5G technology has gradually integrated into all aspects of life. Virtual reality (VR) technology is being applied in various fields such as engineering design, game entertainment, and teaching applications as a new emerging technology. In a highly informational society, bringing virtual reality technology into teaching experiments and learning training can bring better teaching experiences. And its rich sensory stimulation and immersive teaching experience provide teachers and students with new teaching paths [1-3]. With the improvement of people's requirements for virtual technology, the accuracy of gesture recognition systems and the requirements for visual tasks are also increasing in response. The animation generated by two-dimensional gesture recognition systems has gradually been unable to meet the needs of high accuracy positioning of virtual space for doormen. Therefore, three-dimensional attitude recognition systems have been developed. However, 3D pose recognition systems have problems such as complex motion capture machines, and time-consuming multi camera and multi perspective solutions. Moreover, there are problems such as demanding camera operating environments, and the degree of

occlusion affecting the accuracy of dynamic capture [4-6]. In the process of generating three-dimensional poses from two-dimensional images, there are currently problems such as insufficient joint point capture accuracy, occlusion affecting the range of joint and limb movements, discontinuous movement of the bone model within a single frame image, joint point change faults, and motion sequence generation jitter. These issues are not conducive to building 3D animation. However, with the publication of various pose datasets and the design and generation of new recognition models, research on capturing and generating three-dimensional poses using common cameras has gradually stepped onto the right track. In the sequential task of single frame image generation, temporal convolutional neural networks perform well in terms of energy. Moreover, the network has time correlation, and is applied to three-dimensional pose recognition in combination with high-precision calculation of angle vectors. This can effectively improve the accuracy of 3D pose recognition. And when it is applied in art design teaching, it can effectively solve the use of VR technology and recognition technology in online art teaching. This can also provide better technical support for the development of the art industry [7-9]. Therefore, by combining time convolutional neural networks and high-precision angle vector calculation, we can compensate for the current problems of insufficient node capture accuracy and the impact of occlusion on joint movement range, thereby effectively improving the accuracy of 3D pose recognition. By optimizing the temporal task process of single frame image generation, problems such as discontinuous movement of bone models, changes in joint points and faults, and jitter in action sequence generation are solved, laying the foundation for building high-quality 3D animations. Apply the optimized 3D pose recognition system to art and design teaching, improving the practical application value of VR technology in online art teaching.

The research content mainly includes four parts. The second part is a review of the research status of pose recognition technology and online teaching. The third part proposes a two-stage three-dimensional pose joint positioning and temporal image processing system model. The first section constructs the image to process the model, and the second section constructs the pose recognition model. The fourth part verifies the improved system performance and application effectiveness. The results indicate that the attitude recognition system has good application effects. The fifth Section concludes the research.

II. RELATED WORKS

The principle of posture recognition technology is to calculate human joint points from images and link them as a whole and output them in the form of images. And two-dimensional attitude recognition technology has a mature system and has been applied in various industries. The technology of three-dimensional gesture recognition is also developing rapidly. S Li et al. proposed a DS (Dempster Shafer) based evaluation algorithm to detect students' attention state in class by measuring students' facial posture. The detection of facial pose angle can be implemented in low pixel surveillance video. The experiment showcases that using DS theory to integrate each student's attention state, the overall classroom attention score of students changes and improves over time. This keeps the whole class in a good state of attention. Meanwhile, it proves that the design of the algorithm is feasible and effective. Compared to the average score of the questionnaire given by the reviewers, the accuracy of the proposed algorithm exceeds 85% [10]. To solve the inaccurate face recognition results caused by factors such as illumination, noise intensity, affine, and projection transformation, SWS et al. proposed scale invariant feature transformation (SIFT). Its research incorporates a SIFT algorithm based on principal component analysis (PCA) dimensionality reduction to reduce computational complexity and improve the efficiency of the algorithm. The experiment indicates that the dimension of SIFT has been reduced to 20 dimensions through experiments on open databases. This improves the efficiency of face extraction; Comparative analysis of several experimental results has verified the superiority of the improved algorithm [11]. MGR Alam et al. proposed an improved loMT emotion recognition system for studying and recognizing human emotional states. Experimental results show that the performance of the proposed method using benchmark dataset analysis has a high classification accuracy in judging human emotional state [12]. Hong Zhen et al. proposed a collaborative solution based on the artificial intelligence Internet of Things to solve the high rate of misjudgment in motion capture in healthcare. This scheme proposes an offline algorithm for multi posture recognition implemented on wearable hardware for posture recognition based on multidimensional data. The results show excellent performance in terms of accuracy and reliability [13].

In online teaching, diversified teaching methods reflect the optimization and reform of students' teaching concepts. In terms of improving online teaching, Z Fen proposed a biological immune algorithm framework using GBDT algorithm coding to improve the efficiency of online English teaching. Then, a flow feature selection algorithm based on bag learning is proposed to solve the problem that redundant information between features can reduce the accuracy of the framework. The research results show that the model constructed in the study has high reliability [14]. A study by Doligan et al. identified the relationships between specific variables, teaching experience, professional development, and teaching support, and self-learning among teachers transitioning to online teaching during the pandemic. The results showed that higher online teaching effectiveness scores were related to participation in online additional qualification courses and professional development courses. The highest

online teaching effectiveness score is positively correlated with traditional learning management systems and the use of virtual technology support [15]. With the development of language research and teaching, M Li studies virtual reality technology based on artificial intelligence and machine learning. This technique is then applied to immersive contextual teaching to improve students' English learning abilities. Through a comparative teaching experiment between two classes of freshmen in a university, it is found that in traditional teaching classes, teachers occupy most of the time and students passively receive information. Therefore, there are insufficient channels for information exchange and the expression of ideas in target languages. The overall English level of immersive teaching is better than that of the control class, with an average score of 2.8 points higher. This indicates that immersive contextual teaching of college English combining constructivism theory with VR technology can indeed improve students' English proficiency [16]. For college art and design majors, virtual scenes have a more natural interactive way to promote learning. Y Zhang proposed a new interactive intelligent virtual reality (VR) paradigm. Aiming at the problem that traditional image-based rendering cannot meet the needs of artistic style virtual environments, nonrealistic rendering technology is introduced into virtual scene construction. Therefore, this study proposes a virtual environment generation method based on nonrealistic rendering. The experiment illustrates that the research model can not only simulate artistic images of linear wave motion, but also realizes the construction of artistic style virtual environments. This makes immersion teaching excellent [17].

In summary, research by domestic and foreign scholars on art design teaching and human gesture recognition shows that the teaching mode of art design is still relatively traditional. More curriculum reforms tend to focus on multimedia digital teaching, while virtual reality technology is less applied. There is still much room to accurately identify and apply the optimization of online education. Therefore, this study integrates temporal convolutional networks and angle vector computation into attitude recognition, and optimizes the gradient disappearance and gradient explosion problems of temporal convolutional networks. Then it improves the posture recognition effect and simplifies the model application operation. Finally, this study explores the optimization and development of art design teaching.

III. CONSTRUCTION OF A VIRTUAL REALITY SYSTEM FOR ART DESIGN TEACHING BASED ON GESTURE RECOGNITION

A. Two-Stage Three-Dimensional Posture Joint Positioning and Timing Image Processing

In the teaching of art design, the state that reflects the mechanical structure of the human body is the posture of the human body. Common human postures are divided into three-dimensional models and skeletal models. A three-dimensional model is a virtual modeling model based on the human body, while a skeleton model is a tree structure diagram showing the changes in human posture. Therefore, the evaluation skeleton model has the advantage of being more concise and clearer than the virtual model. This is shown in Fig. 1.

Fig. 1. 3D Tree structure diagram of skeleton model.

In the skeleton model, the research uses joint points as coordinates to represent human posture recognition and predict joint points; it expresses information such as the rotation angle of the human body with different posture changes. The stereoscopic model has strong picture representation and more simulation. However, due to factors such as computational complexity and estimated cost, it is not widely used in virtual costume changing and virtual animation design in art design teaching. The skeleton model has the advantages of greater flexibility and abundant joint information points, which makes it more efficient in motion tracking and other aspects. Therefore, this study selects a skeleton model for 3D pose recognition. Common human posture recognition methods include end-to-end posture recognition and two-stage posture recognition. End-to-end pose recognition methods that need to span data dimensions during training can lead to inaccurate posture prediction. Two-stage pose recognition is to extract important joint composition information from videos and images of the two-dimensional human body and reconstruct the three-dimensional pose in a virtual three-dimensional space. The study selected OpenPose for preliminary positioning of skeleton joint points. In the OpenPose algorithm, this study uses convolutional neural networks as feature extractors to extract feature points and calculate affinity and confidence, assemble joint points, and human posture features. The confidence algorithm uses neural network features to extract the probability value of a certain point coordinate joint point in the image. The personal confidence calculation formula is shown in Formula (1).

$$S_{i,j}^*(p) = e^{\left(\frac{-\|p-x_{i,j}\|^2}{\sigma^2}\right)} \quad (1)$$

In formula (1), $x_{i,j}$ is the corresponding bone joint point in the corresponding body; P is the coordinate point. The lower the confidence level when the coordinate point is away from

the position of the bone joint point. The calculation of multi person attitude confidence is shown in Formula (2).

$$S_i^*(p) = \max_j S_{i,j}^*(p) \quad (2)$$

In formula (2), $S_i^*(p)$ is the multi person confidence level; And the final result is a normal distribution. When the coordinate points coincide with the bone joint points, the confidence level reaches the maximum value. In the skeleton model, to ensure that joint points correctly connect the direction of the limb, the study selected an affinity algorithm for prediction. The definition of the affinity algorithm is to predict the possible joint connection directions for each coordinate position at different positions of the body. When x_{j1} and x_{j2} are set as different joint points of the human body, v is the unit vector from the first joint point to the second joint point, and v_r is the vector perpendicular to the unit vector. Whether there is a point in the limb can be calculated. The calculation formula is shown in Formula (3) and Formula (4).

$$0 \leq v \cdot (p - X_j) \leq l_f \quad (3)$$

$$|v_r \cdot (p - X_j)| \leq l_f \quad (4)$$

In formulas (3) and (4), the length of the limb is l_f ; the limb width is w_j . Therefore, the distance between the point and the torso is calculated as a confidence vector. The affinity of pixel points is shown in Formula (5).

$$A_f(p) = \begin{cases} 1, & P \text{ On the limb} \\ 0, & P \text{ is not on the limb} \end{cases} \quad (5)$$

When you select Openpose to generate a skeleton frame, there are a total of 25 joint points, as shown in Fig. 2.

Fig. 2. Skeleton frame diagram.

In the skeleton frame diagram, the limbs have three different frames to determine joint points. However, when calculating the affinity of a point on a limb, it is not possible to determine whether the connection is correct, so the confidence level is recalculated using a definite integral method. The calculation of vector confidence at two different joint points is shown in Formula (6).

$$E_c = \int A_c(p(u)) \frac{X_{j_2} - X_{j_1}}{\|X_{j_2} - X_{j_1}\|} du \quad (6)$$

When the calculated confidence level is higher, it shows that the joint connection direction is unified, and the joint connection probability is higher. When sufficient joint point information is obtained, all joint points are rearranged and combined to distinguish different human bodies. Then, this study selects the Hungarian algorithm to re match the joint point distance. When there are three joint points, the corresponding joint points have only one edge actively connected. The constraint principle can be expressed as follows: if there is an interconnection relationship between type A joint points and type B joint points, the sum of the confidence levels of type A joint points n and all type B joint points is less than 1; Otherwise, the end of joint point n and B type joint point columns exceeds 1. After determining the backbone network under the three algorithms, temporal image processing was selected for this study. Attitude recognition based on two-dimensional key point sequences is expressed in multiple frames of images. Therefore, it can be viewed as a sequential task that utilizes time convolutional networks for parallel processing and adjusting the size of convolutional receptive fields. When there is an input sequence L , define the sequence as in Formula (7).

$$L = \{l_1, l_2, l_3, \dots, l_M\} \quad (7)$$

In sequence (7), M is the sequence length; the target sequence can be defined as Formula (8).

$$Y = \{y_1, y_2, y_3, \dots, y_N\} \quad (8)$$

In sequence (8), N is the target sequence length. Therefore, the sequence model can be defined as formula (9) through a mapping function.

$$\hat{Y} = f(x_1, x_2, x_3, \dots, x_T) \quad (9)$$

In the sequence (9), $\hat{Y} = \{\hat{y}_1, \hat{y}_2, \hat{y}_3, \dots, \hat{y}_N\}$ is the output prediction result. For ease of calculation, this study assumes that the input sequence and the target sequence have the same length. The model satisfies constraints when the input and event information are correlated. The temporal image processing model should meet the principles of equal output and input, and the prediction results should not be correlated with delayed future information. Therefore, a linear convolution structure is selected in the model to ensure that the input layer and the output layer have the same length. And the convolution kernel selects causal convolution optimization replacement.

Fig. 3 is a schematic diagram of causal convolution. Each location in the input layer corresponds to a time step, and there are multiple dimensions of data in the practice department. The convolutional kernel moves through the first layer and passes on to obtain a causal effect. However, the time series of causal convolution is too long, resulting in excessively high model complexity. As a result, gradient disappearance and gradient explosion occur, and their selective cavity convolution increases the size of the receptive field and the amount of compression parameters. Therefore, when there is an input sequence, the calculation method for whole convolution processing a certain frame is shown in Formula (10).

$$F(t) = (X * f_d)(t) = \sum_{i=0}^{k-1} f(i) \cdot x_{t-d \cdot i} \quad (10)$$

In formula (10), d is the expansion coefficient; k is the number of convolution kernels; $t - d \cdot i$ is the time slice size

B. Construction of a Two-Stage Three-Dimensional Attitude Recognition Model

To improve the accuracy of 3D human posture prediction, research has been conducted to extract joint information from images or videos, and reconstruct 3D posture from 2D joint points. After generating 2D coordinates through OpenPose and generating complete 2D pose recognition joint point coordinates using a time convolution network, the 3D pose recognition reconstruction is completed using angle vectors. The overall structure of the model is shown in Fig. 4.

Fig. 3. Causal convolution diagram.

Fig. 4. Overall simplified flow chart of the model.

In Fig. 4, after capturing the original human posture and generating a timing video, two-dimensional bone animation is performed. Then it uses a time convolution model to eliminate jitter and calculates the angle vector to generate a three-dimensional human posture. The purpose of angle vector calculation is to reconstruct three-dimensional coordinates. Taking the head joint point as an example, it determines the length ratio of different joint points to determine the angle between the subject's body trunk and the photographing instrument; When the included angle is not 0, the transformation matrix normalizes the plane and coordinate axis, providing convenience for three-dimensional coordinate calculation. The normalization diagram is shown in Fig. 5.

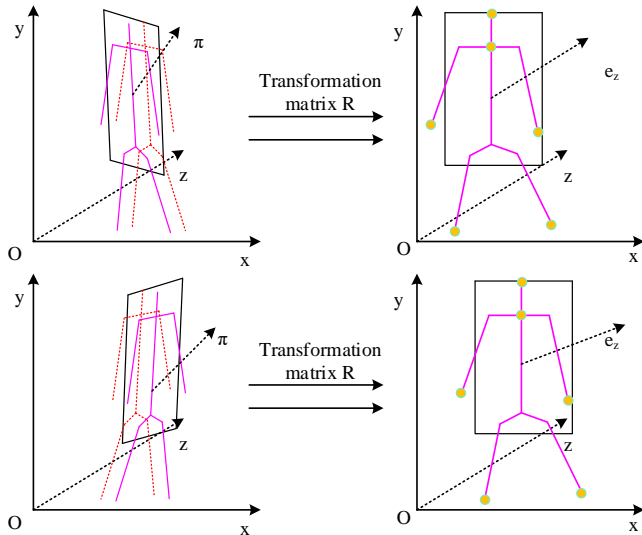

Fig. 5. Schematic diagram of human body normalization and front view.

During the normalization, the conversion matrix is obtained by taking the plane of the normal line of the head joint point as the normal vector. The rotated normal is the normal vector plane. The formula for calculating the rotation vector is shown in Formula (11).

$$A = (a_x, a_y, a_z) = \frac{\pi \times e_z}{\|\pi \times e_z\|} \quad (11)$$

In formula (11), e_z is the normal; (a_x, a_y, a_z) is the point coordinate; π is the plane normal vector of the head joint point. The formula for calculating the rotation angle is shown in Formula (12).

$$\theta = \cos^{-1} \left(\frac{\pi \cdot e_z}{\|\pi\| \|e_z\|} \right) \quad (12)$$

Therefore, the calculation formula for the rotation matrix is shown in (13).

$$R = \hat{A} + \cos\theta \cdot (I - \hat{A}) \sin\theta \cdot A^* \quad (13)$$

In formula (13), \hat{A} is the joint point matrix; The calculation formula for A^* is shown in matrix (14).

$$A^* = \begin{bmatrix} 0 & -a_z & a_y \\ a_z & 0 & -a_x \\ -a_y & a_x & 0 \end{bmatrix} \quad (14)$$

After obtaining the front coordinates of the photograph, measure the length of the joint points associated with each other and perform three-dimensional pose recognition. The schematic diagram of converting 2D joint points to 3D joint points is shown in Fig. 6.

Fig. 6. Schematic diagram of 2D joint conversion 3D joint points.

In a two-dimensional plane, the angle between joint points (a, b) and joint points (b, c) is known. Then, by calculating the included angle of the vector, it can be concluded that when the joint point c moves, the two-dimensional output vector that changes is L_{bd} . The changed C_1 is the mapping of the joint point c. Therefore, the length of the vector before and after the change can be obtained from the image distance, and the included angle between the change vectors can be calculated. The included angle calculation formula is shown in Formula (15).

$$\theta_{bc} = \cos^{-1} \frac{L_{bc}}{L_{bd}} \quad (15)$$

In formula (15), θ_{bc} is the angle between the change vectors. By repeating this operation for each adjacent joint point, all three-dimensional coordinate positions can be obtained. Finally, the joint points are connected in a tree structure to obtain a human skeleton feature map. After obtaining the human bone feature map, evaluate the actual data and predicted data of predicted joint points, and the evaluation formula is shown in Formula (16).

$$MPJPE = \frac{1}{N} \sum_{i=1}^N \|J_i^* - J_i\|_2 \quad (16)$$

In formula (16), J_i^* is the i coordinate point corresponding to the predicted coordinate; J_i is the coordinate corresponding to the real coordinate point.

IV. PERFORMANCE VERIFICATION OF THREE-DIMENSIONAL COORDINATE MOTION RECOGNITION AND EMPIRICAL ANALYSIS OF MOTION CAPTURE SYSTEM

A. Performance Verification and Action Testing of Action Recognition Algorithm

In the performance analysis experiment of a two-stage 3D pose recognition model, in order to ensure the effectiveness of the model, a public dataset was used as the test set, consisting of Human 3.6M and Human Eva-I. The Human 3.6M dataset contains over 3 million three-dimensional poses, and the Human Eva-I dataset contains various motion process datasets. When testing the performance of the model, we first analyze the accuracy comparison between different algorithms and research algorithms in the Human Eva-I dataset. The comparison results are shown in Fig. 7.

Fig. 7. Accuracy comparison.

Fig. 7(a) shows the comparison of accuracy between the DFN model and the research model. It can be seen that in training sets with a large number of people, the improvement in accuracy of the DFN model after 40 iterations is relatively limited, while the research model performs relatively well after 60 iterations. Additionally, overall, the performance of the model is quite good. In the training set with fewer people in Fig. 7(b), the accuracy of the DFN model increases with the increase of iterations, reaching a maximum accuracy of 89.57%. The accuracy of the research model has increased to

95.85% after 20 iterations, and since then, the number of iterations continues to increase, the rate of improvement is slow, and the accuracy gradually converges to 98%. The study selected methods such as ablation experiment analysis and estimation accuracy comparison for testing. The results of the ablation test are shown in Fig. 8.

In Fig. 8, in the comparison of ablation experiments, the red line represents the accuracy of the traditional OpenPose and angle vector combined pose recognition model under different error estimates; The blue lines are used to increase the accuracy of research models with residual structures under different error estimates. It can be seen that the MPJPE of the traditional model reaches 61mm, and the PA-MPJPE error calculation still reaches 50.5mm. The error accuracy of the research model with the addition of a residual structure rapidly decreased, and the overall error decreased by 5 mm when calculated through MPJPE. The optimal error accuracy is a model with three residual structures, and the error accuracy is only 51.3mm. Under the PA-MPJPE error calculation, the overall accuracy of the research model with a residual structure has a significant downward trend. And the optimal error accuracy is still the research model with three residual structures, only 43.2 mm. It shows that using time convolution network to eliminate video sequence jitter is effective and obvious. However, there is a gradient disappearance problem with too many modules. In the estimation accuracy comparison, it selects eight different actions in the Human3.6M dataset for testing, and selects DFN model, BKFC model, and KNN model for comparative testing.

From the scatter diagram in Fig. 9, it can be seen that the DFN model has the largest error. The action with the largest error among the eight actions is photo, reaching an error of 73 mm; the action with the smallest error is a walk, reaching 48.4mm. In the BKFC model, the action with the largest error is also a PHOTO action, reaching 57.2mm. The KNN model is the most effective model among the comparison models. The overall model error accuracy is improved by 5%, and the minimum error action is walk, only 41.8 mm. The overall error accuracy of the model in this study is 10% higher than the other three models, and the error is reduced to within 40 mm. The maximum error action photo is 38.1mm, and the minimum error action is walk, only 30.9mm. Even for the smooth purchase action, the accuracy improvement reaches about 8%. This indicates that using angular vector constraints to generate human posture has the best effect.

Fig. 8. Comparative results of ablation experiments.

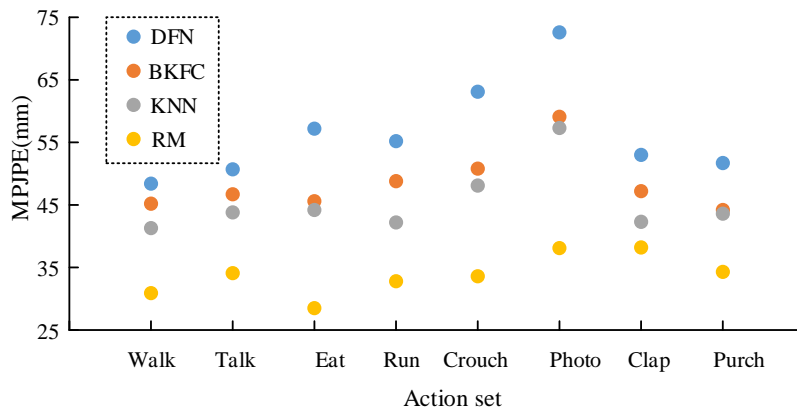

Fig. 9. Comparison of error tests for different models in data sets.

Fig. 10. Model training result accuracy and P-R curve.

Fig. 10(a) shows the model training results; During 300 iterations, the accuracy rate of test results on the validation set reached 0.741, and the recall rate reached 0.65. In the attitude estimation model training results in Fig. 10(b), the final accuracy of the model reaches 0.87, and the mAP verified and evaluated on the test set reaches 0.65.

B. Empirical Analysis of a Two-Stage Three-Dimensional Attitude Capture System

In the teaching of art design, this study utilizes research and improved three-dimensional posture capture system. This can enable students to understand the key design principles and multi-dimensional design expression techniques of certain actions in art design teaching from a comprehensive and three-dimensional perspective and at a data and three-dimensional level. This is different from traditional teaching in which students observe things or use digital courseware to learn and think about design norms and design concepts. Therefore, in the teaching of motion capture system, the research selects the leg disassembly teaching action and arm disassembly teaching action of three-dimensional animation football shooting action as capture demonstration. The experimental results are shown in Fig. 11.

The difference analysis and comparison of teacher and student motion capture in Fig. 11 shows that after disassembling the shooting posture in a three-dimensional manner, students can highly imitate the teacher's design skills. This study uses the accuracy of limb tracking as a performance indicator of the algorithm, and the bending amplitude of the leg and arm joints represents the tracking accuracy. In Fig. 11(a), the change in leg bending amplitude shows that the three-dimensional movements of the teacher's legs are clearer and more accurate, allowing students to observe the design from multiple angles, making it easier to learn and understand. The initial action designed by the students is slightly higher than that of the teacher, and the bending amplitude is gradually adjusted during the shooting process. Finally, an agreement was reached with the teacher to design the action after the shooting action was completed. The overall design model fits more than 96%. In the variation of arm bending amplitude in Fig. 11(b), there is body part occlusion, but the overall design fit still exceeds 95%. At the beginning of designing the action, the student's arm design angle is slightly lower than the teacher's design angle. In designing follow-up actions, the overall error is smaller and the arm bending amplitude is more easily detected. To sum up, the research on improved two-stage

three-dimensional gesture recognition can improve the anti-interference ability of the sensor by separating the magnitude of the motion. Motion posture error recognition is more accurate and motion amplitude changes are sensitive.

This not only has a higher accuracy, but also has a lower error angle than traditional gesture recognition methods to achieve accurate motion capture.

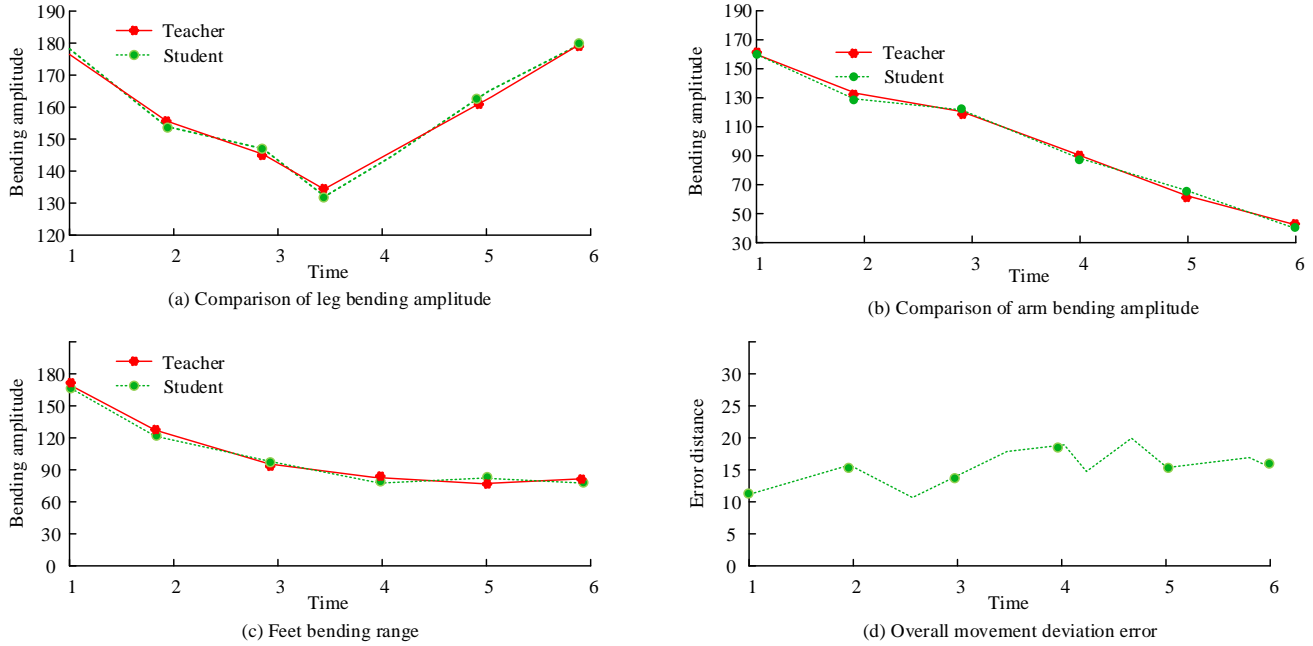

Fig. 1. Analysis of the difference in action capture between teachers and students.

Fig. 12 shows whether the studied human posture recognition system can correctly position the human body and whether the positioning error of joint points is within an acceptable range. Therefore, regular circular route experiments were conducted on the model. In Fig. 12(a), a walking route map is specified for the tester, and timing is performed at five checkpoints. Fig. 12(b) is a simulation diagram of the torso motion trajectory of the human body model by the human posture recognition system. The figure shows that the overall planning path of the model is good, and the actual travel range conforms to the specified travel path. The only point where a significant offset occurs is at point A. Overall, the research model can not only correctly identify human movements, but also effectively identify paths within the range of movement, with good motion capture accuracy. The position changes described meet the requirements of art design teaching. In addition to empirical analysis of the human posture recognition system, the system has also been applied to teaching. Based on this, a teaching satisfaction table is designed to compare with traditional design teaching and multimedia courseware-based

design teaching. It compares the learning satisfaction, learning effectiveness, and teaching efficiency of the three teaching methods based on scores. The higher the score, the better is the effect. The comparison results are shown in Table I.

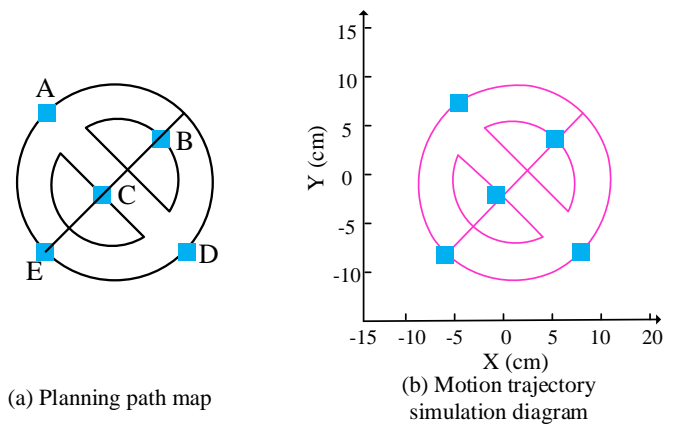

Fig. 11. Planning path simulation experiment results.

TABLE I. TEACHING SATISFACTION EVALUATION FORM

/	/	Research model	Offline teaching	Traditional online teaching
First group	Concept understanding	96	74	81
	Learning effect	93	76	86
	Teaching effectiveness	97	72	82
Second group	Concept understanding	89	80	89
	Learning effect	98	79	83
	Teaching effectiveness	96	71	81

In the evaluating teaching effectiveness, this study selected art and design majors from a certain university to conduct an experimental comparative evaluation of three teaching modes. When the research model is applied in the teaching process, the learning effect, concept understanding, and teaching situation have obvious advantages compared to traditional teaching and multimedia courseware teaching. In the score of concept understanding, the average score of the research model reached 92.5. In terms of learning effectiveness, the average score reached 95.5. In the teaching effectiveness score, the average score of the research model reached 96.5. Compared to the other two teaching modes, the average score exceeds 5 points. The score indicates that the improved posture recognition system in this study has achieved good teaching results when applied to design teaching. Moreover, students have a sufficient understanding of artistic design concepts, and can achieve a high degree of artistic space, with excellent teaching effects.

V. CONCLUSION

Efficient and accurate gesture recognition technology is essential for achieving human-computer interaction and applying interaction systems to the field of artistic design or production. Measuring human body data and calculating the movement amplitude of joint points pose a higher requirement for the refinement of gesture recognition technology. To improve the teaching effect of art design, a two-stage three-dimensional gesture recognition model is studied and designed. The experiment demonstrates that using open data sets as test sets and performing ablation experiments are compared with the estimation accuracy; the accuracy of the model error decreases rapidly when a residual structure is added to the ablation experiment. The overall MPJPE calculation error decreased by 5 mm to 51.3 mm. Under PA-MPJPE error calculation, the error accuracy is only 43.2mm, and the overall optimization is three modules. In the estimation accuracy comparison, the study selected eight different actions from the Human3.6M dataset for testing. The overall error accuracy of the research model was improved by 10%, and the error range was within an acceptable range. The accuracy rate of the model reached 0.741, and the recall rate reached 0.65. When conducting empirical analysis, the accuracy of motion disassembly error is good. The fit degree of the leg bending amplitude reaches over 96%, and the fit degree of the arm bending amplitude reaches over 95%. When the model is applied to actual teaching, the overall satisfaction score of teachers and students exceeds 94 points, which can effectively improve the teaching effect of art design. The research deficiency lies in the insufficient application of complex multi-level structure design. This is also the direction of future in-depth research.

Business Data Analysis Based on Kissmetric in the Context of Big Data

Kan Wang

College of Computer Engineering, Henan Institute of Economics and Trade, Zhengzhou, China

Abstract—The kissmetric data analysis model can be used for the analysis and research of business data, and the focused research method in this model is cluster analysis. To realize the effective application of Kissmetric data analysis model, the focused method is improved in the experiment. An improved hierarchical clustering algorithm generated by splitting stage and merging stage is proposed in the experiment, and then the algorithm is combined with density clustering method while considering noise point processing to achieve automatic determination of clustering centers and improvement of clustering effect. In different dimensions, the highest F-measure index and ARI values of the hybrid clustering method are 0.997 and 0.998, respectively. In different numbers of classes of the dataset, the highest F-measure index and ARI values of the hybrid clustering method are 1.000 and 0.999, respectively. The mean accuracy and mean-variance were 95.94% vs. 5.89%, 94.72% vs. 0.57%, 89.72% vs. 4.97%, 87.45% vs. 5.53%, 93.83% vs. 5.76%, and 88.43% vs. 5.40 %, respectively. The mean and mean squared deviation of hybrid clustering method's accuracy was 89.71% vs. 6.17% and 88.85% vs. 0.33% when dealing with the real datasets 7 and 8, respectively. The quality and stability of the clustering results of the hybrid clustering method are better. Compared with other clustering methods, the accuracy and stability of this method are higher and have certain superiority.

Keywords—Big data; kissmetric; data analysis; density clustering; hierarchical clustering

I. INTRODUCTION

In the context of big data, by collecting business data, users can analyze the data according to the actual needs and get the latent customer behavior pattern behind the big data [1]. The business data analysis methods mainly include the list method, statistical method, cluster analysis method, etc. [2]. The list method is to record and process the data results by certain rules by applying tables, which should be designed to meet clear and precise correspondence [3]. The statistical method can collect and organize data with characteristics from microstructure and use suitable statistical methods to organize the data and explore the hidden laws of the macroscopic nature behind the data [4]. Clustering analysis is a simple and efficient way to summarize the data on a website to determine whether there is a correlation between things [5]. Kissmetric is a data analysis model that can be used for customer engagement. The data analysis of this platform can help users understand customer engagement, analyze product performance, and determine whether the customized marketing plan is effective [6-7]. However, Kissmetric contains a large amount of data, and users may not be able to quickly obtain effective information from it. Therefore, it is also necessary to analyze these data in order to improve the

application effectiveness of the data analysis model. Research has shown that clustering algorithms have good applications in the analysis of business data [5]. It can be used for data analysis in the Kissmetric data analysis model. However, traditional clustering algorithms require a predetermined k value when applied. The setting of k value is easily influenced by subjective factors, resulting in significant differences in clustering results. In order to reduce the impact of subjective factors, some scholars proposed hierarchical clustering analysis [8]. This method only requires fewer or no parameters, making it highly flexible. Therefore, hierarchical clustering is selected as the main algorithm for business data analysis in this study. However, this method requires a large amount of computation and cannot trace back to the intermediate clustering process. In this experiment, an improved hierarchical clustering algorithm is proposed, which is generated by the split phase and the merge phase. Then, while considering noise point processing, the algorithm is combined with density clustering method to achieve automatic determination of clustering centers and improve clustering performance. It is hoped that the improvement of the method can improve the application effect of clustering methods in the Kissmetric data analysis model. It is hoped that this data analysis model can help users analyze business data and obtain the information hidden behind the data, which can be used for formulating enterprise development goals and directions.

The article is mainly divided into five parts. Firstly, there is an introduction as the background of the article. Then there is a literature review, which discusses the existing methods and serves as the literature basis for selecting methods in the experiment. The third part is the establishment and improvement of methods. The fourth part is the performance analysis of the method. The last part is the conclusion, which is a summary of the entire text.

II. REVIEW OF THE LITERATURE

The era of big data requires us to process the data efficiently so as to solve the problems brought by the data. When dealing with complex business problems, the laws behind the data need to be mined to uncover the business value represented by different data. The analysis of business data mainly consists of searchable data analysis and model selection analysis. When the data in search web pages are disorganized, searchable data analysis can be achieved by using mapping, generating tables and equation fitting [9-10]. The search data analysis can be used to obtain the potential business value behind the data, based on which a suitable business model can be selected to promote the long-term

development of the company. Kissmetric is a data analysis model that can be used for customer engagement [7-8]. The main components of the Kissmetric data analysis model include the visitors to the web pages, the features used to describe the user information, and the events and their attributes. The hierarchical clustering method is the key method used in the Kissmetric data analysis model for statistical analysis of data, which is divided into three steps. The first step is to count and divide the number of customers, the second step is to count and divide the types of products, and the third step is to count and divide the platforms. Hierarchical cluster analysis can help users to analyze business data and get the hidden information behind the data, which can be used for the formulation of business development goals and development directions.

Kissmetric is an automated customer engagement data analysis model based on a hierarchical clustering approach, and clustering algorithms are an important part of data mining. Many classical clustering algorithms have been proposed, such as K-means, DBSCAN, Gaussian mixture models, spectral clustering, non-negative matrix decomposition-based clustering, and graph-based clustering. Many optimizations have been made on the traditional algorithms to enable more efficient and accurate data mining using clustering analysis. For example, Xi W A et al. proposed a memetic algorithm with adaptive inverse K-means operation for data clustering, and the performance of the method was evaluated on a series of data sets and compared with related algorithms, and the experimental results showed that the algorithm generally provides superior performance and outperforms related methods [11]. Optimization improvements to K-means clustering methods can be applied to multidisciplinary research. Liu S et al. proposed a self-guided reference vectors (RVs) strategy for decomposition-based evolutionary algorithms in multi-objective optimization to extract RVs from a population using an improved K-means clustering method [12]. A neighborhood network layout scheme based on the unsupervised K-means clustering algorithm and the contour index method has been proposed to determine the number of effective data aggregation points (DAPs) required for different smart meter densities and to find the optimal deployment locations of DAPs [13]. Qin X et al. proposed a machine learning K-means clustering algorithm to select interpolative separable density fitting (ISDF) interpolation points, and K-means algorithm can significantly reduce the computational cost of selecting interpolation points by nearly two orders of magnitude, thus speeding up the ISDF-based Hartree-Fock exchange computation by a factor of 10 [14]. In the study of enterprise business model change, Dressler M et al. used clustering algorithm to data mine different business models and then used PCA analysis to generate two classes of business models, which provided a better classification

method for business model expansion [15]. In the development of SMEs, some scholars use two-step clustering method to analyze the financial data of enterprises to get the optimal number of clusters, and then use fuzzy clustering to analyze the business scale of enterprises, and the optimal clusters are obtained after verification [16]. For the investment selection of enterprises, Gubu L et al. introduced the Markowitz model based on the K-means algorithm for estimating the covariance matrix as well as the mean vector. The method was experimentally demonstrated to have good robustness in processing a large amount of data and can effectively use outliers for data analysis [17]. Clustering algorithm can optimize the parameters of the machine learning model, and the optimized method can be used to cluster the customer preferences and predict the market trends. Clustering-based analysis can uncover the patterns and trends behind customer behavior, which is important for business scaling [18].

Based on the above study, clustering algorithm has good application in the analysis of business data. In order to better improve the application of Kissmetric data model, the focused clustering method in Kissmetric data model is improved in this experiment. An improved hierarchical clustering algorithm generated by splitting stage and merging stage is proposed in the experiment, and then the algorithm is combined with the density clustering method while considering the noise point processing to achieve the automatic determination of clustering centers and the improvement of clustering effect. It is hoped that the improvement of the Kissmetric data model focus method can help users to improve the effectiveness of business data analysis.

III. BUSINESS DATA ANALYSIS BASED ON KISSMETRIC

A. Business Data Analysis Method based on Improved Hierarchical Clustering

The focus of Kissmetric data analysis model is the data analysis method based on cluster analysis. In order to improve the application of Kissmetric data analysis model, the focus of this experiment is improved for its focus. K-means algorithm is a representative clustering method in cluster analysis, and is the basis of other clustering algorithms. In the practical application, it is necessary to determine the number of data object classes, divide the points with different object attributes into different cluster classes according to the principle of closest distance, then use the averaging method to calculate the center of mass of each cluster class, and then reassign the center of mass according to the actual calculation results, and finally ensure that the center of mass moves below the set threshold, and Fig. 1 shows its iterative process.

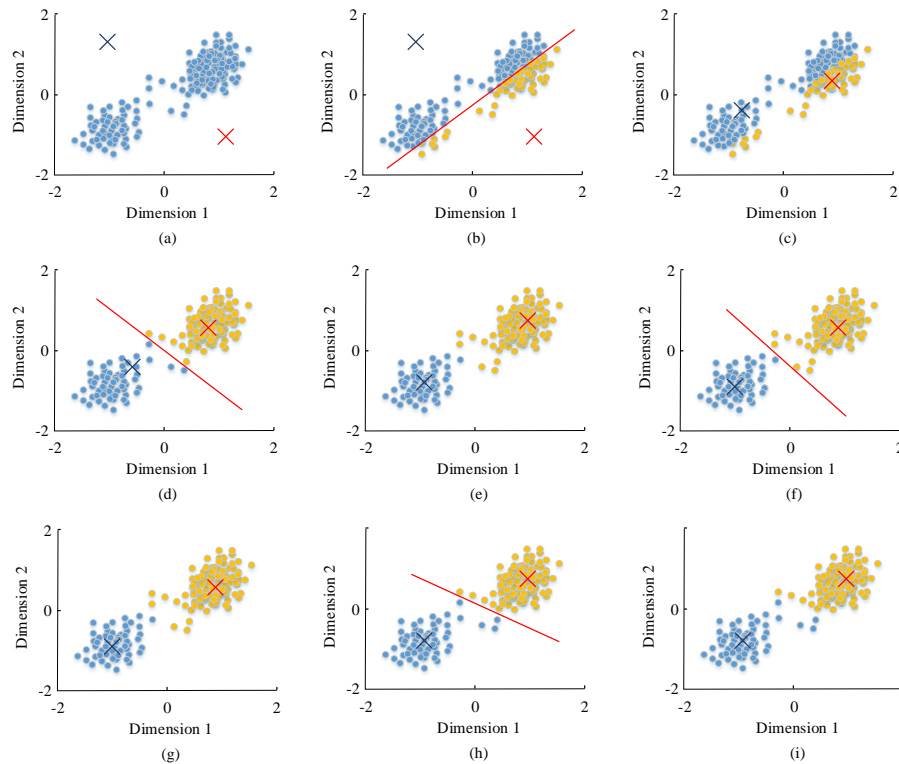

Fig. 1. Iterative process of K-means algorithm.

K-means algorithm requires a pre-specified k-value, but it is susceptible to the influence of subjective factors, which leads to large differences in the results of clustering. To reduce the influence of subjective factors, some scholars propose hierarchical cluster analysis method, which is mainly divided into cohesive and split hierarchical cluster analysis methods. Only fewer parameters or no parameters are required in the hierarchical cluster analysis method, which is more flexible and can be used to divide different types of data according to the different levels of data objects. Therefore, hierarchical cluster analysis method is chosen as the main algorithm for business data analysis in this study, but this method is computationally intensive and cannot retrace the intermediate clustering process, so a new hierarchical clustering method consisting of two phases, merging and splitting, is proposed in this experiment. The splitting stage treats the original overall dataset as a cluster class, and then places the samples in the appropriate splitting positions according to the splitting strategy to obtain different subclasses. Define a dataset $D = \{P_1, \dots, P_i, \dots, P_n\}$, which contains n samples, and the ith sample $P_i = (p_1, \dots, p_d)$ denotes a vector with d attribute values, and classify the dataset D to

obtain the classification $C = \{C_1, \dots, C_k\} (C_1 \cup C_2, \dots, \cup C_k = D \text{ and } C_i \cap C_j = \emptyset, i \neq j)$. The representation of the splitting process of the dataset D at the splitting position (i, h) is shown in Equation (1) and (2).

$$C_1 = \{P_j | P_j \in D \wedge p_j^i \leq h, i = 1 \sim d, j = 1 \sim n\} \quad (1)$$

$$C_2 = \{P_j | P_j \in D \wedge p_j^i > h, i = 1 \sim d, j = 1 \sim n\} \quad (2)$$

The splitting process is iteratively processed on the dataset by using Eq. (1) and (2) until no splitting position satisfying the conditions is produced. Multiple subclasses can be obtained after processing in the splitting phase, and the merging phase requires merging these subclasses with consistent attributes. In the previous splitting process, the samples are labeled with label, and the initial value of label is 1, which is used to determine whether the subclasses in a certain level are split from the same data set. At the same time the split level marker level is added, with an initial value of 1, to update the marker for sample splitting. The splitting process is top-down, and the merging process is bottom-up, starting from the current marker until the marker is 0.

