating the problem of aspect extraction from a supervised text classification to an unsupervised determination of text similarity, hence eliminating the hand-annotating step from the typical approach described earlier. The proposed approach is performed through several steps. The first step is discovering the overall prevailing categories of aspects in the entire body of articles. Semantic k-means clustering is applied on the most important features per the trigram-TFIDF logistic regression model [40]. Also, instead of performing k-means clustering on the full articles, k-means clustering is limited to the reasons for the negative or positive polarity, as understood by the model. The second step is representing each category of aspects through a set of n-grams carrying the distinct semantics of the category. The third step is encoding the n-grams for each category into an embedding using a sentence-embedding procedure (transformer-based multilingual universal encoder and the mean Word2Vec encoder). Next,

the articles are encoded using the same encoder chosen in the third step. Instead of encoding the whole article at once, the article is encoded after paying attention to the relationships between the words and after aspect embedding for improving the goals. Then, for each article, the arc-cosine similarity between the embedded articles is computed, and each of the category embeddings in the third step is computed. Also, a score from 0 to 1 is given for how much each category is related to the article. Finally, the two aspects most associated with the highest scores are picked. Thus, the number 2 is a hyperparameter picked on the basis of reasoning, as will be explained later.

K-means clustering uses the mean Word2Vec vectorizer and needs to choose the number of clusters required by the algorithm for separating the features into. In the present study, after many possibilities were experimented with, ten groups were found to provide good semantic separation between the aspect categories. Hence, some overall categories of reasons (or aspects) were detected for positive and negative sentiments on the basis of k-means clustering. The following are the ten clusters that resulted from k-means clustering using the mean Word2Vec vectorizer based on the semantic unit.

- Clusters 0, 1, and 3 contain articles about profit/revenue increase/decrease, including stock appreciation/depreciation.
- Cluster 4 contains articles about starting/stopping a project or a production line, or anything related to production in general.
- Cluster 6 contains articles about the increase/decrease of the company's capital.
- Cluster 7 contains articles on dividend distribution or non-distribution.
- Cluster 8 contains articles on insurance operation surplus/shortage.
- Cluster 2 contains articles on the approval of various insurance policies.
- Cluster 9 contains articles on the board of directors' signing of agreements/memoranda of understanding, approval, or disapproval on critical issues or on anything related to managerial matters.
- Cluster 5 has miscellaneous articles that have been not considered.

Most of the clusters exhibited sentimental unity rather than semantic unity, which was the present study's aim for the economic aspects. The Universal Sentence Encoder was also applied to cluster the articles into ten groups. However, unlike the mean Word2Vec encoder, it cannot separate the semantics from the sentiments. The mean Word2Vec encoder is thus the best choice for exhibiting only semantic unity, as required. The central economic aspects manually extracted on the basis of the previous results were profit/revenue, projects/production lines, capital, dividends, insurance operations, insurance approval, and managerial/contracts.

Testing the proposed approach using individual articles showed a large percentage for each aspect based on the article's relevance to each aspect. There is testing for the applied algorithms: k-means clustering using the mean Word2Vec vectorizer and attention algorithm. The attention mechanism enhances the encoding of the article instead of treating the constituent words in the article equally. Attention is a method of selectively encoding an article by assigning higher weights to the words that are semantically similar to each corresponding aspect. However, although the two algorithms' results are similar, the normal algorithm has more sensible results in many examples. Table IV contains two tested examples for both algorithms. The first article is about insurance and production lines; the normal algorithm accurately predicts its aspects. Also, the attention algorithm is close to the result, but not to the best one. The second article is about profit, insurance approval, and production. Both algorithms accurately predict the aspects, but with some differences in the arrangement. Thus, it is essential to detect the highest aspect or two aspects to limit the probabilities and to validate the method performance. Thus, the proposed approach predicts the highest uni-aspect and bi-aspects besides the seven aspects' percentages of similarity to the article.

The results look promising but not perfect. The algorithm tends to favor the dividends aspect more than the other aspects, although it does this only when the article talks about profit or loss or financial statements as dividend distribution or non-distribution is closely tied to how a company is faring in the financial aspect. Even when the algorithm deviates from the correct aspect, it favors the closely correlated aspects.

#### IV. RESULTS AND DISCUSSION

##### A. Polarity Prediction

After the performance of many experiments, the trigram algorithm generated high results but a massive number of features. Therefore, a trigram is used with TFIDF to maintain the performance and limit the number of elements simultaneously. Also, the highest number of features is specified using the argument "max\_feature=250000," resulting in fewer features. It chooses features on the basis of their importance, by limiting the features with the best results. Table V includes the logistic regression and BERT model performances which are assessed through model testing and evaluation of the classification by the best model. Model testing requires feature and target data. The classification evaluation for article prediction generates multi-class classification assessment for the best model which is shown in Table VI.

TABLE V. LOGISTIC REGRESSION AND BIDIRECTIONAL ENCODER REPRESENTATIONS FROM TRANSFORMERS MODEL TESTING RESULTS

Model Name	AUC	Accuracy	Precision	Recall	F1-Score
<i>Logistic Regression</i>	0.837542	0.839635	0.837542	0.401299	0.8381
<i>BERT</i>	0.958385	0.877076	0.877822	0.877076	0.877262

Note: AUC = area under the receiver operating characteristic curve.

TABLE VI. MODEL EVALUATION OF MULTI-CLASS CLASSIFICATION

Model Name	Class	Precision	Recall	F1 Score	Support
<i>BERT</i>	Negative	0.801749	0.884244	0.840979	311
	Neutral	0.884444	0.866725	0.875495	1148
	Positive	0.902724	0.897485	0.900097	1551
	Accuracy	-	-	0.884385	3010
	Macro avg	0.862972	0.882818	0.872190	3010
	Weighted avg	0.885319	0.884385	0.884606	3010

Uni-Aspect Distribution

Fig. 2. Highest uni-aspect scoring

Bi-Aspect Distribution

Fig. 3. Highest bi-aspect scoring

### B. Scoring of the Economic Aspects

The results show the percentages of similarity and the highest uni-aspect and bi-aspects for each article's seven aspects. The highest uni-aspect is the aspect that has the highest percentage of similarity. Also, the bi-aspects have the two aspects with the highest percentages of similarity to each article. After the model was applied to the data, the following were the highest uni-aspects among all the aspects: profit (16,799 articles), insurance approval (1,570 articles), capital (195 articles), and insurance operations (51 articles) (see Fig. 2). Moreover, the highest bi-aspects among all the aspects were insurance approval and profit (8,641 articles), and the lowest was insurance approval and operations (1 article) (see Fig. 3). Hence, in each of 2,000 articles, the two highest economic aspects were manually labeled to validate the model's performance. The model was tested on the basis of the labeled data to examine its prediction performance, and its prediction achieved 80% accuracy. The accuracy degree is calculated loosely, such that if the actual class is one of the two predicted classes (bi-aspects), the prediction is accurate. The calculation of accuracy is plausible because the aspects are not mutually exclusive and there is more than one reason in most cases. Therefore, the two highest scores are extracted according to the model, and if the actual aspect is one of the two predicted aspects, the prediction is correct.

C. Polarity Distribution over the Economic Aspect

The final results of both models show the articles' polarity prediction and highest economic aspect as the reason for its negativity or positivity. For instance, the first article in the data is manually labeled positive, predicted by BERT as positive. Its predicted percentages of similarity are highest (79%) for the profit aspect and lowest (63%) for the capital aspect. Also, the highest uni-aspect is the profit aspect, and the highest bi-aspect is profit and production lines.

The insurance approval aspect contains the highest positive news because most of its articles are about the approval of companies' insurance applications, which is good news. Also, the profit aspect has a high percentage of positive articles because most of its articles are about companies' profit and revenue news, which are mostly positive. The insurance operations aspect has the highest percentage of negative news because most of its articles are about the

occurrence of problems and the need for insurance to limit issues, which is bad news. Also, the capital aspect has a high percentage of negative articles because most of its articles are about capital loss news, which are mostly negative (see Fig. 4).

Furthermore, the profit and production lines bi-aspect has the highest percentage of positive news because most of its articles are about companies' profits and revenue from their new projects or production lines, which are good news. The insurance approval and profit bi-aspect also has a high percentage of positive articles because most of its articles are about companies' revenue from the approval of their insurance applications, which are mostly positive. The capital and insurance operations bi-aspect has the highest percentage of negative news because most of its articles are about the occurrence of problems, insurance need, and capital loss, which are mostly negative (see Fig. 5).

Fig. 4. Uni-aspect polarity distribution.

Fig. 5. Bi-aspect polarity distribution.

## V. CONCLUSION

The present study aimed to predict the polarity classification of stock market news and its economic aspect, which affects the polarity. A couple of models were executed to achieve the study aim: the supervised ML model and the unsupervised mean Word2Vec encoder. These models were applied on a prepared and annotated dataset extracted from the Saudi stock market news platform. The supervised ML model includes the logistic regression and BERT models for classifying the sentiments of stock news articles. The unsupervised model, on the other hand, conducts k-means clustering using the universal ML sentence encoder and Word2Vec. The models were applied to textual Arabic stock news by tuning the hyperparameters and features. The logistic regression model was used with lemmatization, trigrams, and the TFIDF vectorizer for the dataset's features to decrease the token numbers. Such model achieved 84% prediction accuracy by setting the maximum features' value (250,000 tokens). The BERT model, on the other hand, achieved 88% prediction accuracy, the highest outcome in a short time for the classification task. The unsupervised model prefers k-means clustering based on Word2Vec to the universal ML sentence encoder to exhibit semantic unity. Unlike the mean Word2Vec encoder, however, k-means clustering using the universal ML sentence encoder cannot separate the semantics from the sentiments. K-means clustering uses the mean Word2Vec vectorizer to choose ten groups that provide the best semantic separation between aspect categories. The manually extracted economic aspects are profit/revenue, projects/production lines, capital, dividends, insurance operations, insurance approval, and managerial/contracts. Moreover, k-means clustering was tested to predict the aspects of the article on the basis of Word2Vec and the attention algorithm performance. Some examples of the results show that the algorithms tend to prefer the dividends aspect to the other aspects. However, when the algorithm deviates from the correct aspect, it predicts correlated aspects. Finally, the mean Word2Vec encoder achieved 80% economic-aspect prediction accuracy. The developed models are valuable resources that classify the Arabic Stock Market news based on their polarity and main economic aspects. The SA and economic aspects extraction models help to perceive the risks based on the news of the stock. They support making the right decision based on the stocks articles sentiments and their main economic reasons of the polarity. Thus, automated decision-making supports predicting the upcoming stock price trends in investing or analysts' evaluation.

# e-Government Usability Evaluation: A Comparison between Algeria and the UK

Mohamed Benaida

Faculty of Computer and Information Systems  
Islamic University of Madinah, Saudi Arabia

**Abstract**—e-Government holds the keys to improving government services provided to citizens and the private sectors within their countries. Although Algeria is the largest country in Africa and has one of the most thriving economies in the continent, it is remarkable that the Algerian EGDI ranking was 120th according to the latest UN e-government survey. This inspired the researcher to investigate the relationship between the success factors of e-services in developed countries and their counterparts in developing countries. The main aim of this study is to explore the factors that influence the level of usability of e-government services between developing and developed countries against a set of specific guidelines to provide means for improving these services in developing countries. The researcher selectively extracted three guideline categories from Research-Based Web Design and Usability Guidelines as a means for expert evaluation of 10 Algerian e-government services compared to British e-government services. Our results show that Algerian e-services lack mostly in Use Frames when Functions Must Remain Accessible, Highlighting Information, and Graphics Should Not Look like Banner Ads (belonging to Page Layout, Text Appearance, and Graphics, Images & Multimedia respectively), whereas UK e-services scored highly across all three categories. These findings further enhance the UN e-government survey and identifies the sub-categories that developing countries need to pay more attention to in order to provide a more reliable and robust e-service to its users and citizens. Furthermore, this study proposes that the Research-Based Web Design & Usability Guidelines can be converted into an evaluation tool to be used by evaluators to easily assess the usability of a website. The combination of relative importance, chapters of the guidelines, and their respective guidelines gathered from Research-Based Web Design & Usability Guidelines, along with the evaluation of these individual guidelines by evaluators will serve as an integral tool for developers when developing e-government services to reach the satisfaction of the users.

**Keywords**— *Human computer interaction; usability evaluation; web design; e-Government; user satisfaction*

## I. INTRODUCTION

The internet officially launched in Algeria in 2001, Seven years later in 2008, e-government services in Algeria were established [1]. Only recently has the Algerian government tried to keep up with modern technology by using online services. However, the shift from centralisation to using electronic services has not been an easy process. Design, logistics infrastructure, internet speed, and adoption of new services; are all factors that are considered great challenges facing the government as it moves into the world of electronic services. Like other governments in developing countries, the

Algerian government seeks to establish an electronic system through which citizens can benefit from the e-services provided by their government in various fields. However, the e-government project encountered many problems regarding infrastructure, use of technology in a sound manner, the quality of services, and ease of access for citizens. The ultimate aim of e-governments is to improve the usability of their services for their users, thus increasing user interaction. There are several definitions of e-government based on its use, however this research focuses on e-government as a system rather than from a technical or social aspect. One definition describes e-government as "the use of information technology to enable and improve the efficiency of government-provided services to citizens, employees, businesses and agencies" [2]. Most governments in developing countries have recently engaged in e-services that aim to conserve effort, time, and money for the population. Many various usability guidelines exist today (such as ISO/CD 9241-151). Thus, it is hard to point out one guideline as the model since every audience around the world has its own culture, background, symbols, language, and political system [3]. Furthermore, the level of the country's economy affects their perception and judgments of everything around them, and therefore each audience has different needs [4], [5].

This study decided to utilise the Research-Based Web Design & Usability Guidelines (RBED&UG) due to its exclusivity and popularity in government agencies, educational programs, and various independent sectors. These guidelines were established by the U.S. Department of Health and Human Services initially in 2003 and further developed in 2006 with the aim of helping designers develop a large range of websites, but mainly information filled government services. The exclusivity of these guidelines lies in their relative importance in rankings whilst also providing references and expert feedback to support their argument. Another reason this study decided to use guidelines is due to the recommendations provided by the authors of these guidelines, which motivates researchers to explore avenues with little or almost no research, as is the case is with Algerian e-government. The latest edition is made up of 18 main chapters, which are divided into multiple guidelines enhanced by the relative importance and strength of evidence providing a total of 209 guidelines across these chapters [6]. This research focused on three chapters of this guideline (Page Layout, Text Appearance, and Graphics, Multimedia, & Images) as it aimed to provide accurate and in-depth results rather than a broad and general set of results which may not be as useful to the web designers of these websites.

The main reasons for picking Algerian e-government services as the subject of this study is that there is a lack of research in this field regarding less developed countries generally [7], and according to our knowledge, even after more than a decade since its establishment, there are no studies that analyse the usability of e-government services in Algeria. Furthermore, this simultaneously fulfils the recommendations of the authors of the RBED&UG of researching into new areas and providing relevant research results. Therefore, the main contribution of this research is that it is the first study to shed light on the usability of Algerian e-government services and provide web designers with a deep insight into how to address the flaws (lack of online services, lack of visual consistency, etc.) which the experts in this study have identified in order to help the government create usable, learnable, and effective e-services that will increase user interaction.

The e-government development index (EGDI) measures a country's capability to deliver online public services and is calculated using three variables including telecommunications infrastructure index (TII), human capital index (HCI), and online service index (OSI). This study compares the Algerian government e-services with the government e-services in the United Kingdom, as Britain is a developed country and ranks high in the EGDI rankings published in the latest United Nations e-government survey so that a comparison can be made between Algeria as a developing country and Britain as a developed country, allowing for better understanding of deficiencies and focusing on the factors that are likely to have an impact on improving the quality of service provided to citizens in developing countries, which facilitates the lives of citizens and makes them more efficient and of better quality. The British are 7th in the EGDI rankings whereas Algeria is ranked 120th in the world [8]. The aim is to explore why there are such big gaps in the e-services provided between developed and less developed countries. Unlike the British e-government services which are all available on one website, Algerian e-government services are all independent and each website serves a different purpose, for example, the ministry of interior, the ministry of sports etc. Therefore, this study selected ten Algerian e-government websites to compare with the British e-government website to serve as a realistic representation of Algerian e-services. The null hypothesis in this study is that there is no significant difference between Algerian and British e-government services, whereas the alternative hypothesis states that there is a significant difference between Algerian and British e-government services.

Another contribution of this study is that it converts the RBED&UG into a questionnaire to be used by web designers to help evaluate and gather relevant data for improving electronic web services. Researchers realised the importance of these guidelines in developing and initiating web systems in various fields and the high potential that it can be used by web designers for evaluating the level of a system and addressing certain issues that may present. Researchers believe that the same concept of converting guidelines into a questionnaire to be used as an evaluating tool for web designers can be implemented with any of the chapters of the RBED&UG. The study only used three chapters as a representative of all

chapters and to show that it can indeed be implemented efficiently and effectively to good use.

This research paper is split into six parts including the introduction which provides an overview of the main components of this research. Then, the literature review dwells on previous research and identifies their key findings and shortcomings which need to be addressed. The methodology details the stages of this research and the demographic data of the participants that were involved. Results and discussion include a detailed analysis which breaks down the various attributes that are suffering or excelling in the usability of e-government services. The conclusion provides an overview of our research along with the main results and contributions it brings forward to the domain of e-government usability. Finally, the limitations and future work marks the end of this research paper.

## II. LITERATURE REVIEW

Information technology is growing rapidly; government services must also be up to date with these technological advancements. In developing countries, this challenge is far greater, since many still suffer from poor IT infrastructure and financial problems, which hinder their progress in providing advanced electronic services to their citizens. Besides, building trust between the citizens and using electronic services is still in development [9]. This section discusses e-government websites and usability, usability evaluation methods and e-governments Algerian websites.

### A. e-Government Websites and Usability

In the last decade, e-government services have become more important than ever before. Many governments have launched at least one or more systems that provide citizens with the necessary information and adequate services. It summarises and stores relevant information based on the quality of the internet and the level of ability of the users to use their internet services. Many factors can affect the performance of these e-government systems such as the educational background of the users, culture, and simplicity of the system, efficiency, robustness and reliability [3]. There are various definitions of e-government depending on the field of interest and the perception of experts [10]. The World Bank (2015) believes that "E-Government refers to the use by government agencies of information technologies (such as Wide Area Networks, the Internet, and mobile computing) that have the ability to transform relations with citizens, businesses, and other arms of government" [11]. However, a comprehensive study on multiple definitions of e-government established six main elements that serve as a widely shared definition. These variables consist of; "(1) the major initiatives of management and delivery of information and public services. (2) Taken by all levels of governments (including agencies and sectors). (3) On behalf of citizens, business. (4) Involving using multi-ways of internet, web site, system integration, and interoperability. (5) To enhance the services (information, communication, policy making), quality and security. (6) As a new key (main, important) strategy or approach" [10].

Usability is defined by the ISO as the "extent to which a system, product or service can be used by specified users to

achieve specified goals with effectiveness, efficiency and satisfaction in a specified context of use” [12]. Any new system or product should achieve its goals and satisfy its end users by ensuring that the system is more interactive and attractive to maximise the benefits of the system. Most e-government projects (35% total failures and 50% partial failures) in less developed countries are unsuccessful [7]. They are unable to fulfil the satisfaction of their users due to the widespread usability issues found on their systems [13]. Nielsen’s description of usability via the implementation of various metrics is widely accepted, thus ten usability guidelines were initiated to identify errors, evaluate the level of effectiveness and efficiency and establish user control, thus, ultimately fulfilling user satisfaction.[3].

Some studies [14] argue that e-government can benefit from usability in two aspects; satisfaction is key due to improved user performance on e-government services, on the other hand, the first impressions are also crucial for attracting users to using e-government online services. e-Government relates to usability in multiple ways correlating to satisfaction; internet speeds [15] loading speed [16] usefulness and ease of use [17]. The abovementioned variables are one of the most influential in the usability of e-government according to previous studies. Poor design interface can affect not only the perception of users, but in some cases can become more serious and influence various factors such as user safety [18]. Therefore, users should be an essential part in the design stages to minimise the errors that end users can face [7] explore the value of e-government and the public value it holds. Through this research, six values were identified; Open Government capabilities, improved ethical behaviour and professionalism, improved public services, improved administrative efficiency, improved social value and well-being, and improved trust and confidence in government. In least developed countries and developing countries, there was a lack of research in attempting to figure out the public value of e-government and the user perception of these services.

Many studies in other countries have attempted to figure out solutions and identify factors that can influence the quality and usability of e-governments services. Studies have shown that usability is the heart of an e-government system that attempts to fulfil the satisfaction of its users. Furthermore, it can directly affect the trust of the users [19]. The meaning of usability may not be clear enough. However, usability is not just how to make the system easy to use; instead, it is the ease of use based on efficiency, effectiveness, learnability, and user satisfaction [20]. Some studies argue that western e-government websites fail to deliver services to their citizens [21]. There were several usability issues identified in developing countries such as Jordan [22], Malaysia [23], China [24], and Sub-Saharan Africa [25] such as South Africa [26] and Tanzania [27]. The usability problems identified included accessibility [28] poor design [29] learnability [30] and text appearance [31]. Furthermore, poor usability design affects the quality of the website and the adoption of users, which drives them away from revisiting the website [5].

Each country faces its own specific usability issues, and many studies have found different factors that can positively or negatively evaluate the level of e-government services and the

quality provided to their citizens. e-Government services in Mauritius Island showed that factors like expected performance and facilitating conditions have a positive relationship with the users' behavioural intentions. On the other hand, computer self-efficacy is negatively related to the users' behavioural intentions. The authors suggest essential steps the government could take to help the citizens adopt their e-government services effectively and efficiently [32]. In Turkey, factors that could help citizens adopt e-government services are Performance Expectancy, Social Influence, Facilitating Conditions, and Trust on the Internet. Authors [33] have initiated a new guideline for policymakers to initiate attractive e-government services by considering the highlighted priorities of the citizens. The authors proposed a new analysis technique that could potentially increase and maximise e-government portals' potential to benefit individuals from various cultural backgrounds. This analysis technique incorporates various factors such as content analysis, user perception, and persuasive quality gap. Culture is another factor that can affect the usability satisfaction level [34], [16]. For example, [35] argue that their suggested approach provides an estimation method to measure the contribution of e-government quality attribute to cross-cultural quality gap. They also examine the satisfaction level of Jordanian citizens when using these e-government services. Several factors influencing satisfaction were identified; security and privacy, trust, accessibility, awareness, and quality. They claim that their findings have proven very useful for industry practitioners and policymakers within the government.

#### *B. Usability Evaluation Methods*

Usability evaluation becomes more crucial in testing usability issues including content and page layout, to create a system that suits the requirements of the user and meets their needs. There are two main usability evaluation methods used to assess usability websites: heuristic evaluation and usability testing.

Many studies use this type of evaluation (see Table I) via Nielsen’s ten heuristics due to its low cost, time efficiency, and how it requires only a few experts to give their opinion about the problems that face certain applications or websites. On the other hand, “usability testing refers to evaluating a product or service by testing it with representative users” [36]. Usability testing gathers a group of users to complete several tasks on the system to assess the usability level and identify any issues within it. The users assessing the system are the same users that the designer is creating a usable system for, thus any issues identified by these participants are crucial and provide a real-life representation of the end user feedback after the official launch of the system. Consequently, designers can take their feedback on board and make the appropriate adjustments to improve the overall system to make it more usable and attractive. For these reasons, this study proposes that the new questionnaire is to be used as a heuristic evaluation method used by evaluators in web design.

### III. METHODOLOGY

#### A. e-Services Evaluated

Ten Algerian e-Government websites were selected for evaluation in this study. They include the following: Minister of Defence, Minister of Interior and Local Government, Minister of Foreign Affairs, Minister of Finance, Minister of Energy, Minister of War Veterans (Moudjahidine), Minister of Religious Affairs and Endowments (Wakfs), Minister of Vocational Education and Training Professionals, Ministry of Culture and Arts, and Minister of National Solidarity, Family and Women's Affairs. There is no unified website in Algeria that can provide more government electronic services, so the researcher had to collect the ten most used Algerian websites to evaluate electronic government services, while in the United Kingdom there is only one website that collects government

electronic services, and accordingly, a comparison was made between these ten sites. After this information was evaluated by experts, the average was collected from each of the ten sites and compared with the standard British site in order to facilitate the evaluation process.

#### B. Proposed Usability Questionnaire Model

After realising the effectiveness of the RBED&UG, researchers believed that these guidelines could be effectively used during usability of e-government services to identify flaws within the usability of these systems. Whilst guidelines are used by web designers when creating a web page, researchers propose that the RBED&UG is transformed and used as a questionnaire to evaluate the system after it is created so that web designers can brush up and improve on the areas that are lacking thus providing a more robust and reliable service. This study decided to selectively examine the effectiveness of three chapters (Page Layout, Text Appearance, Graphics, Images & Multimedia) from the RBED&UG to serve as a strong representative for the other 15 chapters. Since the original guidelines follow a five-point scale, researchers believed it would be most appropriate to be consistent and implement a five-point scale in the questionnaire where one represents "very poor" to five which represents "very strong". Tables II, III and IV display the questionnaires that were provided to the experts before the start of the experiment. They were provided with two copies of each one, totalling to six copies of these questionnaires to evaluate both Algerian and British e-Government services relative to the three selected guidelines. The experts marked their selected scores for the relative e-service and guidelines of these categories. These results will be collated by the researcher at the end of their evaluation and utilised for statistical analysis of the data.

TABLE II. TABLE TYPE STYLES

Usability Page Layout Questionnaire					
	1	2	3	4	5
1. Avoid Cluttered Displays					
2. Place Important Items Consistently					
3. Place Important Items at Top Centre					
4. Structure for Easy Comparison					
5. Establish Level of Importance					
6. Optimize Display Density					
7. Align Items on a Page					
8. Use Fluid Layouts					
9. Avoid Scroll Stoppers					
10. Set Appropriate Page Lengths					
11. Use Moderate White Space					
12. Choose Appropriate Line Lengths					
13. Use Frames when Functions Must Remain Accessible

2. Format Common Items Consistently					
3. Use Mixed-Case for Prose Text					
4. Ensure Visual Consistency					
5. Use Bold Text Sparingly					
6. Use Attention-Attracting Features when Appropriate					
7. Use Familiar Fonts					
8. Use at Least 12-Point Font					
9. Color-Coding and Instructions					
10. Emphasize Importance					
11. Highlighting Information					

TABLE IV. USABILITY GRAPHICS, IMAGES, & MULTIMEDIA QUESTIONNAIRE

Usability Graphics, Images, & Multimedia Questionnaire					
	1	2	3	4	5
1. Use Simple Background Images					
2. Label Clickable Images					
3. Ensure that Images Do Not Slow Downloads					
4. Use Video, Animation, and Audio Meaningfully					
5. Include Logos					
6. Graphics Should Not Look like Banner Ads					
7. Limit Large Images Above the Fold					
8. Ensure Web Site Images Convey Intended Messages					
9. Limit the Use of Images					
10. Include Actual Data with Data Graphics					
11. Display Monitoring Information Graphically					

12. Introduce Animation					
13. Emulate Real-World Objects					
14. Use Thumbnail Images to Preview Larger Images					
15. Use Images to Facilitate Learning					
16. Using Photographs of People					

### C. Procedure

The volunteering experts were provided with all the websites required for this experiment and a brief was given before the beginning of the evaluation process along with copies of the questionnaires they would have to fill out. The brief very simply explained the goals of our research and that the participants are testing the guidelines as a questionnaire for evaluation to explore the issues in Algerian and British e-Government websites. The results would also simultaneously help assess the validity of the proposed questionnaire. The researcher decided to allocate some time for the experts before evaluation to get familiar with these e-services so that they can easily and effectively evaluate them once the process begins. After that the experts evaluated the e-services according to the three dimensions (Page Layout, Text Appearance, and Graphics, Images, & Multimedia) from our usability questionnaire accordingly, freely with no time constraints. Experts were asked to return the questionnaire once complete.

### D. Participants

Since some e-services are only available in English, Arabic, or French, the researcher decided to select seven experts who are confident with all three languages to help gather the results of our study across all platforms with no issues and full understanding. Each expert evaluated the ten selected Algerian e-Government websites and the British e-Government website. The participants who contributed to this research voluntarily are from different educational levels and gender backgrounds. Most participating experts were males aged between 36 and 50 years who are of a postgraduate degree status. Table V shows the expert demographics.

TABLE V. EXPERT DEMOGRAPHICS

Demographic	Category	Number of Participants (7)	%
Age	25-35	1	14
	36-50	4	57
	50+	2	29
Gender	Women	2	29
	Men	5	71
Education Level	Undergraduate Degree	2	29
	Postgraduate Degree	5	71

### E. SPSS Analysis

The results of the expert evaluation gathered via the proposed questionnaire were inserted into the SPSS program and results of importance to this study were extracted such as the paired samples statistics mean and standard deviation, the paired samples test mean and standard deviation, t-values, and p-values. The paired samples statistics mean shows us the average score for each guideline of each chapter, whereas the paired samples statistics standard deviation uses the results of the experts to identify the level of consensus between the set of results. The paired samples test mean is the difference between the paired samples statistics mean of the two tested variables. Furthermore, the p values show us the level of significant differences between our tested samples in each element of the three categories selected. For the data to be considered significantly different, the value of p must be less than 0.05, thus rejecting the null hypothesis which in this study is that there is no difference between the Algerian and British e-Government services, therefore the alternative hypothesis would be accepted instead. However, if the value of p is greater than 0.05, then the data is deemed to be insignificantly different, and the null hypothesis is accepted. This analytical technique helps researchers identify where the main flaws lie in a certain set of data, and in this case, it shows us which guideline suffers the most in the usability of Algerian and British e-Services and where the biggest difference lies between the two.

## IV. RESULTS AND DISCUSSION

Experts evaluated Algerian and British e-Government services via our proposed questionnaire derived from the three categories of the RBED&UG. The results of each of the seven experts were gathered and inserted into the statistical software SPSS. This software provided us with some important data which will be analysed later on. As expected from the results, the British e-Government services scored higher across all three categories overall as seen in Fig. 1. The Algerian e-Government services scored 2.748, in contrast to the British e-Government services which scored 4.758 in the Page Layout category. For Text Appearance, the scores for the Algerian and British e-services were 2.785 and 4.562 respectively. Finally, in the Graphics, Images & Multimedia, the results followed a similar pattern, where the Algerian e-Government services were inferior to the British services (2.594 and 4.143 respectively), however this category suffered the most compared to the other two categories. Furthermore, each category will be discussed independently later on, and an in-depth analysis will be provided. The null hypothesis and alternative hypothesis will be accepted or rejected relevantly in each of the three categories.

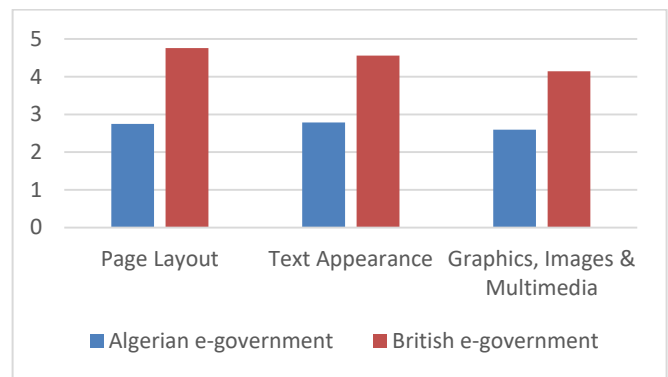

Fig. 1. Chart comparing the mean results of Algerian and British e-Government services across the three selected categories of the RBED&UG

### A. Page Layout

Page layout is the main factor in the user interface; it outlines the position of elements and their dimensions [56]. The most important aspect when designing a page layout is to include necessary information only and to avoid overwhelming the user with unnecessary information that will only lead to confusion and over complication.

With the help of the SPSS software, the researcher was able to extract relevant information as seen in Table VI which presents all this data along with the 13 guidelines of Page Layout that are ranked according to relative importance according to the RBED&UG. The results show that all the guidelines of the Page Layout when comparing the Algerian and British services show significant differences due to the value of p being less than 0.05. Therefore, the British e-Government services according to the experts in this study are significantly different to the Algerian e-Government services. As a result, the null hypothesis for this study is rejected, and the alternative hypothesis is accepted. These results compliment the research conducted by the UN which displays the ranking difference regarding the EGDI, where Algeria falls behind the UK in every attribute of the page layout. Algeria must focus on the page layout as a whole, according to the relative importance of its guidelines to make sure that the most impactful factors of web usability are approached first. According to the experts, the two strongest attributes in the Algerian e-Government services include Establish Level of Importance and Choose Appropriate Line Lengths which both scored 3.571. On the other hand, the experts believed that Choose Appropriate Line Lengths (paired samples statistics mean = 4.929) was the strongest attribute of the British e-Government services. Furthermore, the two lowest scored variables in this section for the Algerian e-Government services include Use Frames when Functions Must Remain

Accessible and Use Moderate White Space which scored 2.429 and 2.500 respectively. Whereas, for the British e-Services, the lowest scored guidelines include Use Frames when Functions Must Remain Accessible and Establish Level of Importance (3.356 and 4.429, respectively). The two highest scoring categories of paired samples test mean values are Structure for Easy Comparison and Use Moderate White Space (both scored -2.143). This variable represents the difference in the level of guidelines between the Algerian and British e-services as identified by the experts. Therefore, this result shows that the biggest difference between the two tested subjects in this study lie in the two abovementioned sections of Page Layout. These results display the areas that require the most attention whilst also simultaneously adhering to the level of importance of these factors to prioritise the level of importance needed to identify which attributes must be first approached or approached with the most attention.

TABLE VI. RESULTS OF THE SPSS ANALYSIS FOR PAGE LAYOUT

Page Layout				
Guidelines	Relative Importance	Paired Samples Statistics Mean (SD) Algerian e-Government & British e-Government	Paired Samples Test Mean (SD)	Significance
1. Avoid Cluttered Displays	5	2.714 (0.184)	-1.929 (0.787)	t=-6.485 p=0.001
		4.642 (0.143)		
2. Place Important Items Consistently	5	3.071 (0.202)	-1.571 (0.731)	t=-5.680 p=0.001
		4.642 (0.180)		
3. Place Important Items at Top Centre	5	2.790 (0.184)	-1.786 (0.756)	t=-6.250 p=0.001
		4.571 (0.170)		
4. Structure for Easy Comparison	4	2.571 (0.202)	-2.143 (0.556)	t=-10.190 p=0.000
		4.715 (0.184)		
5. Establish Level of Importance	4	3.571 (0.170)	-0.857 (0.610)	t=-3.286 p=0.017
		4.429 (0.170)		
6. Optimize Display Density	4	3.286 (0.214)	-1.000 (0.764)	t=-3.464 p=0.013

		4.786(0.149)		
8. Use Fluid Layouts	3	2.714 (0.240)	-2.000 (0.707)	t=-7.483 p=0.000
		4.714 (0.149)		
9. Avoid Scroll	3	2.857 (0.922)	-1.929	t=-27.000

Stoppers		4.786 (0.149)	(0.189)	p=0.000
10. Set Appropriate Page Lengths	3	2.929 (0.202)	-2.000 (0.646)	t=-8.198 p=0.000
		4.929 (0.714)		
11. Use Moderate White Space	3	2.500 (0.110)	-2.143 (0.378)	t=-15.000 p=0.000
		4.643 (0.180)		
12. Choose Appropriate Line Lengths	2	3.571 (0.202)	-1.357 (0.690)	t=-5.203 p=0.002
		4.929 (0.714)		
13. Use Frames when Functions Must Remain Accessible	1	2.429 (0.130)	-0.929 (0.838)	t=-2.931 p=0.026
		3.356 (0.340)		

### B. Text Appearance

Text is the backbone of any website as it expresses and infers a lot about the website whilst also playing a major role in user satisfaction [57]. Therefore, designers must pay more attention to the main points that affect web design usability [58]. Designers must also research the location of their target audience and study their culture as each culture's needs differ [3]. Therefore, further investigation into the level of infrastructures and the level of user adoption must be undergone. Consequently, creating a website with the appropriate font, font size etc. will allow users to become more comfortable while effectively surfing the website. Consistency, and the level of the quality attributes of the content, which include understandability, relevance, accuracy and finally coverage, should also be focused on accordingly as it is crucial when evaluating the usability of text appearance [59], [60].

Table VII which presents the results of the SPSS analysis for Text Appearance also rejects the null hypothesis of this research as none of the p values of its relative guidelines appeared to be greater than 0.05. The analysis also shows that the Algerian e-services matched the British e-services in one category (Emphasis Importance) which holds a relative importance of 2 according to the RBED&UG. The paired samples statistics mean simply represents the average score of all seven experts in their assessment of the level of the attributes within the websites. The results show that for the Algerian e-Government services, use at Least 12-Point Font (4.357) and Use Similar Fonts (4.071) scored the highest. Whereas, for the British e-Government services, the experts believed that Ensure Visual Consistency and Highlighting Information were the strongest attributes of this category, as all experts unanimously agreed to their perfect score of five. On the contrary, the lowest scoring factors of Text Appearance regarding the Algerian e-services belonged to Highlighting Information (1.856) and Use Attention-Attracting Features when Appropriate (2.071). The experts believed that for the British e-Services, the weakest score belonged to Emphasize

Importance (2.786). In addition, the two highest scoring guidelines regarding the paired samples test mean are Highlighting Information and Ensure Visual Consistency, where they scored -3.143 and -2.857, respectively.

TABLE VII. RESULTS OF THE SPSS ANALYSIS FOR TEXT APPEARANCE

Text Appearance				
Guidelines	Relative Importance	Paired Samples Statistics Mean (SD) Algerian e-Government & British e-Government	Paired Samples Test Mean (SD)	Significance
1. Use Black Text on Plain, High-Contrast Backgrounds	4	2.142 (0.210)	-2.143 (0.801)	t= -7.071 p=0.000
		4.186 (0.149)		
2. Format Common Items Consistently	4	2.714 (0.240)	-2.143 (0.748)	t=-7.579 p=0.000
		4.857 (0.092)		
3. Use Mixed-Case for Prose Text	4	3.714 (0.101)	-0.714 (0.636)	t=-2.970 p=0.000
		4.429 (0.170)		
4. Ensure Visual Consistency	4	2.143 (0.210)	-2.857 (0.556)	t= -13.587 p=0.000
		5.000 (0.000)		
5. Use Bold Text Sparingly	3	2.286 (0.184)	-2.714 (0.488)	t=-14.717 p=0.003
		5.000 (0.000)		
6. Use Attention-Attracting Features when Appropriate	3	2.071 (0.202)	-2.429 (0.450)	t=-14.283 p=0.000
		4.500 (0.154)		
7. Use Familiar Fonts	3	4.071 (0.130)	-0.571 (0.535)	t=-2.828 p=0.000
		4.643 (0.143)		
8. Use at Least 12-Point Font	3	4.357 (0.922)	-0.429 (0.345)	t=-3.286 p=0.000
		4.786 (0.101)		
9. Color-Coding and Instructions	2	2.500 (0.154)	-2.500 (0.408)	t=-16.202 p=0.000
		5.000 (0.000)		
10. Emphasize Importance	2	2.786 (0.184)	-1.857 (0.748)	t=-6.569 p=0.011
		2.786 (0.184)		
11. Highlighting Information	2	1.856 (0.210)	-3.143 (0.556)	t=-14.946 p=0.000
		5.000 (0.000)		

### C. Graphics, Images, and Multimedia

Graphics, Images & Multimedia was the densest category amongst the three tested in this study, as it contained a total of 16 guidelines. Graphics, images, and multimedia individually or collectively, play a major role in user interface design. The proper use of graphics can enhance the usability of websites [61]. Studies show that images are a crucial aspect when designing a website [5], [62]. Images also influence the interactive systems of enhancing the positive or negative reaction of the users of websites [63]. On the other hand, multimedia can attract more users and efficiently summarize the message that the designers and the website owners want to deliver to the users [64]. The designer should know the background of the target users to create a website that respects their culture and values [5]. Furthermore, the designer should look to get familiar with the internet speed of the target region, which will dictate the use or lack of graphics, images and multimedia as they can take a while to upload/download or may not upload/download if the internet speed is not enough or if the file is too big. Therefore, designers must ensure that all these factors are considered to avoid failing their target users and avoid providing them with an unattractive website that their internet connection speed is too slow to handle that may potentially disrespect their culture, which ultimately causes the whole website to fail. The abovementioned factors are crucial to the success of any website.

The results from this category (Table VIII) follow a similar pattern to the previous categories, where according to the experts; the British e-Services are a lot superior to the Algerian e-services. Across all guidelines, there is a significant difference between the two tested subjects. However, for Introduce Animation, the value of p is 0.726 which is greater than 0.05 which means that there is no significant difference between the Algerian and British e-Government services in relation to this guideline. Thus, for this category alone which has a relative importance of 2 according to the RBED&UG, the null hypothesis is accepted, and the alternative hypothesis is rejected. The strongest attributes according to the experts regarding the Algerian e-services are Using Photographs of People (4.429) and Include Logos (4.071), whereas the weakest attributes include Graphics Should Not Look like Banner Ads and Ensure Web Site Images Convey Intended Messages which both scored 1.643 according to the average rating of the experts. The Graphics Should Not Look like Banners guideline had the highest paired samples test mean (-3.357) amongst all guidelines of this category. Overall, the results of this category illustrate the shortcomings of the Algerian e-services and how they should approach each category according to its evaluated level by the experts and the relative importance determined by the guidelines.

TABLE VIII. RESULTS OF THE SPSS ANALYSIS FOR PAGE LAYOUT

Graphics, Images, and Multimedia				
Guidelines	Relative Importance	Paired Samples Statistics Mean (SD) Algerian e-Government & British e-Government	Paired Samples Test Mean (SD)	Significance
1. Use Simple Background Images	4	3.429 (0.202)	-1.285 (0.487)	t=-6.971 p=0.000
		4.714 (0.149)		
2. Label Clickable Images	4	2.286 (0.185)	-2.429 (0.535)	t=-12.021 p=0.000
		4.714 (0.101)		
3. Ensure that Images Do Not Slow Downloads	4	1.856 (0.261)	-3.071 (0.732)	t=-11.103 p=0.000
		4.929 (0.714)

16. Using Photographs of People	1	4.429 (0.130)	2.642 (0.801)	t=8.721 p=0.000
		1.787 (0.1184)		

## V. CONCLUSION

This study sheds light on e-government websites that provide electronic services which facilitate communication between government agencies and citizens. User satisfaction influences web design regardless of the domain, therefore their needs and expectations must be met by the developers. The main subject of this study is the Algerian e-Government which according to the UN has an EGDI Global Rank of 120. This rank was surprising for the researcher considering the population size, infrastructure, and economy of the largest country in Africa. Therefore, this study attempted to identify the reasons that may be rooted to the lack of success of Algerian e-Government services at a global level. For this reason, the UK which ranks 7th in the EGDI Global Rank was selected as the second test subject to serve as a comparative tool to help the researcher identify the underlying reasons for the underperformance of these services. However, this study had to decide on an evaluation tool to use to gather relevant data. Consequently, the researcher identified an ideal set of guidelines known as the RBED&UG which was selected in this study due to its exclusivity and popularity in government agencies as the domain of this topic is e-government usability. The interesting factor regarding these guidelines is that it provides relative importance to each guideline. The researcher was really interested by this feature as the researcher believes that the most impactful guidelines must be addressed before the less important ones. Although these guidelines are used as an evaluation when designing websites, the researcher identified the potential of this to be converted into a questionnaire that could be used by experts when evaluating a system. The complexity of certain aspects of these guidelines, or now proposed questionnaire, suggests that it is not appropriate to be evaluated by normal users, but instead by experts within the field. The researcher believes that this proposal can prove to be very effective as experts are able to rate the chapters and guidelines accordingly, thus the developers can really benefit from their evaluation. There are a total of 18 guidelines in RBED&UG; however, after thorough research and information

gathering, the researcher selected only three categories (Page Layout, Text Appearance, and Graphics, Images & Multimedia) due to their proven role in web usability. This research ultimately aims to explore the reasons that influence the usability of Algerian e-Government services via comparing it with UK e-Government services against a set of guidelines. The results were gathered after an experiment which constituted of an expert evaluation of the two selected systems via completing the proposed questionnaires handed out to them. Their results were inputted into SPSS which provided statistical analysis of the set of data. This data helped identify the mean values of each guideline, their standard deviation, and the significance value of each one. The results display the sheer difference in quality between the Algerian and British e-Government services across all three guideline categories. The three weakest guidelines of each chapter for the Algerian e-Government services include Use Frames when Functions Must Remain Accessible, Highlighting Information, and Graphics Should Not Look like Banner Ads (belonging to Page Layout, Text Appearance, and Graphics, Images & Multimedia respectively). The Algerian e-Government services representatives and developers should focus on these results and improve their systems according to the results of this research, giving most attention to the weakest areas as identified by this study whilst also paying attention to their relative importance. The combination of these two integral factors will help provide effectiveness and efficiency during the evaluation and development process of a system.

## VI. LIMITATION AND FUTURE WORK

This study provides solutions specific to the three usability guideline sections researched. Therefore, there is an opportunity for further research to expand on the remaining 15 guidelines of the RBED&UG. In addition, only two countries were examined in this research.

# The Effect of Artificial Neural Network Towards the Number of Particles of Rao-Blackwellized Particle Filter using Laser Distance Sensor

Amirul Jamaludin<sup>1</sup>, Norhidayah Mohamad Yatim<sup>2</sup>, Zarina Mohd Noh<sup>3</sup>

Centre for Telecommunication Research & Innovation (CeTRI)-Fakulti Kejuruteraan Elektronik & Kejuruteraan Komptuer (FKEKK), Universiti Teknikal Melaka (UTeM) Malaysia, Melaka, Malaysia

**Abstract**—Rao-Blackwellized particle filter (RBPF) algorithm aims to solve the Simultaneous Localization and Mapping (SLAM) problem. The performance of RBPF is based on the number of particles. The higher the number of particles, the better the performance of RBPF. However, higher number of particles required high memory and computational cost. Nevertheless, the number of particles can be reduced by using high-end sensor. By using high-end sensor, high performance of RBPF can be achieved and reduced the number of particles. But the development of the robot came at a high cost. A robot can be equipped with low-cost sensor in order to reduce the overall cost of the robot. However, low-cost sensor presented challenges of creating good map accuracy due to the low accuracy of the sensor measurement. For that reason, RBPF is integrated with artificial neural network (ANN) to interpret noisy sensor measurements and achieved better accuracy in SLAM. In this paper, RBPF integrated with ANN is experimented by using Turtlebot3 in real-world experiment. The experiment is evaluated by comparing the resulting maps estimated by RBPF with ANN and RBPF without ANN. The results show that RBPF with ANN has increased the performance of SLAM by 25.17% and achieved 10 out of 10 trials of closed loop map by using only 30 particles compared to RBPF without ANN that needs 400 particles to achieve closed loop map. In conclusion, it shows that, SLAM performance can be improved by integrating RBPF algorithm with ANN and reduces the number of particles.

**Keywords**—SLAM; occupancy grid map; Rao-Blackwellized particle filter; artificial neural network; laser distance sensor

## I. INTRODUCTION

Simultaneous localization and mapping (SLAM) plays an important role in robotics, and particularly in a mobile robot system. SLAM's primary objective is to jointly measure the robot's position as well as map the surrounding of the robot [1]–[5]. The essential of the SLAM algorithm is to map the unknown environment and at the same time exploring the environment. Then, the resulting maps can be used for various applications such as autonomous navigation and search and rescue.

SLAM algorithm commonly used the occupancy grid map (OGM) as a map representation. The maps generate precise metric maps that are close to the detail environmental representations [6]–[8]. This maps require an accurate position of the robot, which makes it a difficult process because of the lack of efficiency of odometric system. The map generated

using raw odometry data only as the position of the robot cannot be sustain and suffers a serious error due to the dead reckoning of odometry system [9]. But these problem can be improved by using Rao-Blackwellized particle filter (RBPF) which can compute more accurate position of the robot. The map is more accurate and globally consistent using RBPF approach. The accuracy of RBPF algorithm is based on the number of particles that required high memory and computational cost [10]–[13]. The higher the number of particles, the more accurate the robot's position and map construction. Therefore it required high memory usage and computational cost to solve the SLAM problem with occupancy grid.

In addition, to achieve high accuracy of occupancy grid map, many notable research have carried out SLAM using high-end sensor to achieve high accuracy map [11], [14]–[18]. Nevertheless, the development of the robot came at a high cost. Therefore, a low-cost sensor could be incorporated to the robot as an alternative to reduce the cost. However, low-cost sensors presented challenges of creating good map accuracy. This is due to the low measurement accuracy of the sensors, which can affect map construction. This problem can be solved by integrating the SLAM technique which is RBPF algorithm with an artificial neural network (ANN) while using low-cost sensors. ANN has been used with occupancy grid maps to interpret noisy sensor measurements and achieved better accuracy of the map [5], [19], [20]. Furthermore, [19] and [5] also shows the number of particles can be reduced with better accuracy of the sensor measurement. Therefore, ANN integrated with RBPF algorithm can reduce the computational cost of the particle filter and achieve better accuracy of OGM. Hence, in this paper, ANN integrated with RBPF algorithm is introduced to improve the sensor measurement and enhance the SLAM technique by using only low-cost sensor.

This paper aims to reduce the number of particles consumption by improving the measurement accuracy of a low-cost laser distance sensor (LDS) and subsequently improve the performance of the SLAM algorithm by incorporating ANN technique with RBPF algorithm. The organization of this paper is as follows: Section 2 reviews the past studies related to the RBPF, sensor measurements accuracy and ANN. Section 3 describes the methodology of the ANN model training and RBPF algorithm framework integrated with ANN. Section 4 analyzes the performance of ANN model after the training and

reports the results of the RBPF algorithm after integrating with ANN. Lastly, section 5 concludes the finding of this paper.

## II. RELATED WORK

The Rao-Blackwellized Particle Filter, also referred to RBPF is employed in the grid-based SLAM algorithm. RBPF is a version of particle filter-based SLAM which is an effective implementation of particle filter-based SLAM. By using Gaussian substructures in the model, RBPF improves the efficiency of the particle filter algorithm [21]. In this approach, RBPF approximates the belief distribution of the robot's pose, while each particle keeps an individual map of the environment, as depicted in Fig. 1. The main contribution of this method is reducing the number of particles used [21]–[24]. This method uses only the most recent observation as well as the most accurate proposal distribution. This can greatly reduce the robot pose uncertainty during filter's prediction step. In addition, the resampling operation is performed selectively in order to address the particle depletion problem. For example in [25], to achieve high accuracy of grid-based SLAM, the classical particle filter required 10000 particles while in [9], RBPF only need 100 particles to achieve high accuracy of SLAM. One of the ROS package implement RBPF algorithm is Gmapping package [26]–[32]. However, since RBPF is based on particle filter-based SLAM, the performance of the algorithm relies on the number of particles. The higher the number of particles, the better is the SLAM performance. This is due to the computation of RBPF itself is based on probability distribution. The higher the number of particles, the higher is the probability to estimate the correct poses and map. As a result, better accuracy of SLAM can be achieved. As in [10], the author shows that with higher number of particles, the map constructed is more accurate than the lower number of particles.

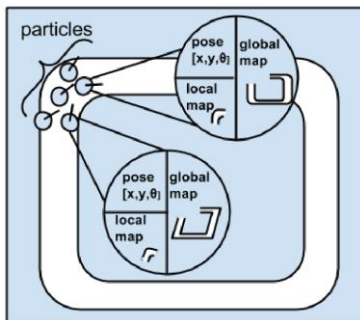

Fig. 1. Each particles contains a hypothesis of robot pose and maintain its own map [10]

A consistent grid-based SLAM algorithm capable to perform loop closure in an unstructured environment. But it requires high precision of the laser scanner to obtain the best hypothesis to build the grid map of the environment. The high precision sensor measurement also can reduce the number of particle usage. For example in [30] and [32], both paper used gmapping package and used the default number of particles which is 30. In [30] the authors successfully achieve high accuracy SLAM by using Hokuyo urg-04lx-ug01 2D lidar which is in high-cost sensor category. While in [32], the map produced is not very accurate since the author only used RGB-D sensor Kinect of Xbox 360 which is low-cost sensor to

perform the SLAM task. But as mention before, low-accuracy SLAM can be mitigated by increasing number of particles. In [10], the author increased the number of particles to 500 to achieve better accuracy SLAM since they used low-cost sensor. However, higher number of particles might suffer from forbidding memory burden and higher computational cost. This problem can be overcome by integrating the SLAM technique with an artificial neural network (ANN) while using low-cost sensors [5], [19], [20], [33]. The noisy dataset from the sensor of the mobile robot are used to train the ANN learner. Afterwards, the ANN model is then applied in the RBPF SLAM algorithm to execute the SLAM task.

In this paper, there are two strategies of dataset that have been reviewed to train the ANN network. Firstly, the training network using the position of each of the grid cells of OGM [5], [19], [33]. Secondly, by using the distance from sensor to obstacles [20]. Firstly, in [19], the author collect the dataset from the front six infrared sensor of E-puck mobile robot as depicted in Fig. 2. Then, the dataset is used as the input layer of the ANN training as shown in ANN configuration in Fig. 3. This ANN is trained to estimate the occupancy probability value  $x, y$  position of the cell. The same architecture of ANN is used in [5], [33]. The authors used the front four sensors' measurements of Khepera III robot that are closest to the cell position as the input of ANN. The same target OGM output of the ANN model which is  $x$  and  $y$  position of the OGM's cell ( $C_{xy}$ ) are used to train the input as shown in Fig. 3.

Fig. 2. E-puck mobile robot is equipped with eight infrared sensors [19]

Fig. 3. A nine-input ANN consisting of infrared sensors, cell position and heading of the robot [19]

While in [20], the dataset is collected based on the reading of the sensor values that contain the estimated distance to obstacle. Then this dataset is trained using ANN to correct the distance measurement to the obstacles by using the real distance as the target output of the ANN. The grid map for the observed region is then built using this corrected measurement. To compute the grid map estimation in this region, only two values are taken into account: 0 for open space and 1 for occupied space (i.e., objects in the space). In the context of computation time, estimation of ANN by using distance to the obstacles is considered faster [20] than estimation by using each of the grid cells [5], [19], [33]. This is due to the estimation by distance does not evaluate cell by cell and only taking value 0 and 1 as mention above. While in the latter approach, the estimation of the map computes each cell of the region by calculating  $x$  and  $y$  cell's occupancy value of the OGM. Cell by cell evaluation can cause slow computation time especially in large environment that required many cells to build the OGM. Hence, real time implementation is not feasible. Therefore, ANN based on the distance is implemented in this paper since it is faster and more suitable for real-time implementation due to the computation does not require for each grid cell but for the entire detected region. The presented methods of ANN training are summarized in Table I.

TABLE I. COMPARISON OF ANN TRAINING METHOD

ANN training method	Input/Output	Pros/Cons
Based on cell-by-cell OGM	Input: Multiple sensor measurement value, cell position $(x, y)$ and robot heading, $\theta$ Target output: Occupancy probability value	Pros: Exploit adjacent sensor measurements and less depending on accuracy of the sensor Cons: slow computation
Based on distance	Input: Sensor measurement value Target output: Actual distance	Pros: Fast computation Cons: more depending on accuracy of the sensor

### III. METHODOLOGY

For the methodology phase, the operation is divided into four phases which is sensor data collection, ANN training, ANN model integrated with RBPF algorithm and lastly, evaluation of the resulting map. Firstly, the LDS data points from the laser distance sensor LDS-01 are collected. The data points are collected from the real-world sensor. These data are collected between the range measurement of 0.12 to 3.5m as shown in Fig. 4(a). At each interval of 0.1m, 2000 measurements were collected. Since LDS-01 sensor is capable to sense 360 degree of the surrounding, the data are taken only at 0 degree. This is because only the measurement at 0 degrees is perpendicular to the wall as shown in Fig. 4(b). The measurements at other degrees facing the wall would not be precisely equal to the ground truth but at longer range as they are slightly slanted towards the wall. Then, these data were used as the input of the ANN training. The actual distance between the mobile robot and the wall was used as the reference or target output.

After the data collection, these data are trained to build ANN model in the second phase. This ANN training employs a multilayer feed-forward network. The architecture of the

network is made up of an input layer, a hidden layer and a single neuron for output layer as depicted in Fig. 5. In this paper, a tangent sigmoidal activation function and a linear transfer function were used for the hidden and output layers, respectively.

Fig. 4. Position of the turtlebot3 to the wall in real-world experiment

Fig. 5. Architecture of ANN model training

After the ANN structure is established, the next step is training the model. A set of input and reference data pairs as well as a training rule are presented during the training procedure. As mention in the first phase, the input is the LDS data point that have been collected and the reference data is the actual distance of the sensor to the wall. The ANN generates its own output from the input and compares it to the reference data. To ensure the difference of the output is small as possible to the reference value, the interconnection weights,  $W$  between the nodes are determined by using training rule. The challenge with learning is finding the optimal weights  $W$  combination

and attempts to minimize the mean-square-error (MSE) between the reference value and the predicted output. The use of a backpropagation algorithm is the most widely used training rule for error minimization. An improved backpropagation algorithm, the Levenberg Marquardt (LM) algorithm, come out to be a faster and more efficient approach for training medium-sized feedforward neural networks [34]–[37]. Therefore, in this paper, the LM algorithm is employed. The output of the network is also computed based on the number of neurons in the hidden layer. The number of neurons in the hidden layer is determined by the response of the output that resulted in the smallest MSE error. At the end of the training phase, 50 number of neurons is selected as the number of neurons which has managed to achieve MSE value of  $9.55 \times 10^{-5}$ .

After the desired ANN model is obtained, the next phase is to integrate the model with Rao-Blackwellized particle filter (RBPF) algorithm as shown in Fig. 6. The RBPF algorithm implemented in Gmapping package of Robot Operating System (ROS) is used in this paper. RBPF requires odometry data as well as sensor observations to solve grid-based SLAM problem. The new sensor observation that has been improved using ANN is integrated in this phase. The main idea of RBPF is to use odometry data,  $u_{1:t-1}$  and observations,  $z_{1:t}$  to estimate the trajectories of robot,  $x_{1:t}$  and map,  $m$ . This joint posterior, which is written as  $p(x_{1:t}, m|z_{1:t}, u_{1:t-1})$  can be factored as follows:

$$p(x_{1:t}, m|z_{1:t}, u_{1:t-1}) = p(m|z_{1:t}, x_{1:t}) \cdot p(x_{1:t}|z_{1:t}, u_{1:t-1}) \quad (1)$$

The computations are made simpler by factorization, which enables the process to be executed in two steps. First, odometry and observation data can be used to estimate the robot's trajectory,  $p(x_{1:t}|z_{1:t}, u_{1:t-1})$ . Once the  $x_{1:t}$  and  $z_{1:t}$  are known, the map  $p(m|z_{1:t}, x_{1:t})$  can be computed.

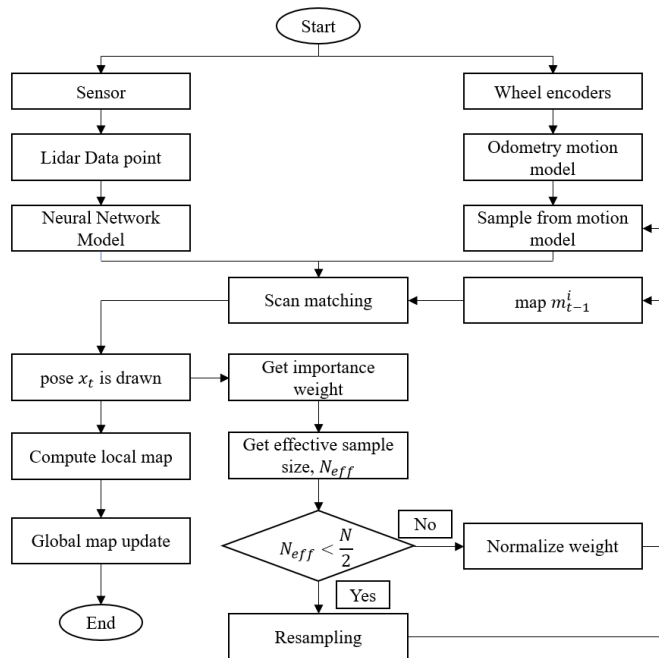

Fig. 6. RBPF algorithm integrated with ANN flow chart

The estimation is more complex with respect to  $p(x_{1:t}|z_{1:t}, u_{1:t-1})$ . A particle filter is used for this purpose where any particle reflects the robot's potential trajectory. Based on the potential trajectory, an individual map for each particles can be computed. Then, the full map is built by the corresponding particles. The sampling importance filter (SIR) is commonly used in this algorithm. The SIR function is used to select the particles with the highest probability and the output of the algorithm is the the associated map. In order to improve the algorithm, the Rao-Blackwellized SIR filter uses the most recent sensor observations and odometry readings where available. Specifically, in RBPF, the approximation of the trajectory  $p(x_{1:t}|z_{1:t}, u_{1:t-1})$  was remodeled to  $p(x_{1:t}|m_{t-1}^i, x_{t-1}^i, z_{1:t}, u_{1:t-1})$  [31]. Scan matching is used to match the observations to the map that has been created so far, optimize observation probabilities, and provide information about the most likely poses of the robot. In this step, accuracy of the sensor measurement is important to get better observation for scan matching step and obtain better pose estimation.

After that, particles are resampled according to their weight. Particles with higher weight will be most likely to be resampled for the next generation. All particles have the same weight after resampling. To avoid the resampling from removing good particles, a careful resampling step is taken. Hence, a selective resampling technique which is effective samples size,  $N_{eff}$  is proposed which is to decide when to perform a resampling step and is described as:

$$N_{eff} = \frac{1}{\sum_{i=1}^N (\omega^i)^2} \quad (2)$$

where  $\omega^i$  represents the normalized weight of  $i$ -th particle. The weights of the samples are approximately equal if they are close to the target distribution. As the samples deviate from the target distribution, their weights variance increases and  $N_{eff}$  decreases. Every time  $N_{eff}$  falls below  $N/2$ , the resampling procedure is initiated (where  $N$  is the number of particles used in the filter). This greatly reduces the risk of replacing useful particles, as resampling is performed only when necessary and the cumulative number of such operations is reduced.

Last phase is to evaluate the performance of RBPF integrated with ANN in real-world experiment. The RBPF with ANN will be compared to RBPF without ANN. The maps that have been obtained from both algorithms respectively will be evaluated with ground truth map using number of inliers evaluation. To evaluate the resulting maps quantitatively, similarities between both maps are measured using number of inliers that are obtained from RANSAC algorithm. RANSAC algorithm can calculate the similarity point (inliers) between resulting maps and ground truth map. The higher the number of inliers, the better the similarity of the resulting map and ground truth map and the better the performance of the map constructed. Ground truth map is obtained by using RBPF algorithm with high number of particles. This is due to the high number of particles can obtained high accuracy of map. In this paper, 1000 particles is used to obtain the ground truth map. Additionally, the robot explored the environment in smaller loops. This process is repeated until a satisfactory ground truth map is obtained. By exploring in smaller loops, the

accumulated error of robot's state estimate is kept to the minimum and robot's trajectory maintain on the correct path and did not diverged. Turtlebot3 robot platform is used in this paper to navigate the environment as shown in Fig. 7. The experiment was conducted at Faculty of Electronics and Computer Engineering Universiti Teknikal Malaysia Melaka. The robot was set to explore wing A of the faculty within the red rectangle by following the path marked using red arrow. The size of this real-world environment is approximately 43 x 16 meters. The Turtlebot3 explored the environment using the teleop operation. The average speed of the robot was about 0.12 m/s and simultaneously recorded by the Rosbag tool. Rosbag tool allows recording and playing back the data of the robot that have been recorded. Hence, the recorded data which is the same data can be applied to other algorithms. This way, RBPF algorithm integrated with ANN and without ANN can be evaluated in equal condition. After that, the RBPF with ANN algorithm was observed if there is any improvement after the ANN integration.

Fig. 7. Layout of wing A of faculty of electronics and computer engineering

#### IV. RESULT

The result is divided into two sections. In the first section, ANN model that have been trained is analyzed by comparing the sensor measurement with ANN and without ANN. Afterwards, in the second section, the RBPF algorithm after integrating with ANN is analyzed by comparing the resulting maps with the ground truth map.

##### A. Performance of ANN

The training of the ANN model has managed to achieve MSE value of  $9.55 \times 10^{-5}$ . 50 number of neurons are selected as it has achieved the lowest MSE value. The synaptic weights in each layer are computed and adjusted according to the lowest mean-squared error (MSE). The training automatically stops when generalization stops improving, as indicated by the lowest MSE of the training samples. Finally, weight and bias vectors for this ANN training were determined after several attempts and ANN model is established.

Afterwards, the ANN model that have been established is analyzed. The performance of the model is analyzed based on the comparison of the sensor measurement before (without ANN) and after the ANN model (with ANN) is used. The data of both sensor measurement for every interval of 0.1m were averaged and plotted in the graph respectively as shown in Fig. 8. The graph shows that the sensor reading without ANN

(green line) is slightly different from the actual distance (red line). The difference of the sensor measurement without ANN and actual distance can be observed in more detail in Fig. 9. The graph shows that the error of sensor measurement without ANN to the actual distance is consistently higher. It is also observed that when the range of the distance increases, the distribution of sensors measurements is wider. Fig. 10 shows the histogram of the LDS sensor measurement at 3 meter distance is wider than the histogram of sensor measurement at 1 meter distance as depicted in Fig. 11. Therefore, the standard deviation of the sensor measurements also increases as the distance increase as shown in Fig. 13.

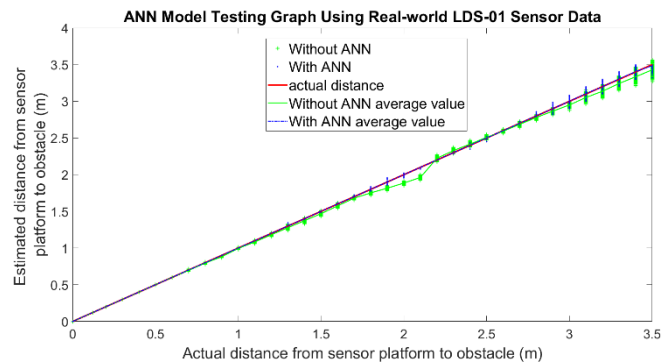

Fig. 8. Graph illustration for the data of ANN model testing using real-world LDS-01 sensor measurements data

Fig. 9. Comparison of error of sensor measurement without ANN (green) and with ANN (blue)

Fig. 10. Histogram of LDS sensor measurement at 3 meter distance

After the LDS sensor data has been applied to the ANN model that have been trained, the value of the data with ANN

(blue line) and the actual distance value (red line) has minimal difference such that the blue and red line are in the same axis as shown in Fig. 8. The error of the sensor measurement also decreased remarkably as shown in Fig. 9. It shows that the non-linearity and the error of the sensor readings are significantly reduced by using ANN. In addition, the histogram of sensor measurement at 3 meter distance using ANN is narrower than the histogram without ANN as shown in Fig. 12. The standard deviation of the sensor measurement with ANN (blue line) is also consistently lower than the standard deviation of the sensor measurement without ANN (green line) as shown in Fig. 13. From these results, it shows that there is a significant improvement of the accuracy of the LDS sensor measurements.

Fig. 11. Histogram of LDS sensor measurement at 1 meter distance (without ANN)

Fig. 13. Standard deviation of LDS-01 sensor data using ANN model before and after testing

### B. Performance of RBPF Algorithm

In this experiment, the number of particles of Gmapping package which is 30 to 400 particles is used. The maps are obtained in the Occupancy Grid map (OGM) representation and saved in pgm format using map saver from map server package. The size of each grid cells of the map is set to  $5\text{ cm}^2$ . In OGM, the black cells are considered occupied, white cells are considered free cells and grey cells are the unknown region that has not been explored yet as shown in Fig. 14. The data that have been recorded is tested 10 times resulting 10 grid maps. Then, the maps that have been obtained using ANN and without ANN are evaluated using number of inliers evaluation to ensure for a consistent result. The dimension of the map is  $1056 \times 608$  cells. Since, the size of the grid cell is  $5\text{ cm}^2$ , this make the size of the real environment in Fig. 14 is approximately  $52.8\text{ m} \times 30.4\text{ m}$ . Within this map, the explored area travelled by Turtlebot3 mobile robot is approximately  $43\text{ m} \times 16\text{ m}$  as stated in Section III.

Primarily, the particles used for the first experiment is 30. From the resulting maps, it is observed that, RBPF algorithm that is not integrated with ANN cannot achieved closed loop condition out of 10 trials as shown in Fig. 15. Most of the resulting maps of RBPF algorithm without ANN show that the algorithm cannot recognize the revisited environment at the loop closure point (green circle) as shown in Fig. 15. This is due to the low accuracy of the LDS sensor measurement reading and consequently effects the RBPF algorithm. To achieve all closed loop condition without using ANN, further experiment is carried out by increasing number of particles. After several trials with increasing number of particles (100, 200 and 400), 400 particles used in the RBPF algorithm without ANN managed to attain loop condition for all trials which is 10 out of 10 as shown in figure 16. The detail results of RBPF with number of particles used are included in Table II. As shown in the table, for 100 and 200 particles, the resulting maps have achieved 4 and 6 closed loop condition out of 10 trials, respectively.

TABLE II. RESULTING MAP CONDITION ACCORDING TO NUMBER OF PARTICLES

SLAM Algorithm	Number of particles	Closed loop map out of 10 trials	Average number of inliers
RBPF without ANN	30	0/10	53
	100	4/10	47.9
	200	6/10	48.5
RBPF with ANN	400	10/10	46.9
	30	10/10	58
	100	10/10	58.3
	200	10/10	61.6
	400	10/10	67.8

It shows that by increasing the number of particles, the accuracy of the grid map can be improved. However, higher number of particles may suffer from limitation of memory capacity and higher computational cost.

Fig. 17 and 18 represent the computational consumption diagrams obtained by the system monitor of Ubuntu for 30 and 400 particles of RBPF algorithm, respectively. The specifications of the computer used are AMD Ryzen 5 3600 GPU 6-core processor with 16GB of RAM. The data is taken after one minute of the execution of one of the tests. It can be observed that RBPF with 400 particles consumed up to 100% of the most cores available during the lapse while 30 particles only consume around 30 to 40% of the cores available. This shows that, higher computational cost is needed to execute higher number of particles.

However, ANN can overcome this problem as mention before by improving the LDS sensor measurement. The ANN model integrated with RBPF algorithm (using 30 particles) is tested 10 times. From the results, it is observed that, RBPF algorithm integrated with ANN have achieved all closed loop map condition which is 10 times out of 10 trials by using only 30 particles. Sensor reading by using ANN has increased the measurement likelihood hence resulting a more accurate estimate in robot localization in the RBPF algorithm. As the localization error has decreased, the robot is able to recognize the revisited area. RBPF with ANN also has proven to achieve this condition with less number of particles more consistently. As a result, we can conclude that the particle consumption can be reduced by integrating ANN with the RBPF algorithm and overcome the computational cost suffers from the high number of particles remarkably. Further experiment by increasing number of particles (100, 200 and 400) is also tested by using ANN. The performance of resulting maps is increased and all resulting maps achieved closed loop condition. As mention in section III, the performance of the resulting maps is compared with the ground truth map (Fig. 14) by using number of inliers. The number of inliers is stated in Table I along with the number of particles.

Then, Fig. 19 plots the performance of the resulting maps by using the number of inliers (y-axis) vs the number of particles (x-axis). As shown in the graph, by using ANN integrated with RBPF, the performance of the resulting maps (red) is consistently higher than the resulting maps without ANN (blue). The performance using ANN is increasing with the number of particles while for RBPF without ANN, the performance is decreasing. We believe that the performance without ANN is decreasing because of the dimension of the resulting maps (without ANN) is less similar to the ground truth map. By using 400 particles (without ANN) better pose estimation is achieved compared to lesser particles. Due to that, closed-loop map condition is achieved when the robot explored the environment and encountered the initial position. Although closed loop map condition is achieved, the dimension of the resulting map is not consistent due to the nonlinearity error of the LDS sensor measurement. As shown in the graph, 30 and 200 particles have achieved higher number of inliers, while 100 and 400 particles achieved lower number of inliers. Due to that, the performance of the resulting maps is not consistent

along the number of particles. Fig. 20 shows one of the examples of the number of inliers point between resulting map (without ANN) and ground truth map by using 400 particles. The dimension of the resulting map (without ANN) is 15.7 m x 42.6 m while ground truth map is 15.9 m x 43 m. Since the dimension of the map is slightly smaller to the ground truth map, hence, only 42 number of inliers point is obtained.

### C. Discussion

It is observed that when using ANN, the quality of the resulting maps is increasing with the number of particles as expected. This is due to the more accurate sensor measurements. Better sensor measurement improved the observation of the robot for scan matching step and obtained better pose estimation as mentioned in Section III. Due to that lower number particles can be used to achieve higher performance of the map building and closed loop condition. For this experiment, only 30 particles are used to accomplished the closed loop condition. Besides, better resulting map is achieved and more similar to the ground truth map by increasing the number of particles using ANN compared to without ANN. As shown in Fig. 21, the number of inliers point between the resulting maps (with ANN) and ground truth map is higher which is 77 inliers compared to without ANN which is 42 as shown in Fig. 20. This is due to the dimension of the map (with ANN) which is 15.95 m x 43.10 m is more similar to the ground truth map (15.9 m x 43 m) compared to without ANN (15.7 m x 42.6 m). Based on the average number of inliers, the overall performance of the resulting maps by using RBPF with ANN has increased by 25.17%. In conclusion, with better accuracy of the sensor measurement integrated with ANN reduces the number of particles consumption. Therefore, ANN can reduce the computational cost of the RBPF algorithm and achieve better accuracy of OGM by using only low-cost sensor.

## V. CONCLUSION

This paper presented the effects of the ANN towards the number of particles of RBPF algorithm using laser distance sensor LDS-01. An investigation has been made to observe the performance of the RBPF algorithm by using ANN and without ANN. The performance of the algorithm is calculated based on the accuracy of the map constructed by both algorithms. Based on the results, RBPF with ANN has achieved all closed loop condition of the resulting maps which is 10 times out of 10 trials by using only 30 particles compared to RBPF without ANN that needs 400 particles to achieved all closed loop condition. Furthermore, the number of inliers of the resulting maps by using RBPF with ANN is higher than RBPF without ANN consistently for the number of particles ranging from 30 to 400 particles and increase the performance by 25.17%. From the results, it can be concluded that using ANN improves the performance of the RBPF algorithm and reduces the number of particles consumption for mobile robot platform with low-cost sensors. For the future works is to test the SLAM algorithm integrated with ANN on cooperative robot. Cooperative robot SLAM has many advantages, including the ability to complete missions quicker and being resilient to the malfunction of any one of the robots. To obtain high accuracy of the cooperative SLAM, many researchers chose to adopt high-end sensor such as 2D SICK and Hokuyo Lidar as robot's perception. But this will cause staggering cost for cooperative robot system. Thus, the alternative is to implement low-cost sensors with limited sensing to perform cooperative SLAM.

## ACKNOWLEDGMENT

We (the authors) would like to acknowledge and express our gratitude to Centre for Research and Innovation Management (CRIM), Centre for Telecommunication Research & Innovation (CeTRI), Fakulti Kejuruteraan Elektronik dan Kejuruteraan Komputer (FKEKK), Universiti Teknikal Malaysia Melaka (UTeM) and the Ministry of Higher Education Malaysia for the grant RACER/1/2019/TK04/UTEM//5 for providing us with the opportunity, facilities, and finances to conduct this study. We also would like to thank Mr. Hee Thien Tack, Mrs. Fatini Kamaruzaman and Mr. Mahadi Salleh for the technical support during this research.

**Abstract**—Community detection is a method to determine and to discover the existence of cluster or group that share the same interest, hobbies, purposes, projects, lifestyles, location or profession. There are some example of community detection algorithms that have been developed, such as strongly connected components algorithm, weakly connected components, label propagation, triangle count and average clustering coefficient, spectral optimization, Newman and Louvain modularity algorithm. Louvain method is the most efficient algorithm to detect communities in large scale network. Expansion of the Louvain Algorithm is carried out by forming a community based on connections between nodes (users) which are developed by adding weights to nodes to form clusters or referred to as clustering relationships. The next step is to perform weighting based on user relationships using a weighting algorithm that is formed by considering user account activity, such as giving each other recommendation comments, or to decide whether the relationship between the followers and the following is exist or not. The results of this study are the best modularity created with a value of 0.879 and the cluster test is 0.776.

**Keywords**—Community detection; Louvain algorithm; modularity; network clustering relationship

## I. INTRODUCTION

Social networks become a well-known instrument to disseminate information and to connect people who have the same thoughts. Public accessibility of this network with the capability to share opinions, thoughts, information and experience, offer tremendous promises for companies and governments. Apart from individuals who use this network to connect with friends or relatives, many companies and governments start to leverage social network platform to deliver their services to the society, citizen and client. Trust is a crucial issues of an effective social network. A social network is defined as a graph that contain set of nodes. Nodes represent objects, actors, people, or organizations while links express collaborations, communications or interactions. A complex network shows a very dense (such as a network of friendships or collaborator) or sparse network[1] [2][3][4].

Social network has received much attention and has been studied during the last decades including community detection in large and complex network[5] The aim of community detection is to divide the network and to illustrate this network in graph's form. The nodes (objects, actors, people, or organizations) that have relationship or correlations are said to be in the same community. Community can be used to obtain various purposes (such as finding targets who like similar product, encounter target markets, defining product ratings popularity, determining product recommendations and much

more [6]. There are lots of information on social media that can be used to cluster the data based on their similarity. Individuals can find peoples' biodata or what they share in their social media. This behavior definitely influenced the consequences of user curiosity. This research will form communities based on books at Gramedia Pustaka Utama.

Clustering is the assignment to separate the object inside the population into number of groups based on certain characteristic. Community will be detected based on the obtained information. Unfortunately, there are some drawback on the previous community detection algorithm. The previous algorithm could not perform well on large data set. Most studies, maximize the quality function to determine the community. This method known as modularity. In modularity, the nodes inside the same community are highly connected but loosely linked to nodes outside their community[7]. Modularity maximization calculates the quality of a particular clustering of a network into communities. It is a matter of processing speed and most of its algorithm use heuristic technique. Amongst the most efficient modularity maximization algorithm is using Louvain method. Louvain methods is a method to extract communities form large scale network. The results obtained from Louvain method give good modularity quality which describe the closeness relationship between nodes. This closeness relationship will be used to compute the confidence level of users in the recommendation system that will be developed[8][9]. Throughout developing Louvain algorithm, the usage of large amount data set from social media network is capable and will generate fast clustering relationship.

Social network influenced the behaviour of users. Therefore, in this research a recommendation system was developed based on the relations that were obtained from the social network[10]. The necessary step to implement clustering relationship formation was by performing scrapping. Scrapping was achieved to obtain relation on Gramedia Pustaka Utama account. The steps taken are scrapping first to get existing relationships with Instagram accounts, then doing weights and forming clusters by developing the Louvain algorithm. The purpose of this study is to develop the Louvain algorithm to produce clustering relationships so that you can see your circle of friends on Instagram social media. The results of this study can be used to produce a recommendation system that is not only based on ratings and reviews, but based on clustering relationships. Purity is used to measure the success of the clusters formed.

## II. LITERATURE

### A. Community Detection Algorithm

Detecting communities is a very essential task as communities helps us in grouping users showing similar behaviour and in this way the social network can be divided into different clusters of nodes with same behaviour. This community information can help us take useful decisions and extract important information about users in a particular community [11].

Community detection is an algorithm to create groups or partitions and to evaluate the formations of these groups. There are many community detection algorithm propose by different researchers, such as :

- Strongly connected components (SCC) are one of the initial graphing algorithms. This algorithm was described by Tarjan in 1972. SCC algorithm defined directed graph into strongly connected components which is a classic application of depth-first reach algorithm [12][13].
- Weakly Connected Components or Union Find algorithm found set of connected nodes in undirected graph, where each node is reachable from any other nodes in the same set. Weakly Connected Components is different from SCC. This algorithm only require an existing path between a pair of nodes in one direction, whereas SCC algorithm requires path to exist in both direction. Like SCC, Weakly Connected Component algorithm often used as initial stage in analyzing the graph's structure [13].
- Label Propagation Algorithm is a fast algorithm to discover communities in graphs. To detect a community using the structure of the network does not require any predefined objective functions nor prior information regarding the community. One of the interesting features of Label Propagation Algorithm is that the algorithm has the option to control the initial label to narrow down the obtained solution. At initial stage, each node has a unique label. Afterwards, labels are assigned iteratively to nodes in a random sequential order in such a way that nodes take the most frequent label of its neighborhood. The label relocation unites when there is no more alteration in the node label. Groups of nodes that have identical nodes at convergence form communities. Although this approach is efficient and does not require user-defined parameter, it is not deterministic due to the random choice of nodes to be labeled and the possibly large number of edges explored during the iterations [14].
- Triangle count and average clustering coefficient algorithm computes the number of triangles in the graph. Triangle is three set of nodes where each node is connected to the other two. In graph terminology triangle is known as 3-clique. The Triangle Count algorithm in Graph Data Science (GDS) library discover triangles only in undirected graphs. Triangle count has gained popularity in Social Network Analysis (SNA). This algorithm is used to detect communities and to measure

the cohesiveness of these communities. It also can be used to define the constancy of a network. Moreover, triangle count can be employed to compute the networks' indexes, such as clustering coefficient and local grouping coefficient [15].

- Another method for community detection is a spectral approach by Newman, which is a top-down hierarchical one that depends on eigenvectors of the modularity matrix. This approach works by iteratively separating the network into two components so that the modularity is maximized.[16]
- Another commonly used method for community detection is based on the modularity maximization , which calculates the quality of a particular clustering of a network into communities. The intuition behind modularity is that nodes inside the same community are highly connected but loosely linked to nodes outside their community.[17][18]
- Louvain modularity is an algorithm for detecting communities in a network. This algorithm maximizes modularity value of each community. Modularity quantifies the quality of assigning nodes to the community by evaluating how much more tightly connected the nodes in the community are, compared to how connected they would be in a random network. Louvain algorithm is one of the fastest modularity algorithm that perform well on large scale graph. This algorithm reveals the hierarchy of communities at different scales, which is useful for understanding the global functioning of the network. To understand Louvain's modularity algorithm, it is important to learn modularity in general.

It can be said that community detection is an effort and process to determine and find a group of people who have the same or the same interests. Community detection or clustering graph becomes part of data analysis in various fields; computer science, science, social network analysis and internet applications. As the data grows on exploratory power. Community detection is widely used in graph analysis. Given the graph  $G = (V, E)$ , the goal of the community detection problem is to identify the partitioning of nodes into "communities" (or "clusters") so that related nodes are assigned to the same community and different or unrelated nodes are assigned to the same community. Different. The community detection problem differs from the classic graph partition problem in that neither the number of communities nor their size distribution are known a priori. Due to its ability to uncover structurally coherent node modules, community detection has become a structure discovery tool in a number of scientific and industrial applications, including biological sciences, social networking, retail and finance.

The concept of community detection exists in network science as a method for finding communities in complex systems through graphical representations. The community detection method finds subnetworks statistically between nodes or graphs in the same community rather than nodes in different communities [19].

The core of community detection is the idea of modularity, a metric of which differs below:

$$Q = \frac{1}{2m} \sum_{i,j} A_{ij} \left( A_{ij} - \frac{k_i k_j}{2} \right) \delta(g_i, g_j) \quad (1)$$

In the above difference Q is modularity,  $A_{ij}$  is the edge weight between vertices  $i$  and  $j$ ,  $k_i$  is the total weight of all edges connecting node  $i$  with all other vertices, and  $2m$  is the total weight of all edges in the graph. The Kronecker delta function  $\delta(g_i, g_j)$  will evaluate to one if the nodes  $i$  and  $j$  belong to the same group, and are zero. Modularity is the defining state of how one decides to divide the network. An unshared network is a network in which each node in its own community will have a modularity equal to zero. The goal of community detection is to find a community that can maximize modularity. There are many efficient algorithms to maximize modularity, including spectral clustering [16] [20]. Fig. 1 shows multiple networks with maximum increased modularity. Notice how the community structure becomes clearer as the value of modularity increases.

Fig. 1. Networks with different maximum modularity (Blondel et al., 2008)

### B. Louvain Algorithm

Louvain's algorithm shows an algorithm that directly maximizes modularity with 2 phase algorithm. This first algorithm consists of nodes moving one by one in one of the neighboring communities to get the maximum increase in modularity, the nodes can be moved multiple times and this procedure stops if maximum locales are obtained, that is, when there is no more movement which increases the modularity. The second algorithm is the formation of a Meta graph where the nodes are the communities found in phase 1 and the links represent the number of connections between communities. The Louvain algorithm is an unsupervised algorithm that does not require input on the number of communities or size before running. The Louvain algorithm is divided into 2 phases, namely Optimizing Modularity and Community Aggregation.

Louvain's algorithm is one of many algorithms for community detection. One of the advantages of the Louvain Algorithm is that it detects communities with maximum modularity and is also faster than other algorithms.

Louvain's algorithm was first introduced to find the Newman-Girvan high partition modularity.

$$M = \frac{1}{2m} \sum_{i,j} A_{ij} (A_{ij} - p_{ij}) \delta(c_i, c_j) = \frac{1}{2m} \sum_{i,j} A_{ij} \left( A_{ij} - \frac{k_i k_j}{2m} \right) \delta(c_i, c_j) \quad (2)$$

$A_{ij}$  is the neighbor matrix entry which represents the weight of the edge connecting vertices  $i$  and  $j$ ,  $k_i = \sum_j A_{ij}$  is the degree of the node  $i$ ,  $c_i$  is the community,  $\delta(c_i, c_j)$  value 1 if  $c_i = c_j$  and 0 if otherwise.  $m = \frac{1}{2} \sum_{i,j} A_{ij}$  is the sum of the weight of all sides on the graph.

Fig. 2. Illustration of a community formed with louvain's algorithm

Louvain's algorithm in Fig. 2. finds two communities with three members on each community. Andien, Alice and Fatin are friends with each other, as are Roy, Ana and Bobby. Roy is the only one who has friends in both communities, but Roy has more friends who have the same characteristics in community two therefore Roy is in that community.

### C. Modularity

Modularity is a measure of how well a group has been partitioned into clusters. It compares the relationships in a cluster against what is expected for a random number of connections. Criteria is known as modularity, its definition involves a comparison of the number of in-cluster links in a real network and the expected number of links in a random graph (regardless of community structure)[7].

## III. LITERATURE

The steps taken to form clustering relationships are as shown in Fig. 3.

Fig. 3. System architecture

In Fig. 4, the system architecture begins with collecting data sets from Gramedia Pustaka Utama. The information obtained from Gramedia Pustaka Utama was related to the object of research, namely bookstores and novels.

Fig. 4. Stages of forming a clustering relationship

After collecting the data set, the preprocessing stage is carried out using a social-based concept to take into account the relationship between users and other users in a social networking application service. The stage that is done is by

doing scrapping to get connectedness between users and aims to see how much users trust other users (shown in Fig. 5).

Fig. 5. Scrapping stage

Network connectivity on Gramedia Pustaka Utama was given a weight and then community detection is carried out using the Louvain method. The next step is to build a trust matrix which is represented by the results of weighting and relationship. This procedure is called a clustering relationship. The next stage is to compute the level of similarity of a user. In this stage every user will produce a rating prediction using collaborative filtering based similarity

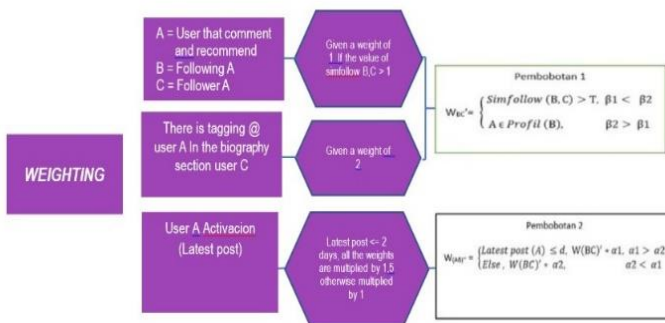

Fig. 6. Weighting process

The weighting procedure is a process that was performed to compute the trust value between users. The process was expected to obtain cluster's weight or value when creating a cluster relationship. This weight or relation value can be used in forming matrix trust. The weight is based on the relationship between A, B, C, users who recommend others and the activeness of user.

The weighting was performed in 2 stages. The first stage was computing the closeness of relationship using variable 1 as WBC (WBC weight). The given value for variable  $\beta_1$  is 1 and for variable  $\beta_2$  is 2. The second stage of the weighting process is to see user's activity. This step is require to obtain the users that are active to form a cluster. The variable that used for 2 is WAB (WAB weight). The given value for variable  $\alpha_1$  is 1.5 and for variable  $\alpha_2$  is 1 as shown in Fig. 6.

In algorithm, weight 1 is the weight for user A who has proximity (simfollow) between B and C > the threshold value, then it is being given weight of 1 and if in Biography C there is a tagging @user A then it is given weight of 2. The value of weigh 1 is set to variable  $\beta_1$ , the weight value of 2 is set to variable  $\beta_2$  where  $\beta_1 < \beta_2$ .

The next step is performed by increasing the weight level. For the second weighting, the weight can be given by looking at user activity (User A) from user A's last post. If user A's last post is less than 2 days, then all user A's weights are multiplied by 1.5, if not multiplied only by 1.

### Algorithm 1: Weighting Algorithm

Input : User A

Output: Followers A(C)

Following A (B)

1. Get Follower A
2. Get Following B
3. Give a weight of 1, if the followers intersect with the following, and give a weight of 2 if the Follower C user has a user A tag in the biography section, using a weighting formula 1:

$$W_{BC} = \begin{cases} Simfollow (B,C) > T, \beta_1 < \beta_2 \\ A \in Profil (B), \beta_1 > \beta_2 \end{cases}$$

4. If the latest post is less than or equal to 2, the weight is multiplied by 1.5 for users connected to the A besides that the weight is multiplied by 1, using the weighting formula 2 :

$$W_{AB} = \begin{cases} Latest Post (A) \leq d, W(BC)' * \alpha_1, \alpha_1 > \alpha_2 \\ Else, W (BC)' * \alpha_2, \alpha_2 < \alpha_1 \end{cases}$$

The multiplier of 1.5 is assigned a variable ( $\alpha_1$ ) and the multiplier of 1 is assigned a variable ( $\alpha_2$ ). The value of  $\alpha_1 < \alpha_2$ . This function is to indicate the activeness of the user. For example, user Osterdamm (A) comments on the book 'The Miracle of Mindbody Medicine\_New', (B) is a user in Following Osterdamm, (C) is all Follower Osterdamm users if they are related or are friends then they are given a weight of 1, if Follower Osterdamm in his biography has the tag '@Osterdamm' then it is given a weight of 2, if Follower Osterdamm last posted less than 2 days then the weight is multiplied by 1.5.

## IV. RESULT

Community detection is a method to find communities in a large and complex network. This method optimized modularity. There are many algorithm to maximize modularity. For example spectral clustering (Newman, 2006) and fast unfolding (Blondel et al., 2008). This research propose Louvain algorithm to detect communities. Louvain algorithm is considered the most suitable method to detect the communities since the algorithm works well on large and complex network. This algorithm does not require data input (Unsupervised learning). Moreover the algorithm can form clusters/communities faster compare to other algorithms. Louvain algorithm is the development of the existing community detection algorithms. Louvain is unsupervised learning algorithm. It does not require input of communities' size or number. The algorithm is divided into two phase; Modularity optimization and community aggregation. Modularity is used in this research to measure how well a group has partitioned into clusters.

Below is the equation to compute modularity:

$$M = \frac{1}{2m} \sum_{i,j} (A_{ij} - p_{ij}) \delta(c_i, c_j) = \frac{1}{2m} \sum_{i,j} (A_{ij} - \frac{k_i k_j}{2m}) \delta(c_i, c_j) \quad (3)$$

$A_{ij}$  is the adjacency matrix that represent the edges weight which connect node  $i$  and node  $j$ ,  $k_i = \sum_j A_{ij}$ .  $A_{ij}$  is the degree of node  $i$ ,  $c_i$  is its community,  $\delta$ -function  $\delta(u, v) = 1$  if  $u = v$  and 0 otherwise.  $m = \frac{1}{2} \sum_{ij} A_{ij}$  is the sum of all weight in a graph.

Fig. 7. A simple graph

Fig. 6 shows a graph with 5 nodes (U1, U2, U3, U4 and U5) and 5 edges (U1-U3, U3-U4, U4-U5, U5-U2, U2-U1). According to the definition of Neighbor Matrix explained by  $A_{ij}$  in the previous section, it will look like Table I.

TABLE I. TABLE GRAPH REPRESENTATION IN MATRIX

	U1	U2	U3	U4	U5
U1	0	1	1	0	0
U2	1	0	0	0	1
U3	1	0	0	1	0
U4	0	0	1	0	1
U5	0	1	0	1	0

Considering assigning the partition as:

Partition 1, U1-U1, U3, U4

Partition 2, U2-U2, U5

Using Modularity equation (1)

1) Node U1 to U1

$$Q = 1/2 * 5((0 - 2 * 2)/(2 * 5)) * 1$$

#node U 1 – U 1

Same member (one partition)

2) Node U1 to U2

$$Q = 1/2 * 5((1 - 2 * 2)/(2 * 5)) * 0$$

#node U 1 – U 2

Not the same member (not one partition)

3) Node U1 to U4

$$Q = 1/2 * 5((0 - 2 * 2)/(2 * 5)) * 1$$

#node U 1 – U 4

Same member (one partition)

4) Node U1 to U5

$$Q = 1/2 * 5((0 - 2 * 2)/(2 * 5)) * 0 \text{ #node U 1 – U 5}$$

Not the same member (not one partition)

5) Node U1 to U3

$$Q = 1/2 * 5((1 - 2 * 2)/(2 * 5)) * 1$$

#node U 1 – U 3

Same member (one partition)

Modularity optimization in this research is illustrated as follows.  $\sum_{in}$  is the sum of edges' weight in  $C$ ,  $\sum_{tot}$  is the sum of all edges to node in  $C$ ,  $k_i$  is the sum of weight from all edges in node  $i$ ,  $k_i, in$  is the sum of edges from node  $i$  to node inside community  $C$  and  $m$  is the sum of weights from all edges in the graph.

Louvain Algorithm PASS 1 and Louvain Algorithm PASS 2. The first step in Louvain Pass 1 algorithm is to select the initial node and computing the modularity transformation that might occur when a node join and formed community with this node close neighbor. The next step is that initial node join the node with the highest modularity change. This process will be repeated for each node until the community is formed. Communities are combined to create super communities and relationships between this super node counts as the sum of the previous links (Self-loop represents the previous relationship and is now hidden in the super node) The resulting graph using the Louvain PASS 1 algorithm can be seen in Fig. 7.

Fig. 8. The created graph with PASS 1 algorithm

The steps for creating a graph in the Louvain PASS 1 algorithm are as follows:

**Algorithm 2: LOUVAIN PASS 1**

Require :  $G = (V, E, w)$  a weighted graph

Ensure : a partition  $P$  of  $V$

Local : increase  $\leftarrow$  true

Local :  $P$  current partition of  $V$

Begin

Forall the nodes  $I$  do

$P[i] \leftarrow \{i\}$

INIT ( $i$ )

While increase do

increase  $\leftarrow$  false

forall the nodes  $i$  do

Remove ( $i, C_{old}$ )

$C \leftarrow P[j] \mid (i, j \in E) \cup \{C_{old}\}$

$C_{old} \leftarrow P[i]$

$C_{new} \leftarrow \operatorname{argmax}_{c \in c} \{GAIN(i, C)\}$

INSERT ( $I, C_{new}$ )

if  $C_{old} \neq C_{new}$  then

increase  $\leftarrow$  true

The resulting graph using the Louvain PASS 2 algorithm can be seen in Fig. 8 below:

Fig. 9. The created graph with PASS 2 algorithm

The steps for creating a graph in the Louvain PASS 2 algorithm are as follows:

**Algorithm 3: LOUVAIN PASS 2**

Require :  $G = (V,E,w)$  a weighted graph

Ensure : a partition  $P$  of  $V$

Begin

Repeat

$P \leftarrow \text{ONEPASS}(G)$

$G \leftarrow \text{Partition} - \text{to} - \text{Graph}(P,G)$

until no improvement is possible

In the Louvain PASS 2 algorithm, steps 1 and 2 are repeated in the path until no further growth in modularity. The PASS 2 algorithm will also repeated until the number of iterations has occurred.

In the initial research conducted using the Louvain PASS 1 and PASS 2 algorithms, the resulting graph can be seen in Fig. 9 and Fig. 10.

Modularity for best partition: 0.9568860789869055

Fig. 10. Visualization of clustering relationship using the louvain pass 1 algorithm

Fig. 9 shows the obtained graph using Louvain algorithm. This figure created from some of the data (219570 data from Gramedia Pustaka Utama’s users). The visualization of Louvain PASS 2 algorithm can be seen in Fig. 10. The obtained value of modularity is 0.5, indicating that the community detection was not good enough.

The proposed Louvain algorithm. In the previous Louvain Algorithm, there are 2 phases of modularity formation. The developed algorithm starts from the input which is the result of weighting the nodes to form communities. The formation starting by defining different communities of each network node. In the initial partition, the number of communities is equal to the number of nodes.

Fig. 11. Visualization of clustering relationship using the louvain pass 2 algorithm

**Algorithm 4: LOUVAIN MURNI**

Input : Dataset of relations between Instagram users

Output : Clustering Relation Graph, list of cluster member

1. Random user to be used as a start point (make  $S$  variable)
  2. Remove users who are neighbors with  $S$  (save to variable  $N$ ) from cluster 1 to a new cluster (cluster 2)
  3. Compute modularity (make it  $mod\_new$  variable); using the modularity formula:
- $$M = \frac{1}{2m} \sum_{i,j} (A_{ij} - p_{ij}) \delta(c_i, c_j) = \frac{1}{2m} \sum_{i,j} (A_{ij} - \frac{k_i k_j}{2m}) \delta(c_i, c_j)$$
4. If  $mod\_new$  is greater than  $mod$ , make  $X=X+1$  and set  $mod = mod\_new$ , if smaller than return to cluster 1
  5. Set  $S = N$
  6. Repeat step (4) ,until all users are counted

For each node  $i$ , the neighboring nodes  $i$ , namely node  $j$  will be considered. Then the value of obtained modularity will be evaluated by removing node  $i$  from its community and then placing node  $i$  in the community of node  $j$ . Node  $i$ , then positioned in the community that provides the greatest value of profit, but only if the value of the gain is positive. If there is no possibility of a positive profit value, node  $i$  will remain in the community from which the node originated. This process will be repeated successively for all nodes until no further improvement can be achieved. With the fulfillment of these conditions, the first phase of the algorithm in this study has been completed.

The previous Louvain algorithm which consists of 2 Louvain phases produces a super cluster which is only a few large clusters. Pure Louvain Algorithm which was developed to get user clusters that have relationships obtained from the previous weighting process, this is needed for the stage of forming a recommendation system based on Trusted Friend.

The results of the pure Louvain Algorithm will be represented in the form of a graph, a list of cluster members and the relationships between users

V. PURITY APPROACH

Purity or a measure of purity historically was the first measurement used in the context of community detection used by Girvan and Newman in their article. Purity has gone by a variety of different names in several articles making it difficult to name a complete list. The purity of a part relative to part Y is expressed in the following equation:

$$Pur(x, Y) = \max \frac{nij}{ni+} \quad (4)$$

In other words, the first thing to do is to identify the part with the largest intersection and then calculate the proportion of the elements. The greater the intersection and the greater the purity value, the greater the correspondence between the two parts being analyzed. Then the total partition X relative to the partition is obtained by adding up the purity of each xi, then given a weight using the following equation:

$$Pur(X, Y) = \sum_i \frac{ni+}{n} Pur(xi, Y) \quad (5)$$

The upper limit on purity is 1, which corresponds to a perfect match between each partition, while the lower limit is 0 which is the opposite value of the upper limit. Purity is not a symmetrical measure, meaning that in the process, purity is relative to the amount considered in each part. Therefore, in general PUR(X,Y) is not the same as PUR(Y,X).

From a community detection point of view, two different purity measurements can be used, depending on whether to calculate the estimated community purity relative to the true value, or vice versa. In cluster analysis, the first version is generally used, and is called simply Purity, while the second version is Inverse Purity. It is difficult to determine which one is actually used in the case of existing community detection. Girvan and Newman provide a very concise description of the size being processed. Purity tends to favor algorithms that identify many small communities. In the most extreme case, if the algorithm identifies n communities containing one node each, one of the clusters gets the maximum purity, because each estimated community is perfectly pure. In contrast, reverse purity supports algorithms that detect multiple large communities. The most extreme case occurs when the algorithm places all nodes in the same community, then a cluster gets the maximum purity, because each community is actually perfectly pure: all the nodes it belongs to belong to the same estimated community. To solve this problem, Newman introduces an additional solution: when the estimated community is majority in some actual community, all the nodes in question are considered to be the wrong classification. The solution generally adopted in cluster analysis consists mainly of processing the F-Measure, which is the average of the harmonics of the two purity versions:

$$F(X, Y) = \frac{2.Pur(X*Y*Pur(Y,X))}{Pur(X,Y)+Pur(Y,X)} \quad (6)$$

The measure obtained from the above equation is symmetrical, and this combination is expected to resolve the aforementioned bias. This approach provides a solution in a similar way by underestimating and overestimating the number of communities. The purity value is calculated for all clusters formed, namely 27 clusters. Calculating the purity value,

starting from the cluster that has a majority value to users who tag the preferred book, as shown in Table II below.

TABLE II. THE OVERALL PURITY OF THE CLUSTER

	Lower Bound	Maximum	Purity
Cluster 1 until Cluster 27	0.0	1	0.776

For example, Cluster 1 the majority value is 25, Each cluster is calculated as the majority value, so that the total of the entire cluster has a purity value of 0.776 as shown in Fig. 11:

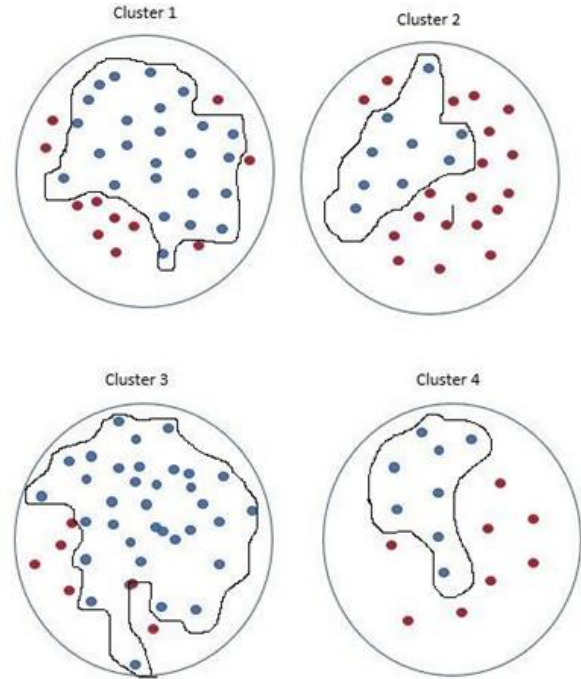

Fig. 12. Purity as an external evaluation criterion for the quality of cluster 1 to cluster 27.

VI. CONCLUSION

Based on a number of tests and analysis of the results of this study, it can be concluded that:

- 1) The social network on Gramedia Pustaka Utama account forms a clustering relationship that is used for the recommendation system by weighting and community detection. The weighted value (α, ) given is proven to affect the results of the community that is formed.
- 2) Clustering Relationship succeeded in forming clusters using the Louvain algorithm, as many as 27 clusters with the best value of high modularity, namely 0.879.
- 3) The value of the modularity of the community that is formed is influenced by the number of relationships between community members where the denser the relationships in the community, the value of modularity will increase or be higher.
- 4) The use of algorithms with modularity optimization has slightly better results because modularity shows how well the community on the network is.

5) Evaluation of the cluster formed using purity produces a satisfactory value of 0.776.

# Implementation Failure Recovery Mechanism using VLAN ID in Software Defined Networks

Heru Nurwarsito<sup>1</sup>, Galih Prasetyo<sup>2</sup>

Faculty of Computer Science, University of Brawijaya, Malang, Indonesia<sup>1,2</sup>

**Abstract**—Link failure is a common problem that occurs in software-defined networks. The most proposed approach for failure recovery is to use pre-configured backup paths in the switch. However, it may increase the number of traffic packets after the traffic is rerouted through the backup path. In this research, the proposed method is the implementation of a failure recovery mechanism by utilizing the fast failover group feature in OpenFlow to store pre-configured backup paths in the switch. The disrupted traffic packets will be labeled using the VLAN ID, which can be used as a matching field. Due to this capability, VLAN ID can aggregate traffic packets into one entry table as a match field in the forwarding rules. Through implementation and evaluation, it is shown that the system can build a backup path in the switch and reroute the disrupted traffic to the backup path. Based on the parameters used, the results show that the proposed approach achieves a recovery time of around 1.02-1.26ms. Additionally, it can reduce the number of traffic packets and has a low amount of packet loss compared to previous methods.

**Keywords**—Software-defined networks; openflow; link failure; failure recovery; VLAN ID; fast failover

## I. INTRODUCTION

Software-defined networking is a new paradigm that changes the current network infrastructure. The SDN concept is to break down the network infrastructure by combining the control logic (control plane) of routers and switches that forward traffic (data plane) [1]. Unlike the conventional network concept, where the control plane and forwarding are tied directly to the same network device. This causes the network administrator to have to configure the device manually. Another disadvantage of conventional networks is that when a device encounters a problem, the network administrator must fix the problem directly on the device.

In SDN, several problems can occur when the routing process is executed, one of which is a link failure. Link failure is one of the problems on the network that causes delays and even packet loss so the throughput value decreases. Link failures consist of direct or indirect failures. In the case of direct failures, the switches detect the failure immediately and recover quickly, whereas, in the case of indirect failures, the link failure is not detected by the respective switch despite traffic overhead. Unidirectional link failures disrupt traffic and create a loop in the switch topology. Multiple link failures reduce network reliability performance [2].

Based on previous research that used proactive SDN methods to solve the link failure problem. When a link fails, a predetermined backup path is created and used in this proactive

method. The switch closest to the link failure point will then reroute through the backup path to reach the destination [3]. Then in another research, using the rerouting method to overcome link failure was examined. When a link fails, high-priority packets are temporarily diverted to an alternate path, and then the packet is sent to the destination using the rerouting method to find the shortest path to the destination [4].

In the several methods previously mentioned, these methods can overcome link failures without involving the controller, thereby reducing failover time on SDN. However, these methods have several downsides, such as the need for a large number of flow entries to build backup lines and complex processes to maintain the lines alive. The backup path that has been created is then difficult to modify or adapt to changing network conditions, allowing for the possibility of congestion during the rerouting procedure.

Based on the problems described above and previous research, a test simulation will be developed to implement failure recovery on SDN by incorporating the fast failover group and VLAN ID features. This method works by creating a backup path for each link using the SDN architecture's fast failover group feature. Next, enable the VLAN ID feature, which is used as a match field in forwarding rules, to reduce traffic when packets are diverted to the backup path. This approach allows the system to recover from failures without involving the controller, reducing recovery time and minimizing the use of flow table memory on switches during link failures.

The rest of the paper is organized as follows: Section II provides a brief review of the literature relevant to our work and describes the main concepts around our approach. Section III explains the methodology of our approach is presented. Section IV explains the results and findings of the research. Section V is the discussion that presents the comparison result and findings with the previous studies. In Section VI, the conclusion of this research.

## II. RELATED WORK

### A. Background

The Group Table-based Rerouting (GTR) method is one of the approaches used to find responses to single link failures through the fast failover (FF) group [5]. In general, a backup path is created for each link between the source and the destination; however, the backup path proposed in this research is created by calculating the most efficient path between adjacent switches. The controller periodically updates the lookup table on the controller and the FF group table on the

switch to determine what changes have occurred in the topology and network traffic. The research proposed a protection scheme for source routing-based backup links [6]. The proposed method controls packets going to the backup link by updating the source routing header. With SDN source routing, it can use VLAN tags to store packet routes in the source routing headers instead of being stored in switch flow entries. By using this method, it can reduce the number of flow entries needed to build a backup link. However, these approaches have limitations in the implementation process, which is quite complex to overcome existing problems in the fast failover mechanism.

Furthermore, in the research conducted [7], flow-based network management was proposed that can be programmed on the OpenFlow network. Researchers propose a method called Path Monitoring (PathMon), which encodes flow and path information as tags that can work flexibly. This method is implemented on a switch and uses OpenFlow 1.3, which supports VLAN tags to encode flow and path information as flexible tags so that the statistical data obtained to monitor network traffic on OpenFlow is more specific. The purpose of using VLAN IDs in this research is to make it easier for network administrators to monitor network traffic and collect the different statistical information needed. In further research, there are problems with the data center caused by the detection of elephant flow, which resulted in high network latency [8]. The proposed method is to use multipath routing, which can break down elephant flows into several mice flows that are distributed evenly on the network without detecting elephant flows. In this research, VLAN-based routing is used to reduce flow entry consumption, where the controller can instruct the switch to enter the path ID in the VLAN ID field in each packet from the flow when routing to the switch. The results showed a 32% reduction in flow entry on switches compared to the method without using VLANs. This research is distinct from one another in that researchers raise different issues. In the proposed approach, the problem to be solved is the use of fast failover, which requires a large number of flow entries when a link failure occurs.

### B. Software Defined Networking

SDN provides a new approach to managing complex end-to-end connectivity and knowing the big picture of a network. A centralized network at the control layer allows management, configuration, security, and network resources to be optimized flexibly, dynamically, and automatically on SDN. It can be used for a variety of purposes, including control manipulation and network management, network virtualization, and providing a platform for building fast services [9].

As shown in Fig. 1, there is an SDN architecture consisting of an infrastructure layer related to the data plane that is in charge of forwarding. In the control layer, there is a component where the SDN controller is located. The application layer functions to make rules for the network. The control layer and the application layer are connected by the northbound API, while the infrastructure layer and the control layer are connected by the southbound API. In the southbound API, there is an SDN protocol, which is known as OpenFlow.

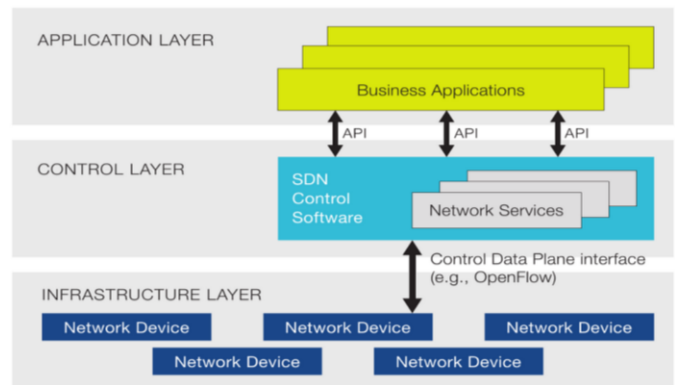

Fig. 1. SDN architecture

### C. OpenFlow

OpenFlow is a standard protocol used in software-defined networks. This protocol is used for communication between the control plane and the data plane. The SDN controller can manage a collection of switches to manage network traffic. The controller communicates with the OpenFlow switch and manages the switch via the OpenFlow protocol [10]. Fig. 2 shows the OpenFlow Controller and the OpenFlow Switch are the two most important components of OpenFlow. The OpenFlow Controller manages the performance of the Switch by controlling paths and flows. Then, the OpenFlow Switch is part of the data plane, which functions to process data such as forwarding packets.

Fig. 2. Components of OpenFlow

In the OpenFlow protocol, each flow table on the switch has a flow entry, where each flow entry has a match field, a set of instructions to be applied to matching packets [11]. There are three main components in OpenFlow: the first is the table, which contains the flow table, meter table, and group table. The second is a secure channel that contains an SSL channel that is between the switch and the SDN controller. The third component is the OF protocol, which is used to control and manage switches [12].

### D. Failure Recovery

Failure recovery is a network process that allows packets or flows that have experienced link failure to be recovered and forwarded to their destination. In the failure recovery process, there are two mechanisms: reactive mechanisms and proactive

mechanisms [13]. In a reactive mechanism, there is no backup path configured in the forwarding plane, so the controller immediately computes an alternative path after receiving a link failure notification message from the switch. Whereas in a proactive mechanism, there are two separate paths (the primary path and the backup path) that are configured by the controller in the forwarding plane before link failure occurs on the network. The fast failover feature is used to implement a backup path on a proactive mechanism. Fast failover is the ability of a flow table to create a group table that provides various ways of forwarding (primary and backup links) [14]. With this capability, fast failover can redirect disrupted flows to a backup link that has been configured in the flow table. Fault recovery is performed directly by the OpenFlow switch without involving the controller. In addition, failure recovery can be combined with backup path calculations, which are proactively installed by the controller.

Fig. 3. Failure recovery mechanisms

Fig. 3 is an example of how the failure recovery mechanism works. There are 5 switches connected to 1 controller, and there are 2 hosts. In this topology, there is a primary path in switch A-B-D and a backup path in switch A-C-E-D. When there is a link failure on link A-B, packets from host 1 will be diverted to the backup path that has been configured in the flow table to switch A-C-E-D, so that packets can be sent to host 2.

Fig. 4. Components of fast failover group

Fig. 4 shows the fast failover group component that is run by the SDN controller. Fast failover is a feature that reconfigures the link in the event of a failure. This feature utilizes OpenFlow 1.3 to run a group table that contains watch ports and action buckets that can monitor and act as long as the

port status changes [15]. The SDN controller configures the switch with a flow table that can help the network recover when a link failure occurs. The flow table contains fast failover group rules that implement a path-switching mechanism if a link is down.

### E. VLAN ID

VLAN-ID is one of the newest features introduced to OpenFlow in version 1.3. The VLAN mechanism can logically divide networks that are grouped based on VLAN ID. With this capability, VLANs can limit broadcast traffic on the network because they can only send packets to hosts that have the same VLAN ID. IEEE 802.1Q is the standard definition of VLANs. A VLAN tag contains 12 bits in the ethernet frame, so there can be up to 4,096 VLANs on a LAN. Implementation of VLAN tagging on the Ethernet protocol can create different broadcast sub-domains on the same LAN by including a VLAN number or tag for each subnet interface on the same switch [16].

In the OpenFlow protocol, in the flow table, there are flow entries that determine how a flow is processed and forwarded. Inside the flow entry, there are matching fields, actions, and counters. The matching field is used to match incoming packets. The action contains a set of instructions that are used to forward packets in various ways, for example, forwarding to a group table, one of which is the fast failover group. Then the counter is used to collect statistics on a particular flow, for example, the number of packets that have been received, the number of bytes, and the duration of the flow.

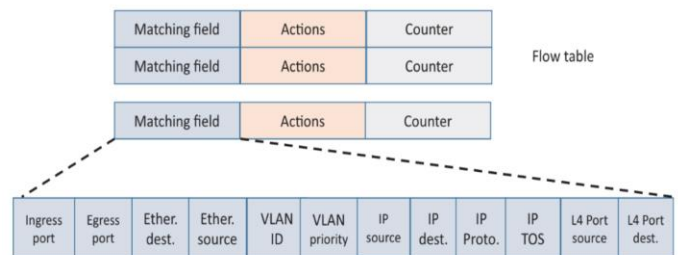

Fig. 5. Fields in the OpenFlow protocol

As shown in Fig. 5, there are 12 match fields, which are collectively referred to as the "basic twelve-tuple of match fields". Flow entries are processed sequentially, and when a match is found, the matching process against the flow table will be stopped [17]. In addition, the flow table is also equipped with a frame/byte counter that provides an indication of flow statistics on all ports so that the controller knows all the conditions that occur in the network [18]. Several actions can be performed by the OpenFlow protocol, such as sending packets to several ports, adding, removing, or modifying a VLAN tag, deleting packets, or sending packets to the controller.

### III. PROPOSED APPROACH

In OpenFlow, a specific flow can be defined as a collection of matching fields. Therefore, VLAN ID can be used as a flow ID, which can be forwarded based on flow entry. The use of VLAN ID can reduce interference with route flow and thus

reduce switch memory consumption. The failure recovery mechanism proposed in this research uses the VLAN ID feature on OpenFlow to collect failed flows. Each switch and a link is associated with a VLAN ID that can redirect flow to a backup path configured by fast failover on the switch.

Based on the topology that will be used in this research, the failure recovery mechanism will be implemented using OpenFlow 1.3. This mechanism provides a primary path for

forwarding and a backup path for diverting packets to an alternative path when a link failure occurs in the primary path. Based on Fig. 6, shows the failure recovery mechanism in the topology. In this topology, there is a primary path in S1-S2-S3-S4, while the backup path is in S2-S5-S6-S7-S4. Then, with the backup path configuration that has been made in S2, traffic can be diverted from port 3 to S5-S6-S7-S4 without making a round trip to the controller, so that packets can be sent to the destination.

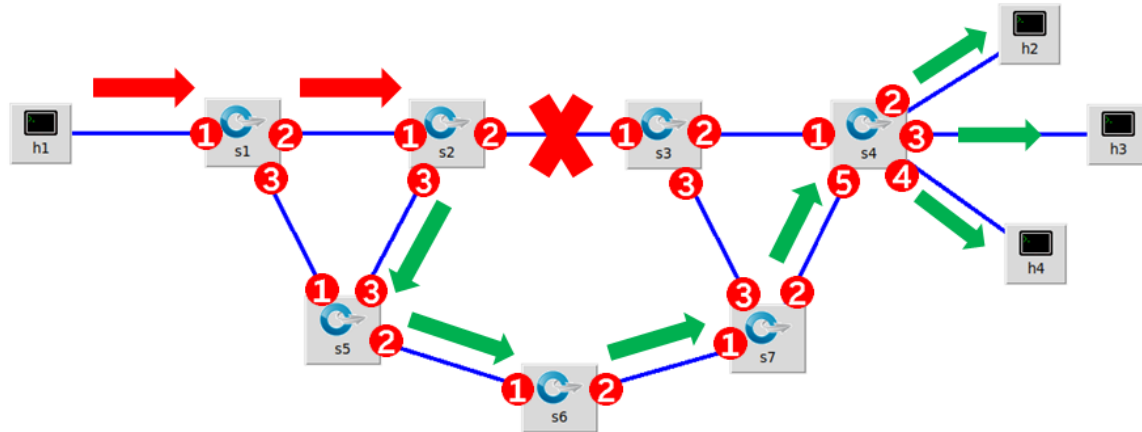

Fig. 6. Experimental topology

In the network topology, there is a link failure in S2-S3, so packets cannot pass through the link. Furthermore, there is H1, which will send packets to H2, H3, and H4, so there are three traffic flows in the topology. When the S2-S3 link fails, the controller will update the network topology by removing the failed link. In flow table S2, traffic is forwarded to group table 2 with the fast failover type, which is sent to output port 3.

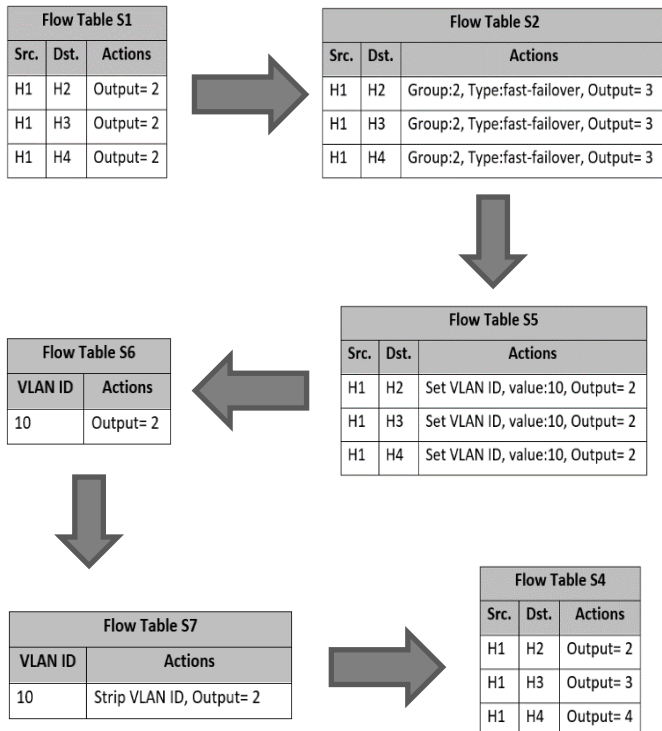

Fig. 7. Labelling process of VLAN ID

In Fig. 7, when the packet arrives at S5, configure the VLAN ID in the access port by accepting all packets that do not have a VLAN header. Then add a VLAN ID tag with a value of 10 for each incoming packet in S5. Then, the value of the VLAN ID is used as a match field in the switch connected to S5 and S6 via port 2. When it arrives at S6, packets will become one flow with a match field VLAN ID of 10. In S6, there is a packet with a VLAN ID as a match field with a value of 10 that has been configured on the previous switch. When a packet with a VLAN ID matches the flow match field, the packet can be forwarded based on the action specified in the flow table. Then, when the flow arrives at S7, there is an action with the Strip VLAN ID that functions to delete the value from the VLAN ID. The process is in the output access port, so the VLAN header has been deleted when it goes to the output port. Furthermore, when the flow arrives at S4, it will be returned to three traffic flows. Thus, in flow table S4, the three traffic rules in S4 without requiring changes to the flow table S4.

#### IV. PERFORMANCE EVALUATION

##### A. Testbed Configuration

The topology shown in Fig. 6 was implemented on Mininet as the network emulator and select Ryu as the controller. Mininet supports different types of switches. In this case, we used OpenVSwitch to support the fast failover group and VLAN ID features in OpenFlow 1.3. Furthermore, because our experiment was carried out in a controlled environment, we used OpenVSwitch to install the flows directly in each switch of the network topology using the script-line program *ovs-ofctl*. To collect statistics and monitor the behavior of TCP traffic generated by the IPERF application. The main characteristics

of the laptop on which the tests were conducted are as follows: Processor: Intel Core i7-8550U, CPU running at 1.99 GHz; RAM: 16 GB; operating system: Linux Ubuntu 20.04 LTS 64-bit on a VMware workstation.

### B. Recovery Time

The recovery time evaluation is carried out to find out how long it takes for packets to be diverted to the backup path when a link fails. The analysis compares the recovery time in failure recovery with VLAN ID and fast failover.

Fig. 8. Failure recovery time

In Fig. 8, there is a graph of the recovery time test. Based on the test results, the minimum time required for failure recovery with a VLAN ID is 1.02 ms, while the maximum time is 1.26ms. As a result, the time required to perform recovery in this mechanism is 1.02-1.26ms. Whereas for fast failover, the minimum time is 1.02ms, and has the maximum time of 1.4ms. As a result, when a link fails, recovery takes 1.02-1.4 ms on fast failover. Based on the results obtained in this test, the recovery time required in the failure recovery mechanism with VLAN ID is smaller than that required in the fast failover mechanism.

### C. Traffic Packets

The Traffic packet evaluation is used to find out how much packet traffic is transmitted to the destination. The analysis of this evaluation is used to determine the performance of the VLAN ID as a matching field in sending packets to the destination.

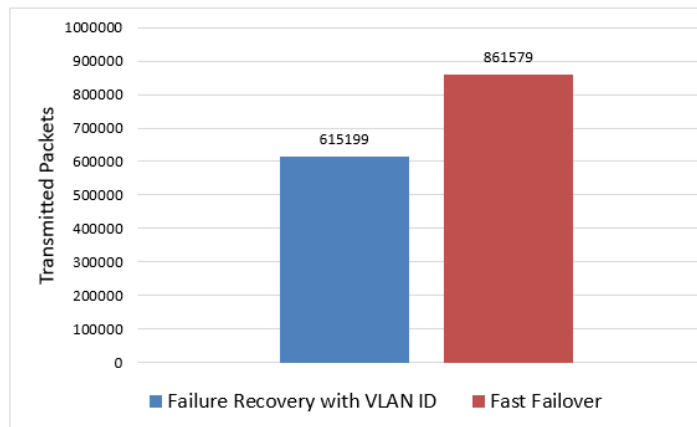

Fig. 9. Total number of traffic packets

As shown in Fig. 9, there is a traffic packet evaluation. Based on the two mechanisms tested, the failure recovery mechanism with VLAN ID resulted in a total of 615,199 traffic packets. Meanwhile, in failure recovery, the number of packets generated in this test was 861,579 packets. According to the results obtained from the test, failure recovery with VLAN ID produces less packet traffic than the fast failover mechanism.

### D. Packet Loss

Packet loss evaluation is carried out to find out how many packets are lost when sending packets from host 1 to host 2 when a link failure occurs. The duration of each test to be carried out is 10 seconds, and the test is carried out five times. The test will be carried out with a different total number of streams.

Fig. 10. Packet loss rate

In Fig. 10, there is a graph of the results of the packet loss evaluation that has been done. In the first test using 5 streams, the failure recovery mechanism with VLAN ID has a packet loss value of 0.067%, and this value increases when the last test uses 25 streams at 0.28%. Whereas in fast failover, in the first test, it has the same packet loss value of 0.067%. But in the last test using 25 streams, the packet loss value was 0.46%. Based on the results obtained in this test, the smallest packet loss value for the two mechanisms is 0.067%. Whereas in the last test, the failure recovery mechanism with VLAN ID had a smaller packet loss value compared to fast failover.

## V. DISCUSSION

In the recovery time test results, the failure recovery mechanism with VLAN ID shows results of 1.02-1.26ms with an average yield of 1.18ms to perform recovery after a link failure occurs. In research conducted [19], the time needed to detect and recover a single link failure is at least around 10-20 ms. Then, research [20], states that the need to detect and perform recovery on operator-scale networks must be carried out in 50ms time intervals. The results of the packet loss test that has been carried out show that the average value of packet loss in the failure recovery mechanism with a VLAN ID is 0.18%, with the highest packet loss being 0.28%. The results of the packet loss test are still considered good, based on research conducted [21] which states that packet loss with a ratio of 5-10% can affect network quality. Whereas in audio and video

stream scenarios, the range of acceptable packet loss is between 1 and 2.5%.

## VI. CONCLUSION

Based on the results of the analysis of this research it can be concluded that compared to the fast failover method used in SDN, it mainly has three advantages: First, in the recovery time test results, the failure recovery mechanism with VLAN ID shows results of 1.02-1.26ms to perform recovery after a link failure occurs. Whereas in the fast failover mechanism, the time needed to perform recovery is 1.02-1.4ms. Second, it shows that the use of VLAN ID in failure recovery is proven to be able to reduce the amount of traffic packet when a link failure occurs. Third, the results of the packet loss evaluation that has been carried out show that the average value of packet loss in the failure recovery mechanism with a VLAN ID is 0.18%, with the highest packet loss is 0.28%. Based on the evaluation results, our proposed approach has better results than the fast failover method. However, the major drawback of our proposed approach is that the mechanism is less dynamic because we implement fast failover groups and VLAN IDs directly in the switch. Perhaps we can present a solution to the problem and provide direction for our future work.

**Abstract**—Forecasting is an accurate indicator to support management decisions. This study aimed to mining sales forecasting on Indonesia's consumer goods companies with business warehouses engaged in the dynamic movement of large data using the Artificial Neural Network method. The sales forecasting used traditional method by inputting data and improvising simple patterns by collecting historical sales and remaining stock. Furthermore, several data variables in business warehouses were employed for sales forecasting. The study also used qualitative method to investigate the quality of data that cannot be measured quantitatively. The results showed with Mean Square Error score of 0.02716 in forecasting sales. The average accuracy generated by the Extreme Learning Machine after nine data tests is 111%. The result shows an opportunity for the company to further analyze the sales profit growth potential. The predicted value generated by Extreme Learning Machine for the last three months reaches 132%. The company's improved decision-making enlarge potential production line demonstrates the usefulness of this study.

**Keywords**—Artificial neural network; business warehouse; extreme learning machine; mining sales forecasting

## I. INTRODUCTION

Sales forecasting is always at the forefront of decision-making and planning [1] and also for business [2]. Forecasting gives an organization the right plan to deal with future demands but does not guarantee the success of a strategy. However, its failure results of wrong decisions in marketing activities caused by the allocation of other resources which constructed on imprecise and uncertain assumptions, hence resulting to wrong decisions [3]. Sales forecasting is an important prerequisite in many aspects of sales chain management. Therefore, further optimization efforts are needed to create sales forecasts that support decision-making by the organization.

This study aimed to explore the potential of scientific forecasting and prove the optimization of existing theories. The forecasting concept uses the *Artificial Neural Network* (ANN) method, representing the human brain's performance [4]. The human brain always experiences a period of learning in the interconnected neurons. Information received by neurons is sent from one neuron layer to another [5].

This study also explained the *Extreme Learning Machine* (ELM) which is widely used in batch, sequential, and incremental learning. The method is used because of its

efficient convergence and learning speed, good generalization ability, and ease of implementation [6]. Furthermore, the study built a suitable model to estimate the data generation process underlying the series. It also estimated the desired number of future observations through this model [6].

Several data variables in the business warehouse were adopted for sales forecasting using the ANN ELM method. Various studies have revealed that the ELM method has an advantage in learning speed which described in the previous section. It helps determine the effectiveness of forecasting, as well as deficiencies and necessary improvements.

## II. RELATED WORK

Prianda and Widodo (2021) used ELM to project foreign tourist visits and obtained a forecast MAPE value of 7.62% [7]. Similarly, Sharma et al. [8] employed an intelligence model to predict sales using sentimental product analysis. The study made the model more productive in obtaining accurate results for each item in the product life cycle. Meanwhile, [9] applied ELM integrated with LSTM to Bitcoin price forecasting. Their study matches the different machine learning algorithms to corresponding multiscale components and constructs the ensemble prediction models based on machine learning and multiscale analysis. The results showed that the ensemble models can achieve a prediction accuracy of 95.12% with enhanced performance than the benchmark models [9]. Moreover, Cholid and Aly [10] forecasted spiral and leaf spring products for four-wheeled vehicles using the Artificial Neural Network Backpropagation method. The study employed a learning rate weight value of 0.1 of four hidden layers with error of 0.01. Several studies use various methods to predict product sales [11]–[13], compare forecasting techniques for financial prediction [14], supply chain [15]–[17], and manufacturing processes [18].

## III. METHOD

This study aimed to predict sales using the ELM method, which applies qualitative approaches. It also intended to investigate, discover and explain the peculiarities of the data influence that cannot be measured or described quantitatively. Fig. 1 presents the proposed methods used in this study.

The proposed method in Fig. 1 consists of five phases. Firstly, problem formulation was formed through the question regarding implementation of forecasting with other fast and accurate methods. After finding the problem formulation, a literature study was performed by collecting sources from previous journals and articles and quarrying up information from company forecasting results.

Furthermore, the ELM method accomplished with the first stage is initializing the input weight and bias to prevent layer activation outputs from detonating or fading gradients during the normalization. Second stages are use of range between 0-1 for normalizing to ensure quality of data during training and testing phase. Training and testing stage then taking into account respectively to train model, discover and learn patterns. Testing data use to evaluate the functioning and improvement of algorithms training and optimize it for better results. The last stage of ELM is denormalizing previous prediction results to compare the output in order to evaluate the model. The final step was to exam the *Mean Square Error* (MSE) using python pseudocode to determine the error rate of the prediction results.

For training and testing of the proposed model, the company's secondary data have been used. From the proposed model, it can be seen that the prediction result process quickly for both training and testing sets. Hence, the proposed model will provide more suitable for the task at forecasting sales compare to other techniques that described in the previous section.

A. Data Type and Source

This study used secondary data from the dataset of a retail company. The data were collected from daily sales based on the company's existing business warehouse system.

B. Data Used

The study used sales data set digitized through the company's SAP Business Warehouse system. The historical data set had 43 rows and 6 parameter features. Furthermore, a time series analysis was conducted on the previous month of sales data. This study also analyzed time, brand, and stock factors affecting sales levels through forecasting methods. The dataset design has been given in Table I.

TABLE I. DATASET DESIGN

1st Data (Time Series)	Feature Stock	Feature 1 Sales	Feature 2 Sales 2	Feature 3 Sales 3	Feature 4 Sales 4
Nov 2017	Vol	Vol	Vol	Vol	Vol
Time Series n	Vol	Vol	Vol	Vol	Vol

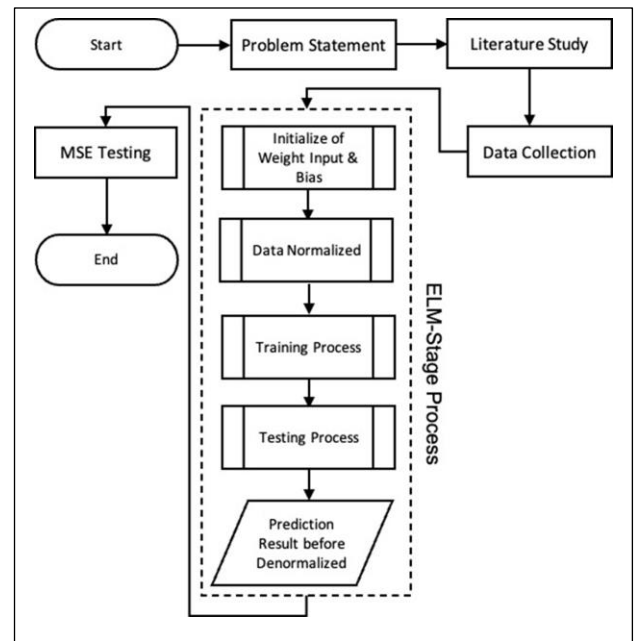

Fig. 1. Proposed forecasting sales through ELM stages

C. Schematic of Research Based on Method

The ELM algorithm was used by entering historical sales data, the number of features and hidden neurons, as well as the percentage of training and testing data as initial input. Fig. 2 shows the stages outlined as follows:

- a) Input weight and bias were processed randomly with values ranging between -1 to 1 based on the number of neurons then. The next step was transposing the matrix and normalizing the data using the range 0 - 1 to calculate the hidden layer output.
- b) The matrix result was multiplied by the transposition before calculating the Moore-Penrose Generalized Inverse matrix using the Moore-Penrose Generalized Inverse matrix equation. The result was multiplied by the transposition of the activated hidden layer output matrix.
- c) The study calculated the output results of the training process to obtain the output weight used in the testing process.
- d) The testing process employed the input weight and bias obtained from the training process. The hidden layer output was then calculated using the activation function.
- e) The output weight value obtained in the training process was used in the testing process to calculate the output layer as the prediction result.
- f) Before the denormalization process, the study calculated the error value on all output layers not denormalized with actual data. This error value is the prediction results obtained. Additionally, the error value was tested using Mean Square Error (MSE).
- g) The last step was denormalization to generate a previously denormalized value back to the original value. Fig. 2 is a flowchart of the problem-solving process with ELM.

D. Input Data

This study employed sales data detailing the monthly sales for November 2017-May 2021. The ELM method processes data by determining several criteria parameters to achieve a small error rate and optimal accuracy. Table II describes several parameters used in processing the dataset, including the input and output layers, hidden neurons, and activation function.

E. ELM Development Method Forecasting

The initial step was to find the optimal value of several input parameters tested. This step ensures that the process in the ELM method produces good predictions during training. After testing the MSE on hidden neurons, the dataset was normalized into the range of 0 – 1. This was followed by data training, testing, denormalization, and sales predictions in the following month.

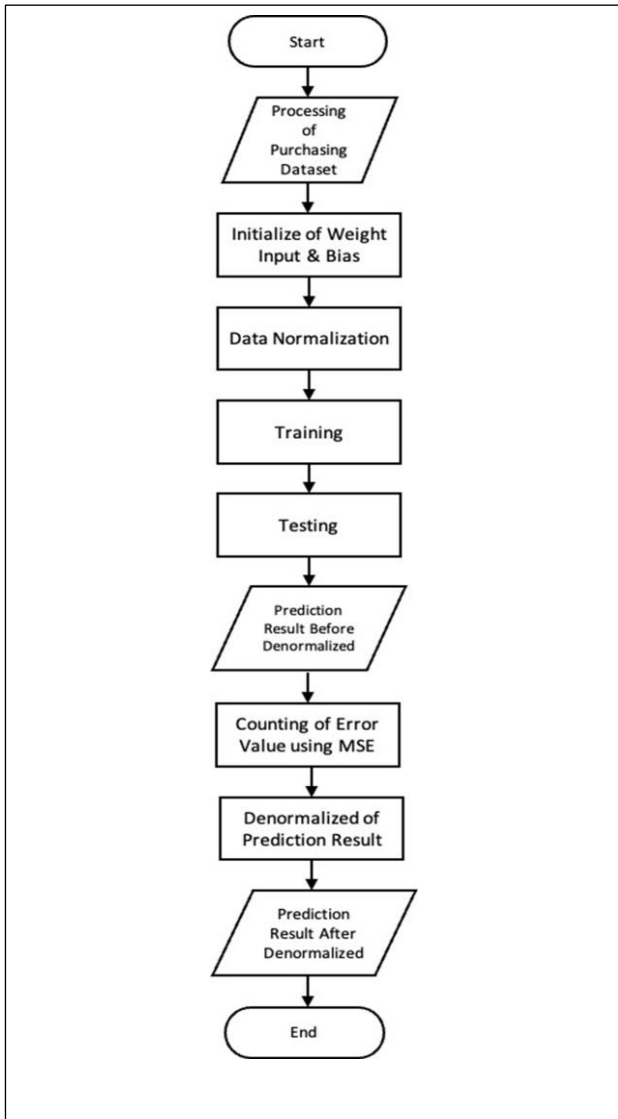

Fig. 2. ELM process diagram

TABLE II. ELM METHOD REQUIREMENT PARAMETERS

Parameter	Total	Description
Input Layer	6	Streak months, Data Stock (Label) & 4 Brand Historical Sales
Output Layer	1 Neuron	Forecasting Results
Hidden Layer	10 Testing	11 - 30 Neuron
Activation Function	1	Sigmoid Biner

IV. IMPLEMENTATION AND RESULT

A. Hidden Neuron Total Network Testing

The number of hidden neurons was tested to determine its effect on the accuracy value in implementing the ELM algorithm. The number of hidden neurons used in this test includes 11, 12, 13, 14, 15, 17, 24, 26, 27, and 30.