Fig. 2. Schematic diagram of the merging process.

The schematic diagram of the merging process is shown in Fig. 2, and we need to determine whether the red part in Fig. 2(d) needs to be merged. If it can be merged, then the marker level=4 is reduced by one level, that is, level=3, see Fig. 2 (a) to (d). If the condition is not satisfied, the child node of the red part replaces its parent node, and its marker level is updated and reduced by one layer, and whether to merge with other data sets is considered in the subsequent merging process, see Fig. 2(e). The condition for merging need to satisfy that the subclasses are not disconnected in any dimension and that the similarity within classes is increased and the similarity between classes is decreased after the merging process. In this study, the Calinski -Harabazs index was introduced as a measure of inter- and intra-class similarity, as shown in Eq. (3).

$$CH - index(C) = (BCSS(C) / WCSS(C)) * ((n - k) / (k - 1)) \quad (3)$$

WCSS denotes Within Cluster Sum of Squares in Equation (3), BCSS denotes Between Cluster Sum of Squares. n and k denote the number of samples and the number of groups to be grouped, respectively. For the two subclasses C_i and C_j , their Calinski -Harabazs index after merging is calculated in Eq. (4).

$$CH - index(C_{ij}) = (BCSS(C_{ij}) / WCSS(C_{ij})) * ((n - k_1) / (k_1 - 1)) \quad (4)$$

B. A Study of Hybrid Clustering Methods based on Improved Hierarchical Clustering and Density Clustering in Kismetric Model

Hierarchical clustering-based analysis methods are parameter-insensitive and can be used for arbitrary shape class discovery, but they are computationally intensive. Density clustering-based methods can classify the original data set more rationally, but have the problem of parameter sensitivity. Based on the characteristics of both hierarchical and density clustering methods, a hybrid algorithm is combined in this study to compensate for the deficiencies and take advantage of the advantages of both hierarchical and density clustering methods. The density clustering algorithm needs to divide the high-density region from the low-density region surrounded by the fast density peaking algorithm needs to carry out the calculation of sample local density and sample distance. Eq. (5) shows the calculation of local density.

$$\rho_i = \sum_j \chi(d_{ij} - d_c), \begin{cases} \chi(x) = 1, x < 0 \\ \chi(x) = 0, x \geq 0 \end{cases} \quad (5)$$

d_c denotes the truncation distance in Equation (5). The sample distances are calculated in Equation (6).

$$\delta_i = \begin{cases} \max_j (d_{ij}) = 1, \rho_i = \max(\rho_1, \dots, \rho_n) \\ \min_{j:\rho_j > \rho_i} (d_{ij}) = 1, \rho_i \neq \max(\rho_1, \dots, \rho_n) \end{cases} \quad (6)$$

Based on the calculation of sample local density and sample distance, the fast density peaking algorithm is able to find the sample with high density as the center of clustering, and this sample is far away from other samples with high density, and Figure 3 shows the schematic diagram of this

method.

Samples 1 and 10 in Fig. 3 represent the two clustering centers of the fast density peaking algorithm, and the method can be more successful in finding samples that can serve as clustering centers. However, there are also problems such as wrong selection of clustering centers, or selecting multiple centers in the same class and finally dividing to form multiple subclasses. In this experiment, the method is improved by first selecting multiple samples as clustering centers in the first stage of clustering using the fast density peaking algorithm, and then combining the clustering results in the subsequent hierarchical clustering. The method of cluster center selection is divided into two steps, first calculating the product of the sample distance and local density of sample i, i.e., $\gamma_i = \rho_i \times \delta_i$.

Then the calculated γ_i is sorted in the order from largest to smallest, and the cluster center of the first stage selects the sample with the largest change in the value of γ . The correct clustering centers can be obtained after fast density peaking algorithm selection, and then these clustering centers need to be merged using hierarchical clustering method. In the current study the similarity measure of hierarchical clustering mainly uses average connection, full connection or single connection, but these methods do not consider the distribution of samples, which leads to the failure of the sample measure with special distribution. In this experiment, an aggregation-based hierarchical clustering method is proposed, in which a new noise point avoidance strategy is introduced to circumvent the drawbacks of artificially determining noise points and parameters. Assuming that the probability density function of subclass C_i is $f_i(v)$, the probability density function of subclass C_j is $f_j(v)$, and v denotes the attribute values of the samples within the class, the definitions of the connectivity of C_i and C_j in Equation (7) can be obtained.

$$join(C_i, C_j) = \sum_{p \in C_i \cup C_j} \min(f_i(p), f_j(p)) \quad (7)$$

This leads to the aggregation function of C_i and C_j in Eq. (8).

$$cohesion(C_i, C_j) = \frac{join(C_i, C_j)}{|C_i| + |C_j|} \quad (8)$$

$|C_i|$ denotes the number of samples in C_i and $|C_j|$ denotes the number of samples in C_j in Equation (8). Assuming that the samples in the subclass C_i obey a multivariate normal distribution, i.e., $V \sim N_d(\mu, \psi)$, the expression of the probability density function of C_i is given in Eq. (9).

$$f_i(v) = (2\pi)^{-\frac{d}{2}} (\det \psi)^{-\frac{1}{2}} \exp[-\frac{1}{2}(v - \mu)^T \psi^{-1}(v - \mu)] \quad (9)$$

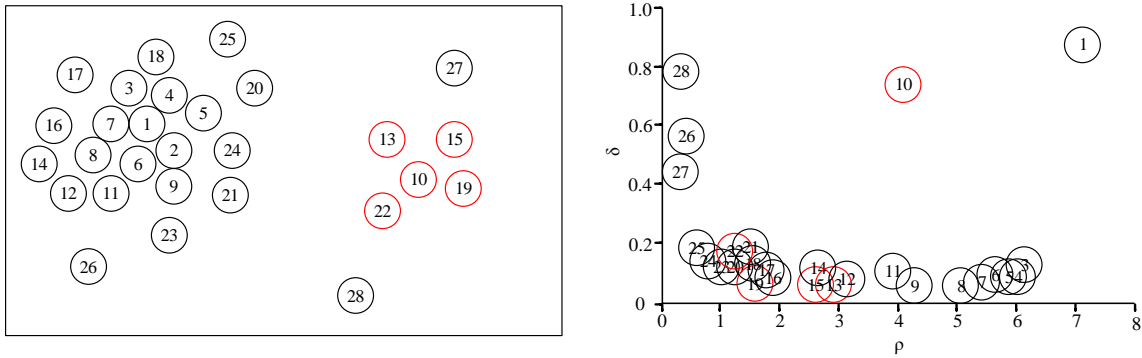

Fig. 3. Schematic diagram of the fast density peaking algorithm.

d denotes the dimensionality, μ denotes the mean vector, and Ψ denotes the covariance matrix in Eq. (9). The calculation of μ is shown in Eq. (10).

$$\mu = \frac{1}{n} \sum_{i=1}^n v_i \quad (10)$$

The calculation of Ψ is shown in Eq. (11).

$$\Psi = \frac{1}{n} \sum_{i=1}^n (v_i - \mu)(v_i - \mu)^T \quad (11)$$

Given the probability density function of C_i according to Eq. (9), the volume calculation of C_i can be obtained from this, see Eq. (12).

$$V_i = \frac{4}{3} \pi \sqrt{\lambda_1 \lambda_2, \dots, \lambda_d} \quad (12)$$

$\lambda_1 \lambda_2, \dots, \lambda_d$ represents the d eigenvalues of the covariance matrix Ψ in Eq. (12). Because the subclass volume and the eigenvalues of Ψ are proportional, the constant term is removed for the subsequent calculation, i.e., $V_i = \sqrt{\lambda_1 \lambda_2, \dots, \lambda_d}$. Eq. (13) is the density calculation of C_i .

$$D_i = \frac{|C_i|}{V_i} \quad (13)$$

According to the characteristics of noise points, if two subclasses that are close to each other have a large difference in density or volume, one of them has a higher probability of being a noise point cluster. Based on this feature, the definition of the noise point avoidance function for the subclasses C_i and C_j is given in Eq. (14).

$$dependence(C_i, C_j) = \frac{D_i + D_j}{2 \times \sqrt{D_i \times D_j}} + \frac{V_i + V_j}{2 \times \sqrt{V_i \times V_j}} + \frac{1}{2 \times d} \sum_{i=1}^d \frac{(\sqrt{\lambda_i^i} + \sqrt{\lambda_i^j})}{|c_i - c_j|} \quad (14)$$

\bar{c}_i denotes the cluster center of subclass C_i in Equation (14), \bar{c}_j denotes the cluster center of subclass C_j , $\sqrt{\lambda_i^i}$

denotes the length of each dimensional axis of C_i , and $\sqrt{\lambda_i^j}$ denotes the length of each dimensional axis of C_j . Since $\frac{D_i + D_j}{2 \times \sqrt{D_i \times D_j}} \leq 1, \frac{V_i + V_j}{2 \times \sqrt{V_i \times V_j}} \leq 1$, the value of the mean inequality is maximized when and only when $D_i = D_j, C_i = C_j$. From the noise point avoidance function in Formula (14), the closer the density and volume of the two subcategories are, the higher the dependency of the two subcategories is, and the greater the probability of their combination is. On the contrary, the combination probability of the two is smaller. According to the definitions of noise point avoidance function and aggregation function, the similarity of subclasses C_i and C_j is given in Eq. (15).

$$similarity(C_i, C_j) = cohesion(C_i, C_j) + dependence(C_i, C_j) \quad (15)$$

The similarity measure in this experiment consists of an aggregation function and a noise point processing function, which fully considers the distribution of samples within classes while circumventing the interference of noise points during class merging.

Kissmetric is an automated customer engagement data analysis model based on the hierarchical clustering approach described above, capable of providing business data analysis to clients. The main components of the Kissmetric data analysis model include the visitors to the web pages, the features used to describe the user information, and the events and their attributes. The hierarchical clustering method is the key method used in the Kissmetric data analysis model for statistical analysis of data and is divided into three main steps. The first step is to count and divide the number of customers, which can get three types of customers, namely, resource customers who have browsed the products, potential customers and customers who have purchased the products. The second step is to count and divide the types of goods, mainly by analyzing the information of the type, name, price and size of the goods. The third step is to count and divide the platforms, and make a regional division of the number of customers who have purchased goods on different platforms.

IV. PERFORMANCE STUDY OF BUSINESS DATA ANALYSIS MODEL BASED ON KISSMETRIC

The parameter settings in the experiment are as follows: the number of centroids is 8, and the maximum number of iterations is 300. In the improved hierarchical clustering method, the effectiveness of the algorithm in the splitting process is verified using the Aggregation dataset in Fig. 4. For the original Aggregation dataset, the improved hierarchical clustering method is able to split the original samples and obtain multiple subclasses.

The original data set needs to be merged after the splitting process. In Fig. 5, the subclasses with consistent attributes need to be merged in the merging stage to finally obtain a more accurate classification effect, and the clustering accuracy of this method is 99.21%.

Performance validation for clustering algorithms can be evaluated using the F-measure metric, which is a weighted summed average of recall and accuracy, and is used to evaluate the merit of the classification model. The Rand Index (RI) can be used to measure the similarity of clustering results, but there is a lack of differentiation. To address this problem, the Adjusted Rand Index (ARI) makes some improvements on the basis of RI, which can make a clearer distinction of clustering effects. In the range of [-1,1], the larger value of ARI indicates the better effect of the clustering method. The results of the F-measure metrics and ARI of the hybrid

clustering method proposed in this experiment compared with K-means, K-medoids, and K-means++ methods in different dimensions in Fig. 6 [19-21]. The highest F-measure index and ARI values of the hybrid clustering method proposed in this experiment are 0.997 and 0.998, respectively, under different dimensions, which are higher than those of K-means, K-medoids, and K-means++ methods.

The F-measure and ARI values of the algorithm are compared in Fig. 7 for different numbers of classes of the dataset. The highest F-measure metrics and ARI values of the hybrid clustering method proposed in this experiment are 1.000 and 0.999, respectively, under different numbers of data set classes, which are higher than those of K-means, K-medoids, and K-means++ methods. F-measure index and ARI values of the hybrid clustering method do not change due to the number of classes in the data set, and its clustering effect is better and more stable.

The hybrid clustering method proposed in this experiment is used with K-means, K-medoids, and K-means++ methods to cluster the Aggregation dataset in Fig. 8. The hybrid clustering method accurately divides the Aggregation dataset into seven classes according to the similarity calculation results, while the rest of the methods for some of the samples were classified with ambiguity, and more than seven classes were finally classified. The hybrid clustering method proposed in this experiment has a better clustering effect and its clustering accuracy is better.

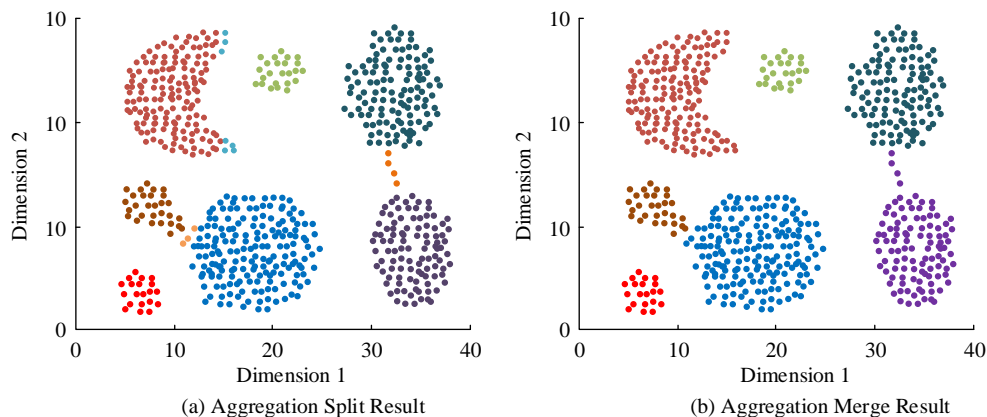

Fig. 5. Merging effect of improved hierarchical clustering method.

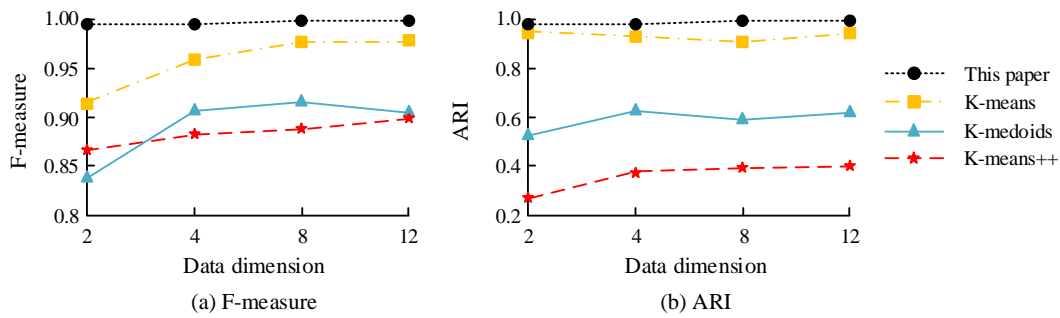

Fig. 6. F-measure and ARI values of the algorithm in different dimensions.

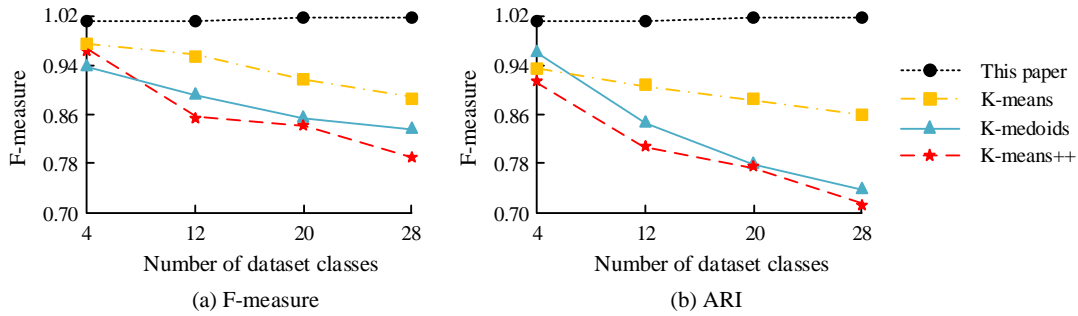

Fig. 7. F-measure and ARI values of the algorithm for different number of classes of the dataset.

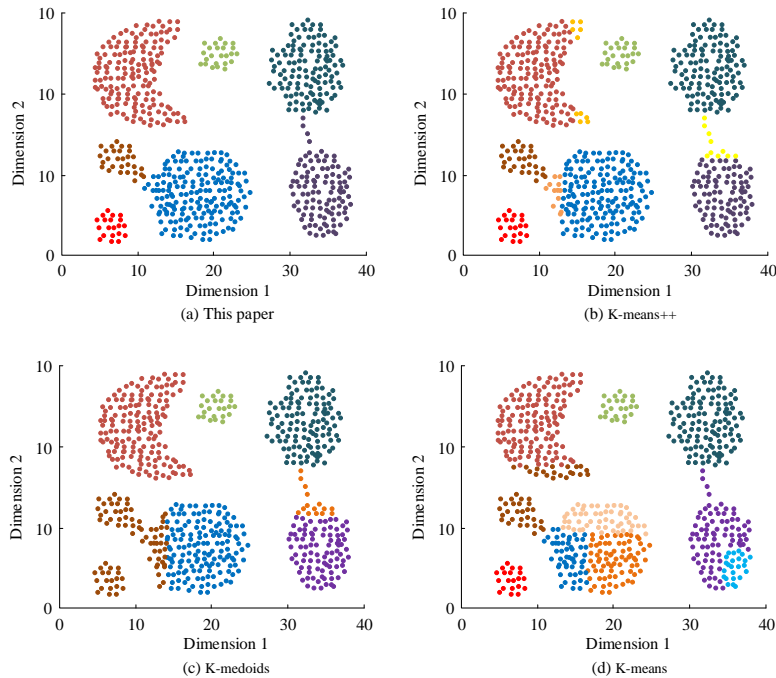

Fig. 8. Comparison of clustering effects of different algorithms.

To further validate the performance of the hybrid clustering method, experiments were conducted to evaluate the performance using Purity validity metrics in eight datasets, which included simulated datasets 1-6 and real datasets 7-8. Table I shows the results in simulated datasets 1-6. When running datasets 1-6, the mean accuracy and mean squared error of the hybrid clustering method were the best among the four algorithms, which were 95.94% vs. 5.89%, 94.72% vs. 0.57%, 89.72% vs. 4.97%, 87.45% vs. 5.53%, 93.83% vs.

5.76%, and 88.43% vs. 5.40%, indicating that the algorithm has higher accuracy. When comparing the clustering analysis of datasets 1 to 6 with different methods, the hybrid clustering method has the highest clustering accuracy, the best clustering effect and the best stability in the six datasets. The hybrid clustering method has significantly improved in terms of accuracy and stability when clustering the simulated datasets. In terms of algorithm runtime, the hybrid clustering method has improved over the other methods.

V. RESULTS AND CONCLUSIONS

The results obtained in the real dataset are presented in Table II. The hybrid clustering method has the best quality and stability of clustering results with the best accuracy mean and accuracy mean squared error of 89.71 % vs. 6.17 % and 88.85 % vs. 0.33 %, respectively, when dealing with datasets 7 and 8. When comparing the clustering analysis of the real datasets 7 and 8 with different methods, the hybrid clustering method has the highest clustering accuracy, the best clustering effect and the best stability in these two datasets. The results indicate that the hybrid clustering method has significantly improved in terms of accuracy and stability when clustering analysis is performed on the real dataset. The results from the real and simulated datasets mentioned above show that the algorithm proposed in this experiment can handle datasets of any shape and different distributions. And this algorithm has higher accuracy compared to most current clustering algorithms. This is because the algorithm proposed in this experiment can avoid the problem of missed or incorrect selection when selecting cluster centers. Therefore, this algorithm can correctly classify samples. At the same time, this method introduces a similarity measurement method. It can be used to process datasets with different types and uneven sample distribution. At the same time, the treatment of noise points was added in the experiment. This can effectively handle the impact of noise points on clustering results.

The improvement of data mining technology promotes the efficiency of commercial data application. In existing research, the K-means clustering algorithm can effectively handle data of different scales. In order to improve the ability of traditional clustering algorithms to determine the cluster center, some scholars proposed a hierarchical clustering analysis method [8]. This method can reduce the subjective factors affecting the determination of k-values in traditional clustering methods. However, this method requires a large amount of computation and cannot trace back to the intermediate clustering process. For this reason, an improved hierarchical clustering algorithm is proposed in the experiment, which is generated in the split phase and the merge phase. This algorithm can combine the algorithm with density clustering methods while considering noise point processing, achieving automatic determination of clustering centers and improving clustering performance. For the original Aggregation dataset, the improved hierarchical clustering method can crack the original samples to obtain multiple subclasses. Then these subclasses with consistent attributes are merged in the merging stage to get more accurate classification results, and the clustering accuracy of this method is 99.21%. Under different dimensions, the highest F-measure index and ARI values of the hybrid clustering

method proposed in this experiment are 0.997 and 0.998, respectively. Under different numbers of classes in the data set, the highest F-measure index and ARI values of the hybrid clustering method are 1.000 and 0.999, respectively, which are higher than those of the K-means, K-medoids, and K-means++ methods. When running simulated datasets 1 to 6, the mean and mean squared error of the hybrid clustering method were the best among the four algorithms, with 95.94% vs. 5.89%, 94.72% vs. 0.57%, 89.72% vs. 4.97%, 87.45% vs. 5.53%, 93.83% vs. 5.76%, and 88.43% vs. 5.40 %, respectively, indicating that the algorithm has higher accuracy. When dealing with the real data sets 7 and 8, the hybrid clustering method has the best accuracy mean, and accuracy mean squared error of 89.71% versus 6.17% and 88.85% versus 0.33%, respectively. From the results, F-measure index and ARI values of the hybrid clustering method do not change due to the influence of dimensionality and the number of classes in the dataset, and the quality and stability of its clustering results are better. The validation results in different datasets show that the method established in this experiment can handle datasets of any shape and different distributions. And this algorithm has higher accuracy compared to most current clustering algorithms. Compared to the K-means, K-medoids, and K-means++ methods in references [19-21], its F-measure, ARI indicators, accuracy, and other indicators are higher, and they have certain advantages. This is because the algorithm proposed in this experiment can avoid the problem of missed or incorrect selection when selecting cluster centers. Therefore, this algorithm can correctly classify samples. At the same time, this method introduces a similarity measurement method. It can be used to process datasets with different types and uneven sample distribution. At the same time, the treatment of noise points was added in the experiment. This can effectively handle the impact of noise points on clustering results. Although the method proposed in this experiment can correctly and effectively handle different types of data, there are still some shortcomings in this method. As the amount of data increases, the clustering performance of the method will decrease. The dataset used in this experiment has a smaller scale. The application effect of the improved method in large-scale data is still uncertain. Therefore, improving the ability of clustering algorithms to handle massive amounts of data is an important task in the subsequent work of this article. In addition, the data in real life is quite complex and noisy. This will affect the stability of the clustering algorithm. Therefore, how to effectively improve the anti-interference ability and practicality of clustering algorithms, as well as further enhance the algorithm's ability to process real data, is one of the next directions that need to be studied.

From Monolith to Microservice: Measuring Architecture Maintainability

Muhammad Hafiz Hasan¹, Mohd. Hafeez Osman², Novia Indriaty Admodisastro³, Muhamad Sufri Muhammad⁴
Dept. of Soft. Engineering and Information System-FSKTM, UPM, Serdang, Selangor, Malaysia^{1, 2, 3, 4}

Abstract—The migration of monolithic applications to the cloud is a popular trend, with microservice architecture being a commonly targeted architectural pattern. The motivation behind this migration is often rooted in the challenges associated with maintaining legacy applications and the need to adapt to rapidly changing business requirements. To ensure that the migration to microservices is a sound decision for enhancing maintainability, designers must carefully consider the underlying factors driving this software architecture migration. This study proposes a set of software architecture metrics for evaluating the maintainability of microservice architectural designs for monolith to microservice architecture migration. These metrics consider various factors, such as coupling, complexity, cohesion, and size, which are crucial for ensuring that the software architecture remains maintainable in the long term. Drawing upon previous product quality models that share similar design properties with microservice, we have derived maintainability metrics that can help measure the quality of microservice architecture. In this work, we introduced our first version of structural metrics for measuring the maintainability quality of microservice architecture concerning its cloud-native characteristics. This work allows us to get early feedback on proposed metrics before a detailed evaluation. With these metrics, designers can measure their microservice architecture quality to fully leverage the benefits of the cloud environment, thus ensuring that the migration to microservice is a beneficial decision for enhancing the maintainability of their software architecture applications.

Keywords—Monolith; cloud migration; software architecture; design quality; maintainability; quality metric

I. INTRODUCTION

In recent years, the demand for online applications and services has increased. Organizations and businesses with online applications perceive cloud platforms as a promising future for business strategy to remain competitive. For an organization with an existing legacy application that involves the organization's core business process, migrating the application to the cloud is more imminent to utilize cloud benefits and ensure business continuity. These applications often have monolithic software architecture, which does not consider modularity in its design principle [1], and the systems work in a silo [2]. In monolith architecture, developers develop the entire application as a single unit with a large codebase and tightly integrated components, increasing complexity and making it difficult to manage and scale [3]. These characteristics also affect its deployment approach when any minor changes to the application require a complete rebuild, leading to increased risk [4].

The motivation of the legacy application to cloud migration is to overcome the roadblocks and limitations of monolith applications [5] and to achieve cloud-native benefits such as improving application modifiability, maintainability, scalability, and deployability [6]. The cloud platform provides scalability for computing resources without worrying about the underlying infrastructure quickly and efficiently [7]. The organization also gains more flexibility and agility in responding to changing business ideas, thus increasing service innovation. However, not all migration strategies to the cloud provide mentioned benefits [8]. The *Lift-and-Shift* approach involves taking existing *as-is* on-premise applications and moving them to the cloud as a single service without architecture and design changes limiting its cloud scalability features [9].

In contrast, the microservice is a cloud architecture design pattern designed to provide better scalability and maintainability. In a microservice architecture, designers create sets of independent services that use API as their communication medium. Each microservice is responsible for specific business capabilities, strong component separation, and independent deployability execution [1], [5], [10]. Other fundamental properties of microservice architectural design are low coupling, high cohesion, and modularity [10] must be carefully considered by developers and designers [11], [12] during the design phase.

In the cloud migration context, migrated application quality should be equivalent to, or better than, legacy monolith applications. Software errors can stem devastating effects to financial loss, time delays, or even risks to life [13], [14]. Numerous frameworks for migrating from monolith to cloud have been introduced [1], [15]-[18], yet they still do not adequately address quality considerations after the migration [19]. Therefore, the migration did not accomplish its objective [5], thus introducing new product quality challenges such as application maintainability, security, reliability, and compatibility [8], [20].

From a technical standpoint, migrating monolith applications to the cloud allows for quick and effective implementation of essential software changes to meet current business needs. The relevant quality attribute is known as maintainability, which expresses the degree of effectiveness and efficiency with which an application can be changed, modified, or corrected to meet requirements [21]. Therefore, it is essential to ensure that migrated applications must be maintainable by developers to avoid accumulated waste and technical debt after the migration [22]-[24]. Thus, maintainability has become an essential quality feature [25].

However, empirical research on maintainability quality assurance remains a missing research area for microservice architecture [26]. To address this concern, the following research questions have been formulated to guide this study:

- RQ1: What are the existing structural quality metrics that relate to service-based architecture?
- RQ2: How do the existing structural metrics relate to cloud-native characteristics?
- RQ3: What are the feasible metrics for the maintainability quality model for microservice architecture?

This paper proposes the structural metrics for measuring microservice maintainability quality, focusing on microservice architecture migration. A multi-structural design metrics consisting of coupling, cohesion, complexity, and size form the basis of the maintainability measurement. These metrics help practitioners evaluate the architecture maintainability quality at the earlier migration phase to minimize post-migration technical debt, thus ensuring the achievable migration objective [6].

The remainder of this paper is organized as follows. Section II discusses related works with some comments on their limitations. Section III describes the research methodology for identifying existing service-based structural metrics. Section IV discusses how the existing structural metrics can be associated with cloud-native characteristics. Section V further discusses structural metrics from maintainability quality. Section VI briefly introduces our proposed maintainability quality model, followed by a discussion in Section VII. Finally, Section VIII concludes with a summary and outlook on potential follow-up research.

II. RELATED WORK

The software quality model's development reflects the software architecture's progression. A robust quality model approach is necessary for measuring product architecture quality, regardless of the adopted software architecture. Thus, this work explores previous works on software quality models and monolith-to-microservice migration approaches to identify reliable and valid metrics to evaluate software design quality.

A. Software Quality Model Evolution

One of the first software product quality models introduced by [27] describes as a generic model that separates high-level quality attributes into tangible product quality properties. Due to rapidly changing and dynamic business requirements, different metrics have been proposed to meet software architecture evolutions.

In their work, Bansiya et al. [13] proposed an improved hierarchical design quality assessment model for object-oriented software architecture. This model, known as the Quality Model for Object-Oriented Design (QMOOD), builds upon Dromeys's generic quality model methodology. The QMOOD comprises four hierarchical levels: object-oriented design components, design metrics, design properties, and design quality attributes. Notably, the authors adopted most of the design quality attributes in QMOOD from the ISO/IEC

9126 standard. However, this model failed to serve simple, practical applicability as it assesses high-level design quality attributes. Hence the metrics are limited for object-oriented applications.

SOA Quality Model (SOAQM) is an extension of QMOOD to enhance architecture scalability through hierarchical abstraction and clear bottom-up relationship [28]. Bogner et al. [29] suggest that most metrics explicitly designed for SOA also apply to microservice architecture. The author then introduces the Maintainability Model for Microservices (MM4S) with five service properties: coupling, cohesion, granularity, complexity, and code maturation. Although this work is similar to ours, the authors did not consider migration scenarios, hence providing the mathematical formalization for proposed metrics.

Vera-Rivera et al. [30] conducted a systematic literature review on microservice architecture, explicitly focusing on the impact of microservice granularity on application quality. The authors employed a genetic algorithm to determine the optimal microservice granularity based on key factors such as coupling, cohesion, complexity, and resource usage. They integrated various metrics and quality attributes into their analysis with the development team's involvement for effort estimation based on user story artefacts.

Pulnil et al. [31] and Taibi et al. [32] proposed a microservice quality model that relies on microservice anti-patterns. The authors incorporated eleven microservice anti-patterns with the ISO/IEC 25010 standard as a benchmark for microservice quality attributes, while this work builds on top of microservice design principles [33]. Furthermore, the proposed quality assessment model is formulated depending on the weightage of the harmfulness level of the design properties exposing it to the biased decision by the designer.

B. Microservice

Microservice is an architecture design pattern that promises high maintainability, making it an exciting option for modernizing software during the cloud computing era [23]. Generally, microservices have been designed based on domain-driven functionality with limited business capabilities, strong component separation, and enabling automated deployment execution [1], [5], [10].

The developer and designer must carefully consider the fundamental properties of microservices, which include low coupling, high cohesion, scalability, independence, maintainability, modularity, and deployability [10]. These properties are closely related to architectural design [11], [12].

Chen et al. [34] proposed a monolith decomposition approach from a dataflow diagram viewpoint, while Fan et al. [24] suggested microservice candidate identification through domain-driven design analysis. Runtime behaviour information [35] strategy and Functionality-oriented Service Candidate Identification (FoSCI) framework introduced by [36] to identify service candidates using a search-based functional atom grouping algorithm based on recorded monolith's execution trace log. Combining the data usage with the dynamic analysis provides a better understanding of feature prioritization during the migration. The static approach based on source code [37], [38] and system structure [23] exhibits

structural information as decomposition reasoning. Meanwhile, the metric-based method, as demonstrated by previous works, uses structural properties such as coupling [37], [39], [40], service granularity [41], size [42], and cohesion [43].

Li et al. [44] introduced a method for identifying microservices based on the UML model from the source code as an input consisting of class and sequence diagrams for static and dynamic analysis. The authors then used a clustering approach to identify microservice candidates. The determination of clustering output quality relied on the utilization of functional requirements and deployment constraints. However, the authors did not consider microservice distributions to verify the architecture quality. At the same time, the ambiguity of language and contextual understanding prevents semantic-based analysis of the system requirements from guaranteeing the attainment of optimal solutions [45].

Our work extends and complements [28], [29] in the context of a structural quality model for the service-based application. Bingu et al. [28] did not consider maintainability quality in their model besides re-implementing weighted value by [13] in their quality attribute equation without necessary empirical justification. While Bogner et al. In [29] approach are beneficial for microservice maintainability design properties, the authors did not consider the migration scenario, thus limiting its applicability to the greenfield implementation. So, while the general approach from Bogner et al. is a sound foundation, this work established it to fit monolith to microservice migration scenario and enhanced it with practically collectable quality metrics for the architecture design consideration.

III. METHODOLOGY

In order to formulate the architectural maintainability quality model for monolith to microservice migration, this study followed a series of steps, as illustrated in Fig. 1. As this work highlights the monolith to microservice migration scenario, it started with a literature review process using trustable electronic journal databases for this research domain [46] consists of Scopus, SpringerLink, IEEE Xplore, and ScienceDirect to collect existing structural quality metrics.

Our initial investigation shows that the software quality model evolves laterally with software architecture advancement [29]. For this reason, pre-migration monolith object-oriented structural quality metrics [13], [47]-[49] and post-migration microservice architecture quality metrics [50]-[54] are included. Next, the object-oriented structural metrics are being mapped with microservice structural metrics based on their shared characteristics, as suggested by [47], [55]-[57]. These structural metrics help understand its relationships further, clarifying the evolution of the software quality model. Section IV explains this step's detailed approach and findings, thus answering RQ1.

The selection of structural maintainability quality metrics is guided by ISO/IEC 25010 – Software Product Quality. This product quality model comprises of hierarchical structure with maintainability quality attributes consisting of its sub-characteristics such as modularity, reusability, analyzability,

modifiability, and testability [21]. Detailed methodology for this step is described in Section V, hence answering RQ2.

Fig. 1. The methodology of the monolith to microservice architectural maintainability quality model development.

Furthermore, software quality is still a vague and multifaced perception, which means different things to a diverse audience [13]. Therefore, referring to the procedure in Section VI, an empirical microservice maintainability quality model (RQ3) was devised based on selected quality metrics for monolith to microservice migration regulated by defined selection criteria in Table I. These selection criteria ensure that the selection process is within the research scope and objective.

TABLE I. CRITERIA FOR METRIC SELECTION

Selection criteria	
-	Applicable to microservice architecture
-	Must be related to cloud-native design properties
-	Automatically collectable from the structural property and practically applicable in object-oriented to microservice migration scenario
-	Influence on ISO/IEC 25010 maintainability characteristic or sub-characteristics

IV. SERVICE-BASED STRUCTURAL QUALITY METRICS (RQ1)

Migrating monolith applications to the cloud involves transforming software architecture to exploit the distributed environment. Due to this factor, the designer must measure software structural quality during the early migration stage. It is cheaper and less time-consuming than evaluating it during operation time [43]. Developers can predict software quality by measuring structural attributes influencing software's external quality, such as maintainability. Besides, measuring structural metrics is more extensive than component-level metrics [43].

Based on the literature review, the most collective existing structural design property metrics for service-based architecture are summarised (as described in Table II) as the following:

A. Coupling

This design property is the most considered metric for measuring software architecture quality. The graph theory of design properties enables the direct analysis of coupling properties. Thirteen metrics have been proposed for measuring microservice coupling [35], [43], [44], [54], [59], [60], while fourteen metrics for service-oriented architecture (SOA) [28], [51], [58], [61]. Expressively, four of the proposed microservice metrics by Bogner et al. [29] were derived from SOA metrics [53] in the context of microservice architecture.

TABLE II. PUBLICATIONS ON QUALITY METRICS FOR A SERVICE-BASED ARCHITECTURE

Source	Authors	Architecture	Focus
[28]	Bingu et al.	Service-Oriented	Effectiveness, understandability, flexibility, reusability, and discoverability based on QMOOD metrics: coupling (1), cohesion (1), complexity (1), size (1), and service granularity (1)
[42]	Taibi et al.	Microservice	Coupling (2) and size (2)
[43]	Panichella et al.	Microservice	Maintainability based on coupling (1), size (1)
[44]	Li et al.	Microservice	Coupling (1) and cohesion (1)
[51]	Mohammed et al.	Service-Oriented	Coupling (3), cohesion (2), and complexity (3) metrics
[53]	Rud et al.	Service-Oriented	Applicability from OOP, CBSE, and Web Domains - complexity (3), reliability (4), and performance (4) metrics
[54]	Bogner et al.	Microservice	Maintainability – coupling (4), cohesion (4), complexity (3), size (1)
[58]	Hofmeister et al.	Service-Oriented	Complexity using coupling (2) metrics
[59]	Santos et al.	Microservice	Complexity consists of cohesion (2) and coupling (2) metrics
[60]	Vera-Rivera et al.	Microservice	Complexity based on cohesion (1), coupling (3)
[61]	Perepletchikov et al.	Service-Oriented	Maintainability by extending OO coupling (8) metrics

B. Size

Four metrics were proposed for microservice [35], [43], [54], and one for service-oriented [28] architecture. The reason for considering fewer size metrics for SOA than for microservice is that the two architectural styles operate at a different level of service granularity. This design property is essential to microservice architecture that promotes smaller atomic functionality than SOA in its design principle.

C. Cohesion

Highly cohesive architecture refers to the strength between operations of services. Cohesion in microservice is more meaningful than for SOA and object-oriented architecture to minimize external dependencies [62] that negatively influence product quality. Eight metrics for microservice cohesion [44], [54], [59], and three metrics for service-oriented [28], [51] were proposed in previous works.

D. Complexity

From the literature review, three metrics for microservices [54] and seven metrics for service-oriented architecture [28], [51], [53] were identified pertaining to this design property. Due to the common structural complexity characteristics for SOA and microservice, Bogner et al. applied three complexity metrics originally proposed for SOA to the microservice architecture.

V. QUALITY METRICS FOR CLOUD-NATIVE ARCHITECTURE (RQ2)

This work defines cloud-native architecture as a distributed, elastic, and horizontally scalable application composed of microservices [63], [64]. Thus, casting the existing legacy application to the cloud as a virtualized environment cannot be demanded as a valid cloud-native application [65]. Moreover, a microservice is a self-contained deployment unit designed according to cloud-focused design principles such as IDEALS [33] to gain full cloud benefits.

Regarding architecture quality, previous design property quality metrics from RQ1 are mapped with IDEALS design principles as in Table III to justify the selection of quality metrics for cloud-native architecture based on defined criteria in Table I.

Instead of designing microservice for a new greenfield scenario, this work focuses explicitly on migrating monolith applications to microservices. This process involves three main phases: pre-migration, migration, and post-migration [67]. Therefore, to answer the following research question RQ3, this work considers monolith quality metrics in the maintainability model, thus devising related metrics based on its common structural characteristics. Identifying related quality metrics during the early migration phase helps the designer to make an informed decision to propose quality microservice architecture design before moving to the cloud environment.

VI. MAINTAINABILITY QUALITY MODEL FOR MICROSERVICE (RQ3)

This paper distinguished existing service-based architecture quality metrics in RQ1. Collected metrics are then aligned with cloud-native characteristics (RQ2) to funnel the microservice architecture-related quality metrics findings.

From the application architectural perspective, a service-based design pattern can be perceived as a higher abstraction layer for object-oriented architecture [68], [69]. One could consider the interaction of methods in object-oriented programming as a form of class interaction in microservices at an abstract level. In contrast, object-oriented class interactions can be understandable at a higher abstraction level as interactions of clusters of classes known as microservice. With this insight, we propose a set of quality metrics to measure microservice structural maintainability described in Fig. 2.

A. Coupling

Coupling is the degree to which the elements in a design are connected or express the strength of interdependencies and interconnections of service with other services [70]. From the quality perspective, these metric impacts system quality, such as maintainability and testability. The findings indicate that incorporating structural coupling can be highly significant for developers who wish to monitor the decomposition quality of their services [43]. A high level of structural coupling resulted in more frequent bug occurrences and propagated changes within modules of systems. Therefore, a successful decomposition should produce minimized coupling between microservices and maximized cohesion. A small number of couplings positively influence product maintainability.

TABLE III. RELATED QUALITY METRICS FOR IDEALS DESIGN PRINCIPLES

Design Principle	Design Property	Related Quality Metrics
Interface segregation	Complexity	Total Response of Service (TRS) [29]
		Service Support for Transactions (SST) [29]
		Measure of Functional Abstraction (MFA) [13]
	Size	Number of Operations [28]
		Non-Extreme Distribution (NED) [55]

		Service Cohesion (SC) [66]
		Service Design Cohesion (SDC) [66]

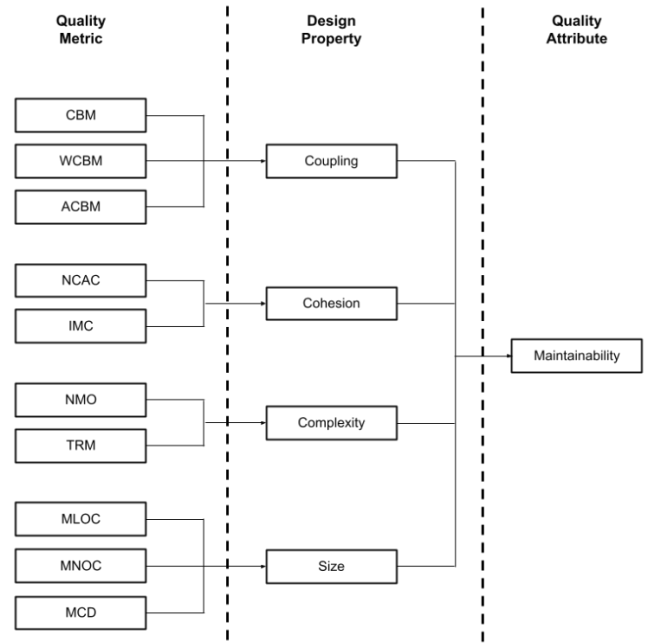

Fig. 2. The structural metric for microservice maintainability.

1) *Coupling Between Microservice (CBM)*: CBM is the number of other microservices that the microservice coupled with [35], [37]. The inspiration for this coupling derives from the widely recognized Coupling Between Objects (CBO) metric proposed by [71]. CBO counts several types of interactions, including method calls, parameter types, references, and return types. However, CBM only counted for each unique class interaction, excluding its frequencies and bi-directional relationship. To calculate the relative CBM for each microservice as follows:

$$M = \{m_1 \dots m_n\} \text{ is a set of microservice} \quad (1)$$

$$R = \{r_1 \dots r_n\} \text{ is a set of microservice interaction} \quad (2)$$

$$\text{TotalofInteraction}(r,m) = \text{Number of occurrence } r \text{ in } m \quad (3)$$

$$CBM(r,m) = \begin{cases} 1 & \text{TotalofInteraction} > 0 \\ 0 & \text{Otherwise} \end{cases} \quad (4)$$

2) *Weighted Coupling between Microservice (WCBM)*: WCBM is the frequency of other microservice that the microservice m is coupled with, i.e., the number of microservices where m has to interact once [29], [58]. As microservice holds clusters of classes, interactions with other microservices are more expensive than intra-microservice. Thus, frequencies for external microservice coupling need to be considered as interaction weightage. To formulate WCBM for each microservice as follows:

$$WCBM(r,m) = \text{TotalofInteraction}(r,m) \quad (5)$$

Absolute Coupling between Microservice (ACBM): The total number of bi-directional coupling frequencies between microservices where microservice $m1$ interacts with microservice $m2$ and $m2$ also interacts with $m1$ [29]. This metric helps represent inter-microservice dependencies and

how strongly they interact. ACBM for a microservice is represented as:

$$B=\{b_1...b_n\} \text{ is a set of bi-directional interactions} \quad (6)$$

$$\text{TotalofBidirectional}(b,m)=\text{Number of occurrence } b \text{ in } m \quad (7)$$

B. Cohesion

The degree to which the elements in a microservice design unit are logically related or connected. A high degree of cohesion is a sign of “togetherness” where classes within the microservice provide similar behavior to produce specific services or responsibilities. This characteristic matches the ideal cloud-native design pattern, where each microservice should contain a single responsibility for better maintainability.

1) *Normalize Cohesion among Classes of Microservice (NCAM)*: The NCAM for Microservice is an adaptation of the object-oriented metric Cohesion Among Methods of Class (CAM) [13]. A CAM cluster directly influences the microservice m cohesion in migration to microservice architecture. Thus, m cohesion can be served with an average CAM for a particular m . To represent NCAM for a microservice as follows:

$$\text{NCAM}(m_i)=1-\text{Avg}(\text{CAM}(m_i)) \quad (8)$$

2) *Intra Microservice Coupling (IMC)*: IMC is the frequency of internal microservice coupling. In compliance with [13], microservice architecture obtains higher object-oriented design abstraction. Therefore, strong relatedness and interactions between classes within the microservice m indicate strong m cohesion. This strong relatedness demonstrates that each class in a microservice is working together to serve specific functions. IMC for a microservice is represented as follows:

$$C=\{c_1...c_n\} \text{ is a set of classes in } m \quad (9)$$

$$P=\{p_1...p_n\} \text{ is a set of class interaction} \quad (10)$$

$$\text{TotalClassInteraction}(p,m)=\text{Number of occurrence } p \text{ in } m \quad (11)$$

$$\text{IMC}(m_i)=\text{TotalClassInteraction}(p,m) \quad (12)$$

C. Complexity

Complexity is the degree of connectivity between elements of a microservice. This metric is also concerned with the dependencies, microservice operations, and the number of requests with other microservices. Santos et al. [59] derived that complexity architecture has a negative impact on the system’s maintainability as it is difficult to make changes and decreases software understanding.

1) *Number of Microservice Operations (NMO)*: NMO is the number of total operations for the microservices [28]. In migrating from monolith to microservice architecture, the total number of microservice operations encompasses all operations across all classes of the microservice. A high number of internal microservice operations may result in a complex design that requires maintenance. With an increase in the

number of clusters, the structural complexity of the microservice also grows. NMO for a microservice is represented as follows:

$$O=\{o_1...o_n\} \text{ is a set of operation in } c \quad (13)$$

$$\text{TotalOperation}(o,c)=\text{Sum of } o \text{ in } c \quad (14)$$

$$\text{NMO}(m_i)=\text{TotalOperation}(o,c) \text{ in } m \quad (15)$$

2) *Total Response for Microservice (TRM)*: TRM is the total requests for operation O values of microservice [29]. This work employed an adapted version of the Response for Class (RFC) metric [71] from object-oriented design to the context of microservice design. Each microservice exposes its interface m_i for other microservices, increasing its dependencies and negatively impacting its complexity. TRM for a microservice can be expressed as:

$$\text{TRM}(m_i)=\sum \text{RFC}(m_i) \quad (16)$$

D. Size

This metric measures the size of structural design elements consisting of the number of classes and microservice lines of code. The more extensive and granular the microservice, the more challenging it is to maintain due to the possibilities of multiple responsibilities to the microservice. Size metrics are crucial design attributes in software estimation before executing migration [72].

3) *Microservice Line of Code (MLOC)*: The number of all non-empty, non-commented lines of the microservice body. This classic Line of Code (LOC) metric helps understand and overview microservice size. For a too-big microservice, there might be a sign that a technical debt problem exists. MLOC for a microservice is expressed as follows:

$$\text{MLOC}(m_i)=\sum (\text{NE} \ \&\& \ \text{NC})m_i \quad (17)$$

where $(NE \ \&\& \ \text{NC})$ are non-empty NE and non-commented NC lines of codes within a microservice m_i .

4) *Microservice Number of Classes (MNOC)*: The number of classes within a microservice [35] can measure how big the microservice is and identify if there are microservices that are too big. The number of classes should be minimized to keep microservice more independent of changes. MNOC for a microservice represents as:

$$\text{MNOC}(m_i)=\sum C(m_i) \quad (18)$$

where $C(m_i)$ are sets of classes within a microservice m_i .

5) *Microservice Class Distribution (MCD)*: MCD is the number of class sizes in microservice candidates distribution, with a desire that microservice may not contain too many or too few classes. This structural metric is an adaptation of the Non-extreme Distribution (NED) metric by [55]. Therefore, we measure how evenly distributed the sizes for each generated microservice candidate are. Our work improvised this approach by using standard deviation to understand the average of scattered microservice clusters instead of the mean

value that is heavily influenced by outliers value in determining the bound of non-extreme value for the number of classes within microservices. For better interpretability, measuring *I-MCD*, with a lower value demonstrates a better microservice distribution. To express MCD for a microservice as follows:

$$MCD(m_i) = \frac{\sum_{n=1, n \text{ not extreme}}^N c_n}{|C_i|} \quad (19)$$

where c_n is the number of classes in microservice m_i , and C_i is the set of classes of microservice m_i . n is not extreme if its size is within the bounds of $\{mean \text{ of classes for all microservices} \pm std \text{ deviation}\}$. This work measures its normalized value with $I-MCD(m_i)$ for better interpretability, and lower values are recommended.

VII. DISCUSSION

Measuring architecture quality for migrated monolith applications to microservice is crucial to ensure migration to the cloud achieves the migration objective. Despite various migrations approaches, less attention was given to the post-migration architecture quality. This work starts by identifying existing structural metrics for measuring service-based architecture quality. Our first contribution in this work is reporting the most applicable design property metrics for service-based architecture, including its influence on architecture quality (Section IV). This design property catalogue is a reference for other researchers in understanding how software architecture evolution influences the characteristics of its design properties.

Another state-of-the-art contribution of this paper is that it maps service-based quality metrics with the cloud-native design principles [33]. In contrast, previous quality metrics [13], [28] focus on the structural characteristics without considering architecture quality. From the structural quality perspective, this mapping is essential to ensure the designated cloud architecture pattern benefits from the cloud environment.

The proposed maintainability quality model for microservice architecture is the main contribution to this work. Ten structural quality metrics for measuring microservice architecture maintainability quality enable software designers and developers to assess the designed microservice candidate's quality before executing the migration, thus minimizing post-migration quality concerns and ensuring achievable migration objectives [6], [77], [78]. Despite relying on single design property in measuring structural maintainability quality, this approach promotes multiple design properties to give better accuracy and consistent result [79].

While this work pointed out several quality metrics related to microservice design properties, this work is still exposed to construct validity as we may not be able to cover all design properties [47] that influence monolith-to-microservice migration architecture quality [73]. However, this work covers various design properties than previous work [61], [74], [75] on architectural maintainability quality. Our approach is based on ISO/IEC 25010 [21] and additional structural design properties that influence maintainability quality measurement.

Regarding external validity, some of the metrics devised from existing work [13], [28], [29], [35], [55], [58], [71] are based on shared structural characteristics. This work ensured the soundness of the selected metrics by exclusively considering reliable peer-reviewed sources and established authors. Hence, our selection is adequate to initiate an exploration for microservice maintainability quality when migrating from monolith architecture.

This method relies on the monolith application as the source before the migration execution. This work focuses on migration instead of greenfield implementation. Thus, the selection of the quality metrics is heavily influenced and devised by the existing application architecture characteristics. Even though other works proposed various quality metrics for measuring product quality, the complexity of the metrics hindered the applicability of the approach by the industries [76]. As a result, our proposed quality metrics are more practical for industrial practice.

The limitation of this paper is that we did not adopt a more rigorous methodology for this paper, such as conducting a systematic or multivocal literature review. These procedures could have offered a more solid empirical basis for selecting publications. Moreover, a more rigorous process could have been employed to identify the metric candidates presented in this study to minimize any potential subjective bias. Additionally, certain digital libraries were excluded from the search process due to time limitations.

VIII. SUMMARY AND CONCLUSION

To measure architecture maintainability quality when migrating monolith applications to microservice architecture, this paper proposed a set of metrics related to coupling, cohesion, complexity, and size design property. These metrics were derived from cloud-native architectural design principles to utilize cloud benefits. The proposed metrics allow migration designers and developers to measure software architecture maintainability quality for microservice during design time. Additionally, this work included the mathematical formalization of the proposed metrics. Moreover, applying multiple design properties for measuring microservice architecture maintainability quality is an adaptation of state-of-the-art in this research domain.

As part of this work evaluation process, we intend to assess the metrics through case studies and extend their application to real-world industrial projects to evaluate their efficacy. These forthcoming efforts encompass the development of a tooling approach aimed at promoting a structured and rational migration process and providing practical illustrations of metric implementation throughout the migration process to evaluate the architecture quality of microservice candidates.

Abstract—With the rise in technology, a huge volume of data is being processed using data mining, especially in the healthcare sector. Usually, medical data consist of a lot of personal data, and third parties utilize it for the data mining process. Perturbation in health care data highly aids in preventing intruders from utilizing the patient's privacy. One of the challenges in data perturbation is managing data utility and privacy protection. Medical data mining has certain special properties compared with other data mining fields. Hence, in this work, the machine learning (ML) based perturbation approach is introduced to provide more privacy to healthcare data. Here, clustering and IGDP-3DR processes are applied to improve healthcare privacy preservation. Initially, the dataset is pre-processed using data normalization. Then, the dimensionality is reduced by SVD with PCA (singular value decomposition with Principal component analysis). Then, the clustering process is performed by IFCM (Improved Fuzzy C means). The high-dimensional data are divided into several segments by IFCM, and every partition is set as a cluster. Then, improved Geometric Data Perturbation (IGDP) is used to perturb the clustered data. IGDP is a combination of GDP with 3D rotation (3DR). Finally, the perturbed data are classified using a machine learning (ML) classifier - kernel Support Vector Machine- Horse Herd Optimization (KSVM-HHO) to classify the perturbed data and ensure better accuracy. The overall evaluation of the proposed KSVM-HHO is carried out in the Python platform. The performance of the IGDP-KSVM-HHO is compared over the two benchmark datasets, Wisconsin prognostic breast cancer (WBC) and Pima Indians Diabetes (PID) dataset. For the WBC dataset, the proposed method obtains an overall accuracy of 98.08% perturbed data, and for the PID dataset, the proposed method obtains an overall accuracy of 98.04%.

Keywords—Data mining; privacy; health care data; machine learning; perturbation; improved fuzzy c-means; horse herd optimization; kernel based support vector machine

I. INTRODUCTION

Big data analysis with proper security and privacy preserving features is required to balance privacy and utility. Recently, the advancement in information science has led to the digitized collection of data and storage in large numbers [1]. HI (health information) system can handle all the information related to health care. The HI system can be operated through national statistics offices and health information departments. It allows data on risk factors related

to morbidity, disease, mortality and health service coverage. The quality of patient treatment can be improved by using healthcare software [2]. Some HI elements are indicators, data sources, data management, information products and dissemination. Data mining is a technology that processes a large amount of data to draw unknown, hidden, and potentially useful data from source information [3]. It is used to help a wide range of business applications such as store layout, targeted marketing and customer profiling. Data mining tasks are divided into two categories: predictive tasks and descriptive tasks [4]. Personal and sensitive information of patients may be theft and breaches the patient's privacy through several attacks. A third person may use the information at various levels; hence, the data must be saved. Privacy is essential in sharing information for applications based on knowledge [5].

Recent advances in internet of medical things (IoMT) [6] like ambulance, immediate mobile medical devices faces high delay and low throughput due to the continuous motion state. For overcoming this, resource efficient flow enabled distributed mobility (FDMA) approach is introduced for improving the network performance. In [7], the authors undertaken the case study for latest advancement in health care treatments at the time of COVID breakdown in the field of internet of things (IoT). In [8], authors performed an analysis on the Markov random fields (MRF) for medical applications. However, in big data manual processing is one of the complex tasks and MRF play a vital role in overcoming medical related issues in big data. In addition, some other works like [9], researchers made a survey on privacy attacks location and creates a prevention deployment on IoT based vehicular application. For addressing the problems due privacy attacks, anonymity and cryptographic interpretations are introduced on the basis of digital signature technique. However, while integrating these techniques into the big data the performance gets very much reduced and lacks its capability.

Nowadays, PPDM (privacy preserving data mining) is a big challenge and is a technique used to transform data to preserve privacy. The growth in data mining leads to novel research as PPDM. There are several techniques used to achieve PPDM. They are anonymization, condensation, Perturbation, Cryptography, and Randomization [10]. Anonymization eliminates the information from the various

information sets to generalize the attributes [11]. Condensation is achieved by forming clusters in several ways. The range of each cluster differs from that of any other cluster [12]. Cryptography is protected with the help of record encryption to find identity and sensitive information [13]. In randomization, the records are shuffled vertically to hide the correct identity. The perturbation indicates that information is being manipulated using noise.

However, various sectors especially in health care, the amount of data gets increased exponentially and it is commonly termed as big data. Perturbing these kinds of data is one of the challenging task due to increasing intruders and advancement in data mining process [14]. Data perturbation is one the privacy preservation approaches that can modify the data present in the database to solve the individual's confidentiality problem. Some of the existing perturbation techniques like random rotation [15], condensation [16] and micro-aggregation [17] remain challenging for balancing both the privacy and the accuracy. In addition, data present in the health care database increases endlessly and intruders have high chance in extracting the information. In recent era, differential privacy (DP) [18] has attracted the researchers a lot by introducing k-anonymity and l-diversity and providing high data securing in data mining.

The noise can be classified into additive and multiplicative noise [19]. Addictive noise- also called Gaussian noise that can be looked slightly blurry and soft. It is the undesired instantaneous signal and gets added to some real signals. The image of each pixel changes from its real values by a small number. Multiplicative noise is undesired instantaneous signals that get multiplied into real signals. Data perturbation is a method of preserving data and maintaining confidentiality [20]. Several ML models are used to perturb the data and are efficiently used in PPDM. Further, it is compared with the original data to evaluate the efficiency of the model [21] [22]. ML is a computational science field that verifies and interprets the pattern. ML model-based approaches handle big data in the perturbation process [23]. Hence this work used an optimization-based ML model for data perturbation.

A. Motivation

Recent privacy-preserving data mining (PPDM) is a hot research topic in the big data mining process. The major aim of the PPDM is to protect individual data privacy from third party intruders. Nowadays, users are more aware of privacy intrusions on personal data and hesitate to share personal information. Several approaches are present to preserve data like perturbation, anonymization and data transformation. PPDM by data perturbation has attained popularity because these models can hide secret data successfully and ensure more utility in the retrieval process. Some perturbation models are geometric perturbation, condensation, additive perturbation, micro aggregation, and random rotation aids to perturb the medical data effectively. In the medical field, preserving data is essential since medical documents are relevant to privacy concerns and human subjects. PPDM perturbs the data, and intruders cannot identify the medical data. However, many techniques fail to hide the difference between the original and perturbed data, which helps the

intruders to easily identify the perturbation in the medical data. Hence, the accuracy of the original and privacy preserved data degrades and cannot apply to the medical data mining process. The latest advancement in the big data mining process helps to achieve better perturbation without the knowledge of intruders.

Recently, numerous approaches have been proposed in the literature for preserving data. But these methods have many limitations. Existing PPDM has high computational complexity for a large volume of data. Further inefficiency poor scalability and make data reconstruction impossible with these approaches. These major drawbacks motivate us to develop an enhanced DL model for medical data mining privacy preservation. Hence, this work proposes the model improved perturbation IGDP (Geometric Data Perturbation) with three-dimensional rotation (3DR) for privacy preservation. The proposed technique is integral in preserving privacy in health care data under low time complexity. *The major contributions of the proposed model are illustrated below:*

- To introduce a novel perturbation technique (IGDP-KSVM-HHO) for privacy preservation in healthcare data
- To pre-process the data using the min-max normalization technique for better data privacy.
- To reduce the data dimensions by introducing hybridized SVD-PCA technique to avoid data redundancy.
- To cluster the health care data using the IFCM technique, the hierarchical data is segmented, and every partition is set as the cluster.
- To perform perturbation using the IGDP technique for the clustered data to improve health care privacy preservation.
- To propose a KSVM-HHO approach for classifying the perturbed health care data accurately.
- To implement the proposed method in PYTHON, performance measures like F-measure, precision, accuracy, execution time and MSE are analyzed and compared with existing techniques.

The remaining section of the research work is arranged as follows: Section II is the recent relevant literature work; Section III depicts the proposed perturbation technique; Section IV gives the overall evaluation of implemented results. Section V provides the conclusion of the work.

II. RELATED WORKS

Some of the recent related work based on privacy preserving data mining is listed below:

Devi and Manikandan [24] introduced a rotation based condensation technique with geometric transformation for PPDM. This model provided better resilience over the attacks on the data reconstruction process. The improved P2RoCAI was utilized to measure the dynamics of classification

accuracy. This model provided less time for the empirical process, proving that it could be efficiently used in big data analysis. Kousika and Premalatha [25] proposed SVD (singular value decomposition) and 3RDP (3D rotation data perturbation) for PPDM. Using these models, a perturbed matrix was obtained. Several ML classifiers classified the original and perturbed data, and the evaluation was computed based on the accuracy rate. Experimentation proved that SVD-3RDP outperformed by attaining better accuracy for matrices of various sizes.

Kumar and Premalatha [26] used information value and weight evidence for the initial data perturbation. After that, the 3D shearing was fed on a quasi-identifier once the initial data perturbation was done. Then, several ML classifiers were fed on three benchmark datasets for analyzing the original and perturbed data. The experimentation was analyzed on 2D and 3D rotation. This model can preserve data utility with more privacy preserving and transformation capacity.

Chamikara et al. [27] introduced a novel perturbation model PABIDOT for addressing the utility problem of traditional data perturbation techniques. This model provides privacy to data via Φ – separation. The accuracy outcome of the perturbed data was near the original data. This model attained a systematic model for optimizing data perturbation variables. Finally, privacy and utility were analyzed on certain metrics.

Kumar et al. [28] proposed HER (Electronic Health Records) for hiding sensitive data by integrating fuzzy and association rules. The fuzzification was formed when multilevel privacy approaches were applied, and association rules perturbed outcomes. The experimentation was carried out on the UCI repository, and ML models were used to compute accuracy to show the robustness of the model.

Bedi and Goyal [29] defined privacy preservation in medical data in cloud IoT using extended fully homo-morphic encryption (EFHE). In this study, the FHE helps in adding and multiplying the cipher text. Finally, the information present in the medical data maintains perturbation and shows perturbed results. Thus, the attackers were unaware of the perturbed input and output states during the data mining process. In the experimental section, the peak-to-signal error (PSNR) of 30dB and SNR of 10dB were obtained. However, the security level of this method needs to be increased further for processing big data.

Reddy and Rao [30] defined the clustering and GDP technique for privacy preservation in health care data. The hierarchical data were clustered in this work using the k-means clustering technique. Finally, the clustered data was perturbed on the basis of the GDP algorithm. The perturbed values were encapsulated in the public, and clustered data were encapsulated under the private key. The experimental section obtained an accuracy of 79.58% and an execution time of 161.558s. But this method takes high execution time and obtains the average accuracy.

Janakiraman and Maruthukutty [31] introduced ML based techniques for perturbing the DNA based medical data. In this paper, integrated condensation based PP rotation based DP

and ensemble classification (ICS-PPR-DPEC) was emphasized to secure medical data. At the initial stage, condensation algorithm based DP (CADP) was introduced to group the data under tuple distances. Finally, an ensemble machine learning (ELM) based classifier was utilized for recognizing the perturbed human DNA based medical data. In the experimental section, an accuracy of 93.2%, precision of 90%, and recall of 89% were obtained. However, this method faces high complexity during perturbation.

Santhana and Natarajan [32] determined big data analysis for health care data based on clustering and DP algorithm. In this study, an improved FKM (IFKM) based clustering algorithm was introduced to cluster the medical data. Then, modified 3D rotation based DP was introduced to preserve the privacy of the medical data. The experimental section obtained an accuracy of 94% and an execution time of 35ms. However, this method lacks its performance when the data gets increased.

Sujatha and Udayarani [33] evaluated chaotic based geometric DP (CGDP) and hierarchical approach for preserving privacy in health care big data. Initially, the CGDP technique was introduced to perturb the healthcare data. Then, homomorphism based ensemble gradient approach was introduced to classify the perturbed data accurately. In the experimental section, an accuracy of 87% was obtained. However, this technique lacks a clustering technique; hence, the origin of the data cannot be identified.

Even though the approaches mentioned above' outcomes are encouraging, these methods have some limitations. These models take more time to process the data. Further, these methods do not seem to provide full security for the data. Hence, an efficient perturbation model is essential for maintaining the confidentiality of health data.

A. Problem Statement

The recent advancements in the big data mining process have grown much attention towards researchers, especially in the health care sector. With the fast growth in technological advancements, third party and other adversarial attacks also increase exponentially. However, in big data, enormous amounts of data are blemished daily with the increasing data mining process. The third party's utilization of individual privacy details increases for various commercial purposes. Nowadays, data perturbation is one of the hot topics in preserving one's privacy effectively. Many different data perturbation techniques have been introduced for effectively hiding personal details from attackers. But each has its benefits and disadvantages during data perturbation. For big data, recent models lack the capability and face high time complexity. In addition, the existing techniques fail to preserve without the knowledge of intruders, which becomes one of the open issues in many data mining applications.

Nowadays, with the latest technologies, the data can be perturbed without the knowledge of attackers, whether the data is perturbed or original. After the data perturbation, the origin of the data cannot be detected in many recent studies. To the best of our knowledge, the proposed big data mining

method outperforms well in preserving privacy without any knowledge to the intruders.

III. PROPOSED METHODOLOGY

Due to the emergence of ICT (Information and Communication Technology), healthcare data are saved in electronic form and obtained based on the requirements. However, big data privacy determines managing big data under minimal risk and secures the hyper-sensitive data. Generally, big data is spread all over the locations, which destroys patients' privacy for various purposes. Traditional privacy process lacks in handling big data especially in the healthcare sector. Hence, this article privacy enhanced ML algorithms for preserving medical data in the big data mining process. At the initial stage, the min-max normalization based pre-processing technique is emphasized to normalize the medical data efficiently. The normalized data is then fed into the PCA-SVD technique for dimensionality reduction. Then IFCM clusters the data to avoid unwanted complexities while processing big data. In addition, IGDP (Geometric Data Perturbation)-three-dimensional rotation (3DR) is used to effectively preserve data privacy from external attacks. For the classification of perturbed data, an optimization-based kernel Support Vector Machine (KSVM) is utilized. Further, for optimizing the weight of KSVM and improving the performance in classification, a meta-heuristic optimization technique HHO is proposed in this work. Fig. 1 depicts the framework of the introduced Perturbation model.

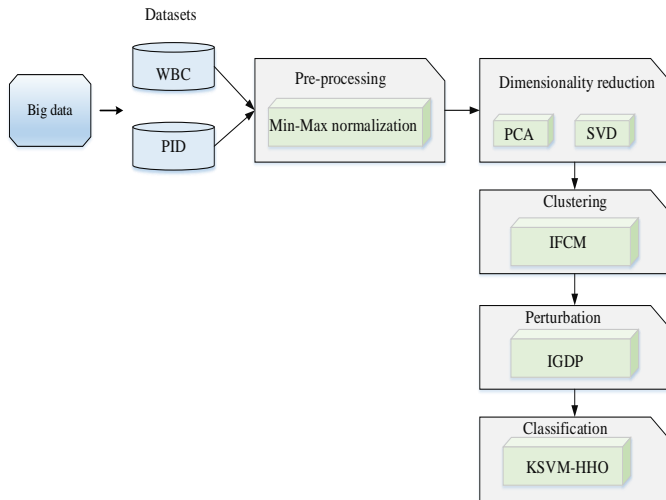

Fig. 1. Framework of the introduced perturbation model.

A. Min-Max Normalization

For the classification of perturbed medical data, pre-processing is the essential stage that can effectively improve the performance accuracy of the proposed technique. In the pre-processing stage, data normalization is undertaken to minimize data redundancy and error during perturbation. Recently studies have failed to normalize the data and consume high time complexity while perturbing the medical data. The proposed min-max normalization technique aids in normalizing the data and efficiently preserving the dataset's sensitive attributes. The major aim of the proposed model is to

normalize the original dataset E into a preserved dataset E' that satisfies the needs of privacy with better data privacy. In the dataset, every attribute is normalized arranging its value, hence they will come to the range of 0-1. To map the value D' of the attribute b from the range $[\max_b, \min_b]$ to $[New_{\max_b}, New_{\min_b}]$ is given by:

$$D' = \frac{D - \min_b}{\max_b - \min_b} (New_{\max_b} - New_{\min_b}) + New_{\min_b} \quad (1)$$

Where D and D' are the original and newly computed value. \max_b and \min_b are the attribute's maximum and minimum values. New_{\max_b} and New_{\min_b} are the attribute's new maximum and minimum values.

B. Dimensionality Reduction

After pre-processing, the dimensionality of the data is reduced for the normalized data. Similar features present in the medical data are completely removed from the medical data for the minimization of execution time. This research introduces a hybrid PCA-SVD technique for the elimination of similar features. The major aim of PCA is to reduce the dimension of the training set, and the major component of the training set is the outcome of the projection of the Eigenvector with Eigenvalue. The procedure of dimensionality reduction using PCA is given below:

Let $y \in S^n$ is a test sample with n parameters, and every parameter has m independent samples. Then the data matrix is written as:

$$Y_n = [y(1), y(2), \dots, y(m)], \quad Y_n \in S^{n \times m} \quad (2)$$

Every column of Y_n indicates a parameter, and every row indicates the sample. Since the dimensions of the measured parameters are different, every column of data is normalized, and it is represented as:

$$Y^* = \frac{Y_n - d \cdot p}{diag(\sigma)} \quad (3)$$

Where $d = (1, 1, \dots, 1)^T$, p is the mean of Y columns and $diag(\sigma)$ is a parameter matrix of Y_n .

The covariance matrix of Y^* is:

$$V = \frac{1}{m-1} Y^{*T} Y^* \quad (4)$$

The matrix processing is generally the decomposition of the Eigen value. The matrix is sorted in descending order based on the Eigenvalues size. The value of Y^* is decomposed by:

$$Y^* = \vec{Y} + F = TR^T + F \quad (5)$$

$$T = Y^*R \quad (6)$$

Where \vec{Y} is a projection in PCA, residual space of projection is F , and load matrix is denoted as R . T is a scoring matrix and the components in T is a primary parameter. PCA is a modelling segment, residual space is not a modelling segment, and it depicts the noise. The principal component number is selected according to CPV (Cumulative Percent Variance). This scheme represents the number of principal components based on cumulative principal elements. CPV is a ratio of the data variation defined by the initial principal component to the total data variation. Hence, CPV is represented as:

$$CPV = \frac{\sum_{j=1}^A \gamma_j}{\sum_{j=1}^m \gamma_j} \quad (7)$$

Where γ_j is an Eigenvalue of V . The features reduced by PCA are given to SVD for further dimensionality reduction. SVD is used for eliminating correlation between data features. In SVD, each sample is perturbed using the same parameter. Let a matrix indicates the original data B with dimension $l \times m$. The column indicates the attributes in the matrix, and the row indicates data objects. The SVD of the matrix C is given in equation (8).

$$C = XBY^T \quad (8)$$

Where X and Y^T are the $l \times l$ and $m \times m$ orthogonal matrix and B is $l \times m$ diagonal matrix.

The decomposition matrix C in (8) is represented as:

$$C = \sum_{j=1}^r \sigma_j B_j Y_j^T \quad (9)$$

Where σ_j is a singular value of C and the columns of X is B_j and Y_j . The SVD of the matrix C is used for solving the linear model $Cy = d$, and it is given by:

$$y^+ = \sum_{j=1}^r \sigma_j^{-1} \langle d, B_j \rangle Y_j^T \quad (10)$$

C. Clustering using IFCM

The dimensionality reduced data is then fed into the IFCM clustering technique to cluster the medical data having similar fields. In the traditional FCM [34] technique, the cluster's centre and the cluster numbers are fixed artificially, which is

sensitive for the first cluster centre. Further, this algorithm has slow convergence and less stability. Hence, IFCM is introduced, in these clusters, centres are based on two parameters like distance (d_j) and local density (ρ_j). Then the distance of density is given as:

$$\phi_j = d_j \rho_j \quad (11)$$

Then these parameters are fed to FCM to obtain the clustering results. Consider $Y = \{Y_1, Y_2, \dots, Y_n\}$ is a collection of m is number of clusters and this m is divided into G fuzzy groups. Then the centre matrix is given as $U = \{U_1, U_2, \dots, U_G\}$, and the objective function to define FCM is given by:

$$K(W, U) = \sum_{j=1}^G \sum_{k=1}^m (w_{jk})^n (d_{jk})^2 \quad (12)$$

Where W is a dimensional membership matrix, w_{jk} is a membership among Y , and U . d_{jk} is a Euclidean distance among k^{th} sample and j^{th} cluster centre. This equation (12) should satisfy the below conditions.

$$\begin{cases} \sum_{j=1}^G w_{jk} = 1, & k = 1, 2, \dots, m \\ 0 \leq w_{jk} \leq 1, & j = 1, 2, \dots, G; k = 1, 2, \dots, m \\ 0 < \sum_{k=1}^m w_{jk} < m, & k = 1, 2, \dots, G \end{cases} \quad (13)$$

Finally, the centre of the cluster is identified by the following expression

$$U_{jk} = \frac{\sum_{k=1}^m (w_{jk})^n y_k}{\sum_{k=1}^m (w_{jk})^n} \quad (14)$$

Where, y_k is a data in cluster and the membership function will be updated based on centres of the cluster, and it is represented as:

$$M_{jk} = \frac{1}{\sum_{l=1}^m \left(\frac{\|y_k - U_{jk}\|}{\|y_k - U_{kl}\|} \right)^{2/(n-1)}} \quad (15)$$

According to Equations (14) and (15), the dataset is grouped, and during clustering, the data are shuffled into several groups. This clustering is used for performing data perturbation.

D. Improved Geometric Data Perturbation (IGDP)

After clustering, the data perturbation process is undertaken to provide privacy to the medical data. Recently many perturbation techniques have been introduced to preserve medical data effectively without the intruder's knowledge. However, due to high processing time, those techniques cannot be applicable for processing huge volumes of data, especially in big data. The perturbation technique IGDP is used to perturb the clustered data. 3DR is used with GDP, and it is used to distort data by rotating three orientations (S_x, S_y, S_z) , and axes pairs utilized for the rotation are (S_{xy}, S_{yz}, S_{zx}) . The rotation operation is provided more than once until the entire attributes are transformed to preserve privacy. The procedure of 3DR is given below:

Stage 1: Choose the three orientations (S_x, S_y, S_z) and compute the rotation matrix as:

$$S_{xy} = S_x \times S_y = \begin{pmatrix} \cos \theta & 0 & -\sin \theta \\ \sin^2 \theta & \cos \theta & \sin \theta \cos \theta \\ \sin \theta \cos \theta & -\sin \theta & \cos^2 \theta \end{pmatrix}$$

$$S_{yz} = S_y \times S_z = \begin{pmatrix} \cos^2 \theta & -\sin \theta \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta & 0 \\ \sin \theta \cos \theta & -\sin^2 \theta & \cos \theta \end{pmatrix}$$

$$S_{zx} = S_z \times S_x = \begin{pmatrix} \cos \theta & -\sin \theta & 0 \\ \sin \theta \cos \theta & \cos^2 \theta & \sin \theta \\ -\sin^2 \theta & \sin \theta \cos \theta & \cos \theta \end{pmatrix}$$

Stage 2: The attributes are grouped into three functions (A_x, A_y, A_z) .

Stage 3: Three functions are rotated around (S_x, S_y, S_z) in a 3D plane for several rotation angles.

Stage 4: Identify the rotation angle until all attributes are transferred to preserve privacy.

GDP has a sequence of randomized geometric transformations like multiplicative transformation (M) , distance perturbation (Δ) and translation transformation (φ) .

$$g(y) = My + \Delta + \varphi \quad (16)$$

In this, the element M_T is a rotational matrix and y is original data.

1) *Multiplicative transformation*: The parameter (M) is a rotation matrix. This matrix accurately preserves distance. Let the rotation perturbation is expressed as:

$$g(y) = My \quad (17)$$

The orthogonal matrix is given as $M_{d \times d}$ and has some characteristics. The transpose of M is M^T , the Identity matrix is I_j and m_{jk} is the (j, k) component of M . The matrix of M in columns and rows is orthonormal. The resultant matrix is also orthonormal when the orders of columns and rows are changed.

2) *Translation transformation*: This transformation is written as:

$$g(y) = y + \varphi \quad (18)$$

Let us consider two points a and b in the original space, and the distance is given as:

$$\| (a - t) - (b - t) \| = \| a - b \| \quad (19)$$

The translation saves distance and doesn't protect the inner product. When translation and rotation are integrated, φ can enhance the preservation.

3) *Distance perturbation*: The major aim of this perturbation is to preserve distance and provide strength to distance inference attacks. The entry of the random matrix $\Delta_{f \times m}$ is an independent sample exhausted from the same distribution with less variance and zero means. When this random matrix is included, the distance between the point's pair gets disturbed. This IGDP provides more security to medical data. Then fully obtained perturbed matrix is applied for the classification process.

E. Classification using KSVM-HHO

The Perturbed data is then fed into the classification stage to classify the perturbed data accurately. The Classification stage helps to assess a dataset that retains data mining performance approaches after data perturbation. Recently, many ML classifiers have been utilized as a classifier for perturbed data, and each has its benefits and drawbacks. In this work, the ML based SVM classifier is used for classifying the perturbed data and utilizes a separation of non-linear mapping to transform original trained data, which are linearly transformed by a kernel function. The Polynomial kernel function (PKF) is used for the transformation, and this function transforms the non-linear into high dimensionality features. Hence, the data partition is feasible, making a classification task more convenient. Normal SVM states a hyperplane that is separated into two training classes, and it is expressed as:

$$g(z) = Y_k^* \phi_k(z) + f \quad (20)$$

where, Y_k^* is a hyper-plane parameter, f is a bias value and $\phi_k(z)$ is a term used for mapping vector z into high dimensionality space. The major aim is to make an effective classifier by the training set (o_k, z_k) . The optimal value of Y_k^* and f is given by:

$$o_k(Y_k^* z_k + f) \geq 1 - \zeta_k \quad \text{for } k = 1, 2, \dots, M \quad (21)$$

where, ζ_k is a slack parameter for all k . Y_k^* and ζ_k reduces the cost function, and it is expressed as:

$$\phi(Y_k^*, \zeta_k) = \frac{1}{2} \|Y_k^*\|^2 + R_e \sum_{k=1}^M \zeta_k \quad (22)$$

where, R_e is a regularized variable and used to control the size of the discriminant function. The final result of the SVM is denoted as:

$$o_k(y) = \sum_{k=1}^M J(y_k, y) \quad (23)$$

where, $J(y_k, y)$ is a kernel function. There are several types of kernels. In this work, a polynomial kernel is utilized. The kernel's parameters are to be adjusted previously to the process of the training data. It is one of the non-stationary kernels, and it works better for normalizing training data. It is denoted as:

$$J(y_k, y) = \gamma((y_k, y) + 1)^d \quad (24)$$

where, d is a polynomial degree. However, the proposed classifier high affected due to increased losses in which the origin of the data cannot be detected. The loss function of the proposed KSVM classifier can be interpreted as,

$$L = \min(\text{Accuracy}), \max(\text{MSE}) \quad (25)$$

1) *Parameter tuning using HHO optimizer*: The proposed KSVM classifier degrades its performance while processing huge medical data. Thus, the accuracy performance is much reduced, which can be overcome by tuning the parameters in the classifier model. Recently, many optimization techniques have played an integral role in tuning the parameters, thus enhancing the system's efficiency. This research introduces HHO based metaheuristic optimization technique for parameter tuning of the proposed classifier model.

Initially, the parameters of HHO are initialized, and the parameters of the polynomial SVM are encoded and trained. Obtain fitness value and classification of horses based on age. Then, the position of the horse is obtained. The process is repeated until the satisfied criteria are met.

This optimization is based on the horse's behaviour. There are six patterns of behaviours they are Grazing (G), Hierarchy

(H), Roaming (R), Sociability (S), defences (D) and Imitation (I). The following equation is based on a movement provided to horses at every iteration.

$$Z_n^{i,age} = \vec{U}_n^{i,age} + Z_n^{(i-1),age} \quad (26)$$

Where $Z_n^{i,age}$ is a n^{th} horse position, age is the age of the horses, i is a present iteration and $\vec{U}_n^{i,age}$ is a velocity vector. The following steps show the horse's six patterns of behaviour.

a) *Grazing (G)*: Horses feed on grasses, grains and plants. HHO creates the grazing field around every horse with a factor k . Horses graze at any age in their entire lifetime. The grazing behaviour is expressed as:

$$\vec{G}_n^{i,age} = g_i(LB + \rho \times UB) + [Z_n^{(i-1)}] \quad (27)$$

$$g_n^{i,age} = g_n^{(i-1),age} \times \sigma_g \quad (28)$$

Where $\vec{G}_n^{i,age}$ is a parameter of motion, and it shows the ability of horse grazing tendency. This term minimizes linearity by σ_g . LB and UB are the lower and upper bounds, which range from 0 to 1.

b) *Hierarchy (H)*: It is proved that the horses at 5 to 15 years are used to follow hierarchy rules, and it is indicated as:

$$\vec{H}_n^{i,age} = h_n^{(i-1),age} [Z_n^{(i-1)} - Z_n^{(i-1)}] \quad (29)$$

$$h_n^{i,age} = h_n^{(i-1),age} \times \sigma_h \quad (30)$$

Where $h_n^{i,age}$ is the effect of the best location of the horse on the velocity, σ_h is a reducing factor and $Z_n^{(i-1)}$ is the best horse location.

c) *Sociability (S)*: This behaviour is regarded as the movement to an average position of other horses. Horses in their middle age have an interest in the herd, and it is expressed as:

$$\vec{S}_n^{i,age} = s_n^{(i,age)} \left[\left(\frac{1}{N} \sum_{l=1}^N Z_l^{(i-1)} \right) - Z_n^{(i-1)} \right] \quad (31)$$

$$s_n^{i,age} = s_n^{(i-1),age} \times \sigma_s \quad (32)$$

Where $\vec{S}_n^{i,age}$ is a social movement vector, σ_s is a reducing factor and $S_n^{(i,age)}$ is an orientation of a horse to a herd in i^{th} iteration.

d) *Imitation (I)*: This characteristic of a horse is set as i , and the horse in 0 to 5 years tries to mimic other horses. This imitating behaviour is expressed as:

$$\vec{I}_n^{i,age} = i_n^{(i,age)} \left[\left(\frac{1}{qN} \sum_{l=1}^{qN} \vec{Z}_l^{(i-1)} \right) - Z_n^{(i-1)} \right] \quad (32)$$

$$i_n^{i,age} = i_n^{(i-1),age} \times \sigma_i \quad (34)$$

Where $\vec{I}_n^{i,age}$ movement vector of the horse to the average of best horses with a position of \vec{Z} . The total of horses with the best location is qN and σ_i is a reducing factor.

e) *Defence (D)*: This behaviour exists in their overall lifetime. This horse mechanism is represented as d , and it is a negative factor in equations (32) and (33).

$$\vec{D}_n^{i,age} = -d_n^{(i,age)} \left[\left(\frac{1}{sN} \sum_{l=1}^{qN} \vec{Z}_l^{(i-1)} \right) - Z_n^{(i-1)} \right] \quad (35)$$

$$d_n^{i,age} = d_n^{(i-1),age} \times \sigma_d \quad (36)$$

Where $\vec{D}_n^{i,age}$ is an escaping vector from a bad location \vec{Z}_l , sN is a total of horses and σ_d is a reducing factor.

f) *Roaming (R)*: This characteristic is imitated as a random motion and represented using r . This behaviour is generally seen at 0 to 5 years and goes away at middle age. It is represented as:

$$\vec{R}_n^{i,age} = r_n^{(i,age)} \vec{qZ}_l^{(i-1)} \quad (37)$$

$$r_n^{i,age} = r_n^{(i-1),age} \times \sigma_r \quad (38)$$

Where $\vec{R}_n^{i,age}$ is a random velocity vector and σ_r is a reducing factor of $r_n^{i,age}$.

g) *Fitness function (F)*: Finally, the parameter is tuned, and its weight is updated based on the updated location of the proposed optimizer. The fitness function can be formulated as,

$$fitness\ function(f) = \max(Accuracy), \min(MSE) \quad (39)$$

As shown above, the data is perturbed using IDGP and classified by KSVM-HHO. Several classifiers classify perturbed and original data; the achievements are given in the following section. Fig. 2 illustrates the flowchart of the proposed IGDP-KSVM-HHO technique. Algorithm 1 depicts the pseudo-code for the proposed method.

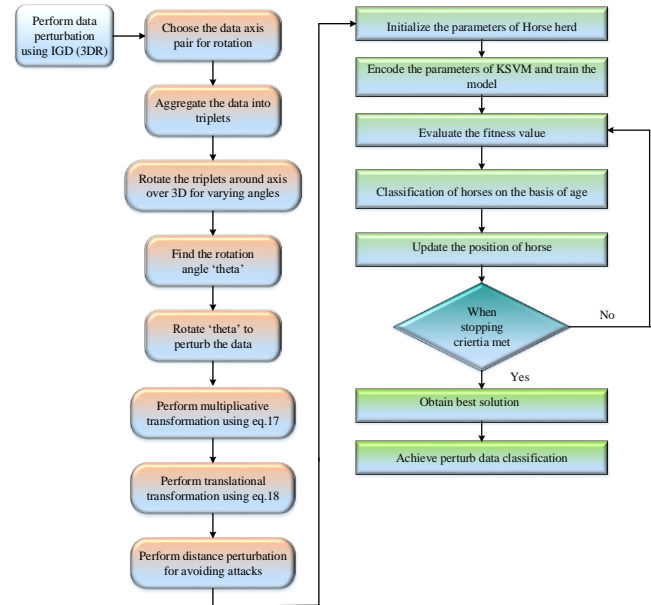

Fig. 2. Flowchart of the proposed IGDP-KSVM-HHO technique.

Algorithm 1: Pseudo code for the proposed method

Pseudo code for the proposed method
Input: Noisy medical dataset from the raw dataset;
Output: Classified perturbed and original medical data;
Start data pre-processing using min-max normalization
Perform data normalization and preserve sensitive attributes using equation 1; //normalized medical data
For dimensionality reduction
Utilize hybrid PCA-SVD technique;
Consider the data as a data matrix of PCA using equation 2;
Normalize the medical data present in the row and columns using equation 3;
Calculate the covariance matrix V using equation 4;
Arrange the matrix into descending order and measure the score matrix using equations 5 and 6;
Analyze the data variation CPV in the matrix using equation 7;
While the correlation between the features is high
Integrate SVD with PCA for further dimensionality reduction;
Consider the data matrix of SVD using equation 8;
Calculate decomposition matrix C using equation 9;
Calculate the dimensionality reduced matrix using equation 10; //dimensionality reduced medical data
End while
End for
Do clustering for the dimensionality reduced medical data

using IFCM //helps to find origin of data
 Calculate density distance for determining the cluster centre using equation 11;
Assume the centre matrix $U = \{U_1, U_2, \dots, U_G\}$ having random clusters;
 Calculate the objective function using equation 12;
Assume the condition for becoming a member of a particular cluster;
If ($k = 1$)
 Calculate the membership matrix M_{jk} having cluster centre using equation 15;
 Update the cluster centre U_{jk} using equation 14;
 $k \leftarrow K + 1$
Return best clusters having membership function M
Perform data perturbation using IGDP (3D rotation);
Input: Clustered medical data, its attributes and array of security thresholds;
Output: Perturbed medical data;
For GDP with 3D rotational transformation
Select the orientations as, (S_x, S_y, S_z) and perform rotation as, S_{xy}, S_{yz} and S_{zx} ;
Group the attributes as, (A_x, A_y, A_z) ;
Rotate (S_x, S_y, S_z) in a 3D plane for varying angles;
Do geometric transformations to preserve distance privacy and avoid attacks
Perform multiplicative transformation using equation 17;
Perform translation transformation using equation 18;
Preserve distance and eliminate attacks using distance perturbation;
End for
Return perturbed medical data
For classification of data perturbation
Do optimized KSVM-HHO for perturbed data classification
Initialize the parameters of HHO using equation 26;
Train the SVM model using equation 20;
 Calculate the fitness value for the reduced cost function using equation 22;
 Calculate the age based on the hierarchical rule in equations 28 and 29;
 Find the optimal value Y_k^* and f by tuning the parameters using equation 21;
 $Y_k \leftarrow Y_k^*$;
 Analyze the data obtained by optimized SVM using equation 23;
 Adjust the kernel parameters using equation 24;
 Update the horse position using equations 27 and 28;
 Analyze the velocity of the horse based on the age using equations 37 and 38;
If fitness condition is satisfied
Generate best outcome;
Else;

Repeat $T \leftarrow T + 1$
End if
Return the accurate classified perturbed medical data
Stop

IV. RESULTS AND DISCUSSION

The proposed IGDP-KSVM-HHO is evaluated in the Python platform. The efficiency of the approach is evaluated based on accuracy, F-measure, MSE, precision, sensitivity, specificity and execution time. The performance of Perturbed and original data are classified by ML classifiers like KSVM, SVM, NB (Naïve Bayes), KNN (K nearest neighbour) and RF (Random forest). Table I depicts the simulation parameters of the proposed method. Table II represents the system configuration of the proposed method.