The tests were performed ten times, and the number of hidden neuron networks was processed into python pseudocode. Furthermore, the test was carried out repeatedly by changing the number of neurons, as shown in Table III.

TABLE III. HIDDEN NEURON TEST RESULTS

No	Total Hidden	MSE	Time (second)
1	11	0.06755	0.0515
2	12	0.02716	0.0525
3	13	0.04812	0.0528
4	14	0.08318	0.0545
5	15	0.10937	0.0526
6	17	0.12538	0.0532
7	24	0.13625	0.0550
8	26	0.21435	0.0548
9	27	0.18092	0.0545
10	30	0.24473	0.0547

Fig. 3 shows that changes occur when there is a change in the total of hidden layers. Therefore, the optimal network value was obtained in the second test with an MSE of 0.02716 and a time of 0.00525 seconds.

Fig. 3. Optimal hidden network graph plot

### B. Preprocessing

Data processing was performed after creating the hidden neuron network. The data collected were then normalized using Min-Max normalization or transformed into a range of 0-1 to obtain a value for each auxiliary variable.

The input process used monthly time series, stock, and sales variables by brand. The data were divided for testing and training via Python's `train_test_split` function. Furthermore, the study compared the performance of the models used in forecasting sales data. The training and testing data distribution was 80% and 20%, respectively. Tables IV and V show that the output data were broken down into two parts and formed a range of numbers 0-1 equated with numbers 0-1.

-248.036551
-35.957942
-295.455812
32.925058

*D. Testing*

The testing process aimed to measure the performance of the network model built during the training process. Although the steps used were similar to the training process, all weights were taken from the training results, implying no calculation of the  $\beta$  weight. The data used differed from the training process explained in the preprocessing stage. The accuracy level was calculated in the same way as in the training process. The output data testing is presented in Table VIII.

TABLE VIII. OUTPUT DATA TESTING

Feature 1	Feature 2	Feature 3	Feature 4	Feature 5	Feature 6
0.4845	0.3535	0.4272	0.3497	0.6984	0.7266
0.4350	0.3596	0.4261	0.3445	0.6451	0.3672
0.4585	0.3433	0.4015	0.3601	0.6953	0.6747
0.4653	0.3631	0.4806	0.4619	0.7620	0.7604
0.4785	0.3469	0.4560	0.3546	0.7662	0.7934
0.4943	0.3657	0.5082	0.3548	0.5909	0.6125
0.4847	0.3513	0.4697	0.3683	0.6406	0.6719
0.5277	0.3410	0.4041	0.3765	0.7328	0.7106
0.4990	0.3542	0.4139	0.3530	0.3672	0.7837

Table IX shows that the results generated from the training process had an average prediction of 111%.

TABLE IX. OUTPUT TARGET TESTING VS PREDICTION TESTING RESULTS

Data To-	20% target data (Y)	Prediction Results (y) Accuracy	
Data to-1	0.4057	0.5270	130%
Data to-2	0.2980	0.5998	201%
Data to-3	0.3145	0.5494	175%
Data to-4	0.7608	0.5992	79%
Data to-5	0.4882	0.5891	121%
Data to-6	0.6600	0.5091	77%
Data to-7	0.5859	0.5569	95%
Data to-8	0.5570	0.6899	124%
Data to-9	0.4179	0.3409	82%
Average	0.4987	0.5513	111%

*E. Denormalization*

In the denormalization stage, the predicted test data in the 0-1 output range were converted to the actual value in kilograms. This was done to ensure that the target data and predicted results were read on a wider scale than the original value.

The denormalized data in Table X results from nine data tested and predicted to compare each accuracy per line. The accuracy from the average of the final data line was 101%.

TABLE X. DENORMALIZATION OF TARGET TESTING

Data	20% Target Data (Y)	Prediction Results (y)	%
Data to-1	57.521	67.931	118%
Data to-2	47.425	74.235	157%
Data to-3	49.077	69.851	142%
Data to-4	90.227	74.183	82%
Data to-5	64.634	73.293	113%
Data to-6	79.734	66.413	83%
Data to-7	73.014	70.497	97%
Data to-8	70.499	82.638	117%
Data to-9	58.587	51.616	88%
Average	67.367	68.250	101%
Data to-7 - 9			

*F. Next Month Prediction Results*

The predictions made via pseudocode python showed that the value on the 44th data or the following month from the processed dataset is 70.524 kg, as shown in Fig. 4. In Fig. 4, the red line on the y-axis explains that sales occur in the 44th data, a decrease from the previous month.

Fig. 4. The plot of the next month's prediction results

### G. Forecasting Exist Sales

Retail companies have a forecast to predict sales within the next three months. This is known through an analysis of traditional time series forecasting. Table XI and Table XII shows forecast existing and actual sales respectively. Table XIII compares the prediction made and the actual from the total forecasting, showing a gap with an accuracy of 86%.

TABLE XI. FORECAST EXISTING

Brands	March	April	May	Total
Promina	8.996	751	15.558	8.435
SUN	36.524	3.577	33.461	24.520
Govit	1.439	122	1.962	1.174
Gowell	2.844	1.233	21.270	8.449
Total	49.802	5.682	72.251	42.579

TABLE XII. ACTUAL SALES

Brands	March	April	May	Total
Promina	9.697	904	22.218	10.940
SUN	36.771	3.708	54.311	31.597
Govit	1.108	64	1.348	840
Gowell	11.010	1.553	12.349	8.304
Total	58.587	6.229	90.227	51.681

TABLE XIII. COMPARISON OF EXIST VS ACTUAL FORECASTING

Brands	March	April	May	Average
Forecast	49.802	5.682	72.251	42.579
Actual	58.587	6.229	90.227	51.681
Accuracy	85%	91%	80%	82%

Where:

*Forecast:* The forecasting performed by Retail companies in units of volume

Actual: Sales in March, April, and May

Accuracy: *Forecast/Actual Sales*

The average data for three months of prediction in Table XIII confirm that the average accuracy is only 82%. A less-than-actual plot accuracy warns the company of insufficient stock available to supply future sales. This means that sales would not be maximized.

### H. Comparison of Exist vs ELM Development Methods

*ELM exist vs development method matrix:* From the implementation of sales forecasting proposed model, a comparison matrix could be made between the Exist versus ELM Method as given in Table XIV. Based on the forecast matrix, it can be seen that the average 3-month forecast value reached 68,250 kilograms by using the ELM method, while the traditional method reached 42,579 kilograms. The average value of 3 months is actual sales 51,681 kilogram has been used for comparison the ELM and traditional method. Based on results, it can be concluded that predictions by ELM provide more better accuracy to provide adequate stock for the next sale. It mean that sales be able to run optimally for company. Meanwhile, based on accuracy matrix the ELM method can achieve admirable accuracy values, this is due to the stock feature as basic calculation label are carried out to acquire the smallest error value as well as several tests also has been done. Some of these features are support in providing stimulation to achieve better accuracy.

### V. CONCLUSIONS

Based on the test results and discussion, the following conclusions were obtained:

- As measured by the Mean Square Error (MSE) in forecasting sales results, the error rate is 0.02716 with a time of 0.0525.
- The ten neuron network tests showed that more hidden neurons do not measure algorithm optimization. Therefore, using 12 of 30 hidden neurons produces fewer error values.
- The average accuracy value generated by the ELM forecasting method when testing nine data is 111%. This illustrates an opportunity for the company to further analyze the sales profit growth potential.
- The predicted value produced by ELM for the last three months reaches 132% compared to traditional methods, which only achieve 82%.

TABLE XIV. COMPARISON OF THE EXIST VS ELM METHOD

Matrix	Method	Average Unit (Kg)	Description
Forecast	Exist (Traditional)	42.579	The average 3-month forecast value conducted by the company using the traditional method is 42.579 kilograms. This value is obtained from Table XI.
	ELM	68.250	The average value of the 3-month forecast using the ELM method is 68.250 kilograms. This value is obtained from Table XIII.
	Actual Average 3 Months	51.681	The average value of 3 months compared to actual sales is 51.681 kilograms. This value is obtained from Table XIII.
Accuracy	Exist (Traditional)	82%	Comparison of Exist / Traditional Forecast Values compared to Actual. Value calculated using spread sheet gets a relatively good accuracy value but has not yet reached the optimal value. This is because the calculated forecast still applies manual estimation as a measuring basis by dividing average monthly sales and adding sales estimates according to forecast growth.
	ELM	132%	Comparison of ELM Forecast Value compared to Actual. In line with the proof method described in the previous discussion, the accuracy value of the ELM method could achieve a very good accuracy value. This is due to the featured stock, the reference label for calculations, and several tests are conducted to get the smallest error value and the best accuracy. Some of these features help in providing stimulation to achieve optimal accuracy.

Sales forecasting still requires extensive machine learning and statistics knowledge. Addition features of input layer such as number of workers, demographic trends, and behavioral indicators should be involved in future studies to improve the model.

**Abstract**—It is critical to develop a method for detecting cracks in historic building concrete structures. This is due to the fact that it is a method of preserving historic building and protecting visitors from the collapse of a historic structure. The purpose of this research is to determine the best method for identifying cracks in the concrete surface of old buildings by using cracked images of old buildings. The various surface textures, crack irregularities, and background complexity that distinguish crack detection from other forms of image detection research present challenges in crack detection of old buildings. This study presents a framework for detecting concrete cracks in old buildings in Semarang's old town using a modified Convolutional Neural Network with a combination of several convolutional layers. This study employs ten convolutional layers (Deca Convolutional Layer Neural Network (DCL-NN)) to provide mapping features for images of concrete cracks in ancient buildings at preservation area. This study also compares commonly used machine learning models such as KNeighbors (n neighbors=3), Random Forest, Support Vector Machine (SVM), ExtraTrees (n estimators=10), and other CNN-pretained models such as VGG19, Xception, and MobileNet. Four performance indicators are used to validate each model's performance: accuracy, recall, precision, F1-score, Matthews Correlation Coefficient (MCC), and Cohen Kappa (CK). This study's data set is comprised of primary data obtained from cracked and normal images of several buildings in Semarang's old town. The accuracy of this study using DCL-NN is 98.87%, recall is 99.40%, precision is 98.33%, F1 is 98.86%, MCC is 97.74%, and CK is 98.86% for crack class. From this study, it was found that the ten convolution layers have higher classification performance compared to other comparison models such as machine learning and other CNN models and are more effective in detecting cracks in concrete structures.

**Keywords**—Cracks; concrete; Deca-CNN; features mapping; performance

## I. INTRODUCTION

It is critical to understand the shape of cracks in historic buildings in order to preserve historic areas. The Old Town area of Semarang, which is a UNESCO World Heritage Site, is one area that is vulnerable to building cracks [1]. The total number of buildings, which reached 274 units, demonstrates that the old town area was previously a residential area; now,

out of a total of 157 units with the status of occupied buildings (both for housing and offices, dominated by offices), 87 units are status as vacant buildings (both those that are still being maintained or damaged/abandoned), 28 units are leased (offices), and only 2 units are currently sold [2]. Historic ancient buildings are architectural creations that serve as a nation's cultural heritage and have very high artistic and historical values, so their long-term viability must be ensured. The ability of a sturdy building structure supports the building's strength, which causes the building to last a long time. Cracks in concrete structures are a common sign of faulty concrete. The presence of cracks affects the structural condition and increases the risk of unexpected damage and collapse of the building [3][4]. Therefore, crack detection must be done on a regular basis in order to maintain the concrete structures of historic ancient buildings.

## II. RELATED WORKS

Traditionally, professional images of cracks in a building's concrete structure are used. The use of an expert to inspect concrete structures for cracks is costly, time-consuming, and sometimes dangerous for direct inspection [5]. The Ultrasonic Pulse Velocity Test (UPVT) in the form of ultrasonic waves in the cracks where holes are made for the ultrasonic wave propagation area is then used as another method of measuring building cracks [6]. This creates the possibility for buildings to become more dangerous as a result of the influence of other building structures. However, as computer-aided design (CAD)-based image processing technology advances, many experts are turning to machine learning-based image processing for the automatic detection of cracks in concrete structures [7]. Many techniques for detecting building cracks have been proposed by researchers, including the use of thresholding methods [8], edge detection, and wavelet transform. Surface texture, crack irregularity, and background complexity distinguish crack detection from other images in research that leads to machine learning-based image processing solutions for automatic detection of cracks in concrete structures.

Deep learning-based models, especially multilayer neural networks, currently play an important role in feature learning [9]. Moreover, the availability of high-performance computers and the continuous improvement of good training methods on

available datasets are driving the rapid development of deep learning. Conversely, convolutional neural networks (CNNs) are feed-forward neural networks characterized by high-resolution image processing [10]. Some of these models are suitable for feature extraction in various applications, but their accuracy needs to be improved to detect cracks in concrete.

In this work, CNN-based transfer learning using pre-trained models to achieve efficient performance, reduce training time, overcome the drawbacks of large datasets, and yield significant results. A law has been proposed [11]. Some previous researchers have done some work to identify and classify cracks in buildings. Zhang et al. [12] proposed a 6-layer convolutional neural network (CNN) architecture for road crack detection and used 640,000, 160,000, and 200,000 images to train, validate, and validate the network. bottom. and tested. Kings. [13] proposed a CNN architecture with three convolutions and he two fully connected layers to detect cracks in asphalt. On the other hand, the author of this study says that for training he used 640,000 images and for testing he used 120,000 models. Fan et al. [14] proposed an efficient automatic road crack detection and measurement model based on an ensemble of CNN models. The authors of this study calculated the final failure probability by combining the probability values from each CNN model using the weighted overall average technique. Xu et al. [15] He trained a 28-layer end-to-end CNN model to detect cracks in concrete bridges. To obtain multiscale contextual information, the authors of this study used the concept of combining Atlas Spatial Pyramids (ASPP) and depth convolution to reduce the number of parameters in the network. This study describes a framework for detecting concrete cracks in old buildings in Semarang Old Town using a modified convolutional neural network that combines multiple layers of convolution. Scaffolding helps identify the presence and location of cracks in concrete surface patterns.

This study suggests early detection of cracks in historic buildings. Citra captures images that do not show cracks and uses existing image processing algorithms to distinguish them from images that show cracks. The uniqueness of this study is that this study DCL-CNN model to help identify and classify crack types. Do these cracks appear in concrete or only on the surface of old buildings in Semarang city? Because of the insufficiency of observational methods for concrete structures, the study intends to make the following major contributions:

1) An effective and efficient classification framework with a combination of the number of convolution layers based on crack candidate areas is proposed to effectively categorize cracks and non-cracks. The more feature mapping that results from the number of convolution layers, the more detailed the system will be in detecting cracks in surface structures and deep fracture structures.

2) Comparison with other transfer learning methods and machine learning so that the CNN model produces the desired performance in classifying cracked and normal building locations

The image of cracks in ancient and historic buildings in Semarang, Indonesia, was used as data in this study. In this study, crack classification in old town buildings in Semarang requires several stages, as illustrated in Fig. 1. Images of old

building cracks are preprocessed. Preprocessing includes size adjustment, rotation, position translation, and flip processes.

The Citra image data set is split into a training data set and a validation (test) data set. Use preprocessed data to extract modal feature information from images using a pretrained model with transfer learning. This model is fed to a fully connected layer (FC) and trained after fusion. The top two layers of the FC layer contain 512 hidden units followed by the ReLU activation function. The final layer contains hidden units, followed by a sigmoidal activation function used for crack detection. Evaluate system performance using metrics such as Accuracy, Search Rate, Accuracy, F1 Score, MCC, and CK.

Fig. 1. Condition from the front side of the cracks of several ancient buildings in the old town of Semarang

### III. METHODOLOGY

The methodology for this paper shows in the Fig. 2. At the beginning, we need to process the crack image into through several levels of pre-processing, data augmentation, and training for each model. It is including modifications to the CNN model, retained model, and machine learning model, and all algorithms are tested using data testing

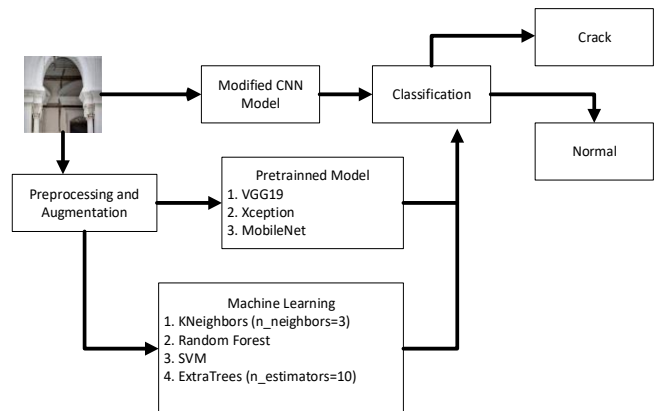

Fig. 2. Research methodology diagram

The experimental program is divided into four phases:

- creating a classified image dataset from primary data;
- developing the convolution layer from the CNN standard;
- comparing with machine learning and pre-trained models;
- running training experiments. The following sections provide information about each phase.

#### A. Image Data Set

The dataset employs for this study consists of 10,000 images with 512 x 512-pixel resolution. The image was taken from various concrete specimens after mechanical testing in the Semarang old town building. The main idea is to collect concrete service images from various surface views in order to diversify the data set and, as a result, the AI system that learns from this data set. The images were sliced into 224 x 224-pixel images to increase the data set without sacrificing resolution, resulting in a final data set of 10,000 samples, which were then manually classified into two categories: concrete surfaces with and without cracks. The dataset contains 5,000 images with cracks and 5,000 images without cracks. With a 70/30 split, the dataset is divided into training and validation datasets.

#### B. Convolution Layer from the CNN Standard

CNN1 is known as the base of the CNN method. For identified the crack building using Citra, this study used four variations of the CNN architecture. The usage of four variations of the CNN architecture used to find the best architecture for detecting the condition of cracks in ancient building structures in Semarang's old town. This study used GPU GTX 1650 RAM 2 x 8 GB 2400 MHz DDR4 for the computation.

Fig. 3 shows a diagram of the CNN1 architecture. This basic design can be extended to create CNN2 or CNN3 architectures. CNN3 is extensible to CNN4. CNN architectures are built to determine the impact of CONV layers and their activation functions on classification accuracy. Additionally, comparisons can be made between CNN1, CNN2, CNN3, and CNN4, or between design groups to determine if the best type of design is used for classifying old building crack images.

#### C. The Performance between Machine Learning and Pre-Trained Models

To evaluate classification performance, precision, recall, and accuracy matrices are used [16], [17]. To calculate the metric, add the sums of TP, FP, FN, and TN. True positive is represented by TP, false positive by FP, false negative by FN, and true negative by TN and properly measure ratios as positive detected elements, taking only positive predictions into account.

$$\text{Precision} = \frac{TP}{TP+FP} \quad (1)$$

The precision is stored in the denominator by FP; if it is high, the precision is low. However, the majority of the elements are predictably incorrect, and only a few are correct as positive, resulting in high precision values even if there are many FNs. As a result, a measure of the number of FN, namely recall, is required.

$$\text{Recall} = \frac{TP}{TP+FN} \quad (2)$$

and correctly measure ratios as positively detected elements, taking into account only elements with positive ground truth annotations. If the FN amount is large, the drawdown will be small and measures the ratio of correct predictions to all predictions.

$$\text{Accuracy} = \frac{TP+TN}{TP+FP+FN+TN} \quad (3)$$

Accuracy can be used as a reliable summary metric for classification performance because the dataset is symmetric.

Table III displays the outcomes of all models in the primary dataset. To validate the model, we only use the test folder dataset. To compare performance, two statistical tests were performed: the Matthews correlation coefficient (MCC) and the Cohen's Kappa statistic [18-19]. In the case of unbalanced data sets, the Matthews correlation coefficient (MCC) is a popular performance metric. Despite the fact that the dataset used in this paper is balanced, it is defined by the mathematical equation number (4):

$$MCC = \frac{(TP \times TN) - (FP \times FN)}{\sqrt{(TP+FP) \times (TP+FN) \times (TN+FP) \times (TN+FN)}} \quad (4)$$

The MCC range is [1-1]. A MCC value closer to one is preferable. All of the models that were used performed admirably. The value is close to 1. In other words, the model correctly classifies the fracture image. Cohen's Kappa statistic is used to assess the degree of agreement between two raters who categorize objects into mutually exclusive groups, as shown mathematically in Equation (5).

$$CK = \frac{(p_o - p_e)}{(1 - p_e)} \quad (5)$$

In this case,  $p_o$  represents the rater's observations' relative agreement. The theoretical probability of random agreement is denoted by  $p_e$ . Using Equations (6)-(8), we can calculate  $p_o$  and  $p_e$  between raters (9).

$$p_o = \frac{TP+TN}{TP+TN+FP+FN} \quad (6)$$

$$P_e = \text{Probability of Positive} + \text{Propobability of Negative} \quad (7)$$

$$\text{Propability of Positive} = \frac{TP+FP}{TP+TN+FP+FN} \times \frac{TP+FN}{TP+TN+FP+FN} \quad (8)$$

$$\text{Propability of Negative} = \frac{FP+TP}{TP+TN+FP+FN} \times \frac{FN+TN}{TP+TN+FP+FN} \quad (9)$$

Fig. 3. Visualization for each CNN mode

Fig. 3 shows the architectural layout. CNN1 is the basis of the CNN method. This study employed four variations of the CNN architecture to determine the best architecture for detecting the presence or absence of cracks in ancient building structures in Semarang's old town. For the computation this study used GPU GTX 1650 RAM 2 x 8 GB 2400 MHz DDR4.

This basic design can be extended to create CNN2 or CNN3 architectures, as shown in the CNN1 architecture diagram in Fig. 3. CNN3 is extensible to CNN4. CNN architectures are built to determine the impact of CONV layers and their activation functions on classification accuracy. In addition, comparisons can be made between CNN1, CNN2, CNN3, and CNN4 or between design groups to determine if the most appropriate type of design is being used for classifying old building crack images.

IV. EXPERIMENT AND DISCUSSION

Fig. 4(a) shows Model 1 with two convolution layers correctly predicts 1459 (TP) normal and 1442 (TN) cracked images, while 41 (FN) normal images are predicted to be cracked and 58 (FP) cracked images are predicted to be normal

Fig. 4(b) shows Model 2 with four convolution layers correctly predicts 1489 (TP) normal and 1473 (TN) cracked images, while 11 (FN) normal images are predicted to be cracked and 27 (FP) cracked images are predicted to be normal. Fig. 4(c) shows Model 3 with 8 convolution layers correctly predicts 1487 (TP) normal and 1467 (TN) cracked images, as well as 13 (FN) normal images that are cracked and 33 (FP) cracked images that are normal. Fig. 4(d) shows Model 4 with 10 convolution layers correctly predicts 1491 (TP) normal and 1475 (TN) crack images, as well as 9 (FN) normal images that are cracked and 25 (FP) cracked images that are

normal. The FN on Model 1.d is smaller than on the other three models.

(a) Model 1.2 Convolutional Layer, (b). Model 2.4 Convolutional Layer

(c) Model 3.8 Convolutional Layer, (d). Model 4.10 Convolutional Layer

Fig. 4. Confusion matrix results for each CNN modification model

By identifying knowing TP, TN, FN, FP, performance values it generates such as accuracy, precision, recall, F1, MCC and CK values as shown in Table I, Table II and Table III. Table I shows the performance of Fig. 4 Confusion Matrix Results for each CNN modification model

TABLE I. PERFORMANCE COMPARISON OF DIFFERENT CNN MODIFICATION METHODS

N_LAYER CONVOLUTIONAL	ACCURACY SCORE	RECALL SCORE	PRECISION SCORE	F1 SCORE	MCC (%)	CK (%)
2 LAYER	96.70	97.23	96.13	96.68	93.41	96.69
4 LAYER	98.73	99.26	98.20	98.73	97.47	98.73
8 LAYER	98.43	98.34	98.53	98.43	96.94	98.46
10 LAYER	98.87	99.40	98.33	98.86	97.74	98.86

Table I displays that the convolution layer design with 10 convolution layers has the highest F1 score of 98.86% and 98.87% accuracy among other models, as well as 98.33% precision and 99.40% recall. The Deca Convolutiol Layer Neural Network (DCL-NN) outperforms the other models in the popular statistical tests MCC and CK (Cohen's Kappa), with values of 97.74% and 98.86%.

(a). KNeighbors (n\_neighbors=3) (b). Random Forest

(c) SVM (d) ExtraTrees (n\_estimators=10)

Fig. 5. Confusion matrix results for each machine learning model

In Fig. 5(a), the KNN model correctly predicts 1000 (TP) normal and 476 (TN) crack images, while 524 (FN) normal images are predicted as cracked and 0 (FP) cracked images are predicted as normal. In Fig. 5(b), the Random Forest model correctly predicts 973 (TP) normal and 960 (TN) cracked images, with 40 (FN) normal images predicted as cracked and 27 (FP) cracked images predicted as normal. In Fig. 5(c), the SVM model correctly predicts 976 (TP) normal and 811 (TN) cracked images, with 189 (FN) normal images predicted to be cracked and 13 (FP) cracked images predicted to be normal. In Fig. 5(d), the Extra Tree model correctly predicts 987 (TP) normal and 972 (TN) cracked images, with 28 (FN) normal images predicted as cracked and 13 (FP) cracked images predicted as normal. When compared to the other three machine learning models, the Extra Trees model has a lower FN. Table II shows the performance of Fig. 5. Confusion Matrix Results for each machine learning model

TABLE II. PERFORMANCE COMPARISON OF DIFFERENT MACHINE LEARNING METHODS

Machine Learning	Accuracy Score	Recall Score	Precision Score	F1 Score	MCC (%)	CK (%)
K Neighbors (n_neighbors=3)	74	83	74	72	55.89	69.85
Random Forest	97	97	97	97	93.31	96.64
SVM	89	90	89	90	79.79	88.89
ExtraTrees (n_estimators=10)	98	98	98	98	95.91	97.94

According to Table II, the ExtraTrees machine learning model has the highest F1 score of 98% and 98% accuracy among other models, as well as 98% precision and 98% recall. In the case of popular statistical tests such as MCC and CK (Cohen's Kappa), the ExtraTrees machine learning model outperforms the other models with values of 95.91% and 97.94%, respectively.

Fig. 6(a) illustrates the transfer learning model VGG19 correctly predicts 1487 (TP) normal and 1470 (TN) cracked images, with 13 (FN) normal images predicted to be cracked and 30 (FP) cracked images predicted to be normal. As for the Fig. 6(b) shows the Xception model correctly predicts 1444 (TP) normal and 1497 (TN) cracked images, with 56 (FN) normal images predicted as cracked and 3 (FP) cracked images predicted as normal. Fig. 6(c) illustrates the MobileNet model correctly predicts 1472 (TP) normal and 1434 (TN) cracked images, with 28 (FN) normal images predicted as cracked and

66 (FP) cracked images predicted as normal. The VGG19 model has a lower FN than the other three transfer learning models. The performance of Fig. 6, Matric Confusion Results for each model of Pre-Trained CNN is shown in Table III.

Fig. 6. Matric confusion results for each model of pre-trained CNN

TABLE III. PERFORMANCE COMPARISON OF DIFFERENT TRANSFER LEARNING METHODS

Transfer Learning	Accuracy Score	Recall Score	Precision Score	F1_Score	MCC (%)	CK (%)
VGG19	98.57	99.12	98.00	98.56	97.14	98.56
Xception	98.03	96.39	99.80	98.07	96.13	98.05
MobileNet	96.87	98.08	95.60	96.83	93.76	96.85

Table III shows that the VGG19 model transfer learning design had the highest F1 score of 98.56% and 98.57% accuracy, as well as 98.00% precision and 99.12% recall among other models. The transfer learning performance of the VGG19 model outperforms the other models in popular statistical tests such as MCC and CK (Cohen's Kappa), with values of 97.14% and 98.56%, respectively.

In Model 1, after 10 iterations, the program automatically stops training, and the correct model rate is approximately 97.67%. (Loss 0.1141). As illustrated in Fig. 9, the maximum true rate is reached after the tenth iteration. It takes about 13 seconds. As illustrated in Fig. 7, the correct rate gradually stabilizes in later training stages due to the continuous reduction of the learning rate. In Model 2, after 10 iterations, the program automatically stops training, and the correct model rate is approximately 98.57% (0.0646).

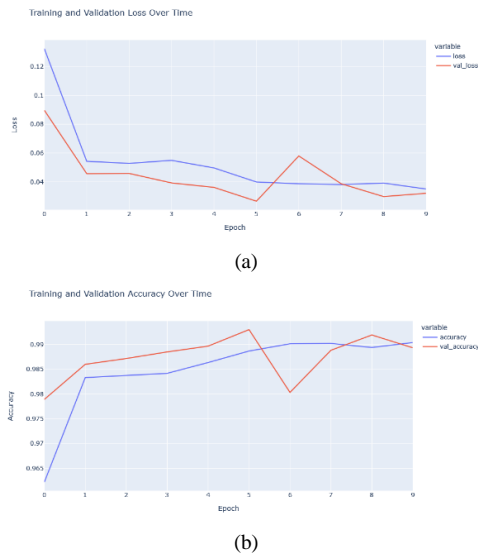

Fig. 7. Graph of accuracy and loss in model 1 with 2 convolutional layer

Fig. 8 shows that the maximum true rate is reached after the tenth iteration. It takes about 28 seconds. As shown in Fig. 8, the correct rate gradually stabilizes in later training stages due to the continuous reduction of the learning rate. In Model 2, after 10 iterations, the program automatically stops training, and the correct model rate is approximately 98.90% (Loss 0.0561).

Fig. 8. Graph of accuracy and loss in model 2 with 4 convolutional layer

Figure 9 shows that the maximum true rate is reached after the tenth iteration. It takes about 31 seconds. As illustrated in Figure 9, the correct rate gradually stabilizes in later training stages due to the continuous reduction of the learning rate. In Model 4, after 10 iterations, the program automatically stops training, and the correct model rate is approximately 99.17%. (Loss 0.0284)

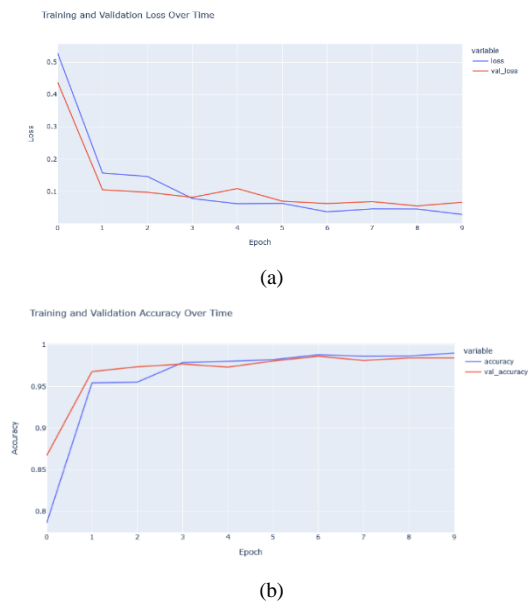

Fig. 9. Graph of accuracy and loss in model 2 with 8 convolutional layer

Fig. 12 shows that the maximum true rate is reached after the tenth iteration. It takes about 32 seconds. As illustrated in Fig. 12, the correct rate gradually stabilizes in later training stages due to the continuous reduction of the learning rate.

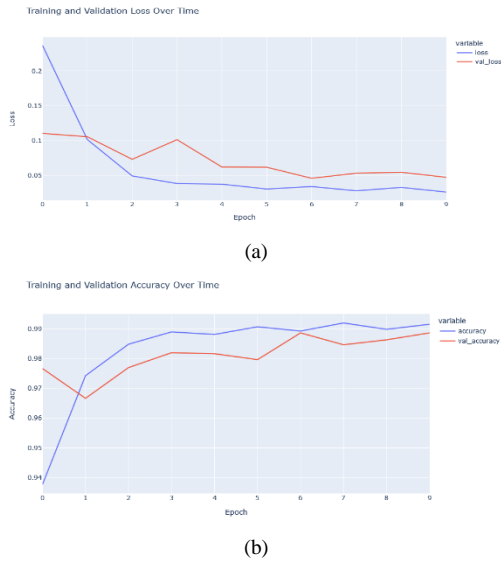

Fig. 10. Graph of accuracy and loss in model 2 with 10 convolutional layer

Fig. 10 shows that the maximum true rate is reached after the tenth iteration. It takes about 32 seconds. As illustrated in Fig. 10, the correct rate gradually stabilizes in later training stages due to the continuous reduction of the learning rate.

The CNN model's performance is also compared to that of other transfer learning models, such as VGG19, Exception, and MobilNet. The following performance graphs are generated for each transfer learning model:

The VGG model automatically stops training after 10 iterations, and the correct model rate is approximately 98.93%. (Loss 0.0384). As shown in Fig. 13, the maximum true rate is reached after the tenth iteration. It takes approximately 61 seconds. As shown in Fig. 13, the correct rate gradually stabilizes in later training stages due to the continuous reduction of the learning rate. In Model Exception, the program automatically stops training after 10 iterations, and the correct model rate is approximately 98.67% (Loss 0.0526).

As shown in Fig. 11, the maximum true rate is reached after the tenth iteration. It takes approximately 61 seconds. As shown in Fig. 11, the correct rate gradually stabilizes in later training stages due to the continuous reduction of the learning rate. In Model Exception, the program automatically stops training after 10 iterations, and the correct model rate is approximately 98.67% (Loss 0.0526).

Fig. 11. VGG19 model accuracy and loss graphs

As illustrated in Fig. 12, the maximum true rate is reached after the tenth iteration. It takes about 63 seconds. As illustrated in Fig. 12, the correct rate gradually stabilizes in later training stages due to the continuous reduction of the learning rate. The MobileNet model, after 10 iterations, the program automatically stops training, and the correct model rate is approximately 96.67% (Loss 0.0993).

Fig. 12. Graph of accuracy and loss in exception model

As shown in Fig. 13, the maximum true rate is reached after the tenth iteration. It takes approximately 30 seconds. As shown in Fig. 13, the correct rate gradually stabilizes in later training stages due to the continuous reduction of the learning rate.

## V. CONCLUSION

This research contributes to crack classification at historical building by using four architectural design variants of convolutional neural networks (CNNs), namely, CNN1-CNN4. The research methodology used in this study is an experimental cracking classification using four variations of convolutional neural network (CNN) architecture design (CNN1 - CNN4).

Experimental results show that CNN4 (Deca Convolutional Layer Neural Network/DCL-NN) provides the best classification results for concrete cracks in old buildings compared to other architectural designs tested. The DCL-NN architecture has an accuracy of 98.87%, precision of 99.40%, recall of 98.33%, F1 score of 98.86%, MCC of 97.74%, and CK of 98.86%.

In addition, results from comparisons with pre-trained CNN algorithm methods such as VGG19, Xception, MobileNet, and machine algorithms such as KNeighbors (n neighbors=3), Random Forests, Support Vector Machines (SVM), ExtraTrees (n estimators) Classification using learning. = 10), he shows the superiority of DCL-NN in classifying concrete cracks in old buildings in Semarang city.

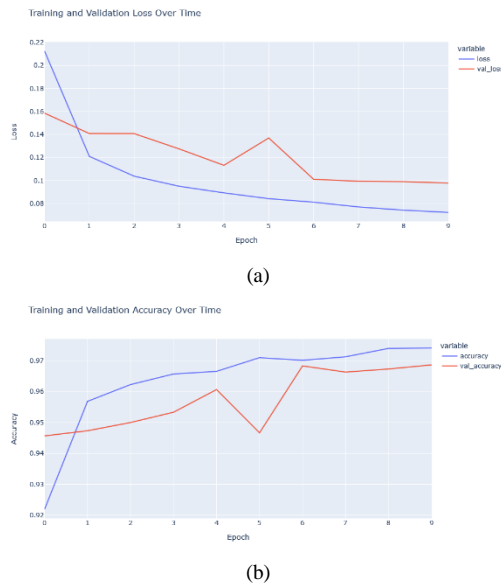

Fig. 13. Accuracy and loss graphs on the MobileNet model

Researchers in this study conducted research that was also compared to other researchers using the same dataset. Zhang et al. [20] classified cracks using CNN and four convolution layers, two of which were fully connected. ConvNets is the name of the method used. Precision and recall rates are 86.96% and 92.51%, respectively. In classifying aligned images, Fang et al. [21] employ three convolution layers and three Fully Connected Layers. Precision and recall rates for experiments using the same data as the researchers were 18.4% and 94.3%, respectively. While the researchers used 10 convolution layers and one Fully Connected layer to achieve a recall and precision of 99.40% and 98.33%, respectively. Our model outperforms both works [1] and [2], as shown in the Table IV below.

TABLE IV. COMPARISON OF PERFORMA WITH OTHER RESEARCHERS

Other Researchers	Number of Convolution Layers	Number of Fully Connected Layers	Precision	Recall
Zhang et al. [20]	4	2	86.96%	92.51%
Fang et al. [21]	3	2	18.40%	94.30%
Proposed Model	10	1	98.33%	99.40%

Each neuron in the convolution layer needs to be transformed into one-dimensional data. First before it can be included in a fully-connected layer. Also, because it causes the data to lose its spatial information and is not reversible, while the fully connected layer can only be implemented at the end of the network CNN [22].

Prior researchers used 2 Fully Connected Layers (FCL) to prevent loss of image spatial information and a long duration so that classification performance can be maintained, but with this study, we used a large number of convolution layers and a low number of FCL, to produce high performance.

# Convolutional Transformer based Local and Global Feature Learning for Speech Enhancement

Chaitanya Jannu<sup>1</sup>, Sunny Dayal Vanambathina<sup>2</sup>

School of Electronics Engineering, VIT-AP University, Amaravati, India<sup>1,2</sup>

**Abstract**—Speech enhancement (SE) is an important method for improving speech quality and intelligibility in noisy environments where received speech is severely distorted by noise. An efficient speech enhancement system relies on accurately modelling the long-term dependencies of noisy speech. Deep learning has greatly benefited by the use of transformers where long-term dependencies can be modelled more efficiently with multi-head attention (MHA) by using sequence similarity. Transformers frequently outperform recurrent neural network (RNN) and convolutional neural network (CNN) models in many tasks while utilizing parallel processing. In this paper we proposed a two-stage convolutional transformer for speech enhancement in time domain. The transformer considers global information as well as parallel computing, resulting in a reduction of long-term noise. In the proposed work unlike two-stage transformer neural network (TSTNN) different transformer structures for intra and inter transformers are used for extracting the local as well as global features of noisy speech. Moreover, a CNN module is added to the transformer so that short-term noise can be reduced more effectively, based on the ability of CNN to extract local information. The experimental findings demonstrate that the proposed model outperformed the other existing models in terms of STOI (short-time objective intelligibility), and PESQ (perceptual evaluation of the speech quality).

**Keywords**—Convolutional neural network; recurrent neural network; speech enhancement; multi-head attention; two-stage convolutional transformer; feed-forward network

## I. INTRODUCTION

In the area of speech processing, speech enhancement is crucial. The main objective is to enhance speech that has been impaired by background noise in terms of clarity and quality. Numerous applications including powerful speech recognition, teleconferencing, and hearing aids, employ it as a pre-processor. Recent advances in deep learning have made it possible to develop several data driven methods to solve traditional estimation problems without having to rely on supervision. The majority of existing deep learning models for speech enhancement, such as convolutional neural network (CNN) and recurrent neural network (RNN), are implemented in the time-frequency (T-F) domain. Those methods use short-time Fourier transforms (STFT) to train on spectral magnitude. To reconstruct the time-domain signal using the inverse short-time Fourier transform (iSTFT), it is necessary to take into account the phase of noisy speech along with the improved speech magnitude. Despite some impressive results [1-4], T-F domain methods still have two key drawbacks. In the first place, Fourier transforms add an additional overhead to fast speech denoising. Second, during the denoising

process, the noisy phase is generally ignored. Nevertheless, phase information has been shown to be significant for improving speech quality [5]. To achieve better enhancement results, there are some studies that look at magnitude as well as phase simultaneously during training [6]. Several recent works have directly estimated the clean speech in time domain from noisy raw data [7-11].

## II. RELATED WORK

A fully convolutional network (FCN) has been proposed by Fu et al. [12] for raw waveform-based speech enhancement which improves the quality compared to masking-based methods [13-14]. In distinction to both masking and mapping techniques that use noisy phase to reconstruct enhanced speech, FCN provides speech enhancement by simply mapping from a noisy speech to the matching clean speech. Many studies have looked into CNN or RNN-based encoder-decoder frameworks. CNN requires more convolutional layers to enlarge the receptive field when modelling long-range sequences such as speech. The Convolutional recurrent networks (CRNs) [15] are used to extract long-context information using CNN's which are familiar for feature extraction and RNNs' which are familiar for temporal modelling. For processing long-term temporal sequences, a dilated convolutional neural network has been proposed [16]. K. Tan et al. [17] proposed GRN with Dilated convolutions for supervised SE. The convolutions with dilation enlarge the receptive field without sacrificing resolution compared to regular convolutions by maintaining the same kernel size and network depth. At various SNR levels the GRN exhibits higher generalization ability to untrained speakers when compared to the LSTM model in [18]. A CNN model in time domain is presented by considering frequency domain loss to enhance the quality of corrupted speech [19]. Although the work in [19] can achieve cutting-edge performance, the issue of real-time enhancement is not addressed. Later the same authors proposed densely connected network [20] for real time SE and achieved better performance than [19].

The RNNs such as Long Short-Term Memory (LSTM) and Gated Recurrent Units (GRU) are usually used to model long-term sequences with order information. Although introducing temporal convolutional network (TCN) blocks [10] or LSTM layers between encoder and decoder can improve denoising performance by extracting higher-level features and expanding receptive fields [11], the contextual information of speech is generally ignored, limiting denoising performance. Recently Li, Qinglong, et al. [21] proposed a DCTCRN model for speech enhancement where discrete cosine transform is used as input to the model for processing noisy speech and uses

LSTM as bottleneck. Even though the performance of the model is better, the LSTMs are easily prone to the problem of overfitting and it also requires large time to train and are also sensitive to random weight initializations. Kai Zhen et al. proposed a DCCRN [22] network for SE in time domain where densenets and GRUs are used for context aggregation. This model yields better intelligibility scores compared to convolutional base line models but quality is less compared to Wave-U-Net model [7]. Recently Lin et al. proposed a SASE model [23] with self-attention for speech enhancement which extracts speaker information using LSTM layers and also CRN model is used for speech enhancement based on embedding of speaker information which performs better than CRNs and LSTM models but the quality is not satisfactory. A unique ARN for time-domain speech improvement was recently proposed by Pandey A., et al. [24] in order to promote cross-corpus generalization. Self-attention and feedforward blocks are added to RNN to create ARN. It has been shown that transformer neural networks are capable of resolving the long-dependency problem effectively and are capable of operating in parallel, so they are good at tackling a wide range of natural language processing tasks [25]. As the transformer only uses the attention mechanism, the vanishing gradient and exploding gradient problem of RNNs are also solved. A transformer model for speech enhancement was proposed in [26], which has a comparatively large size of model. Transformer enhances the training speed and prediction accuracy compared to RNNs [25]. By combining the advantages of LSTM and multi-head attention mechanism, Yu et al. [27] proposed SETransformer. When compared with a standard transformer and an LSTM model, SETransformer showed better denoising performance. Recently Wang et al. [28] introduced an end-to-end speech enhancement two-stage transformer neural network (TSTNN).

The limitations of existing frameworks are the CNN models [12,19] requires more convolutional layers to enlarge the receptive field when modelling long-range sequences such as speech. The disadvantage of RNN-based models [18] is that they cannot perform parallel processing, resulting in high computation complexity. The limitation of TCN [10] is that the contextual information of speech is generally ignored, limiting denoising performance. The CRN model [21] suffers with computational complexity. The transformer models present in [26], [27] performs better than convolutional and RNN baselines but they are implemented in the time-frequency (T-F) domain. To achieve better enhancement results, there are some studies that look at magnitude as well as phase simultaneously during training. Recently Wang et al. [28] introduced an end-to-end speech enhancement two-stage transformer neural network (TSTNN) which performs better than [26] and [27]. But in TSTNN model same structure of FFN is used for extracting local and global features. And also, they have not concentrated on the local (short-term) noises present at the output of encoder.

Motivated by recent success of transformer neural networks in natural language processing tasks [25] and SE [26-28] we propose a novel two-stage convolutional transformer neural network that enhances monaural speech in a time domain. The transformers are capable of resolving the

long-range dependency problem effectively and are capable of operating in parallel. As the transformer only uses the attention mechanism, the vanishing gradient and exploding gradient problem of RNNs are also solved. In this work, we propose a two-stage convolutional transformer neural network that enhances monaural speech in a time domain from end to end which differs from the existing transformer models such as T-gsa [26], SETransformer [27] and two-stage transformer neural network (TSTNN) [28]. Based on the transformer's ability to model sequences and the dual-path network's ability to extract contextual information [29], we propose a two-stage convolutional transformer neural network.

In this paper the proposed transformer considers global information as well as parallel computing, resulting in a reduction of long-term noise. Unlike the transformer proposed in [28], we proposed a novel transformer structure for intra and inter transformers to extract the local as well as global features of noisy speech using CNN and RNN layers [30]. A 1D-Conv layer and temporal convolution module (TCM) are used in intra transformer where local features are extracted and a 1D-Conv layer and Bi-directional long short-term memory (Bi-LSTM) are used in inter transformer where global features are extracted.

Moreover, in the proposed model, a CNN module is also added to intra and inter transformers so that short-term noise can be reduced more effectively, based on the ability of CNN to extract local information. The proposed model enhances the local information modelling capability of the traditional transformer model by adding a convolution layer. The convolutional module consists of Depth and Point wise convolutions instead of normal convolution to increase the speed of operation of model and both of them have less parameters compared to normal convolution. The details of convolutional module and modified layers of feed forward network are explained in the following sections.

Our contributions:

- In contrast to RNNs and CNNs, the proposed transformer model uses parallel processing and the long-term dependencies can be modelled more efficiently with multi-head attention (MHA) by using sequence similarity.
- The novelty of the proposed work is different transformer structures for intra and inter transformers are used for extracting the local as well as global features of noisy speech using CNN and RNN layers. In the proposed model a CNN module is also added to intra and inter transformers so that short-term noise can be reduced more effectively, based on the ability of CNN to extract local information.
- The proposed model enhances the local information modelling capability of the traditional transformer model by adding a CNN module.

The remainder of this work is structured as follows. The presents the related works. Section II presents related works and we explained the details of proposed two-stage convolutional transformer in Section III. Section IV presents

the experimental findings. Section V presents discussion and the paper is concluded in Section VI.

### III. ARCHITECTURE OF PROPOSED TWO-STAGE CONVOLUTIONAL TRANSFORMER

The overall architecture of proposed model is shown in Fig. 1. The model consists of four modules: Encoder, Transformer module, Masking module and Decoder. There are two convolution layers in the encoder among them the first one is to increase the channels to 64 and the second one is

used to halve the size of the frame. The transformer module internally consists of four transformer blocks responsible for feature extraction. The detailed transformer module is explained in following Section 3.C. The masking module is used to obtain the mask using 2-way convolution and nonlinear activations. In the decoding phase the reconstruction of features is done by using dilated dense block and sub-pixel convolution. Finally, we will get the enhanced speech after normalization and PReLU.

Fig. 1. Architecture of proposed convolutional transformer

#### A. Segmentation and Overlap-Add

In this stage the input noisy speech  $Y \in R^{1 \times L}$  is splitted into frames with length of each frame as  $F$  and hop size as  $H$ . The 3D tensor  $I \in R^{1 \times N \times F}$  is then created by stacking all frames as input to the encoder. The length of input noisy speech is denoted by  $L$  and total frame count is denoted by  $N$ .

$$N = [(L - F)/(F - H) + 1] \quad (1)$$

To recover the enhanced speech waveform the overlap-add operation is used at decoder.

#### B. Encoder

There are two convolution layers in the encoder among them the first one is to increase the channels to 64 with filter

size of (1,1) and the second one is used to halve the frame size with filter and stride of (1,3) and (1,2). And a 4-layer dilated dense block [20] is inserted in between them. The Layer normalization and PReLU nonlinearity [30-31] are applied to all convolutional layers.

#### C. Transformer Module

The transformer module internally consists of four transformer blocks stacked together where feature extraction is performed to extract local as well as global features. Before giving the output of encoder to input of transformer, we use convolution with a kernel of size (1, 1) followed by PReLU activation to halve the channel dimension to reduce the computational complexity of the transformer network. The transformer block is shown in below Fig. 2.

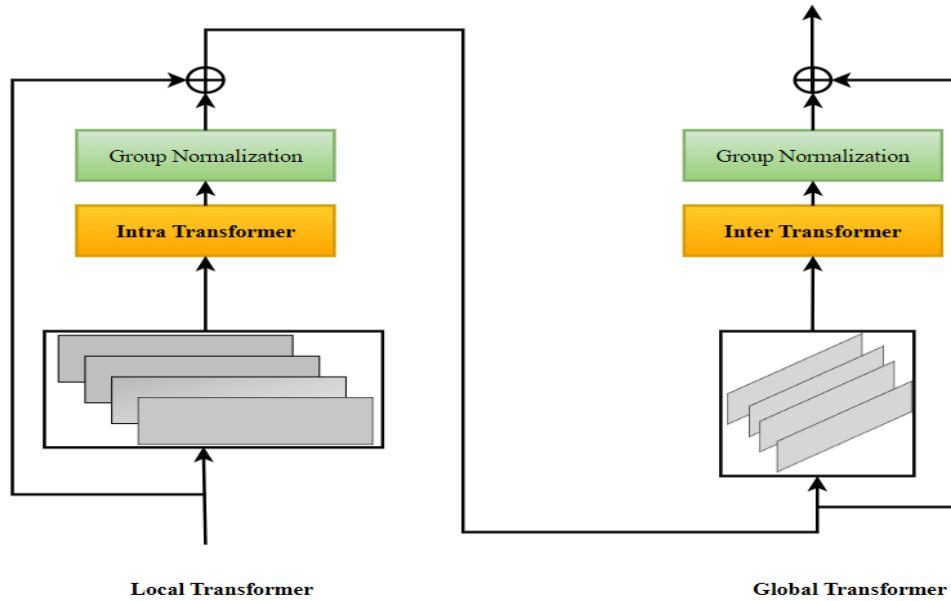

Fig. 2. Transformer block

1) *Improved transformer*: The transformer block consists of intra and inter transformers as shown in above Fig. 2. To independently model the local chunks intra transformer is used and inter transformer is used to extract global dependencies by summarizing information of all blocks.

Three important modules are included in the original transformer encoder [25]: positional encoding, multi-head

attention, and position-wise feed-forward. Due to the fact that the positional encoding is not appropriate for acoustic sequences the authors of baseline model [28] designed GRUs to learn positional information by replacing the first fully connected layer of feed-forward networks with RNNs to track order information [32-33]. The structure of feed forward network used in baseline model [28] is shown in Fig. 3.

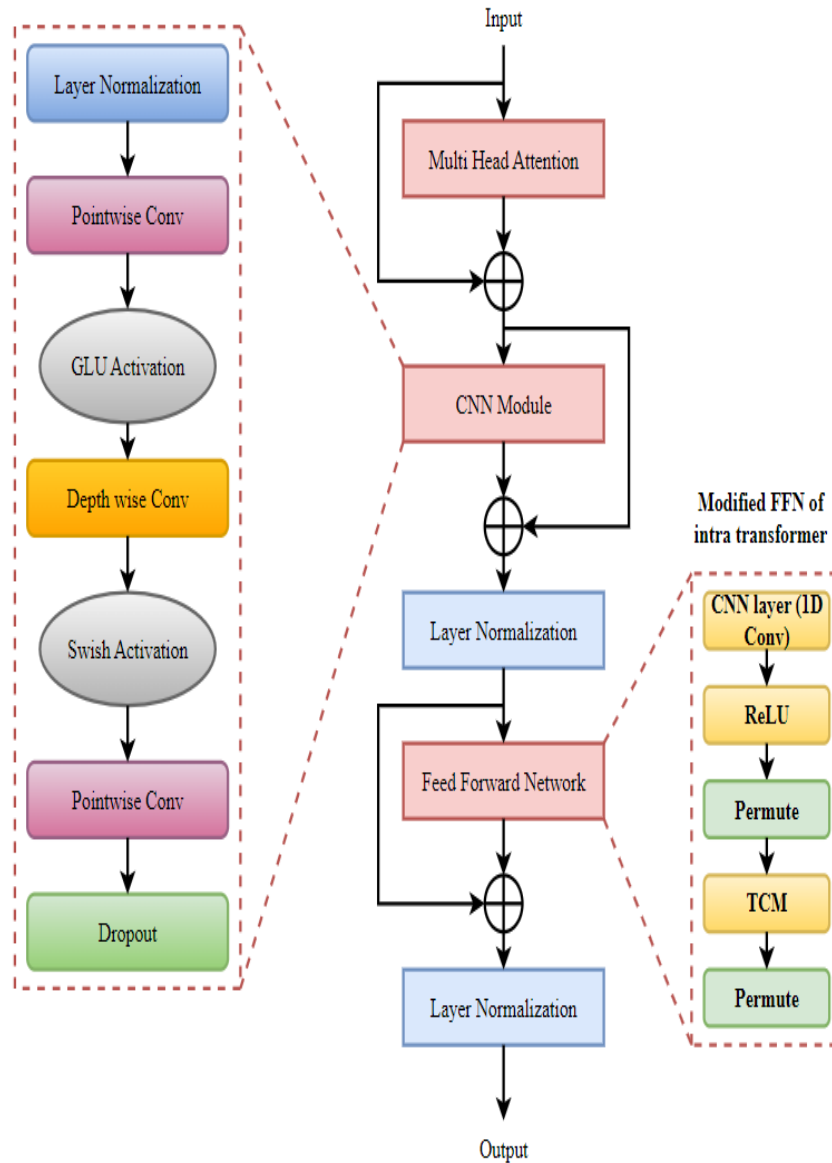

Fig. 3. The structure of feed forward network in baseline model

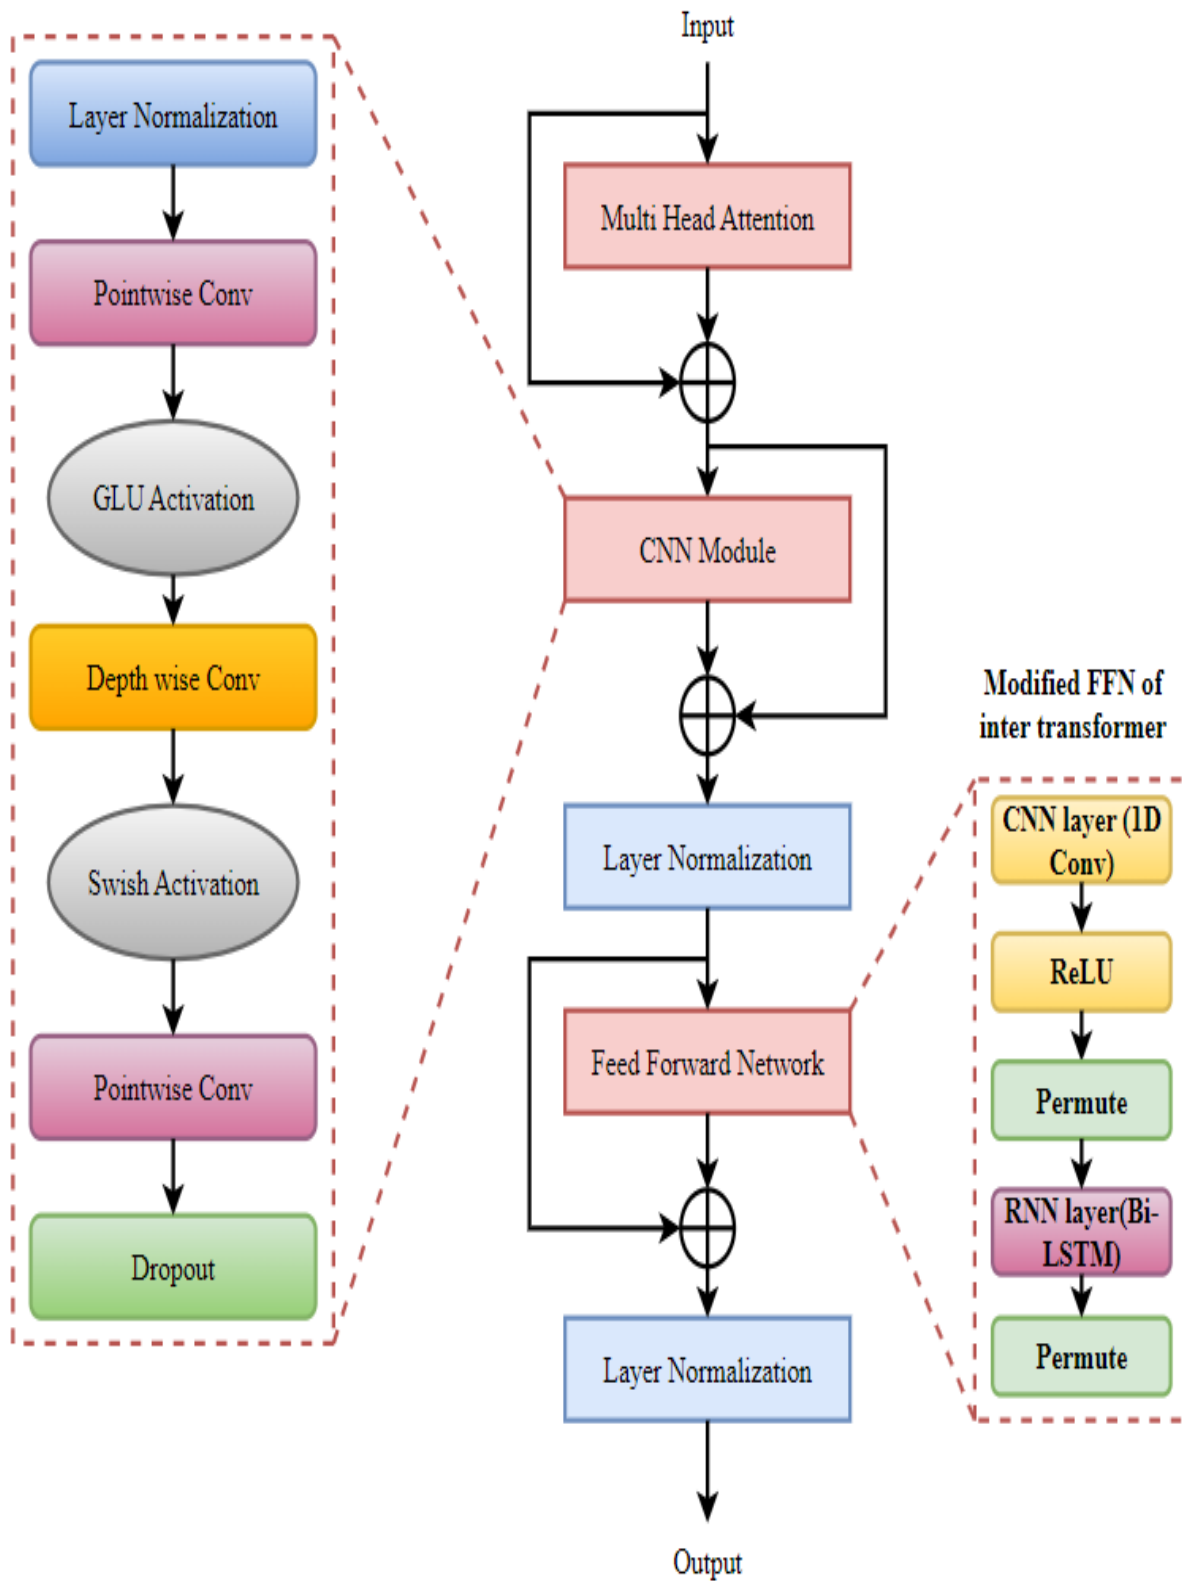

In the baseline model same structure of feed forward network is used in both intra and inter transformers of transformer block. In the proposed method unlike baseline, we introduced two different feed forward network layer structures in the intra and inter transformers of transformer block to well model the local and global features. In addition to this we have also added a convolutional module to the baseline intra and inter transformers of transformer block to further filter the local (short-term) noises present at the output of encoder. Due to the powerful feature self-learning ability of the CNN model, it will increase the local feature extraction ability of the transformer model. The proposed model enhances the local information modelling ability of the traditional transformer model by adding a convolution layer. The structure of proposed intra and inter transformers along with convolutional module are shown in below Fig. 4(a) and 4(b). The

convolutional module consists of Depth and Point wise convolutions instead of normal convolution to increase the speed of operation of model and both of them have less parameters compared to normal convolution.

2) *Proposed intra and inter transformer:* The key distinction between intra and inter transformer is in its structure of Feed Forward Network (FFN). A CNN layer (1D-Conv) and temporal convolution module (TCM) are used in intra transformer to learn long-term dependency of speech from the encoder output. The layer details of TCM are shown in below Fig. 5. A CNN layer (1D-Conv) and Bi-directional long short-term memory (Bi-LSTM) [34] are used in inter transformer to extract long-distance global features.

(a)

(b)

Fig. 4. The structure of inter transformer in transformer block

Fig. 5. The Layers of TCM

In general, Multi-Head Attention (MHA) works as follows:

In the MHA block, the input (Y) is first mapped  $h$ -times with different, learnable linear transformations to obtain queries, keys, and values representations, respectively.

$$Q_i = YW_i^Q, K_i = YW_i^K, V_i = YW_i^V \quad (2)$$

In the above Eq. 1  $Q_i, K_i, V_i \in R^{l \times d/h}$  are mapped query, key and value.  $W_i^Q, W_i^K, W_i^V \in R^{d \times d/h}$  represents  $i^{th}$  linear projection matrix for query, key and value.

The query will be dot produced with all keys and a constant is divided by the dot product. After that a softmax is applied to the values to obtain weights. According to Eq.2, each head's attention is a dot product of its weight and value.

$$Head_i = Attention(Q_i, K_i, V_i) = softmax\left(\frac{Q_i K_i^T}{\sqrt{d}}\right) V_i, i = 1, 2, \dots, h \quad (3)$$

The number of parallel attention heads are represented by  $h$ . In our proposed work  $h$  is considered as 4. The final output is obtained by concatenating the attentions of all heads and linearly projecting them again.

$$MultiHead(Q, K, V) = concat(Head_1, \dots, Head_h)W^O \quad (4)$$

In the above Eq. 3  $W_i^O \in R^{d \times d}$  is linear projection matrix.

Next, it follows residual connection as shown in Eq. (4).

$$out = Y + MultiHead(Q, K, V) \quad (5)$$

In the above Eq. 4  $Y \in R^{l \times d}$  represents input. Where  $l$  is sequence length and  $d$  is dimension.

To get the final output of intra and inter transformers of transformer block, the output of multi-head attention block is then processed by convolutional module and corresponding feed-forward networks, as well as residual connections and layer normalization [18].

The output of convolutional module is given as

$$\begin{aligned} Conv\ Module\ (out) \\ = Dropout(PointwiseConv(Swish(DepthWiseConv \\ (GLU(PointwiseConv \\ (LayerNormalization(out))))))) \quad (6) \\ CM_{out} = \\ LayerNormalization(out + (Conv\ Module\ (out))) \quad (7) \end{aligned}$$

The final output of intra transformer is given as

$$FFN_{intra}(CM_{out}) = TCN(ReLU(Conv1D(CM_{out}))) \quad (8)$$

$$Finaloutput_{intra} = LayerNormalization(CM_{out} + FFN_{intra}(CM_{out})) \quad (9)$$

The final output of inter transformer is given as:

$$FFN_{inter}(CM_{out}) = \text{Bi-LSTM}(\text{ReLU}(\text{Conv1D}(CM_{out}))) \quad (10)$$

$$\text{Finaloutput}_{inter} = \text{LayerNormalization}(CM_{out} + FFN_{inter}(CM_{out})) \quad (11)$$

3) *Proposed two-stage transformer block*: In the proposed 2-stage transformer block there are two transformers called intra and inter transformers as shown in Fig. 2, which are used for extracting local and global context information respectively. The local transformer with the input as a 3-D tensor with dimensions as [C, N, F] is first applied to each chunk and local information is processed in parallel on the last dimension F of the input tensor. For learning global dependency, the global transformer uses the information of output from the local transformer which is implemented on tensor dimension N. Moreover, each transformer undergoes a group normalization and residual connections are also used.

#### D. Masking Module

A masking network obtains denoising masks by utilizing transformer module's output features. First to match the output of the encoder, transformer module output is doubled along the channel dimension using PReLU and convolution. Afterwards, it undergoes two-way 2D convolution and nonlinearity, with the outputs multiplying together to form the input of two-dimensional convolution and PReLU. In order to obtain the final masked encoder feature, the mask and the encoder's output are multiplied element-wise.

#### E. Decoder

At this stage decoding the encoder feature into enhanced speech features is accomplished via dilated dense blocks and sub-pixel convolutions [35]. Using 2D Conv with filter size (1, 1), the enhanced speech feature's channel dimension is recovered into one and the enhanced waveform is produced by overlap-add.

#### F. Loss Function

The loss in the T-F domain can direct the model to acquire extra information, resulting in improved intelligibility as well as quality [19]. To train the model, we combine two losses. First, a waveform is created using the overlap-and-add approach utilizing the improved frames. Using the mean squared error among the enhanced and clean utterances, an utterance level loss is computed in the temporal domain.

It is said that the time-domain loss is:

$$L_t(y, \hat{y}) = \frac{1}{M} \sum_{n=0}^{M-1} (y_i[n] - \hat{y}_i[n])^2 \quad (12)$$

where M is the utterance length,  $y[n]$  is the nth sample of the clean utterance and  $\hat{y}[n]$  is nth sample of enhanced utterance.

The loss in frequency-domain is given as:

$$L_f(y, \hat{y}) = \frac{1}{T \cdot F} \sum_{t=1}^T \sum_{f=1}^F (|Y(t, f)_r| + |Y(t, f)_i|) - (|\hat{Y}(t, f)_r| + |\hat{Y}(t, f)_i|) \quad (13)$$

where  $Y(t, f)$  and  $\hat{Y}(t, f)$  denotes T-F units of STFT's of Y and  $\hat{Y}$  respectively. Where T denotes total frames number

and F denotes frequency bins count. The real and imaginary components of a complex variable Y is denoted by  $Y_r$  and  $Y_i$ , respectively.

Finally, the T-F domain loss is given by

$$L(y, \hat{y}) = \alpha * L_t(y, \hat{y}) + (1 - \alpha) * L_f(y, \hat{y}) \quad (14)$$

The hyper-parameter  $\alpha$  is set to 0.2.

## IV. EXPERIMENTS

### A. Datasets

We conducted the experiments using a 2 data sets one is public dataset published by Valentini et al. in [36]. This database contains 30 utterers from the Voice Bank corpus [37], among them 28 utterers are utilized to train the model and 2 are utilized for testing. There are 11,572 pairs of clean-noisy speeches in the training set. The noisy environments comprise 10 types of noises. Among them 8 noises are from the DEMAND dataset [38] and 2 are synthetic sounds at SNRs of 0, 5, 10 and 15 dB. The test set contains 824 mixtures using 5 noises from [38] which are not present in training set at SNRs of 17.5 dB, 12.5 dB, 7.5 dB and 2.5 dB.

Additionally, we assess the performance of our model in unseen environments. To test the generalization capability of proposed model we considered large Librispeech dataset [39]. To train the model we have chosen clean speech with duration of 50h from train-clean-100. A randomly selected set of noises from DEMAND dataset [38] and music samples from MUSAN [40] was used in the training set, with SNR ranges from -10dB to 10 dB. For each of the six DEMAND categories, we used two out of three types of noise. The test set of 500 samples are randomly taken from test-clean and the babble noise from NOISEX-92 dataset [41] and the noises river and restaurant are taken from DEMAND which are different from training set. The SNR are -5dB, 0dB, 5dB, 10dB, and 15dB. The sampling rate of all utterances is 16KHz.

### B. Experimental Setup

Each speech is resampled to a 16 kHz frequency. A rectangle window with a 32 ms (512 samples) size and overlap length of 16 ms is used to extract the frames. If an utterance lasts more than 4 seconds, we chunk a random 4 second chunk from it during each training session. To make the smaller utterances in the batch the same size as the largest utterance, zero padding is used. we train the model over the course of 100 epochs and optimization employs the Adam optimizer. Gradient clipping is used with a maximum L2-norm of 5 to prevent gradient explosion. During the training phase, dynamic strategies are used to determine learning rate [13]. In this experiment, learning rates are linearly increased during training and then reduced by 0.98 every two epochs.

### C. Evaluation Metrics

In this study, speech quality is measured by using STOI [42], whose values normally fall between 0 and 1, and PESQ [43], whose ranges are -0.5 to 4.5. Speech quality improves with a higher PESQ value. Speech intelligibility increases with increased STOI.

#### D. Results and Analysis

1) *Comparison with existing works on Valentini et al. dataset [36]*: The experiment was carried out with two different datasets. The proposed convolutional transformer model was compared with various existing models such as SEGAN [8], CGAN [44], Wave-U-Net [7], MMSE-GAN [2], Metric GAN [3], DCUnet-16 [6], DEMUCS-small [11], SE-Transformer [27], TSTNN [28]. All the existing models used

for comparison are trained with similar dataset used to train our model. All the models are reproduced for comparison. As a comparison to the number of existing models stated in the original papers, we calculated the metric scores of our model. The proposed model was assessed by using the STOI and PESQ. The PESQ and STOI values for Valentini et al. dataset [36] are given in Table I.

TABLE I. ASSESSMENT OF PESQ AND STOI OF PROPOSED MODEL WITH PREVIOUSLY PUBLISHED BASELINE SCORES USING THE VALENTINI ET AL. DATASET

MODEL	PESQ	STOI (%)
Noisy	1.97	91
SEGAN [8]-2017	2.16	93
CGAN [44]-2018	2.34	93
Wave-U-Net [7]-2018	2.40	-
MMSE-GAN [2]-2018	2.53	93
Metric GAN [3]-2019	2.86	-
DCUnet-16 [6]-2019	2.93	-
DEMUCS-small [11]-2020	2.93	95
SE-Transformer [27]-2022	2.62	93
TSTNN [28]-2021	2.96	95
Convolutional TSTNN (proposed)	3.12	96

The above Table I gives the PESQ and STOI scores for proposed and various existing models such as SEGAN [8], CGAN [44], Wave-U-Net [7], MMSE-GAN [2], Metric GAN [3], DCUnet-16 [6], DEMUCS-small [11], SE-Transformer [27], and TSTNN [28].

The PESQ score for SEGAN [8] is 2.16 and for the proposed is 3.12. The STOI score for SEGAN [8] is 93% and for the proposed is 96%. The SEGAN is an end-to-end SE model where only strided convolutions are used in the generator and discriminator. The PESQ score for CGAN [44] is 2.34 and for the proposed is 3.12. The STOI score for CGAN [44] is 93% and for the proposed is 96%. The CGAN is a CNN based GAN operates in T-F domain. In both the GAN models only, ordinary convolutional layers are used. The PESQ score for DEMUCS-small [11] is 2.93 and for the proposed is 3.12. The STOI score for DEMUCS-small [11] is 95% and for the proposed is 96%. The DEMUCS model is a time domain U-Net model with ordinary convolutions and LSTM bottle neck. The CNN alone cannot well model the long-range dependencies of speech signal. In the proposed model to further enhance the performance of the model in addition to ordinary convolution a dilated dense block is used

in both encoder and decoder. At various resolutions, the dilated convolutions aid with context aggregation and the dense connectivity provides feature map with more precise target information by passing through multiple layers. A transformer block is used for extracting the local and global features from a noisy speech signal. The PESQ score for SE-Transformer [27] is 2.62 and for the proposed is 3.12. The STOI score for SE-Transformer [27] is 93% and for the proposed is 96%. The SE-transformer uses only LSTMs, multi-head attention and 1D convolution for SE. The PESQ score for TSTNN [28] is 2.96 and for the proposed is 3.12. The STOI score for TSTNN [28] is 95% and for the proposed is 96%.

2) *Comparison with existing works on librispeech dataset [39]*: To test the generalization ability of our proposed model we conducted experiments with large Librispeech dataset. The average PESQ and STOI scores for three types of noises at SNRs of -5dB, 0dB, 5dB, 10dB, and 15dB are presented in Table II. The proposed convolutional transformer model was compared with DNS-baseline [45], DEMUCS [11] and TSTNN [28].

TABLE II. EVALUATION OF PESQ AND STOI OF OUR MODEL AND EXISTING MODELS IN THE EXISTENCE OF BABBLE NOISE ON LIBRISPEECH DATASET

Model	Noisy		DNS [45]		DEMUCS [11]		TSTNN [28]		Proposed	
	PESQ	STOI	PESQ	STOI	PESQ	STOI	PESQ	STOI	PESQ	STOI
<b>-5dB</b>	1.11	0.66	1.23	0.70	1.50	0.82	1.58	0.83	1.69	0.84
<b>0dB</b>	1.19	0.77	1.48	0.82	1.92	0.90	2.10	0.91	2.32	0.92
<b>5dB</b>	1.40	0.86	1.86	0.90	2.36	0.94	2.49	0.94	2.68	0.94
<b>10dB</b>	1.75	0.92	2.29	0.94	2.76	0.96	2.88	0.97	3.04	0.96
<b>15dB</b>	2.25	0.96	2.71	0.96	3.07	0.98	3.19	0.98	3.58	0.98

From Table II, in the existence of babble noise at -5dB input SNR, the PESQ value for the proposed method is 1.69 and for existing DNS baseline [45], DEMUCS [11] and TSTNN [28] are 1.23, 1.50 and 1.58. The STOI score of the proposed method is 0.84 and for existing DNS baseline [45], DEMUCS [11] and TSTNN [28] are 0.70, 0.82 and 0.83.

From Table II, in the existence of babble noise at 5dB input SNR, the PESQ value for the proposed method is 2.68 and for existing DNS baseline [45], DEMUCS [11] and TSTNN [28] are 1.86, 2.36 and 2.49. The STOI score of the proposed method is 0.94 and for existing DNS baseline [45], DEMUCS [11] and TSTNN [28] are 0.90, 0.94 and 0.94.

From Table II, in the existence of babble noise at 15dB input SNR, the PESQ value for the proposed method is 3.58 and for existing DNS baseline [45], DEMUCS [11] and TSTNN [28] are 2.71, 3.07 and 3.19. The STOI score of the proposed method is 0.98 and for existing DNS baseline [45], DEMUCS [11] and TSTNN [28] are 0.96, 0.98 and 0.98.

From Table II in the existence of babble noise at all input SNR conditions it is noted the proposed model performs better than that of DNS baseline [45], DEMUCS [11] and TSTNN [28] models. The proposed convolutional transformer delivers improved performance because the local and global features are well modelled by CNN and RNN layers. Moreover, a CNN module is added to deal with short-term noise.

TABLE III. EVALUATION OF PESQ AND STOI OF PROPOSED MODEL AND EXISTING MODELS IN THE EXISTENCE OF RIVER NOISE ON LIBRISPEECH DATASET

Model	Noisy		DNS [45]		DEMUCS [11]		TSTNN [28]		Proposed	
	PESQ	STOI	PESQ	STOI	PESQ	STOI	PESQ	STOI	PESQ	STOI
<b>-5dB</b>	1.23	0.80	1.81	0.86	2.05	0.90	2.12	0.91	2.28	0.92
<b>0dB</b>	1.45	0.87	2.17	0.91	2.37	0.94	2.46	0.94	2.67	0.95
<b>5dB</b>	1.78	0.92	2.55	0.95	2.66	0.96	2.84	0.96	2.96	0.96
<b>10dB</b>	2.23	0.96	2.92	0.96	3.98	0.97	3.12	0.97	3.42	0.97
<b>15dB</b>	2.78	0.98	3.23	0.98	3.33	0.98	3.41	0.98	3.64	0.98

From Table III, in the existence of river noise at 0dB input SNR, the PESQ value for the proposed method is 2.67 and for existing DNS baseline [45], DEMUCS [11] and TSTNN [28] are 2.17, 2.37 and 2.46. The STOI score of the proposed method is 0.95 and for existing DNS baseline [45], DEMUCS [11] and TSTNN [28] are 0.91, 0.94 and 0.94.

From Table III, in the existence of river noise at 5dB input SNR, the PESQ value for the proposed method is 2.96 and for existing DNS baseline [45], DEMUCS [11] and TSTNN [28] are 2.55, 2.66 and 2.84. The STOI score of the proposed method is 0.96 and for existing DNS baseline [45], DEMUCS [11] and TSTNN [28] are 0.95, 0.96 and 0.96.

From Table III, in the existence of river noise at 10dB input SNR, the PESQ value for the proposed method is 3.42 and for existing DNS baseline [45], DEMUCS [11] and TSTNN [28] are 2.92, 3.98 and 3.12. The STOI score of the proposed method is 0.97 and for existing DNS baseline [45], DEMUCS [11] and TSTNN [28] are 0.96, 0.96 and 0.97.

From Table III in the existence of river noise at all input SNR conditions it is noted the proposed model performs better than that of DNS baseline [45], DEMUCS [11] and TSTNN [28] models. The proposed convolutional transformer delivers improved performance because the local and global features are well modelled by CNN and RNN layers. Moreover, a CNN module is added to deal with short-term noise.

TABLE IV. EVALUATION OF PESQ AND STOI OF PROPOSED MODEL AND EXISTING MODELS IN THE EXISTENCE OF RESTAURANT NOISE ON LIBRISPEECH DATASET

Model	Noisy		DNS [45]		DEMUCS [11]		TSTNN [28]		Proposed	
	PESQ	STOI	PESQ	STOI	PESQ	STOI	PESQ	STOI	PESQ	STOI
-5dB	1.09	0.63	1.21	0.68	1.38	0.78	1.49	0.79	1.62	0.81
0dB	1.15	0.75	1.43	0.80	1.68	0.88	1.85	0.91	1.98	0.92
5dB	1.31	0.84	1.76	0.88	1.99	0.93	2.29	0.94	2.41	0.94
10dB	1.62	0.91	2.16	0.93	2.33	0.95	2.67	0.95	2.87	0.96
15dB	2.07	0.95	2.59	0.96	2.70	0.97	2.94	0.97	3.18	0.97

From Table IV, in the existence of restaurant noise at 0dB input SNR, the PESQ value for the proposed method is 1.98 and for existing DNS baseline [45], DEMUCS [11] and TSTNN [28] are 1.43, 1.68 and 1.85. The STOI score of the proposed method is 0.92 and for existing DNS baseline [45], DEMUCS [11] and TSTNN [28] are 0.80, 0.88 and 0.91.

From Table IV, in the existence of restaurant noise at 10dB input SNR, the PESQ value for the proposed method is 2.67 and for existing DNS baseline [45], DEMUCS [11] and TSTNN [28] are 2.16, 2.33 and 2.67. The STOI score of the proposed method is 0.96 and for existing DNS baseline [45], DEMUCS [11] and TSTNN [28] are 0.93, 0.95 and 0.95.

From Table IV, in the existence of restaurant noise at 15dB input SNR, the PESQ value for the proposed method is 3.18 and for existing DNS baseline [45], DEMUCS [11] and TSTNN [28] are 2.59, 2.70 and 2.94. The STOI score of the proposed method is 0.97 and for existing DNS baseline [45], DEMUCS [11] and TSTNN [28] are 0.96, 0.97 and 0.97.

From Table IV in the existence of restaurant noise at all input SNR conditions it is noted the proposed model performs better than that of DNS baseline [45], DEMUCS [11] and TSTNN [28] models. The proposed convolutional transformer delivers improved performance because the local and global features are well modelled by CNN and RNN layers. Moreover, a CNN module is added to deal with short-term noise.

From Table II, Table III, and Table IV, it is noted the transformer-based models performs better than that of DNS baseline [45] and DEMUCS [11]. The proposed convolutional transformer delivers improved performance in terms of enhanced signal quality than all existing methods for all types of noises at all SNR conditions.

## V. DISCUSSION

The results from experimental studies show that the proposed convolutional transformer consistently improves speech quality as well as intelligibility. The performance of proposed transformer is better than the existing models such as SEGAN, CGAN, Wave-U-Net, MMSE-GAN, Metric GAN, DCUnet-16 and TSTNN. In the existing models CNN alone cannot well model the long-range dependencies of speech signal. In the proposed model to further enhance the performance of the model in addition to ordinary convolution

a dilated dense block is used in both encoder and decoder. At various resolutions, the dilated convolutions aid with context aggregation and the dense connectivity provides feature map with more precise target information by passing through multiple layers. A transformer block is used for extracting the local and global features from a noisy speech signal. In TSTNN model same structure of FFN is used in both intra and inter transformers. And also, they have not concentrated on the local (short-term) noises present at the output of encoder. To further enhance the performance in the proposed model we used TCM in the intra transformer and Bi-LSTM in the inter transformer as CNN's are good at extracting local features and the RNN's are good at extracting global features from the noisy speech signal. In the proposed model the transformer considers global information as well as parallel computing, resulting in a reduction of long-term noise. In contrast to RNNs and CNNs, the proposed transformer model uses parallel processing and the long-term dependencies can be modelled more efficiently with multi-head attention (MHA) by using sequence similarity. Moreover, a CNN module is added to the transformer so that short-term noise can be reduced more effectively, based on the ability of CNN to extract local information. We observe that the performance drop is more without CNN module that means on the basis of the transformer model CNN module is able to capture locally relevant context information based on global contextual information.

## VI. CONCLUSION

In this paper we proposed a two-stage convolutional transformer for speech enhancement in time domain. The transformer considers global information as well as parallel computing, resulting in a reduction of long-term noise. In the proposed work unlike two-stage transformer neural network (TSTNN) different transformer structures for intra and inter transformers are used for extracting the local as well as global features of noisy speech. Moreover, a CNN module is added to the transformer so that short-term noise can be reduced more effectively, based on the ability of CNN to extract local information. The experimental findings demonstrate that the proposed model outperformed the other existing models on both the datasets in terms of STOI (short-time objective intelligibility), and PESQ (perceptual evaluation of the speech quality). In future, we would like to analyze the performance of the transformer in T-F domain by adding new layers like Time Frequency attention (TFA) and also apply it in speech separation and multi-channel speech enhancement.

**Abstract**—Internet 2.0 Things connected to the Internet not only manage data supply through devices but also control the commands that flow through it. The communication technology created by the desired sensor is used by a new computing model so that the collected data appears in Web 2.0 for management. In addition to enhancing Sense efficiency through the simple IoT computing process, it is used in many cases for example video surveillance, and improved and intelligent manufacturing. Every fragment of the system is carefully continued and supervised in this process by software collection using a large number of recurs. An important process for this is to access web APIs from various public platforms in an efficient way. The use of different APIs by developers for the integration of different IoT devices and the deployment process required for this is unnecessary. Obtaining configured target APIs makes it easy to know where and how to get started with the workflow approach. Rapid industrial development can be achieved through this powerful API approach. But finding adequately powerful APIs from a large number of APIs has become a great challenge. However, due to the massive spike in the count of APIs, combining the two APIs has now become a major challenge. In this paper, for the time being, only the relationships between users and the API are considered. In this case, they had to face difficulties in extracting contextual value from their interpretation. So better accuracy could not be obtained due to this. The consequence of the user's time aspect on the cryptographic properties concerning the information collected from the API contextual description can be enhanced by the Deep Learning Probabilistic Matrix Factorization (DL-PMF) method, which improves the accuracy of the API recommendation in considering the cryptographic features of the user in the API recommendation. In this paper, we have used CNN (Convulsive Neural Network) for web elements such as APIs, and LSTM (Long-Term and Short-Term Memory) Network, which works with a diligent mechanism to find hidden features, to find hidden features that suit the tastes of the users. In conclusion, the combination of PMF (Probabilistic Matrix Factorization) evaluation of the recommended results was obtained as described above. The combination of DL-PMF method experimental results was found to be better than previous PMF, ConvMF, and other methods, thus improving the recommended accuracy.

**Keywords**—Implicit feature; API's recommendation; IoT; collaborative filtering; matrix factorization

## I. INTRODUCTION

In this new era due to the huge explosion in data registration as an online platform, consumers have to face various big problems in big data usage. Retrieving large data and other necessary information by communicators using [1]

technology in a very short period has not been very successful. In addition to providing services tailored to the personal preferences of different users, this method also answers the major problem of data overload. This order, which was recommended by a mature process developed by a highly researched cooperative filtering method, became highly publicized. This has been referred to as neighborhood and model-based practices [2]. Better results than neighborhood-based recommended policy outcomes can be obtained by recommending using PMF and SVD methods with model-based approaches [3]. The probability factor established by the model-based approaches PMF and SVD plays a major role in gradually improving the effectiveness of the recommended process. The PMF approach turned out to be effective in uncovering the hidden features of consumers by rating matrix but has failed to make effective and efficient utilization of this informational interpretation in terms of useful and vital customer information and services.

In this case, the recommendation system was applied through approaches undertaken by several researchers with the knowledge gained from the in-depth study. As a result, the recommended system has been improved by eliminating the flaws in the traditional recommendation method and utilizing information efficiently through complex approaches. There are still some errors that need to be corrected. Two CNNs (Conventional Neural Networks) were created in parallel to capture the underlying elements of Web API description information and the factor evaluation mechanism from the customer evaluation description [4]. The impact of consumer preferences on the recommendation system could not be ascertained due to the time factor not taking into account the consumer preferences in this model. For better recommendation, we have combined both the denoising autoencoder and the CDL model, which can effectively obtain encryption components through auxiliary information, and achieve better results [5]. The hierarchical Bayesian model approach is proposed later in this series.

The methods described by the above research have not been able to achieve better results in extracting relevant information from the content description. CNN and PMF have been used interchangeably, as described in the research papers [6] and [7] to identify latent properties as the basis of object content. But this does not allow us to find out the latent features of the user using the user information. The model [8], developed by combining CNN and latent factors, was successful in capturing users' object attributes but failed to achieve better-optimized hidden attributes. RNN (Repeated

\*Corresponding Author.

Neural Network) assists in the detection of consumer data irregularities [9] and the output of received news messages for recommendation by taking what is collected and received as input for what was previously considered the Browsing History Helpline. Dimensionally we get output messages that have the same dimension size as the input in the feature learning process. This requires the use of optimized dimensionality. In addition to extracting latent features from the user information description, the time it takes to use them in the process is also calculated using the RNN-based model [10] proposed by the collaborative filtering algorithm. Failed to fully extract from the elements the comprehensive latent features based on the model described in this sequence.

It has now become a challenge to capture the latent features according to their real, precise needs according to the information in the description of the consumer items. Integrating the PMF model with Deep Learning has been proposed for its solution. The text descriptive for this system is given as input for recommendation and the whole process is done in three steps. The latent features were learned from the description of the elements in the first stage, the latent features of the users in the second stage, and finally, the total latent features were trained by merging the two latent features into the PMF. To this end, in the aforementioned paper, we have attached a technique with particular care to capture and better understand the exact latent nature of CNN from element description [11, 12]. Care is taken to remove useless information in the service description as well as to learn the latent features according to the tastes of the customers [13]. In this paper, LSTM has been adapted LSTM to find the latent features appropriate to the needs of real and accurate users [14, 15]. The impact of consumption time on consumer pre-history discussions and consumer tastes has been taken into account in the process of learning these hidden features. Finally, it was made possible by combining users' hidden features with PMF for content-based assessment of user preference using both elements and user description. The combination of ConvMF and PMF has been verified by proposing Deep Learning-based PMF for greatly improved accuracy in the recommendation and enhanced accuracy capability by experimenting on a data set that has been crawled from a website called Programmableweb.

## II. RELATED WORK

The section includes, the most widely used CF algorithms in service recommendation [16, 17, 18] are currently reviewed by Mac as algorithms relevant to service and API recommendations. In this paper, Mache proposes a hybrid CF algorithm to overcome the shortcomings of CF algorithms [17] following current traditional methods. For this purpose, the information of the web APIs was collected by the first collecting mechanism and a new method of weight calculation was used. This algorithm then improved the accuracy of the recommendation by combining the user and item-based CF model with different weights. The web API information description was collected by a mechanism proposed in [16]. Different weights were added to the user and item-based CF model through the new-weight calculation method.

The revised proposal has sparked renewed interest in APIs in recent years as a means of addressing the guideline's flaws. The algorithms in this sector are separated into API and Mashup suggestions. The authors of [19] advised mashups for consumers based on customer preferences and service social networks for Mashup Recommendation. Historical usage data from the mashup is used to determine user interest. For the mashup service, a social network of web services was developed using a description of the information included in the API and associated tags. The network has uncovered and integrated user interest in web services. As noted in [16], potential affiliates have been discovered as a set of API mashups produced by authors from among APIs. It also focuses on an excavation in the context of Mashup's proposal for a shared API invoice model, as implemented by the excavated association recommended model. The potential model here improves the streamlined latent correlation.

The framework based on the Knowledge Graph was submitted by the authors of [20] on the recommendation of the APIs. It first recognizes the invite relationship between APIs and also identifies key information related to categories and labels. This information is used to form the relationship component between entities. The input is part of the recommendation in the knowledge graph. The authors later [21] proposed the recommendation of the framework obtained by applying random walks on the Knowledge Graph. The information on the most useful APIs was first compiled by the authors using the knowledge graph and the nodes were filtered based on the semantic information contained. The relationship between the candidate and the nominee was re-evaluated by the authors using random walks. Different networks are used to resolve different relationships represented by multiple links and multiple types of objects. A diverse information network is built by the authors by combining the API information with the information contained in [22] about the mashup and its related features, and group preference can be obtained for the mashup by following a clustering approach to the information in the network. Fixed issues with authors [23] currently having problems getting permission to search for API representative services by search engines. In addition, the recovery process was proposed by the new authors with the help of a collaborative network of services and the visualization technique provided for easier browsing.

Recommendations for APIs are made by traditional CF algorithms. The CF algorithm was proposed by the author in a paper [24] due to an item-based API recommendation. Item similarity can be achieved by making the customer group based on customers who have similar preferences. Furthermore, the CF algorithm applies a specific item based on each user group. It has been confirmed that better performance than neighbor-based CF can be achieved with MF model-based CF, with the authors attempting to assess user preferences when presenting invitations in [25] and terms of APIs and mashups. This assessment was made possible by the authors incorporating user preferences into the MF model to create a new recommendation model.

Even though recent procedures have a high level of suggestion accuracy, the content of the data has not been accomplished. Because most consumers use different objects at

various times throughout the day, Chen et al. [26] argued that contextual factors are crucial in the brilliant object suggestion of the Internet of Things. The researchers projected a time-aware, bright object recommendation model integrating user interest across times and creative object resemblance. Duan et al. [27] suggested JointRec, a deep learning-based joint video streaming recommendation system for IoT, to deliver precise video ways for a better marginal of users. Item descriptor information in IoT is generally diverse and multimodal, according to Huang et al. [28]. The paper presents a new heterogeneous representation learning-based strategy to improve predictive performance in IoT. In [29], Hu et al. suggested automotive ad-hoc network representation training for IoT recommendations since trajectory data better knowledge of human movement patterns. In contrast to these approaches, we investigate the potential linkages between users and API attributes in this research. To uncover implicit information, we use collaborative learning. Finally, we propose multiple models for IIoT devices and API recommendations grounded on the association between users and APIs. A clustering technique called Word-Embedded Clustering (AUG-LDA) is suggested in [30] for improved outcomes with a significant influence on word vector quality. This method can offer more efficiency and accuracy in mashup service innovation. DMM-Gibbs (Dirichlet Multinomial Mixer with Gibbs) predicts better clustering performance by reducing the number of features represented [31].

### III. PRIOR KNOWLEDGE

In this segment, we critically summarize the most popular collaborative filtering technique called “Matrix Factorization (MF)” and the “Convolutional Neural Network (CNN)”.

The MF method operates in a process-sharing cryptocurrency that calculates the strengths of the user-object relationship with the rating given by the consumer on the object, intending to collect hidden patterns of the object [3]. Let's assume we have  $N$  consumers and  $S$  web services and a ranking index for user service is  $R \in \mathbb{R}^{N \times S}$ . In MF,  $k$ -dimensional structures,  $u_i \in \mathbb{R}^k$  and  $s_j \in \mathbb{R}^k$  are represented as the latent structures of consumer  $i$  and service  $j$ . A user  $i$  and service  $j$ 's ranking  $r_{ij}$  is approximated by the inner-product of the related latent user  $i$  and service  $j$  models (i.e.  $r_{ij} \approx \hat{r}_{ij} = u_i^T s_j$ ). One possible simple way to better minimize the damage function  $\mathcal{L}$  value is to train Latin models. It has a policy of having total-squared-error terms between ratings and actual ratings, and  $L_2$  regularized terms. To better avoid the major problem of over-fitting, try to improve it as shown below:

$$\mathcal{L} = \sum_i^N \sum_j^S I_{ij} (s_{ij} - u_i^T s_j)^2 + \lambda_u \sum_i^N \|u_i\|^2 + \lambda_v \sum_j^S \|s_j\|^2 \quad (1)$$

Where an indicator function  $I_{ij}$  exists such that, if the user is given a rating it is 1 otherwise 0.

A "Convolutional Neural Network" (CNN) is called feed-forward and is a type of neural network that varies with the following components: 1) To construct local attributes, the convolution layer is used; 2) The pooling layer is used to represent only the data as an abbreviated representation, called the sub-template. Via activation functions, all of the

representatives with the highest score from the previous layer send local features to the next layer.

Although CNN was originally used to develop computer-vision-based applications, its main idea was to retrieve information and, in particular, to return the NLP search query [32], to model sentences [33], and additionally perform NLP tasks in traditional methods [34]. Here NLP has led to significant changes in the structure of CNN for the betterment of work and better results in the performance of the NLP's diverse work.

However, in reality, CNN is not yet well used in some areas, especially in the recommendation system. To the best of our knowledge, van den Ord et al. CNN [35] was first applied to music recommendation. There they analyzed the songs via CNN from a sound analysis perspective. And the desired pattern for calculating ratings is based on the latent pattern of the song obtained by sound CNN. The CNN model has not shown enough improvement in processing the documents and retrieving the sound signal. The reason for this is that the quality of the documents, the sound signals, and the features around them differ inherently with some variation. At a given time i.e. a signal with a short time difference is equal to the surrounding signals. And the word in a document at a certain point differs greatly from the meanings of the surrounding words. So, in the end, there is a great need for CNN to have such different variations and different structures to influence the quality of features locally. Also, the cooperative information of the model is not fully available. In particular, service latent features are determined by the analysis results obtained by CNN to convey the audio signal rather than the collaborative information. Therefore, "weighted matrix factorization (WMF)" [36] alone cannot improve the performance of the entire recommendation system, and it is one of the traditional collaborative filter MF-based methods that deals only with datasets with latent features.

### IV. METHODOLOGY OF DL-PMF MODEL

Matrix factors can be considered models by PMF as a potential solution. User preference in service selection is explained by the use of a potential combination of low-dimensional feature vectors, and potential properties are mapped by API and customer element information based on the potential angle to the low-dimensional mapping space. The process of identifying matrix factors as a potential solution was used as a model by the PMF. To assist in the dimensional mapping of a small area, it has used a low dimensional feature vector to highlight important information potential features in the API and user information. Specifically, this simple combination makes it possible to take customer preference into account in the process description recommended by the API. In this paper, the main purpose is to get better results using the proposed DL-PMF model. For this, the service / APIs and customer information through the continuous iteration process are used to find hidden vectors with the help of the PMF method. The performance of this model can be seen in a step-by-step sequence as shown in Table I below and Fig. 1 below.

TABLE I. THE ARRANGEMENT OF STEPS IN THE DEEP-LEARNING BASED PMF MODEL

Algorithm	The arrangement of steps in the Deep-Learning based PMF model
Step 1	Incidentally, both U and $W_S$ variables are generated and configured as rating matrix R.
Step 2	Attention-CNN updates S depending on R and U.
Step 3	S is trained using the PMF method while U is trained using the LSTM algorithm using Attention-CNN and LSTM.
Step 4	Steps 2 and 3 should be repeated until the loop convergence is reached.

Fig. 1. DL-PMF model framework

The hidden feature vectors are detected by the Attention-CNN used from the service information. The DL-PMF model is part of a CNN-based network that is interested in this process. We were able to obtain accurate results based on the achievement of the natural language processing process for application programs to text emotion classification as well as analysis. Potential features can be easily extracted from global information using CNN [4, 6, 5, 7]. The focus is on each characteristic of the customer information description and the features of most of the API information description, in line with the visual approach and human information. These features and their meaning can also be obtained due to the in-depth study that is part of the attention process. The combination of CNN and the Focus Approach makes it possible to easily get better features as well as remove useless features from the Global Information filter. We will see in the proposed DL-PMF model how to retrieve hidden feature vectors using user information by LSTM with memory function. Current and past interests can be fulfilled based on history record information by remembering precise guarantees for customer perceptions and timing, and by remembering the implicit connection features between their respective APIs. The internal construction of Attention-CNN, as well as LSTM, is an overview as shown below.

A. The Structure of Attention-CNN Network

The Attention-CNN architecture is known as the network architecture seen in Fig. 2 and this architecture's main objective is to identify and acquire its tacit vectors based on the details contained in the document's service specification. Here, in the service text description, we convert the data into digital quantity and take it as input to the Attention-CNN model. Complex instances are correlated with word embedding and hence controllable measurements can be obtained. In this proposed model, we've introduced the embedding process.

Fig. 2. Architecture of attention-CNN

1) *Language embedding layer*: The language embedding layer collects the raw material for the next level of the convolution layer and converts it into a dense numeric matrix and gives it as input. The word description of the service is used to input the words in the documents into  $d$  word vectors, converting the document into a matrix and input to the language embedding layer. Each word in the document is converted to a low-dimensional numeric vector using the pre-trained word2vec tool. We get the output of the layer as  $X \in R^{k \times d}$ , denoting the maximum length  $d$  of the vectors.

$$X = \begin{bmatrix} | & | & | & \dots & | & | & | & | \\ x_1 & x_2 & x_3 & \dots & x_{i-1} & x_i & x_{i+1} & \dots & x_d \\ | & | & | & \dots & | & | & | & | \end{bmatrix} \quad (2)$$

Where  $k$  is each word vector's dimension,  $x_i \in R^k$ .

2) *Convolution layer*: The key role of this layer has been described as gathering feature information related to the text. It is used to locate text attributes with different sharing weights using various convolution kernels. The length of the kernel window is then defined as  $l$ , and Eq. (3) is used to express the mutual weight matrix. The properties gained by the convolution kernel's layer  $j$  are expressed as follows.

$$t^j = [t_1^j, t_2^j, \dots, t_i^j, \dots, t_{d-l+1}^j] \quad (3)$$

The output eigenvalue obtained by a convolution kernel concerning region  $ix$  is denoted by  $t_i^j$ , and  $t_i^j = f(W^j \otimes X_{(i:(i+l-1))} + b^j)$ . The paper will specify the configuration operator as  $\otimes$ , the non-linear activation function as  $f(\cdot)$ , and the activation function as ReLU. From the  $i$  column of  $X$  to  $i + l - 1$  column by  $X_{(i:(i+l-1))}$ , and we identified the mapping matrix  $W^j$  and the bias by  $b^j$ .

This layer's outcome is:

$$T = [t^1, t^2, t^3, \dots, t^i, \dots, t^n] \quad (4)$$

Here,  $n$  is the kernel convolution number.

3) *Pooling layer*: This current layer captures the representative properties through the convolution layer on the

back, and constructs a fixed-length vector of equal length with the document variable following the pooling operation. The variable length obtained by the convolution layer represents a contextual feature vector with  $d - l + 1$ . This constant change in length makes it difficult to form subsequent layers. So we used max-pooling in this case. The maximum contextual characteristic of a piece of information is derived from each contextual feature vector that represents it and is represented by a shorter fixed-length vector. To substitute the output of that position in the network, this layer utilizes the general features of an adjacent output at a region. The layer's outcome is:

$$P = [p_1, p_2, \dots, p_i, \dots, p_n] \quad (5)$$

Where  $P_i = \max(t^i)$ ,  $\max(\cdot)$  is the maximum in  $t^i$ .

4) *Attention Layer*: At this stage, the layer has been introduced with more attention-grabbing approaches. The service weight is calculated from the information weight in each term based on the attention matrix approach. This not only highlights some of the important features but also leaves out unnecessary information using weight value in terms of size. So the corresponding weight for each word is calculated according to (6).

$$\alpha_i = g(W^{attn} * (p_i^{attn})^T + b^{attn}) \quad (6)$$

Where  $P_i^{attn} = [P_{i+\frac{-m+1}{2}}, P_{i+\frac{-m+3}{2}}, \dots, P_i, \dots, P_{i+\frac{m-1}{2}}]$ ,  $m$  is the magnitude of the sliding window.  $W^{attn} \in R^{l \times m}$ ,  $b^{attn} \in R$ .  $g(\cdot)$  is a function of non-linear activation.

The outcome of this current layer is

$$\Phi = [\omega_1, \omega_2, \dots, \omega_i, \dots, \omega_n] \quad (7)$$

Where  $\omega_i \in \alpha_i P_i$ .

5) *Output layer*: After obtaining high-level attributes from the previous layer in this sequence, they must be changed gradually for specific work as soon as the output layer is reached. That is, high-dimensional attributes are converted into a specific size feature vector and a latent attribute representation for customer service after reaching the layer before the output layer. The output to the output layer can be specified as follows.

$$s_j = \tanh(W_o \Phi + b_o) \quad (8)$$

From the above equation, we reference to  $W_o \in R^{D \times n}$  as the mapping matrix,  $b_o \in R^D$  as the bias, and  $s_j \in R^D$  as the service's latent characteristic vector  $j$ .

### B. LSTM Neural Network Structure

The correlation between customer and service features is very strong. This paper considers it a series of tasks to identify user characteristics for this correlation exploration. In this series of processes, we use the LSTM model to thoroughly search and dig into the correlations between expected features and to identify service users individually. Neural networks are specifically designed as "Recurrent Neural Networks (RNN)" and are used to process sequences of data. This allows each layer to be output to the next layer as well as its current state

for processing and RNNs are good at mining the interrelationships between cryptographic patterns. RNN showed better results in gradient disappearance and gradient explosion. Developed an evolutionary version of RNN called "Long Short-Term Memory (LSTM)" [37].

Another special type of RNN, LSTM, replaces the complex neural network structure by internally filling cells with low-cell neurons [38] Here, the LSTM of RNN is used to explore the properties of services that are interrelated through this framework and to independently evaluate the features of the services. Also, in evaluating subsequent characteristics, the LSTM internal structure indicates the secret state in the pre-history information and works better in the sequence modeling process. As input information, it takes complete sequence information, models it, and processes it into a single-dimensional vector. The inner component structure of the contributing LSTM-Cell can be described as shown in Fig. 3.

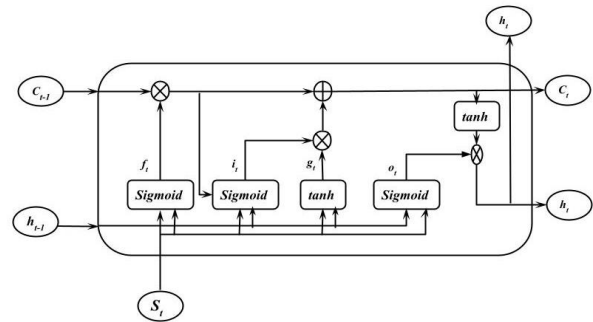

Fig. 3. Inner components of LSTM-Cell

Initially, LSTM, like RNN, considers service inputs to be interconnected and considered as a time series, and finally, its internal structure has become an excellent answer to the problem of bursting and disappearing gradient problems [16]. Below are the four significant aspects of the LSTM model. As shown in the figure: the input gate, forget gate, gate of the input module, and gate of the output. The gate and output gates of the module are used via the input gate to change the status of the cell, forget the maintenance gate, and control the deletion. The numerical method can be represented by the following equations for this procedure.

$$\left\{ \begin{array}{l} i_t = \text{sigmoid}(W_i * s_t + W_i * h_{t-1} + b_i) \\ f_t = \text{sigmoid}(W_f * s_t + W_f * h_{t-1} + b_f) \\ o_t = \text{sigmoid}(W_o * s_t + W_o * h_{t-1} + b_o) \\ g_t = \tanh(W_g * s_t + W_g * h_{t-1} + b_g) \\ C_t = f_t \cdot C_{t-1} + i_t \cdot g_t \\ h_t = \tanh(g_t) \end{array} \right. \quad (9)$$

Where the current cell status value, last time frame cell status value, and the update for the current cell status value are expressed by  $C_t$ ,  $C_{t-1}$ , and  $g_t$ . Input gate, forget gate, and output gate, respectively, are the notations  $i_t$ ,  $f_t$ , and  $o_t$ . With suitable input parameters, according to Eqs (9), the output value  $h_t$  is determined based on  $g_t$  and  $C_{t-1}$  values. Based on the difference between the output value and the actual value

after the back-propagation through time (BPTT) algorithm [39], all weights, including:  $W_i$ ,  $W_f$ ,  $W_o$ , and  $W_g$ , are modified.

This paper describes how the latent feature vector is derived from users' historical record information. The services used in the information in the usage history record over time need to be considered in the acquisition process and for this, the process of learning the latent feature vector can be considered as a time series approach. The answer to this approach is to use the LSTM architecture shown in Fig. 4 below to extract the latent feature vector from user information.

Fig. 4. LSTM External Architecture

The output and latent feature vectors of historical customer services can be obtained by input series, chronologically inserted into the LSTM model.

$$\left\{ \begin{array}{l} C_t = \sigma(W_1 \cdot [h_{t-1}, s_t^i] + b_1) * \tanh(W_2 \cdot [h_{t-1}, s_t^i] + b_2) + \\ \quad \sigma(W_3 \cdot [h_{t-1}, s_t^i] + b_3) * C_{t-1} \\ h_t = \sigma(W_4 \cdot [h_{t-1}, s_t^i] + b_4) * \tanh(C_t) \\ y_t^i = h_t \end{array} \right. \quad (10)$$

The mapping templates are denoted by  $W_1$ ,  $W_2$ ,  $W_3$ , and  $W_4$ , the bias is denoted by  $b_1$ ,  $b_2$ ,  $b_3$  and  $b_4$ , and the cell state by  $C_t$  at  $t$ , the latent attribute vector relative to the user  $i$  by  $y_t^i \in R^D$  and here  $\sigma(\cdot)$  is the activation function related to the sigmoid.

### C. Methodology for Proposed Model

In Fig. 1, the user  $i$ 's latent feature vector is denoted as  $U_i \in R^D$ , the latent attribute vector of the service  $j$  as  $S_j \in R^D$ , and the user  $i$  rating of the service  $j$  as  $R_{ij}$ . The variation of the Gaussian distribution of  $U_i$  and  $S_j$  is denoted by  $\sigma_U^2$  and  $\sigma_S^2$ , respectively.

The probability of a true conditional rating matrix [14] is determined as follows:

$$P(R|U, S, \sigma^2) = \prod_i^N \prod_j^M [N(R_{ij}|U_i^T S_j, \sigma^2)]^{I_{ij}} \quad (11)$$

The probability density of the Gaussian distribution with the  $\mu$ 's mean and  $\sigma^2$  variance is given by  $N(x|\mu, \sigma^2)$  suggested here. If the user  $i$  rates the service  $j$ , the index function  $I_{ij}$  value is set to 1, otherwise, its value is set to 0 will allocate. Assuming that the total number of users is  $N$  and the services are  $M$ , we identify the user's feature matrix by  $U \in R^{D \times N}$  and the latent feature matrix of services by  $S \in R^{D \times M}$ .

PMF is a sequence of consumers' and services' latent feature vectors that are independent of each other. Also, before the Gaussian distribution, the likelihood assumes the formula shown below for a zero-mean value.

$$(U|\sigma_U^2) = \prod_{i=1}^N N(U_i|0, \sigma_U^2 I) \quad (12)$$

$$P(U|\sigma_S^2) = \prod_{j=1}^M N(S_j|0, \sigma_S^2 I) \quad (13)$$

It is possible to substitute the Attention-CNN and LSTM outputs with equations (12) and (13).

$$P(U|W_U, X_U, \sigma_U^2) = \prod_{i=1}^N N(U_i|y^i, \sigma_U^2 I) \quad (14)$$

$$P(U|W_S, X_S, \sigma_S^2) = \prod_{j=1}^M N(S_j|s_j, \sigma_S^2 I) \quad (15)$$

In LSTM,  $W_U$  is used to denote the whole mapping matrix and its biases, and  $W_S$  is used to denote both mapping matrices with their biases. We can understand that the latent potential of the latent feature matrix for customers and services can be satisfied using the following formula, according to the Bayesian formula.

$$\begin{aligned} P(U, S, W_U, W_V|R, X, \sigma^2, \sigma_U^2, \sigma_S^2, \sigma_{W_U}^2, \sigma_{W_S}^2) \approx \\ P(R|U, S, \sigma^2) \times P(U|W_U, X_U, \sigma_U^2) \times P(W_U|\sigma_U^2) \times \\ P(S|W_S, X_S, \sigma_S^2) \times P(W_S|\sigma_S^2) \end{aligned} \quad (16)$$

For the prior probability distribution  $P(W_U|\sigma_{W_U}^2) = \prod_{\theta}^{\Omega} N(0, w_{\theta}|\sigma_{W_U}^2 I)$  relative to  $W_U$ , the total representation mapping matrix in the LSTM network can be observed as  $W_U$ . Priority probability distribution concerning  $W_S$  is  $P(W_S|\sigma_{W_S}^2) = \prod_{\phi}^{\mathfrak{R}} N(0, w_{\phi}|\sigma_{W_S}^2 I)$ , the total mapping matrix represented in Attention-CNN Can be observed as  $W_S$ . Also  $X_U$  in LSTM and  $X_S$  in Attention-CNN are referred to as the input set respectively.

In estimating the maximum posterior likelihood, the estimation matrix  $R$  found based on the DL-PMF model offered a nice solution.

$$\begin{aligned} \max \left( P(U, S, W_U, W_V|R, X, \sigma^2, \sigma_U^2, \sigma_S^2, \sigma_{W_U}^2, \sigma_{W_S}^2) \right) = \\ \max \left( P(R|U, S, \sigma^2) \times P(U|W_U, X_U, \sigma_U^2) \times P(W_U|\sigma_U^2) \times \right. \\ \left. P(S|W_S, X_S, \sigma_S^2) \times P(W_S|\sigma_S^2) \right) \end{aligned} \quad (17)$$

We consider the natural logarithm for the above equation for convenience. In

$$\begin{aligned} \left( P(U, S, W_U, W_V|R, X, \sigma^2, \sigma_U^2, \sigma_S^2, \sigma_{W_U}^2, \sigma_{W_S}^2) \right) = \\ -\frac{1}{2\sigma^2} \sum_{i=1}^N \sum_{j=1}^M I_{ij} (R_{ij} - U_i^T S_j)^2 - \frac{1}{2\sigma_U^2} \sum_{j=1}^M \|S_j - \\ s_j\|^2 - \frac{1}{2\sigma_U^2} \sum_{i=1}^N \|U_i - y^i\|^2 - \frac{1}{2\sigma_{W_U}^2} \sum_{\theta}^{\Omega} \|w_{\theta}\|^2 - \\ \frac{1}{2\sigma_{W_S}^2} \sum_{\phi}^{\mathfrak{R}} \|w_{\phi}\|^2 + C \end{aligned} \quad (18)$$

The LSTM, Attention CNN mapping matrix numbers, are denoted as  $\Omega$  and  $\mathfrak{R}$  respectively, and the matrix entries in the equation (16) can be omitted since the LSTM, Attention CNN mapping matrices, are constructed randomly according to the distribution basis of Gaussian.

To make the maximum value of equation (18) equal to the minimum, the following equation is used:

$$\begin{aligned} f = \sum_{i=1}^N \sum_{j=1}^M I_{ij} (R_{ij} - U_i^T S_j)^2 + \chi \sum_{j=1}^M \|S_j - s_j\|^2 + \\ \beta \frac{1}{2\sigma_U^2} \sum_{i=1}^N \|U_i - y^i\|^2 \end{aligned} \quad (19)$$

Where  $\chi = \sigma^2/\sigma_s^2$ ,  $\beta = \sigma^2/\sigma_u^2$ .

The algorithm of coordinate descent is used in this paper to find and solve the minimum value of  $f$ . The  $U_i$  and  $S_j$  updates are expressed as follows:

$$U_i \leftarrow \left( 2(2\beta I_k + \sum_{j=1}^M I_{ij} S_j S_j^T) \right)^{-1} * (\beta * y^i + \sum_{j=1}^M R_{ij} I_{ij} S_j) \quad (20)$$

$$S_j \leftarrow \left( 2(2\chi I_k + \sum_{i=1}^M I_{ij} U_i U_i^T) \right)^{-1} * (\beta * v_j + \sum_{i=1}^M R_{ij} I_{ij} U_i) \quad (21)$$

## V. EXPERIMENTAL EVALUATION

Initially, each value of the matrix in the process results indicated here is denoted by 0 or 1 and equated with the performance of the four other methods. In this case, any API followed by the user is marked as '0' and otherwise as '1'.

### A. Datasets

We used as a package the existing API data from the website called *programmableweb* and the API dataset was scrambled with comprehensive information about them. We scrambled a count of 17412 API data for this data set. It includes a list of followers for each API, as well as developer information, a quick summary, a range of names, and a post date. And here we have extracted the new follow feature from the web along with customer information. Consumer information description is considered equivalent to the performance of the goods. As followers of 17412 APIs, we have compiled the data of 140,000 users for this purpose and we have included the details in Table II.

TABLE II. STATISTICS FROM CRAWLED DATASET

<i>Scrambled Dataset</i>	<i>Total (#)</i>
User profiles	17412
API's	22032
Invocation files	248530

All the data in the scrambled dataset is split into training, validation, and test sets to evaluate the results of the experiments we perform. Random selection of training sets to 90%, 80%, 70%, 60%, and 10% is possible due to the arrangement of the data settings. In this experiment, 90 data sets for training, 5 for validation, and 5 percent for test density were analyzed first, and for the other four data settings for 10% validation of the data in the data set, the remaining data for the test set was composed. I.e. training, certification, and test sets with 10%, 10%, and 80% concentrations were taken. Thus experiments were performed ten times for each group. We analyzed all the results for each group experiment with MAE (Mean Absolute Error) and RMSE (Root-mean-square error) values.

### B. Evaluation Metrics

There has been an introduction to a recommended model to estimate a type. The goal is to determine the prediction accuracy of the API suggestion estimates based on the trials

completed. We used the MAE and RMSE as evaluation criteria.

$$MAE = \frac{1}{N} \sum_{i,j} |R_{ij} - \hat{R}_{ij}| \quad (22)$$

$$RMSE = \sqrt{\frac{1}{N} \sum_{i,j} (R_{ij} - \hat{R}_{ij})^2} \quad (23)$$

N stands for the numeral of tests,  $R_{ij}$  stands for the user's rating of service  $j$ , and  $\hat{R}_{ij}$  stands for the user's estimated rating of service  $j$  using the stated method.

### C. Parameter Setting

Since the model, we proposed above depends on the latent factor method (LFM), this model is particularly affected by two parameters. The first is the total quantity of hidden features: though its value is too high it cannot be understood by the model. Yet if this value is too low, we will get negative effects from the model. So, we took this number to be 10. The second introduced a parameter called regularization  $\lambda$  to adjust the weight of the term. As part of this,  $\lambda$  is set to 0.1, as well as the regularization value  $\lambda_u, \lambda_a$  is set to 0.01 related to user terms and related API terms.

### D. Comparative Result Evaluation of Performance

To evaluate the effectiveness of the proposed strategy, we used the following methods and the experimental findings are listed in below Table III.

TABLE III. EXPERIMENT RESULTS

Method	The density of the Training set (T)									
	T=90%		T=80%		T=70%		T=60%		T = 10%	
	MAE	RMS E	MAE	RMS E	MAE	RMS E	MAE	RMS E	MAE	RMS E
PNF	0.39		0.41		0.42		0.44		0.63	
	1	0.555	1	0.571	6	0.584	1	0.596	5	0.739
NMF	0.26		0.28		0.31		0.39		0.40	
	5	0.531	3	0.564	5	0.623	5	0.747	2	0.818
ConvMF	0.46		0.46		0.47		0.48		0.48	
	8	0.684	9	0.685	1	0.69	1	0.696	2	0.719
Autoencoder	0.29		0.33		0.34		0.37		0.41	
	9	0.378	2	0.378	4	0.387	7	0.377	7	0.45
DL-PMF	0.15		0.16		0.17		0.19		0.42	
	1	0.204	3	0.223	6	0.246	3	0.276	4	0.646

1) *PMF* [40]: For collaborative filtering, Probabilistic Matrix Factorization incorporates ratings.

2) *NMF (Non-Negative MF)* [41]: A Non-Negative matrix factorization is modeled as the product of the two non-negative matrices.

3) *ConvMF* [7]: CNN is used to extract item information in Convolutional Matrix Factorization.

4) *Autoencoder* [42]: A multilayer neural network that is commonly used in feature learning to reduce dimensionality.

5) *DL-PMF*. Our method combines the PMF with a CNN and an LSTM network to predict recommendation results.

Fig. 5. Impact on MAE

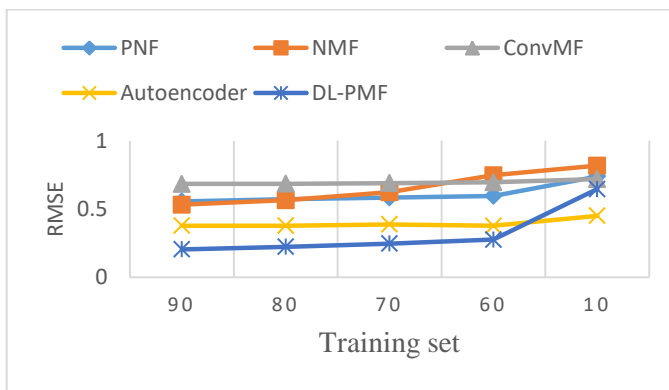

Fig. 6. Impact on RMSE

We have shown the line chart as shown in Fig. 5 and Fig. 6, clearly describing the model proposed by us by comparing the working methods of different methods with training sets of different densities and describing its typical performance. Fig. 5 and Fig. 6 show the MAE and RMSE values for training sets of different densities. The consistent performance of the test set with relatively different densities is maintained in the NMF approach. So, depending on this it is understood that the logistic regression here is relatively constant. The difference is huge. MAE and RMSE values are higher in the autoencoder model than in ConvMF when the concentration of the test set is 90%. In general, the value of this difference is much lower in the model proposed by us and works better than in any other algorithm. In IoT, our approach will deliver stronger API recommendations not only in terms of data efficiency but also in terms of perceiving features related to large data obtained in the IoT system.

## VI. CONCLUSION

The DL-PMF algorithm purposed for mentioned paper enhances the efficiency of the recommendation model by perceiving the implicit nature of the users and API elements. For this purpose, the model of the API treats only relevant information by filtering non-interfering information in the description. Our launch results have demonstrated that obtaining the latent characteristics of users and API elements

effectively through our proposed DL-PMF model can significantly raise the recommendation's accuracy. In this instance, the recommendation accuracy will not only be considered as contextual information but in future work, we will consider the collection of features in the description information by RCNN.

# Unsupervised Learning-based New Seed-Expanding Approach using Influential Nodes for Community Detection in Social Networks

Khaoula AIT RAI<sup>1</sup>, Mustapha MACHKOUR<sup>1</sup>, Jilali ANTARI<sup>2</sup>

Computer System and Vision Laboratory-Faculty of Sciences, Ibn Zohr University, Agadir BP8106, Morocco<sup>1</sup>  
Laboratory of Computer Systems Engineering-Mathematics and Applications-Polydisciplinary Faculty of Taroudant, Ibn Zohr University, Morocco<sup>2</sup>

**Abstract**—Several recent studies focus on community structure due to its importance in analyzing and understanding complex networks. Communities are groups of nodes highly connected with themselves and not much connected to the rest of the network. Community detection helps us to understand the properties of the dynamic process within a network. In this paper, we propose a novel seed-centric approach based on TOPSIS (Technique for Order Preference by Similarity to an Ideal Solution) and k-means algorithm to find communities in a social network. TOPSIS is used to find the seeds within this network using the benefits of multiple measure centralities. The use of a single centrality to determine seeds within a network, like in classical algorithms of community detection, doesn't succeed in the majority of cases to reach the best selection of seeds. Therefore, we consider all centrality metrics as a multi-attribute of TOPSIS and we rank nodes based on the TOPSIS' relative closeness. The Top-K nodes extracted from TOPSIS will be considered as seeds in the proposed approach. Afterwards, we apply the k-means algorithm using these seeds as starting centroids to detect and construct communities within a social network. The proposed approach is tested on Facebook ego network and validated on the famous dataset having the ground-truth community structure Zachary karate club. Experimental results on Facebook ego network show that the dynamic k-means provides reasonable communities in terms of distribution of nodes. These results are confirmed using Zachary karate club. Two detected communities are detected with higher normalized mutual information NMI and Adjusted Rand Index ARI compared to other seed centric algorithms such as Yasca, LICOD, etc. The proposed method is effective, feasible, and provides better results than other available state-of-the-art community detection algorithms.

**Keywords**—Complex network; community detection; TOPSIS; seed-centric approach; ground-truth; k-means

## I. INTRODUCTION

Many complex real-world systems can be represented and studied as networks. Complex networks cover diverse networks as the Internet, metabolic networks, social networks, and many others. Studies conducted on the physical significance and mathematical properties of complex networks have found that these networks share macroscopic properties. Among these properties, we cite prototype properties such as the small-world effect [1] and the free-scale [2], dynamic properties such as diffusion [3][4] and structural properties

such as community structure. The community structure property appears to be common to many complex networks and helps to understand the relationship between a single node in microscopy and groups in macroscopy. Communities are defined as parts of the network with numerous internal connections but few exterior connections. They are closely related to the functional components of real-world networks, such as metabolic networks cycles and pathways and protein complexes in protein-protein interaction networks. They can have very different topological properties than the whole network and then affect the dynamic of the network. Therefore, community structure discovery has been the focus of several recent efforts. Numerous approaches have been suggested to detect community structures in networks, some are based on similarity measures, and others rely on network dynamics such as random walk dynamics [5] and label propagation [6]. Other approaches rely on statistical models end on the optimization of quality functions. For instance, the well-known Newman-Girvan modularity [7] can be used as a method of community discovery and as an objective technique to measure the quality of community partitions.

In this paper, we propose a new approach to discover communities within a social network. The proposed approach uses sequentially two techniques. At the beginning, we apply TOPSIS (Technique for Order Preference by Similarity to an Ideal Solution) methodology [8] which aggregates centrality measures (degree centrality [9], betweenness centrality [10], closeness centrality [9], and eigenvector centrality [11]) as multi-attribute to rank nodes in a complex network, and then we run the k-means algorithm which is an unsupervised learning algorithm widely used for data clustering. To take advantage of this algorithm of clustering, we use the output of TOPSIS as initial centroids for k-means to get communities that may be in a complex network. To do so, we need to initialize the value of k by the desired output number of clusters. We did this in two ways; classical k-means and dynamic k-means using Elbow [12] and silhouette [13] methods. TOPSIS is a famous technique of multi criteria decision analysis. It's used in different fields such as Supplier selection [14], selecting the best wood type [15], selecting techniques for future avian influenza surveillance in Canada [16], personnel selection [17], etc.

The main contributions of this work are as follows:

- Taking advantage of different indexes of centrality gathered in TOPSIS to identify influential nodes.
- Based on top-K important nodes extracted from TOPSIS we propose a seed centric algorithm based on k-means to discover communities in complex networks. Experiments are realized using adjacency matrix as centrality measures of top-K influential nodes.
- To determine the optimal K we use Elbow and Silhouette methods and then applying the proposed approach with the optimal value of k.

This paper is then organized as following. Section II presents a general overview on seed centric algorithms. Section III details the general context and related concepts. Section IV explains the proposed approach. Section V presents the analysis and results of the experiments. The paper is concluded in Section VI.

## II. SEED CENTRIC ALGORITHMS: GENERAL OUTLINES AND RELATED WORKS

The algorithm of seed centric approaches is based on three important phases that are: the calculation of seeds, the calculation of seed local community, and community calculation from the previous step. In community detection field, there are several seed-based algorithms proposed by researchers. These algorithms are classified according to several factors. For the first phase for instance, we can find approaches that use single seed or group of seeds, linked or not [18]. Apart from the nature of the seeds (single or group)[19] [20], the number of seeds is also a factor that differs from an algorithm to another. There are some algorithms that have the number of seeds as an input, like the application of the classical k-means algorithm. Other algorithms use heuristic approaches to compute adequate seeds, for example, the approaches proposed by D. Shah et al. [18], [21] and Kanawati [18] based on leaders. D.Shah et al. [22] proposed two algorithms; Leader Follower Algorithm (LFA) and Fast Leader Follower Algorithm (FLFA). These algorithms find leaders as seeds of the community, and then they search its other members. During this process of leaders' search, they consider leaders as nodes with lower degree than their followers. Although the FLFA is fast, LFA can detect more communities in some networks. LICOD algorithm proposed by Kanawati [18] is also based on identifying leaders in the network then affecting the remaining nodes to these leaders to build communities. LICOD calculates the number of communities to detect automatically.

The selection of seeds can be random or informed. Random selection means choosing randomly adequate seeds with repetitive process while informed selection consists of choosing a set of nodes or subgraphs. LICOD algorithm proceeds by informed selection. It selects nodes with higher centrality.

For calculating seed local community, two approaches are applied by researchers in this area; expanding approach and agglomerative approach.

Expanding approach [23] relies on ego-centred algorithms for community detection. The limit of this approach is that it does not take into account all of the network's nodes. To overcome this problem, Whang et al. [24] proposed to attach outliers to the nearest community. The second approach for calculating seed local community is the agglomerative approach, where nodes are agglomerated into communities with nearest identified seed [18] [21].

The last common phase of all community detection algorithms is community calculation which leads to the final communities based on local seeds communities calculated in the precedent step. Fig. 1 illustrates the link between these approaches and algorithms.

Fig. 1. Summary of seed centric algorithms' characteristics

In the last decade, several seed centric algorithms for community discovery have been proposed in the scientific literature. Each one relies on different seeds finding and different approaches for community calculation. Kanawati et al. [18] proposed Licod algorithm based on two nodes in the community: leaders and followers. Leaders are nodes with high centrality, whatever the centrality is. Followers are founded by computing community membership. Weskida [25] also search in this field how to select seeds using some evolutionary algorithms. The problem in this kind of algorithms is when the evaluation functions are noisy, they will not work. Yufeng Wang et al. [26] proposed an algorithm that selects seeds using page rank-like algorithm. Kanawati proposed also the Yasca algorithm that computes partitions in graphs using local community identification [27]. This algorithm applies an ensemble clustering to the local communities detected for each seed. Akrowska and Bader proposed also a seed set expansion algorithm of dynamic greedy [28]. In each iteration, the algorithm updates the local communities from an initial partition that is obtained via a set seed expansion method. Table I highlights several seed-centric algorithms' properties.

TABLE I. PROPERTIES OF SOME SEED CENTRIC ALGORITHMS [29]

Algorithm	Seed Nature	Seed number	Seed selection	Local community
Licod [18]	Set	Computed	Informed	Agglomerative
Yasca [27]	Single	Computed	Informed	Expansion
[30]	Subgraph	Computed	Informed	Expansion
[24]	Single	Computed	Informed	Expansion
[31]	Subgraph	Computed	Informed	Expansion
[32]	Set	Computed	Automatic	Expansion

### III. GENERAL CONTEXT

In this section, we present fundamental concepts that constitute the general context of the proposed approach. These concepts complete each other to emphasize the proposed idea.

#### A. TOPSIS Methodology

The Technique for Order Preference by Similarity to the Ideal Solution (TOPSIS) [8] emerged in the 1980s as a decision-making method based on several criteria. It chooses the alternative of the shortest Euclidean distance from the ideal solution and the longest distance from the negative ideal solution. TOPSIS demonstrates its power to solve this MCDM (Multi-Criteria Decision Making) problem in different fields such as supply chain management, engineering, health, design, etc. TOPSIS has gained considerable interest from the scientific community due to its success in various areas. TOPSIS was applied for supplier selection [33]. Different factors are considered by Chen et al [33] like quality and technological power. Yong used TOPSIS also to choose the plant location [34]. In the field of human resource management, Kelemenis and Askounis [17] used the fuzzy TOPSIS to select the best management member in an IT department. Wang and Elhag [35] used Fuzzy TOPSIS and nonlinear programming for selecting a system analysis engineer. Kaya et Kahraman [36] applied fuzzy TOPSIS combined with fuzzy AHP to Select the best energy technology alternative.

The process of TOPSIS consists of the following main steps [8]:

**Step 1:** construction of the normalized decision matrix

**Step 2:** construction of the weighted normalized decision matrix

**Step 3:** determination of the positive and the negative ideal solutions

**Step 4:** calculation of the separation of each alternative

**Step 5:** the calculation of the relative closeness to the ideal solution.

How each step is modeled and used is explained in the Section III.

#### B. Centrality Measures

The computation of centrality measures has been an important issue in the field of social network analysis for several decades [37]. Centrality is a notion that makes it possible to account the popularity or the visibility of an element within a group. Freeman's article "Centrality in social networks: Conceptual clarification [9]" represents arguably one of the most important contributions in the field of social network analysis. In his article, Freeman proposes three formal definitions of the concept of centrality that we present below. We also present a fourth centrality measure introduced by Bonacich.

1) *Degree centrality*: It represents the basic and the most concise way of the notion of centrality. It is based on the concept that a person's influence within a group depends on the total number of individuals he knows or has direct contact

with [9]. According to this measurement, indicating the value of a node in a graph depends on the number of its neighboring vertices, i.e. the number of its incident links. In graph theory, Degree Centrality originally comes from this number, which is known as the node's degree.

Because it simply considers a node's immediate neighborhood and ignores the overall structure of the network, degree centrality is also known as local centrality measure [38]. While degree centrality is pertinent in some contexts, it is ineffective in others, such as the analysis of web page graphs [39].

2) *Closeness centrality*: It is a measure of global centrality based on the assumption that a node occupies a strategic (or favorable) position in a graph if it is globally nearby to the other nodes of this graph [9]. For example, in a social network, this metric refers to the fact that an actor is influential if he can quickly get in touch with a lot of other actors while exerting the least amount of effort (the effort here is relative to the size paths).

3) *Betweenness centrality*: It is another metric of global centrality that Freeman has presented [9]. The idea behind this measurement is that a node in a graph is important if a maximum number of other nodes cross it. More precisely, a node with a strong betweenness centrality is a node through which passes a large number of geodesic paths (i.e. shortest paths) in the graph. In a social network, an actor with a strong betweenness centrality is a node on which depends a large number of interactions between non-adjacent nodes [40]. In a communication network, betweenness centrality of a node can be considered as the probability that information transmitted between two nodes passes through this intermediate node [40].

4) *Eigenvector centrality*: It's a measure suggested by Bonacich[11] based the idea that the centrality of a node is determined by the centrality of the nodes to which it is connected. In a social network, this refers to the concept that an actor is influential when he is linked to other influential actors. In fact, it is an extension of degree centrality in which the same weight is not given to the neighboring nodes. Practically talking, Bonacich proposes to consider the centrality of a node as being dependent on the linear combination of the centralities of its neighboring nodes[11].

#### C. K-means Algorithm

K-means is an unsupervised algorithm widely used in data clustering. It proceeds by analyzing a set of data characterized by a set of descriptors, in order to group "similar" data into groups (or clusters).

To split a dataset into k distinct clusters, k-means algorithm needs a way to compare the degree of similarity between all the observations. Usually, the distance between two elements to compute their similarity is used.

Thus, two similar data will have a small dissimilarity distance, while two different data will have a big separation distance. The famous used metric to measure such similarity is the Euclidean distance [41], and it is the one used in this paper.

1) *Euclidian distance*: It's a geometric distance that considers a matrix  $X$  with  $n$  quantitative variables in the vector space  $E^n$ . The Euclidean distance  $d$  between two observations  $x_1$  and  $x_2$  is calculated as follows:

$$d(x_1, x_2) = \sqrt{\sum_{j=1}^n (x_{1n} - x_{2n})^2} \quad (1)$$

Algorithm 1 shows the principal of k-means algorithm. The beginning is the choice of  $k$  elements chosen arbitrarily from the dataset as centroids. Then the distance between all the elements and each one of these centroids is computed. Each element belongs then to the cluster whose centroid is closest to it. As a second step, new centroids are computed as the mean of all the elements of each cluster. These steps are repeated until there is no new centroid.

The purpose of clustering algorithms in general and K-Means specifically is to form clusters of similar elements. As long as they are stored in a data matrix, these items can be any kind of thing.

2) *K-means principal*: The sum of the distances between each item and the centroid is minimized by the iterative algorithm k-means. The outcome depends on the original selection of centroids.

Adopting a cloud of a given set of points, K-Means updates the members of each cluster until the sum can no longer reduce. Depending on picking the right value  $K$  for the number of clusters, the outcome is a collection of compact and separate clusters.

```
Algorithm 1: K-means algorithm
INPUT
    K: number of clusters to construct
    The training set
BEGIN
    Randomly choose K points from the dataset that will be
    the centroids of the starting clusters
REPEAT
    Assign each point (element of the dataset) to the cluster
    to which it is closest
    Update the centroid of each cluster by the mean of its
    points.
UNTIL convergence OR stabilization of total population
    inertia
END
```

The k-means algorithm may converge under one of the following cases:

- When the number of iterations is fixed in advance, K-means will run its iterations and then end, regardless of how the compound clusters are shaped.
- Stabilization of cluster centers (centroids no longer move during iterations).

The main challenge of k-means algorithm is the value of  $k$ . Indeed, it is not always evident to choose  $k$  as the number of clusters; particularly, if the dataset is sizable, and we don't

have a priori assumptions on the data. A big value of  $k$  can generate too fragmented partitioning data. This will prevent discovering interesting patterns in the data. That is on one hand; on the other hand, too small value of  $k$  will potentially generate general clusters containing a lot of data. In this case, there will be no "fine" patterns to discover. We need then to know the optimal value of  $k$ . The most used methods for this purpose are the Elbow and the Silhouette methods and the technique is called dynamic k-means.

#### D. Dynamic k-means

The challenge of any clustering algorithm is to determine the optimal number of clusters in which the data can be grouped. For the k-means, Elbow and Silhouette methods are the most popular methods for determining this optimal  $k$  value.

1) *Elbow method*: The Elbow Method [12] is one of the most popular methods that helps to find the optimal number of groups to which the k-means algorithm splits the dataset. The idea starts by varying the number of clusters  $k$  from 1 to  $N$ , assuming that the data has already been divided into  $k$  clusters by a clustering method. For each value of  $k$ , the WCSS (Within-Cluster Sum of Square) which is the sum of the squared distance between each point and the centroid of a cluster is calculated. The plot generated then in the visualization looks like an elbow. That's why it's nomination. Fig. 2 shows an example of the relation between WCSS values and clusters' number. While the WCSS value is decreasing, the value of  $k$  is increasing. The X-axis value where the curve appears as if it starts to bend represents the optimal value of  $k$ . This deformation value represents the elbow of the curve.

Fig. 2. Example of WCSS plot

2) *Silhouette method*: The silhouette algorithm [13] is usually used to find the optimal number of clusters for an unsupervised learning technique. In the Silhouette algorithm, we suppose that data has already been split into  $k$  groups by a clustering technique (typically k-means algorithm). It proceeds by computing silhouette coefficient for each data point to measure how well this point is assigned to the most appropriate cluster. Its value varies between -1 and 1. A value close to 1 means that the sample is assigned to the best cluster and vice versa. To compute the silhouette coefficient, the following values is needed:

$C(i)$ : the cluster assigned to the  $i^{\text{th}}$  data point.

$|C(i)|$ : the number of data points in  $C(i)$

$a(i)$  : gives a measure of the quality of the assignment of the  $i$ th data point to its cluster.

$$a(i) = \frac{1}{|C(i)|-1} \sum_{C(i), i \neq j} d(i, j) \quad (2)$$

$b(i)$ : It is defined as the average dissimilarity with the nearest cluster.

$$b(i) = \min_{i \neq j} \left( \frac{1}{|C(j)|} \sum_{j \in C(j)} d(i, j) \right) \quad (3)$$

The silhouette coefficient  $s(i)$  is then given by:

$$s(i) = \frac{b(i)-a(i)}{\max(a(i), b(i))} \quad (4)$$

Equation (4) gives the silhouette coefficient for each value of  $k$ , and the  $k$  having the maximum value of  $S(i)$  is taken as the optimal number of clusters for the unsupervised learning algorithm. Fig. 3 illustrates the plot corresponding to the silhouette coefficient's value for each value of  $k$ . From that plot we notice that the optimal value of  $k$  is 4.

Fig. 3. Silhouette coefficient's plot (maximum value of  $S(i)$  is 4)

#### IV. PROPOSED APPROACH

The main goal of the proposed approach is to detect communities in a social network. It's a task of clustering the dataset that requires the application of an appropriate algorithm. The famous algorithm used for clustering is k-means. Since this algorithm requires starting with a value of  $k$ , the main idea here is to use the top-  $K$  influential nodes within the used dataset. These nodes are detected using TOPSIS methodology and then are used as centroids to run k-means algorithm. These steps are synthesized in Algorithm 2 and Fig. 4.

##### Algorithm 2: Steps of the proposed algorithm

**Input:**  $G(V, E)$  : A social network,  
 $K$  : the number of influential nodes (number of communities),  
 $k = \{k_1, k_2, \dots, k_n\}$  : a set of centrality measures,  
 $w$  : weight given centralities.

**Output:** detected communities

**Begin**

1. Select the top- $K$  influential nodes  $P$  using TOPSIS:  
 $P \leftarrow \text{TOPSIS}(G, k, w, K)$
2. Use each influential nodes  $v \in P$  as a centroid of a community  
 $CP_{centroid} \leftarrow \{\{v\} | v \in P\}$
3. Enlarge communities into  $CP_{centroid}$  :  
 $CP \leftarrow \text{Enlarging}(G, CP_{centroid})$
4. Return communities detected  $CP$

**End**

The main two steps in the proposed method are influential nodes detection using TOPSIS and then the community detection using k-means. These two steps are respectively highlighted in Algorithm 2 and Algorithm 3.