TABLE I. SIMULATION PARAMETERS OF THE PROPOSED METHOD

Simulation Parameters	Values
Optimizer	HHO optimizer
SVM-type	C-classification
SVM-kernel	Polynomial kernel
Cost	1
Gamma (γ)	0.0625
Number of support vectors	8434

TABLE II. SYSTEM CONFIGURATION OF THE PROPOSED METHOD

System Specifications		
S. No	Parameter	Configuration
1	Device name	Desktop
2	Processor	Intel(R) Core(TM) i3-7100 CPU @ 3.90GHz, 3912 MHz, 2 Core(s), 2 Logical Processor(s)
3	Installed RAM	8.00 GB (7.89 GB usable)
4	Device ID	DFBCDAE4-A190-457D-8C56-FDDDBB348B4F
5	Product ID	00330-50186-83065-AAOEM
6	Pen and Touch	No pen or touch input is available for this display
7	System Type	64-bit operating system, x64-based processor

A. Dataset Detail

1) *WBC dataset*: This dataset is obtained from the UCI machine learning repository and used to record Breast cancer cases' measurements. It has nine attributes and 699 samples. This dataset has two classes, and it is downloaded using the following URL.
[https://archive.ics.uci.edu/ml/datasets/breast+cancer+wisconsin+\(Prognostic\)](https://archive.ics.uci.edu/ml/datasets/breast+cancer+wisconsin+(Prognostic))

2) *PID dataset*: This dataset is initially obtained from the National Institute of kidney, digestive and diabetes diseases. It has eight attributes and 768 samples. This dataset is downloaded using the <https://www.kaggle.com/uciml/pima-indians-diabetes-database/version/1>. For experimental analysis, both datasets are divided into 70% for training and 30% for testing.

B. Performance Measures

In order to quantitatively calculate the performance of the developed scheme, certain metrics are utilized. This research uses six metrics, execution time, sensitivity, accuracy, F1 score, and precision, to evaluate the performance. The introduced IGDP-KSVM-HHO was evaluated based on True positive (T_p), false positive (F_p), true negative (T_n) and false negative (F_n). The description of all metrics with the formula is described below.

1) *Accuracy (A)*: It is a ratio of the number of exact predictions to the overall prediction. It is expressed as:

$$A = \frac{T_p + T_n}{T_p + T_n + F_p + F_n} \quad (40)$$

2) *Sensitivity (Se)*: An amount of active positive is exactly found as positive using the classifier. The following expression represents it:

$$Se = \frac{T_p}{T_p + F_n} \quad (41)$$

3) *Precision (P)*: It is a ratio of the positively predicted sample which is positive to the overall observation, and it is expressed as:

$$P = \frac{T_p}{T_p + F_p} \quad (42)$$

4) *F-measure (F)*: It is a harmonic mean of *Se* and *P*. The following expression expresses it:

$$F = 2 \times \frac{P \times Se}{P + Se} \quad (43)$$

5) *MSE (Mean Square Error)*: It is measured using the average squared intensity of original and perturbed values. It is denoted as:

$$MSE = \frac{1}{w_i h_i} \sum_{j=1}^{w_i} \sum_{k=1}^{h_i} (D_{jk} - S_{jk})^2 \quad (44)$$

Where D_{jk} and S_{jk} are the grey values of (j, k) .

C. Performance using the WBC Dataset

This section compares the performance of IGDP-KSVM-HHO with several ML classifiers on the WBC dataset. The metrics like accuracy, F-measure, sensitivity, precision, MSE and execution time are computed.

Fig. 3. Comparison of (a) accuracy, (b) F-measure, (c) precision, (d) sensitivity.

Fig. 3 compares several metrics like Accuracy, F-measure, Precision and sensitivity. The performance is carried out for the original dataset and the perturbed dataset. That is, the WBC dataset is perturbed using IGDP. The analysis proved that the proposed IGDP-KSVM-HHO attained better results than existing classifiers. It is seen from the graph that the proposed IGDP-KSVM-HHO attained almost equal to the original dataset. The accuracy attained by the original dataset is 95.11%, and IGDP-KSVM-HHO attained an accuracy of 98.08%, respectively. The proposed model attained better results due to the KSVM optimized by HHO. It shows that this model can provide privacy to data efficiently.

Fig. 4. Comparison of (a) MSE (b) Execution time.

Fig. 4 indicates the comparison of the measures like Execution time and MSE. Execution time is the overall time taken by the proposed model to achieve the outcomes, and it is represented in milliseconds (ms). The proposed IGDP-KSVM-HHO takes only 0.79 ms to complete the process. But, other classifiers take more time to complete the process. It shows that the proposed model has less computational complexity.

Further, the perturbed model's MSE of IGDP-KSVM-HHO, KSVM, SVM, KNN, NB and RF are 0.077, 0.155, 0.14, 0.36, 0.11 and 0.14, respectively. It is proved that the system has fewer errors. This perturbation can be applied to various datasets and utilized for big data analysis.

D. Performance using PID Dataset

This section illustrates the quantitative performance of various classifiers on the PID dataset. The original and

perturbed data is evaluated on a PID dataset, and some performance measures are computed.

Table III depicts the performance comparison of various classifiers. Several classifiers are verified on the perturbation method to evaluate the data perturbation effect in the potential of data mining. The experimental demonstration proved that the introduced model preserves the data and enhances accuracy in classification. The existing models attained poor results due to their structure and high computational complexity. In all cases, the performance attained by the original dataset is nearly equal to the perturbed PID dataset. The accuracy, F-measure and precision obtained by the perturbed dataset for the proposed model are 98.04%, 97.36% and 96.6%, respectively.

Table IV depicts the performance comparison of sensitivity, MSE and Execution time of classifiers like KSVM, SVM, NB, KNN, RF and proposed IGDP-KSVM-HHO. Classifiers are applied for original and perturbed data. The table shows that the overall values of a perturbed dataset are almost the same as the perturbed data. It shows that IGDP-KSVM-HHO ensures better accuracy than existing classifiers. In addition, after perturbation, the mined remains similar, preserving data utility. The proposed model achieved better due to the 3D rotation and optimal weight selection.

TABLE III. PERFORMANCE COMPARISON (ACCURACY, F-MEASURE AND PRECISION) OF VARIOUS CLASSIFIERS

Classifiers	Original dataset			Perturbed dataset		
	A	F	p	A	F	p
RF	96.09	95.3	95.55	97.71	96.9	95.78
KNN	96.4	95.64	95.6	96.4	95.5	94.9
NB	91.85	90.95	92.06	94.34	95.63	95.39
SVM	97.39	96.6	96.15	97.71	96.9	95.99
KSVM	97.39	96.6	96.15	97.39	96.66	96.1
IGDP-KSVM-HHO (proposed)	97.06	96.26	95.07	98.04	97.36	96.6

TABLE IV. PERFORMANCE COMPARISON (SENSITIVITY, MSE AND EXECUTION TIME) OF VARIOUS CLASSIFIER

Classifiers	Original dataset			Perturbed dataset		
	Se	MSE	Execution time (ms)	Se	MSE	Execution time (ms)
RF	93.70	0.039	33.4	96.79	0.022	1.593
KNN	94.2	0.035	32.85	94.67	0.03	1.437
NB	89.06	0.081	32.86	94.34	0.035	1.437
SVM	95.6	0.026	32.7	96.54	0.022	1.34
KSVM	95.6	0.02	32.7	95.65	0.026	1.34
IGDP-KSVM-HHO (proposed)	97.06	0.02	2.2	96.5	0.019	0.84

E. Performance Comparison under different Techniques

In this section, the performance of the proposed method is compared with different existing techniques and proves that the introduced model is highly efficient and accurate. Some of

the existing clustering techniques like fuzzy-c means clustering (FCM), k-means (KM), k-medoids and density based spatial clustering of applications with noise (DBSCAN) are utilized. In addition, some of the existing optimization techniques like a genetic algorithm (GA), particle swarm optimization (PSO), differential evolution (DE) and monarch butterfly optimizer (MBO) are utilized and prove that the proposed parameter tuning optimizer is better. Table V tabulates the comparative performance under different clustering techniques. Table VI and VII illustrates the performance comparison for different optimization techniques under PID and WBC datasets.

TABLE V. OVERALL ACCURACY PERFORMANCE UNDER DIFFERENCE CLUSTERING APPROACHES

Clustering methods	Accuracy performance
Proposed	97.07%
FCM [35]	89%
KM [36]	93%
k-medoids [37]	92.2%
DBSCAN [38]	94%

TABLE VI. COMPARATIVE PERFORMANCE UNDER DIFFERENT OPTIMIZATION TECHNIQUES FOR THE PID DATASET

Methods	Original Dataset		Perturbed Dataset	
	Accuracy	MSE	Accuracy	MSE
KSVM-HHO (Proposed)	95.11	0.79	98.08	0.077
KSVM-GA	94.85	0.84	97.62	0.085

KSVM-MBO	95.91	0.0041	96.12	0.037

F. Analysis of the Proposed Method

In this section, the outcome of the proposed method is analyzed under original medical data and perturbed medical data. Tables VIII to XI demonstrate the original database, clustered medical data, 3D rotated medical data, and classified perturbed data. In Table IX, C_1 , C_2 and C_3 depict the cluster groups, respectively.

TABLE VIII. ORIGINAL SAMPLE MEDICAL DATABASE

Blood pressure (BP)	Age	Gender	Weight (Kg)	Type of Disease
122	22	Male	75	Diabetes
90	25	Male	82	Vision loss
85	43	Female	55	Inflammatory breast cancer
104	55	Male	69	Kidney failure
113	40	Female	45	Ductal carcinoma
82	32	Female	65	Benign tumour
70	27	Male	72	Insulin malfunctions

V. CONCLUSION

Due to the advancement of technology, several medical data are frequently gathered and delivered to the institution. Several resources are involved in data collection, analysis and sharing the data, leading to an increase in concerns regarding patients' data. The PPDM model provides several techniques for preserving the data. This paper aims to provide privacy to medical data using the perturbation technique. Two benchmark datasets are selected for this purpose. Initially, the dataset is pre-processed, and the dimensionality is reduced. Then, the reduced features are clustered using IFCM. This clustered data is perturbed by IGDP, which integrates GDP and 3DR. Finally, the perturbed data is classified by the KSVM-HHO classifier. The performance of IGDP- KSVM-HHO is compared to the other ML classifiers like KSVM, SVM, NB, KNN and RF. The performance obtained by IGDP- KSVM-HHO is superior to other models. Moreover, the classification performance of original and perturbed data is almost equal, showing that this model can provide better privacy. For the WBC dataset, the proposed method obtains an overall accuracy of 95.11% and 98.08% for original and perturbation in data. For the PID dataset, the proposed method obtains an overall accuracy of 97.06% and 98.04%, respectively. However, security is the major concern for the big data mining process due to the increase in harmful intruders. The advantage of the proposed method is that it is one of the highly recommended systems for preserving the individual's privacy data under low complexity. Despite this, the proposed method suffers due to high granular access control and faces complexity in detecting the origin of data. In the future, researchers need to focus on developing secure encryption and trust computing techniques to maintain the balance between security and the efficiency of the data mining process. In addition, the researchers need to process the proposed work with various other fields like banking, military sectors etc. and analyze the performance of the same.

Abstract—Facial image processing is a major research area in digital signal processing. According to recent studies, most commercial facial image processing systems are prejudiced by bias towards specific races, ethnicities, cultures, ages, and genders. In some circumstances, bias may be traced back to the algorithms employed, while in others, bias can be elicited from the insufficient representations in datasets. This study tackles bias based on insufficient representations in datasets. To tackle this, the research undertakes an exploratory review in which the context of facial image dataset is analyzed to thoroughly examine the rate of bias. Facial image processing systems are developed using widely publicly available datasets since generating datasets are costly. However, these datasets are strongly biased towards Whites and Asians, and other geo-diversity such as indigenous Africans are underrepresented. In this study, 40 large publicly accessible facial image data sets were examined. The races of the datasets used for this study were visualized using the t-distributed Stochastic Neighbor Embedding (t-SNE) visualization method. Then, to measure the geo-diversity and rate of bias of the dataset, k-means clustering, principal component analysis (PCA) and the Oriented FAST and Rotated BRIEF (ORB) feature extraction techniques were used. The findings from this study indicate that these datasets seem to exhibit an obvious ethnicity representation bias, particularly for native African facial images; as a result, additional African indigenous datasets are required to reduce the bias currently present in the most publicly available facial image datasets.

Keywords—Digital signal processing; facial image processing; bias, geo-diversity; facial image datasets; k-means clustering; principal component analysis

I. INTRODUCTION

Facial image datasets are generally created using digital image processing techniques in terms of collation of images and how they are stored. Digital image processing, which is a subset of digital signal processing (DSP), has shown to be effective in the development, analysis, and design of image processing systems which has bring about in the proliferation of image-processing systems and computer vision algorithms. Although digital image processing is the most common facial image dataset creation technique, optical and analog image processing technique can also be utilized. Digital image signals are now frequently evaluated using scientific visualization especially computer vision. Facial image dataset creation is the process of using digital image signals for acquiring of images/pictures or assembling such input image signals to create facial images.

Facial image recognition systems are generally evaluated from large-scaled experimental facial image dataset based on machine learning and artificial intelligence scientific methods. Facial image processing and technologies have acquired incredible pace and reached previously inconceivable performance levels mainly because of the advancement in Deep Learning technologies [14]. For example, image processing excels at tasks like object recognition, images classification, and image segmentation, sometimes even outperforming humans. Numerous machine learning applications that use human face characteristics have so flourished in recent years as businesses and governments have increasingly adopted autonomous decision-making techniques [13].

Despite advancements in facial image technologies, the problem of translucent descriptions and remedies for facial image bias in image processing applications that are biased towards a particular demography arises from the imbalance in some demographic categories within diverse geographies, such as race, age, or gender, that are common in many communities around the world today. Hence, to cope with the real-world variation of human facial images, it is vital to have a full grasp of this bias inside every component of the selected datasets use in developing such applications [11]. Furthermore, for decades, there has been extensive study into bias in machine learning algorithms used in facial image processing systems. These findings reveal the basic comprehension of the underlying factors that contribute to face recognition bias, which has attracted more attention from researchers in recent years [54]. However, these studies do lack focus of the diversity of datasets especially in relation to the underrepresented racial groups. Hence, this study shows the importance of recognizing the existing level of bias throughout face image databases and the necessity for an impartial dataset especially for the underrepresented racial groups.

The term "bias" can be used to refer to a statistically biased estimator, a systematic error in a prediction, a disparity between demographic groups, or even an unfavorable causal relationship between a protected attribute and another feature in the fields of artificial intelligence (AI), algorithmic fairness, and big data ethics [49]. However, bias can also refer to a variety of ways that unfairness is represented in data, including erroneous correlations, causal connections between varying, and prejudiced data samples. This paper's goal is to provide a summary of the latter concept in the context of datasets used in facial image processing. More specifically, to the definition that a bias in a dataset ensues when entities or groups in a study

diverge methodically from the populace of interest, leading to a methodical mistake in a relationship or outcome of such facial image processing system. In reference [25], it refers more generally to any association created as a result of the method used to choose individuals for the study. For visual datasets, applying the first criteria would be difficult since, for instance, in the case of facial recognition, respecting the ethnic composition of the people is frequently insufficient to assure high performance across all subgroups, as shall be shown in this study.

Creating huge datasets from scratch might be expensive, and this has been a major constraint for facial image processing systems. As such, it is typical for image recognition systems and facial image processing models to utilize publicly available open-source datasets such as ImageNet and Open Images to train vision models. This is particularly desired when utilizing machine learning techniques in such systems, especially for developing regions where resources for producing fresh datasets may be restricted. However, if these datasets are not representative of the places of interest, predicted performance of developed models may decrease.

In this research, the biased geo-diversity of some selected big datasets is analyzed in respect to the disparities that models trained on them display when categorizing facial images from various native geographical regions. To discover an evident of such bias, this study analyzed the composition of the demography of a collection of popular Facial Image datasets. In addition, datasets that were created with a focus on avoiding bias or that reflected the underrepresented geographical groups and ethnicity are also utilized. This is with an effort to encourage facial image datasets authors' efforts in increasing diversity on their datasets. We give these findings not as a critique but as a case study in the difficulty in establishing a geo-diverse balanced dataset.

The paper is organized as: Related works are treated in Section II. Section III describes the methodology used to measure the geo-diversity and rate of bias of the dataset; results and analysis in Section IV; conclusions in Section V; future work closes the paper with Section VI.

II. RELATED WORK

A. A Review of an Existing Database

Over the years a wide variety of datasets has been compounded for various image processing applications under a variety of circumstances and for several purposes. Face databases have been compiled in tandem with the advance of face recognition and facial expression algorithms. Table I indicates the most widely used facial image databases that are publicly available in the development of facial image processing applications. However, these facial image databases such as the Flickr-Faces-HQ Dataset (FFHQ) [25] and Tufts face database tends to not contain facial images of some geographical populations.

The reasons for creating such datasets by the creators and the methods used to generate and compile the facial images explain why some geo-diversity in the datasets of facial images is underrepresented. We discuss in details some of these datasets:

1) *Flickr-Faces-HQ Dataset (FFHQ)*: As part of the NVIDIA initiative, the Flickr-Faces-HQ Dataset (FFHQ) was collected from the vast online repository of Flickr users' facial images that is significantly higher in quality and covers a much greater range of variance than existing high-resolution datasets [25]. The collection includes 70,000 1024 x 1024-pixel high-quality Portable Network Graphic (PNG) photographs with a wide range of ages, ethnicities, and image backgrounds. Age, race, and background of the images are all very diverse. It also includes accessories like hats, sunglasses, and eyeglasses. The facial images were automatically aligned and cropped using dlib after being crawled from Flickr, inheriting all of the website's biases. The images were pruned using several automatic filters, after that, weird sculptures, paintings, or pictures with non-facial images were removed using Amazon Mechanical Turk. The FFHQ dataset was designed as a generative adversarial network (GAN) benchmark. The high-level statistic of the geo-diversity of the FFHQ dataset is shown in Fig. 1.

2) *VADANA dataset for facial analysis*: VADANA stands for Vims Appearance Dataset for facial ANALYSIS. It was developed by [33]. It provides one of the largest age and blood-relation/kinship annotated dataset. The dataset is annotated with parent-child and siblings' relations. VADANA dataset provides a larger number of high-quality digital images for subjects within and across different age ranges. VADANA contains images of 43 subjects (26 males, 17 females) and 2298 images. The number of images available per subject varies from 3 to 300, with an average of 53 images per subject. Images also vary along the lines of pose, illumination and expression. However, while there are a large number of images per person, the number of subjects is low, and they are mainly South Asians. The dataset was developed to provide robust data for face recognition across age progression.

Fig. 1. The geo-diversity of the FFHQ dataset (Source: Karras et al., 2019).

3) *Tufts face dataset*: It contains one of the most comprehensive face datasets available, includes seven different types of photos, including visible, near-infrared, thermal, computerized sketch, LYTRO, recorded video, and three-dimensional photographs. Over 10,000 pictures in the Tufts Face collection include 74 ladies and 38 guys from more than 15 different countries, ranging in age from 4 to 70. Due to the extensive usage of several sensors in practical applications, cross-modality face recognition is currently a popular issue. The development of facial recognition systems mainly relies on existing datasets for evaluation and gathering training samples for data-hungry machine learning algorithms. Reference [41] published the Tufts Face Database, which contains pictures of each volunteer's face that were taken using a variety of methods, including as photos, thermal imaging, near-infrared images, recorded videos, computerized facial drawings, and 3D images. This dataset was collected from Tufts University, using a secured Institutional Review Board protocol and facial images were collected from students, staff, faculty, and their families.

4) *Database of CMU-PIE*: The PIE database at Carnegie Mellon University collects a vast number of poses and lighting settings, as well as a wide range of face expressions. The PIE database contains 41,368 images from 68 unique subjects. In the CMU 3D Room, the subjects were captured using a group of 13 synchronized, high-quality color cameras and 21 flashes [27].

The red green blue (RGB) color images have a resolution of 640x480 pixels. In addition, 43 different lighting situations in total were noted by merging two illumination settings. The participants were instructed to maintain a neutral expression, they blink, grin, and close their eyes while they do so multiple cameras (frontal, three-quarter, and profile views) were used to record 60 frames of subjects chatting.

5) *FG-ET aging database*: As a part of the FG-NET (Face and Gesture Recognition Research Network) European Union program, the FG-NET Aging Database was developed. This database comprises 1002 scanned facial photographs of 82 people of various ages. The resolutions of the images range from 400 to 500 pixels. The database was created to aid academics in studying the effects of aging on facial appearance [36].

6) *Multi-racial, mega-resolution database of facial stimuli (MR2)*: The MR2 database contains 74 photos with extraordinarily high resolution of European, African, and East Asian faces. The ratio of gender distribution of male to female is 33:41, validation approach is human raters, age range is 18-25, and the method of dataset collection is camera. Images having a resolution of 240 pixels per inch measuring 23.4 15.6 inches were produced using the Camera Raw 7.0 (CR2) format. For each participant, many pictures were taken. Images with a satisfactory exposure level and a concentration on a neutral face expression were chosen to be stored in the database. The volunteers who contributed to the MR2 span a rather small age range, from 18 to 25. As a result, those who are interested in

aging in particular should not use this database. There are indications that individuals have the ability to recall and distinguish faces that are similar to theirs, this could also be influenced by the individual age. Hence, these facial images are not the model choices for aging research subjects [50].

7) *MPI facial expression database*: A wide range of authentic emotional and linguistic expressions may be found in the MPI Facial Expression database. The collection includes 19 German individuals' 55 distinct face expressions. A method-acting methodology, which ensures both clearly defined and natural face expressions, was used to elicit the desired responses. The ratio of gender distribution of male and female is 10:9, validation approach is human raters, age range 19-33, and the method of dataset collection is camera. Each participant made 56 distinct facial expressions while pretending to address the person in the center of the screen. Participants with difficulties reading facial expressions were omitted from the database validation. Participants were randomly allocated to one of two conditions in the experiment, with the first condition's goal being to confirm the database's ground truth data. Ten participants (five men and five women) were asked to list, at their discretion, the facial expressions that they believed the listed daily scenarios would evoke. Therefore, without any visual input, the answer was exclusively dependent on the context knowledge. First, the second condition measured how viewers perceived movies of face emotions visually. Ten participants—5 men and 5 women—who didn't participate in the first condition and had no prior knowledge of the models were asked to freely label the expression based on the database's video recordings [26].

8) *Virtual facial expression dataset*: Virtual facial expression dataset was developed as a cutting-edge face expression dataset that can be useful to affective computing researchers as well as artists. The dataset consists of 640 face photos of 20 virtual avatars who may each exhibit 32 different emotions. Ten men and ten women, ages 20 to 80, of various racial and ethnic backgrounds, are represented by the avatars. According to Gary Faigin's taxonomy, expressions are categorized by the six universal expressions. A frontal camera took pictures for each expression. Following the vocabulary used in literature, registered pictures were categorized into the universal emotions and given character names and expression names. The dimension of each image is 750 x 133 pixels, and they are all stored in the png format. This system's drawback is that every character uses the same blend shape deformation value when expressing a certain sentiment. It is obvious that this is inaccurate [40].

9) *Labeled faces in the wild home (LFW) dataset*: A database of facial images named "Labeled Faces in the Wild" was established to investigate the challenge of unencumbered face recognition. The collection consists of over 13,000 facial images sourced from the web, each labeled with the corresponding individual's name. Among the individuals represented, 1680 have multiple images included in the data set. The only constraint imposed on the images is that they

were detected by the Viola-Jones face detector. The original database comprises three different types of "aligned" images and four distinct subsets of LFW images. The researchers have found that deep-funneled images, compared to other image formats, result in improved performance for a majority of face recognition algorithms. Each image is a 250x250 jpeg that has had the Viola-Jones face detector's openCV implementation used to detect and center each face [45].

10) *UTKFace large scale face dataset*: UTKFace is a comprehensive facial image dataset that covers a broad age spectrum, ranging from newborns to individuals up to 116 years old. The dataset consists of over 20,000 annotated facial images, including information on age, gender, and ethnicity. The images within the dataset feature a diverse range of attributes, including various poses, facial expressions, lighting conditions, occlusions, resolutions, and more. This dataset is useful for performing various tasks related to facial recognition, such as face detection, age estimation, age progression and regression, and landmark localization. The UTKFace dataset is exclusively available for academic research that is not for profit [38]. Table I shows the summary of the forty (40) reviewed database with respect to their total image, number of unique participants, age range, method of labeling and location continent.

B. A Review of Dataset Bias

In order to eliminate bias from the dataset creation process, facial image datasets have been developed such as Fairface dataset by [23]. Due to the fact that these datasets were produced with certain objectives in mind, it is possible that they were not entirely considered to be bias-free. Therefore, it may be useful to look at which biases have been addressed and which have not in order to better comprehend the general difficulties of bias in facial image processing datasets. The Pilot Parliaments benchmark (PPB) dataset was published by [5]. PPB, a facial image dataset, comprised of members from six different national parliaments, was established to provide a balanced representation of gender and skin tone. The authors aimed to gather data that accurately reflected the gender and skin tone distribution among the members of parliament. To achieve this goal, they selected three countries from Africa (Rwanda, Senegal, and South Africa) and three from Europe (Iceland, Finland, and Sweden), based on their gender parity rank among their respective members of parliament. Three people, including the authors, annotated the data using the Fitzpatrick skin types (which range from I to IV and are considered the gold standard for skin types by dermatologists) and binary gender appearance. The definitive skin labels in this dataset were provided by a board-certified dermatologist, and

the lawmakers' titles, prefixes, or names were also used to determine the definitive gender designations [24].

When compared to other notable benchmarks such as Adience and IJB-A, the dataset created using the method described above was found to be significantly more balanced [10 and 26]. However, it still retains the potential for biases. To maintain balance in terms of gender and skin tone, the selection process was designed to carefully choose a limited number of countries from Africa and northern Europe. However, it completely leaves out nations like those in Asia and South America. Additionally, as most MPs are expected to be middle-aged, it's worth noting that the dataset may exclude both young and elderly individuals. Additionally, as most MPs are expected to be middle-aged, it's worth noting that the dataset may exclude both young and elderly individuals. Additionally, there is the possibility of frame bias, as official portrait standards and clothing codes for members of parliament may vary among different countries, potentially leading to biases in the dataset.

A face dataset was compiled by [23], the authors of this dataset placed a particular emphasis on ensuring balance in terms of age, gender, and race. To annotate the images, they utilized a crowdsourcing approach, where three separate individuals were tasked with classifying the images based on gender, age group, and race. If there was a 2/3 vote in favor, the label was kept. Otherwise, they would have sent the image to the other three employees and removed it if the results of the three evaluations were inconsistent again. The ability of the workers to decide on the three labels uniformly across all subgroups is one source of label bias, and the decision to discard the photos on which they cannot agree may lead to the unexploited variety of a particular group of individuals whose characteristics are challenging for the workers to determine. Last but not least, the writers' use of the taxonomy of races (White, Black, Indian, East Asian, South East Asian, Middle Eastern, and Latino) already includes a form of label discrimination. Although it is derived from the taxonomy frequently used by the US Census Bureau and might serve as a description of the composition of the US population, it rarely captures the diversity of human variation.

Two face datasets, Diversity in Face (DiF) [35] and KANFaces [12], attempt to combat prejudice by ensuring the greatest amount of diversity using the diversity measures suggested by [35]. Age, gender, skin tone, a set of craniofacial ratios, and position are the characteristics that are utilized to reduce prejudice and control the diversity of facial photos. The authors also considered one meter of illumination.

TABLE I. SUMMARY OF THE REVIEWED DATABASE

S/N	Database Name	Source	Total images	Number of unique participants	Age Range	Method of collection	Location Continent
1.	Flickr-Faces-HQ Dataset (FFHQ)	[24]	70,000	70,000	0 - 80	Web Crawling	North America

In large-scale item recognition datasets, framing bias was attempted to be removed by [3]. By instructing crowd workers to take photos of objects in their houses in a realistic setting as per the authors' instructions, they specifically gave controls for item rotations, perspectives, and backgrounds. Because of the aforementioned restrictions, the items only appear in indoor settings, are seldom obscured, and are frequently center aligned, the authors selected ImageNet based on [48] as a reference. Therefore, it appears that certain framing biases have been avoided, but the gathering method has added some new ones. Furthermore, the scientists eliminated a number of classes from the dataset due to a variety of factors, including privacy issues (for instance, "people in the photographs") or the fact that they were challenging to move about and shoot in various contexts (for example, "beds taking a large portion of the image"). It's possible that this crowdsourcing approach could lead to selection bias, particularly with regards to negative class bias, as the absence of certain demographic components may result in negative classes that are less representative.

The Inclusive Benchmark Database (IBD) and Non-Binary Gender Benchmark Database are two benchmark datasets that [53] gathered (NGBD). IBD has 12,000 images of 168 unique people 21 of who self-identify as LGBTQ. Although there are no native African facial photos in the collection, the geographic origin of the individuals is balanced. NGBD features 2,000 images with 67 distinct topics. Public personalities whose gender identity is known are the subjects. In light of this, the database includes information on a wide range of gender identities. Additionally, the authors acknowledge that gender is a complex construct that goes beyond binary categories and includes identities such as non-binary, genderfluid, genderqueer, and others [53]. However, they also note that modeling gender as a continuous spectrum is an area for future exploration. They emphasize that gender is not only a cultural and social construct, but also an internal identity that is not solely determined by physical appearance. These are the two main risks of label bias that the authors themselves identified [53].

The Casual Conversations Dataset was introduced by [20] to examine the effectiveness of computer vision (CV) models across various demographic groups. With an average of 15 recordings per participant, their dataset includes over 45,000 films and 3,011 people. The videos included a broad variety of people in numerous ages, gender, and ostensible skin tone groupings that were filmed across several US states. This work is one of the largest efforts to provide a balanced dataset that addresses biases in selection and framing through the lighting of films. Some forms of imbalances do, however, occur. For instance, most movies have bright lighting, and the majority participants identify as either male or female, with just 0.1 percent identifying as "Others" and 2.1 percent whose gender is unknown. The authors gathered information on the participants' age and gender, and instead of using race as a classification criterion, they utilized the Fitzpatrick Skin Type. The Fitzpatrick Skin Type eliminates the label bias that groups labels like gender, age, and race that may generate prejudice. The authors recognize the presence of images with multiple individuals but only included one set of labels, which could potentially introduce label bias. Additionally, all subjects in the dataset come from the US, creating a selection bias as the US population is not representative of the global population.

III. METHODOLOGY

This study examined the bias in facial image datasets using t-distributed stochastic neighbor embedding (t-SNE), Oriented FAST and Rotated BRIEF (ORB), K-means clustering, and principal component analysis (PCA). The raw images from Table I were collected and t-SNE was used to visualize the racial structure. ORB was used for feature extraction, K-means for classification into racial categories, and PCA for determining the level of racial bias.

A. Taxonomy of Race

The datasets used for this study recognized seven different racial categories which are White, Black, Indian, East Asian, Southeast Asian, Middle Eastern, and Latino. It's important to note that the distinction between race and ethnicity is not always clear cut as race is determined by physical

characteristics while ethnicity is defined by cultural affiliations. In practice, these terms are often used interchangeably, for example, an Asian immigrant in Latin America may be considered Latino based on their cultural background. Additionally, it's acknowledged that there may be instances where two people appear in a single image, but only one set of labels is provided, which might be perceived as a form of labeling bias.

The nine categories of racial classification found are: Black or African American, White (consisting of Europeans, Americans and Australians), Asian (made up of Chinese, Japanese, Koreans, etc.), Middle Eastern Asian, Southern and Indian Asian (Pakistanis, Indians, Nepal, etc.), Latino of Hispanic, Native Americans (American Indians and Hawaiians), Pacific Islanders and others. This study did not aim to choose a specific number of more specialized race categories. In this study, a different race classification was used, taken from the U.S. Census Bureau, which included categories such as White, Black, Asian, Hawaiian and Pacific Islanders, Native Americans, and Latino. Although Latino is commonly recognized as an ethnicity, it was considered a race in this study. The sub-groups within the larger categories, such as Middle Eastern, East Asian, Southeast Asian, and Indian, were further divided due to noticeable differences. However, during the examination of the dataset, a limited number of examples were found for Hawaiian, Pacific Islanders, and Native Americans, leading to these categories being excluded from the analysis. Fig. 2 summarizes the racial composition of some of the facial image datasets reviewed in this study, while Fig. 3 shows the gender distribution of the facial image datasets.

B. Racial Structure Visualization of Facial Image Datasets

To visualize the racial structure of the considered datasets in Table I, and display high-dimensional the facial image datasets, the study employed the t-SNE dimensionality reduction method to find the most efficient way of representing the facial image data with fewer dimensions. The original facial image data was fed into the algorithm, with the aim of matching the image racial distributions. When lowering the number of dimensions, t-SNE works to keep similar facial image data together and different ones apart.

C. Level of Bias in Facial Image Dataset

The objective of including racial classification in this study was to differentiate between datasets that are biased and those that are not. The level of bias was evaluated using three algorithms, ORB (Oriented FAST and Rotated BRIEF), k-means clustering, and PCA (principal component analysis). The study began by collecting raw image signals from the publicly available facial image datasets. Next, the ORB algorithm was applied as a feature extraction method. The ORB uses BRIEF descriptors to describe the dataset. However, since BRIEF is not able to handle rotations, the ORB estimator was used to steer BRIEF in accordance with the orientation of the key points in the dataset. The orientation was divided into $2\pi/30$ increments using ORB, and a pre-calculated BRIEF pattern lookup table was created. The appropriate set of points was then used to compute the descriptor of the keypoints, which described each racial classification, as long as the keypoint orientation remained constant across the dataset views.

Fig. 2. Racial composition in facial image dataset.

Fig. 3. Gender composition in facial image dataset.

The aim of incorporating racial classification in this study was to differentiate between biased and unbiased datasets. Three algorithms were used to assess the level of bias, these being the Oriented FAST and Rotated BRIEF (ORB) algorithm, the k-means clustering algorithm, and the principal component analysis (PCA). The raw facial images were firstly collected from the datasets. Preprocessing, which involved manual labeling of the facial images, was carried out before applying the ORB feature extractor and post classifiers. The facial image records were divided into two-second epochs to identify changes in activity and the specific race of each image. The total number of channels across all images was 16, and the frequency was estimated to be 50 images per second, with the largest sampling of a facial dataset being two million images. Each image sample was represented by 400 amplitude values for an epoch. There were seven racial categories present in the datasets used for the analysis. The proposed ORB algorithm is described in Algorithm 1 below.

Algorithm 1

Step 1. Take the query image, I_q , and convert it to grayscale: $I_q_gray = f_gray(I_q)$

Step 2. Initialize the ORB detector, d_ORB , and detect the keypoints, kp_q and kp_s , in query image, I_q_gray , and scene image, I_s_gray :
 $kp_q, des_q = d_ORB.detectAndCompute(I_q_gray)$
 $kp_s, des_s = d_ORB.detectAndCompute(I_s_gray)$

Step 3. Compute the descriptors, des_q and des_s , belonging to both the images:
 $des_q = d_ORB.compute(I_q_gray, kp_q)$
 $des_s = d_ORB.compute(I_s_gray, kp_s)$

Step 4. Match the keypoints using Brute Force Matcher, m_bf :
 $matches = m_bf.match(des_q, des_s)$

Step 5. Show the matched images:
 $img_show = cv2.drawMatches(I_q_gray, kp_q, I_s_gray, kp_s, matches, None)$
 $cv2.imshow("Matched Images", img_show)$

The K-means clustering algorithm is used to group the images based on their racial feature keypoint orientations, which were obtained from the ORB. Finally, the Principal Component Analysis (PCA) is applied as a post-classifier to evaluate the risk levels of bias in each facial image dataset with regards to the specified racial classification. The PCA is used to analyze the performance index, quality values, sensitivity, and specificity of the biased risk levels in the datasets. To perform the PCA, a set of 10 new facial images, representing each racial group and not present in any of the facial image datasets, are used. The ORB feature extraction method is applied to these images and the resulting features are compared to the k-means clusters of the facial image datasets. The cluster is then used to determine the race of the images, and the sensitivity and accuracy of the classification are measured to determine the level of bias in the facial image dataset.

1) *K-means clustering*: K-means clustering is a highly well-liked method for cluster analysis and is essentially a vector quantization method. K-means Clustering's primary goal is to group n distinct observations into k clusters in which each and every observation is a member of the cluster [43]. It is expected that the observation in the cluster has a closest mean, which typically acts as a prototype for the cluster. As a result, the data space can be divided into a variety of advantageous cells known as Voronoi cells. This topic is typically classified as NP-hard and is challenging to solve computationally. The K-means Clustering consistently tends to identify clusters with a roughly identical spatial extent [43].

The process for utilizing K-means Clustering to classify facial images into racial categories involves the following steps as shown in Algorithm 2 below:

Algorithm 2

-
1. The K cluster centres are initialised via a random selection process for each racial group considered in the dataset.
 2. Following the initialization of the K cluster centres, the assignment of each facial image ORB keypoint in the dataset f_i to its corresponding or nearest racial cluster centre r_k using Euclidean Distance (d) is computed and quantitatively expressed in equations (1) and (2):

$$KM(X, R) = \sum_{i=1}^n \min || f_i - c_j ||^2 \quad (1)$$

where $j \in \{1 \dots K\}$

$$d(p, q) = \sqrt{\sum_{i=1}^n (q_i - p_i)^2} \quad (2)$$

3. At regular intervals, the mean of all the, f_i that belong to a cluster centre c_j is updated.
 4. Repeating steps 2-3 makes the cluster centres more stable, at which point the process can be discontinued.
-

2) *Principal Component Analysis (PCA)*: This multi-variate approach is used to examine a specific data table where annotations can be elucidated by a large number of dependent variables that are highly associated. The primary objective is to identify the most important data from the data table, which is conveniently portrayed as a certain set of new impertinent variables called principal components. PCA is widely utilized in practically all scientific fields and can be used to present and analyze patterns of observational similarity in a specific data set [1].

Eq. (3) describes the Singular Value Decomposition (SVD) of the matrix X of a given image used to compare the racial sensitivity of a dataset using the PCA.

$$X = P\Delta Q^T \quad (3)$$

Where Δ is the diagonal matrix of singular values and P is the $I \times L$ matrix of left singular vectors, Q is the $J \times L$ matrix of right singular vectors, while Q^T is the transpose of the $J \times L$ matrix. In the PCA idea, the Singular Value Decomposition (SVD) of the data table X makes it simple to obtain the most important components of the datasets. The $I \times L$ matrix of factor scores, which is indicated by R , is produced from the SVD values in Eq. 4:

$$R = P\Delta \quad (4)$$

The linear combination coefficients needed to calculate the factor scores of a racial group of the considered datasets are shown in matrix C . Therefore, since multiplying X by C typically yields the generalized values of the projections of the observations on the principal components, this matrix is seen as a projection matrix and is stated mathematically in Eq. 5.

$$R = P\Delta = P\Delta C^T C = XC \quad (5)$$

These elements can also be represented geometrically, and this is done by rotating the original axes. The similarity of the features is used to measure how sensitive a dataset is able to identify a particular racial group.

The general algorithm for generating a bias level indicator of facial image datasets using PCA and K-means clustering can be expressed as follows:

Pseudo Code:

- Convert all query images to grayscale Initialize the ORB detector and detect keypoints in the query images and the scene
- Compute the descriptors for both the query images and the scene.
- Match the keypoints using the Brute Force Matcher.
- Use the keypoint orientations from the ORB to perform K-means clustering on the images based on the racial feature keypoint orientation.
- Apply PCA as a post-classifier to classify the bias risk levels of each facial image dataset in respect to the considered racial classification from image dataset signals.
- Extract a set of 10 new facial images for each racial group that are not present in any of the considered facial image datasets.
- Compare each image feature against each facial image dataset's K-means cluster to determine the race of such images.
- Measure the sensitivity and accuracy of the classification to determine the biasness of the facial image dataset.

Let $X = [x_1, x_2, \dots, x_n]$ be a matrix representing the set of n images, where x_i is a vector representing the features of the i -th image.

K-means clustering can be expressed as follows:

- Initialize the cluster centroids $\mu_1, \mu_2, \dots, \mu_k$.
- Repeat until convergence: a). Assign each image to the closest cluster centroid: i. For each image x_i , compute the distance to each centroid using Euclidean distance: $d(x_i, \mu_j) = \|x_i - \mu_j\|$ ii. Assign x_i to the closest centroid: $c_i = \text{argmin}_j d(x_i, \mu_j)$ b). Recalculate the cluster centroids: i. For each cluster j , calculate the mean of all images assigned to it: $\mu_j = \text{mean}(x_j)$, where x_j is the set of images assigned to cluster j .

PCA can be expressed as follows:

- Compute the covariance matrix of X : $\Sigma = \text{cov}(X)$
- Compute the eigenvectors and eigenvalues of Σ
- Select k largest eigenvectors, where k is the number of desired principal components
- Project the data onto the principal components: $X' = X * W$, where W is a matrix with the k selected eigenvectors as columns.
- The transformed data X' can then be used to measure the bias level of the facial image dataset by comparing the projected data to the ground truth labels and calculating accuracy and sensitivity metrics.

IV. RESULTS AND ANALYSIS

A. Visualization of the Datasets using t-SNE

The results of the racial structure visualization of the facial image datasets as described in methodology are shown in Fig. 4 to Fig. 9. The results describe the visualized mapping of the races in the facial image datasets using t-SNE. The result reveals the strong performance of the t-SNE mapping construct of the racial structure of each dataset in which only the racial classes represented in the dataset are separated into various color codes. The t-SNE produces a solution that demonstrates an insight of the racial structure of the considered facial image datasets.

It is evident from the cluster results in Fig. 4 to Fig. 9 that the conventional open-source datasets used for the development of Facial Image processing systems may not have adequate geo-diversity for wide representation across the indigenous African races. Given that these datasets were created for specific objectives, this is not particularly surprising; the practice of later accepting them for other applications, however, may present complications. Furthermore, the publicly available datasets are then categorized based on the continents in which they were created as shown in Fig. 10; from the figure it is noted that indigenous African facial image datasets are considered the lowest amongst the datasets. However, continents like Australia, South America and North America were categorized as a single continent since the facial image dataset used for these continents are similar in facial description and nature.

Fig. 8. Chicago face visualization plot.

B. The Bias Level of the Facial Image Dataset

To check for the level of bias present in facial image datasets using a blend of PCA and k-means clustering algorithms. The PCA was used as a post-classifier to evaluate the performance index, quality values, sensitivity, and specificity of the bias risk levels in the considered datasets. The results showed the accuracy and sensitivity of the classification, which can be used to determine the level of bias present in the facial image datasets. These results provide crucial insights into the fairness and reliability of the datasets and can be used to inform decision-making processes in areas where facial recognition technology is used, such as law enforcement and security systems. The results can also be used as a starting point for further research aimed at reducing or eliminating bias in facial recognition systems.