To get nodes' influence ranking using TOPSIS methodology involves four centrality measures as multi-attribute criteria. These measures are degree centrality (DC), betweenness centrality (BC), closeness centrality (CC) and eigen-vector centrality (EC) that have already been introduced in the subsection III.B. Algorithm 3 details technically the five steps highlighted in the subsection III.A.

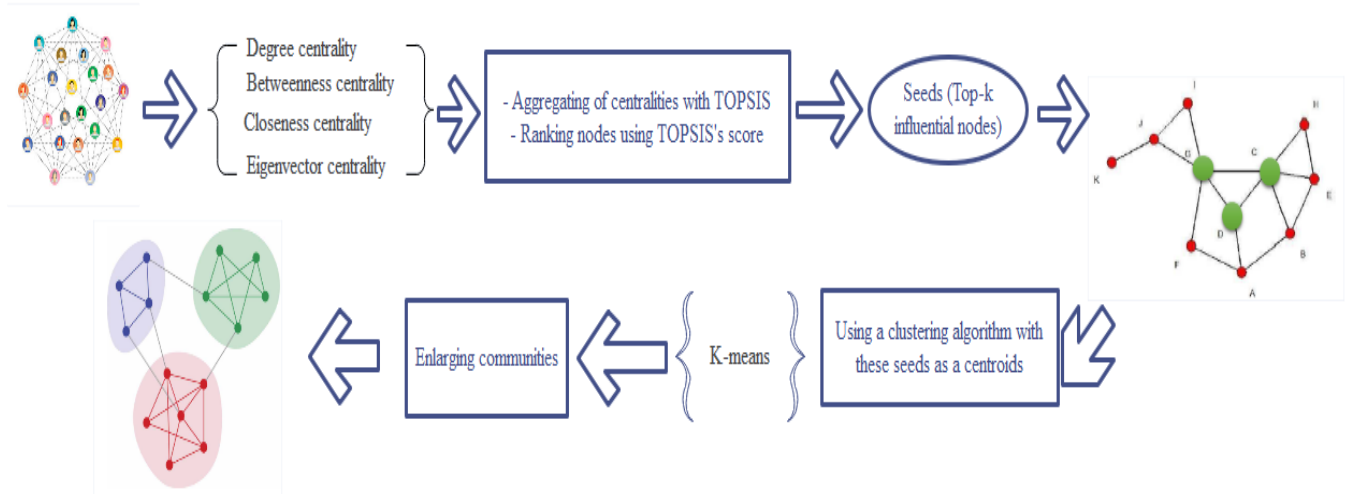

Fig. 4. The research methodology for seeds selection and expansion

**Algorithm 3:** Selection of top-K influential nodes as centroids using TOPSIS' scores.

**Input:**  $G(V, E)$  : A social network,  
 $K$  : the number of influential nodes (number of communities),  
 $k = \{k_1, k_2, \dots, k_n\}$  : a set of centrality measures,  
 $w = \{w_1, w_2, \dots, w_n\}$  : a set of weights assigned to centralities.

**Output:**  $P$  top-K influential nodes (a set of centroids)  
**Begin**

1. Create a decision matrix  $D$  based on  $k$  measures of centrality where  $i = 1, 2, \dots, n$  and  $j = 1, 2, \dots, k$  and  $n$  is the number of nodes

$$D = \begin{bmatrix} d_{11} & \dots & d_{1k} \\ \vdots & \ddots & \vdots \\ d_{n1} & \dots & d_{nk} \end{bmatrix}$$

2. Normalize the decision matrix  $D$ :

$$\text{For each } d_{ij} \text{ in } D \text{ do } t_{ij} = \frac{d_{ij}}{\sqrt{\sum_{i=1}^k d_{ij}^2}}$$

$$N = \begin{bmatrix} t_{11} & \dots & t_{1k} \\ \vdots & \ddots & \vdots \\ t_{n1} & \dots & t_{nk} \end{bmatrix}$$

3. Make the decision matrix normalized and weighted to obtain the matrix  $R$

$$\text{For each } t_{ij} \text{ in } N \text{ do } r_{ij} = t_{ij} * w_j$$

$$R = \begin{bmatrix} r_{11} & \dots & r_{1k} \\ \vdots & \ddots & \vdots \\ r_{n1} & \dots & r_{nk} \end{bmatrix}$$

4. Calculate the ideal best solution  $A^+$  and negative ideal solution  $A^-$  (centrality measures are taken as benefit attributes)

$$A^+ = \max(r_{ij}) \text{ and } A^- = \min(r_{ij})$$

5. Calculate separation from ideal and negative solutions

$$Sep_p = \sqrt{\sum_{j=1}^k (r_{ij} - A^+)^2} \text{ and}$$

$$Sep_n = \sqrt{\sum_{j=1}^k (r_{ij} - A^-)^2}$$

6. Calculate the relative closeness score of each node

$$\text{For each } r_{ij} \text{ in } R \text{ do } C_i = \frac{Sep_n}{Sep_n + Sep_p}$$

7. Rank nodes based on  $C_i$  the higher score means important node
8. Select  $K$  nodes using top- $K$   $C_i$  :  $P \leftarrow top\_k(V, C_i, K)$

**End**

The output of this algorithm is the first  $k$  influential nodes. A node's influence depends on its score. The higher the score is, the more influential the node is. The idea of the proposed approach is to use the top- $K$  influential nodes as initial centroids to start  $k$ -means algorithm in order to detect communities in the network. The number of these nodes can be specified by the user or found automatically using the elbow method or silhouette method.

The process of community detection in the proposed approach is given in Algorithm 3. Communities within a network can be modeled as groups of individuals that have a kind of similarity. In this paper this similarity is computed by the Euclidean distance between these individuals. The value given to  $k$  will correspond to the number of the output communities. Each top- $K$  influential node resulted from Algorithm 2 is considered as a reference to all the nodes of the network. Euclidean distances are computed between each centroid and all the other nodes. Each centroid gathers around it the nodes that are closest to it, and the new centroid of each cluster is computed by the mean of all its elements. These steps are repeated until there are no new computed centroids. The last clusters are the detected communities in the network and their centroids are the resulted seeds.

**Algorithm 4:** Computing communities using k-means

**Input:**  $(V, E)$  : A social network,  
 $CP_{centroid}$  : Top-K influential nodes (the output of Algorithm 2)

**Output:**  $CP$  detected communities

**Begin**

1. Initialize the centroids with Top-k influential nodes  
/\*number of communities to be found/
2. For each community  $CP_j$ , REPEAT
  - 2.1 Assign each node  $v$  to the communities which has the closest mean based on their centrality measures

$$c^{(i)} = \arg \min_j \|v^{(i)} - CP_{centroid}^i\|^2$$

- 2.2 Compute new centroids for each community

$$CP_{centroid}^i = \frac{\sum_{i=1}^m 1\{c_{(i)}=j\}v^i}{\sum_{i=1}^m 1\{c_{(i)}=j\}}$$

3. UNTIL convergence criteria is reached
4. END FOR
5. Return detected communities  $CP$

**End**

V. EXPERIMENTAL SETUP

In this section a series of experiments are managed to show the efficiency of the proposed approach. In the beginning network with ground truth is used in order to validate the proposed approach referring to the reference of each network. Thereafter, this approach is applied to a larger network without ground truth to find different communities within it. These series of experiments have been performed using Python (3.7.14) as a tool of implementation. The use of Python is argued by its richness by a large number of useful libraries that make the data analysis and computing with visualization easier and simplest. For instance, in these experimentations we took advantage of the libraries; NetworkX for the manipulation of the complex network, Numpy for the scientific computing, Pandas for data analysis, Matplotlib for visualizations, Scikit-learn for clustering, CDlib for evaluating communities.

A. Networks Presentation

1) *Facebook ego network*: This dataset consists of 'circles' (or 'friends' lists) from Facebook. It includes node features (profiles), circles, and ego networks. It's downloadable from the Stanford large network dataset collection [42]. Fig. 5 presents this dataset. It has 4039 nodes and 88234 edges. Table II presents some characteristics of the dataset.

Fig. 5. Facebook ego network

TABLE II. CHARACTERISTICS OF THE DATASET

NODES	4039
EDGES	88234
NODES IN LARGEST WCC	4039 (1.000)
EDGES IN LARGEST WCC	88234 (1.000)
NODES IN LARGEST SCC	4039 (1.000)
EDGES IN LARGEST SCC	88234 (1.000)
AVERAGE CLUSTERING COEFFICIENT	0.6055
NUMBER OF TRIANGLES	1612010
FRACTION OF CLOSED TRIANGLES	0.2647
DIAMETER (LONGEST SHORTEST PATH)	8
90-PERCENTILE EFFECTIVE DIAMETER	4.7

2) *Zachary karate club network*: It's a real-world network that is well-known in the domain of community structure [43]. The data was collected from a university of karate club in 1977 by Zachary. It represents relationships between members of the karate club. The network is split into two groups after a dispute between the two masters John A and Mr. Hi. Table III presents the characteristics of this dataset.

TABLE III. CHARACTERISTICS OF ZACHARY DATASET

Nodes  N	Edges	Max degree	Average degree	Diameter
34	78	17	4.588 24	5

### B. Results and Discussion

This subsection details all the steps of the proposed approach with the two versions of k-means applied on the datasets presented above. We start the experimentation on Facebook dataset and then we validate it on Zachary network that has a ground truth of the detected communities within it.

1) *Top-K influential nodes detection*: Facebook data has been anonymized by replacing the Facebook-internal ids for each user with a new value. For each ego-network, files for circles, edges, egofeat, feat and featnames are provided. As we are going to cluster people only by their friendship, we only consider the edges file. The first step to implement TOPSIS is the construction of the evaluation matrix. Centrality measures are calculated beforehand and concatenated in a decision matrix. The measures DC, BC, CC and EC constitute the columns of this matrix, and each node in the network constitutes one of its rows. This matrix will be normalized and weighted in the next step to be ready for the following steps, see Algorithm 3.

After implementing and running TOPSIS methodology, we consider  $k=10$  to return the top-10 influential nodes presented by descending sort in Table IV. These nodes are numbered in the column named "Node" and their scores are given in the column named "TOPSIS". The ranking of these nodes is as following: 107>1684>1912>3437>0>1085>698>567>58>428, with ">" means more influential.

TABLE IV. TOP-10 INFLUENTIAL NODES USING TOPSIS

Node	SCORE
107	0,913277
1684	0,695566
1912	0,496063
3437	0,488865
0	0,304321
1085	0,297379
698	0,231106
567	0,193646
58	0,169464

428	0,132923
-----	----------

The Susceptible-Infected (SI) model is used to look at the spreading effect of top-K influential nodes in order to assess the effectiveness of the ranking model. The SI model is frequently used to study the dynamics of epidemics on networks. Every node in the SI model has two distinctive states:

a) Susceptible  $S(t)$  indicates the number of people who are susceptible to the disease but have not yet obtained it;

b) Infected  $I(t)$  reflects the number of people who have contracted the disease and are able to disseminate it to susceptible people. For each contaminated node, one randomly sensitive neighbor contracts the disease with probability at each step (here,  $\lambda = 0.3$  for uniformity).

For this epidemic model,  $\lambda$  indicates the range across which a node can have an effect on epidemic spreading on networks. Through the intermediaries, an infected node can spread the infection not just to its immediate neighbors but also to its higher order neighbors. In this mode,  $F(t)$  stands for the number of contaminated nodes at time  $t$ . Using different initially infected nodes, the number of infected nodes should be equal to the overall number of nodes in networks. The average number of infected nodes at each iteration or the spreading rate is the indicator to assess the influence of the initial infected node. The proposed technique is compared with degree, closeness, betweenness, and eigenvector centrality using the SI model. Each implementation identifies the top 10 nodes to infect, and then the SI model is used to determine how the information spreads throughout the network. The influence of the nodes that either presents in the top-10 rankings by the proposed model and the four metrics of centrality are studied. In order to increase the precision of the results, the algorithm will be repeated 10000 times. Thus, the variation (standard deviation) and the mean of each iteration will be calculated. Fig. 6 presents the results.  $F(t)$  is the cumulative infected nodes The simulations are on  $F(t)$  as a function of time for the proposed network.  $F(t)$  increases with time and finally reaches the steady value. According to Fig. 6, the proposed method outperforms DC, CC and EC. The results between BC and the proposed approach are close. Their lines almost overlap as shown in the Fig. 6 and the members of their top-10 lists are the same.

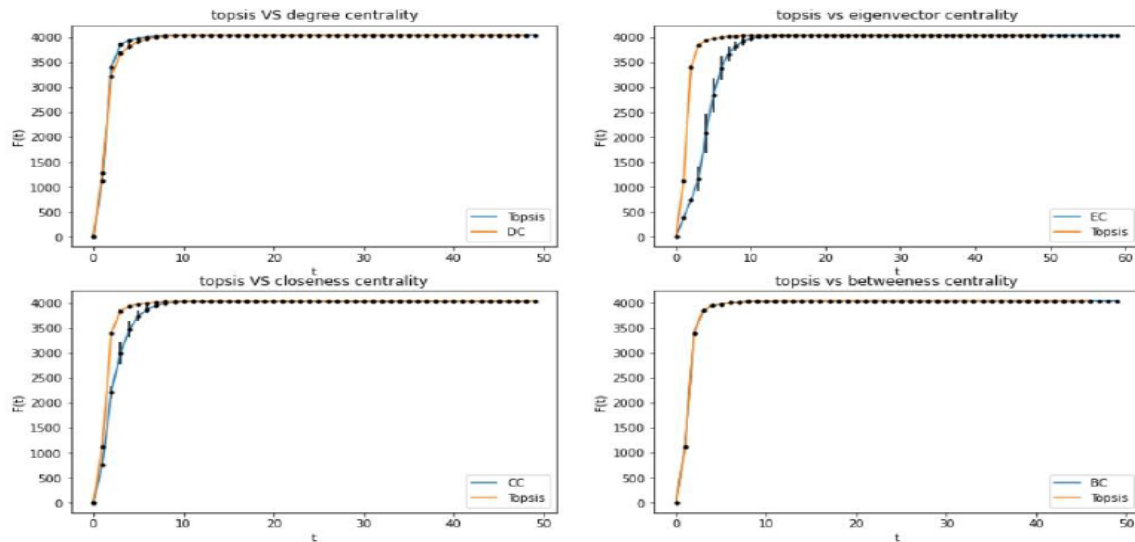

Fig. 6. The cumulative number of infected nodes as a time function, with the initially infected are the top-10 list by the proposed method, DC, CC, BC, and EC. Results are obtained by averaging over 100000 implements ( $\beta=0.3$ ).

2) *Community detection using static k-means*: The second step of the proposed approach is to run k-means algorithm, with  $k=10$ . The starting centroids for the k-means are the top-10 influential nodes computed by TOPSIS methodology and given in Table IV. Concretely, these nodes are:

$$CP_{centroid}^0 = node_{107}, CP_{centroid}^1 = node_{1684}, \dots, CP_{centroid}^9 = node_{428}.$$

The k-means algorithm is applied in two ways; one with the centrality measures and the other with the k-means algorithm is applied in two ways; one with the centrality measures and the other with the adjacency matrix.

a) *K-means with centrality measures*: In this first way of application of k-means, the centrality measures of top-10 influential nodes are calculated as a training data. Fig. 7 demonstrates the clustering using centrality measures, the big nodes with different colors present the top-10 influential nodes.

Fig. 7. Clustering based on k-means using centrality measures with initialization with top-10 influential nodes

b) *K-means with adjacency matrix*: We're going straight in this step to construct the adjacency matrix of the network, then the matrix of the top-10 nodes. An adjacency matrix is a way of representing a graph as a matrix of Booleans; 0 when two nodes are not connected, and 1 when two nodes are connected.

Fig. 8. Clustering based on k-means using adjacency matrix with initialization with top-K influential nodes

According to Fig. 8, it appears that implementing k-means using centrality measures gives good results in terms of distribution of nodes than using adjacency matrix. Although the algorithm is initialized with Top-10 influential nodes, one dominant cluster (blue cluster) is obtained which explains that the majority of nodes are grouped in this cluster. To confirm this result we resort to the scatterplot of these two approaches. The scatterplot below in Fig. 9(a) shows the distribution of nodes by their cluster.

(a)The scatterplot of nodes and their cluster with initialization of top-10 influential nodes using centrality measure

(b)The scatterplot of nodes and their cluster with initialization of top-10 influential nodes using adjacency matrix

Fig. 9. Distribution of nodes in their clusters using centrality measures and adjacency matrix

From Fig. 9(b) the cluster 8 contains the majority of the network’s nodes; the other nodes are distributed to the cluster 9, the cluster 7 and the cluster 6. Other clusters contain just one node. Fig. 9(a) demonstrates the distribution of nodes using centrality measures as node features for k-means training data. Nodes in this clustering are not also well distributed and the top-10 nodes have been isolated in 6 separate clusters as Table V shows.

In this clustering some of the top-10 nodes are the lonely nodes in their cluster like 107, 1684, 1912 and 3437. While the nodes 0, 1085, 567 and 698 are gathered in one cluster and the two other nodes of the top-10 nodes are grouped with some few nodes in the same cluster. The k-means algorithm using the centrality measures clusters the nodes based on their influence in the network, that’s why we notice that the more

the nodes have more influence in the network, the more they are isolated in other clusters. This kind of clustering can be applied to minimize the influence in social networks. The influence minimization can predict the spread of deprecatory rumors, fake news, and spread of disease.

TABLE V. DISTRIBUTIONS OF INFLUENTIAL NODES IN THEIR FINAL CLUSTERS

Node	TOPSIS	Cluster
107	0.913277	0
1684	0.695566	1
1912	0.496063	2
3437	0.488865	3
0	0.304321	4
1085	0.297379	4
698	0.231106	4
567	0.193646	4
58	0.169464	5
428	0.132923	5

3) *Community detection using dynamic k-means:* Although the proposed approach is simple and fast, yet there are also some limitations. From the scatterplots in Fig. 9, we conclude that the value 10 given to k is big and not precise. We need then to assign an optimal value to k before starting the k-means algorithm. It’s hard to know this value from the beginning, reason for what we need to apply the dynamic K-means. As discussed in the section D, we implement Elbow and Silhouette methods for this purpose. The two approaches based on the centrality measures and also the adjacency matrix is also used in this context. Centrality measures exceeds adjacency matrix in terms of defining the optimal-k. The problem of working with the adjacency matrix is the instability of defining the optimal k because we get different values of k for each execution. Hence, we focus on centrality measures to define the optimal value for k. The value generated using the Elbow method and Silhouette method are respectively k=6 and k=7, Fig. 10. From the previous experiments where k=10, we concluded that big values of k don’t give good clustering. So we consider the optimal value of k is 6 and then we apply the proposed approach using the first six influential nodes as starting centroids for k-means algorithm. The output of the proposed approach into six clusters is highlighted in Fig. 11 below.

(a) Elbow

(b) Silhouette

Fig. 10. The clustering of Facebook ego network using dynamic k-means

According to the graph in Fig. 11, it seems that we have four dominant communities in the network which is confirmed by the scatterplot in Fig. 12. The distribution of nodes to the detected communities looks reasonable in this results compared to the previous one. This means that when  $k$  is well defined, the proposed approach gives better results. These results need to be confirmed on datasets with ground truth.

Fig. 11. The clustering of facebook ego network using dynamic k-means

Fig. 12. The scatterplot of Facebook ego network using dynamic k-means

4) *Evaluation metrics:* It is necessary to use specific performance measures to measure the similarity between the two dataset partitions. In this experimental study, two classical measures are used.

The first one is the Rand index [44]. It is the portion of point pairs  $(x_1, x_2)$  that are organized similarly in both divisions. Either  $x_1$  and  $x_2$  are members of the same cluster in both the situations or they are members of different clusters.

The Rand index can be inflated artificially by predicting many clusters. Numerous pairs of points will belong to separate clusters, and the possibility that two points with different labels will be found in two different clusters will be considerable. This effect is remedied by The Adjusted Rand Index (*ARI*), which normalizes the Rand Index (*RI*) [45]:

$$ARI = \frac{RI - E(RI)}{\max(RI) - E(RI)} \quad (5)$$

Where  $E(RI)$  is the expectation of the value of the Rand index, in other words, the index obtained by randomly splitting the data. This adjusted index is only close to 1 when the clustering exactly matches the original partition and is close to 0 otherwise.

The second measure used in this experimental study is the normalized mutual information [46]. In probability theory and information theory, the mutual information of two random variables is a quantity measuring of the statistical dependence of these variables. Normalized mutual information *NMI* is a variant of mutual information. Its value is between 0 and 1. The closer *NMI* is to 1, the closer the result is to the ground truth. It can be defined as:

$$NMI(X, Y) = \frac{I(X, Y)}{\sqrt{H(X)H(Y)}} \quad (6)$$

Where,  $I()$  is the mutual information and  $H()$  is the entropy.

5) *Experiments on dataset with ground-truth:* The evaluation of detected communities is still an open issue in the scientific community because of the lack of models and references. Since the availability of a ground truth community structure for large real networks is difficult, we choose to validate the proposed approach on Zachary karate club network.

In this experiment, we rely on the dynamic k-means to get the optimal value of  $k$ . In this case the optimal  $k=2$  by the silhouette method as shown in Fig. 13. We test k-means with top-2 influential nodes using centrality measures but the

results are not satisfactory reason for which we use dynamic k-means with the adjacency matrix on Zachary network. Fig. 15 shows the obtained results and Fig. 14 gives the ground-truth community structure of Zachary karate club.

Fig. 13. The optimal-k of Zachary dataset given by silhouette method

Fig. 14. The ground-truth community structure of Zachary karate club

Fig. 15. The community structure detected by the proposed approach

Table VI presents the obtained results on Zachary compared to other algorithms of community detection like Louvain [47], Newman [48], Walktrap [5], Licod [18] and Yasca [27]. Compared to the ground-truth community structure, the proposed approach also detects 2 communities in

Zachary as displayed in Fig. 15. Although some nodes deviate from the ground-truth community structure, the quality of the discovered communities is higher than other algorithms as mentioned in Table VI. NMI and ARI values are higher compared to other community detection algorithms.

TABLE VI. COMPARISON BETWEEN ALGORITHMS OF COMMUNITY DETECTION AND THE PROPOSED APPROACH ON ZACHARY KARATE CLUB.

Zachary (2 groups)	Algorithm	ARI	NMI	Detected communities
	Newman	0,46	0,57	5
	Louvain	0,46	0,58	4
	Walktrap	0,33	0,50	5
	Licod	0,62	0,60	3
	YASCA	0,69	0,77	2
	<b>Proposed ML approach</b>	<b>0,88</b>	<b>0,83</b>	2

## VI. CONCLUSION

In this paper, a new seed-expanding algorithm to detect communities in social networks is introduced. The selection of seeds is based on centrality measures, gathered as multi-attribute in TOPSIS. The Top-K influential nodes obtained by TOPSIS methodology are used as starting centroids to run the k-means algorithm. In the experimental study, k-means is implemented using centrality measures and adjacency matrix as training data to compare the results. We notice that on large real networks like Facebook, the centrality measures behave well than adjacency matrix in terms of nodes distribution except that we found difficulties to determine the good values of k for the clustering. That is why we proceed to dynamic k-means using Elbow and silhouette methods to get the optimal values of k. Thereafter we observe that the results seem more reasonable with the dynamic k-means. Eventually, for assessing the quality of the discovered communities, we use Zachary karate club to validate the proposed model instead of Facebook because of the unavailability of a ground-truth for Facebook. ARI and NMI are two measures used for the test, and the results show that the proposed approach is better than other available algorithms for community detection. Many possible future directions have been opened up by this work. For example, implementing other clustering methods for the purpose of detecting communities such as K-medoids, C-means, fuzzy k-means and compare the results with the K-mean algorithms. As we can extend this work on other networks apart from social networks by using other centralities in the initial phase which are adequate for these types of networks.

College of Industrial Technology, Negros Oriental State University, Dumaguete City, Philippines<sup>5</sup>  
College of Information and Computing Studies, Northern Iloilo State University, Iloilo, Philippines<sup>6</sup>

**Abstract**—The purpose of this study was to assess the level of awareness of the management and the personnel within the academic institution and identify the implementation status of the ICTCP to the implementing SUCs. The researchers used the BCM Framework was utilized in this study as the model for identifying the level of awareness of the personnel within the institution about the ICTCP. The research respondents were the personnel employed in the different States, Universities, and Colleges (SUCs) within the province of Negros Occidental. The respondents were selected through random sampling, they were provided by a google form link to answer the survey questionnaire. A total of thirty-five (35) IT personnel were included in the study's sample size. It was found out that most SUCs have consistent ICT system uptime because they can continuously provide services; surprisingly, this is independent of an ICT business continuity plan. Most SUCs do not entirely implement their ICT business continuity plans. Lastly, it is recommended that SUCs can significantly enhance service delivery if ICT business continuity planning is taken seriously, adopted, and entirely carried out.

**Keywords**—Business continuity plan (BCP); information, communication; and technology continuity Plan (ICTCP); state universities and colleges (SUCs); business continuity management (BCM) framework

## I. INTRODUCTION

The importance of technology for information and communication (ICT) as component of enterprises worldwide has become crucial. It comprises communication technologies, infrastructure, hardware, and software related to information systems. This technology and systems will eventually malfunction due to unexpected catastrophes or causes. The ICT systems must be recovered and put back into operation with the fewest possible downtimes because they are a crucial component of corporate functions. According to [1], the speed at which business operations recover guarantees that it will outperform its rivals and provide customers with a high degree of satisfaction.

In the Philippine setting, one of the legal bases is the Data Privacy Act of 2012 (RA10173), ensuring that all government institutions, like States, Universities, and Colleges (SUCs), will craft its ICT Continuity Plan (ICTCP) to protect their business process and provide excellent service to their clients.

Furthermore, on March 24, 2020, Republic Act No. 11469, known as the "Bayanihan to Heal as One Act" was signed into law. In this regard, the DICT hereby directs all public telecommunication entities (PTEs) and government agencies, including academic institutions, to submit their Business Continuity Plan (BCP) and other measures to ensure uninterrupted service and to address the increased demand for ICT services.

In this regard, this study aimed to assess the level of awareness of the management and the personnel within the academic institution and identify the implementation status of the ICTCP to the implementing SUCs. Ascertain the extent of the use of computers using ICT at the State Universities and Colleges (SUCs) in Negros Occidental, Philippines. Ascertain how frequently the ICT systems SUCs relied on broke down and if the continuity plan is in place. Lastly, to ascertain how an ICT business continuity plan affected the provision of services.

## II. RELATED WORKS

ICT business continuity planning is a system of practices, guidelines, and proactive preparation that guarantees the restoration of vital ICT-dependent services in an emergency [2]. It enables the company to make crucial strategic, tactical, and operational decisions on the availability of essential systems [3]. In preparation for any system outage, resources such as software, hardware, technical experience, monitoring, time, and other infrastructure are established during an ICT business continuity plan.

The implementation must be maintained periodically and managed adequately. However, some studies concerning IT Audit found that some of the existing Business Continuity Plan (BCP) that is not entirely and correctly updated and will fail the business to continue its operation when disruption happens [4]. This was also seconded by the study [2] that due to the ICT business continuity plan not being viewed as a strategic component of the company, it has not been completely implemented and was neglected. According to [5], many organizations did not feel the need to deal with the BCP in the past because the dependence on ICT was not so significant, and production could run for some time regardless of a data network in the organization.

BCP was beneficial for all of the organizations that were surveyed. Still, more focus is required on managing societal and individual impacts, building employee resilience, identifying influential crisis leaders, right-sizing plans, and planning to take advantage of opportunities after a disaster. It is also essential to assess employees' awareness of the general coordination of information technology regarding these processes [6].

### III. IMPLEMENTATION

The study's general objective is to ascertain how ICT continuity plans affects on service delivery and assess the level of awareness of the personnel of State, Universities, and Colleges (SUCs) in the Philippines, specifically in Negros Occidental. Furthermore, it is to identify the advantages of an ICT business continuity strategy for SUCs in Negros Occidental. The study is based on the descriptive type, which involved a primary gathering of data from the respondents in terms of their profile and assessment of the availability of the ICTCP in their respective institutions.

#### A. The Business Continuity Plan (BCM) Framework

The BCM Framework was utilized in this study as the model for identifying the level of awareness of the personnel within the institution about the ICTCP (Fig. 1). The six elements of the BCM life cycle, according to the international standards, the management of the business continuity program, instilling knowledge and skills into the organizational culture, knowing the organization, choosing options for business continuity, creating and putting into practice a business continuity response, and practicing and testing the developed plans [7].

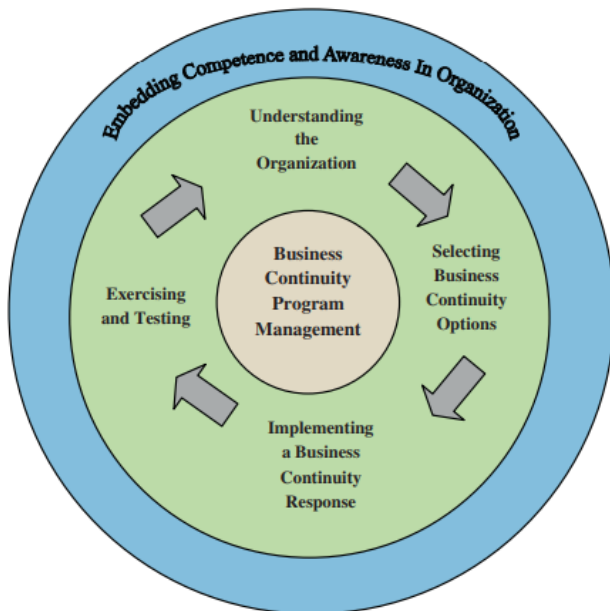

Fig. 1. The lifecycle of BCM [7].

#### B. Understanding the Organization

According to [8], the outcomes of the BCP implementation show that all framework components can be implemented, but some activity changes must be made to suit the organizational

conditions. Personnel in the organization must be aware of the implementation because they are the ones providing the services. This component aims to offer crucial details that will aid in understanding the company's goods, resources, and services [9]. Furthermore, the principal target objective, specific objectives, and policy are visible and disseminated to the employee from the top management to the office personnel.

Table I presents the role and responsibilities of the BCP team for SUCs. The team composed of the top management who see to it the requirements, budget allocation, and implementation of the ICTCP would be successful.

TABLE I. ROLE AND RESPONSIBILITIES FOR BCP TEAM

BCP Member	Roles
BCP Manager	<ul style="list-style-type: none"> <li>Ensures that the ICTCP is established, maintained, and reviewed periodically.</li> <li>Approves allocation of resources to ensure successful implementation of the plan.</li> </ul>
Vice President for Administration and Finance	<ul style="list-style-type: none"> <li>Ensures implementation and compliance with the ICTCP.</li> <li>Ensures the continual improvement of the ICTCP.</li> </ul>
Planning Officer	<ul style="list-style-type: none"> <li>Consolidates and evaluates personnel needs required to ensure the continuity of ICTCP critical unit functions and operations.</li> <li>Ensures continual improvement.</li> </ul>

Table II shows the composition of the ICT Response Team. The team must ensure that the ICTCP implementation is successful. The SUCs may designate a working team with expertise in ICT.

TABLE II. ROLE AND RESPONSIBILITIES OF ICT RESPONSE TEAM

Member	Roles
IT/MIS Officer	Establish, implement, and maintain a continuity of the ICT Business Operation of the University.
Data Privacy Officer	Inform and provide advice on data protection obligations, assist the University in monitoring internal compliance.
System Administrator	System administrators are the guardians of an organization and its data, ensuring that internal systems are safe and secure and are shielded from attacks and viruses.
Network Administrator	Ensuring ICT equipment remains updated and providing solutions to restore functionality.
Development Communication and Information Officer	Consolidates, controls, and validates all official information for dissemination.  Creating information, education, and communication (IEC) items in both English and regional dialects.

#### C. Selecting Business Continuity Options

Threats could appear out of nowhere at any time. Business continuity management is necessary to prepare for and address the problem. The last step in completing business continuity management is the requirement for a framework for a business continuity strategy. This framework will guide the organization using the business continuity plan document to

address threats or disasters [10]. Good decision on what framework to adapt is vital for the success of the implementation of the ICTCP.

#### D. Implementing a Business Continuity Response

According to [11], the fundamental idea behind business continuity is that to maintain company operations at an acceptable level, an organization must have the strategic and tactical capabilities to plan for and respond to business accidents and disruptions. Readiness is also vital in implementing a business continuity plan from management perspective and fulfilling the gap existing with a business continuity plan using a standard tool [12]. Many SUCs appear unfamiliar with and uncertain about which Business Continuity Management (BCM) option can be used for implementation. Organizations are becoming increasingly aware that being unprepared to handle disruptive occurrences could have disastrous results. BCM is a novel strategy to accomplish this goal. When a BCM is implemented in a company, there are three primary stages that need to be taken. The key items for the company should be recognized first. The Business Impact Analysis (BIA) technique can assist in this step by assisting in the systematic selection of those crucial products. Second, by carrying out the risk assessment process and creating the risk matrix, those risks that endanger the delivery of crucial products should be recognized and categorized. Finally, a BCP must be chosen for each disruption risk listed in the BCP section of the risk matrix and poses a danger to a significant product [13].

#### IV. RESULTS

The research respondents were the personnel employed in the different States, Universities, and Colleges (SUCs) within the province of Negros Occidental. The study utilized an adopted questionnaire from the study [2] on ICT Business Continuity Plan and Service delivery.

The respondents were selected through random sampling, they were provided by a google form link to answer the survey questionnaire. A total of fifty (50) people were included in the study's sample size. As shown in Table III, fifteen (15) from Central Philippines State University, ten (10) from Northern Negros State College of Science & Technology, fifteen (15) from Carlos Hilado Memorial State University, and ten (10) Technological University of the Philippines – Visayas.

A scale of 1 to 5 was used based on the Likert scale, and a non-comparative scaling approach was used.

The study expected a target of 50 respondents to answer the survey questionnaire. However, 35 of the estimated number filled out the surveys and returned them. Thus, as shown in Table III, the answer rate was 70%. This response rate was deemed suitable for analysis since, according to [14], a minimum of 70% or higher is exceptional for analysis.

TABLE III. DISTRIBUTION OF RESPONDENTS

SUC	Expected Responses	Percentage	Responses Received	Percentage
Central Philippines State University	15	30.00	15	42.90
Northern Negros State College of Science & Technology	10	20.00	5	14.29
Carlos Hilado Memorial State University	15	30.00	10	28.58
Technological University of the Philippines - Visayas	10	20.00	5	14.29
Total	50	100.00	35	100.00

#### V. DISCUSSION

##### A. Use of ICT

The purpose of the study was to ascertain the extent of the use of computers using ICT at the State Universities and Colleges (SUCs) in Negros Occidental, Philippines, which necessitated the creation of a business continuity plan for ICT. According to Table IV below, 0% of respondents did not rely on ICT for all their key operations, whereas 100% used ICT for all their essential duties. The value of information and communication technology (ICT) in education is unquestionable on a global scale. It has the potential to be very effective to use ICT to increase educational opportunities. ICT has the potential to improve the relevance and standard of education while expanding access to it [15].

TABLE IV. EXTENT OF ICT USAGE

Responses	Frequency	Percentage
Yes	50	100.00
No	0	0.00
Total	50	100.00

##### B. Failure of ICT core systems

The study aimed to ascertain how frequently the ICT systems SUCs relied on broke down. According to Table V below, 82.6% of respondents said their systems failed only occasionally, while 17.4% said it happened sometimes. 33.1% of the respondents reported that system failure-causing disasters never or only occasionally happened, compared to 45.6% who experienced disasters sparingly and 21.3% who never experienced system outages due to disasters. According to [16] it is crucial to improve their capability for ICT policy, respond to shifts in the ICT ecosystem, develop robust cybersecurity regulations, and make sure the private sector operates under predictable conditions.

TABLE V. FAILURE OF ICT CORE SYSTEMS

Responses' Percentage Distribution					
System Failures	Never	Rarely	Sometimes	Always	Total
Your systems fail frequently.	0.0%	82.6%	17.4%	0.0%	100%
Disasters occur, causing system outages	21.3%	45.6%	33.1%	0.0%	100%

C. Access to the ICT Continuity Plan

The study aimed to ascertain whether the four SUCs in the Philippine province of Negros Occidental had an ICT business continuity plan in place to lessen or avert the results of system malfunctions brought on by emergencies. Table VI demonstrates that only 2 SUCs had an ICT business continuity plan compared to the other 2 SUCs. Maintaining organizational operations in the face of potential threats, risks, the causes of power outages, cyberattacks, or epidemiological attacks, or natural disasters. BCP is therefore crucial in SUCs to plan for any risk [17].

TABLE VI. AVAILABILITY OF ICT CONTINUITY PLAN

Responses	Frequency	Percentage
Yes	2	50.00
No	2	50.00
Total	5	100.00

D. Availability of ICTCP Policies

The study looked into any internal guidelines for managing, regulating, and controlling the ICT business continuity plan. This was done to assess the level of implementation of ICT business continuity plans (Table VII). Two SUCs had established policies, while the other two did not.

TABLE VII. AVAILABILITY OF ICT BUSINESS CONTINUITY PLAN POLICIES

Responses	Frequency	Percentage
Yes	2	50.00
No	2	50.00
Total	4	100.00

E. Availability of Disaster Recovery Site

The study examined whether it was possible to check the effectiveness of the ICT business continuity plan at an off-site location for disaster recovery. One SUC lacked a recovery site, while the other three had them to help with recovery (Table VIII).

TABLE VIII. SITE FOR DISASTER RECOVERY IS ACCESSIBLE

Responses	Frequency	Percentage
Yes	3	75.00
No	1	25.00
Total	4	100.00

F. Challenges of ICTCP

The study aimed to identify the problems and develop an ICT business continuity strategy for the SUCs in the Philippine province of Negros Occidental. Table IX below shows that responses with a mean of 4.52 demonstrated strategies fail due to insufficient resources. With a standard of 3.80, respondents responded that the ICT plan requires an extensive planning for the second significant difficulty, and stakeholders in the firm do not have access to enough information concerning ICT business continuity plans. Limited resources were rated as the main obstacle to an ICT business continuity plan by 2.6. The institution's ICT strategy is not seen as a strategic component, according to respondents with a mean score of 2.41. According to respondents, with a mean of 2.57, the ICT business continuity plan is seen as an ICT-only job that excludes other departments. A standard of 2.5 respondents revealed that managing the ICT business continuity plan required technical competence and that stakeholders were not properly informed about what an ICT business continuity plan involved inside the organization.

TABLE IX. ICT BUSINESS CONTINUITY PLAN CHALLENGES

Items	N	Mean	Std. Deviation
ICT plans fail as a result of insufficient resources.	35	4.52	.936640
Plans for ICT business continuity need to be carefully thought out.	35	3.80	1.222376
The company's stakeholders are not adequately informed about what an ICT business continuity plan entails.	35	3.80	1.222376
The amount of time required to implement an ICT business continuity plan is excessive.	35	2.57	.654970
ICT business continuity plans cannot be updated as quickly as technology does.	35	2.41	.932764
ICT systems experience system failures more frequently than earlier manual processes, necessitating ongoing monitoring.	35	2.60	1.139540
The institution does not view the ICT business continuity plan as a strategic component.	35	2.41	.932764
The management of an ICT business continuity plan requires technical expertise.	35	2.57	.781736
There are no regulations in place to support the administration of the plan.	35	2.90	.987849
According to some, the ICT business continuity plan only pertains to ICT and excludes other departments.	35	2.57	.654970

G. Service Delivery

The study's goal was to ascertain how an ICT business continuity plan affected the provision of services. Table X demonstrates that the companies' profit margins increased as a result of customer satisfaction for the SUCs was based on the quality of services offered, offered superior goods and services with a mean of 3.57, and with a mean of 2.57, service delivery was boosted through the institution's adoption of an ICT business continuity plan.

TABLE X. SERVICE DELIVERY

Items	N	Mean	Std. Deviation
Customer satisfaction depends on how well services are provided.	35	3.57	1.184644
Service delivery is improved thanks to our company's adoption of an ICT business continuity plan.	35	2.57	.654970

## VI. CONCLUSION

The study found out the advantages of an ICT business continuity plan that most SUCs believed it benefited from the shortened time needed for system recovery after a failure. Other advantages were the development of teamwork and system understanding through employee engagement plans, the realization, and reduction of points of failure during the testing of the ICT business continuity plan, the ability to know what to do in the event of a disaster, reduction of losses caused by unforeseen disasters, effective resource planning for the company in the event of a disaster.

According to the study's findings, ICT has been widely adopted in SUCs, and it is clear that these institutions need their systems to operate continually with little chance of failure. Most insurance businesses implement an ICT business continuity plan to ensure fewer system disruptions and downtimes. Most SUCs have consistent ICT system uptime because they can continuously provide services; surprisingly, this is independent of an ICT business continuity plan. Most SUCs do not entirely implement their ICT business continuity plans. The ICT business continuity plan was easily overlooked or misunderstood as an ICT role because it had not been considered a strategic business need. It was also found to be resource-intensive and time- and planning-intensive.

The study's conclusions allow for the following recommendations: SUCs can significantly enhance service delivery if ICT business continuity planning is taken seriously, adopted, and entirely carried out. This is due to several reasons, including that they impact how services are delivered. An ICT business continuity strategy will ensure that ICT systems are always accessible to prevent service disruptions.

The proper management of ICT business continuity plans requires clearly defined rules, guidelines, and policies, efficient testing intervals, the availability of disaster recovery sites, enough time, hardware, software, and technology resources, as well as technical expertise and teamwork.

## ACKNOWLEDGMENT

The researchers would like to thank Dr. Felicisimo V. Wenceslao, Jr., professor of College of Information and Computing Studies at the Northern Iloilo State University, for introducing us to this topic and providing invaluable guidance and support during the research.

# Towards a Machine Learning-based Model for Automated Crop Type Mapping

Asmae DAKIR, Fatimazahra BARRAMOU, Omar Bachir ALAMI

Team (SGEO) - Laboratory of Systems Engineering

Hassania School of Public Works (EHTP)

Casablanca, Morocco

**Abstract**— In the field of smart farming, automated crop type mapping is a challenging task to guarantee fast and automatic management of the agricultural sector. With the emergence of advanced technologies such as artificial intelligence and geospatial technologies, new concepts were developed to provide realistic solutions to precision agriculture. The present study aims to present a machine learning-based model for automated crop-type mapping with high accuracy. The proposed model is based on the use of both optical and radar satellite images for the classification of crop types with machine learning-based algorithms. Random Forest and Support Vector Machine, were employed to classify the time series of vegetation indices. Several indices extracted from both optical and radar data were calculated. Harmonical modelization was also applied to optical indices, and decomposed into harmonic terms to calculate the fitted values of the time series. The proposed model was implemented using the geospatial processing services of Google Earth Engine and tested with a case study with about 147 satellite images. The results show the annual variability of crops and allowed performing classifications and crop type mapping with accuracy that exceeds the performances of the other existing models.

**Keywords**—Smart farming; artificial intelligence; machine learning; precision agriculture; random forest; SVM

## I. INTRODUCTION

Agriculture has been a challenging economical sector, and a vital pillar of development in many countries. The first challenge is to ensure food self-sufficiency and respond to the increasing requirements of a growing population. The Food and Agriculture Organization of the United Nations [1] global report highlighted food insecurity and its accelerating rising trend. The report suggested that to prevent severe hunger, daring transformation must be conducted in the agri-food systems. Many recent technics and systems aimed to ensure the sustainable development of agriculture [2] and new concepts were developed like precision agriculture [3]. The recent revolution of digital technologies has radically changed agricultural management, like the employment of geospatial technologies, remote sensing data [4], and artificial intelligence [5], [6]. This study proposes a new model to show the contribution of machine learning algorithms in the

identification of crop types using both optical and radar satellite images with time series of different vegetation indices. The general aim is to establish a method for improving crop type mapping accuracies, with the demonstration of the contribution of optical and radar data and their complementarity.

The paper proceeds as follows: providing related works in Section II. Section III, introduces the proposed model. The case study is presented in Section IV. Section V presents and discusses the results, and Section VI concludes and gives the intended future works.

## II. RELATED WORKS

Crop-type mapping using remote sensing data and machine learning technics is the subject of multiple research [7]–[10]. Optical data has been a reference data for crop mapping studies because of the ease to link phenological development and biological properties of crops with optical acquisitions to differentiate crop species [11]–[13]. Also, it identifies various growing stages of a single crop, rice as in this case study [14]. The author in [11] used Sentinel-2 time series data with gap filling method to overcome data discontinuity caused by cloud cover. Interpolation technics were also used by [11] in the DATimes software to capture seasonal vegetation dynamics. Different optical sensors were also combined to increase time series temporal frequency and to catch field-level phenologies [15]. Both optical and radar data were used by [16] to detect paddy rice fields using phenological variations and a textural-based strategy. Radar images only were investigated by [17] to detect winter wheat phenological stages. They analyzed the temporal variations of the Sentinel -1 time series in the function of different phenological phases. The author in [18] as well used Sentinel-1 time series to conduct classification considering Spatiotemporal phenological information.

Different machine-learning algorithms were employed to produce accurate crop maps. The support vector machine (SVM), and random forest (RF) classifiers have been the most popular in recent years for the classification of satellite images [19]. Many papers reported better performance of SVM [8], [20]–[22] as well as DT and RF algorithms compared to other techniques.

Fig. 1. Proposed model

The goal of mapping crops was approached using different methods, technics and datasets in the literature review. Although the obtained results presented good accuracies, the development of geospatial technics has imported its evolution; the integration of the Google Earth Engine allows producing large treatments instantly that can be employed to identify crops early in the season. The obtained accuracies in the state of the art are yet to be improved by exploiting complementarity between radar and optical time-series and their indices.

This research proposes a new machine-learning method combining time-series indices extracted from optical and radar satellite images and machine-learning classifiers to perform automated and high-accuracy crop-type mapping.

### III. PROPOSED MODEL

The proposed model employs time series from both optical and radar data. The model was performed using the geospatial processing services of Google Earth Engine (Fig. 1):

#### A. Preprocessing

**Cloud masking:** An important step of pre-processing the image collection is to omit the disturbance caused by clouds and shadows from the imagery. The cloud masking process was performed using the cloud probability band that was created with the Sentinel 2 cloud detector library. The maximum cloud probability was limited to 25. The gaps in the masked image were then filled with the previous interpolated image.

**Speckle filtering:** satellite images are usually affected by speckle noise. Multiple statistical methods were developed to remove the speckle in the concern to preserve image details. The study conducted by [23] compared different filtering methods dedicated to speckle suppression in SAR images and found that Lee-Sigma and Gamma-MAP are showing relatively good detail preserving abilities than other filter types. The author in [24] also concluded that the Gamma Map filter is reliable as proved by the comparison between the Lee filter, frost filter, and Gamma Map. In the present model, the Gamma-MAP filter is used, which is based on the Bayesian analysis of image statistics. It uses the Maximum A-Posteriori (MAP) estimation method. While using this filter, Gamma distribution is assumed for the underlying image and the speckle noise in it. Thus, this filter works best for geospatial images containing homogenous areas such as oceans, forests, fields, etc.

#### B. Training Sample

1) **Indices calculation and time series composites:** Optical data provide information in multiple bands that can produce valuable information about the state of vegetation. For the purpose to capture spatiotemporal variation in photosynthetically active vegetation, multiple optical indices were developed in the literature to characterize and monitor the development of crops [19], [25]. The author in [25] calculated the EVI and NDVI indices from the time series to extract metrics for crop discrimination. In this study, different

indices were calculated for each image in the image collection (Table I). The main used bands are Red (R), Green (G), Near InfraRed (NIR), and Short-Wavelength InfraRed (SWIR) from the optical images, and both polarization VV and VH from radar images.

TABLE I. OPTICAL AND BACKSCATTER CALCULATED INDICES

Index	Abbreviation	Formula
Normalized Difference Vegetation Index	NDVI	$NDVI = \frac{NIR-R}{NIR+R} \quad (1)$
Normalized Difference Water Index	NDWI	$NDWI = \frac{G-NIR}{G+NIR} \quad (2)$
Normalized Difference Moisture Index	NDMI	$NDMI = \frac{NIR-SWIR}{NIR+SWIR} \quad (3)$
Normalized Ratio Procedure between Bands	NRPB	$NRPB = \frac{\sigma_{VH} - \sigma_{VV}}{\sigma_{VH} + \sigma_{VV}} \quad (4)$
The polarization ratio	Ratio	$Ratio = \frac{\sigma_{VV}}{\sigma_{VH}} \quad (5)$

2) *Harmonic modelization of optical time series*: Time series from the optical indices depends on the phenological cycle of crops throughout the year. The analysis of the variations is represented by applying harmonic modeling also named Fourier analysis. The analysis consists of decomposing the time-dependent periodic event into a series of sinusoidal functions, with phase and amplitude values. The general equation of a time series is presented by [26] in eq. (6).

$$A \cos(2\pi\omega t - \varphi) = \beta_2 \cos(2\pi\omega t) + \beta_3 \sin(2\pi\omega t) \quad (6)$$

Considering the linear model, where A is amplitude,  $\omega$  is a random error,  $\omega$  is frequency, and  $\varphi$  is phase:

$$P_t = NDVI_t = \beta_0 + \beta_1 t + A \cos(2\pi\omega t - \varphi) + \epsilon_t$$

$$= \beta_0 + \beta_1 t + \beta_2 \cos(2\pi\omega t) + \beta_3 \sin(2\pi\omega t) + \epsilon_t$$

$$\text{And } \beta_2 = A \cos(\varphi) \quad \beta_3 = A \sin(\varphi)$$

$$A = \text{amplitude} = (\beta_2^2 + \beta_3^2)^{1/2} \quad \varphi = \text{phase} = \text{atan}(\beta_3/\beta_2)$$

For each optical index, the harmonic modeling was then applied, and time series were decomposed into harmonic terms to calculate the fitted values of the time series.

3) *Training set selection*: To guarantee a good presentation of each class, training samples should respect a good representation of each class taking into consideration spatial distribution. 20% of the samples are set for validation and accuracy calculations, and 80% were used for training and extraction features from the formulated time series.

### C. Classification and Validation

In the literature, different classification methods are employed for land cover and land mapping. This study, employed two classifiers which are the most performant [8], [20]–[22].

1) *Machine learning classification*: Random Forest RF classifier is based on building multiple trees from samples of the training data. Each tree is built using a different subset from the original training variables. Its advantage is that the algorithm can handle a huge amount of input data. The decision of belonging to a given class is determined by the majority vote of the trees.

Support Vector Machine (SVM) is a supervised non-parametric statistical technique. The decision to separate between classes is made by calculating the hyperplane that maximizes the margin between classes. The separation between data points is based on the applied kernel function (Linear, Polynomial, Gaussian, Radial Basis Function (RBF), or Sigmoid) that determines the efficiency of the classification.

2) *Accuracy assessment*: Two performance criteria were used to assess the result's accuracy. The main index of Cohen's kappa is a statistical measure of interrater reliability for categorical variables. It takes into account the possibility of the accord occurring by chance (eq. 7).

$$\frac{p_0 - pc}{1 - pc} \quad (7)$$

While  $p_0$  = Observed accuracy.  $p$  is the sum of relative frequency in the diagonal of the error matrix.  $pc$  = Chance agreement.

F1 score also a measure of a model's accuracy can be interpreted as a harmonic mean of the precision and recall of the confusion matrix. F1-score is calculated per class for a multiclass classification problem (eq. 8).

$$F1 \text{ Score} = \frac{2}{\frac{1}{\frac{Recall}{precision}} + 1} = \frac{2 * Precision * Recall}{Precision + Recall} \quad (8)$$

$$\text{Where: recall} = \frac{Tp}{Tp + Fn} \text{ and precision} = \frac{Tp}{Tp + Fp}$$

## IV. CASE STUDY

### A. Study Area

To evaluate the radar and optical indices using a supervised classification method, the proposed model is tested in an agricultural zone in Minnesota State in the United States (Fig. 2). Minnesota is located in the Western part of the Great Lakes region and ranks fifth in the United States for total crop sales, the major crops are corn, Soybean, sugar beets, and dry beans.

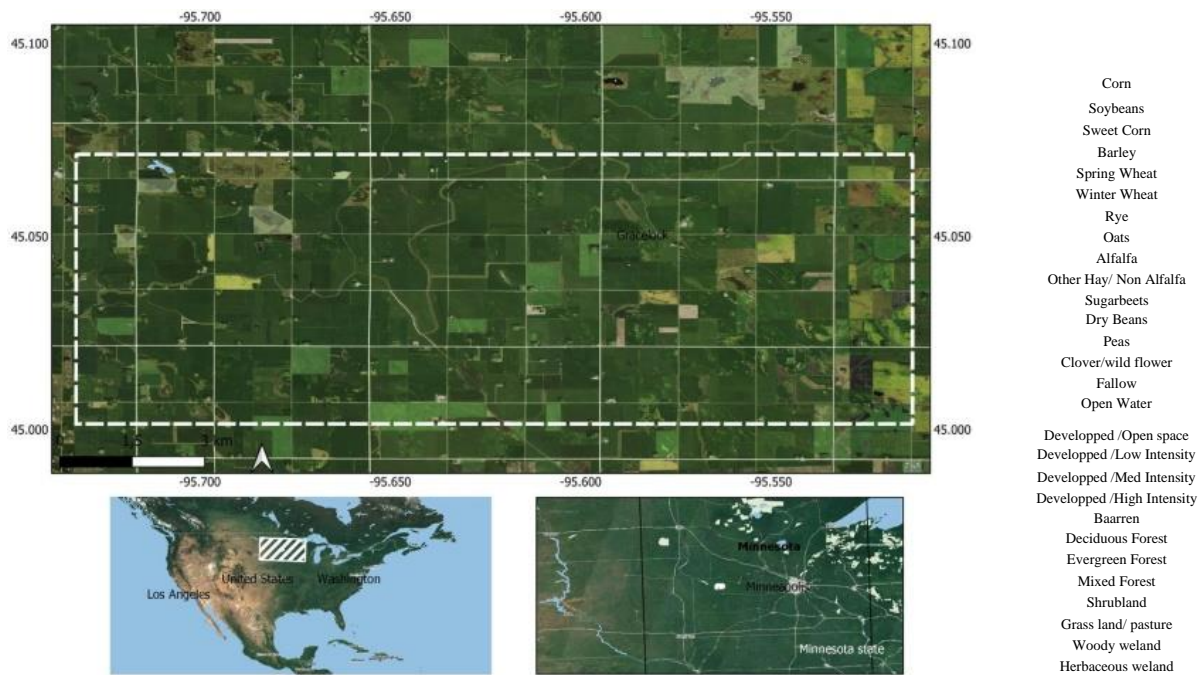

Fig. 2. Study area in the Minnesota state and the studied classes

### B. Crop Inventory Data

The reference data were collected from the cropland data layer (CDL) produced by United States Department of Agriculture. The layer contains annual crops from extensive agricultural ground truth with 30m spatial resolution. The process of training started with random points selection taking into consideration to cover the totality of the study area, and covering all the agricultural types. 80 % of data presenting 5989 points were selected for training the model, and 20% for validation. The selected zone contains 14 types of crops with 4 major types.

### C. Optical and Radar Data

Both radar (Sentinel 1) and optical (Sentinel 2) images were used in this study. The Sentinel 1 mission provides C-band Synthetic Aperture Radar data (SAR). The image catalog of Sentinel 1 data provides preprocessed images, terrain corrected and radiometrically calibrated. A total of 29 scenes of Synthetic Aperture Radar images were used from 01-01-2019 to 30-12-2019. The images were restricted to single-polarization VV and VH. The active sensor expands the possibilities of acquiring data in cloudy weather allowing then better monitoring of the vegetation evolution.

The Sentinel-2 mission provides multispectral high-resolution imagery with 12 spectral bands. The image collection contains 145 optical images covering all the studied periods.

### D. Analysis Platform

The development of the remote sensing field imported different offers and a large amount of data from different sensors, and several platforms have been elaborated to handle geospatial analysis and processing. The Google Earth Engine was introduced as a multi-petabyte catalog and cloud computing platform with high-performance computation

capabilities and has been investigated in land cover studies [27] and agricultural studies [28], [29].

The proposed process was all performed in the Google Earth Engine (GEE) platform, from the Sentinel image selection to the validation process. The GEE platform allowed the process of large-density images for pixel-based image analysis as well as the classification algorithms due to the high cloud calculation performance the platform offers.

### E. Time Series Formulation, Training, and Machine Learning Algorithms

The first steps of processing time series are conducted as detailed in the previous section. After the preprocessing, calculating optical and radar indices of each imagery data was performed.

SAR indices were extracted from the single-polarization bands. The Normalized Ratio Procedure between Bands (NRPB) and the ratio were estimated using the equation in Table I where  $\sigma_{VH}$  and  $\sigma_{VV}$  are the backscatter VH and VV polarization. In the same way, the NDVI, NDMI, and NDWI optical indices were calculated, then applied the harmonic modelization of the time series.

The training was then applied to the formulated input, the training set was selected randomly from the time series stack generated from all the SAR and optical calculated indices. The input features are then fed to the employed machine learning-based classifiers.

Multiple parameters were tested for obtaining perfect results. The final parameters for the SVM classifier were set to the Radial Basis Function (RBF), 0.5 for gamma and 10 for the cost. Random Forest is applied using 800 trees and 20 variables per split.

## V. RESULTS AND DISCUSSION

### A. Time Series of Vegetation Indices

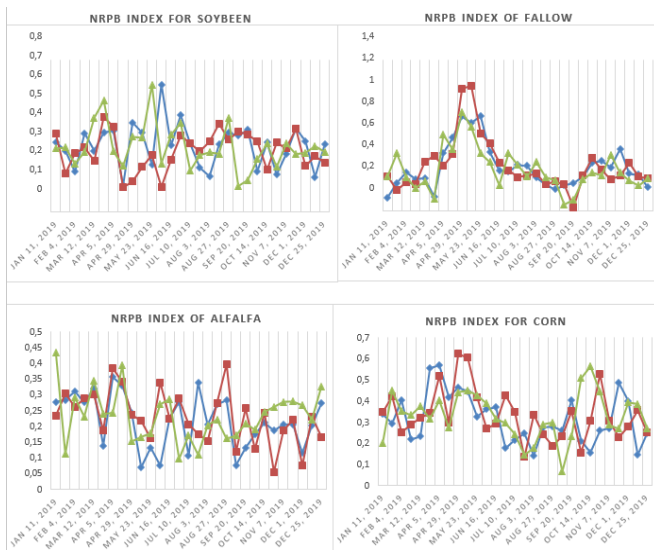

Fig. 3. NRPB index time series of major crops in the studied zone

Fig. 4. Ratio index time series of major crops in the studied zone

From the SAR indices, the NRPB and ratio index time series were presented in Fig. 3 and Fig. 4 with a selection of 4 major crops. The time series of the Normalized Ratio Procedure between Bands and the ratio index can monitor the vegetation changes. The temporal signature of different considered crop types is showing different signature behavior. The NRPB time series of corn alfalfa and soybean know significant variations whereas Fallow parcels responded smoothly and monotonously to changes over the year.

Fig. 5. NDVI time series and fitted values of major crops in the studied zone

The variations are a function of soil surface conditions, moisture, roughness, and biomass development of crops. The NRPB index was also used by [30] to generate metrics for the input set of the model to aid the prediction of NDVI and highlighted the similarity found in the NDVI and  $\sigma_{VH}/\sigma_{VV}$  ratios with crops and finally found that insertion of the NRPB variable in machine learning models, like RF, gives better results.

Times series of the NDVI allows the characterization of each crop. Since the NDVI is a perfect index to describe the chlorophyll activity of crops, a dense and healthy state is presented by a high value of the NDVI index reaching 1, in the opposite case, the value approaches 0. Then, the time series is presenting the phenological cycle of each crop.

Fig. 5 presents a selection of 4 crops of the NDVI time series in the studied area and the harmonic modeling values. The model is suitable for smoothing the spectral curves and allows distinction between crops. Corn, dry beans, and soybeans are presenting a unimodal periodic model, with a high value for corn culture. The resulting phenological cycles match the phenological calendar provided by the USDA National Agricultural Statistics. Corn starts in late April and is harvested in early November. While the phenological cycle of Soybean Starts with the plantation in early May and is harvested in late October. Alfalfa is presenting the highest amplitude values and a different curve from other crops due to agricultural practices. Alfalfa is harvested repeatedly during the growing season starting from early April to late October. The results of the obtained phenological cycles were compatible with the crop calendar as given by the USDA in the region of Minnesota.

Fig. 6. Crop type mapping: Final results of RF and SVM classifications.

### B. Classification Results

SVM and Random Forest have demonstrated their advantage in classifying agricultural cover maps. The validation of the classification results was conducted by calculating the confusion matrix. 20% of random samples were used to validate the final result. Both classifiers had given good results with the advantage of the random forest classifier with 0.95 kappa index, and 0.85 for SVM. Table II presents accuracy metrics with good accuracy results, with the advantage of the RF classifier. Other studies had demonstrated the complementarity of optical and radar data [20], [31]–[34]. The authors in [35] have found an overall accuracy of 93.83% from combined inputs. The authors in [8] have found an overall accuracy between 73% and 95% depending on the input dataset used, using the SVM classifier.

Fig. 6 presents the final classification using SVM and RF algorithms. The results are showing similar classes except for slight visual differences.

Performances metrics were calculated, other than the kappa index, the F1-score, and Producer accuracy are presented in Table II. The Producer accuracy represents the probability that a particular sample of a particular class is classified correctly. The most correctly attributed classes are barley, corn, soybeans, and winter wheat.

### VI. CONCLUSION

This research study deals with the problem of crop type identification. A machine learning-based model for automated crop type mapping is proposed. The novelty of the model is to improve crop type mapping accuracy using time series from both optical and radar images by extracting vegetation indices. The model presents several advantages. It demonstrate the complementarity between optical and radar satellite images for crop type mapping studies. Secondly, the results pointed the advantage of Random Forest classifier over SVM. The resulted accuracy outperformed existing models in the state of the art with a kappa index of 95%.

The proposed model was implemented using Google Earth Engine and tested with a specific case study in an agricultural zone in Minnesota State in the United States. Future works intend to assess and compare the performances of deep learning and machine learning algorithms for crop-type mapping.

### ACKNOWLEDGMENT

We are very thankful to Unites State Department of Agriculture (USDA), and the National Agricultural Statistics Service (NASS) for providing the Crop Data Layer from which crop types were identified.

TABLE II. VALIDATION ACCURACY METRICS OF RANDOM FOREST AND SVM CLASSIFICATIONS

Classes	F1-SCORE RF	F1-SCORE SVM	Producer accuracy RF	Producer accuracy SVM

**Abstract**—Fingerprint biometric as an identification tool for children recognition was started in the late 19<sup>th</sup> century by Sir Galton. However, it is still not matured for children as adult fingerprint identification even after the span of two centuries. There is an increasing need for biometric identification of children because more than one million children are missing every year as per the report of International Centre of missing and exploited children. This paper presents a robust method of children identification by combining Discrete Cosine Transform (DCT) features and machine learning classifiers with Deep learning algorithms. The handcrafted features of fingerprint are extracted using DCT coefficient's mid and high frequency bands. Gaussian Naïve Base (GNB) classifier is best fitted among machine learning classifiers to find the match score between training and testing images. Further, the Transfer learning model is used to extract the deep features and to get the identification score. To make the model robust and accurate score level fusion of both the models is performed. The proposed model is validated on two publicly available fingerprint databases of children named as CMBD and NITG databases and it is compared with state-of-the-art methods. The rank-1 identification accuracy obtained with the proposed method is 99 %, which is remarkable compared to the literature.

**Keywords**—Discrete Cosine Transform (DCT); Curve DCT; biometric recognition; machine learning; convolutional neural network; AlexNet

## I. INTRODUCTION

Children missing, swapping and abduction is caused due to non-recognition of them from their faces or other biometrics as they are in the developing stage in this age. The rate of mishaps happening to them is increasing day by day due to non-availability of the authentic system for recognition of them. Researchers studied the different biometrics like face [1,2,3,4], palmprint [5], footprint [6], ear [7] and headprints [8] for recognition of children.

Fingerprint modality is most widely used biometric for recognition of adults. Dr. Faulds [9] used fingerprints for identification of persons in 1870. As per Sir Galton theory, the fingerprint similarity chance in two different persons is 1 in 64 billion [10]. In children, the fingerprints show distinctive features which can differentiate them from others, though they are in the developing stage.

Fingerprint recognition can be done by two methods: minutiae matching and pattern matching. Minutiae are small details in fingerprints like ridge, valley, ridge ending, bifurcation. In minutiae matching, different minutiae are matched against each other and the highest match probability is considered as the correct match. The problem with minutia match for children recognition is biometric aging. The displacement of minutiae points due to growth in fingers. One needs a growth model to recognise the longitudinal (after time lapse) fingerprint images of children. The second method of pattern matching is based on the texture of fingerprint images. Fingerprint images are rich in texture and hence frequency domain representation is suited for it. The basic block diagram of fingerprint recognition is as shown in Fig. 1. Original fingerprint is processed and enhanced to get the most suitable features. The features are extracted using the feature extraction algorithms. These features are stored as feature vectors in the training process. The test phase is similar up to feature extraction, then these features are compared with stored features with the help of a matching algorithm or by using a classifier. The estimated match with the test image is the output of the identification system.

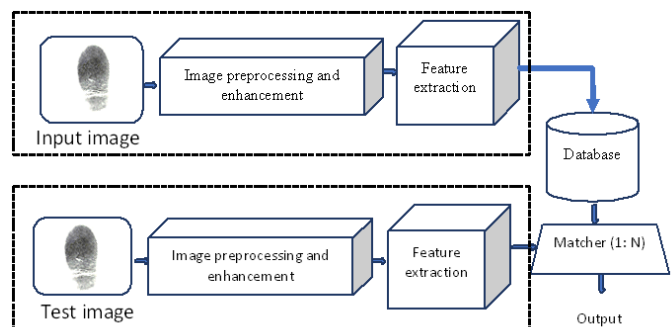

Fig. 1. Basic block diagram of image identification

## A. Literature Review

Automatic recognition of children using fingerprints was first studied by Jain et al. [11] in 2014 to increase the coverage of vaccination for the age group of 0 to 4 years. They used the up-sampling process by a factor of 1.8 to match the finger ridge distance to adults. Camacho et al. [12] also proposed a solution of up-sampling the fingerprint by an interpolation

factor based on children's ridge distance. Preciozzi et al. [13] formulated a scale factor based on distance between the ridges of adults to the distance between ridges of an age of child. By using these scale factors, the verification accuracy of children's fingerprints increases. Haraksim et al. [14] computed fingerprint minutiae-based growth model to reduce the biometric aging result on children recognition

Further, the hardware implementation of the fingerprint systems is also done to verify the accuracy of the fingerprints recognition. Koda et al. [15], designed the high resolution (1270 ppi) fingerprint scanner for scanning the minute details of children's fingerprints. Kalisky et al. [16] also designed high resolution platen free optical scanner. Engelsma et al. [17] studied the infants of 0 to 3 months to reduce the mortality of infants. They used a 1900 ppi scanner to capture the details of the infant's fingerprint. Improvement in the accuracy is observed by increasing resolution of the scanner. Macharia et al. [18] showed the Android based system for recognition of children and discussed the fingerprint quality of children. Engelsma et al. [19] further studied the problem of recognition of children for vaccination and nutritional supply with the 1900 ppi RaspiReader designed by him.

Most of the researchers used Commercial Software Defined Kits (SDK) for the recognition of children [20,21]. Jain et al. [22] continued his research in children recognition and this time collected the longitudinal database of infants. CNN is used for improving the quality of images. Feature extraction and matching is done with Commercial SDK. The longitudinal study is continued by Jain et al [23] for children verification. They used an Automatic fingerprint recognition system for feature extraction and matching. Engelsma et al. [19] extracted features using a texture based Convolutional Neural Network (CNN) matcher with two Commercial off the shelf matchers (COTS). Patil et al. [24] designed a fingerprint recognition system for infants and toddlers by extracting the finger codes by Gabor filtering and matching them using Euclidean distance. Moolla et al [25] investigated for the best modality for infants' recognition among fingerprint, iris and ear. The Research done in children fingerprint recognition is very less. The publicly available databases of children's fingerprints are also less. It is observed that feature extraction and matching of children's fingerprints is majorly done using commercial recognition systems. In latest research CNN and COTS systems are studied and are combined to achieve high accuracy. Transform based features are rarely studied for the biometrics of children. Fingerprint image is rich in frequency domain features therefore transform domain features should be derived.

In this paper, we are proposing a hybrid model of children fingerprint recognition by combining identification scores of DCT features with GNB classifier and CNN. As seen from Fig. 1 fingerprints of children are tiny as compared to adult fingerprints. Finding Minutia from such images is a difficult task. Finding the frequency domain features will integrate minutia and other texture features. The structure of fingerprints of two different people are shown in Fig. 2. The frequency related to each area is shown in it. The most dissimilar portion needs to separate out from the fingerprint

image. This portion is the mid to high frequency core area of the fingerprint.

Fig. 2. Frequency distribution in fingerprint image.

The DCT has strong ability to remove correlation between the pixels like KL transform [26]. DCT allows selection of the bands directly in the frequency. Hence, we are proposing a hybrid model in which scores of classifiers GNB and CNN on the feature extracted using DCT and texture features of CNN are combined.

The contributions of research are:

- Studied transform and texture features of fingerprints for recognition of children.
- Combined Transform domain features with Machine Learning approach.
- Score level fusion of traditional method and deep learning method.
- Identification of children for this age group is studied for the first time in the literature.

The sections of the paper include Introduction, which elaborate the basic blocks and need of fingerprint recognition of children; methodology, which gives an overall idea of methods used in the proposed algorithm. Experimental Results gives information about the database used and results of different approaches. Finally, the conclusion and future scope gives insight on findings of the experimentation and future direction of study.

## II. METHODOLOGY

In this hybrid method, transform domain approaches combined with machine learning are presented and it gives promising results. The different approaches of experimentations are carried as follows:

a) DCT, Curve DCT feature extraction (Standard Deviation) and Canberra distance for feature matching is used.

b) DCT, Curve DCT used to calculate standard deviation and these features are classified using machine learning classifiers.

c) Transfer learning AlexNet model [27] used to compare with the transform domain approach.

d) The Score level fusion of Transform domain approach and Transfer learning approach is done using Max Rule, Sum Rule and Product Rule. The workflow of the research is elaborated in Fig. 3.

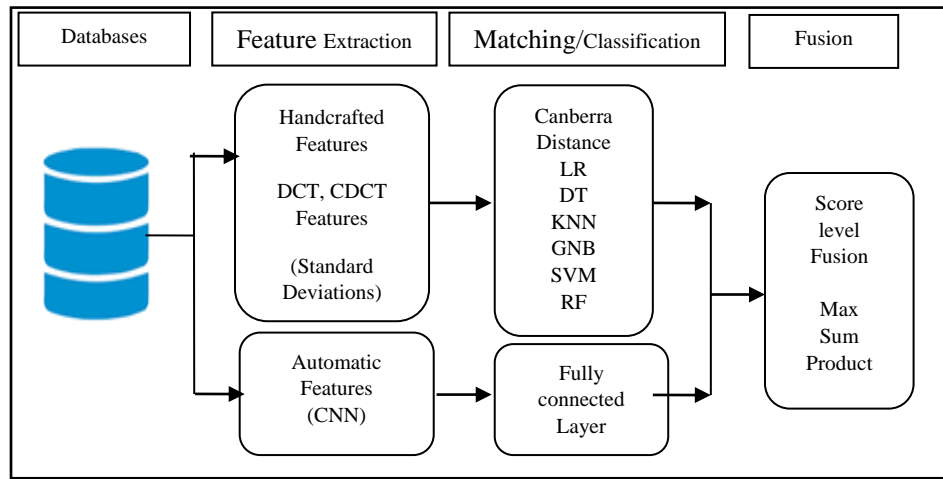

Fig. 3. Work flow of the research

A. Image Enhancement and ROI Extraction

Children's fingerprints are difficult to capture and captured fingerprints are not clear. It cannot be used directly for any algorithm. Fingerprint pre-processing and enhancement plays a crucial role in the recognition process. The most dissimilar portion shown in Fig. 2 needs to separate out from the fingerprint image. This portion is the high frequency core area of the fingerprint. To separate out the high (discriminative) frequency portion, the enhancement [28] and ROI extraction [29] steps are elaborated below.

1) *Image normalisation and segmentation*: First an input fingerprint image is normalized using mean  $M0 = 100$  and variance  $VAR0 = 100$ . The fingerprint is normalised with the help equation 1. After normalising the image segmentation is done. The standard deviation is calculated of the segmented region.

The Normalized image is defined as:

$$G(l, m) = \begin{cases} M0 + \sqrt{\frac{VAR0(I(l,m)-M)^2}{VAR}}, & \text{if } I(l, m) > M \\ M0 - \sqrt{\frac{VAR0(I(l,m)-M)^2}{VAR}}, & \text{otherwise,} \end{cases} \quad (1)$$

Where,  $I(l, m)$  are gray level values at pixel  $(l, m)$ ,  $M$  and  $VAR$  are estimated mean and variance of  $I$ ,  $G(l, m)$  is normalized Gray-level value at pixel  $(l, m)$ ,  $M0$  and  $VAR0$  are the desired mean and variance values.

2) *Local orientation estimation*: The normalized fingerprint image is used for the orientation estimation. The local ridge orientation at  $(l,m)$  is computed using eq. (2). The local ridge orientation is given in eq. (2).

$$O(l, m) = \frac{1}{2} \tan \frac{\phi'_y(l,m)}{\phi'_x(l,m)} \quad (2)$$

Where,  $\phi'_x, \phi'_y$  is image vector for lowpass filtering  $\theta(l, m)$  is the least square estimate of the local ridge orientation at the block centred at pixel  $(l, m)$ .

3) *Local frequency estimation*: The local frequency is estimated using normalized and estimated orientation image. It is given in eq. (3).

$$F(l, m) = \sum_{u=-\frac{w_l}{2}}^{\frac{w_l}{2}} \sum_{v=-\frac{w_l}{2}}^{\frac{w_l}{2}} W_l(u, v) \Omega'(1-uw), (m-vw) \quad (3)$$

Where,  $w_l$  is a two-dimensional low pass filter with unit length.  $w_l = 7$  is the size of the filter.  $\Omega'$  = interpolated frequency

4) *Mask estimation*: Normalized image is pixelwise divided into recoverable or an unrecoverable part depending upon local ridges and valleys. The three characteristics for each part are calculated, which are differences between the mean value of peak and mean value of valley. Second is the mean number of pixels between two peaks and third is the variance of the local part. These characteristics are used to classify the image in recoverable or an unrecoverable part.

5) *Filtering*: A bank of Gabor filters used as bandpass filters to remove the noise. These filters are tuned with orientation and frequency of local parts. The final enhanced image is obtained using eq. (4).

$$E(i, j) = \begin{cases} 255, & \text{if } R(i, j) = 0 \\ \sum_{u=-\frac{w_g}{2}}^{\frac{w_g}{2}} \sum_{v=-\frac{w_g}{2}}^{\frac{w_g}{2}} h(u, v : O(i, j), F(i, j)) G(i-u)(j-v), & \text{otherwise} \end{cases} \quad (4)$$

Where,  $G$  = normalized fingerprint images,  $O$  = orientation image,  $F$  = frequency image,  $R$  = recoverable mask, where  $w_g = 11$  gives the size of the Gabor filters.

6) *ROI extraction*: In the enhanced image the core point is detected using slope technique as described in paper [take from email of madam]. The original image, enhanced image and ROI extracted image is shown in Fig. 4.

Fig. 4. (a) Original image, (b) Enhanced image, (c) ROI of enhanced image.

### B. Feature Extraction

Fingerprint texture consists of repetitive patterns of pixel intensities and it is unique to every person. To extract the texture features (standard deviations) from fingerprint images DCT, CurvedDCT are applied to the ROI of fingerprint images.

1) *DCT*: DCT is one of the most used transforms for image compression, feature extraction and recognition. The important properties of DCT are decorrelation, energy compaction and fast implementation. These properties are explored for the fingerprint feature extraction. The 2D- DCT of an image  $f(x, y)$  is given in eq. (5). The size of the image is  $M \times N$ . Variations of  $MN$  are  $U = 0$  to  $M-1$   $V = 0$  to  $N-1$ .

$$T(u, v) = \frac{1}{\sqrt{MN}} \sum_{x=0}^{M-1} \sum_{y=0}^{N-1} f(x, y) \cos\left(\frac{(2x+1)u\pi}{2M}\right) \cos\left(\frac{(2y+1)v\pi}{2N}\right) \quad (5)$$

The ROI is divided into four non-overlapping parts as shown in Fig. 5. The DCT is applied to each part, from each part 9 standard deviations are derived by grouping different frequency coefficients as shown in Fig. 6. Here low frequency coefficients are omitted as fingerprint image is mid and high frequency texture image as shown in Fig. 2. Total 36 features are extracted from four parts of the finger. Training is done with 4 images and average standard deviation is stored as a feature vector. Partitioning of the image gives better energy compaction and decorrelation. The mean and standard deviation is calculated from the eq. (6) and (7).

Fig. 5. (a) ROI (b) ROI is divided in four parts

The mean ( $m$ ) and standard deviation ( $sd$ ) is calculated from the eq. (6) and (7).

$$(m) = \frac{1}{N^2} \sum_{i,j=1}^N p(i, j) \quad (6)$$

$$(sd) = \sqrt{\frac{1}{N^2} \sum_{i,j=1}^N [p(i, j) - m]^2} \quad (7)$$

Thus, the total features are  $36 \times 500 = 18000$  derived from the DCT standard deviation of the images from the database.

Fig. 6. DCT blocks of fingerprint image

Fig. 7. Curvature bands of coefficients

### 2) Curve-DCT (CDCT)

First fingerprint image is divided as shown in Fig. 5, into four parts. For every part, 2D-DCT transform is applied and coefficients are grouped in 9 bands in a curvature manner as shown in Fig. 7. Looking at the distribution from top left corner to right bottom corner of the coefficients and their grouping, curvature form is more appropriate. For every band standard deviation is calculated. Total 36 features from four parts are stored as a training dataset.

### C. Evaluation Parameters

Evaluation of the experiments is done with class-wise identification accuracy. It is shown in eq. (8).

$$\text{Class-wise identification accuracy} = \frac{tp_i + tn_i}{tp_i + fn_i + fp_i + tn_i} \quad (8)$$

The  $tp_i$  is  $i^{\text{th}}$  true positive,  $tn_i$  is  $i^{\text{th}}$  true negative,  $fn_i$  is  $i^{\text{th}}$  false negative,  $fp_i$  is  $i^{\text{th}}$  false positive where  $i$  ranges from 1 to 100.

The CMC curves are used to show the Rank wise accuracy of the fusion models. Rank 1 accuracy is the accuracy achieved when the outcome is the same as ground truth at the first match by model. It can also be called as top 1 accuracy.

### III. EXPERIMENTAL RESULTS

#### A. Children Fingerprint Database

There are several fingerprint databases such as MSU-ITF, VaxTrac, CMBD [30] and NITG [24,31] of the children's fingerprints. Most of the databases are not available due to security reasons except Children's Multimodal Biometric Database (CMBD) of IIT Delhi and National Institute of Technology, Goa (NITG) database for research purposes. In this work CMBD and NITG databases are used. Total 1000 images of the left thumb from both the databases and 100 subjects from each database are used for experimentation. Both the databases used Slap fingerprint scanner with 500 ppi resolution. Some sample images of these databases are shown in Fig. 8.

Fig. 8. (a) Right thumb, (b) left thumb of CMBD [30] and (c) Right thumb (d) left thumb of NITG database [24,31]

The performance of DCT domain features is checked for children's fingerprints. The DCT is applied on cropped fingerprint images and standard deviation is calculated for a group of DCT coefficients. In the first experiment, after grouping of coefficients is done in two ways as explained in section 2.2.1 and 2.2.2. The recognition rate in identification mode is calculated using Canberra distance. This distance is normalized as seen from the eq. (8), and it is giving better accuracy than Euclidean distance. The Canberra distance between vectors a and b is in the eq. (9).

$$d(a, b) = \sum_{i=1}^n \frac{|a_i - b_i|}{|a_i + b_i|} \quad (9)$$

The recognition rate obtained is shown in Table I. The maximum recognition rate (RR) is obtained with DCT features and using a simple distance classifier for 100 subjects is 63 % for the train test split of 80-20.

TABLE I. RECOGNITION RATE (RR) WITH DCT, CDCT FEATURES AND CANBERRA DISTANCE FOR CLASSIFICATION ON CMBD AND NITG DATABASES

Features	RR for CMBD	RR for NITG
DCT	42	63
CDCT	29	37

This recognition rate (RR) is less and to improve upon it, the same feature set is given to machine learning classifiers in the next experiment. Machine learning (ML) Supervised learning classifiers are used for classification of labeled databases of children's fingerprints. These classifiers learn on their own classification of objects/images depending upon the data/features presented at the input. As machine learning are data driven models, it analyses input features, learns from it and gives the classification [32]. Choosing the best ML classifier for an application depends on the data set available, the number of features derived, data is labelled or not, variance of features etc. In this experiment the same DCT and CDCT features are given to the different classifiers such as Logistic Regression (LR), Decision Tree (DT), K- Nearest Neighbour (KNN), Gaussian Naïve Bayes (GNB), Support Vector Machine (SVM) and Random Forest (RF). In image classification not only the features of the images but also the classification algorithms play a crucial role. The recognition rate after applying the different classifiers to the DCT, CDCT feature set is shown in Table II. As seen from the table, results obtained with CDCT features and GNB classifiers show significant improvement as compared to the first experiment. Gaussian Naïve Bayes is a Generative classifier. It requires a smaller number of parameters for classification. This classifier is probability based, where conditional and prior probabilities are calculated using Maximum Likelihood Estimation [33].

In the third experiment, the Neural Network approach is tested. As the database is small, a pre-trained AlexNet model is used for classification. Here the ROI of fingerprint image is resized to 200 X 200. Total images are split in 80-20 for training and testing. The Optimizer used is Stochastic Gradient Descent and the loss function is Sparse Categorical Cross Entropy. The recognition accuracy of AlexNet is shown in Table III for both the databases. The results obtained for CMBD database with both approaches are comparable but for NITG database DCT features and machine learning approach gives better results. Model accuracy and model loss of AlexNet approach on both the databases is shown in Fig. 9 and 10.

TABLE II. DCT AND CDCT FEATURES (STANDARD DEVIATION) EXTRACTION AND MACHINE LEARNING CLASSIFIERS ON CMBD AND NITG DATABASES

Recognition rate of CMBD database on ML classifiers						
Feature Extractor	LR	DT	KNN	GNB	SVM	RF
DCT	34.1	68.8	27.5	83.3	11.6	47
CDCT	29	71	19	92	10	44
Recognition rate of NITG database on ML classifiers						
Feature Extractor	LR	DT	KNN	GNB	SVM	RF
DCT	52.8	66.4	36.4	81.6	33.6	61
CDCT	36	66	25	96	22	45

TABLE III. COMPARISON OF PROPOSED METHOD WITH ALEXNET

Methods	NITG (100)		CMBD (100)	
	Model Accuracy	Model Loss	Model Accuracy	Model Loss
AleNet	88 %	0.5350	92 %	0.3975

Fig. 9. AlexNet validation (a) accuracy and (b) loss on NITG database

Fig. 10. AlexNet validation (a) accuracy and (b) loss on CMB database

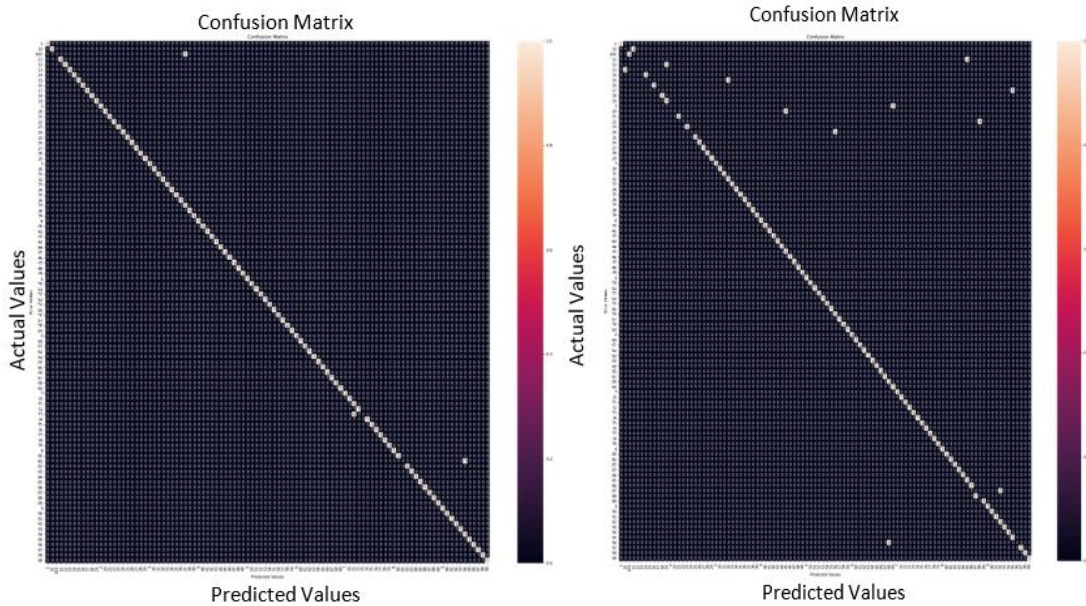

Fig. 11. Confusion matrix of AlexNet model on (a) NITG and (b) CMBD database

TABLE IV. SCORE LEVEL FUSION RESULT

Score Level Fusion	NITG		CMBD	
	Rank 1	Rank 10	Rank 1	Rank 10
Max Fusion	99	100	99	100
Sum Fusion	74.5	99	50	90
Product Fusion	56	98	43	67

The confusion matrix for both the databases is presented in the Fig. 11. In which the actual class versus predicted class is plotted. It is observed that more subjects from CMBD database are falsely classified than the NITG database as model accuracy is more for this database.

To improve the accuracy further, the hybrid mode is built by combining the scores of DCT with machine learning and AlexNet model. The Score level fusion [34] of CDCT features and Machine learning classifier with class wise identification score of AlexNet model is done. The rank1 and rank 10 accuracy for both the databases is shown in Table IV. As it is class wise identification score, max fusion is giving good accuracy because there are very few cases where both the algorithms falsely predict the same class.

The identification accuracy obtained with the proposed method is compared with the literature in Table V, Improvement in the accuracy is observed with the use of score level fusion.

TABLE V. COMPARISON OF PROPOSED METHOD WITH LITERATURE

Paper	Methods	Age	Identification Accuracy
A.K. Jain [15]	CNN, COTS	0-12 months	≤ 4 weeks 38.44 %
			> 4 weeks 73.98 %
Proposed	DCT, GNB and CNN	0 – 5 years	99 %

#### IV. CONCLUSION AND FUTURE SCOPE

This paper proposed a hybrid method of children fingerprint identification which is based on transform domain DCT and convolution feature extraction for local and global features of fingerprint images. DCT’s standard deviation features with machine learning classifier Gaussian Naïve base gives comparable accuracy as that of CNN model accuracy. We can deploy simple model based on DCT and GNB for children's fingerprint recognition, where we have fewer databases instead of the heavy CNN model. In this way, computational complexity and the need for higher version hardware is reduced. However, for higher accuracy over the period we require deep neural network models only. Here the score level combination of both algorithms is the most appropriate generalized solution for a robust model of children fingerprint identification, that is 1:N comparison is studied and implemented for children fingerprints (unimodal). The frequency domain features using DCT and CDCT, which gives compact representation of fingerprint texture image, is presented first time in this paper. The rank-1 identification accuracy achieved is 99 % using Max fusion which is higher than the literature.

The future work for this research is considering the feature level fusion. The accuracy of the children recognition can improve by using multimodal fusion with multiple modalities or multiple algorithms.

**Abstract**—Machine learning has advanced rapidly in the last decade, promising to significantly change and improve the function of big data analysis in a variety of fields. When compared to traditional methods, machine learning provides significant advantages in complex problem solving, computing performance, uncertainty propagation and handling, and decision support. In this paper, we present a novel end-to-end strategy for improving the overall accuracy of earthquake detection by simultaneously improving each step of the detection pipeline. In addition, we propose a Conv2D convolutional neural network (CNN) architecture for processing seismic waveforms collected across a geophysical system. The proposed Conv2D method for earthquake detection was compared to various machine-learning approaches and state-of-the-art methods. All of the methods used were trained and tested on real data collected in Kazakhstan over the last 97 years, from 1906 to 2022. The proposed model outperformed the other models with accuracy, precision, recall, and f-score scores of 63%, 82.4%, 62.7%, and 83%, respectively. Based on the results, it is possible to conclude that the proposed Conv2D model is useful for predicting real-world earthquakes in seismic zones.

**Keywords**—Earthquake; prediction; deep learning; machine learning; classification

## I. INTRODUCTION

Over the last decade, the number and magnitude of induced earthquakes have increased dramatically, and several technological innovations [1] for effective disaster management have been developed. Nonetheless, much work remains to be done to mitigate the impact and harm caused by uncontrollable natural disasters. The proposed study is an important step toward effectively implementing modern technologies for accurate disaster detection, which remains a critical and major goal for successful emergency management.

Every year, a large number of seismic events occur around the world as a result of the release of cumulative pressure in the Earth's mantle. Catastrophic earthquakes in hilly areas may have caused several collapses on high mountainsides [2]. These and other seismic events may cause environmental issues, critical infrastructure problems, and housing developments, ultimately resulting in tragic economic losses and human casualties. Furthermore, earthquake-caused landslides dam river systems, forming lakes that may be threatened by debris flows and outburst floods that endanger people and property downstream [3, 4]. Characterizing and forecasting the geographical distribution of seismic activity landslides is recommended for disaster mitigation [5].

Determining the geographic patterns of earthquakes is difficult because the main determinants of earthquake occurrences are their parameters, landscape, soil characteristics, tectonic plates, and human impacts [6]. As a result, it may be difficult to predict where landslides will occur after an earthquake [7]. Over the last 20 years, many prediction models have been developed to pinpoint locations vulnerable to landslides caused by earthquakes, and they can be divided into two categories: (1) models with a physical and numerical foundation [8]; and (2) models for determining susceptibility [9].

The physically based models were developed using the mechanisms of gradient commencement and runoff. The first of these methods, pseudo-static analysis, proposed that the earthquake force represents an additional permanent physical force to statically conservation equations [10]. Despite the fact that selecting a pseudo-static coefficient requires criterion and always yields conservative results, pseudo-static modelling is theoretically simple [11]. Following that, the stress-deformation assessment method was proposed as an extension of finite-element simulation that is capable of simulating slope dynamic deformation.

This method, which is based on mathematical calculations and has the potential to resolve physical issues such as complicated geometries, material properties, and boundary conditions, is appropriate for investigating the stability of artificial slopes [12]. Permanent-displacement examination was proposed shortly after its deployment to calculate the displacements of landslides caused by seismic activity. Its sophistication is somewhere between the two methods discussed above. Landslides are modelled as rigid-plastic bodies sliding on an inclined plane in this analysis. The Newmark model and its variants are the most commonly used models in permanent-displacement analysis [13].

Over the last few years, advances in EQIL mechanism analysis have greatly improved the accuracy of physically based models. Because of the enormous number of parameter values required, physical-based models can only be used in a limited number of locations [11].

Later, scientists began looking into vulnerable assessment methods that could reflect a possible link between earthquake detection and causal factors for identifying earthquake-prone areas [14]. Landslide susceptibility modelling has grown in popularity over the last decade due to rapid advances in technology, geographic information systems (GIS), and data analysis [15]. These models are divided into two categories:

knowledge-driven approaches based on expert knowledge data and data-driven models based on historical landslide inventories and associated spatial landslide causative data [16].

The knowledge-based models, which use expert knowledge to explain the link between the incidence of landslides and causal causes in terms of quantity [17], believe the analytic hierarchy process to be the most representative. Numerous statistical and machine learning techniques have been developed to predict the likelihood of a landslide using data-driven models. These approaches primarily include multivariate logistic regression and artificial neural networks (ANN) [18]. According to the results, data-driven models outperform knowledge-driven models in susceptibility mapping. Data-driven models can predict earthquake dispersion patterns, which the human eye cannot [19].

The majority of the data-driven models discussed above, which are classified as classic machine-learning techniques [20-21], can represent a single layer of linear or nonlinear relationships between causal variables and the incidence of landslides. As a result, when dealing with complex data, such models are prone to overfitting or becoming trapped on a local optimum [22]. However, due to an earthquake inventory constraint that always captures an earthquake as points or polygons, these landslide prediction models rarely take the distinction between landslide source and accumulation into account.

In the last ten years, numerous deep learning algorithms have produced impressive results in computer vision, speech recognition, and intelligent robot control. Geohazard experts have gradually become aware of these algorithms' ability to exploit the potential of multiple relationships in massive data [23]. As a result, deep neural networks (DNNs), convolutional neural networks (CNNs), and their derivative models have been successfully used for landslide recognition and forecasting [24].

In seismic event prediction, there are some research gaps. The first issue in earthquake forecasting is a lack of data. Second, despite extensive research in the field of earthquake forecasting, forecasting accuracy remains low.

Third, the majority of studies employ machine learning and traditional methods that are highly dependent on the type of dataset and cannot be extrapolated to other earthquake cases.

In our research, we use the following contributions to solve these types of problems. First, we present a dataset of earthquake cases spanning the years 1906 to 2022. Second, for earthquake forecasting, we propose a Conv2D CNN model. We leave the groundwork for future research by highlighting various important parameters for training deep learning models.

Reminder of this paper is as following: Section II presents related works in the extraction and categorization of features from seismic events. Section III discusses the imagery capture procedure and demonstrates the proposed method. Section IV summarizes the findings as well as the testing and discussions surrounding the proposed approach. Section V contains a conclusion and suggestions for future research.

## II. RELATED WORKS

### A. Machine Learning in Earthquake Forecasting

Artificial intelligence techniques have been widely used to predict earthquakes [25-26]. One study [27] looked at how previous seismic occurrences in long short-term memory could be used to predict earthquake penetration rates.

Several indicators were used to determine whether seismic activity would occur within the next five minutes, including magnitude, depth, time, place, statistics, and entropy factors. Based on a spatial analysis of magnitude dispersion, an automated clustering-based adaptive neuro-fuzzy inference system for earthquake prediction was proposed [28]. However, these techniques struggle to condense useful guidelines for EQP activities [29]. As solutions to the earthquake prediction problem, several superficial machine learning experiments, such as [29-32], have been proposed. Shi et al. [33] were the first to use an artificial neural network in earthquake prediction, and they also discovered a correlation between earthquake magnitude and epicentral severity.

Subsequently, a support vector regressive and hybrid neural network was created to predict earthquakes [34]. The important indicators in this study were extracted using the criterion of greatest relevance and least redundancy. Eventually, earthquake predictions were made using traditional machine learning methods [35]. Another study [36] used a principal component analysis-based random forest to generate new datasets and reduce data dimension in order to generalize preexisting prediction models. The results show that these generalized techniques outperformed current methods in terms of average accuracy. Nonetheless, variations in geological features limit their applicability.

### B. Deep Learning in Earthquake Forecasting

Deep learning techniques are capable of calculating hundreds of complex indicators on their own. As a result, recurrent neural networks (RNNs) and convolutional neural networks (CNNs) have piqued the interest of many earthquake prediction researchers (CNNs). For example, [37] developed static-stress-based criteria for forecasting aftershock locations without assuming fault direction. It also provided a more accurate method of predicting aftershock locations and pinpointing the physical factors that governed earthquake triggering while the earthquake cycle was still active. Due to the dynamic and unpredictable nature of earthquakes, [38] developed long short-term memory to investigate the spatiotemporal association between earthquakes at various sites.

They were also able to demonstrate the dependability and efficiency of their approach. However, it is difficult for DL-based EQP techniques to produce predictions based on historical data because they require a large amount of training data to ensure accuracy [25].

Several machine-learning techniques are used on historical earthquakes to predict impending tectonic events based on earthquake waveforms. These models are used in support vector machines, random forests, k-nearest neighbours, and artificial networks [39-40]. In this study, we focus on the most

powerful RNN methods for prediction on calm and seismic days, such as LSTM models. An artificial neural network was used in one study [35] to identify earthquake precursors using TEC data, while genetic algorithms were used in another study [41].

When using machine learning algorithms to identify earthquake precursors, the TEC data of the learning pattern is considered. A-TEC data irregularity may occur prior to the earthquake in certain machine learning-based situations. In Indonesia, particularly Sumatera, efforts have been made to identify earthquake precursors using machine learning methods based on N-Model Artificial Neural Networks [42]. According to the authors of [43], QuakeCast is a one-of-a-kind technique that uses global ionosphere TEC data to identify short-term earthquakes. Using a conventional logistic regression model and a deep learning ConvLSTM autoencoder, the proposed technique investigates whether signals in an ionosphere layer TEC dataset predict earthquakes.

Without explicitly modelling specific properties, deep learning was able to forecast earthquakes. As a result, more academics are turning their attention to deep learning techniques. The authors proposed a novel ground vibration monitoring strategy for MEMS-sensed data using a deep learning approach [44]. The following study created a network for magnitude estimation using convolutional and recurrent layers [45]. In subsequent research, ConvNetQuake was developed to identify nearby micro-earthquakes based on signal waveforms. They also show how ConvNetQuake works well with different types of seismic data. Lomax et al. used CNN to quickly describe the earthquake's location, magnitude, and other characteristics [46]. S. Mostafa Mousavi investigated CNN-RNN to predict earthquakes quickly by detecting weak signals [47].

Authors then estimated the likelihood of earthquakes on the Indian subcontinent by looking at the CNN network [48]. The author in [49] investigated another CNN earthquake damage assessment model. J. A. Bayona provided two well-known seismic models to evaluate seismic dangers [50]. The experimental results indicate that certain implicit traits may be able to approach the earthquake forecasting problem from a different perspective. Although deep learning techniques can fully exploit the hidden information in earthquakes, they are not theoretically interpretable. Table I demonstrates comparison of different approaches for seismic events prediction.

TABLE I. COMPARISON OF APPROACHES FOR EARTHQUAKE MAGNITUDE PREDICTION

Reference	Applied method	Features	Dataset	Results
[33]	SVM	Magnitude	CAPCEA	69% accuracy
[34]	KMC algorithm	-	0.76	70% accuracy
[35]	HKMC, ANN	Magnitude	BMKG, USGS	Between 56% to 72% when $M \geq 6$
[36]	ACC algorithm	-	-	41.488 average distance
[37]	HKMC, ANN	-	BMKG, USGS	75% accuracy
[38]	RNN, RF, LP Boost	-	CES and USGS	79% accuracy

In this research, we want to characterize calm and earthquake days in the target station zone using total electron content (TEC) values from the ionosphere layer based on previous research in this area. The primary goal of this research is to predict faster earthquakes.

### III. DATA

It was necessary to collect data for the training sample in order to build a mathematical model. At the same time, keep in mind that the model should have constant access to new data segments in order to predict within and for a specific time period.

It is worth noting that data from the Institute of Seismology of the Republic of Kazakhstan were available during the hypothesis' development. However, because this data was only uploaded once and there was no integration with seismology institute endpoints, there was no guarantee that it could be supplied continuously. In this regard, it was decided to supplement it with additional data from the United States Geological Survey (USGS) database, which is accessible via API.

A combination of datasets from earthquake.usgs.gov and data from the Institute of Seismology of the Republic of Kazakhstan was used. Where there were columns such as place, time, magnitude, and depth. After some transformations, the dataset took the form of [year, region, rolling\_aggregations\_over\_the\_retro\_data (depth and magnitude), binary target (where 1 means there will be a devastating event, and 0 means there will not be a devastating event)].

There were 2629 events detected in the Kazakhstan area from 1906 till 2022. The final shape of the dataset after all aggregation transformations is 1170 observations and 352 parameters.

A combination of datasets from earthquake.usgs.gov and data from the Institute of Seismology of the Republic of Kazakhstan was used. Where there were columns for place, time, magnitude, and depth. After some transformations, the dataset looked like this: [year, region, rolling aggregations over the retro data (depth and magnitude), binary target (where 1 means there will be a devastating event, and 0 means there will not be a devastating event)].

From 1906 to 2022, 2629 events were detected in Kazakhstan. The dataset's final shape after all aggregation transformations is 1170 observations and 352 parameters.

The actual records span the years 1906 to 2022. There are approximately 2.5 thousand records of unique earthquake events for this period in Kazakhstan and its surroundings.

In terms of the general population, the majority of the events occurred outside of Kazakhstan (approx. 300 events). However, we believe that these events may have had an impact on Kazakhstani territory, even if they were recorded on the territory of neighboring countries in Fig. 1.

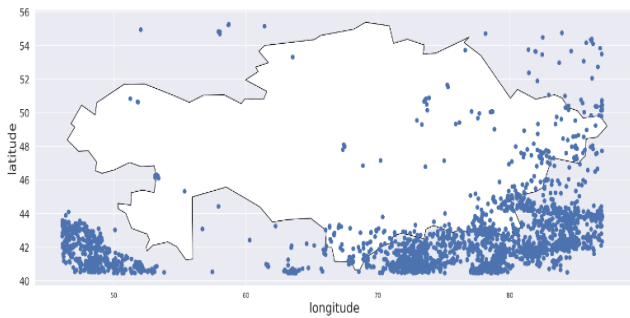

Fig. 1. Map with all events of earthquakes

Fig. 2 demonstrates distribution of earthquake cases in Kazakhstan and its neighbourhoods. Most of data are fixed after 1960. There is a peak between 1998 and 2005. Moreover, it highlights a gradual growth of earthquake cases for last 25 years, which is mainly caused by an increase of sensors and their accuracy.

Fig. 2. Distribution of earthquakes for observed time

In order to test the hypothesis, it is advisable to divide the map of Kazakhstan into segments to predict the probability of a target event. The following methods were proposed for the segmentation of objects in the context of which predictions will be made:

- 1) Lithospheric plates
- 2) Conditional grid that divides the map of Kazakhstan (polygons)
- 3) Administrative areas

In this approach, we will try to break the map of Kazakhstan into regions, and try to aggregate the indicators grouping by regions. Since most of the events took place outside of Kazakhstan, many coordinates could not be marked with an area. Out of 2.5 thousands, 300 events remained (~11%), which is insufficient for building high-quality analytics. Nevertheless, we managed to build a baseline from this amount of data.

It is proposed to assign shocks that occurred outside the Republic of Kazakhstan, though being close to a separate area, to mark the event with a nearby area. For a purpose of forming the target events and the training sample, the main groups are specified by Area and Year parameters, aggregating the following indicators:

- 1) Minimum values in the group by the "Magnitude" and the "Depth" parameters
- 2) The maximum value in the group by the "Magnitude" and the "Depth" parameters
- 3) Median value in the group by the "Magnitude" and the "Depth" parameters
- 4) The average value in the group by the "Magnitude" and the "Depth" parameters
- 5) Standard deviation in the group by the "Magnitude" and the "Depth" parameters
- 6) Number of events in a group

Afterwards, we filled empty standard deviation values with 0. It is important to note that the sample is inconsistent over the years, as there are gaps without events between years, or they possibly were not recorded. For this reason, the following years were not indicated in the sample: 1980, 1981, 1982, 1983, 1984, 1985, and 1986.

#### IV. MATERIALS AND METHODS

In this section, we show the materials and methods used in this study. In the first section, we show how a proposed system architecture and feature extraction problem work. The following section demonstrates the proposed earthquake forecasting model. The final section shows evaluation parameters for comparing the proposed model to other machine learning models for the given problem.

##### A. Proposed System Architecture

In this research, we aimed to forecast earthquake magnitude prediction using deep learning techniques. Fig. 3 demonstrates a flowchart of our research for the prediction of earthquakes. Firstly, we get earthquake waveforms data and clean the data. The data cleaning or preprocessing process consists of four parts data cleaning, data integration, data transformation, and data reduction or dimension reduction. After preprocessing we train a deep-learning model for earthquake prediction. The architecture of the proposed deep learning model for earthquake prediction is presented in Section 3.2. The next stage is the prediction and evaluation of the proposed deep learning model.

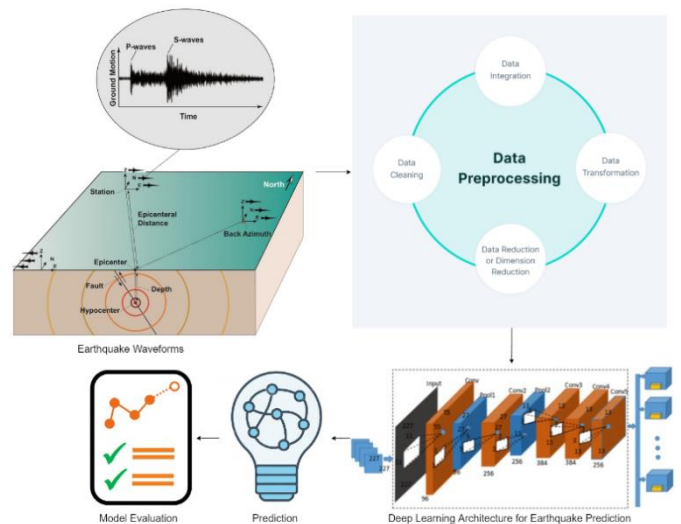

Fig. 3. Proposed architecture of earthquake forecasting

**B. Feature Extraction**

The timeline is one of the characteristics of earthquake prediction model training. Fig. 4 depicts a timeline for feature generation. Because we are at the start of the current year and have retro information about previous earthquake events (aggregated depth and magnitude parameters), our prediction is for the maximum magnitude during the year.

Fig. 4. Earthquake timeline as a feature

Fig. 5. Distribution of earthquakes for observed time

Fig. 5 depicts a relationship between depth and magnitude. While smaller earthquakes can and do occur at all depths down to around 700 km, the largest earthquakes occur at shallower depths in the earth's crust. Earthquakes occur in the crust, the earth's highest layer, which ranges in thickness from 7 to 30 km. The earth's crust, which contains numerous fault networks that can cause earthquakes, is the planet's coldest and most vulnerable region. These earthquakes are caused by frictional sliding on faults caused by tectonic stress accumulation.

**C. Proposed Model**

The proposed deep learning prediction architecture employs the Convolutional neural network strategy, as illustrated in Fig. 6. A Rectified Linear Unit (ReLU) activation function layer precedes the Maxpooling2D layer with a filter size of (33) and is followed by a Conv2D layer with a size of (128) and a filter size of (33). The first epoch assigns the autoencoder model's received output to these layers. The second stage, like the first, employs a Conv2D layer with a size of (64). From the third to the eighth stage, only the Conv2D layer with a filter size of (33) and ReLU activation are operational.

The output of the eighth stage is flattened by the ninth stage. Following that, in stages 10 and 11, we use completely linked layers with 50 and 10 neurons, respectively. Two scenarios are also included in the proposed regression model. Initially, we use a single output neuron to estimate the magnitude. Second, we use three neurons to estimate both magnitude and position.

The important feature mappings, which are retrieved by each convolutional layer in the proposed CNN technique, are adapted as a matrix of pixels from an image. Each feature mapping is identified by equation (1):

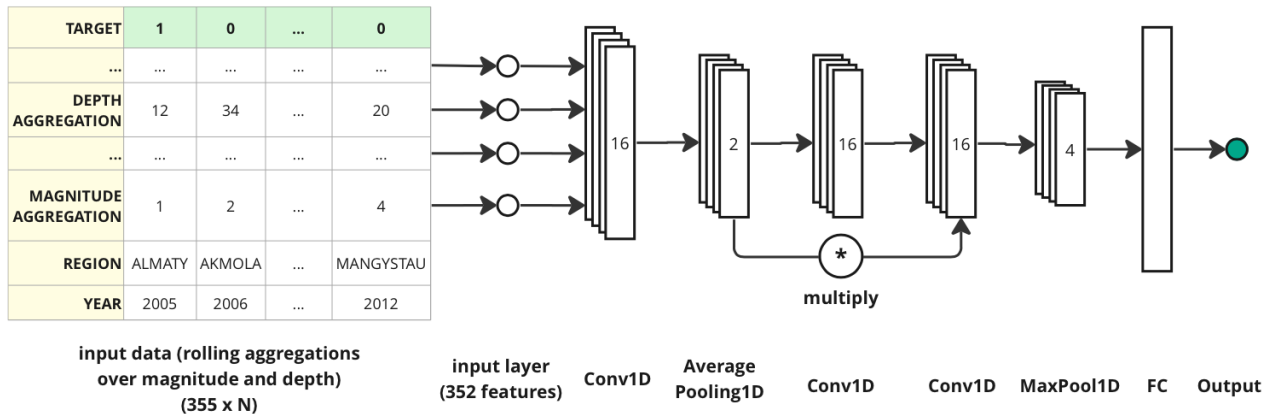

Fig. 6. Proposed Conv2D CNN architecture

$$\begin{aligned}
 FM[m, n] &= (g * k)[m, n] \\
 &= \sum_i^{\phi} \sum_j^{\psi} (X^{CNN}[m + i, n + j] * C[i, j]) \quad (1) \\
 \forall m, n \notin X^{CNN}, m \neq n,
 \end{aligned}$$

The critical feature mappings are extracted from an image as a matrix of pixels by each convolutional layer in the proposed Conv 2D convolutional neural network approach. Equation (2) identifies each feature mapping of the proposed approach.

$$f(m, n) = \max(0, FM(m, n)) \quad (2)$$

The Maxpooling layer, which is described by following formula is subsequently used to increase the number of feature maps, deepen the proposed neural network, and reduce the network dimension. Equation (3) describes maxpooling layer for the given deep learning model.

$$MP(m, n) = \max f(m + l, n + d) \quad (3)$$

where l and d are the Maxpooling window dimension.

#### D. Evaluation Method

The prediction outcomes are analyzed using the metrics of accuracy, precision, recall, and F1-score [43-46]. The accuracy indicator displays the rate of model prediction accuracy across all parameters. It is calculated as the proportion of correct predictions made by a model. This is especially useful when all of the courses have the same value. It is calculated by dividing the number of correct predictions by the total number of predictions made. This is the probability that the class will be adequately anticipated. The precision of the formula is shown in Equation (4).

$$Accuracy(a) = \frac{\sum_{i=1}^N [a(x_i) = y_i]}{N} \quad (4)$$

$$= \frac{TP + TN}{TP + TN + FP + FN}$$

Here, TP is true positives, TN is true negatives, FP is false positives, FN is false negatives. Sum of all this cases gives a number of all cases.

Precision offers a reliable picture of the veracity of our positive detections in comparison to the unchanging truth. How many of the objects we predicted in a given image matched the ground truth annotation? Formula (5) describes precision [47].

$$precision = \frac{TP}{TP + FP} \quad (5)$$

When striving to accurately describe the extent to which our pessimistic expectations match the reality, recall or sensitivity is a good statistic to utilize. Out of all the challenges in our ground truth, how many favorable forecasts did we get? [47]

$$recall = \frac{TP}{TP + FN} \quad (6)$$

The symbol F-measure stands for the harmonic mean of accuracy and completeness. This statistic decreases as accuracy or completeness approach zero. The formula for the F-measure evaluation parameter is shown in equation (7).

$$F_{measure} = \frac{2 Precision Recall}{Precision + Recall} \quad (7)$$

#### V. EXPERIMENT RESULTS

This section presents the experimental results of the proposed model for earthquake detection and compares them to

classical machine learning methods and state-of-the-art models. The confusion matrix for the given problem is shown in Fig. 4. The proposed deep model has a high prediction percentage, as evidenced by the results.

Fig. 7. Earthquake timeline as a feature

Fig. 7 depicts the results of earthquake forecasting. There, we show the results of three machine learning algorithms for earthquake detection after ten training epochs. As the results show, the light gradient boosting machine (lightgun) outperforms other machine learning methods in terms of accuracy and ROC-AUC. In each evaluation parameter, the neural network has the lowest efficiency. Random Forest performs well in some parameters such as ROC-OUC, recall.

Fig. 8. Precision and recall for 10 epochs

Table II compares various machine learning algorithms and the proposed deep learning model for earthquake forecasting problems. According to the test results, the proposed deep model outperforms traditional machine learning algorithms in every evaluation parameter. It means that the proposed deep model is practical (see Fig. 8).

TABLE II. COMPARISON OF APPROACHES FOR EARTHQUAKE MAGNITUDE PREDICTION

Algorithm	Accuracy	Precision	Recall	F-score	AUC-ROC	Threshold
Proposed Model	0.874	0.63	0.824	0.627	0.83	0.998
LightGBM	0.832	0.500	0.712	0.587	0.801	0.998
Random Forest	0.795	0.443	0.797	0.570	0.758	0.774
Neural Network	0.766	0.365	0.525	0.431	0.595	0.766
SVM	0.742	0.387	0.506	0.428	0.587	0.628
Decision Tree	0.512	0.536	0.483	0.417	0.561	0.637

Fig. 9. ROC curve for 10 epochs

The area under the curve receiver operating characteristics (AUC-ROC) curve for the proposed model for earthquake forecasting problems is depicted in Fig. 9 in terms of the combination of false positive rate and true positive rate for 10 training epochs. The AUC-ROC curve is greater than 0.5, indicating that the proposed deep model is practically acceptable and feasible in real life. The horizontal axis stands for false positive rates, the vertical axis means true positive rate. The results show that the proposed deep convolutional neural network demonstrates high AUC-ROC value by achieving higher value than the other applied models in ten epochs. Obtained results show that the proposed model can be applied for real case (see Fig. 10).

## VI. DISCUSSION AND FUTURE RESEARCH

As shown in the figures above, the results appear promising, though it is worth noting that the model is not stable due to a lack of training data. The hypothesis is that earthquake events occur in cycles, and that retro data based solely on magnitude and depth predictors can predict the future appearance of destructive earthquakes. Machine learning algorithms are clearly based solely on statistics, and they should not be regarded as magical black boxes. The model has no idea what an earthquake is. There is a hypothesis that goes something like this: "In order for computers to understand earthquake concepts, we should pass fundamental features that describe physical concepts of earthquake nature."

Many suggestions are aimed at improving the model. For example, a hypothesis is proposed to test with new features such as: The impact of lithospheric plate movements:

- The impact of natural disasters and macroeconomic indicators on climate change
- The impact of events in neighboring regions (Relative features)
- Mining's impact on deposits
- Formulas for physical sense.

Other suggestions include: Scaling down the grid - Making predictions in quarters and months rather than years.

- Create a project with a trigger so that local emergency services can respond.

## VII. CONCLUSION

The proposed approach demonstrates that the presented deep learning model outperforms approaches using traditional

Fig. 10. Ratio between impacts on model output (SHAP value) to feature value

machine learning methods and cutting-edge deep models that employ traditional features. The provided time series-based method has the potential to improve the accuracy of earthquake forecasting issues. The applied dataset of earthquakes for the years 1906 to 2022 with magnitudes between 4 and 7 increases by 8.5% using the proposed deep learning architecture with the provided features, indicating that the proposed approach is somewhat successful on datasets with a pretty large size. Recent studies have shown that massive data analytics and machine learning can improve earthquake prediction accuracy. The proposed deep learning model performed well in earthquake forecasting, with accuracy, precision, recall, f-score, and AUC-ROC of 87.4%, 63%, 82.4%, 62.7%, and 83%, respectively. Specifically, incorporating the proposed deep learning architecture provided spatial and temporal characteristics, allowing earthquakes to be predicted to some extent.

Department of Mechanical Engineering, Vivekananda Global University, Jaipur, Rajasthan, India<sup>5</sup>

**Abstract**—Weather alert applications can save precious lives in time-critical risk situations; however, even the most widely used applications may fall short in intuitive interface and content design, possibly due to limitations in the users participation in the design process and in the users range considered. The objective of this study was to investigate whether the application of UCD principles and usability guidelines can improve the use of and satisfaction of time-critical weather alert apps by the public and or expert users. A prototype of a UCD-based weather alert application was developed and evaluated. Initially, thirty-two voluntaries participated in the identification of the important features that lead to the development of the porotype, and then the prototype was tested with another eighty participants (40 young and 40 elderly). The prototype includes five enhancements: auto-suggested location search, an all-inclusive interface for weather forecasts, message alert, visual and intuitive map settings, and minimalism-oriented alert settings. The enhanced functionality was compared to similar functionality in existing commercial weather applications. Effectiveness (completion rate, error count, error severity, and error cause), efficiency (time to completion), and satisfaction (post-task and post-test surveys) were measured. The results showed the enhancements significantly improved performance and satisfaction across both age groups compared to equivalent functionality in the existing app. The Mann-Whitney U test showed a statistically significant difference ( $p < 0.001$ ) in task satisfaction and number of errors between the two apps for all tasks. The Mann-Whitney U test showed a significant difference ( $p < 0.001$ ) in the across all tasks between the two apps Also, overall, young people with existing apps outperformed elderly, and both young and elderly with enhanced apps performed very high. Therefore, the enhancements implemented through the UCD process and usability guidelines significantly improved performance and satisfaction across both age groups to facilitate timely action necessary during a crisis.

## I. INTRODUCTION

With the advancement of smartphone technology, countless people have started to receive weather information on the smartphone platform. Due to the requirement for immediate action weather apps are important and potentially life-saving tools in time-critical severe weather events such as flooding and tornadoes. Specifically, usability issues with a poorly designed weather app interface can disproportionately affect certain end-user groups, especially the elderly. Elder users often experience problems with age, such as decreased working

memory, and decreased visual, motor abilities, difficulties and cognitive [1-3]. In addition to physical and cognitive difficulties, elderly often struggle to cope with the rapid development of smartphone technology [4]; however, smartphone usage among older users continues to grow. As of 2017, nearly 74% of the U.S. population aged 50 to 64 and 42% of the population aged 65 and older owned a smartphone [5]. Numerous studies have focused on age differences in the use of smartphone apps in various fields, including information technology [6], healthcare [7], and communication [8]. However, to our knowledge, there are limited studies on usability testing of weather apps [9, 10], and no one has applied user-centered design (UCD) to include a wide range of users, especially elderly.

Drogalis et al. [10] identified usability issues with weather alert applications, such as the inclusion of hidden map menus that required prior counterintuitive actions and the lack of feedback on actions that were performed. Khamaj and Kang [9] investigate usability issues such as poor visualization of critical weather information, inappropriate language usage in time-critical alert messages, and inefficient location search functionality. However, neither of the two studies mentioned above addresses the question of how to effectively meet users' issues and needs. One possible way to address usability issues is to apply a user-centered design (UCD) approach, especially when it comes to end-users of different age groups. In detail, UCD refers to a cycle of design stages in which developers consider the needs, capabilities, and constraints of target users at each stage [11]. Norman [12] and Mao et al. [13] established a general UCD framework and applied to the human factors by Schnall et al. [14]. Careful consideration of each stage is believed to result in an interface that is easy to use and deemed useful [15]. The purpose of this study is to investigate whether the UCD approach could address usability issues for young and elderly when interacting with a smartphone weather alert application.

## II. METHOD

The specific contribution of this research is to (1) characterize and classify the issues and needs of users with a broad age range in the design of weather alert applications, and (2) relate these issues and needs to usability guidelines (or principles), (3) design a prototype based on these guidelines, and (4) evaluate the prototype by selecting a target group (i.e., young and elderly). The results could impact the entire design

process of a weather alert app (or other similar apps) that could save lives in a time-critical event.

Fig. 1 provides a summary of the framework used and applied by the afore-mentioned researchers. Following the framework provided in Fig. 1, the first stage of the UCD process is to describe the user's issues and needs when interacting with an existing application. Issues and requirements can be aligned with major usability guidelines, such as those presented by Nielsen [16] and Rogers et al. [17] and smartphone app design specifications, such as those presented by Gove [18]. At this stage, a broad range of users can be recruited to investigate various problems and needs that they can characterize and classified.

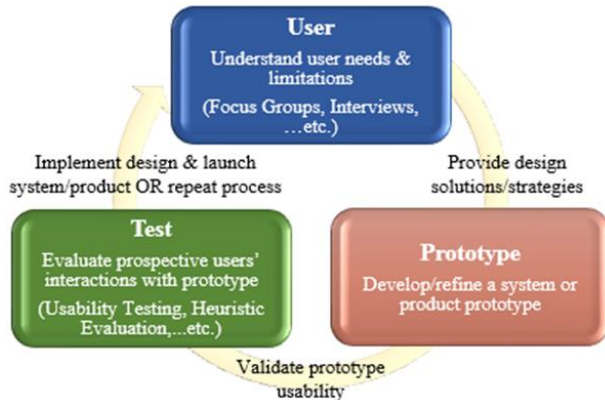

Fig. 1. Summary of the user-centered design framework (Jung et al. [15])

Specific to the weather app, questions and needs may relate to any of the features available on any typical weather app, such as location search, weather forecast, alert messages/notifications, alert settings, and radar/maps. The analyzed data can be characterized and classified using content analysis methods. One possible approach is thematic analysis [19]. This approach has been applied to critically evaluate and describe datasets, as well as to implicitly and explicitly identify provided ideas in form of codes refined as themes and sub-themes [20, 21].

The next stage is to develop a prototype based on the issues and needs of the target end users. For example, if a user asks about the inability to obtain weather forecasts effectively, especially in severe weather, and the need to easily map such forecasts with the locations they add; then these can be design and is implemented by adding location associations to the home screens, which can be accessed with a swipe whenever users open their weather app.

The final stage is to evaluate the developed prototype. In particular, we can consider the effectiveness of the prototype by targeting specific populations such as the older. In this case, we need to consider at least two factors: the type of application (i.e. existing vs. new prototypes) and the age group (i.e. young vs. older). Additionally, usability testing can be conducted using several qualitative and quantitative measures, such as completion rates, error counts, error severity ratings, error reasons, completion times, and satisfaction surveys.

### III. UCD PHASE 1: UNDERSTAND USER NEEDS AND LIMITATIONS

**Participants:** In this study, 32 participants were recruited voluntarily, were ( $32 \pm 6.4$ ) years (mean  $\pm$  SD), and ranged in age from 18 to 47 years. Participants were students at the University of Oklahoma and regular users of 11 popular smartphone weather apps running on different operating systems.

**Design:** The participants were guided by skilled moderators and assistant moderators. Several topics related to user perceptions and behaviors of smartphone weather application usability are discussed. These questions are intended to capture general information: (for example, trends in downloading specific weather apps, prioritization of weather apps in critical and non-critical time weather conditions, and positive and negative usability understandings of weather apps), and specific information: (for example, using different location search methods, controlling alert settings, content and display of critical alert messages, and using menu icons and labels).

**Apparatus:** A Nikon D3200 camera was used to record the sessions with the participants. A desktop computer, a projector device, and a large whiteboard surface were used to display the questions to the participants.

**Procedure:** Participants were held in a well maintained controlled environment at the University of Oklahoma. Participants signed a consent form upon arrival and then described the purpose of the study. After that, discussions begin, with each session lasting approximately 90 minutes.

**Data analysis:** Data was collected through video recording sessions. Afterwards, the collected data was transcribed, characterized and classified using qualitative thematic analysis [19]. Specifically, using thematic analysis methods, the data are: 1) transcribed verbatim, 2) encoded using representative words and phrases, and 3) re-fined into common themes.

#### A. Results of Phase 1

Participants presented three main themes: usage efficiency, user cognitive load, and effectiveness. These themes are primarily associated with common features on most popular weather apps (location search, weather forecast, alert messages, alert settings, and radar maps), as detailed below.

1) *Usage efficiency:* Participants were highly concerned with the time and number of steps required to access time-critical information, such as in a weather app. Participants shared several examples of inefficiencies in the design of the location search feature in popular weather apps. For example, in addition to conventional search methods (such as zip and/or city), the widely used weather app Weather Radio has recently adopted a precise location search feature (which enables users to search and save the specific locations) to provide users with accurate weather forecast. The application restricts users from searching for the different locations as required to navigate on the map and identify the desired location (see the example in Fig. 2(a)). Therefore, end users need an effective search method, since this feature needs a great degree of knowledge of the geographic area of the map, widespread visual attention,

and repeated zooming in/out inside the small smartphone screen. Another efficiency requirement has to do with weather forecasting (such as humidity and temperature) feature. Users indicated that a limited number of steps were required because they felt it was accessed more frequently than other features. Several current weather applications involve multiple steps on several screens to access weather forecasts (see examples in Fig. 3(a-d)).

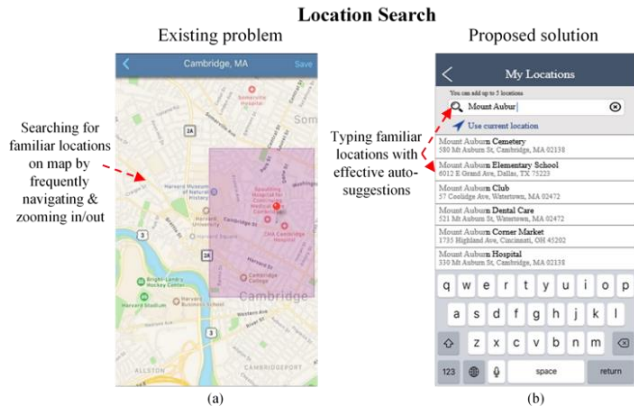

Fig. 2. Screenshot example of a user's main problem with the location search feature and proposed solution. (a) Screenshot of location search in the Weather Radio app, which has efficiency issues where users spend a lot of time navigating and zooming in/out on the map to find familiar locations. (b) Screenshot of a proposed efficiency solution in the UCD app, where the user simply types a familiar location and selects it from a list of auto-suggestions

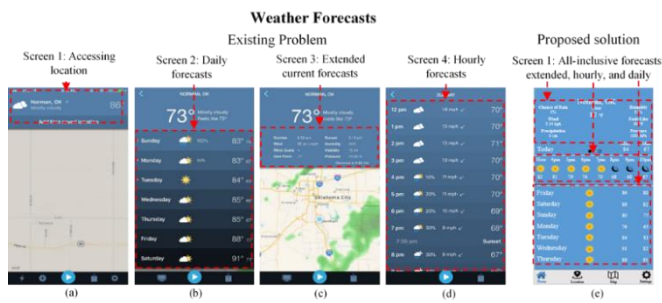

Fig. 3. Screenshot example of a user's main problem with the weather forecasts feature and proposed solution. Screens (a) to (d) are screenshots of weather forecasts in the Weather Radio app with efficiency issues: multi-screen/step forecasts, where the user must access each set of forecasts from a different screen. Screen (e) is a screenshot of the proposed efficiency solution in the UCD app, where users can access predictions for all locations within one screen immediately after opening the app

2) *User cognitive load*: Due to critical situations associated with extreme weather conditions, users also expressed a need for weather apps to simplify their cognitive processes and decision-making strategies. For example, users place high emphasis on the requirement for concise and structured push alert messages throughout severe weather conditions; alerts are created by the weather agency's systems and automatically directed to third parties, including weather apps, where they push them to the end user exactly as they are received. This is because alerts often contain technical data (such as geographic area codes) and cluttered data (see the

example in Fig. 4(a)), which can hinder users' understanding of the alert and rise their cognitive load. Additionally, alerts often contain a huge quantity of evidence; most of this is not related to user-saved locations (e.g. names and information for all alert areas). While retrieving information about distant or isolated locations is critical for some operators in certain usage contexts, such as when traveling, making them a major part of alerts can be detrimental to users. Users also need a radar map feature that is built-in to identify and understand. Participants shared several examples of few popular weather applications that lack intuitive and/or visible instructions on in what way to access maps of the respective saved localities or control their settings (see examples in Fig. 5(a, b)).

3) *Effectiveness*: Owing to the limited smartphones screen size and the critical information displayed, users demand optimized and flexible functionality. For example, in the alert settings feature, the weather app either lets users control of all types of weather alerts and sub-alerts (see example in Fig. 6(a, b)), or does not permit the control of any alerts, but automatically uses active warnings as alerts. For this reason, users have expressed concern about large numbers of weather warnings, most of which are rarely needed and / or insignificant for the average user. Additionally, notifications that push any active alerts without end-user control are considered mandatory interactions. Therefore, users have expressed the need for the ability to control only a few relevant alerts.

#### IV. UCD PHASE 2: DEVELOP PRODUCT PROTOTYPE

A prototype weather app was developed after understanding the specific concerns and needs of users and taking into account widely used smartphone design heuristics, age-related constraints and needs, and common usability guidelines. The prototype application was designed using the InVision application software (<https://www.invisionapp.com/company>) called "EZ Weather".

##### A. Design Proposal Overview

The proposed design solution for the weather app features has been implemented in the EZ Weather app. To address the location search problem, a similar approach to the Google Maps app could greatly improve the efficiency of this feature: enter a familiar location with effective auto-suggestions. With this feature, the user can add an exact location by typing the location name/address (e.g. hospital name/address) in the search bar of the application and selecting it from the auto-suggest list (see example in Fig 2(b)). To reduce the time and number of steps to access weather forecasts, it may be helpful to have all weather forecasts for each saved location in one screen: all-inclusive weather forecast in one screen (see example in Fig 3(e)). For alert messages, a method for filtering the content of the message can significantly reduce the cognitive load on the user by including only relevant and necessary information on the main alert screen that is relevant to the user's saved location; all other information can be accessed from the secondary menu, including distant under-alert area.

In addition, simple language and hierarchically structured information using everyday language can enhance user understanding of messages and responses to alert threats. See Fig. 4(b)), for an example, content that is structured, prioritized, and language simplified. In addition, to facilitate the user's identification and understanding of the radar map feature, it may be helpful to display the list of all saved locations; from which the user can visually select the desired location; then the map of the selected location and its settings are displayed: use the visible and intuitive Map menu (see example in Fig. 5 (c & d)).

To avoid an excessive number of alerts that the user needs to control and interact with, and to give the user the freedom to control the push alert notifications, it may be beneficial to include the most critical and common alerts (on/off) to control. In bad weather, users will receive alert notifications about the time-critical alerts they have turned on (e.g. tornado warnings). Alerts that are not time-critical, such as wind, are not spontaneously sent to the user as notifications; these alerts only appear after clicking the respective symbol on the affected location screen (Fig. 6 (c & d)).

Other key usability and smartphone application guidelines may also need to be considered to improve the overall user experience. These guidelines include labeling all icons with representative text labels, using short descriptive information next to menu options, providing appropriate feedback on user actions, and using appropriate colors with easily distinguishable contrast to visualize and indicate weather conditions (e.g. red screen for locations under a warning alert), provide shortcuts (for example, constant main icons across all screens), text in relatively large fonts, and use a consistent and intuitive layout.

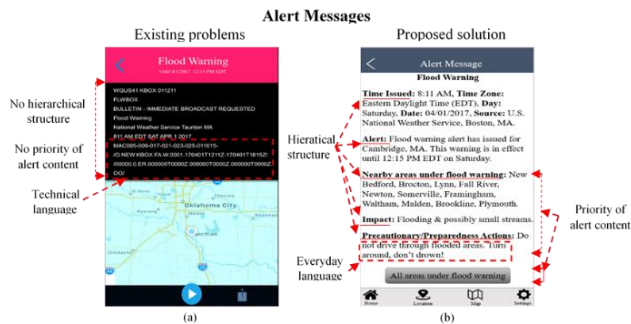

Fig. 4. Screenshot example of a user's main problem with an alert messages feature and proposed solution. Screen (a) is a screenshot of an alert message in the Weather Radio app, showing information about all alert-deficient areas within a scrollable area, uses code and technical language, and without hierarchical information. Screen (b) is a screenshot of the proposed solution in the UCD app, by prioritizing alert content (information about under-alert saved location and nearby areas on main screen and distant under-alert areas accessed from a secondary screen), using everyday language, and with structure hierarchical information

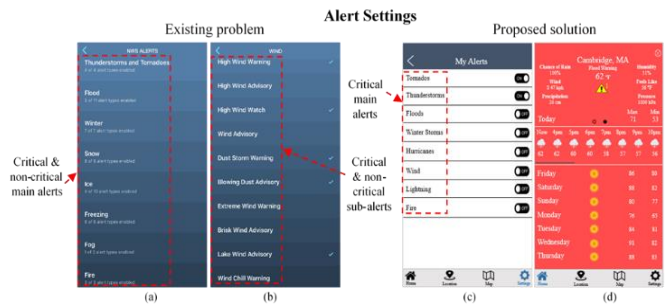

Fig. 6. Screenshot example of a user's main problem with alert settings feature and proposed solution. Screens (a) & (b) are screenshots of alert settings in the Weather Radio app, where users are required to scroll up/down and control the settings of all-weather types' main alerts and sub-alerts (e.g. wind alert has 16 sub-alerts), including critical and non-critical alerts. Screens (c) & (d) are screenshots of a proposed solution of minimalist alert settings in the UCD app, where users need to control the settings of only critical alerts as in (c); non-critical alerts' information can be directly accessed from screen of affected location (e.g. by tapping yellow alert icon as in (d))

## V. UCD PHASE 3: EVALUATE PROSPECTIVE USERS' INTERACTIONS WITH PROTOTYPE

### A. Method of Phase 3

Participants: In this study, eighty (40 young and 40 elder) regular users of the iOS smartphone weather app (first-time users of the tested app) were voluntarily recruited for the experiment. The younger and older participants were  $25.9 \pm 4.8$  years (mean  $\pm$  SD) and  $57.4 \pm 4.3$  years, respectively, and ranged in age from 18 to 35 years and 50 to 66 years, respectively. The participants were assigned randomly to perform tasks in two test apps (Weather Radio and EZ Weather). Both applications were used by 40 users (20 young and 20 elder). Recruitment was based on personal communications, mass emails from universities and flyers hanging on doors of various public buildings. Participants signed a consent form upon arrival and then described the purpose of the study. The experimental protocol was approved by the ethical committee of the department of Human Research Participant Protection (HRPP), University of Oklahoma, Norman campus with IRB: 6681/2021.

Apparatus: For the present study, both the applications i.e., Weather Radio (version 3.0.5) and EZ Weather (version 1.0.0) are installed on iOS Smartphone. Using high fidelity simulations (InVision), a powerful interaction design system, we displayed recorded alert messages on the Weather radio at any time during the experiment. To record user interactions, in particular to calculate the time to complete a given task, to

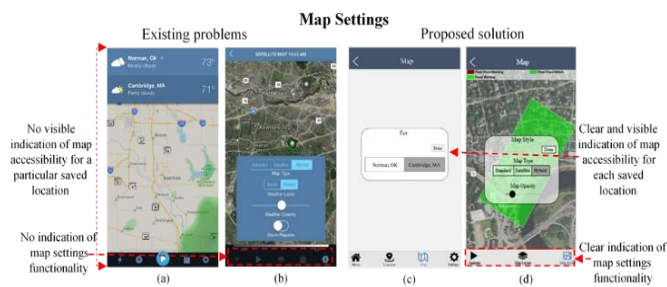

Fig. 5. Screenshot example of a user's main problem with radar/map feature and proposed solutions. Screens (a) & (b) are screenshots of radar/map in Weather Radio app that includes visibility and recognition issues, as neither indication is available on how to access map of a desired saved location as in (a) nor the functionality of icons is easily recognized as in (b). Screens (c) & (d) are screenshots of proposed solutions in the UCD app, where (c) shows all saved locations for a user to select and access map of a desired location and (d) provides icon labels to ease functionality recognition

count and classify errors the Nikon L340 camera was used. Demographics, post-task and post-test surveys were printed on paper.

**Scenario & Tasks:** Participants were given a scenario in which their grandmother was admitted to Mount Auburn Hospital in Cambridge, MA, and noticed that a flood warning had been announced in the Cambridge area. To understand grandmother's exact location alert risk level and access all relevant information, participants can search for and add to grandmother's exact location, access and identify relevant weather forecasts and alert messages. Further, participants need to view alerts on map in map settings and adjust alert settings to receive relevant alert notifications. Fig. 7 shows the successful completion of the scenarios and tasks.

**Procedure:** First, participants were explained the purpose of the survey, signed a written consent form, and then completed the demographic survey. None of the participants received training and were not given the opportunity to practice themselves using the test app; the participants were given scenario and task guidelines and were asked to start the experiment after they were told they were ready. Weather Radio is a running application, so participants won't see any alert messages unless during an active alert, so Weather Radio's alert message assignment was presented to participants through a smartphone interface designed by InVision. The alert message displayed to participants is a flood warning posted to Weather app users in Cambridge, MA on April 1, 2017. After finishing each task, participants were asked to complete a post-task survey to provide their instant feelings about each task/feature. Finally, participants were asked to complete a post-test survey to evaluate their satisfaction with the test app.

**Experimental Design & Variables:** Full factorial design (2 levels of app \* 2 levels of age group) were used in the present study as independent variables. The dependent variables were effectiveness, efficiency, and user satisfaction. The control variable was user experience; all users in both age groups must have at least six months of experience with iOS smartphones and the Weather app (excluding the app tested). Error metrics are the reasons for errors made (usability issues), how often they occur, the proportion of users who make mistakes, and the severity level of the cause of the error. The error severity ratings used in this study are based on a rating scale proposed by Nielsen [23] (Table I).

Finally, Pearson correlation test (r) was also performed to define the relationship between the usability measures used in this study.

The post-task survey was done by using a Single Ease Question (SEQ) with 7-point Likert rating scale [22]. This question was used because it was found to be as effective as other complex measures of task difficulty, namely the Usability Magnitude Estimate (UME) and Subjective Mental Effort (SMEQ) questionnaires [23]. The post-test survey was done by using User Interface Satisfaction (QUIS) questionnaire [24].