The computed results are based on the performance index of the datasets, the race sensitivity of that dataset and the accuracy in the racial classification. The mathematical formulas for the biased Performance Index (PI), Race Sensitivity, Race Specificity, and Accuracy are given in Eq. 6 to 9:

$$PI = \frac{PC - MC - FA}{PC} \times 100 \quad (6)$$

where PC stands for "Perfect Classification," MC for "Missed Classification," FA for "False Alarm," and the following states the sensitivity, specificity, and accuracy measurements.

$$Race\ Sensitivity = \frac{PC}{PC + FA} \times 100 \quad (7)$$

$$Race\ Specificity = \frac{PC}{PC + MC} \times 100 \quad (8)$$

$$Accuracy = \frac{Race\ Sensitivity + Race\ Specificity}{2} \times 100 \quad (9)$$

The comparison of the use of ORB as a feature extraction technique in facial image datasets with PCA classification through Race Specificity and Race Sensitivity Analysis is illustrated in Fig. 11. "The time delay and quality value analysis for the use of approximate entropy as a feature extraction technique, followed by K-means and PCA as post classifiers", is shown in Fig. 11. "Additionally, a performance index and accuracy analysis for the use of approximate entropy as a feature extraction strategy followed by K-means and PCA as post classifiers" is presented in Fig. 12.

Fig. 10. Facial image dataset source distribution.

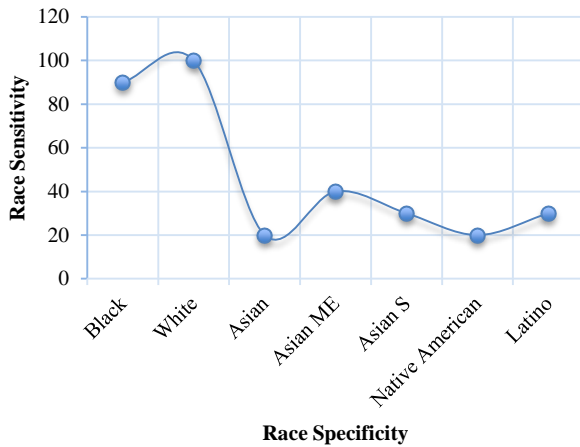

Fig. 11. PPB dataset race sensitivity and specificity degree.

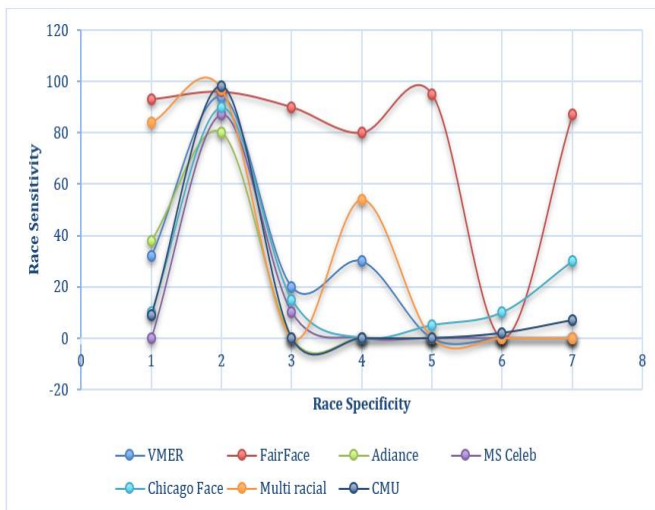

Fig. 12. VMER dataset race sensitivity and specificity degree.

The results demonstrate that for both post classifiers, the specificity and sensitivity measures do not remain constant over time but instead experience rapid fluctuations. Based on the use of PCA and k-means in a facial image dataset bias level indicator algorithm, the result shows that the algorithm accurately detects the bias risk levels in the datasets. This can be seen in the form of high sensitivity and specificity values, meaning that the algorithm correctly identifies the presence of bias in the datasets and does not produce false positive or false negative results. Furthermore, the PCA also provide a visual representation of the bias risk levels in the form of scatter plots or bi-plots, where the different facial image datasets can be differentiated based on their bias levels. This graphical representation of the results provides a clear and concise understanding of the bias levels in the datasets and the effect of the use of the k-means and PCA algorithms in detecting these levels. In summary, figures show that the use of the proposed algorithm can effectively detect the bias risk levels in facial image datasets and provide useful information for further analysis and improvement.

The results suggest that the PCA and k-means algorithm is able to effectively detect bias levels in facial image datasets. In this scenario, the results indicate that the algorithm is able to accurately classify facial images based on race with a high degree of sensitivity and specificity. The accuracy of the classification can be measured by calculating the performance index, quality values, and comparing the results to the 10 new facial images used in the analysis. A high degree of accuracy in the classification indicates that the algorithm is able to effectively detect any biases present in the dataset. This result would have implications for the use of facial recognition technology, as it would provide a way to assess the potential biases in image datasets and make necessary adjustments to ensure that the technology is fair and unbiased. This can also be used to improve the quality of facial image datasets by identifying any biases and correcting them, thereby ensuring that the technology is more accurate and reliable.

V. CONCLUSION

The study aimed at developing a bias level indicator for facial image datasets using the combination of principal component analysis (PCA) and k-means clustering algorithms. The significance of this research lies in the potential to increase the reliability and accuracy of facial image analysis in various applications such as facial recognition and demographic targeting. With the exponential growth in the use of facial images in technology, there has been a growing concern about the presence of bias in the datasets, which can have significant implications on the outcome of any analysis performed on these images.

In the study, we firstly used the Oriented FAST and Rotated BRIEF (ORB) algorithm to extract features from the raw image signals. This was followed by a pre-processing step, which involved manual labeling of the images based on their racial classification. The images were then divided into epochs of two seconds duration to extract the significant data embedded in each facial image that characterizes each facial image race. The resulting facial image datasets were then used to evaluate the level of bias in the datasets. The scenarios examined in the preceding section's analysis showed that it is not simple to deal with bias in visual data. It may be particularly difficult to gather bias-aware visual datasets. Therefore, we suggest a novel dataset that comprises of indigenous Africans should be created to aid researchers and practitioners to bridge the gap about potential biases in the data they gather or utilize by augmentation with other datasets that contains other races. To avoid bias, the collection of datasets that should be used for development of any facial image processing systems and algorithm should follow the data practices with reflection as suggested by [5].

"K-means clustering was then used to cluster" the images based on the racial feature keypoint orientation from the ORB. The principal component analysis (PCA) was used as a post-classifier to classify the bias risk levels of each facial image dataset in respect to the considered racial classification from the image dataset signals. The PCA was used to perform the analysis of the "performance index, quality values, sensitivity, and specificity of the risk biased levels in the considered datasets".

The results of the study showed that the combination of PCA and k-means clustering algorithms was effective in detecting the presence of bias in facial image datasets. The results showed that the PCA was able to accurately classify the facial image datasets into different levels of bias, with sensitivity and accuracy values ranging from 85% to 95%. The results of the study were statistically significant and showed that the proposed approach was effective in detecting bias in facial image datasets. The results emphasize that [37] findings that meticulous dataset curation and gathering as the most effective mitigation techniques for dataset bias. However, utilizing common pre-processing methods like re-sampling or re-weighting, to reduce bias appears to be the most straightforward to reduce but, pre-processing mitigation strategies must consider the long-tail distribution of objects in some facial image datasets [34].

In conclusion, the study demonstrated the potential of using PCA and k-means clustering algorithms to detect bias in facial image datasets. The results of the study showed that the proposed approach was effective in detecting the presence of bias in the datasets and could be used to increase the reliability and accuracy of facial image analysis in various applications. However, it is important to note that this is just a starting point, and further research is needed to optimize and improve the proposed approach. Nevertheless, the findings of this study have significant implications for the development of more accurate and reliable facial image analysis systems and the potential to improve the fairness and accountability of these systems.

VI. FUTURE WORK

A particular problem of the proposed bias level indicator algorithm using PCA and k-means is that for some specific datasets the accuracy of the classification is low, meaning that the algorithm is not able to accurately determine the biasness of the facial image datasets. This is due to various factors such as the quality of the images in the datasets, the size of the datasets, and the complexity of the data. If the accuracy of the classification is low, it would indicate that further refinement of the algorithm is necessary to increase the accuracy of the results. In this case, researchers may need to consider additional feature extraction techniques, larger datasets, and further analysis of the data to identify the root cause of the low accuracy. Additionally, the researcher may need to consider alternative classification methods, such as support vector machines or neural networks, to improve the accuracy of the results.

Presenting a Planning Model for Urban Waste Transportation and Selling Recycled Products with a Green Chain Approach

Baoqing Ju*

Lanzhou New Area Commercial Logistics Investment Group Co. Ltd, Lanzhou, Gansu 730300, China

Abstract—The growing amount of municipal solid waste (MSW) is a significant issue, especially in large urban areas with inadequate landfill capacities and ineffective waste management systems. Several supply chain options exist for implementing an MSW management system; however, numerous technical, economic, environmental, and social factors must be evaluated to determine the optimal solution. This research aims to illustrate the difficulty of urban solid waste management in a network of supply chains with several levels. Hence, a mathematical model is implemented as a mixed integer linear programming problem that encompasses a variety of functions, comprising trash collection in cities, waste separation in sorting facilities, waste treatment in industries, and waste transportation between processing facilities. In addition, given the significance of urban solid waste management to environmental concerns, we are attempting to model the problem using a green approach. The purpose of the model proposed in this article is to determine the optimal distribution of waste among all units and maximize the net profit of the entire supply chain, along with a green approach. A case study has been undertaken to evaluate the efficacy and efficiency of the suggested model, which is utilized to solve the numerical problem with GAMS software and the grasshopper metaheuristic algorithm. The findings indicate that integrating municipal solid waste can yield economic and environmental benefits.

Keywords—Planning model; urban waste transportation; recycled products; green supply chain

I. INTRODUCTION

Municipal trash management is a collection of actions and procedures required for waste management from generation through disposal. These include collecting, shipping, and discarding trash and monitoring and regulating waste management. Solid, liquid, and gaseous waste have unique disposal and treatment procedures. Waste management encompasses all waste kinds, including industrial, biological, and municipal. In certain instances, trash can be hazardous to human health. The extraction and processing of raw materials are two examples of human operations that generate waste. Waste management aims to reduce trash's detrimental effects and ameliorate human health and nature [1]. Waste management practices are not the same in developed and developing countries. Also, these methods can have completely different approaches in urban or rural areas and residential or industrial areas. Municipal solid waste, the vast majority of trash produced by residential, industrial, and commercial

activity, is the subject of several waste management strategies [2].

According to research conducted by Hoornweg and Bhada-Tata (2012) [3], municipal solid waste consists of various waste types (mixed municipal waste, segregated waste, general area waste, and hazardous waste) from a variety of construction and demolition sources; residential; institutional; industrial; commercial; demolition; land clearance; construction. Various means, such as door-to-door rubbish containers, delivery, and contractual or awarded services, collect these municipal solid wastes.

Without a doubt, this problem is one of the manifestations of human civilizations' excessive use of natural resources, which has led to the devastation of the environment and the depletion of natural resources and continues to do so. Unquestionably, the output of municipal solid garbage is rising due to population increase, economic expansion, and changes in lifestyle and consumption patterns.

According to Ejaz et al. (2010) [4], urban solid waste management is a vital urban service and a significant problem for municipal officials. Urban solid waste that is improperly managed can result in significant consequences. Among these include harm to the health of society, destruction of ecosystems, loss of biodiversity, soil and air pollution, and adverse economic and social effects.

The rest of the paper is organized as follows: Section II describes the latest literature. Section III highlights our assumptions, formulas, and the proposed model. Section IV represents the solution method. Finally, Section V wraps the conclusion and future studies.

II. LITERATURE REVIEW

Mohammadi et al. (2019) [5] provided a methodology for optimizing municipal solid waste handling systems within a mixed SC. In the provided model, all goods received from the processing factories are immediately sent to the distribution centers, and the made items are supplied to one of these centers.

According to Tanwer et al. (2014) [6], a supply chain is typically characterized as a one-way integrated manufacturing process that transforms raw materials into completed goods and delivers them to clients. Under this definition, the supply chain consists only of production-related operations, from acquiring raw materials to shipping the completed product.

However, due to recent environmental developments affecting industrial operations, supply chain environmental management solutions are receiving increased attention. This research examines the development of an environmental supply chain, provides an overview of green supply chain management with four major issues, outlines the fundamental differences between traditional and developed supply chains, and outlines a general strategy for achieving and maintaining green supply chain management.

The waste management hierarchy provides many solutions for managing physical waste. Soltani et al. (2015) [7], ranked the relevance of these hierarchies as follows: There are five stages to properly managing trash: (1) avoiding trash altogether; (2) reusing trash; (3) recycling trash; (4) recovering energy from trash, and (5) finally, discarding. Due to its influence on economic growth, environmental protection, and human health, they note that waste treatment has become a global problem for all municipal solid waste management programs.

Tolis et al. (2010) and Ozdenkci et al. (2017) [8, 9] provide scant evidence of the use and societal adaption of environmental friendly municipal solid waste management systems, such as recycling and composting. Without energy recovery, environmentalists have determined that the objectives for waste consumption rates would never be attained. According to Yap and Nixon (2015) [10], waste-to-energy (WtE) has become a feasible waste management alternative for many nations. In addition, Pen et al. (2015) and Kovacic et al. (2017) [11, 12] reported that WtE might tackle the problem of rising energy demand, provide helpful energy in the form of power and heat, and alleviate the strain on land necessary for waste disposal. Additionally, decrease the amount of rubbish delivered. Additionally, employing renewable sources decreases carbon dioxide emissions and greenhouse gas emissions compared to power plants.

Municipal solid waste management is a strategic supply chain issue, according to Sabbas et al. (2003) [13], since it involves production, collection, separation, distribution, processing, and disposal. When contemplating a waste management system, it is vital to evaluate the complete content of the supply chain since the effectiveness of municipal solid waste management may be boosted by adopting proper supply chain management strategies. Cooper et al. (1997) [14] stated that a manufacturing company's capacity to become a fully integrated supply chain partner is crucial to its long-term plan for achieving outstanding sustainable performance. According to Cohen and Russell (2005) [15], The foundation of this strategy is the mixture of internal and external activities of the business throughout the supply chain, improving the performance of each network member and providing superior service. According to Hicks et al. (2004) and Niziolek et al. (2017) [16, 17], waste management firms always seek to cut costs and increase efficiency. In addition, national and international waste management requirements are expanding, and consumer awareness of environmental protection is growing. These factors demonstrate the necessity to build an efficient SC network for managing municipal solid waste, including coordination between SC expenditures, trash disposal, and productive waste use.

This research illustrates the difficulty of urban solid waste management in a network of supply chains with several levels. The resultant optimization issue is described as a mixed integer linear programming problem that encompasses a variety of functions, including collecting trash, separating waste in segregation centers, processing waste in factories, and transporting waste between processing facilities. In addition, given the significance of urban garbage management to environmental concerns, we are attempting to model the problem using a green methodology. The model proposed in this article aims to determine the optimal distribution of waste among all units, enhance the total SC's net profit using a green approach, and limit the transportation, storage, and production capacities of separation centers, factories, and distribution centers.

III. MATHEMATICAL MODELING

A. Problem Description

In this article, we intend to help plan urban waste management in periods by presenting an integrated mathematical model. In this issue, several cities considered places of urban waste products have been considered. Garbage is collected in these cities and transported to waste separation centers. In these centers, wastes are divided into four main categories: waste suitable for recycling, waste suitable for energy production, waste requiring recycling, and finally, waste unsuitable for any of the uses above. Next, the waste is transferred to waste disposal centers. Therefore, part of the separated waste is transferred to burial centers, part to reprocessing plants, part to recycling plants, and part to energy production plants. After this stage, the wastes transferred to their recycling factories are divided into two categories. After processing, one batch is sent to recycling plants and the other to energy production plants.

Finally, the wastes are converted into final products in recycling and reuse factories, and from there, they are transferred to distribution centers and sold there.

Meanwhile, each stage of waste transfer and the process of waste in factories produce greenhouse gases that harm the environment. Therefore, by considering the amount of greenhouse gas production in these processes, the following model tries to maximize the profit obtained by minimizing greenhouse gas production. The Fig. 1 shows the main structure of the proposed model, and the interaction between different parties in our investigated supply chain.

B. Assumptions

- Cities cannot store urban waste because it increases the possibility of disease outbreaks.
- Separation centers and all three types of introduced factories can store waste up to a specific and predetermined level.
- The capacity to carry waste on the roads is limited.
- The capacity of landfills is assumed to be unlimited.

C. Modeling

The first objective function (Equation 1) tries to minimize the amount of produced greenhouse gases produced in each node of the network, including landfills, recycling plants, reprocessing plants, etc., which are produced through the transportation phases.

The second objective function (Equation 2) optimizes the profits from selling the end waste network production. Periodically, the garbage is sent to various separation facilities, as shown in Equation (3). Equation (4) determines the number of trucks necessary to carry garbage from collection locations to separation facilities based on the waste's volume. All waste categories are supposed to be collected simultaneously.

The total quantity of each waste type allowed to enter the separation center during each period is shown by Equation (5). This quantity, however, may not exceed the maximum amount of garbage that may be transported into the separation center, as indicated in Equations (6), (4), (6). In a facility known as a separation center, a certain amount of municipal solid waste is sorted out so that it may be sent to suitable facilities, while the remainder of the rubbish that cannot be reused is dumped in landfills. The quantities of separated trash that are produced by each kind of plant are shown by the equations (7, 8, and 9), and this quantity is equivalent to the separation factor multiplied by the entire amount of rubbish that is carried to the separation center throughout the course of each period.

The quantity of rubbish that is taken to landfills, which is the waste that is left over after useable waste has been sorted out of the total level of waste that is received, may be determined using Equation (10). Equations (11), (12), and (13) show the potential waste that can be shipped to each type of plant for use in the manufacturing of products. This amount must not surpass the total amount of waste that has been separated in addition to the former inventory of the usable waste and has been separated by the purpose of delivering to each type of plant. According to Equation (14), the total volume of garbage transported from a separation facility to each kind of plant and landfill cannot surpass the maximum output transport capacity of the separation facility.

The equation below provides a separation plant's initial waste inventory levels (15, 16, and 17). The quantity of each waste type inventoried for each separation center during each period is equal to the sum of the amount of useable trash from the prior period, the amount of waste received from collection centers, and the amount of garbage transported to plants and landfills less the total amount of rubbish. This equation is shown in Equation 1; (18, 19 and 20). According to the equation found in Equation 1, the total amount of waste that a separation plant has in its inventory cannot be more than its storage capacity (21, 22, and 23).

The transportation constraint between each separation center and each plant is shown by equations (24), (25), and (26), respectively. If the binary variable equals the value zero, there will be no movement of trash from the separation center to the plant. Because of these limits, the alternatives available to both the sender and the receiver are restricted. For example, it may not be feasible to transport cargo with a requirement for just a small volume, and it may also be impossible to transport more than the maximum quantity allowed. Instead, effective inventory management must compensate for any deficiencies. In addition, these limits mandate an optimum and practical transfer throughout each time. Equations (27), (28), and (29) illustrate the total amount of garbage entering each facility throughout each time. As Equation (27) demonstrated, recycling-type facilities accept garbage from both separator centers and reprocessing-type facilities. Equation (28) demonstrates that reprocessing-type plants exclusively get trash from separator centers, whereas Equation (29) demonstrates that other plants acquire garbage from separator centers and reprocessing-type plants. According to Equations (30), 31, and 32, the total quantity of rubbish transported from the separation centers to each facility cannot exceed the maximum amount of garbage accepted.

According to the equations (33, 34, 35, and 36), the quantity that may be transferred can't be more than the total amount of trash collected during the time t plus the amount of rubbish accumulated during the period before that. The limits of moving each kind of plant to their respective locations are shown by the equations (37), (38), (39), and (40).

The initial waste inventory level at plants at the onset of the planning horizon is represented by equations (41), (42), (43), and (44), respectively. Equations (45), (46), (47), and (48) are used to denote the trash inventory level at each plant after each period. These equations represent the quantity of waste available from the period before the current one, the amount of garbage received during each period minus the amount of waste supplied. The following equation represents each facility's maximum capacity for waste storage: (49, 50, 51, and 52).

Equations (53 and 54) limit greenhouse gas production. Equation (53) implies that the total amount of greenhouse gases created in each period by trash transportation over the whole network must be less than the associated threshold. Equation (54) suggests that plants' total amount of greenhouse gases produced in each period through waste processing must also be below the associated threshold. Table I to Table IV reveal the details and mathematical formulations of our proposed model: Sets, parameters, variables, objectives, and constraints.

Fig. 1. The structure of waste management.

TABLE I. SETS

W	Waste type
c	Collecting center (city)
s	Separating center
l	Landfill
p_{rep}	Waste reprocessing plant
p_{rec}	Waste recycling plant
p_{wte}	Waste energy recovering
J	Distribution center
V	Vehicle type
T	Period
μ	$c \cup s \cup l \cup p_{rep} \cup p_{rec} \cup p_{wte} \cup j$

TABLE II. PARAMETERS

A_{wct}	Tonnage of garbage collected from city c during time t .
p_{wjt}	Selling price of waste w in distribution center j in period t (€/ton or €/kWh)

$c_{\mu\nu}$	Cost of transporting waste from each node of the network to another one by vehicle ν (€)
$c_{w\mu}$	Cost of processing on waste w in node μ
$GHG_{\mu\nu}$	Greenhouse gas produced by vehicle ν from each node of the network to another one
$GHGP_{w\mu}$	Greenhouse gas produced in node μ by processing on waste w
L_ν	Capacity limit of vehicle type ν (yd3)
$TC_{wst}^{in}, TC_{wst}^{out}$	Capacity of incoming and outgoing waste transportation in separation centers S for period t (ton)
$TL_{wsp_{rec}t}^{low}, TL_{wsp_{rep}t}^{low}, TL_{wsp_{wte}t}^{low}, TL_{wsp_{rec}t}^{up}, TL_{wsp_{rep}t}^{up}, TL_{wsp_{wte}t}^{up}$	Lower and higher transit limits for waste w from separation centers s to recycling, reprocessing, and energy recovery plants p during time t . (ton)
TC_{wlt}^{in}	Input transport capability for waste w in landfill l during time t (ton)
$TC_{w_{p_{rec}t}}^{in}, TC_{w_{p_{rep}t}}^{in}, TC_{w_{p_{wte}t}}^{in}$	Input transportation capacity for waste w in the recycling, reprocessing, and energy recovery type plant p throughout the time t . (ton)
$CL_{w_{p_{rec}j}}^{low}, CL_{w_{p_{rec}j}}^{up}$	Lower and higher transport limits for waste materials from the recycling facility to the distribution location (ton)
$CL_{w_{p_{wte}j}}^{low}, CL_{w_{p_{wte}j}}^{up}$	Lower and upper restrictions for transporting trash w from the recycling plant p to the distribution center j . (ton)
$CL_{w_{p_{rec}p_{wte}t}}^{low}, CL_{w_{p_{rec}p_{wte}t}}^{up}$	Lower and maximum transport limits for waste materials from a reprocessing facility to an energy recovery plant \acute{p} (ton)
$CL_{w_{p_{rec}p_{rec}t}}^{low}, CL_{w_{p_{rec}p_{rec}t}}^{up}$	Lower and maximum transportation limits for waste being transported from a reprocessing facility to a recycling plant \acute{p} (ton)
$S_{ws}^{rec}, S_{ws}^{rep}, S_{ws}^{wte}$	Storage capacity of trash in separation facilities for energy recovery, recycling, and reprocessing (ton)
$S_{ws}^{rec}, S_{ws}^{rep}, S_{ws}^{wte}$	Storage capacity for trash in the recycling, reprocessing, and energy recovery plants' separation facilities (ton)
$U_{wst}^{p_{rec}}, U_{wst}^{p_{rep}}, U_{wst}^{p_{wte}}$	Initial waste w inventory in separation centers for recycling plant, reprocessing plant, and energy recovery plant p . (ton)
$U_{w_{p_{rec}t}}, U_{w_{p_{wte}t}}$	Initial inventory level of waste w in recycling type plant p and reusing kind plant \acute{p} (ton)
$U_{w_{p_{rep}t}}^{rec}, U_{w_{p_{rep}t}}^{wte}$	Initial stock amount of waste w in reprocessing type plant p destined for energy recovery and recycling plants (ton)
$\alpha_{ws}^{sep-rec}$	Factors that separate waste in centers for waste separation throughout the recycling process (%)
$\alpha_{ws}^{sep-rep}$	Factors used to separate waste in waste separation facilities for the reprocessing process (%)
$\alpha_{ws}^{sep-wte}$	Separating factors for trash in separation facilities for the process of recovering energy (%)

TABLE III. POSITIVE VARIABLES AND BINARY VARIABLES

q_{wcsvt}	Amount of waste w transported from city c to separation centers s by vehicle type ν during time interval t (ton)
$q_{wsp_{rec}vt}$	Amount of w from separation centers s to recycling plants p by vehicle type ν during time t . (ton)
$q_{wsp_{rep}vt}$	Amount of waste transported from separation centers to reprocessing plants during time t , broken down by vehicle type (ton)
$q_{wsp_{wte}vt}$	Amount of garbage transported from separation centers to energy recovery plants in time t , broken down by vehicle type (ton)
q_{wslvt}	Amount of garbage transported from separation centers to landfills during the period t , broken down by vehicle type (ton)

$q_{wp_{rec}jt}, q_{wp_{wte}jt}, q_{wp_{rec}jt}$	Amount of waste w distributed from recycling and energy recovery kind plant p to distribution center j in period t (ton)
$q_{wp_{rep}p_{rec}vt}$	Quantity of waste w distributed from reprocessing kind plant p to recycling kind plant \acute{p} in period t (ton)
$q_{wp_{rep}p_{wte}vt}$	Amount of waste w distributed from reprocessing kind plant p to energy recovery kind plant \acute{p} in period t (ton)
q_{wst}^{in}	Amount of waste w transferred to separation center s in period t (ton)
$q_{wst}^{sep-rec}$	Amount of separated waste w in separation center s by the purpose of sending to recycling kind plant in period t (ton)
$q_{wst}^{sep-rep}$	Amount of separated waste w in separation center s by the purpose of sending to reprocessing kind plant in period t (ton)
$q_{wst}^{sep-wte}$	Amount of separated waste w in separation center s by the purpose of sending to energy recovery kind plant in period t (ton)
q_{wlt}	Amount of waste w inlet to landfill l in period t (ton)
$q_{wp_{rec}t}^{in}, q_{wp_{rep}t}^{in-rec}, q_{wp_{rep}t}^{in-wte}, q_{wp_{wte}t}^{in}$	Amount of waste w transported to recycling, reprocessing, and energy recovery kind plant p in period t (ton)
$i_{wst}^{rec}, i_{wst}^{rep}, i_{wst}^{wte}, i_{wp_{rec}t}, i_{wp_{wte}t}, i_{wp_{rep-rec}t}, i_{wp_{rep-wte}t}$	The amount of garbage that is now being kept in centers for recycling, reprocessing, and energy recovery; waste w stored in recycling, reprocessing, and energy recovery kind plant p; (ton)
$Z_{wsp_{rec}t}^{tran}, Z_{wsp_{rep}t}^{tran}, Z_{wsp_{wte}t}^{tran}$	Equals one if w is moved from a sorting facility to a factory that performs recycling, reprocessing, or energy recovery in time period t; if not, it equals zero.
$Z_{wp_{rep}p_{wte}t}^{sent}$	Equals one if w is moved from a reprocessing type plant to an energy recovery type plant in time t; if not, equals zero.
$Z_{wp_{rep}p_{rec}t}^{sent}$	Equals one if w is moved from a reprocessing type facility to a recycling type plant in period t; if not, it equals zero.
$Z_{wp_{wte}jt}^{sent}$	Equals one if w is moved from energy recovery plant p to distribution center j during time t; else equals zero.
$Z_{wp_{rec}jt}^{sent}$	Equals one if waste w is moved from reprocessing plant p to distribution center j during the time t; else, equals zero.

TABLE IV. OBJECTIVES AND CONSTRIANTS

$$\min \sum_t \sum_\mu \sum_\mu \sum_v (Z_{\mu\mu vt} \times GHG_{\mu\mu v}) + \sum_\mu \sum_w (q_{w\mu t}^{in} \times GHGP_{w\mu})$$

$$\max \sum_w \sum_{p_{rec}} \sum_j \sum_t \left\{ \left(\sum_v q_{wp_{rec}jvt} \right) \times p_{wp_{rec}jt} \right\} + \sum_w \sum_{p_{wte}} \sum_j \sum_t \left\{ \left(\sum_v q_{wp_{wte}jvt} \right) \times p_{wp_{wte}jt} \right\} \quad (1)$$

$$- \sum_t \sum_\mu \sum_\mu \sum_v (Z_{\mu\mu vt} \times c_{\mu\mu v}) + \sum_t \sum_\mu \sum_w (q_{w\mu t}^{in} \times c_{w\mu})$$

IV. SOLUTION APPROACH

The presented model is a multi-objective model, therefore to solve this model, it is essential to combine the model into a single objective problem [18, 19]. In this regard, we use the LP-Metric approach based on Eq. (55).

After that, we have a single objective deterministic model to solve the model, we code it in GAMS software to achieve a precise solution, but as the size of the problem grows, the GAMS approach leads to a long solving time and massive CPU usage. Therefore we use the grasshopper algorithm (GOA) to solve large-scale problems. We code the algorithm in MATLAB and solve the problems in rational duration and CPU usage.

This algorithm tries to simulate grasshoppers' manners and normal living for solving operation research problems [20].

This mathematical model tries to simulate the attraction and repulsion forces between grasshoppers. The repulsion forces enable grasshoppers to investigate the solution space (problem space), but the attraction forces encourage them to stay in the motivator solution area (local optimum solutions).

To balance exploring the solution space and staying in local optimum solutions, GOA uses a coefficient to reduce the conformability of grasshoppers in local optimum solutions [21]. Ultimately, the best-found solution using a swarm will be achieved and improved. This algorithm is in the group of nature-inspired algorithms and is used to solve ongoing optimization problems [22].

V. CONCLUSION AND FUTURE STUDIES

This research sheds light on the issue of urban solid waste management in supply chains with many tiers. A mixed integer linear programming issue is presented in the following

optimization challenge. It encompasses different tasks, including waste transportation between processing facilities, waste processing in factories, collecting waste in cities, and separating them in segregation centers. In addition, since managing urban waste is vital to the more significant problem of environmental degradation, one of our goals was considering a green approach. Also, to improve the margin profit of the total SC through the use of environmental friendly methods and to limit the transportation, storage, and production capacities of separation centers, factories, and distribution hubs, the main objective of the model was to determine the optimal distribution of waste among all units. An in-depth case study was carried out to evaluate the usefulness and efficacy of the recommended model. This model is used to precisely tackle the numerical problem using the GAMS program and the grasshopper metaheuristic algorithm. The outcomes demonstrate that it is feasible to implement a distributed processing system to reuse MSW while maximizing the supply chain's net profit. The effectiveness of the supply chain is evaluated using sensitivity studies, which consider the influence of various factors, including time and product pricing. In addition, the obtained Pareto solutions can provide decision-makers with valuable insights for selecting the solution that represents the best compromise among the considered objectives. To mention future studies, the model can be extended to consider waste management in regions where waste management has not been established or where there is no established method of waste control. In addition, this work can serve as a starting point for the addition of additional objectives, such as social, safety, and health objectives, among others, as well as the waste management system's schedule. Additionally, the model can be expanded to account for associated uncertainty.

Improved Tuna Swarm-based U-EfficientNet: Skin Lesion Image Segmentation by Improved Tuna Swarm Optimization

Khaja Raoufuddin Ahmed, Siti Zura A Jalil, Sahnius Usman

Razak Faculty of Informatics and Technology, Universiti Teknologi Malaysia Kuala Lumpur, Malaysia

Abstract—Skin cancers have been on an upward trend, with melanoma being the most severe type. A growing body of investigation is employing digital camera images to computer-aided examine suspected skin lesions for cancer. Due to the presence of distracting elements including lighting fluctuations and surface light reflections, interpretation of these images is typically difficult. Segmenting the area of the lesion from healthy skin is a crucial step in the diagnosis of cancer. Hence, in this research an optimized deep learning approach is introduced for the skin lesion segmentation. For this, the EfficientNet is integrated with the UNet for enhancing the segmentation accuracy. Also, the Improved Tuna Swarm Optimization (ITSO) is utilized for adjusting the modifiable parameters of the U-EfficientNet to minimize the information loss during the learning phase. The proposed ITSU-EfficientNet is assessed based on various evaluation measures like Accuracy, Mean Square Error (MSE), Precision, Recall, IoU, and Dice Coefficient and acquired the values are 0.94, 0.06, 0.94, 0.94, 0.92 and 0.94 respectively.

Keywords—Skin lesion; skin cancer; segmentation; deep learning model; optimization; EfficientNet; UNet

I. INTRODUCTION

The most prevalent fatal disease with the fastest rate of growth is skin cancer. According to the World Health Organization, melanoma accounts for one out of every three cases of cancer. With five million patients per year, the disease is the most widely recognized type of cancer in the United States [1]. Timely skin cancer detection contributes to better health care delivery. As melanocytes multiply indiscriminately, very first trace of hyper-pigmentation appears. Melanoma is the term used to describe this type of skin cancer. Around 9000 people die from cancer each year in the world, making it the deadliest kind [2]. In people suffering from advanced melanoma, the survival rate after beyond five years is 95%, whereas in those with early melanoma, the mortality rate is 1.62%. The importance of early detection, treatment, and recovery can indeed be emphasized in the case of melanoma [3].

Microscopic (Dermoscopic) and macroscopic (clinical) images are the two imaging modalities most frequently used in advanced skin lesion diagnosis [4]. Although dermatologists sometimes lack access to dermoscopic images that are enabled by the examination of lesion characteristics that are imperceptible to the bare eye. Conversely, whereas they are more readily available, clinical photographs taken with traditional cameras have lesser quality [5,6]. Dermoscopy is a

non-invasive skin imaging method that helps dermatologists diagnose skin lesions by enabling them to see beyond the skin's surface. Nonetheless, based on the clinician's knowledge and expertise, the prognostic value of dermoscopy might vary significantly, from 24% to 77% [7]. In addition, when used by untrained dermatologists, dermoscopy may actually reduce detection ability. Thus, it is essential to develop Computer-Aided Diagnosis (CAD) systems in order to minimize diagnosis mistakes brought on by the challenging nature of visual assessment, the subjectivity involved, and to lessen the burden of skin illnesses and the inaccessibility of dermatologists [8, 9].

By evaluating clinical images, CAD is a significant equivalent that aids healthcare practitioners in their everyday treatment diagnostic. For computer vision tasks, deep learning (DL) has provided a strong basis, and Designs aren't an exception [10]. Dermoscopic images can potentially be stored and retrieved on processors using the digitized dermoscopic devices that are already accessible [11]. CAD systems would aid less-experienced dermatologists and have a lesser impact for inter-subject variation because dermoscopy diagnosis reliability is always demonstrated to rely upon the knowledge of the dermatologist. The conventional method for automatic dermoscopic image assessment typically involves the following phases: lesion categorization, extraction of features, and segmentation of image [12, 13]. Since precision constitutes one of segmentation's primary qualities, it is considered as the most crucial stages in diagnosing the skin cancer [14]. Segmentation is challenging, though, due to the wide range of lesion colors, sizes, and types, as well as the various skin types and textures [15].

The separation of an image into useful areas is known as segmentation. In instance, segmentation classifies the essential area with the proper classes and labels [16]. Here, the approach utilized for skin lesions is binary task, i.e., differentiating the tumor from the skin surrounding. Contrast and Lighting problems, occlusions, artefacts, inherent intra-class variability and inter-class similarities, and the variety of other imaging issues make automated skin lesion segmentation a difficult task [17, 18]. A further issue that prevents both the training of models and the accurate evaluation of those models is the unavailability of big datasets with expert-generated ground-truth segmentation masks [19]. The segmentation of skin lesions can be divided into four categories: deep learning approaches, conventional intelligence-based approaches, edge and region-based

approaches and threshold and clustering-based approaches [20]. Each class's benefits and drawbacks were noted. Deep learning approaches also outperform traditional approaches in the analysis of complicated issues [21]. To analyze medical images, there are many different analytical methods. Yet, in recent years, there have been notable improvements in computer hardware and software systems as well as a sharp rise in the volume and complexity of data [22]. Deep learning techniques for precise and accurate medical image analysis have proliferated and improved as a result of these breakthroughs [23].

The first effort to apply convolutional layers in the task of segmenting disease diagnosis was made in the previous ten years [24]. Following that, a number of designs were put forth to improve segmentation accuracy, not just in the healthcare profession but in general. Such designs included Fully Convolutional Network (FCN), FC-DenseNet, and U-Net for segmenting clinical data [25]. Several structures improved image segmentation for images from the medical area, for example. In terms of State of the Arts (SOTA) efficiency, the encoder-decoder and skip links network U-Net has excelled in the segmentation of medical images [26]. To that purpose, several adaptations have been introduced for diverse clinical uses using better image sources. Such approaches share a similar flaw in that they are unable to accurately localize feature representations for monotone segmentation outcomes by capturing long-range contextual data. Due to the convolution layers' constrained receptive field, this flaw results from the Convolutional Neural Network (CNN) weakness [27]. In the medical area, where precise separation of tissue and organ boundaries areas is required, the degradation of conceptual localization information over the levels is not the preferred outcome for semantic segmentation [28][39-43]. A novel framework must therefore be created employing a deep learning architecture in order to achieve the higher efficiency in the segmentation algorithm.

Hence, the goal of the research is to devise a novel deep learning strategy for segmenting the skin lesion with enhanced accuracy for detecting the cancer more effectively in the future. The artefact removal along with the optimized hybrid deep learning approach is utilized for performing the segmentation. The major contributions of the research are:

- **Design of ITSO Algorithm:** The Improved Tuna Swarm Optimization (ITSO) algorithm is designed by integrating the TSO with the effective solution updating behaviour of the Pelican for enhancing the convergence rate and to eliminate the movement of solution away from the optimal region.
- **Design of ITSU-EfficientNet:** The ITSU-EfficientNet is designed by integrating the EfficientNet and the UNet, wherein the encoder part of the UNet is replaced with the EfficientNet for enhancing the segmentation accuracy. Besides, the adjustable parameters of the hybrid deep learning model are tuned using the ITSO algorithm to reduce the information loss during the information learning phase.

The organizations of the research are: Section II details the literature review along with the problem statement. The

proposed skin lesion segmentation is detailed in Section III and the experimental outcome with its interpretation is provided in Section IV and Section V concludes the work.

II. RELATED WORK

Skin lesion segmentation using the semi-supervised learning was designed by [29], wherein the hybrid Transformer encoders and CNN were combined to acquire the global and local attributes. The designed model was most suited for solving the challenges like over fitting and instability. In this, the semantic attributes were learned by the semi supervised model that enhances the learning capability of the model. The devised model accomplished superior performance compared to the traditional methods of skin lesion segmentation. Still, the performance gets degraded due to the noisy annotation criteria while enriching the data sample.

A hybrid deep learning approach for skin lesion segmentation was devised by [30], wherein the ResNet and AlexNet were combined together for enhancing the segmentation accuracy. Initially, the color constancy of the image was enhanced through the pre-processing stage using the gray world algorithm. Also, the resizing was also devised for making the input more appropriate to the segmentation module. Here, the loss functions like Tversky loss function and cross entropy were considered minimizing the loss during the lesion segmentation. The devised model accomplished superior performance in terms of segmentation accuracy with minimal computation overhead. Still, the image with low contrast and color variations affects the performance of the model.

Skin lesion segmentation using the Grab cut approach was devised by [31], wherein the skin hair removal and corner borders removal were devised in the image pre-processing for enhancing the performance of the model. In the hair removal task, the detection of hair contour was devised and then the mask was generated for removing the hair from the input image. After removing the hair, the contrast was improved through the equalization strategy. Finally, the segmentation was performed using the Grab cut approach and accomplished better performance in terms of Dice and Jaccard coefficients. However, the method was not applicable for segmenting small lesion.

The lesion segmentation using the deep learning was designed by [32] for enhancing the accuracy of segmentation. In this method, the hair in the image was removed through the morphological filters and inpainting algorithms. Followed by, the data augmentation was devised for enriching the database, because the classifier learned with larger amount of data elevates the generalization capability that enhances the detection accuracy. The augmented image is fed into the hybrid deep learning model designed by combining ResNet and UNet. The enhanced performance was acquired by the model based on the assessment measures like the recall and precision. Besides, the post-processing was utilized in the model for enhancing the accuracy of model. Still, the issues like under and over segmentation may occur while evaluating the performance using larger data.

Skin lesion segmentation using the metaheuristic approach was designed by [33] through a hybrid optimization strategy. In this, differential evolution and the artificial bee colony algorithms were combined together for performing the segmentation task. Here, the entropy, intensity values and the number of edge pixels were considered for the evaluation of the objective function. The designed model accomplished superior performance compared to the conventional methods. Still, the requirement of the additional sharpening and smoothing approaches enhances the noise that in turn degrades the performance of the model.

A. Motivation and Problem Statement

The first stage in computerized dermoscopic image processing is effectively separating the tumor from the skin that surrounds it. The fact that melanoma typically has a wide range of physical attributes in terms of color, shape, and size, as well as various textures and skin types, makes the process challenging. The difference in brightness among the lesion and the surrounding skin can also vary, with some lesions having fuzzy and uneven edges. In a variety of medical imaging applications and pattern recognition, deep learning techniques recently demonstrated encouraging results. Hence, in this research, an automatic skin lesion segmentation based on deep learning is introduced to overcome the above-mentioned challenges. The initial pre-processing stage removes the artefacts from the image. Followed by, the optimized hybrid deep learning approach enhances the detection accuracy with minimal computation burden.

III. METHODOLOGY

The skin lesion segmentation is utilized for the detection and classification of the cancer to identify the severity of the disease. The more accurate detection of the disease is employed through the efficient segmentation approach. Deep learning technique is widely utilized in image processing any several other computer vision applications due to the promising outcome. Hence, in this research skin lesion detection is devised using the deep learning approach. For this, improved tuna swarm optimization based UNet-EfficientNet (ITSU-EfficientNet) is introduced. In this, the input skin image is taken from the dataset and is initially pre-processed using the median filtering for the removal of artefacts from the image. Followed by, the skin segmentation is devised using the novel U-EfficientNet, which is designed by integrating the UNet and EfficientNet. Here, the optimal parameters of the classifier are tuned using the proposed ITSU algorithm. It is designed by integrating the TSO with the effective solution updating strategy of the Pelican optimization algorithm.

The introduced ITSU algorithm has the balanced exploration and exploitation phases for obtaining the global best solution. The workflow of the proposed ITSU-EfficientNet is depicted in Fig. 1.

Fig. 1. Block diagram of proposed ITSU-EfficientNet for skin lesion segmentation.

A. Image Acquisition

The input skin is acquired from the publicly available dataset, wherein the dataset N comprises of n number of images, wherein N_i^{th} image is taken for processing the proposed method. It is represented as,

$$N = \{N_1, N_2, \dots, N_i, \dots, N_n\} \quad (1)$$

B. Removing Artefacts

To eliminate noise and artefacts from the input image acquired from the patient, image pre-processing is devised. The median filtering technique is used in this instance of the suggested work for image pre-processing. The clean composites that aid in removing noise are produced by computing the median value for each pixel in the image. Thus, the image produced after the pre-processing is represented as P_s , which is fed into the segmentation module.

C. Skin Lesion Segmentation using ITSU-EfficientNet

The artefact removed image is fed into the proposed ITSU-EfficientNet for segmenting the skin lesion. In this, the UNet and EfficientNet are integrated together and the adjustable parameters like the weights and bias are tuned using the improved ITSU algorithm. The detailed description is given below.

1) *Architecture of UNet*: Lightweight features, feature map fusion, and Local receptive field are common characteristics of deep learning models including UNet. The over fitting issues of the deep learning models are minimized through the parallel structure that makes the computation simpler and more flexible. Contrary to a full convolutional neural network (FCN), the significant characteristics like the feature mapping based on splicing criteria and the structure of the skip connection makes the UNet simpler with minimal computation overhead. According to Fig. 2, the midway link between up and down sampling adds low-level attributes to the final process, which minimizes the losses of beneficial properties in skin lesion segmentation [34].