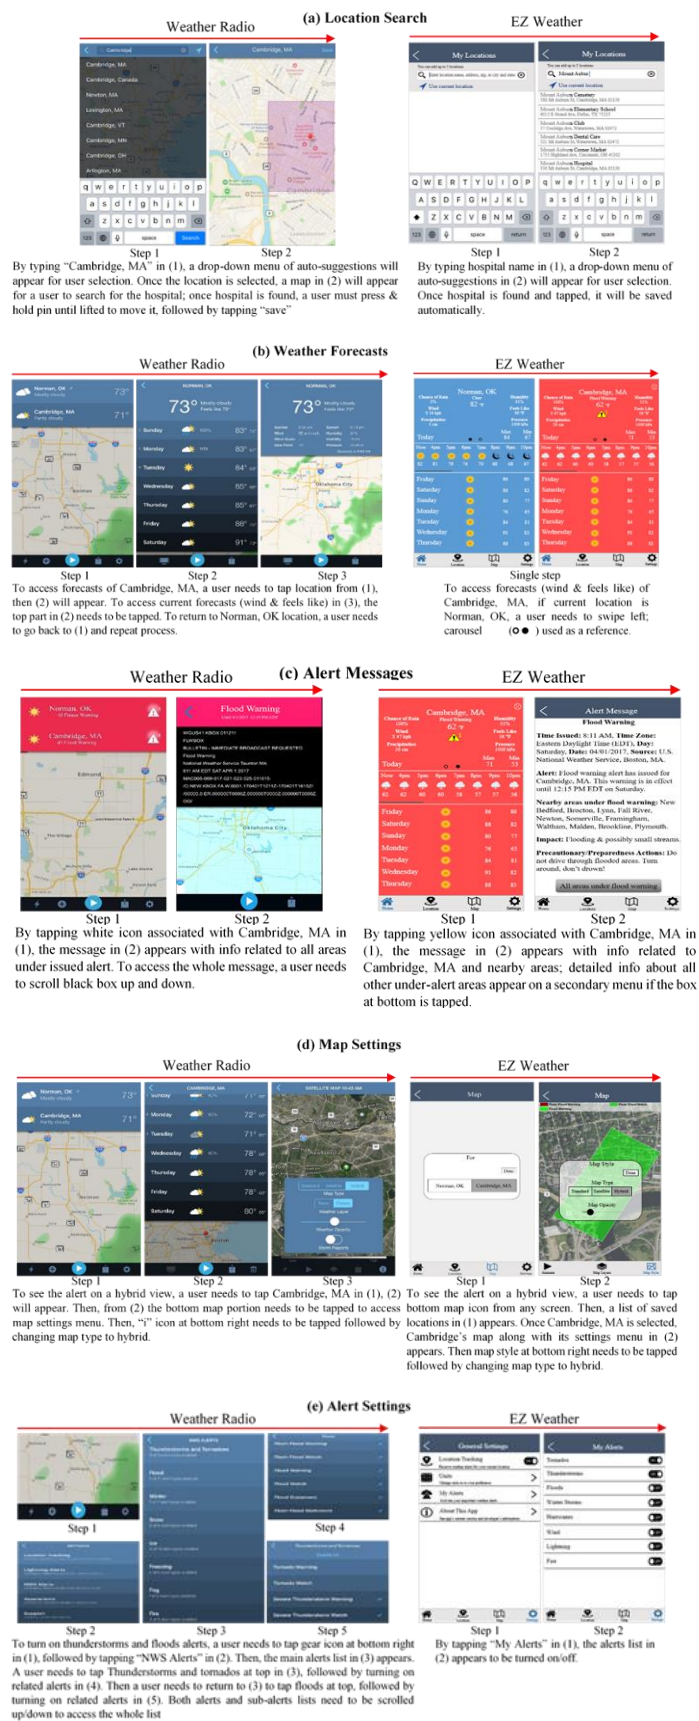

Fig. 7. (a-e). Process of performing tasks on Weather Radio vs. EZ Weather

Data Analysis: All data's were analyzed using SPSS version 23. A two-way analysis of variance (ANOVA) between subjects was performed to determine the effect of both application used and age group task completion time for all tasks. The Mann-Whitney U test was used to examine the size of the differences between the app and age group variables used, both in terms of the number of errors and the metrics of the post-task satisfaction survey. For post-test satisfaction surveys, mean and standard deviation errors were calculated.

TABLE I. NIELSEN'S SEVERITY RATING SCALE OF THE USABILITY PROBLEMS

Rating	Nature of usability problems
0	I don't agree that this is a usability problem at all
1	Cosmetic problem only: need not be fixed unless extra time is available on project
2	Minor usability problem: fixing this should be given low priority
3	Major usability problem: important to fix, so should be given high priority
4	Usability catastrophe: imperative to fix this before product can be released

B. Results of Phase 3

1) Effectiveness

a) Completion rate: Fig. 8 shows that all users in both groups were able to complete a given task in EZ Weather successfully. However, several users were unable to complete all three tasks on Weather Radio, and older users had a higher failure rate on the location search task.

Fig. 8. Proportions of successful task completion rate for both app

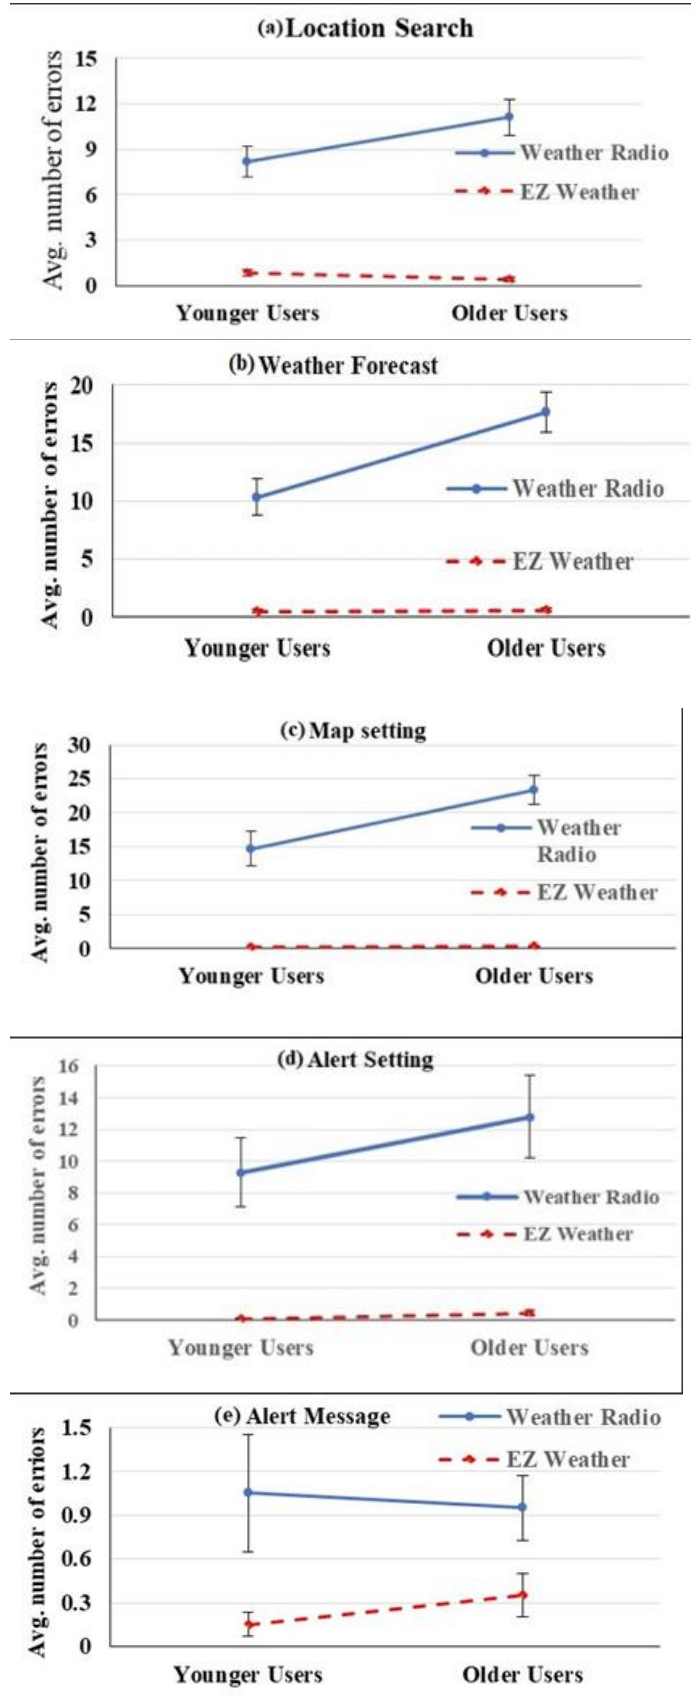

Fig. 9. (a-e). Average number of errors using both apps

TABLE II. MAN-WHITNEY TEST SUMMARY FOR NUMBER OF ERRORS

Task	Source	Z-score	U-test	P-value
Location Search	Age group	-1.22	677.50	0.223
	App used	-7.86	9	<0.001
Weather Forecast	Age group	-2.14	582	0.033
	App used	-6.64	123	<0.001
Alert Message	Age group	-.56	743	0.575
	App used	-7.68	20	<0.001
Map Settings	Age group	-2.42	655.5	0.015
	App used	-7.51	34.5	<0.001
Alert Settings	Age group	-.91	710.5	0.364
	App used	-8.01	10	<0.001

TABLE III. CAUSES OF ERRORS, FREQUENCY OF ISSUE, (PROPORTIONS OF USERS WHO MADE ERRORS), AND AVERAGE SEVERITY RATINGS ON WEATHER RADIO

Feature	Cause of errors (Usability problem)	Frequency of issues		Average Severity Rating
		Young Users	Older Users	
Location Search	Users are having trouble finding locations and moving pins on the map.	178	253	3.5
Weather Forecast	Users couldn't easily find the weather forecast. The area that causes the prediction, if clicked, appears to be unclickable.	231	366	3.5
Alert Message	Users couldn't easily access the necessary information of the time-critical weather alert message because of cluttered & unstructured information and poor use of language.	21	17	4
Map Settings	Users struggle to start the task due to counterintuitive steps and an invisible map settings menu.	166	287	3
Map Settings	Users are unaware of the functionality of the map settings icons because these icons are neither marked nor standardized across mobile applications.	126	194	2.5
Alert Settings	Users do not understand the function of home screen icons because these icons are neither marked nor standardized in smartphone applications. Also, the large number of alerts and sub-alerts seems to confuse users about the options required for the task.	186	256	3.5

b) *Errors*: Fig. 9(a-e) shows that errors on EZ Weather are significantly less than those on Weather Radio for all tasks, for both young and older users. The results showed that the older users had made more mistakes on both the apps compared to younger participants on all tasks except Weather Radio's alert message task and EZ Weather's location search

task. The Mann-Whitney U test showed a significant difference ( $p < 0.001$ ) in the number of errors across all tasks between the two apps (Table II). The results showed no significant error differences for all tasks between the both groups, except for the weather forecast and map setting tasks. For other error-related metrics, almost all users in both groups made errors, and with different frequencies, due to the usability issues with every task in Weather Radio except the Alert Messages task (Table III). Nearly half of the participants made mistakes due to alert message usability issues. In contrast, fewer users made mistakes in EZ Weather's tasks, with a much lower frequency and average severity rating, compared to Weather Radio. Errors on EZ Weather are mainly caused by swipe actions (such as spelling mistakes and accidental clicks on adjacent function icons) (Table IV).

TABLE IV. CAUSES OF ERRORS, FREQUENCY OF ISSUES, (PROPORTIONS OF USERS WHO MADE ERRORS), AND AVERAGE SEVERITY RATINGS ON EZ WEATHER

Feature	Cause of errors (Usability problem)	Frequency of issue		Average Severity Rating
		Young Users	Older Users	
Location Search	Users made typing errors when typing location name.	17	9	0
Weather Forecast	Users couldn't easily figure out that accessing weather forecasts of different locations was through swiping the screen right or left.	10	12	1.5
Alert Message	Users didn't expect the alert message icon to be clickable and/or required to access the message, when clicked.	3	7	1
Map Settings	Users mistakenly tapped adjacent icons of unrelated functions.	4	6	0
Alert Settings	Users mistakenly tapped adjacent icons of unrelated functions.	2	9	0

2) *Efficiency (task time)*: Fig. 10(a-e) shows that, on an average, the younger and older participants take fewer time to accomplish each task of EZ Weather compared to Weather Radio. The two age groups had relatively taken same times on all tasks for both apps. Therefore, two-way ANOVA (Table V) shows that on both weather apps, there were no significant time differences between young and elder users for all tasks except the map setting task. In the weather app tested, however, the time to complete all tasks was significantly different ( $p < 0.001$ ) between the both groups. In addition, there was no significant interaction between the both group and the app used for all tasks.

3) *Post-task satisfaction ratings*: Fig. 11(a-e) shows that both young and older participants found the EZ Weather task easier than the Weather Radio task. Younger users rated the ease of use for both apps higher compared to older participants, though the difference was not huge. In addition, the Mann-Whitney U test showed a statistically significant difference ( $p < 0.001$ ) in task satisfaction between the two apps

for all tasks (Table VI). It also showed that young and older users were similarly satisfied with all tasks.

Fig. 10. (a-e). Average time spent (in seconds) in completion of tasks

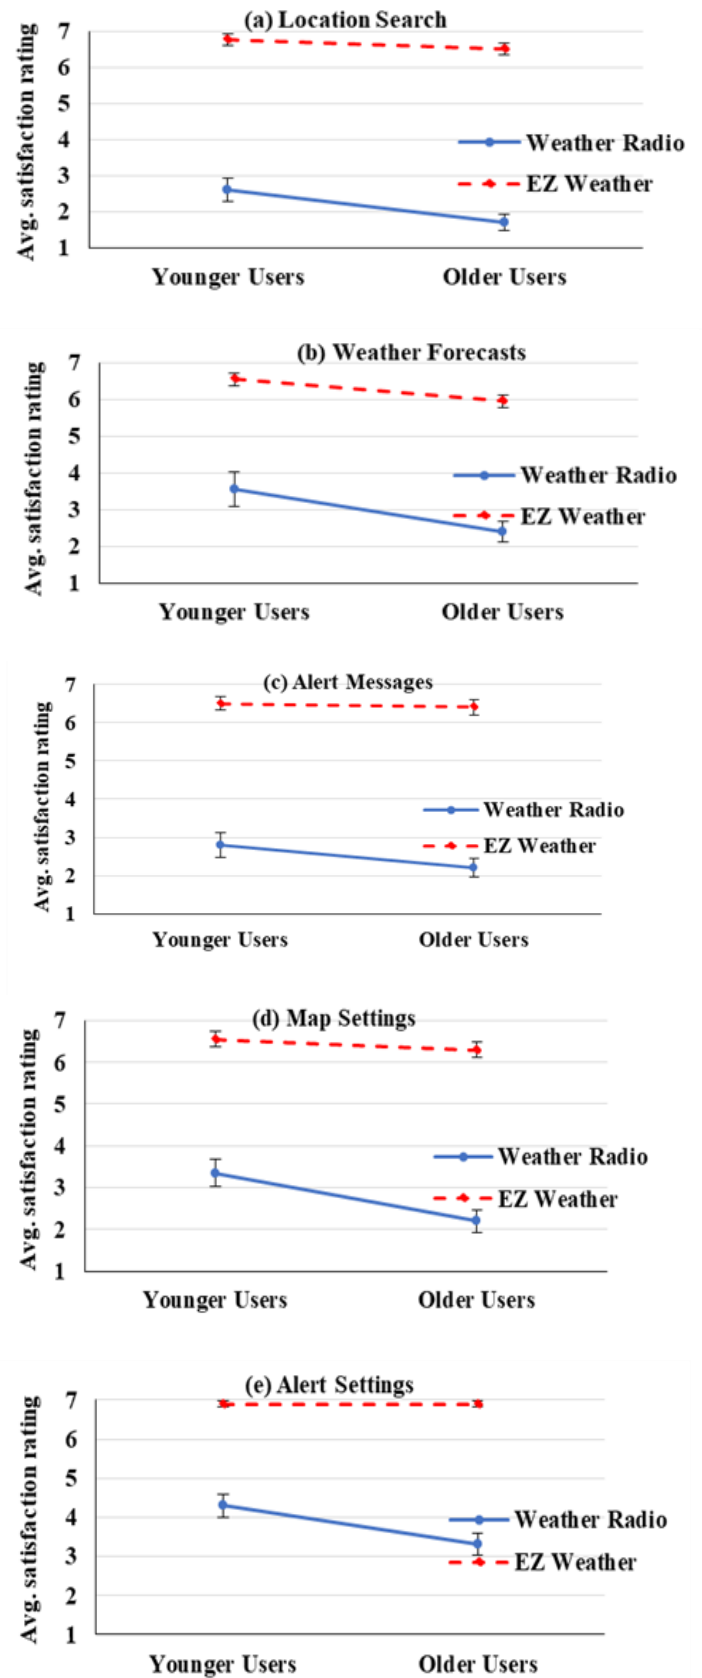

Fig. 11. (a-e). Average post-task satisfaction ratings of SEQ survey

TABLE V. TWO-WAY ANOVA SUMMARY FOR TASK TIME

Task	Source	F	P-value
Location Search	Age group	1.401	0.240
	App Used	445.554	<0.001
	User * App	0.949	0.333
Weather Forecasts	Age group	3.916	0.051
	App Used	127.384	<0.001
	User * App	0.805	0.373
Alert Messages	Age group	1.010	0.318
	App Used	189.608	<0.001
	User * App	0.023	0.879
Map Settings	Age group	6.012	0.017
	App Used	116.856	<0.001
	User * App	1.205	0.276
Alert Settings	Age group	0.332	0.566
	App Used	242.835	<0.001
	User * App	0.194	0.661

TABLE VI. MAN-WHITNEY TEST SUMMARY FOR POST-TASK SATISFACTION RATINGS

Task	Source	Z-score	U-test	P-value
Location Search	Age group	-0.298	769.5	0.766
	App used	-7.76	5	<0.001
Weather Forecast	Age group	-1.32	665	0.187
	App used	-7.58	25	<0.001
Alert Message	Age group	-0.842	727.5	0.401
	App used	-2.68	569	0.007
Map Settings	Age group	-1.33	667	0.184
	App used	-7.97	1.5	<0.001
Alert Settings	Age group	-1.32	668	0.185
	App used	-7.09	93.5	<0.001

4) *Post-test satisfaction ratings:* Overall, the results in Fig. 12 and 13 was based on the QUIS questions [24], where the same questions were asked to both groups of participants under same parameters, suggesting that younger and older participants feel comparatively similar to the interface de-sign specifications, and younger users are more satisfied. In addition, all participants were very pleased with EZ Weather, while most users of Weather Radio were disappointed. Users report that the screen design of EZ Weather is very good, the text and images are very clear, the fonts are very clear, the amount of information presented is sufficient, and the arrangement is reasonable. However, participants were

appeared to be disappointed with the amount of information displayed on Weather Radio; they observed that there was too much information, particularly about time-critical alerts.

Users have found consistent terminology and messaging throughout EZ Weather as well as the location of on-screen instructions. Participants reported that performing any action produced predictable results in EZ Weather, with a very acceptable delay between actions. However, many participants noted that they were not sure what to expect when performing multiple actions in Weather Radio. Compared to Weather Radio, users report that using EZ Weather is very easy to pick up, learn, and efficient. Additionally, users seem to be very pleased with the number and order of steps required to accomplish each EZ Weather task. They also liked the feedback they received as they completed each task. Navigating features and remembering names and commands was also easy for participants in both groups. When it comes to the EZ Weather feature, although many users made no mistakes during the experiment, they reported that errors and typos were easy to correct. Users also like their ability to perform or undo actions using shortcuts. In addition, they say that users of any experience level can easily and consistently complete their tasks. The choices of color for both apps seem natural enough for most users, with EZ Weather having a higher user satisfaction rate.

5) *Correlations among usability measures:* Tables VII and VIII show the Spearman rho correlation ( $\rho$ ) results among all the indicators in this study. Since all users successfully performed a given task, the correlation between completion rates for the two age groups and other metrics on EZ Weather was not performed. The results showed a strong positive correlation between task time and errors, and between post-task and post-test satisfaction, for both age groups for both applications. However, the time spent on each task and errors were negatively correlated with post-task and post-test satisfaction scores.

TABLE VII. CORRELATION MATRIX FOR BOTH YOUNGER AND OLDER USERS ON WEATHER RADIO, IN TERMS OF P & (P-VALUES).

	Younger User			
	Time	Errors	Task-Sat	Test-Sat
<b>Completion rate</b>	-0.615 (0.002)	-0.682 (0.003)	0.766 (<0.001)	0.870 (<0.001)

## VI. DISCUSSION

Overall, this study establish that the UCD weather app (EZ Weather) was considerably more useful compared to the other popular weather app (Weather Radio) for all the evaluation metrics used. Also, younger and older participants seem to have comparable results on all tasks for both the weather application, with younger users experiencing marginally greater performance and satisfaction. These results show that regard-less of age, an application's interface design significantly affects end-user performance and perceptions (positive or negative) of application usability. The results further demonstrate that adopting a UCD approach to applications that contain time-critical data, such as weather applications, will result in extremely interactive and usable systems. Results for all metrics had showed that prioritizing and structuring critical evidence and using everyday terms throughout the EZ Weather interface greatly helps participants easily interacting with inherent features and finds them beneficial. For example, all young and older participants were able to complete alert message tasks in EZ Weather with far greater efficacy and task satisfaction compared to Weather Radio features.

Additionally, only a handful of users had errors in some of the usability issues category in EZ Weather's alert messages task, while nearly half of participants of each group had errors in this task for Weather Radio due to usability issues in the catastrophe category. In addition, the alert message task further demonstrate that the push alerts will greatly help end participants to correctly perceive alert threats and respond effectively to alert threats, particularly in the forthcoming weather conditions.

The greater usability of the EZ Weather is also due in part to consideration of efficiency principles during the design phase. This is supported by the very limited time and steps required to access any feature on EZ Weather. A good example

is the weather forecast feature that includes all weather prediction information for respectively saved location within same screen (all-inclusive weather forecast); with just one swipe right or left, the user can access other saved locations' weather forecast. Although some users couldn't figure out the swipe functionality, from the first test, all success-fully completed the weather forecast task with significantly greater efficacy and task satisfaction, with fewer and less errors, than Weather Radio multiple-screen weather forecasts feature. Another example of an efficient feature of EZ Weather is the location search feature. With efficient auto-suggestions to type in familiar locations, both groups of users can complete the corresponding task in seconds. By contrast, navigating maps and pinpointing locations within the limited smartphone screen size is not only inefficient, but also ineffective, especially for older users, as demonstrated by Weather Radio's high failure rate and completion time for location searches.

Users' greater performance and satisfaction with EZ Weather than Weather Radio may also be related to EZ Weather's simple design. For example, limiting user-controlled alerts to the most common and critical alarms on EZ Weather (using a minimalist alarm setup) enables users to effectively and efficiently perform alarm set-up tasks with great satisfaction. Moreover, EZ Weather also permits participants to use non-critical alerts (via an illustrative icon displayed on the exaggerated location screen) during active alerts. The significant drop in performance and satisfaction with Weather Radio's alerts setting tasks was primarily because of the huge number of alerts and sub- alerts that users need to navigate and control (e.g., 16 sub- alerts for wind alerts alone). Two other important principles considered in the design of the EZ Weather interface are its usability and ease of recognition. For example, while the map setting task on both apps requires interaction with similar step and function icons. EZ Weather's greater performance and satisfaction on this task is supposed to be recognized to the visualization and intuitive menus (using the visualization and intuitive map menu), and appropriately labeled icons. These factors and results show that the actions have been performed with expectable results in a logical sequence. However, invisible elements in smartphone apps (such as the map settings menu bar) and icons that are neither marked nor standardized may be one of the main reasons for the dramatic drop in performance and satisfaction with Weather Radio tasks.

The usability and design principles monitored in the design of EZ Weather that may have ultimately contributed to great results include: feedback on system status (e.g. confirmation messages to perform activities), uniformity of application elements (e.g. settings menu), shortcuts usability to expedite interaction and correct errors, provide short descriptive information to help users understand the functionality of the corresponding feature, and use large text fonts along with high contrast and indicative colors to address age-related limitations for older users. The post-test satisfaction survey results were consistent with those of the task-based metrics. The two apps differed significantly in satisfaction with all interface standards across the two age groups, suggesting that applying usability guidelines to interface design not only results in high performance but also satisfaction for users. Also, on most

QUIS survey items, the two age groups are highly similar in satisfaction, meaning that age differences do not significantly affect user satisfaction. The strong correlations between all used metrics complement the results of previous study [25], which suggest that usability metrics are interdependent aspects that inform the usability of an interface. However, Frøkjær et al. [26] showed the dependence of usability metrics depends on whether the tested interface contains highly complex functionality. If the domain of interest includes complex features, a weak correlation is expected; if not, a strong correlation is most likely.

## VII. CONCLUSION

This study validated the usability of the UCD weather app (EZ Weather) by comparing it to a popular app (Weather Radio). In addition, this study also considered young and older users to determine whether the usability of the test app would be highly influenced by age differences. Results for all metrics showed that users' performance and satisfaction on EZ Weather improved significantly regardless of age, demonstrating the importance of considering UCD methods, usability heuristics, and smartphone design rules in interface development.

## ACKNOWLEDGMENTS

The authors would like to thank all team members and support staff who were directly or indirectly involved during the development and testing of this application.

**Abstract**—In teleoperation of a crawler robot in a disaster-stricken enclosed space, distress of the crawler robot due to communication breakdown is a problem. We present a robot teleoperation system using LoRaWAN as a subcommunication infrastructure to solve this problem. In this system, the crawler robot is operated by teleoperation using a subcommunication infrastructure in a place where a wireless local area network (LAN) communication is possible. In this study, we assume an environment in which the crawler robot must ascend and descend stairs to evacuate to a place where wireless LAN communication is possible. In addition, the disaster-stricken environment is considered as an environment where obstacles are expected to suddenly occur, and the crawler robot has difficulty avoiding obstacles on the stairs. In this paper, we propose a teleoperation communication protocol that considers the risk of sudden appearance of obstacles and confirm its effectiveness using evaluation experiments in a real environment.

**Keywords**—LoRaWAN; teleoperation; crawler robot; disaster-reduction activity; teleoperation protocol

## I. INTRODUCTION

When a large-scale disaster occurs, information gathering is required to assess the damage in the affected area [1]. The methods of information gathering in affected areas include aerial photography using drones, monitoring of existing infrastructures, and onsite activities by rescue workers [2-4]. However, collecting information from the sky in an enclosed space is difficult. Existing infrastructure may become inaccessible due to malfunction or lack of power supply. When rescue workers search a disaster-stricken enclosed space, human casualties due to collapsed buildings and debris may be expected. Therefore, information gathering using mobile robots has been considered in enclosed spaces after disasters [5-7].

Two types of communication methods that use mobile robots are available: wired and wireless. The wired system offers the advantages of stable power supply to the mobile robot via cable and maintains communication quality between the operator and mobile robot [8]. However, teleoperation of the mobile robot using a wired system suffers from problems such as cable tangling and snagging as well as cable handling at the time of return. On the other hand, the wireless method does not reduce the operability due to cables, and mobile robots can maintain high operability. However, as the mobile robot moves, the distance from the base station increases, and the electric-field-strength decreases. As a result, the mobile

robot faces the risk of going into locations where radio waves cannot reach and communication is interrupted. When teleoperating a mobile robot, considering the merits and demerits of wired and wireless communication methods and deciding on a communication method that suits a disaster-stricken environment are important [9-10]. In the present study, we present a wireless teleoperation method for a mobile robot in environments where the mobile robot has difficulty exploring using wired communication.

Related research on information gathering using mobile robots in enclosed spaces includes the robot wireless sensor networks (RWSNs) (Fig. 1) [11-12]. RWSN is a method of extending the communication range between the operator and mobile robot by installing a sensor node (SN), which consists of wireless repeaters, on the mobile robot and deploying them along its movement path. Whereas teleoperation using RWSN enables a wider range of information gathering, the mobile robot may be isolated due to communication breakdown caused by SN failure, battery failure, and radio interference. Distress of the mobile robot can not only interrupt information gathering but also cause secondary disasters because a mobile robot in distress becomes an obstacle or may ignite from its onboard battery. Therefore, in the present study, we present a teleoperation method using a subcommunication infrastructure as a distress-prevention method when the main communication infrastructure [wireless local area network (LAN)] is disconnected.

In the distress-prevention method that uses a subcommunication infrastructure, the operator PC, SN, and mobile robot are equipped with communication devices for the subcommunication infrastructure, and the network is constructed by letting them communicate in a multistage relay. The operator then uses the network to teleoperate the mobile robot and evacuates it to the place where wireless LAN communication is possible.

Subcommunication infrastructure is described as a network that is built based on a wireless-communication standard different from that of wireless LAN. Further, it must be able to continue communication even in an environment where wireless LAN is disconnected. Therefore, when SN becomes unavailable due to SN or battery failure, capability to jump over the failed SN is necessary to ensure continuous communication between the operator and mobile robot. Thus, the subcommunication infrastructure should be a wireless

communication standard that is superior in terms of communication range compared with wireless LAN. In addition, the subcommunication infrastructure must be a communication standard in a frequency band that is different from that of wireless LAN to prevent communication disconnection due to radio interference with wireless LAN. Therefore, in the present study, we realize the proposed method using LoRaWAN, which satisfies the abovementioned conditions as a subcommunication infrastructure (Fig. 2).

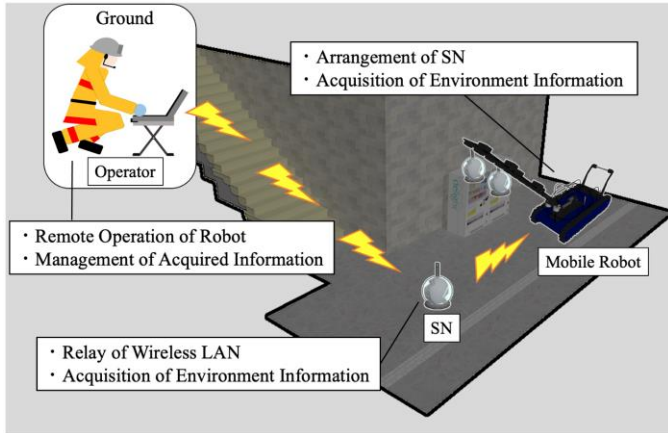

Fig. 1. Information-gathering system using a mobile robot (RWSN)

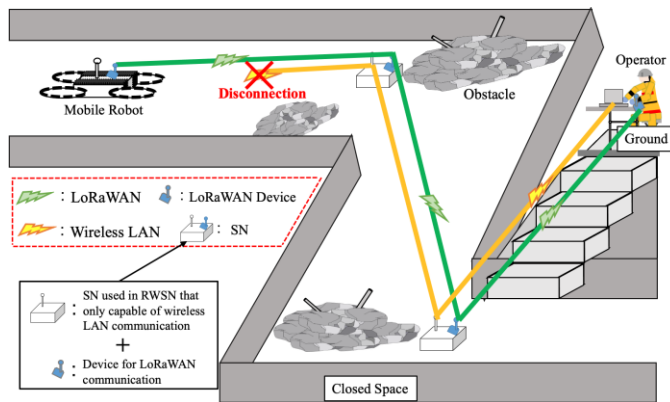

Fig. 2. Distress-prevention methods of mobile robots by teleoperation using LoRaWAN

In the disaster-stricken enclosed space assumed in this study, sudden appearance of obstacles such as collapsed debris is expected. Therefore, when an obstacle is found during the evacuation to the place where wireless LAN communication is available, the mobile robot is required to bypass or climb over the obstacles. The slope of the staircase changes when an obstacle appears in the stair environment. Therefore, if the mobile robot runs on the stairs, it faces the risk of falling down due to insufficient hill-climbing ability. In addition, if the mobile robot climbs over an unstable obstacle, a risk exists in which the robot may fall over or the obstacle collapses. Therefore, shortening the teleoperation time and completing the stair climbing-process before sudden obstacles appear during the stair climbing are necessary by teleoperation using LoRaWAN.

In this paper, we propose an interventional teleoperation protocol. The proposed protocol eliminates the factors that

increase the teleoperation time in existing teleoperation protocols. In the experiment, we performed teleoperation using the proposed and existing methods in a real environment and confirmed that the proposed method could reduce the teleoperation time and demonstrated its effectiveness.

## II. LORAWAN OVERVIEW

LoRaWAN is one of the communication standards categorized as low-power wide-area standard, which is a generic term for wireless-communication technologies that save power and can communicate over long distances. LoRaWAN is designed for Internet of Things and is suitable for acquiring information from a large number of geographically dispersed sensors [13]. In the agricultural field, it is used to manage sensors that measure cultivation-environment information such as temperature, humidity, and soil moisture and to transmit the sensor information, which contributes to smart agriculture [14]. Smart meters are expected to enhance power resilience and optimization of power transmission and distribution networks, and LoRaWAN is being considered as a network-connection method for these smart meters [15]. An early-detection system for forest fires using LoRaWAN sensor networks has been proposed, which can contribute to the mitigation of forest-fire damages [16]. Thus, LoRaWAN is being implemented or considered for deployment in many fields.

In the field of teleoperation of mobile robots in enclosed spaces, videos are mainly used to investigate the environment. However, LoRaWAN, which has a maximum bit rate of 50 kbps, suffers from the difficulty of transmitting videos. Hence, few discussions are available on the use of LoRaWAN in the field of teleoperation of mobile robots. On the other hand, LoRaWAN is capable of long-distance communication (2–5 km in urban areas and 15 km in suburban areas) [17]. Therefore, LoRaWAN offers the potential for continuous communication even in an environment where wireless LAN (IEEE802.11.g), which has a communication distance of approximately 100 m, is disconnected. Moreover, because LoRaWAN has a frequency bandwidth of 920 MHz, it has high diffusivity and the potential to continue communication even in an enclosed space with many obstacles. Therefore, LoRaWAN is considered to be a suitable wireless-communication standard for subcommunication infrastructures. Thus, in this study, we adopt LoRaWAN as subcommunication infrastructure and explain the teleoperation method that considers the features of LoRaWAN.

## III. TELEOPERATION USING LORAWAN

### A. Existing Teleoperation Protocol using LoRaWAN

In the teleoperation using wireless LAN, the mobile-robot environment is mainly monitored via videos, and the mobile robot is operated using a controller. Because the video is updated at any time, the operator always knows the difference between the current position of the mobile robot and target position and operates the mobile robot to the target position. However, the low bit rate of LoRaWAN makes employing such method of simultaneously learning the environment and moving the mobile robot in teleoperation using LoRaWAN

difficult. Therefore, teleoperation using LoRaWAN requires a separate operation for learning the environment and moving.

In the LoRaWAN communication, a communication path is constructed by designating two communication terminals as a coordinator and an end device. Packets are transmitted from the end device to the coordinator. In the existing teleoperation protocol, the mobile robot transmits information or performs actions in response to commands sent by the operator by considering this feature into account (Fig. 3) [18]. The mobile robot can be operated using such protocol after acquiring the necessary information for teleoperation even in low-bit-rate LoRaWAN. In the next section, we describe the environment learning and operation methods for teleoperation using LoRaWAN.

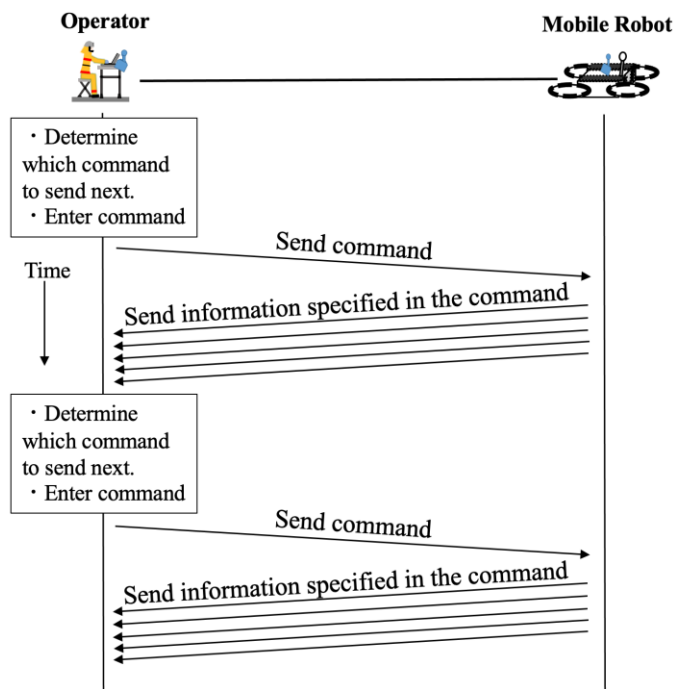

Fig. 3. Teleoperation protocol using LoRaWAN considering a one-direction communication

**B. Related Work**

When teleoperating a mobile robot, learning the surrounding is necessary to confirm the obstacles around the mobile robot and determine its movement path. Therefore, accurately learning the environment in teleoperation using LoRaWAN is necessary. In LoRaWAN, a method for learning the environment using images has been proposed [19]. In this method, the obtained image is transmitted in segments, and the receiver reconstructs the received image elements to obtain the original image.

A teleoperation method using a graphical user interface (GUI) has been proposed to move a mobile robot to a target position (Fig. 4) [20]. In this method, the environment is learned based on the obstacle information obtained by LRF, in addition to the images. The black squares at the interface indicate the presence of obstacles, whereas the ochre squares indicate the absence of obstacles and possibility of movement. Then, when the mobile robot is operated using GUI, its

movement path is determined by sequentially selecting the adjacent ochre-colored cells from the cells where the mobile robot is located. However, this method assumes movement on a level ground with obstacles and cannot handle movement in a 3D space such as a staircase. Therefore, if a distressed mobile robot is required to ascend or descend stairs to evacuate to a place where wireless LAN communication is possible, it cannot achieve its purpose. Hence, we need to consider the process of ascending and descending stairs by the mobile robot using LoRaWAN teleoperation. Section C describes the mobile robot used for stair climbing and descending, and Section D describes the teleoperation method in the considered stair environment.

**C. Mobile Robots Used in Staircase Environment**

Mobile robots with a flipper arm, which is a crawler mechanism (crawler robots), show higher operating performance on uneven terrain such as stairs than wheeled mobile robots. Therefore, in dealing with the Fukushima Daiichi Nuclear Power Plant accident, crawler robots such as the PackBot, Quince, and Survey Runner, which were introduced to collect information in the buildings, were required to climb and descend stairs [21-22]. On the basis of this information, the present study investigates the process of ascending and descending stairs using crawler robots.

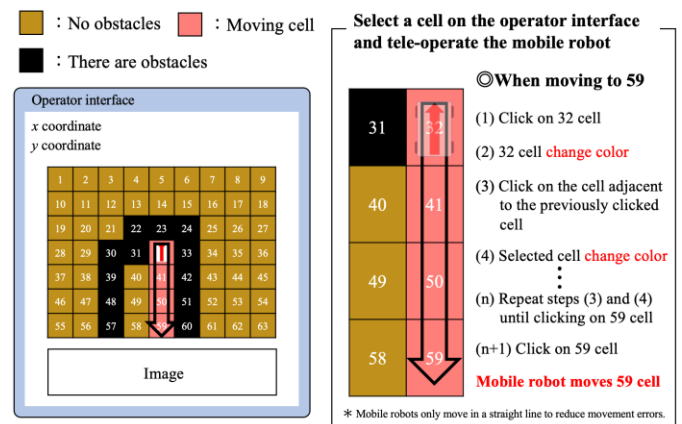

Fig. 4. GUI for remote control using LoRaWAN that considers remote control under a low transmission-capacity communication.

**D. Command-Input Operation Method**

The crawler robot moves and turns by rotating the main crawler and adjusting its posture using its flipper arm. Therefore, in order that the crawler robot can be teleoperated, the operator must be able to send an arbitrary operation command to the main crawler and flipper arm. In addition, for the LoRaWAN teleoperation, moving the crawler robot to the target position based on the acquired information is necessary. The low bit rate of LoRaWAN makes video transmission difficult. Therefore, the current position of the crawler robot as it moves cannot be known in real time. In such an environment, the operator does not know how far the crawler robot has moved if the controller is used in the same manner as that in operation using wireless LAN. Therefore, teleoperating the crawler robot to its target position using a controller is difficult.

Hence, we propose a command-input operation method as a teleoperation method for crawler robots in a staircase

environment. In this method, the operator and crawler robot share a correspondence table of actions, as shown in Fig. 5, and the operator operates the crawler robot by transmitting the numbers in the table. The amount of performed selected operations is determined by specifying the amount of movements such as distance or angle. Thus, the operator can teleoperate the crawler robot to the target position and posture using this method even in an environment where the operator does not learn the change in the current position of the crawler robot in real time. In this study, we select the information required by the operator as follows, i.e., factors (1)–(5), to use the command-input operation method.

- 1) Multiple camera images
- 2) IMU sensor information
- 3) Staircase information (slope, kick-up width, and tread)
- 4) Distance information between the crawler robot and stairs
- 5) Obstacles and staircase-shape information

Item (1) is needed to confirm a safe place where the crawler robot can move forward by learning the stair environment such as the presence or absence of obstacles on the staircase and missing staircase parts. Item (2) is necessary to obtain the posture of the crawler robot in the staircase environment and determine the degree of movement to the target posture. Items (3) and (4) are necessary for determining the amount of movement to move the crawler robot to the target position. Item (5) denotes a factor that determines whether the staircase contains obstacles or part of the staircase is missing. If so, it determines whether these obstacles affect the crawler-robot operation.

#### IV. TELEOPERATION PROTOCOL USING LoRAWAN

##### A. Problem of Teleoperation using LoRaWAN in a Staircase Environment

In a disaster-stricken enclosed space, obstacles exist, which are assumed to block the path. If an obstacle exists in the crawler-robot direction of movement during the evacuation action, it needs to run through the obstacle by climbing over it or by avoiding it using an obstacle-free path.

If obstacles are present in the stair environment, the slope of the stair changes. If the crawler robot tries to avoid these obstacles by climbing over it, it may fall down due to its insufficient climbing ability and very steep gradient when descending (Fig. 6). In addition, if the crawler robot rides on an unstable obstacle, a risk exists in that the crawler robot may fall over because of collapse of the obstacle. Moreover, if the crawler robot tries to avoid the staircase by diverting to an unobstructed area, it may lose its balance and fall down when it turns on the staircase. Thus, a risk exists in which the crawler robot may fail to ascend or descend stairs if obstacles are present in the stair environment.

The disaster-stricken environment assumed in this study is subject to rapid environmental changes and sudden occurrence of obstacles. In addition, the transmission of various sensor information required to send a single operation command takes several minutes. These factors indicate that a risk of failure in the evacuation actions exist because of the occurrence of sudden obstacles in the staircase environment during climbing and descending stairs by teleoperating using LoRaWAN. Therefore, for successful evacuation in staircases with risk of sudden occurrence of obstacles, teleoperation using LoRaWAN is required to shorten the time needed for climbing or descending stairs and completing the stair-climbing process before obstacles appear.

If the amount of transmitted information is limited, e.g., by limiting the number of transmitted images, the teleoperation time can be shortened, but a risk exist in not being able to accurately learn the environment. Therefore, when the teleoperation time is reduced, we must not reduce the information-transmission time during teleoperation but increase the ratio of the time when information is transmitted by reducing the time when no information is transmitted.

As presented in Section III, in the existing teleoperation protocol that uses LoRaWAN, the crawler robot transmits information or performs action in response to a command transmitted by the operator. Therefore, the operator that teleoperates the crawler robot repeatedly decides the command, inputs the command, and receives data. In the existing protocol, no communication occurs when the operator decides which command to send next and when the command is input (bandwidth is not used). Under the same transmission-capacity environment, the amount of data transmission depends on the bandwidth utilization. Therefore, the time required to obtain the information necessary for operation increases with decreasing bandwidth utilization and decreases with increasing bandwidth utilization. On the basis of this discussion, the proposed protocol needs to reduce the teleoperation time by improving the bandwidth utilization.

In the existing protocol, when the operator transmits an incorrect command, the operator cannot interfere and must wait until the crawler robot finishes executing the issued command. Therefore, the teleoperation time is increased by the execution of the wrong command. Hence, the proposed protocol must be able to deal with wrong command execution.

In this paper, we propose a teleoperation protocol that reduces the teleoperation time by taking into account what has been described in this section.

Fig. 6. Crawler robot ascending or descending stairs when obstacles are present on stairs

### B. Interventional Teleoperation Protocol

In this paper, we propose an interventional teleoperation protocol as a teleoperation protocol that satisfies the required specifications. The proposed protocol reduces the command input time and improves bandwidth utilization by sequentially transmitting information necessary for operation according to a predetermined order, instead of transmitting information according to the command received from the operator. However, in this communication flow, even if sufficient information is collected to determine the operation command, transmission is not interrupted, and we need to wait until all the information transmission is completed. Therefore, this communication flow may increase the bandwidth utilization but may not reduce the teleoperation time. Hence, in the proposed protocol, information transmission can be interrupted at arbitrary times using an interventional command, and operation commands can be executed. In addition, the operator can also interrupt the execution of a wrong command using an interventional command.

In the interventional teleoperation protocol, the system must be able to transmit packets from the operator to the crawler robot while it transmits packets to the operator. Therefore, when this method is employed, we assume that two communication paths exist: “operator→crawler robot” and “crawler robot→operator.”

The proposed interventional teleoperation protocol is shown in Fig. 7, and its flow and processing are described hereunder.

1) The operator transmits a synchronized flag (SYN) packet to the crawler robot.

2) The crawler robot sends back an acknowledgement flag (ACK) packet as an acknowledgement of the SYN packet to

the address from which the SYN packet was sent. The crawler robot also transmits SYN packets to verify that packets from the crawler robot reach the operator.

3) The operator confirms the communication connection by receiving an ACK packet and returns the ACK packet in response to a SYN packet sent by the crawler robot.

4) The crawler robot sequentially transmits the sensor information acquired by it after receiving ACK in (3). The order of transmission is concrete numerical information (shape information of obstacles and stairs, IMU sensor information, and distance information between the crawler robot and stairs) and images. In the process of ascending or descending stairs by the crawler robot, we assume that multiple images such as subjective and bird's-eye-view images are used, and the order in which these multiple images are transmitted is set in advance.

5) When a task with a higher priority occurs during the image transmission, an interventional command is sent, the current task is interrupted, and the contents of the command are executed. For example, during image transmission, changing the transmission order of predefined images may be necessary, some images may be lost due to packet loss, or learning of the environment may be completed without waiting for all images to be acquired. Then, when the transmission order of the images is changed, the order is changed by transmitting a new image-transmission order as an interventional command. If the priority of retransmission of a packet-lost image is high, the interventional command to execute the retransmission process is transmitted, and the current image transmission is interrupted to execute the command contents. When information gathering is completed, the operation command is transmitted as an interventional command to operate the crawler robot. When the crawler robot has completed executing the interventional commands other than the operation command, it resumes the task it performed before the intervention command was sent.

When a wrong command is executed, its execution can be interrupted by transmitting the interventional command. Thus, the interventional command can be used to reduce the time used in the bandwidth and to deal with the execution of wrong command contents.

6) When the crawler robot receives an operation command as an interventional command in (5), it interrupts the image transmission and executes the command. When the crawler robot moves, highly real-time information such as IMU sensor or encoder information is always transmitted to the operator.

7) The operator checks whether the crawler robot has moved more than the specified distance based on the information obtained in (6) and transmits an interventional command to stop the crawler robot if necessary.

V. EVALUATION EXPERIMENT

A. Purpose and Content of the Experiment

The purpose of this experiment is to confirm whether the proposed method can reduce the teleoperation time of the crawler robot. In our experiments, we measure the bandwidth utilization and teleoperation time of the crawler robot by conducting stair climbing and descending using the proposed and existing teleoperation protocols. Bandwidth utilization is defined as the ratio of the time the crawler robot transmits packets to the operator during the teleoperation time. Teleoperation time is defined as the time from that when the crawler robot transmits the first packet to the operator to the time when the crawler robot completes ascending or descending the stairs and confirms that it is at the floor or landing level.

B. Experimental Environment and Equipment

The experimental environment is shown in Fig. 9. In the experiment, LRF, which was mounted in front of the crawler robot, was used to acquire information on the shape of the obstacles and stairs as well as the distance between the crawler robot and stairs. Three cameras were used, which were positioned to acquire subjective, overhead, and rearward images. The control system used in this experiment was Raspberry Pi 4 Model B, and the LoRaWAN module was ES920LR manufactured by EASEL Corporation.

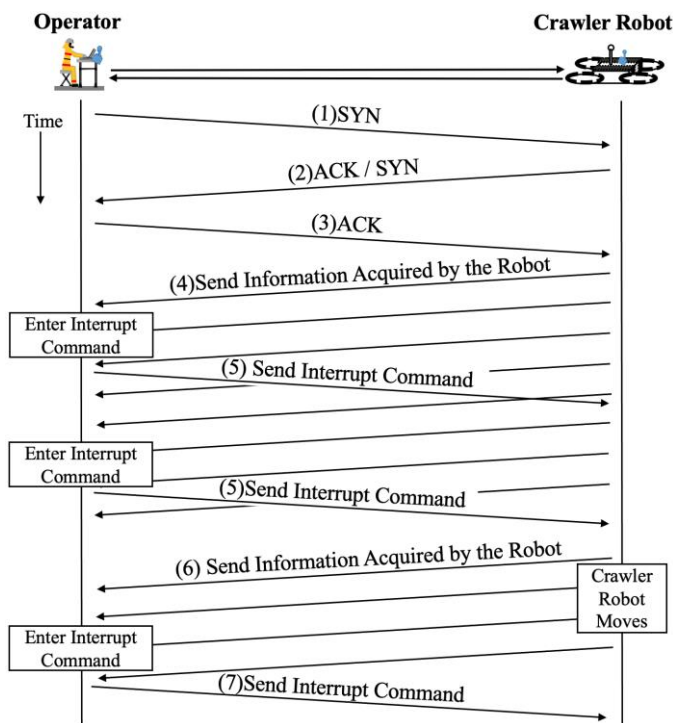

Fig. 7. Interventional teleoperation protocol

The packet format used in the proposed protocol is shown in Fig. 8. The interventional command that is part of the packet used in (5) contains commands to “change the order of image transmission,” “retransmission processing,” “image-quality conversion,” and “cancellation of the last sent command”.

The packet format used in (4)–(6) contains a packet number at the end. This packet number is a number expressed in ascending order starting from zero, and the operator can understand the order of packets that the crawler robot have sent. When the order of packets transmitted by the crawler robot and that received by the operator are different, the operator can learn the difference using these packet numbers. In addition, if the same command is delivered to the crawler robot more than once, the packet number can be used to cancel multiple executions of the same command.

Header Fields					1 Byte
Frame Control	PAN ID	Destination Address	Sender Address	Communication Route	SYN/ACK

Packet used to send SYN/ACK packet in (1), (2), and (3)

Header Fields					Variable	1 Byte
Frame Control	PAN ID	Destination Address	Sender Address	Communication Route	Sensor Information	Packet Number

Packet used to send sensor information in (4), (6)

Header Fields					1 Byte	Variable	1 Byte

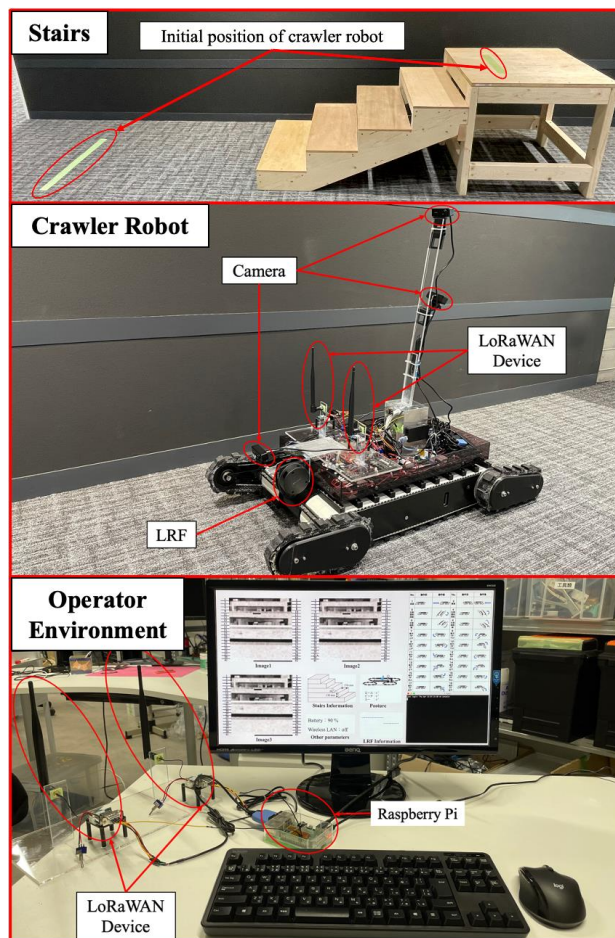

Fig. 9. Experimental environment

### C. Experimental Result

In the experiment, the crawler robot was able to ascend and descend stairs without tipping over once in both cases. Fig. 10 shows the experimental results that used the existing method, and Fig. 11 shows those that used the proposed method. The vertical axis indicates whether the bandwidth was used or not, where one denotes that the bandwidth was used and zero indicates that the bandwidth was not used.

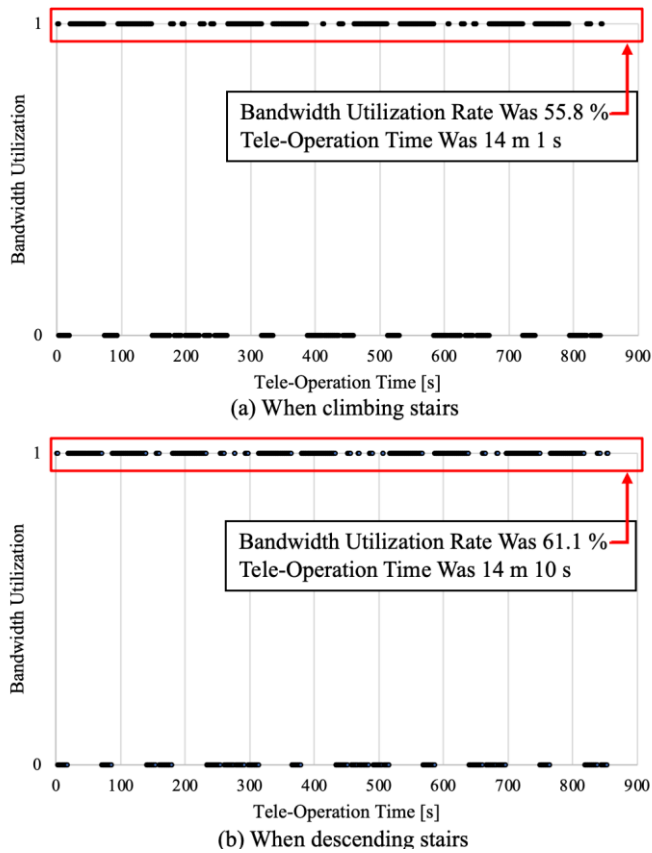

Fig. 10. Results of the experiment (existing protocol)

In the ascent process using the existing method, concrete numerical information (IMU sensor information, distance between the crawler robot and stairs, and shape information of the obstacles and stairs) was transmitted seven times, images were transmitted eight times, and the crawler robot moved six times. In the case where the existing method was used, concrete numerical information was transmitted six times, images were transmitted nine times, and the crawler robot was moved seven times. In the case of the ascent process using the proposed method, concrete numerical information was transmitted seven times, images were transmitted ten times, and the crawler robot was moved six times. In the case of the descent process using the proposed method, concrete numerical information was transmitted nine times, images were transmitted ten times, and the crawler robot moved eight times.

In the ascent process, the concrete numerical information and number of times the crawler robot moved were the same in both methods, but the number of images acquired by the proposed method increased by two. The bandwidth utilization improved by 38.3% from 55.8% to 94.1%, and the

teleoperation time decreased by 2 min and 9 s from 14 min and 1 s to 11 min and 52 s. In the descent process, the amount of concrete numerical information acquired using the proposed method was increased by three, the number of images was increased by one, and the number of crawler-robot movements was increased by one. The bandwidth utilization improved by 32.5% from 61.1% to 93.6%, and the teleoperation time decreased by 1 min 58 s from 14 min 10 s to 12 min 12 s.

Fig. 11. Results of the experiment (proposed protocol)

The average time required to determine and input the next command using the existing method was 19.6 s for ascending and 15.7 s for descending. In the proposed method, the average time from the completion of obtaining the necessary information to inputting of the operation command was 21.8 s for ascending and 17.0 s for descending.

### VI. DISCUSSION

We confirmed that the proposed method could reduce the teleoperation time, although two more images were obtained in addition to the information acquired by the existing method when the crawler robot was ascending. We confirmed that the proposed method could shorten the teleoperation time, although three times of concrete numerical information and one more image were obtained in addition to the information acquired by the existing method when the crawler robot was descending. Furthermore, the average time of the proposed method from acquisition of the necessary information to inputting of the operation command was longer than the average time required for the decision and inputting of the next

command in the existing method, both in the stair climbing and descending processes. Therefore, the reduction in the teleoperation time in the experiment did not depend on the time to decide and input the commands. Hence, the teleoperation time could be reduced by reducing the number of command inputs and improving the bandwidth utilization using interventional commands. Therefore, this method is considered to be effective for teleoperation in staircases with a large number of command inputs because of the need for concrete numerical information and multiple images.

The teleoperation that uses the proposed method could interrupt the execution of a command sent by mistake because we confirmed that the interventional process could be executed. Therefore, this method is considered to be effective because it could deal with increased teleoperation time when wrong command contents were executed.

## VII. CONCLUSION

In the teleoperation of crawler robots in a disaster-stricken enclosed space, the distress of the crawler robot due to communication breakdown is a problem. In this study, we have presented a teleoperation method using LoRaWAN as a subcommunication infrastructure to move a distressed crawler robot to the place where wireless LAN communication is possible. In this study, we have also assumed an environment in which the crawler robot was required to ascend and descend stairs when evacuating to the place where wireless LAN communication was possible. We have presented the operation method of the crawler robot on stairs.

In the disaster-stricken environment assumed in this study, sudden appearance of obstacles is expected. When obstacles appear on the staircase, the slope of the staircase changes and the crawler robot may fail to ascend or descend the stairs because of its insufficient climbing ability. In addition, because of the low bit rate of LoRaWAN, several minutes is required to obtain the necessary information to transmit a single operation command. Hence, a risk exists in terms of failure in evacuation actions due to the occurrence of obstacles during stair climbing or descending teleoperation using LoRaWAN. Therefore, shortening the time required for stair climbing or descending and completing the stair climbing or descending process are important before obstacles appear in the teleoperation using LoRaWAN. Hence, we propose an interventional teleoperation protocol to reduce the teleoperation time.

The proposed method reduces the teleoperation time by reducing the number of command decisions and inputs and employing an interventional command. In addition, the proposed method can interrupt the execution of erroneous commands using interventional commands. Through experiments in real environments, we confirmed that the proposed method could improve the bandwidth utilization and shorten the teleoperation time.

In this study, we developed a multipath communication method that increased the bandwidth by adding more communication paths. Therefore, we plan to increase the transmission capacity of the bandwidth by adding a communication path from the crawler robot to the operator to further shorten the teleoperation time.

# Business Intelligence Data Visualization for Diabetes Health Prediction

## Data Analytics and Insights for Diabetes Prediction

Samantha Siow Jia Qi, Sarasvathi Nagalingham

Faculty of Data Science and Information Technology  
INTI International University, Nilai, Negeri Sembilan, Malaysia

**Abstract**—In today's environment, Business Intelligence (BI) is transforming the world at a rapid pace across domains. Business intelligence has been around for a long time, but when combined with technology, the results are astounding. BI is also playing an important role in the healthcare domain. Centers for Disease Control and Prevention (CDC) is the largest science-based, data-driven service provider in the country for public health protection. For over 70 years, has been using science to fight disease and keep families, businesses, and communities healthy. However, research indicates that the prevalence of diabetes in the US is rising alarmingly. As a result, if diabetes is not treated, it can lead to life-threatening complications such as heart disease, loss of feeling, blindness, kidney failure, and amputations. As a result, this study was conducted to analyze people's health conditions and daily lifestyles in order to predict which type of diabetes they would most likely diagnose with the implementation of business intelligence using Tableau dashboard. Furthermore, background research is conducted on CDC to understand their work, challenges, and opportunities. By the end of the project, the information obtained and visualized should be able to enhance business choices and make better decisions on controlling diabetes in the future.

**Keywords**—Diabetes; business intelligence; prediction; dashboard visualization; data analysis; centers for disease control and prevention

### I. INTRODUCTION

#### A. Business Intelligence Methodology

Healthcare analytics and business intelligence (BI) are two emerging technologies that offer analytical capability to aid the healthcare sector in enhancing service quality, lowering expenses, and managing risks. With the increasing volume of data and the desire to learn from it, demand for BI applications for healthcare continues to rise. The need for data management and analysis expertise in healthcare is rapidly increasing. With the help of Business Intelligence, companies can make better decisions by displaying current and historical data within the context of their business. Analysts may use BI to generate the company's performance and competitive standards, which will help the companies operate more smoothly and effectively as well as identify the market trends for enhancement. In any BI project, a consistent methodology and approach must be defined as they can let decision-makers develop, support, and integrate best management practices within the organization. Moreover, it can achieve a higher chance of success, save time and effort, eliminate unnecessary

operations, and ensure accurate reporting and analysis. Therefore, the Agile BI methodology will be adopted in the context of our domain, Centers for Disease Control and Prevention (CDC).

Fig. 1. Phases of agile methodology.

The Agile BI methodology is a project management strategy that focuses on continuous improvement and is suitable for those that demand speed and flexibility to satisfy customer requirements. It is considerably more accessible than it looks to apply Agile BI methodology to an organization's internal business processes [5]-[6]. The following are the phases of the developing an Agile BI methodology (Fig. 1):

- **Requirement:** In this phase, the project team specifies the requirements. They should outline the business opportunities of the project that can result in profit and business growth, along with estimating the time and effort required to complete it. Technical and economic feasibility can be determined as well as whether the project is worth pursuing based on this information.
- **Design:** This phase required working with the company's stakeholders to determine the requirements once the project had been identified. Diagrams such as flow diagrams and high-level UML diagrams are used to demonstrate how the new features perform and how they integrate into the existing system.
- **Development:** The works begin once the project team has identified the requirements based on stakeholder feedback. UX designers and developers start working on the project's initial iteration to deliver a viable product. The product will go through several phases of improvement to meet the stakeholder's requirements.

- **Testing:** The Quality Assurance team will check the product's performance and address any defects and bugs that produce unexpected results. The software engineer team will finalize the system and user documentation once the product is satisfied.
- **Deployment:** This phase includes ongoing software release support, especially when the project team must keep the system working well and demonstrate users on using the system. The production phase comes to an end when the support has ended.
- **Review:** The final phase is to get feedback from the stakeholder once the product has been released. The project team will receive feedback on the development and work through it to improve their work for the next project.

### B. Literature Review

The Centers for Disease Control and Prevention (CDC) is the United States' main public health agency. It is a government agency of the United States that belongs to the Department of Health and Human Services and is headquartered in Atlanta, Georgia. The agency's primary aim is to protect public health and safety by controlling and preventing disease, injury, and disability in the United States and around the world. The CDC concentrates national attention on developing and implementing disease control and prevention strategies [7].

The Behavioral Risk Factor Surveillance System (BRFSS) is a health-related telephone survey conducted annually by the Centers for Disease Control and Prevention (CDC). The survey collects data from over 400,000 Americans each year on health-related risk behaviors, chronic health issues, and use of preventative treatments. It has been conducted every year since 1984. According to the CDC, 34.2 million Americans have diabetes and 88 million have prediabetes as of 2018. Furthermore, the CDC indicates that one in every five diabetics and about eight out of ten pre diabetics are unaware of their risk. To improve preventive care, EHR is necessary, which can monitor the patient's state of health and track treatment progress to make preventative care easier.

The main purpose of this business is to implement electronic health records (EHR) to give better care to patients. EHR and the ability to exchange health information electronically can help patients receive better quality and safer care while also providing substantial profit to the business. It automates a multitude of operations for the practice and allows for instant access to patient records for better coordinated and efficient care when compared to manually inserting, updating, or deleting data using a csv file. To improve productivity and work-life balance, physicians are allowed to share electronic information with one another remotely and in real time [1].

Furthermore, early diagnosis is essential since it can lead to lifestyle changes and more effective treatment, making diabetes risk prediction models important tools for the general population and public health officials. Health analytics are given by applying EHR, which can help to recognize patterns, predict diagnoses, and recommend potential treatment

alternatives. Rather of relying on trial-and-error methods, these analytics lead to more successful overall patient results the first time.

### C. Challenges faced by CDC

Various changes are occurring in the Centers for Disease Control and Prevention (CDC), creating new challenges to both large and small medical businesses. To name a few, the integration of services, technological developments, and patient preferences have created a new environment in which performing a medical treatment is no longer solely about treating patients.

First, big data development is well received in the medical world, but implementation may not be as easy. Non-relational databases combine patient data from several sources to provide meaningful metrics. The technology appears at the ideal time to meet the demand for newly available patient information warehouses. Relational databases have traditionally been used by healthcare providers to manage and store patient records. Nevertheless, relational databases are incapable of managing unstructured data, such as medical documentation and transcripts. Only a small fraction of healthcare providers has successfully transitioned from relational to non-relational databases using standard electronic health records (EHRs). Most firms that effectively employ non-relational information systems are big and financially secure.

Besides that protecting the devices that protect public health is important as many developments in healthcare technology use Internet connectivity. However, this convenience extends to cyber attackers as well. Malicious cyber-attacks will become more common as the Internet-connected medical device industry evolves. The US authorities warned people in 2015 that hackers may command infusion pumps to deliver harmful drug doses. The leak raised the prospect of malevolent programmers infiltrating medical devices and causing harm to people. Moreover, hackers utilize medical equipment to invade care provider networks, stealing research and clinical trial data as well [13]. Presently, no medical equipment has been infiltrated by hackers, resulting in a fatal event. Yet, cyber security experts warn that an assault on an untrained care provider can harm an organization in a variety of ways.

Furthermore, as patients are becoming more liable for a growing amount of their medical expenses, health providers are listing patient collections as their top revenue cycle management challenge. Providers must comply with patient payment preferences to urge patients to make payments on time. Invoice statements should be patient-friendly to meet the expectations of patients and enhance their user experience. For example, e-Statements and a range of payment alternatives, such as credit cards, etc. through an online patient portal can be used. However, setting up such billing and payment processing systems in-house can be difficult and expensive for medical offices. They must not only discuss agreements with each payment processor and develop the infrastructure, but they must also bear the continuous administrative costs of such technology. Besides, healthcare professionals must adhere to stringent criteria to preserve patient information.

You must ensure that your payment interface and processing system are entirely compliant, or you may face a severe penalty.

Lastly, in recent years, there have been substantial changes in the health insurance sector of the CDC. As more patients bear a greater share of their medical costs, they naturally expect greater services from their providers. The CDC will confront increased competition in gaining and maintaining patients who seek a level of customer service comparable to that of other retail chains. For example, they expect a streamlined patient experience in which they can "self-service" to settle most doubts, problems, or concerns whenever, wherever, and however they see fit [2], [14]-[15].

#### D. Opportunities of CDC

After looking into the difficulties or problems that arise in the disease control and prevention centers, we have identified some alternative solutions as well as opportunities to ensure the organization remains sustainable. The opportunities of disease control and prevention centers are listed as follows.

Due to the Centers for Disease Control and Prevention (CDC) currently using the traditional spreadsheet approach to store and manage patient records, it slows down the workflow of the organization. Therefore, CDC needs to transition from using a spreadsheet like Microsoft Excel to an electronic health records (EHR) system. The EHR system helps their CDC staff to capture and access information gathered during patient appointments with just a click. It is more user-friendly than a spreadsheet since the process of adding, updating, viewing, and deleting the patient's data can be done systematically and more simply. Moreover, the EHR system allows multiple staff to have simultaneous access to health records anytime and anywhere. And most significantly, it also enables the staff to share information with other practices suchlike emergency facilities, specialists, and laboratories, to contain all the information clinicians provide for patient care [9]-[10].

Besides that CDC will be able to expand the view of patient care and ensure every patient has gotten the medical services they need. With the use of the EHR system, it has provided a variety of useful functions like the capability to generate the analytical report based on clinical data collected from ongoing patient care. In healthcare, the analytical report is used to detect or predict early signs of patient deterioration and aids in the more definitive patient diagnosis, followed by the appropriate treatment of the identified indication. Accurate preventive measures have been shown to reduce mortality and morbidity rates in diagnosed patients.

Lastly, a high level of security management retains patients as EHR systems provide better security of confidential records. Certain users might be granted varying levels of access to patients' data to ensure that the sensitive files are protected and kept safe. The unauthorized individuals who aim to access the system will be restricted. The probability of valuable records being stolen by theft or hacker is lower. As a result, CDC has gained trust and built loyalty among patients.

## II. PROPOSING BI SOLUTIONS

Predictive analytics is one of the top business intelligence trends for the past two years in a row, but the potential applications extend well beyond business and far into the future. CDC can build a database for predictive analytics tools that would enhance care delivery. This is especially important in the case of individuals who have a complicated medical history and are suffering from various illnesses. The purpose of healthcare internet business intelligence is to assist doctors in making data-driven choices in seconds and improving patient care. The purpose of healthcare internet business intelligence is to assist health care agencies in making data-driven choices in seconds and improving the health of the United States citizens. CDC can also use BI tools to make a predictive diabetes analysis in detail. With these, we can clearly know the health of the United States citizens and identify the key factors about who are getting diseases. Then, CDC can find the best solution to reduce the Americans' diseases. However, new BI solutions and tools would also be able to anticipate who is at risk of diabetes, so it is advised on extra testing or weight control [8].

In addition to predictive analysis, BI tools may assist firms in analysing clinical data such as assessing lab test results, the incidence of unfilled prescriptions, and so on. This allows CDC to track disease entails determining what causes individuals to get ill as well as the most efficient measures to avoid illness. It can also assist local committees in determining which regions require further funding.

Moreover, business intelligence is a relatively recent concept that refers to the gathering and analysis of data to better business operations and strategic planning. This similar paradigm underpins healthcare business intelligence, but the data in issue is patient data obtained through several sources. Using the BI tools can improve the decision making and ensure the data quality [12]. Using BI tools can also quickly generate accurate reports. BI tools make it simpler and easier for businesses to develop and share dashboards and gather information [11]. For example, Tableau includes several ready-made templates for users in the healthcare agency, which aids in installation by allowing firms to easily drill down into their data. Healthcare BI software is a subset of BI software that is aimed specifically at the healthcare sector. These technologies increase the ability of medical experts to examine data obtained from various sources. These sources might include patient files and medical data, but they can also include extra information.

## III. DATASET ANALYSIS

The dataset used in this project is retrieved from National Health and Nutrition Examine Survey (NHANES) by CDC [3]. The author did some analysis on the dataset and found out that the dataset is a health record of diabetes chronic disease representing the United States population of all ages. The dataset consists of attributes describing various blood testing, body mass index (BMI) and other symptoms that could cause diabetes. Moreover, it is also found that the dataset does not contain any individual's personal information as health records are confidential information. Due to the NHANES Data Release and Access Policy, these records are designated

as classified official documents because they include private and personal information. Therefore, it must be given a high level of data protection.

### A. Description of Dataset

This dataset contains around 200,000 records with 22 attributes. The attributes and its data type as well as description are shown below (Table I):

TABLE I. DESCRIPTION OF DATASET

No	Attribute Name	Data Type	Description
1	Diabetes_012	Numerical (Interval Scale)	Disease status 0 = no diabetes 1 = prediabetes 2 = diabetes
2	HighBP	Boolean	Blood pressure 0 = no high BP 1 = high BP
3	HighChol	Boolean	Cholesterol 0 = no high cholesterol 1 = high cholesterol
4	CholCheck	Boolean	Cholesterol check 0 = no cholesterol check in 5 years 1 = yes, having cholesterol check in 5 years
5	BMI	Numeric (Continuous)	Value of body Mass Index based on patient weight and height
6	Smoker	Boolean	Have ever smoked more than 100 cigarettes (5 packs) in a lifetime 0 = no 1 = yes
7	Stroke	Boolean	Have ever experienced a stroke 0 = no 1 = yes
8	HeartDiseaseorAttack	Boolean	Have ever experiencing coronary heart disease (CHD) or myocardial infarction (MI) 0 = no 1 = yes
9	PhysActivity	Boolean	Physical activity within the past 30 days 0 = no 1 = yes
10	Fruits	Boolean	Consume fruit at least one or more times per day 0 = no 1 = yes
11	Veggies	Boolean	Consume vegetables at least one or more times per day 0 = no 1 = yes
12	HvyAlcoholConsump	Boolean	Heavy drinkers • Adult men – having more than 14 drinks per week • Adult women – having more than 7 drinks per week 0 = no 1 = yes
13	AnyHealthcare	Boolean	Have any type of health care coverage (health insurance, prepaid plans like HMO)

			0 = no 1 = yes
14	NoDocbcCost	Boolean	In the past 12 months, have you had a need to see a doctor but couldn't because of the cost? 0 = no 1 = yes
15	GenHlth	Numerical (Interval Scale)	Would you say that your overall health is: Scale 1-5 1 = excellent 2 = very good 3 = good 4 = fair 5 = poor
16	MentHlth	Numerical (Interval Scale)	In the last 30 days, how many days did you have poor mental health, including stress, depression, emotional issues? Scale 1-30 days
17	PhysHlth	Numerical (Interval Scale)	In the last 30 days, how many days did you have poor physical health, including physical illness and injury? Scale 1-30 days
18	DiffWalk	Boolean	Have trouble walking or climbing stairwells? 0 = no 1 = yes
19	Sex	Nominal Scale	Gender 0 = female 1 = male
20	Age	Numerical (Ratio Scale)	Level age category 1 = Age 18 to 24 2 = Age 25 to 29 3 = Age 30 to 34 4 = Age 35 to 39 5 = Age 40 to 44 6 = Age 45 to 49 7 = Age 50 to 54 8 = Age 55 to 59 9 = Age 60 to 64 10 = Age 65 to 69 11 = Age 70 to 74 12 = Age 75 to 79 13 = Age 80 or older
21	Education	Numerical (Ratio Scale)	Education level Scale 1-6 1 = Never attended school or only kindergarten 2 = Grades 1 through 8 (Elementary) 3 = Grades 9 through 11 (Some high school) 4 = Grade 12 or GED (High school graduate) 5 = College 1 year to 3 years (Some college or technical school) 6 = College 4 years or more (College graduate)
22	Income	Numerical (Ratio Scale)	Income Scale 1-8 1 = less than \$10,000 5 = less than \$35,000 8 = \$75,000 or more

### B. Data Cleaning

The practice of correcting or deleting inaccurate, damaged, improperly formatted, duplicate, or incomplete data from a dataset is known as data cleaning. There are numerous ways for data to be duplicated or incorrectly categorized when merging multiple data sources. Even if results and algorithms appear to be correct, they are unreliable if the data is inaccurate. Because the procedures will differ from dataset to dataset, there is no one definitive way to specify the precise phases in the data cleaning process. But it is essential to create a template for your data cleaning procedure so you can be sure you are carrying it out correctly each time. The following techniques demonstrate how the dataset is cleaned by using Microsoft Excel and RStudio.

Microsoft Excel provides a lot of functions to the user and allows the user to show the data analysis results in a variety of ways. The data analysis results can be displayed as charts that emphasize the significant points in the data, and the audience will immediately comprehend what you want to project in the data. Excel allows us to visualize the data to reveal hidden data and identify data patterns. Several features have been picked from the vast array to be used in this project.

- Checking Missing Values

Fig. 2. Filter function in excel.

Filter function is used to filter a range of data depending on the criteria you define (Fig. 2). The filter function allows users to filter out all the data in a column, allowing them to see an overview of the data values. Furthermore, use this method to determine whether there is a null value in the column.

Fig. 3. Find function in excel.

The find function allows the user to check the missing value (Fig. 3). After that put all the missing values as blank. It means the dataset occurs missing value if it manages to be replaced as a blank field. So, it is required to handle it when

there is a null value to ensure data accuracy and improve data quality.

- Remove Duplicate Data

Fig. 4. Remove duplicate function.

Duplicate data might be valuable in some cases, but it can also make it difficult to interpret your data (Fig. 4). To discover and highlight duplicate data, conditional formatting can be used. That way, you may go through the duplicates and determine whether to eliminate them. It allows you to select the formatting you wish to apply to the duplicate values in the box next to values with.

Fig. 5. Remove duplicates feature.

The duplicate data will be permanently removed if you utilize the Remove Duplicates feature (Fig. 5). Before deleting the duplicates, it's a good practice to transfer the original data to another worksheet so you don't lose any information inadvertently. It is also more convenient for users to remove all the duplicate data. It will remove all the duplicate values and remain unique.

Fig. 6. Remove all duplicates.

As a result, used this method to retrieve the unique value efficiently and quickly from the specified column (Fig. 6). Besides, this function can ensure all the data quality to generate a better virtualization. Duplicating tough checks by humans is inefficient and time consuming. In the worst-case scenario, it is the result of human error.

Furthermore, RStudio is used as well for data cleaning as is an Integrated Development Environment (IDE) that provides a one-stop solution for all statistical computation and graphics. It is a powerful and simple way to engage with R programming. The RStudio is a more advanced version of R that has a multi-pane window setup that allows users to access all the important info on a single screen (such as source, console, environment & history, files, photos, graphs). RStudio was used in this project because various activities

required the use of the R language to help in the visualization and pre-processing of data. The data may be noisy, contain outliers, or simply contain inaccuracies that must be dealt with to increase completeness and compellability. R has excellent data wrangling support. Packages such as dplyr and readr can convert unstructured data into structured data. Therefore, it can improve the efficiency of data pre-processing.

- Handle missing value

```
#=====Identify missing value=====#
#Calculate total missing values
sum(is.na(diabetes))
mean(is.na(diabetes))#Percentage of missing values
colSums(is.na(diabetes))
```

Fig. 7. Handle missing values.

This function identifies the missing value in our dataset (Fig. 7). The sum(is.na()) function shows us how many total missing values there are in this data frame. The mean(is.na()) function displays the overall proportion of missing values in this data collection. Before deal with missing values, must first figure out which columns have missing values. Therefore, may use the colSums(is.na()) function to check.

- Replace missing value with mean

```
#Replacing the missing value with mean
meanAge <- mean(diabetes$Age, na.rm=TRUE)
meanAge
format(round(meanAge, 0), nsma11 = 0)
diabetes$Age[is.na(diabetes$Age)] <-format(round(meanAge, 1), nsma11 = 1)
```

Fig. 8. Replace missing value.

This function will be used when wants to replace the missing value with mean (Fig. 8). It'll start by calculating the mean of the value, then use the format() function to round it to the nearest integer. The is.na() function checks each value to see whether it is NA, and if it is, it replaces the NA values with mean.

- Remove missing value

```
#Remove the missing value
diabetes <- diabetes %>% drop_na(Diabetes_binary)
```

Fig. 9. Remove missing value.

This function will remove any missing values in a specific column (Fig. 9). Pipe operator (%>%) is used to connect the datasets and the select function. The drop\_na() function drops rows that have a missing value in the Diabetes binary columns.

- Remove duplicated data

```
#=====Check duplicate data=====#
duplicated(diabetes)
sum(duplicated(diabetes))
#delete duplicated rows
diabetes <- diabetes %>% distinct()
```

Fig. 10. Remove duplicated data function.

This function removes any duplicated rows from the data frame (Fig. 10). The sum(duplicated ()) function displays the total number of duplicated data in this data frame. The distinct() function can be used to keep just unique or distinct

rows from a data frame. Only the first row is kept if there are duplicate rows.

- Remove outliers of data

```
#-----Identify the OUTLIERS-----#
outvals = boxplot(diabetes$BMI, main = "Boxplot of BMI")$out
#Remove outliers
q1 <- quantile(diabetes$BMI, 0.25)
q3 <- quantile(diabetes$BMI, 0.75)
iqr <- IQR(diabetes$BMI)
diabetes <- subset(diabetes, diabetes$BMI > (q1 - 1.5 * iqr) & diabetes$BMI < (q3 + 1.5 * iqr))
```

Fig. 11. Remove outlier data.

Fig. 12. Boxplot of BMI before and after removing outliers.

Box plots graphically represent the distribution of numerical data and skewness by displaying data quartiles and averages, which can be used to identify outliers within a data collection (Fig. 11 and 12). When analyzing a box plot, an outlier is defined as a data point that lies outside the whiskers of the box plot. The subset() function is then used to remove the BMI values that are more than 1.5 times the interquartile range above the upper quartile and less than 1.5 times the lower quartile (Q1 - 1.5 \* IQR) & (Q3 + 1.5 \* IQR).

- Analysis of data frame's value

```
summary(diabetes)
table(diabetes$Diabetes_012)
```

Fig. 13. Summary function.

```
> table(diabetes$Diabetes_012)
 0      1      2
190055 4629 35097
```

Fig. 14. Table function.

The summary() and table() functions are used to construct and provide the summarized result to the user (Fig. 13 and 14). It is especially handy when the user wants to know the frequency of occurrence of each value in a specific column or data frame. According to the figure above, the table() function is used to analyze the Diabetes 012 column by generating a result in terms of how frequently each value occurs.

```

Fig. 15. Summary function result of diabetes dataset.

The summary() function can be used to generate a summary of the entire data frame by listing out its columns

and displaying the data quartiles, min, max, and average for each variable (Fig. 15).

- Read and Write function