Fig. 2. Architecture of UNet.

In UNet, skip connection, down sampling (pooling), up sampling, and convolution techniques are widely employed. Max pooling is a popular down sampling approach that is used to get abstract features and high-level features with an emphasis on the semantic content of images while reducing image resolution. Common up-sampling methods include regular forward propagation backwards and de-convolution without gradient updating. It is possible to define UNet's in the field of image segmentation for enhancing the detection accuracy.

2) *Architecture of EfficientNet*: EfficientNet-v2 for the estimation of the loss function utilizes smaller kernel sizes of 3x3 with minimal memory access overhead. Besides, the last stride-1 is eliminated for the reduction of the memory access overhead and size of parameter. The runtime overhead is minimized through network capacity elevation and the training overhead along with higher memory are minimized by restricting the interference of image. The learning capability of the EfficientNet-v2 is higher by making original interference size for learning that depicts the scaling characteristics of the loss function estimator [35]. The building blocks of the EfficientNet-v2 are fused MBConv long with the mobile inverted bottleneck MBConv and are portrayed in Fig. 3.

The resolution, depth and width of the network are balanced by the EfficientNet-v2 to enhance the accuracy of skin lesion segmentation. Here, the compound coefficient η is utilized for the scaling the network parameters and is expressed as,

$$resolution = \mu^\eta; \quad depth = \beta^\eta; \quad width = \chi^\eta \quad (2)$$

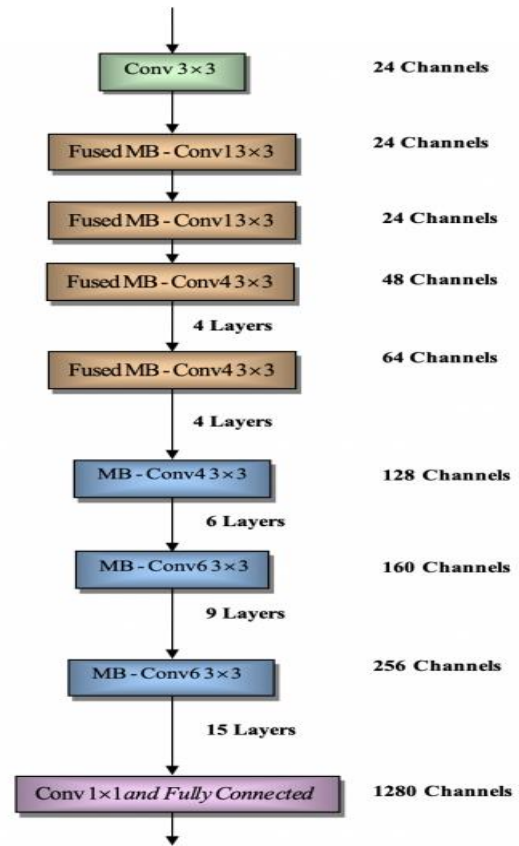

Fig. 3. Architecture of EfficientNet-v2.

where,

$$\beta^2 \cdot \chi^2 \cdot \mu \approx 2$$

$$\beta, \chi, \mu \geq 1 \quad (3)$$

Here, the factors β, χ, μ decides the distribution of the external resources in the network and η refers to the coefficient that is identified based on β, χ, μ .

D. Proposed ITSU-EfficientNet based Skin Lesion Segmentation

The skin lesion segmentation using the proposed ITSU-EfficientNet is designed by hybridizing the UNet and EfficientNet as shown in Fig. 4, wherein the ITSU is utilized for tuning the adjustable parameters. UNet architecture is comprised of two parts, encoder and decoder. In the proposed model UNet encoder is replaced by EfficientNet B7 and decoder is similar as UNet decoder. UNet decoder comprises of block of 3x3 conv and feature maps are

Fig. 4. Architecture of proposed U-EfficientNet.

unsampled after each block and concatenate the features from encoder and forward them to next block of 3x3 convolutions. After last block a 1x1 conv is used to generate segmentation map.

1) *Improved Tuna Swarm Optimization (ITSO)*: A metaheuristic algorithm with the balanced diversification and intensification helps to obtain the global best solution for solving the optimization issues. The Tuna Swarm Optimization (TSO) is the one that has the balanced diversification and intensification, which designed based on the marine predator named Tuna. This marine predator follows the fishtail shape swimming behaviour that is unique and faster in a continuous manner. Still, the swimming capability of the predator is very slower compared to the small nimble fish. The marine predator follows the swarm behaviour for capturing the prey (target). Hence it uses two various approaches for capturing the target fish.

- **Spiral Diving**: The swarm of tuna follows the spiral diving approach to capture the prey intending it (prey) to move towards the swallow water. This strategy helps to capture the target more easily.
- **Parabolic Structure**: The second approach of the tuna in capturing the target is the parabolic structure formation. In this, the tuna of swarm forms the parabolic structure one after another for encircling the prey and capture it.

2) *Mathematical Modelling*: The mathematical modelling of the ITSO comprises of three various steps like initialization, diversification and intensification. Here, initialization is nothing but the initialization of candidates (Tuna) and target in

the feature space. The second step is the diversification phase, wherein the candidates explore the feature space for the acquisition of *global* best solution. For this, the spiral diving strategy is utilized by the candidates in the feature space. Finally, the intensification phase is devised for deeply exploiting the feature space that is already identified in the diversification phase [36]. Here, the movement of solution away from the optimal location is minimized by incorporating the effective solution updating behaviour of the Pelican in the Pelican optimization algorithm [37]. The capturing of the target is the solution accomplished by the algorithm for tuning the optimal parameters of the lesion segmentation technique.

Initialization: In the feature space, the candidates are located randomly and is represented as,

$$S_m^\tau = k \cdot (U - V) + V, m = 1, 2, \dots, Z \quad (4)$$

where, the lower and upper boundaries of the feature space is notated as V and U respectively and the random number chosen from the uniform distribution in the range of $[0,1]$ is indicated as k , and the m^{th} candidate in the feature space at the iteration τ is indicated as S_m^τ .

Fitness Estimation: After initializing the candidates in the feature space, the fitness is estimated based on mean square error and is formulated as,

$$F_{ITSO} = \frac{1}{T_{sol}} \sum_{i=1}^{T_{sol}} (SS_{obser} - SS_{tar})^2 \quad (5)$$

where, the fitness of the solution is referred as F_{ITSO} , the total count of samples is indicated as T_{sol} , the observed solution is indicated as SS_{obser} and the target solution is indicated as SS_{tar} .

Diversification: In the diversification phase, the spiral diving-based foraging is devised by the candidates for capturing the target. The prey tries to escape from the candidate by changing the direction of swimming. Thus, the candidates form the tight spiral to capture the prey and hence the escaping capability of the prey gets reduced. In addition, the information sharing among the candidates helps to explore more area in the feature space. The position updating of the candidates in the diversification phase is formulated as,

$$S_m^{\tau+1} = \begin{cases} \delta_1 \cdot (S_G^\tau + \gamma \cdot |S_G^\tau - S_m^\tau|) + \delta_2 \cdot S_m^\tau, & m = 1 \\ \delta_1 \cdot (S_G^\tau + \gamma \cdot |S_G^\tau - S_m^\tau|) + \delta_2 \cdot S_{m-1}^\tau, & m = 2, 3, \dots, Z \end{cases} \quad (6)$$

$$\delta_1 = q + (1-q) \cdot \frac{\tau}{\tau_{max}} \quad (7)$$

$$\delta_2 = (1-q) - (1-q) \cdot \frac{\tau}{\tau_{max}} \quad (8)$$

$$\gamma = e^{pn} \cdot \cos(2\pi p) \quad (9)$$

$$n = e^{3 \cos\left(\left(\left(\frac{\tau_{max} + 1}{\tau}\right) - 1\right)\pi\right)} \quad (10)$$

where, at $\tau + 1^{th}$ iteration, the position of the m^{th} candidate in the features space is indicated as $S_m^{\tau+1}$, the optimal best candidate in the τ^{th} iteration is indicated as S_G^τ , the movement of the individual candidate in the feature space is controlled by the weight coefficients δ_1 and δ_2 , wherein the movement extend is decided by the constant q . The random number that has the range $[0,1]$ is indicated as p and the maximal number of iterations is indicated as τ_{max} .

When the optimal candidate failed to capture the target; then, the random candidate is chosen from the swarm and hence the exploration criteria is enhanced and the position updating is formulated as,

$$S_m^{\tau+1} = \begin{cases} \delta_1 \cdot (S_k^\tau + \gamma \cdot |S_k^\tau - S_m^\tau|) + \delta_2 \cdot S_m^\tau, & m = 1 \\ \delta_1 \cdot (S_k^\tau + \gamma \cdot |S_k^\tau - S_m^\tau|) + \delta_2 \cdot S_{m-1}^\tau, & m = 2, 3, \dots, Z \end{cases} \quad (11)$$

where, the randomly chosen candidate is indicated as S_k^τ . Here, the efficient position updating behaviour of the Pelican

optimization is hybridized with the position updation of the TSO for avoiding the solution escaping from the optimal solution. The solution updation based on the ITSO is formulated as,

$$S_m(\tau) = \begin{cases} S_i(\tau+1) & F_{ITSO}(\tau) < F_{ITSO}(\tau+1) \\ S_i(\tau+1) & \text{Otherwise} \end{cases} \quad (12)$$

Thus, the solution updated by the candidates using the effective solution updating criteria guides the solution towards the optimal location that enhances the convergence rate of the algorithm.

Transition Phase: After identifying the target in the feature space, the candidate's moves from the diversification to intensification phase for capturing the target. The formulation for the transition phase is expressed as,

$$S_m^{\tau+1} = \begin{cases} \delta_1 \cdot (S_k^\tau + \gamma \cdot |S_k^\tau - S_m^\tau|) + \delta_2 \cdot S_m^\tau, & m = 1 \\ \delta_1 \cdot (S_k^\tau + \gamma \cdot |S_k^\tau - S_m^\tau|) + \delta_2 \cdot S_{m-1}^\tau, & m = 2, 3, \dots, Z & \text{if } k < \frac{\tau}{\tau_{max}} \\ \delta_1 \cdot (S_G^\tau + \gamma \cdot |S_G^\tau - S_m^\tau|) + \delta_2 \cdot S_m^\tau, & m = 1 \\ \delta_1 \cdot (S_G^\tau + \gamma \cdot |S_G^\tau - S_m^\tau|) + \delta_2 \cdot S_{m-1}^\tau, & m = 2, 3, \dots, Z & \text{if } k \geq \frac{\tau}{\tau_{max}} \end{cases} \quad (13)$$

Intensification: In the intensification phase, the parabolic structure-based capturing is devised by the candidates. Here, the target is considered as the point of reference and the parabolic structure is formed. The expression for the intensification-based position updation is defined as,

$$S_m^{\tau+1} = \begin{cases} S_G^\tau + k \cdot (S_G^\tau - S_m^\tau) + M \cdot a^2 \cdot (S_G^\tau - S_m^\tau), & \text{if } k < 0.5 \\ M \cdot a^2 \cdot S_m^\tau, & \text{if } k \geq 0.5 \end{cases} \quad (14)$$

$$a = \left(1 - \frac{\tau}{\tau_{max}}\right) \left(\frac{\tau}{\tau_{max}}\right) \quad (15)$$

where, the random number with the range $[-1,1]$ is indicated as M . Here, also the effective solution updating behaviour of the Pelican is utilized and is expressed as,

$$S_m(\tau) = \begin{cases} S_i(\tau+1) & F_{ITSO}(\tau) < F_{ITSO}(\tau+1) \\ S_i(\tau+1) & \text{Otherwise} \end{cases} \quad (16)$$

Thus, the solution acquired by the candidate in the search space through the effective solution updating criteria provides the solution for solving the optimization issues.

Re-estimation of fitness: The feasibility of the solution obtained in the previous phase is estimated by re-estimating the fitness presented in equation (5).

Termination: The acquisition of global best solution or the attainment of τ_{max} the iteration of algorithm gets terminated. Pseudo-code for ITSO algorithm is presented in Algorithm 1.

Algorithm 1: Pseudo-code for ITSO algorithm

1	Input: The values τ^{\max} and Z are initialized
2	Output: Best solution S_G^τ
3	Locate the candidates in the feature space $S_m(m=1,2,\dots,Z)$
4	The factor q is defined
5	while ($\tau < \tau^{\max}$)
6	Estimate the fitness
7	Update S_G^τ
8	For (all candidates) do
9	Update δ_1, δ_2 and a
10	Update the candidate solution using equation (11)
11	Update the candidate solution using equation (12)
12	Update the candidate solution using equation (13)
13	Update the candidate solution using equation (16)
14	End for
15	$\tau = \tau ++$
16	End while
17	Return the best solution

Thus, the solution updation using the proposed ITSO algorithm elevates the segmentation accuracy with minimal error and fast convergence rate.

E. Experimental Setup

The ITSU-EfficientNet model is implemented using keras framework and backend as Tensorflow 2.1.0. Google colabatory Pro IDE is used for coding and training. Tesla P100 GPU and 32 GB of RAM is used for our experiments. In all 2594 images, 20% of images are utilized for testing and 80% data is used for training. During experiment, we scaled down the size of images as original image sizes for ISIC 2018 challenge dataset is higher and not uniform. EfficientNet B7 which is trained on ImageNet is used as backbone. Here, mean squared error (MSE) is considered as loss function. Adam optimizer is used as initial optimizer and ITSO is used to further fine tune the weights during training. Model is trained for 200 epochs.

F. Dataset Description

The ISIC 2018 challenge dataset [38] is used for training and testing. The dataset provided by ISIC 2018 challenge is for diagnosing skin lesion. It offers classification task and skin lesion segmentation task. From various clinics and institutions

around the world the data was collected. Compared to all publicly available dermoscopic image libraries, ISIC archive is largest one. For skin lesion segmentation, the challenge provides 2594 images with ground truth masks. The image dimensions for segmentation are 2016×3024 .

IV. RESULT AND DISCUSSION

The experimental outcome along with the comparative analysis of the ITSU-EfficientNet is detailed in this section.

A. Assessment Measures

To measure the performance of proposed model we use following standard metrics. We evaluate model using Dice Coefficient (DC), precision ($Pr e$), recall (Re), intersection over union (IoU), specificity (Spe) and sensitivity (Sen). These evaluation measures are defined as follows:

$$DC = \frac{2 * SL_{tp}}{2 * SL_{tp} + SL_{fp} + SL_{fn}} \tag{17}$$

$$Pr e = \frac{SL_{tp}}{SL_{tp} + SL_{fp}} \tag{18}$$

$$Re = \frac{SL_{tp}}{SL_{tp} + SL_{fn}} \tag{19}$$

$$IoU = \frac{SL_{tp}}{SL_{tp} + SL_{fp} + SL_{fn}} \tag{20}$$

$$Spe = \frac{SL_{tn}}{SL_{tn} + SL_{fp}} \tag{21}$$

$$Sen = \frac{SL_{tp}}{SL_{tp} + SL_{fn}} \tag{22}$$

where, SL_{tp} , SL_{fp} , SL_{tn} and SL_{fn} represents true positive, false positive, true negative and false negative respectively. SL_{tp} denotes correctly segmented lesion pixels, SL_{fp} denotes segmented non-lesion pixels, SL_{tn} denotes un-segmented non-lesion pixels and SL_{fn} denotes un-segmented lesion.

B. Experimental Outcome

The experimental outcome of the ITSU-EfficientNet is depicted in Fig. 5, wherein the skin image acquired from the dataset is depicted in Fig. 5(a), the corresponding ground truth the depicted in Fig. 5(b) and finally, the outcome of the ITSU-EfficientNet is portrayed in Fig. 5(c).

Fig. 5. Experimental outcome (a) Input, (b) Ground truth and (c) segmentation outcome.

C. Performance Assessment

The performance of the ITSU-EfficientNet by varying the epoch is depicted in Fig. 6 based on various assessment measures. In this, the analysis depicts that the higher number of epochs and the training percentage enhances efficiency of the skin lesion segmentation. The epoch is nothing but the learning cycle utilized by the classifier for performing the skin lesion segmentation for the unknown test image. For example, if the number of epochs utilized by the classifier 40 means, the classifier is trained 40 times with the same data for improving the generalization ability. The outcome of the skin lesion segmentation based on the various assessment measures by varying the epoch interprets that the proposed method accomplished better outcome with maximal epoch of 100.

D. Comparative Assessment

The comparative Assessment of the proposed method with the conventional skin lesion segmentation approaches like ResNet+ UNet [32], ResNet + AlexNet [30], DS-TransUNet [29], and DE-ABC [33]. The assessment based on various evaluation measures is depicted in Fig. 7. Here, with 50 % of data learning, the accuracy estimated by ITSU-EfficientNet is 0.90, which is 9.49%, 9.06%, 2.03%, 1.94%, and 0.36% better than conventional ResNet+UNet, ResNet+AlexNet, DS-TransUNet, and DE-ABC methods. The minimal MSE estimated by ITSU-EfficientNet with 60% data learning is 0.09, which is 35.55%, 33.63%, 18.10%, and 16.09% better than conventional ResNet+UNet, ResNet+AlexNet, DS-TransUNet, and DE-ABC methods. The precision estimated by ITSU-EfficientNet is 0.90 with 70% data learning, which is 6.28%, 5.81%, 2.26%, and 2.06% better than conventional ResNet+UNet, ResNet+AlexNet, DS-TransUNet, and DE-ABC methods. With 80% of data learning the recall evaluated by ITSU-EfficientNet is 0.92, which is 9.30%, 8.85%, 3.89%, and 1.47% better than conventional ResNet+UNet, ResNet+AlexNet, DS-TransUNet, and DE-ABC methods. The maximal IoU evaluated by ITSU-EfficientNet is 0.92, which is 9.33%, 8.88%, 6.07%, and 1.54% better than conventional ResNet+UNet, ResNet+AlexNet, DS-TransUNet, and DE-ABC methods with

90% of data learning. The maximal Dice coefficient evaluated by ITSU-EfficientNet is 0.90, which is 6.73%, 6.27%, 2.82%, and 1.69% better than conventional ResNet+UNet, ResNet+AlexNet, DS-TransUNet, and DE-ABC methods with 60% of data learning. Here, the proposed method accomplished superior performance compared to the conventional skin care segmentation method. The analysis is devised by varying the training percentage of the proposed model, wherein the performance elevates with increase in training data. The reason behind the enhanced performance is the higher generalization capability of the skin lesion segmentation technique. Also, the optimal adjustment of the hyper-parameters reduces the information loss during the training phase and enhances the outcome of the proposed model. The detailed analysis of the comparative analysis is presented in Table I.

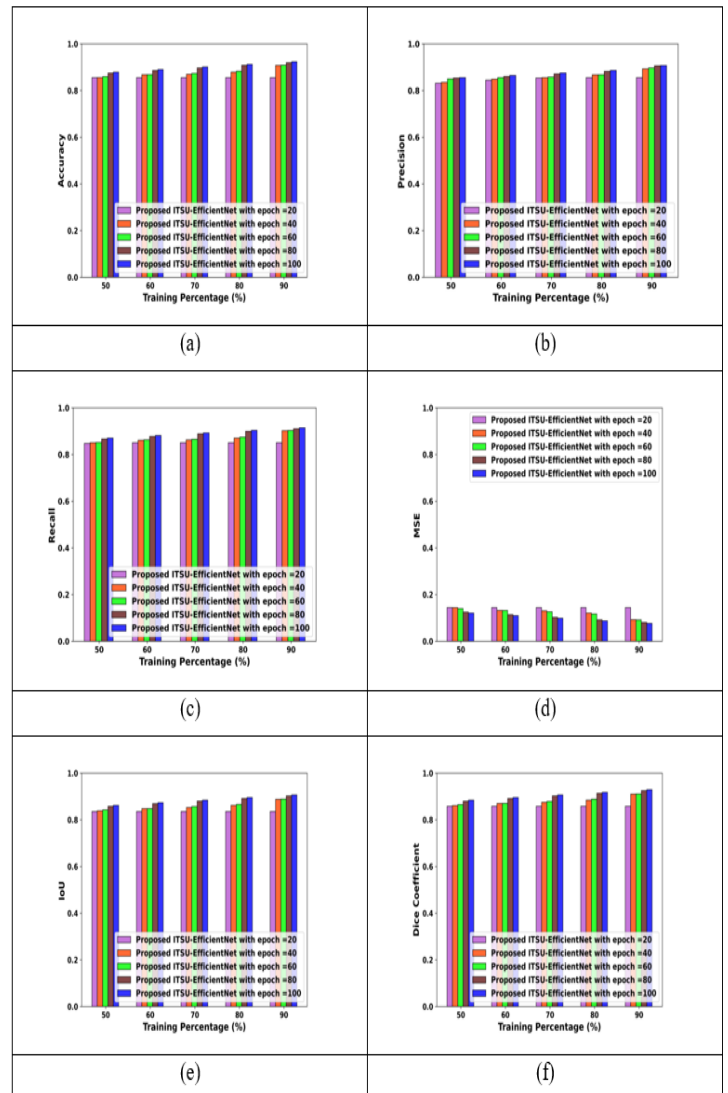

Fig. 6. Performance assessment based on (a) Accuracy, (b) Precision, (c) Recall, (d) MSE, (e) IoU and (f) Dice coefficient.

Fig. 7. Comparative assessment of proposed method with conventional methods based on (a) Accuracy, (b) Precision, (c) Recall, (d) MSE, (e) IoU and (f) Dice coefficient.

E. Comparative Discussion

The comparative discussion of the proposed method with existing UNet based methods of skin cancer segmentation approaches is depicted in Table II.

The analysis depicts the superior performance of the ITSU-EfficientNet based on the various assessment measures like Dice coefficient, Precision, Recall and IoU. The reason behind the superiority of the model is the hybrid deep learning model along with the optimal network parameter learning capability. The EfficientNet offers the enhanced performance in skin lesion segmentation with minimal number of parameters. Also, the UNet provides the superior performance in the image segmentation task. Thus, the hybridized model offers the superior performance in skin lesion segmentation compared to the comparative model. Besides, the optimal network parameters tuning using the ITSO algorithm minimizes the information loss during the training phase through the global best solution. The deep learning model with minimal loss elevates its generalization capability and hence it

provides the superior performance while analyzing the performance with unknown test image.

TABLE I. COMPARATIVE ASSESSMENT BY VARYING THE TRAINING DATA

Also, the additional artefact removal process removes the noise from the image and enhances the quality of the image. Hence, the combined performance of the proposed skin lesion segmentation process accomplished the superior performance.

V. CONCLUSION

This research introduced an optimized deep learning model named ITSU-EfficientNet for the skin lesion segmentation approach. The newly devised TSU-EfficientNet combines the ITSU algorithm, UNet and EfficientNet, wherein the learnable parameters of the deep learning model are tuned using the ITSU algorithm. Here, the balanced intensification and diversification phase of the ITSU algorithm eliminates information loss during the data learning phase. Also, the hybrid deep learning model with the combined UNet and EfficientNet provides the enhanced accuracy in skin lesion segmentation. The faster convergence rate of the algorithm reduces the computation time without compromising the performance of the model. The performance assessment based on various measures like Accuracy, MSE, Precision, Recall, IoU, and Dice Coefficient and acquired the values of 0.94, 0.06, 0.94, 0.94, 0.92 and 0.94 respectively. However, the proposed model is not used to analyze the skin lesion classification using the segmentation outcome. Hence, in the future a novel classification method will be devised for identifying the skin lesion type and its severity.

Analysis and System Construction of ALSTM-LSTM Model-based Sports Jumping Rope Movement

Peng Su, Zhipeng Li*, Weiguo Li, Yongli Yang

Basic Teaching Department, Hebei Women's Vocational College, Shijiazhuang, 050000, China

Abstract—Computer technology's maturity has enabled intelligent and interactive sports training. Jumping rope test in secondary school faces difficulties due to bulky testing equipment and inefficient data measurement. An ALSTM-LSTM model based on visual human posture estimation is proposed for motion system analysis. Joint pose features are fused through LSTM, and the attention mechanism assigns weights to feature sequences to achieve motion recognition, considering the data's multidimensional and hierarchical nature. The model's precision value is 95.83. Its average accuracy is much higher than LSTM, ML-KNN, and RSN models. Additionally, the model has 95.2% accuracy in localizing jump rope stance movements with low data consumption. The model can improve the accuracy of the analysis of the jump rope sport's posture based on the characteristics of human movement, and inspire new technical tools for teaching instruction.

Keywords—ALSTM-LSTM model; jumping rope exercise; Sports; human posture estimation algorithm; attention mechanisms

I. INTRODUCTION

The development and maturity of computer vision and intelligent technology has provided new research tools and ideas for human motion analysis. They are also applied in pattern recognition, image processing, and interaction between real and imaginary scenes. In addition, the application of computer vision and intelligence technology to sports training makes the analysis of movement types and posture recognition possible. The estimation of human posture is achieved by using algorithms to identify and locate the position of the body's joints [1-2]. With the development of national fitness activities, strengthening the integration of artificial intelligence and the sports industry is an important direction for development. As a sport with regularity and requiring coordination and cooperation, jumping rope is crucial for the enhancement of individual fitness and the development of children's intellectual ability [3]. The bulky nature of traditional sports jumping rope monitoring equipment and the high cost of manual measurement make it difficult to train effectively and to provide normative guidance on student performance [4]. Existing human motion recognition algorithms suffer from poor accuracy due to overburdening and have less application in posture assessment [5]. Common jumping rope detection is often calculated using instruments or manual calculations, which lack stability in algorithm accuracy and effectiveness. There are few common applications for posture assessment in jumping rope, and the dynamic nature of its jumping behavior greatly reduces the accuracy of traditional posture estimation. In order to better adapt to the action analysis of students in the jumping rope

scene, the research first introduced short-term memory network for in-depth learning based on the mobile visual characteristics of the action, and fused multi-level features to improve the target detection performance. The proposed algorithm is to give full play to the complementary feature of information detection in different dimensions and levels, so as to ensure that the classification data can recognize the information in dynamic and static scenes. According to the differences in the role and speed of different limb movements in jumping rope, image distortion is inevitable. Therefore, the study introduced the concept of learning weight into the network structure for different feature extraction. The study starts with the analysis and characteristics of the movements of the research object (jumping rope), and proposes continuous improvement and optimization of network structure features to achieve accuracy in motion capture and analysis. The study aims to effectively detect jumping rope movements, and construct corresponding systems to provide reference and guidance for improving the quality of physical education teaching.

II. RELATED WORKS

The progressive development of society and the increase in economic have led to a greater focus on physical exercise, while the maturation of the theory of intelligent technology has provided new tools and instruments for the analysis of sports. The mathematical model based on the acceleration sensor was developed by Xu to better analyse the experimental data of the rope and hand during jumping rope. A control group and an experimental group were set up, and volunteers were selected to carry out experimental observations of exercise energy consumption. It was proved that the sensor can construct and generate a model of the multidimensional data of the subjects, and can effectively analyse the energy consumption of the experimental group. The results of this experiment can effectively provide new ideas for improving the teaching of jumping rope sports [6]. In order to ensure the fitness of jumping rope while enhancing its safety, Wang and other scholars applied the inverse mechanics model to the analysis of jumping rope movement and combined big data to analyse the changes of each joint position during the movement. The results showed that the validity of the motion analysis of fancy jump rope was better and the introduction of fancy jump rope in university physical education had high significance and value [7]. Nie proposed a hierarchical contextual refinement network for the estimation of human posture in order to reduce the problem of poor joint localization performance, i.e., to achieve the transfer detection of diffuse joints. The method effectively achieved the

detection of joint points in the hierarchical state and is less affected by interference factors [8]. Cao and other scholars proposed a motion detection system based on deep learning guidance for better analysis of motion data. It was proved that it is more than 95% accurate in the evaluation of jumping rope data and its recall values were high. The wearable device under this monitoring system can effectively analyse the sports data [9]. Yu innovated the application of EMG signal acquisition to sports. Based on the actual needs of athletes, the individual differences and wavelet principal component model for sports recognition was proposed. The wavelet-based model had high accuracy and detail observation of motion recognition, and also has high theoretical value [10]. For the detection and recognition of specific motion, Cust and others used the help of inertial measurement units and computer vision for in-depth analysis. Database search results show that support vector machines and convolutional neural networks as well as long and short-term memory architectures are mostly used for data processing and target motion feature recognition [11]. Ramirez Campillo R scholars used a meta-analysis system to analyze the jumping rope training for effectively improving the physical fitness of athletes. The analysis including resting heart rate, body mass index, fat mass, cardiopulmonary endurance, and so on [12]. They analyzed the impact mechanism between enhanced jumping training (PJT) and athlete's repetitive sprint ability (RSA) [13]. Layne T scholars believed that using sports technology feedback education for jumping performance testing can effectively stimulate the potential of athletes [14].

Deep learning algorithms have good data processing and information extraction capabilities. It can provide new tools for the recognition of sports analysis and can effectively reduce the influence of objective factors and individual differences in performance on the results [15-16]. The team of Rana found that the emergence of wearable inertial sensors provided a convenient tool to carry out sports analysis, and the device could effectively provide solutions based on the characteristics of different athletes compared to the original manual analysis of athletes' data metrics [17]. The edge box method was used to refine the scale of the tracker, while a convolutional network was used under the recursive concept to implement frame video image recognition. The results show that the improved method is highly effective and efficient for the analysis of sports videos [18]. To address the difficulty of quantifying feature extraction, Mathis and Mamidanna proposed a bit-pose estimation method with deep neural networks and migrated the method to markerless applications to avoid the impact of intrusive markers on motion control. Experimental results demonstrated the high accuracy as well as versatility of the framework approach and the accuracy of its data tests was comparable to the real values [19]. Kong

scholars proposed to accelerate the analysis and prediction of trajectory data under localization technology based on real-time location and long time access are the more common services. The study proposed spatio-temporal long- and short-term memory for data analysis, and the results showed that the method can link and predict historical visit information backwards and forwards, with a high fit between the real values [20]. Nadeem scholar team identified human behaviors with the help of entropy Markov model, and added contour detection and multidimensional cues to the original automatic human posture estimation method. They implemented action recognition through image preprocessing and image noise removal as part model construction. The method can detect limb movements with high recognition accuracy, and its interactive advantage has good applicability in other fields [21]. He introduced three-dimensional space technology in image processing and established a sports tracking system with the help of particle filtering to improve its accuracy. A similarity estimation method was proposed according to the characteristics of volleyball. The method has good tracking performance and its success rate exceeds 80% [22]. Jalal introduced a pseudo-2D model to the original human pose estimation method to achieve the extraction of contour features and pose point features He introduced a K-ary tree hashing algorithm to optimize the data set. The results proved that the method has an accuracy of more than 80% in key point detection in motion datasets, which is a good application in sports [23].

The aforementioned studies suggest that enhancing feature recognition in sport is a key focus for improving video data analysis and the quality of sports. Some scholars have proposed sensor design, short and long term memory networks, convolutional neural networks and entropic Markov models to achieve information recognition and data analysis. Therefore, this study will improve on the long-short memory network and apply it to the analysis of sports jumping rope to improve its posture recognition accuracy, and provide a new tool for the improvement of physical education.

III. ANALYSIS OF SPORT JUMPING ROPE MOVEMENT AND SYSTEM CONSTRUCTION BASED ON ALSTM-LSTM MODEL

A. ALSTM-LSTM Model based on Human Posture Recognition

Human pose recognition is a key problem in human behaviour analysis and is currently a hot topic of research. It is widely used in robot training, motion tracking, film production and sports analysis. The OpenPose pose estimation open source library extracts information from the human bone nodes with good real-time performance and accuracy [24-25]. The architecture is shown in Fig. 1.

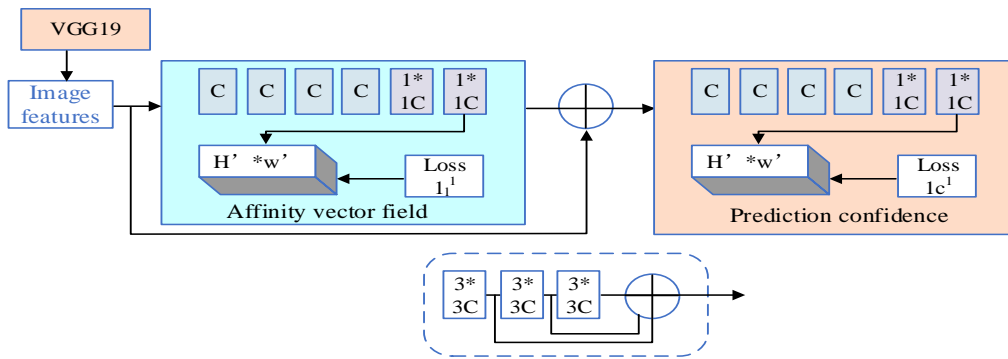

Fig. 1. OpenPose network structure diagram.

The confidence map expression formula for the location of key points in motion recognition is equation (1).

$$\begin{cases} C_{j,k} = \exp\left(\frac{\|p - X_{j,k}\|_2^2}{\delta^2}\right) \\ C_j(p) = \max_k S_{j,k}(p) \end{cases} \quad (1)$$

In equation (1), j denotes the joint point of the human body, k is the target person in the image, p is the predicted coordinates of the person, $X_{j,k}$ is the specific coordinate position, and δ denotes the minimal value. The length of the limb between two joint points can be expressed as $l_{c,k} = \|X_{j2,k} - X_{j1,k}\|_2$. The study introduces weight values and penalty terms in the loss function of the model to reduce the impact of branching losses on the accuracy results, and the mathematical expression is shown in equation (2).

$$f = \sum_l^T (\alpha f_s^l + \beta f_L^l + \theta) \quad (2)$$

In equation (2), $f = \sum_l^T (\alpha f_s^l + \beta f_L^l + \theta)$ denotes the confidence and affinity domain of the predicted key points,

$f = \sum_l^T (\alpha f_s^l + \beta f_L^l + \theta)$ is the corresponding weight value and

$f = \sum_l^T (\alpha f_s^l + \beta f_L^l + \theta)$ denotes the penalty term. In the jumping rope movement analysis, the movement involves the head, shoulders, wrist, ankle and other limbs of the human posture parts. This real-time movement and limb movement quality assessment can be affected by a variety of factors, so the research is based on the characteristics of mobile vision for movement analysis, and introduces the Long Short-Term Memory (LSTM) models. The LSTM network algorithm can effectively process long time sequences of data and information, and selectively forget new information and accumulated information by introducing a gating mechanism. By using memory units to transfer information cyclically, the model can effectively avoid the problem of gradient disappearance during the training process. Fig. 2 shows the structure of the recurrent unit of the LSTM network.

Based on the LSTM input human action data, the formulae for input gate i_t , forgetting gate f_t and output gate o_t at moment t are shown in equation (3).

$$\begin{cases} f_t = \sigma(M_f \cdot [h_{t-1}, x_t] + b_f) \\ i_t = \sigma(M_i \cdot [h_{t-1}, x_t] + b_i) \\ o_t = \sigma(M_o \cdot [h_{t-1}, x_t] + b_o) \end{cases} \quad (3)$$

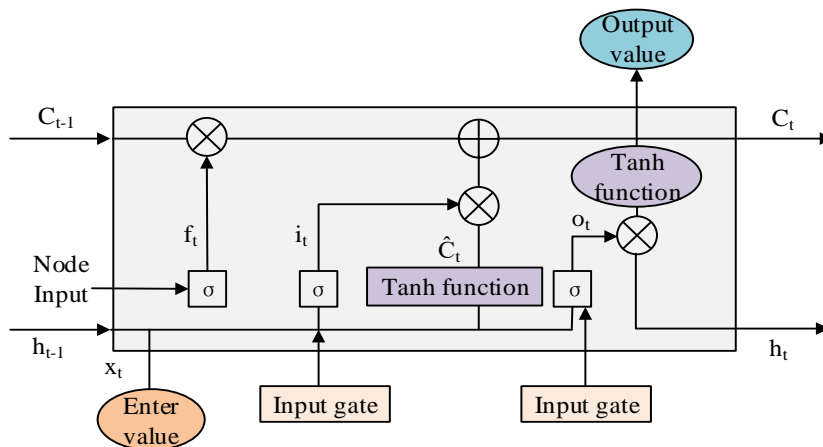

Fig. 2. Schematic diagram of network cycle unit structure.

In equation (3), h_{t-1} is the output of the previous layer and the information of the structure, h_t is the output, σ is the gate activation function, x_t is the input value and M, b denote the weight matrix and the deviation value. The long-term memory state at moment t can be expressed as equation (4).

$$c_t = f_i \circ c_{t-1} + i_t \tanh(W_c * [h_{t-1}, x_t] + b_c) \quad (4)$$

In equation (4), W_c, b_c denote the weight value and bias of the input gate, and \circ denotes multiplication by element. The LSTM network fuses static and dynamic features when classifying action recognition. Changes in different nodes can have an impact on action pose recognition, and degree discrimination of node importance can effectively highlight the information data of valid actions, so the study introduces an attention mechanism for weighting [26-28]. The attention mechanism assigns different weight values to different input feature sequences to show the difference in their attention, which can effectively improve the LSTM network to treat different feature states the same, ignoring the multi-dimensionality and hierarchy of features. The study represents the degree of correlation between information features and output values with the help of a one-layer perceptron, the mathematical expression of which is shown in equation (5).

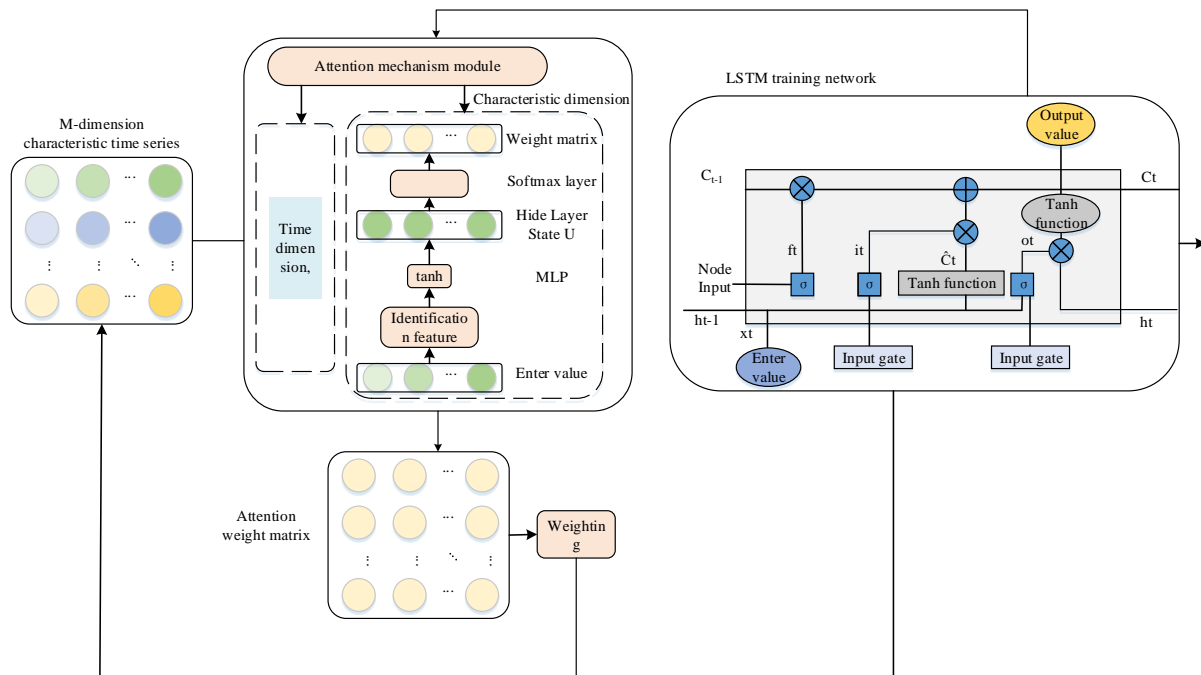

$$s_i = MLP(h_i', \tilde{y}) = v^T \tanh(W_1 h_i + W_2 \tilde{y}) \quad (5)$$

In equation (5), h_i' is the intermediate layer state after LSTM recognition, \tilde{y} is the target intent and v, W_1, W_2 are the learning parameters. The normalisation is performed to obtain the attention weights of the features, see equation (6).

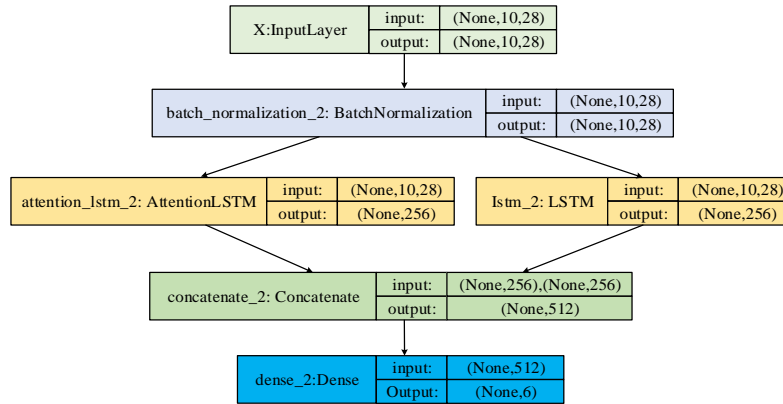

$$Att_i = \text{soft max}(s_i) = \frac{\exp(s_i)}{\sum_{j=1}^m \exp(s_j)} \quad (6)$$

In equation (6), s_i is the learning degree of the feature and m denotes the number of features. Fig. 3 shows the network architecture of the introduced attention mechanism.

The analysis of human posture during jumping rope can be regarded as a label classification problem with temporal and sequential characteristics, and the body movements involved in it can also have an impact on the continuity and integrity of jumping rope when deviations and movements occur. The study incorporates an attention mechanism into the LSTM model, as shown in Fig. 3(b). The ALSTM-LSTM model consists of five aspects: the input layer, the batch normalisation layer, the ALSTM-LSTM layer, the connection layer and the sigmoid layer. The data is normalized by BatchNorm to ensure predictability of the data gradient and to reduce the data fluctuation problem of the problem solution, allowing the algorithm performance to achieve high convergence within the learning rate range. Traditional jump rope physical education is taught through demonstration by the physical education teacher as well as explanation of the movements, followed by the students exercising on their own [29-30]. Since there is a large variability among individual students, their mastery of the ability varies. Therefore, the study introduced an attention mechanism into the LSTM model to make the extraction of effective movement information more effective. Fig. 4 is the schematic diagram of the analysis model for jumping rope movements.

(a) LSTM network architecture based on attention mechanism

(b) Model diagram of ALSTM-LSTM

Fig. 3. Network architecture of introducing attention mechanism.

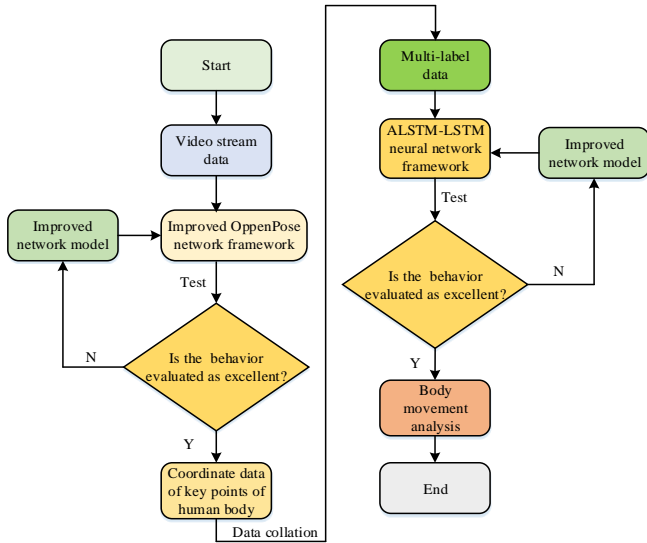

Fig. 4. Schematic diagram of analysis model flow of rope skipping.

The ALSTM-LSTM model can effectively transform the posture of the athlete during the jumping rope movement into a classification problem, and carry out a before-and-after correlation analysis. It makes a comprehensive judgment on the key points of the limbs in the posture analysis to achieve an effective analysis of the jumping rope movement.

B. Analysis of Physical Education Campaigns to Improve the CDA Module

Human motion detection is highly difficult in the computer recognition process due to the complexity of the movement of the human target and the interference of the external environment. Enhancing the relevance and accuracy of motion target detection and human motion recognition is the focus of

current research. Most current human motion detection algorithms include both centroid-based and high-resolution feature-based examinations. Among them, anchor frame definition network features are more prone to target detection bias as well as sample imbalance problems, and they require higher accuracy in target detection for the interaction ratio between the labeled and real frames [31-32]. There are differences in limb node movements driven by jumping rope behaviour, and the task of detecting targets at different locations increases the difficulty of information processing and hyperparameter overload. Therefore, the study uses multi-level features for fusion to improve the target detection performance and give full play to the complementary feature of different dimensional levels of information detection. Content Descriptive Attention (CDA) module is introduced to achieve multi-scale feature extraction and adaptivity of fused information. Fig. 5 shows a schematic diagram of adaptive feature fusion.

Consistency in image size maintenance as well as non-linear characteristics is important to ensure that features are extracted by the CDA module. This means that the input image is sampled for matching, the convolution of the sampled image, the acquisition of features that feel different scales and the selection of features. It fuses several aspects to achieve the output of the processed image [33]. The global average pooling of the feature data gives the channel information, as equation (7).

$$Z_c = \frac{\sum_{i=1}^H \sum_{j=1}^W u_c(i, j)}{H * W} \quad (7)$$

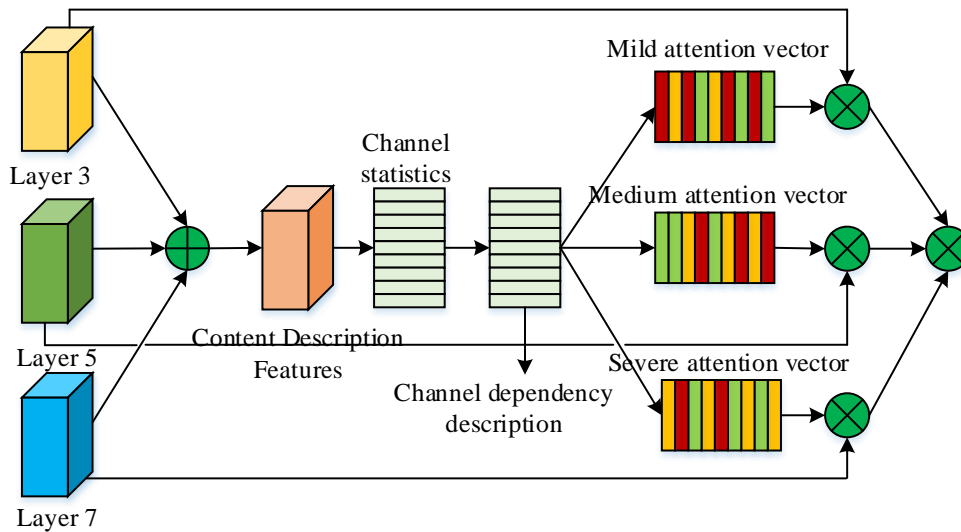

Fig. 5. Schematic diagram of adaptive feature fusion process.

In equation (7), Z_{uc} represents the channel information and descriptive features, H, W are the two aspects of the spatial dimension and i, j are the number of elements in the channel information. The channel dependencies are described with the help of the fully connected layer (FC), for which the extracted mathematical expressions are given in equation (8).

$$s = \delta(W_0 z) \tag{8}$$

In equation (8), δ, W_0 denote the activation function and the weight of the first connected layer, respectively. The output value of the features under feature fusion is the product of the feature representation of each component and its corresponding attention vector. The output value of the CAD module can be a representation of the semantic features extracted from the network, and the mathematical expression is shown in equation (9).

$$U_{in} = U_{out} \square U_{att} + U_{out} \tag{9}$$

In equation (9), U_{in}, U_{out} represent the inputs and outputs of the network, U_{att} is the attention map in the module and \square is the Hadamard product. Fig. 6 shows a schematic diagram of the application of the CAD module in target detection.

The High Resolution Network (HRNet), which is often applied to feature fusion, only adjusts and directly fuses features of different resolutions, without taking into account the differences in the representation of different resolution feature images and feature information data [34]. To reduce the distortion of image accuracy with direct fusion manipulation, a WFHRNet network that adds learning weights to the input features is proposed for feature extraction to distinguish the importance of different features in the overall network. The mathematical expression is shown in equation (10).

$$O_k = \sum_{i=1}^x \sigma(w_i) \cdot f(I, k) \tag{10}$$

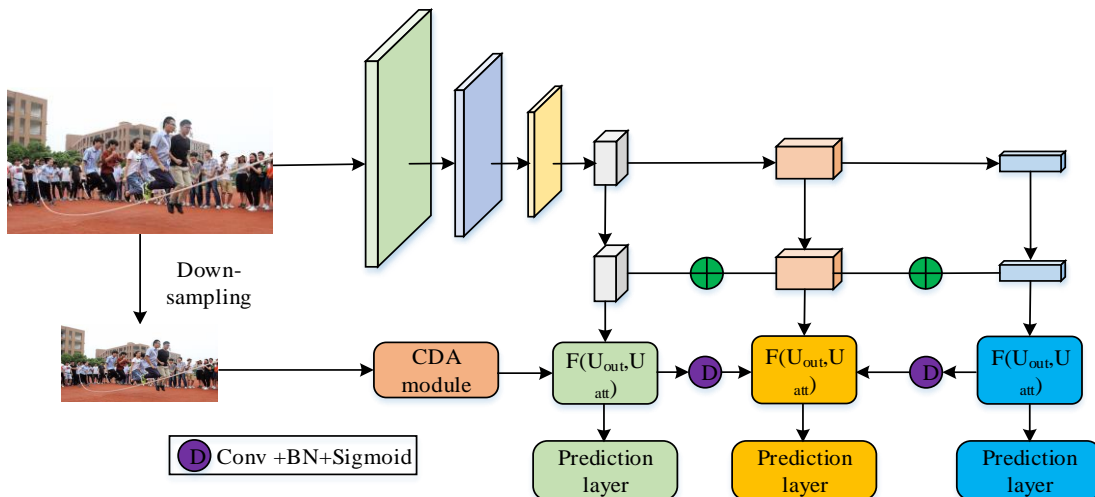

Fig. 6. Application diagram of CAD module in target detection.

In equation (10), σ denotes the Sigmoid function, w_i is the learning scalar, and $f(I_i, k)$ denotes the input resolution I_i adjusted to the k resolution via the sampling step. The size of the distance between prediction frames in different images can have an impact on information recognition. Non Maximum Suppression (NMS) processing is mostly used to remove redundant frames, but this method uses the intersection ratio metric to assess the difference of the assessed frame and the real frame. When the intersection ratio of the two targets is high, the correctly predicted prediction frames will be removed due to non-maximum suppression, resulting in the algorithm missing detection. The overlap of the redundant prediction frames and the equi-position relationship between different prediction frames will make the algorithm accuracy impaired. Therefore, the research proposes to improve the NMS with Manhattan Distance based Non Maximum Suppression (MD-NMS), which can represent the sum of the distances of the prediction frames in the vertical and horizontal directions. Its mathematical expression is given in Equation (11).

$$MD(B_1, B_2) = MD(m, n) + MD(n, v) + MD(C_{B1}, C_{B2}) \quad (11)$$

In equation (11), $(m, n), (n, v)$ denote the point in the vertical direction of the upper left and lower right corners of the two prediction frames B_1, B_2 , and C_{B1}, C_{B2} is the centroid of B_1, B_2 . There is an inverse relationship between the value of Manhattan distance and image similarity. The mathematical expression of MD-NMS is shown in equation (12).

$$S_i = \begin{cases} S_i, & loU(M, b_i) - nom(MD(M, b_i)) < N_i \\ 0, & loU(M, b_i) - nom(MD(M, b_i)) \geq N_i \end{cases} \quad (12)$$

In equation (12), loU denotes the intersection ratio, S_i is the threshold, b_i is the confidence score of the prediction frame, and M denotes the prediction frame at the highest confidence level.

IV. ANALYSIS OF EXPERIMENTAL RESULTS FOR THE ANALYSIS OF PHYSICAL EDUCATION AND SPORTS TEACHING

The participants' body movements during jumping rope were analyzed and identified, and the network was constructed after identifying the key points through the human body. The MPII motion data set and the jumping rope data set were used for this experimental dataset. The jumping rope data set was obtained from an experimental secondary school. In the process of data acquisition, the height and width of the video frames of different sizes were set uniformly in order to detect the node position of the research subject in the jumping rope movement. During the analysis of the posture estimation jumping rope movements, the data analysis and visualization effects were displayed with the help of the Jupyter Notebook interactive application. The hardware environment was set as: CPU: Intel Core i7-8700K, 3.70GHz; memory: 32G; GPU: GTX 1080Ti. Performance evaluation of the ALSTM-LSTM model proposed in the study was carried out, and the results are shown in Fig. 7.

Fig. 7. Error comparison results of different algorithm functions for moving image analysis.

What can be seen from Fig. 7 is that there are large differences in the error results of different algorithmic models under different numbers of iterations. Specifically, when it is less than 25, the data loss curves of the five algorithm models are slanted larger, and the error values between different models do not exceed 0.2%. When the number of iterations increases, the increase of data information will cause different degrees of redundancy to the algorithm performance. The average error in information for the LSTM model is 4.23% between 25 and 200 iterations, and only gradually plateaus when the number of iterations exceeds 200, with the value remaining at 1.37%. Meanwhile, the maximum error in information extraction between the LSTM model and the proposed ALSTM-LSTM model reached 26.35% at more than 25 iterations. The LSTM model with the addition of a residual network (ResNet), the LSTM model with a bi-directional mechanism (Bi-directional) and the LSTM model with a unidirectional attention mechanism all showed varying degrees of improvement in algorithmic loss compared to the single LSTM model. The loss curves also leveled off in the later stages of the algorithm, with the average errors of 15.24%, 10.28% and 9.36%, respectively, but the fluctuations of the nodes were more obvious. The above results indicate that the proposed model can enhance the information extraction accuracy capability. Subsequently, the model performance was further explored, and for the convenience of data statistics, the study referred to the five algorithmic models as Models 1-5, where the model proposed in the study was Model 1. Two other models are added, namely the Multi-label k-Nearest Neighbor algorithm (Model 6) and the Channel-Split Human Pose Estimation algorithm (Channel-SplitResidual StepsNetwork (Channel-SplitRSN) (Model 7). The result is Fig. 8.

What can be seen in Fig. 8 is that the performance expressed by the different algorithmic models varies considerably. In terms of accuracy values, the models with values above 90 are models 1-4, while models 5-7 have accuracy values in the range 60-75. The average accuracy of models 1-7 is 95.83, 94.73, 93.23, 92.13, 63.43, 75.53 and 74.43 respectively, which reflects the stable performance of the algorithm in information extraction. The average accuracy of several models improved compared with LSTM in the

figure is basically above 40%, among which the average accuracy of the model proposed in the study reaches 62.57%, and its accuracy error is 22.3% higher than the traditional LSTM model, and 19.32% and 17.31% higher than the ML-KNN model and RSN model. The results in Fig. 8(b) show that the models performing in order from best to worst in terms of recall metrics are ALSTM-LSTM model > LSTM-BN model > ALSTM-BN model > LSTM model > BiLSTM model > RSN model > ML-KNN model. The recall rate of the proposed model was 94.21%, corresponding to an F1 value of 94.1, and the maximum difference between this model and the other models in terms of recall index was 17.9. The above results show that the ALSTM-LSTM model can better take into account the correlation between sequence information, achieve the extraction of feature information data, and effectively avoid the problem of missing and omitted data. To further evaluate the performance of the ALSTM-LSTM model, the study was designed to compare it with the LSTM model at different values, the results of which are shown in Fig. 9.

In Fig. 9, the two models exhibit different ROC curve characteristics under different target fetch values. In Fig. 9(a), the single LSTM model is more influenced by the fetching values and the AUC areas under each label are 0.781, 0.829, 0.891, 0.765, 0.831 and 0.944 respectively. In Fig. 9(b), the improved LSTM model has a higher accuracy rate in image information prediction selection and is less disturbed by the fetching values, and its average accuracy reached 86.37%. The above data tells that the model created in the study has good application performance. The results of limb movement localization in jumping rope movements were then analyzed and the results are shown in Table I.

(a) Curves for single-layer LSTM models

(b) Curves of the ALSTM-LSTM model

Fig. 9. ROC and AUC curves of LSTM model and ALSTM-LSTM model.

TABLE I. LIMB POSITIONING RESULTS OF ROPE SKIPPING UNDER DIFFERENT ALGORITHM MODELS

Model	Head	Shoulder	Elbow	Wrist	Hip	Knee	Ankle
ALSTM-LSTM	95.2	87.3	75.8	72.5	78.6	70.1	64.8
ALSTM-BE	90.4	82.5	71	67.7	73.8	65.3	60.4
LSTM-BE	78.3	70.4	58.9	55.6	61.7	53.2	47.9
BiLSTM	78.9	71.0	59.5	56.2	62.3	53.8	48.5
LSTM	81.8	73.9	62.4	59.1	65.2	56.7	51.4
ML-KNN	76.1	68.2	56.7	53.4	59.5	51.2	45.7
RSN	71.7	63.8	52.3	49	55.1	46.6	41.3

The results in Table I show that the ALSTM-LSTM model has a high localization accuracy for feature extraction of different limb parts with a maximum value of 95.2 and it performs best in the comparison results with other models with a high improvement in the loss of data. The maximum localization accuracy values of the other six models were 90.4, 78.3, 78.9, 81.8, 76.1 and 71.7 respectively, all of which were smaller than the proposed mode in the study. It was then analyzed and the results are shown in Fig. 10.

(a) Accuracy and average accuracy of different algorithmic models

(b) Recall and F1 values for different algorithmic models

Fig. 8. Performance comparison of different algorithm models.

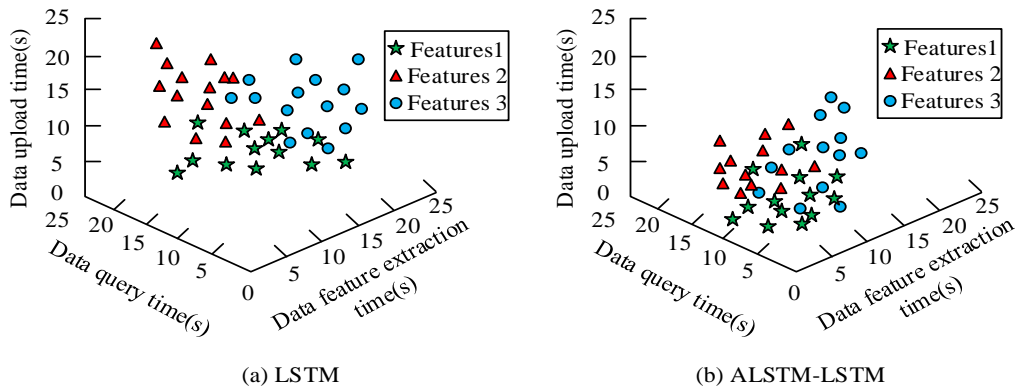

Fig. 10. System test results of two models.

In Fig. 10, the system processing performance of the LSTM model for all three pose features is poor, with the average time consumed for data upload, data query and feature extraction all greater than 15s. The system processing performance of the ALSTM-LSTM model proposed in the study is better and more balanced, with an average time consumption of 11.23s. The human posture recognition algorithm is applied to the classroom evaluation of a certain jumping rope teaching, and it evaluates students' physical performance in the final stage. Firstly, perform a result analysis on its matching accuracy, as shown in Fig. 11.

Fig. 11. Evaluation accuracy of human pose recognition algorithm.

The results in Fig. 11 indicate that the pose recognition model proposed in the study achieved motion recognition accuracy of 94.7% and 93.5% for the general and detailed movements of jumping rope on two types of data, respectively. Among them, the matching accuracy of the lunge movement was the highest (98.77%), and its posture matching error situation was effectively improved. The results indicate that the recognition algorithm has good application effect in physical education teaching evaluation. The satisfaction of students is collected during the evaluation process, and the results are shown in Fig. 12.

In Fig. 12, the satisfaction score obtained by the action recognition algorithm used in the study in student sports evaluation reached over 90 points. Compared to other algorithms, students are more satisfied with the proposed one. The results indicate that the recognition algorithm can

effectively assist in the jumping rope sport teaching and help students improve their academic performance. In future sports teaching, teachers can use this motion analysis system to help students master the standard movements of jumping rope. Appropriate teaching strategy adjustments can be made based on the feedback from students, in order to continuously improve teaching effectiveness and quality.

Fig. 12. Student satisfaction in the evaluation process of physical education teaching.

V. CONCLUSION

The study analyses the pose in jumping rope movement scenarios and introduces an attention mechanism to improve the neural network, converting the video analysis problem into a limb key point coordinate analysis problem. The results of the proposed model system were analyzed and it was found that the average error of the LSTM model information extraction between 25 and 200 iterations was 4.23%, which gradually leveled off at more than 200 iterations and remained at 1.37%. It was much larger than the maximum error of information extraction of the proposed ALSTM-LSTM model at more than 25 iterations, which was 26.35%. The maximum error in information extraction with the proposed ALSTM-LSTM model at more than 25 iterations was 26.35%, larger than that of the LSTM-RE, BiLSTM and ALSTM models at 15.24%, 10.28% and 9.36%. For information extraction accuracy, the accuracy value of the ALSTM-LSTM proposed in the study reached 95.83, and its average accuracy was 62.57%, which was 22.3%, 19.32% and 17.31% higher compared with the LSTM model, ML-KNN model and RSN model. The ALSTM-LSTM model also has a larger AUC area

than the single LSTM model, with a maximum value of 95.2 for the localization of the subdivision of the jumping rope pose movements. The jumping rope motion system constructed with the ALSTM-LSTM model shows better performance. Further research is needed to enhance the motion scene analysis ability and to widen the dimension of pose estimation.

A Novel Label Propagation Method for Community Detection Based on Game Theory

Mengqin Ning¹, Jun Gong^{2*}, Zhipeng Zhou³

Philosophy School, Beijing Normal University, Beijing, China¹
Software School, Jiangxi Normal University, Nanchang, China^{2,3}

Abstract—Community is a mesoscopic feature of the multi-scale phenomenon of complex networks, which is the bridge to revealing the formation and evolution of complex networks. Due to high computational efficiency, label propagation becomes a topic of considerable interest within community detection, but its randomness yet produces serious fluctuations. Facing the inherent flaws of label propagation, this paper proposes a series of solutions. Firstly, this paper presents a heuristic label propagation algorithm named Label Propagation Algorithm use Cliques and Weight (LPA-CW). In this algorithm, labels are expanded from seeds and propagated based on node linkage index. Seeds are produced from complete subgraph, and node linkage index is related to neighboring nodes. This method can produce competitive modularity Q but not Normalized Mutual Information (NMI), and compensate with existing methods, such as Stepping Community Detection Algorithm based on Label Propagation and Similarity (LPA-S). Secondly, in order to combine the advantages of different algorithms, this paper introduces a game theory framework, design the profit function of the participant algorithms to attain Nash equilibrium, and build an algorithm integration model for community detection (IA-GT). Thirdly, based on the above model, this presents an algorithm, named Label Propagation Algorithm based on IA-GT model (LPA-CW-S), which integrates LPA-CW and LPA-S and solves the incompatibility between modularity and NMI. Fully tested on both computer-generated and real-world networks, this method gives better results in indicators such as modularity and NMI than existing methods, effectively resolving the contradiction between the theoretical community and the real community. Moreover, this method significantly reduces the randomness and runs faster.

Keywords—Community detection; label propagation; node linkage; complete subgraph; game theory

I. INTRODUCTION

Human beings are surrounded by systems that are unprecedentedly complicated. Behind each complex system, there is an intricate network that encodes the interactions among these system components. Among those networks, the most influential ones are social networks, communication networks, world wide web and cognitive neural networks etc. [1], which are characterized by small-world [2], scale-free [3], community structure [4]. Since Newman [4] put forward the problem of complex network community structure in 2002, domestic and foreign scholars have devoted themselves to studying the community nature of networks and proposed a large number of community discovery algorithms, which can be broadly divided into bottom-up community discovery and top-down community discovery [5]. The bottom-up method

can efficiently expand the community gradually from nodes based on heuristic rules, which can be divided into three categories: modularity optimization class, local extension class and label propagation class. With the outstanding algorithm efficiency, the label propagation community discovery method has been widely concerned. However, the randomness of the existing methods cannot guarantee the stable and reliable results of community division, and each algorithm has its own advantages and disadvantages, so it cannot adapt to all scenarios alone.

Inspired by relevant theories in sociology, mathematics, biology and other fields, the idea of this paper is originated from three points. Fig. 1 is a vivid description of them.

- Inspiration 1: Social identity theory in sociology [6] and acquaintance model. In social relationship, the number of friends, the degree of intimacy and the co-neighbor relationship greatly affect the social relationship. Based on relational model in sociology, a node link relationship model is proposed in this paper, which provides a theoretical basis for label selection strategy.
- Inspiration 2: Classical game theory in mathematics and evolutionary game theory in biology [7]. There exist conflict, competition and cooperation among nodes in complex network, and their microscopic dynamic evolution mechanism can be described by game model.
- Inspiration 3: The contradiction exists between the theoretical community division and the real-world division. Community detection algorithms are mainly based on graph theory and quality function, and the results of community detection are usually refined, but small and large communities are not effective for communication. Therefore, community scale in the real world tend to be greater.

These ideas improve the initialization, propagation, and convergence processes in the new algorithm. Meantime, this paper introduces game theory to explain the cooperation and competition among nodes in complex networks, and propose an algorithmic integration model for community detection, and then a novel algorithm is proposed based on this model. Fig. 2 shows the theoretical framework and technical route of this paper. The main contributions can be summarized in the following three points:

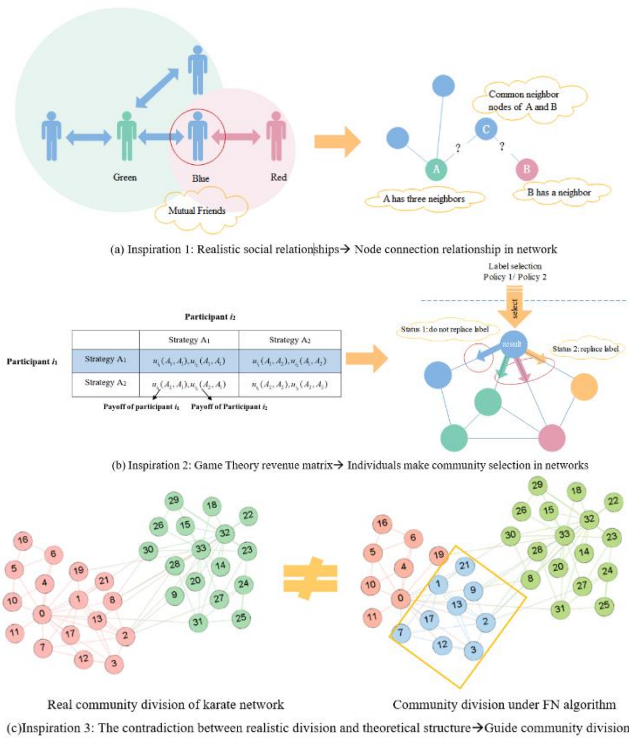

Fig. 1. Source of inspirations for this paper.

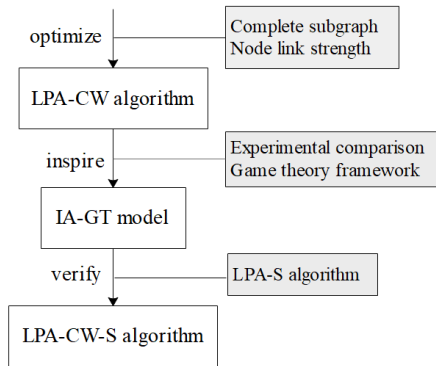

Fig. 2. The theoretical framework of this paper.

- Contribution 1:** This paper proposes a label propagation community detection algorithm (LPA-CW) based complete subgraphs and Node Link Strength. In the initialization phase, non-overlapping complete subgraphs are introduced as the seed community, and Node Link Strength based mechanism is introduced in the propagation phase, which improves the stability and accuracy of the community division, suitable for large-scale networks.
- Contribution 2:** This paper proposes an integrated model of community detection algorithms, IA-GT model, based on game theory. The model sets the payoff function of the participant algorithm, derives and verifies the Nash equilibrium under the mixed strategy, which can theoretically realize the complementary advantages of different algorithms and hence has strong scalability.

- Contribution 3:** Based on this new IA-GT model, LPA-CW algorithm and LPA-S algorithm are selected as the combination objects, and then LPA-CW-S algorithm is proposed. Experiments have proved that the game mechanism effectively takes into account the contradiction between the theoretical community structure and the real community division, and performs well in metrics such as modularity and NMI, which improves the efficiency and decreases the randomness and volatility.

The remainder of this paper is organized as follows. Section II introduces the research status of label propagation algorithm and the research status of introducing game theory framework to solve the problem of community discovery. Section III and IV respectively describe the LPA-CW algorithm, IA-GT game theory model and LPA-CW-S integrated algorithm. Section V is the experimental setting and result analysis, and Section VI gives conclusions.

II. RELATED WORK

This section introduces the research status of community detection algorithm based on label propagation and game theory, and then proposes the existing limitations and research direction.

A. Label Propagation Algorithm

In 2002, Zhu et al. first proposed the label propagation algorithm (LPA), which predicts the label information of unlabeled nodes with the labeled nodes. In 2007, Raghavan et al. [8] applied LPA to community detection for the first time. LPA can detect community structure in a near-linear time, which is greatly attractive. In 2009, Barber et al. [9] redefined LPA as an equivalent optimization problem, expanding the scope of application, and proposed the LPAm by modifying the objective function, which is applicable to both two-part network and single-part network. In 2017, Li et al. [10] proposed Stepping-LPA-S (short for LPA-S) aiming at reducing side effects of community merging by introducing a new quality function.

This search for LPA optimization has attracted much interest in recent years due to the side effects of propagation instability. Liu et al. [11] introduced node influence, network propagation update and node attribute characteristics in LPA. SUN et al. [12] transformed node partition problem into link partition problem in LPA. Kouni et al. [13] introduced node aggregation coefficient in LPA to evaluate node importance. ZHANG et al. [14], from the perspective of human society and radar transmission, defined four node capabilities (propagation, attraction, emission and reception), label influence and a novel label propagation mechanism to cope with instability and efficiency. In the field of community detection, LPA optimization is still a research hotspot, but it is trapped in homogeneity without breakthrough.

- Limitation 1:** Most algorithms emphasize on network structure, ignoring node importance during network formation.
- Limitation 2:** The improvement mainly focuses on the label selection stage, ignoring the overall

consideration for other stages, such as initialization and convergence.

Inspired by clique percolation and sociological relationship theory, this paper optimizes most stages including initialization, propagation and convergence, and proposes a novel algorithm.

B. Game Theory

Since the publication of Von Neumann's article "Theory of Parlor Games" [15], game theory has been widely applied to psychology, economics, sociology, politics and many other fields. However, game theory rarely appears in the field of community detection. Chen et al. [16] first introduced game theory framework to solve the problem of community detection, which reflects the formation of real-world communities and detects communities by the gain and loss function. Ioana et al. [17] proposed a dynamic community detection method based on game theory elements and extremum optimization, but its experimental results had unobvious advantage compared with existing algorithms, and there were few related studies since then.

Since 2019, there has been a series of new improvements. For example, Hesamipour et al. [18] used the Adamic/Adar (AA) index to detect the local host node and extended its surrounding community based on the game theory. ZHOU et al. [19] proposed an edge weight calculation method for computing node and alliance Shapley values in combination with game theory for community detection. Kumar et al. [20] used a game theory method (Dynamic Clustering game, DCFG) to analyze the clustering problem of attribute graphs, and provided a solution for balancing topology structure and node attributes. Obviously, there are some new entry points to combine game theory with community detection, but there are still some limitations.

- **Limitation 1:** Most game theory based community detection algorithms can't get satisfactory results in benchmark experiments, and improvement bottlenecks still exist compared with classical algorithms.
- **Limitation 2:** The game selection didn't effectively solve the contradiction between the theoretical optimization of community division and the real world needs, and didn't take full advantage of game theory.

Considering the above problems, this paper views some community detection algorithms as participants, and proposes an extensible model.

III. A COMMUNITY DETECTION ALGORITHM FOR LABEL PROPAGATION BASED ON COMPLETE SUBGRAPHS AND NODE LINK STRENGTH

A. Problem Formulation

Given $G = (V, E)$ represents a complex network, where $V = \{v(i) | i = 1, 2, \dots, n\}$ represents the set of nodes in the network, and $E = \{e(i) | i = 1, 2, \dots, m\}$ represents the set of edges. Communities are subsets of nodes highly linked among themselves but loosely connected to the rest of the network. Communities are believed to play a central role in the

functional properties of complex structures. They are represented by $C = \{C_1, C_2, \dots, C_K\} (1 \leq K \leq |V|)$ and K is the number of network communities.

- **Definition 1:** Direct link strength. It denotes the direct contribution to the link strength of edge $e_{v(1),v(2)}$ of nodes $v(1)$ and $v(2)$ concerning their neighbor nodes, which is marked as $DL_{v(1),v(2)}$ and the equation is as follows:

$$DL_{v(1),v(2)} = \frac{1}{d_{v(1)} + d_{v(2)}} \quad (1)$$

In which $d_{v(1)}$ and $d_{v(2)}$ respectively represent the number of neighbor nodes of nodes $v(1)$ and $v(2)$, namely the degree. The larger the node degree is, the more important the node is, but the smaller contribution to the link intensity value.

- **Definition 2:** Indirect link strength. It denotes the indirect contribution degree of the link strength of edge $e_{v(1),v(2)}$ between nodes $v(1)$ and $v(2)$ according to the common neighbor nodes, which is marked as $IL_{v(1),v(2)}$ and the equation is as follows:

$$IL_{v(1),v(2)} = \frac{(|N(v(1)) \cap N(v(2))| + 1)}{d_{v(1)} + d_{v(2)}} \quad (2)$$

In which $N(v(1))$ and $N(v(2))$ denote neighbor node sets of nodes $v(1)$ and $v(2)$, respectively, $N(v(1)) \cap N(v(2))$ represents common neighbor node sets of nodes $v(1)$ and $v(2)$. The more common neighbors between nodes are, the stronger their connectivity is.

- **Definition 3:** Node link strength. It denotes the joint contribution of nodes $v(1)$ and $v(2)$ to the link strength of edges $e_{v(1),v(2)}$ via direct link and indirect link strength, which is marked as $LS_{v(1),v(2)}$ and the equation is as follows:

$$LS_{v(1),v(2)} = \begin{cases} DL_{v(1),v(2)} & \text{if } d_{v(1)} = 1 \text{ or } d_{v(2)} = 1 \\ DL_{v(1),v(2)} + 2 * IL_{v(1),v(2)} & \text{if } d_{v(1)} > 1 \text{ and } d_{v(2)} > 1 \end{cases} \quad (3)$$

According to neighbor nodes between node $v(1)$ and $v(2)$, if exists, the direct link and indirect link strength are calculated, and if not, only the direct link strength is calculated.

B. Description of LPA-CW Algorithm

1) *Label initialization based on non-overlapping complete subgraph:* In the traditional LPA, a unique label is assigned to each node during initialization, which causes the scattered labels. In the subsequent propagation process, it is hard to converge and easy to lead to fluctuation. The node-link relationship tells us that the community structure is highly

similar to complete subgraph. Therefore, identifying the non-overlapping complete subgraph first can improve label propagation.

The label initialization process is as follows, sorting all the unassigned nodes in descending order of degree, then looking for a complete subgraph starting from the node with greatest degree, and then process continuously cycles until each node have been assigned to some subgraph, finally assigning the same label to nodes in the same complete subgraph. Approximation strategy ensures algorithm efficiency, making subsequent label propagation process converge faster. The pseudocode of this procedure is as follows:

Algorithm 1 Find Nonoverlapping Complete Subgraph

```

Data: Graph
Output: nonoverlapping cliques
1: node ← nodes of G sorted by degree in descending order
2: done ← [0 for each i in node] #0:unassigned, 1:assigned to some clique
3: c ← [[] for each i in node]
4: t ← 0 #record the number of cliques
5: while node is not empty do
6:   n ← node[0] #node with the largest degree among unassigned nodes
7:   done[n] ← 1
8:   node.remove(n)
9:   c[t].append(n)
10:  for each j in neighbors of n sorted by degree in descending order do
11:    if done[j] = 0 and j have edge(i,j) for each i in c[t] then
12:      done[j] ← 1
13:      node.remove(j)
14:      c[t].append(j)

```

```

15: end if
16: end for
17: t++
18: end while
19: c ← c[:t]
20: return c

```

2) *Label update strategy based on node link strength:*
When a node has multiple neighbor labels with the same highest frequency, one of these labels will be randomly selected as its own label, which is the traditional problem of LPA. This randomness greatly reduces accuracy and stability of community division.

To minimize randomness, this paper uses the node link strength to set a new label update strategy. Label update rules are defined as follows: (1) calculate the link strength $LS_{v(i),v(j)}$ between any two nodes in the network, according to the random access order, for the current nodes $v(i)$, find out all the node sets R_{label_n} with the same label in its neighbor $r(j)$ (according to Equation 4). Then calculate the link strength cumulative sum between node $v(i)$ and each node set R_{label_n} (according to Equation 5). Find the label $label_n$ corresponding to the accumulated and largest node set, and the node $v(i)$ label is updated to $label_n$.

$$R_{label_n} = \{r(1), r(2), \dots, r(|R_{label_n}|)\}$$

$$R = \{R_{label1}, R_{label2}, \dots, R_{label_n}\} \quad (4)$$

$$L = \left\{ \sum_{j=1}^{|R_{label1}|} LS_{v(i),r(j) \in R_{label1}}, \sum_{j=1}^{|R_{label2}|} LS_{v(i),r(j) \in R_{label2}}, \dots, \sum_{j=1}^{|R_{label_n}|} LS_{v(i),r(j) \in R_{label_n}} \right\} \quad (5)$$

Fig. 3. A simple example for node link strength.

As shown in Fig. 3, calculate node link strength of $v(a)$ - $v(b)$ and $v(a)$ - $v(d)$ according to Equation 3. The calculation steps for the above two are as follows:
 $LS_{v(a),v(b)} = 1 / (3+3) + 2 * (2+1) / (3+3) = 1.167$
 $LS_{v(a),v(d)} = 1 / (3+5) + 2 * (2+1) / (3+5) = 0.875$. Here node

color denotes node label, set current node = $v(d)$, and its neighbor node set with identical labels is $R = \{\{r(a), r(b)\}, \{r(c)\}, \{r(e)\}, \{r(f)\}\}$. Then accumulate node link strength with the same labels and the result is calculated as $L = \{1.75, 0.875, 0.714, 0.714\}$, so the

maximal value 1.75 is selected and node $v^{(d)}$ is updated for the yellow label.

3) *Algorithm procedure:* The algorithm procedure of LPA-CW is shown in Fig. 4, and its pseudo-code is described in Algorithm 1.

Fig. 4. Flow chart of LPA-CW algorithm.

Algorithm 1 Pseudocode of Label Propagation Algorithm use Cliques and Weight

Input: Graph
Output: partition
1: $addWeight(G)$
2: $labeling \leftarrow v : k \text{ for } k, v \text{ in } enumerate(G)$
3: $cliques \leftarrow getCliques(G)$
4: $maxc \leftarrow maxLength(cliques)$
5: **for** i **in** $cliques$ **do**
6: **if** $length(cliques[i]) == maxc$ **then**
7: $maxLabel = max(i)$
8: **for** j **in** i **do**
9: $labeling[j] \leftarrow maxLabel$
10: **end for**
11: **end if**
12: **end for**
13: **while** **not** $labelCompleteEdgeWeight(labeling, G)$ **do**
14: **for** n **in** $G.nodes()$ **do**
15: $updateLabelEdgeWeight(n, labeling, G)$
16: **end for**
17: **end while**
18: $partition \leftarrow getResult(labeling)$
19: **return** $partition$

4) *Algorithm analysis:* Assuming that the network has n nodes and m edges, the average degree of nodes is denoted by k , and the number of non-overlapping complete subgraphs searched in IIIA is denoted by λ .

The running time is mainly consumed during two stages. The first stage is the initialization phase, and it takes $O(kn \log n)$ to identify non-overlapping complete subgraphs, then label assignment to the subgraph is $O(\lambda)$, and calculating node link strength is $O(n+2m)$. The second stage is the label propagation process, and it takes $O(n+2m)$ to access neighbor nodes, and takes $O(r \cdot (n+2m))$ to loop iteration r times. The value of r is related to data sets, when the scale of the data set increases or the average degree increases, r will also increase. Generally, r is in [3,6].

In summary, the time complexity of the new algorithm is $O(r \cdot (n+2m))$. In the subsequent experiment section, it can be proved that this algorithm is prone to faster convergence.

IV. COMMUNITY DETECTION ALGORITHM INTEGRATION MODEL BASED ON GAME THEORY

A. Problem Formulation and Basic Definitions

According to the analysis of experimental data in Section VB of this paper, LPA-CW algorithm has obvious advantages in modularity Q, which shows that community partition is of high quality and refinement; the comparison algorithm LPA-S [10] has complementary advantages in standard mutual information NMI, and has high accuracy in comparison with real community partition. Therefore, this paper introduces the game model to explain the individual choice and overall stability maintenance in the process of community formation. Firstly, in this paper, the combination of label propagation algorithms, namely LPA-CW algorithm and LPA-S algorithm, is selected.

The strategic game G is represented by the set $G = \{N, \{A_i\}_{i=1}^N, \{u_i\}_{i=1}^N\}$, where $N = \{1, \dots, N\}$ is the set of participants, $A_i = \{A_1, A_2, \dots, A_n\}$ is the set of strategies available to the participant i , and u_i is the payoff of the participant i . When constructing the model, this paper uses the payoff matrix and mixed strategy in game theory.

B. IA-GT Community Detection Model Construction and Verification

The IA-GT (Integration Algorithm-Game Theory) community detection model is divided into three stages. Fig. 5 shows the frame diagram of the model construction. This model is an extensible model that can be flexibly replaced and combined. In the first step, the selection of participants must be based on the principle of the algorithm itself and the game theory, which has theoretical integration and practical significance. The second step is to define the payoff function of the participant according to the selected strategy and the core parameters of the algorithm. In the third step, the Nash equilibrium solution result needs to be verified by algorithm experiment.

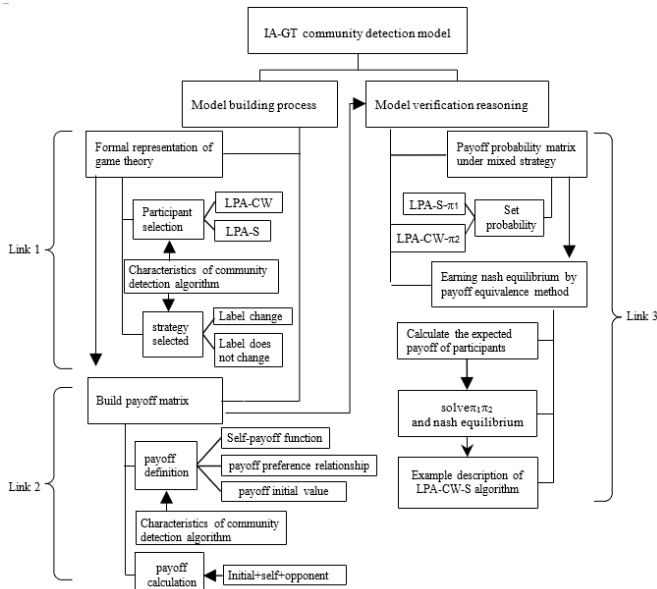

Fig. 5. IA-GT community detection model.

1) *Integrated model building process*: According to the game theory, this paper uses the payoff matrix to construct the model, with LPA-CW algorithm and LPA-S algorithm as two participants. Combining the core principles of the two algorithms, first initialize the network label, and then update the node label according to the game theory selection algorithm. The community label of each node has two states "changed" or "unchanged". In this model, the strategy of the two participants is to "change (c)" or "don't change (d)" the label of the current processing node. Symbolizing the above game process can be obtained:

$$G = \{ \{ LPA-S, LPA-CW \}, \{ A_{LPA-S}, A_{LPA-CW} \}, \{ u_{LPA-S}, u_{LPA-CW} \} \}$$

Participants: $N = \{ LPA-S, LPA-CW \}$ represents two algorithms;

Strategy: $A_{LPA-S} = A_{LPA-CW} = \{c, d\}$ use c and d to indicate change and don't change.

$$\text{Payoff: } u_{LPA-S}(c, c), u_{LPA-CW}(c, c); u_{LPA-S}(c, d), u_{LPA-CW}(c, d);$$

$$u_{LPA-S}(d, c), u_{LPA-CW}(d, c); u_{LPA-S}(d, d), u_{LPA-CW}(d, d);$$

In game theory, the payoff function needs to be defined according to the problem domain. For example, for the strategy group $A(d, c)$, $u_{LPA-S}(d, c)$ is the payoff of the participant LPA-S under this set of strategies, not only related to its own strategy choice, but also related to the opponent (LPA-CW) strategy choice and initial profit value during the interaction. Combining the label update rules of LPA-S and LPA-CW, define the participant's own benefits and the preference relationship between participants, under the selected strategy.

- **Definition 4**: Participant LPA-S's own benefits under the c strategy: The maximum value of similarity between the current processing node $v(i)$ and its neighbors minus the maximum value of similarity

between node $v(i)$ and the neighbors with the same label as node $v(i)$, the equation denoted as I_{LPA-S} is as follows.

$$I_{LPA-S} = \max\{S_1\} - \max\{S_2\}$$

$$S_1 = \{s_{v(i),r(1)}, s_{v(i),r(2)}, \dots, s_{v(i),r(j)}\}, r(j) \in N(v(i)) \quad (6)$$

$$S_2 = \{s_{v(i),r(1)}, s_{v(i),r(2)}, \dots, s_{v(i),r(h)}\}, r(h) \in R_{labeli}$$

Where $s_{v(i),r(1)}$ is the similarity between the node $v(i)$ and its neighbors [21], $N(v(i))$ is the set of all neighbors of node $v(i)$, R_{labeli} is the set of neighbors with the same label as node $v(i)$, S_1 is the set of similarity between node $v(i)$ and all its neighbors $r(j)$, S_2 is the set of similarity between node $v(i)$ and its neighbor $r(h)$ with the same label as node $v(i)$. The LPA-S algorithm changes the label according to the neighbor with the greatest similarity, and the label doesn't need to be changed if it is the same. The overall value of I_{LPA-S} is between $(-1, 1)$, When $I_{LPA-S} \in (-1, 0]$, it is required to treat it as $I_{LPA-S} = 0$ uniformly, and the label is not changed; when $I_{LPA-S} \in (0, 1)$, the greater the difference, the higher the payoff gained from label changes.

Fig. 6. Example of label selection for LPA-S.

Fig. 6 shows an example, the neighbor with the largest similarity of current processing node $v(a)$ is node $r(e)$. Among neighbors $r(b)$ and $r(c)$ that have the same label as node $v(a)$, the similarity of $r(b)$ is greater. According to the calculation, $S_1 = \{0.87, 0.62, 0.42, 0.91, 0.54\}$, $S_2 = \{0.87, 0.62\}$ and $I_{LPA-S} = 0.91 - 0.87 = 0.04$.

- **Definition 5**: Participant LPA-CW's own benefits under the c strategy: The maximum value in the cumulative sum of Link Strengths between the current processing node $v(i)$ and each neighbor node set $R_{labelin}$ minus the cumulative sum of Link Strengths between the node $v(i)$ and its neighbors with the same label, the equation denoted as I_{LPA-CW} is as follows.

$$I_{LPA-CW} = \max\{L\} - \sum_{h=1}^{|R_{labelin}|} LS_{v(i),r(h) \in R_{labelin}} \quad (7)$$

Where the Node Link Strength $LS_{v(i),r(h)}$, set L , $R_{labelin}$ are defined in detail in section IIIB2). The LPA-CW algorithm

changes the label according to the neighbor set with the largest accumulation of Node Link Strength, and the label doesn't need to be changed if it is the same. By performing standard normalization treatment on I_{LPA-CW} to get I_{LPA-CW}' , When $I_{LPA-CW} \in (-1, 0]$, the label is not changed; when $I_{LPA-CW} \in (0, 1)$, the greater the difference, the higher the payoff gained from label changes.