```
#####Read Data#####  
diabetes <- read.csv("C:\\Users\\User\\Downloads\\diabetes_012_health_indicators_BRFSS2015.csv")  
#####Write Data#####  
write.csv(diabetes,"Diabetes.csv",row.names = FALSE)
```

Fig. 16. Read and write function.

These functions are used to read a csv file from the folder that was imported into RStudio and save it to a variable, as well as to export an analyzed data frame from RStudio to a csv file and save it to our computer (Fig. 16). The read.csv function in the code above attempts to read the csv file from the folder and load it into the diabetes variable as a data frame. After completing the data pre-processing, the write.csv function may be used to write the clean diabetes data frame into a csv file called "Diabetes.csv" and exported to a folder.

### C. Data Modeling

Data modelling is the act of developing a visual representation of an entire information system or certain components of it to convey relationships between various data points and organizational structures. The objective is to provide examples of the different types of data that are used and stored inside the system, their relationships, possible groupings and organizational structures, formats, and attributes.

An algorithm is a group of calculations and heuristics used in data mining (also known as machine learning) to build a model from data. The algorithm initially examines the data you submit, searching for kinds of patterns or trends before building a model. In numerous iterations, the algorithm uses the findings of this research to choose the best parameters for building the mining model. The full data collection is then subjected to these criteria to extract useful patterns and thorough statistics. In this section, the algorithm used include decision tree, support vector machine (SVM) and Naïve Bayes algorithm.

1) *Decision tree*: A supervised learning approach that works with both discrete and continuous variables is a decision tree. The dataset is divided into subgroups based on the dataset's most important attribute. The algorithms determine how this attribute is identified by the decision tree and how this splitting is carried out. The root node, which represents the most important predictor, splits into decision nodes, which are sub-nodes, and terminal or leaf nodes, which do not further split.

2) *Support Vector Machine (SVM)*: Finding a hyperplane in an N-dimensional space (N is the number of features) that categorizes the data points clearly is the goal of the support vector machine algorithm (Fig. 17). There are a variety of different hyperplanes that might be used to split the two classes of data points. Finding a plane with the greatest margin, that is, the greatest separation between data points from both classes. Maximizing the margin distance adds some support,

increasing the confidence with which future data points can be categorized.

Fig. 17. SVM algorithm.

3) *Naïve Bayes algorithm*: Naïve Bayes algorithm is a classification method built on the Bayes Theorem and predicated on the idea of predictor independence. A Naive Bayes classifier, to put it simply, believes that the presence of one feature in a class has nothing to do with the presence of any other feature. The formula for Bayes' theorem is as follows (Fig. 18):

$$P(A|B) = \frac{P(B|A)P(A)}{P(B)}$$

Fig. 18. Calculation for Bayes' theorem.

- The posterior probability, or P(A|B), measures the likelihood that a given hypothesis (A) will really occur.
- P(B|A) stands for Likelihood Probability, which measures how likely it is based on the evidence at hand that a given hypothesis is correct.
- Priority probability, or P(A), is the likelihood of a theory before seeing the evidence.
- The probability of evidence is marginal probability, or P(B).

## IV. BUSINESS INTELLIGENCE ARCHITECTURE

A business intelligence architecture is the structure that an organization uses to operate business intelligence and analytics applications. It covers the information technology systems and software tools used to gather, combine, store, and analyze BI data before presenting it to high-level executives and other business users as information on daily operations and statistics. The underlying BI architecture is a critical component in implementing an effective business intelligence program that makes data analysis and reporting to assist an organization in tracking business performance, optimizing business processes, identifying new revenue opportunities, improving strategic planning, and providing better decisions overall [4].

Putting such a framework in place helps the healthcare BI team to operate in a coordinated and organized manner to construct an organizational BI solution that fulfils the data analytics requirements of its company. The BI architecture also assists BI and data managers in developing an effective method for processing and handling data that is delivered into the environment (Fig. 19).

Fig. 19. Proposed BI architecture.

- Data source

These are all the sources that gather and store the data specified as important for the enterprise BI program such as EPR, PRM, radiology, insurance and so on. Secondary sources, such as patient databases from third-party information providers, might also be included. As a result, both internal and external data sources are frequently included in BI architectures. Data relevance, data validity, data quality, and the amount of information in the accessible data sets are all important factors in the data source selection process. Furthermore, to fulfil the data analysis and decision-making requirements of executives and other business users, a combination of structured, semi - structured and unstructured data types may be necessary.

- ETL (Extract, Transform and Load)

ETL is a data integration process that integrates data from numerous data sources into a single, consistent data repository that is then put into a data warehouse. ETL cleanses and organizes data using a set of business rules to fulfil business intelligence objectives, such as monthly reporting, but it may also handle more complex analytics to enhance back-end operations or end user experiences.

- Data Storage

This contains all the repositories where BI data is stored and handled. The most common is a data warehouse that holds structured data in a relational or multidimensional database and allows easy access for querying and analysis. Data warehouse can be linked to smaller data marts which are created for departments data customized to their BI requirements.

- Analytics

In the step, the focus will be on data analysis after handling, processing, and cleaning the data in the previous steps with the aid of a data warehouse. The analytics layer is a series of steps that comprise a toolbox that can be used for any form of analytics. BI application tools are used to meet the pervasive demand for successful analysis to enable organizations of all sizes to develop and earn profit. The four big data analytics techniques include classification, prediction, clustering, and association rules. Besides, a set of technologies may be implemented into a BI architecture to evaluate data and deliver information to business users such as ad hoc query, OLAP and data mining, BI. Specifically in the case of ad hoc query analysis, which allows for higher freedom, flexibility as well as usability in conducting analysis and assisting in the rapid and correct response to crucial business

problems. Moreover, the increased use of self-service BI tools allows managers and business analysts to execute queries on their own rather than depending on members of the BI team to do so. In addition, data visualization tools are also included in BI software and can be used to produce graphical representations of data such like graphs, charts, diagrams and so on to show patterns, outlier elements, and trends in datasets.

- Optimization

In general, an optimization process refers to any process that systematically proposes a better solution and results than previously used solutions. It is the practice of fine-tuning a process to optimize a collection of parameters while keeping within a series of constraints. The main purpose of process optimization is to provide more options for modifying the analytics layer's findings. The optimization block comprises a variety of approaches ranging from mathematical programming to gradient methods and stochastic to distributed.

- Presentation

This layer contains tools that present information to different users in a variety of forms. In the presentation layer, the type of technology includes dashboards, reports, and portals. All these information delivery tools allow business users to see the results and insights of BI and analytics applications for additional data analysis through built-in data visualization and the usual self-service capabilities. Executives and managers who want a broad picture of their organization's performance might use data visualization tools such like dashboards. A dashboard is a handy tool that lets users view data using graphs or charts, colored metrics as well as tables. Furthermore, users may also enable users to visualize more specific information regarding key performance indicators (KPIs) in their organizations. With the help of dashboards, they can more effectively track their progress towards setting goals. Besides, web portals refer to software that makes surfing the internet easier. By using the proposed BI architecture, they can retrieve files in file systems belonging to the Healthcare company or information given by web servers in private networks. Dashboards and web portals may both be configured to enable real-time data access with flexible views and drill-down capabilities. Reports have a more static framework for presenting data.

## V. DATAWAREHOUSE AND OLAP MODEL

The dimensional model above determined the simplest type of data warehouse schema, which is the star schema. This schema is commonly used to design or construct a data warehouse and dimensional data marts. In a data warehouse, a star schema can include one fact table and a series of interconnected dimension tables in the center. In the star schema above, the fact table includes keys to the five-dimension table such as Patient\_ID, Living\_ID, Disease\_ID, HealthCheck\_ID, Service\_ID and other attributes like BMI (Body Mass Index) and diagnostic status. The following are the list of attributes in each of the dimension table:

- Patient dimension table: Sex, Age, Education and Income
- Health service dimension table: AnyHealthcare, NoDocbcCost, CholCheck
- Health check dimension table: High BP, HighChol, GenHlth, MentalHlth, PhysHlth, DiffWalk
- Disease dimension table: Stroke, HeartDiseaseOrAttack
- Living habit dimension table: Smoking, PhysActivity, Fruits, Veggies, HeavyAlcoholConsump.

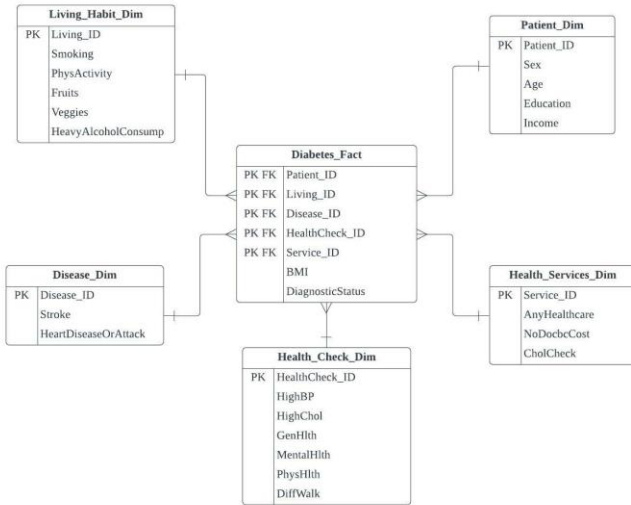

Fig. 20. Star schema.

The advantage of star schema is that all OLAP systems implement the star schema to efficiently create OLAP cubes (Fig. 20). In contrast, many OLAP systems have a ROLAP mode of operation that allows users to use a star schema as a source without having to create a cube structure. Moreover, star schema gains in query performance when compared to fully normalized schemas as it can give improvements in performance for read-only reporting applications.

### VI. DASHBOARD VISUALIZATION

There are two dashboards created for this project which are the diabetes analytics dashboard and patient analysis dashboard. By providing it with a visual context via maps or graphs, data visualization helps us understand what the information means. As a result, it is simpler to spot trends, patterns, and outliers in enormous data sets since the data is easier for the human mind to understand.

#### A. Dashboard for Diabetes Analysis

A dashboard refers to an electronic tracking tool that organizations use to present and summarize their data collection. The dashboard in Fig. 21 shows the information about the overall diabetes analytics according to the Centers for Disease Control and Prevention (CDC). CDC may use a dashboard to determine the rates of diagnosed diabetes, prediabetes, and no diabetes in the general population as well as the leading causes of diabetes. For example, it displays the

number of patients’ diagnostic statuses based on their status of smoking, stroke, heart disease or attack, blood pressure and cholesterol as well as physical activity. Moreover, the dashboard enables CDC to keep track of their patient’s health conditions, so that they can predict the risk and early signs of diabetes and provide the appropriate treatment.

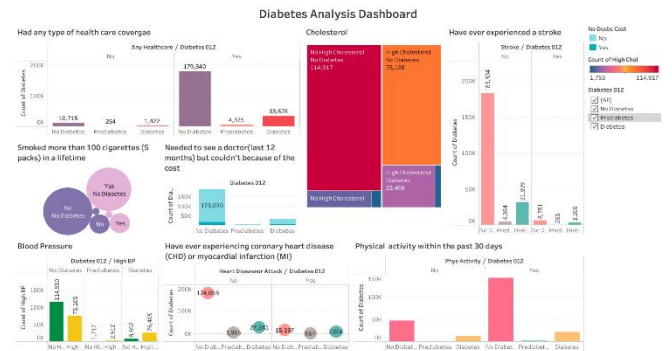

Fig. 21. Diabetes analysis dashboard.

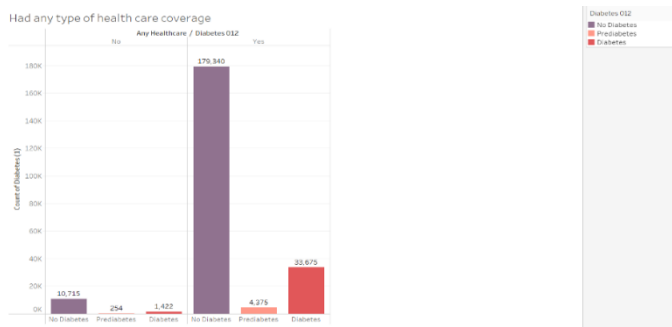

Fig. 22. Healthcare coverage on patient’s diagnostic status.

According to the Fig. 22, a side-by-side bar graph has been used to categorize and present data that results from classifying a group of things based on two or more factors. It shows the number of patients who have or have not had health care coverage based on the patient's diagnostic status (no diabetes, prediabetes, diabetes). The bar graph depicts the patient's diagnostic status using three different colors. Patients without diabetes are represented by purple, those with prediabetes by light pink, and those with diabetes by red. Based on the graph, the number of patients without diabetes with healthcare coverage is 179,340, which is dramatically more than the number of patients without diabetes with healthcare coverage, which is 10,715. As a result, can conclude that patients who have healthcare coverage, such as health insurance or prepaid plans like HMO, can help with diabetes prevention.

The stacked bar graph in Fig. 23 is used to show the count of the patients’ diagnostic status (no diabetes, prediabetes, diabetes) based on the NoDocbcCost in the last 12 months. A stacked bar graph is a type of graph which is utilized to divide and compare parts of a whole. Each bar in the graph represents a whole, and each section represents a different part or category of that whole. The various categories in the bar are represented by different colors. Light blue for no (the patient could see the doctor without worrying about the cost) and dark blue for yes (the patient could not see a doctor because of the

cost). Based on the graph, the number of patients without diabetes who could see a doctor without being concerned about the cost is 173,070, which is noticeably higher than the number of patients without diabetes who could not see a doctor due to the cost, which is 16,985. In addition to that the number of diabetic patients who could see a doctor without worrying about the cost is 31,355, which is higher than the number of diabetic patients who could not see a doctor because of the cost, which is 3,742. As a result, can conclude that most patients do not have to be worried about the cost of seeing a doctor, and that it has little impact on a patient's risk of developing diabetes.

Fig. 23. Count of patients' diagnostic status based on medical fees.

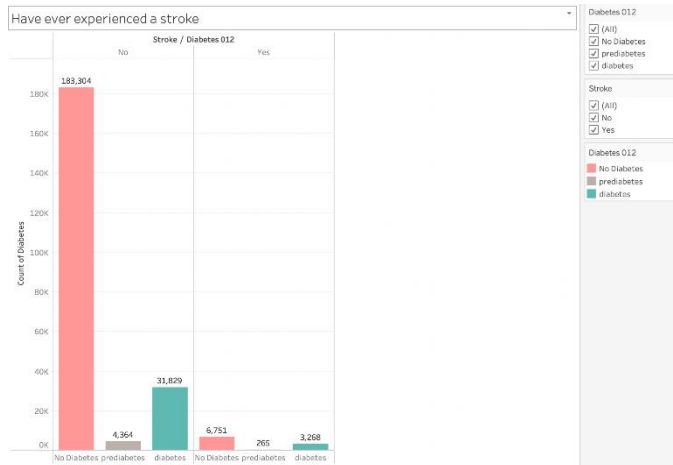

Fig. 24. Patients' diagnostic status based on stroke.

Fig. 24 represents the patients' diagnostic status which includes no diabetes, prediabetes, diabetes based on stroke and non-stroke. There are two categorical variables which are displayed using the side-by-side column graph. A side-by-side column graph is used to illustrate two category variables. The results collected when the patients are classified according to diagnostic status (no diabetes, prediabetes, diabetes) and the state of stroke (has stroke, no stroke) are displayed in the side-by-side column graph above. The bar graph uses three unique colors to indicate the patient's diagnostic status which is categorized by the diabetes status. Pink color for no diabetes, grey color for prediabetes and green color for diabetes. The filter option in the upper right corner can help you select and display only the data you want to view, making comparison and analysis easier as well. Furthermore, also observe that no diabetes has the highest count within no diabetes which is

183304 out of 219497, and no diabetes has the highest count within stroke which is 6751 out of 10284. Besides that, can see that the number of patients with diabetes and prediabetes who have no stroke is higher than the number of patients who have stroke, reaching 36193 respectively, compared to the number of patients who have heart disease and attack, which is 3798. To conclude, stroke is not the main reason to get diabetes because the number of patients with non-stroke is higher than the patients with stroke.

Fig. 25. Patients' diagnostic status based on heart disease.

Fig. 25 represents the patients' diagnostic status which includes no diabetes, prediabetes, and diabetes, based on whether the patient has heart disease and attack, and non-heart disease and attack. A Multi-Category Chart is useful when you have data for components that fall into multiple categories. With this, can show comparative data in more than one category. You can distinguish various states based on their varied colors using the card in the upper right corner. Based on the graph above, pink represents no diabetes, grey represents prediabetes, and green represents diabetes. It shows that the highest count inside no diabetes is 174 858 out of 206064, while the greatest count within stroke is 15197 out of 23717. Patients who get heart disease and attack with no diabetes accounted half of the total. However, can observe that the count of diabetes and prediabetes in no heart disease or attack is higher than the patients who had heart disease or attack, reaching 31377 respectively, compared to the count of those who have heart disease and attack, which is 8520. From this, it can be stated that heart disease rarely affects diabetes.

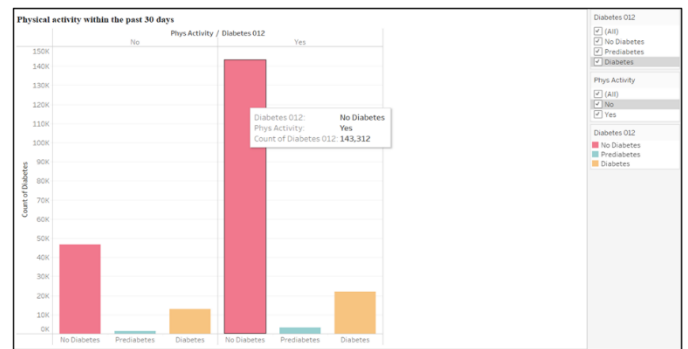

Fig. 26. Patients' diagnostic status based on physical activity.

Fig. 26 depicted the count of patients' diagnostic status (no diabetes, prediabetes, diabetes) based on physical activity and no physical activity. The two categorical variables are displayed using side-by-side column graph. A side-by-side column graph can be used to organize and present data that results from categorizing a group of people or things using two or more criteria. For example, the side-by-side column graph above displays the data obtained when patients are categorized according to diagnostic status (no diabetes, prediabetes, diabetes) and state of exercise (has physical activity, no physical activity). The bar graph uses three unique colors to indicate the patient's diagnostic status. According to the legend, the pink column represents patients who do not have diabetes, the green represents patient who have prediabetes, and yellow represent patients who have diabetes. The filter option in the right corner can assist in filtering and displaying only the data that you want to see, making comparison and analysis easier. Based on the graph, it demonstrates that the number of patients without diabetes who engage in physical activity is 143312, which is significantly higher than the number of patients without diabetes who do not engage in physical activity, which is 46743. From this, it can be assumed that physical activity can aid in the development of resistance and the prevention of diabetes.

Fig. 28. High blood pressure status based on patient's diagnostic status.

Fig. 28 shows the count of high blood pressure and no high blood pressure based on the patient's diagnostic status (no diabetes, prediabetes, diabetes). A side-by-side bar graph is used to organize and present data that results from categorizing a group of things according to two or more criteria. The bar graph displays two distinct colors to depict whether the patient has blood pressure. Patients with no high blood pressure are represented by green, while those with high blood pressure are represented by yellow. From this graph, the number of patients without diabetes and having high blood pressure is 75105 which is much lower than the number of patients without diabetes and no high blood pressure at 114950. However, it depicts that for prediabetic and diabetic patients, the count of high blood pressure is relatively high, reaching 2912 and 26405 respectively, compared to the count of no high blood pressure, which is 1717 and 8692.

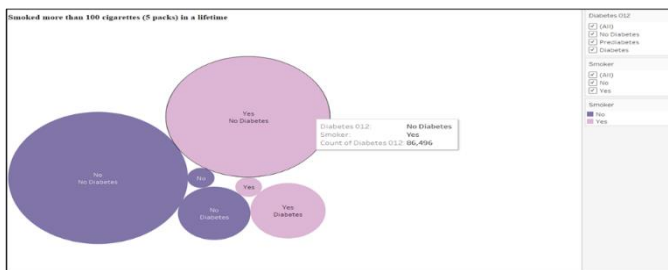

Fig. 27. Association between the diagnostic status and smoking.

In Fig. 27 above, a cluster of circles represents the association between the diagnostic status (no diabetes, prediabetes, diabetes) and smoking. To make the best use of space, the bubbles are packed in as tightly as possible. The individual bubbles are defined by the category field, and the bubble size is represented by the value field. Above, it shows at diagnostic status and smoking. While, can't control how the bubbles are arranged, but can control how big they are by putting a measure on size, in this case, and use the count of diagnostic status. The size of the bubbles represents the count of diagnostic status for various combinations of diagnostic and smoking status. This function is especially beneficial since the size of the bubble clearly shows the difference between them. The larger the circle, the larger is the proportion of the total. When a legend field is assigned to the Packed Bubble chart, the grouping mode is selected by default. It colorizes and divides the bubbles further based on the legend field. The color scheme is classified into two categories: smokers and non-smokers. According to the graph, most diabetic patients are heavy smokers (18223), while the majority of non-diabetic patients are non-smokers. Therefore, may conclude that smoking has a significant impact on causing diabetes.

Fig. 29. High cholesterol status based on patient's diagnostic status.

As depicted in Fig. 29 above, it shows high cholesterol and non-cholesterol counts according to the patient's diagnostic status. The tree map is a visual representation consisting of nested rectangles. These rectangles indicate different categories within a given dimension and are arranged in a tree-like hierarchy. The tree map chart displays various distinct colors to distinguish between high cholesterol and non-

cholesterol in different diagnostic statuses. When looking for insights in a tree map, the largest box represents the largest portion of the entire, while the smallest box represents the smallest portion.

Fig. 30 below depicts the total number of no high cholesterol and high cholesterol for each diagnostic status such as no diabetes, prediabetes, and diabetes. From this table, we can analyze whether high cholesterol has a strong effect on causing diabetes.

High Chol	No Diab..	Prediab..	Diabetes
No High Cholesterol	114,917	1,755	11,601
High Cholesterol	75,138	2,874	23,496

Fig. 30. Total number of high cholesterol status for each diagnostic status.

### B. Dashboard for Patient Analysis

The spreadsheets and dashboards shown below are mainly focused on patient-related data, starting from the patient's gender, age group, education level and their income. The purpose is to obtain a broad perspective of patient's personal information and acquire relevant knowledge for Centers for Disease Control and Prevention (CDC) management to analyze whether these personal factors will cause diabetes and may use that as a reference to make a better decision for prevention.

Fig. 31. Patient based on age group.

In Fig. 31 above represented the horizontal bar of patient based on their age group separated by gender. The stacked bar graph can differentiate the gender based on their distinct colors, which is described at the card on the top right corner. If click one of the genders in the horizontal bar chart, it will direct us to another worksheet which is specifically filter out based on the gender have chosen by using filter action.

The figures are the age group filtered out by gender (Fig. 32). The left figure represents the age group by male while the right figure represents the age group by female. Tableau action filters enable us to transfer information between worksheets (Fig. 33). Generally, when you choose marks from one worksheet, that information is sent to other worksheets, resulting in the display of the relevant information. Behind the scenes, action filters deliver data

values from appropriate source fields to the destination worksheet as filters. By implementing this function, the CDC management will be able to identify and focus the age groups based on gender.

Fig. 32. Total number of high cholesterol status for each diagnostic status.

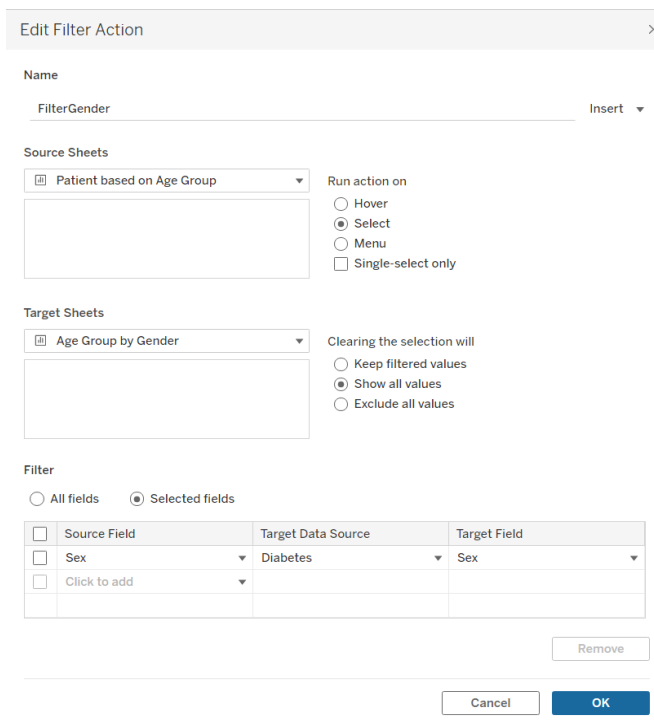

Fig. 33. Filter action in tableau.

Fig. 34. Patient based on gender.

The pie chart above (Fig. 34) shows the number of patients based on gender. The pie chart displays two different colors, each representing a gender. Male is represented by blue, while female is represented by pink. This provides a general

estimate of the proportion of male and female customer patient collected from the database. The figure can clearly find that male has a greater number than female, which male has several 128,854 and 100,927 for females.

Fig. 35. Education level.

Fig. 35 above determines the highest education level patient had taken. There are six level of education which are never attended school or only kindergarten, Grade 1 through 8, Grade 9 through 11, Grade 12 or General Education Diploma (GED), College 1 year to 3 years, College 4 years or more. It basically shows whether the level of education play a role in diabetes. For instance, the number of patients whose highest education level is 4 years college or more and does not diagnose with diabetes are 76,746 people. Studies shows that education levels may increase the adoption of health behaviors such as sufficient eating and medication adherence. As a result, it is likely that education levels work as a fundamental cause of disease by using resources such as knowledge, which have a substantial effect on people's ability to decrease risks that may prevent or delay diabetes or better treat the disease once it comes.

Fig. 36. Income level.

Fig. 36 above determines the whether the patient has a time in the past 12 months when needed to see a doctor but could not be due to the cost of treatment based on their income level. Studies shows that people who have low income likely to have a higher risk of diagnose with diabetes. It can find there is a big different between the side-by-side circle visualization. As a result, this can be assumed that most patients who have an income of \$75,000 or more do not have to worry about the treatment cost, that is, 69,117 people (see Fig. 37).

Fig. 37. Patient analysis dashboard.

## VII. CONCLUSION

The goal of Business Intelligence is to assist and enable better business decisions. BI provides organizations with access to information that is crucial to the success of a variety of areas and departments. Effectively integrating BI will give the organization with more actionable data, valuable insights into market trends, and a more strategically orientated decision-making approach. In this project, the author has investigated Centers for Disease Control (CDC) to create a BI solution for them to make better decision after visualization the insight from the dataset.

Before visualizing the data, author must do some in-depth research on the domain background, their problem, and opportunities, create a project charter, data identification, designing BI logical architecture as well as data warehouse model. Once all of this has been done, the author will start building dashboards that can develop insights to the executive and assist them in making a better decision by using Tableau. Tableau is a powerful tool for quickly creating interactive data visualizations and user-friendly. The author has created 2 dashboards which contain patient information analysis and health information analysis.

Finally, BI solution is important as it aids in the production of reliable reports by collecting data directly from the data source. Today's BI solutions minimize the time-consuming effort of manually aggregating data since BI technologies provide up-to-date data, executives can monitor firms in real time. As a result, the author thinks that the project's results might be improved further for developing a best-fit BI solution and data visualization for CDC. With the enhancement and improvement, it will undoubtedly assist CDC in striving for greater opportunities in terms of patients, health and so on.

# Augmented, Virtual and Mixed Reality Research in Cultural Heritage: A Bibliometric Study

Nilam Upasani<sup>1</sup>, Asmita Manna<sup>2</sup>, Manjiri Ranjanikar<sup>3</sup>

Balaji Institute of Technology and Management, Sri Balaji University, Pune, India<sup>1</sup>

Department of Computer Engineering, Pimpri Chinchwad College of Engineering, Pune, India<sup>2,3</sup>

**Abstract**—Heritage allows us to learn about the different monuments of importance and the inherited traditions from our ancestors. However, many times the monuments get partly ruined due to natural wear and tear, sometimes due to attacks by invaders. To preserve the cultural heritage virtually, many researchers have used augmented, virtual and mixed reality for bringing ancient environments to live in those heritage sites. This study aims to identify publications related to virtual, augmented and mixed reality in cultural heritage and to present the bibliometric analysis of these studies. The research articles on virtual, augmented, and mixed reality in cultural heritage are retrieved using the Scopus database. The analysis is performed using VOSviewer and various parameters such as bibliographic coupling of the countries, publications, journals, authors, and co-occurrences of the author keywords are performed. From the analysis done in this study, it is discovered that the augmented, virtual and mixed reality research in the domain of cultural heritage is mostly concentrated in Italy and surrounding European countries. However, it is also found that the research in this domain is lagging in many countries even if those countries are the homes of various heritage sites. This study provides an extensive analysis of the recent literature related to augmented, virtual and mixed reality research in cultural heritage. This information science based analysis will help researchers to identify the prominent journals in this domain, recognize stalwarts in this field and follow their works, find out path-breaking publications to refer to, and predict the direction of future studies.

**Keywords**—Augmented reality; bibliometric analysis; cultural heritage; information science; mixed reality; virtual reality

## I. INTRODUCTION

For the essential growth of a community, its history plays a vital role. Heritage allows us to learn about the history, culture and inherited traditions from ancestors by observing the monuments, archaeological sites, forts, historical city centres, museums, etc. [1][2][3]. Millions of tourists visit the historical sites every year to get a feel of individual and collective identity. It contributes to the cohesion of various cultures across the world. This feel of cohesion can be enhanced by combining the real and digital content to provide sensory experiences. Depending upon the involvement of the user in this virtual environment, the technologies can be classified into three types namely, immersive, non-immersive and semi-immersive.

Immersive technologies create a virtual world by combining the physical world with a digital or simulated reality such that the user feels that (s)he is actually engrossed in that

virtual world. On the other hand, non-immersive technologies also generate a virtual world for the user; however, the complete control of that virtual world lies with the user only. Semi-immersive technologies create a partial virtual environment that allows users to feel the virtually created world and remain aware about the physical surroundings simultaneously.

Augmented Reality (AR) is an immersive technology where real-world objects are upgraded with computer-aided non-cognitive visual and/or auditory information. Virtual Reality (VR) is a simulated experience that might be comparable to or wholly different from reality [4]. Mixed Reality (MR) is a combination of physical reality, AR, and VR. Virtual and mixed reality experiences can be fully immersive, semi-immersive or non-immersive. There are many applications of AR, VR and MR that include Education (such as medical or military training), Entertainment (such as movies, and video games), Business (such as virtual meetings), Tourism (virtual tours of cultural heritage and ancient structures sites), etc. [5].

Rejuvenating the demolished structures with augmented, and virtual reality helps the younger generation to understand the rich heritage of ancestral civilizations, their customs and traditions, the culture followed, and the stories of bravery and ethics. Storytelling using virtual reality enriches the learning experience of the young generation for exploring the rich heritage.

With the advent of mixed reality, countries having rich cultural heritage are coming up with mixed reality-based projects as well to preserve and protect their heritage architecture and assets.

### A. Motivation and Contribution

With more researchers taking up similar projects, especially to preserve the cultural heritage of respective countries, more and more young people are getting aware of their own culture and tradition. However, there is a lack of thorough analysis of the difficulties in the field's research or its future directions. This study is done to review the current status of research in cultural heritage connected to AR, VR, and MR.

Research objectives of this paper are to:

1) Compile the peer-reviewed articles and conference papers on applications of AR/VR in cultural heritage during the period of 1999 to 2022.

- 2) Ascertain the spread of this field using bibliometric coupling of publications, journals, and authors.
- 3) Understand which countries have the most publications in this area.
- 4) Which technologies were employed for the implementation of cultural heritage projects.

This is accomplished through the use of bibliometric analysis. As defined by Pritchard, bibliometrics is “the application of mathematical and statistical methods to books and other media of communication” [48]. In this study, bibliometric analysis has been carried out for classifying the publications based on AR/VR in cultural heritage. The bibliographic information, like citations, keywords, link strengths, countries, journals, and authors of a publication has been considered for the analysis. Good quality publications have been selected from the widely-used and well-recognized online Scopus database for this study. This database includes almost all the important research papers in this domain. After retrieving the data, the same has been analyzed using the bibliometric visualization tool called VOSviewer.

### B. Organization of the Paper

Section II presents a summary of cultural heritage projects where AR, VR, or MR has been deployed; Section III discusses the research methodology used for the bibliometric analysis; the results are analyzed in Section IV; Section V discusses the insights obtained from the results; are conclusions are available in Section VI.

## II. SUMMARY OF CULTURAL HERITAGE PROJECTS

This section presents a survey of various immersive, non-immersive, and semi-immersive projects implemented across the globe. The category-wise distribution is shown in Table I.

TABLE I. CATEGORIZATION OF CULTURAL HERITAGE PROJECTS

Project	Reference
Immersive	[6-8], [9-11], [12], [13-14], [15-16], [17], [18], [19-20], [21-22], [23-24]
Non-immersive	[25], [26], [27-28], [29], [30-31], [32-33], [34]
Semi-immersive	[35], [36-40], [41-42], [43], [44]

In the “Museum of Pure Form” [6-8] project, a virtual museum was created where users are allowed to have an immersive experience of interacting with an art piece by nestling before that art piece. A project entitled “CREATE” [9-11] was developed for creation and maneuvering of virtual worlds by using actual data source and integrating auditory and other haptic senses. Another research in Japan [12], included an interaction system with sight, hearing, smell, and touch for a digital museum. The “National Archaeological Museum” of Italy’s Marche offered a novel blend of actual and virtual settings, as well as an immersive solution, to improve the understanding, knowledge, and holistic perception of museum visitors [13-14]. A project called “The Feelies” attempted to create a multi-sensory solution in 2015 using virtual reality in theatre settings, with a focus on developing, filming, and distributing quality content [15-16]. The “Interactive Haptic System for Archery” was designed with the objective of constructing engineering solutions for training purposes

through virtual reality simulations, enabling users to engage in classical archery [17]. The project “Thresholds,” showcased in the UK and Turkey, generated a virtual world that could be researched in a space that was emulated in person keeping with the virtual scenario [18]. The project “Zelige Door on Golborne Road” in London emphasised the connection between interaction design and people’s perceptions by providing an augmented reality app with sensory technologies to overlay pre-recorded video and aromas [19-20]. The “M5SAR” project’s approach for a mobile multi-sensory AR system for museums aimed to create an AR system that could serve as a tour guide for historical and cultural events [21-22]. The project “SensiMAR” proposed an AR based mobile experience outdoors that would render additional information during searching an archeological location in Portugal [23-24].

The “Haptic Museum” was a groundbreaking experiment that provided visitors a non-immersive experience by providing an opportunity to study 3-D works of art by virtually “touching” those art pieces via the internet [25]. In the Civic Museum of Como, Italy, the temporary museum exhibit named “The Fire and the Mountain” was designed with the intention of promoting active and social learning through a variety of media and multi-sensory experience [26]. Commercial haptic devices were incorporated for visitors to observe, hear, and feel virtual equivalences of the actual objects for a virtual exhibition in Colombia [27-28]. A virtual museum called “Museu3I” was created to enable users to conduct virtual tours using haptic devices [29]. A project entitled “Hapto-visual and Auditory Rendering,” combined the senses of sight, hearing, and touch for museum visitors [30-31]. The multisensory study “The Reconstructed Historical City of Tomis,” was developed to provide various assistance with the help of haptic devices in Romania [32-33]. A study on one more project to provide a multisensory experience was presented in [34].

The “SenSpace” initiative, deployed and tried in the USA, employed tactile, auditory, and visual evidence to help users understand the Narcissus story of Greek mythology in a physical environment in a semi-immersive way [35]. The project “MediaEvo” is a gaming application to examine the rebuilt historical setting of the Middle Ages through VR [36-40]. Another semi-immersive project called “Virtual Kyoto” provided users an opportunity to experience the Gion Festival, in Japan, with the help of optic and tactile senses, high-quality festival music, and a virtual Yamahoko float ceremony in 3D [41-42]. Some more studies on the projects that improved user experience statistically are presented in [43-44].

As observed from Table I, most of the museum tour related projects are based on immersive technology and comparatively less work is done in non-immersive and semi-immersive areas. Digging down further, it can be found that these projects mainly rely on stimulating the optic senses of users, followed by the haptic, auditory, smell, and taste senses.

Other than the domain of museology, AR, VR has widely been used in the reconstruction of demolished / semi-demolished historical sites as well. One of the most talked about reconstruction project was the Rome Reborn project where the concept of virtual reality was used to demonstrate the urban development of ancient Rome [45].

To preserve the virtual heritage of the first Afro-American Church of the Indianapolis, USA, the 3D reconstruction project “Virtual Bethel” was taken up by Indiana University, USA [46].

Another ambitious 3D-reconstruction project of an ancient monument in Istanbul, Turkey was the “Virtual Hagia Sophia” developed by researchers from MIRALab at the University of Geneva [47].

From the above discussion, it can be understood that AR, VR and MR have widely been employed in the domains of 3D reconstruction and in providing immersive or semi-immersive experiences to tourists at different historical sites and museums. However, there is a dearth of comprehensive studies for ascertaining the spread of this field in terms of good journals, pathbreaking researchers, technologies used by various researchers, and so on and so forth. This study is aiming to find such answers.

### III. RESEARCH METHODOLOGY

The various databases available for retrieving the research work available in different domains are Scopus, ACM Digital Library, ERIC, IEEE Xplore, PubMed, ScienceDirect, Web of Science etc. Out of these databases, ERIC is specific to research articles related to Education, PubMed hosts papers related to medical science, IEEE Xplore hosts research articles related to engineering, while ACM Digital Library focuses primarily on Computer Science related articles. Scopus, ScienceDirect and Web of Science are multidisciplinary databases. For this bibliometric analysis, the Scopus database has been chosen as this is a widely accepted and reliable database. The database was searched on 11<sup>th</sup> August 2022 to find publications related to AR/VR in cultural heritage and 3D reconstruction.

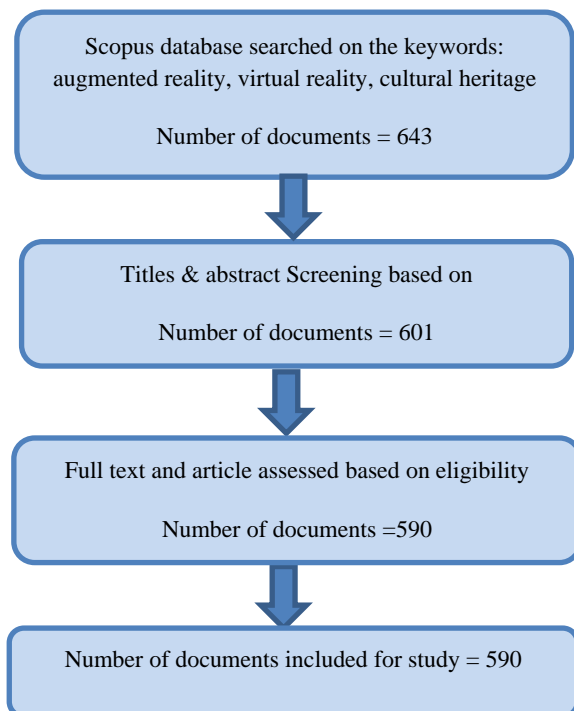

Fig. 1. PRISMA diagram.

Research articles in the duration of 1999 to 2022 have been considered for this study. Based on this search criteria, a total of 643 publications are acquired from the Scopus database. The author, affiliation, journal, year of publication, keywords, and counts of citations are all exported into CSV format for these 643 papers. However, a manual review is needed to assess whether all the retrieved publications are pertinent to the topic. The detailed process to finalize the list of documents as a part of the systematic review [49], is shown as a “Preferred Reporting Items for Systematic Reviews and Meta-Analyses” (PRISMA) flow diagram in Fig. 1.

As shown in Fig. 1, after scrutinizing the titles and abstracts of the papers, some of the publications related to 3D reconstructions in the medical surgery domain are removed resulting in 601 documents. Out of 601 documents, some are removed after full text analysis based on various parameters such as not sufficient data, no diagnostic criteria, etc. So, the final bibliometric analysis is presented based on 590 publications. The year-wise distribution of these documents is shown in Fig. 2.

Fig. 2. Year-wise distribution of the shortlisted documents.

From Fig. 2, it can be observed that even if the research started before the year 2000, it started getting more attention from the year 2015 and it gained actual momentum from 2018 onwards.

As per the study, VOSviewer and CitNetExplorer are among the most popular computer visualization tools for bibliometric analysis [50-53]. Here, we have used VOSViewer version 1.6.17 for constructing and visualizing the bibliometric networks for analyzing the bibliographic information, like citations, keywords, link strengths, countries, journals, and authors of a publication.

### IV. RESULTS

This segment discusses the results of various bibliometric analyses. The term ‘Bibliographic coupling’ was coined by Kessler in the early 1960s [54-56]. It is a method for grouping scientific and technical publications. In this paper, the Bibliographic coupling of countries, journals, authors, publications, and author keyword co-occurrences of identified publications, discussed in Section 2, are analyzed. The results are presented in such a manner that helps researchers to understand the linkage by starting with more general information like major countries contributing research in this

domain to more specific information such as the most cited author or keywords-coupling of different publications.

A. Bibliographic Coupling of the Countries

A bibliographic connection of the countries is shown in Fig. 3 and Table II, along with a network visualization. There is a ten-country restriction per document. A country's minimum requirement for publications is 12. Thirteen of the seventy-one countries met the requirements. For each country, the number of documents, citations, and total link strength is computed. The countries with the most total connections are selected. Italy came in first with 157 publications, 1489 citations, and 3398 overall link strength. Rest countries are; United Kingdom (53; 1546; 2533), Spain (45; 338; 2121), Greece (61; 733; 2027), Portugal (29; 151; 1757), France (27; 354; 1124), Australia (17;

348; 953), South Korea (25; 352; 917), Germany (28; 296; 722), China (30; 61; 641), Malaysia (12; 48; 601), United States (22; 120; 498), and Indonesia (13; 39; 154). The first figure inside the parentheses indicates the number of documents, the second indicates the total citations, and the total strength of the other nations' links is indicated by the third figure.

Different colours in Fig. 3 represent different clusters that are more commonly related to one another. It indicates that studies from nations in the same cluster are more likely to cite each other. Spain, Portugal, France, Germany, Greece, UK, and China, make up the largest cluster. The second cluster includes Australia, Indonesia, Italy, and Malaysia. The third cluster includes South Korea and the United States.

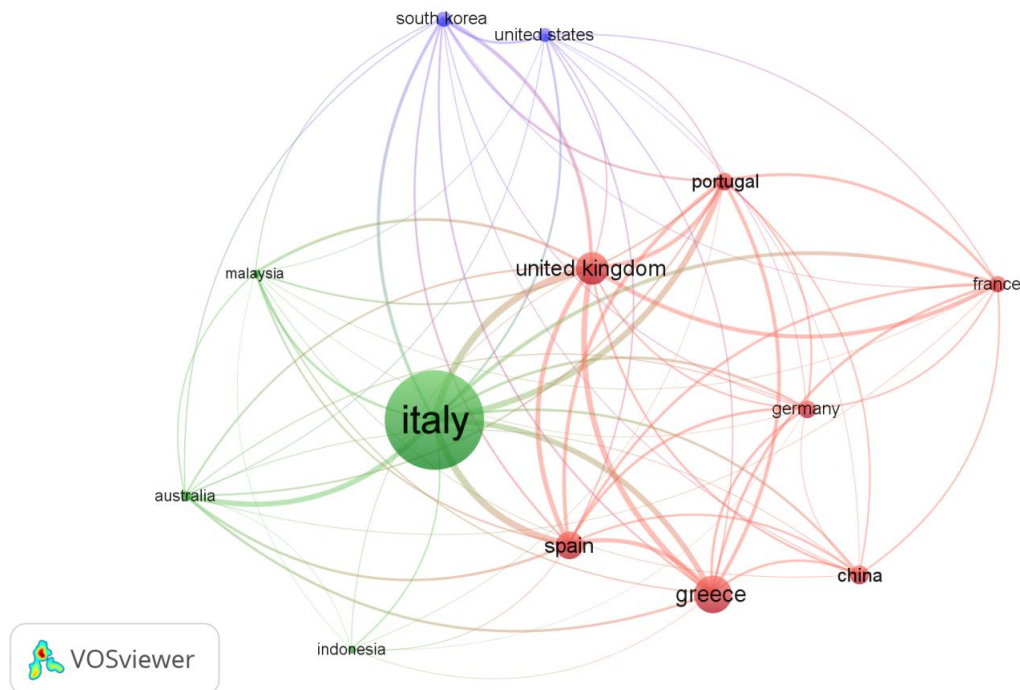

Fig. 3. Countries bibliographic coupling (network visualization).

TABLE II. COUNTRIES BIBLIOGRAPHIC COUPLING

Country	Documents	Citations	Total link strength
Italy	157	1489	3398
United Kingdom	53	1546	2533
Spain	45	338	2121
Greece	61	733	2027
Portugal	29	151	1757
France	27	354	1124
Australia	17	348	953
South Korea	25	352	917
Germany	28	296	722
China	30	61	641
Malaysia	12	48	601
United States	22	120	498
Indonesia	13	39	154

### B. Bibliographic Coupling of the Journals

The bibliographic connection of the journals with density visualization is depicted in Fig. 4. As an inclusion criterion, the journal should have at least a specific number of articles. Only ten journals out of 288 passed the test. For those ten journals, the number of articles, citations, and total strength of bibliographic coupling relationships with other journals are calculated. The journals with the most total link strength are chosen and arranged as per the total link strength as shown in Table III.

Each circle in Fig. 4 depicts a journal, with varying colors representing the density of the journal. The density visualization is weighted based on the number of articles for each journal. The colors shifting to yellow and then red indicate that the associated journal has published more articles.

With 94 publications, 711 citations, and 647 total link strengths, the Lecture Notes in Computer Science series is the

most popular. The “Journal on Computing and Cultural Heritage” is ranked second in terms of citations (396), overall link strength (429), but fifth in terms of content count (13 publications).

The second-highest number of articles (26), with the third-highest citations (202) and a link strength of 137, are published in “International archives of photogrammetry, remote sensing, and spatial information sciences”.

### C. Bibliographic Coupling of the Authors

Fig. 5 uses overlay visualization to demonstrate the authors' bibliographic connection. An author needs to have a minimum of six publications to be considered for this study. Only ten authors are chosen from a total of 1672. For each author, the number of documents, citations, and total link strength is calculated. The authors with the most total link strengths are chosen and arranged as per the total link strength as shown in Table IV.

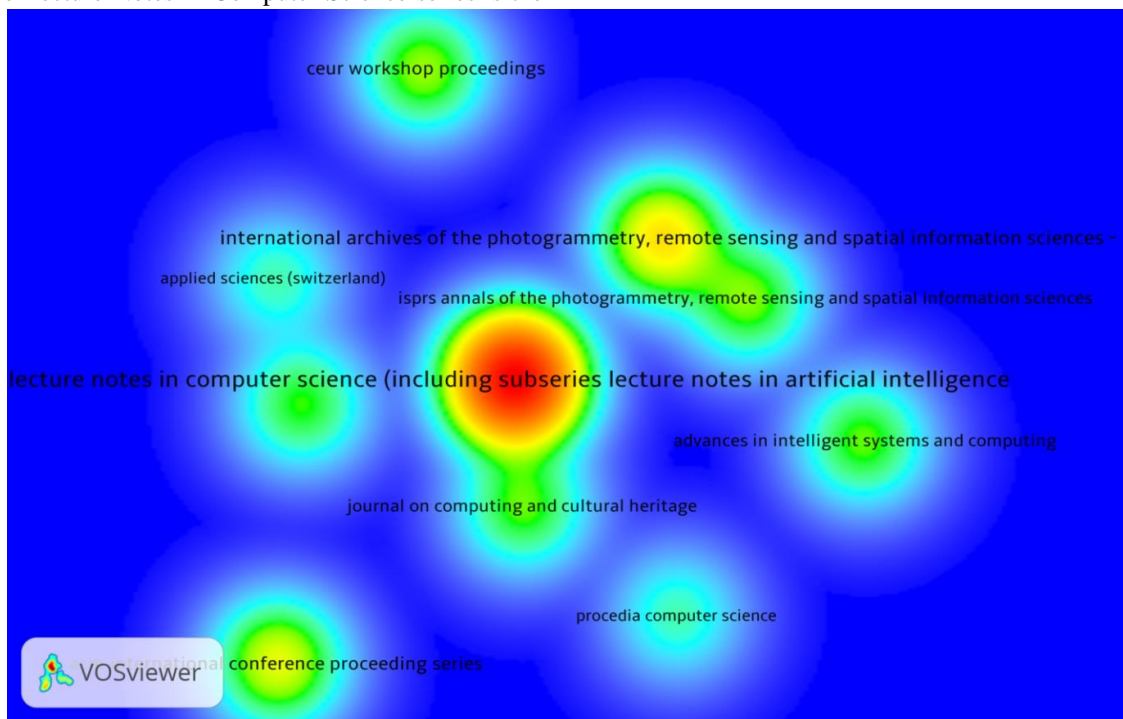

Fig. 4. Journals' bibliographic coupling (density visualization).

TABLE III. JOURNALS' BIBLIOGRAPHIC COUPLING

Source	Documents	Citations	Total link strength
“Lecture notes in computer science”	94	711	647
“Journal on computing and cultural”	13	396	429
“Applied sciences (Switzerland)”	7	28	263
“ACM international conference proceedings”	20	118	172
“ISPRS annals of photogrammetry, remote sensing, and spatial information sciences”	14	61	164
“Communications in computer and information science”	12	21	153
“International Archives of the photogrammetry, remote sensing, and spatial information sciences”	26	202	137
“Advances in intelligent systems and computing”	13	20	98
“CEUR workshop proceedings”	15	27	73
“Procedia computer science”	7	31	56

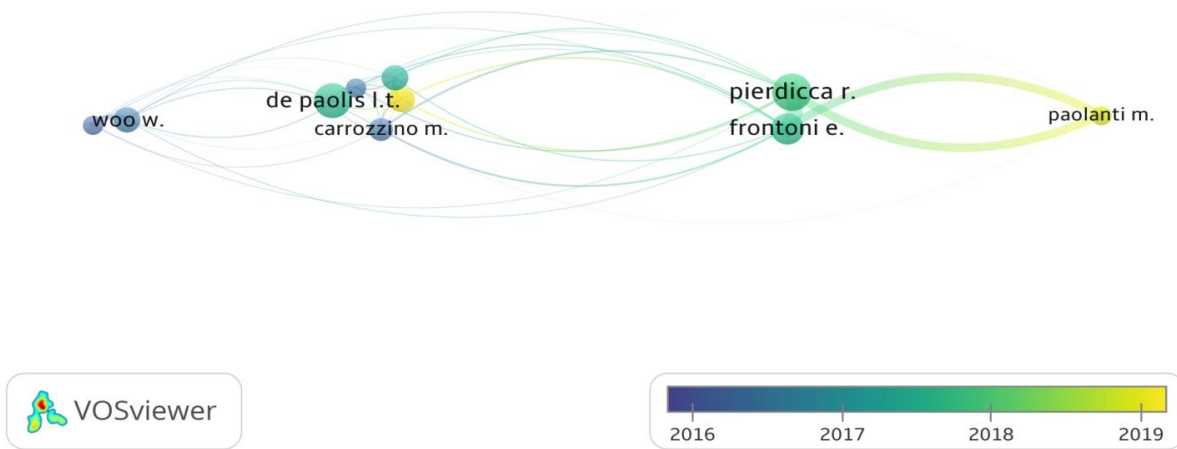

Fig. 5. Authors' bibliographic coupling (overlay visualization).

TABLE IV. AUTHORS' BIBLIOGRAPHIC COUPLING

Author	Documents	Citations	Total link strength
Pierdicca R.	12	339	804
Frontoni E.	10	337	798
Paolanti M.	6	46	423
Woo W.	8	66	161
Marto A.	8	34	143
Kim J.	6	54	138
Carrozzino M.	7	66	118
Liarokapis F.	8	290	94
Bostanci E.	6	66	87
De Paolis L.T.	11	214	62

With 12 publications, 339 citations, and a total link strength of 804, Pierdicca R. (Università Politecnica Delle Marche, Italy) was the most prominent author. With 10 articles and 798 links, Frontoni E. (Università Politecnica Delle Marche, Italy) is the second most cited author (337). Lucio Tommaso De Paolis (Università del Salento, Italy) is the second strongest author in terms of documents (11), citations (214), and link strength (62).

Liarokapis F. (Cyprus University of Technology, Cyprus) is the third strongest author in terms of citations (290), with 8 publications and 94 link strengths.

The first number reflects the total number of documents, the total number of citations are represented by the second number, and the total number of link strengths by the third number. The remaining authors are listed in order of total link strength: Paolanti Marina (University of Macerata, Italy) (6; 46; 423), Woo Woontack (Korea Advanced Institute of Science and Technology, Korea) (8; 66; 161), Marto Anabela (Polytechnic of Leiria, Leiria, Portugal) (8; 34; 143), Kim J. (Seoul National University, Seoul, Korea) (6; 54; 138), Carrozzino (6; 66; 87). There are five experts from Italy, two from South Korea, and one each from Turkey, Cyprus, and Portugal among the top ten authors.

It demonstrates Italy's dominance in this field of study. The color disparities in Fig. 5 depict the groupings of those writers

based on the years in which their research is published. It reveals that among these authors, Paolanti Marina, Pierdicca, and Frontoni E. have the most recent studies.

#### D. Bibliographic Coupling of the Publications

Fig. 6 shows the publications' bibliographic coupling with network visualization. The papers with at least 100 number of citations are considered for this study. Only 10 documents out of 590 met the criteria, and three of those do not have any coupling with other papers. As a result, just seven publications are studied. For each article, the number of citations and overall link strength is calculated.

The documents are arranged as per the total link strength as shown in Table V. Anderson et al. (2010) [57] has the highest link strength of 8 and the second highest citations of 205. Bekele et al. (2018) [58], on the other hand, have the most citations 240 and the second strongest link strength of 5. Styliani et al [2009; (207; 4)] [59], Wojciechowski et al [2004; (228; 3)] [60], Schmalstieg et al [2007; (115; 2)] [61], Tom Dieck et al. [2017; (101; 1)] [62], Sylaiou et al [2010; (146; 1)] [63] are the other papers listed in order of overall link strength.

The first number inside the parentheses represents the number of citations, while the second is the total link strength for each article.

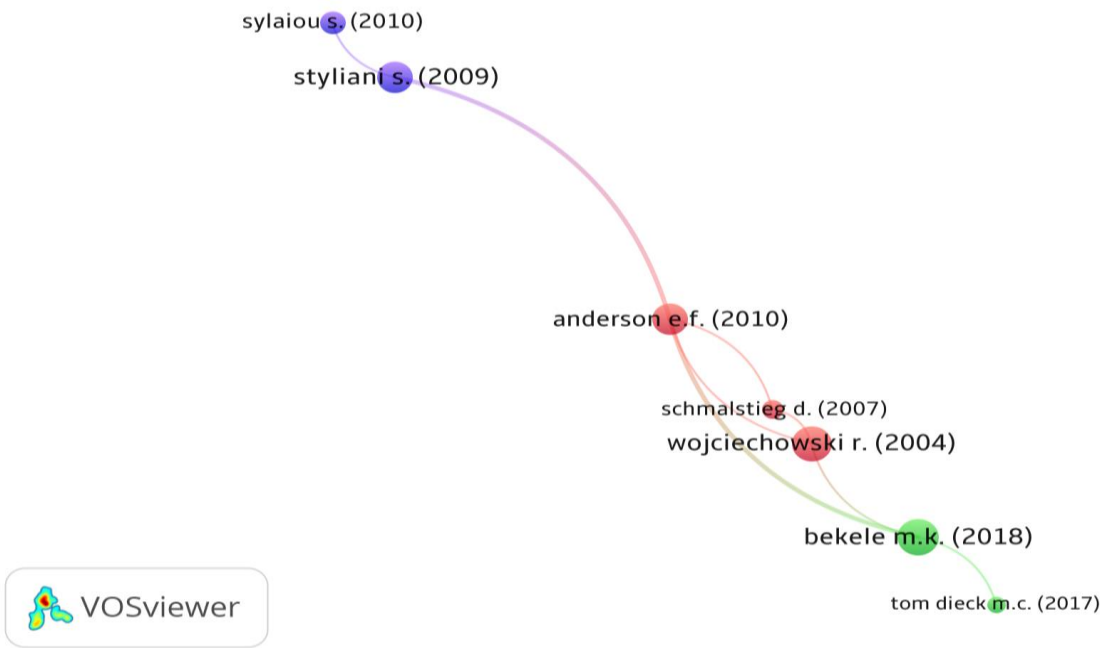

Fig. 6. Publications' bibliographic coupling (network visualization).

TABLE V. PUBLICATIONS' BIBLIOGRAPHIC COUPLING

Document	Citations	Total link strength	Domain of discussion
Anderson E.F.(2010)	205	8	Game Development for Cultural Heritage
Bekele M.K.(2018)	240	5	AR,VR and MR in Cultural Heritage
Styliani S.(2009)	207	4	Virtual Museums
Wojciechowski R.(2004)	228	3	AR, VR in museum exhibition
Schmalstieg D.(2007)	115	2	Handheld AR
Tom Diek M.C. (2017)	101	1	Visitor experience at heritage sites
Sylaious S. (2010)	146	1	Virtual Museum

E. Co-occurrences of the Author Keywords

Fig. 7 shows the author keywords' co-occurrences in a network format. The minimal number of occurrences of a keyword is 12 as an inclusion criterion. Only 14 of the 1296 keywords passed the test.

The frequency and its linkage with other keywords is computed for each keyword. Keywords with the most total link strength are chosen as shown in Table VI. With 332 occurrences and 377 total link strength, Augmented Reality is the most popular keyword. With 282 occurrences and 343 total link strength, Cultural Heritage is the second most popular keyword. Virtual Reality (91; 126), Mixed Reality (33; 67), Photogrammetry (23; 39), Storytelling (13; 30), 3D Reconstruction (14; 29), Education (16; 28), User Experience (15; 26), 3D Modeling (15; 23), Intangible Cultural Heritage (16; 20), Mobile Application (12; 20), Museums (12; 19),

Mobile augmented Reality (22; 17). For the rest, the first number inside the parentheses represents the number of occurrences, and the total link strength is represented by the second number.

Fig. 7 depicts different colored clusters representing the more frequently connected keywords. Education, Intangible Cultural Heritage, Mixed Reality, Mobile Augmented Reality, Narrative, and User Experience make up the largest cluster. The second cluster is comprised of augmented Reality, Cultural Heritage, Mobile Application, Photogrammetry, and 3D-Reconstruction. Each of the other three clusters consists of a single element each, viz. 3D-Modeling, Virtual Reality, And Museums. The research is mainly done in two broader areas. The first one is learning about cultural heritage through mobile applications using Mixed Reality. The second one is a 3D-reconstruction of cultural heritage using augmented Reality and photogrammetry.

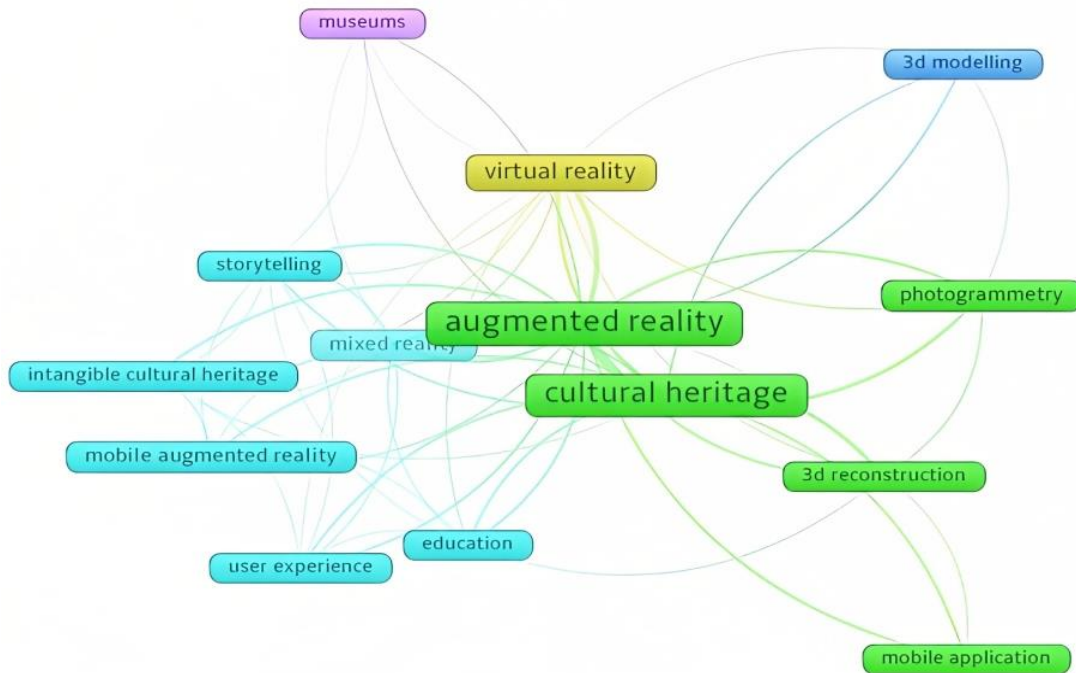

Fig. 7. The author keywords' co-occurrences (network visualization).

TABLE VI. THE AUTHOR KEYWORDS' CO-OCCURRENCES

Keyword	Occurrences	Total link strength
Augmented Reality	332	377
Cultural Heritage	282	343
Virtual Reality	91	126
Mixed Reality	33	67
Photogrammetry	23	39
Storytelling	13	30
3D-Reconstruction	14	29
Education	16	28
User Experience	15	26
3D-Modelling	15	23
Intangible Cultural Heritage	16	20
Mobile Application	12	20
Museums	12	19
Mobile Augmented Reality	22	17

## V. DISCUSSION

The following paragraph discusses how the research objectives specified in Section I.A, are achieved through bibliometric analysis and systematic literature survey.

1) Compile the peer-reviewed articles and conference papers on applications of AR/VR in cultural heritage during the period of 1999 to 2022.

In this work, publications from the Scopus database those are relevant to Augmented Reality or Virtual Reality-based solutions for learning and reconstruction of cultural heritage

are retrieved, analyzed, and visualized using descriptive and evaluative bibliometric analytic methodologies. To evaluate and visualize the linked data, VOSviewer 1.6.17 software is employed. Bibliographic coupling of publications, journals, countries, authors, and author keywords co-occurrences from associated publications are examined and illustrated.

2) Ascertain the spread of this field using bibliometric coupling of publications, journals, and authors.

As per the journals' bibliographic coupling, the premier journal in AR and VR literature related to cultural heritage is "Lecture notes in the computer science" series with the highest

publications, citations, and total link strength. Few more important journals in this area are; "Journal on computing and cultural heritage" (impact factor: 2.64), "International Archives of the photogrammetry, remote sensing and special information sciences" (impact factor: 0.82), "Applied sciences" (impact factor: 2.73), ACM International conference proceeding series (impact score: 0.61), "ISPRS Annals of the photogrammetry remote sensing and special information sciences" (impact score: 1.45), "Communications in Computer and information science" (impact factor: 0.48), "Advances in intelligent systems and computing" (impact factor: 0.63), CEUR workshop proceedings (impact score: 0.55), and "Procedia Computer science" (impact score: 2.09). The scopes of top journals are innovative usage of AR/VR for the discovery, reconstruction, experiencing, and learning of cultural heritage.

As observed from Table IV and Table V, the highest cited paper in this area is written by Anderson E. F. (2010) [57] which is co-authored by Liarokapis who is the eighth author as per the total link strength. Similarly, it is also observed that the second highest cited publication is by Bekele M. K. (2018) [58] and co-authored by Pierdicca R. and Frontoni E., who are the most cited authors. The third most cited publication is by Styliani S. (2009) [59] which is also co-authored by Liarokapis.

3) Understand which countries have the most publications in this area.

As per results shown in Table II related to the bibliographic coupling of countries, the maximum work in this area has been done in Italy which is the home of 58 UNESCO world heritage sites. The next three countries as per the number of publications are Greece with 18 UNESCO sites, the United Kingdom with 33 UNESCO sites, and Spain with 49 UNESCO sites. The other important countries have been: Portugal, France, Australia, South Korea, Germany, China, Malaysia, the United States, and Indonesia.

As per the authors' bibliographic coupling, the top three authors, Pierdicca, Frontoni E., and Paolanti are from Italy and worked together in many of the publications. Among the 10 strongest authors five are from Italy out of which the first two authors are from the same university that is Università Politecnica Delle Marche, Italy.

4) Which technologies were employed for implementation of cultural heritage projects?

As observed from Table I, most of the museum tour related projects are based on immersive technology and comparatively less work is done in non-immersive and semi-immersive areas. It is also found that mainly the immersive experience is provided by stimulating the optic senses of users, followed by the haptic, auditory, smell and taste senses.

The co-occurrences of author keywords show that the authors have largely employed augmented reality for 3D-reconstruction of cultural heritage using photogrammetry. It is also seen that Augmented Reality is used more often than Virtual Reality to provide users with an immersive experience of ancient cultural heritage.

By examining the co-occurrences of author keywords, the publications' and journals' bibliographic couplings, it can be

concluded that most of the researchers either tried to reconstruct the ancient environment of cultural heritage through mobile applications using Augmented Reality and photogrammetry or the researchers tried to create a submerging user experience of intangible cultural heritage through storytelling and using the Mixed Reality, especially for educational purpose. The most cited review papers by Anderson et.al (2010) [57] and Bekele et.al (2018)[58] also support this finding.

## VI. CONCLUSION AND FUTURE WORK

The results of the different types of analysis performed here indicate that the AR,VR and MR related research in the field of cultural heritage is mostly concentrated in Italy and surrounding European countries which are the home of many ancient monuments and other heritage sites. Other than Europe, some researchers from South Korea are also working in the same domain for providing information about their cultural heritage sites through mobile applications. It is also observed that although Mexico has 35 UNESCO heritage sites, the research in this area is still lagging behind there.

This study would help researchers to identify the prominent journals in the said domain, recognize stalwarts in the field and follow their works, find out path-breaking publications to refer to, predict the direction of future studies, etc. Here, we have presented the bibliometric analysis of the publications related to AR,VR and MR in cultural heritage. The work can be further extended to include publications related to specific areas such as 3D-reconstruction of heritage sites, gaming and educational applications related to this domain, etc. In a conclusion, it can be commented that AR, VR and MR in cultural heritage and 3D-reconstruction has a great scope and potential for immediate research.

## VII. CONFLICTS OF INTEREST

The authors have no conflicts of interest to declare.

#### AUTHORS' PROFILE

Nilam Upasani is working as an Associate Professor in the Dept. Of Computer Engineering at Pimpri Chinchwad college of Engineering, Pune, India. She received her Bachelor and Master degree in Computer Engineering from Pune University, India. She received her Ph.D. in Computer Science and Engineering from IIT (ISM), Dhanbad, India. She has published several research papers in International Journals and presented many at International conferences of high repute. Her research interests include Data Science, Machine learning, Biomedical applications, and rare-class detection.

Asmita Manna is working as an Assistant Professor in the Dept of Computer Engineering, Pimpri Chinchwad College of Engineering. She obtained her Ph. D degree from Jadavpur University, Kolkata, India. Prior to that She obtained her Master Degree in Software Engineering from Jadavpur University, Kolkata, India and Bachelors Degree in Information Technology from Bengal Engineering and Science University, Shibpur (presently known as IEST, Shibpur). She has published multiple research papers in International Journals and presented at many conferences of international standards. Her research interests are Cyber Security, Information Systems, Data Science and Machine Learning.

Manjiri A. Ranjanikar received the B.E. and ME degree in Computer Science and Engineering from MGM's COE, Nanded and PhD. degree from Department of Computer Science and Engineering, SGGGS Institute of Engineering and Technology, Nanded, Maharashtra state, India in 2010, 2013, and 2020 respectively. Currently she is working as Assistant Professor in the Department of Computer Engineering, Pimpri Chinchwad College of Engineering, Pune, MH, India. She has published about 15 papers in international and national journals and conferences and 3 patents. She has reviewed IEEE Conference papers and book chapters. She is having 11 years of experience in teaching. Her areas of interest are Image processing, machine learning, Computer Vision, and Pattern classification.

# Implementation of Business Intelligence Solution for United Airlines

## Business Insights and Data Analytics for United Airlines Industry

Ng Iris, Sarasvathi Nagalingham

Faculty of Data Science and Information Technology, INTI International University, Nilai, Negeri Sembilan, Malaysia

**Abstract**—US Airline is recognized as the world's largest airline, with a massive number of daily departures completed and a combined fleet of over 2700 aircraft. US Airlines have carried major 18 airlines, categorized as mainline, regional, and freight airlines. United Airline is one of the major airlines in the US after American Airlines and Delta Airlines in the world. Today, companies received as much feedback from their customers. Customers can share their opinion and emotion through social media platforms, such as Twitter. Thus, collecting and understanding customer's opinion become the key benefits for the aviation industry to get actionable insights while increasing their competitiveness. Such insights are useful in planning and execution to increase the relationship with customers. Thus, this study was conducted to analyze customer's feedback in different airlines to discover actionable insights that increase the competitiveness of United Airline. The analysis result will be visualized on Tableau dashboards and BI solutions will be provided. By implementing the BI solutions, United Airline can make accurate decisions and define next strategies by identifying those positive and negative references. Thus, United Airline can improve the quality of their service, enhance customers loyalty, and boost business profitability.

**Keywords**—Business intelligence; aviation industry; dashboard visualization; tableau; data analytics

### I. INTRODUCTION

The COVID-19 pandemic is having a significant impact on the aviation industry, including a sharp decline in demand for passenger air travel. Demand for airline services has fallen dramatically because of changes in passenger behavior brought on by the COVID-19 crisis and travel restrictions. Additionally, containment efforts are endangering the viability of numerous businesses in the aviation industry as a whole, putting many jobs at risk. Despite some setbacks from the COVID-19 wave, the herd vaccination campaign is now beginning to pay off. Many nations have carried out their plans to resume some semblance of normality by removing numerous health restrictions, easing travel stipulations, and reopening borders. The momentum generated by the reopening had a positive and immediate impact on global demand for air travel.

Big data insights can provide airlines with a significant competitive advantage. The airline industry can learn a lot about their customers during the booking, check-in, boarding, and even during the flight. Airlines, along with loyalty programmes, generate arguably more customer data than any

other industry. This data contains vast amounts of valuable intelligence that affects operations, efficiency, and service.

### A. Business Intelligence Methodology

Business intelligence is a collection of technologies that are used to help businesses make better use of data to enhance decision-making quality. It is a process of extracting a large amount of data from information and knowledge to provide accurate intelligence on the nature of the market [1]. With business intelligence, the term business analysis is often used interchangeably. Business analysis, however, is a subset of business intelligence because business intelligence addresses strategies and instruments, while business analysis focuses more on techniques. Business intelligence is descriptive, whereas forecasts for business analysis are indicative and used to solve problems or business issues [2].

Business intelligence tools are application software that can be used to gather and process vast amounts of unstructured data. With the BI tools, it can also help the business to prepare data information for analysis, making it easy to build organizational reports and create dashboards to make visualizations of the information. As a result, decision-making can be accelerated and improved by staff and managers, operational efficiency improved, new revenue potential clarified, market trends identified, true KPIs reported, and new business opportunities identified [3]. There are many types of business intelligence tools such as Tableau, Power BI, Yellowfin BI, and more [4]. They can perform data analysis by generating reports, summaries, dashboards, maps, graphs, and charts that are informative and easy to understand.

### B. Overview of United Airline

US Airline is also recognized as the world's largest airline, with a massive number of daily departures completed and a combined fleet of over 2700 aircraft. There are flights departing and arriving every day from different countries. There are almost 889 million passengers being transported in 2018, according to the research, which can be recognized as the largest air travel market in any single country. US Airlines have carried major 18 airlines, categorized as mainline, regional, and freight airlines. United Airline is one of the major airlines in the US whose headquarters are located at Willis Tower in Chicago. United Airlines is as known as the third largest airline after American Airlines and Delta Airlines in the world. The slogan of United Airlines is "Fly the Friendly Skies" [5].

The main business goal of United Airline was to provide the highest quality of service for every single passenger wherever they encounter the airline. Moreover, to create repeat customers through satisfying them on their leisure or business travel. To achieve this, United Airlines had to provide top quality service which must deal with the customer in a respectful and helpful way. Furthermore, ensure their service meets customer needs by exploring the new alternatives and goods for enhancing customer loyalty [6].

Since the United States is a prosperous country, there are also many people traveling between countries. Therefore, many customers book or buy air tickets online or at the counter every day. United Airlines must collect the associated information to understand the daily flights, customer purchase records, and so on. Through the data collected, United Airlines can improve the quality of service, improve customer loyalty, meet everchanging customer needs, and boost business profitability.

### C. Challenges Faced by United Airline

- **Stiff competition:** The aviation industry has the characteristics of high investment, high risk, high technology, and low profit. In the United States, there are a lot of airline companies such as United Airlines, Delta Airlines, Southwest Airlines, Virgin Airlines etc. In the airline industry, demand for air travel and capacity has seen tremendous growth, but profitability is comparatively poor, even though unit costs have decreased by half in the past 40 years. Much of the productivity benefits from reduced prices have been passed on in the form of lower airfares to consumers [7].
- **Social media:** Over the past few years, social media has changed the Internet completely. Social media creates a bigger and easier forum for consumers to communicate and share knowledge and opinions. The content discussed and posted on social media can come in many shapes and forms, such as text, pictures, audio, and video, which can be used to communicate different types of messages for different scenarios. Airlines also receive airport and flight experience complaints from travelers. In addition to formal grievances, individuals nowadays often express views on social media about their travel experience, especially when unsatisfied. Such feedback regarding the preferences of customers is highly revealing. The knowledge is used by advanced data analytics to identify patterns and best practices in customer service.
- **Digital transformation:** Customer data, product data and operational data are required for the aviation company to stand out from competitors. United Airlines can collect thousands of operational and transaction data every day from various departments. Thus, how to analyze the data is important to get the information insights and discover hidden knowledge. The data itself has no value what matters what United Airlines is do with the data. Poor data quality such as missing values, noisy data and outliers may become a big challenge for the United

Airlines when processing with [8]. Without general knowledge of the various methods of data processing, incorrect information can be presented. It can be very risky for decision makers without the aid of a trained data scientist to analyze the data. Therefore, several prejudices can exist, and their decision making cannot be validated by the evidence.

### D. Opportunities of United Airline

- **Enhance customer experience:** Companies that truly recognize and prioritize their consumer demand benefit from crucial competitive advantages such as higher revenue and market shares and more loyal customers. They can distinguish themselves and improve customer loyalty from their rivals. Introducing new channels to their customer service, such as chatbots on websites, or event-trigger customized deals or communications, the customer experience is enhanced by data analytics. These tools detect trends based on previous experiences and provide clients with optimized solutions to their most common problems, leaving human interaction to solve more complicated problems [9].
- **Improve customer loyalty:** Airline companies get access to detailed information about each individual customer. They manage to obtain the customers' recent social media interactions with them and even access to customers' previous journey. With the help of BI, airline companies can get a holistic view of each customer. More specific marketing communications can be offered by airlines companies and personalize customer experience. This eventually improves the conversion of campaigns and consumer satisfaction. Hence, retain the customer loyalty [9].
- **Reduce marketing expenses:** Among the various airline companies, it can be competitive for the customer to choose the right airline for them. It might depend on different factors, such as overall ratings for the airline company, the seat cleanliness of the airplane, the food and beverage that was provided on plane and the value for money. A customer would choose their preferred airline company over another. Some might choose United Airlines because of the tidiness of the seats. With the help of BI solution, the company would be able to analyze the preferences of each customer and get to know how these factors affect the customers and give impact to the company. The marketing expenses could be reduced, and more revenue could be used on other sectors.

## II. DATASET ANALYSIS

The dataset is grabbed from Kaggle which is the Twitter airline sentiment. The original source version is slightly reformatted from Crowdfower's Data for Everyone library [10]. Both a CSV and SQLite files are included with it. The dataset basically contains the sentiment of tweets for 4 airline companies, which are Delta Airline, Southwest Airline, United Airline and Virgin Airline. The Table I and Table II identify the description of each attribute for two different datasets.

TABLE I. DATASET ATTRIBUTES AND DESCRIPTION: TWEET

No.	Attribute Name	Description
1	tweet_id	The unique ID of this tweet
2	airline_sentiment	The customer's opinion whether it was positive, neutral, or negative
3	negativereason	The reason why customers give negative opinions or feedback
4	airline	The name of the airline
5	name	The username of the Twitter account
6	retweet_count	The number of Twitter retweets
7	text	User's feedback
8	tweet_coord	The coordinate that the tweet has been created
9	tweet_created	The date the user posted the tweet
10	tweet_location	The tweet location of the user
11	user_timezone	The time zone of the user

TABLE II. DATASET ATTRIBUTES AND DESCRIPTION: AIRLINE REVIEWS

No.	Attribute Name	Description
1	airline	The name of the airline
2	overall	The overall rating
3	author	Passenger name
4	review_date	Date that the customer review
5	customer_review	Passenger review on their flight experience
6	aircraft	The type of aircraft
7	traveller_type	The purpose of the customer's flight
8	cabin	The cabin class of accommodation on a passenger ship
9	route	Flight path of the airline
10	seat_comfort	Passenger ratings for inflight seat comfortability
11	cabin_service	Passenger ratings for inflight cabin service
12	food_beverage	Passenger ratings for inflight food and beverage
13	entertainment	Passenger ratings for inflight entertainment
14	ground_service	Passenger ratings for ground service
15	value_for_money	Whether the travel is value for money or not
16	recommended	Whether the passenger will recommend to their friends or not

### A. Dataset Cleaning

Microsoft Excel is a software that can be used to store, manipulate, and present the data sets. It provides various types of tools to make sense of the datasets using its characteristics and formulas. Thus, Microsoft Excel will be used to clean the datasets, so that noisy data and duplicate values can be identified and removed.

- **Remove duplication:** Large datasets appear to have redundant material. Identifying duplicate data and deleting it is the first step in data pre-processing. Duplicate data has given us little benefit. The performance and quality of the dashboard will be reduced. Thus, the duplicate records are removed from the datasets. There are a total of 70711 duplicate records have been removed. Now the datasets remain 61185 unique values.

- **Split texts into columns:** To perform text analysis using word cloud, it is necessary to split the whole text into each individual column. Thus, select the entire column of the text then split text to column with delimiters. It is required to select the delimiter type to split the text into columns. The selected delimiters include semicolon, comma, space, and full stop.

### III. BUSINESS INTELLIGENCE ARCHITECTURE

Business intelligence architecture refers to the architecture used by an organization to define their data source of collection information processing and all the technology that supports their business intelligence. BI architecture consists of various parts and layers and every single of them are important as each of the components have its own purpose [11]. The components include:

- **Data collection:** The very first steps of business intelligence. Nowadays data is becoming more and more important to drive a business to success. Depending on a company's criteria and finances, a company may obtain their data through different data sources, such as CRM, ERP, databases, files, or APIs. These applications and methodologies collect data from internal processes and external sources of organisations.
- **Data integration:** The following step will be data integration which uses the data collected previously and proceeds on with the Extract, Transform and Load (ETL) process. For extract, the data will be pulled out from external sources. Then transform the data into a demand standard which also ensures the data is clean with no noise data. After that, load it into the destination data warehouse.
- **Data warehouse:** This is the place where all the data is being stored. The data warehouse outlines data for upstream applications in dimensions and fact tables. Processes performed in a data centre are data cleansing, metadata management, data distribution, resource management, recovery, and backup planning.
- **Data analysis:** This phase will be focused on data processing after it has been handled, transformed, and cleaned in previous steps by the data warehouse. The ubiquitous need for effective analysis to enable businesses of all sizes to grow and benefit is accomplished through BI application tools. Modern BI tools like Tableau enable users to create queries using drag and drop, building visualization graphs within a few clicks.
- **Data distribution:** When it comes to sharing information and providing stakeholders with indispensable perspectives to achieve sustainable business growth, data distribution is one of the most critical processes. distributed can be performed in 3 ways which are reporting, dashboard and embedding. Reports can be viewed and shared among recipients on a defined schedule. Alternatively, a dashboard can be shared for the recipient to view but not able to make changes. Without the need to mark the BI tool on external

applications of intranets, your own application may use dashboards as a means of analytics and reporting.

- Actionable insights: Data driven decision will be the final stage for the BI architecture. With the insight taken from the previous stage, higher management like CEO will have the ability to produce true, specific, data-based decisions that will assist them to move forward. This helps a high-level manager to get an understanding of strategic growth and future decisions to build a profitable organisation. Fig. 1 shows the example of BI architecture.

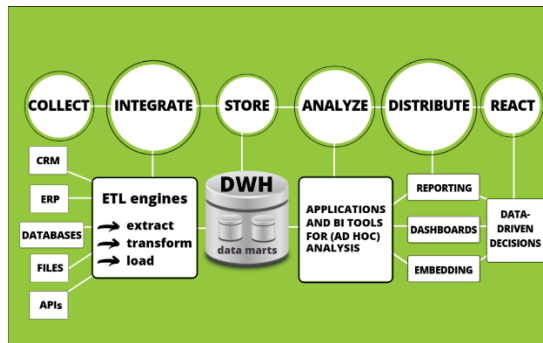

Fig. 1. Example of BI architecture.

#### IV. DIMENSIONAL MODEL

A dimensional model is a data structure consisting of a table of facts and tables of measurements. A fact table consists of measures that allow us to quantify quantitative data with ease of dimensional modelling. The dimension tables include descriptions of the fact table that surrounds the business process case. The following section discusses five steps to construct a dimensional model [12].

- Identify business process: Business process must be identified because it needs to define how the data stores in the data warehouse. The way to store the data should be efficient to process the data analysis. The data is scraped on the Internet and compared between the different companies. It could be used to identify the pros and cons of the different airline companies and help the company in terms of their decision making on marketing purposes.
- Identify granularity: This step is to identify the granularity of each table of facts and the business procedure. It defines the fact and dimensions table during this process. The dataset should include daily monthly quarterly granularity in a table.
- Identify dimensions: The time dimension must be specified because to know when the metrics which have been reported. The dimension would be the user, airline, tweet, location, and date. The date would have the granularities such as month, week, and day.
- Identify facts: A fact table contains information about measurements and foreign keys to dimension tables. The fact table includes numerical measurements, retweet\_count, airline\_sentiment\_confidence, negativereason\_confidence, overall, seat comfort, foodbev, valueformoney,

foodbev, value for money are the measurements for this fact table. The foreign keys would be the primary keys of each dimension.

- Build schema: Star schema is chosen for this research because it is easy to implement. The dimension tables are joined with the fact table with a common key attribute. Each dimension is highly denormalized in a single table. This could allow the system to optimize the query processing time. The schema can be implemented on the data warehouse with the help of ETL process which processes dimensional modelling. Fig. 2 shows the star schema developed for United Airline.

Fig. 2. Star schema for united airline.

#### V. DASHBOARD VISUALIZATION

There are 4 dashboards created for this study, Airline Recommendation Analysis, Passenger Review Analysis, Customer Sentiment Analysis, and Airline Rating Analysis. Fig. 3 section describes the dashboards in detail.

##### A. Airline Recommendation Analysis

The airline recommendation analysis is a dashboard which provides insights from different perspectives. There are four major airline companies which are Delta Airlines, Southwest Airlines, United Airlines, and Virgin America. This dashboard is focused on the recommendation of the users whether the users would recommend the particular airline which they have tried before, this could be critical because it might affect the customer's loyalty and company's profits. It allows the users to have a better understanding of the overall recommendation of each airline company. Moreover, it provides some drill-down features about the airline companies and the cabin types.

Fig. 4 shows the total percentage of users who are recommended and not recommended to the airline companies. So, from the pie chart below it shows that the users who have taken flight before do not recommend their airline companies which they have taken before. This might be related to several reasons, such as food and beverage availability in the airplane, the comfortless of the seat on the plane, and the value for their money.

Fig. 3. Airline recommendation analysis.

Fig. 4. Recommendation percentage.

Fig. 5. Airline recommendation.

Fig. 5 shows the number of users who recommend and not recommend the airline company. Although Virgin America has the least number of records which has a total of 0.56%, most of the customers who had travelled with it were willing to recommend the airline to others. The company United Airlines has the highest number of customers who had travelled with them before, but most of the customers do not recommend it to others which consists of 58.24% among all the airline companies. From the customer perspective, it indicates that the United Airlines does not do a great job to serve their customers and it might be better to choose the other airlines rather than United Airlines. Although there are many customers who do not recommend United Airlines, there are still many customers who have taken flight with them. The reason behind this might be because of the cost of the air ticket since most people only care about the cost and want to keep the cost to the lowest. Fig. 6 stacked bar chart shows the drill-down features with the airlines and cabin types. The users would have a clear understanding of each cabin type and how they relate to the number of customers. In the economy class of the cabin type, all the four airline companies own the highest number of passengers. The reason for this might be

that the cost for the air ticket is the cheapest and most value of money when compared with the other cabin types. Among the economy class passengers, it indicates that most customers are from United Airlines which is true from the previous section, because it sold the most air tickets among his competitors.

**B. Passenger Review Analysis**

Fig. 7 shows dashboard for passenger’s review analysis that is able to provide useful insight to the airline company. The overall review of cabin class can give insight of which type of cabin class should be improved more to meet passenger’s satisfaction. The number of reviews shows the total number of passengers reviewed from the year of 2014 to 2018. Count of cabin will define the cabin type taken for the passengers. Lastly the word cloud of review will display the most frequent word collected from passengers’ review. The dashboard will be split and explained in more details in following page.

Fig. 6. Recommendation cabin.

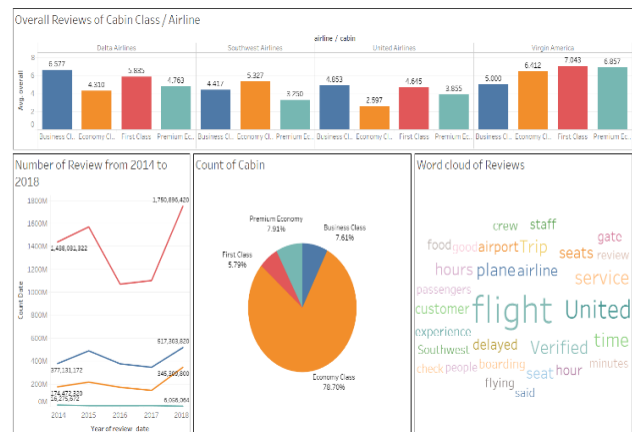

Fig. 7. Passenger review analysis.

Fig. 8. Count of cabin class.

In addition to that, the Fig. 8 shows the total number count of airline cabin classes of all flights from the year of 2009 to 2019. There are 4 types of cabins provided for the passengers which are Economy class, Premium Economy, Business Class, and First-Class cabin. According to the diagram, it is obvious that most of the passengers took the economy class cabin which consisted of 78.70% and overwhelming other types of class. Business Class and Premium Economy class are very close to each other where only have a difference of 0.3%. However, Premium Economy cabins manage to get the second highest count with a percentage of 7.91%. Lastly, First Class cabins only have 5.79% of count due to the high price and luxury service which is not affordable by normal passengers.

Fig. 10. Word cloud of reviews.

Other than that, the Fig. 10 shows the reviews from the customer are important for the airline company as they can obtain information from it and make improvements. However, there are more than millions of reviews and the time taken for the airline company to read one by one will be a waste of time and effortless. This is the place where word cloud plays an important part as it will display the most relevant word from the reviews. Figure above shows the top 30-word from the customer. The larger the word the higher the count of the word. The largest word that observed from the diagram above was “flight” which means the reviews are related to flight. Furthermore, the author noticed that “delayed”, “hours” and “minutes” appear on the word cloud which mean that there are many reviews related to the flight delay which can up from minutes to hours. Another word “service”, “good” and “experience” can be concluded as the passengers’ experience with the good service.

Fig. 9. Overall reviews of cabin class.

Apart from that, the Fig. 9 shows the overall reviews of the cabin types in each airline. There are four types of cabins which are business class, economy class, first class and premium economy. In the United Airlines, the economy class is the lowest selling ticket which only consists of 2.597 in average. This could lead to some serious problems because most of the seats in the airplane are economy class and if the more seats are empty, United Airlines would not be able to obtain the highest profitability on each flight. To get the highest profitability in terms of efficiency and effectiveness, the ticket sold on each cabin class should be equally distributed which would result in the plane being filled with customers in each flight.

Fig. 11. Number of reviews.

Furthermore, the Fig. 11 shows the number of reviews that the airlines companies received from 2014 to 2019. There are four airline companies related in this diagram which are United airline, Delta airline, Southwest airline, and Virgin America airline. The number of reviews received for Virgin America was the lowest when comparing to other airline companies. In the year 2014 it only had 16,275,672 times of review and it encountered small drops steadily all the way to the year of 2018 until 6,056,064 times of review. For Southwest and Delta Airline they encounter slight upward and downward from 2014 to 2018. Both airlines were increased from 174,472,320 to 345,309,800 and 377,131,172 to 517,303,820, respectively. For United airline, it had the greatest number of reviews, and it is overwhelming the other 3 airlines. In the beginning of 2014, it only had 1400 millions of reviews while in 2018, United airline reviews rose to a new high of 1750 million.

C. Customer Sentiment Analysis

In this section, the customer opinions as well as emotions towards the services that the airline companies provided will be discussed in detail. This dashboard provides information from a different viewpoint. Sentiment analysis, also known as opinion mining, helps airline companies to analyze the sentiment of a piece of text and present it in the form of a dashboard. Basically, the study of text sentiment helps us to get an understanding of whether a piece of text is positive, negative, or neutral. While at the time the airline companies gathered the tweets, this gives them a clear sense of the public's opinion about the service they provided and tells the airline companies anything about what exactly people were talking about positively or negatively. Sentiment analysis will tell the airline companies what a piece of text's sentiment is. But people-generated text typically talks about more than one thing and sometimes has more than one emotion. Someone might write, for instance, that they didn't like the customer services of the United Airlines, but they liked the inflight experiences and feel comfortable on the journey, and a model of document-level sentiment analysis would only look at the whole document and sum up whether the overall feeling was mostly positive or negative.

Fig. 12. Customer sentiment analysis dashboard.

Fig. 13. Customer emotion.

Customer satisfaction plays an important role within the airline company (Fig. 12). It is not only the leading metric for assessing consumer satisfaction, recognizing dissatisfied customers, minimizing turnover, and increasing revenue, but it

is also a crucial point of differentiation that allows you in competitive market environments to gain new customers. Thus, airline companies need to analyze and understand the customer's experience to improve the services and products provided. Fig. 13 shows the percentage of customer's emotion about the flight. Based on the result, we can conclude that most of the passengers were not satisfied with the services provided by the airlines company. More than 60% of the passengers write a negative response to the airline companies, while only 16.86% of passengers feel satisfied with the services provided by the airlines company. While 23% of the passengers did not specify their emotions on the flight experience. Since most of the passengers were not satisfied with the service provided by the airline companies, thus the airline companies need to figure out the reason why the customer's feel bad about the flight. Else, the companies may lose a lot of customers and profit from that.

Fig. 14. Customer emotion on each airline.

Since the overall sentiment of customers towards the U.S. aviation industry has been analyzed, drill down is also necessary to know the customer's emotion on the specified airlines companies, so that we can compare the customer's reviews of United Airlines and its competitors, which are Delta Airline, Southwest Airline, and the Virgin Airline. The Fig. 14 shows the customer emotions in each airline. There are three types of emotions which are positive, negative, and neutral. In the United Airlines, 44.83% of customers have negative emotions about the services provided, while around 12% of passengers did not express their emotions, and only 8.38% of the passengers feel satisfied with the services provided by the United Airlines. However, if we look at the other airline companies, the gap in customer satisfaction with service is not very large. This result could lead to some serious problems which may result in loss in both customers and profit, since the customers are more likely to pursue better services. Thus, if the United Airlines did not figure out why customers were not satisfied with the services provided, it is possible for the customers to switch to the competitive airlines.

As the Fig. 14 analyzed how many people feel unsatisfied with the service provided by the airline companies, it is important for the airline companies to look at the negative reviews to find out the reason. The Fig. 15 shows the number of negative reasons for each airline. The negative reasons are basically classified in several types, such as customer service issues, flight cancelled, luggage lost and damaged, flight

booking problems, longlines, etc. Among them, around 26% of passengers did not like the customer services, while around 20% of the passengers feel unhappy because of the flight delays. Around 10% of passengers unhappy because their luggage lost and damaged during the transportation, while 7.40% of passengers unhappy because their flight was cancelled. These are the major reasons which tell the airline companies why the passengers did not satisfy the airline service. Remaining 20% of the passengers feel unhappy because the booking system is not efficient, or unhappy because of the longlines which required them to waste a lot of time booking for a flight and waiting for the flight. However, 15% of passengers did not want to tell why they feel unhappy on the service. Thus, it is important for the airline company to know in detail which service needs to be improved to fulfil the customer needs.

Fig. 15. Negative reason.

Fig. 16. Negative reason for each airline.

The United Airlines should understand why the customer was not satisfied with the services provided as it is the critical element to increase the number of customers. To achieve this, United Airline must prepare analysis with the negative reviews to see how they performed if compared with other airline companies, so that United Airline can know what they can improve to attract the customer. Fig. 16 above shows the dashboard which tells the United Airline negative reasons of the customer. The insights are not accurate for Virgin America because the amount of negative reasons for them are not sufficient to compare with other airlines. So, the insights will be focusing on the three other airlines which are Delta Airlines, Southwest Airlines and United Airlines. Based on the

result, we can know that the top three negative reasons are customer service issues, flight delay, and loss of luggage. Among them, most of the customers which are 1926549 feel unhappy because they were not satisfied with the customer service. Thus, the airline company needs to improve their customer service to the customers. For example, providing training to the cabin crew and the ground service crew which can greatly improve the customer experience. Besides, 1,485,225 customers feel unhappy because of the delayed flight. Flight delay may disrupt the customer's schedule, especially for the businessman. There are 761,001 unhappy customers because of their luggage lost during the transportation. It can be critical issues as it may cause customer losses on financial.

#### D. Airline Rating Analysis

The Fig. 17 shows the number of travelers with different traveler's types for different airlines. According to the figure, there are four traveler types which are business travelers, couple leisure travelers, family leisure travelers, and solo leisure travelers. The airlines include Delta Airlines, Southwest Airlines, United Airlines and Virgin America Airlines. It is obvious that the United Airlines has the most travelers regardless of the travelers' type. For the United Airlines, the count of each traveler type is different which have business travelers have the count 1750476, couple leisure travelers have 1819272, family leisure travelers have 1521156 and solo leisure traveler have 2721264. The fewest number of family leisure travelers travel on United Airlines. On the other hand, the number of solo leisure travelers traveling through United Airlines are the most. Meanwhile, from the figure, Virgin America gets the least travelers compared to other four airlines. This is because Virgin America is not the major airline in the U.S.

The Fig. 18 shows the traveler's average rating to the seat comfort between the different cabins. Usually, there are four types of cabins which are business class, economy class, first class, and premium economy. Different types of cabins, the price is also different, and the services provided are also not the same. According to the Fig. 18, the rating given by the passenger of the seat comfort is high and low, compared to the different airlines and different cabins. We can see that the highest average rating of seat comfort is given by the family leisure travelers of the business class of Southwest Airlines and the couple leisure travelers of the premium economy of Virgin American. Southwest Airlines and Virgin America Airlines have significantly different ratings of seat comfort given by passengers. In contrast, the average ratings given by passengers of Delta Airlines and United Airlines are not much different. Both get the 5 of average rating, this means that the travelers feel it is comfortable when they sit on the seat. On the other hand, the lowest average rating that we can view from the figure is given by the travelers, which are the couple leisure travelers of business class of Southwest Airlines and family leisure travelers of the premium economy of Southwest Airlines. The average rating is the 1 score given by travelers. The reason why travelers are given a low rating might be that they feel that the seat is not comfortable.

Fig. 17. Airline rating analysis dashboard.

Fig. 18. Seat comfort rating.

Fig. 19. Food beverage rating.

Usually, the stewardess on the plane will push the food truck to ask each passenger if they need food and beverage, or some passengers have already ordered the food and beverage they need when buying tickets. Therefore, the Fig. 19 shows how satisfied the passenger is with food and beverage. From the Fig. 19, passengers of different airlines have different levels of satisfaction with food and beverages. The passengers of Delta Airlines gave an average rating of satisfaction with food and beverage between 2.5 and 3.5. So, we can know that they are not very satisfied or dissatisfied with the food and beverages provided by the airline. We can see that the highest rating of food and beverage is given by the family leisure travellers of the business class of Southwest Airlines. Then, solo leisure travellers of the first-class cabin of Virgin America gave the second-highest rating for the food and beverage. The average rating for both is 5.0 and 4.3. This shows that passengers are very satisfied with the food and

drinks provided by the airline. On the contrary, the business travellers of the first-class cabin of Virgin America gave the lowest rating for the food and beverage. The second-lowest rating is given by the business travellers of the economy class of United Airlines. The average rating given by both is 1.0 and 1.7. The reason they are given low ratings may be that they feel that food and drink cannot satisfy them.

When passengers take a long-haul flight, they may feel bored on the flight. Therefore, some of the airlines have provided entertainment for their passengers to spend time. There are many entertainments on the plane for the passengers such as in-flight WI-FI, music library, TV shows and movies, games, digital shopping and so on. The Fig. 20 shows the average rating of passengers on the entertainment provided on plane. Overall, we can see that the first-class cabin of the passenger is more satisfied with the entertainments that provide on the plane than the passenger of the economy class. This is normal because the ticket price of the first-class cabin is higher than that of the economy class, so the entertainment provided is different. The highest average rating was given by the solo leisure travellers of the first-class cabin of Virgin America which have 4.5 of average rating. Because Virgin America has been voted as the airline which has the best in-flight entertainment for the passenger, that is why it got the highest rating. On the other hand, the lowest average rating from the above figure is business travellers of the economy class of United Airlines which have 1.725 of average rating. Meanwhile, the overall entertainment rating of the economy class and first-class cabin of United Airlines is lower than other economy class and first-class cabins of the airlines. Thus, United Airlines must figure out the problem and improve to provide better entertainment for its passengers.

Fig. 20. Entertainment rating.

Fig. 21. Cabin service rating.

The Fig. 21 shows how satisfied the passenger was with the service provided by the stewardess in a different cabin. According to the graph, the rating given by the passenger is different. The cabin service provided by Delta Airlines overall is more average. Besides that, the average rating of Southwest Airlines and Virgin Airlines some are high, and some are low. The highest rating that was given by the family leisure travelers of business class of Southwest Airlines and couple leisure travelers of the premium economy class of Virgin America, both get 5 average ratings each. Meanwhile, the lowest rating that was given by the family leisure travelers of premium economy class of Southwest Airlines and couple leisure travelers of the first class of Virgin America, both get 1 average rating each. Thus, the airlines must figure out the problem and provide solutions to prevent loss of customers and achieve a good reputation. To prevent this, the airlines can provide training for their stewardess and other staff, instill the concept of customer first. In addition, give punishment for those who had bad service that was provided to the passenger.

## VI. CONCLUSION

In conclusion, this paper demonstrates the importance of business intelligence in the aviation industry. United Airlines needs to uncover hidden knowledge and gain a more competitive advantage. This study has analyzed the customer reviews on Twitter to understand customers' opinions and emotions on the aviation industry. The authors believe that the insights and BI solutions included in this study can help United Airline to improve their business values.

# Model Predictive Controlled Quasi Z Source Inverter Fed Induction Motor Drive System

D. Himabindu<sup>1</sup>, G. Sreenivasan<sup>2</sup>, R. Kiranmayi<sup>3</sup>  
Research Scholar, Dept of EEE, JNTUA, Ananthapur<sup>1</sup>  
Professor, Dept of EEE, PVKKIT, Ananthapur<sup>2</sup>  
Professor, Dept of EEE, JNTUA, Ananthapur<sup>3</sup>

**Abstract**—Ongoing advancements in inverters have offered pathway to high gain quasi Z source inverter Circuit (QZSIC). High gain QZSIC can be found between Semi Converter (SC) and three phase Induction Motor Loads (TPIML). This paper proposes suitable controller for closed loop controlled QZSIC-TPIML. This strive deals within improvement in time- response of QZSIC fed induction motor system. The objective of this effort tis to design a closed loop controlled QZSI\*fed-induction motor framework that provides a stable-rotor-speed. The QZSIC is settled to switch it to “3phase AC”. The yield of 3phase inverter is sieved before it’s applied to a‘3phase-Induction-motor’. Closed loop control of QZSIC-TPIML using SMC and MPC is simulated &their rejoinders are compared. The ‘Model Predictive controller (MPC)’ is acclaimed to retain persistent significance of-speed. The result obtained via MP-controlled QZS-IIMD-method is compared with Sliding mode-controlled (SMC) QZS-IIMD systems for change in input voltage. The wished-for MP controlled-QZS-IIMD method has benefits like fast settling-time and less steady state speed error.PIC16F84basedhardware for 0.5HP, QZSIC-IMDS is implemented.

**Keywords**—QZSIC; TPIML; CLSC; SMC; MPC; IMDS

LIST OF ABBREVIATIONS
QZSIC-Quasi Z source Inverter circuit
TPIML- Three Phase Induction Motor Load
MPC - ‘Model Predictive controller
SMC - Sliding Mode-Controller
IMDS – Induction Motor Drive System
CLSC- Closed Loop Semi Converter

## I. INTRODUCTION

‘The ZSI were having the solitary stage buck-boost amendment capacity’. "The framework was having an uncommon impedance circuit for coupling the basic circuit of converter with focal point for getting a particular brand name which wouldn't be acknowledged by using the common voltage source inverter and current-source-inverter".

An exchanged inductor semi Z-source inverter (SI-qZSI) showed a higher increase than a semi Z-source inverter (qZSI) while keeping nonstop information current. Like sustainable power age frameworks that outcome in low information voltage, SI-qZSI displays helping capacity that may not be sufficient at times. A voltage-lifting unit can be framed by exchanging one of the diodes in the switch inductor unit. A high move forward geography, for example, qZSI with

voltage-lifting unit (qZSI-VL), can be derived [1].

M. Padma priya, et al. [2] proposed a plan and reproduction of further developed diode helped voltage took care of three stage semi z-source inverter for photovoltaic application. Variable shoot through time span was produced by adding low recurrence voltage with steady voltage and the control signal for variable shoot was created utilizing support PWM control. The result nature of three stage QZSI was improved by supplanting the diode with dynamic power switch in Switch Boost Inverter (SBI) [2].

Another QZSI, which lessens input current waves, relative abundance of sounds created, and further developing the result voltage waveform, conveyed to the organization was presented. In the geography of the proposed converter, two batteries were put in lined up with capacitors in the circuit. The batteries will diminish current waves brought about by changes happened in light power and its bearing. Besides, a changed dynamic/receptive power control was introduced and applied in proposed QZSI (PQZSI) to control the genuine and responsive result force of the PV, separately [3].

This work was expected to upgrade both the powerful execution and effectiveness of SPIM for water siphon application at evaluated speed. Multi-objective streamlining was performed by utilizing the hereditary calculation utilizing a Maxwell-2D transient solver. The examination introduced the correlation between the streamlined and essential engine plans while thinking about different assembling limitations. The review proposed a structure for execution upgrade of SPIM while checking the ideal arrangement through responsiveness examination [4].

"Z-source T-type-inverter-for RES with PR" was recommended by Ozdemir. ‘Here in examination, an innovative Z-source T-type-inverter for network associated RES’ was proposed [5]. The proposed framework had capacity of heightening-voltage-level with no extra DC’DC-converter/transformer over the~Z-impedance position. The extent-of-the framework was decreased by disposing of DC’DC-converter / venture up-transformer prerequisite. Versatile-closed-loop-state-control framework-for-a3level-neutral-point-clamped-ZSI was given by Wolffe.

The mix of a novel modified QZS with a solitary stage proportioned ~hybrid 3level ~inverter so as to help the inverter 3level yield voltage was presented. The anticipated distinct stage MQZS-hybrid 3level ~inverter gave a sophisticated enhancement capacity & lessens the quantity of

~inductors in the –source-impedance, contrasted & equally the solitary stage 3 level three phase inverter QZSIC and the AC stage rectified to QZS 3phase inverter. AC stage rectified to QZSIC with decreased capacitance utilizing adjusted modulation and twofold recurrence ripple concealment control" was given by Li. Fathi recommended "Improved lift ~ZSI-with exchanged Z impedance".

The principle focal point of the examination was to explore which procedure mining calculation could prompt generation of procedure models that separate replay the occasions accurately with 100% degree of wellness, exactness, speculation and straightforwardness. The outcomes demonstrated that alpha calculation brought about the generalization of procedure models with great straightforwardness however with poor accuracy and speculation. Heuristic calculation brought about the generalization of procedure models with great exactness however with poor speculation and effortlessness. Model predictive calculation brought about generation of rather basic procedure models with great accuracy and speculation. Besides, the models/diagrams created through Model predictive-calculation could separate the majority of the cases accurately with 100% degree of wellness as an approval measure. Procedure mining and students' conduct investigation in a collective and electronic multi-table top condition was proposed by Porouhan.

S. Ozdemir deals with "Z-supply T-kind inverter for renewable electricity systems with proportional resonant controller [5]. M. Stempfle affords adaptive closed loop country manage machine for a 3 degree neutral factor clamped Z supply inverter [6]. A.V. Ho labored on Single section modified quasi Z supply cascaded hybrid five degree Inverter [7]. Reduction of common mode voltage and conducted EMI through three phase inverter topology is given by Ham [8]. E. Babari has advanced embedded switched Z source inverter [9]. Improving performance of OTT systems the use of fuzzy mining technique is given by way of Premchaiswadi [10].

V. Jagan, S. Das cope with two tapped inductor quasi impedance source inverter (2TL-QZSIC) for PV applications [11]. Sliding mode manage of the planar switched reluctance motor for interference suppression is given through Xu [12].

In this topic, the existing work is exposed with version predictive manage to improve the dynamic response of QZSI-IMDS and is organized in six sections. Section I presents the studies gap. In Section II, topology of QZSI-IMDS is given. The behaviour of QZSI-IMDS in closed loop is offered in phase 4. The manage strategies for QZSI-IMDS are evaluated in Section III and Section IV offers the experimental results for QZSI-IMDS. Conclusion is mentioned in the closing Section V.

There is a want to regulate the velocity of QZSI-IMDS because of exchange in load or supply voltage the usage of closed loop controller .Hence this paper in particular makes a specialty of identifying a premier controller for a QZSI-IMDS used for constant pace packages. Generally there is a more call for constant speed loads. A closed loop control is delivered inside the QZSI-circuit with a purpose to attain regular pace quickly.

The exceeding literature doesn't percent with OTT-filter for QZ-SIIMD method. This painting proposes OTT-clear out for QZSIC-IMDS. The exceeding literature doesn't percent with enhancement of small scale balance with the use of MP-managed-QZ-SIIMD-method. Hence, the present exertion offers with assessment of SMC and MP-managed-QZ-SIIMD-techniques. This exertion proposes MPC for QZSIC-IMDS.

## II. SYSTEM DESCRIPTION

DC is renewed to 3phaseAC by way of QZSI.OTT-filter out reduces harmonics. The response of OTTF is applied to TPIM. Speediness is delimited by way of SMC. The "block diagram of proposed SMC and MPC QZSIC system" is out in Fig. 1. Speediness is appraised with the mentioned speediness and the inaccuracy is targeted to a SMC/MPC. The "result of SMC/MPC" panels the PW of the rectifier. The function of speed loop is to regulate the speed of IMS.

Fig. 1. 'Block diagram of SMC/ MPC controlled-QZSIC-system'.

## III. SIMULATION-RESULTS

Circuit diagram of CLSCQZSIIM with SMC is demarcated in Fig. 2. Supply Voltage is demarcated in Fig. 4. The-step-conversion is perceived and the assessment of supply Voltage is augmented from 200V to 230V at t =2.6 sec. Voltage across motor load of CLSCQZSIIM with SMC is demarcated in Fig. 5 and the value of Voltage across Motor Load of CLSCQZSICIM with SM controller is 340V. Current Through Motor Load of CL-SCQZSICIM with SM controller is demarcated in Fig. 6 and the value is 0.019A.

Fig. 2. CLSCQZSIIM with SMC.

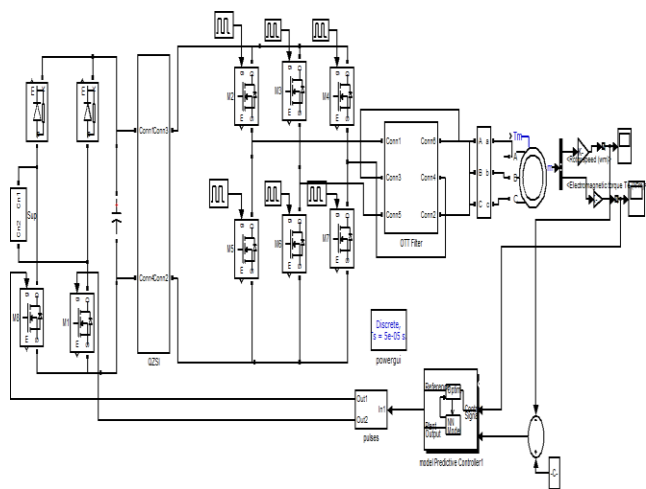

Fig. 3. CL-SC-QZSICIM with MPC.

CLSCQZSIIM with MPC is demarcated in Fig. 3. The MPC in the present work uses only speed and torque signals. Hence the CLSCQZSIIM with MPC is simpler. The contributions to MPC are speediness and torque.

Motor Speed of-CLSC-QZSICIM-with SMC and MPC is shown in Fig. 4. The significance of Motor Speed is 1296RPM. Speediness settles quickly with MPC. Number of speed-oscillations is higher with SMC than MPC.

Motor Torque of CLSCQZSIIM with SMC and MPC is shown in Fig. 5. The significance of Motor torque is 0.28N-m. Amplitude of torque oscillations is higher with SMC than MPC. Torque oscillations are lesser with MP-controller.

Evaluation of Time domain Parameters (speed) by means of SMC &MPC is specified in Table I. By means of MPC, the rise-time is reduced to 3.0Sec; peak-time is reduced to 3.18Sec; settling time is reduced to 3.36 Sec; steady-stateerror is reduced to 1.28RPM.

Evaluation of Time-domain-Parameters (motor-torque) by means of SMC &MPC is specified in Table II. By means of MPC, the rise-time is reduced to 3.12Sec; peak-time is reduced to 3.25 Sec; settling-time is reduced to 3.39Sec; steady-state-error is reduced to 0.03N-m. Hereafter, Closed-loop-QZSIC-fed-IM with MP controller is superior to Closed loop QZSIC-fed-IM with SMC.

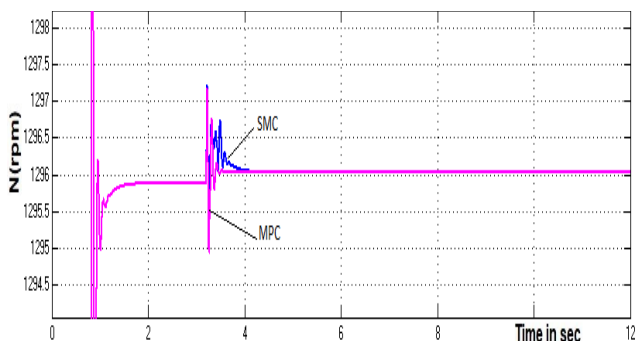

Fig. 4. Motor speed of-CLSCQZSIIM with SMC and MPC.

Fig. 5. Motor-Torque of CLSCQZSIIM-with SMC and MPC.

TABLE I. EVALUATION OF TIME DOMAIN PARAMETERS (MOTOR SPEED) BY MEANS OF SMC AND MPC

CL Controller	Rise-time (S)	Settling-time (S)	Peak-Time(S)	Steady-state-error (Rpm)
SMC	3.1	3.65	3.26	1.76
MPC	3.0	3.36	3.18	1.28

TABLE II. EVALUATION OF TIME-DOMAIN-PARAMETERS (TORQUE) BY MEANS OF SMC AND MPC

CL Controller	Rise-time (S)	Settling-time (S)	Peak Time(S)	Steady-state-error (N-m)
SMC	3.23	3.55	3.33	0.04
MPC	3.12	3.39	3.25	0.03

#### IV. EXPERIMENTAL-RESULTS AND DISCUSSIONS OF QZSICIMDS

QZSICIMDS hardware snap-shot is out in Fig. 6. The hardware embraces of rectifier, QZS, 3Ø-inverter, Transformer, Control-Circuit & 3Ø motor-load. PIC16F84 is used to generate pulses for the switches of QZSI. Current through motor load of QZSICIMDS is demarcated in Fig. 7. The spikes in current are due to change in switching sequence. Voltage of across motor of QZSICIMDS is shown in Fig. 8 and the spikes are due to change in current in inductance of IM.

Fig. 6. Hardware-snap-shot of QZSICIMDS.

Fig. 7. Current through IMD.

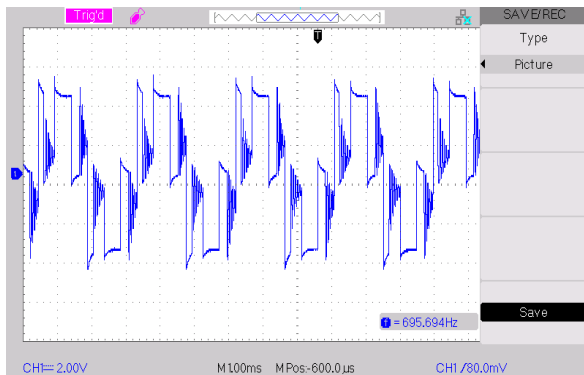

Fig. 8. Voltage across IMD.

## V. CONCLUSION OF SCQZSICIMD

The evaluation of SMC and MPC managed QZSIC is completed by way of Simulink. Simulation consequences are related via time domain parameters. SCQZSICIMD machine is efficiently intended, exhibited and-simulated the use of SMC and MP-Controllers for exchange in input voltage. By using MPC, settling-time is reduced to 3.39Sec; steady-state-error is reduced to 1.28RPM. The simulation consequences designate that, the response of MPCQZSIC is superior to SMC- QZSIC. The involvement of this exertion is to enrich the vibrant-reaction of QZSIIMD by MPC. The earnings of MPC-QZSIC are excessive expansion and fast dynamic reaction. Hence, first-rate voltage growth, amended performance and time retort of the machine makes the QZSIC much more proficiency making the SC-QZSICS suitable for input voltage assets. The downside is that SCQZSIC requires two additional controlled switches. The contribution of this work is to decorate small scale stability of QZSIIMD power using MPC and reduce THD using the use of OTT filter. This QZSIIMD is extra suitable for programs like electric motors and compressors.

The existent attempt pacts with “SMC & MP controlled QZSIC”. The evaluation among FLC & ANN QZSICS may be completed in-destiny. The hardware of QZSIIMD is applied using PIC16F84. The hardware of QZSIIMD can be implemented the usage of DSPIC to boom the switching frequency. High power QZSIIMD- may be carried out using IGBTs. Cost analysis of “SMC & MP controlled QZSIC” can be done in future.

Her-exploration interests comprise Power Electronics, Electrical Machines, & Modeling & Analysis of ACDrives. She is a life member of ‘ISTE’.

Dr. G. Sreenivasan employed as a ‘Professor Department of EEE’ in PVKKIT, Anantapur AP. His-extents of concern comprise Power Systems, Control Systems & Electrical Machines. He is a life member of “ISTE & IEI”.

Dr. R. Kiranmayi employed as a Professor in Department of EEE in JNTUA College of Engineering, Anantapur AP. Her extents of concern comprise Renewable energy resources & Electrical power systems. She is a ‘life member’ of “ISTE & IEI”.

# Visualization of Business Intelligence Insights into Aviation Accidents

## Aviation Accidents Discovery: Actionable Insights and Data Visualization

Loe Piin Piin<sup>1</sup>, Sarasvathi Nagalingham<sup>2</sup>

Faculty of Data Science and Information Technology, INTI International University  
Nilai, Negeri Sembilan, Malaysia<sup>1,2</sup>

**Abstract**—Despite the recent tragic loss activity, flying is often said to be the safest form of transport, and this is at least true in terms of fatalities per distance travelled. The Civil Aviation Authority reports that the death rate per billion kilometers travelled by aircraft is 0.003, which is much lower than the rates of 0.27 for train travel and 2.57 for vehicle travel. Despite the fact that safety has been the aviation industry's top focus for the last century and a half, accidents involving aircraft continue to be a source of horror even in the present day. Hence, the aim of this project is to identify the major causes and reasons that led to accidents in the aviation industry and to carry out research, finding, design, build and suggest a Business Intelligence (BI) solution to the problem. Throughout the project, it will discover problems, both elementary and critical which needs to be corrected or changed in order to prevent major negative happenings and improve the current situation in a positive way. Tableau will be the primary BI tool used in this process. Data visualization is the graphic depiction of information and data. Data visualization tools offer an easy approach to data analysis that observe and find patterns, outliers, and patterns in data by employing visual elements like charts, graphs, and maps. The project will also cover the initial to building and deployment stage of the BI solution to improve and prevent further accidents.

**Keywords**—Aviation; accidents; business intelligence; prediction; dashboard visualization; data analysis

### I. INTRODUCTION

#### A. Business Intelligence Methodology

Businesses can improve their decision-making processes with the help of Business Intelligence (BI), which showcases current and historical data within the context of the company's operations. BI may be used by analysts to establish the business's performance and competitive benchmarks, which will help businesses operate more seamlessly and productively and also uncover market trends that can be improved upon [14]. Every BI project has to specify a systematic methodology and strategy in order to provide decision-makers with the ability to adopt, implement, and integrate sustainable management practices across the company. In addition, it may improve the likelihood of accomplishment, reduce the amount of time and effort required, eliminate redundant procedures, and guarantee accurate reporting and analysis. As a result, the Polar's BI methodology will be used, which consist of five major steps. It helps organizations by delivering meaningful insights and develops new solutions to meet the problems based on

recommended steps. Fig. 1 depicts the stages that are included in the phase of constructing a Polar's BI methodology:

Fig. 1. Diagram for polar BI methodology

- **Visualize:** This step will involve defining the business requirement, which in our case, will be to identify trends and causes that leads to aviation accidents. It establishes a roadmap which will define the information clearly.
- **Planning and Architecture:** This step involves detailed business, data, and requirements by the system to produce the implementation plan accordingly including detailing the architecture of the system along with design specifications to provide solution. It is vital to define each requirement obtained from visualization and define a proper scope. It includes clearly defining the basic software and hardware requirements.
- **Development and Implement:** This phase is where the requirements are transformed into reality with a tested software production. Data will be populated into the

defined data structure through ETL process. After which database must be developed and software testing has to be conducted to ensure smooth functioning of the system and customer satisfaction. Finally, extensive documentation has to be prepared before deployment.

- **Deployment:** This is the implementation phase where the system will be finally implemented into the production environment to facilitate information exchange and migration of database structures and components. It gathers the readiness of the users and infrastructure, and the deployment plan will be shared with the initial set of users. The product would be deployed, and the system will be checked for correctness and accuracy.
- **Maintenance:** After the deployment, the system will need proper maintenance to ensure long term functionality and flow. This will include administration control, regular monitoring and performance updates and tuning.

### B. Overview of Boeing Company

Boeing Co., Major U.S. firm that is the world's biggest aviation organization and principal creator of business fly vehicles. It was established by William E. Boeing (1881-1956) in 1916 (as Aero Products Company). In the last part of the 1920s it turned out to be essential for United Aircraft and Transport Corp., however it reappeared as a free element in 1934 when that organization was separated to conform to antitrust regulation [1]. Boeing spearheaded the advancement of single-wing planes during the 1930s; its B-17 Flying Fortress (first flown 1935) and B-29 Superfortress (1942) assumed noticeable parts in World War II.

It is additionally a main maker of military airplane, helicopters, space vehicles, and rockets, a standing essentially improved with the organization's procurement of the aviation and safeguard units of Rockwell International Corporation in 1996 and its consolidation with McDonnell Douglas Corporation in 1997. Previously Boeing Airplane Company, the firm accepted that its present name in 1961 to mirror its venture into fields past airplane make. Central commands were in Seattle until 2001, when Boeing migrated to Chicago.

Boeing Company's constituent specialty units are coordinated around three primary gatherings of items and administrations business planes, military airplane and rockets, and space and correspondences. Boeing fabricates seven particular groups of business airplane, which are gathered in two offices Renton, and Everett-in Washington State and one office in California. The Renton plant fabricates the restricted body Boeing 737 and previously constructed the 757 airplanes (ended in 2004), while the wide-body Boeing 767 and 777 airplanes and a predetermined number of the plane, to a great extent suspended 747s is gathered at the Everett plant. The 787 airplanes are collected at the Everett plant and at an office in North Charleston, South Carolina. Boeing Business Jets, a joint endeavor of Boeing and General Electric Co., makes and markets business jets in view of the 737-700 aircraft as well as VIP forms of the 747, 777, and 787 carriers.

### C. Challenges Faced by Boeing Company

It is critical for businesses to be able to identify and forecast existing and future challenges that they may encounter. Identifying difficulties early on may assist the firm in developing a better solution sooner rather than later, which can help the company lower its losses. Aside from that, businesses may transform issues into chances for growth, allowing them to become more profitable in the long run. Being the largest producer of commercial and military aircraft and having the highest revenue compared to its competitors, the company has faced and faces several challenges.

First, Boeing being the leading company in the aviation sector has many responsibilities and must abide government-imposed norms without fail as well as manage their business operations without defect. Certain time sudden laws and restrictions can cause the company to change its business layout in order to adjust. For example, in 1977, Boeing faced travel cost competition when the US administration brought down air travel restrictions which promoted more newer airlines to offer the same services at very competitive prices by the year 1999. Another scenario of rapid change was during the Covid pandemic which affected many businesses but demanded a complete shutdown of aviation travel.

As the making of an airplane is directly related to safety, it has to undergo various tests in order to prove its feasibility and safety mechanisms. These include various additional costs and takes a long time. When Boeing developed the '787 Dreamliner' to save fuel and minimize stopovers, the airplane was made to be 50% carbon fiber-reinforced plastics, 12% titanium and almost 80% reduction of the use of aluminum which was primarily used in the old plane models. When it decided to use Lithium-ion batteries there was a concern that it would overheat to a level where it would stimulate fire. In order to solve this issue, it had to undergo various tests to determine its feasibility.

Besides, there is a high risk of the parts not being suitable and face trouble when interlocking since the company has partnerships and contracts with many other production companies for different parts of the plane. Therefore, they have to be returned back in order to be reproduced which increases the initial cost and also is very time consuming. Also, the aviation industry is very much dependable on service and the satisfaction of passengers. Therefore, the airline production companies have to meet the demands of the purchasing airlines in order to produce the model that will meet current consumer expectations as well as balance business costs.

Technological advancement is one of the major challenges of the industry. In order to implement newer software, sometimes with additional measures, the construction plan of the flight model has to be altered in order to compile it with the newer changes. These may take longer times as it must be planned and the whole company has to be suited with the model in order to train the employees such as engineers, software developers and other employees. Changes like this cannot be executed frequently as it is a very complex process, and it will also require additional training for existing pilots all around the world. Suppose the technical advancement is not

considered to be great, airline will switch companies to buy airplanes in order to save their pilots from additional training which takes up time as well as money.

#### D. Opportunities of Boeing

Boeing has always been at the top among aerospace-based organisations. However, Boeing still faces some disparity with other modern gaming companies. Based on the studies found on the current environment of the company and gaming industry, there are some key business opportunities that can be implemented into the standard operation procedure of the company.

The first opportunity that presents itself to the organisation is in the field of technology application. For example, the sharing of digital information among air traffic control, the flight deck, and the operations centre of an airline to enhance the effectiveness of flight routing and ensure passenger safety. An electronic flight bag software that utilises next-generation communications may provide information on alternative flight paths to pilots in the event that the conditions of the weather so need. In addition, connected cabin technologies that enhance common areas, such as galleys and restrooms, as well as monitor environmental factors, like as temperature and humidity allow automatic adjustments. Lastly, the installation of cameras will provide a greater number of passengers a view of the world beyond the window of the aeroplane.

Over the last several decades, safer and more dependable designs have been responsible for most of the progress gained in lowering accident rates and boosting efficiency. This breakthrough has been made possible by advancements in engines, systems, and structures. Furthermore, design has long been acknowledged as a component in minimizing and managing human mistake. When Boeing embarks on a new design activity, previous operating experience, operational objectives, and scientific understanding establish the human factors design criteria. To examine how well alternative design solutions fit these objectives, analytical approaches such as mockup or simulator assessments are performed. A human-centered design philosophy underpins this work, which has been confirmed by millions of flights and decades of experience.

When there is a big change in the design of a plane it has to undergo various tests which consume time and large sum of money. Since bringing lengthy changes to a plane is necessarily not a desired output in the short term, the company can adjust only the required mechanisms and not change the whole flight design which further causes workers to consume more time and gain used to the working process. This can be achieved by analyzing the areas which can be improved only to the level where it doesn't require additional guarantee tests and slowly bring changes over time to maintain balance in the business operations and revenue as well as providing a safe machine to its consumers.

Finally, the 787 can travel farther distances than its predecessors because to its improved fuel efficiency. As a result, it has enabled the creation of more than 50 nonstop routes throughout the globe. The design and construction of the Dreamliner are both ground-breaking. New composite

materials are used in the construction of fifty percent of the principal structure of the Boeing 787, which includes the fuselage and the wings. Both the speed of the aircraft and its fuel efficiency may be boosted thanks to the design and construction of the wings.

## II. PROPOSING BI SOLUTIONS

Business intelligence is a term that encapsulates the processes and methods used to collect, store, and analyze data from business operations or activities in order to improve performance [10]. All of these factors combine to provide a full image of a company, allowing customers to make better, more decisive decisions. In this section, the proposed business intelligence solutions assisting the business opportunities and solving the problems would be discussed.

Accident or crash rate is a calculation between the number of aircraft crash that unfold in a given period (crash frequency) and number of flights conducted within the same period. BI tools enable the accident rate to be calculated faster. In addition, the metrics for calculating the crash rate can be analyzed individually too to provide more insights, such as the crash frequency. Thus, the company can predict the probability of crash happening in the following years and put up a countermeasure to reduce it.

Through BI tools, the company will be able to discover factors that contribute to airplanes crashes. It allows the company to correlate the cause of the accidents, either its human errors or machine malfunctions, and any other piece of information together. Based on the piece of information founded, the factors that lead to aircraft crash can be grouped based on certain criteria to provide better insight which can also be used for comparison purposes. Therefore, a more specific study of aircraft crash on each criterion can be performed and a plan to address each category problem can be addressed.

Predictive maintenance is a proactive approach to machine maintenance, which is made possible through utilizing BI tools. It provides the company to organize schedules based on continuous condition monitoring. To minimize additional costly failures, broken parts are fixed or replaced if unfavorable patterns are discovered. Lower maintenance costs, longer equipment life, less downtime, increased production capacity, and improved safety are just a few of the advantages the company can expect.

## III. DATASET ANALYSIS

To describe how BI can improve Boeing performance, the NTSB aviation accident dataset was used as our data source. NTSB is an independent U.S. government investigation agency that identify and report on aviation accident. The NTSB aviation accident database contains information on civil aviation accidents and selected incidents that occurred in the United States, its territories and possessions, and international waterways. For our research, the dataset that we use contains information on aviation accidents from 1962 to present [5].

The reason the records are up to date is made possible by the continuous update of the accidents into the database. First,

a preliminary report will be available online within a few days of an accident. When available, information is added, and when the investigation is complete, the preliminary report is replaced with a final description of the accident and its probable cause. Full narrative descriptions may not be available for cases prior to 1993, those under revision, or those in which the NTSB did not have primary investigative responsibility. It's worth noting that the information isn't limited to just commercial jets. On September 18, 2002, data from 1962 to 1982 were added to the aircraft accident database. The structure and type of data given in previous briefs may change from that contained in subsequent reports.

An aviation accident is described as an event occurring due to aircraft operation happening between the time people boards the aircraft with the aim of flight and the time people depart, in which people are mortally or severely injured, the aircraft sustains severe damage or structural failure, or the aircraft goes missing or becomes totally inaccessible, according to Annex 13 of the Convention on International Civil Aviation. An aviation incident is defined in Annex 13 as any occurrence, other than an accident, related with the operation of an aircraft that affects or has the potential to influence the safety of operation. Government agencies such as the FAA and the NTSB examine accidents and occurrences.

A. Description of Dataset

Our dataset is obtained NTSB from aviation accident database containing information about civil aviation accidents within the United States and its territories including international water from the year 1962. The dataset comes in a single data sheet and consists of 31 columns describing details about the recorded aviation accident [5]. The table below shows the detailed description of each attribute in the dataset and what it represents (Table I).

TABLE I. DESCRIPTION OF DATASET

No	Attribute Name	Data Type	Description
1	Event ID	ID	Unique alphanumeric for each of the row about the accident
2	Investigation Type	ID	Conveys if the scenario was an accident or incident
3	Accident Number	ID	Specific number given to the accident/incident
4	Event Date	Date	Date at which the accident occurred, displayed in the format "YYYY-MM-DD"
5	Location	String	Location at which the accident took place
6	Country	String	Country the accident took place
7	Latitude	Numeric (Continuous)	Angle of latitude which ranges from 0 degree at the Equator to 90 degrees (North or South) at the poles
8	Longitude	Numeric (Continuous)	Longitude which is the measurement east or west of the prime meridian
9	Airport Code	String	The airport code, which is unique for each and every airport in the world and is usually represented by three letters or four letters

10	Airport Name	String	The name of the Airport
11	Injury Severity	Nominal	Severity of the injury
12	Aircraft Damage	Nominal	The damage level to the aircraft
13	Aircraft Category	Nominal	Type of aircraft, ranging from Airplane, helicopter, glider, etc.
14	Registration Number	ID	Registration number of the aircraft
15	Make	Nominal	Brand type of the aircraft
16	Model	Nominal	Model number of the aircraft
17	Amateur Built	Boolean	True or false statement confirming if the aircraft is amateur built, meaning if they were built by people for their own education and recreation and not officially by an enterprise
18	Number of Engines	Numeric (Discrete)	Number of engines the aircraft had
19	Engine Type	Nominal	Type of engine the aircraft had
20	FAR Description	String	Description by Federal Aviation Regulations
21	Schedule	String	Represents the aircraft's schedule
22	Purpose of Flight	Nominal	Purpose of the flight, whether personal, instructional or others
23	Air Carrier	String	Airline company of the aircraft
24	Total Fatal Injuries	Numeric (Discrete)	Total number of fatal injuries due to the accident
25	Total Serious Injuries	Numeric (Discrete)	Total serious injuries due to the accident
26	Total Minor Injuries	Numeric (Discrete)	Total minor injuries due to the accident
27	Total Uninjured	Numeric (Discrete)	Total number of people uninjured after the accident
28	Weather Condition	Nominal	Condition of the weather at the time of accident
29	Broad Phase of Flight	Nominal	Phase of flight when the accident occurred
30	Report Status	Nominal	Status of the accident when reported
31	Publication Date	Date	Publication date of the accident

B. Data Preprocessing

With the dataset obtained from NTSB, we went through several rounds of data cleaning and preparation to make sure the data is in a clean format and is ready to be used for our BI dashboards. To perform data cleaning and preparation, we have used two programs, namely Microsoft Excel and R Studio. The programs were used to look at the state of the dataset (i.e. number of missing values for every column). We will go further and explain the techniques that we used in these two programs to aid our data cleaning and preparation process [6].

Microsoft Excel is an excellent software owned by Microsoft incorporation. It serves the purpose to organize, clean, arrange and simplify the data. Among the hundreds of features it has, some are being mentioned below.

1) *Conditions based formatting*: If you want to format the data based on conditions, then MS Excel is the best tool. For instance, you want to see only the Boeing Planes with a

seating capacity of less than 300 people. Then you can apply these conditions and see them. To use this feature, you need to select the desired column. In this case, the Fig. 2 demonstrates Column "Seating Capacity" is selected:

	A
1	Seating Capacity
2	500
3	400
4	325
5	235
6	215
7	150
8	200
9	575
10	600

Fig. 2. Select "Seating Capacity" column

Once you have selected the column go to "Home" option in toolbar and click on "Conditional Formatting" as shown in Fig. 3.

Fig. 3. Selection of "Conditional Formatting"

Once you hover the mouse over it, you can see the following options as shown in Fig. 4.

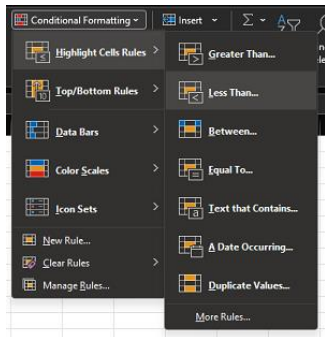

Fig. 4. Options in "Conditional Formatting"

In this case I have selected "Less Than..." as a condition. Once we click on "less than..." as shown in Fig. 5.

Fig. 5. Options in "Less Than..."

Here we can put the desired value and then the results will highlight in the column as depicted in Fig. 6.

	A
1	Seating Capacity
2	500
3	400
4	325
5	235
6	215
7	150
8	200
9	575
10	600

Fig. 6. Results of "Conditional Formatting"

2) *Removing duplicate columns:* There is a high probability that a data might have duplicate columns. MS excel provides a fantastic feature to remove them. You don't have to select each column in Dataset to remove them. Instead, there is an amazing feature in Excel which lets you remove duplicate columns automatically as shown in Fig. 7.

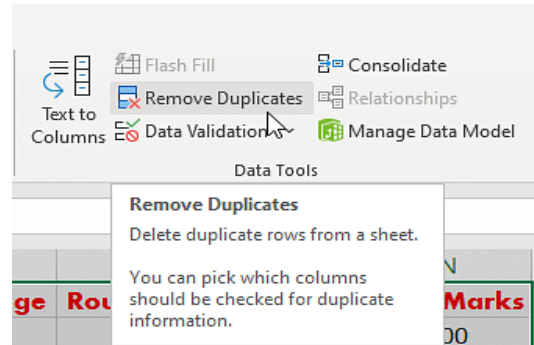

Fig. 7. Remove duplicates feature in excel

To access this feature, you can go to Data option placed in tool bar, there you can see "Remove Duplicate" feature as Fig. 8. Once you click on it, it will show you the duplicates and you can remove them if you want.

Fig. 8. Remove duplicates window

Once you are satisfied with columns checking you can hit ok and excel will remove duplicate column successfully.

3) *Spell check*: MS Excel has another useful feature as shown in Fig. 9 which helps you check for spelling mistakes in a data. This feature can come very handy in pointing out typos. For this feature to work, you can select your desired column from database and then click on “Review” option from tool bar. There you can see spell check option.

Fig. 9. Spelling check in excel

Once you click on it, Excel will automatically scan for any spelling mistakes in the data and will show as per the Fig. 10.

Fig. 10. Spelling check configuration

You can see this Pop-up, from here you can choose which spelling is suitable for you. If you think the word spell is ok, you can click on “Add to Dictionary” or “Ignore All/once”. If you want to change the word with the given suggestions, you can highlight preferred suggestion and click on “Change /Change All”. If you want the system to automatically correct, you can click on “Auto Correct”. If there are no spelling errors the following pop up will appear as shown in Fig. 11.

Fig. 11. Successful configuration of spelling check

RStudio is an open-source IDE (integrated development environment) for R programming that has been widely utilised by the community for statistical and computing purposes. The RStudio was utilised in this project since various tasks required the use of the R language to aid in data visualisation and pre-processing. Due to the ease of access and pre-experiences of the program being used, the authors decided to use this program as the pre-processing tool due to the familiarity of library tools usage from the past and the

flexibility of data processing it provides. Fig. 12 demonstrates the techniques that were used in R Studio to perform data cleaning and preparation:

4) *Display summary of a data frame*: `summary(df)`

```
> summary(avia)
  Event.Id      Investigation.Type Accident.Number
Length:87282  Length:87282      Length:87282
Class :character  Class :character  Class :character
Mode :character   Mode :character   Mode :character

  Airport.Code      Airport.Name      Injury.Severity
Length:87282      Length:87282      Length:87282
Class :character  Class :character  Class :character
Mode :character   Mode :character   Mode :character
```

Fig. 12. Display summary of non-numerical attributes of a data frame

Using this function, we will get a summary of every attribute in a data frame as shown in Fig. 12. For each attribute, it will display the number of records and the attribute type.

```
Total.Serious.Injuries Total.Minor.Injuries Total.Uninjured
Min. : 0.000      Min. : 0.000      Min. : 0.000
1st Qu.: 0.000    1st Qu.: 0.000    1st Qu.: 0.000
Median : 0.000    Median : 0.000    Median : 1.000
Mean : 0.281      Mean : 0.361      Mean : 5.312
3rd Qu.: 0.000    3rd Qu.: 0.000    3rd Qu.: 2.000
Max. :161.000     Max. :380.000     Max. :699.000
NA's :12510       NA's :11933       NA's :5912
```

Fig. 13. Display summary of numerical attributes of a data frame

For numerical attributes, R will be able to display even more details of the attribute, like the first quarter value, third quarter value, minimum and maximum value found, number of missing values etc as shown in Fig. 13. Using this function, we will be able to check the type of every attribute and also the number of missing values. However, as this function is unable to display more information about non-numerical attributes, we have to use other functions to learn more about our dataset.

5) *Display number of missing values or empty columns for each attribute*:

```
colSums(is.na(df)| df == "")
```

```
> colSums(is.na(avia)| avia == "")
  Event.Id      Investigation.Type      Accident.Number      Event.Date
0            0                0                0
Longitude      Airport.Code      Airport.Name      Injury.Severity
54218          37812            35254            883
Make           Model            Amateur.Built      Number.of.Engines
62            89                102            5749
Purpose.of.flight Air.carrier      Total.Fatal.Injuries Total.Serious.Injuries
5789          71311            11401            12510
Broad.phase.of.flight Report.Status      Publication.Date
25558         5211             13653
```

Fig. 14. Display number of missing values or empty columns for each attribute

Through this function, we are able to clearly see the number of missing values and empty columns every attribute has as shown in Fig. 14. Any missing values or empty columns are bad for making visualizations through BI dashboards. Thus, we have to figure out what to deal with attributes that have an overwhelming number of missing values or empty columns.

6) *Remove columns from a data frame*:

```
df = subset(df, select = -c(attribute1, attribute2, attribute3))
```

With this function, we are subsetting attributes to create a new data frame. However, as we are specifying the “-c” argument, we are actually creating a new data frame that excludes the attributes mentioned in the command. We used this function to remove any attributes that have way too many missing values or empty columns to be used in our BI dashboard visualizations.

7) *Remove rows with missing values:*

```
df <- na.omit(df)
```

We used this function to remove the rows that had only missing values in our data frame.

8) *Format values in an attribute:* In our data set, the attribute that mentions the injury severity of aviation accidents also mention the number of fatal injuries in Fig. 15 (i.e. Fatal(4) meaning four meaning suffered fatal injuries). As the data set already has an attribute that stores the number of fatal injuries, we can make this attribute to only mention whether the injury severity is fatal, non-fatal or incidental. To achieve this, we used two functions:

```
unique(df[c("attribute1")])  
  
> unique(avia_clean[c("Injury.Severity")])  
      Injury.Severity  
1          Fatal(2)  
2          Fatal(4)  
3          Fatal(3)  
5          Fatal(1)  
6        Non-Fatal  
24         Incident  
26          Fatal(8)  
85          Fatal(78)  
166         Fatal(7)  
436         Fatal(6)  
608         Fatal(5)  
1872        Fatal(153)
```

Fig. 15. Display unique values in an attribute

Fig. 15 shows us the unique values in an attribute. Using this command, we first checked whether the attribute had a big number of unique attributes, which is bad for a categorical attribute.

```
df$attribute1 <- sub("Searched sting", "Substitute string",  
df$attribute1, ignore.case = TRUE)
```

```
avia_clean$Injury.Severity <- sub("Fatal\\(\\d+)", "Fatal", avia_clean$Injury.Severity, ignore.case = TRUE)
```

Fig. 16. Command to replace strings in an attribute

As shown in Fig. 16, we managed to automatically clear out the number of fatal injuries in this attribute, leaving only the word “Fatal”. Displaying the unique values again as per the Fig. 17, the command was successful in clearing out the number of fatal injuries in the attribute.

```
> unique(avia_clean[c("Injury.Severity")])  
      Injury.Severity  
1          Fatal  
6        Non-Fatal  
24         Incident
```

Fig. 17. Display unique values after replacing strings

9) *Read and write files:*

```
df <- read.csv("File location path")
```

```
#Load csv file  
avia <- read.csv("C:\\Users\\Daniel\\Documents\\Personal Files\\School Files\\Unif\\IBM4207 Business Intelligence  
\\Group Assignment\\archive\\aviationdata.csv")
```

Fig. 18. Command to read CSV file into a data frame

Fig. 18 depicts that we could read the csv format file that our data set came in. A csv file is a delimited text file which uses commas to separate between different values, and using this function, we imported the file into R Studio as a data frame to perform data cleaning and preparation.

```
write.xlsx(df, "File location path")
```

```
#write into excel document  
write.xlsx(avia_clean, "C:\\Users\\Daniel\\Documents\\Personal Files\\School Files\\Unif\\IBM4207 Business Intelligence  
\\Group Assignment\\aviationclean.xlsx")
```

Fig. 19. Command to write data frame into an excel document

After our data cleaning and preparation is completed, we want to export our data frame into an Excel file so that it can be used for our BI dashboards. We used this function, which is part of the “openxlsx” R library to write our clean data frame into an Excel file as shown in Fig. 19.

Due to challenges during data recording and such, several attributes of our dataset had a large number of missing values/empty columns. For example, the air carrier column had 71,311 missing values, longitude and latitude had 54,218 and 54,209 missing values each. As our dataset has 87,282 records in total, including attributes like these with a large number of missing values will be problematic. We also cannot try to fill in the missing values with techniques like using the mean as it will distort the meaning of the data. Because of this issue, we decided to outright remove the attributes that has a large number of missing values.

C. *Data Modeling*

The process of generating a visual representation of a comprehensive information system or specific components of that system in order to express the relationships that exist between different data points and organizational structures is known as data modelling [4]. The purpose of data modelling is to offer illustrations of the many kinds of data that are utilized and stored inside the system, as well as representations of their connections, potential groupings and organizational structures, format types, and attribute values.

In data mining, an algorithm is a set of related computations and heuristics that are used to construct a model based on a collection of data. Before designing a model, the algorithm does an initial analysis on the data that people provide, looking for different sorts of patterns or trends. The results of this study are used by the algorithm, which goes through a number of rounds to determine which parameters will provide the most accurate mining model [12]. After that, the whole of the data gathering is analyzed using these criteria in order to derive actionable patterns and comprehensive statistics. In this section, the algorithms that were employed are the decision tree method, the Support Vector Machine (SVM) algorithm, and the Naïve Bayes algorithm.

1) *Naïve bayes algorithm*: The Naïve Bayes algorithm is a classification approach that is based on the Bayes Theorem and operates on the assumption that predictors are independent of one another [3]. To put it simply, a Naïve Bayes classifier is one that operates on the assumption that the existence of one feature in a class has absolutely no bearing on the presence of any other feature. The Fig. 20 illustrates an example of the formula for Bayes' theorem:

$$P(A|B) = \frac{P(B|A)P(A)}{P(B)}$$

Fig. 20. Calculation for bayes' theorem

- The possibility that a certain hypothesis (A) will in fact come to pass is quantified by the posterior probability, abbreviated as P(A|B).
- Likelihood Probability, abbreviated as P(B|A), is a measurement that determines how probable it is, based on the data that is now available, that a particular hypothesis is right.
- Priority probability, sometimes abbreviated as P(A), refers to the possibility that a hypothesis exists prior to seeing the data.
- The likelihood of evidence is referred to as P(B), which stands for marginal probability.

2) *Decision tree*: A decision tree is a technique of supervised learning that may be used with both discrete and continuous variables in its analysis [6]. The most essential aspect of the dataset is used to determine the subgroups that are created from the dataset. The algorithms are what decide how this characteristic is categorized by the decision tree and how the divisions are made between the categories. The terminal or leaf nodes, which do not further split, are created when the root node, which represents the most significant predictor, divides into decision nodes, which are sub-nodes as shown in Fig. 21 [7].

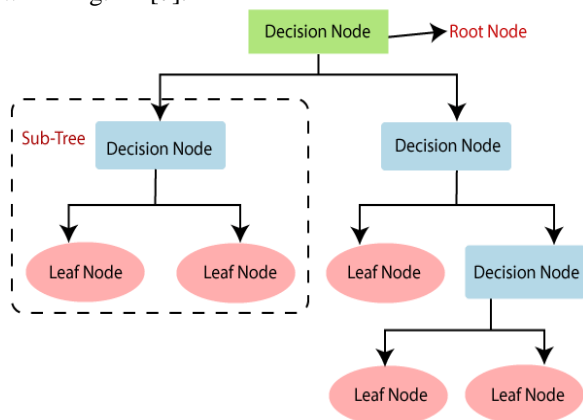

Fig. 21. Decision tree structure

3) *Support vector machine (SVM)*: The objective of the Support Vector Machine technique is to locate, in a space of N dimensions (where N represents the number of features), a hyperplane that categorizes the data points in a way that is unambiguous [8]. The two distinct groups of data points may be partitioned using any one of several hyperplanes that are available to choose from [9]. Finding a plane that has the highest margin, or the greatest separation between the data points of both classes, is the goal here. As per Fig. 22, When the margin distance is increased to its maximum, more support is added, which in turn increases the level of confidence with which subsequent data points may be categorized.

Fig. 22. SVM algorithm

#### IV. BUSINESS INTELLIGENCE ARCHITECTURE

The framework that a business establishes in order to run applications for business intelligence and analytics is referred to as a business intelligence architecture. It discusses the information technology platforms and software tools that are used to collect, integrate, store, and analyze business intelligence data before providing it to high-level executives and other corporate users as information on operational processes and statistics. Implementing an efficient BI program that allows data analysis and reporting to assist an organisation in monitoring business performance, optimizing business processes, recognizing new revenue opportunities, working on improving strategic planning, and providing better decisions overall requires a critical component known as the underlying BI architecture.

The BI architecture design shows how all the data and processes are connected to each other to support Valve business. The diagram shows the seven main components and the flow in Valve when dealing with data through business intelligence [2]. The seven main components consist of data sources, ETL (extract, transform and loading), data repository, business intelligence tools, interfaces, data management and security management as shown in Fig. 23.

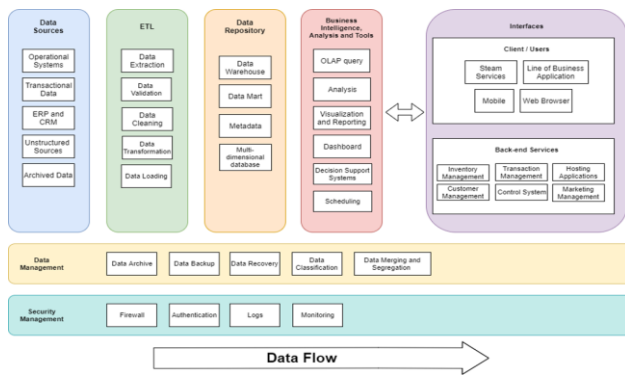

Fig. 23. Proposed BI architecture

### A. Data Source

Data sources mainly refer to where data is obtained. Any business organisation would get data differently depending on their mode of business, and their operations done. In Valve, data can come from multiple sources. For instance, transactions or purchases on games and the accessories can be categorised into transactional data, whereas daily processes and routines would contribute to data obtained from operational systems. This architecture design suggests that data sources may also involve data from unstructured forms, archives, and other systems such as ERP and CRM. All these data will then be staged into the ETL stage.

### B. ETL (Extract, Transform and Load)

This stage involves three major steps in dealing with data. First, data identified from the various data sources are extracted. There are multiple methods to extract data. It is crucial to discover which extraction method and platform would benefit the business the most. Usually when data are extracted from various data sources, the data vary from each other in terms of formatting. For instance, two data sources might store “date” data differently from each other. This is where the second step, transformation comes in. Transformation relates to changing the data into the wanted and appropriate format. This step also involves data cleaning and attributes derivations. This step is significant to ensure data integrity and quality, while making sure that the data would reach a common dimension and storage method. The data will then be loaded into the repository once all the data has been transformed.

### C. Data Repository

Data repository refers to where data is stored after being processed. Valve stores over ten million of players’ data, and management side. Therefore, Valve will need numerous data repositories and in different forms, such as data marts and data warehouses. For example, data that are generated to players and require high availability would be stored in data marts, and data that are not frequently used can be placed into data warehouses. Valve can store summarised and transformed data in data marts for respective departments to ensure productivity, while metadata that describes data and the relationships, together with raw data can be stored in a data warehouse. Multidimensional databases can help integrate data warehouses and OLAP applications to generate complex data to users [11].

### D. Business Intelligence, Analytics and Tools

This section comprises of all the business intelligence tools used in Valve. All of these tools assist the organisation in making better decisions and supporting the interfaces on both clients and back-end services. The tools include OLAP operations, analysis, visualisation, reporting, dashboard, and decision support applications.

### E. Interfaces

The interfaces involve how input and output would result through different platforms such as mobile, web applications, line of business application and steam application. Interfaces comprise of back-end services from within the company and externally from third-party services. These services extend to aid in the management side in Valve, such as inventory management, transaction management, customer management and more. Interface is the result where the client and users can view on the screen. The interfaces will communicate with the business intelligence part in order to output the wanted information.

### F. Data Management

It is important for every organisation to have a sustainable data management plan to ensure that data can be kept up to date and saved. This will help to maintain data quality and availability. It is also vital to archive and backup data in a set time interval to avoid any losses due to data loss or breach of security to protect the business operations. Data management is usually done by the administrators and certain technical employees throughout the data processes up to the interfaces.

### G. Security Management

Data is a crucial component in any organisation. Hence, they need to be protected and maintained at all times. A well-secured organisation would only allow authorized and recognized personnel to access the operational part of the organisation. Hence, firewalls and authentication are highly required in order to protect the data used by Valve. It is also crucial to monitor the activities of the personnel involved in the business operations in order to find out the culprit when there is a breach of security or data loss through logs. This is because Valve is a big company, comprising hundreds of employees and, which suggests that anything could happen.

## V. DATAWAREHOUSE AND OLAP MODEL

The dimensional model serves as the foundation for all analytics and reporting. It is used throughout the entire science of dimensional modelling, not only in the construction of the model but also in the execution of reports and queries, the development of extract, transform, and load tools, and the use of business intelligence tools [13]. Even though the business people in the organisation might never get to see the actual data models that are developed, they would become very acquainted with the reports and dashboards they help produce. Unless those models are capable of generating transparent, effective reporting and analysis, they will be ineffective in assisting the company in viewing data and using it to make informed choices that have an impact on operations. The ability to generate this vital business information is dependent on the use of dimensional modelling.

The dimensional model provides a logical data model for the presentation level of a Data Warehousing and Business Intelligence (DWBI) application, through which the end-user dashboards would take data. It contains a list of the entities and attributes required for the envisioned dashboards. The entities that provide measures are referred to as facts [12][13]. It is termed dimensions when they provide qualifiers that allow facts to be disaggregated, filtered, and organised in various ways. The Steam Sales Schema's data warehouse architecture is centred on the classic star model. Compared to the Snowflake and Starflake schema models, the star schema design has been the most useful when dealing with historical information since it has the lowest query complexity. This allows them to operate at peak performance in data warehouses, data marts, business intelligence applications, and online analytical processing (OLAP).

The fact data can be organised in a fact table at the model's centre, whereas the dimensional data is organised in dimension tables and surrounds the fact table. The fact table is the integration component at the heart of the data warehouse's star structure. They allow machine learning algorithms to analyse the data in its totality and concurrent access to the data by other subsystems. The star schema's dimension tables have no foreign keys. This allows star schema databases to be optimised for lookup and query performance using actual dimensions. They may also be customised to give the best performance and the specific parameters that are deemed most important or often queried by the organization in question. Data may be inputted transactionally as it is received, or it can be imported in bulk and subsequently validated and correctly denormalized.

The fact table of Boeing's dimensional model is the accident fact table, which holds details of the accident like the accident date, publication date, latitude, longitude, number of injuries by type, weather condition when the accident happened, flight phase during the accident and the report's status. From the fact table, it is connected to three dimension tables, namely, the flight dimension, state dimension and the airport dimension.

In the flight dimension, it has an ID number to identify the flight, along with the flight's schedule, purpose and number of passengers. It connects to the aircraft dimension, which records the aircraft's damage, category and identifies whether it is amateurly built. From the aircraft dimension, it connects to two dimensions. The first one is the airline dimension, which identifies the airline owning the aircraft, along with their name, country, region, email and contact number. The second dimension is the model dimension, which identifies the model of the aircraft, with the make, number of engines, engine type and description provided by the Federal Aviation Regulations (FAR). The airline dimension is connected to the manufacturer dimension, which identifies the manufacturer's details and contact methods.

The airport dimension holds information about the flight's departing airport, with details like the airport code, name, country, region, email and contact number. On the other hand, the state dimension recalls where the accident happened, along with the state name. It is connected to the country dimension,

which holds information like the country name and the country's region.

These nine tables make up the dimensional model designed for The Boeing Company. It enables the company to keep track of aviation accidents with paper reports and BI dashboards, while updating it with new records regularly.

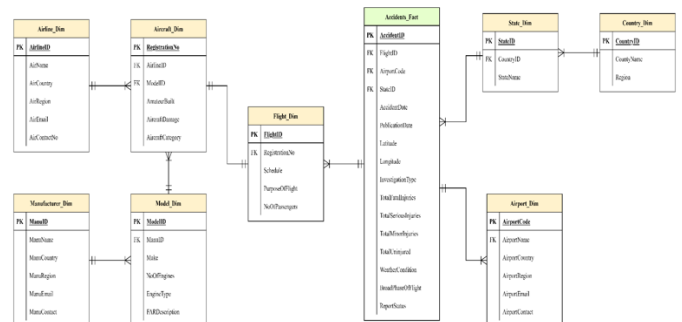

Fig. 24. Diagram of data warehouse schema

The dimensional model that was developed for The Boeing Company uses the snowflake schema as depicted in Fig. 24. Due to the complexity of records to be kept for an aviation accident, the dimensional model needs to use the snowflake schema in order to avoid data redundancy and ensure relevant data is stored in their respective tables. This is possible through the normalization of the dimensional structure, which causes the tables to form this snowflake-like shape, where the name comes from.

## VI. DASHBOARD VISUALIZATION

This project calls for the development of five different dashboards, each of which will be based on an analysis of either aircraft MAKE as shown in Fig. 25, purpose of flight, injury, weather condition or aircraft engine, respectively. Through the use of maps and graphs, data visualization enables us to better comprehend the significance of the information by putting it in a visual context. Due to the fact that the information is simpler to comprehend by the human mind, it is thus far less difficult to recognize trends, patterns, and outliers in massive data sets.

### A. Dashboard for Aircraft MAKE Analysis

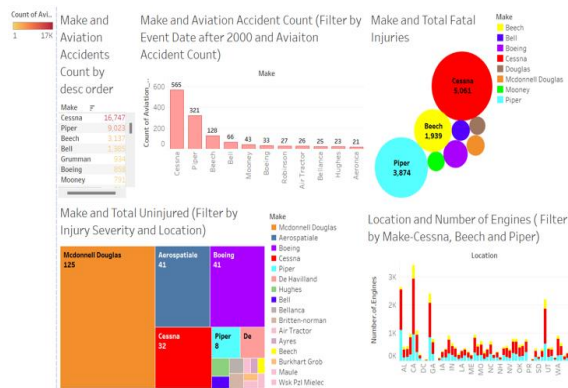

Fig. 25. Dashboard for aircraft MAKE analysis

The term “dashboard” refers to an electronic tracking tool that is used by companies to show and summarize the data that they have collected. The figure above demonstrates the overview of the dashboard showing factors with the “Make” column. This column represents the brand type of the aircraft. As evident from the above dashboard, the Make data is compared with aviation accidents total count, and another similar case where it is also filtered by event date of accidents that occurred after the year 2000. It is also visually represented along with total fatal injuries, denoting only the major ones. Total uninjured is also compared where it is filtered by severity of the accident and location. Final set of comparison has been done taking the top 3 makes having the most fatal injuries and representing them in a bar graph based on location and the number of engines. The dashboard gives an overview of the idea that can be gained by analyzing the representations.

On comparison of make with the count of aviation accidents, it can be found that Cessna had the highest count of accidents being 16,747, which is followed by Piper (9,023) and Beech (3,137) shown in Fig. 26. Evidently, when make is compared with total fatal injuries, Cessna has the highest rate with it being 5,061 and Piper and Beech following the same previous pattern having 3,874 and 1,939 fatal injuries, respectively.

Fig. 26. Make and aviation accidents count by descending order

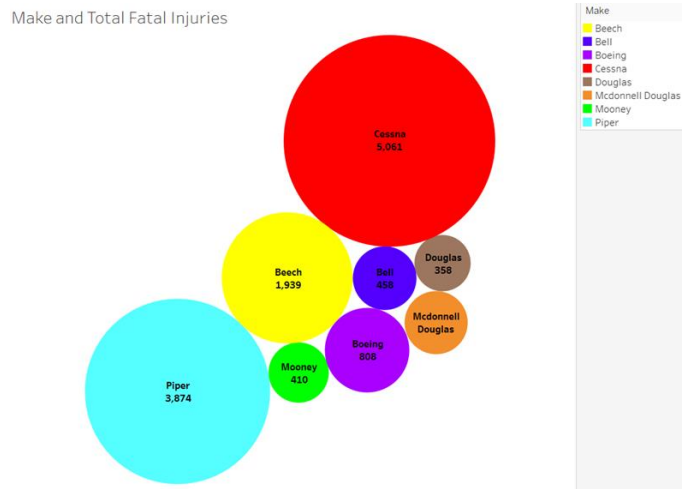

Fig. 27. Make and total fatal injuries

The two visual represents go hand in hand with each other and can aid the company in identifying the makes that have the highest rate of accidents and thus dig deeper into finding the reasons considering other real-life factors into account. It can also be noted that in the first representation, the number is arranged in the decreasing order with the color gradient being darker for the highest number and fading as it lowers. These tools are great for having a more toned representation of data. In the comparison with total fatal injuries, the packed bubble representation gives out a very clear and easy to understand pictorial representation with different makes being color-coded and the higher number having a larger bubble with the count represented as label in Fig. 27.

Based on the insights gained by the previous comparisons, the data can be filtered according to the needs of the user to display certain factors. For example, the tri-colored bar chart has specifically been filtered by the top 3 makes involved in the highest accidents (Cessna, Piper and Beech) and compared with the location of the accident and the number of engines present in the aircraft as shown in Fig. 28.

Fig. 28. Location and number of engines, filter by make

Each color represents one of the makes and exhibits a very organized pattern as information. By making use of previously identified information and viewing such representation based on specific requirement, more focused insights can be

obtained. For example, it is proof that Arizona (AZ) has the highest number of accidents happening with the three makes.

Make and Aviation Accident Count (Filter by Event Date after 2000 and Aviation Accident Count)

Fig. 29. Make and aviation accident count, filter by event date

Another example can be the bar chart in Fig. 29 depicting the make with the aviation count which is filtered by data to only show those that happened after the year 2000 and by already knowing the major values from the text tables, it has been filtered to show only those with count 21 and above as these alone give a large contrast between the highest values. This allows viewing specific data as per requirement and constraint. In this case, it can be seen that Cessna takes the lead of accidents even in this decade.

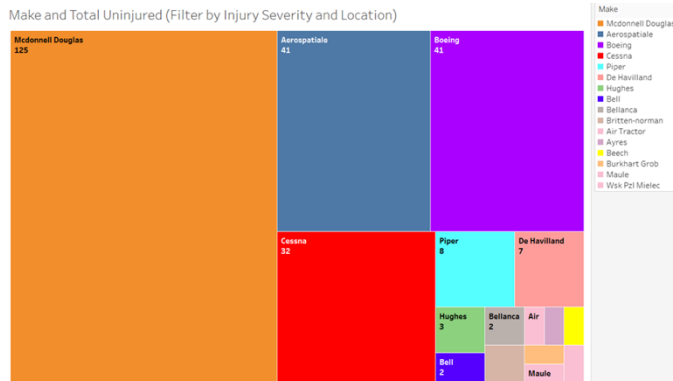

Fig. 30. Make and total uninjured, filter by severity and location

Finally, the Fig. 30 tree-maps present a colorful view of the make and total uninjured in each case that has been filtered by injury severity and location. In this example, two different categories have been allocated as filters with each allocation allowing the flexibility to choose the type and amount of data to be filtered with.

Fig. 31. Filter severity

Fig. 32. Filter location

In this case, the severity has been filtered by selecting ‘fatal’ and the location has been restricted to Alaska (AK), Alabama (AL), Arkansas (AR), Arizona (AZ) as shown in Fig. 31 and Fig. 32. Using only these constraints, the output has been presented. This is usually effective when deep analysis has to be made for a specific area or with a unique set of categories.

**B. Dashboard for Purpose of Flight Analysis**

Fig. 33. Dashboard view for purpose of flight analysis

The Fig. 33 represents the dashboard that compares the purpose of flight with multiple factors present in the dataset. The dashboard is useful in providing an overall view of all the insights that have been gathered which can be further used to improve the current situation and identify relations between different factors. In this case, the factor has been compared with total fatal injuries, aviation accidents, total serious injury, total minor injuries and total uninjured.

Fig. 34. Tree map for purpose of flight by total uninjured

The Fig. 34 tree-maps represent, the purpose of flight with total uninjured. It can be seen that majority of the flights were due to personal reasons and they also have the highest number of total uninjured people (32,746). With this visual presentation of data, some important information can be collected. In this case, the major reason for travel can be identified, along with the least factor that causes people to travel which is aerial observation.

Fig. 35. Bar graph for purpose of flight by aviation accidents

The Fig. 35 bar chart presents the purpose of flight with aviation accidents count. It can be noted that the highest number of accidents is 27,344 and those were people travelling for personal reasons. This is very much related to the previous comparison as both cases denote majority of the people involved in the accidents, travelled for personal use and therefore, they also contribute to a higher number of people uninjured. Bar chart gives a clear and defined view of the data in a very cleansed manner.

Fig. 36. Bullet graph for purpose of flight by serious injury

The Fig. 36 bullet graph shows the relation between purpose of flight and the number of serious injuries. The highest number of serious injuries is 5,505 which is among people travelling for personal use. As the insight gathered before, we can here specifically identify injury level among passengers travelling with different purposes.

Fig. 37. Packed bubble graph for purpose of flight by total fatal injuries

The Fig. 37 bubble chart shows the amount of people who have been fatally injured due to the accidents and the reasons they travelled. Out of the many categories, many people who travelled for personal and business reasons had fatal injuries. A total of 10,556 injured people were personal travelling passengers while there were around 1,556 business passengers. In this case, the size of the bubble presents the fatal injury count whereas the color represents the different categories of passengers. It shows a very precise and easy to understand view of the data for insight gathering.

Fig. 38. Pie chart for purpose of flight by total minor injuries

The Fig. 38 pie chart represents the purpose of flight compared with total minor injuries. The different colours depict different categories of passengers while the space occupied by a colour represents the quantity of the people injured. As evident from the previous visual representations, many numbers of people were traveling for personal purposes and therefore, people from that category had the most numbers of injured and uninjured people. In this case, there was a total of 8,255 people from the personal travel category who were had minor injury. The above depictions show the identification of the highest category of people travelling and a deeper insight into the accident and injury data for those different categories.

### C. Dashboard for Injury Analysis

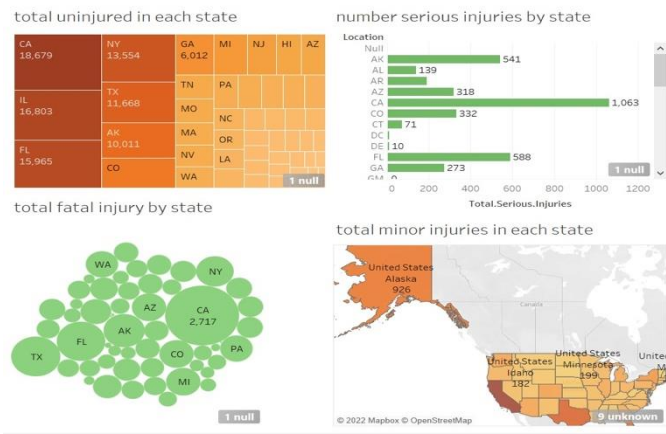

Fig. 39. Dashboard for injury analysis

The Fig. 39 illustrates an overview of the dashboard showing multiple factors from “Location” column. The location column shows the factors according to each state. In this case I used 4 factors named ‘total uninjured, total serious, total fatal and total minor’. Each of which is represented using four different kinds of figures. The dashboard talks all about injuries and deaths. This will help the airline companies to improve their security measures in each state according to the data. Fact Bubbles easily identify where the factor is in high value. Maps are easy to identify geographically. Tree maps can easily give scores for each state and is easy to identify using colour scheme too. Bar charts give accurate statistics of the factors. Following is the explanation of each:

Fig. 40. Bar graph for number of serious injuries by state

According to this Fig. 40, we can analyze that in US, most of the serious injuries are in state CA (California) which are almost close to 1000. After that second highest injuries are in FL and AK. Meanwhile GM and GU have zero serious injuries.

Fig. 41. Tree map for total uninjured in each state

The Fig. 41 relates to uninjured people in each state. We have seen that California had most serious injuries in previous figure but on the other hand it also has most injured people among other states too. IL, FL, and NY are on 2<sup>nd</sup>, 3<sup>rd</sup> and 4<sup>th</sup> ranks respectively, each having more than 10,000 people uninjured.

Now coming to the injuries which almost led to death, California is again ranked 1<sup>st</sup> with 2,717 fatal injuries. This might be because of excess number of travellers in CA. TX again is in 2<sup>nd</sup> position with more than 1200 fatal injuries and FL is ranked 3<sup>rd</sup>. Other states have very less reported fatal injuries due to less travellers as shown in Fig. 42.

Fig. 42. Packed bubble graph for total fatal injury by state

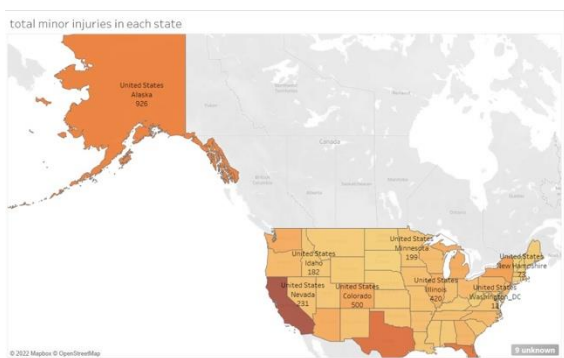

Fig. 43. Map for total minor injuries in each state

Coming to the minor injuries in each state, we used maps to locate them out. The region with most minor injuries is Alaska, with over 900 minor injuries confirmed. Second is Colorado with exactly 500 minor injuries and then ranks Illinois with 420 minor injuries as shown in Fig. 43.

D. Dashboard for Weather Condition Analysis

Fig. 44. Dashboard for weather condition analysis

The Fig. 44 displays a dashboard that compares data based on the chosen criteria. In this dashboard, five pieces of information are shown. Three pieces of information used weather conditions as the factor to be compared to another criteria. One other displayed information of damage sustained based on the quality of the builder, which can be seen in the

bottom left. The last one, investigation type is compared with the number of accidents that happened. One of the benefits of a dashboard is that it provides us with the means to view and analyze the key data that has been constructed. Hence, a conclusion can be drawn, and plans can be made accordingly.

Number of Each Types of Injuries by Weather Conditions

Weather	Total.Fatal.Injuries	Total.Serious.Injuries	Total.Minor.Injuries	Total.Injuries
VMC	12,854	8,068	13,911	34,833
IMC	5,093	1,189	1,654	7,936
UNK	635	77	116	828

Fig. 45. Table for number of each types of injuries by weather conditions

The Fig. 45 represents the number of injuries based on the weather conditions. It is displayed in the form of a highlighted text table. The table is constructed to enable the engineers to understand the weather situation that leads to accidents and what types of injuries it leads to. The total injuries caused by a particular weather condition can be analyzed too. Example, the above table shows that VMC generates a higher number of injuries compared to IMC on every level. From there, it can be concluded that humans tend to make more errors even with the situation is favorable. This is because IMC technically describe poor conditions, so machines are more heavily used. Therefore, the engineers can build parts that can improve the performance of humans (pilot and co-pilot).

Fig. 46. Stacked bar graph for number of aviation accidents by weather condition

The Fig. 46 bar chart shows the number of accidents caused by weather conditions, where the bar chart is stacked with information on the severity of injury. The severity of injury inside the bar chart is separated with colour marks so the data can be easier to understood. In addition, the number of accidents per severity of injury is also displayed. The data visualization has a similar purpose to the previous one. The difference is that in this data, it describes a more detailed representation of the injury.

Fig. 47. Stacked bar graph for number of accidents by investigation type

The Fig. 47 stacked bar chart shows the type of accidents. It illustrates the differences in number of each accident type by separating it inside the bar. To differentiate between the

investigation types, colour marks are used. Moreover, the number of accidents for each accident type is also displayed.

There are two reasons why stacked bar is used. The first is to fit the dashboard. The second is because we are dealing with small data where the factor is only one. For efficiency purposes, the number of accidents attribute is put in the column side. This data can be used by engineers to understand the fatalities of the events. An accident is described as an unexpected event that leads to damage and injury. While incident is described as an unexpected event that leads to some minor injury.

Fig. 48. Graph for investigating how the build quality affects the damages aircrafts' sustained

The data above is visualized using a bar chart in Fig. 48 that displays the damage aircraft sustained because of the build quality. The graph is constructed through two dimensions; the build quality and aircraft damage, and compare it by the number of accidents. The build quality is divided into two parts that compromise the components of aircraft damage. Colour is included to indicate the volume of the data in each criterion. The percentage in the chart above is over the total accidents.

The purpose of the above chart is not to compare directly the number of aircraft damages between aircraft that are maturely built or not. This is because the data distribution between the two criteria is too far. Hence, the above can be used to show the damage distribution on the aircraft. In each build quality, the aircraft mostly sustained substantial damage. It can also be noted that rarely aircraft suffered minor damage during aviation accidents.

### E. Dashboard for Aircraft Engine Analysis

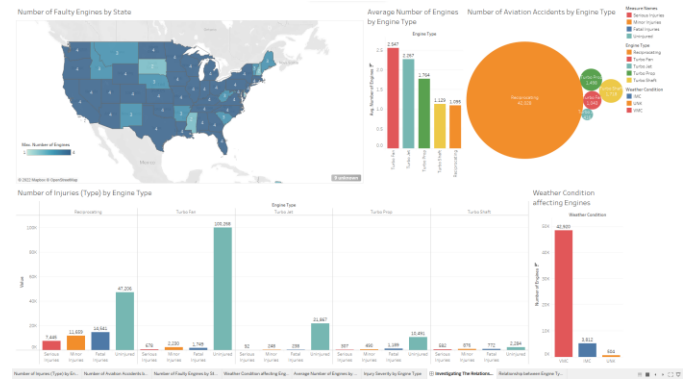

Fig. 49. Dashboard for aircraft engine analysis

Fig. 49 shows a dashboard, it uses information about the aircraft's engines to perform visualizations. In here, there are five different graphs, all designed to help engineers inside of The Boeing Company to get statistics about their aircraft's engines. All these five graphs are there to help engineers and analysts in The Boeing Company to identify faults in their engine's designs or implementation through the performance and safety data. With this information, improvements or changes can be made to the aircrafts produced by Boeing in an effort to increase the safety of the flights and ensure the security of their flight crew and passengers.

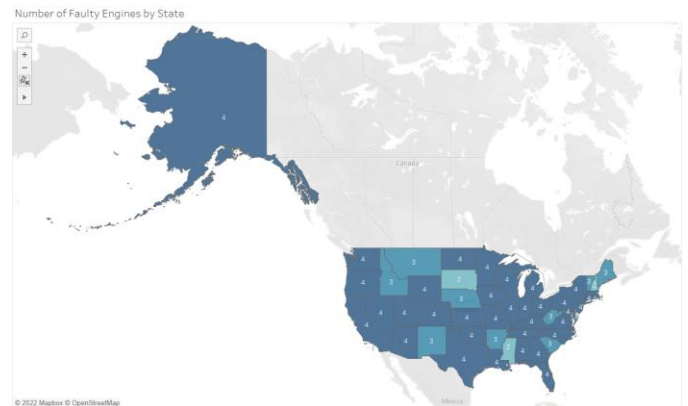

Fig. 50. Map visualization for the number of faulty engines by state

The first graph in the dashboard is a map that Fig. 50 illustrates the number of faulty engines for aviation accidents from each state in the US. It is done by using the state data, along with the maximum number of engines in the accident records for that particular state.

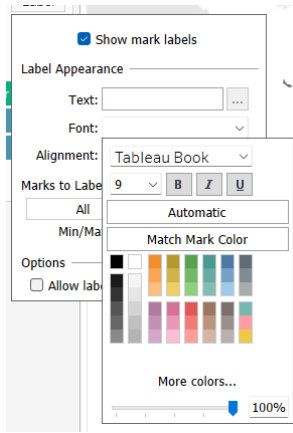

Fig. 51. Settings for label on map

At first, the map only provides an illustration of the number of faulty engines through the shade of the blue colour, being the darker the blue, the more engines that are faulty for that state. However, we thought that this is unclear and would not be enough for the analysts and engineers inside Boeing. Thus, the “Show mark labels” option was enabled as shown Fig. 51, with the label’s text colour adjusted to white, as a black font might be hard to read with dark blues.

This map graph is created so the engineers in Boeing can get to know the maximum number of engines that turned out to be faulty for each of their aircrafts. It is supported with the map to differentiate the data by state, so that in the future, if the departure point of the flight is available for Boeing’s BI dashboard, the engineers can measure the distance between the departing point and point of accident, while investigating the effects from the number of engines used.

Fig. 52. Bar graph of the average number of engines crashed by engine type

For the second visualization, Fig. 52 it is a bar graph which shows the average number of engines in aircrafts that crashed, separated by its engine type. The different types of engines are shown with the colour mark, which allows for easy reading of the visualization and data. The average number of engines by engine type is also shown, as a label, on top of each bar.

The bar graph would help the aircraft engineers understand the average number of engines installed for each engine type which was involved in aviation accidents. With this data, the engineers can perform a more thorough investigation on the

relationship between the number of engines installed, the installed engine type, its performance and reliability.

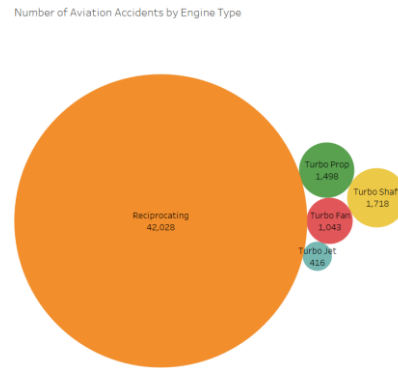

Fig. 53. Packed bubble visualization for the number of aviation accidents by engine type

The third visualization for the engine dashboard is the packed bubble graph as shown in Fig. 53, which shows the number of aviation accidents by its engine type. The packed bubble graph illustrates the difference in accidents between each engine type by differentiating each bubble’s size. The bubbles are also identified with the colour marking option, to make it more easily readable.

The purpose for comparing the number of aviation accidents caused by each engine type through this packed bubble graph is to allow for an easier to understand visualization of the relationship between these two data. The data analysts and engineers can look at this graph and get to know the number of accidents involved by each different engine type. For example, the packed bubble graph shows that the reciprocating engine type caused the greatest number of aviation accidents. Thus, they can investigate into the reason behind the engine type’s performance, to determine whether improvements should be made, or a different engine should be used.

Fig. 54. Bar graph of the number of injuries (type) by engine type

The fourth visualization is shown in Fig. 54 bar graph, which shows the difference in number of each injury type, separated by the engine type. This graph is possible by putting the total number of fatal injuries, serious injuries, minor injuries and uninjured into one measure values group, then comparing it with the engine type. Each engine type is divided

into one section, with five sections in total. While the number of injuries by type are shown for each engine type using different colours for each injury type.

This bar graph can be considered as the one that ties all of the previous visualization together. This is because it shows the total for each type of injury, compared among different engine types. Previously, we had a bar graph which showed the average number of engines for each engine type and a packed bubble graph to illustrate the number of aviation accidents by engine type. From these two graphs, the engineer or the analyst inside Boeing may conclude that the low number of average engines is one of the reasons that reciprocating engine types were involved in most aviation accidents. While the turbo fan engine type used, on average, the most engines per aircraft, at the same time having the second least aviation accidents.

This bar graph goes further to help the analysis by showing that, while luckily most of the passengers involved were uninjured, the reciprocating engine type had the greatest number of injuries for every injury type. On the other hand, the high average number of engines used for turbo fan aircrafts attained the greatest number of uninjured passengers. Judging from the data on the dashboard, the engineers may try to incorporate characteristics or improvements of turbo fan engines into reciprocating engines, in hopes to improve the safety and reliability of aircrafts with the engine type. Otherwise, the engineers can phase out reciprocating engine aircrafts in favour for safer engine types.

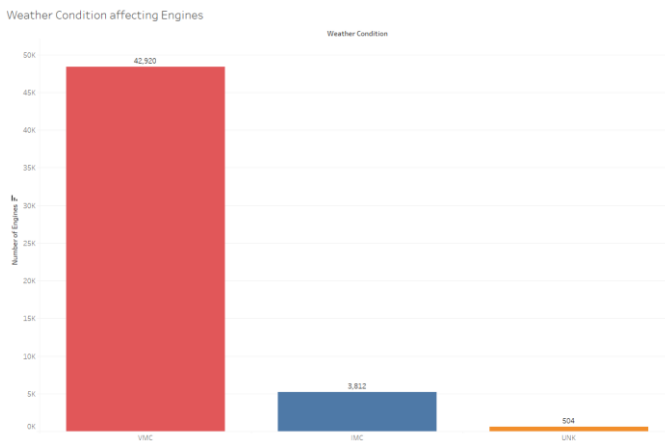

Fig. 55. Bar graph for the weather condition affecting engines

The last visualization for this engine dashboard is shown in Fig. 55 the bar graph which shows the how the different weather conditions affect the aircraft's engines. It is done by color coding the different weather conditions and comparing them with the accident numbers with the engine types.

In aviation, VMC means that the weather condition is good enough that the pilot can attain visuals of the skies, nearby possible aircrafts and the nearby terrain. Meanwhile, IMC describes when the visibility of the aircraft's surroundings is limited by bad weather conditions or when flying through thick clouds. In a situation like this, trained pilots will have to rely on the hearing equipment available in the cockpit to

remain updated about the aircraft's current whereabouts and surroundings.

This current state of the graph eliminates one common suspicion of engineers, which is that bad weather conditions are the main reasons that aviation accidents happen. However according to this bar graph, it is not the case as most of the accidents recorded actually happened when the weather condition is satisfactory for flight. While bad weather conditions do also play considerably small part in affecting the chance of an aviation accident happening, pilots nowadays have access to more modern and advanced monitoring equipment that allows them to keep track of the plane's status, location, elevation and such. This lends into the argument that weather conditions do not necessarily cause aviation accidents, but instead fault in the aircraft's design or the pilot's inexperience or mistake had caused the accident to happen.

## VII. CONCLUSION

BI is put into action using programming or devices which assemble tremendous measures of information and change them into valuable data which can be investigated to likewise acquire bits of knowledge and decide. Utilizing this methodology, the association will actually want to recognize past patterns and information that untruths concealed inside verifiable information gathered throughout the long term.

Boeing being the main organization in the flying area has numerous obligations and should stand against all the challenges it is facing right now. Most of the challenges include unexpected government regulations, market demands; technological advancements market demands, global coordination risk and preapproval tests. Boeing can combat all these problems easily by working on the market opportunities. For instance, it can increase its seating capacity and produce engines with more fuel efficiency as compared to competitors. Moreover, the Boeing team can analyze past incidents and an effective design change considering past accidents.

Finally, it can improve its technological side by doing some advancement in exchange of digital information, weather prediction, connected cabin systems and cameras to provide passengers a view of outside plane. Coming to the solutions, Boeing can implement prediction of encountering into a crash using BI and then use countermeasures to prevent it from happening. Another application where BI can be used is aircraft maintenance scheduling using predictive maintenance. Business Intelligence is also extremely beneficial in identifying the cause of aircraft crash. The autopilot system also learns from such situations and prevents the craft from being going into deadly situations too.

To sum this up BI is an essential tool in modern day businesses and organizations. It helps companies falling from mishaps and increases their performance along with user security. The data was clearly assessed in this assignment, and we got valuable statistics from it which can also help the company improve its insights.

# Metaphor Recognition Method based on Graph Neural Network

Zhou Chuwei<sup>1</sup>, SHI Yunmei<sup>2</sup>

Beijing Information Science and Technology University, Beijing Key Laboratory of Internet Culture Digital Dissemination,  
Beijing 100101, Beijing, China<sup>1,2</sup>  
School of Computer, Beijing University of Information Technology, Beijing 100101, Beijing, China<sup>1,2</sup>

**Abstract**—This Metaphor is a very common language phenomenon. Human language often uses metaphor to express emotion, and metaphor recognition is also an important research content in the field of NLP. Official documents are a serious style and do not usually use rhetorical sentences. This paper aims to identify rhetorical metaphorical sentences in official documents. The use of metaphors in metaphorical sentences depends on the context. Based on this linguistic feature, this paper proposes a BertGAT model, which uses Bert to extract semantic features of sentences and transform the dependency relationship between Chinese text and sentences into connected graphs. Finally, the graph attention neural network is used to learn semantic features and syntactic structure information to complete sentence metaphor recognition. The proposed model is tested on the constructed domain dataset and the sentiment public dataset respectively. Experimental results show that the method proposed in this paper can effectively improve the recognition ability of metaphorical emotional sentences.

**Keywords**—Sentiment analysis; metaphor recognition; graph neural network; attention mechanism

## I. INTRODUCTION

The use of metaphorical sentences can make the described things more imaginative and vivid, and can show stronger emotions. However, official documents are issued by legal organs or organizations, and their contents should be clear and specific, and their expressions should be simple and easy to understand, so they do not need to deliberately pursue rhetoric and generally do not use metaphors, lyricism and symbols. Metaphor is a common rhetorical technique in metaphorical sentences, but it is generally not used in official documents for standardization. It is a time-consuming and laborious task to manually check metaphorical sentences in official documents, and using automatic detection tools can greatly reduce the workload of document writers and increase the accuracy and efficiency of identification.

Metaphor sentence recognition is the identification of the presence or absence of metaphorical usage in a sentence, which is essentially a dichotomous classification task. There are rule-based methods, statistical machine learning methods and deep learning methods for metaphor recognition. Using rule-based approaches [1][2] can effectively address simple, common metaphor types, but requires a lot of manual effort to design rules and does not easily cover the full range of identified types. Using traditional machine learning methods [3][4] can identify more comprehensive types of metaphorical sentences with higher recognition rates, but the method is

difficult to learn deep semantic features and the model generalization is more difficult. In recent years, deep learning methods have become popular, and deep learning-based methods are widely used in metaphor recognition [5][6][7][8][9][10], which are similar to text classification tasks, where text is first transformed into vector form, and then neural network models are used to learn the semantic information of sentences. A better recognition result is usually obtained given enough corpus. In the last two years, the introduction of pre-trained language models [12] has further improved metaphor recognition, but the existing studies do not use syntactic structure information or do not deeply integrate syntactic structure information into the models.

Metaphorical sentences appear in a specific contextual environment, and without the contextual relationship, there is no meaning of metaphorical sentences. Therefore, identifying metaphorical sentences requires establishing a good contextual relationship between words, so as to identify whether a sentence has words containing metaphorical relationships. In this paper, we use Bert to extract the semantic features of sentences, convert the text into word embedding information, then perform syntactic dependency analysis, and integrate semantic information with syntactic structure information when constructing sentence connectivity graphs, and finally use Graph Attention Networks (GAT) to learn the semantic and syntactic structure information of sentences, and fully extract the sentence feature information to identify metaphorical sentences.

The contributions of this paper are as follows:

The proposed BertGAT model for recognizing metaphorical sentences in Kumon is proposed, which incorporates syntactic structure information of sentences based on the external knowledge of the pre-trained model to make sentence modeling more refined.

The proposed BertGAT model can learn the sentence structure information and weight the word nodes with varying importance, which in turn enriches the text feature information.

A rhetorical implicit sentiment recognition dataset for the metaphor class in the public domain is constructed, and the proposed BertGAT model in this paper achieves accurate results not only in this dataset, but also in the public dataset ChnSentiCorp with good results.

In this paper, a metaphor recognition model based on graph neural network and pre-training model bert is proposed.

Therefore, the graph neural network and pre-training model are introduced respectively. Finally, the validity of the model in domain data set and public data set is verified by experiments.

## II. RELATED STUDIES

### A. Metaphorical Sentence Recognition

Recognition of metaphorical sentences is a common and important problem in Natural Language Processing (NLP) and has been studied by researchers for a long time. The earliest metaphor recognition is the rule-based template approach proposed by Krishnakumaran [1], which relies on WordNet, an a priori knowledge base, to identify "A is B" noun metaphors, "verb+noun" verb metaphors, and "adjective+noun" metaphors by using its contextual relations and setting frequency thresholds "noun" verb metaphor and "adj+noun" adjective metaphor. The drawback of this method is that it relies too much on the a priori knowledge base WordNet and the identified metaphor sentences are simple. Noun metaphors are the most common expressions in lines, followed by verb metaphors, so researchers generally focus on the identification of these two types of metaphorical sentences [2][3][5][6][7][8][9][10].

Su Chang [2] proposed four algorithms to identify noun metaphors from different perspectives and recognized rich types of noun metaphor sentences with high accuracy, but the method relied entirely on WordNet. Shutova [6] proposed a clustering-based approach to identify verb metaphor sentences by taking verb subject groups and verb object groups that have been labeled as metaphorical expressions as seed sets and continuously expanding the seed sets by clustering. When these phrases appear in a sentence, it is judged as a metaphorical sentence, and the performance of this method depends on the quality and diversity of the seed words. Su Chang et al [3] mined multi-level features based on multi-level semantic networks, including full-text features, attribute features, perceptual features, etc., but for some complex metaphorical sentences, some attributes of the target domain are difficult to extract.

In recent years, deep learning has been developed and applied more and more widely in the field of NLP. The classical CNN model is not only simple but also powerful, Kim Y et al [4] applied CNN to text classification and achieved good results, while metaphor recognition is essentially text classification, some researchers use CNN models [7][9] in metaphor recognition to capture locally relevant features of text. Different ranges of semantic features can be captured by convolutional kernels of different sizes. Kui-Lin Su [9] used a pre-trained model Bert with external semantic knowledge and fused it with a CNN model for noun metaphor recognition.

BiLSTM (Bi-directional Long Short-Term Memory) is formed by combining forward LSTM with backward LSTM, which has stronger bi-directional semantic dependency capture capability, and also effectively prevents the gradient explosion and gradient disappearance problems of long text sequences by using gate mechanism and memory units. Jiaying Zhu [7] combined CNN and BiLSTM for metaphor recognition, in

which CNNs with different windows were used to obtain semantic features in different ranges, and BiLSTM was used to concatenate local semantic features extracted by CNNs and obtain full-text features from them, and the model could recognize verb metaphors, noun metaphors, preposition metaphors, etc. Chuandong Su et al [8] based on Bert used five features for metaphor recognition to identify whether the sentence and the query words are metaphorically related.

Shenglong Zhang [10] used pre-trained language models to extract sentence semantic features, used Graph Convolutional Network (GCN) to extract syntactic features from syntactic structure information, and finally obtained classification results of sentence metaphors by splicing sentence semantic features and syntactic features classification, which achieved better recognition results on verb metaphors and noun metaphors.

Existing deep learning-based studies make full use of sentence sequence information or incorporate external semantic knowledge from pre-trained models, but do not make full use of the supporting role of sentence structure, and some studies have shown that word dependencies are subject-verb structures or verb-direct object structures, which are more likely to be expressed metaphorically [11]. This shows that syntactic structure is also an important feature for identifying metaphors.

In this paper, we propose a pre-trained language model as a word embedding layer for the recognition of metaphorical types of rhetoric in the public domain, and construct a connected graph using dependency syntactic analysis with nodes embedded in the corresponding word vectors, which enables the graph attention neural network to learn sentence semantic and syntactic structure information more fully and improve the effectiveness of metaphor recognition.

### B. Bert Model

Bert [12] is a pre-trained model proposed by Google AI Research Institute in October 2018. Bert stacks multiple bi-directional Transformer structures and uses residual connections to address the limitations of traditional models in one direction and the problem of long-term dependencies. The use of the pre-trained language model Bert is divided into two phases: model pre-training and model fine-tuning.

In the model pre-training phase, there are two training tasks, namely word masking task and next sentence prediction task, through which the Bert model learns the relationships between words and lays the foundation for downstream tasks.

Bert's excellent performance and strong generalization performance make it widely used in the field of NLP, and many researchers have developed on the Bert model and then proposed improved models based on Bert, which has become one of the most commonly used techniques in the field of NLP.

The Bert model can replace word vectors, and in addition to transforming text into a computer-processable vector, it can further extract the deeper information embedded in the text. The Bert model introduces the relative position information

between words, so it can effectively extract the correlation and difference between ontology and metaphor in metaphor [13].

### C. Graphical Neural Networks

Graph neural network is an algorithm that fuses deep learning and graph structure, and its main idea is to use graph propagation mechanism and then update the features of nodes using deep learning. With stronger interpretability and good at processing graph structured data, graph neural networks are widely used in social systems, transportation networks, knowledge graphs and other fields.

In recent years, graph neural networks have received increasing attention, and the field of NLP has likewise introduced the study of graph neural networks. When graph neural networks are used for text processing, serialized text needs to be modeled first so as to introduce text structure information and then combined with downstream tasks to process text data using deep learning-based graph propagation algorithms. Graph neural networks use words as nodes and can introduce additional information to enrich features, such as dependency relationships [14], co-occurrence information between words [15], etc.

In the field of NLP, there are two common graph neural networks, GCN and GAT, in which the neighboring nodes of a node have the same weight, but the association between nodes

usually has different importance, and GAT improves this by using the attention mechanism. The use of multi-headed attention also prevents overfitting the multi-headed attention mechanism and enhances the expressive power of the network [16].

The graph neural network model for metaphor recognition proposed in this paper introduces the dependent syntactic structure information between words in order to fully integrate the sentence structure information, and makes use of the powerful language structure modeling capability and structured feature extraction capability of GAT in order to learn the dependent syntactic information from the sentence dependent syntactic tree [17].

### III. METAPHOR RECOGNITION MODEL BERTGAT

The metaphor recognition model BertGAT proposed in this paper is divided into 4 layers, which are input layer, coding layer, graph attention layer and output layer, as shown in Fig. 1. First, the text is input to Bert and converted into word embedding information; then the sentence connectivity graph is constructed using LTP, feature extraction is performed using GAT, and finally the features are fed into the classifier to get the probability of each category. The coding layer and the graph attention layer are the core parts of the model.

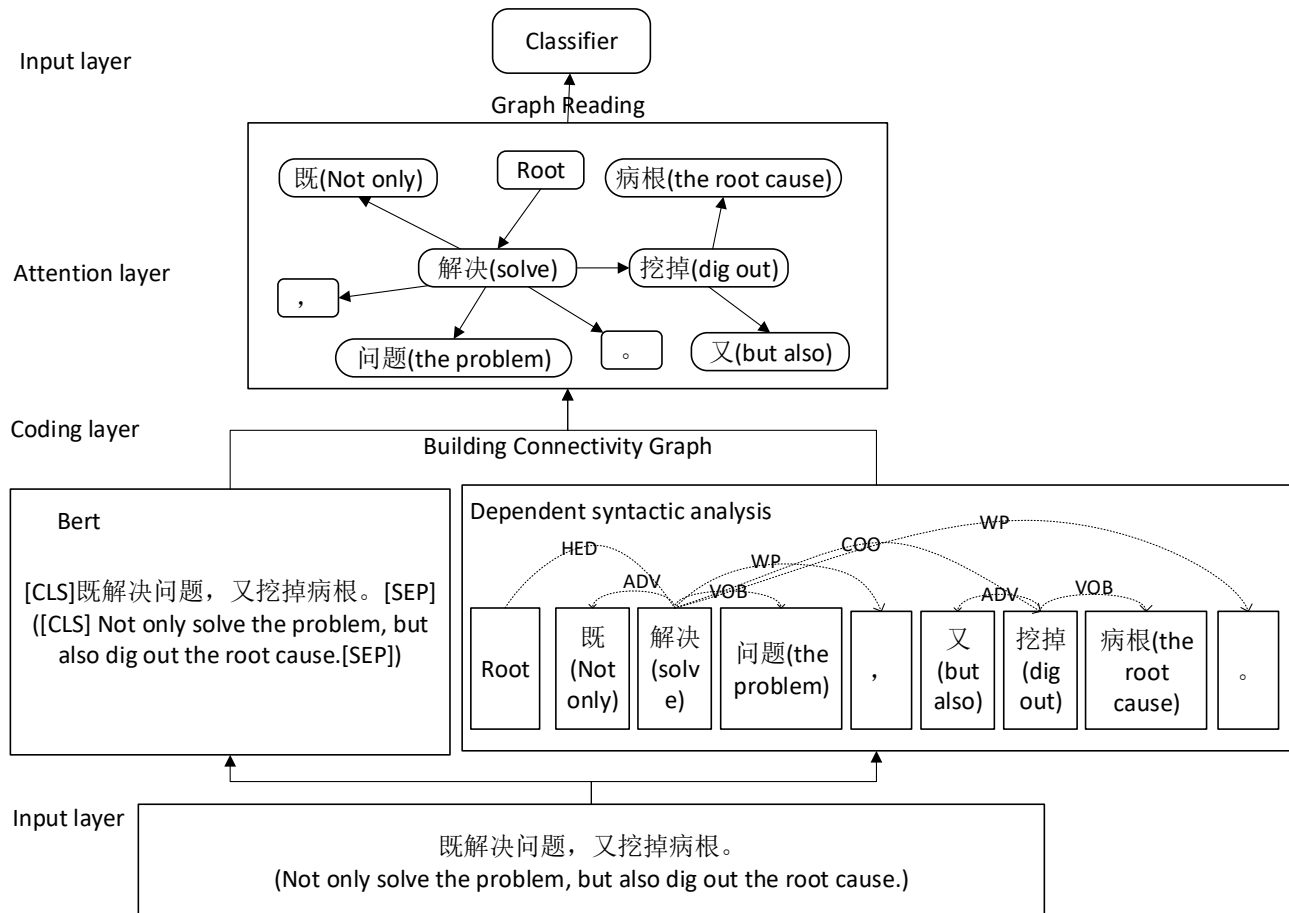

Fig. 1. Structure of BertGAT model.

The coding layer consists of Bert and the dependent syntactic analysis module. In the Bert pre-trained language model, sentences S in the text are sliced into word or character sequences, and after Bert processing, the output is a sequence of word vectors. It has been demonstrated that the dependency syntactic tree helps to improve the recognition rate of sentiment analysis [18][19] because it provides dependency connections between words, which leads the model to better learn the dependency information between long-distance words. In order for the model to fully learn the dependency information between words, the open source LTP tool of Harbin Institute of Technology is used for dependency syntactic analysis to obtain sentence dependencies and their clauses, and the word vectors belonging to the same clause are summed to construct a sentence connectivity graph by combining the dependencies, and the dependencies on each edge are embedded in low-dimensional vectors, and the graph nodes are embedded in word or character vectors.

The graph attention layer processes the connected graph of sentences to fully obtain the syntactic structure and semantic information of sentences, and finally outputs graph representation vectors as sentence features and input them into the classifier.

#### A. Input Layer

The role of the input layer is to perform data pre-processing in preparation for input to the encoding layer.

Before input to the Bert model, the sentence is cut into a sequence of words or characters, as shown in Equation (1).

$$S1 = \{[CLS], c_1, c_2, c_3, \dots, c_n, [SEP]\} \quad (1)$$

[CLS] and [SEP] are special identifiers for Bert, where [CLS] is added at the beginning of the sentence and [SEP] is added at the end of the sentence, and  $c_i$  is the character or word after the sentence is cut.

Chinese word separation is performed before input to the syntactic analysis module.

$$S2 = \{w_1, w_2, w_3, \dots, w_n\} \quad (2)$$

$w_i$  is the word after sentence segmentation.

#### B. Coding Layer

The encoding layer consists of the Bert module and the dependent syntactic analysis module. The pre-trained language model used in the Bert module is the original bert-base-chinese released by Google, containing 12 Transformer coding blocks, which are fine-tuned and trained together with the parameters of the attention layer to achieve metaphorical sentence recognition in Kumon.

Fig. 2 shows the model structure of Bert, which transforms the text sequence [CLS],  $c_1, c_2, c_3, \dots, c_n$  [SEP] into a word or character vector  $e_{[CLS]}, e_1, e_2, \dots, e_n, e_{[SEP]}$ , and the final output is  $x_{[CLS]}, x_1, x_2, x_3, \dots, x_n, x_{[SEP]}$ , which is the vector generated by the encoder capturing the semantics of the multilayer Transformer structure.

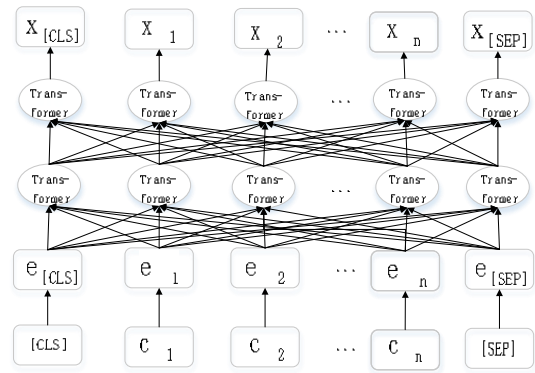

Fig. 2. Bert model structure.

This sequence S1 is input to the Bert model, and the Bert layer converts the text sequence S1 into the form of a vector and captures the semantics of each word or character using the Transform encoder to generate an embedded sequence X containing contextual semantic information, as shown in equation (3).

$$X = \{x_{[CLS]}, x_1, x_2, x_3, \dots, x_n, x_{[SEP]}\} \quad (3)$$

The output after the Bert module is a character-level vector embedding, while the generation of word-level vector embeddings is combined with LTP dependent syntactic analysis.

The LTP tool transforms the sentence sequence S2 into a triplet sequence  $T = \{t_1, t_2, t_3, \dots, t_n\}$ . The triad  $t_j$  is shown as follows.

$$t_j = (g, q, d) \quad (4)$$

where  $t_j$  is the  $j$ th set of dependency information,  $g$  is the dominant word,  $q$  is the modifier, and  $d$  is the dependency.

Finally, Bert is used to generate word embeddings, which are combined with LTP tool dependent syntactic analysis to generate a connected graph representation of the sentences.

The character-level vectors generated by the Bert pre-training model are represented as word vectors by summing the word vectors belonging to the same word.

#### C. Attention Layer

The role of this layer is to mine the sentiment association between word nodes and construct a connectivity graph based on a sequence of triples, where the nodes are word vectors or character vectors and the edges are dependencies represented by onehot. Based on the constructed sentence connectivity graph, the features between nodes are captured using graph attention network learning.

The following shows the node  $i$  at layer  $l$ . The similarity coefficients between it and its neighbor nodes are calculated one by one.

$$a_{ij}^l = \frac{\exp(f(a_i^T [W^l h_i^l] \| [W^l h_j^l] \| d_{ij})))}{\sum_{j \in \{i\}} \exp(f(a_i^T [W^l h_i^l] \| [W^l h_j^l] \| d_{ij})))} \quad (5)$$

The above  $a_{ij}^l$  denotes the layer  $l$ , the weights of node  $i$  to neighbor node  $j$ .  $W^l$  is the weight matrix of the model trained at layer  $l$ .  $h_i^l$  is the word vector representation of node  $i$  at layer  $l$ .  $n[i]$  is the set of neighbor nodes of node  $i$ .  $d_{ij}$  is the dependency between the  $i$  node and the  $j$  node.

The weights between the word nodes and the  $n$  neighbors can be calculated by equation (5).

$$a_i^l = \{a_{i1}^l, a_{i2}^l, \dots, a_{in}^l\} \quad (6)$$

$a_i^l$  identifies the importance level between word node  $i$  and its neighbor nodes, and combined with the node vector of the previous layer, the word node word vector of layer  $l+1$  can be updated.

$$h_i^{l+1} = \sigma(\sum_{j \in n[i]} a_{ij}^l w^l h_j^l) \quad (7)$$

$h_i^{l+1}$  is the word vector representation of point  $i$  at layer  $l+1$ , and  $\sigma$  is the ELU activation function. In a sentence, there are usually key words that determine the sentiment of the sentence, so the attention mechanism can be used to identify these key words and give them a greater weight. In the sentence "to solve the problem but also to dig out the root of the disease", the word "root of the disease" has a more obvious emotional tendency, so the weight value will be higher and the influence on neighboring nodes will be greater.

A study [11] pointed out that syntactic structure helps in metaphor recognition, so the graph constructed based on dependent syntactic analysis with dependencies can add syntactic structure information to enable the model to mine possible metaphorical expressions, in addition to directing the model to focus on important words.

The use of the multi-headed attention mechanism enables the model to mine information from multiple dimensions and prevents the model from overfitting, and the output after the introduction of the multi-headed attention mechanism is shown in the following equation.

$$h_i^{l+1} = \sigma(\frac{1}{K} \sum_{k=1}^K \sum_{j \in n[i]} a_{kij}^l w_k^l h_j^l) \quad (8)$$

$h_i^{l+1}$  is the feature vector of node  $i$  in this layer after feature extraction by the graph neural network with multi-head attention mechanism.  $K$  indicates that  $K$  attention heads are used;  $a_{kij}^l$  is the similarity coefficient between node  $i$  and node  $j$  after calculation by the attention mechanism of the  $k$

head;  $w_k^l$  is the weight matrix of the linear transformation of the input vector at the  $k$  head.

#### D. Output Layer

After the above feature extraction of graph attention neural network, the graph representation vector is obtained by reading out all graph node features using Sum. After the calculation of the multi-headed attention mechanism, the obtained graph representation vector is  $R(H)$  as in the following equation.

$$H = \{h_1, h_2, h_3, \dots, h_n\} \quad (9)$$

$$R(H) = \sum_{i=1}^n h_i \quad (10)$$

$H$  is the whole graph and  $h_i$  is the  $i$  node feature vector of the graph.  $R(H)$  is the readout of the whole graph  $H$  using node Sum.

After obtaining the graph representation vector representing the sentence feature information, a fully connected softmax function is used to classify the sentiment, where the category with the highest probability is the sentiment category of the predicted text, as shown in the following formula:

$$p = \text{softmax}(wR(H) + b) \quad (11)$$

$w$  is the weight matrix of the model training,  $b$  is the bias matrix,  $p$  is the prediction category of the model.

## IV. EXPERIMENT

### A. Authors and Affiliations Data sets and Assessment Indicators

This experiment is oriented to the recognition of sentences containing implicit sentiment in government official documents, for which there is no data available, so we need to construct a domain dataset. We search for metaphorical sentences commonly used in official documents in the Internet, among which are mainly noun metaphor sentences, and combine the verb metaphor and noun metaphor sentences in the Chinese metaphor recognition dataset released in the CCL 2018 Chinese Metaphor Recognition and Sentiment Analysis Task, a total of about 5000 sentences as positive examples; we use a crawler to crawl 30,000 official documents on government official document websites, and randomly select about 5000 sentences as counterexamples. Several sentences in the dataset are listed in Table I.

TABLE I. EXAMPLE TABLE OF METAPHORICAL SENTENCES

Text	Category	Source
切忌眉毛胡子一把抓，防止芝麻西瓜一起抱。 (Do not browbeat, to prevent the sesame seeds and watermelons together to hold.)	Noun Metaphor	Internet
经济转型中，政府必须起到催化剂的作用。 (The government must act as a catalyst in economic transformation.)	Noun Metaphor	CCL 2018
栽培社会所需要的集体主义精神。 (Cultivate the spirit of collectivism that society needs.)	Verb Metaphor	CCL 2018
中国青年是有深厚家国情怀的青年。 (Chinese youth are young people with a deep sense of family and country.)	Literary	Internet

In the first sentence of Table I, eyebrows and beards, sesame seeds and watermelons are metaphors for priorities and sub-priorities in work, which are noun metaphors. These sentences are often used in speeches of leaders to promote their policies, ideas and work, but not in strictly official documents. The second sentence is a noun metaphor, comparing the government to a catalyst. The third sentence is a verb metaphor, where the verb "cultivate" refers to planting and nurturing, but the sentence refers to cultivating.

To further validate the model for sentiment recognition, the public dataset ChnSentiCorp [20] was used to further validate the model effect.

The training set, validation set and test set were assigned in the ratio of 8:1:1.

The result evaluation metrics used recall, precision, accuracy and F1 value formulas as shown in (12) to (15) below.

$$\text{recall} = \frac{TP}{TP+FN} \times 100\% \quad (12)$$

$$\text{precision} = \frac{TP}{TP+FP} \times 100\% \quad (13)$$

$$F1 = 2 \times \frac{\text{precision} \times \text{recall}}{(\text{precision} + \text{recall})} \times 100\% \quad (14)$$

$$\text{accuracy} = \frac{TP+TN}{TP+TN+FP+FN} \times 100\% \quad (15)$$

### B. Parameter Setting and Experimental Environment

The experimental parameters of the BertGAT model proposed in this paper are set as follows:

1) *Experimental environment*: Using deep learning framework pytorch, operating system ubuntuServer 18.04.5, GPU is Tesla P100, memory 60G, programming language python3.8.

2) *Parameter setting in Bert*: Bert uses the original Bert-base-Chinese released by Google, the dropout is set to 0.3, the optimizer uses AdamW, the maximum number of individual text words is 300, the initial learning rate is set to 5e-5, the number of iterations is 40, and the Batch Size is set to 16.

3) *Parameter settings in the GAT*: In order to avoid the potential problem of over-smoothing the nodes of the graph neural network, the experiment of GAT layer setting is conducted in this paper. From the experimental results, we can know that the model effect gradually decreases when the number of GAT layers is greater than two, and the model achieves the optimal effect at two layers, see Fig. 3.

4) *Graph reading methods in GAT*: There are three methods to calculate the graph representation, Sum, Mean and Max respectively, where Sum is to sum the nodes, Mean is to average the nodes and Max is to take the maximum value of the nodes.

In order to determine the optimal graph readout method and training learning rate of the model, the following experiments are set up in this paper, from the experimental results, we can see that the graph readout method is optimal

using node Sum, and the learning rate is optimal using 5e-5 for fine-tuning, see Table II and Table III.

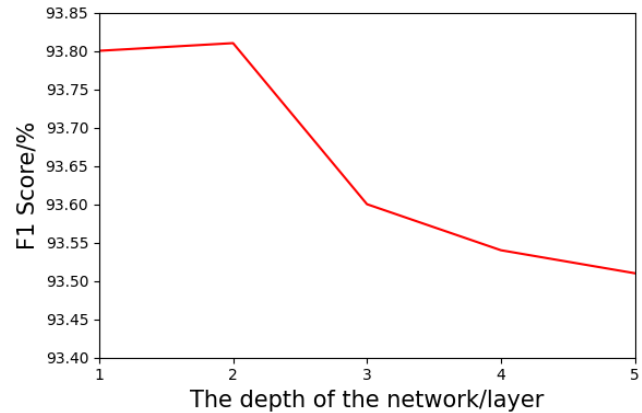

Fig. 3. Experimental results of graph attention neural networks with different layers.

TABLE II. WAYS OF READING GRAPH

Graph reading mode	Indicators			
	Acc	Precision	Recall	F1
Max	0.9379	0.9377	0.9387	0.9379
Sum	<b>0.9383</b>	<b>0.9380</b>	<b>0.9384</b>	<b>0.9381</b>
Mean	0.9352	0.9349	0.9352	0.9351

TABLE III. LEARNING RATE SETTINGS

	Acc	Precision	Recall	F1
5e-4	0.9366	0.9362	0.9368	0.9364
5e-5	<b>0.9383</b>	<b>0.9380</b>	<b>0.9384</b>	<b>0.9381</b>
5e-6	0.9355	0.9354	0.9365	0.9355

### C. Experimental Results

CNN, BiLSTM and BertGCN are chosen as baseline models. CNN, BiLSTM and other models use word2vec trained from wiki Chinese corpus as word vector, the maximum number of single text words is 300, the dimension of word vector is 200, and different sizes of convolutional kernels are set in the convolutional layer to extract different features from different dimensions. Three sizes of convolutional kernels are set with the size of 3\* 200, 4\* 200 and 5\* 200 respectively.

The baseline experimental results are shown in Tables IV and V below, and it can be seen that the proposed method in this paper achieves the best performance in both the constructed public domain dataset and the public sentiment dataset. From the experimental results, it can be seen that the performance of the model with the introduction of graph neural network in this paper has been improved, where the biggest difference between GCN and GAT is that the way of aggregating neighbor nodes is different, and GAT utilizes attention coefficient, so the correlation between nodes calculated by GAT will be stronger to some extent. The experimental results show that the comparison of the experimental results processed using GAT is more

advantageous than GCN, which indicates that GAT is better than GCN in learning the structural information of the sentences.

TABLE IV. METAPHOR RECOGNITION RESULTS OF DIFFERENT MODELS IN DOMAIN DATASETS

Model	Indicators			
	Acc	Precision	Recall	F1
CNN	0.8839	0.8845	0.8853	0.8838
BiLSTM	0.9111	0.9109	0.9118	0.9110
Bert	0.9349	0.9346	0.9355	0.9348
BertGCN	0.9366	0.9367	0.9361	0.9364
BertGAT	<b>0.9383</b>	<b>0.9380</b>	<b>0.9384</b>	<b>0.9381</b>

The results of the experiments on the dataset ChnSentiCorp are shown in Table V. In this paper, ChnSentiCorp-6000 is selected for the experiments, and there are 3000 positive and negative sentiment sentences each in this dataset. In this public dataset experiment, model CNN, BiLSTM, AttBiLSTM, DCNN, ADCNN, and experimental result data are used from Zhu Ye et al [21], through the experiment, it can be seen that the sentiment recognition effect of BertGAT model is better than the baseline model in Precision, Recall and F1, and comparing Bert has a significant improvement, which indicates that the model proposed in this paper is advanced in emotion recognition.

TABLE V. EMOTION RECOGNITION EFFECT OF DIFFERENT MODELS IN THE PUBLIC DATASET CHNSENTICORP-6000

Model	Indicators			
	Acc	Precision	Recall	F1
CNN	0.8550	0.8557	0.8550	0.8553
BiLSTM	0.8790	0.8796	0.8790	0.8793
AttBiLSTM	0.8810	0.8827	0.8816	0.8821
DCNN	0.8865	0.8865	0.8865	0.8865
ADCNN	0.8897	0.8898	0.8895	0.8896
Bert	0.8893	0.8891	0.8897	0.8893
BertGCN	0.8850	0.8898	0.8827	0.8840
BertGAT	<b>0.9035</b>	<b>0.9045</b>	<b>0.9030</b>	<b>0.9033</b>

The main reason why the metaphor recognition model BertGAT proposed in this paper is ahead of other comparative models is the introduction of syntactic structure information and GAT graph attention network, which is based on GCN graph convolutional network and introduces the attention idea. GAT can avoid a large number of matrix operations compared with GCN, and it can also obtain the node feature information with stronger dependency.

## V. CONCLUSION

In this paper, we propose an implicit sentiment classification model BertGAT for rhetorical types. To fully capture the semantic and syntactic structural information in text sequences, the model uses the Bert pre-trained language model and the GAT graph attention network. To verify the

effectiveness of the model, experiments were conducted on both domain datasets and public datasets, and the experimental results outperformed the baseline model, which demonstrated the effectiveness of the model.

It is difficult to satisfy all downstream tasks by simple metaphor recognition classification alone. Metaphorical sentences contain mappings from ontology to metaphor, and our further research hopes to extract ontology, mapping words and their metaphors with the help of advanced Chinese named entity recognition techniques [22]. Besides, the different cognitive perspectives and cultural value orientations of English and Chinese can lead to different semantics of the same metaphorical word, and the syntactic structures of English and Chinese, two different languages, are also different [23].

we're actively engaged in follow-up this work. The next step will be to identify the similarities and differences between English metaphorical sentences and Chinese metaphorical sentences from several perspectives in order to improve the model to make it more generalizable.

**Abstract**—The drone will be a commonly used technology by a significant portion of society, and simulating a given drone dynamic will be an essential requirement. There are drone dynamic simulation models to simulate popular commercial drones. In addition, there are many Newtonian and fluid dynamics-based generic drone dynamic models. However, these models consist of many model parameters, and it is impracticable to evaluate the required model parameters to simulate a custom-made drone. A simple method to develop a machine learning-based dynamic drone simulation model to simulate custom-made drones mitigates the issues mentioned above. Specifically, the authors' research is associated with the development of a machine learning-based drone dynamic model integrated with a virtual reality environment and validation of the user-perceived physical and behavioural realism of the entire solution. A figure of eight manoeuvring patterns was used to collect the data related to drone behaviour and drone pilot inputs. A Neural Network-based approach was employed to develop the machine learning-based drone dynamic model. Validations were done against real-world drone manoeuvres and user tests. Validation results show that the simulations provided by machine learning are accurate at the beginning and it decreases the accuracy with time. However, users also make mistakes/misjudgments while perceiving the real-world or virtual world. Hence, we explored the user perceive motion prediction accuracy of the simulation environment which is associated with the behavioural realism of the simulation environment. User tests show that the entire simulation environment maintains substantial physical realism.

**Keywords**—Drone; simulation; machine learning; drone dynamics; virtual reality

## I. INTRODUCTION

Drone is an unmanned aircraft controlled by a ground base station, used primarily to carry out air-based missions, such as surveillance, transportation and entertainment [1], [2]. Historically drones were first used by the military for ground surveying and spying missions, and they were called Unmanned Aerial Vehicles (UAVs) [3], [4].

Nowadays the term drone is widely used for quadcopters, vertical takeoff and land (VTOL) type miniaturized aircraft, with four propeller blades, pushing air downwards to maintain itself on air, while moving back and forward using the thrust created by the same propellers [5]. Such drones come in many sizes ranging from a few inches up to several feet and are used in many applications including for toys, entertainment, photography, land surveillance and scientific research [1], [6], [7], [8].

According to the Stanford University Intelligent Systems Laboratory and National Aeronautics and Space Administration (NASA), within the next few years, Low-Altitude airspace will be congested with Low-Altitude Remotely Piloted Aircrafts [9]. This will be a common technology used by a significant portion of society. Due to the maturing of the technology, it requires a skilled and qualified human resource to use the technology and train pilots for specific tasks and missions. At the same time, it allows individuals and various organizations to build custom-made drones at their own pace.

Therefore, drone pilot training for custom-made drones via simulations is essential. It provides the knowledge and practical skills that are necessary to safely and efficiently operate unmanned aircraft for commercial and non-commercial use [10], [11]. Hence, drone pilot training simulators will be a very important requirement. Depending on the safety-critical level of the drone operation, there is a requirement of simulates the drone operations prior to the real real-world operation. This type of simulation supports the identification of potential disasters due to the manoeuvring capability of the drone and the pilot. Hence, drone simulators with required realism will be essential in future [1].

There are solutions to simulate real-time drone dynamics, such as the DJI drone simulator. These simulators are capable of simulating the bundled series of drones belonging to a particular vendor. There are many proposed generalized drone dynamic simulation models and most of these models are based on Newtonian dynamics and fluid dynamics. Simulating custom-built drones with these generalized drone dynamics is a highly challenging task. It requires evaluating model parameters related to the custom build drone and it needs many experiments to be conducted with the given ideal conditions, domain-specific knowledge and a wide range of practical issues. A machine learning-based drone dynamic model avoids most of the above issues. There is significant value to explore the possibility of developing a machine learning-based drone dynamic model and incorporating it with a Virtual Reality (VR) environment to simulate a custom-built drone. It is highly essential to evaluate the realism level of such a drone dynamic model and the VR environment. Overall realism of a virtual environment can be expressed with physical realism and behavioural realism. Behavioural realism expresses the accuracy of dynamic activities such as motion predictions. Physical realism expresses the physical infrastructure of the simulated environment [12], [13], [14], [15].

The remainder of this paper is structured as follows: State-of-the-art drone simulation models are critically evaluated in Section II. Section III discusses initial research initiatives such as data collection techniques. The development processes of the machine learning model and VR environment for the proposed dynamic drone simulator are covered in Sections IV and V, respectively. Section VI presents the experimental and validation results of the simulator under different criteria. Finally, Section VII, concludes the paper along with prospective research directions.

## II. RELATED WORKS

There are many proposed drone dynamic simulation models and most of these models are based on Newtonian dynamics and fluid dynamics [16], [17]. These models were used to simulate drones for different applications and comparisons of different simulation models were reported [18], [19]. However, the evaluation of required model parameters and simulations of existing drones is not discussed.

There are commercial simulators that could use for the simulation of drones. For example, the DJI Assistant 2 software is a drone simulator provided by DJI used to simulate selected DJI drones [20], [21]. The DJI Assistant 2 is programmed/programmable to simulate drones with offline remote control data. Real Flight drone/flight simulator [22], Simpro drone simulator [23], Liftoff by Immersion RC [24] and HELIX professional R/C flight simulator [25] are some of the reviewed commercial drone simulators which can be employed to simulate particular commercial drone.

There are many research and development works carried out by employing machine-related theories in drone-related ICT solution developments [26], [27], [28], [29], [30], [31], [32]. However, most of these applications are related to designing and developing autonomous drones and target tracking in outdoor/indoor environments.

Jemin et al. presented a method to control a quadrotor with a neural network trained using reinforcement learning techniques [33]. They demonstrated the performance of the trained policy both in simulation and with a real quadrotor. The trained policy shows outstanding performance and remains computationally cheap simultaneously. Furthermore, it shows many other advantages of neural network policies that are not limited to their versatility. This experiment is limited to a small space covering approximately a 2m x 2m x 2m controlled area.

Osman Çakira and Tolga Yükselb [34] developed a neural network-based controller for quadrotors. In this study, neural network control of quadrotors is aimed to obtain an artificial intelligence-based drone controller and the results show that neural network controllers achieve satisfactory trajectory tracking results. This experiment is also limited to a small space that approximately covers 5m x 3m x 3m controlled area.

Jeong, Baek and Lee propose a prediction model of the vehicle trajectory [35]. Their approach is not based on physics-based motion models and there are no kinematic and dynamic models, laws of physics and fluid dynamics. They employed a Deep Neural Network that takes as input vehicle velocity, acceleration, yaw rate, steering, and road curvature. The authors

discussed the advantages of employing deep neural network-based predictions to avoid several potential issues in similar physics-based vehicle simulation requirements.

Jeong et al. proposed Deep Neural Network (DNN) that considers preprocessed vehicle velocity, acceleration, yaw rate, steering, and road curvature as the input layer and eventually reaches the output layer via multiple hidden layers. DNN uses an activation function with a function called a rectified linear unit (ReLU) [36], [37]. However, a ReLU function is not a perfect match to be used in this study because the final outputs of our DNN model include expected future lateral movements, which can be negative. Hence, Leaky ReLU was employed for the activation function, which is slightly different from the original ReLU [35]. The results of the proposed study confirm the feasibility of Deep Neural Network-based long-term trajectory prediction for vehicles driving on roads with a certain level of road conditions such as varying curvature.

Jackson et al. employed the machine-learning technique to design and develop a dynamic model of a rotorcraft [38]. Their key justification for this approach is that widely used physical-law-based and substantially accurate rotorcraft dynamic models need to be simplified to make real-time motion predictions. Hence, it leads to motion prediction errors compared to the real vehicle. In their current work, machine-learning techniques are employed to train a rotorcraft dynamic model to predict the dynamic on-axis motion responses such as pitch rate, roll rate and yaw. The employed machine learning was designed with a Gaussian Process (GP) non-linear autoregressive model [39]. They have proven that the machine-learning approach can be successfully utilized to predict the on-axis motions of a rotorcraft. The obtained level of accuracy is generally higher than the physics-based dynamic models.

Punjani proposed a helicopter dynamic modelling method with a Rectified Linear Unit (ReLU) Network Model [40]. The reasons for selecting this approach are helicopter has a complex dynamic system with rigid body dynamics with aerodynamics, engine dynamics, vibration and other factors such as manoeuvring patterns. They described several baseline models and shows that the helicopter dynamics with ReLU significantly outperformed other considered baseline models. Furthermore, It improves acceleration prediction over state-of-the-art methods and they presented performance gains techniques with hyperparameters fine-tuning. They selected a range of manoeuvres such as forward/sideways flight, vertical sweeps, inverted vertical sweeps, stop-and-go, flips, loops, turns, circles, dodging, orientation sweeps, orientation sweeps with motion, gentle freestyle and aggressive freestyle.

Considered, baseline models are based on Linear Acceleration Model and it serves as a direct state-of-the-art performance baseline. Validations, efficacy investigations, compare and contrast among baseline models and the ReLU-based model were done by using data obtained from the Stanford Autonomous Helicopter Project [41]. Following Fig. 2 presents observed and predicted accelerations in the up-down direction for selected three different aerobatic manoeuvres. It shows that the baseline Linear Acceleration model performs poorly compared to the novel ReLU Network Model [40].

Sandaruwan et al. proposed a machine learning-based approach to simulate drone dynamics related to the figure of

Eight Manoeuvring pattern [1]. Authors have obtained satisfactory results and proven that the machine-learning approach can be successfully utilized to predict drone motions. However, they have not published the evaluation of the developed drone dynamic model and simulation environment.

Zhang et al. investigated users' situational awareness of virtual outdoor, virtual indoor, real-world indoor, and real-world outdoor environments. They considered distance judgment for their experiments and identified potential error factors and other considerations [42]. They also investigate the impact of users' real-world scene awareness on distance judgment in the same simulated scene in a virtual environment. Their results suggest that both the virtual and real-world environments have an impact on distance judgment in VR which affects the users' ability to perceive the realism of VR environment [42].

Ziemer et al. also explored the order in which people experience real and virtual environments that influence their distance estimates. They also identified potential error factors, error percentages and other considerations in estimating distance in real and virtual environments. Their results provide facts and figures to measure users' situational awareness of the virtual and real scenes [43]. They presented the importance of presence and reality judgment in the VR environment and aspects that contribute to creating a person's reality judgment in a given scenario in the VR environment. They discuss the problem of "How do people decide whether something is real or not?". Their work aims to design a self-report measure that assesses both constructs [44].

Sandaruwan et al. conducted several research studies to design and deploy a Maritime VR Environment [14], [13]. They discuss essential factors/considerations related to validating the user perception of the physical & behavioural realism of a maritime VR environment. They employed several techniques & methods to validate the physical & behavioural realism of the maritime VR environment. Moreover, they used techniques such as comparing real vehicle trials and simulated vehicle trials, simulation of simple possible scenarios and user tests [15]. However, those techniques & methods are applicable to most VR environments with dynamic vehicle models.

By considering the above-reviewed literature and the main objective of designing and developing a machine learning-based drone dynamic model for outdoor simulation of a custom-built drone, the following actions were executed: 1) Deep Neural Network-based approach with Leaky ReLU or any other appropriate activation function. 2) The figure of eight manoeuvring pattern-based outdoor data collection to build the machine learning model. 3) Conduct evaluation/validation such as comparing real drone trials and simulated drone trials, simulation of simple possible scenarios and user tests to measure the user perceive realism of the develop machine learning-based drone dynamic model.

Analysis of Newtonian dynamic and fluid dynamic-based analytical solution used by the researchers [16], [17], [18], [19] shows that takeoff & landing of the drone is more complicated and needs more accurate complex dynamics. In addition, real-world wind flows with a turbulent effect make the situation further complicated. Hence, this research does not focus on the takeoff & landing of the drone, and all experiments and tests were carried out in a calm outdoor environment with

negligible wind effect.

### III. PRELIMINARIES AND DATA COLLECTION

Four-rotor drones are a subset of multirotor systems and these drones use four rotors to keep them flying. A popular example of these multirotor drones is the widely used Phantom drone made by the SZ DJI Technology Co. Ltd [45]. Drone movements are controlled by a handheld radio controller. The drone changes its position and orientation based on the given radio controller inputs. This research focuses on a machine learning-based four-rotor drone dynamic model to build the relationship between the drone pilot's radio controller inputs and the drone's position and orientation. The Phantom drone by the SZ DJI Technology Co Ltd was selected for the experiments and it has six degrees of freedom motions (Three rotational motions & three translational motions).

DJI Phantom quadcopter drone comes with four propulsors that enable vertical takeoff and landing. It has four key controllable variables which move the drone in the 3D space [45], named throttle, pitch, roll & yaw. Fig. 1 illustrates a radio controller with key controllable variables. Based on the key controllable variable inputs, the drone changes its position and orientation.

Fig. 1. A radio controller with key controllable variables.

Movement in the horizontal frame is achieved by tilting the platform with the different thrusts of the motors. Vertical movement is achieved by changing the total thrust of the motors.

DJI Phantom 4 [45] consists of many inbuilt sensors such as accelerometers, proximity sensors, GPS and GLONASS. That sensor assists with precision flying, precise hovering and much more. In addition, it provides a flight log consisting of flight position and orientation data & radio controller input data with the frequency of 10 sample points per second (10Hz). DJI Phantom 4 Pro [46] drone maintains 1.5-meter position accuracy with inbuilt GPS sensors & it can be enhanced up to 1cm accuracy by configuring external sensors.

The required machine learning-based drone dynamic model must predict the drone's position and orientation against the radio controller input. Hence, the required data can be categorized into two main categories as given below:

- Drone pilot inputs are entered via the drone Radio Controller (RC) and represent the given inputs, such as throttle and rudder values that are responsible for the drone position and orientation changes.
- The Drone's position and orientation change with time, and all other relevant sensor information vary with time (E.g. Battery level, accelerations, velocities).

If all manoeuvres are performed with fully charged batteries and the battery level is within 97% and 100%. Then it reduced the potential performance variation of the drone due to the battery power variations. The recorded data set consists of over forty parameters that vary with time. After examining the time-varying fields of the raw data set, the following observations were made:

- Certain sets of parameters directly imply the other set of available parameters. E.g. Latitude, Longitude and Altitude present the position of the drone in 3D space. All data stamps were recorded with a constant time gap. VelocityX, VelocityY and VelocityZ also present the position of the drone in 3D space.
- There are certain sets of parameters that are constant during the experiment or indicate negligible variation. E.g. GpsCount, GpsLevel Battery Power(%), Battery Voltage, Battery Voltage Deviation, Battery Cell Voltages.
- There are other sets of parameters that are static due to the selected settings of the drone or provide Tips and warnings. E.g. App Tip, App Warning, App Message and Flight Mode.

Hence, after considering the above fact extracting the required data and selected key parameters of the data set are described below:

- Time (seconds): Time elapsed since the power-up.
- RcAileron: Rc signals for roll.
- RcElevator: Rc signals to control the horizontal pitch attitude of the drone.
- RcRudder: Rc signals to control the yaw of the drone.
- RcThrottle: Rc signals control the engine's speed and indicate how fast or slow the drone's movement.
- x,y,z: Cartesian conversion of Longitude and Latitude.
- Orientation: Bearing of the head of the drone in degrees.

The above parameters describe the drone pilot input via the radio controller & resultant position and orientation of the drone. Hence, the above parameters were taken into consideration to develop a machine-learning drone dynamic model.

#### IV. DEVELOPMENT OF MACHINE LEARNING MODEL

This research focuses on a machine learning-based drone dynamic model based on a subset of artificial intelligence. Machine learning consists of several subsections. Deep learning is one of the subsets of machine learning in which artificial neural networks adapt and learn from a large amount of data [47].

Machine learning models/methods or learnings are based on what it has learned only. Neural network structures/arrange algorithms in layers of fashion that can learn and make intelligent decisions on their own [48]. Neural networks are more suited to solve complex machine-learning problems. Neural networks can learn and model the relationships between inputs and outputs that are nonlinear and complex. This can be

used to generalize input-output relationships, and reveal hidden relationships, patterns and predictions. It supports modelling highly volatile time series data and capable of predictions [49]. Neural networks require much more data than traditional Machine Learning algorithms to complete the model development. Depending on the requirement, building a customized neural network model that is perfectly suited. However, it takes more time compared to the traditional ML algorithm. A neural network consumes a longer time to train rather than a traditional machine learning model. It requires continuous computational resources, depending on the architecture of the neural network and the size of the data [50].

This research deals with complex rapidly changing input data set and output data set (Drone pilot's radio controller inputs and drone's position and orientation). The relationships between inputs and outputs are nonlinear. A single drone pilot trial consists of thousands of data points and the entire data set consists of over 200 thousand data points. A continuous computational resource is not a vital issue with the available technological infrastructure. Hence, an Artificial Neural Network (ANN) based approach was selected.

An artificial neural network has parameters that cannot be directly estimated from the data. This type of model parameter is referred hyperparameter. No analytical solution is available to calculate appropriate values for hyperparameters [51]. An artificial neural network has many hyperparameters. However, two key hyperparameters are the number of layers and nodes in each hidden layer. It controls the entire architecture/topology of the artificial neural network. In addition, there are other hyperparameters such as activation function, the number of epochs, batch size, learning rate, Mini-batch size, and Learning rate, which are identified as other potential hyperparameters [52].

Several frameworks and libraries have been developed in the last few years to fulfil machine learning-related necessities. Industry and academia use various frameworks and libraries to expedite the neural network-based model development, training and good results. Hence, model development and training have become easier. Based on the star ratings on Github, and our similar project experiences in the field, TensorFlow [53] was selected as the most effective and easy-to-use framework and library.

TensorFlow is a full-fledged open-source deep learning framework designed and developed by Google. It was initially released in 2015 and it comes with documentation, training support, scalability options and support for different platforms. In addition, TensorFlow is associated with flexible, comprehensive community resources, libraries, frameworks and tools that facilitate developing and deploying machine learning solutions [53]. Keras [54] is a high-level neural network library that runs on top of TensorFlow. Further, Keras supports building high-level API to be used for easily building and training models. Keras is a built-in Python. Keras is an open-source software framework that provides a Python interface for designing and developing artificial neural networks.

On top of TensorFlow and Keras, a sequential machine-learning model was developed and tuned to produce optimum results. The developed model has three layers, consecutively 56 and 112 nodes in the first and second hidden layers and one

node in the output layer. The activation function for all three layers is linear. The loss is calculated using the mean squared logarithm error while using the Adam optimizer.

### V. DEVELOPMENT OF VR ENVIRONMENT

According to the 3D graphics rendering pipeline and commonly used game engine architectures, this type of 3D drone simulation environment consists of a real-time computational drone motion prediction module, configuration module (Configure environment, drone drill, etc.), The visual rendering engine, sound generation engine and seamless display system/head-mounted display [55]. Real-time motion prediction carries out by the proposed machine learning model which considers user interactions and defined environmental conditions to predict real-time drone motions. The visual rendering engine considers the predicted state of the drone-requested view of the virtual environment (first-person view, third-person view, etc.) to generate the relevant scenery. Finally, the user can see the generated visual through a seamless display system or head-mounted display. Integration of a sound generation engine brings more realism to the solution. A high-level structure of the virtual environment is illustrated in Fig. 2.

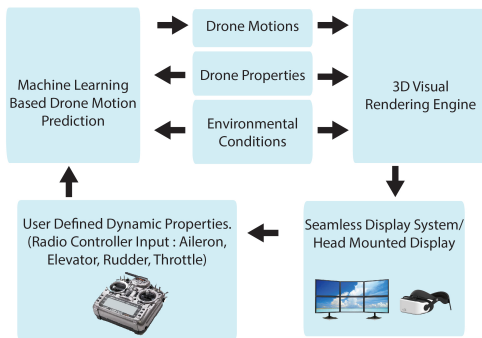

Fig. 2. The high level structure of the 3D virtual environment

There are many open-source, free and commercial frameworks, libraries and engines to develop 3D VR environments [56], [57], [58], [59]. Mairaj, et al. carried out comprehensive literature review related to the design and development of drone simulators and analyzed available frameworks, libraries and engines [60]. Based on the Mairaj, et al. review, authors' own experience gained during the last ten years [61], GitHub Star rating and other reviews, Microsoft Aerial Informatics and Robotics Simulation (AirSim) [62], [63] open-source robotics simulation platform was selected to design and develop the proposed 3D virtual environment to simulate drone dynamics.

AirSim is developed for AI research to experiment with deep learning, computer vision and reinforcement learning algorithms for autonomous vehicles. However, AirSim provides APIs to retrieve data and control vehicles in a platform-independent way. Hence, several modules of AirSim were decoupled and several API facilities, such as retrieve data and control vehicles were slightly modified to develop the proposed 3D drone simulation environment [62]. Fig. 3 presents the high-level architecture of the modified Microsoft AirSim

simulation platform which was used to develop the 3D drone simulation environment.

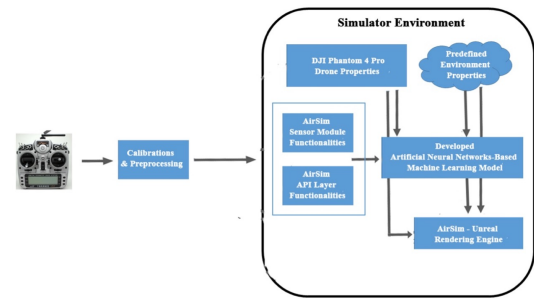

Fig. 3. High-level architecture of the modified microsoft airsims simulation platform

AirSim simulation platform was configured with an Unreal environment because the Unreal Marketplace has several environments available that can be used to generate realistic 3D scenarios easily. As illustrated in Fig. 3, AirSim physics engine was replaced with a developed machine learning-based drone dynamic model. The selected functionalities of the AirSim sensor module and AirSim API layer were reused to connect the real physical radio controller and virtual environment. However, a real Fr-Sky Taranis radio transmitter & receiver was used to capture drone pilot inputs and feed input stream to develop a machine learning-based drone dynamic model in the simulated environment. Hence, a separate calibration/preprocessing module was developed to align/map Fr-Sky Taranis radio transmitter inputs and DJI Phantom 4 Pro drone radio controller inputs. Fig. 4 presents the Fr-Sky Taranis radio transmitter/radio controller, which can be configured to align with DJI Phantom 4 Pro drone radio controller.

Fig. 4. Fr-sky taranis radio transmitter/radio controller

Fig. 5 presents the design and development of the proposed machine learning-based drone dynamic simulation environment. It uses an Intel Core i7 CPU with 3.6 Hz, GTX 1070 graphic card and Ram 32 GB to run the entire solution-inducing Unreal rendering engine and machine learning model. 32-inch screen connected to visualize the rendered image stream, and it makes continuous sensation for the users (Drone pilots) who interact with the virtual environment via Fr-Sky Taranis radio controller. Depending on the user's/drone pilot's preference instated of the screen, a head-mounted display such as Oculus Quest-2 can be connected with the solution.

### VI. EXPERIMENTAL RESULTS AND VALIDATION

The entire simulated environment can be validated under different criteria. As discussed before, simulation represents

Fig. 5. Developed machine learning based drone dynamic simulation environment.

a real-world scenario with assumptions, limitations and simplifications. Comparison of the simulated results against its actual real-world scenario is one of the validation methods employed in this type of research and development work. This can be done by considering comparisons such as positions and orientations with the timestamps. The user test is another vital validation technique to validate the user's perception of the simulated environment. In this technique, the virtual environment is validated based on the observations of pilots with much drone experience.

Some of these validation techniques are quantitative, while others are qualitative. For example, quantitative validation methods can be used to validate activities such as the accuracy of the motion predictions and qualitative validation methods can be used to validate components such as user perception enhancement and ecological validity of the simulated environment.

The validation process of the proposed virtual environment was divided into the following four segments:

- Carry out short-term motion predictions with the developed machine learning model: In this approach, real-world scenarios were simulated in the simulated environment and investigate the accuracy of the predictions against the radio controller input variations.
- Carry out long-term predictions with simple possible scenarios and investigate the acceptability of the obtained results.
- Carry out long-term motion predictions: In this approach, real-world scenarios were simulated in the simulated environment and compare-contrast the predictions against the real-world scenario.
- User tests: Compare the real-world user perception and the user perception of the VR solution with drone pilots who have much experience with drones. This can be used to compare the numerical and user-perceived accuracy and ecological validity of the VR solution.

As mentioned in the related work, we analyzed previously carried out research work such as [13], [14], [15], [42], [43], [44]. The analysis shows that users' awareness of the location of a real-world outdoor scene or virtual-world outdoor scene consists of percentage-based errors ranging from 10% to 25%.

As motioned above, the developed machine learning model predicts the drone's position and orations against the radio controller inputs throttle, pitch, roll & yaw. Due to the assumptions and limitations, it works under negligible wind effects while drones perform forward and lateral movements. Under the simulation of short-term motion predictions, a single prediction was made by considering the drone's current position, oration and controller inputs throttle, pitch, roll & yaw. We considered several figures of eight shape drone trials and considered the drone's actual position, orientation and ratio controller inputs, then predicted the drone's position and orientation after 0.1 seconds. Then closely investigate the effect of the factors on prediction error. Fig. 6 illustrates the Actual positions of the drone and predicted positions of the drone.

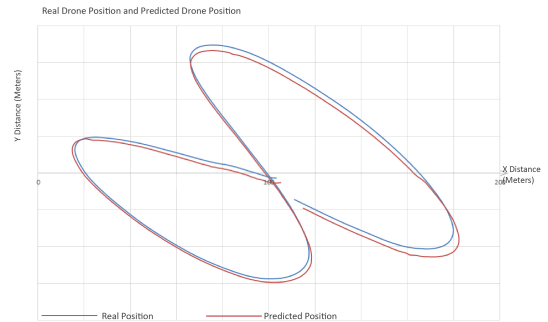

Fig. 6. Actual positions of the drone and predicted positions of the drone.

Fig. 7 illustrates the variation of the prediction error of the developed machine learning model against the time. It shows that the variation of the error is within 0.5 meters, and it is required to investigate the factors that affect the error.

Fig. 7. Variation of the prediction error of the machine learning model against the time.

Table I presents the correlation between radio controller inputs (RcAileron, RcElevator, RcRudder, RcThrottle) and the machine learning model's prediction error. Further, it shows that the prediction error highly depends on the RcRudder-radio controller input.

Fig. 8 illustrates the acceleration error of the machine learning model against time. Fig. 9 depicts the magnified segment of Fig. 8 that illustrates the acceleration error of the machine learning model against time.

Fig. 8 and 9 show that most of the time, acceleration error is significantly less. Compared with the rudder variation pattern and acceleration error, it shows that the acceleration error rapidly increases with the rudder. However, smaller rudder variations in the developed machine-learning model

TABLE I. CORRELATION BETWEEN CONTROLLER INPUTS (RCAILERON, RCELEVATOR, RCRUDDER, RCTHROTTLE) AND PREDICTION ERROR

Correlation between Prediction Error and Radio Controller Inputs	Correlation Coefficient
Correlation between Prediction Error and RcAileron	0.003580433
Correlation between Prediction Error and RcElevator	0.369202804
Correlation between Prediction Error and RcRudder	0.989092821
Correlation between Prediction Error and RcThrottle	0.242975470

Fig. 8. Acceleration error of the machine learning model against time.

provide substantial accuracy. As previously mentioned, a real-world outdoor scene or virtual-world outdoor scene consists of percentage-based errors ranging from 10% to 25%. Hence, the developed model and its short-term motion prediction results provide encouraging results to perform long-term predictions and further validate the model.

#### A. Long-Term Drone Motion Predictions with Simple Possible Scenarios

As explained above (Subsection: Design and development of the VR solution), the Fr-Sky Taranis radio transmitter & receiver was connected to the solution and make enabled user interactions via an actual radio controller. Fig. 5, presents the designed and developed machine learning-based drone dynamic simulation environment. Three experienced pilots were exposed to the VR environment and asked to perform simple drills such as the figure eight type manoeuvre, manoeuvre along a straight line and circular manoeuvre. Their responses were assigned to a typical Likert scale with a five-point agreement scale related to simulation results produced by the solution. The five points of the Likert scale are strongly agreed, agree but no idea, disagree, and strongly disagree. The overall Likert scale results show that the three experienced pilots agreed with the results produced by the designed and developed simulation environment.

#### B. Long-Term Drone Motion Predictions and Validate against Real-World Scenario

Under the assumptions and limitations of the drone dynamic model, a simulation of long-term motion predictions was made. We consider several figures of eight-shape drone trials for this validation. We considered the drone's initial settled/stabled position, orientation in the outdoor environment and ratio controller inputs, then predicted the drone's position, and orientation continuously. Then closely investigate the deviations between the actual drone trial results and predicted results. Fig. 10 and Fig. 11 illustrate the actual trajectory of the drone and the predicted trajectory of the drone.

Fig. 9. Magnified segment of the previous graph that presents the acceleration error against time.

Fig. 10. Actual trajectory of the drone.

The above results show that the predictions are deviated/deviating with the time, and initial position predictions are closer to the actual position of the drone. As we discussed above, users perceive the position of an outdoor drone or users perceive the position of a drone in an outdoor VR environment is accolated with a percentage-based error ranging from 10% to 25%. We consider the average of this error and define error merging for the predicted results. Fig. 12 illustrates the initial segment of the predicted drone trajectories and real drone trajectory with probable user perceive rejoin of the drone.

#### C. User Tests

The developed machine learning-based drone dynamic simulation environment needs to be validated to determine the immersive feeling "sense of being there" or "how users perceive" in the VR environment. The most common method of measuring this presence or "sense of being there" is to use questionnaires [64], [65]. Questionnaires give subjective measurement, and in most questionnaires, participants' responses to each question are assigned to a numerical scale [14]. Finally, the immersive feeling "sense of being there" in the VR solution can be reflected as a percentage. In the research validation phase, our primary focus is on subjective measurements. Hence, the user test was designed with a questionnaire. It targets three experienced drone pilots, including the drone pilot involved in the data gathering/recording pace, and the user test can be summarized as follows:

Simulate known conditions and record experienced drone pilots' responses. First, concerning each participant's response (feeling about the simulated scenario), qualitative properties of the simulated scenario will be assigned to a numerical scale (Likert scale) as follows [66]. Next, the quantitative properties of the simulated scenario will be directly recorded. Finally, the deviation from the expected value will be calculated. Under

Fig. 11. Predicted trajectory of the drone

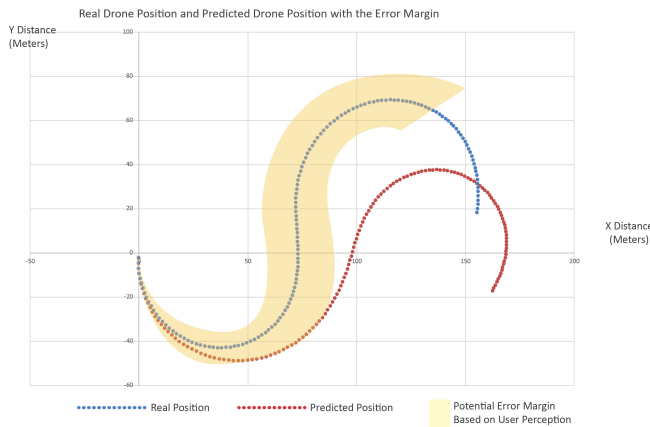

Fig. 12. Initial segment of the predicted drone trajectory and real drone trajectory with probable user perceive rejoin of the drone.

the simulated scenarios, many responses were recorded and selected questions/statements are given below:

- Approximated travel distance  $\approx 300\text{m}-400\text{m}$   $\rightarrow$  What is the approximated travel distance?
- What is the current velocity?
- Asked to perform figure eight manoeuvre. What is the approximate size of the performed figure eight manoeuvre?
- Compared to the real-world figure eight manoeuvre with Phantom 4 Pro, the drones' response to the radio controller during that figure eight manoeuvre carried out in the simulated environment is realistic.
- Used radio controller: Ease of Use/ realism level compared to the real-world Phantom 4 Pro radio controller is it perfect/realistic?
- How many vehicles were there on the ground surface?
- Presence (the user's sense of immersion or "being within" the environment) is perfect.
- Three drone pilots were exposed virtual environment with large flat screen-based visualization. Do you recommend HMD or any other visualization method?

The actual and simulated scenarios' qualitative and quantitative properties were compared throughout this user test.

TABLE II. SELECTED RESULTS OF THE CARRIED OUT USER TESTS

Simulated Scenario	Pilot Response Numerical Indicator
Physical realism of the entire VR environment (Input Methods/ Controllers/Output methods/ Visualizations)	1.4 (from -2 to 2)
Realism of the Drone Maneuverability	1.0 ( from -2 to 2)
Deviation of the size of the performed trial/covered area during the circular/ figure eight maneuvers	20%
Deviation of travel distance judgment	25%
Deviation of speed judgment	15%
Awareness and information gathering capability	1.4 (from -2 to 2)
Presence (immersion or "being within" the environment)	1.0 (from -2 to 2)

The main focus is to identify spatial awareness (The user's implicit knowledge of his position and orientation within the environment - during and after travel), information gathering (the user's ability to actively obtain information from the environment - during travel), and accuracy of the drone motion prediction against the real-world situation. Table II presents selected results of the carried out user tests.

## VII. CONCLUSIONS AND FUTURE WORK

The overall objective of the presented work is to propose a machine learning-based drone dynamic model and VR environment that can simulate existing drones without domain-specific knowledge and sophisticated laboratory infrastructure. Under selected circumstances, the proposed solution's accuracy and user-perceived accuracy were evaluated, and the authors were able to get promising results. The following conclusions and recommendations can be made based on the entire research.

- The proposed and developed machine learning model and its evaluation experiments were carried out by using Commodity-Off-The-Shelf hardware.
- If an accurate location tracker is available, the same procedure can be followed, and a similar machine-learning model can be developed for any existing drone.
- Short-term predictions of the proposed and developed machine learning model are within the user-perceived accuracy of both the real-world outer door scene and the virtual world outer door scene.
- The accuracy of the predictions mainly depends on the rudder variation. If the rate change of the rudder is more significant, then predictions of the proposed and developed machine learning model are less.
- Long-term predictions of the proposed and developed machine learning model are within the user-perceived accuracy of both the real-world outer door scene and the virtual world outer door scene for a limited period, and it gradually deviates with time.
- However, user test results show that the experience drone pilots agree with the simulated drone's physical realism and manoeuvrability. Moreover, there is a deviation between the user perceived position/speed of the simulated drone and the actual position/speed of the simulated drone.

- According to the evaluation results, early-stage predictions provided by the proposed and developed drone simulator are substantially accurate with rudder variations. Hence, drone piloting drills/missions/exercisers that require a short period (less than 25 seconds) for the entire activity can be simulated with substantial user perceive realism, behavioural realism and physical realism.

There is physical and behavioural realism in the proposed machine learning-based drone simulation environment. However, a wide range of further research work can be carried out to improve existing physical and behavioural realism. Some of the most critical and selected future research works are described below.

- Perform a wide range of drone manoeuvres and collect larger data sets that cover more drone dynamics and enhance behavioural realism by increasing the accuracy of the machine learning-based drone dynamic model.
- Design and develop a cylindrical or spherical display system, connect head-mounted display (HMD) and carry out experiments to enhance the physical realism and user perceive accuracy.

# Stacking Deep-Learning Model, Stories and Drawing Properties for Automatic Scene Generation

Samir Elloumi<sup>1</sup>, Nzamba Bignoumba<sup>2</sup>  
University of Jeddah, Jeddah, Saudi Arabia<sup>1</sup>  
Tallinn University of Technology, Estonia<sup>2</sup>

**Abstract**—Text-image mapping is of great interest to the scientific community, especially for educational purposes. It helps young learners, mainly those with learning difficulties, to better understand the content of stories. In this paper, we propose to capture the teacher’s experience in manually building relevant scenes for animal behavior stories. This manual work, which consists of a pair of texts and a set of elementary images, is fed into a Long Short-Term Memory (LSTM) followed by a Conditional Random Field (CRF) that aims to associate the relevant words in the text with their corresponding elementary image while preserving the drawing properties. This association is then used for scene construction. Several experiments were conducted to show how better the constructed scenes convey textual information than the scenes constructed from the competitor’s models.

**Keywords**—Text to image conversion; elementary image; image composition; deep-learning; drawing properties

## I. INTRODUCTION

The use of simple illustrative approaches by instructors to facilitate and make new concepts easier to comprehend dates back to when kids first start school. For example, they have used pins to stick the images on woody boards to explain actions, verbs or any other pedagogical purpose. A set of elementary images (EIs) such as a boy, a ball, a tree, to name but a few, were carefully preserved in the drawers and reused to compose new images or scenes as needed. Consequently, the main goal of this research is to replicate EI composition.

Text to image mapping has witnessed a great interest for the scientific community, in particular for the educational purposes and early learners, especially those who have reading disabilities. Many multimedia systems proposed to visually explain topics, news streams or stories by annotating news articles with pictures [1], enriching textual content [2], [3] or composing scenes [4]. Nevertheless, there are some common limitations in the existing systems which have not been properly addressed:

- Several existing multimedia systems can retrieve pictures automatically from the image search engine and generate illustrations [5], [6], [7], [8]. However, manual work is required to filter out inappropriate pictures, which reveals the excessive manual efforts behind these systems as indicated in [4].
- Multimedia systems for illustrating Arabic text are very limited, which reflects the current technical difficulties in understanding Arabic text.
- Many pictures are available on the web, but they lack textual descriptions or captions to be included in a relevant image search.

- Most of existing multimedia systems can illustrate text based on retrieved images. However, none of them, to our best knowledge, considers extracting elementary objects from retrieved images and using them for composing new pictures from scratch.

Although the use of a multimedia repository (MR) is one of the most common approaches to building scenes from sentences, obtaining the appropriate images from this repository to construct scenes is far from being an easy task. In some cases, we may not even be able to find accurate images that match the input sentence. However, the MR may contain EI images whose assembly may perfectly match the input sentence. The main objective of our work is then to propose a model that builds scenes with EIs while preserving the relevant implicit or explicit information contained in the sentence.

To achieve this, we implemented a model based on Recurrent Neural Networks (RNN) coupled with the Conditional Random Field (CRF) model to first identify in the input sentence words that correspond to EIs and secondly, predicting the dimensions and positions of these EIs in a such a way that the information contained in the input sentence is preserved. The EIs names and their respective dimensions and positions, which are represented in matrix form, will be transmitted to a system that will be responsible for building the scene. We implement our model and building system with python because it contains very advanced machine learning libraries such as Keras and TensorFlow. The sentences we are addressing are those relating to animal behavior.

The remainder of the paper is organized as follows. We first provide a literature review in Section II and then elaborate on our proposed method in Section III. We present experimental results in Section IV and evaluation in Section VI. Finally, we conclude this paper and discuss future directions in Section VII.

## II. RELATED WORK

Generating images from text (T2I), is an area of growing interest in computer science. Indeed, many approaches have been proposed, inspired by the way the human brain proceeds when trying to understand simple to more complex sentences. Based on his cognitive memory (human being), the comprehension of a simple text can be done by associating with each word of a text an image [9]. This process of understanding a text from an image has given rise to several approaches, which consist in generating scenes (set of images) from elementary annotated images. For instance, Coyne and Sproat [10], generate scenes from the WordsEye

image database by retrieving the images whose annotations match the words of the sentences. Rather than relying on all the words in the sentence to construct the scenes, Zhu et al. [11], proposed another approach that consists of identifying the most relevant concepts in the sentence and constructing the scene by merging the pictorial representations of these concepts. As the position of the elementary images may play a salient role in adequately conveying the meaning of the sentence, Yamada et al. [12], proposed a geometric model where the scenes are built considering the spatial constraints of the object described in the text. While these aforementioned approaches work well in practice for simple sentences, they quickly find their limit with complex ones. Indeed, their image database is not exhaustive, i.e. some words do not have their corresponding images. Moreover, even if one assumes to have an exhaustive image database, some abstract words like “lying, politics” cannot be represented by an image. To overcome this limitation, Rada et al. [13], implemented a system that generates scenes from complex sentences by coupling text and images to overcome this limitation. Although this last approach attempts to solve the abstract word problem, it is also limited by its exhaustive image database. It should be mentioned that all the approaches mentioned so far do not deal with spatial constraint and abstract word issues simultaneously. Moreover, the goal of T2I systems is to generate realistic scenes with exclusively images (which can be difficult when the embedded images have different backgrounds). In order to propose a model that addresses these issues simultaneously, the researchers turned to a deep learning model called GAN, proposed by Goodfellow et al. [14].

Originally proposed to generate realistic images by learning pixel distribution from a train image dataset, GAN is made up of two adversarial neural networks: a generator  $G$  and a discriminator  $D$ .  $G$  is trained to generate images by learning the distribution of real images and fooling the discriminator, in contrast  $D$  is trained to identify which images are generated or real. The spectacular results, obtained with GAN, have generated enormous enthusiasm in the creation of models derived from the latter. Thus, in order to improve the MNIST digit generation, Mirza et al. [15], proposed a conditional GAN (cGAN) where the generator and discriminator are conditioned by a class label  $y$ . Inspired by this approach for the T2I task, rather than conditioning the generation process by a  $y$ -class label, Reed et al. [16], proposed to condition it by the whole sentence embedding obtained from a pre-trained text encoder. Compared to [16] where the generated images had a resolution of  $64 \times 64$ , the authors in [17], proposed a Tac-gan-text conditioned auxiliary classifier generative adversarial network (TAC-GAN) capable of generating a higher resolution image i.e.  $128 \times 128$ . In order to improve image resolution, another paradigm based on generators and discriminators stacking has emerged. Zhang and al. in [18], proposed a model called StackGAN composed of two generative stages. The first stage is dedicated to the generation of a coarse  $64 \times 64$  pixel image given a random noise vector and textual conditioning vector, while the second produces an image of  $256 \times 256$ . An improved version of [18], composed of three stacked generators and discriminators, was proposed in [19]. To avoid stacking several pairs of discriminators and generators layers, other approaches like [20] [21] proposed to reduce the number of generator and increase the number of discriminator (or vice versa). As

with these stacked listed generative models, a generated image is dependent on a previous one (except for the initial), the poor quality of the latter can lead to an inaccurate generated image. Therefore, to prevent this from happening, the authors proposed Dynamic Memory Generating Adversarial Networks (DM-GANs) in which a dynamic memory unit is designed to select important textual information based on the content of the initial generated image and then use it to generate the next image. In addition to the features extracted from the generated image, the authors in [22], integrated also aspect-level features (processed from the input text) to update and enhance word-level feature in order to refine the next image.

By making the assumption that an image generated from text should be based on the relevant words in addition to the whole sentence (attention), Xu et al. in [23], built a fine-grained text to image generation with Attentional Generative Adversarial Networks (AttnGAN). Huang et al. [24], proposed a grid-based attention model that involves applying an attention mechanism between object-grid regions and word phrases. Similar to our work, part-of-speech tagging is applied to extract word features. Other models applying attention in different fashion like [25], [26], [27], [28] were also proposed.

Initially proposed to solve signature and face verification problems, Siamese networks designed with two branches (split-parameter neural networks) processing a pair of inputs have been also repurposed for the T2I task in [29], [26]. In both, each branch takes as input a text (caption) and generates an image. However, in [29] the objective loss function is employed to minimize / maximize the distance between the features extracted in each branch to learn a semantically meaningful representation, depending on whether the two captions are from the same ground truth image (intra-class pair) or not (inter-class pair) in [26], the objective loss function aims to minimize the feature distance between generated image and corresponding ground truth image while maximizing the distance to another real image associated with a different caption. In [30], the authors proposed a model derived from Siamese networks called Text-SeGAN in which negative sampling of image pairs is carried out with several strategies so that the model is able to detect the most subtle differences between two images and therefore improve the generation process. Another T2I approach, called cycle-consistent image generation by re-description architectures inspired by CycleGAN [31], was also implemented in [32], [33]. The principle of this approach is to learn a semantically consistent representation between text and image by appending a captioning network and train the network to produce a semantically similar caption from the generated image.

Unlike the CycleGAN derived models where the image generation process is conditioned by some inputs, unconditional generative models [34], [35], [36] were built upon unconditional image generation models [37], [38] for T2I purpose. For example, in [35], the authors proposed a model called textStyleGAN in which the text is previously passed through a pre-trained image-to-text matching network to compute the embedded representation of the whole text as well as the words of this last. These embedded representations are combined with noise and fed into textStyleGAN to generate an image. Instead of only generating images from texts, other approaches have added additional supervision tricks. For example, to

generate complex images (images with several objects also called scenes) from Microsoft Common Objects in Context (MS COCO), Sharma et al. proposed ChatPainter [39] where, in addition to scene captions, they also rely on dialogues (pairs of question-answers) describing the scenes. Other works, in [40], [41], [42], were also relying on dialogue approach. The authors, in [43], [44], used multiple captions to iteratively improve the image quality.

Although GAN models are tending to democratize to the detriment of classical approaches (due to their much higher performance requiring less and less human intervention), the generation of complex images remains a challenge. In order to overcome this challenge, we proposed a model based on a combination of the classical approach, probabilistic graphical model and deep learning models. Each of these approaches contributes as follows:

- The classic approach consists of using annotated images from a Multimedia Repository (MR).
- Deep learning is to explore the sequential pattern while encoding each word in the text.
- And probabilistic graphical model to match the latent word representation emitted by the deep learning model to their corresponding part-of-speech tag;

The novelty of our proposal which, is the introduction of new types of part-of-speech tags that describe the action performed by a specific object and define the coordinates of the latter in the scene. This part-of-speech tagging step of associating each word of the text with a tag based on the action, position and dimension of the object in the scene is the basis of our system.

### III. OUR APPROACH: SCENE BUILDER BASED ON ELEMENTARY IMAGES

As depicted in Fig. 1, there are three phases in our builder system. In phase 1, we need to prepare the dataset as an input for the tag matching phase. In phase 2, the model performing the tag matching stage, is fed with the word-tokens of the sentences (stories) and their corresponding tags (object names, positions and sizes) processed in phase 1. Finally, in phase 3, a scene builder is implemented to build the scenes from the input sentences, based on the tag matrices obtained in the tag matching stage.

#### A. Phase 1: Learning Dataset Preparation

We have developed a graphical tool that allows an instructor to write a story's text and manually draws its related scene by inserting Elementary images (EIs) in a graphical drawing area. Based on his expertise, the instructor selects the most relevant images and arranges them in the graphical area to fit the story's meaning. We consider that this expertise is the key point on which we based our approach. Hence, we collect all instructor actions, namely the selected images, their positions and sizes, and we save them in a database. While choosing an image from the toolbox, the user selects its related textual parts in the story. This is considered as an implicit image annotation that serves later to map a text into an image. In the following, we give more details about the tools and the EIs repository already prepared in [45].

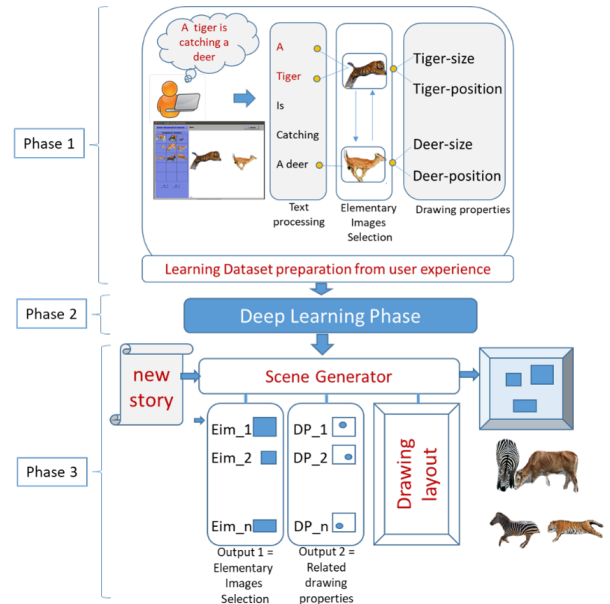

Fig. 1. System architecture.

1) *Elementary Images Repository*: An initial EIs repository was constructed in [45]. It contains around 1540 EIs collected from Google image and ImageNet. The EIs were obtained by following a particular process. In fact, based on existing online libraries such as Google Images, ImageNet, etc., a set of images were collected and stored in a local folder. For each image, the model Mask R-CNN [46] object extraction tool was applied in order to obtain EIs with some of their drawing properties. Subsequently, an image captioning process was applied on extracted elementary objects in order to automatically assign a caption for each one of them.

2) *The Tool*: In our Image Story Generator tool, image composing is designed in two ways: manual image composing and automatic image composing. In our current tool version, we compose new images or pictures manually, allowing thereby flexible working with the tool. We briefly describe how a user composes new images using our tool. First, a user input keywords in an input field on the top of the tool main interface and hits enter. Note, we use single keyword only at this current version. The retrieved EIs from EMR are displayed in a panel on the Graphical Toolbox on the left side of the main interface, as indicated in Fig. 2. The user or the teacher can drag and drop the main interface, locate images and resize them, thereby composing a new scene describing the input sentence. The teacher can successively search for other EIs doing same steps as described. Thus, the teacher can show the final illustration to the students. The newly created image is stored locally. Therefore, the system extracts the image sizes, positions, etc. This information is saved as drawing properties and will be further used for generating new pictures/images dynamically.

3) *Input preparation for the tag matching stage*: In this phase, we arrange the database content to fit the deep learning model dedicated to the tag matching stage.

Once getting a manually satisfactory scene, i.e., arranging the EIs and setting their sizes, positions as it should be,

Fig. 2. Scene drawing tool

the prepared image is saved. More specifically, the metadata related to this composite image such as the names of EIs, their respective position and dimension, within the global one image, their links to some parts of the initial text are saved as well.

The saved file will act as our data set. It will then be processed by a deep learning model so that from a sentence  $\mathbf{t} = [t_0 \ t_1 \ \dots \ t_{n-1}]$  where  $t_n$  is the token code for the  $n^{th}$  word in  $\mathbf{t}$ , a corresponding matrix tag  $\mathbf{M}_{n,m}$  is generated.  $n$  is the number of words in the sentence  $\mathbf{t}$  and  $m$  is the number of tag types. Hence, the matrix is defined by eq. 1:

$$\mathbf{M} = \begin{matrix} t_0 \\ \vdots \\ t_{n-1} \end{matrix} \begin{bmatrix} \hat{y}_{0,0} & \hat{y}_{0,1} & \cdots & \hat{y}_{0,m-1} \\ \vdots & \vdots & \vdots & \vdots \\ \hat{y}_{n-1,0} & \hat{y}_{n-1,1} & \cdots & \hat{y}_{n-1,m-1} \end{bmatrix} \quad (1)$$

$y_{n,m}$  is the tag  $m$  associated with the sentence's word at position  $n$ . For our study,  $m$  is equal to 3 since we attempt to generate the word type (whether it is an object or not), it's size, and it's position. Note that, we used the Beginning, Inside, Outside (B-I-O) notation, for the tag's representation with reference to the "Named Entity Recognition" (NER) information extraction technique [47]. This technique allows capturing the action performed by an object (if animal type) in the sentence. For each word in a sentence, we associate a three tags vector. The first value of this tag vector is an image tag that determines whether the image is an object and identifies which word describes the action performed by the object. The second one is the position tag, which determines the position in which the *EI* will be placed. The third one, which is the size tag, determines the size that the *EI* will have within the scene. The Table I illustrates an example of a phrase and its different tags. It is worth mentioning that the Inside notation is only applied to image tag generation because we want to identify the action performed by an animal-type *EI*. Which is not a necessity for position and size tags, which are spatial tags.

- The values of the "Image Tag" column allows identifying the names of the EIs in the sentence as well as the actions they perform (if any). The names and actions

TABLE I. A SENTENCE WITH THREE TAGS

Sentence	Image Tag	Position Tag	Size Tag
A	'O'	'O'	'O'
lion	'B-object'	'B-w1Lh2B'	'B-large'
lying	'I-object'	'O'	'O'
in	'O'	'O'	'O'
the	'O'	'O'	'O'
savannah	'B-object'	'B-w0Rh0B'	'B-entire'
observes	'O'	'O'	'O'
a	'O'	'O'	'O'
gazelle	'B-object'	'B-w1Rh1B'	'B-middle'
.	'O'	'O'	'O'

of these objects will make it possible to construct the path to retrieve the appropriate *EI*. If we take for example the sentence of Table I, the paths obtained will be:  $\dots/lying/lion$ ;  $\dots/savannah$ ;  $\dots/gazelle$ . So the *EIs* that will constitute the scene will be a lying lion, a gazelle and the savannah. The savannah object like other objects such as the street, the river etc. present in our sentences are background objects. They are associated with the size tag "B-entire".

- The "Position Tag" column allows defining the position of *EIs* in the scene. Rather than considering the exact positions in pixel, we have considered regions landmark. In fact, the entire image is discretized or split in  $n \times p$  parts (where  $n$  and  $p$  are positive numbers). Suppose that the image dimension is  $w \times h$  (where  $w$  represents its width and  $h$  its height respectively in pixels). The scene (i.e. the entire image) is discretized in  $\frac{w}{n} = w_1 + w_2 + w_3 + \dots + w_n$  width parts and  $\frac{h}{p} = h_1 + h_2 + h_3 + \dots + h_p$  length parts. Based on that, each *EI* is associated with a position tag of type  $B - w_x H h_y V$ . Hence,  $w_x$  indicates that the image should be positioned from the  $x^{ieth}$  width part of the scene, starting in a  $H$  direction where  $H \in \{L, R\}$  (L for left, R for right) and  $h_y$  to indicate to the system that the image should be positioned from the  $y^{ith}$  part in the height of the scene, starting in a direction  $V$  where  $V \in \{T, B\}$  (T for top, B for bottom). In the example shown in Fig. 3, the image is divided in  $n = 6$  width parts and  $p = 5$  height parts. In this scene we have three *EI* which are: the lion, the gazelle and the savannah in the background. To each of these images, the following position tags are respectively assigned to them:  $B - w_1 L h_2 B$ ,  $B - w_1 R h_1 B$ ,  $B - w_0 L h_0 B$ .
- The values of the "Size Tag" column allows defining the size of the EIs within the scene. In this column, we have 4 different tags. Each one of them is associated with a predefined width and height.

The next step is the learning model preparation.

### B. Phase 2: Tag Matching

The tag matching stage involves associating a triplet of tags with each word of the sentence. Due to their ability of data extraction and high accuracy in classification and

Fig. 3. Discretized image

prediction tasks [48], [49], we used stacked deep learning models (Embedding, Bi-LSTM and Dense layers) to perform the data extraction in the tag matching stage. Technically, we subsequently pass our sentence input through an Embedding layers, then into a Bi-LSTM layer and finally into a Dense layer wrapped by a TimeDistributed layer. Their respective roles are as follows:

- Embedding layer: it aims to associate with each word of the sentence, a vector of real numbers encoding the semantics of the latter and its relationship with the other words.
- Bi-LSTM: it re-encodes vectors outputted from the Embedding layer to another vectors of real numbers for which the encoding process leverage on the sequential pattern existing in the input text.
- Dense layer: It extracts the information contained in the vectors obtained from the Bi-LSTM layer. It is wrapped by a TimeDistributed because a simple Dense layer can only be fed by a single vector. In our case, we have as many vectors as there are words in the sentence, that is why we used a TimeDistributed layer.

As CRF [50] has achieved leading results in speech part tagging, we appended it to our model for the tag matching stage. Technically, the output of the Dense layer is passed through three different CRF layers where, each one is dedicated to matching image, position, and size tags. The whole architecture of the tag matching stage is depicted in Fig. 4.

These steps will be repeated during the training phase in order to define the optimal parameters of the model. The loss function for parameter optimization is defined as follows:

$$loss = loss_{image} + loss_{position} + loss_{size} \quad (2)$$

$$loss_{tag} = -(\ln(p(\mathbf{y}|\mathbf{t})_f) + \ln(p(\mathbf{y}|\mathbf{t})_b)) \quad (3)$$

$$p(\mathbf{y}|\mathbf{t}) = \frac{e^{S(\mathbf{y},\mathbf{t})}}{\sum_{\mathbf{y}' \in \mathbf{Y}} e^{S(\mathbf{y}',\mathbf{t})}} \quad (4)$$

$$S(\mathbf{y}, \mathbf{t}) = \sum_{i=0}^{N-1} \mathbf{A}_{y_i, y_{i+1}} + \sum_{i=1}^{N-1} \mathbf{P}_{i, y_i} \quad (5)$$

Where  $tag \in \{image, position, size\}$ ,  $\mathbf{t}$  the input sentence vector, and  $\mathbf{y}$  the corresponding tag vector.  $f$  stands for forward-pass and  $b$  for backward-pass in the Bi-LSTM layer.  $S$  is the cross-score function between words in  $\mathbf{t}$  and tags in  $\mathbf{y}$ .  $\mathbf{A}$  is a matrix where coefficients are the transition score from  $y_i$  to  $y_{i+1}$ .  $\mathbf{P}$  is a matrix whose coefficients are the scores of the pairs  $(t_i, y_i)$ . Once the matrix is generated, a mapping between its values and all the  $EIS$  to build our scenes is performed. In the next subsection, we formally describe how scenes are constructed.

### C. Phase 3: Scene Construction

In phase 3, the scene constructor system is ready to map a new story to a scene by mapping the words of the input sentence which their corresponding images base on the tags in  $\mathbf{M}$ . It is formally described as follows:

$$f(\mathbf{t}, \mathbf{M}, EIS) = \hat{S} \quad (6)$$

Where  $\hat{S}$  represents the scene built from the sentence  $\mathbf{t}$ . The first objective of the function  $f$ , is to map each word (if they are objects), to their corresponding elementary image  $EI \in EIS$ . Second, each  $EI$  will be positioned in the scene respecting its generated size and position. The Pseudo-Algorithm 1 presents the mains steps for Scene Constructor.

---

#### Algorithm 1 Scene Constructor $f$

---

**Require:**  $\mathbf{M}, \mathbf{t}, EIS$

**Ensure:**  $\hat{S}$

- 1:  $\hat{S} \leftarrow \text{init}(\text{Matrix})$   $\triangleright$  We initialize the scene, i.e. we create an image with only white pixels.
  - 2:  $\mathbf{Tags} \leftarrow \text{getTags}(\mathbf{M})$   $\triangleright$   $\mathbf{Tags}$ , is a matrix where each row  $i$  represents the path ( $\mathbf{Tags}[i, 0]$ ), the position ( $\mathbf{Tags}[i, 1]$ ) and size ( $\mathbf{Tags}[i, 2]$ ) of an object in  $\mathbf{t}$ . The path is processed based on the generated image tags.
  - 3: **for**  $i, \mathbf{tgs} \leftarrow \text{enumerate}(\mathbf{Tags})$  **do**
  - 4:      $EI \leftarrow \text{getEI}(\mathbf{tgs}[0], EIS)$
  - 5:     **if**  $\mathbf{tgs}[1] \neq \text{"B-entire"}$  **then**
  - 6:          $\text{Draw}(\hat{S}, EI, \mathbf{tgs}[1], \mathbf{tgs}[2])$   $\triangleright$  This function draws EI in the scene according to their position and their size.
  - 7:     **else**
  - 8:          $k \leftarrow i$
  - 9:     **end if**
  - 10: **end for**
  - 11:  $EI \leftarrow \text{getEI}(\mathbf{Tags}[k, 0], EIS)$   $\triangleright$  After saving the index  $i$  associated with the object with B-integer as size tag, we draw this object at the end to avoid overlapping other EIs.
  - 12:  $\text{Draw}(\hat{S}, EI, \mathbf{Tags}[k, 1], \mathbf{Tags}[k, 2])$
  - 13: **return**  $\hat{S}$
- 

## IV. EXPERIMENTAL STUDY

In this section, we first present the dataset used to evaluate our model and the hyperparameters retained after a grid search. Second, we benchmark the model against state-of-the-art competitors. For the implementation, we used Python machine learning libraries: TensorFlow and Keras. NumPy,

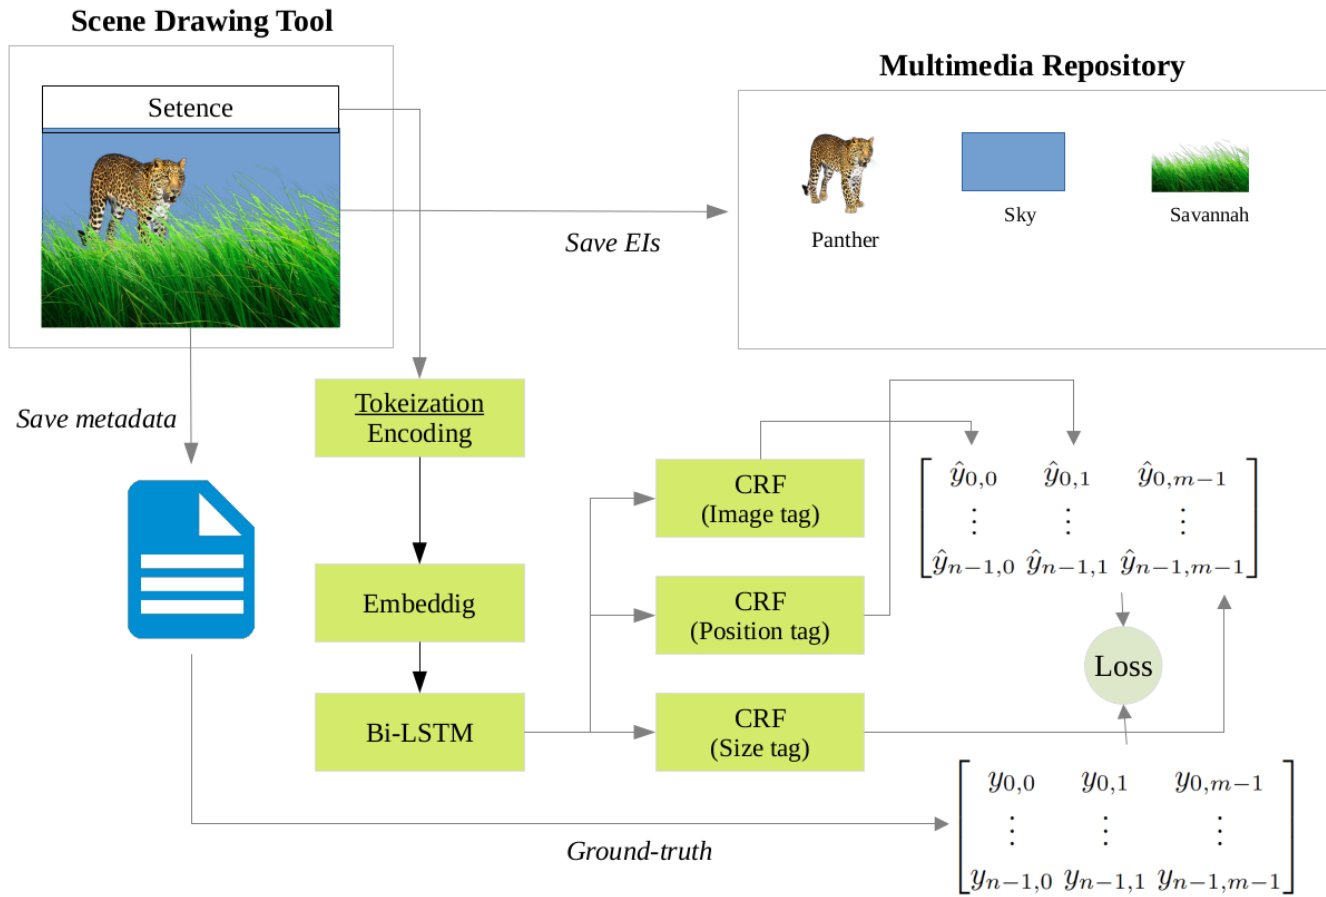

Fig. 4. Tags prediction model architecture: learning phase.

Pandas and Matplotlib were also used for the preprocessing stage and the scene construction stage.

#### A. Dataset

The dataset we used (see Table II) consists of 210 sentences that describe the behavior of 52 animals and their interactions with 34 objects that are not animals (e.g. vegetables, wood, etc.). We used 190 sentences for training (90%) and 21 sentences for testing (10%). The sentences are the same ones we used to manually build scenes and record metadata in the graphical tool. They are organized in such a way that the same action can be associated with different EIs of the animal type. This allows the model to better understand that actions are more related to words representing EIs of animal type. Take the example of the sentences “Lions eat meat” and “Cats eat meat in front of the door”. These two sentences are similar. Lions and cats, which are EIs of animal type, perform the same action: eating. Thus, the model will figure out that the action of eating is more related to animal-type EIs than to other EIs in the sentence.

#### B. Hyperparameters

After a grid search, the different hyperparameters of the layers that make up our model were set as follows:

##### a) Embedding layer:

- The number of distinct words in the corpus 166.
- The dimension of the vector space into which each word initially encoded with the one-hot encoding technique will be projected is set to 40.
- The fixed length of the input sentence is 100.
- The Boolean parameter that specifies whether the token 0 is a padding token or not is set to *True*. This is because the input sentences are of different lengths.

##### b) BI-LSTM layer:

- The number of cells in each of our LSTM forward and LSTM backward networks is 100.
- The Boolean parameter allowing to indicate whether the BI-LSTM network should return either a sequence of token (in vector forms) or just one token is set to *True* because, we need to match a tag for each word in the input sentence.
- The recurrent dropout, which is a regularization technique that prevents over-fitting [51], [52] is set to 0.7. This means that the probability that a Bi-LSTM cell is skipped during training is 0.7.

TABLE II. TRAINING SET DESCRIPTION

	Total number of objects	Total number of distinct objects
Animal objects	258	52
Other objects	153	34
Total	411	86

c) *Time Distributed:*

- the TimeDistributed layer is a layer that wraps each Bi-LSTM output in a Dense layer. The number of cells in this Dense layer is set to 100. We used the *Relu* activation function in this layer.

d) *CRF:*

- The CRF parameter we set here is the number of tags that could match for each EI in the input sentence. Each EI can have 3 image tags which corresponds to the number of units in the CRF layer dedicated to the image tag; 54 position tags which corresponds to the number of units in the CRF layer dedicated to the position tag; 5 size tag which corresponds to the number of units in the CRF layer dedicated to the size tag.

For the training phase, we set the number of epochs to 300 and the batch size to 3. We used the gradient descent optimizer [53], [54], to update the model weights.

In the next section, we present the results obtained, and the metrics used to evaluate them.

### C. Experimental Results

To evaluate the tag generation component, we considered the F1-score metric [55] computed from precision and recall. They are defined as follows :

- Precision: Designates the number of classes different from the class “O” which are correctly predicted by the system divided by the total number of positive classes predicted by the system [55].

$$\frac{|true\ positives|}{|true\ positives| + |false\ positives|} \quad (7)$$

- Recall: Designates the number of classes different from the class “O” which are correctly predicted by the system out of the total number of classes which are not “O” [55].

$$\frac{|true\ positives|}{|true\ positives| + |false\ negatives|} \quad (8)$$

- The F1-score: Designates the ratio of the product of the recall by the precision on their sum [55].

$$F_{\beta} = (1 + \beta^2) \frac{PR}{\beta^2 P + R} \quad (9)$$

Where  $\beta = 1$  determines the balance coefficient between precision and recall. The results, in Table III, summarize the F1 score obtained for the image, position and size generation.

We can see that they are quite satisfactory. The lower F1 score obtained with the position tag generation component is explained by its high number of tags, which makes it less stable. On the other hand, due to their low number of tags, the image and size tag components have higher F1 scores. We hypothesize that the F1 score of the image tag component is better than that of the size tag component (which has a similar number of tags) due to the use of the Inside notation, which reinforces the generation process.

The evaluation we performed with the F1 score just allowed us to find the optimal hyperparameters for the generation of the tag matrices. In the next section, we present the scenes built from these tag matrices.

## V. BUILDING SCENES

To build scenes, we will couple our tag prediction model to our scene building tool. The latter will take as input a sentence  $t_i$ , its corresponding tag matrix (the one predicted by the model)  $M_i$  as well as all of our EIs. For application, 21 test sentences and their corresponding tag matrix are considered. The results obtained are presented in Tables IV, V.

Among the 21 sentences, 18 images correctly reflect the corresponding input texts. So we have a success rate of 18/21 or 85.7%. However, if our system succeeds in: placing EI in positions that reflect the interactions between them; producing very realistic scenes thanks to a position label class that allows the entire background to be painted with an EI and; clearly representing the action performed by the EI, errors and anomalies are to be underlined. First, we can see in Table V line 1, that the predicted tag matrix contains errors. The model classifies the word “next” as an action performed by the object “elephant”, which is inconsistent. Secondly, in Table V line 2, we see that for the dimension tag, the class assigned to “fly” is “B-entire” so the latter is considered as a background EI. Therefore, since its dimension is smaller than the background, it cannot cover it completely. In the opposite case (if it has the same dimension as the background), it would make no sense to have a “fly” as a background image. Although errors are observed when predicting the tags, the model is still able to provide images that are more or less correlated with the sentences.

After evaluating our model with our corpus, we will evaluate it with another corpus and compare the results obtained against those of state-of-the-art text-to-image systems and models.

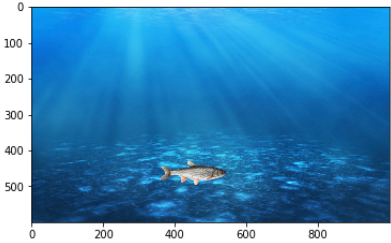

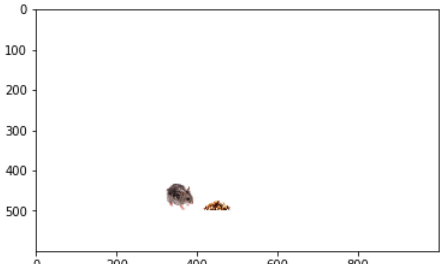

## VI. EVALUATION OF THE MODEL AGAINST THE GOOGLE IMAGE SEARCH ENGINE, THE MULTIMEDIA SYSTEM AND A GAN MODEL

This approach, which consists of building scenes manually rather than automatically from elementary images, has already

image and to the GAN model.

#### A. Corpus of Sentences

To evaluate our model, the chosen corpus of sentences will be used to evaluate the multimedia system [45]. This choice is

simply justified by the fact that our model is an improvement of the previous one. Instead of building the scenes manually, as is the case in this multimedia system, we will build them automatically. The number of sentences contained in this corpus is 20. All relating to animal behavior. We will take

8 for our evaluation. It should nevertheless be noted before the evaluation that our model does not yet take into account the cardinality of EIs. For example, in the following sentences, “two birds” and “three flowers”, the model cannot draw 2 birds or 3 flowers.

### *B. Results*

In this section, we present the different results provided by the multimedia system, Google image, the GAN model and our system. As far as the multimedia system and Google image are concerned, we will simply retrieve the results from [45]. For each sentence we associate its related image as provided by each system. The results are depicted in Tables VI, VII, VIII, IX and X.

For the comparison analysis, we consider three criteria. The first one is Principal actors (PA). It allows evaluating to what extent the objects present in the sentence are present in the generated image. The second criterion, the event (EV), consists in evaluating to what extent the event described in the text is represented in the generated image. The third and last criterion assess to what extent the spatial positions of the objects and the temporal aspect (S & T) are respected. Each of these evaluations will be out of five as indicated in the Table XI. Thereafter, we will calculate an average specific to each sentence for each model and for each model we will calculate the average of each criterion obtained for all eight sentences.

We can see through the Table XI that our model outperforms both the Google Image system and the GAN model. The latter is the worst one. However, still our previous multimedia system [45] gives the best results since the construction of the scenes is done manually. However, still the multimedia system [45] gives the best results since the construction of the scenes is done manually. However, our model can be used for short texts that might be addressed to a large young learners students.

TABLE VI. RESULTS FOR EACH SYSTEM (PART 1)

Phrases	Google image	Multimedia System	GAN Model	Our System
The tiger is running behind a herd of deer			No Object Found in the System	
The two hungry bears were wandering through the forest				
The crocodile grapples with zebras				
Zebras, bulls and tiger drink water from the lake				

TABLE VII. RESULTS FOR EACH SYSTEM PART 2

Phrases	Google image	Multimedia System	GAN Model	Our System
The camels walked and crouched on the sand				
Elephants smashed the rabbit's house				
The horses and the zebras run behind the elephants in the stadium				
A group of cats jumps behind small butterflies				

TABLE VIII. RESULTS FOR EACH SYSTEM PART 3

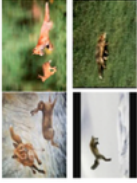

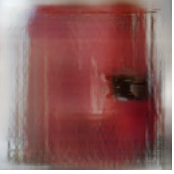

Phrases	Google image	Multimedia System	GAN Model	Our System
The rabbits and the turtles eat lettuce.			No Object Found in the System	
The fox is running behind the little rabbit.			No Object Found in the System	
The horses and the bulls are running in the playground.				
The bulls eat leaves of trees.				

TABLE IX. RESULTS FOR EACH SYSTEM PART 4

Phrases	Google image	Multimedia System	GAN Model	Our System
Two tigers and one lion eat meat.			No Object Found in the System	
The dogs and the foxes run behind the deer.				 
The turtles dive in the lake.			No Object Found in the System	
The two bears stand on two trees with behives.	 			

TABLE X. RESULTS FOR EACH SYSTEM PART 5

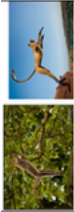

Phrases	Google image	Multimedia System	GAN Model	Our System
The crows are standing on a high tree.				
The monkey jumped over sleeping rabbits.			No Object Found in the System	
The camels eat grass.				
The crows flew with the butterflies over the tree.

## VII. CONCLUSION

In this paper, we have discussed how we could capture a user expertise to produce a new tool for automatic Stories illustration. The requirement is an available set of elementary images representing different types of objects that a user (or a tutor) uses from a toolbox and draw a scene related to a given story. The originality of our work is that we suggest capturing the “know-how” of the tutor and make it transfer to a deep-learning based model. The latter is coupled with a drawing tool in order to build automatically stories illustration by images compositions. We have conducted several experiments to find the optimal values for the deep-learning model such as: “Loss function”, “Batch size”, “Number of epochs”, etc. In addition, comparisons with existing approaches that make scene generation were also presented. Obviously, the quality of the “manually” constructed scenes remains the best one, nevertheless, our new approach gives very interesting results.

Even though we obtain satisfactory results, we agree that our approach face some limitations. One of them is that the Mask-CNN that we used to extract the EIs is not trained in end-to-end fashion. In our future work, we plan to train it in this way so that the model becomes more accurate. As we noticed in the results Subsection VI-B, in some cases the model fails to construct the scene (empty background) as the appropriate EI was not available on our Multimedia Repository. Therefore, we also plan to diversify the sources of image databases so that the MASK-CNN can extract more EIs. Due to the complexity of the sentences, we specifically focused our work on sentences related to animal’s behaviors. We then plan to incrementally integrate sentences related to other facts to make the model more generic.

## ACKNOWLEDGMENT

This work was funded by the University of Jeddah, Jeddah, Saudi Arabia, under grant No. (UJ-22-DR-96). The authors, therefore, acknowledge with thanks the University of Jeddah for its technical and financial support.

**Abstract**—Bacterial and Fungal diseases may affect the yield of stone fruit and cause damage to the Chlorophyll synthesis process, which is crucial for tree growth and fruiting. However, due to their similar visual shot-hole symptoms, novice agriculturalists and ordinary farmers usually cannot identify and differentiate these two diseases. This work investigates and evaluates the use of machine learning for diagnosing these two diseases. It aims at paving the way toward creating a generic deep learning-based model that can be embedded in a mobile phone application or in a web service to provide a fast, reliable, and cheap diagnosis for plant diseases which help reduce the excessive, unnecessary, or improper use of pesticides, which can harm public health and the environment. The dataset consists of hundreds of samples collected from stone fruit farms in the north of Jordan under normal field conditions. The image features were extracted using a CNN algorithm that was pre-trained with millions of images, and the diseases were identified using three machine learning classification algorithms: (1) K-nearest neighbour (KNN); (2) Stochastic Gradient Descent (SGD); and (3) Random Forests (RF). The resulting models were evaluated using 10-fold cross-validation, with CNN-KNN achieving the best AUC performance with a score of 98.5%. On the other hand, the CNN-SGD model performed best in Classification Accuracy (CA) with a score of 93.7%. The results shown in the Confusion Matrix, ROC, Lift, and Calibration curves also confirmed the validity and robustness of the constructed models.

**Keywords**—Deep Learning; Machine Learning; Classification; Plant Diseases; Disease Diagnosis

## I. INTRODUCTION

In Jordan and other Mediterranean countries, agriculture participates with a high share of the annual GDP, and stone fruit trees are among the most important sources of crop yield [1]. However, Bacterial and Fungal diseases, which appear as shot holes in the leaves, may affect the yield of the trees and may eventually cause damage to the Chlorophyll synthesis process, which is crucial for plant growth and fruiting.

Shot hole disease is caused by several pathogens. The fungal shot hole, or the *Coryneum* blight, is caused by *Wilsonomyces carpophilus* (Lev.) [2]. This fungus is common in the Mediterranean region, but it also spreads in America, Australia, Africa, Asia, Oceania, and Europe [3]. It infects stone fruit trees of Prunus, mainly apricot, peach, nectarine, and cherry. However, the first three are the most commonly affected hosts [4], [5]. It damages twigs, buds, blossoms, fruits, and leaves. The damage is most noticeable on the leaves, however. The causal agent thrives in cool and moist conditions between summer and fall, mainly in early spring and anytime during wet

weather conditions [3], [6]. It develops rapidly under warmer temperatures [3] and overwinters on blossom buds, and cankers of branches [7]. The symptoms appear on the infected leaves as small, round reddish to purplish-brown specks with light green or yellow rings around them. Lesions can be circular to slightly ellipsoid; their tissues can become raised and scurfy and will tear along the lesion margins and may hang on at one attached point. It often dries up and falls away, giving the shot hole; as if someone fired a shotgun at the leaf [5].

As the disease spreads, more leaves get damaged until they fall. Significant infections can reduce photosynthesis, weaken the plant, and decrease the fruit yield eventually, which makes it a major concern for the stone fruit industry worldwide [8]. The other causal agent of the shot hole disease is the bacterium *Xanthomonas Arboricola* PV. *Pruni* (Xap) [9]. The symptoms of this bacterium are circular to irregular, water-soaked lesions on leaves. Later, lesions turn purple or brown. Usually, halos and cracks can be seen between the affected tissue and the surrounding healthy tissue. In the later stage, the infected tissue will be broken away under various natural forces, especially wind, and finally drop out, leaving a hole. Leaves with many holes or lesions will turn yellow or prematurely drop off [9]. It infects leaves, twigs, and fruits of the same stone fruit hosts of the *W. Carpophilus* fungus. The favourable conditions for the disease occurrence and spread are largely the same as the fungal shot hole, but it overwinters mainly in twig lesions (OEPP/EPPO, 2003). The disease is considered the most limiting factor to cherry Laurel production in landscapes and nursery production. Losses exceed 75% in the nursery due to this disease (unpublished data, J. Williams-Woodward). However, these diseases, which affect different parts of the trees and produce holes in leaves, are caused by different pathogens such as *Wilsonomyces Carpophilus* fungus and *Xanthomonas Arboricola* PV. *Pruni* bacteria. Sometimes it is difficult to differentiate the symptoms to identify the pathogen, even further, to identify if the symptoms are caused by a pathogen or insect feeding. This makes it difficult to specify suitable pesticides or implement a control plan to avoid damage to the trees.

Nonetheless, the infections caused by these diseases are difficult to identify and cure as they are usually confused with viral pest infections and with other soil and nutrition deficiencies. The accurate identification and diagnosis of these diseases infections through visual signs and symptoms may require deep knowledge and thorough experience, which is usually lacking in most ordinary farmers, and yet they may also

require laboratory tests and identification procedures, which are usually expensive to perform for most farmers. Yet, fighting these bacterial and fungal infections without a proper diagnosis may fail or may require using a wide spectrum of pesticides, placing additional financial costs which add to the short-term losses in the fruit yield and the long-term damages made to the trees, which may affect their lifespan. In addition, the use of pesticides may harm the trees and may also place concerns over food safety, which may cause several marketing challenges due to allowable limits imposed by food and drug administrations and may ultimately affect customer confidence. This all adds to other environmental concerns that are related to pesticide leaks into the soil and water and their short-term and long-term influence on wildlife.

Novice agriculturalists and farmers not knowing much about the disease may confuse the infections with other viral and pest diseases and deficiencies caused by factors related to soil, water, or other environmental conditions. They might also confuse these diseases with symptoms associated with other issues related to the incorrect use of pesticides and fertilisers. Therefore, the false identification and diagnosis of fungal and bacterial may waste farmers' time and effort in solving irrelevant issues. This in fact, lay additional financial pressure on farmers and may also cause other serious environmental and health-related issues, such as those related to the improper use of pesticides or unintentional insect feeding. Moreover, the spread of fungal and bacterial diseases in various environments may also contribute to the evolution of new races of causal agents with different symptoms, thus making them hard to diagnose under normal field conditions [6].

Machine learning techniques in general [10], and deep learning algorithms in particular such as convolutional neural networks [11], [12], [13] have recently witnessed impressive success in several scientific and commercial applications, particularly in the fields of computer vision, image recognition [14], [15], [16], and other classification applications [17], [18], [19]. One of the potential applications of machine learning is identifying and diagnosing plant diseases' infections [20], and their other related issues [21]. In this research, we have conducted an end-to-end empirical study that involves collecting, diagnosing, and identifying many stone fruit leaf samples that suffer from bacterial and fungal infections. The sample leaves have been photographed, categorised and then used to train and test three machine learning classifier models, which are created by combining convolutional neural networks with three classical machine learning algorithms: (1) K-nearest neighbour (KNN); (2) Stochastic Gradient Descent (SGD); and (3) Random Forests (RF). These algorithms were selected due to their reported success in image classification. All the constructed models will be evaluated using Classification Accuracy (CA), Area Under the Curve (AUC), Precision and F1 metrics, in addition, the Confusion Matrix, ROC, Lift and Calibration curves will also be used to confirm the validity and robustness of the created models.

The following four subsections are dedicated to investigating the related work and defining the research hypothesis, question, and aims. Section II provides details regarding the research methodology, materials and data collection, and an overview of the techniques applied and their performance metrics. Section III presents the results of model building and

evaluation which is followed by Section IV, which analyses the results obtained in this work in light of the research hypothesis, question, and objectives. It also compares the results with those reported by others. Section V provides a conclusion of the findings and comments of the result on the limitation of the study and highlights the contribution of this study. It also comments on the significance of the results and their potential applicability, as well as on the possible future work that is related to the study.

#### A. Related Work

In this subsection we investigate nine of the most popular related works and most cited studies that have been published in the last six years.

A study that was published in [22] reported 78% accuracy in classifying diseases that infect apple trees using the field-collected dataset, while [23] reported accuracy of 81% in classifying four grapes diseases using images that have been captured under field normal condition. On the other hand, [24] reported accuracy of 82% in classifying cucumber diseases using a research centner dataset, while [25] reported an accuracy of 83% in classifying disease that infects potato using images of their tubers which have been collected from potato fields. [26] reported yet another field-based study that involved classifying diseases that infect tea plants with an accuracy of 90%. [27] reported accuracy of 88% in classifying banana diseases using the plant village public dataset which is very close to the results reported by [28] which aimed at detecting and classifying diseases that infect tomato leaves and which also depended on using a public dataset that was downloaded from plant village. [29] reported an accuracy of 99% in classifying soybeans disease also using plant village public datasets. [30] also reported a 99% of classification accuracy using the plant village dataset, but this time for classifying twenty-six diseases that hit fourteen different crops. A recent study reported in [31] achieved classification accuracy of 96.63% using the ResNet-50 deep learning algorithm to predict 15 disease classes using 20,000 public dataset that is published by plant village. Another study published by [32] reported an accuracy of 96% using unsupervised learning. However, the study provides no details regarding the number of the samples in the dataset. Another study published in [33], reported an accuracy of 92.57% using YOLOv5 model for classifying 61 categories of plant diseases that hit ten different plant species. The dataset consisted of 36,258 images. A more recent study that used Multiple Linear Regression (MLP) reported 91% accuracy in identifying blister blight in tea plants[34], while another recent study reported the use of CNN algorithm to detect 13 different diseases achieved precision of 96.3% [35].

The analysis of the related work shows that most of the reported applied techniques scored a classification accuracy which ranged between 78% and 99%. It was noticed that the majority of the investigated works reported a classification accuracy above 90% depended on huge public datasets which involved thousands of images that have been captured in a controlled environment with a standardised camera type, images orientation, images resolution, images aspect ratio, lightning and sometimes the growth conditions of the plant itself. On the other hand, the studies that reported performance

of less than 90% depended on using a less number of images (a few hundred images) captured using ordinary cameras and for leaves of plants that were grown in field normal conditions. Furthermore, only few of the reviewed studies spent effort in diagnosing the plant diseases and investigating their cause and pathogens. Most of the other studies depended only on the disease's visual symptoms, which shade doubt on the validity of their findings. In addition, few of the surveyed studies commented on the utilisation and the practical use of their obtained results.

### B. Research Hypothesis

The research suggests that deep learning pre-trained algorithms can be used for the automatic identification of image features and then be classified using other machine learning classification algorithms to provide an accurate diagnosis of stone fruit fungal and bacterial diseases.

### C. Research Question

The research question seeks to answer the question: Can we build a successful machine learning model to diagnose stone fruit fungal and bacterial diseases?

### D. Research Aim

Creating a machine learning model for diagnosing stone fruit diseases will pave the way towards creating a generic deep learning-based model that can be embedded in a mobile phone application or a web service for the purpose of providing a fast, reliable, and cheap diagnosis of plant diseases, which helps to reduce the excessive, unnecessary, or improper use of pesticides in agriculture, which can be harmful to public health and the environment.

## II. MATERIALS AND METHODS

This section provides a brief description of the technology applied and the methodology implemented in order to automate and tackle the problem of stone fruit disease diagnosis in this research to tackle.

### A. Materials

The dataset consists of 500 sample images. 294 of the images belong to the Fungal class, while 106 images belong to the Bacterial class. 99 belong to the control healthy class. The dataset creation involved collecting and photographing hundreds of images of stone fruit that are infected with the bacterium *Xanthomonas arboricola* P.v. *Pruni* (*Xap*) and *Wilsonomyces Carpophilus* fungus.

The leaves were collected from various farms in the north of Jordan during the mid of August, which are located in a region with a moderate Mediterranean mountainous climate with an elevation between 630-950 Metres above sea level. The average temperature between April and September is 29.7 °C during the day and 17.2 °C, while the average humidity is 45% and the average pressure is 1008 mBar. The rain is very scarce during the data collection period. Fig 1 shows sample leaves that suffer from bacterial and fungal infections. The samples were collected and photographed in the field normal conditions.

The dataset has an equal number of images for each infection class. The stone fruit leaves were first collected and then photographed using a mobile phone camera with an 8M pixels resolution. The leaves were then examined by two domain experts who work as plant diseases experts and professors at al-Balqa applied University and Mutah University. The disease experts diagnosed the infection in each leaf and placed the leaves' images in their corresponding folders. The diagnosis of each leaf was then confirmed using plant disease literature and also by using the plant disease database sponsored by the European and Mediterranean Plant Protection Organisation (EPPO).

### B. Methods

The methods applied in this research involve performing three major steps: (1) The extraction of significant image features using deep learning convolutional neural networks VGG16 algorithms ; (2) the classification of images into Bacterial and Fungal classes using the KNN, SGD and RF machine learning algorithms; and (3) models evaluation based on 10-folds cross-validation and using confusion matrix, ROC, AUC, classification Accuracy and Precision metrics. Fig. 2 illustrates the three major steps in the proposed research methodology.

1) *Features Extraction*: The features in each image are extracted using the convolutional neural network VGG16 implementation that was pre-trained using 14 million images from the ImageNet database which correspond to 1000 labelled classes[36]. The algorithm was originally proposed by Simonyan and Zisserman to introduce several improvements to AlexNet which was developed earlier by google [37], [38].

The applied implementation was based on the Keras framework using Python and Caffe framework. Keras is a deep learning Python Library that focuses on simplifying deep learning model construction and visualising its using Tensor Flow, while Caffe is a deep learning framework that was developed by the BAIR AI research group at the University of California, Berkeley [39]. It enables constructing expressive, modularised and fast deep learning models [40], [41]

The constructed vectors for each image feature were then preprocessed, first by normalising the image features values within the interval between -1 and 1 and then, by removing the sparse features for each feature with missing values exceeding the ratio of 5%.

Deep learning is one of the most popular contemporary technology in machine learning that has recently witnessed unprecedented success in several applications, particularly in image and voice recognition. as it requires no or minimal feature engineering[11]. Deep learning is simply, a back propagation neural network algorithm that is based on creating a machine learning model using several layers, where each represents a level of abstraction[11].

Convolutional neural networks (CNN) are a class of deep learning algorithms that uses feed-forward neural networks to extract and learn image features using multiple layers[11], [42]. CNN has achieved success in several machine learning applications, particularly in image processing, recognition and classification. In convolutional neural networks, and each layer,

Fig. 1. Image samples that were collected and photographed in the field normal conditions for stone fruit leaves that suffer from fungal and bacterial infections.

the image dimensionality is reduced and its features are automatically identified, extracted, stored in vectors and then passed to a more specialised deeper layer which extracts even more features using its own "convolutions". A convolution does a job in terms of feature extraction that is analogous to light filters in optics[42], [43], [11]. Convolutional Neural Network (CNN) algorithms were used for extracting and analysing image features. The identified feature was then used for creating three machine learning classification models for identifying the stone fruit fungal and bacterial diseases using a dataset that consists of hundreds of images that have been captured for the infected leaves. Convolutions are used to learn the image features in a fashion analogous to filters, in each layer the dimensionality of the image is reduced using convolution and then fed into the lower layer [43]. The convolution at the top layer is used to filter, extract and learn the most generic features in the image and then pass them down toward the convolutions in the deeper layers that are used to filter, extract and learn the more specific features as illustrated in Fig. 2.

2) *Classification*: Machine learning (ML) concerns enabling computers to learn and improve from previous examples and prior experience using a wide spectrum of artificial intelligence techniques and algorithms[44], [45], [46]. Modern technology and recent advances in machine learning are the driving force behind what is called "The fourth industrial revolution."

Machine learning tries to mimic the ability of human beings and other intelligent species to learn and attain knowledge from prior experience and examples and then generalise and use this knowledge to respond to future situations and process unknown data. In machine learning classifiers, a model is built and then trained to predict the outcome or responses in a precooked dataset which is called "training data." The model is then validated by testing its ability to predict the unknown outcomes and responses in unknown datasets or situations, which is called "validation data."

Selecting the appropriate machine learning modelling technique is important and must take into consideration the nature of the dataset, study objectives, and the potential of the applied technique [46], [45], [47]. In this research, three algorithms have been applied to the targeted images and then evaluated to find the best machine learning algorithm that can be coupled with the deep learning convolutional neural networks VGG16 algorithm to diagnose the targeted leaves and classify their infection. The applied algorithms involve KNN, SGD, and RF. These algorithms will be introduced and discussed in detail in this section.

*K-Nearest Neighbours Algorithm (KNN)*: An instance-based learning technique that is used for classifying data samples by measuring their proximity to neighbouring data points that belong to a set of pre-labelled classes. This technique was first introduced by Evelyn Fix and JL Hodges, Jr. in their unpublished technical report while working at the USAF School of aviation [48]. KNN measures the Euclidean distance between predicted and training values belonging to a predefined class in a two-dimensional space using equation 1. The predicted classes for a point are determined based on a popularity vote regarding its distance from other neighbouring data points that belong to the neighbouring classes. KNN was used in several image classification applications that included classifying brain CT Scan [49] and recognising images of various objects [50]. In both applications, it achieved a classification accuracy of 80%.

$$\Delta(x_i, x_j) = \sqrt{\sum_{i=1}^n (|x_{in} - x_{jn}|)^2} \quad (1)$$

*Stochastic Gradient Descent (SGD)*: This algorithm classifies samples iteratively. In each iteration, the weights of the classification model are updated using equation 2.

Fig. 2. An illustration of the applied research methodology, where CNN is used for extracting images' features and that are then fed to KNN, SGD, and RF classification algorithms.

$$\omega_{t+1} = \omega_t - \gamma \frac{1}{n} \sum_{i=1}^n \nabla_{\omega} Q(z_i, \omega_t) \quad (2)$$

Where  $\gamma$  denotes the model gain and  $\omega$  denotes the model weights which have to be close to optimal.

The estimated value  $z$  is randomly selected given the weight  $w_t$  for each iteration  $t$ . This process helps to optimise the resulting value in each iteration provided that the selected values are based on the ground truth distribution. The convergence of the SGD model assumes a gradual decline in the value of model gain  $\gamma$  which must be neither too fast nor too slow. The optimal value for the convergence is achieved when  $\gamma_t$  is close to the value  $t^{-1}$  which causes a decline in the error rate at the same speed [51].

SGD has been successfully used in several image classification applications. These applications involved introducing some minor modifications to improve their performance by optimising their parameters and also by combining it with other machine learning techniques such as Artificial Neural Networks (ANN) [52], [53], [54].

**Random Forests (RF):** A non-parametric, powerful machine learning technique that is used for both regression and classification [55]. The random Forests model consists of a number of regression trees that are built concurrently and then voted on selecting the best-performing model [56].

Random Forests was reported successful for image classification in several applications, which covers a wide spectrum of image processing domains [57], [58], [55]. This makes Random forests a good candidate for classifying stone fruit diseases in this study.

**3) Model Evaluation:** Cross-validation is the most widely accepted technique for evaluating the performance of machine learning classifiers [59], [60]. In this method, samples are split into several equal-size folds, and then the validation process is carried out considering one fold for testing the classification model each time, while the rest are used for training the classification model. The model validation is then repeated several times, which is equal to the number of folds. At the end of the validation process, the performance of the model is calculated by averaging the model performance for each fold.

The confusion matrix is a common evaluation method that is used to measure the performance of a machine learning model across classes. The confusion matrix is drawn in a tabular form that shows the numbers or percentage of the classified samples as illustrated in Fig. 3. It shows four types of information: (A) True positive values, which refer are the number of samples that were predicted positive and are indeed positive; (B) False-positive, which refers to the number of samples that are predicted positively by the model but they are in fact negative; (C) False-negative which refers to the number of samples that are predicted negative, but they are in fact positive, and (D) True negative which refers to the number of samples that are predicted negative and they are indeed negative.

In addition to the Classification Accuracy (CA), four other performance measures were used for evaluating the classification model: (1) Area Under the Curve (AUC); (2) F1; and (4) Precision. The confusion matrix, Receiver Operating Characteristic (ROC), Lift, and Calibration curves were also used to confirm the validity and robustness of the models performance. The ROC curve maps the false positive rate to the true positive rate of the class prediction. This curve is widely accepted as an excellent and accurate metric of the machine learning model's performance [61], [62]. In the ROC curve, the

Fig. 3. An illustration of the confusion matrix. Rows show the predicted classes, while columns show the actual classes

further is a line drawn from the middle of the chart (diagonal), indicating a better performance achieved by the model. The ROC curve is also used as a basis for calculating the AUC performance metric, which is simply defined as the Area Under the ROC curve (AUC). The larger the area is, the better performance is achieved by the model [63]. The calibration curve measure the model’s performance in predicting true positive values versus false positive values, while the Lift chart measure the model’s performance in predicting positive values [64].

Classification Accuracy (CA) is one of the most commonly used performance metrics in machine learning [65]. It is used to evaluate the model’s performance in predicting the learned classes by calculating the ratio between the number of the correctly classified samples compared to the total samples, which are expressed equation 3.

$$CA = \frac{(TP + TN)}{Total} \quad (3)$$

The precision metric is also another common measure that is used for evaluating the classification model’s performance by calculating the ratio between the number of true positive values and the total number of both true positive and false positive values [65], which is expressed by equation 4.

$$Precision = \frac{TP}{(TP + FP)} \quad (4)$$

### III. RESULTS

The results obtained in this empirical study involved creating and evaluating three machine learning models using KNN, SGD, and RF algorithms. Each of these models has been created based on the feature vectors that have been extracted using the pre-trained deep learning convolutional neural networks VGG16 algorithm and using images that have been captured for stone fruit leaves that are infected with bacterial and fungal diseases.

In the first phase, the features in each image were by submitting the captured images using Keras API to a remote VGG16 algorithm implementation that is pre-trained using millions of images from the ImageNet database. Fig. 4 shows a set of images that have been generated by the VGG16 algorithm, for example, a leaf using the algorithm convolutions, pooling, and normalisation procedures. The image is a sample

of the images that are generated by each convolution in the model layers. The image was first converted into a grey-scale and was then passed to the VGG16 layers. The extracted features were stored in vectors that contain the most important descriptors for each image and saved on the local machine. The image features in the vectors were then loaded into the classifier models.

Fig. 4. Filtered image features of a leaf that suffers from fungal infection.

In the second phase, three classification models were constructed using the features extracted in the first phase. The first model was constructed using the KNN algorithm and then trained using the training dataset to predict the image classification into the two pre-labelled classes. The second model was constructed using the SGD algorithm, while the third was built using the RF algorithm.

In the third phase, the models constructed in the second phase were trained using the image dataset that was described earlier in Section II-A, which consisted of tens of images of leaves that suffer bacterial and fungal disease infections. In the fourth stage, the models were then evaluated using 10-fold cross-validation. The evaluation of each model involved measuring the performance of the classifier using: (1) Classification Accuracy; (2) Precision test; and (3) Area Under the Curve (AUC). In addition, a confusion matrix was constructed

to validate the performance of each model that was visualised using the ROC, Lift and Calibration curves [66].

The confusion matrix for the three constructed models is shown in Table IV, II, and III. The values on the diagonal of the table –highlighted with dark shadow– represent the image samples that have been correctly classified in each class, while the values to the left and the right of the table diagonal highlighted with bright shadow–, represent those images that have been wrongly classified. The values in the rows represent the actual values that, in fact, belong to the corresponding class, while the values in the columns show the values that are predicted to belong to the corresponding class.

The evaluation of the classifier models has shown good performance based on the results of the confusion matrix, ROC, Lift and calibration curves, in addition to classification accuracy and sensitivity metrics. All the applied techniques have scored more than 87.4% in classification accuracy and precision performance metrics and more than 93.9% in the AUC metric, which is an even more efficient metric for evaluating the performance of the classifiers.

The CNN-KNN outperformed the other two models in the AUC metric. It scored 98.5% in AUC, while the CNN-SGD and CNN-RF models scored 95.4% and 93.9%, respectively. On the other hand, the CNN-SGD achieved the highest score in the classification accuracy metric, which was 93.6%. In contrast, the CNN-KNN and CNN-RF models scored classification accuracy of 92.4% and 87.4%, respectively. The results of the precision and F1 support the model's scores in classification accuracy. The CNN-SGD model scored 93.7% in F1 and 94.% in Precision metrics. The CNN-KNN model scored an F1 of 92.3% and a Precision of 92.3%, while the CNN-RF scored 85.9% and 88% in F1 and Precision metrics. In the AUC metric, the CNN-KNN model scored an even higher result, just over 95.6%, while the CNN-SGD scored 89.4%. The CNN-RF model scored 88.3%. Table I compares the performance of the three models in the applied metrics.

TABLE I. A COMPARISON OF THE PERFORMANCE OF THE THREE CREATED CLASSIFICATION MODELS: CNN-KNN, CNN-SGD AND CNN-RF BASED ON AUC, ACCURACY AND PRECISION METRICS

	AUC	CA	F1	Precision
<b>CNN-KNN</b>	98.5%	92.4%	92.3%	92.3%
<b>CNN-SGD</b>	95.4%	93.6%	93.7%	94.1%
<b>CNN-RF</b>	93.9%	87.4%	85.9%	88.0%

TABLE II. THE CONFUSION MATRIX FOR THE CNN-KNN MODEL

		Predicted			Total
		Bacterial	Fungal	Healthy	
Actual	Bacterial	<b>84</b>	22	0	106
	Fungal	15	<b>279</b>	1	295
	Healthy	0	0	<b>99</b>	99
Total		99	301	100	500

The performance curves of the ROC charts also confirmed the accuracy and precision of the metric result. It showed that the CNN-KNN model by far outperformed both the SGD and RF models. These results were also apparent in predicting the fungal class and, to a lesser extent, in predicting the bacterial class. However, while the CNN-SGD model performed relatively well according to the ROC chart, the performance of

TABLE III. THE CONFUSION MATRIX FOR THE CNN-SGM MODEL

		Predicted			Total
		Bacterial	Fungal	Healthy	
Actual	Bacterial	<b>97</b>	8	1	106
	Fungal	23	<b>272</b>	0	295
	Healthy	0	0	<b>99</b>	99
Total		120	280	100	500

TABLE IV. THE CONFUSION MATRIX FOR THE CNN-RF MODEL

		Predicted			Total
		Bacterial	Fungal	Healthy	
Actual	Bacterial	<b>49</b>	57	0	106

	Healthy	0	0	<b>99</b>	99
Total		55	346	99	500

the RF model lagged. Fig. 5 illustrate the performance of the three constructed models using the ROC chart. Furthermore, a calibration curve was created for all the constructed models, which compares them in classifying true and false positive classes. The threshold of the P value was set to 0.50, which is shown in Fig. 6. The SGD classifier scored a rate of 91.5% and 10% in predicting true positive and 8.8% in predicting false positive samples. The KNN classifier scored 79.2% and 3.8% in predicting the true positive and false positive samples, respectively, while the Random Forests model scored 39.6% and 10% in predicting the true positive and false positive samples, respectively. These results, yet again, show that both the SGD and KNN significantly outperformed the Random Forest model. However, the SGD model achieved the best performance, particularly in predicting true positive values. The Lift curve in Fig. 7 shows the performance of the three classifiers in predicting the positive values (Positive rate). Based on the Lift curve, the SGD model achieved the best performance, followed by the KNN and SGD models.

The champion two models were constructed by combining the pre-trained convolutional network algorithm VGG16 with the KNN and SGD algorithms. The CNN-KNN model scored 98.5% in the AUC metric, while the CNN-SGD scored a classification accuracy of 93.6%. However, the AUC metric is considered by many data mining practitioners as the best performance metric for evaluating machine learning models [63].

#### IV. DISCUSSION

This research involved collecting and photographing hundreds of leaves from stone fruit trees that are grown in the north of Jordan that suffer from bacterial and fungal diseases. The leaves were photographed and then classified based on their identified infections. The images were then fed into a deep learning convolutional network neural network algorithm that was used to identify the significant features involved in each of them. The resulting features were then used as input for three machine learning algorithms that have been used for classifying the leaves' images according to their infected diseases. The constructed models were then trained, and their performances were measured and evaluated based on a 10-fold cross validation.

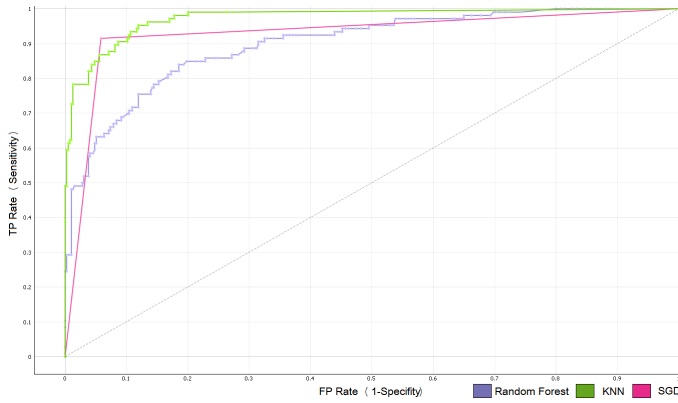

Fig. 5. An ROC chart that compares the performance of the three created classification models.

Fig. 6. A Calibration curve showing the performance of the three created classification models in predicting true positive and false positive classes

Fig. 7. A Lift curve showing the performance of the three created classification models in terms of the relationship between lift and the classification positive rate

The results confirmed the research hypothesis, which suggested that pre-trained deep learning algorithms can provide an efficient method for diagnosing stone fruit fungal and bacterial diseases by identifying image features and then using them in classifying the diseases' images using machine learning classification algorithms.

The results also provides a positive answer to the research question by creating classification models that were able to

diagnose the stone fruit fungal and bacterial infections with an accuracy performance of 93.6% using the CNN-SGD model and an AUC performance of 98.5% using the CNN-KNN model.

The study was successful in achieving the preset research objectives, which aimed at creating a computational model that would help create an automated prediction model that can be embedded in a mobile phone application or a web service to provide a fast, cheap, and reliable diagnosis of fungal and bacterial infections through photographing the visual symptoms that on plant leaves using standard mobile cameras and under the field's normal conditions. The findings of the research confirm the validity of our proposed approach to achieve the research objectives through combining CNN algorithm for feature extraction with three classical machine learning classifiers: KNN, SGD and Random Forest.

The performance of the classification model created in this study was above the average performance of other models that have been reported in similar and previous studies, particularly when compared to other studies that involved collecting, photographing, and analysing hundreds of plant leaf images under normal field conditions [22], [23], [25], [26], [27]. However, other studies that used public datasets with controlled conditions and larger dataset achieved better results as reported in [29], [30], [31], [32], [35].

The CNN-KNN model outperformed both CNN-SGD and CNN-RF in the AUC metric, as it scored a performance of 98.5%, while they scored an AUC performance of 95.4% and 93.9%, respectively. On the other hand, the CNN-SGD model outperformed the other two models based on the classification accuracy metric as its scored performance of 93.6%. The CNN-KNN and CNN-RF models scored a classification accuracy of 92.8% and 87.4%, respectively. However, most of the other studies that reported better results used thousands of images from public benchmark datasets that were acquired under controlled environments and conditions. In contrast, our study did not suffer some of the problems that are related to the degradation of model performance when leaves were taken on a different background, as reported in [30].

The models created in the present study is quite rigorous, even when images were taken in different aspect ratios and at different orientations. In addition, most of the studies that we have referred to in the related work section lack consideration for the prospect of the acquired knowledge and for the practical deployment and realisation of the generated model, which was considered from the beginning and to the end of this study.

## V. CONCLUSION

In this research, the power of deep learning in feature extraction and detection was combined with the classification power of three machine learning algorithms: KNN, SGD, and RF, for analysing leaf infections visually using image recognition and classification technology.

The study concerned conducting end-to-end empirical research, which involved collecting hundreds of stone fruit leaf samples from fields that suffer from bacterial and fungal infections. The samples were collected and then photographed from farms in various locations in the north of Jordan. The

bacterial and fungal infections were diagnosed and identified by two experts in plant diseases and confirmed using literature and using the European and Mediterranean Plant Protection Organisation (EPPO) database repository, which covers 1,700 pests and 88,000 plant species.

The results confirm the applicability and validity of combining the deep learning CNN algorithm with other machine learning classification algorithms for identifying and diagnosing plant bacterial and fungal diseases based on their visual signs and symptoms. The CNN-KNN model outperformed both the CNN-SGD and CNN-RF models based on the AUC metric and ROC curve, as it scored a performance of 98.5% in AUC. On the other hand, the CNN-SGD model's performance was the best in the classification accuracy metric, scoring 93.6%. The CNN-KNN model scored 92.4%, while the CNN-RF model scored 87.4%. Nevertheless, the limitations of this study come from its specialisation in one crop rather than others, as well as in its limited coverage of bacterial and fungal infections rather than other diseases and deficiencies. Nevertheless, this limitation was noticed in most of the previous works, including those that used public and field datasets. Expanding the research to cover more plants and more diseases would provide a more comprehensive image of other crops and other diseases.

The future work of this research may involve conducting further research to cover a wider range of crops and diseases under the field's normal conditions and using thousands of images. It may also involve using more deep learning methods and machine learning algorithms to achieve better results. In addition, constructing a data repository for all the diagnosed diseases would also help in enhancing the accuracy of future models by providing more images for model training and testing.

Furthermore, the success of these applications can be utilised in deploying machine learning classification models that can be embedded in a mobile application that can provide fast, cheap, and reliable identification of plant diseases or can be integrated into a web-based service that can help farmers across the globe to diagnose their plant's diseases by photographing the leaf infections in their crops using their mobile phones and upload the images to the web service.

#### ACKNOWLEDGEMENT

We would like to thank Mr. Abu Hmiadan and other anonymous farmers who facilitated the collection of samples.

# Enhancing Collaborative Interaction with the Augmentation of Sign Language for the Vocally Challenged

Sukruth G L, Dr. Vijaya Kumar B P, Tejas M R, Rithvik K, Trisha Ann Tharakan  
Department of Information Science and Engineering, M S Ramaiah Institute of Technology  
Bangalore, Karnataka, India

**Abstract**—As per Census 2011, in India, there were 26.8 million differently abled people, out of which more than 25% of the people faced difficulty in vocal communication. They use Indian Sign Language (ISL) to communicate with others. The proposed solution is developing a sensor-based Hand Gesture Recognition (HGR) wearable device capable of translating and conveying messages from the vocally challenged community. The proposed method involves designing the hand glove by integrating flex and Inertial Measurement Unit (IMU) sensors within the HGR wearable device, wherein the hand and finger movements are captured as gestures. They are mapped to the ISL dictionary using machine learning techniques that learn the spatio-temporal variations in the gestures for classification. The novelty of the work is to enhance the capacity of HGR by extracting the spatio-temporal variations of the individual's gestures and adapt it to their dynamics with aging and context factors by proposing Dynamic Spatio-temporal Warping (DSTW) technique along with long short term memory based learning model. Using the sequence of identified gestures along with their ISL mapping, grammatically correct sentences are constructed using transformer-based Natural Language Processing (NLP) models. Later, the sentences are conveyed to the user through a suitable communicable media, such as, text-to-voice, text-image, etc. Implementation of the proposed HGR device along with the Bidirectional Long-Short Memory (BiLSTM) and DSTW techniques is carried out to evaluate the performance with respect to accuracy, precision and reliability for gesture recognition. Experiments were carried out to capture the varied gestures and their recognition, and an accuracy of 98.91% was observed.

**Keywords**—*Hand Gesture Recognition (HGR); wearable sensors; Long-Short Term Memory (LSTM); Natural Language Processing (NLP); Dynamic Spatio-Temporal Warping (DSTW); Indian Sign Language (ISL)*

## I. INTRODUCTION

The need for communication stems from our natural desire to express ourselves. In a world that is becoming more inclusive, no one should feel left behind. The differently-abled community has been struggling historically to assimilate with the society. There exist natural communication barriers between the differently abled and abled people. This is because, the differently abled community, generally the vocally challenged community, uses sign language to communicate with others. Around 99% of the world do not understand sign language [1]. This creates a massive communication gap between the people in such communities who only use sign language for communication and those who do not understand sign language. The traditional solution for this has been to use an interpreter, who specializes in both sign language and

spoken language. With the advent of technology, especially in the fields of artificial intelligence and machine learning, a hand gesture recognition system for sign language can be developed which can replace the interpreter, making the people of the differently abled people independent.

Sign languages (also known as signed languages) are languages that use the visual-manual modality to convey meaning. In India, the primary sign language used is the Indian Sign Language (ISL). ISL is used in the deaf and/or dumb community all over India.

ISL interpreters are an urgent requirement at institutes and places where communication between deaf and hearing people takes place, but India has around 300 certified interpreters, which is minuscule to the number of interpreters that are required [2]. The needs of the deaf and/or dumb community have long been ignored, and the problems have been documented by various organizations working for them. The aim is to bridge this gap with the help of a sign language interpreter by using HGR.

This paper proposes the use of sensor-based gesture recognition where sensors are placed on each finger and on the hand, through which the sensor data is collected based on the hand and finger movements. Such raw data is transformed to gesture data and classified using machine learning algorithms. The obtained results on classification of sequence of gestures is fed to the NLP models involving segmentation and grammar correction. Finally, the sentences are conveyed suitably through communicable media devices like speakers, displays, braille tablets, etc.

The remaining paper has been structured as follows. Section II discusses some related works done and the key points from different research papers. Section III elaborates on the proposed model for sign language gesture recognition. Section IV explains the implementation methodologies. Section V describes along with the inferences for the proposed model and results with respect to performance parameters. Section VI provides the concluding remarks and future scope.

## II. RELATED WORK

Some of the related works in the areas of hand gesture recognition and NLP related to differently abled communication are abstracted and discussed in the section.

Flex sensors are used to develop a HGR based system by capturing the finger movements by making use of the

Flex ADC values, voltage, resistance, and the ratio between the flex voltage and source voltage values. These inputs are then processed through a GRU and classification is done by implementing maximum a posteriori [3].

Another methodology wherein a yarn based stretchable sensor array (YSSAs) was made use of, which is based on the change in voltage as and when a gesture is being performed [4]. It is noticed here that the YSSAs, is not a commercially available product. The Flex or the IMU sensors are available commercially and at a low cost, which would provide ease of access to the materials of the data glove.

In a system of sensor-based HGR by making use of accelerators and gyroscopes, the most important part is the determination of the starting and stopping points whilst performing the continuous hand gesture and it was solved by implementing an LSTM model in [5]. Based on a many-to-many interface scheme, where output is produced by the LSTM at each time step, a collection of the output sequence is viewed as an output path.

To tackle long-distance dependencies, a frame stream density compression (FSDC) algorithm is introduced in [6] for detecting and reducing redundant similar frames. The traditional encoder is replaced in a neural machine translation (NMT) module with an improved architecture, which incorporates a temporal convolution (T-Conv) unit and a dynamic hierarchical bidirectional GRU (DH-BiGRU) unit sequentially.

It is often necessary in practical situations to attempt parsing an incorrect or incomplete input. Since there are no signs for articles (i.e., the, is, an, etc.) most sentences performed using ISL will be structurally and grammatically incorrect. To tackle this issue certain NLP solutions were explored, one of them was parsing incomplete sentences. A chart parser was used in [7] to try all possible parses on all possible inputs. The result is a parse forest for all the grammatically acceptable sentences that can be generated by the (non-necessarily deterministic) finite state automaton.

Recent work on Grammar Error Correction (GEC) has highlighted the importance of language modeling to improve the performance and also compared the probabilities of the proposed edits. The approach in [8] involves using Google's BERT and OpenAI's Generative Pre-Trained Transformer (GPT) and GPT-2. Using simple heuristics, the language model generates a score such that it reduces the error and confusion set of sentences.

A more efficient algorithm using the distant measurement scheme of Dynamic Time Warping (DTW) and learning method of Restricted Coulomb Energy (RCE) neural network is proposed in [9]. A test platform is constructed using an IMU sensor to verify that real-time learning and recognition was possible using the proposed algorithm. DTW-based acknowledgment calculations have shown great execution for HGR.

Inferencing from the above literature review, using sensors and a hand glove design is provided with a sensor-based data collection system to capture finger and hand movements, a gesture classification unit along with dynamic spatio-temporal warping (DSTW) algorithm, grammar correction unit and a text to communicable media unit.

The data collected from the glove is in the form of time-series data, which is a type of Sequential Data. Sequential neural networks are designed to classify sequential data. Recurrent neural networks have the vanishing and exploding gradient problems, which is handled by LSTM by introducing cell state to decide what information to retain and forget long term. BiLSTM is used because it has shown better accuracy than LSTM models.

### III. PROPOSED MODEL

In this work, the novelty involves in designing a suitable sensor-based glove that consists of flex and IMU sensors to collect the hand and finger movements as signs and gestures. Here, the glove is calibrated for different dynamics of hand and finger movements collected as time-series data. Such time-series data is analyzed for spatio-temporal variations using machine learning algorithms that use neuro-computing models. The different spatio-temporal variations are mapped to the respective gestures taken from ISL dictionary [10]. However, to capture similar gestures performed by individuals that vary w.r.t time and space, the dynamic spatio-temporal warping technique is adopted. To improve the accuracy and generalization, different gestures with time and space variations with continuous learning for classification and repeated mapping to the ISL dictionary can be performed to avoid over-fitting and under-fitting. From the trained model, a given series of gestures is converted to a meaningful sentence using a transformer-based Natural Language Processing (NLP) model. Such sentences can be converted into the text/speech or any other media that an abled human can understand.

Here, the learning methods include feed forward neural network model with memory-based learning integrated with DSTW as similarity metric along with a BiLSTM neural network model with Online Learning. Gestures belonging to the same category which are partially and semantically similar can be classified accurately even if there are time and space variations in any given gesture, as the experience increases with learning. The basic idea of training using memory-based learning is that it classifies the different gestures and also their similarities with the previously seen gesture data.

The ability of the proposed system is to compute and abstract the spatio-temporal variations in the data items derived from hand and finger movements, as time-series data items and their correlations using feed-forward neuro-computing models.

In time-series data analysis, dynamic spatio-temporal warping is an algorithm for measuring similarity between two temporal sequences, which may vary in time and space. For instance, similarities in walking could be detected using DSTW, even if one person is walking faster than the other, or if there is acceleration and/or deceleration during the course of an action. DSTW is illustrated in Section IVB with mathematical formulation.

The complete proposed model and its functional modules is shown in Fig. 1. The sensors data corresponding to a gesture taken from ISL video dictionary [10], is collected from the hand glove and it is pre-processed to extract time and spatial features for its respective meaning. Such mapping is continuously fed into neuro-computing learning modules until the gesture meanings are mapped correspondingly. However,

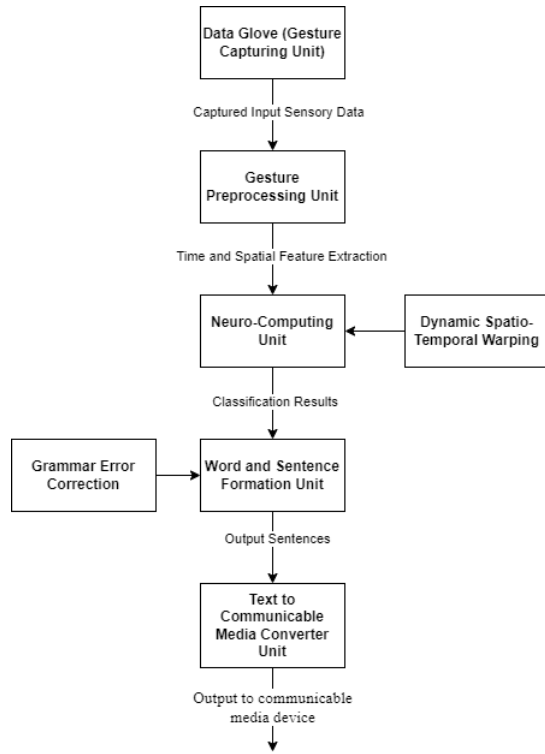

Fig. 1. Functional modules of the proposed hand gesture recognition (HGR) system.

the speed and area of occupancy in performing the same gestures by different individuals will vary, hence, DSTW algorithm is integrated to classify and map the meaning to the ISL dictionary. The sequence of gestures performed are integrated to generate meanings by using transformer-based NLP model with grammar correction to obtain a grammatically correct sentence. Such generated sentences are converted into communicable media by using text-to-speech, text-to-images, etc. as per the user's requirement.

#### A. Moving Average Smoothing

The captured data for the performed gestures will be in the form of time-series data and is bound to be noisy. To eliminate the fine-grained fluctuation between time steps, smoothing is used over the time-series data. Here, the smoothing is intended to reduce noise and thus clearly reveal the signal of underlying causal processes. For time-series data, moving averages are a straightforward and widely used method of smoothing. Moving Average Smoothing, represented in Fig. 2, involves creating a new time-series where the values are the average of raw observations in the original time-series.

A window size, referred to as the window width, is necessary when using a moving average. This specifies how many unprocessed observations were utilized to determine the moving average value. In order to calculate the average values in the new series, the window defined by the window width is moved along the time-series, hence giving the name "moving average".

After the noise has been removed through the moving

average smoothing process, the time and spatial features (i.e. the bend angle of flex sensors and the Roll, Pitch and Yaw of the IMU Sensor) is fed to the neuro-computing unit, wherein the preprocessed data is fed to various machine learning and neural network models for the classification of the gestures performed.

#### B. Dynamic Spatio-Temporal Warping (DSTW)

This subsection discusses the dynamic spatio-temporal warping algorithm used for comparing the ISL gesture data collected through the glove, consisting of flex and IMU sensors placed suitably to abstract the clear movement of fingers and hand.

DSTW uses time and space variations as that of time in DTW [11], [12]. The DSTW algorithm and how it can be applied to handle time and space variations of two similar gestures and their analysis is explained below.

Considering two data sequences belonging to gestures  $S$  and  $T$  of varying time lengths  $N$  and  $M$  samples, which are sampled at the same rate (i.e. the time taken to perform the two gestures  $S$  and  $T$  may not be the same). Let:

$$S = (S_1, S_2, \dots, S_N) \text{ and } T = (T_1, T_2, \dots, T_M) \quad (1)$$

be the measured values at the sampling times  $t_1, t_2, \dots, t_N$  &  $t_1, t_2, \dots, t_M$  for  $S$  and  $T$ , respectively.

In order to find the similarities between the two sequences, a cost matrix  $C$  of  $N \times M$  dimension is defined and is formulated using the following equations:

$$C(0, 0) = 0 \quad (2)$$

$$C(i, 0) = \infty \quad \forall i \in [1, N] \quad (3)$$

$$C(0, j) = \infty \quad \forall j \in [1, M] \quad (4)$$

$$C(i, j) = |S_i - T_j| + \min(C(i-1, j), C(i, j-1), C(i-1, j-1)) \quad \forall i \in [1, N] \text{ and } j \in [1, M] \quad (5)$$

With this cost matrix, the goal is to find the optimal path, which has the minimal overall cost that leads to gestures  $S$  and  $T$  having similarities to the maximum extent as compared to dissimilar gestures, as per the gestures given in the ISL video dictionary.

In order to have accuracy in the similarity measure is to follow certain necessary conditions i.e. to find the optimal path by traversing the minimum value in the cost matrix involving the time series gesture data formulated in eq. (5) are: (i) To travel the cost matrix from top left corner to bottom right corner, (ii) the path should be incremental in steps, (iii) the path should move from one cell  $(i, j)$  at a time, either to the right  $(i+1, j)$  or bottom  $(i, j+1)$  or bottom-right  $(i+1, j+1)$  cell by choosing the cell with minimum of the costs  $C(i+1, j)$ ,  $C(i, j+1)$ ,  $C(i+1, j+1)$  respectively as represented by equations 8, 9, 10, respectively.

Here, the optimal path  $O$  with length  $L$  can be obtained by traversing the minimum value of the cost matrix, is as follows:

Fig. 2. Moving average implementation on gestures captured by data glove.

Fig. 3. Comparing two similar gestures of varying lengths with DSTW.

$$O = (O_1, \dots, O_l, \dots, O_L) \quad (6)$$

$$O_l = (i, j) \text{ for some } i \in [1, N] \text{ and } j \in [1, M] \quad (7)$$

$$O_1 = (1, 1) \text{ and } O_L = (N, M) \quad (8)$$

$$O_1 \leq O_2 \leq \dots \leq O_{L-1} \leq O_L \quad (9)$$

$$(O_{l+1} - O_l) \in (1, 0), (0, 1), (1, 1) \text{ for } l \in [1, L - 1] \quad (10)$$

The time series data discussed above and their respective mapping in space and time domain along with their sampled values is illustrated with examples below.

Two gestures of the same kind having different time and space variations can be compared using DSTW. Consider two gestures of the same kind,  $G = [1, 2, 3, 4, 5]$  and  $G' = [1, 1, 2, 2, 3, 3, 4, 4, 5, 5]$ . Both the gestures are the same but the first gesture is being performed twice as fast as the second one. The same is the case with space variations. Consider two gestures of the same kind  $G = [2, 2, 3, 3, 3]$  and  $G' = [3, 3, 4, 4, 4]$ . These gestures are varying with respect to space, which means the magnitude of the gestures being performed is different, but the gesture remains the same.

In order to handle the above situation, DSTW Algorithm 1 is proposed to integrate time and space for comparing the gestures carried out with different time durations to handle both the intra-sampling and inter-sampling variations. Comparison of two gestures using DSTW algorithm is shown in Fig. 3. The output of Algorithm 1 is the distance between the two gestures  $G$  and  $G'$ .

### C. BiLSTM Architecture

Similarly, the spatio-temporal variations with similarity principles are considered intrinsically in BiLSTM architecture and is explained below. BiLSTM architecture for classifying the gestures, as shown in Fig. 4, consists of two LSTM cells; forward LSTM and backward LSTM [13]. The forward LSTM processes the time-series gesture information from left to right and its hidden state  $\vec{h}$  can be shown as

$$\vec{h} = LSTM(x_t, \vec{h}_{t-1}) \quad (11)$$

where  $x_t$  is the time series gesture data point at time  $t$  and  $\vec{h}_i$  is the hidden state of the forward LSTM at time  $t = i$ .

The backward LSTM processes the time-series gesture information from right to left and its hidden state  $\overleftarrow{h}$  can be expressed as

$$\overleftarrow{h} = LSTM(x_t, \overleftarrow{h}_{t+1}) \quad (12)$$

where  $\overleftarrow{h}_i$  is the hidden state of the backward LSTM at time  $t = i$ .

Finally, the output of BiLSTM can be summarized by concatenating the forward and backward states as

$$h_t = [\vec{h}_t, \overleftarrow{h}_t] \quad (13)$$

Correlation of  $\vec{h}_t$  and  $\overleftarrow{h}_t$  at time  $t$  is performed to get better classification and feature extraction, since gestures will have spatio-temporal variations with redundant and varying features in different time spans.

In order to bring better accuracy of feature extraction in gestures, online learning is proposed. Online learning represented in Fig. 5 is done by performing the training process with one data point at a time. Fig. 5 shows the training process of the model where  $G_i$  is processed at time  $t = i$ . This approach is common when working with sequential data.

Once these gestures are classified and their meanings are mapped using ISL, then the obtained meanings are fed sequentially into the word and sentence formation unit with transformer-based NLP model to form grammatically correct sentences.

**Algorithm 1:** Dynamic Spatio-Temporal Warping

**Input:** Collected data for two gestures  $G = [g_1, \dots, g_N]$ , and  $G' = [g'_1, \dots, g'_M]$  as arrays of varying lengths  $N$  and  $M$   
**Output:** Similarity measure between  $G$  and  $G'$   
 $SpaceTimeGap \leftarrow matrix[0 \dots N, 0 \dots M]$   
for  $i \leftarrow 0$  to  $N$  do  
  for  $j \leftarrow 0$  to  $M$  do  
     $SpaceTimeGap[i, j] \leftarrow \infty$   
 $SpaceTimeGap[0, 0] \leftarrow 0$   
for  $i \leftarrow 1$  to  $N$  do  
  for  $j \leftarrow 1$  to  $M$  do  
     $cost \leftarrow distanceMeasure(g_i, g'_j)$   
     $SpaceTimeGap[i, j] \leftarrow cost + \min(SpaceTimeGap[i - 1, j], SpaceTimeGap[i, j - 1], SpaceTimeGap[i - 1, j - 1])$   
return  $SpaceTimeGap[N, M]$

IV. IMPLEMENTATION

Using the proposed model discussed in Section IV, a sensor-based HGR data glove was developed, is shown in Fig. 6 and its circuit diagram in Fig. 7, that is capable of capturing hand and finger movements.

The data glove was developed from scratch by making use of five 4.5” Flex Sensors, one for each finger and an MPU6050 GY-521 IMU sensor on the dorsal (back) side of the hand and an Arduino Mega 2560 microcontroller. The flex sensor is used to calculate the finger bend angle for each of the fingers and the IMU sensor is used to calculate the Euler Yaw, Pitch and Roll values. A second glove was developed in the same fashion to replicate the process and validate the feasibility of building of the glove. Both the gloves are shown in Fig. 6.

Fig. 6. Developed hand glove with embedded and sensing device to test the proposed model.

The raw data collected by the data glove is then processed by amplifying the signal and passed through low-pass filters to get rid of interferences and noises by using Moving Average Smoothing. It is then passed to the A/D converter of the microcontroller, capable of processing the time series data for machine learning algorithms to extract the features relating to the hand and finger movements carried out for the gestures intended by the users. This data is then processed through a neuro-computing system capable of classifying the gesture being performed in real time. The various hand gestures are mapped to their respective meanings and stored in a dictionary. These act as classes to create a labeled dataset for further training process.

Different gestures are considered for training the feed-forward neural network model integrated with DSTW and the BiLSTM model. For each gesture, 100 data frames were collected. After collecting the data, having taken 5 flex sensor angles shown in Fig. 8 captured at intervals of 20ms. A feed-forward neural network architecture is used with memory-based learning as the learning method to classify the gestures into their meanings. Dynamic spatio-temporal warping is used to compare time series data with spatial and temporal variations. The algorithm shows time complexity of  $O(m * n)$ . During the experimentation, numba python library for multi-processing was used to bring down the computation time from 1 hour to around 30 seconds. This resulted in increasing the

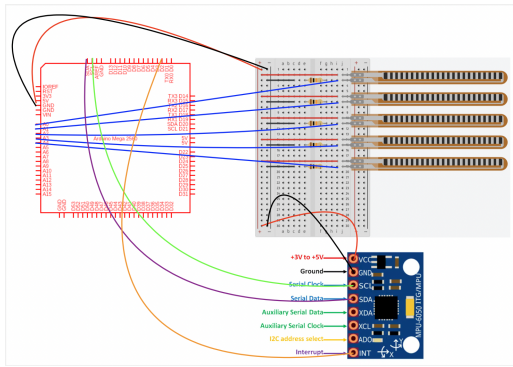

Fig. 7. Circuit diagram of the proposed HGR model.

TABLE I. GRAMMAR ERROR CORRECTION (GEC) OUTPUTS FOR SAMPLE INPUTS

Input	Restructured Sentence	GingerIt	Gramformer	Actual Sentence
Your phone number what	What your phone number	What's Your phone number	'What is your phone number?', 'What is Your phone number.'	'What is your number?'
I go theatre	I go theatre	I go theatre	'I go to the-atre.', 'I went to theatre'	I go to a the-atre

number of times the gestures were trained in a given period of time.

Once the gestures are classified, they act as the input to the NLP model that aims to determining the start and stop of a sentence and further segmentation is performed. They are then processed to correct the grammar and form meaningful sentences. DeepSegment [14], is a GloVe + BiLSTM Conditional Random Field (CRF) sequence model, to segment sentences with no punctuations. A trend was noticed in the ISL structure and grammar, where the interrogative sentences ended with the wh-pronoun, and the sentence was restructured by making use of the spaCy [15] library. However, the sentences were still incomplete, as there are no signs in ISL for articles. To combat this, grammar correcting libraries such as GingerIt [16], an LSTM based architecture, and Gramformer [17], a GPT-2 based model were used. Once this is done, the grammatically correct sentence then acts as an input to the text-to-speech generative algorithm which aims at conversion of the sentence to audio which can be played over a sound system / mobile device / speaker which helps the person at the receiving end understand what the user is trying to communicate. Table I illustrates the comparison between some of the grammar correction technologies like GingerIt and Gramformer. It was observed that Gramformer gave more accurate results with respect to grammar correction.

The data is fed into a BiLSTM model represented in Fig. 9 with 64 neurons in its input layer, which are BiLSTM in nature, another BiLSTM layer with 64 neurons as the hidden layer, and one neuron in the output layer, which gives us the class of the gesture. Adam Optimizer is used with Mean Square Error as the loss function.

The simulation of the collected Flex Sensor angles is shown

in Fig. 10. It represents the angles collected for 10 fingers on both hands using 10 graphs. To simulate the angle at which the finger is bent, two line segments are used having the same angle between them. One line segment is the line segment joining (0.0, 1.0) and (1.0, 1.0) and the other line segment is plotted using the Circle equation with center at (h, k),  $(x - h)^2 + (y - k)^2 = a^2$  for which the points on the circle are  $x = h + a \cos(\theta)$  and  $y = k + a \sin(\theta)$ . Therefore, for the circle with center at (1, 1) and radius  $a = 1$ , the circle equation becomes  $(x - 1)^2 + (y - 1)^2 = 1$  and for which the points on the circle becomes  $x = 1 + \cos(\theta)$  and  $y = 1 + \sin(\theta)$ . Since the angles being plotted are in the fourth quadrant,  $\theta = 360^\circ - \theta_f$  where  $\theta_f$  is the flex angle.

## V. RESULTS AND DISCUSSION

Performance of the model was carried for different gestures in Indian sign language involving hand and finger movements. Feed-forward neural network with memory-based learning integrated with Dynamic Spatio-temporal Warping and BiLSTM models were compared to classify the time series data collected from the data gloves. BiLSTM was found to have better performance during the experimentation. Transformer-based NLP model for grammar correction modules was found to work accurately for the contexts considered during the experimentation. Different performance parameters were considered in the experimentation, some of them are discussed below.

With the Feed forward neural network model integrated with DSTW, the data is split into train data - 70% and test data - 30% resulting in an accuracy of 96.74% as shown in Fig. 11.

With the BiLSTM model, the data is split into train data - 70% and test data - 30% resulting in an accuracy of 98.91% as shown in Fig. 12.

## VI. CONCLUSION

The development of wearable devices for sign language translation enhances the collaborative interaction with the augmentation of reality. In comparison to the vast number of existing technologies present to aid the deaf population, such specific wearable devices will be inexpensive and easy to use. Flex and IMU sensors calibrated and integrated by using hardware and software filters to collect accurate data of hand and finger movements with low amount of noise are proposed. Machine learning methodologies like Feed-forward neural network with memory-based learning and BiLSTM integrated with DSTW has enhanced the performance of gesture recognition as per the ISL video gestures. From the experimentation, BiLSTM model was found to have better performance with Feed-forward neural network with DSTW with accuracy of 98.91%. Multiprocessing features were used to improve the computation time during the classification. The gesture sequences with meanings used by NLP models for grammar correction were compared and it was found that transformer-based models outperformed other types of models and parsers. Obtained sentences were conveyed to the user through communicable media as per the user's requirement.

Gesture recognition devices can be used in multiple ways and in various fields of science, like in the medical field for

remote operations/surgeries using HGR, as well as during the recovery of the patients either through physical rehabilitation or physical therapy that can be done remotely with gesture recognition. In other examples it can be used in interacting with a computer through HGR, virtual and augmented reality applications using gesture recognition, gesture controlled IoT home appliances and much more.

### A. Future Scope

This proposed model can be built on and adapted to enable the communication between varied disabled communities, like a person from the deaf community and a person from the blind community. The placement of the sensors on the glove could be optimized to ensure that the data collected is representative of the hand gesture being performed. To make the glove more responsive and usable in real-world scenarios, the data processing and classification can be improved to work in real-time. The number of classes of gestures that the glove is able to recognize should include all the gestures in the ISL.

### ACKNOWLEDGMENT

The authors thank the Artificial Intelligence and Robotics Technology Park (ARTPARK) division of the Indian Institute of Science (IISc), Bangalore for providing resources and technical support. We also acknowledge the Information Science and Engineering department of M S Ramaiah Institute of Technology for their support.

**Abstract**— Current traditional shipping models are increasingly revealing many shortcomings and affecting the interests of sellers and buyers due to having to depend on trusted third parties. For example, the Cash-on-Delivery (CoD) model must depend on the carrier/shipper, or the Letter-of-Credit (LoC) model depends on the place of the Letter certification (i.e., bank). There have been many examples demonstrating the riskiness of the two models above. Specifically, in developing countries (e.g., Vietnam), the demand for exporting goods and trading between sellers and buyers have not yet applied the benefits of current technology to improve traditional shipping models. Two typical examples in the last five years that have demonstrated the risks of both sellers and buyers when applying CoD and LoC models are the problem of keeping the money of the seller of GNN Expresses (2017) as well as risks in losing control of 4 containers of cashew nuts when exporting from Vietnam to Italy (2021). A series of studies have proposed solutions based on distributed storage, blockchain, and smart contracts to solve the above problems. However, the role of the shipper has not been considered in some approaches or is not suitable for deployment in a developed country (i.e., Vietnam). In this paper, we propose a combination model between the traditional CoD model and blockchain technology, smart contracts, and NFT to solve the above problems. Specifically, our contribution includes four aspects: a) proposing a shipping model based on blockchain technology and smart contracts; b) proposing a model for storing package information based on Ethereum's NFT technology (i.e. ERC721); c) implementing the proposed model by designing smart contracts that support the creation and transfer of NFTs between sellers and buyers; d) deploy smart contracts on four EVM-enabled platforms including BNB Smart chain, Fantom, Celo, and Polygon to find a suitable platform for the proposed model.

## I. INTRODUCTION

Today, delivery from sellers and buyers is growing constantly where many traditional shipping models (e.g. Cash-on-delivery (CoD)[1], Letter-of-Credit (LoC) [2]) to transportation models applying advanced technologies (e.g. blockchain, RFID, smart contracts) [3]. The main purpose of these models is to shorten delivery and pickup times and make it possible for sellers and buyers to trace the location and expected time of delivery [4]. For developing countries (i.e. Vietnam), the current delivery and receipt process still applies the traditional delivery and receipt model. Specifically, with the steps of delivery and receipt of goods within a city or between cities,

the common model applied between sellers and buyers is CoD - the buyer will send money directly to the delivery party. The seller is responsible for shipping the item to the buyer through the shipping company (i.e. shippers). For cross-border transactions (i.e. between Vietnam and other countries - in the region or in the world), the commonly used model is LoC. All exchanges between the two parties are recorded and authenticated by a trusted third party (i.e. a bank).

However, both models have a lot of risks. With the LoC model, in case either party (i.e. exporter and importer) loses the original document (i.e. letter), the possibility of a loss of goods/money is very high. Because the seller only receives the full amount when the buyer receives the goods. For the CoD model, the seller must accept the risk of trusting and authorizing the shipping company (i.e. money, goods). Specifically, the number of goods that will be returned to the seller by the shipping company after a fixed period of time (e.g. monthly, quarterly) or a certain amount is reached. For this type of shipping, the risk for the seller is very high because the shipping companies can use their money for something other than sending the money back to the seller. Most of today's processing is based on an agreement between two parties (i.e. seller and carrier).

The application of traditional freight forwarding and payment models in Vietnam is facing a number of problems in the past five years. For the LoC model, in case one of the parties loses the original documents (i.e. letter), the possibility of losing goods/money is very high. A specific example happened in 2021 for the cashew nut export model from Vietnam to Italy. Specifically, four out of 100 containers of cashews exported from Vietnam to Italy are at risk of being lost because exporting companies in Vietnam cannot present original documents.<sup>1</sup> Fortunately this issue was resolved with the involvement of the State Department Vietnam and the Consulate General of Vietnam in Italy. For the traditional CoD model, an example of a seller being stolen by GNN Express occurred in Vietnam in 2017 and 2018.<sup>2</sup> Specifically, the entire amount of goods worth about \$154,900 was not transferred to the seller but was used by GNN Express for other purposes.

To solve the above problem, a series of models have proposed Blockchain technology and smart contracts to easily trace the origin of packages as well as reduce the risk from

<sup>1</sup><https://vietnamnet.vn/en/100-containers-of-cashew-nuts-exported-to-italy-suspected-of-being-scammed-821553.html>

<sup>2</sup><https://vir.com.vn/gnn-scandal-rocks-delivery-segment-62710.html>

untrusted parties. This model (i.e. in theory) can operate independently of a third party (i.e. no trusted third party required). However, if there is a conflict between the seller and the buyer, the arbitration must still be requested (i.e. the arbitrator receives a fee known as the conciliation fee). One of the popular examples of this pattern is Bitcoin[5], and Ethereum [6]. Specifically, all transactions will be routed through the seller/buyer's wallet address [7]. In addition, state-of-the-art has extended the above two models to solve the traditional freight problem (see the Related work section for more details). For research directions related to the transportation of goods for developing countries (i.e. Vietnam). There are not many in-depth approaches to ensure the transportation of traditional goods (i.e. see related work for more details).

In addition to the problems related to the implementation of a blockchain-based shipping system and smart contracts in Vietnam, the above method encounters some limitations when it ignores an important group of people who are shippers. Specifically, the role of this user group is ignored when shipping goods from the seller and the buyer. This can affect the arbitration process when there is any conflict between the seller, and buyer [8]. This has prompted several theoretical studies that combine the role of shippers using blockchain technology and smart contracts [9].

However, the above approaches still face a challenge when transporting packages between different shippers or shipping companies in Vietnam. In particular, packages can get damaged in transit - it's difficult to know who is responsible (i.e. seller, buyer, or carrier) as all interactions are done on paper and are not legally binding. Therefore, in this study, we aim to determine the package contents and related information when moving from seller to buyer. Specifically, we apply NFT technology to generate package-related information (i.e. sender, recipient, order content, weight, estimated delivery time, etc.). When the buyer receives the package, he can check the information sent from the seller. This technology is easy to deploy in developing countries because it does not require too high of a technology-based infrastructure to maintain the system. Some countries have implemented delivery models based on Blockchain, smart contracts, and NFT technologies.

Therefore, our contribution includes four aspects: a) proposing a shipping model based on blockchain technology and smart contracts applicable to the delivery environment in Vietnam; b) proposing a model for storing package information based on Ethereum's NFT technology (i.e. ERC721); c) implementing the proposed model by designing smart contracts that support the creation and transfer of NFTs between sellers and buyers; d) deploying smart contracts on four EVM-enabled platforms including BNB Smart chain, Fantom, Celo, and Polygon to find a suitable platform for the proposed model.<sup>3</sup>

The rest of the paper consists of seven parts. After the introduction is the related work section, which presents state-of-the-art with the same research problem. The next two sections present our approach and the proposed model implementation (i.e., Sections III, IV). To demonstrate our effectiveness, Section V presents our evaluation steps in different scenarios

<sup>3</sup>We do not implement smart contracts on ETH because the execution fee of smart contracts is too high.

before making comments in Section VI. The Section VII summarizes and outlines the next steps for development.

## II. RELATED WORK

This section presents approaches from traditional shipping (i.e. post office, third party - courier companies, and e-commerce platforms) to proposed theoretical models based on technology. Blockchain and smart contracts.

### A. Traditional Delivery Method

The demand for transporting goods is increasingly diverse (especially in developing countries). In this paper, we summarize the common approaches applied to Vietnam. In particular, the simplest approach is based on the postal system, which plays an important role in transporting goods. All information about the sender and receiver is done through a third party (i.e. bank employee)<sup>4</sup>. In the traditional model, shipping and delivery management is managed in a decentralized and centralized manner. Specifically, each city and province has a post office that acts as a receiving and transit point to sub-post offices in the districts (i.e. low-level). The post office in the district receives and sends the sender's item to a corresponding location on the package.

The benefits of this approach are low transportation costs and no need for smart devices/systems (i.e. smartphones, sensors). However, it also brings a lot of disadvantages i) it is difficult for users to get information about their packages; ii) long transit times; iii) if the recipient cannot be found, it will take time to send it back to the sender; iv) requires a large number of service workers due to lack of technology support (these risks are introduced in detail in the Introduction section).

In a more advanced approach, courier companies were born to ensure on-time delivery - with a higher fee. Specifically, courier companies will ensure delivery in the shortest time. A few popular courier companies in Vietnam include two groups: domestic courier companies: Viettel Post, Vietnam Post J&T Express<sup>5</sup> and has its headquarters abroad: Fedex<sup>6</sup>, ASL<sup>7</sup>, DHL<sup>8</sup>.

In addition, e-commerce platforms have also changed the shipping trend in Vietnam in the past 10 years [10]. Specifically, e-commerce platforms act as intermediaries to link sellers and buyers. In other words, they bridge the gap between the two - finding products required by buyers and finding potential user groups for sellers. For sellers, they put their products on e-commerce platforms instead of having to open a store in real life. Buyers also save time shopping and commuting. Famous e-commerce platforms in Vietnam today include Lazada<sup>9</sup>, Tiki<sup>10</sup>, SenDo<sup>11</sup>, Amazon<sup>12</sup>, and Shopee<sup>13</sup>. In

<sup>13</sup><https://shopee.vn/>

addition, the role of freight is guaranteed by shipping companies of a small size (i.e. between cities or within the same city). These people will be the ones who directly receive the money from the buyer and deliver it back to the seller (i.e. Cash-on-delivery). The disadvantage of this model is that the seller can lose money when the delivery company goes bankrupt. The closest example to this is GNN Express<sup>14</sup>. Specifically, the company GNN Express took money from the seller to make up for the company's loss. Currently, this company is bankrupt and unable to pay. Another example related to cross-border freight took place in early 2021 between Vietnam and Italy. An Italian company exploited vulnerabilities in the Letter-of-Credit delivery method to hijack four containers of cashews. While the above issues have been addressed, we clearly see undeniable flaws in traditional delivery models.

### B. Delivery Method based on Blockchain Technology

Previous approaches to deploying their proof-of-concept are mainly on the two platforms Hyperledger Fabric and Ethereum

1) *Ethereum*: The common point of these protocols is the use of ETH as the mainstream payment currency. For example, the Ethereum ecosystem has proposed localEthereum a method to facilitate transactions or DeFi Dapps between providers and claimants [7]. In addition, a new protocol that aims to help ship products from supplier to requester [11] has mined an ETH-based transaction to propose a COD/LOC mechanism. Similarly, OpenBazaar [12] is developed based on the extension of the Ethereum ecosystem, supporting sellers and buyers in the process of exchanging goods. Specifically, the transaction is identified based on the wallet address (i.e. transfers funds from the buyer's wallet address to the seller's wallet address) and is easily authenticated by the relevant parties without the need for a trusted third party. However, unlike localEthereum, OpenBazaar involves three parties: the provider, the requestor, and the moderator (that is, a new control role). Specifically, instead of just applying the entire transaction based on a default smart contract, OpenBazaar supports middleman (i.e. owner of smart contracts) to define corresponding policies and penalties to control the process. the process of transporting goods to determine the subject of compensation if an incident occurs. However, these systems suffer from a single point of failure problem - ignoring the role of the carrier. Specifically, the carrier will not be affected if there is any conflict between the seller and the buyer (i.e. purchase of poor quality goods, loss of the package) - even if it is the fault of the carrier's side [13].

2) *Hyperledger Fabric*: The common point between the approaches developed on the Hyperledger Fabric platform is to highlight the role of the carrier - the carrier is also responsible for the exchange of goods. Specifically, policies designed in the chain code (i.e. smart contracts) identify violations by all three groups of participants including seller, buyer, and person/shipping company[14]. For example, Son et al. [15] have proposed a baseline model of carriers, sellers, and buyers to replace the current CoD model. However, this approach requires no deposit constraints - conflicts are handled by a trusted third party (i.e. arbitration). To solve this problem, a

few (e.g. [16], [17]) have proposed a model that combines blockchain technology and smart contracts in shipping packages between sellers and buyers. In which, the violations of the parties involved are sanctioned with a fee deducted from the previous deposit. Specifically, [17] supports a variety of shippers - multiple shippers can be involved in the delivery instead of just one object/shipping company as [16] suggests. To accommodate transit times (i.e. not limited by geographical distance), Duong et al. [18] proposes a new approach based on multi-section. For the purpose of supporting payment on a variety of platforms - users can create an account at one e-commerce platform and make purchases at all other exchanges. In addition to solutions to support sellers and buyers in the process of exchanging goods, Son et al. [1] also proposes a cross-platform model connecting many different markets, where sellers and buyers are not limited by payment tools between e-commerce platforms. Ha et al. [19] has proposed a personal information protection model (i.e. seller and buyer) based on the access control model [20], [21]. Specifically, sensitive information such as addresses and phone numbers can only be accessed by those with [22] permissions. This solution greatly helps in protecting the personal information of the seller and the buyer because this information is always available on other electronic exchanges (even those that do not play a role in the corresponding transaction). For cross-border transactions, Khoi et al. [2] have proposed a mechanism for transporting goods between countries that are not dependent on a trusted third party (i.e. bank) called Letter-of-Credit. This approach strives for an open policy across countries (i.e. unconstrained by the policies of one country, geographic region [23], [24]).

However, all of the above approaches are still bound when transferring orders between shippers or between seller - shipper or shipper - buyer. In particular, the package may be damaged in transit and it is difficult to determine who is responsible for this damage. To solve this problem, we propose a shipping model based on a combination of some outstanding technologies today, such as blockchain, smart contracts, and NFT. The next section describes in detail the model and how to operate the system.

## III. LETTER-OF-CREDIT CHAIN ARCHITECTURE

### A. The Traditional Model of Freight Transport

In this section, we analyze the popular traditional freight model in Vietnam (i.e. CoD). Fig. 1 shows the six steps of shipping goods from the seller and the buyer. Specifically, the seller and the buyer discuss the price and form of payment. In Vietnam, this process is done based on social networking platforms (i.e. Facebook) or based on e-commerce platforms (i.e. sellers share product information and prices - buyers - buyers) product selection). The seller checks whether the product is in stock (step 2) before packing the product (step 3). In step 4, the seller chooses a reputable shipping company because the shipping company holds the customer's payment before returning it to them. Step 5 shows the process of shippers coming to pick up the goods from the seller and get the shipping address. Finally, the shippers ship the item to the buyer (step 6). The difficulties and risks of the traditional CoD model have been analyzed by us in the Introduction and Related work sections.

<sup>14</sup><https://vir.com.vn/gnn-scandal-rocks-delivery-segment-62710.html>

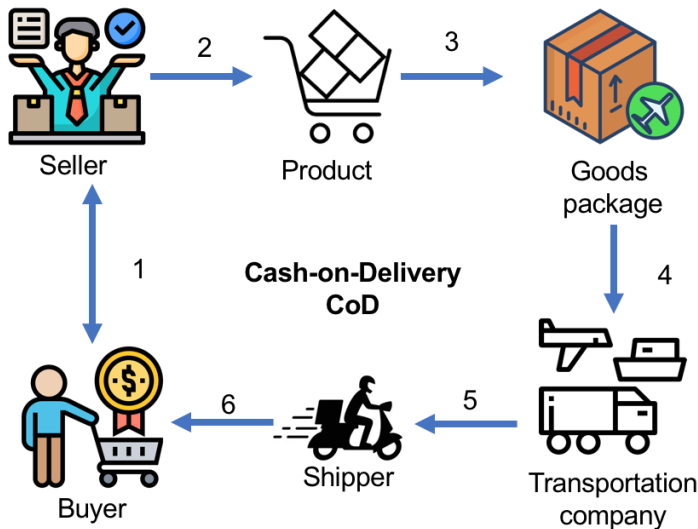

Fig. 1. The Traditional Model w.r.t cash-on-delivery of Freight Transport.

For the process of transporting goods between countries, we have an article that specifically analyzes the risks of the traditional model (i.e. LoC) and presents the blockchain-based approach and smart contracts in the process. [2]. In this section we focus on solving the problem of transporting goods within the territory of Vietnam (i.e. between cities or within the same city). Depending on the shipping distance, step 6 (i.e. Fig. 1) includes one or more shippers. The next section presents our proposal process based on a combination of Blockchain technology, smart contracts, and NFT.

#### B. Cargo Transport Model based on Blockchain Technology, Smart Contracts and NFT

Fig. 2 presents our proposed model based on blockchain technology, smart contracts, and NFT (i.e. consisting of nine steps). We assume that the seller and the buyer have agreed on the delivery method as well as the price for the product. In this section, we design the system to move goods from seller to buyer. Specifically, step 1 shows the seller to pack the product and prepare the necessary declaration information related to the package (i.e. weight, unit price, item type, etc. see Implement section) in step 2 ( i.e. based on system support services). These services call the respective functions in smart contracts to create a shipping contract (step 3). The seller selects the corresponding shipping company (step 4). Step 5 presents the deposit confirmation process for each participating group. In it, the seller still has to enter an amount of money to ensure delivery of the correct goods and of the right quality (i.e. if the seller intentionally violates the information provided in smart contracts - step 2 - this amount is used to compensation to the carrier and the buyer). For shippers, their management company must pay a guarantee fee to avoid the shipper losing the goods or in case the company goes bankrupt before the time to refund the buyer (i.e. the amount of money). Their deposit depends on the exchange between the seller and the shipping company). In the event of a conflict (i.e. shippers lose or damage goods or the shipping company goes bankrupt) smart contracts automatically transfer the company's deposit to the seller via their address. The

buyer's deposit includes the shipping fee and part of the deposit of the product (i.e. depending on the agreement between the seller and the buyer). In case the buyer refuses to purchase the product, the shipping fee and deposit of the product are automatically transferred to the address of the shipping company and the seller, respectively. The above conventions are monitored through protocols designed on smart contracts and stored on NFTs with the consent of all three parties (i.e. seller, buyer, and shipping company) - step 6. Step 7 presents the shipping process between shippers (i.e. depending on the distance the number of shippers is 1 person or many). This process is managed and operated by shipping companies. Step 8 presents the final shipment (i.e. the buyer receives the item) - confirmation from the buyer that the package is correct and that the information is stored in the NFT. The transactions are conducted specifically, the buyer pays the remaining amount of the product; the shipping company receives the deposit and shipping; The seller receives the money for the sale of the product. Risks and breaches of contract are resolved based on the cases designed in step 5. Finally, smart contracts update transactions to the distributed ledger and prepare for a new shipping process.

#### IV. IMPLEMENTATION

Our reality model focuses on two main purposes i) data manipulation (i.e. package) - initialization, query and update - on blockchain platform and ii) generation of NFT for each order for easy traceability by sellers and buyers (i.e. product reviews before and after delivery).

##### A. Initialize Data / NFT

Fig. 3 shows the data row startup step packages. These package types include information related to the sender (i.e. receiving address, weight, type of item), and the recipient (i.e. receiving address, expected delivery time). In addition, the exchange and receipt of goods require an account deposit of all three parties depending on the purpose and transaction between the parties to ensure automatic conflict resolution on smart contracts. . In addition, information about which carrier belongs to which company, time, and place of delivery and collection is also added to the package's metadata. This is extremely important in cases where more than one shipper is involved in the transportation of household goods (i.e. the same or different shipping company). For storage, services support concurrent storage (i.e. processing partitions as a peer-to-peer network) on a distributed ledger - Supports more than one user for concurrent storage, the speed drop of the whole system. In general, the package data is organized as follows:<sup>15</sup>

```
goodsObject = {  
  "goodsID": goodsID,  
  "deliveryCompanyID": deliveryCompanyID,  
  "shipperID": shipperID,  
  "type": type of goods,  
  "buyerID": buyerID,  
  "sellerID": sellerID,  
  "quantity": quantity,  
}
```

<sup>15</sup>The information related to the system participants is not listed in the article. Readers can read more about the group's previous research at [25], [18], [1].

Fig. 2. Cargo Transport Model based on Blockchain Technology, Smart Contracts and NFT.

Fig. 3. Initialize Data/NFT.

of orders (e.g. 10) as well as which “packageID” they are assigned to. After receiving packages from the seller, the shipper checks them for compliance and waits for validation before syncing up the chain (i.e., temporarily stored on the data warehouse). Then the pre-designed constraints in Smart Contracts are called through the API (i.e. name of the function) to sync them up the chain. This inspection role is extremely important because they directly affect the shipping process of goods, as well as the premise for conflict resolution when any problems arise (e.g. damage. goods, lost packages). For the processes of initiating NFTs for orders (i.e. determining the deposit amount of the seller, buyer, and carrier), the content of the NFT is defined as follows:

```
"unit": unit,
"packageID": packageID,
"addressReceived": received address,
"addressDelivery": delivery address,
"time": estimated delivery time,
"location": location,
"state": Null
};
```

Specifically, in addition to information for content extraction (i.e. place of origin, weight, item type, etc.), we also store information regarding the status of the package at “addressReceived” (i.e. “state” - default value is Null). Specifically, “state” changes to 1 if the corresponding package has been received and shipped by the shipping company (i.e. “shipperID”); value 0 - pending (i.e. waiting for the shipper to pick up the item). In addition, “unit” stores the number

```
NFT PACKAGE = {
"shipperID": shipperID,
"sellerID": sellerID,
"buyerID": buyerID,
"packageID": packageID,
"type": type of goods,
"quantity": quantity,
"addressReceived": received address,
"addressDelivery": delivery address,
"depositShipper": deposit of shipper,
"depositSeller": deposit of seller,
"depositBuyer": deposit of buyer,
"time": estimated delivery time
};
```

The information on the NFT contributes to conflict reso-

lution (e.g. delivery delays). Definitions related to stakeholder deposit have been defined in our previous articles.

B. Data Query

Fig. 4. Data Query.

Similar to the data initialization steps, the data query process also supports simultaneous access by many participants to the system (i.e. distributed model). Support services receive requests from shippers or sellers/buyers to access data (i.e. respective packages). Depending on the query object, we have different access purposes. Specifically, shippers query for the purpose of identifying consignee information and their addresses. In contrast, sellers/buyers view the status of their orders (i.e. after being delivered and received) as well as handling conflicts when something goes wrong. Fig. 4 shows the steps to query the order data. These requests are sent as requests (i.e. pre-designed services as API calls) from users to smart contracts available in the system (i.e. name of the function) before retrieving data from the distributed ledger. All retrieval requests are also saved as query history for each individual or organization. For a shipping process that involves multiple discounts (i.e. multiple shippers delivering and receiving the goods before reaching the buyer's address), NFTs are similarly created between shippers (i.e. within or different shipping companies). In case the corresponding information is not found (e.g. wrong ID), the system will send a message not found results. For the NFT query process, all support services are provided as APIs.

C. Data Updated

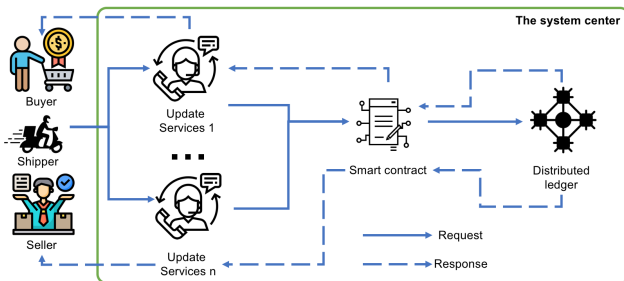

Fig. 5. Data Updated.

The data update procedure is invoked only after verifying that the data exists on the chain (i.e. after executing the corresponding data query procedure). In this section, we assume that the search data exists on the string. Where none exists, the system sends the same message to the user (see

IV-B for details). Similar to the two processes of query and data initialization, we support update services in the form of APIs to receive requests from users before passing them to smart contracts (i.e., name of the function) for processing. The purpose of this process is to update the status of the package during transit as well as handle conflicts when something goes wrong (i.e. a combination of smart contracts and NFT). Fig. 5 shows the process of updating order data. For NFTs (i.e., available), the update process includes only the transfer from the owner's address to the new address (i.e., new owner). If any information is updated on an existing NFT, it will be stored as a new NFT (see IV-A for details).

V. EVALUATION

Because of the connection model between seller - shipper - buyer and support for payment currency (i.e. consensus protocol), we implement the proposed model on blockchain platforms that support EVM instead of mining platforms. belongs to the Hyperledger eco-system. In addition, assessments based on system responsiveness (i.e. number of requests responded successfully/failed, system latency - min, max, average) were evaluated by us in the tests. previous research paper. Therefore, in this paper, we determine the suitable platform for our proposed model. Specifically, we install a recommendation system on four popular blockchain platforms today, supporting Ethereum Virtual Machine (EVM), including Binance Smart Chain (BNB Smart Chain)<sup>16</sup>; Polygon<sup>17</sup>; Fantom<sup>18</sup>; and Celo<sup>19</sup>. Our implementations on these four platforms are also shared

BNB Smart Chain	2,731,184 (100%)	109,162 (100%)	57,003 (1.9%)
Fantom	2,736,284 (100%)	115,762 (100%)	68,003 (93.41%)
Polygon	2,736,284 (100%)	115,762 (100%)	68,003 (93.41%)
Celo	2,729,784 (76.92%)	109,262 (76.92%)	59,803 (69.8%)

as a contribution to the article to collect transaction fees corresponding to the four platforms' supporting coins<sup>20</sup>, i.e. BNB<sup>21</sup>; MATIC<sup>22</sup>; FTM<sup>23</sup>; and CELO<sup>24</sup>. For example, Figure 6 details our three evaluations of a successful installation on BNB Smart Chain (i.e. similar settings are shown for the other three platforms). Our implementations to evaluate the execution cost of smart contracts (i.e. designed based on Solidity language) run on testnet environments of four platforms in order to choose the most cost-effective platform to deploy. reality. Our detailed assessments focus on the cost of performing contract creation, NFT generation (see Fig. 7) and NFT retrieval/transfer (i.e. NFT ownership update - see Fig. 8) presented in the respective subsections related to i) Transaction Fee; ii) Gas limit; iii) Gas Used by Transaction; and iv) Gas Price.

#### A. Transaction Fee

Table I shows the cost of creating contracts for the four platforms. It is easy to see that the highest transaction fee of the three requirements is contract creation for all four platforms. In which, the cost of BNB Smart Chain is the highest with the highest cost when creating a contract is 0.02731184 BNB (\$8.32); whereas, the lowest cost recorded by the Fantom platform with the highest cost for contract initiation is less than 0.009576994 FTM (\$0.001850). Meanwhile, the cost to enforce Celo's contract initiation requirement is lower than Polygon's with only \$0.004 compared to \$0.01. For the remaining two requirements (Create NFT and Transfer

NFT), we note that the cost of implementing them for all three platforms, Polygon, Celo, and Fantom is very low (i.e. negligible) given the cost. trades close to \$0.00. However, this cost is still very high when deployed on BNB Smart Chain with 0.00109162 BNB (\$0.33) and 0.00057003 BNB (\$0.17) for Create NFT and Transfer NFT, respectively.

#### B. Gas Limit

Table II shows the gas limit for each transaction. Our observations show that the gas limits of the three platforms (i.e. BNB, Polygon, and Fantom) are roughly equivalent - where Polygon and Fantom are similar in the first two transactions. Particularly in the third transaction, BNB's gas limit was extremely high at 3,000,000. While the gas volume of Polygon and Fantom is equivalent to 72,803. The other platform (i.e., Celo) has the highest gas limit in the first two transactions with 3,548,719; 142,040, respectively.

#### C. Gas Used by Transaction

Table III shows the amount of gas used when executing the transaction (i.e. what percentage of gas in total gas is shown in Table II). Specifically, the three platforms BNB, Polygon, and Fantom use 100% of the Gas Limit for the two Contracts Creation and Create NFT transactions. Meanwhile, Celo uses 76.92% of the Gas limit for the above two transactions. For the last transaction of Transfer NFT, BNB's Gas level was only 1.9% with 57,003 (i.e., lowest) while the highest Gas level was recorded by Fantom and Polygon with 93.41% of Gas limit; while BNB and Celo use 79.17% and 69.8% of Gas limit.

#### D. Gas Price

Table IV shows the value of Gas for all four platforms. Specifically, BNB, Fantom, and Celo have the same Gas value in all three transactions with values of 10 Gwei (i.e. the highest of the three platforms), 3.5 Gwei, and 2.7 Gwei, respectively. Meanwhile, the Gas value of Polygon platform (i.e. MATIC) has the lowest value and fluctuates around 2.5 Gwei.

## VI. DISCUSSION

According to our observation, the transaction value depends on the market capitalization of the respective coin. The total market capitalization of the 4 platforms used in our review (i.e. BNB (Binance Smart Chain); MATIC (Polygon); FTM (Fantom); and CELO (Celo)) are \$50,959,673,206, respectively; \$7,652,386,190; \$486,510,485; and \$244,775,762.<sup>25</sup> This directly affects the coin value of that platform - although the number of coins issued at the time of system implementation also plays a

TABLE IV. GAS PRICE

	Contracts Creation	Create NFT	Transfer NFT
BNB Smart Chain	0.00000001 BNB (10 Gwei)	0.00000001 BNB (10 Gwei)	0.00000001 BNB (10 Gwei)
Fantom	0.0000000035 FTM (3.5 Gwei)	0.0000000035 FTM (3.5 Gwei)	0.0000000035 FTM (3.5 Gwei)
Polygon	0.000000002500000012 MATIC (2.500000012 Gwei)	0.000000002500000016 MATIC (2.500000016 Gwei)	0.000000002500000016 MATIC (2.500000016 Gwei)
Celo	0.0000000026 CELO (Max Fee per Gas: 2.7 Gwei)	0.0000000026 CELO (Max Fee per Gas: 2.7 Gwei)	0.0000000026 CELO (Max Fee per Gas: 2.7 Gwei)

huge role. The total issuance of the four coins BNB, MATIC, FTM, and CELO is 163,276,974/163,276,974 coins, respectively; 8,868,740,690/10,000,000,000 coins; 2,541,152,731/3,175,000,000 coins and 473,376,178/1,000,000,000 coins. The value of the coin is conventionally based on the number of coins issued and the total market capitalization with a value of \$314.98; \$0.863099; \$0.1909; and \$0.528049 for BNB, MATIC, FTM, and CELO, respectively.

Based on the measurements and analysis in Section V, we have concluded that the proposed model deployed on Faltom brings many benefits related to system operating costs. In particular, generating and receiving NFTs has an almost zero fee (i.e. negligible). Also, the cost of creating contracts with transaction execution value is also very low (i.e. less than \$0.002).

In future work, we proceed to implement more complex methods/algorithms (ie, encryption and decryption) as well as more complex data structures to observe the costs for the respective transactions. Deploying the proposed model in a real environment is also a possible approach (i.e. implementing the recommendation system on the FTM mainnet). In our current analysis, we have not considered issues related to the privacy policy of users (i.e. access control [25], [20], dynamic policy [23], [24]) - a possible approach would be implemented in upcoming research activities. Finally, infrastructure-based approaches (i.e. gRPC [26], [27]; Microservices [28], [29]; Dynamic transmission messages [30] and Brokerless [31]) can be integrated into the model of us to increase user interaction (i.e. API-call-based approach).

## VII. CONCLUSION

Our research paper aims to expand the traditional delivery system (i.e. dependent on trusted third parties). For example, in the CoD model, the shipper receives the product deposit and payment from the buyer and then passes it back to the seller. The article highlights the risks in applying traditional models as well as the limitations of current approaches. Thereby, we propose a model that combines Blockchain technology, smart contracts, and NFT to eliminate the role of a trusted third party. Specifically, in our proposed model, the deposits of all three parties (i.e. seller, buyer, and carrier) are stored and noted as NFTs - the processing is stored in smart contracts. We have implemented the proposed model as proof-of-concept based on the Ethereum platform and Solidity language. We also deploy our smart contracts on four popular platforms supporting EVM (i.e. BNB, MATIC, FTM, CELO). Our analysis on all four platforms in all three transactions (i.e. contracts creation, NFT creation, NFT transfer) found that our proposed model is suitable for installation on the Fantom platform - having the lowest transaction costs compared to the other three platforms.

Possible development directions for our proposed model are presented in the discussion.

## ACKNOWLEDGMENT

This work was supported by Engineer Le Thanh Tuan and Dr. Ha Xuan Son during the process of brainstorming, implementation, and evaluation of the system. This work was also supported by the FPT University Cantho Campus, Vietnam.

# Integrated Assessment of Teaching Efficacy: A Natural Language Processing Approach

Lalitha Manasa Chandrapati<sup>1</sup>, Dr. Ch.Koteswara Rao<sup>2</sup>  
School of Computer Science and Engineering, VIT-AP University  
Beside Secretariat, Amaravathi 522237  
Andhra Pradesh, India

**Abstract**—The most significant component in the education domain is evaluation. Apart from student evaluation, teacher evaluation plays a vital role in the colleges or universities. The implementation of a scientific and appropriate assessment method for enhancing teaching standards in educational institutions is absolutely essential. Conventional teacher assessment techniques have always been bounded to bias and injustice for single dimensional assessment criteria, biased scoring, and ineffective integration. In this regard, it is crucial to develop a specialized teacher evaluation assistant (TEA) system that integrates with some computational intelligence algorithms. This research concentrates on using Natural language processing (NLP) based techniques for empirically analysing teaching effectiveness. We develop a model in which a teacher is evaluated based on the content he delivers during a lecture. Two techniques are employed to evaluate teacher effectiveness using topic modelling and text clustering. By the application of topic modelling, an accuracy of 75% is achieved and text clustering achieved an accuracy of 80%. Thus, the method can effectively be deployed to assess and predict the effectiveness of a teacher's teaching.

**Keywords**—Teacher evaluation; topic modeling; clustering; Latent Dirichlet Allocation (LDA); K-means

## I. INTRODUCTION

The acute necessity for experts is an aspect of present socio-economic upheaval. It contributes significantly to the level of potential nurturing at the pedagogical stage. Universities and colleges should improve the monitoring of teacher efficacy in classroom and develop an appropriate evaluation system since the competence of teachers directly determines the teaching standards and the understanding of performance of pupils [1].

Teaching and teacher activity are intrinsically diverse and complicated entities. Teaching entails a multitude of activities and interactions both inside and beyond the classroom. Although the concept of evaluating quality of teacher seems simple, in reality it includes identifying, describing, gathering data on, and inferring from hundreds of complicated component variables. Teacher's competencies significantly influence quality of teaching and learner's knowledge reception; accordingly, universities or colleges should improve classroom supervision and develop a realistic scoring scheme [2]. Teachers can receive feedback on the implementation outcomes to reinforce or improve particular areas of their training and make sure that they finish their assignments within the allotted amount of time by monitoring and evaluating the quality of their student's learning [19]. To continually increase student's learning abilities and teacher's teaching abilities, a faultless,

complete, and appropriate teaching performance evaluation system must be established [3].

At this moment, the implementation of a quantitative assessment method is necessary. The conventional form of teaching assessment continues to be used in the majority of universities and colleges [4]. The conventional teaching assessment methodology has proven inadequate to match the instructional criteria in the effective instructional procedure [5]. However, the conventional assessment methods do have some drawbacks, such as the single dimension of the indexes and the absence of a fairly neutral evaluation criteria [6].

Deep-learning is used in various aspects such as object detection, deep auto-encoders [21], image-captioning [24], sentiment analysis [22,25], etc. With the continual advancement in the areas of Deep learning and NLP, it is relatively possible to monitor teaching efficacy of a teacher in real time [7,20]. Teacher evaluation assistance system plays a crucial part in enhancing the effectiveness of potential nurturing at the teaching level [2,23]. Besides that, the teacher will get an opportunity of being awarded by the organization relying on the TEA system's results. Several factors can be taken into consideration while evaluating a teacher. Sentiment [17], presentation abilities, speaking skills, and student reviews are some of the common features. In this paper, we propose a TEA system that presents the teacher effectiveness score which solely depends on the content that the teacher delivers irrespective of his body postures, voice, etc.

$$TUS \propto \text{bodypostures} + \text{gestures} + \text{voice} + \text{accent} + \text{content} \quad (1)$$

In the eq. (1), TUS represents teacher uniqueness score

The teacher uniqueness score (TUS) is a measure that describes how distinct a teacher is from the others. As shown in the eq. (1), TUS depends on the body postures, gestures, voice, language and content. We consider 'content' as the main feature.

TABLE I. FEATURE INTERPRETATION IN TEA

Features/Aspects	TEA	[8]	[9]
Text extraction	yes	no	no
Student reviews	no	yes	yes
Context based	yes	no	no
Clustering	yes	no	no
Topic Heterogeneity	yes	no	no

The Table I displays the main discrepancies between our findings and that of others. As previously stated, this approach

incorporates text extraction, whereas the other two do not. Student reviews are required for assessing the teacher for the analysis done in [8] and [9], however they are not considered in this study. This research is solely context based, which has not been presented in prior studies. In this work, the clustering technique is applied for teacher assessment, whereas [8] and [9] use deep neural networks, deep denoising autoencoders, and support vector regression models. Topic heterogeneity, that is, different topics are considered when acquiring the dataset, unlike in the prior works.

The contributions of this article includes the following:

- This research developed a novel teaching quality assessment technique for universities and colleges based on topic modelling and clustering techniques.
- The proposed system solely concentrates on the content delivered by the teacher while instructing a class unlike other research works.
- This system can be used to assess a teacher as well as determine 'how effective a speaker is' in any given video.

The rest of this paper is organised in the following way. Section II addresses significant contribution in the field. Section III provides the proposed methodology of this system, Section IV describes experimental details followed by the results and finally, the conclusion is given in Section V.

## II. PRIOR RESEARCH AND NOVELTY OF TEA

The key approach for cultivating talents for a new generation is the enhancement of teaching excellence in academia, where the most significant aspect being the improvement of the foundation of teaching quality administrative systems. An efficient teacher assessment system in academia can depict teaching accomplishments in real times. The research on teacher assessment techniques in advanced nations seems to be more established owing to the early emergence of the education sector. In their paper [8], a comprehensive network for assessing teacher performance in universities and colleges was developed. The assemble evaluation data sets for the network, were collected from three different groups: students, peers, and leaders through survey questionnaire. The network of Student-NET, Peer-NET and Leader-NET was individually trained upon every dataset to build the hypothetical correlations between various evaluation indexes and outcomes from three perspectives. An integrated network Integrated-NET was implemented to merge the evaluations from the preceding networks in order to familiarise multi-dimensional analyses. This research eventually developed and implemented an online teaching assessment system, relying on the SSM framework, with a user-friendly functionality.

Yu Liu [9] in their study, analysed the traits and existent concerns of teacher's teaching assessment along with the critical aspects and approaches of university teacher teaching assessment. They designed an efficient methodology, a distinctive blend of deep denoising autoencoder and support vector regression model to assess the teaching effectiveness of college and university teachers. The model was built on multiple hidden layers and executed multiple feature transformations throughout the unsupervised training stage to achieve the

reconstruction between the output data and the input data. The developed approach was assessed in order to highlight the method's exceptional efficacy in enhancing decision-making about teacher effectiveness and its ability to accurately evaluate and anticipate the excellence of university education.

A research framework for analysing Physical Education teaching was proposed by Yuansheng Zeng [10], in which the authors developed a model for assessing both the teaching ability of the teacher and student's learning impact relying on a hybrid technology of data mining and the hidden Markov model respectively. Eventually, the cumulative assessment score is obtained.

In academic contexts, teachers, students, graduates and employers are often surveyed and this survey questionnaire includes open ended questions whose analyzation requires large amount of time and workload. To overcome this challenge, Buenano-Fernandez et al. in their study [11] suggested the use of a comprehensive technique based on topic modelling and text network modelling, which enables researcher to extract significant data from surveys containing open-ended questions. By use of these assessments vital data is gathered with the intention of determining the level of satisfaction that the aforementioned entities have with institutional education procedures.

A unique approach for evaluating the impact of practical knowledge on educational accomplishments was indicated by M. M. Rahman et al., in their study [12]. A remarkable approach for retrieving latent features and corresponding association rules from a legitimate dataset is presented in this research. For data clustering, an unsupervised k-means clustering technique is utilised, followed by the frequent pattern-growth approach for association rule mining. Using this framework many significant and relevant features were derived that are strongly linked to the learner's activities. To analyse the association among pragmatic (e.g. programming, logical implementations, etc.) abilities and entire scholastic accomplishment, statistical aspects of students are assessed, and the associated findings are presented. Relying on the determined latent attributes, a range of significant recommendations are presented for students for each cluster. Furthermore, the empirical outcomes of this study can assist teachers in developing productive instructional strategies, assessing programmes with precise arrangements, and pinpointing student's academic inadequacies.

By merging DBSCAN and k-means algorithms [13], the authors developed an ensemble unsupervised clustering paradigm for assessing student's behavioural traits. The efficiency of the suggested methodology is assessed by performing research on six categories of behavioural data generated by students at a Beijing university and assess the associations among diverse behavioural traits and student's grade point averages (GPAs). Besides detecting aberrant behavioural trends, the conclusions drawn from experiment also detect conventional behavioural trends more reliably.

As shown in Table II the prior work had some limitations. As it is seen, the data collected primarily was based on only reviews by different groups in their research [8]. Apart from those expressions, content, etc. could have been considered to evaluate the teacher. In their research [9], the data was collected only from teaching procedure with students, would

TABLE II. SUMMARY OF RELATED WORK

Reference #	Methodology	Findings	Limitations
[8]	Implemented an online teaching assessment system, relying on the datasets gathered from three distinct groups of people. To achieve this, they used ANNs.	An accuracy of 98.59% was achieved on verification dataset. The results of the testing reveal that the system acts effectively and fits the criteria to encourage pedagogical improvement in universities and colleges.	The data obtained for evaluating a teacher is primarily based only on the reviews from students, peers and leaders. But they could have considered other sources like expressions, content, etc., for evaluating the teacher.
[9]	A novel framework was designed by combining deep denoising encoder and support vector regression model to evaluate quality of teaching.	In comparison to other models, this model attained an accuracy of 85.23%	It would have been better if they could have considered other parameters too for evaluation, rather than depending only on the data taken from teaching procedure with students.
[10]	Combination of data mining and hidden markov models to evaluate PE teaching effectiveness with regard to both teachers and students, in universities was proposed.	Attained better accuracy and also high computational efficiency compared to other models.	The training data should be large in size for the model to perform better and the computation time is high in this case.
[11]	LDA for topic modelling and text network modelling was used to glean relevant insight from questionnaires containing open-ended questions.	The deployment of this approach allows the optimization of effort and time required to adhere with the assessment of the text data produced by the open questions.	Equitably finite amount of data was considered in the proposed research and it is a challenging task to retrieve topics from concise text.
[12]	K-means clustering and FP-growth techniques were used to identify the correlation and affinity among practical skills and academic performance.	According to the study, it is concluded that stronger practical abilities have a good influence on academic success.	K value of the enhanced k-means clustering method may vary depending on the dataset and might result in yielding stronger or even worse outcomes for varied datasets.
[13]	Proposed the application of DBSCAN and K-means clustering to analyse the behavioural patterns of the students.	The outcomes of this research help in providing students, effective services and governance, like psychological assistance and educational counselling.	The issue of this research arises when applying the suggested method to multisource behavioural characteristics with high dimensions.

be better if other parameters are considered. In their study [10], large dataset should be taken for the model to predict better results. It is a challenging task to retrieve topics from concise text [11] considering finite amount of data. The limitation in the study [12] is that the k-value of the enhanced k-means method varies depending on the dataset resulting in yielding stronger or even worse outcomes for varied datasets. The issue of the research [13] arises when applying the suggested method to multisource behavioural characteristics with high dimensions.

Taking into account the shortcomings of previous studies, a novel approach for teacher evaluation is proposed. The study's novelty includes the teacher being evaluated solely on the content of his lectures, regardless of feedback or ratings.

### III. PROPOSED METHODOLOGY FOR TEA

For a college or university to develop and prosper, teaching standards must be of the highest calibre. So we try to implement a model that identify good teacher on their domain without human support. The detailed methodology is further discussed in this session.

#### A. A System level overview of TEA to evaluate teacher effectiveness

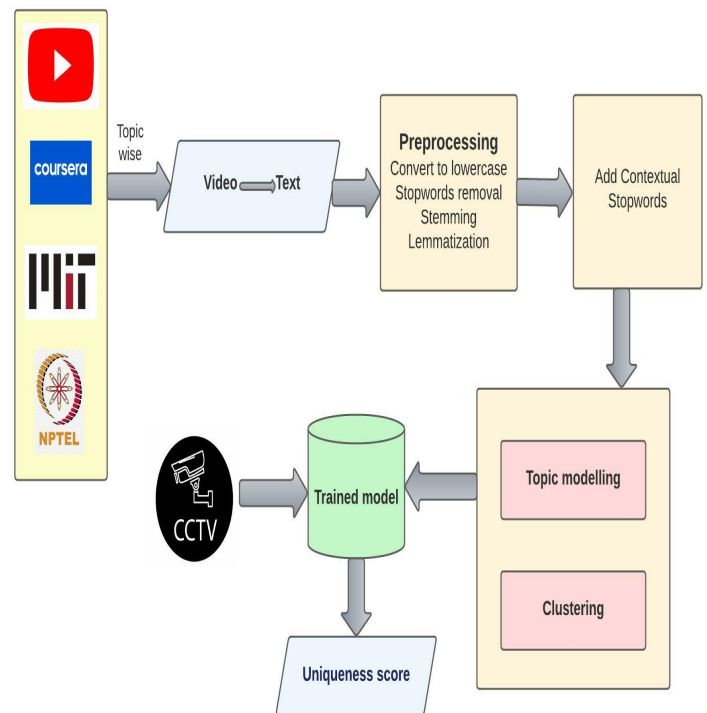

Fig. 1. Framework of the model to evaluate teacher

Fig. 1 depicts a schematic representation of the model for the TEA system. As illustrated in the Fig. 1, the steps involved in teacher evaluation are as follows:

- Videos spanning multiple sources such as YouTube, MIT courses, NPTEL, Coursera, and so on are considered.
- Using the IBM Watson and FFmpeg libraries, the acquired videos are transcribed to text and this text is treated as input.
- Pre-processing operations including converting to lowercase, stemming, lemmatization, stop word elimination, and so on are applied to the input text.
- Contextual stop words are added to the list.
- Topic modelling and Clustering approaches are employed on the pre-processed text and the trained model is stored.
- The lecture videos are acquired from the CCTVs installed in the classrooms, and are undergone through the trained model to provide a uniqueness score which describes “How effective a lecture of the teacher is?”

### B. Flowchart of the Proposed Model for Teacher Assessment

This research, which is based on topic modelling and clustering strategies, proposes a novel framework for teacher evaluation in universities and colleges, the flowchart of which is illustrated in Fig. 2.

Fig. 2. Flow chart of the evaluation model for TEA based on topic modelling and clustering techniques

It can be seen from Fig. 2 that includes data required for the evaluation model is generated from Faculty footage

acquired of installed CCTVs at classrooms, then the generated data is undergone text extraction and text pre-processing steps. Finally, using both topic modelling and clustering techniques a uniqueness score is produced which evaluates the teacher effectiveness.

### C. Preparation of Data

As data acquired from CCTVs are videos, there is a need to transcript these videos to text format and also the transcribed text should be preprocessed.

1) *Text extraction*:: Converting videos to text can be accomplished in a variety of approaches, including utilising python, existing web APIs and soon. We transcript the videos using python FFmpeg and IBM Watson libraries here. The first phase includes conversion of video to audio using FFmpeg library. The second phase involves using IBM Watson library, which is SaaS provider for AI applications. The IBM Cloud offers a variety of solutions such as Text to Speech, Speech to Text, Natural Language Classifier, Language Translator, Visual Recognition, and so on. The Speech to Text service converts audio to text so that applications could use voice transcription features.

2) *Text preprocessing*: Text data is extensively available and is utilised to assess and solve business challenges. However, prior to actually using the data for research or prediction, it must be processed. Text preprocessing is used to prepare text data for model formulation. It is the first stage in any NLP project. Some of the preprocessing steps are: Removing punctuations like . , ! \$( ) \* % @, Removing Stop words, Removing URLs, Tokenization, Lower casing, Lemmatization, Stemming. Based on the dataset, we need to perform the appropriate preprocessing steps. For our dataset, we considered using Tokenization, Lowercasing, stop words removal, Lemmatization.

- **Tokenization**: The text is fragmented into small components in this stage. Based on our task specification, we can employ either sentence tokenization or word tokenization.
- **Lowercasing**: One of the most common preprocessing tasks is to convert the text to the same case, ideally lower case.
- **Stop words removal**: Stopwords are frequently used words that are eliminated from the text because they provide no relevance to the assessment. Those terms have little or zero significance. Apart from the existing list of stop words in NLTK library, we can modify the list by adding or eliminating terms depending on the scenario.
- **Stemming**: It involves stemming or reducing the words to it’s core form. For instance, programmer, programming, gets reduced to the word “program”. However, the drawback of stemming is that it separates the phrases, that the base form lacks meaning or is not reduced to a valid English word.
- **Lemmatization**: The difference between stemming and lemmatization is that it stems the term yet ensures that it retains its meaning.

#### D. Methodologies

For our research we have deployed two existing technologies to evaluate the teacher. The techniques used here are: Topic modelling and Clustering.

1) *Topic modelling-latent Dirichlet allocation*: Topic modelling is a type of unsupervised NLP that is used to depict a text document combining numerous topics that help describe the inherent content in a specific document. Analysis of text data is done using a model and clusters of words are generated on that dataset. Latent Dirichlet Allocation [14] is the most effectively used model for topic modeling approach [15].

In LDA, latent represents the underlying concepts in the data, while Dirichlet is a kind of distribution. The Dirichlet distribution is not same as normal distribution. In LDA [18], the topics for every document are allocated in the following manner:

- 1) For K number of predefined topics, in every document each word to a topic is arbitrarily configured.
- 2) For each document d:  
Determine the following for every word w in the document:
  - P(topic t / document d): The percentage of words in document d allocated to subject t.
  - P(word w / topic t): The percentage of assignments to topic t from words in w among all documents.
- 3) Given all previous words and their topic assignments, reassign topic T' to word w with probability  $p(t'/d)*p(w/t')$ .

The final phase is performed several times until we reach a stable condition in which the topic allocations do not vary any further. These topic allocations are then used to establish the percentage of subjects for each document.

2) *Clustering-K means*: The process of dividing a dataset into clusters is called Clustering. The idea is to divide the data so that elements within a single group are relatively same and those in different clusters are dissimilar. It defines how unlabelled data is categorized. In the context of using text data, it is Text Clustering, which involves different phases including Text pre-processing, feature extraction, Clustering. Text clustering uses machine learning and NLP to recognize and analyse textual data. The most well researched clustering algorithm is K Means [16], and it persistently tends to produce good results.

The main goal is to categorise given data collection into prespecified k number of distinct groups. The algorithm is divided into two phases: the initial step is to establish k centroids for each cluster, the following stage is to choose each point from the provided dataset and connect it to the closest centroid. To compute the distance among data points and centroids, Euclidean distance method is used extensively. Once all the elements are included in certain clusters, the first phase is accomplished. The revised centroids must be reassessed at this stage since the addition of new points could cause a variation in the centroids of the clusters. Once k new centroids are identified, a new association among the same data points and the closest new centroid is established, resulting in a

loop. As a consequence of this loop, the k centroid's locations may vary in a step-by-step process and this leads to a condition called clustering convergence which means the centroids stop drifting.

#### E. Our Proposed Methodology

1) *Evaluation parameters*: We consider normalized value of likes/views of a video as a parameter for evaluating a teacher. It is known that for a real time lecture footage, neither likes nor views exist. For this purpose, we deploy a model where the real time videos are compared to you tube videos taking NL/V into consideration. As a result, if the video needs to be uploaded to a web source, then the effectiveness score can be known prior to uploading thus making it easy to identify whether the video be success or not.

##### 2) Users of our system:

- Public domain(YouTube, MIT, Coursera, etc.)  
As mentioned earlier it would be easy to depict a video to be success or not using our proposed model. This can help the trainer to improve his presentation and provide better videos. Also, the effectiveness of the speaker in a video can also be depicted.
- College/University Management  
They can be benefited in varied ways like to assess a teacher without direct classroom intervention. A trainer can also be recognised and awarded by the management for his teaching abilities by application of this model.

## IV. VALIDATION OF TEA

### A. Dataset Collection

The major source of dataset for evaluating a teacher is the lecture footage acquired from classrooms. It is a challenging task to accumulate a significant amount of data based just on footage in a short span of time. As a result, we used YouTube videos to train the model, and once the model gives constructive results, it can be applied on real-time lecture footage.

Videos are converted to text format and the data is undergone through pre-processing techniques thus resulting in providing clean data. Topic modelling and clustering approaches, LDA and K-Means, respectively are deployed on the data to assess the teacher.

As shown in Table III, videos for each sample topic are acquired and processed according to our research. Videos are converted to text format and the data is undergone through pre-processing techniques thus resulting in providing clean data. Topic modelling and clustering approaches, LDA and K Means respectively are deployed on the data to assess the teacher. Likes and views of each video is taken and percentage of likes to views is calculated. As the videos are of varied durations, there is a need for normalizing the likes/views value. The normalization technique used here is minmax normalization. We contemplate NL/V as evaluation parameter, it is equal to 1 indicates that likes of the video are identical as the views of video. This depicts that the video is best as "who all viewed it, liked it". Hence, it can be deduced from the above said logic that  $NL/V = 1$  means the video is best of all.

TABLE III. DATASET

B. Experimental Procedure

1) *Topic modelling*: Data pre-processing is performed first. After pre-processing the data, topic modelling is implemented on the data to extract significant topics. Word frequency count is calculated on the collection of words obtained for each topic. Frequent words with a threshold value of 4 or less are removed as more frequently occurred words in the corpus determines that the speaker tried to deliver the significant content by insisting those words. Average word count and average normalized count of the words are computed.

$$WC = \sum \text{frequency of words in topics} \quad (2)$$

$$AWC = \frac{\sum WC}{\text{Total no. of topics}} \quad (3)$$

2) *Clustering*: For clustering approach, the data is summarized using python code. K-Means clustering was deployed on the summarized data thus resulting in clusters. The optimal number of clusters is predicted by the usage of elbow method. Once the clusters were formed the participation ratio of every video across each cluster is calculated. Average clustering score for each video is also calculated. High average clustering score depicts the corresponding video being the best of all.

$$PR = \frac{\text{No. of sentences of a video in the cluster}}{\text{Total no. of sentences across the cluster}} \quad (4)$$

Where PR = Participation Ratio of video

$$ACS = \frac{\sum_{i=1}^k PR}{k} \quad (5)$$

Where ACS = Average clustering score, K = Total number of clusters

C. Results and Analysis

After applying topic modelling on each video of the dataset, topics are generated which are a collection of words. Word count and Average Word Count are calculated using the eq. (2) and (3), respectively across each topic for all the videos. Average word count is normalized using minmax normalization to obtain average normalized count values.

*Intertopic distance plot* The intertopic distance plot is also created using the topics that were generated. It presents a broad perspective of the topics and their difference from one another, whilst providing for a detailed analysis of the words most intrinsically correlated with each topic. The areas of the circles encode the relative prevalence of each topic. The horizontal bar chart is illustrated on the right whose bars indicate the distinct words which are most beneficial for comprehending the present topic of interest on the left.

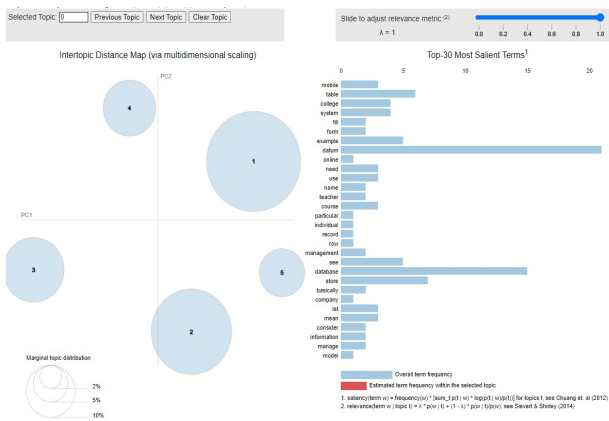

Fig. 5. Intertopic distance plot for database

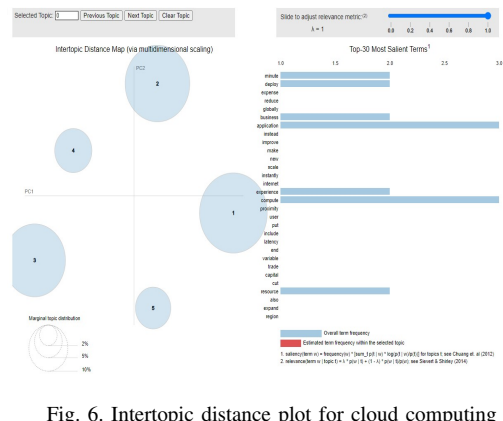

Fig. 6. Intertopic distance plot for cloud computing

Fig. 7. Intertopic distance plot for datamining

The images Fig. 3 through Fig. 7 depicts the intertopic distance plots of the five sample topics. It can be depicted that in distance plot the size of the circle represents each topic's population in the corpora. Each bubble depicts a distinct topic. The greater size of the bubble indicates the greater proportion of terms related to that topic. The greater the distance between the bubbles, the greater the degree to which they differ from one another. When there is more space between the bubbles, there is a huge differentiation among each of the individual bubbles. On the right side, the box plot represents the top thirty salient terms of each topic and their respective frequencies. The term frequency across the whole document is represented by blue bars and the red bars are categorized by the significance of the words within every topic.

As it is shown in Fig. 3 and Fig. 4, the bubble 1 is selected, thus red bars indicate the particular term's frequency inside the topic 1 for both respectively. For example, it can be seen in Fig. 4 that the term "machine" is the most frequently used for 48 times. The red bar depicts that the word is used for 32 times in that particular topic 1. Similarly in the plots Fig. 5, Fig. 6, Fig. 7, the frequency of each term in the corpus is shown by blue bars. The blue bars indicate that no topic is selected and hence, most widely spoken terms are presented. In Fig. 5, the most frequently used words are datum and database. As the plot is obtained from the sample topic that discusses about database, it is clear that the teacher is trying to induce the topic by concentrating on those words.

The Table IV represents the statistical measures calculated after acquiring topics by implementing LDA on the dataset. We calculated the term frequencies across the whole corpus for five topics over all the videos in the dataset and it is represented as WC, by using eq. (2). The average word count is obtained by usage of eq. (3) and can be identified as AC. ANC is the normalized value of AC. As seen in the Table IV ANC score is high for 15 sample topics out of 20 sample topics. Those fifteen instances whose ANC is high, it can be observed that their respective video's NL/V value is 1. Hence, a conclusion can be drawn from the observed pattern that ANC score is high for the videos whose NL/V value is equal to 1 which comprehends that the particular video is the best. The Fig. 8

represents a graph for the distribution of the sampled topics whose average normal count is high. The videos with high ANC are considered to be the best videos and it can be deduced that the teacher delivered the lecture in an effective manner compared to other two videos.

Fig. 8. Distribution plot of videos after topic modelling

TABLE V. TABLE OF CLUSTERING SCORE

Sample Videos	K	ACS(HIGH)	NL/V=1
what is an activation function	5	v2=0.401	v2
what is neural network	5	v6=0.128	v6
what is virtualization?	6	v3=0.18	v2
what is database?	8	v1=0.12	v1
what is cloud computing?	4	v4=0.2	v4
what is data mining?	8	v3=0.162	v3
Explain generations of computers	7	v9=0.121	v9
Explain OOPs concepts	7	v4=0.178	v10
Explain GSM architecture	6	v2=0.38	v2
what is MQTT protocol?	3	v2=0.37	v2

After applying clustering to the dataset, the clusters are formed and number of optimal clusters is identified by using elbow method. Using the eq. (4), participation ratio of the videos across the clusters for all the videos is calculated. ACS, average clustering score of all the sample topics is calculated using the eq. (5). The Table V depicts the number of optimum clusters for sample topics and their highest ACS score among the videos. It can be seen in Table V that 8 out of 10 sample topics have highest average clustering score of the corresponding video are same as the video having NL/V is equal to 1. Thus it can be concluded that the best videos of the sample topics after clustering have the highest average clustering score.

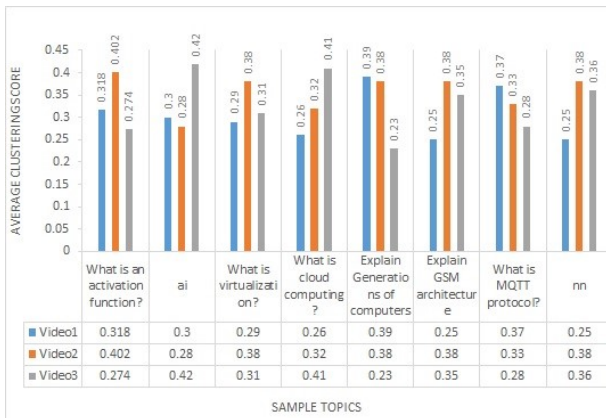

Fig. 9. Distribution plot of videos after clustering

The Fig. 9 shows the distribution plot of the sample topics after clustering technique been applied. It portrays the occurrences that have the highest average clustering score. Finally, We have drawn a conclusion from the patterns observed that by applying topic modelling and clustering methods, teacher evaluation can be performed based on the content and it got successful results with an accuracy of 75% and 80%, respectively.

## V. CONCLUSION

In this paper, LDA topic modelling and K-Means clustering methods are deployed on the dataset to evaluate a teacher's teaching effectiveness. The main feature for this research is considered as the content that the teacher delivers. Based on this context, videos from public domain are gathered for the dataset and applied the said models on the data resulting in obtaining an accuracy 75% and 80% of LDA, K-Means respectively. The utilization of two models is beneficial for acquiring effective results, like topic modelling consumes less computing time and clustering gives best accuracy. Finally, this paper provides a teacher evaluation system which is based on the content of the lecture distinct from traditional methods which are based on the reviews, emotion detection and so on.

**Abstract**—The curriculum ideological and political education (CIPE) has caused the attention of China's leaders and state departments in Chinese education, but its effect assessment is still an open issue should be address for the efficient and effective implementation of CIPE. The engineering education conception has been widely adopted in Chinese higher education, in recent years, due to its effectiveness. Therefore, in this paper, under the background of Chinese engineering education, we study the CIPE effect quantification. We propose a CIPE effect assessment system for higher education, and a CIPE effect quantitative method based on the achievements of graduation requirements for each student. The proposed system provides visualization information of achievements and CIPE effect for students and teachers. This helps students to locate themselves in their major learns, and teachers to continuously improve their teaching methods.

**Keywords**—Curriculum ideology and politics; assessment; engineering education; ideological and political education; outcomes-based education

## I. INTRODUCTION

Recent years, Chinese national leader and institutions, e.g., State Department and Education Ministry, put a high value on the curriculum ideological and political education (CIPE), to raise the ideological and ethical standards of Chinese students. They require all educators must pay equal attention to the professional ability training and the ideological and political education (IPE). In addition, IPE must be integrated into all aspects of education, instead of only relying on only a few IPE curricula. The Chinese Ministry of Education and other nine national-level government bodies jointly issued the official document of *Work Programme for Fully Pushing Forward the Construction of "Great Ideological and Political Course"* in July 2022 [1], which plans to fully mobilize social forces and resources for CIPE in all universities, middle and primary schools in China.

Therefore, many Chinese researcher study on how to organically integrating IPE into the professional education in various subjects, e.g., computer science [2], [3], [4], mathematics [5], [6], agronomy [7], and so on, to the isolated island phenomenon in IPE [8], and develop the world-class modern education with Chinese characteristics [9]. For example, Lu [10] applied new media network platform and block chain

technology to design a CIPE information exchange approach, to improve the sharing efficiency of IPE resources. This work also used the bad information screening technology to filter out negative information. Liu and Ni [11] exploited SWOT analysis method qualitatively analysing the inherent strengths and weaknesses as well as the external opportunities and challenges of the IPE politics employed by universities and colleges, currently, in HeiLongJiang province of China. Lin et al. [3] introduced a strategy for integrating IPE into the artificial intelligence course, and designed the IPE achievement goals of the course, based on the idea of outcome-based education (OBE). Zhang et al. [12] studied the combination of CIPE and Chinese engineering education accreditation, and integrated IPE into various educational phases including the educational goals, graduation requirements' indicators, the course system, and teaching designs. These works studied the integration strategy of CIPE in some aspects, but didn't consider to evaluate the effectiveness of their strategy in improving ideological and political achievements for students.

There are several works on the effect assessment of IPE education. Zhang [13] proposed to exploit industry education integration for CIPE education, which combined field practice and classroom teaching, to improve the mental health of students, by increasing the attraction of IPE education. Tang [14] studied the CIPE education reform for innovation and entrepreneurship education, to improve the self-efficacy of fresh graduates in their job applications. These works used grouping comparison to evaluate the effectiveness of CIPE strategies. Chen and Yu [15] used the principal component analysis technology to reduce the information redundancy of CIPE assessment criteria, and performed the weighted sum on the principal components to establish the evaluation model for CIPE education effect. Similarly, Zhang [16] employed the clustering algorithm to find the similarities of data indices, and built a CIPE evaluation data model by assigning the weight coefficient of each index class produced by factor analysis. Mo et al. [17] utilized triple helix model to combine the assessment data from three subjects, school, enterprise, and government, and established a fuzzy synthetic evaluating model for evaluating the CIPE effect. Ding et al. [18] used the back propagation neural network to evaluate the the CIPE teaching quality of teachers, with the data scored by students.

This work employed the traditional idea of teacher-centered instead of student- or learner-centered education. Zhang et al. [19] applied deep learn model for analysing the CIPE teaching quality, with multi-source data from on-line and classroom teaching, and produced the deficiency of teaching. Guo [20] designed an evaluation system of CIPE effect based on the authenticity evaluation theory for vocational education. All of these above works achieved the data through scoring subjective questions, leading to objectivity of CIPE effect assessment. Lv et al. [21] developed a data management system for IPE, where the evaluation of IPE effect is same to that of usual curricula, where teachers scoring.

To our best knowledge, there is lack of objective and quantitative evaluation method for CIPE effect. Existing works evaluated results of CIPE, ignoring the dynamic of the political and ideological status for each student. Therefore, in this paper, we study on the quantitative evaluation strategy for CIPE effect, based on the dynamic of achievements of students during their school years. The achievements of every student is the progress that the student reaches the graduation requirements specified in its specialty personnel training program (PTP). The graduation requirements are the main goal that undergraduates pursue in their four-year university or college life, in the context of engineering education with the idea of outcome-based education (OBE), in China. The graduation requirements are stable during students' school years. Thus, the fluctuates of students' achievements can reflect their IPE states. Such as, an improvement of achievements imply a better IPE effect (self-discipline) for a student. Our work complements to existing works, and helps to provide a more comprehensive assessment information of CIPE effect.

The rest of this paper is organized as follows. In Section II, we present preliminary knowledge on the Engineering Education. Section III illustrates our CIPE effect assessment system, and Section IV details the assessment method for quantifying the CIPE effect based on achievement data. In Section V, we illustrates some application cases for students and teachers, on the CIPE effect. In Section VI, we conclude this work and present our future work.

## II. PREPARATORY KNOWLEDGE ON ENGINEERING EDUCATION

In 2016, China became the 18th official member of Washington Accord, and the undergraduate engineering degree is mutual recognition among the countries joining the Washington Accord, for certified engineering specialties. This promotes the development of internationalization and modernization of Chinese higher education. Therefore, numerous Chinese universities actively apply for engineering education certification. In 2022, almost 2,000 university specialties have gained the certification from China Engineering Education Certification Association (CEEAA) [22].

### A. Engineering Education Conception

The concepts of engineering education are student-center, outcome orientation, and continuous improvement. There are one kind of eventual outcomes (cultivation goals) and two kinds of intermediate outcomes (graduation requirements and course objectives) in engineering education, As shown in

Fig. 1. The cultivation goals are the capacities that students will have after graduating about five years, which are designed and continuously improved based on the developments of social demands and expectations, the school and specialty orientations, etc. Graduation requirements are the capacities that students graduated with, by the college or university education. Graduation requirements are designed on the principle that they can support the reaching of cultivation goals. Course objectives are the capacities obtained by students through various courses directly. The accumulation of course objectives must support the achievements of all graduation requirements. And the course objectives are accomplished by corresponding teaching contents and methods.

As shown in Fig. 1, there are four continuous improvement circles or closed loops in engineering education, as illustrated in the followings.

- 1) The ultimate goal of engineering education is enabling students to achieve cultivation goals. Thus, the cultivation goals must be designed legitimately, as they decides the rationality of the whole PTP. Thus, when the cultivation goals are designed, their rationality must be assessed by related enterprise, industry, and education experts. When the assessed rationality is low, the cultivation goals are improved based on expert comments. These above steps are repeated for improving the cultivation goals until they are assessed to be rationality. The improving process is conducted periodically, as the social needs are changed with the world development. Usually, a major improvement is made in the cultivation goals every four years, and a minor one is made every two years, in Chinese higher schools.
- 2) Given the reasonable cultivation goals, the graduation requirements are designed to enabling students to have the ability to achieve these goals after graduation. Thus, the rationality of designed graduation requirements can be evaluated by the reaching degree of cultivation goals. If the reaching degree is low, the design of graduation requirements cannot support the achievements of cultivation goals, and thus need to be improved. These process is conducted when the cultivation goals are changed in the first continuous improvement circle or their evaluation results do not meet expectations.
- 3) Cultivation goals and graduation requirements are the high-level designs of PTP. Graduation requirements are the achievements that a student get in its about four years of engineering education, by various courses. Therefore, the course system must be built carefully, and designed course objectives need be equivalent to graduation requirements. After completing a course, a student accomplishes corresponding course objectives, and gets closer to corresponding graduation requirements. Thus, if the achievements of graduation requirements are evaluated to be poor for fresh graduates, there is a strong likelihood that course objectives are improper and they need to be improved to guarantee that students meet graduation requirements if they achieve all course objectives.
- 4) For each course objective, its accomplishment for students is implemented by reasonable designs and

Fig. 1. The core concepts of engineering education

arrangements of course teaching contents and methods. When the accomplishment degree is low for a course objective, the corresponding teaching contents and methods need to be improved.

### B. Graduation Achievement Quantification

Given from CEEAA, certification standards show that there are 12 graduation requirements including engineering knowledge, problem analysis, solution design/develop, research, etc. To easily evaluating the achievement, each graduation requirement is decomposed into 2–5 smaller requirements, which can help students achieve the graduation requirement progressively and accumulatively.

Assuming that there are total  $N$  graduation requirements ( $g_i$ ) and  $M$  course objectives ( $c_j$ ). The relationship between graduation requirements and course objectives can be represented as a support matrix ( $\mathbf{W}$ ), where item  $w_{i,j}$  on line  $i$  column  $j$  is the support weight/degree of  $c_j$  to  $g_i$ . If  $c_j$  don't support  $g_i$ ,  $w_{i,j} = 0$ . For each graduation requirement, the achievement is quantified by the weighted sum of course objectives' accomplishment degrees, as shown in Eq. (1). Where  $r_i$  and  $o_j$  are respectively the achievement and accomplishment degrees of  $g_i$  and  $c_j$ , and they are both in the range from 0 to 1. And thus  $\sum_{j=1}^M w_{i,j} = 1$ , representing course objectives with non-zero weight jointly support the achieving for every graduation requirement. The accomplishment degree of each course objective is obtained by testing in the corresponding course.

$$r_i = \sum_{j=1}^M w_{i,j} \cdot o_j \quad (1)$$

All course objectives are tested only when near the graduation, as courses are run on all time periods (e.g. terms) of every student's school life. Thus, the graduation requirements are achieved incrementally for each student in its school life. In this paper, we focus on the fluctuation of graduation requirement achievements to quantify the CIPE effect for each student. Therefore, we normalizes graduation requirement

Fig. 2. The framework of CIPE effect assessment system

achievement degrees as achieving ratios in a same value range  $([0, 1])$  at any time, using following processes.

As course objectives are tested at different times, a student's school life can be divided into  $M$  time periods, by these test times. Without loss of generality, the test order is  $c_1, c_2, \dots, c_M$ . The  $j$ th time period,  $t_j$ , is the period between the times of testing  $c_{j-1}$  and  $c_j$ , and we can obtain the accomplishment degree of  $c_j$  at the end of  $t_j$ . Then, we define the achieving ratio ( $AR_{i,j}$ ) of  $g_i$  at  $t_j$  as the ratio of the current achievement degree of  $g_i$  to the full degree when  $o_{j'} = 1, \forall j' \leq j$ , as in Eq. (2).

$$AR_{i,j} = \frac{\sum_{j'=1}^j w_{i,j'} \cdot o_{j'}}{\sum_{j'=1}^j w_{i,j'}} \quad (2)$$

### III. CIPE EFFECT ASSESSMENT SYSTEM

The framework of CIPE effect assessment system is shown in Fig. 2. There are mainly six modules in the system, as detailed in the followings, respectively.

- M1. Course objective accomplishment entry module** provides entry interfaces (keyboarding, file import, etc.) for various courses' test data to teachers, and formats entered data into course objective accomplishment degree. For example, a course has two course objectives ( $c_1$  and  $c_2$ ), and its test data include scores of two assignments (80% and 75% for a student case), one middle exam (65%), and the final exam (77%). When the accomplishment of  $c_1$  is supported by these two assignments equally, and  $c_2$  by these two exams equally, the accomplishment degrees of  $c_1$  and  $c_2$  are respectively  $0.775 (\frac{80\%+75\%}{2})$  and  $0.71 (\frac{65\%+77\%}{2})$ , for the student case.
- M2. Achieving ratio calculation module** updates corresponding achieving ratios when the accomplishment degrees of some new courses objectives are calculated by M1 for some students, using Eq. (2).
- M3. CIPE effect quantification module** calculate the quantified data for the CIPE effect for each student, based on the fluctuation and the statistical information of achieving ratios. The quantification method is illustrated in Section IV.
- M4. Achievement data visualization module** uses some visualization tools to show the achievement data of graduation requirements for every student, including

the current achievement degrees and the fluctuations of achieving ratios. This can help the student to know its position in the specialty. For teachers, the module shows the statistical information of achievement data. In Section V, we will present some cases to illustrate the visualization of achievement data.

**M5. CIPE effect data visualization module** is similar to **M4**, which visualizes the CIPE effect data obtained from **M3**. Some cases will be illustrated in Section V.

**M6. Incentives and feedback module** recommends incentive strategies to students and teachers according to the historical achievement and CIPE effect data, and evaluates the effectiveness of an incentive strategy by testing whether there is a different before and after performing the incentive strategy. The recommendation of incentive strategies can be implemented by modern artificial intelligent algorithms, which is one of our future works.

#### IV. CIPE EFFECT QUANTITATIVE METHOD

In this paper, we design a CIPE effect quantitative metric based on the achieving ratio of each graduation requirement according to following principles.

- CIPE effect will be good if the achieving ratio is increased, and opposite when the achieving ratio is decreased.
- The small fluctuation of the achieving ratio can reflect the discipline of the student, and thus corresponds to a good CIPE effect.
- If the rank of a student is risen, the CIPE effect is likely to be good.

Thus, we construct the CIPE effect quantitative metric using following indicators.

- The increment of the two successive achieving ratios.  $\Delta_{i,j} = (AR_{i,j} - AR_{i,j-1})$  is the current increment at  $t_j$  for  $g_i$ .  $\Delta_{i,j}$  can be negative when the achieving ratio is decreased.
- The number of the achieving ratio increasing.  $I_{i,j} = \sum_{j'=1}^j (\Delta_{i,j'} > 0)$  represents the number for  $g_i$  at  $t_j$ , where  $(\Delta_{i,j'} > 0)$  returns 1 if  $\Delta_{i,j'} > 0$  and otherwise 0.
- The number of the achieving ratio decreasing,  $D_{i,j} = \sum_{j'=1}^j (\Delta_{i,j'} < 0)$ , similar to the previous indicator.
- The standard deviation of historical achieving ratios,  $\sigma_{i,j} = \sqrt{\sum_{j'=1}^j (AR_{i,j'} - \mu_{i,j})^2 / j}$ , where  $\mu_{i,j}$  is the average of achieving ratios, which is  $\sum_{j'=1}^j AR_{i,j'} / j$ . This indicator reflects the fluctuation degree of the achieving ratio.

The CIPE effect quantitative metric is defined by Eq. (3) based these above four indicators, for each graduation requirement, and the overall CIPE effect quantitative metric is defined

by Eq. (4). The greater values these metrics have, the better CIPE effect is.

$$e_{i,j} = \begin{cases} \frac{I_{i,j} \cdot (1 + \Delta_{i,j})}{\sigma_{i,j} \cdot D_{i,j}} & \text{if } \Delta_{i,j} > 0 \\ \frac{I_{i,j}}{\sigma_{i,j} \cdot D_{i,j} \cdot (1 - \Delta_{i,j})} & \text{else} \end{cases} \quad (3)$$

$$E_j = \sum_{i=1}^N \frac{e_{i,j}}{\max_{1 \leq i \leq N} e_{i,j}} \quad (4)$$

#### V. CASE STUDY

In this section, we first present cases for illustrating how students and teachers can be benefited from our CIPE effect assessment system by visualization information.

##### A. Visualization for a Student

For each student, our system first provides its latest achieving ratios for all graduation requirements by a combination chart, as shown in Fig. 3. As shown in the figure, the system provides not only its achieving ratios, but also the average and the best ones of all students, for the student. In addition, the chart highlights the achieving ratios not passing in red color. By comparing its achieving ratios with the average ones or the passing lines, the student can get a clear sight in its position and reasonably plan next goals.

In addition, the CIPE effect assessment system provides the dynamic changes of each graduation requirement achieving ratio for a student, in two forms, as shown in Fig. 4 and 5, respectively. Fig. 4 gives the achieving ratio for the first graduation requirement in all time periods. The system also provides the achieving ratios of others graduation requirements for the student, as same as Fig. 4. From Fig. 4, the student can see its achieving ratios, as well as the average and the best ones. In addition, Fig. 4 gives the suggest of the next goal for the student, according to its current achieving ratio. The suggested goal is set as the average achieving ratio of students with a higher grade than the current achieving ratio. For example, for a student, the current achieving ratio is 0.73. The average achieving ratio of students with achieving ratios between 0.8 and 0.9 is 0.84. Then the next goal is suggested to be 0.84. To give a more clear sight of the fluctuation of the achieving ratio, the system also provides the variations of the achieving ratio for each student, as shown in Fig. 5.

Based on the achieving ratio, the system calculates the overall CIPE effect by Eq. (4), and shows the result by a bar graph, as Fig. 6. By this graph, the system provides the overall CIPE effect, and the average and the best one for every student, which helps it to locate itself in its major learn and CIPE effect.

##### B. Visualization for a Teacher

For a teacher, the assessment system provides the statistical information on achieving ratio and CIPE effect by boxplot graphs, as Fig. 7 and 8, respectively. From these graphs, the teacher can see clearly the relative difference among achievements and CIPE effects of all graduation requirements. With the knowledge of which graduation requirement has poor or good achievements and CIPE effects statistically, the teacher can analysis the strengths and weaknesses of its teaching methods, and hasten the strengthening and make up for the weaknesses in the future.

Fig. 3. The latest achieving ratios of a student

Fig. 4. The dynamical change of a graduation achievement for a student (Qa-b represents the time period, meaning the bth time period in the ath term)

Fig. 5. The fluctuation of graduation achievement for a student

## VI. CONCLUSION

In this paper, we study on the CIPE effect assessment for Chinese higher education. We present a CIPE effect assessment system to manage the data of graduation achievements and the CIPE effect assessment of students, and propose a CIPE effect quantification method for the CIPE effect based on the graduation achievements. Our CIPE effect assessment system and method can be helpful for continuous improvements on achievements of students and teaching methods of teachers.

Fig. 6. The overall CIPE effect assessed value for a student

Fig. 7. The statistical information on achieving ratio for a teacher

To our best knowledge, this is the first attempt for quantify the CIPE effect based on objective data. In the future, we will study on the integration of our method with the subjective assessment for the CIPE effect, to provide more comprehensive knowledge for students and teachers.

## ACKNOWLEDGMENT

The authors would like to thank the anonymous reviewers for their valuable comments and suggestions. The research was supported by Henan Higher Education Teaching Reform Research

# Navigation of Autonomous Vehicles using Reinforcement Learning with Generalized Advantage Estimation

Edwar Jacinto<sup>1</sup>, Fernando Martínez<sup>2</sup>, Fredy Martínez<sup>3</sup>  
Universidad Distrital, Francisco José de Caldas  
Bogotá D.C., Colombia

**Abstract**—This study proposes a reinforcement learning approach using Generalized Advantage Estimation (GAE) for autonomous vehicle navigation in complex environments. The method is based on the actor-critic framework, where the actor network predicts actions and the critic network estimates state values. GAE is used to compute the advantage of each action, which is then used to update the actor and critic networks. The approach was evaluated in a simulation of an autonomous vehicle navigating through challenging environments and it was found to effectively learn and improve navigation performance over time. The results suggest GAE as a promising direction for further research in autonomous vehicle navigation in complex environments.

**Keywords**—Actor-critic; autonomous vehicles; generalized advantage estimation; navigation; reinforcement learning

## I. INTRODUCTION

Autonomous vehicles have the potential to revolutionize transportation by reducing accidents, improving efficiency, and providing access to mobility for those who may not be able to drive [1], [2]. However, their deployment is limited by their ability to navigate complex environments, which can be affected by various factors such as weather, traffic, and pedestrians [3]. In addition, traditional approaches to autonomous navigation often rely on hand-designed rules or pre-defined maps, which may need to be revised to handle the variety and unpredictability of real-world environments [4], [5]. This can lead to poor performance and even accidents in complex scenarios.

From the point of view of robotic applications, one of the main problems in autonomous navigation is localizing the robot's position and orientation in the environment [6], [7]. This is typically done using sensors such as cameras, lasers, and inertial measurement units (IMUs), which provide noisy and partial observations of the environment [8], [9]. The robot must then fuse these observations with a map of the environment and estimate its pose using techniques such as Kalman filters, particle filters, or SLAM (simultaneous localization and mapping). However, these techniques can suffer from drift, ambiguity, and inconsistency, especially in dynamic or cluttered environments, leading to erroneous or uncertain pose estimates [10].

Another problem is planning and executing safe, efficient, and feasible trajectories [11], [12]. The robot must consider various constraints and objectives, such as avoiding collisions, respecting traffic rules, minimizing energy consumption, and

following a given path or mission [13]. This requires sophisticated algorithms that can reason about the robot's dynamics, kinematics, sensor models, and the environment's geometry, dynamics, and hazards [14]. These algorithms may include motion planners, path followers, and trajectory optimizers, which can be implemented using sampling-based planning, optimal control, and reinforcement learning techniques [15]. However, these techniques can be computationally intensive and may only sometimes find a solution, especially in complex or changing environments.

A third problem is adapting and learning from the environment [16]. The robot must learn and generalize from past experiences and observations to improve its performance, robustness, and flexibility [17]. This requires deep learning, transfer learning, and meta-learning, enabling the robot to learn features, models, and policies from data and transfer them to new tasks or situations [18], [19]. However, these techniques require large amounts of data and computation and may suffer from overfitting, generalization error, and sample efficiency.

To address this problem, a reinforcement learning approach using Generalized Advantage Estimation (GAE) to enable autonomous vehicles to learn to navigate complex environments is proposed [20], [21]. Reinforcement learning enables agents to learn by interacting with their environment and receiving feedback as rewards or penalties [22]. It has been successfully applied to various problems, including autonomous navigation [23]. However, traditional reinforcement learning approaches often require many interactions with the environment to learn effectively, which can be impractical in real-time scenarios such as autonomous navigation.

## II. BACKGROUND

GAE is a method for estimating the advantage of each action in a reinforcement learning algorithm, which is used to update the policy [24]. It was developed to address the problem of high variance in traditional reinforcement learning approaches, which can lead to slow learning and poor performance. GAE uses a linear combination of the value function and the reward to compute the advantage, which helps to reduce the variance and accelerate learning. It is effective in various environments, including robotic manipulation tasks [25].

To this end [26] propose Observational Imitation Learning (OIL), a novel imitation learning variant that supports online

training and automatic selection of optimal behavior by observing multiple imperfect teachers. [27] describe a generic navigation algorithm that uses data from sensors onboard the drone to guide the drone to the site of the problem. [28] propose a two-stage reinforcement learning (RL) based multi-UAV collision avoidance approach without explicitly modeling the uncertainty and noise in the environment. It is particularly an arduous task when handling multi-agent systems where the delay of one agent could spread to other agents. To resolve this problem [29] propose a novel framework to deal with delays as well as the non-stationary training issue of multi-agent tasks with model-free deep reinforcement learning. MIDAS uses an attention mechanism to handle an arbitrary number of other agents and includes a “driver-type” parameter to learn a single policy that aims of [30]. A neural network-based reactive controller is proposed for a quadrotor to fly autonomously in an unknown outdoor environment [31]. [32] aim to combine cloud robotics technologies with deep reinforcement learning to build a distributed training architecture and accelerate the learning procedure of autonomous systems. A deep reinforcement learning-based UANO (USVs autonomous navigation and obstacle avoidance) method is proposed [33]. Nowadays, modern Deep-RL can be successfully applied to solve a wide range of complex decision-making tasks for many types of vehicles. Based on this context [34] propose the use of Deep-RL to perform autonomous mapless navigation for Hybrid Unmanned Aerial Underwater Vehicles (HUAUVs), robots that can operate in both, air or water media. Other influential work includes [35].

This work proposes a reinforcement learning approach using GAE for autonomous vehicles navigating complex environments. Our method is based on the actor-critic framework, where the actor-network predicts the actions to take, and the critic network estimates the value of each state. GAE is used to compute the advantage of each action, which is applied to update the actor and critic networks. Our method is evaluated on a simulation of an autonomous vehicle navigating through a series of challenging environments and show that it can learn to navigate effectively and improve its performance over time. Our results demonstrate the potential of GAE for enabling autonomous vehicles to navigate through complex environments and suggest that it could be a promising direction for further research.

### III. PROBLEM STATEMENT

Autonomous vehicles have the potential to revolutionize transportation, but their ability to navigate complex environments is crucial for their practical deployment. Unfortunately, traditional approaches to autonomous navigation often rely on hand-designed rules or pre-defined maps, which may need to be revised to handle the variety and unpredictability of real-world environments. This can lead to poor performance and even accidents in complex scenarios.

Reinforcement learning is a promising approach for enabling autonomous vehicles to learn to navigate through complex environments. However, traditional reinforcement learning approaches often require many interactions with the environment to learn effectively, which can be impractical in real-time scenarios such as autonomous navigation. To address this problem, the use Generalized Advantage Estimation (GAE) to

reduce the variance and accelerate learning in reinforcement learning for autonomous vehicles is proposed.

This research aims to develop a reinforcement learning approach using GAE for autonomous vehicles navigating through complex environments and evaluate its performance on a simulation of an autonomous vehicle navigating through a series of challenging environments. The aim is to demonstrate that our method can learn to navigate effectively and improve its performance over time and to show that GAE has the potential to be a promising direction for further research in this area.

A simplified example to illustrate the basic ideas of using GAE to enable an autonomous vehicle to navigate through a complex environment can be seen in Algorithm 1. In practice, additional factors such as perception, planning, and dealing with real-world constraints and uncertainties must be considered. In this example, the environment is represented by the *Environment* class, which simulates the vehicle’s interactions with the environment. The *actor\_network* and *critic\_network* are neural networks that predict the actions to take and the value of each state, respectively. The Adam optimizer is used to update the networks based on the loss.

The algorithm’s main loop runs through the episodes, where an episode represents one complete run through the environment. Within each episode, the algorithm runs through the timesteps, where a timestep represents one action taken by the vehicle. At each time step, the algorithm predicts the *action* and the *value* using the actor and critic networks, takes action, and observes the next *state*, *reward*, and *done* flag. The *reward* and the *value* are stored in buffers, and the state is updated.

When the episode is complete, the algorithm computes the advantage using the GAE algorithm. It does this by first predicting the *value* of the final state using the critic network and then using this value along with the rewards and values from the episode to compute the returns using the *compute\_gae* function. The difference between *returns* and *values* then defines the *advantages*.

Then actor and critic losses are calculated. Actor loss is a measure of the quality of the action selection. It is computed using the log probability of the action taken, as predicted by the actor-network, and the advantage, as estimated by the GAE. The advantage represents the excess reward obtained from an action over the baseline value, and it reflects the relative importance of the action in the long run. The log probability represents the confidence of the actor-network in the action and reflects the risk of the action in the short run. The actor loss is defined as the negative dot product of these two quantities, which indicates the trade-off between exploration and exploitation. The actor loss is minimized during training to improve the action selection of the robot. Mathematically, the actor loss is defined as (Eq. 1):

$$actor\_loss = -mean(log\_probs \times advantages) \quad (1)$$

where *log\_probs* is a tensor of log probabilities, and *advantages* is a tensor of advantages.

```

---

The critic loss is a measure of the quality of the value estimation. It is computed using the advantage, as estimated by the GAE, and the value, as predicted by the critic network. The advantage represents the excess reward obtained from a sequence of actions over the baseline value, and it reflects the relative importance of the actions in the long run. The value represents the expected reward obtained from a state or action, and it reflects the long-term potential of the state or action. The critic loss is defined as the mean squared error between these two quantities, which indicates the deviation of the value from the true advantage. The critic loss is minimized during training to improve the value estimation of the robot. Mathematically, the critic loss is defined as (Eq. 2):

$$critic\_loss = mean(advantages.pow(2)) \quad (2)$$

where advantages is a tensor of advantages.

Finally, losses are backpropagated, and the model weights are updated. The losses are backpropagated through the model's computation graph to compute the model weights' gradients concerning the losses. The gradients are accumulated over an episode's timesteps and are used to update the model weights using the optimizer algorithm. The optimizer algorithm performs stochastic gradient descent on the model weights, using the gradients as the updated direction and the learning rate as the updated step size.

#### IV. METHODS

The algorithm is developed for a small autonomous robot under the following considerations that replicate the functional characteristics of our working platform (the robot could move to any of the four adjacent cells in the grid by selecting one of the following actions: up, down, left, or right). [36]:

- The robot has a state space of size four, representing the state of the robot in the environment.
- The robot has an action space of size two, which represents the actions that the robot can take in the environment.
- The robot can be rewarded for performing a specific action in the environment.
- The robot's state can change after taking action in the environment.
- The robot's episode can be terminated (done flag set to True) based on a particular environmental condition.
- The robot has an actor-network, which takes in the current state of the robot and outputs a probability distribution over the possible actions.
- The robot has a critic-network, which takes in the current state of the robot and outputs a value estimate for the current state.

Python and PyTorch are used for the implementation. The first step consists of importing the libraries and defining algorithm parameters, such as the number of episodes (1000) and the learning rate (0.001). Next, the actor and critic networks is

defined using PyTorch. The actor-network is a simple feedforward neural network with four input units (corresponding to the state size), two output units (corresponding to the action size), and two hidden layers with eight units each. The critic network is also a simple feedforward neural network with four input units (corresponding to the state size) and one output unit (corresponding to the value estimate). Both networks use ReLU activation functions.

Then, a function called `compute_gae()` is defined to compute the generalized advantage estimate for a given set of rewards, values, and discount factor. This function takes in the following value estimate, the rewards, the values, the discount factor, and the weight factor for the advantage, and returns the generalized advantage estimates.

The next step would be to define the environment with which the robot will interact. This can be done by creating a class for the environment, which should have methods for resetting the environment, stepping through the environment with an action, and checking if the episode is done. The environment should also have necessary attributes, such as the state and reward at each timestep and other relevant information. For example, in the case of a small robot navigating through a maze, the environment may have a 2D grid representation of the maze, with the state being the current position of the robot and the reward being based on the distance to the goal.

Finally, the algorithm's main loop is implemented, consisting of running through a series of episodes. In each episode, the environment is restarted, and the state is initialized. At each time step, the actor and critic networks are used to predict the action and the value, respectively, and the action is performed on the environment. The reward and value are stored in buffers. Once the episode is terminated (either by a termination condition or by reaching a maximum number of timesteps), the GAE algorithm is used to compute the rewards. For this purpose, the function `compute_gae()` is used, which takes the following value (predicted by the critical network), the rewards, the values (predicted by the critical network at each timestep), the discount factor (*gamma*) and the weight factor (*beta*). In the end, it returns the calculated payoffs. The losses of the actor and the critic are calculated using the advantages and the stored probabilities and values. These losses are backpropagated through the networks, and the optimizer updates the networks. This process is repeated for the specified number of episodes, updating the actor and critic networks at each iteration based on the observed rewards and advantages.

## V. RESULTS

The experimental setup was designed entirely in Python 3.8.16 (GCC 7.5.0) and respected the motion constraints of our ARMOS TurtleBot robot as well as the experimental navigation environment. The robot was modeled as an agent of the environment. The Deep-RL algorithm with GEA was also implemented with Python and the PyTorch 1.13.0 library.

For all training episodes, the initial position of the vehicle was set at the origin of the environment (lower left corner), with coordinates (0.0, 0.0), with its front pointing towards the positive x-axis. In each episode, a randomly generated target

point (final navigation destination) was created in the environment that the agent had to reach. In case of encountering an obstacle, or a boundary of the environment, the agent turns its position at a random angle and continues to move forward. The episode ends if the vehicle has reached a total of 1000 steps in that episode. Reaching the target point does not terminate the episode.

The Adam optimizer was used to train the actor and critical neural networks, with a learning rate of 0.001 for each method. In both instances, a 256-piece minibatch size was chosen. According to the reward values the agents attained, a training cap of 1000 episodes was established. In order to ensure a robust and effective learning algorithm, an exploration rate of 0.5 was employed for the actor network and 0.2 for the critic network.

The reward value of one of the tests developed can be seen in Fig. 1. It can be observed that it takes on average a little more than 200 episodes to start learning the task, but after this stage, it increases almost steadily the reward value until it reaches close to the maximum saturation value.

Fig. 1. Moving of the reward over 1000 episodes of the training

Our algorithm has been extensively validated and has consistently demonstrated accurate and effective agent behavior in the environment. The agents were able to learn the features of the environment and generalize their knowledge to successfully navigate without the use of external maps. In addition, they were able to adapt and learn how to avoid obstacles to reach their target destination. These results demonstrate the effectiveness of our algorithm in training intelligent agents to navigate complex environments in a lifelike simulation. This has important practical implications as it shows that our approach can be used to train agents for real-world navigation tasks without the need for external maps. Overall, our findings highlight the potential of our algorithm as a powerful tool for comprehending and learning complex behaviors in simulated environments.

## VI. DISCUSSION

The results of this study demonstrate the effectiveness of using a Deep-RL algorithm with GEA for navigation tasks in a simulated environment for a TurtleBot robot. The experimental setup, implemented in Python and utilizing the PyTorch library, successfully modeled the robot as an agent of the environment

and respected the motion constraints of the TurtleBot. The Adam optimizer was used to train the actor and critic neural networks, with a learning rate of 0.001 and a minibatch size of 256. The exploration rate was set to 0.5 for the actor network and 0.2 for the critic network.

The results show that the agent was able to effectively navigate to the randomly generated target points in the environment, while also avoiding obstacles and boundaries. It was observed that it took on average a little more than 200 episodes for the agent to start learning the task, but after this stage, the reward value increases almost steadily until it reaches close to the maximum saturation value. This suggests that the agent is able to learn the navigation task in a relatively short amount of time and perform well in the environment.

One limitation of this study is that the experiments were conducted in a simulated environment, which may not fully reflect the complexities of a real-world environment. Additionally, the agent's decision-making process was based on a predetermined set of rules, which may not be optimal in all situations. However, the study's results are still a promising step towards the development of intelligent robots that can navigate autonomously in complex environments.

In conclusion, this study has successfully demonstrated the effectiveness of using a Deep-RL algorithm with GEA for navigation tasks in a simulated environment for a TurtleBot robot. The results show that the agent is able to learn the navigation task in a relatively short amount of time and perform well in the environment. Future work can further improve the algorithm's performance by incorporating more realistic environments, and exploring other decision-making methods.

## VII. CONCLUSION

In this paper, a reinforcement learning algorithm for a small robot using generalized advantage estimation (GAE) is presented. The algorithm was implemented in Python and was designed to enable the robot to navigate and interact with its environment to maximize its reward. The robot was designed to operate in a simple 2D environment. The environment consisted of a grid of cells, each of which could be occupied by the robot or contain an obstacle. The robot could move to any of the four adjacent cells in the grid by selecting one of the following actions: up, down, left, or right. At each timestep, the robot received a reward based on its current position and the presence or absence of obstacles in its environment. To enable the robot to learn how to navigate its environment and maximize its reward, a reinforcement learning algorithm using GAE is implemented. The algorithm consisted of two key components: an actor-network and a critic network. The actor network was responsible for predicting the action the robot should take at each timestep based on the current state of the environment. The critic network was responsible for predicting the value of each state, which was used to estimate the expected future reward of each action. A combination of supervised learning and reinforcement learning to train the actor and critic networks is used. Specifically, the actor-network to predict the action the robot should take at each timestep based on the current state of the environment is used. The actor-network was trained using supervised learning,

with the input being the current state of the environment and the output being the predicted action. The critic network was trained using reinforcement learning, with the input being the current state of the environment and the output being the predicted value.

The algorithm was run for a series of episodes, resetting the environment and initializing the state at the beginning of each episode. At each timestep, the actor and critic networks predict the action and value, respectively, and the action is performed on the environment. The reward and value are stored in buffers. Once the episode is terminated, the GAE algorithm calculates the payoffs, and the losses for the actor and critic networks are calculated. These losses are backpropagated and used to update the networks. The results of our experiments show that the robot can successfully navigate through the environment and reach the goal state, with the average reward increasing throughout training. It was observed that the losses of actor and critic networks decrease as training progresses, indicating that the networks are learning effectively.

Overall, our implementation of the GAE algorithm for the small robot demonstrates its effectiveness in learning to navigate through an environment and reach a specific goal state. Furthermore, this algorithm can be extended to other reinforcement learning tasks in various environments, such as control and decision-making.

# A Low-Cost Wearable Autonomous System for the Protection of Bicycle Users

Daniel Mejia<sup>1</sup>, Sergio Gómez<sup>2</sup>, Fredy Martínez<sup>3</sup>  
Universidad Distrital, Francisco José de Caldas  
Bogotá D.C., Colombia

**Abstract**—A bicycle is a form of transport that not only positively impacts the health of users, and the general population by reducing pollution levels but also constitutes an accessible and affordable means of transport for developing societies. However, when coexisting with other forms of transport, the accident rate is elevated, and the risk is high. Among the factors contributing to accidents involving bicycles are collisions with motor vehicles. These accidents can occur when a motor vehicle maneuvers and does not see the bicycle or when a motorist drives distracted. These types of accidents can be avoided if cyclists and motorists are aware of the environment and respect traffic laws and safety regulations. This research aims to develop a low-cost autonomous electronic system that provides extra protection to bicycle users, particularly by making them visible to other road users on cloudy days or at night. The system uses a 32-bit processor with brightness and acceleration sensors that trigger visual alerts to both the bicycle user and possible nearby vehicles. It also monitors and logs the signals on a server for route evaluation. The laboratory successfully evaluated the prototype, demonstrating its autonomy and performance. The test results obtained demonstrate the system's capacity to provide extra protection, in addition to its robustness and accuracy.

**Keywords**—Autonomous system; bicycle users; embedded system; protection; wearable

## I. INTRODUCTION

The bicycle is a mode of transportation that has gained increasing importance in developing countries such as Colombia due to its multiple benefits [1]. First, it is an affordable and accessible form of transportation for many people who cannot afford to buy or maintain a motorized vehicle [2]. In addition, the bicycle is an environmentally friendly means of transportation, as it does not emit polluting gases or produce noise, making it an attractive option in urban environments where air pollution and noise can be severe problems [3].

Another advantage of the bicycle as a means of transportation is its positive impact on people's health [4]. Cycling as a means of transportation is a physical activity that can help improve cardiovascular fitness and burn calories, which can help prevent diseases related to sedentary lifestyles [5]. Furthermore, in developing countries where access to health services can sometimes be limited, cycling can effectively improve the population's health [6].

Cycling can also be an efficient form of transportation in environments with little or no road infrastructure [7]. In many developing countries, road infrastructure can be poor or non-existent, making cycling a practical and effective form of transportation [8]. In addition, cycling as a mode of transport can help reduce traffic congestion in cities, as it takes up less space on roads and streets.

Despite its many benefits, cycling also needs some help as a means of transportation [9]. One of the main problems is the need for adequate cycling infrastructure in many cities and rural areas [10]. This can include a need for dedicated bicycle lanes or safe and adequate parking spaces. This lack of infrastructure can make it difficult and dangerous to use bicycles as a means of transportation in some areas.

Another problem is the need for more acceptance and respect by motor vehicle drivers for bicyclists [11]. So often, drivers are not habituated to sharing the road with cyclists and may be inconsiderate or hostile towards them [12], [13]. This can make it difficult and dangerous for cyclists to share the road with motor vehicles.

Bicycle user accidents in developing countries are a serious and worrying problem [14]. Bicycle accidents can have severe consequences for those involved, including serious injury or death. In addition, bicycle accidents can have a significant economic and social impact, as they can require costly medical care and disrupt people's ability to work and support their families.

Several factors can contribute to bicycle accidents [15]. One of the main factors is the need for adequate infrastructure for bicyclists, such as dedicated bicycle lanes or safe and adequate places to park bicycles. This lack of infrastructure can make it difficult and dangerous to use bicycles as a means of transportation in some areas. However, the most critical factor is the need for more awareness and respect by motor vehicle drivers for cyclists [16]. Often, drivers are not accustomed to sharing the road with cyclists and may be inconsiderate or hostile towards them. In addition, lighting and visibility conditions on the road increase the risk of bicycle accidents.

Lack of adequate lighting on roads and streets is a significant factor in nighttime bicycle accidents [17], [18]. When there is little or no lighting, it can be difficult for bicyclists and other road users to see obstacles or potential hazards, increasing the risk of accidents [19]. In addition, poor lighting can make it difficult for motor vehicle drivers to see bicyclists, which can also increase the risk of crashes [20].

This research proposes a low-cost electronic system capable of increasing the visibility of bicycle users [21]. This system incorporates a 32-bit microcontroller with two cores capable of high-speed response and Wi-Fi and Bluetooth communication [22], [23]. This processor works hand in hand with an illumination level sensor (illuminance) to identify risk states and generate visual and acoustic alerts [24], [25].

The problem addressed in this research is the high accident rate of bicycles when coexisting with other forms of transporta-

tion, particularly motor vehicles. Bicycle accidents can occur when a motorist does not see the bicycle or when the motorist is distracted. These accidents can have severe consequences for cyclists, including injury or death.

One contributing factor to these accidents is the difficulty in seeing bicycles, especially on cloudy days or at night. Cyclists may not be visible to other road users, leading to collisions. In developing societies, where bicycles are often an affordable and accessible form of transportation, this problem is especially relevant.

To address this problem, the research aims to develop a low-cost autonomous electronic system that provides extra protection to bicycle users by making them more visible to other road users. The system uses a 32-bit processor with brightness and acceleration sensors that trigger visual alerts to both the bicycle user and nearby vehicles. It also monitors and logs the signals on a server for route evaluation. The goal is to create a robust, accurate system, and capable of providing extra protection to bicycle users to reduce the risk of accidents.

The following section presents a review of the background considered in the design of the prototype, both at the functional and implementation levels. The methods section summarizes the design criteria, its implementation, and system usage considerations. The results section presents the performance tests and the behavior recorded in laboratory conditions, and finally the conclusions section presents the summarized results.

## II. BACKGROUND

In recent years, there has been a growing interest in the development of innovative Human Activity Recognition (HAR) systems that exploit the potential of wearable devices integrated with deep learning techniques. One such example is presented by [26], who propose an innovative HAR system with the aim of recognizing the most common daily activities of a person at home. The authors use a combination of wearable sensors and deep learning techniques to accurately classify activities such as walking, sitting, and standing. They evaluate the performance of their system using a dataset of daily activities collected from 20 participants and achieve an overall accuracy of 96.7%. This study highlights the potential of using wearable devices and deep learning techniques for accurate recognition of daily activities.

Another area of research in the field of robotics and intelligent systems is the design and construction of low-cost Internet of Things (IoT) sensor meshes for remote measurement of parameters. The author in [27] present a design and construction of a low-cost IoT sensor mesh that enables the remote measurement of parameters of large-scale orchards. The authors propose the use of a mesh network of low-cost, low-power sensors to collect data on temperature, humidity, and soil moisture. The sensor mesh is designed to be easy to deploy, maintain and provides real-time data to the farmers. The system is evaluated in a commercial orchard and the results demonstrate that it can accurately measure temperature, humidity, and soil moisture.

[28] explore the technical development of a multi-user multi-modal traffic simulation platform that expands on the capabilities of traditional traffic simulators. The authors propose

a platform that combines traditional traffic simulation with virtual reality (VR) technology, allowing for multi-user and multi-modal simulations. The platform is evaluated through a case study of a complex urban intersection and the results demonstrate its ability to accurately simulate traffic flow and pedestrian behavior. This study highlights the potential of using VR technology to enhance the capabilities of traditional traffic simulation platforms and improve their accuracy in simulating complex traffic scenarios.

[29] introduce a novel low-cost solar-powered wearable assistive technology (AT) device, whose aim is to provide continuous, real-time object recognition to ease the finding of the objects for visually impaired (VI) people in daily life. The authors propose the use of a low-cost, solar-powered wearable device equipped with a camera and a deep learning-based object recognition system. The device is evaluated through user studies with VI individuals and the results demonstrate its ability to accurately recognize objects in real-time and improve the independence of VI individuals in their daily life.

[30] present a new “active mask” paradigm, in which the wearable device is equipped with smart sensors and actuators to both detect the presence of airborne pathogens in real time and take appropriate action to mitigate the threat. The authors propose the use of an active mask equipped with sensors for detecting airborne pathogens and actuators for releasing disinfectants. The device is evaluated through laboratory tests and the results demonstrate its ability to accurately detect pathogens and effectively release disinfectants.

[31] aim at helping the mobility-challenged individuals with a novel robotic companion, which is a walker-type mobile robot capable of accompanying the human user and keeping user at the center for protection and possible power assistance. The authors propose a robot that can assist mobility-challenged individuals with navigation, object recognition, and power assistance. The robot is evaluated through user studies with mobility-challenged individuals and the results demonstrate its ability to improve the independence and safety of the users.

[32] use VR 360° panoramic technology to develop a virtual wetland ecological system for applications in environmental education. The authors propose the use of VR technology to create an immersive virtual wetland ecosystem for educational purposes. The virtual wetland is evaluated through a user study with students and the results demonstrate its ability to improve the understanding and engagement of students in learning about wetland ecology. This study highlights the potential of using VR technology in environmental education to create immersive and interactive learning experiences.

[33] present a new “active mask” paradigm, similar to the one presented by [30], in which the wearable device is equipped with smart sensors and actuators to both detect the presence of airborne pathogens in real time and take appropriate action to mitigate the threat. The authors propose an active mask equipped with sensors for detecting COVID-19 and actuators for releasing disinfectants. The device is evaluated through laboratory tests and the results demonstrate its ability to accurately detect COVID-19 and effectively release disinfectants.

[34] introduce an artificial intelligence-powered multi-modal robotic sensing system (M-Bot) with an all-printed

mass-producible soft electronic skin-based human-machine interface. The authors propose a robot that can sense and interact with its environment through an electronic skin interface. The robot is equipped with AI algorithms for object recognition and tactile sensing. The robot is evaluated through laboratory tests and the results demonstrate its ability to accurately sense and interact with its environment through its electronic skin interface.

[35] develop an air quality monitoring platform that comprises a wearable device embedding low-cost metal oxide semiconductor (MOS) gas sensors, a PM sensor, and a smartphone for collecting the data using Bluetooth Low Energy (BLE) communication. The authors propose a wearable device for monitoring air quality, specifically for PM and gas pollutants. The device is evaluated through laboratory tests and the results demonstrate its ability to accurately measure PM and gas pollutants in the air.

### III. METHODS

The project's objective was to develop a low-cost wearable system (accessible to the average user) with high processing and communication capabilities. To meet these criteria, a vest was developed with embedded electronics equipped with sensors and display units, both for the user and individuals on the road. The control unit selected was the ESP32 SoC (System On a Chip) from Espressif Systems, which is supported by a 32-bit, dual-core Tensilica Xtensa LX6 microprocessor. This processor supports a clock frequency of up to 240 MHz, with a performance of up to 600 DMIPS (Dhrystone Million Instructions Per Second). In addition, the SoC has Wi-Fi/Bluetooth functionalities that cover the protection system's communication requirements.

The protective vest also incorporates other essential safety elements for urban cyclists, among them are the following:

- **Reflective elements:** The vest includes reflective stripes and other reflective elements to help make the wearer more visible to other road users, especially in low-light conditions.
- **High visibility colors:** The design of the vest uses brightly colored and evident materials, such as neon yellow and orange, to help improve visibility.
- **LED lights:** A signaling system with LED lights have been incorporated into the vest to increase visibility. The protection system control unit controls these lights.
- **Breathability:** Breathable materials have been used in the vest design, which is especially important if you are cycling in hot climates to avoid overheating.
- **Fit:** The vest incorporates adjustable straps to fit different body types. To improve safety, a good fit should be ensured, and comfort should be improved.
- **Durability:** The vest must be made of durable materials that can withstand regular use and wear.
- **Water resistance:** Special care was taken to ensure that the vest would function in wet conditions. In

addition, a water-resistant vest can help keep the wearer dry and comfortable.

A series of sensors were incorporated into the control unit, including the illuminance sensor (luminous flux per unit area). The BH1750 sensor was used, a digital light sensor that measures in Lux (lumen/m<sup>2</sup>). The sensor uses I<sup>2</sup>C communication, has high precision, and ranges from 1 to 65535 lx. This sensor was calibrated in the laboratory with a reference lux meter in a dark room with lighting control (Fig. 1). Low values correspond to low illumination conditions, and high values to high illumination conditions. The measured error averaged 4.8%, with maximum values of 14.6%.

Other sensors and peripherals incorporated into the system include:

- A U-Blox NEO-6M GPS (Global Positioning System) U-Blox NEO-6M, a high-accuracy, low-cost GPS module for global tracking.
- A GY-521 MPU-6050 module incorporating a gyroscope and accelerometer, both with MEMS technology, has six axes of freedom (three axes of the accelerometer and three axes of the gyroscope).
- Two 32×8 pixel LEDs grid with Bluetooth to alert people close to the cyclist.
- One 84×48 pixel monochrome graphic display with PCD8544 controller for communication with the user.
- A small Lithium-ion (Li-ion) battery pack.

A road safety vest for cyclists is a portable system designed to increase the visibility and safety of cyclists when riding on the road. Functionally, the essential part is the control unit, based in our case on the ESP32 SoC, which is responsible for processing the inputs coming from the sensors and controlling the output of the vest. The following describes in detail how the control unit of the road safety vest works with illuminance sensors, gyroscope, accelerometer, GPS, and LED displays to show the status to vehicle drivers and a display to inform the user.

First, let's consider the role of the illuminance sensors. These sensors detect the ambient light level in the environment where the vest is being worn. This information is vital because the vest's LED displays, which communicate the wearer's status to vehicle drivers, need to be bright enough to be seen in low-light conditions but not too bright to be distracting in bright-light conditions. The SoC control unit will use the illuminance sensors' data to adjust the LED displays' brightness accordingly. The information displayed is congruent with the state of the cyclist, which is supported by the accelerometer. Therefore, this information is accentuated in the LED array, as well as if he/she is stopped or brakes suddenly.

Next, let's consider the role of the gyroscope and accelerometer. These sensors are used to detect the movement and orientation of the vest. The gyroscope measures angular velocity, which allows the microcontroller control unit to determine the vest's orientation in space. The accelerometer measures acceleration, which allows the microcontroller control unit to determine the vest's movement. This information is helpful for several reasons. For example, suppose the vest is

Fig. 1. Illuminance sensor vs. reference sensor characteristics

worn while cycling. In that case, the accelerometer can detect when the wearer is braking or accelerating, which can activate the LED displays to alert vehicle drivers of the wearer's intentions. Likewise, the gyroscope can detect when the wearer is turning, which can also activate the LED displays to alert vehicle drivers of the wearer's intentions.

The GPS (Global Positioning System) sensor determines the vest's location. This information is used by the SoC control unit to display the wearer's location on the display screen and to report the tracking information to a web server, which can be helpful for navigation purposes. Additionally, the GPS data can activate the LED displays when the vest is approaching a location where it is vital for the wearer to be more visible, such as a busy intersection.

The LED displays on the vest are used to communicate the wearer's status to vehicle drivers. For example, the LED displays can be activated to show a solid red light when the wearer is braking, a solid yellow light when the wearer is turning, and a solid green light when the wearer is accelerating. The LED displays can also display a flashing red light when the vest is approaching a location where it is crucial for the wearer to be more visible, such as a busy intersection.

Finally, the vest should also have a display screen to inform the user of various information, such as the vest's battery level, the current time, and the wearer's location on a map. The SoC control unit can use the data from the various sensors to update this information on the display screen in real time.

The SoC control unit of the road safety vest incorporates illuminance sensors, a gyroscope, accelerometer, GPS, LED displays to show the status to vehicle drivers, and a display to inform the user should function by using the data from the various sensors to control the output of the vest. The illuminance sensors are used to adjust the brightness of the LED displays, the gyroscope and accelerometer are used to detect the vest's movement and orientation, the GPS sensor is used to determine the vest's location, and the LED displays

are used to communicate the condition of the cyclist to other road users, primary drivers of motorized vehicles (Fig. 2).

#### IV. RESULTS AND DISCUSSION

The performance evaluation of the system was aimed at ensuring that the vest effectively increases cyclists' visibility and safety when riding on the road. In this regard, firstly, the role of illuminance sensors was considered. The performance of these sensors can be evaluated by measuring the accuracy of the ambient light level readings they provide. This was done by comparing the sensor readings with the actual ambient light level in the environment using a light meter. The sensors must provide accurate readings because the vest's LED displays, which are used to communicate the wearer's status to vehicle drivers, must be bright enough to be seen in low light conditions but not too bright to be distracting in bright light conditions (Fig. 3).

Another critical part of the testing considered the role of the gyroscope and accelerometer. The performance of these sensors was evaluated by measuring the accuracy of the angular velocity and acceleration readings they provide. This was done by comparing the sensor readings with the actual angular velocity and acceleration of the vest using a separate device (a gyroscope and a high-precision accelerometer). The sensors must provide accurate readings because they are used to detect the vest's motion and orientation, which activate the LED displays that alert vehicle drivers of the wearer's intentions.

The performance of the GPS (Global Positioning System) sensor was evaluated by measuring the accuracy of the location readings it provides. This was done by comparing the sensor readings with the actual location of the vest using an independent GPS device and a map. Accurate location readings are essential for the sensor because the vest's display uses this information to show the user's location. This information is also used to track the user on the Internet. In addition, the

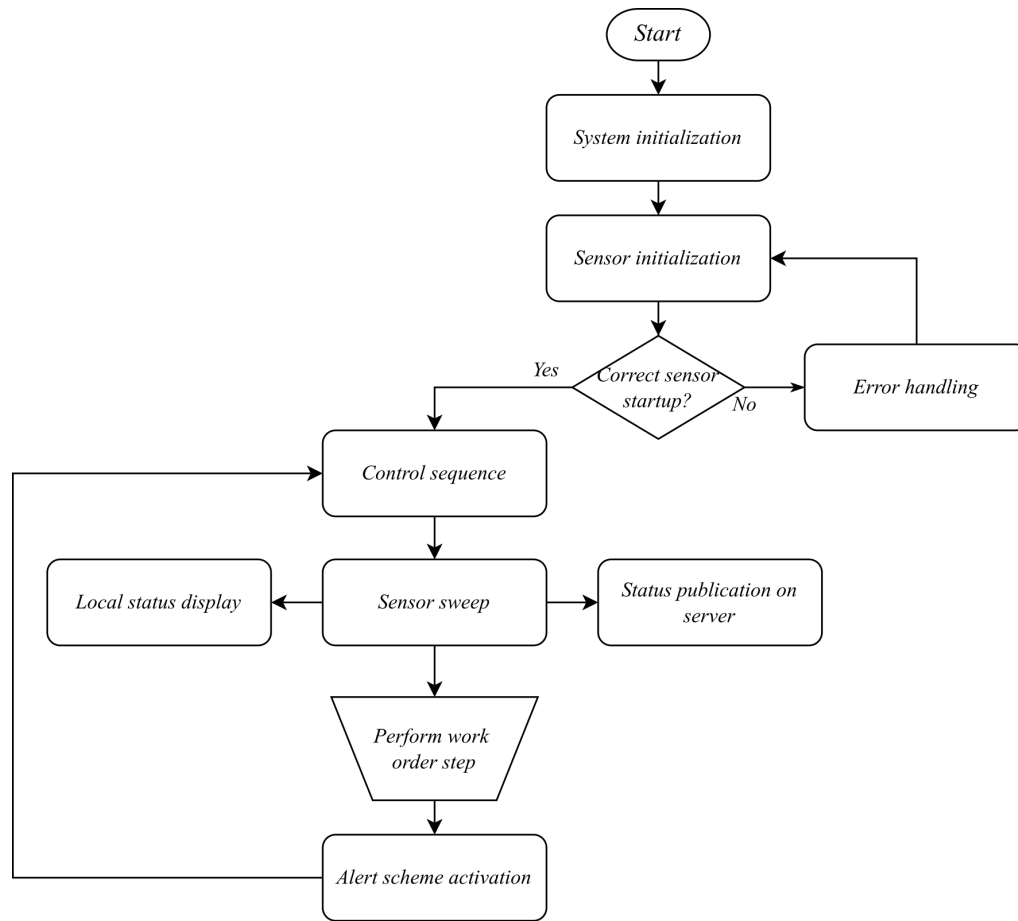

Fig. 2. Proposed operating strategy

Fig. 3. Illuminance sensor tests

at different angles as they communicate the wearer's status to vehicle drivers.

Finally, the performance of the display screen that informs the user of various data, such as the vest's battery level, the current time and the user's location coordinates, was evaluated by measuring the accuracy and readability of the information it displays. This was done by comparing the information displayed on the screen with that of another device and by viewing the screen from different positions while wearing the vest. The display screen must provide accurate and legible information because it is used to inform the wearer of various vital details. In addition, the logging of information of all variables detected by the vest to the web server was verified, which should include the date and time information, and match the information displayed to the user in real-time (Fig. 4).

GPS data is used to activate the LED displays when the vest approaches a location where it is vital for the wearer to be more visible, such as a busy intersection.

The performance of the LED displays was evaluated by measuring their visibility from different distances and angles. This was done by observing the displays from different positions while wearing the vest and comparing the visibility to a standard. The displays must be evident from a distance and

In summary, the cycling safety vest's performance meets the design profile's performance expectations. It has an excellent response to changes in illuminance and provides high visibility by combining LED lights with bright, high-visibility colors. The response characteristics to sudden changes in acceleration and geographic location increase user protection in situations beyond their control. The system will be further tested for mechanical robustness, ergonomics and comfort to meet additional design parameters.

Fig. 4. Tracking of system variables

## V. CONCLUSION

In conclusion, the proposed safety vest for cyclists is a portable and innovative device that aims to improve the visibility and safety of cyclists on the road. The vest incorporates illuminance sensors, a gyroscope, an accelerometer, GPS, and LED displays to show the status to vehicle drivers and a display to inform the user. The SoC that controls the vest is responsible for processing the information from the different sensors and controlling the output of the vest. The illuminance sensors measure the ambient light level in the environment in which the vest is worn, which is vital for adjusting the brightness of the LED displays accordingly. The gyroscope and accelerometer, meanwhile, measure the movement and orientation of the vest and are used to activate the LED displays and alert vehicle drivers of the wearer's intentions. The GPS sensor determines the location of the vest. It is used to display the wearer's location on the screen and to activate the LED displays when the vest approaches a location where the wearer needs to be more visible, such as a busy intersection. All detected information is transmitted in real-time to a web server for logging and tracking. LED displays are used to communicate the user's status to vehicle drivers, showing solid red light when the user brakes, solid yellow light when turning, and a solid green light when accelerating. They can also be used to display a flashing red light when the vest approaches a location where the wearer needs to be more visible. Finally, the vest also has a display that informs the user of the vest's battery level, the current time and the user's location on a map.

The results of the laboratory tests show that the vest is a well-designed and effective device that can significantly improve the visibility and safety of cyclists. The ability to adjust the brightness of the LED displays based on the ambient light level detected by the illuminance sensors ensures that the displays are always visible to vehicle drivers, regardless of lighting conditions. In addition, the gyroscope and accelerometer allow the vest to detect the wearer's movement and orientation, which can activate the LED displays and alert drivers of the wearer's intentions. Finally, the GPS sensor allows the vest to determine its location, which can be displayed on a map on the display screen for navigation purposes and used to

activate the LED displays when the vest approaches a location where the wearer must be more visible.

Future work on this vest could include the integration of additional sensors, such as a heart rate monitor, to provide the user with even more information about their physical condition while cycling. Another potential improvement could be the integration of a communication system, such as a two-way radio, to allow the user to communicate with other cyclists or vehicle drivers in their vicinity. Additionally, the vest could be integrated with a smart phone app that allows the user to remotely control the vest's functions and view real-time data from the sensors. Finally, further testing and evaluation of the vest in real-world conditions, including in different weather conditions, would help to further optimize its performance and effectiveness.

## ACKNOWLEDGMENT

This work was supported by the Universidad Distrital Francisco José de Caldas, specifically by the Technological Faculty. The views expressed in this paper are not necessarily endorsed by Universidad Distrital. The authors thank all the students and researchers of the research group ARMOS for their support in the development of this work.

# An Automated Impact Analysis Approach for Test Cases based on Changes of Use Case based Requirement Specifications

Adisak Intana<sup>1</sup>, Kanjana Laosen<sup>2</sup>, Thiwatip Sriraksa<sup>3</sup>  
College of Computing, Prince of Songkla University, Phuket, Thailand

**Abstract**—Change Impact Analysis (CIA) is essential to the software development process that identifies the potential effects of changes during the development process. The changing of requirements always impacts on the software testing because some parts of the existing test cases may not be used to test the software. This affects new test cases to be entirely generated from the changed version of software requirements specification that causes a considerable amount of time and effort to generate new test cases to re-test the modified system. Therefore, this paper proposes a novel automatic impact analysis approach of test cases based on changes of use case based requirement specification. This approach enables a framework and CIA algorithm where the impact of test cases is analysed when the requirement specification is changed. To detect the change, two versions as before-change and after-change of the use case model are compared. Consequently, the patterns representing the cause of variable changes are classified and analysed. This results in the existing test cases to be analysed whether they are completely reused, partly updated as well as additionally generated. The new test cases are generated automatically by using the Combination of Equivalence and Classification Tree Method (CCTM). This benefits the level of testing coverage with a minimised number of test cases to be enabled and the redundant test cases to be eliminated. The automation of this approach is demonstrated with the developed prototype tool. The validation and evaluation result with two real case studies from Hospital Information System (HIS) together with perspective views of practical specialists confirms the contribution of this tool that we seek.

**Keywords**—Change impact analysis approach; test case; black-box testing; use case based requirement specification; combination of equivalence and classification tree method

## I. INTRODUCTION

Software testing is one of the most necessary and integral stages in the software development life cycle [1]. It consists of a set of activities that are performed by using a systematic approach. This enables a System Under Test (SUT) to be executed on a set of test cases to ensure that the software system is free from error. Black-box testing is one of the software testing methods that examines the functionality of software without knowing the internal structures or mechanisms. It is sometimes called specification-based testing as this type of software testing is being performed to validate the complete or integrated software based on the Software Requirements Specification (SRS) document. Test cases are usually derived from software artifacts such as specifications and design. Software testers initially go through the requirement document to understand requirements and specifications before designing and generating test cases.

Recently, black-box testing techniques have been widely applied in many practical software development domains including Point of Sales (POSs) [2], Internet of Things (IoTs) [3], School Payment Information System [4] and e-Learning system [5]. The result of this application can confirm that black-box testing can guarantee the correctness of the system functionality whether it meets the expected users' needs. Furthermore, in the software testing community, several black-box testing techniques have been introduced. The widely known black-box testing techniques include Equivalence Class Partition (ECP) [1], Boundary Value Analysis (BVA) [1], Classification Tree Method (CTM) [6], [7], Decision Table-Based Testing [1], State Transition Testing [1]. These influence the benefit which maximises test case coverage with a minimised number of test cases. However, one of the research challenges in software testing is that since the generated test case is normally derived from the SRS document, changing requirements always impacts on the existing previous test cases which are unable to be retested in the modified system [8], [9]. As the advanced technology demands businesses grow and evolve their needs, the requirement of systems becomes more complex and continuously changes. Over time, some domain features may not be needed, therefore either removing or replacing them with a new feature, whilst may be refined [8], [9]. Whenever the software requirement is changed, the testing process is affected. This leads to new test cases being created from the changed version of software requirements specification. Consequently, this causes considerable time and resource effort to generate test cases to test all new systems to ensure that all components in the system are connected and functioning correctly. Thus, Change Impact Analysis (CIA) for testing is needed to determine how much software testing and test automation should be performed by software testers after the change.

Therefore, in our previous work [10], we proposed the conceptual vision of impact analysis framework of test cases based on changes of use case based requirements. This framework analyses the impact on changes of test cases when variables in use case specification are changed. Five patterns of atomic changes were designed specifically according to the change of use case specification affecting the test case as 1) change of variable name, 2) change of variable type, 3) change of variable range value, 4) change of number of variables, and 5) change of variable order. The result of this impact analysis enables the existing test cases to be completely reused, partly updated as well as additionally generated. The modified version of test cases is generated with the Combination of Equivalence

and Classification Tree Method (CCTM), the hybrid testing generation approach of ECP with CTM testing technique. The combination of testing technique increases the level of testing coverage and reduces the redundant test cases. The effectiveness of this framework was demonstrated manually with the real case study, *Kidney Failure Diagnosis (KFD) system*.

The work proposed in this paper is extended from our previous work [10]. This paper presents an automated impact analysis approach of test cases based on changes of use case based requirement specification. The automation of this approach is demonstrated by an automatic prototype tool in which the CIA algorithm of the approach is implemented in this tool. To detect changes, the tool provides consistency checking by comparing two versions as before-change and after-change of use case XML files. Five patterns of atomic changes designed specifically are encoded into this tool to analyse and classify the cause of the change. The tool also performs the analysis of level of change impact on the before-change version of test cases that are classified into four groups as *no-change*, *delete*, *update* and *create* categories. To create the new test cases, CCTM was implemented in the tool. Furthermore, we show the applicability and efficiency of the proposed automatic approach and tool with two case studies formulated from real-world Hospital Information System (HIS) with perspective views of practical specialists. The result of this test case generation from these case studies by the tool was compared with the expected test cases that were calculated manually to validate the accuracy and effectiveness of both approach and implementation. The reusability level of test cases was also evaluated by the case studies. Moreover, the satisfactory level of the proposed approach and tool was evaluated from practical specialists for potential application in the future.

The rest of the paper is structured as follows. Section II gives the necessary background and related work. Then, Section III describes and demonstrates the proposed impact analysis approach and the detailed algorithm with our experienced case study. In Section IV, we demonstrate the proof of concept of our proposed approach through the evaluation of implemented prototype tool for impact analysis of test cases with two real-world case studies. Section V presents lesson learned and discussions of this study. Finally, conclusions and areas of future work are summarised in Section VI.

## II. RELATED WORK

There are some research studies dealing with the application of the CIA approach to analyse the effect level of test case changes [11], [12], [9], [8], [13]. Some of these focus on the impact analysis of test cases from changes in database schema such as the work proposed by [12], [13]. The author in [12] presented a tool for analysing the changes of database schema encoding in terms of embedded SQL in the source code. The database schema change is detected from the recorded log file before the impact of the corresponding embedded SQL in the source code is analysed and new test cases are finally generated. In [13], the impact of changes in database schema requirements such as addition, deletion, modification or change of some schema values is analysed before a set of test cases corresponding to the change is generated.

Some research studies proposed a CIA framework for test cases from the change of specification [11], [9], [8], [14]. The author in [11], [9] proposed the impact analysis framework of test cases from the change of use case specification. The author in [11] proposed a test case selection framework based on the change of two versions of use case description. These two versions of the use case description are encoded in XML file format and used as input for this framework. Requirement validation matrix mapping the use case with its corresponding generated test cases is used to check and track the change of use cases. When there are changes in the use case, the existing test case affected from the change is considered whether it can be reusable. The author in [9] extended the capability of [11] in which the requirement validation matrix is generated automatically from the old version of use case description when it does not exist. However, both former research studies only analyse the impact results in either the existing test case from the previous version can be reused or the new test case must be generated. They do not classify the cause of change into a pattern which may help testers to analyse the change of test cases faster and more efficiently. Furthermore, their framework does not support the automatic test case generation in the case that new test cases are required to be generated due to the added feature or requirement. Recently, [14] proposed a CIA approach for test cases affected from the change of inputs or outputs of functional requirements. The approach offers the change process enabling the change control over functional requirements, test cases and database schema. The rollback mechanism is also provided to support in the case of cancelling of changes. Similar to other earlier mentioned studies, the cause of change is not classified and the level of reusability is not specified in this work.

The closely related work is proposed by [8]. They proposed the impact analysis framework of test cases from the change of use case specification. They introduced seven patterns indicating the cause of changes into their impact analysis tool. This includes the change of 1) variable name, 2) data type, 3) variable value, 4) variable tag, 5) order, 6) link and 7) variable number. They are used to analyse the two versions of HTML document and XML schema file representing the previous and changed version of input and output specified in the Graphic User Interface (GUI) of web application. ECP and BVA testing techniques are used to generate the new test case. From our literature reviews, we can conclude that there are few attempts at the specification level. Therefore, our challenge is to contribute an impact analysis approach for test case based on changes of requirement specification.

## III. MATERIALS AND APPROACH

### A. Framework of Impact Analysis of Test Cases

A conceptual overview of an impact analysis framework of test cases based on changes of use case proposed in our preliminary work [10] as shown in Fig. 1. This framework is divided into four steps: 1) variables in two versions as before-change and after-change of the use case specification model are extracted. Then, 2) the extracted variables from these two versions are compared. This results in the variables affected from the requirement change to be identified. The cause of changes is also identified. There are five patterns of atomic changes classified for the cause of changes that are a) change of

variable name, b) change of variable type, c) change of variable range value, d) change of number of variables and e) changes of variable order. After that 3) the impact analysis of test cases is performed. This enables the corresponding test case from the before-change version recorded on the database to be retrieved in order to analyse the level of change impact. Consequently, the analysed test cases are classified into four groups that are *no-change*, *delete*, *update* and *create* categories. In the case of no change effect, the test case is totally reused in the new version. However, if change impacts of test cases are detected, either the affected test case is updated giving it improvement or 4) the new test case is fully generated according to the additional requirement by using CCTM technique.

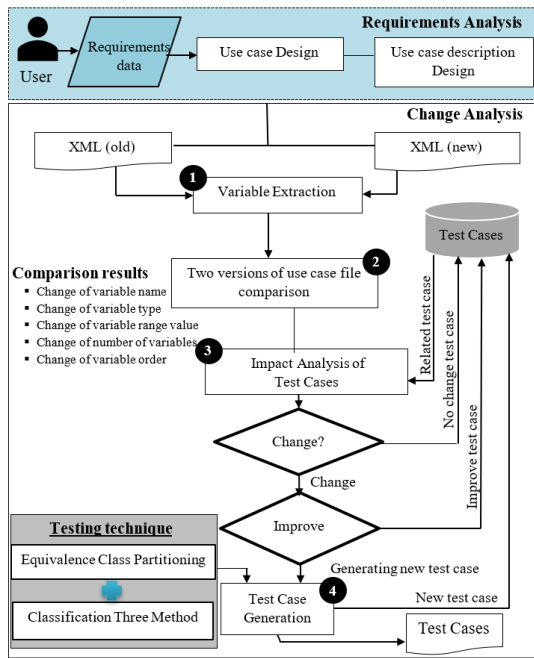

Fig. 1. Framework of impact analysis of test cases [10]

### B. Case Study

To demonstrate the effectiveness of our approach, we formulate our case study, Medical Record System (MRS) from a real-world system, Hospital Information System (HIS)<sup>1</sup>, an open-source software based on Java platform. The system was deployed over 90 hospitals in Thailand. This system has been chosen as it is a safety-critical system related to human diagnosis that requires a high degree of correctness. Furthermore, we select two real case studies from the subsystem that has the requirements changing issues, these types of modules require a high degree of accuracy calculation and measurement. To explore the effectiveness of our approach, we chose Kidney Failure Diagnosis (KFD) and Online Nursing Assessment (ONA) subsystems from HIS. Table I shows the criteria of the selected case studies from the different level of complexity. Number of implemented use cases is the first criteria to demonstrate the complexity of system. As the Cartesian product method is used in testing technique in which all variable range value are multiplied together to generate test

cases, number of variable is the second criteria. Number of change requests influencing five patterns of atomic changes is the other criteria used for case study selection. As can be seen in this table, KFD is a simple case study that is used to demonstrate and evaluate how the proposed approach and its implemented prototype tool work. ONA is a more complex case study compared to KFD in terms of number of use cases, variables and change requests. Moreover, it contains the change requests covering all patterns of atomic changes. Therefore, ONA is more focused on the evaluation of the efficiency of the approach and implementation. Specifications of these systems are described in the following sections.

TABLE I. CASE STUDIES CHARACTERISTICS

System	# use cases	# variables	# change requests	# change of				
				variable name	variable type	variable range value	number of variables	variable order
KFD	3	6	3	×	×	-	×	×
ONA	5	19	4	×	×	×	×	×

1) *Kidney Failure Diagnosis (KFD) Subsystem*: KFD is a subsystem in MRS that records the history of patient treatment. KFD subsystem provides the result of kidney failure analysis to physicians helping them to diagnose whether their patients kidney disorders are abnormal. The Chronic Kidney Disease (CKD) of a patient is calculated and used to interpret the stage of kidney disease by this system. This calculation is based on two factors: *Glomerular Filtration Rate (GFR)* and *Uric Acid Creatinine (UO)*. *GFR* is a calculation that is used to determine how well the kidneys function by estimating the blood that is filtered by the kidneys. *GFR* is normally calculated by using mathematical formula including the *Age*, *Gender* and *Serum Creatinine (Scr)* of patients. Failure of the patient kidney is interpreted by determining *GFR* values together with the effects of *UO*. This results in the stage of kidney failure to be interpreted and suggests what treatment is applied to the patient. After this diagnosis and applying the treatment to the patient, the nurse records the information regarding the measured factors, interpretation and diagnosis results into the system, so that the physician can view the history of treatment in order to monitor the patient disease later.

**Requirements.** The requirements of this system are summarised as follows:

- **REQ1:** The system shall automatically calculate *GFR* value for the patient from *Gender*, *Age* and *Scr*.
- **REQ2:** The system shall accurately perform the kidney failure state from *GFR* and *UO* value mapping in five stages.
  - *Stage 1 (Risk Stage):*  $GFR \geq 90$  AND  $UO > 300$  mg/g
  - *Stage 2 (Injury):*  $GFR = 60-89$  AND  $UO > 300$  mg/g
  - *Stage 3 (Failure):*  $GFR = 30-59$  AND ( $UO = 30-300$  mg/g OR  $UO > 300$  mg/g)
  - *Stage 4 (Loss):*  $GFR = 15-29$  AND ( $UO <$

<sup>1</sup><http://www.opensource-technology.com>

- 30 mg/g OR UO = 30-300 mg/g OR UO > 300 mg/g)
- o Stage 5 (ESRD): GFR < 15 AND (UO < 30 mg/g OR UO = 30-300 mg/g OR UO > 300 mg/g)
- **REQ3:** The interpreter of kidney failure states per a patient must be displayed at only one stage.

**Use Case based Specification Model.** The use case diagram of KFD subsystem is shown in Fig. 2. It consists of three modules as demonstrated as use cases UC001-UC003 that covers all KFD functionality including GFR calculation, interpretation and display that correspond to requirements REQ1-REQ3, respectively. The detailed functionality of each use case is represented in the form of use case description as shown in Fig. 3. This figure demonstrates a brief description of use case UC001 that describes the behaviour of function GFR calculation. It explains the sequence of the step for use case UC001 including *main flow of events*, *alternative of events* and *exception flow* of each use case. The flow of events demonstrates the main step-by-step of GFR calculation. Furthermore, the input for GFR calculation including *Gender*, *Age* and *SCr* used to calculate *GFR* is also indicated in the corresponding step. After the GFR calculation, the GFR stage is interpreted as an output of this functionality. Based on the input and output, the relevant variables affected the change of test cases can be analysed and stored in the XML dictionary document for generating test data.

Fig. 2. Use case model for KFD subsystem

Use Case#	UC001: GFR Calculation
Pre-conditions:	System shows the menu to record GFR
Primary Actor:	Nurse
Flow of Events:	1 The system shows the GUI to input data. 2 The nurse inputs medical record ( <i>Gender</i> , <i>Age</i> and <i>SCr</i> ). 3 The nurse saves the medical record. 4 The system calculates GFR [E1] [E2] [E3]. 5 The system interprets GFR stage via the use case UC002, <i>GFR Interpretation</i> . 6 The system displays GFR stage via the use case UC003, <i>GFR Display</i> .
Alternative of Events:	...
Exception Flows:	1 [E1] If the nurse inputs the variables ( <i>Gender</i> , <i>Age</i> and <i>SCr</i> ) that are not in the correct range, the system will display "Error GFR calculation". 2 [E2] If the system maps wrong input of variables, the system will display "Wrong Interpretation". 3 [E3] If the system maps input that is not in the correct range, the system will display "GFR stage does not match".
Version	01

Fig. 3. Example of use case description of UC001 (Version 1)

Considering each use case diagram of the KFD subsystem, variables from the data dictionary of the system are introduced and used as input data, as shown in Table II. This table contains *variable names*, *variable types* and *data range* values. The type of variable and the range value of data for each variable are determined for the purpose of creating the test data such as

valid variables of *Gender* are *F* and *M*, variable *Age* contains the correct data range values: *0-120*, which is in the range of data interest.

TABLE II. DATA DICTIONARY OF UC001 (VERSION 1)

Variable Name	Description	Data Type	Data Range
Gender	Gender of patients	Varchar(1)	F, M
Age	Age of patients	Integer	0-120
SCr	Serum Creatinine	Float	0.0-10.0
UO	Urine Albumin	Integer	0-∞
GFR	Glomerular Filtration Rate	Integer	0-∞
Stage	Kidney Failure Stage	Varchar(255)	Stage 1-Stage 5

**Requirement Change Requests.** There were the changes of the detailed requirement in the first version of use case based specification model from the user that were recorded in the requirement change request form as shown in Table III. The user requested to change the formula for GFR calculation as identified in **CH01**. This change request affected the functionality of requirement **REQ1**. In the first version, only a single formula was used to calculate GFR for all ages. In the changed version, five formulas are used for different ages instead as demonstrated in Table IV. The GFR calculation is measured separately for an adult patient whose age is greater than and equal to 18 with different *Sex* and *SCr* and a child patient who has age less than 18. Moreover, the factor *Height* is also included in the changed formula for the child patient. There was also change request **CH02** that results in the change in requirement **REQ2** in which variable *Gender* was renamed to be *Sex*. In the last change request **CH03**, the data type of GFR were also changed from integer to float. The relevant variables in the changed version are analysed as shown in Table V.

TABLE III. THE CHANGE REQUEST OF KFD SUBSYSTEM

Change ID	Change Description	Affected Requirement ID	Affected Use Case ID
CH01	Change the formula for GFR Calculation	REQ1	UC001
CH02	The name of variable change from gender to sex based on the table of GFR formula	REQ2	UC003
CH03	Change data type of <i>GFR</i> to decimal	REQ3	UC002

TABLE IV. THE CHANGED GFR FORMULA

Age	Sex	SCr	Formula
≥ 18	F	≤ 0.7	$GFR=144 \times (SCr/0.7)^{-0.329} \times (0.993)^{Age}$
		> 0.7	$GFR=144 \times (SCr/0.7)^{-1.209} \times (0.993)^{Age}$
	M	≤ 0.9	$GFR=141 \times (SCr/0.9)^{-0.411} \times (0.993)^{Age}$
		> 0.9	$GFR=141 \times (SCr/0.9)^{-1.209} \times (0.993)^{Age}$
< 18	F/M		$GFR=0.413 \times Height(cm)/SCr(mg/dL)$

Note: F=Female, M=Male

Fig. 4 and Table V describe the use case description and its corresponding details of data dictionary in the changed version respectively. Based on the requirement change, there is a change in variable *Age* in which the data range value of this variable is changed from *0-120* to two range values that are *0-17 (<18)* and *18-120 (≥ 18)*. As the value of variable *SCr* is calculated based on the value of variables *Sex* and *Age*

as shown as the different equations in Table IV, This affects the value of this variable to be changed. The range value of factor *SCr* is divided into two main criteria for female and male which is ( $\leq 0.7$ ,  $> 0.7$ ) and ( $\leq 0.9$ ,  $> 0.9$ ) respectively. Furthermore, as the height of patients is included into the changed formula, variable *Height* with its range value (0-300) is added into the new version of data dictionary. Finally, the type of variables *GFR* is changed from integer to floating point as to increase more accurate and precise result interpretation.

Use Case#	UC001: GFR Calculation
Pre-conditions:	System shows the menu to record GFR
Primary Actor:	Nurse
Flow of Events:	<ol style="list-style-type: none"> <li>1 The system shows the GUI to input data.</li> <li>2 The nurse inputs medical record (<i>Gender, Age, Height and SCr</i>).</li> <li>3 The nurse saves the medical record.</li> <li>4 The system calculates GFR by using the formula depends on <i>Gender</i> and <i>Age</i> [E1] [E2] [E3].</li> <li>5 The system interprets GFR stage via the use case <i>UC002, GFR Interpretation</i>.</li> <li>6 The system displays GFR stage via the use case <i>UC003, GFR Display</i>.</li> </ol>

2) *Online nursing assessment (ONA) subsystem*: ONA subsystem is used to record the clinical information of the patient in order to be used to evaluate the symptoms of the patient and consider the treatment for the doctor including medicine dispensing to patients and accurate treatment.

**Requirement.** The following are the requirements of this subsystem:

- **REQ1:** Nurses shall record nursing assessment data such as patient severity (*Triage*), service type (*Visit-Type*), service status (*VisitStatus*), *allergy, pregnancy, and lactation* status.
- **REQ2:** Nurses shall record the clinical information of the patient including vital signs (V/S), which includes pulse rate (*pulse*), respiratory rate (*RR*), body temperature (*Temp*) and blood pressure (*BP*), as well as weight (*weight*), height (*height*) and waistline (*waistline*) for patients. The normal range value of each clinical information is shown as follows.
  - *Pulse:* 60-100 time/min.
  - *PR:* 12-18 time/min.
  - *Temp:* 36.5-37.5 °C
  - *BP:* 90/60-120/80 mmHg

- **REQ3:** The system shall automatically calculate Body Mass Index (*BMI*) for patients. The formula is calculated as *BMI = Weight divided by square meter of height*.
- **REQ4:** The level of nutrition is divided into five levels as follows [15]:
  - *BMI < 18.5:* Underweight
  - *BMI ≤ 18.5 and BMI ≥ 24.9:* Normal weight
  - *BMI ≤ 25.0 and BMI ≥ 29.9:* Pre-obesity
  - *BMI ≤ 30.0 and BMI ≥ 34.9:* Obesity class I
  - *BMI ≤ 35.0 and BMI ≥ 39.9:* Obesity class II
  - *BMI ≥ 40.0:* Obesity class III

**Use Case based Specification Model.** The use case diagram corresponding to the requirements described in the previous section is shown in Fig. 5. There are two actors specified in this use case, the nurse and doctor. Two main use cases are identified, *UC01: Assessment Record* and *UC02: Vital Sign Record*. Use case *UC01* implements requirement **REQ1** regarding nursing assessment record, whereas requirement **REQ2** regarding operation recording the clinical information of the patient is implemented by use case *UC02*. After recording such clinical information, the calculation and interpretation operation is performed based on requirements **REQ3** and **REQ4**. Therefore, three use cases that are *UC021: BMI Calculation*, *UC022: Nutrition Interpretation* and *UC023: Nutrition Display* are included by use case *UC02*.

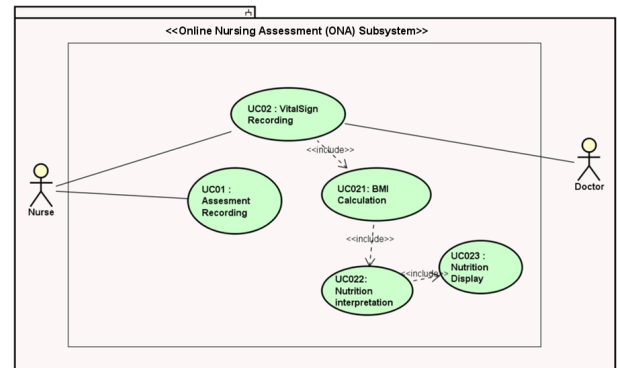

Fig. 5. Use case model for ONA subsystem

Fig. 6 shows the use case description of use case *UC01* (Version 1). This figure specifies the details of use case including the sequence of each step of use case *UC01* including *Main Flow of Events*, *Alternative of Events* and *Exception Flows*. As can be seen in this figure, the description of use case *UC01* is explained regarding the functionality of nursing assessment record. Considering the flow of events in this table, variables *Triage*, *VisitType*, *VisitStatus*, *Allergy*, *Pregnancy*, *Lactation* and *PainScore* are indicated as an input data. These variables and their data structure are defined in the data dictionary as the form of XML file format. This file is used later to generate test data. These variables including their data structure and possible data range are shown in Table VI. There are 19 variables included in the first version of data dictionary used by the functionality of ONA subsystem. For example, variable *VisitType* that has data type as a string for recording the reason of visit. This variable contains nominal data value to be *Self*, *Relative* and *Other*. Another example is variable *Triage* that

determines the priority of patients’ treatments based on the severity of their condition. This variable has ordinal data range value of a character from 1 to 5.

Use Case#	UC01: Assessment Recording
Pre-conditions:	Select the patient from the system
Primary Actor:	Nurse
Flow of Events:	1 The system displays the assessment recording window. 2 The nurse inputs assessment information including severity ( <i>Triage</i> ), type of service ( <i>VisitType</i> ), service situation ( <i>VisitStatus</i> ), <i>Allergy</i> , <i>Pregnancy</i> , <i>Lactation</i> and <i>PainScore</i> of patients. 3 The nurse clicks “Save” button to save assessment information [A1].
Alternative of Events:	1 [A1] The nurse clicks “Cancel” button in the case of cancellation [E1].
Exception Flows:	1 [E1] The system will clear screen.

TABLE VI. DATA DICTIONARY OF UC01 (VERSION 1)

Variable Name	Description	Data Type	Data Range
Sex	Gender of patients	Varchar(1)	F, M
Age	Age of patients	Integer	1-120
Pulse	Pulse Rate	Integer	0-201
RR	Respiratory Rate	Integer	0-120
Temp	Body Temperature	Integer	35-46
BP_upper	Systolic blood pressure	Integer	0-350
BP_lower	Diastolic blood pressure	Integer	0-350
Weight	Weight of patients	Integer	0-200
Height	Height of patients	Integer	0-300
WL	Waist of patients	Integer	5-80"
BMI	Body Mass Index	Float	18.50-30.00
VisitType	Service Type	Varchar(255)	Self, Relative, Other
VisitStatus	Service Status	Varchar(255)	Walk, Wheelchair, Other
Triage	Triage Level	Varchar(1)	1-5
Allergy	Allergy Status	Varchar(1)	Y, N
Preg	Pregnancy Status	Varchar(1)	Y, N
Lactation	Lactation Status	Varchar(1)	Y, N
Pain Score	Pain Level	Integer	1-10
NT Level	Nutrition Level	Varchar(2)	L1-L5

**Requirement change requests.** After we analysed the requirement change request, we discovered that this change of requirements affected the functionality of requirement as shown in Table VII. There are two types of changes, deleting and adding some requirements respectively. This impacted the use case description and data dictionary to be changed as shown in Fig. 7 and Table VIII, respectively. According to change request **CH01**, *Pregnancy* and *Lactation* of patient are excluded from inputs of assessment information in the second version of the use case description. This affected the variables *Preg* and *Lactation* specified in the first version of data dictionary were deleted. Change request **CH02** introduces the new functionality into the subsystem to display the nursing record information after assessment recording functionality, the new use case (*UC011*) is added and extended from *UC01*. This added use case results in variable *DateTime* to be added in order to record the patient information based on the selected date. This variable contains nominal data range values *CD* and *UD* for the current date and updated date respectively. Furthermore, some variables changed their data range value. For example, from change request **CH03**, variable *Pulse* were separated from one partition (0-201) into two partitions as 60-100 and 90-130 for different age groups respectively. Change request **CH04** affected the name of variable *NT Level* to be renamed to *BMI Level* according to the international standard name based on WHO.

TABLE VII. THE CHANGE REQUEST OF ONA SYSTEM

Change ID	Change Description	Affected Requirement ID	Affected Use Case ID
CH01	Delete pregnancy and lactation details	REQ1	UC01
CH02	The system can display the nursing record information based on the selected date (current date: <i>CD</i> and updated date: <i>UD</i> )	REQ2	UC011
CH03	Adjust the patient’s normal range including <i>Pause</i> : 90-130 times per minute for children aged 18 years old and 60-100 times per minute for adult aged over 18 years old	REQ3	UC02
CH04	Rename the nutrition level display to BMI level	REQ4	UC021
	Change data type of <i>Weight</i> and <i>Height</i> to decimal	REQ4	UC023

Use Case#	UC01: Assessment Recording
Pre-conditions:	Select the patient from the system

### C. CIA Algorithm

To achieve a better understanding of our impact analysis framework as described in Section III-A, the detailed algorithm is explained in this section. This is demonstrated with using our experienced case study, KFD subsystem as an example.

**Step 1: Variable Extraction.** After the change request is identified by the change analysis, variables specified in the use case diagram are extracted. As variables and their data structure are normally defined in the data dictionary, the XML of data dictionary that is extended from the XML of conformed use case is used as a source for this variable extraction in our developed prototype tool. The variable information in the XLM file including *use case id*, *variable name*, *variable type*, *variable range value*, *variable number* and *variable order* are extracted before it is analysed for the level of change impact.

Fig. 8 demonstrates an example of the changed version of the XML of data dictionary that conforms to the changed version of use case description. The information of variables *Sex*, *Age*, *Height* and *SCr* encoded in this XML file is extracted. Especially, the data structure that are *variable type* and *variable range value* from the extracted information is normally used as information to generate test cases or test data. For instance, considering variable *Age* which has data type as an integer, there are four possible test cases to be considered, the age in the range of 0-17, 18-120 and out of the range that are less than 0 and greater than 120.

**Step 2: Two Versions of Use Case File Comparison.** This step performs consistency checking in order to identify the variables affected from the change of requirement. Two versions of the extracted variable information between before-change and after-change of the used case diagram from the previous step are compared and analysed. This results in the

TABLE VIII. DATA DICTIONARY OF UC01 (VERSION 2)

Variable Name	Description	Data Type	Data Range
Sex	Gender of patients	Varchar(1)	F, M
Age	Age of patients	Integer	1-120
Pulse	Pulse Rate	Integer	60-100 for children aged 18 years old, 90-130 for adult aged above 18 years old
RR	Respiratory Rate	Integer	0-120
Temp	Body Temperature	Integer	35-46

Fig. 8. The XML file of UC001 (Version 2)

cause of changes to be identified and analysed. There are five patterns of atomic changes for determining the cause of changes that are 1) change of variable name, 2) change of variable type, 3) change of variable range value, 4) change of number of variables and 5) change of variable order. The possible cause of change patterns affects to the addition, deletion and modification of target variables.

Considering the changed GFR calculation formulas in KFD subsystem as shown in Table IV, for example, the comparison of two versions of use case enables us to discover the causes

of variable changes. 1) the modification of variable value is detected as the range value of variable *Age* was changed from 0-120 to 0-17 and 18-120. Furthermore, 2) the addition of variable is identified as variable *Height* for GFR calculation. The before-changed test cases directly affected from these variable changes are later discovered to be re-generated.

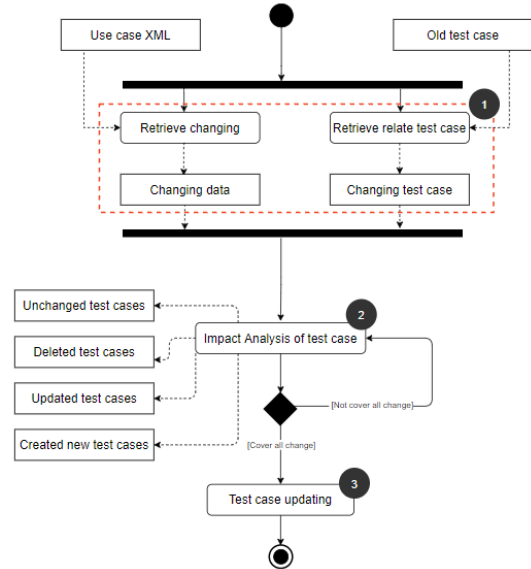

Fig. 9. Procedure of impact analysis of test cases

**Step 3: Impact Analysis of Test Cases.** After the variable affected by the change is identified and considered, the change impact of test cases is analysed. Fig. 9 shows the procedure of the change impact of test cases that is divided into three steps.

(1) *Retrieve Inputs for Impact Analysis:* this step retrieves and prepares the necessary inputs used for analysing the change impact of test cases. Two sets of data are prepared in this step: the information of changed variables and a set of before-changed test cases. To prepare this, the information of the changed variables together with the cause of changes is input from the previous step, whereas a set of before-changed test cases is retrieved from the test case database. This results in the information of changing data in affected variables and changing test cases to be generated and used in the next step.

(2) *Impact Analysis of Test Cases:* the information of changed variables prepared from the previous steps is used to analyse and validate the impact on the before-changed test cases. This results in these test cases being classified into four groups that are *no-change*, *delete*, *update* and *create* categories. Our developed tool also supports this step to analyse effectively the change impact from the multiple various change patterns occurring in parallel at the same time. The patterns for identifying the action of effect on test cases based on type of change impact are summarised in Table IX. The percentage of estimated reusability is also calculated for each pattern.

Considering in the case of 1) the change of variable name, the impact of this case affects the corresponding test cases of this variable to be not changed. Thus, they can be totally reused (100%). For 2) the change of data type, the existing

TABLE IX. SUMMARY OF FIVE PATTERNS OF AUTOMATIC CHANGES WITH EFFECT ON TEST CASES

Type of Impact		Action				% Est. Reuse
		No Change	Update	Delete	New	
Change of variable name	-	×				100
Change of data type	-		×			100
Change of number of variables	Add			×	×	0
	Delete			×	×	0
Change of variable value	Add	×	×		×	50
	Delete	×	×	×		50
	Update		×			100
Change of variable order	-			×	×	0

test cases can be 100% reused with only updating their data type. 3) the change of number of variables, in both cases of adding and deleting the variables, results in all existing test cases not to be totally reused. This is because of the Cartesian product used for generating test cases needs to recalculate the multiplication of all variable range value to support the deletion or addition of variable. This affects the existing test cases corresponding to these variables to be the deleted and the new test cases to be generated. 4) The change of range value of variables is divided into three possible cases (4.1) adding a new range value in which the valid partition is added or extended from the other valid partition. This results in all test cases generated from this partition are totally reused as there is no change in the valid partition. However, this case causes the intersection of range values between the addition valid partition and the other invalid partition. This, therefore, results in the range value of affected invalid partition to be reduced by removing the overlapped value. As a result of this, the existing test cases affected from this reduced invalid partition to be updated and new test cases are generated from the additional valid partition. Similar to this, (4.2) deleting existing range value affects the existing test cases generated from unchanged partition to be totally reused and those generated from deleted partition to be deleted. Furthermore, this case affects the range value of invalid partition to be expanded to cover the deleted partition. Therefore, this results in the test case corresponding to this to be updated. In cases (4.1) and (4.2), the percentage of reusable test cases is estimated to be 50%. In the case of (4.3) updating existing range value that one partition is split into two partitions, this causes the existing test cases to be updated (100% of reusability). Finally, we have discovered that the change number of variables as adding new variables and deleting existing variable affects the order of variable. Thus, 5) the change of variable order affects some existing test cases to be deleted and new test cases to be generated.

(3) *Test Case Modification*: the before-changed test cases are considered to be modified based on the result of impact analysis that is classified into the impact group as mentioned earlier. For the test case that is classified into *no-change* group, it can be totally reused for the new version. However, the before-changed test cases have their value updated or are deleted when the result of impact analysis is classified into the *update* or *delete* groups respectively. If the impact analysis of test cases results in the *create* group, a new test case is generated. All modified and created test cases are generated by using CCTM algorithm.

Table X shows an example of the variable partitions for test case generation after analysing the impact of test cases. As can be seen in this table, based on the requirement change request of GFR Calculation module mentioned before, the range of variable *Age* is changed from one partition (partition 5 in variable before change) for the valid test case, 0-120 years old, to two partitions (partitions 5 and 6 in variable after change) for the valid test case, 0-17 and 18-120 years old. This causes the updated test case to be improved by creating a new version of test cases corresponding to the updated partition as shown in Table XI. The new test cases corresponding to the separated partitions after the change (0-17 and 18-120 years old) are re-generated as in test cases 2-3 (as shown in the highlighted row in the table). Furthermore, from the no-change group of impact analysis, there are two original (unchanged) test cases that are totally reused in the new set of test cases, test cases 1, 4-5 respectively.

TABLE X. EXAMPLE OF UPDATING THE VALUE OF A VARIABLE AFTER CHANGING

Variables before change					Variables after change				
Class	Var.	Min.	Max.	Type	Class	Var.	Min.	Max.	Type
1	Sex	F	F	Valid	1	Sex	F	F	Valid
2		M	M	Valid	2		M	M	Valid
3		N/A	N/A	Invalid	3		N/A	N/A	Invalid
4	Age	-∞	-1	Invalid	4	Age	-∞	-1	Invalid
5		0	120	Valid	5		0	17	Valid
6		121	∞	Invalid	6		18	120	Valid
					7		121	∞	Invalid

TABLE XI. EXAMPLE OF TEST CASES AFTER CHANGING

#TC	Class	Variable name		Sequence		Type
		Sex	Age	Sex	Age	
1	1,4	F	-4	1	2	Invalid
2	1,5	F	12	1	2	Valid
3	1,6	F	55	1	2	Valid
4	1,7	F	176	1	2	Invalid
...	...	...	...	...	...	...

**Step 4: Test Case Generation.** The approach performs test case generation when test cases need to be recreated. CCTM, the combination technique of ECP and CTM, is applied to cover generated test cases with all functions as required. The main steps are as follows:

**Step 4.1: Analyse Requirements using a Classification Tree:**

The classification tree technique basically enables a set of requirements in the specification to be classified as a branch in the tree. The top of the tree as a root is the main use case in the system before the sub use case is considered to extend the root to create the sub-tree. A lower level of the tree, variables of the use case are identified as terminal classification. The terminal class is the range value of the variable and identified at the lowest level as a leaf of the classification tree. There are seven principle combination patterns proposed in [16]. One example of these combination patterns that was revealed by the tool is shown in Fig. 10. The tool detected two redundant classification trees that were built to support the calculation of two age groups as shown in Fig. 10a and 10b respectively. These redundant terminal classes were eliminated by CTM enabling in our tool. The terminal class values were combined into the same tree as shown in Fig. 10c. This influences the

benefit to test case generation step in which the potential redundancy of generated test cases is reduced.

Fig. 10. Example of a combined use case

Fig. 11 shows an example of classification tree of GFR calculation module after the analysis of changes. It contains the variables and their corresponding possible range value visualising in terminal classification (parent node) and terminal class (leaf node) respectively. The range value of all relevant variables demonstrated in this tree can be explained as follows: *Sex* = *F*, *M*, *Age* = *0-17*, *18-120*, *Height* = *0-300* and *SCr* = *0-0.9*, *1.0-10.0*. These are considered to create equivalence class partitioning with ECP technique for the next step.

Fig. 11. The classification tree of GFR module

**Step 4.2: Generate Test Case from the Equivalence Class Partitioning:** This step generates the test case from the terminal class by using the ECP technique enabled by CCTM method. The value of variable indicated in this terminal class is considered to create the partition. In our developed prototype, the partition of changed variables is generated automatically resulting as in Fig. 12. This figure illustrates the partition created from the terminal class in the updated classification tree demonstrated in Fig. 11. Variable *Age* is divided into four partitions (two valid partitions and two invalid partitions) corresponding to the changed version of variables. To generate test cases, ECP performs the Cartesian product of multiplying a data value selected from all partitions.

#### IV. PROOF OF CONCEPT

##### A. Tool Development

A prototype tool was developed to demonstrate the effectiveness of the CIA framework for test cases explained in Section III-A. It is a Java based web application implemented in the Node.js 8.9.4<sup>2</sup>, JavaScript run-time environment which is widely used as a standard for large-scale application. MySQL

<sup>2</sup><https://nodejs.org/en/about/>

Fig. 12. Example of equivalence class partitioning

version 5.7.22<sup>3</sup> is used to keep the data of use case version, variables and test data for test suite export.

Fig. 13 demonstrates an example of our developed prototype tool. Fig. 13a is the screen showing two versions (before-change and after-change) of XML file of use case diagram after they are uploaded before the consistency checking performs. Then, the tool performs variable analysis of each version of the XML file. All variables defined in the use case are analysed. This includes variable name, variable type and variable range value as demonstrated in Fig. 13b. Fig. 13c shows the screen of impact analysis result. It shows the summary of impact analysis which is divided into two parts. The first part reports the number of changes classified and grouped into five patterns of atomic changes as we proposed in the framework as mentioned in Section III-A. The reuse percentage of test cases affected from the change is also calculated and reported on this screen. The latter part reports the number of test cases affected from the changes grouped by the causes of changes that are *No Change*, *Delete*, *Update*, *New (Create)*. Finally, test case generation is performed when test cases need to be recreated. CCTM technique is used for test case generation. This results in the classification tree and its corresponding equivalence class partitions is created and analysed as shown in Fig. 11 and 12, respectively before generating the test cases and test data.

##### B. Tool Validation

Before evaluating the the effectiveness and efficiency of our proposed approach, we validated the correctness of the tool to confirm whether all functionalities of the tool demonstrated in Section IV-A perform correctly according to the framework presented in Section III-A. Therefore, we conducted experimental validation aiming to answer the following question.

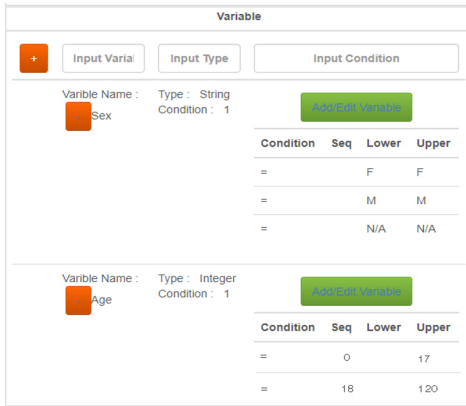

**EQ1:** *Are all functionalities implemented in the tool implemented and do they perform correctly according to the proposed approach?*

To accomplish this, three test scenarios corresponding to four steps of the CIA algorithm described in were designed as shown in Table XII including 1) *TS-01 : Validate Comparing Two Versions of Variable Function*, 2) *TS-02: Validate Test Case Analysis Function* and 3) *TS-03: Validate CCTM function*. Test scenario *TS-01* aims to validate the comparison

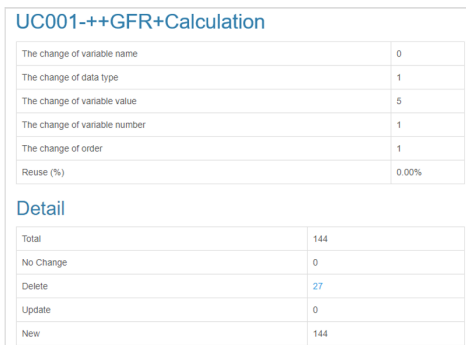

<sup>3</sup><https://www.mysql.com/>

(a) screen of XML version

(b) variable management

(c) impact analysis

Fig. 13. Example of the tool screens

operation of versions of variable XML function according to Steps 1 and 2 in CIA algorithm, after two versions of the XML data dictionary containing the data structure of variables are uploaded. The change of variables is compared based on the proposed five patterns. For test scenario *TS-02* aiming at the validation from Step 3 of the algorithm, impact analysis of test case function is validated after the comparison of change of variable based on five patterns. Test scenario *TS-03* is used to validate the operation of classification tree generation by CCTM technique. As the main objective of CCTM technique is to reduce the duplicated test cases by merging the duplicated classification tree caused from the redundant requirements, we also created the scenario for validating this tree merging operation.

Table XIII shows the result of testing. Test cases in test scenario *TS-03* enabled us to reveal the fault in our developed tool. As can be seen in this table, seven test cases were designed from merging two classification approach proposed in [16] and used to validate our merging classification tree

TABLE XII. THE RESULT OF TOOL TESTING

Test Scenario	Corresponding Steps	Result	Revision
TS-01 Validate Comparing Two Versions of Variable Function	Steps 1 and 2	Fail	Pass
TS-02 Validate Test Case Analysis Function	Step 3	Pass	-
TS-03 Validate CCTM Function	Step 4	Fail	Pass

function. We discovered the fault in test case *TC-037* regarding the case that two use cases have the same variable name but some range value of variable in one use case is overlapped with that of the other. The expected result of this test case should result in three sub-trees to be created after merging tree as the intersection of variable range between two use cases and two exteriors of variable range in both use cases. The test result revealed that our tool created only two sub-trees instead of three sub-trees after merging tree operation. This led us to fix the code to perform the correct operation of this merging tree case. Furthermore, the fault was also found in test scenario *TS-01* caused by the problem of XML data dictionary that could not trace the change of variable. Thus, we redesigned the XML data dictionary and retested this function. All revision tests were passed as we expected.

TABLE XIII. THE TESTING RESULT OF TEST CASE IN TEST SCENARIO *TS-03*

Test Cases	Objective	Pass/Fail
TC-031	The integration of two use cases in which the other use case has no information	Pass
TC-032	The integration of two use cases that have the same terminal sub-tree	Pass
TC-033	The integration of two use cases in which these two use cases have the same variable name and value range	Pass
TC-034	The integration of two sub-use cases in which share the same use case (parent) but have the different variable name and value range	Pass
TC-035	The integration of two use cases in which these two use cases have the same variable name but different value range	Pass
TC-036	The integration of two use cases in which these two use cases have the same variable name but all value range of variable in one use case is in that of the other	Pass
TC-037	The integration of two use cases in which these two use cases have the same variable name but some value range of variable in one use case is overlap with that of the other	Fail

Based on experimental validation, the testing result of test scenarios and cases confirms the accuracy and coverage of functionality in which all functionalities corresponding to the steps in CIA algorithm were implemented in the tool and they performed correctly according to the proposed approach.

### C. Tool Evaluation

The effectiveness and efficiency of our proposed approach were evaluated by using two real-world case studies, 1) KFD and 2) ONA subsystems, explained in Section III-B. The result of change impact analysis and test case regeneration from these two case studies generated automatically from the tool was compared with that of manual operation. Furthermore, we evaluated the satisfactory level of the developed tool from the target user for potential application in the future. The aim of tool evaluation is to answer the following evaluation questions.

**EQ2:** How error-prone can be identified from the comparison between manual CIA and automated tool?

**EQ3:** How the impact analysis result can influence the level of reusability of existing use cases?

**EQ4:** How do potential users assess a satisfactory result of CIA from the automated tool compared with the manual CIA?

1) *Effectiveness evaluation:* To answer **EQ2**, the comparison between the actual result of impact analysis created by the automatic tool and the expected result calculated by experts was conducted. The precision, recall and F-measure computation were calculated by comparing the result produced by the manual CIA and automated tool. The computation metrics were adapted from [17] as follows.

$$Precision = \frac{|\{Expert\ Identified\} \cap \{Tool\ Identified\}|}{|\{Tool\ Identified\}|} \times 100 \quad (1)$$

$$Recall = \frac{|\{Expert\ Identified\} \cap \{Tool\ Identified\}|}{|\{Expert\ Identified\}|} \times 100 \quad (2)$$

$$F - measure = \frac{2 \times Precision \times Recall}{Precision + Recall} \quad (3)$$

Table XIV demonstrates the result of impact analysis. We compared the number of actual test cases after performing impact analysis generated automatically by the tool with the number of expected test cases calculated manually by experts. Considering the calculated F-measure with precision and recall of KFD case study, the accuracy of the automatic tool performing with this case study is very high. This is because the KFD case study is not a complex case study containing basic changes such as renaming a variable name and change the variable type which did not affect much to the test cases. However, as ONA is a more complex case study containing change of variable range value that was not specified in KFD case study, the accuracy of the automatic tool performing with ONA case study in that pattern is low. This also affected the accuracy of analysing pattern change of variable order to be low. After we revealed the tool, we discovered that that tool excluded the additional range value affected from the adjusted value of variables. This led us to correct the tool to include this case when the tool performs test case generation. After fixing the tool, the number of regenerated test cases by the tool is the same as that of expected test cases hand-operated by experts. The result produced by the corrected tool is shown in Table XV.

2) *The level of reusability:* To answer question **EQ3** regarding the level of reusability, we considered the impact analysis result of test case evaluated from two case studies as shown in Table XV. This table shows the total number of test cases generated after change impact analysis of all use cases of two case studies obtained from the developed tool. The amount of reuse equation adapted from [18] is used to assess the level of reusability of test cases as shown in Eq. (4).

$$\%Reuse = \frac{\# of\ Reused\ Test\ Cases}{\# of\ Total\ Test\ Cases} \times 100 \quad (4)$$

In KFD subsystem, 185 test cases were generated. Based on this number, three types of changes are discovered by the tool. (1) Changing variable name in use case *UC003* resulted in 6

test cases of the first version to be totally reused. Furthermore, 35 test cases to be updated due to changing data type in use case *UC002*. Considering the case of (3) adding a new variable (as *Height*) in use case *UC001*, 27 test cases of version 1 were deleted and 144 of new test cases were generated for version 2. Furthermore, the reusability level of test cases was also measured from the no-change and update group of test cases resulted from the impact analysis. Around 22% of existing test cases for KFD subsystem testing can be reused in the new version of test cases. The reusability rate is low. This is because of the effect from the addition of new variable. As the Cartesian product of multiplying all variable range value is used to generate test cases, all existing test cases affecting to this change were not totally reused. All existing test cases regarding to these variable to be deleted and new test cases to be created by recalculating the Cartesian product instead.

In ONA subsystem, five types that cover all possible changes were identified by the tool. (1) Changing variable name in use case *UC023* affected to 21 test cases of the first version to be totally reused. (2) Changing data type in use case *UC023* resulted in 9 test cases to be updated. Furthermore, (3) adding a new variable as in use case *UC011* caused 6 of new test cases to be generated for after-changed version. (4) Deleting an existing variable in use case *UC01* resulted in 2,592 of test cases to be deleted and 288 of new test cases to be created for version 2. Lastly, there was (5) the addition of variable range value occurred in use case *UC02* of this case study, in which the first case study did not have, was revealed by the tool. This resulted in 4,374 test cases in version 1 to be reused 100 percent (no change), another 4,374 test cases in this before-changed version to be updated and 17,496 of new test cases to be generated. The reusability level of test cases for ONA subsystem is approximately 33% of existing test cases being reused in the new version. This is because there was change of variable range value. This affects half of existing test cases related to this change effect can be totally reused.

3) *Satisfaction evaluation:* To answer **EQ4**, we evaluated the satisfaction of our proposed approach and tool from the target user. Practical specialists who have experience in HIS system development for more than five years were selected as the target user. This was also chosen from the wide range of the role in the development team that are 1 development manager, 2 software testers and 1 developer. The evaluation process started with the tool being demonstrated and trained to specialists before they used the tool with the prepared case study. The satisfactory level with the tool was evaluated by using the evaluation form. Likert scale ranking from strongly agree (5) to strongly disagree (1) indicated a satisfactory level in each question of the evaluation form.

Table XVI demonstrates the question used in a satisfactory evaluation form and the evaluation analysis result is shown in Fig. 14. Most specialists strongly agreed that the tool enables the accurate and appropriate impact analysis of changes in test cases and recommends the accurate and appropriate results based on this impact analysis (Q1 and Q2 respectively). Furthermore, all specialists strongly agreed (Q3) that they are confident in the high accuracy level of test case generation provided by this tool. For future application (Q4), 75% of specialists agreed that the tool will be applied to other systems

TABLE XIV. THE RESULT OF IMPACT ANALYSIS

System	Type of atomic changes	# Test cases		Precision	Recall	F-measure
		identified by an expert	identified by the tool			
KFD	Change of variable name	6	6	100%	100%	100%
	Change of variable type	35	35	100%	100%	100%
	Change of variable range value	-	-	-	-	-
	Change of number of variables	144	144	100%	100%	100%
	Change of variable order	185	185	100%	100%	100%
ONA	Change of variable name	21	21	100%	100%	100%
	Change of variable type	9	9	100%	100%	100%
	Change of variable range value	26,244	8,748	100%	33.33%	50%
	Change of number of variables	294	294	100%	100%	100%
	Change of variable order	26,568	9,072	100%	34.15%	52%

TABLE XV. SUMMARY OF THE IMPACT ANALYSIS OF TEST CASE BASE ON REQUIREMENT CHANGING

System	#Test Cases	Impact	Type of Changes (Number of Test Cases)								
			Variable Name	Data Type	Number of Variable		Variable Value			Variable Order	
					Add	Delete	Add	Delete	Update		
KFD	185	No Change	6	-	-	-	-	-	-	-	-
		Update	-	35	-	-	-	-	-	-	185
		Delete	-	-	27	-	-	-	-	-	-
		New	-	-	144	-	-	-	-	-	-
ONA	26,568	No Change	21	-	-	-	4,374	-	-	-	-
		Update	-	9	-	-	4,374	-	-	-	26,568
		Delete	-	-	-	2,592	-	-	-	-	-
		New	-	-	6	288	17,496	-	-	-	-

in the future. Moreover, specialists also gave feedback in the questionnaire (Q5). Most specialists said that the tool is accurate, reliable and easy to use. The tool enables the benefit in which the test case from the previous can be reused. However, some of them gave very useful feedback for the future improvement. They suggested that the tool should support other input file formats rather than just XML file format. We will use all feedback and suggestions from the specialists to improve the tool in the future. Overall, the specialists were mostly satisfied with our impact analysis tool.

TABLE XVI. SATISFACTION QUESTIONS

Questions	Average
Q1. The tool provides accurate and appropriate analysis of the impact of changes in test cases.	Likert scale (Mandatory)
Q2. The tool can offer accurate and appropriate results and recommendations based on the impact analysis.	Likert scale (Mandatory)
Q3. The tool can generate accurate and appropriate test cases.	Likert scale (Mandatory)
Q4. The tool can be applied to other system case studies in the future.	Likert scale (Mandatory)
Q5. Comments and suggestions for the tool application and improvement	Open-ended question

Fig. 14. Results of the four Likert scale questions

## V. LESSON LEARNED AND DISCUSSION

### A. Discussion

The key findings discovered from our developed tool is the ability to analyse the impact of test cases based on changes of use case based requirement specification that conforms to the proposed approach and framework. Based on the analysis and evaluation results, the developed tool can perform the impact analysis from the change of the requirements in two versions as before-change and after-change of the use case specification model according to the proposed five patterns of the cause of changes. These patterns are designed specifically for use case based specification including 1) change of variable name, 2) change of variable type, 3) change of variable range value, 4) change of number of variables and 5) changes of variable order. Compared with the study work of [8], they classified the cause of changes into seven patterns in which the first five patterns are the same as our proposed patterns. The other two patterns were not included as they are related to the change on web tag a link that is specific to web application. The decision after the impact analysis is also classified by this tool into four groups as *no-change*, *update*, *delete* and *create* groups as we expected.

Furthermore, CCTM is integrated into this tool to support automatic generation when new test cases require to be created. The validation and evaluation results confirm the key findings that our proposed approach supports all cases for merging two classification trees proposed by [19] as explained in Section IV-B and IV-C. From the validation and evaluation results, we can confirm that CCTM influences the benefit that reduces the time and increases the testing coverage for new test case generation. However, it has the limitation of testing a large and complex system that may not complete with a single classification tree as found in [6], [7]. We suggest that it needs to separate the testing into several testing units. From our experiences, for example, we separated the testing of our SUT,

MRS, into two testing units, one is for KFD subsystem and the other for ONA subsystem.

### B. Comparison of the Proposed Approach and Other Approaches

This section describes the comparison of our proposed approach with other approaches by [11], [9], [8]. Five criteria are considered for this comparison including *Impact Analysis Methods, System Domain, Source Type, Test Case Generation Techniques* and *Reusability Supports* as shown in Table XVII.

Our approach performs the impact analysis from the change of the requirements and classifies the cause of the change into five patterns as mentioned earlier. Comparing this with the approach proposed by [8], the cause of changes of a web application is classified into seven patterns in which the first five patterns are the same as our proposed patterns. Unlike the work of [11] and [9], it does not classify the cause of change into patterns during impact analysis. The existing test cases affected from the change is only analysed whether they can be reused.

Furthermore, as new test cases are required to be generated in the case that new features or requirements are added, CCTM, the hybrid testing approach that integrates ECP with CTM test case generation technique, is integrated into this tool to support automatic generation when new test cases require to be created. With the CTM technique, classification trees merging approach enables the test case redundant from two classification trees to be eliminated. Moreover, ECP technique in the CCTM provides the test case coverage of all possible scenarios as well as failure scenario. Comparing our implemented test case generation technique with the work of [8], [11] and [9]. In the work proposed by [8], their impact analysis framework provides ECP and BVA. These testing techniques only provide the test case coverage of all possible scenarios from the various range of separated partition. Unlike the work proposed by [11] and [9], they only focus on the impact analysis methodology that results in only the consideration of the affected test cases in the old version to be usable or unusable. Their framework, therefore, does not provide test case generation technique for the new test case generation.

Lastly, considering the comparison in terms of the reusability supports as demonstrated in Table XVII, our proposed approach provides the reusability level of test cases as a percentage from the impacted test cases that are implemented in a similar way with the work proposed by [8]. In the work proposed by [11] and [9], they classified only two levels of reusability of the existing test cases that are reusable or unusable.

## VI. CONCLUSION AND FUTURE WORK

This paper has demonstrated an automatic impact analysis approach of test cases based on changes of use case based requirement specification. Our experiment results with two case studies, KFD and ONA, have shown that the developed tool enables the benefits in which the impact on changes of test cases is analysed from the change of variables in use case specification. Two versions as before-change and after-change of the use case model are compared for consistency checking to detect the change. This results in the cause of variable

changes to be classified into five patterns of atomic changes are encoded in this tool. These classified patterns enable the impact on changes of the existing test cases to be analysed whether the existing test cases to be completely reused, partly updated as well as additionally generated. Consequently, the level of reusability of existing test cases is measured and the time to create the whole new cases for the after-changed version is reduced. Furthermore, CCTM, the hybrid test case generation technique encoded in the tool for generating new test cases influences the benefit to increase the level of testing coverage with a minimised number of test cases and reduces the redundant test cases as demonstrated. The beneficial contribution delivered by our proposed approach and tool is also confirmed by the validation and evaluation results from the practical specialists which are consistency with the results discovered from the researchers' perspective.

As our proposed approach and developed CIA tool supports the impact analysis of change of variable types that are only primitive programming data types including integer, floating-point number, boolean, character and string, the adjustment of the tool to support the ready-made "real world" data type e.g. date and time have been considered for the future work. To increase the capability and reliability of the tool, another research issue is the further evaluation of the tool with different system domains as suggested by the practical specialists.

## DEPLOYMENT AND AVAILABILITY

Our developed tool is available at <https://sites.google.com/phuket.psu.ac.th/testciatool/>. User guide manual document and source of example case studies (KFD and ONA subsystems) are also available on the website.

# Trust Management for Deep Autoencoder based Anomaly Detection in Social IoT

Rashmi M R<sup>1</sup>, C Vidya Raj<sup>2</sup>  
Research Scholar, VTU, Belagavi<sup>1</sup>

Department of Computer Science and Engineering, NIE, Mysore, India<sup>1,2</sup>

**Abstract**—Social IoT has gained huge traction with the advent of 5G and beyond communication. In this connected world of devices, the trust management is crucial for protecting the data. There are many attacks, while DDOS is the most prevalent BotNet attack. The infected devices earnestly require anomaly detection to learn and curb the malwares soon. This paper considers 9 IoT devices deployed in a Social IoT environment. We introduce a couple of attacks like Bash lite and Mirai by compromising a network node. We then look for traces of malicious behavior using AI algorithms. The investigation starts from a simple network approach - Multi-Layer Perceptron (MLP) then proceeds to ML - Random Forest (RF). While MLP detected the malicious node with an accuracy of 89.39%, RF proved 90.0% accurate. Motivated by the results, the Deep learning approach - Deep autoencoder was employed and found to be more accurate than MLP and RF. The results are encouraging and verified for scalability, efficiency, and reliability.

**Keywords**—Social IoT; trust management; anomaly detection; DDoS; deep autoencoder

## I. INTRODUCTION

IoT is a disruptive network technology that has advanced quickly over the past ten years in every technology field, including smart cities, satellites, smart homes, smart businesses, smart transportation, and smart healthcare [1]-[4]. It consists of several IoT devices (Things) that may gather and share data through the conventional internet thanks to their various sensors, actuators, storage, computing, and communication capabilities [5]. The industry's security concerns resulting from the enormous range of IoT devices and vendors. On the off chance that security and protection are not accommodated their organizations and information, partners are probably not going to broadly embrace IoT innovations. Recent cyber security reports [6] have revealed that assaults against IoT settings have increased in frequency due to the IoT ecosystem's expanding attack surface, which extends from the edge to the cloud [7]. Therefore, a significant ongoing problem for engineers in this industry is designing and creating secure IoT systems [8]. The sensitive nature of the data collected and processed within the IoT network necessitates security from potential breaches. As the first line of defense against potential security attacks [9]-[10] on weak devices [11], like distributed denial of service (DDoS) attacks [12], various security mechanisms are currently used to protect sensitive data. These mechanisms include firewalls, authentication protocols, encryption methods, antivirus software, and more. Such assaults are carried out against another network entity, such as a business or a government, by a collection of infected machines (bots) that are part of a botnet and are under the attacker's control via a C&C (Command and Control) server. Due to the extensive

use of data, several new anomalies—original and mutations of previously observed anomalies—are often produced.

The Compromise of IoT devices and their enrollment into IoT botnets under attackers' control is one of the main threats to IoT networks and devices. Well-known IoT botnets like BASHLITE and Mirai continue to pose substantial DDoS risks, according to the conclusions of a Hundred of active command and control (C & C) servers are included in the Distributed Denial of Service (DDoS) report for the first quarter of 2021 [13]. Due to the IoT's primary characteristics, which must be considered: heterogeneity, scalability, and limited resources, mitigating such threats could be very difficult (power, memory, and processor). As a result, creating solutions for IoT environments that can detect aberrant behaviors and assaults has emerged as a major problem in the field of IoT cyber security and a hot topic for researchers. Subsequently, an IoT organization can profit from extra protection from security attacks thanks to an anomaly identification framework that can act as a second line of guard. Furthermore, enterprises in this market sector are primarily focused on fusing IoT technology with other slashing technologies like AI (AI algorithms are used for data processing and analysis), Big Data (handling a huge amount of information from IoT devices), or 5G connectivity (mobility and broadband links for IoT sensors). Since it merges AI with IoT, the AI of Things (A-IoT), a disruptive technology that aims to analyze data to make autonomous and automated decisions on IoT networks, is receiving special attention [14].

To increase anomaly detection accuracy, researchers have recently looked into machine learning (ML) and deep learning (DL) techniques. Studies have shown that both ML and DL approaches are useful for extracting characteristics from network traffic that can be used to classify the traffic as benign or abnormal [15]. The DL has shown effective at learning relevant attributes from the raw data because of its deep model, which provides a variety of abstractions for learning intricate features for precise predictions [16]. Due to the huge volume of data generated by IoT devices, these characteristics of DNN have made it a suitable methodology to be adopted for anomaly detection schemes created for IoT networks [17]. Larger networks, however, might find these solutions impractical. In addition, because a separate model needs to be updated and maintained for individual IoT sensor, using several auto encoders might make network security challenging to establish and administer. We offer three methods. Deep auto-encoder, Random Forest, and Multilevel Perceptron for identifying anomalies in IoT networks by observing and analysing the innocuous "snapshots" of behaviour from each IoT device, we suggest a deep auto-encoder-based anomaly

## II. BACKGROUND

### A. Categorization of IOT Anomalies

An anomaly is a data point in a modelled system that is not aligned to the normal behaviour. Rare occurrences or observations known as anomalies differ dramatically from typical behaviour or patterns seen in a single data point or throughout the full dataset. An aim of algorithm will probably find an irregularity's event and characterize/gather its objective in light of the fact that in principle, anomalies are brought about by outside powers like sensor breakdown or outer assault. The estimation structure that best matches the expected information conduct is fundamental in the twofold order of a peculiarity. Additionally, each application needs a unique detection approach due to the complexity of numerous circumstances [19].

Taking into account the arrangements from earlier examinations like Fahim and Sillitti [20] and Cook et al. [21], an IoT peculiarity discovery approach is partitioned into four classes. According to the problem they address, how they are used, the kind of method used, and the algorithm's latency, they are divided into different categories. Fig. 1 presents an example overview of the four groups.

(i) **By Method:** The methods can use machine learning, statistics, or geometrical methods. Geometrical approaches are based on the presumption that the anticipated and abnormal data are separated when distance- and density-based representations of a given dataset are used. The reasoning behind detachment or density-based approaches is that peculiarities arise in scanty districts in a bunch of data of interest. These procedures classify irregularities utilizing a static or dynamic magnitude value ( $t$ ) on the assessed distance ( $d$ ), which is given as:

$$d = \begin{cases} < t, Normal(underthreshold) \\ > t, Anomaly(abovehethreshold) \end{cases} \quad (1)$$

(ii) **By Application:** The three methods that an application uses to categorize anomalies are data cleansing, data destruction, and constructive categorization. The world of elderly people's everyday activities to ensure safe and its evaluation of the efficiency of multilayer perceptron (MLP), SVM classifiers, and k-nearest neighbours (KNN), offer value when applications are constructive or positive in nature.

(iii) **By Anomaly Type:** The situation-specific type, such as the point, contextual, and collective, is one of the most frequently observed types. If just one piece of data deviates from the norm, it qualifies as an anomaly. The identification of fraud with credit cards is one instance. An incident that might be seen as abnormal in a certain context is called a contextual anomaly. The last kind of anomaly, collective anomaly, examines the complete dataset, unlike a point or contextual anomaly.

(iv) **By Latency:** Whether a detection technique is conducted immediately during the data collecting stage or after it has been stored depends on its latency and scalability [18]. An online technique can serially analyse data with a single point of information or window without having access to the

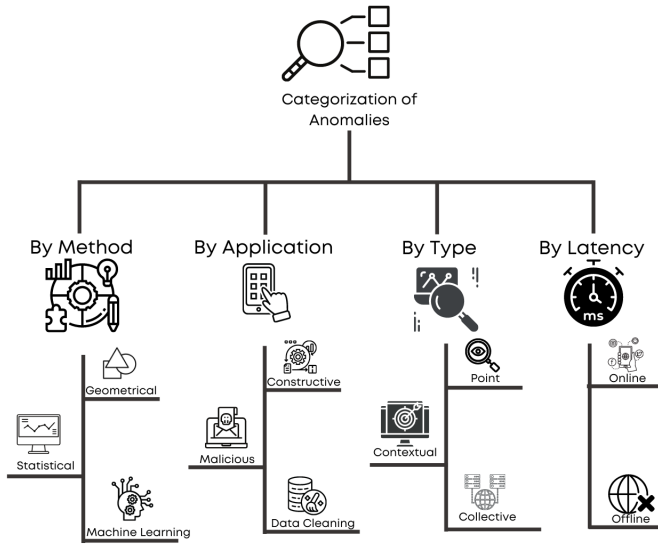

Fig. 1. Categories of anomaly in IoT

detection system as a viable method for identifying botnet attacks. The experiment is built on a test bed network of nine IoT devices and simulates the BASHLITE and Mirai botnets, two well-known botnets. Auto-encoders well defined for each IoT gadget is used to gain proficiency with the regular traffic properties and to caution when they can't recreate the harmless traffic samples.

The main contribution of the work is three-fold:

- First, a brief review of the constraints and vulnerabilities of Social IoT networks, various attacks, and anomalies is presented.
- Next, we deploy 9 IoT devices in a Social set-up while injecting one node with BASHLITE and Mirai infection resulting in the DDOS attack.
- Finally, we employ ML, NN, and DL-based approaches - RF, MLP, and Deep Auto-encoder- to detect anomalies accurately and ascertain the results for scalability, efficiency, and reliability.

The following is how the paper is structured. Section II introduces anomaly detection and discusses numerous sorts of anomalies in the IoT context. Furthermore, it situates the topic within the framework of DDoS attacks and gives a taxonomy of DDoS attacks. Section III discusses anomaly detection strategies and forms of anomaly attacks in the social IoT and finishes with the deep autoencoder as a solution for anomaly identification. The proposed framework for anomaly detection and the evaluation metric to validate the performance of the proposed method are then presented (Section IV). We then examine the intriguing results that demonstrate the superiority of the suggested strategy over rival schemes in Section V. The final remarks are discussed in Section VI.

TABLE I. ATTACK TYPE CLASSIFICATION FOR IoT

Sl.No	IoT Attack	Description
1	Dos	This type of attack involves the deliberate sending of bugs or packets to render resources unavailable to hosts connected to the internet.
2	Data Type probing	This exploit involves a hostile attacker writing an unintended data type .
3	Malicious Control	This type of attack allows the attacker unapproved access to the user's system
4	Malicious Operation	In general, the malware was a factor in this attack. Attacker engages in bogus activity on a system that has been authenticated
5	Scan (SC)	In this assault, equipment sporadically scans the framework for information to obtain, which might ruin information
6	Spying (SP)	In this attack, the attacker targets the system's weak spots and gains access via a backdoor to steal sensitive data
7	Wrong Setup	It is an assault, wherein culprit deliberately sends bugs or parcels for making asset inaccessible for the host associated with the web
8	Normal	This attack may have been planned or unintentional, but it might still cause harm by upsetting the system.

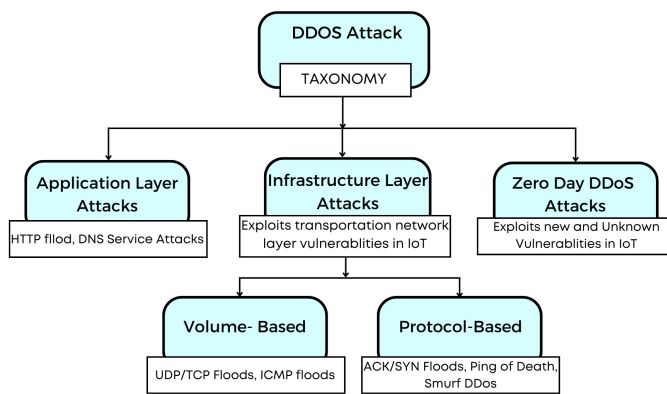

Fig. 2. Taxonomy of DDoS attacks

complete input. Traditional and online geometry and statistical methodologies include the distance-, density-, and angle-based approaches listed above. Offline algorithms, however, have complete access to the information. They employ difficult, computationally expensive, sophisticated methods to solve the problem in a reasonable amount of time. Anomalies are brought on by external forces like sensor malfunction or an external attack. The various types of attacks in IoT have been summarized in Table I. The most common kind of assault that may be launched against any application is a DDoS attack. DDoS attacks are the loudest kind of cyber attacks.

### B. Distributed Denial of Service Attacks

The DDoS attack is undertaken to overwhelm the target and interrupt services, as the name suggests. IoT devices are highly suited for the DDoS attack because it needs a lot of devices to conduct an attack. Users won't recognise that the gadget is compromised, as is typically the case. There is a pressing need to identify assaults quickly in order to remove affected devices as the number of IoT devices grows. BASHLITE and Mirai employed IoT devices as Botnets in a large DDoS attack, and other similar attacks have also occurred [22]. The various types of DDoS attacks have been illustrated in Fig. 2.

DDoS attacks have demonstrated a variety of attacking strategies over the years, and a variety of potential attacks are continuously being tested. IoT-specific DDoS attack strategies are not much different from conventional DDoS attack strategies. They use similar methods to take advantage of flaws in

both IoT devices and conventional systems. However, because of the heterogeneity present in IoT devices, DDoS assaults targeted specifically at IoT are more varied and complex. We will use the fundamental layered architecture of an IoT network to categorise DDoS assaults in this section.

Three different types of DDoS attacks are illustrated in a comparative analysis in Table II. DDoS assaults have affected well-known service companies like Amazon Web Services. AWS, Cloud are, KrebsOnSecurity, and other security service providers against similar assaults are also DDoS attack victims. Therefore, assaults on these significant institutions affect enterprises financially and reputationally. In a DoS attack, the attacker makes bogus requests using the target's resources in an effort to disrupt the target's services. DDoS involves simultaneous demands coming from several sources. DDoS attack mitigation becomes challenging as a result. There are many different types of DDoS attacks, such as Teardrop, Smurf, TCP SYN Flood, Smurf, Teardrop, Botnet attack and Ping of Death. DDoS assaults can also be categorised as amplification and reflection assaults. The request and response sizes are equal in a reflection attack [23], however in an amplification assault, the response size is significantly larger than the request size [24].

1) *Compromising an IoT device (BoT) and BotNets:*  
Due to the inherent characteristics of botnets, namely the existence of widely dispersed peers and C&C servers across the Internet with masked communication techniques, there is no secure strategy that can be utilized to shut down all bot movement without disrupting real traffic. Bot malware like Mirai actively searches the network for weak points, hunting for devices that allow unauthenticated access or that use weak or default credentials. After the defence is broken, a concise bootstrap script is executed, which downloads the whole program from the C&C. Other methods of spreading the dangerous bot code include the widespread use of phishing emails and freeware promotions to trick people into downloading it on their PCs. Making sure the bot binaries avoid antivirus programmes, which often employ signature-based detection techniques, is just as crucial as the bot binaries' distribution mechanism. It was found that Storm was doing this by repeating the encoding its un authorized two times every hour. Although, as IoT sensors lack the processing capacity required to run sophisticated anti-virus software, botnets that target them may conveniently ignore this complexity.

The rallying phase, which occurs after infection, entails

TABLE II. ATTACK TYPE CLASSIFICATION FOR IOT

Variety of Attack	Attacker's Objective	Size Measured in	Examples	Existing Countermeasure to the Attack
Volumetric Attack	Take up the entire bandwidth between the target and the internet	Bits per Second (bps)	UDP, TCP, DNS floods and amplification of NTP	On-demand scalable scrubbing centres get the rerouted traffic so they can handle it.
Protocol Based Attack	To use server, firewall, and load balancer resources	Packets per Second (pps)	Flooding the TCP SYN, Death Ping, Smurf Attack	Recognizable proof method is utilized regularly to separate among authentic and ill-conceived traffic to impede the assault prior to arriving at the objective server.
Application Layer Attack	To exhaust target resources	Requests per Second (rps)	HTTP Flood, DNS Flood	These are by and large sluggish assaults and relieved by recognizing bot conduct utilizing manual human tests and comparative procedures

developing a hidden method for receiving instructions from the CC [25]. This stage's fundamental objectives are to hide the address of the C&C and ensure that any orders shipped off the bots are encoded. Among the components are the "fast flux" strategy (Tempest), which rapidly pivots the C&C server's tends to behind a DNS name, and the utilization of Domain-Generation Algorithm (DGA) [26]-[27], Which require each recently tainted machine to attempt to determine haphazardly created area names to recognize its C&C. Later changes enjoy taken benefit of distributed correspondence, which further clouds the C&C [28]-[29].

### III. ANOMALY DETECTION TECHNIQUE

Anomaly or outlier detection problems can be used to frame the task of identifying an assault. This is predicated on the idea that malware and regular network traffic would differ in certain ways, allowing an algorithm to distinguish between the two. In this piece of research, we employ deep learning techniques. The utilization of sophisticated artificial neural networks architecture, that is modeled after the human brain and compute in a completely different way from conventional digital methods, is the cornerstone of deep learning approaches. To learn the weights of the network and create a model that can distinguish between assaults and normal behaviour, deep networks in a NADS technique need to know something about the valid data class.

The utilization of autoencoders in non-linear cooperation and for applications requiring network traffic highlights is an expected system for anomaly identification. Autoencoders can learn more effectively with less training data when depth is used because it lowers the computational cost of modelling functions [30]. These affirmations propelled us to test a Deep autoencoder model for irregularity detection in IoT system. An autoencoder is a neural network-based unsupervised learning model that has been trained to reconstruct the input into the output. It is made up of two parts: an encoder and a decoder. The encoder is used for input, and the decoder is used for output (code).

#### A. Deep Autoencoder

Deep Auto Encoder (DAE) is a tool for unsupervised learning of effective coding. The simplest DAE architecture consists of an input layer, several hidden layers, and an output layer that contains the same number of neurons for reconstruction as the input layer. It becomes a deep autoencoder when both the encoder and the decoder, the two parts of the autoencoder, are deep networks. The decoder's layers are inverted, but

both devices share a similar construction. A deep autoencoder features of Deep autoencoder are:

- 1) A array  $X$  representing  $n$  dimension input data, where  $X = (X_1, X_2, \dots, X_n)$
- 2) Fig. 3 shows several hidden layers that stand in for various encoding and decoding levels. These layers produce an irregular illustration of the data input and reconstruct it for the output layer.
- 3) The array  $X' = (X'_1, X'_2, \dots, X'_n)$  is an output layer. The output, which is a recovered copy of the input data, is the same size as the input.

4) In addition to weights and biases, an activation function. An activation function is used by each neuron in a layer to determine its output based on the weighted sum of its input.

There are two types of activation functions utilised in DL models: direct capabilities and non-straight capabilities. The most famous nonlinear actuation capabilities are the sigmoid (calculated), exaggerated digression, and corrected direct unit (ReLU). The exaggerated digression capability is generally used in two-class characterization, the sigmoid capability is explicitly utilized while determining the result as a likelihood, and the ReLU capability is the most often utilized in basically all profound brain organizations. In our examination, we applied the Sigmoid capability (1) to the last layer of the decoder and the ReLU capability (2) to each secret layer of the autoencoder.

$$S(x) = \frac{1}{1 + e^x} \tag{2}$$

$$R(x) = \begin{cases} x, & x > 0 \\ 0, & x \leq 0 \end{cases} \tag{3}$$

A machine learning model's learnable parameters are weights and biases. The biases and weights are assigned to the inputs before they are passed across neurons. While biases guarantee that neuron activation will still occur even if all the inputs are zeros, loads show the amount of impact the info possesses on the result. In a profound autoencoder, layer  $l$  is addressed by  $W_{ij}^l$ , which addresses the weight applied to the connection between hub  $j$  of layer  $l - 1$  and hub of layer  $l$ , and  $b_i^{(l)}$ , which addresses the predisposition connected with the hub. Following formula is used to determine neuron  $i$ 's output value from layer  $l$ .

$$O_i^l = F\left(\sum(W_{ik}^{(l)}) + b_i^l\right) \tag{4}$$

Fig. 3. Deep autoencoder

where  $F$  denoted as activation function,  $x_j$  is a neuron's input value that was acquired from the layer  $l - 1$  output of node  $j$ . Nodes on the subsequent layer  $l$  output from node  $l$  as input. This input data is often transformed into an encoding map by autoencoders, which is then further decoded to produce an output layer that represents the input layer's recovered version.

$$X' = D(E(X)) \quad (5)$$

To utilize autoencoders, E and D should be prepared to lessen the contrast among  $X$  and  $X_0$ . An expense capability that works out the mistake between the real and expected values is utilized to contrast the delivered yield  $X_0$  with the info  $X$  (that is supposed to be created). The model loads are changed during preparing until a decent planning of contributions to yields is delivered to lessen blunder (cost). Deep autoencoders can also use the ANN-specific loss functions. The Mean Squared Error (MSE) is frequently employed. Binary cross-entropy loss is recommended if the input solely contains binary values.

#### IV. PROPOSED METHOD

The research work's methodology is presented in this part. Everyone is aware that the Internet of Things (IoT) is susceptible to a wide range of assaults, including network, software, physical, and privacy-related ones. The new safe IoT framework we provide here allows for the detection of attacks in the IoT environment using a Deep Auto-encoder method. Information extraction from IoT sensor organizations, information preprocessing, information cleaning, highlight extraction, preparing profound learning models, irregularity identification, and effectiveness estimation with accuracy, confusion matrix, recall, and FPR and TPR curves are just a few of the processes that are integrated into the overall framework. This methodology works well for detecting attacks and anomalies in IoT infrastructure. Fig. 4 shows the proposed framework's overall image, which combines numerous distinct sub-processes.

#### A. Data Source

Our research's main objective is to create a clever, secure, and trustworthy framework for identifying anomalies and assaults in IoT sensor networks. The N-BaIoT dataset, an open-source dataset obtained from Kaggle, is used for experiments with our model. The accuracy, recall, and confusion matrices of the dataset are used to assess the model's efficacy. Our experiments' foundational dataset, N-BaIoT, has likewise been utilized in various examinations on botnet assault location. The vast majority of them utilize parallel or multi-class characterization and classification-based techniques. Our goal is to find an appropriate approach to identifying IoT network traffic anomalies without labelling the raw data first. Network sniffing tools are used to intercept IoT network communications. Some freely accessible tools, such tcp dump and Wireshark, can be used for this. The primary duty is to record network packs, which must subsequently be examined and visualised for analysis. A dataset contains the features that have been retrieved from the network packets.

#### B. Data Processing

1) *Data pre-processing*: Data pre-processing is an important stage in learning theories since network data derived from network activity also include these data, which are typically loosely regulated and lead to irrelevant or redundant data values. It cleans up network data by removing unnecessary, distracting, or irrelevant information, which enhances the effectiveness of DE techniques for identifying attack behaviours. The following describes the production, reduction, conversion, and normalisation of features as part of data pre-processing for network data. The preprocessed separated highlights are then used to wipe out repetitive streams, standardize consistent elements, and onehot encode straight out highlights.

2) *Data cleaning*: We initially locate and eliminate mistakes and duplicate values from the dataset in this process. After that, enter a specific value as "NaN" to replace any missing values. Any machine learning algorithm or model's accuracy and effectiveness can be improved with the aid of this procedure.

3) *Feature extraction*: We take a conduct depiction of the hosts and conventions that imparted this parcel each time a bundle shows up. The depiction accumulates traffic measurements over various fleeting windows to order the information that was all sent between the source and objective IPs (channel), the source and objective Macintosh addresses, the source and objective TCP/UDP attachments, and the source and objective IPs overall (attachment). Similar arrangement of elements are removed across different time spans. These attributes may be quickly and incrementally calculated, making it easier to identify fraudulent packets in real time. Additionally, despite being general, these qualities can catch specific activities such source IP ridiculing [2], a component of attacks by Mirai. For example, the highlights collected by the Source MACIP, Source IP, and Channel will rapidly uncover a critical irregularity inferable from the concealed conduct coming from the faked IP address when a compromised IoT gadget parodies an IP.

Fig. 4. Proposed Framework for Anomaly Detection

### C. Split Dataset

- **Training Data:** We prepared and streamline a profound autoencoder on 2/3 of the harmless information from every one of the nine IoT gadgets (i.e., the preparation set of every gadget). To record regular organization traffic designs, this was finished.

- **Testing Data:** Every one of the malevolent information as well as the excess third of harmless information made up every gadget's test information. We utilized the relating trained autoencoder as an anomaly finder on each test set. The detection of anomalies—the hacks perpetrated from each of the aforementioned IoT devices—was successful 100% of the time.

### D. Train the Deep Autoencoder

The Harmless and Inconsistency samples are then picked as the objective highlights for the DNN's training on the Train dataset utilizing twofold characterization. A prepared DNN model is made after this stage. We utilize Deep autoencoder as our essential anomaly identifier and exclusively keep a model for each IoT gadget. A neural network that has been trained to adapt its contributions after some upgradation is called an autoencoder. The system will become familiar with the connections between its feedback highlights and important ideas on account of the pressure. An autoencoder will find lasting success at reproducing typical perceptions on the off chance that it is exclusively prepared on harmless cases, yet it

Fig. 5. Distribution of benign and infected devices in dataset

will neglect to recuperate unusual perceptions (obscure ideas). We mark the gave perceptions as strange when a sizable reproduction blunder is found.

We amplify the genuine positive rate (TPR, distinguishing assaults when they happen) and diminish the bogus positive rate in each preparing model by streamlining its boundaries and hyperparameters (FPR, wrongly stamping harmless information as vindictive). The model learns examples of ordinary movement from two different datasets that are used for training and optimization and only contain benign data.

### E. Testing / Detection

The Test dataset is then used to put the trained model to the test, identifying records as either benign or anomalous flows. Benign traffic was permitted to pass through unimpeded if it was anticipated. On the other side, if an anomaly is anticipated, the network administrator is alerted to take further action.

In order to categorise each instance as benign or anomalous, we eventually apply the improved model to feature vectors collected from constantly monitored packets. Then, whether the entire related stream is benign or anomalous is determined by a majority vote on a series of marked occurrences. As a result, if an abnormal stream is found, an alarm might be sent because it might be a sign of malicious activity on an IoT device.

### F. Evaluation Metric

It is possible to calculate accuracy using the proposed deep learning framework. Additionally, we can quantify the complexity of our deep learning models, which refers to how many parameters the model contains and how much weight it has when stored to disc, as well as how long the training process takes to obtain good accuracy in terms of time in seconds. The accuracy, precision, false-positive rate, and recall may then be determined for the task of anomaly detection system, which determines the proportion of actual properly recognises instances by model. Eq. (3) demonstrates how to compute recall using (8).

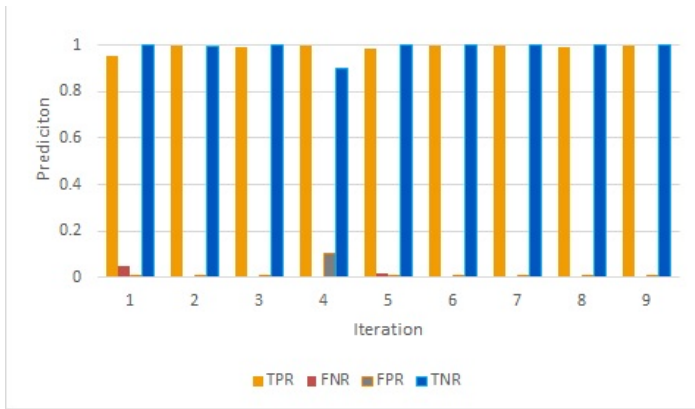

Fig. 6. Prediction probability factor for multi layer perceptron

Fig. 7. Prediction probability factor for random forest

$$ACC = \frac{TP + TN}{TP + TN + FP + FN} \quad (6)$$

$$PR = \frac{TP}{FP + TN} \quad (7)$$

$$FPR = \frac{FP}{FP + TN} \quad (8)$$

$$Recall = \frac{TP}{TP + FN} \quad (9)$$

Whereas, TP termed as True Positive, FP as False Positive, TN as True Negative, and FN as False Negative, FPR as False Positive Rate, TPR as True Positive Rate, TNR as True Negative Rate, and FNR as False Negative Rate.

## V. RESULTS AND DISCUSSION

Python was utilised as a platform for implementing the suggested model, and experiments were carried out on an N-BaIoT dataset of an IoT sensor environment. The nine innocuous data sets that we gathered correlate to the nine IoT devices. Fig. 5 shows how different infected and healthy devices are distributed throughout the dataset.

Fig. 8. Confusion matrix of multi layer perceptron

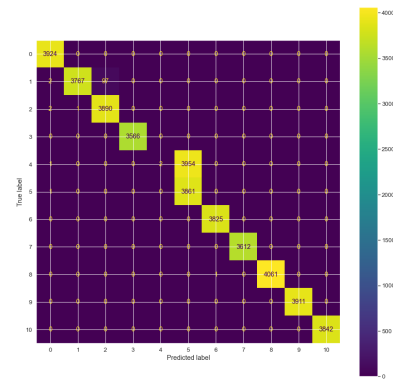

Fig. 9. Confusion matrix of random forest

We offer a comparison of the proposed model, MLP, and RF schemes, with the results for the performance metrics Accuracy, confusion matrix, Precision, F1-Score, Recall and TPR, TNR, FPR, FNR, to confirm the accuracy of the suggested technique. The results of the performance metric taken into account in this study with regard to MLP and RF schemes are summarised in Table III. It is easily shown that the multi-layer perceptron neural network scheme is outperformed by the machine learning-based random forest scheme.

The likelihood of prediction rate for TPR, FPR, TNR, and FNR in MLP and RF systems is shown in Fig. 6 and 7. Misunderstanding Matrix is also constructed for MLP and RF techniques, as shown in Fig. 8 and 9, respectively, to make it simple to spot class-related confusion. It is also referred to as an error matrix and is offered as a table matrix for displaying algorithmic performance and ambiguity in classifier predictions. The performance of the RF technique would not, however, provide the accuracy that is promised as the IoT network's size increases. In light of the massive data set generated by the IoT environment's many IoT devices, the Deep learning-based autoencoder approach is seen as a viable mechanism.

We choose the Window size as 82, Learning rate as 0.01, Optimizer as Adam, activation function as Relu in encoder, and Relu and Sigmoid are utilised in decoder while building the deep learning based autoencoder, referred to as deep autoencoder in this work. The training process's Loss function is the mean square error. Tensorflow was utilised for training.

TABLE III. PERFORMANCE SUMMARY OF MULTI LAYER PERCEPTRON AND RANDOM FOREST

Scheme	Accuracy	Recall	F1 Macro	F1 Micro	TPR	FNR	FPR	TNR
MLP	89.39%	89.52%	0.86	0.89	0.89386	0.16014	0.01061	0.98939
RF	90.0%	91.0%	0.87627	0.90482	0.90482	0.09518	0.00952	0.99048

Fig. 10. Loss function of deep autoencoder

The dimension of the input layer for each autoencoder was equal to the number of features in the dataset (i.e. 115). For proper compression of the input layer between encoder and decoder and to reflect its fundamental properties, the autoencoder must effectively execute dimensionality reduction internally.

It is important to appraise the blunder for the model's present status as a component of the improvement technique more than once. To refresh the loads and lower the misfortune on the ensuing assessment, it is important to choose a mistake capability, otherwise called a misfortune capability, that might be utilized to gauge the deficiency of the model. A planning from contributions to yields is advanced by brain network models through models, and the misfortune capability utilized should be suitable for the particular prescient displaying task being tended to, like grouping or relapse. Also, the result layer's design should be reasonable for the chosen misfortune capability. Fig. 10 compares the loss functions for MLP and Deep autoencoder models; when the number of IoT devices is lower, both techniques perform similarly (up to 2). However, when the number of IoT devices grows, the suggested deep autoencoder model outperforms MLP in terms of performance.

The performance of the Deep autoencoder is summarised in Table IV. When compared to MLP and RF techniques, the suggested Deep autoencoder methodology performs better. The outcomes attest to the proposed IoT network solution's superiority. Additionally, it is noted that among the three schemes taken into account in this study, the RF technique is the second-best model and the MLP is the poorest.

## VI. CONCLUSION

Current internet security measures, such as firewalls and gateways, are ineffective at identifying sophisticated and unidentified assaults in an IoT environment. It is essential to secure this network infrastructure as demand for IoT networks grows. This study explains how AI works to identify assaults

TABLE IV. PERFORMANCE SUMMARY OF DEEP AUTOENCODER

Node Number	Shape of Data	Detected Anomalies
1	(22154, 115)	0.0%
2	(96781, 115)	100.0%
3	(60554, 115)	100.0%
4	(65746, 115)	100.0%
5	(156248, 115)	99.94%
6	(56681, 115)	100.0%

and anomalies in the environment of IoT sensors. The detection and classification of IoT botnet attacks using deep learning techniques showed good accuracy. These approaches also function well with a variety of feature counts, and in general, more features do not degrade their efficiency, allowing for the use of all data features in a real-world setting. To recognize benign and irregular traffic, this study proposes a proficient anomaly detection technique in view of deep learning for IoT network design. This system actually gains significant complex examples from IoT network streams. suggested to train and test On the recently made available IoT-Botnet 2020 dataset, a deep autoencoder is tested. Several data processing procedures, including feature extraction, data cleaning, and data pre-processing, are carried out to provide the best outcomes. We construct a number of metrics, including Accuracy, Precision, Recall, Confusion Matrix, and FPR, to assess how well our suggested model performs. A comparison between the proposed model and the current RF and MLP approaches is also done as proof. The ML based RF scheme works with an efficiency of 90.0%, and the neural network based scheme MLP shown the accuracy of 83.39%, while the proposed Deep Learning scheme, deep autoencoder has proved its superiority among the other two methods considered in this study.

The data under consideration in this inquiry is N-BaIoT, which presents 115 aspects of the data samples. A botnet is the type of DDoS attack under consideration. The viruses BASHLITE and Mirai are used to cause network anomalies. For the aforementioned considerations, the results reported in this paper are validated. However, there is still need to investigate the performance of deep autoencoders for various types of datasets and malwares.

# Machine Learning Techniques to Enhance the Mental Age of Down Syndrome Individuals: A Detailed Review

Irfan M. Leghari<sup>1</sup>, Hamimah Ujir<sup>2</sup>, SA Ali<sup>3</sup>, Irwandi Hipiny<sup>4</sup>

Faculty of Computer Science and Information Technology, Universiti Malaysia Sarawak, 94300 Kota Samarahan, Sarawak<sup>1, 2, 4</sup>  
Faculty of Artificial Intelligence & Mathematical Sciences, SMIU, Karachi-74000, Pakistan<sup>3</sup>

**Abstract**—Down syndrome individuals are known as intellectually disabled people. Their intellectual ability is classified into four categories known as mild, moderate, severe, and profound. These individuals have significant limitations in learning and adapting skills. Psychologists evaluate mental capability of such individuals using conventional intellectual quotient method instead of using any technology. The research matrix shows most of research has been carried out on analyzing neuroimaging, antenatal screening, and hearing impairment of individuals. But there is still an obvious gap of evaluating mental age using artificial intelligence. We have proposed an artificial neural network model, which supervises how software is used to obtain dataset using Knowledge Base Decision Support System. In a survey (N = 120) individuals examined by psychiatrist, medical expert, and a teacher to assess the presence of Down's syndrome by analyzing their physical and facial appearances, and communication skills. Only (N = 62) individuals declared as Down syndrome. Selected individuals invited to perform mental ability assessment using Interactive Mental Learning Software. The results of mental age of Down syndrome with a raise in IQ from severe to moderate (20% to 35%), moderate to mild (35% to 75%) severity were carried out with the help of assessing the interactive series of software opinion polls based on comparison, logic, and basic mathematical operations using initial IQ (iIQ), and enhanced IQ (eIQ) variables input and output parameters.

**Keywords**—Artificial Intelligence; Artificial Neural Network (ANN); Down Syndrome Individuals (DSI); Interactive Mental Learning Software (IMLS)

## I. INTRODUCTION

The usage of artificial intelligence (AI) in biological fields is increasing, but it's usage in mental disorders is only partial [1-2]. Machine learning (ML) supports the integration of psychological, clinical, and social aspects when approaching the diagnosis of impairments [3]. Artificial intelligence-based applications have promptly been developed for psychiatric diagnosis [4-9]. Furthermore, AI has enormous potential for defining the diagnosis of mental illnesses [10-12]. The purpose of this research is to provide a smart way of learning for Down syndrome individuals (DSI). Of course, this will be helpful for them in practical and professional life, so that they can behave independently with less assistance from their parents or teachers. Until now, research has been carried out on their facial expressions, prediction of their inhibitory capacity, and prediction of mental deficiency using clinical technologies, but still, no work has been done on learning using artificial

intelligence technology, which is very important and needs to be focused on. Artificial intelligence techniques provide the best solution using machine learning and artificial neural networks, this work will be explained in section 4.3.

Born with multiple challenges, Down syndrome individuals are part of every society. They are supposed to be a social and economic burden on families and society. Down syndrome is caused by the presence of an extra copy of chromosome-21. The prevalence level of DSI is approximately 1 in every 800 births [13]. These individuals may have significant cognitive impairments and have an intelligence quotient (IQ) ranging from 30 to 70 percent. In addition, mental abilities that are mostly decreased in these individuals including expressive language, memory, and fine motor skills. Such individuals also have significant limitations in learning and adapting. Adaptive abilities are linked with general mental skills measured with IQ [14]. While the quality of life for DS individuals is improving in both the educational and social domains [15].

The learning process associated with cultural and environmental factors is important for DS individuals due to their social requirements and independency [16-18]. Hence, due to the common difficulties in mental and fine-motor skills, the potential of the individual with Down syndrome as a learner might be perceived as limited [19-21]. They face several different problems in daily life activities while walking, talking, chewing, and learning [20]. The learning ability of DS individuals is classified into four categories: mild, moderate, severe, and profound (Fig. 1). These categories are classified according to their mental age. But in general practice, DS people are grouped as per their physical age. This classification depends on the range of intelligent quotient scores and symptoms [14].

	A normal mind	75 - 100%
a.	Mild	50 - 75%
b.	Moderate	35 - 50%
c.	Severe	20 - 35%
d.	Profound	10 - 20%

Fig. 1. Level of mental impairment of Down Syndrome Individuals.

- 1) Learn in homogeneous educational environments and perform social activities with the least support.
- 2) Individuals need partial support from parents and teachers to carry out tasks. The practitioners use rehabilitation tactics for development ranging from moderate to mild.
- 3) This category requires continued learning and support to carry out an activity.
- 4) Significant deficits in adaptive and functional skills.

The research plan demonstrates the selection criteria using a survey bifurcated into two parts, i.e., general, and technological. After seeking the research gap the research contributions propose the technical way to evaluating unidentified mental age of DS individuals. The research further discusses the implementation of software-based ANN model (Fig. 2).

Fig. 2. Proposed research plan.

## II. LITERATURE REVIEW

During the artificial intelligence age of the last decade (2012-2022), an essential number of studies have addressed the use of AI techniques to support people with intellectual disability. The comprehensive literature presents review of the highly illustrative research work of the past ten years i.e., 2012-2022. Furthermore, a research paper matrix is used to identify the research gap in the context of the previous decade (Table I).

Vicari et al., Rosen et al., & Hategan et al., [22-24] proposed a neuroimaging technique using machine learning (ML). Potential bio-supportive artificial intelligence models used to predict mental age are based on brain or neuroimaging data, which serve as neuroimaging data with ML techniques that provide excessive insights for developmental disabilities in Down syndrome children. Machine language models were proposed using imaging recognition features. Research carried out to present knowledge of the neurocognitive, psychopathological, and neurobiological assessment and treatment of patients with Down Syndrome, which suggested rehabilitation as sole effective method for improving cognitive and linguistic abilities.

Amanda Saksida et al., [25] highlighted the problem of cognitive and hearing impairment that happened to most DS children during early childhood. The authors evaluated the effects of hearing impairment on receptive language and

hearing skills and observed main factors of cognitive decline using audiometry testing. In a survey over 41 participants aged between 3 and 10 with DS out of 150 excluding individuals with serious disorders of language, visionary, and cognitive with an IQ of 40, were referred for the audio-logical inspection process. Cognitive skills of 17 individuals of 6 years were measured.

Falin H.E et al., [26] presented a machine learning model to predict Down syndrome in third trimester antenatal screening. The authors used the machine learning (ML) random forest model to predict Down's syndrome. In a survey, around 58,972 pregnant women underwent screening to analyze predictive efficiency. The ML model predicted ratio of 66.7% DS, with a 5% false positive rate in the data set. The model achieved a DS detection rate of 85.2%, with a 5% false positive rate. The study showed that the ML model expands the DS prediction rate with a similar false positive ratio in contrast to the laboratory risk model.

Furthermore, Jojoa-Acosta et al. [27] investigated how does a neuropsychological assessment of intellectual functioning in people with Down syndrome changes over time. The purpose of the research was to predict repressive control capacity using a novel data-driven method. A sample of  $n = 188$ ; 49.47% men; and  $33.6 \pm 8.8$  DS adult individuals having mild-moderate levels of mental retardation was taken into the process. Machine learning Random Forest model used to support vector machine and logistic regression algorithms for the prediction of inhibition capacity. The neuropsychological method was applied for data collection of assessment of memory skills, language skills, executive functions, and praxis was submitted for execution in an algorithm. The outcomes reveal that the finest interpreters for inhibition capacity were verbal memory, constructive praxis, planning, immediate memory, and written verbal comprehension.

In a research led by Children's National Hospital [28] a software device built using machine learning and deep learning technology that detects the presence of the genetic syndrome. The innovation of a software device helps children without any access to specific clinics. The designed software increases access and ML technology to predict the syndrome. The method detects the existence of genetic syndromes using facial photographs. The researchers trained data from 2,800 pediatric DS individuals from different countries.

Similarly, Aida Catic et al. [29] proposed an image processing recognition method to identify affected fetuses early in pregnancy through accurate genetic testing to provide the woman with the preference for the selective continuation of the pregnancy or termination. They intend to replace the traditional process of chromosome photographs with image processing recognition and rule-based classification algorithms. A sample of 2500 pregnant women was collected to determine the figures of maternal levels. All women underwent an ultrasound examination. After the ultrasound examination and maternal blood sample, the blood samples were analyzed using the Prisca software. Artificial Neural Network expert system parameters indicate the tested subject has one of the prenatal syndromes or is healthy.

TABLE I. RESEARCH PAPER MATRIX (IDENTIFYING RESEARCH GAP) MACHINE LEARNING TECHNIQUES TO ENHANCE THE INTELLIGENT QUOTIENT LEVEL OF DOWN SYNDROME INDIVIDUALS

James H. Cole et al. [30] employed a machine learning approach to predict mental age of DS individuals using a structural neuroimaging dataset (N = 46). The chronological age subtracted from predicted age to get a different score of brain-predicted age. The research model analyzed the brain-predicted age calculation at three levels. In the first level, the similarity index of the Gaussian Processes (GP) regression model using a magnetic resonance imaging (MRI) dataset was

collected. In the second level model accuracy was assessed for differentiating brain-predicted age. In the third and fourth levels, testing and brain age were predicted. The authors emphasized the need to examine trajectories of change in DS individuals to get further information about the likelihood of future neurologic decline and negative brain ageing.

Moreover, James H. Cole et al., 2017 [31] analyzed the brain diseases burden of age-associated functional decline. A supervised machine learning model proposed for brain age prediction. Neuroimaging data obtained from MRI scans using machine learning regression model. Cross-validation included 90% of participants and a predicted age of let out of 10%. The predicted mental age was compared with the chronological age of test-set participants. The brain-predicted age difference between brain age and chronological age is assumed to reflect advanced ageing and younger brains. The authors have emphasized that the technical aspects of analyzing brain age are further improved. Neuroimaging brain age measures could be used to evaluate neuroprotective impediments.

To improve the communication ability Vanessa G. Felix et al. [32] developed HATLE application to provide a computer-assisted technique for DS individuals. The data was obtained through a survey of DS participants speaking Spanish aged between 6 and 15 years. IQ scores were not available for any of the participants. The average age of DS individuals was 10.4 years. During the assessment, literacy skills including letter identification, reading, handwriting, and spelling were assessed. A score of all assessments from 0 to 10 was obtained. The training with HATLE was processed group-wise using Android tablets and computers. The outcome of the research reveals that the initial recognition level was set at 0.5, which slowly increased the accuracy rate of further demanding thresholds in steps of 0.1.

Housseem Turki et al. [33] proposed a Dynamic Bayesian Network (DBN) for knowledge extraction from historical data on temporal data to develop a structured learning algorithm for predicting mental retardation in Down syndrome individuals. The experiment took place at the Medical Genetics and Child Psychiatry departments at a hospital in Tunisia. The authors obtained a heterogeneous dataset in collaboration with a team of experts. The purpose of the research is the extraction of knowledge from a great number of datasets that evolve dynamically.

Jamie O. Edgin et al. [34] analyzed a problem with late-developing neural systems in DS individuals and the function of the prefrontal cortex. The assessment of functions was observed relatively less as compared to other aspects of cognition. The results observed were that implicit memory and spatial position are less affected than an object in episodic memory. The authors recommended further study of the fractionated skills patterns in DS individuals, which may benefit developmental change of cognitive functions.

To provide similar learning opportunities for differently abled people Syed Ali [35] proposed a model for adaptation of the Heterogeneous Education System (HES) to the Homogeneous Education System (HES) proposing information technology tools of speech recognition and mathematics. The proposed model suggests that by providing the procedure of conversion and tools, equal opportunities can be provided to different disabilities in the same learning environments. The research has not particularly been done for DS individuals, but the mechanism strongly suggests for all individuals with perform differently. Hence, the research delivers importance to enhance learning and to improve communication difficulties.

In neuroimaging data retrieval, Vicari et al., [22] proposed techniques assessed, including magnetic resonance imaging (MRI), a biotechnology body and brain imaging scanning technology. Rosen et al.; Hategan et al.; Raznahan et al.; & Wintermark et al. [23-24], [36-37] proposed that magnetic imaging is the leading clinical technique to evaluate the level of mental impairment. This technique is used to analyze psychiatric abnormalities that are difficult to detect using computed tomography (CT) For example, AI multimodal learning applications and deep learning methods have been developed for brain imaging [38]. Moreover, convolutional neural networks [39] and deep neural networks [40-42] engaged in neuroimaging to explain the neural relationships of mental disorders [40] [43-46].

Heinsfeld et al., [47] proposed that electroencephalography (EEG) signals are important to understanding how the human mind works and evaluating mental impairment. In contrast to MRI and CT, electroencephalography has greater resolution [48] analysed by Grotegerd et al. In addition, EEG data graphs were evaluated using artificial intelligence models presented by Hannesdóttir et al.; Avram et al., Thibodeau et al., & Hosseinifard [49-52].

### III. RESEARCH CONTRIBUTIONS

#### A. Mental Age Evaluation

This research illustrated the valuable studies that tried to solve problems in evaluating and diagnosing mostly researched cognitive impairment, i.e., Down syndrome. Wherein, artificial intelligence neural network model-based techniques and software approaches are implemented to bring down syndrome analysis and seek ratio of their mental approach and to further strengthen them with software. The proposed model (Fig. 3) is divided into two portions (*A and B*). Firstly, the model evaluates the identification of Down syndrome. Here, the model reveals three major components of cognitive psychology known as cognitive neuroscience, human psychology, and information processing through computers. As per the neuroscience perspective, thinking abilities depend on working memory. The area of cognitive psychology considers the study of mental functions in which people require knowledge to understand their experiences. The model emphasizes both artificial intelligence and biological methods. The investigation is applied to individuals diagnosed with Down syndrome.

A survey comprised over 120 individuals with DS of different age groups ( $\geq 8$  &  $\leq 30$ ) was included to identify different cognitive traits (Fig. 5). The survey was based on interviews conducted by a team consisting of a psychiatrist, special education instructor and parents accompanying the DS individual. The team of psychiatrists, based on observations and professional knowledge, identified intellectual disability using facial expressions and psychological traits of DS individuals. Distinct facial features include distinctive slanting eyes, a small chin, abnormal outer ears, a flat nasal bridge, and a flattened nose. Psychological traits include talking, paying attention, and social rules. A team of special education teachers used simple mathematical problems to evaluate numerical skills, reasoning, and decision-making skills. The research contributions are further based on an artificial neural network model to evaluate the intelligent quotient of Down syndrome

individuals. The intelligent algorithm reveals the criteria of the artificial neural network model. The software access repeatedly until their mental functioning improves from severe to moderate and from moderate to mild levels using variables initial IQ (iIQ), and enhanced IQ (eIQ) denoted as input and output parameters based on the practical, creative, and analytical testing. The method constructs membership functions building set of rules into the knowledge base and evaluates rules in the Inference Engine (Table II).

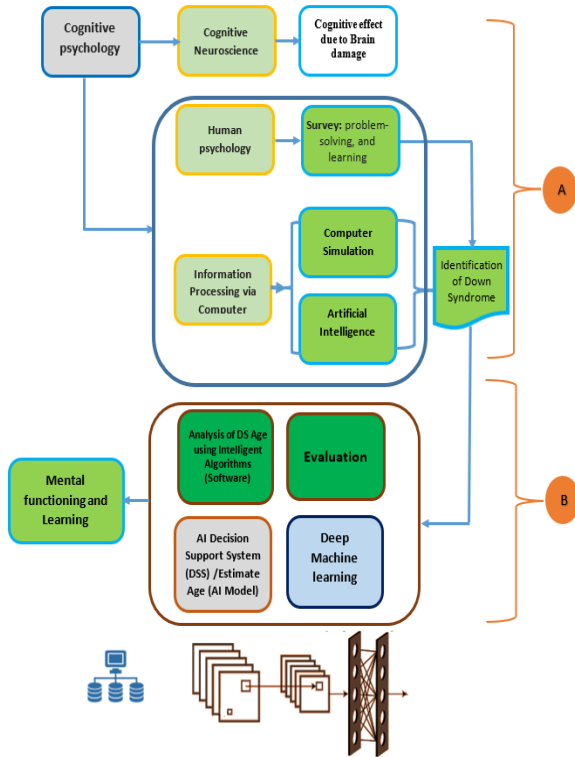

Fig. 3. A proposed model of mixed approach.

The artificial neural network model presents the mechanism of the intelligent algorithm for repeating the usability of the interactive software, denoted as the middle layer of the ANN model (Fig. 4). The neural network model is supposed to judge the cognitive traits of individuals to analyze the IQ. The middle layer plays a part in the manifest of the interactive software application. The overall process is based on three layers. The input layer holds the initial data of the learning process of DS individuals (8–30 years). The intermediate hidden layer represents long-term memory, sensing, decision-making, perception, supervisory skills, thinking, logic, and learning complexities of the DS individuals. The hidden layer performs a nonlinear transformation of the inputs entering the network. The computations from the hidden layer are transformed into the output layer to reveal data to the outside world in the form of the computed mental level and capability.

Fig. 4. Artificial neural network model.

TABLE II. INTELLIGENT ALGORITHMS OF INTERACTIVE MENTAL LEARNING SOFTWARE

<p><i>Step 1 – Define variables and parameters</i>  <i>Variables or parameters are inputs and their outputs like parameter for IQ are,</i>  <i>IQ (iq) = {practical, creative, analytical}</i>  <i>Every member of this set is covering some level of intelligence IQ values.</i>  <b>Create a matrix of based on their syndrome and mental impairment. Build a set of rules into the knowledge base in the form of IF-THEN-ELSE structures.</b>                  If {level of Down Syndrome is <b>Mild</b>} then (IQ level <b>50-75</b>) Else                  If {level of Down Syndrome is <b>Moderate</b>} then (IQ level <b>35-50</b>) Else                  If {level of Down Syndrome is <b>Severe</b>} then (IQ level <b>20-35</b>) Else                  If {level of Down Syndrome is <b>Profound</b>} then (IQ level <b>10-20</b>)</p> <p><i>Step 2 – Construct membership functions for Step 1</i>  <i>Step3 – Maintained knowledge base rules</i>  <i>Step 4 – Evaluate rules in the rule base (Inference Engine)</i>                  End</p>
---

**B. Supervised Learning Algorithm**

We have implemented ML algorithms to evaluate the projected mental age of the DS individuals. Individuals with Down syndrome's brain/mental age efficiency improves with practice on a software based on supervised learning algorithm. The end of the exponential research (N = 120), an efficient framework is proposed to identify and improve the mental age of Down syndrome children and young adults (Table III). For the analysis of training set sizes, bootstrapping techniques are used to estimate the reliability of the ML algorithm for different training set sizes. In the ANN technique, the resampling method is used to resample the original training set with a replacement to get a new training set of the chosen sample size. The advantage of this technique is that it allows us to judge the toughness of performance around training dataset sizes and to recognize the smallest training set sizes essential for checking the performance above the expected level.

**C. Multicriteria Decision Support System (DSS)**

To improve the learning abilities of DS individuals, the Knowledge Base Decision Support System (DBSS) is used in cascading fashion. The decision support system is based on four multiple criteria for DS individuals for learning and problem solving. The decision support system checks all the four criteria of Down syndrome in cascade and fixes the criteria based on the minimum criterion. The algorithm is based on decision-based criteria over an alleged cascading in descending order of the learning model on minimum criteria.

- Call at the Dataset.
- A cascading effect scenario to detect.
- Decision support algorithm is used for deciding the set accordingly to minimum criteria.
- Intelligent Quotient (IQ).

**D. Interactive Mental Learning Software**

The interactive graphical environment is based on 30 public opinion polls (Table IV). Software provides an interactive and simple platform to use opinion pool with the help of teacher or parents. The series of opinion polls contain questions based on comparison, logic, and basic mathematical operations. Individuals are supposed to search for the best option to increase their mental score at the end of the pool (Fig. 6).

The software is accessible through laptop, desktop, or smartphone. Input is selected using a mouse, keypad or by touchpad. Different series of questions appears showing three options to choose best one. Colorful shapes of birds, fruit, and vegetables, colors, vehicles enhance interest of individuals and reduce frustration. The comparison covers the questions of the basic shapes and figures, which helps in developing the logic of the DS individuals. Making comparisons between numbers and alphabets helps DS individuals develop their decision-making abilities. Basic mathematical operations cover only addition (+) operation. The mathematical console is comprised of the addition of birds, animals, shapes, and numbers. The assessment process is divided into three rounds (Round-I, II &

III). Round-I process (N = 20) individuals (Table V). Round-II processed (N = 20) (Table VI) and Round-II processed (N = 22) individuals (Table VII).

TABLE III. ARCHITECTURE FOR MENTAL AGE (MA) OF DS INDIVIDUALS

Age assessment Module		System	Inference Engine (Decision Support System)	System Module
Mild	50-75	It stores IF-THEN rules provided by experts.	It simulates the human reasoning process by making system inference on the inputs and IF-THEN rules.	It transforms the set obtained by the inference engine into a crisp value.
Moderate	35-50			
Severe	20-35			
Profound	10-20

#### IV. DISCUSSION AND FUTURE WORK

The research carried out to investigate the mental age of DS individuals. The literature matrix identified the research gap of assessing actual mental age using AI-ANN model. The technology claims to enhance mental age of DS individuals having least IQ level. The interactive and simplest platform of software increase usability interest and reduce frustration. The different question of logical, mathematical, and analytical reasoning boosts the thinking ability, perception, reasoning, logic, and memory of the individuals. Such traits result change in IQ from severe to moderate (IQ>20% to 35%), moderate to mild (IQ>35% to 75%). Research outcomes also show the comparison and authenticity between software-based IQ assessment and traditional methods. The variation in the mental age is identified with yellow line of the graphical illustration (Fig.7, 8 and 9).

Fig. 7. Graph - software driven mental age round-I.

Fig. 8. Graph - software driven mental age round-II.

Fig. 9. Graph - software driven mental age round-III.

In future work, more feature added system for enhancement of severe level of mental retardation may be suggested for academic purpose to help different intellectual disabilities in special education and job oriented technical training to make them independent.

#### ACKNOWLEDGMENT

The authors fully acknowledged Universiti Malaysia Sarawak for all the support which makes this important research viable and effective. The acknowledgement is also extended to all participants who were voluntary involved in the dataset collection.

Chongqing Key Laboratory of Image Cognition, China, Chongqing

**Abstract**—Alzheimer's disease (AD) is an irreversible neurological disorder, so early medical diagnosis is extremely important. Magnetic resonance imaging (MRI) is one of the main medical imaging methods used clinically to detect and diagnose AD. However, most existing computer-aided diagnostic methods only use MRI slices for model architecture design. They ignore informational differences between all slices. In addition, physicians often use multimodal data, such as medical images and clinical information, to diagnose patients. The approach helps physicians to make more accurate judgments. Therefore, we propose an adaptive weighted multimodal integration model (AMIM) for AD classification. The model uses global information images, maximum information slices and clinical information as data inputs for the first time. It adopts adaptive weights integration method for classification. Experimental results show that our model achieves an accuracy of 99.00% for AD versus normal controls (NC), and 82.86% for mild cognitive impairment (MCI) versus NC. The proposed model achieves best classification performance in terms of accuracy, compared with most state-of-the-art methods.

**Keywords**—MRI; global information images; maximum information slices; adaptive weights; integration method

## I. INTRODUCTION

Alzheimer's disease, a chronic neurodegenerative disease causing the death of nerve cells and tissue loss throughout the brain, usually starts slowly and worsens over time. AD is expected to affect 1 out of 85 people in the world by the year 2050 [1]. The progression of AD gradually leads to memory degradation and impairment of cognitive function, eventually leading to irreversible neuronal damage [2]. Although no treatment has been proven to be effective in preventing the progression of AD [3], the early diagnosis of AD remains important for subsequent treatment to delay the onset of cognitive symptoms [4].

Since 2013, deep learning has begun to gain considerable attention in AD detection research, with the number of published papers in this area increasing drastically since 2017 [5]. Early unsupervised methods used autoencoders or restricted Boltzmann machine methods to extract features that were then used for the classification of Alzheimer's disease [6]–[8]. Supervised learning applied to the diagnosis of Alzheimer's disease has been particularly well studied compared to unsupervised methods. Convolutional neural networks (CNNs) are the most successful deep models for image analysis, aiming to make better use of spatial information by taking 2D/3D images as input and extracting features by stacking several

convolutional layers; the result is a hierarchy of progressively abstracted features [9], [10]. Most studies on Alzheimer's disease have been mainly architected by 2D CNNs or 3D CNNs as depth models. A large number of studies have performed feature extraction of MRI slices by 2D CNNs for ADNI classification [11]–[16]. Since MRI provides 3D images, how to select MRI slices is a question worth thinking about. Meanwhile, 2D slices cannot contain all the information of 3D MRI, so it is missing the global information. 3D CNN is widely used for diagnosis of 3D MRI, which does not require slice selection and also contains global information. However, AD detection must take the whole image or some ROI as input [17], [18]. This results in a steep increase in the number of parameters, which can create problems such as large amount of computation, time-consuming, and overlapping data. The joint 2D-3D CNN [19]–[21] first performs 3D feature extraction by multiple 3D data inputs, and then obtains the final classification result by 2D CNN. Likewise, there are also problems such as large amount of computational cost and time consuming. In addition, in the early detection of Alzheimer's disease, the degree of brain atrophy is less variable, and assessment by a single modality of MRI alone may have a certain bias; a combined assessment with multiple modalities will yield a relatively more accurate diagnosis.

Based on slice-level classification, there is a lack of three-dimensional spatial information and the subjective uncertainty of slice selection. We proposed to effectively superimpose all slices to generate a dynamic 2D picture containing multiple slice information changes, i.e. a global information image. At the same time, the slice with the largest amount of information is also selected through the method of image entropy, and the clinical information is used as the input of the multi-dimensional feature auxiliary integrated approach. From our experiment, the proposed AMIM model has improved the performance significantly. The main contributions of our study are summarized in the following three folds.

- We propose an adaptive weighted multimodal ensemble model. The model uses an adaptive weighted method to optimize the different branches weights. It can effectively reduce the large amount of computational cost and time, compared with the grid search method.
- For the first time, we propose a new MRI image preprocessing method, which uses dynamic images and maximum information entropy slices as the input

of MRI images; at the same time, clinical information modality is introduced to obtain better classification performance.

- A comprehensive evaluation is conducted on ADNI dataset. Experiments show that our method achieves best classification performance in terms of accuracy, compared with most state-of-the-art methods.

The rest of the paper is structured in sections and represented as follows. In Section II, related work describes the research status of Alzheimer’s disease classification in detail. Section III introduces the structure and algorithm of the AMIM model. Section IV introduces the classification performance of the model on the ADNI dataset. Section V discusses the performance analysis of different views. Section VI concludes the paper.

## II. RELATED WORK

With the rapid development of deep learning since 2012, there are more and more researches on the diagnosis of Alzheimer’s disease. Researches based on Alzheimer’s disease classification can be divided into the following branches according to input: ROI level, Patch level, 3D Subject level and 2D slice level. With ROI models [22], [23], manual selection of regions is required to extract the region of interest of the original brain image as the input of CNN model, which is a time-consuming task. With patch models [19]–[21], multiple patches can be obtained from the entire 3D MRI, but there is a problem of data overlap. It is much more straightforward and desirable to use the entire image as input. At the 3D subject level, Korolev et al. [17] adopted 3D VGG and 3D ResNet as the backbone network for feature extraction, but the classification accuracy was only more than 80. Spasov et al. [18] proposed a method combining 3D MRI with clinical information, which can obtain good classification results. However, regardless of single mode or multi-mode 3D MRI, there is a large amount of calculation and long running time. In 2D slice classification method, it can reduce the number of hyperparameters to a certain extent. Due to the small sample size of medical dataset, Hon et al. [11] proposed to apply transfer learning to the classification of Alzheimer’s disease. 32 slices were taken from each object as the dataset, and the model performed well. However, this result was only for the image level, without considering the subject level. Islam et al. [12] proposed a deep convolutional neural network for the diagnosis of Alzheimer’s disease using brain MRI data analysis, and obtained good classification results. Zhang and colleagues [13] performed a systematic evaluation of CNN models with different structures and capacities, and the experimental results showed that the advanced structural models with medium capacity performed better than the models with maximum capacity. Good results have also been obtained. However, these methods are based on 2D images and cannot contain all the information of brain scan. They ignore the spatial information of 3D. The same situation exists in other slice classification studies [14]–[16]. According to the above analysis, we propose a new AD classification network architecture, AMIM, combining 2D-3D MRI and clinical information.

Fig. 1. The AMIM for alzheimer’s disease classification based on MRI and clinical information

## III. METHODS

In this paper, we propose an AMIM model that combines 2D-3D MRI to solve the problem of missing 3D spatial information for slice based classification. Clinical information is also introduced as the input of another modality. The model uses an adaptive weighted method to learn the weight shares of different classifier. Its architecture is shown in Fig. 1. Our proposed method is flexible and can in principle integrate other imaging modalities, such as positron emission computed tomography (PET), as well as other different clinical datasets. With the inspiration of the idea of transfer learning, we use the classical neural network pre-trained by ImageNet and removing the last classification layer as the backbone network of feature extraction [24]. Resnet18 as a backbone network will be introduced here.

In the following, we present our method in four parts. First, we introduce the dynamic image generation method and the maximum information entropy slicing method, respectively. Then, we present the adaptive weighted multimodal integration method. Finally, we introduce the training and optimization.

### A. Dynamic Image

In the non-medical field, a popular method to represent a series of images is to apply a temporal pooling operator to the features extracted at individual images, for instance, temporal templates [25], ranking functions [26] and other traditional pooling operator [27]. We use the Z-dimension of the 3D MRI as the temporal dimension of the video to extract a fixed slice representation of each object. Since the extracted fixed representation retains all the dynamic characteristics of slices (i.e. the changes from slice to slice), we call it dynamic image. We calculate the coefficient  $\theta_t$  of slice  $I_t$  and assume that the feature vector of this slice is  $V_t$ . Multiply this coefficient with the average of all feature vectors from  $V_1$  to  $V_t$  to get the new feature vector and finally accumulate the new feature vectors to get the final dynamic image. See Fig. 2 for an example. The calculation formula is as follows.

$$I_D = \sum_{t=1}^T \theta_t \psi(V_t) \quad (1)$$

Fig. 2. MRI sample slices and corresponding dynamic images of AD, MCI and NC participants

where  $\psi(V_t) = \frac{1}{t} \sum_{\tau=1}^t V_\tau$  is the slices average of features up to slice  $t$ , and  $\theta_t = 2t - T - 1$  is the coefficient associated to feature  $\psi(V_t)$ .

The algorithm for processing dynamic images is shown in Algorithm 1.

---

**Algorithm 1** Algorithm for Obtaining Dynamic Images

---

**Input:** Origin 3D MRI:  $\{X_{MRI}^1, X_{MRI}^2, \dots, X_{MRI}^N\}$ .

**Output:** Dynamic images  $\{I_D^1, I_D^2, \dots, I_D^N\}$ .

- 1: **for**  $i = 1$  to  $N$  **do**
  - 2:  $I_O^j \leftarrow \text{slice}(X_{MRI}^i), j = \{1, 2, \dots, T\}$  // Obtaining original axial slices.
  - 3:  $V_j \leftarrow \text{quantify}(I_O^j)$  // Obtaining feature vectors.
  - 4: **for**  $t = 1$  to  $T$  **do**
  - 5:  $\theta_t \leftarrow 2t - T - 1$  // Calculating the coefficient  $\theta_t$  of slice  $I_O^t$ .
  - 6:  $\psi(V_t) \leftarrow \frac{1}{t} \sum_{\tau=1}^t V_\tau$  // Calculating the vector mean  $\psi(V_t)$  of the features vectors  $V_1$  to  $V_t$ .
  - 7: **end for**
  - 8:  $I_D^i \leftarrow \sum_{t=1}^T \theta_t \psi(V_t)$  // All new feature vectors are summed to get the final dynamic image by Eq.(1).
  - 9: **end for**
- 

### B. Slice with Maximum Information

Typically, there are a large number of slices to choose from in 3D MRI scan. One method of slices selection is to manually select slices based on the highest similarity of anatomical features without knowing the clinical diagnosis information [28]. However, this approach needs to be chosen by professionals, which will cost a lot of labor and be subjective. Instead, we use image entropy to extract the most informative slices to train the network. Therefore, we will calculate the image entropy of each slice. Generally speaking, for a set of  $M$  symbols with probabilities  $P_1, P_2, \dots, P_m$ . Entropy can be calculated as [29]:

$$H = - \sum_{i=0}^{255} P_i \log P_i \quad (2)$$

where  $H$  is the one-dimensional gray-scale entropy and  $P_i$  is the proportion of grayscale value  $i$ .

### C. Adaptive Weighted Multimodal Integration

In this section, we introduce the composition of classifiers and the adaptive weighted integration of the classifier, respectively.

For these classifiers we use the same composition structure. We add relu activation function and dropout between each layer of mapping to reduce the potential overfitting risks. Specifically the feature images are first dropout, and then through three layers of mapping, relu and dropout are added between each layer of mapping. Finally, softmax activation function is used to obtain the category probability value. Dropout set to 0.5. The output expression of each of these classifiers is shown as follows:

$$O_i = \varphi^i(F_i, C_i) \quad i \in \{1, 2, 3\} \quad (3)$$

where  $F_i$  stands for the input of the feature map,  $C_i$  is the weight parameter of the  $i$ -th classifier,  $\varphi^i(F_i, C_i)$  represents a function to be learned in an effort to transform the input,  $F_i$ , to probability value  $O_i$ .

$$O_4 = \varphi^4(X_{cli}, C_4) \quad (4)$$

where  $O_4$  is the probability value in the 4-th classifier,  $X_{cli}$  is the clinical information.  $C_4$  is the weight parameter of the 4-th classifier.  $\varphi^4$  denotes the operation of the 4-th classifier. We normalized for clinical characteristics, i.e. demographic, neuropsychological, and the apolipoprotein E (APOE4) genotyping data. They all followed the same feature scaling procedure, with values normalized between [0, 1] for each independent clinical factor.

We propose an ensemble learning method with adaptive weights to improve the performance of the model and the confidence of prediction. For the probability values of multiple classifiers, we use the integration method of soft voting for the final output. Suppose we have  $M$  classifiers, the soft voting can be computed as:

$$O_t = \sum_{i=1}^M \alpha_i O_i \quad (5)$$

where  $O_i$  is the probability value in the  $i$ -th classifier,  $\alpha_i$  represents the weight given to the  $i$ -th classifier.  $O_t$  stands for the total output after overall soft voting integration. First we initialize the weights. To automatically compute the hyperparameter  $\alpha_i$ , we use a simple but effective approach: setting the hyperparameter  $\alpha_i$  as a trainable parameter in order to automatically and adaptively coordinate the importance learning of each attribute task. When multiple branch tasks are learned simultaneously, the ‘‘important’’ branches should be given high weights (i.e.  $\alpha_i$ ) to increase the loss size of the corresponding branch. We take a small learning rate for updating the network parameters and automatically learn the score weights for different classifiers.

### D. Training and Optimization

We use cross-entropy as the loss function. We construct loss function for the output of individual classifier. The loss function is:

$$L_i = - \frac{1}{N} \sum_{j=1}^N \left[ y_j \cdot \log(O_i^j) + (1 - y_j) \cdot \log(1 - O_i^j) \right] \quad i \in \{1, 2, 3, 4\} \quad (6)$$

where the label  $y_j = 0$  indicates that sample  $j$  is a negative sample and  $y_j = 1$  indicates that sample  $j$  is a positive sample.  $N$  is the total number of samples in the data set.  $O_t^j$  denotes the output probability value of sample  $j$  of the  $i$ -th classifier. In the training phase, with the loss function constructed from the output of each classifier, i.e., Equation 6, we can optimize the network parameters in each of them.

For the backbone network, the weights are fixed in the first stage and are not optimized. The weights are unfrozen in the second stage, we first optimize the backbone network 1 and backbone network 2 under the loss functions constructed from the classifier 1 output and classifier 2 output, respectively. Then the backbone network is further optimized by the loss function 3.

After we get the output of each classifier, we can get the final output, which is Equation 5. Then the loss function of the integrated output is shown below:

$$L_5 = -\frac{1}{N} \sum_{j=1}^N \left[ y_j \cdot \log \left( O_t^j \right) + (1 - y_j) \cdot \log \left( 1 - O_t^j \right) \right] \quad (7)$$

where  $\alpha_i$  is the weight of the output probability values of the  $i$ -th classifier.  $O_t^j$  represents the output probability value of the soft voting integration of sample  $j$  through multiple classifiers. The hyperparameter  $\alpha_i$  is key part of the network. If we use the grid search method to obtain  $\alpha_i$ , this will be time consuming. We use the adaptive weighted method to update the network weights. The loss combines these weights as an integrate one to supervise the process of network training by adopting the back-propagation algorithm.

#### IV. EXPERIMENTS

##### A. Dataset

We use the publicly available dataset from the Alzheimer's Disease Neuroimaging Initiative (ADNI) for our work. Specifically, we trained CNNs with the data from the "spatially normalized, masked, and N3-corrected T1 images" category. The brain MRI image size is  $110 \times 110 \times 110$ . Since a subject may have multiple MRI scans in the database, we use the most recent scan of each subject to avoid data leakage. All the data we used are summarized in Table I. Among them are 132 men and 92 women, aged between 55 and 90.3 years old. Friedman's ANOVA was used to test the difference in median age between groups, and the Fisher's exact test was used to test the gender interaction of the x group. These interactions are not statistically significant ( $p > .05$ ). And the following data: demographic data (age, gender, education level), neuropsychological cognitive assessment tests such as the Dementia Rating Scale (CDRSB), Alzheimer's Disease Assessment Scale (ADAS11, ADAS13), Rey Auditory Verbal Learning Test (RAVLT), as well as APOE4 genotyping. All data used in this study is from baseline assessments.

##### B. Evaluation Metrics

The proposed AMIM method mainly validates the AD classification (AD vs. NC), MCI classification (MCI vs. NC). The performance was evaluated using three metrics. Namely, accuracy, the percentage of correctly predicted samples; F1,

TABLE I. DEMOGRAPHICS OF THE ADNI DATASET

	F/M	Education	Age	APOE4	MMSE	CDRSB	ADAS11	ADAS13	RAVLT IR	RAVLT PF
CN	28/28	16.45±2.95	73.11±5.64	0.16±0.23	28.59±1.82	0.44±1.09	6.32±4.23	9.85±6.19	41.68±10.46	47.48±32.84
MCI	48/75	15.80±2.67	72.95±7.39	0.34±0.34	26.29±3.34	2.23±1.98	11.25±6.45	17.64±9.37	31.50±11.58	66.98±33.84
AD	16/29	15.37±2.89	74.66±8.54	0.39±0.33	21.67±3.94	5.81±2.40	24.07±7.48	34.78±9.01	19.56±6.71	93.68±13.35

the harmonic mean of precision (Eq. 9) and recall (Eq. 10); Area Under Curve (receiver operating characteristic curve determined by true positive rate and false positive rate). These metrics are defined as:

$$ACC = \frac{TP + TN}{TP + TN + FP + FN} \quad (8)$$

$$\text{Precision} = \frac{TP}{TP + FP} \quad (9)$$

$$\text{Recall} = \frac{TP}{TP + FN} \quad (10)$$

$$F1 = 2 \cdot \frac{\text{Precision} \cdot \text{Recall}}{\text{Precision} + \text{Recall}} \quad (11)$$

where TP, TN, FP and FN stands for true positive, true negative, false positive and false negative, respectively. A higher value indicates better performance.

In the following, experiments are conducted to evaluate the performance of the proposed method. Specifically, Section IV-D focuses on testing the impact of unimodal and multimodal on the performance metrics of the experiments, respectively. Section IV-E1 aims to analyze the classification performance of the same dataset in different methods.

##### C. Complements

We use five-fold cross-validation for experiments. Since the proportion of data samples is unbalanced, a weighted loss function is used to ensure the balance of the samples. The loss function uses a cross-entropy loss function. Using the Adam optimizer, the learning rate is 10 to the negative 5-th power, except that the learning rate of  $L_5$  is adjusted to  $5 \times 10^{-6}$ . The classifier performs linear mapping, it will perform a dropout of 0.5 to prevent overfitting. To activate relu, the last layer uses the softmax function to output the probability value of the category.

##### D. Single Modality vs. Multiple Modalities

In this section, the effects of unimodal and multimodal data on the model are presented separately. For MRI, resnet18, which has been pre-trained and removed the last classification layer, is used as the backbone network to extract features. The output of clinical information is obtained through a multi-layer perceptron network model. We performed single-modal experiments on dynamic images, slices, and clinical information. As shown in the Table II, we can see that in the column of AD versus NC, the evaluation index of clinical information is very high. Thus we made t-SNE visualization for the data, as shown in Fig. 3. The data distribution of AD group and NC group is shown on the left. It is found that the two types of data have obvious dividing lines. The distributions of the MCI and NC groups on the right do not have obvious dividing

TABLE II. COMPARISON OF PERFORMANCE OF SINGLE-MODAL AND MULTIMODAL CLASSIFICATION METHODS

Methods	AD vs. NC (%)			MCI vs. NC (%)		
	ACC	AUC	F1	ACC	AUC	F1
Dynamic	90.00	91.90	88.63	77.10	74.45	84.61
Slice	83.14	82.59	83.09	71.00	62.34	80.76
Clinical Info	97.00	98.03	97.41	77.67	78.65	85.53
Combined	92.00	93.62	91.06	74.29	72.39	82.26
Fusion	<b>99.00</b>	<b>99.12</b>	<b>98.67</b>	<b>81.63</b>	<b>82.41</b>	<b>87.06</b>

lines, and their evaluation indexes in Table II are not very satisfactory. This remains consistent with our results. Then we take the dynamic images and slices of medical imaging as input to obtain the integrated results of medical imaging. Specifically, the decision fusion of Output 1, Output 2 and Output 3 of the model in Fig. 1 is carried out. The specific experiment is introduced in the subsequent result chapter. It can be seen from the table that the integration results of slices combined with pictures of 3D spatial information changes are improved compared with single-mode medical imaging. Finally, we proposed the method, in which AD/NC accuracy reached 99.00%, MCI/NC accuracy also reached 81.63%.

### E. Comparison of Different Methods

1) *Comparison With baseline methods:* We compared several other methods on the same dataset. Korolev et al. proposed a deep three-dimensional convolutional neural network structure for brain MRI scan classification [17]. In this work [18], structural magnetic resonance imaging (MRI), demography, neuropsychology and APOE4 gene were used as data inputs, and 3D separable convolutional layers were used as backbone networks for classification. Xing et al converted the 3D full image into 2D dynamic image, and then took the classical neural network and attention mechanism as the network model [30]. For these baseline methods, we maintain the parameter settings of the original paper. The results of evaluation indicators are shown in Table III. It can be found that our proposed method is the best in most indicators.

2) *Comparison with state-of-the-art methods:* In this section, we focus on comparing the classification performance of other widely used methods. The work investigated [31]–[37] and other MRI monomodal classification performance, see Table IV below. Multi-modality [32]–[34], [36], [38]–[41] includes MRI + PET, MRI + PET + biomarkers, MRI + DTI, and MRI + Cognitive scores, as shown in Table V.

TABLE III. COMPARISON OF PERFORMANCE OF DIFFERENT CLASSIFICATION METHODS

Methods	Type	AD vs. NC (%)			MCI vs. NC (%)		
		ACC	AUC	F1	ACC	AUC	F1

CSF = Cerebrospinal fluid

For AD/NC classification, the accuracy of the single-modal methods listed in Table IV has classification results below 90.00%, while the accuracy of most multi-modal methods is above 90.00%. For MCI/NC classification, the accuracy of most single-modal methods is below 80.00%, while the accuracy of most multi-modal methods is above 80%. Among the listed studies, Zhu et al. [32], Liu et al. [33], Aderghal et al. [34] and Shao et al. [36] performed single-modal and multi-modal tests on the proposed method. The results show that, compared with single-modal data, the use of multi-modal data can obtain higher classification accuracy. In addition, our method achieves the best performance of 99.00% in the AD/NC classification and 81.63% in the MCI/NC classification with resnet18 as the backbone network. It is worth noting that, due to potential differences in data selection, preprocessing and even data set division, the results obtained by different methods are actually incomparable. The purpose of the comparison is only to provide an overview of other results and to show the baseline of existing methods.

3) *Different backbone neural networks:* We performed other backbone neural network training. To evaluate the classification performance of different backbone neural networks, we used a five-fold cross-validation strategy to calculate the classification performance. Specifically, the entire subject sample set was divided into five subsets equally, and the subject samples within one subset were selected as test samples each time, and all remaining subject samples within the other four subsets were used to train the classifiers. This process was repeated five times independently to avoid any bias introduced by randomly dividing the dataset in cross-validation. We take the average of the three experiments as the final result of the data. The results are shown in the Table VI and Table VII.

TABLE VI. PERFORMANCE OF DIFFERENT BACKBONE NEURAL NETWORKS FOR AD VS. NC (%)

## V. DISCUSSION

### A. Performance analysis of different views

3D MRI exists three views (axial, coronal and sagittal view). We used the axial view. The different views of the 3D global information and the maximum information slice are shown in Fig. 4. Pan et al. [42] proposed a Multi-view Separable Pyramid Network (MiSePyNet), in which representations are learned from axial, coronal and sagittal views of PET scans so as to offer complementary information and then combined to make a decision jointly. The experimental results show that the performance of the axial view is the best and multi-view fusion effect is better than the single-view. Next, this paper will discuss and analysis the classification performance of different views through experiments.

We performed experiments for different views by using the same parameter settings. The overall experimental results of AD versus NC and MCI versus NC are shown in Table VIII and Table IX. The classification performance of different views for each model has been given in the table. The best evaluation metrics are shown in bold. The experimental results show that AD versus NC and MCI versus NC experimental

Fig. 4. Different views of the global information image and the maximum information slice

TABLE VIII. PERFORMANCE OF DIFFERENT VIEWS FOR AD VS. NC (%)

Type	Views	ACC	AUC	F1
Slice	Axial view	83.14	82.59	<b>83.09</b>
	Coronal view	<b>85.24</b>	<b>87.49</b>	82.39
	Sagittal view	81.19	86.23	79.41
Dynamic	Axial view	<b>90.00</b>	91.90	<b>88.63</b>
	Coronal view	86.05	87.49	86.44
	Sagittal view	89.05	<b>93.82</b>	88.58
Fusion	Axial view	<b>92.00</b>	<b>93.62</b>	<b>91.06</b>
	Coronal view	86.10	84.33	85.45
	Sagittal view	86.14	85.48	85.39

TABLE IX. PERFORMANCE OF DIFFERENT VIEWS FOR MCI VS. NC (%)

Type	Views	ACC	AUC	F1
Slice	Axial view	71.00	62.34	80.76
	Coronal view	<b>72.10</b>	<b>67.71</b>	<b>81.35</b>
	Sagittal view	69.89	63.97	80.89
Dynamic	Axial view	<b>77.10</b>	<b>74.45</b>	<b>84.61</b>
	Coronal view	72.65	66.63	82.23
	Sagittal view	72.10	62.72	82.66
Fusion	Axial view	<b>74.29</b>	<b>72.39</b>	<b>82.26</b>
	Coronal view	71.54	55.46	81.14
	Sagittal view	70.44	54.81	79.65

classification performance are similar. In the model with only slices as input, the overall evaluation metrics of coronal view are the best, the evaluation metrics of the other two views have small differences with them. In the model with only dynamic images as input, the AUC and F1 metrics of the axial view are the highest. In the whole hybrid model of dynamic image and slices, all evaluation metrics of the axial plane is the highest.

For the overall results obtained from these three different views, we can find that the classification performance of each view is not very different and the axial view is relatively better. In this paper, we only conducted experiments for one view. In the future, we will analyze three views of the image together. Different views show different information and how to obtain more comprehensive information plays a more important role

for Alzheimer's disease diagnostic.

## B. Data Pairing

The dataset we used is from the "Spatially normalized, masked and N3-corrected T1 images" category in the ADNI public dataset. The dataset in this category contain paired MRI and clinical information. However, for the other categories of dataset in the ADNI, there were cases where subjects had not undergone the MMSE, ADAS11 examination. For patients with clinical information, we effectively combined the clinical information, which helped to improve the classification performance of the model. In the future, we will try to improve the diagnostic performance of ADNI with only some of the subjects' basic information (gender, age, etc.).

## VI. CONCLUSION

In this paper, we proposed a multimodal adaptive weighted model, which takes global information images, maximum information slices and clinical information as multimodal inputs for the first time. Our model can effectively solve the problem of missing global information in slice classification. At the same time, the use of image information entropy selection slices can solve the subjective uncertainty of human selection. Using an adaptive weighting method to optimize the weights, it can combine the weights of different models more accurately than the grid search method. Our model achieves the best results in terms of classification performance, compared with the latest methods. The combination of medical images and clinical information for Alzheimer's disease classification is the future trend. Next, we will try to investigate how to better combine clinical information with medical images.

## ACKNOWLEDGMENT

The authors would like to thank the anonymous reviewers for their help.