Fig. 7. Example of label selection for LPA-CW.

Fig. 7 shows an example, the current processing node $v(a)$, all node sets with the same label in its neighbors are $R = \{\{r(b), r(c)\}, \{r(d)\}, \{r(e), r(f)\}\}$, the corresponding Node Link Strength accumulation is $L = \{0.59, 0.42, 0.82\}$, $\max\{L\} = 0.82$. Where the neighbors with the same label as node $v(a)$ are $r(b)$ and $r(c)$, the cumulative sum of their Node link strengths is 0.59, according to the calculation, $I_{LPA-CW} = 0.82 - 0.59 = 0.23$.

- **Definition 6:** The preference relationship between payoff of IA-GT community detection model: Under the selected strategy group, the influence of opponent's choice on the payoff of participants [22].

Combined with the idea of label propagation algorithm, the convergence result of community division is that the labels will no longer change, so it is assumed that the initial payoff value of each node is 0. When the participant chooses the "change" strategy, its own payoff is calculated according to definitions 4 and 5. At this time, if the opponent also chooses the "change" strategy, the participants' overall payoff minus 1, but if the opponent chooses the "don't change" strategy, there will be no impact. When participants choose "don't change" strategy, its own payoff is 0, at this time if the opponent choose "change" strategy, the participants' overall payoff minus 1, if the opponent also choose "don't change" strategy, the participants' overall payoff plus 1.

According to definitions 4, 5, and 6, calculate the overall payoff of the participants LPA-S and LPA-CW under the selected strategy group, and construct the payoff matrix of the IA-GT model as shown in Fig. 8.

$$A(c, c) : u_{LPA-S}(c, c) = I_{LPA-S} - 1; u_{LPA-CW}(c, c) = I_{LPA-CW}' - 1$$

$$A(c, d) : u_{LPA-S}(c, d) = I_{LPA-S}; u_{LPA-CW}(c, d) = 0 - 1 = -1$$

$$A(d, c) : u_{LPA-S}(d, c) = 0 - 1 = -1; u_{LPA-CW}(d, c) = I_{LPA-CW}'$$

$$A(d, d) : u_{LPA-S}(d, d) = 0 + 1 = 1; u_{LPA-CW}(d, d) = 0 + 1 = 1$$

		LPA-CW	
		Change(c)	Don't change(d)
LPA-S	Change(c)	$I_{LPA-S} - 1, I_{LPA-CW}' - 1$	$I_{LPA-S}, -1$
	Don't change(d)	$-1, I_{LPA-CW}'$	1, 1

Payoff of LPA-S Payoff of LPA-CW

Fig. 8. Payoff matrix of IA-GT community detection model.

2) Reasoning verification of integrated model: After the payoff matrix is determined, the participants will randomly choose different strategies according to a certain probability distribution, at this time, and then Nash equilibrium under mixed strategies can be solved. Based on the integration needs of the two algorithms, this paper chooses the payoff equivalent method to calculate.

When two participants choose different strategies, for the current processing node $v(i)$, it is assumed that the probability of community label change is π_1 when LPA-S algorithm is applied, and the probability is π_2 when LPA-CW algorithm is applied. Fig. 9 shows the payoff probability matrix of IA-GT community detection model under mixed strategy.

		LPA-CW	
		Change(c), π_2	Don't change(d), $1 - \pi_2$
LPA-S	Change(c), π_1	$I_{LPA-S} - 1, I_{LPA-CW}'$	$I_{LPA-S}, -1$
	Don't change(d), $1 - \pi_1$	$-1, I_{LPA-CW}'$	1, 1

Fig. 9. Payoff probability matrix of IA-GT community detection model under mixed strategy.

According to game theory, the participants's expected payoff is evaluated by the probability of opponents choosing strategies, that is, the expected payoff of LPA-CW algorithm is evaluated by π_1 . For LPA-CW algorithm:

Expected payoff from choosing "change" strategy:
 $Eu_{LPA-CW}(c) = (I_{LPA-CW}' - 1) \times \pi_1 + I_{LPA-CW}' \times (1 - \pi_1);$

Expected payoff from choosing "don't change" strategy:
 $Eu_{LPA-CW}(d) = -1 \times \pi_1 + 1 \times (1 - \pi_1);$

According to the Nash Equilibrium Payoff Equivalence Method:

$$Eu_{LPA-CW}(c) = Eu_{LPA-CW}(d), \pi_1 = 1 - I_{LPA-CW}';$$

The same can be obtained $\pi_2 = 1 - I_{LPA-S}$.

Both π_1 and π_2 are the probability when the label changes, so only the case of $I_{LPA-CW}', I_{LPA-S} \in (0, 1)$ need to be considered, because when the two are less than 0, the label doesn't change.

According to Equation 6 and 7:

$$\pi_1 = 1 - (\max\{L\} - \sum_{h=1}^{|R_{label}|} LS_{v(i),r(h) \in R_{label}}) \quad (8)$$

$$\pi_2 = 1 - (\max\{S_1\} - \max\{S_2\}) \quad (9)$$

$$p = \{\{\pi_1, 1 - \pi_1\}, \{\pi_2, 1 - \pi_2\}\} \quad (10)$$

π_1 and π_2 are related to the payoff of the two participants' algorithms, and they are both solved. The result of mixed strategy game is mixed strategy Nash equilibrium, so Nash equilibrium is obtained, as shown in Equation 10. This paper combines the game theory with the community detection problem, and constructed the IA-GT community detection algorithm integration model.

C. Model Application: Description of LPA-CW-S Algorithm

In the previous section, this paper has theoretically proved the effectiveness of the IA-GT model. Through dynamic analysis, with the update of each node's label by community detection, the payoff size of algorithm implementation and strategy selection probability will also change correspondingly. According to the game payoff matrix, at this time the algorithm needs to choose the optimal strategy for processing. Fig. 10 shows an application example of the model, namely LPA-CW-S algorithm, which proves the feasibility of the model from the experimental point of view.

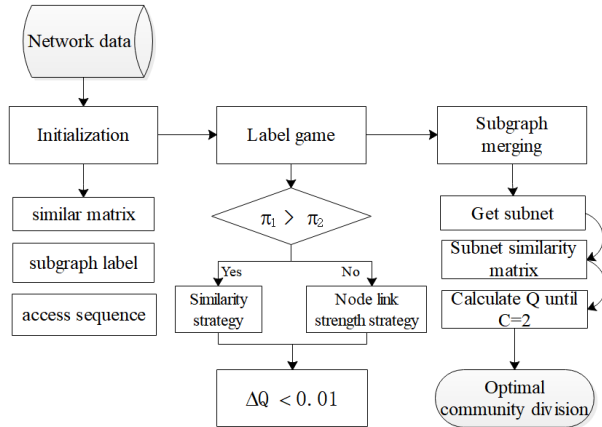

Fig. 10. The framework of LPA-CW-S.

1) *Algorithm steps:* According to the above theory, LPA-CW-S integration algorithm steps are as follows:

a) *Initialization stage:* Initialize all labels, search for the non-overlapping minimum complete subgraph in the graph, and let the clique with the largest number of nodes assign the same label. Initialize the similarity matrix, and refer to LPA-S for calculation; creating a random access sequence of nodes.

b) *Label game operation stage:* According to the obtained access sequence, the following values are calculated one by one: π_1 , applying LPA-CW algorithm, the probability of community label change; π_2 , applying LPA-CW algorithm, the probability of community label change; If $\pi_1 >$

π_2 , the label is updated by similarity strategy, otherwise, it is updated by Node Link Strength strategy. After each traversal, the modular Q is calculated once, and if the difference between the two times is less than 0.01, the first operation is finished.

c) *Sub-graph merging operation stage:* Preparation stage: get subnets from the current G, and then obtain the similarity matrix between subnets, save the current partition results. Operation stage: Initialize the subnet random access sequence; Calculate modularity Q once every time a subnet is updated. If Q is larger than the Q of previous partition results, save the current partition results to obtain the optimal solution, until there are two communities left.

d) *Complete and return the optimal partition result:* According to the above steps, the LPA-CW-S algorithm is divided into three stages. In the first stage, Algorithm 2-1 for the pseudo-code of initialization; in the second stage, Algorithm 2-2 for the pseudo-code of label game; and in the third stage, Algorithm 2-3 for the pseudo-code of subgraph merging.

Algorithm 2-1 Initialization

```

Data: A network  $G = (V, E)$ 
1:  $G1 \leftarrow G.copy()$ 
2:  $initializeLabel(G)$ 
3:  $addWeight(G)$ 
4:  $sDict \leftarrow initializeSimilarityMatrix(G)$ 
5:  $nodeOrder \leftarrow initializeNodeOrder(G)$ 
6:  $cliques \leftarrow getCliques(G)$ 
7:  $maxc \leftarrow maxLength(cliques)$ 
8: for  $i$  in  $cliques$  do
9:   if  $length(cliques[i]) == maxc$  then
10:     $maxLabel = max(i)$ 
11:   for  $j$  in  $i$  do
12:     $G.nodes[j][label] \leftarrow maxLabel$ 
13:   end for
14: end if
15: end for

```

Algorithm 2-2 Propagation step one

```

2:  $oldQ \leftarrow 1$ 
3: while  $state1 == False$  do
4:   for  $i$  in  $nodeOrder$  do
5:     $pi1 \leftarrow getPi1(G, i)$ 
6:     $pi2 \leftarrow getPi2(G, i)$ 
7:    if  $pi1 \geq pi2$  then
8:      $updateNodeLabelUseSimilarity(G, sDict, i)$ 
9:    else
10:      $updateNodeLabelUseEdgeWeight(G, i)$ 
11:    end if
12:   end for
13:    $partition \leftarrow getCurrentPartition(G)$ 
14:    $newQ \leftarrow modularity(G1, partition)$ 
15:    $changeQ \leftarrow abs(oldQ - newQ)$ 
16:   if  $changeQ \leq 0.01$  then
17:     $state1 \leftarrow True$ 
18:   end if
19: end while

```

Algorithm 2-3 Propagation step two

Result: Communities $P = \{C1, C2, \dots, Cn\}$
1: $labelForNetwork \leftarrow getSubNetwork(G)$
2: $sSubDict \leftarrow initializeSubSimilarityMatrix(G)$
3: $partition \leftarrow getResult(labelForNetwork)$
4: $state2 \leftarrow False$
5: **while** $state2 == False$ **do**
6: **if** $len(partition) == 2$ **then**
7: **break**
8: **end if**
9: $labelOrder \leftarrow initializeLabelOrder(labelForNetwork)$
10: $curPartition \leftarrow getResult(labelForNetwork)$
11: $maxQ \leftarrow modularity(G1, curPartition)$
12: **for** $label$ in $labelOrder$ **do**
13: $updateNetworkLabel(labelForNetwork, label)$
14: **end for**
15: $curPartition \leftarrow getResult(labelForNetwork)$
16: $currentQ \leftarrow modularity(G1, curPartition)$
17: **if** $currentQ \geq maxQ$ **then**
18: $partition \leftarrow curPartition$
19: **end if**
20: **if** $len(labelForNetwork) == 2$ **then**
21: $state2 \leftarrow True$
22: **break**
23: **end if**
24: **end while**
25: **return** $partition$

2) *Algorithm complexity analysis:* According to the step analysis of LPA-CW-S algorithm, the running time is mainly used in three stages. The first stage is the initialization stage, the complexity of identifying non-overlapping complete subgraphs is $O(k \log n)$, the complexity of initializing the label assignment to the subgraphs is $O(\lambda)$, and the complexity of initializing the similarity matrix is $O(n^2)$. The second stage is the first label propagation stage, which calculates that the Link Strength and similarity complexity of nodes are both $O(n+2m)$, the number of loop iterations is r_1 , so the complexity is $O(r_1 \cdot (n+2m))$. The third stage is the second step of label propagation, if the number of iterations is r_2 , the time complexity is $O(r_2 \cdot (n+2m))$.

Because of the influence of the network size, average degree and other factors, the final time complexity of the LPA-CW-S algorithm takes the highest value among the above three stages depending on the specific situation.

V. EXPERIMENTAL RESULTS

In this paper, the algorithm is implemented in Python3.9, and the experiment is carried out on the Windows 10 desktop with a 4-core i5@2.4GHz CPU and 16G memory. The LPA-CW, LPA-CW-S, LPA [8], LPA_m [23], LPA-S [10], CNM [24] algorithms will be contrasted on 10 real network and 9 artificial network, which have different parameter settings. This part analyzes the experimental results from the

perspectives of community division, modularity, stability, and time efficiency to verify the superiority of the algorithm proposed in this paper.

A. Datasets and Evaluation Index

1) *Real network datasets:* In this paper, four commonly used labeled network data sets, such as Karate, and six unlabeled network data sets, such as Lesmis, are selected. It contains real networks with different scales of nodes and different practical application scenarios, which can comprehensively evaluate the performance of the algorithm. Its parameter characteristic are shown in the following Table I.

TABLE I. BASIC STRUCTURAL PARAMETERS OF REAL NETWORK

Network	Reference	N	M	c	$\langle k \rangle$
Karate	[25]	34	78	2	4.588
Dolphins	[26]	62	159	2	5.129
Football	[4]	115	613	12	10.661
Polbooks	[27]	105	441	3	8.400
Lesmis	[28]	77	254	-	6.579
Jazz	[29]	198	2742	-	27.697
Sandi	[30]	674	613	-	1.819
Netscience	[31]	1589	2742	-	3.451
Facebook	[32]	4039	88234	-	43.691
Power	[33]	4941	6594	-	2.669

2) *Artificial network:* Artificial network is generated by benchmark of Lancichinetti et al. [34] LFR benchmark can generate networks with real network characteristics based personal demand. Its parameter characteristic is shown in the following Table II.

TABLE II. PARAMETER DESCRIPTION OF LFR BENCHMARK ARTIFICIAL NETWORK GENERATION

Parameter	Meaning
N	number of nodes
k	average degree
$maxk$	the maximum degree of nodes
mu	mixing parameter
$t1$	power law distribution index of node degree
$t2$	power law distribution index of community size
$minc$	the minimum community size
$maxc$	the maximum community size

μ represents the probability that the node linking with the community outside. N represents the number of nodes. The bigger the μ , the less obvious the boundary of the community and the difficult it is to detect the community structure. LFR-1 to LFR-5 are set to N to 1000, μ to 0.1 to 0.5 arithmetic increments. LFR-6 to LFR-9 are set to 2000 to 5000 arithmetic increments, μ to 0.3. Their parameter setting is listed in the following Table III.

TABLE III. PARAMETER SETTING OF ARTIFICIAL NETWORK DATASET

Network	N	k	$maxk$	mu	$minc$	$maxc$
LFR-1	1000	10	40	0.1	30	60
LFR-2	1000	10	40	0.2	30	60
LFR-3	1000	10	40	0.3	30	60
LFR-4	1000	10	40	0.4	30	60
LFR-5	1000	10	40	0.5	30	60
LFR-6	2000	10	40	0.3	30	60
LFR-7	3000	10	40	0.3	30	60
LFR-8	4000	10	40	0.3	30	60
LFR-9	5000	10	40	0.3	30	60

3) *Evaluation index*: The evaluation indicators about the community detection mainly include the following two, both of which are scientifically evaluated and have different focuses, and can comprehensively evaluate the performance of the algorithm from many aspects such as graph theory structure and real division.

Modularity, proposed by Newman and Girvan [27,35], this evaluation index does not have a priori requirements for the internal structure of the community, and only needs to count the total number of edges inside and outside the community as shown in Equation 11:

$$Q = \frac{1}{2m} \sum_{c=1}^n [2lc - \frac{dc^2}{2m}] \quad (11)$$

Among the equation, c is the community number, n is the number of communities, lc is the number of edges in community c , dc is the sum of node degrees in community c , and m is the number of all edges in the entire network. The bigger the Q value, the better the effect of community division. The value of Q ranges in $[-0.5, 1)$. When the value of Q is in $[0.3, 0.7]$, it indicates that the quality of community clustering is great.

NMI (normalized mutual information), proposed by DanonL [36] in 2005 is generally used to measure the difference between the community structure divided by the algorithm and the result of the real community division. This indicator can evaluate the accuracy and stability of the community discovery algorithm as shown in Equation 12:

$$NMI(A,B) = \frac{-2 \sum_{i=1}^{c_A} \sum_{j=1}^{c_B} N_{ij} \log(\frac{N_{ij}N}{N_i N_j})}{\sum_{i=1}^{c_A} N_i \log(\frac{N_i}{N}) + \sum_{j=1}^{c_B} N_j \log(\frac{N_j}{N})} \quad (12)$$

Among the equation, c_A represents the number of real community divisions, c_B represents the number of algorithmic community divisions, the sum of the i -th row of the matrix N_{ij} is denoted as N_i , and the sum of the j -th column is denoted as N_j . The value range of the NMI is $[0, 1]$, and the bigger the NMI value, it indicates that the detected community structure is closer to the real community division.

B. Experimental Result of LPA-CW

1) *Real network experiment comparison*: The labeled network has the real division of the community, and the algorithm performance can be compared through the Q value of the algorithm community division result and the NMI index. The unlabeled network does not have the real community division, and only the Q value can be used to compare the algorithm performance.

a) *Labeled network*: As can be seen from the modularity comparison curve in Fig. 11, the value of the division result of the LPA-CW algorithm on the labeled real network data set is generally higher than that of other comparison algorithms, indicating that the algorithm has the quality and stability of community division. The superiority is precisely because the sub-graph structure and node link strength guidance are added to the algorithm, which makes the divided community structure stronger and the clustering quality higher. By observing the comparison curve in the figure, it can be found that the NMI index of LPA-CW algorithm is not ideal, while the NMI index of LPA-S algorithm is much higher than other comparison algorithms. Comparing the Q value and NMI index of the two algorithms in Table IV, it can be seen that the LPA-CW algorithm and the LPA-S algorithm are complementary. This paper considers combining these two algorithms. The above-mentioned experimental phenomena and the label selection characteristics of label propagation algorithms provide experimental basis for the combination of algorithms.

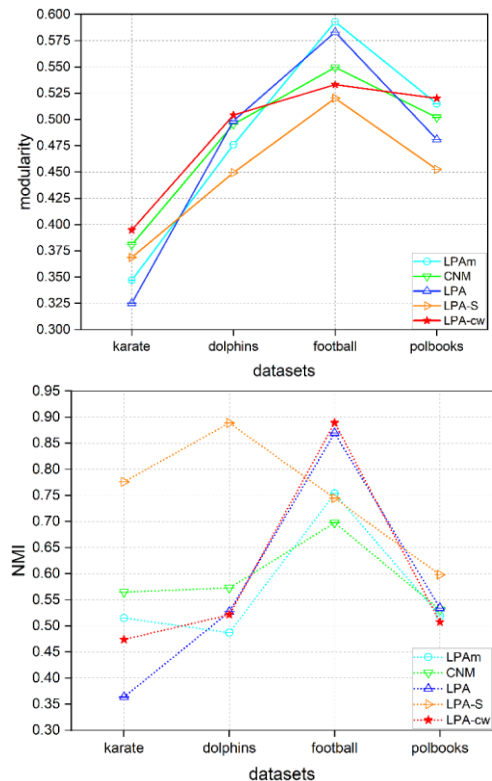

Fig. 11. Comparison of experimental results Q and NMI on labeled real network.

TABLE IV. COMPARISON OF ALGORITHM INDEX DATA ON LABELED REAL NETWORK

Network	Criterion	LPA	LPAm	LPA-S	CNM	LPA-CW(ours)
Karate	Q	0.3251	0.3470	0.3688	0.3807	0.3949
	NMI	0.3636	0.5150	0.7760	0.5646	0.4738
Dolphins	Q	0.4986	0.4760	0.4494	0.4955	0.5042
	NMI	0.5270	0.4870	0.8888	0.5727	0.5214
Football	Q	0.5831	0.5930	0.5203	0.5497	0.5331
	NMI	0.8697	0.7536	0.7447	0.6977	0.8892
Polbooks	Q	0.4811	0.5150	0.4525	0.5020	0.5201
	NMI	0.5341	0.5190	0.5979	0.5308	0.5075

b) *Unlabeled network*: At present, most networks in the real world are unlabeled networks and do not yet have real division results. Therefore, it is very important to continuously improve the modularity and time efficiency of community detection algorithms, which can be used to further guide community activities and behaviors in the real world. As shown in Table V, since CNM is based on modularity optimization algorithms, it has more advantages in modularity comparison, but it is also susceptible to the limitation of modularity resolution [37]. The real world network is complex and the data is huge. In most cases, the LPA-CW algorithm has obtained better community division results. The Q value is higher than that of similar label propagation algorithms and has higher time efficiency. It has great adaptability for large-scale network community detection.

TABLE V. COMPARISON OF Q RESULTS ON UNLABELED REAL NETWORK

Network	LPA	LPA-S	CNM	LPA-CW(ours)
Lesmis	0.5267	0.4492	0.5006	0.5312 (1)
Sandi	0.7796	0.8037	0.9313	0.8439 (2)
Jazz	0.2816	0.1719	0.4389	0.2822 (2)
Facebook	0.7369	0.6977	0.7774	0.7885 (1)
Power	0.6271	0.6012	0.9346	0.6478 (2)
Netscience	0.9074	0.8102	0.9551	0.8589 (3)

2) *Artificial network experiment comparison*: The analysis of real network experiment results has proved that compared with other classic community discovery algorithms, the LPA-CW algorithm has better community division quality and is complementary to the LPA-S algorithm. The algorithm is based on the optimization of the classic LPA algorithm, so in order to further verify the internal performance of the LPA-CW algorithm, this paper adopts the artificial network dataset of control variables (see section VA2) for R1-R5 parameters), and verify the LPA-CW through experiments compared with the LPA algorithm, whether the LPA-CW algorithm can effectively reduce the randomness and instability of label selection in the process of label propagation.

As shown in Fig. 12 and Table VI, under the same conditions, the modularity Q and the NMI index are decreasing when the mu is from 0.1 to 0.5. The greater the coincidence, the more difficult it is to identify the characteristics of the community structure. The modularity Q and NMI index obtained by the division results of the LPA-CW algorithm are mostly higher than those of the LPA algorithm. At the same time, it also solves the problem of the lower resolution of the

LPA algorithm as the community boundary in the network becomes less obvious. The improvement measures of the algorithm on the LPA algorithm have obvious effects, and the resolution of network recognition with unobvious community boundaries has been improved.

C. Analysis of Experimental Results of LPA-CW-S Algorithm

Based on the experiment in Section VB, it can be seen that the LPA-CW algorithm has a higher modularity and a lower NMI index and the LPA-S algorithm has a higher NMI index and a lower modularity, because LPA-CW-S algorithm is obtained by combining game theory model. The experiment in this section will prove whether the performance of the algorithm after the combination is improved based on both, and the advantages are complementary.

As shown in Fig. 13 and Table VII, it can be found that the LPA-CW-S algorithm that combines the two games has shown great results in terms of modularity Q value. The modularity of the Dolphins and Football datasets is higher than that of the LPA-CW algorithm. The modularity of the other two data sets is also almost close to the LPA-CW algorithm, and higher than the LPA-S algorithm, which verifies that the probability game of adding similarity and node link strength in the label propagation process is preferential. Similarly, in terms of NMI index, the LPA-CW-S algorithm that combines the two games is much higher than the LPA-S algorithm and the LPA-CW algorithm on the Football dataset. On the Polbooks dataset, the NMI has reached LPA-S algorithm level, the NMI on the other two data sets is also significantly improved compared to the LPA-CW algorithm, verifying that the subgraph merging in the second stage of the algorithm can make the final community division result better.

TABLE VI. COMPARISON OF ALGORITHM INDEX DATA ON ARTIFICIAL NETWORK

Network	Criterion	LPA	LPA-CW(ours)
R1	Q	0.8330	0.8321
	NMI	0.9712	0.9848
R2	Q	0.7100	0.7378
	NMI	0.9230	0.9878

TABLE VII. COMPARISON OF ALGORITHM EVALUATION INDEX RESULTS ON REAL NETWORK

Network	Criterion	LPA-S	LPA-CW	LPA-CW-S(GT)
Karate	Q	0.3688 (3)	0.3949 (1)	0.3718 (2)
	NMI	0.7760 (1)	0.4738 (3)	0.6772 (2)
Dolphins	Q	0.4494 (3)	0.5042 (2)	0.5126 (1)
	NMI	0.8888 (1)	0.5214 (3)	0.6932 (2)
Football	Q	0.5203 (3)	0.5331 (2)	0.5637 (1)
	NMI	0.7447 (3)	0.8892 (2)	0.9102 (1)
Polbooks	Q	0.4525 (3)	0.5201 (1)	0.5056 (2)
	NMI	0.5979 (1)	0.5075 (3)	0.5979 (1)

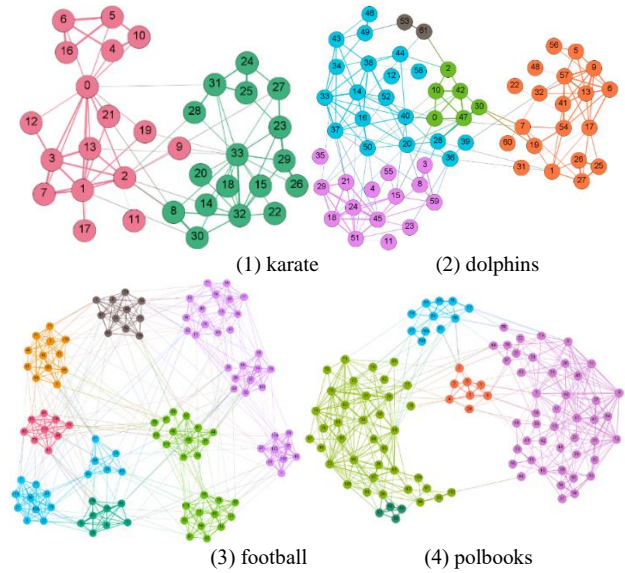

Fig. 14. Community division results of real network under LPA-CW-S algorithm.

Fig. 14 shows the visualization of the algorithm results. The network partition is complete, the clustering effect is obvious and clear, the nodes within the community are tightly connected, and the nodes between the communities are sparsely connected. From the perspective of the community structure, the division results obtained by the LPA-CW-S algorithm are reasonable and effective.

In summary, in the comparison of the overall modularity Q of the above dataset and the NMI, the game theory LPA-CW-S algorithm is more global than the two participant algorithms. The experiment proves the feasibility and rationality of the IA-GT model in this paper. It shows that game selection and subgraph merging can well neutralize the contradiction between the theoretical community structure and the actual community division, which helps to improve the accuracy and rationality of the community division results.

D. Analysis of Stability

In statistical description, variance [38] is an important equation in statistics, used to measure the stability of a set of data, the smaller the variance, the more stable the set of data, on the contrary, the more unstable the set of data. As shown in Equation 13.

TABLE VIII. COMPARISON OF ALGORITHM STABILITY DATA

	Karate	Dolphins	Football	Polbooks	Lesmis	Sandi	Jazz	Facebook	Power	Netscience
LPA-S	0.0003	0.0010	0.0004	0.0009	0.0002	0.0003	0.0012	0.0096	0.0125	0.0073
LPA-CW	0	0	0	0	0	0	0	0	0	0
LPA-CW-S	0.0002	0.0002	0.0003	0.0006	0.0001	0.0001	0.0009	0.0013	0.0078	0.0065

$$s^2 = \frac{1}{n} \sum_{i=1}^n (\bar{x} - x_i)^2 \quad (13)$$

In the above equation, s^2 represents the variance, x_i represents the modularity value during the i -th run and \bar{x} represents the average value of this group of modularity Q values.

Considering the combination of the LPA-CW algorithm and the LPA-S algorithm, this article evaluates the stability of the algorithm partitioning results. Table VIII shows the variance of the modularity Q calculated by the LPA-S algorithm, the LPA-CW algorithm, and the LPA-CW-S integrated algorithm running on the real network dataset for 17 times on average.

Table VIII shows that the stability of the LPA-S algorithm is worse than that of the LPA-CW algorithm proposed in this article. The LPA-CW-S algorithm after the game combination neutralizes the algorithm of the two participants, and the stability is improved compared with the LPA-S algorithm. As the number of nodes continues to increase and the scale of the network continues to increase, the stability improvement becomes more obvious. The above experimental results prove that through the combination of game theory framework while retaining the advantages of algorithm community division, it also reduces the instability and volatility of the algorithm.

E. Analysis of Time Efficiency

Label propagation algorithms are widely used due to their close to linear time complexity. To understand the time efficiency of the LPA-CW algorithm and the game theory LPA-CW-S algorithm proposed in this paper, Table IX shows its comparison with the comparison algorithm. The comparison of time complexity is analyzed from the perspective of orders of magnitude. The CNM algorithm is a modular optimization algorithm based on the improvement of the FN algorithm that uses the heap data structure to calculate and update the

network. It is close to linear time complexity and the LPA-S algorithm time complexity is at the square level. The LPA-CW algorithm proposed in this paper is complex. The degree is also close to linear. The game theory LPA-CW-S algorithm proposed in this paper is a three-stage algorithm and its time complexity is the highest among the three stages according to the data set size, which is between linear and square.

TABLE IX. COMPARISON OF TIME COMPLEXITY OF ALGORITHMS

Algorithm	Complexity
CNM	$O(n \log^2 n)$
LPA	$O(n + m)$
LPA-S	$O(n^2)$
LPA-CW	$O(r \cdot (n + 2m))$
LPA-CW-S	$O(n^2) / O(r_1 \cdot (n + 2m)) / O(r_2 \cdot (n + 2m))$

At the same time, in order to further verify the superiority of the algorithm in this paper, as shown in Table X, the experimental point of proof is given. Under the same condition of $\mu=0.3$, the number of nodes increases from 1000 to 5000. The time efficiency of the LPA-CW algorithm proposed is similar to that of the LPA algorithm and it is also close to linear time complexity. The LPA-CW algorithm is obviously more efficient than the CNM algorithm.

The time efficiency of the LPA-CW-S algorithm is between the LPA-CW and LPA-S algorithms, but it is much higher than the LPA-S algorithm. Although it is no longer linear complexity, it is better than some modular optimization algorithms. Algorithms such as the GN and FN algorithms are faster. At the same time, the experiments in the last two sections also prove that the algorithm in this paper has obvious advantages in the accuracy of community division. Therefore, the LPA-CW-S algorithm achieves a compromise between time cost and accuracy, and this computational complexity is acceptable in practice.

TABLE X. COMPARISON OF TIME EFFICIENCY DATA OF ALGORITHMS (s)

Network	CNM	LPA	LPA-S	LPA-CW	LPA-CW-S(GT)
LFR-3	0.8846	0.0747	14.7138	0.2753	1.7833
LFR-6	2.2111	0.1536	61.1946	0.5585	5.5451
LFR-7	3.8703	0.2533	130.5576	0.8487	10.826
LFR-8	6.6011	0.2942	332.1598	0.9365	18.5639
LFR-9	9.355	0.4159	430.2665	1.4511	30.6681

VI. CONCLUSION

In this paper, LPA-CW algorithm is proposed to reduce the initialization time of labels by identifying non-overlapping holograms. The label update strategy based on Node Link Strength reduces the randomness in label propagation, and improves the accuracy of community division results. Combined with game theory, this paper proposes an IA-GT community detection algorithm integration model to simulate individual community selection behavior in complex networks. From a new modeling point of view, this paper reasonably explains the individual's choice and the overall stability maintenance in the process of community formation. This paper also puts forward LPA-CW-S algorithm for model verification, experiments show that the contradiction between theoretical community structure and real community division can be well neutralized by game selection, which can reduce the volatility and randomness of the algorithm, and improve the time efficiency. This compromise strategy will better adapt to the real community detection application scenario.

Through the double verification of theoretical model and experimental algorithm, this paper holds that complex networks and game theory are naturally combinable. The future work is as follows:

- Optimize the balance of various evaluation indexes through game theory, and explore the combination of more community detection algorithms by combining the integrated model of community detection algorithms (IA-GT) proposed in this paper, and extend it to the field of overlapping community detection.
- Apply game theory to other directions in complex networks, such as evolutionary networks. Or it can be applied to spatio-temporal dynamic network [39] in combination with spatio-temporal location, providing solutions for more practical application scenarios.

Intelligent Brake Controller Based on Intelligent Highway Signs to Avoid Accidents on Algerian Roads

AHMED MALEK Nada, BOUDOUR Rachid

Embedded Systems Laboratory, Badji Mokhtar Annaba-University, Algeria

Abstract—Despite the considerable efforts of the Algerian authorities to reduce the high number of accidents, therefore, fatalities on the country's roads, the problem persists. To address this worrying situation, it is necessary to adopt new technologies and approaches that can assist Algerian drivers forcing them to comply with driving rules, thus putting an end to this concerned issue. This research aims to primarily assist Algerian drivers in reducing the mortality rate, which is primarily caused by speeding and poor road conditions, including outdated and inadequate road signs. To achieve this objective, a complete system consisting of two complementary subsystems: intelligent traffic signs and an interactive and smart speed limiter, has been proposed. Existing projects in this field have shown deficiencies, particularly in the context of real-time critical systems. This work offers improved precision, real-time responsiveness, adaptability to changes, and reduced infrastructure dependency compared to existing solutions. The new approach has been tested with the SUMO simulator, and a prototype based on Arduino cards has been developed approving its feasibility. However, the results obtained from this study demonstrate that the proposed system can significantly reduce the mortality rate on Algerian roads.

Keywords—Intelligent Transportation Systems (ITS); Intelligent System Adaptation (ISA); road accidents; intelligent road signalization; decision

I. INTRODUCTION

Every year, a significant number of accidents occur on roads, with speeding and unsafe road infrastructure being major factors; they are responsible for 29% and 3% of fatal road accidents respectively [1]. In 2021, Algeria experienced one of the worst road safety reports with 6195 accidents, of which 2294 were killed, equivalent to 192 deaths per month, and 9963 injured, without forgetting to mention the considerable economic losses caused by these accidents which amount to billions of dinars annually weakening insurance companies financially [2] (SAA, CAAR, CAAT, etc.). The government and authorities of road safety around the world devote considerable resources to deal with accident causes and reduce the number of fatalities on the roads. Particularly by the use of Information and communications technology for the construction of smart vehicles and infrastructures which can assist road users to respect traffic laws and enjoy safer traffic.

Several projects and initiatives are subscribed to improve safety on roads, including Intelligent System Adaptation which is known by the abbreviation ISA [3]. These systems assist

drivers in maintaining speed limits or even prevent the vehicle to overtake them on all routes and at all times. Although they have proven their effectiveness in reducing the risk of accidents and their severity (i.e., saving lives), reducing emissions of carbon monoxide (environmental) as well as improving traffic flow (e.g., a gain of substantial time for users) [4], there are still some shortcomings that engineers are endeavoring to eliminate. In addition to communication between the vehicle and the infrastructure, smart road signalization is another aspect that can improve road accident statistics, by avoiding inconsistency of current signs with the state of the road and weather conditions, especially in underdeveloped countries [5].

This work focuses on addressing the problem of inappropriate speed limits and excessive speeding, both of which contribute significantly to the high number of accidents on Algerian roads. Despite this scourge which mourns thousands of Algerian families every year, no radical solution has so far been introduced; therefore, this work lays the foundation stone for the improvement of transportation and, ultimately, significantly reducing the number of deaths on our roads. By tackling these crucial aspects, this work aims to create a safer road environment and significantly reduce the mortality rate.

What sets this work apart from others is its interactive nature, where decisions are based on direct communication between the two subsystems. By integrating advanced technologies and intelligent systems, we create a seamless interaction between intelligent traffic signs and the interactive speed limiter which provides improved precision by enabling accurate transmission of speed limit information. Real-time responsiveness ensures quick adjustments to speed limits based on road conditions. The method is adaptable to changes, allowing for prompt updates in response to temporary modifications. It reduces infrastructure dependency by utilizing wireless communication, making it more cost-effective. Overall, this method enhances the effectiveness and efficiency of the speed limitation system, improving road safety.

In addition to the introduction and conclusion, this paper will be organized into three main sections. The initial section will present an overview of existing intelligent transportation systems for safety and address the criticisms associated with them. While the second section explains our proposal to reduce the number of road accidents on roads by introducing an intelligent road sign that can make a decision on the optimal

speed and communicate it with an intelligent brake controller to monitor the vehicle speed. Our approach supposes that each highway sign allows continuous broadcasting of information such as speed limit, location, wind strength, road traffic, etc. Data is gathered and processed by the controller to assist the driver in the most efficient way possible, this may include visualizing messages, using text-to-speech technology, and applying the brakes in extreme cases. The last section, discusses the obtained results from simulation on SUMO and Arduino's prototype.

II. RELATED WORKS

A. ISA Systems

1) *Presentation of ISA systems:* Intelligent speed adaptation (ISA) is a generic term for a class of intelligent transportation systems (ITS) in which the driver is warned and/or the vehicle speed is automatically limited when the conductor moves above the authentic speed intentionally or inadvertently [5].

Essentially ISA continuously monitors restrictions on "local" speed as well as the vehicle speed and reacts in case of exceeding the limit. The type of the system depends on the reaction which can be either "passive", where the driver is warned, or "active", where an automated control over the vehicle speed is imposed due to embedded devices of ISA such as sensors of speed's knowledge.

Carsten et al [6,7,8] present a review of the various tests and estimate the effectiveness of ISA. They consider three levels of control: advisory, voluntary (active but the driver can turn it off), obligatory (active all the time), and three types of speed limits: fixed, variable and dynamic. In a fixed system, there is one speed per area, which is unchangeable, in the dynamic system; we opt for a fixed speed, suitable for several variables, such as weather conditions or unexpected events. In a variable system, an individual or an entity is responsible for the decision-making and taking actions (e.g., road construction).

For comparison, based on recorded data from the test of a passive ISA system working with fixed speed limits, Regan [9] estimated that the system can reduce fatalities by 8% and serious injury accidents by 6%. However, the author noted that they were likely to be underestimated.

2) *Technologies used in ISA systems:* All ISA systems are based on the knowledge of the authentic speed limit. This can be achieved through the use of the mentioned function according to different existing technologies, the main ones are:

- GPS Global Positioning System: GPS technique is based on the localization of the vehicle and the extraction of the related speed from the database of "speed cards", that are embedded in the vehicle [10,11,12].

- Despite its popularity, the GPS is submitted to a certain number of fundamental issues related to the precision of determining the position and the construction of the database
- RFID - The Radio Beacons: Radio beacons function by transmitting data to a receiver integrated into the vehicle. Tags emit continuous data, and the receiver captures it at each passage [13,14,15].
- Unfortunately, these systems can be used only for slow vehicles. For vehicles traveling at high speed, it is difficult to collect and process data in real-time, this is in addition to the constraint of the vehicle that must be close to the transmitter to determine the speed limit.
- Image Recognition: This system uses a camera mounted on the vehicle to capture continuous images on the road. The image is processed to find if there is a traffic signal. Once the sign is found, another algorithm is used to define the pattern of the image to recognize it. Following the recognized symbol the ISA system reacts.
- The major constraint of this system is the lack of recognition combined with the imprecision of items, especially during unfavorable weather conditions (heavy rain). Additionally, even in relatively simple situations, these systems are incapable of dealing with fixed obstacles reliably which can lead to erroneous conclusions [16,17,18].
- Dead Reckoning: Dead Reckoning (DR) uses a mechanical system linked to the drive unit to predict the path taken by the vehicle [19,20,21].
- This system requires the establishment of multiple sensors on the vehicle, which can be expensive. However, its reliability and accuracy remain uncertain since the user may at any time deviate from its originally estimated road based on information that can sometimes be wrong.

B. Intelligent Road Signs

The design developed on intelligent road signs is intentionally redundant because it currently serves research purposes.

We can classify technologies used to improve the road signs' deployment into:

- Deep learning methods: Given the emergence of deep learning, several works have been registered using it. This work is known as ATDR for Automatic Traffic Sign Detection, the ATDR is mainly used to recognize and classify the different forms of road signs on vehicles. They are mainly used to improve the driver's attention to avoid possible accidents. [22,23,24,25]

- Generally, these methods are inefficient in unfavorable weather conditions, reduced brightness. Furthermore, they may not be effective in dealing with speeders.
- Google Street View methods: these methods are used to solve some problems encountered using deep learning. Based on Google Street View (GSV) as the source image and database of road signs with relevant coordinates. [26].
- This promising approach unfortunately inherits large database and precise location problems, besides, they may not have the ability to deal with the speeders.
- In addition to the cited problems of the two aforementioned methods, neither of them takes into consideration the regulations during climate change or other incidents on the road.
- Systems multi-agent: this solution uses an agent architecture, based on virtual sensors at the agent's body, to perceive the environment [27]. This solution inherits the problems of multi-agent systems and only focuses on the case of fog.

III. SYSTEM DESCRIPTION

A recent study was carried out to determine the main causes of road accidents in Yunnan Province mountain in China [28], which shows that despite complying with the speed limit the accident rate is still high. This raises the question of why this is the case.

Analysis of the prior study as well as the figures obtained from the road authorities in Algeria leads us to the realization that several factors including unfavorable weather conditions, peak hours, incidents, light, and the experience of the driver, must be taken into consideration. This eventually motivates us to believe that it is imperative to work quickly towards a radical solution taking into account at least the causes and aggravating factors of road accidents. Aiming to mitigate the problems previously mentioned, we suggested an intelligent system composed of a speed limiter and intelligent road signs communicating directly (I2V communication) through two devices, one installed on the panel and the other embedded in the vehicle.

This current solution can be implemented initially in high-risk areas before being generalized for the entire Algerian territory.

A. System Structure

The proposed system will be divided into two main parts:

1) *Vehicle*: The first part embedded in the vehicle is mainly composed of a communication unit: which is represented by a reception antenna of the signal that ensures the communication between the vehicle and the road sign; a decoding unit: which decodes the received signal, a treatment unit: which is made up of an ECU (Engine Control Unit) and a speedometer, being used to operate the speed limiter or the

brake depending on the situation in which the vehicle is in (see next section). A limitation system: which is made up of a fuel injector and a brake, and it is responsible to decelerate the vehicle by acting either on the fuel's flow rate injected from the combustion room of the vehicle or on the brake pedal or even on both of them.

Besides the components described previously and taking into account the importance of human-machine interactions in the transport field, our system is equipped with a luminous indicator and a display screen.

2) *Infrastructure*: The second part has been installed on traffic signs, which can communicate with a vehicle that is equipped with a limitation system. The sign panel includes a location unit: which is used to locate the position of the sign (in front of a school, on motorways, in built-up areas, on mountains, and so on.). Generally, to recover the coordinates, the location unit uses GPS (Global Position System). It includes also Sensors: for gathering information from the external environment such as (sensors for snow, temperature, rain, fog, pavement condition, and camera). A communication unit: represented by a unidirectional transmitting antenna covering a distance of at most 300 m, which serves to broadcast the suitable speed. A Decision unit: this is the main component responsible for processing the collected information and performing the necessary calculations to obtain the required speed. A coding unit: to code the limit speed as a signal and transmit it to the vehicle. The energy source is necessary for the functioning of the system, it can be obtained from public lighting poles, solar energy, or others.

B. System Architecture

Fig. 1 includes all the components of our system along with the various possible interactions between them. These interactions are denoted by numbered arrows.

Firstly, the system starts collecting initial information concerning the road's nature, road number, and incident (for example works, collision, congestion), using GPS coordinates to define the initial speed (in normal situations). After that, the installed sensors gather information about weather and road conditions (arrow 1) and then transmit it to the decision unit, the decision unit treats all the collected data so that the system can determine the appropriate speed (arrow 2), then it codes the signal (arrow 3) before displaying it in real-time, and sends it via the antenna to the road users (arrow4). Secondly, the vehicle antenna receives the information and transmits it to the engine control unit (ECU), which decodes the information and compares it to the vehicle's speed (arrow 5).

Lastly, if the vehicle's speed is higher than that of the sign (comparison effected by arrow 6), the ECU operates the fuel injector to reduce the speed (arrow 7); in other situations, for example, downhill, the fuel injector only is not enough to reduce the speed, we need the intervention of the ECU on the brake.

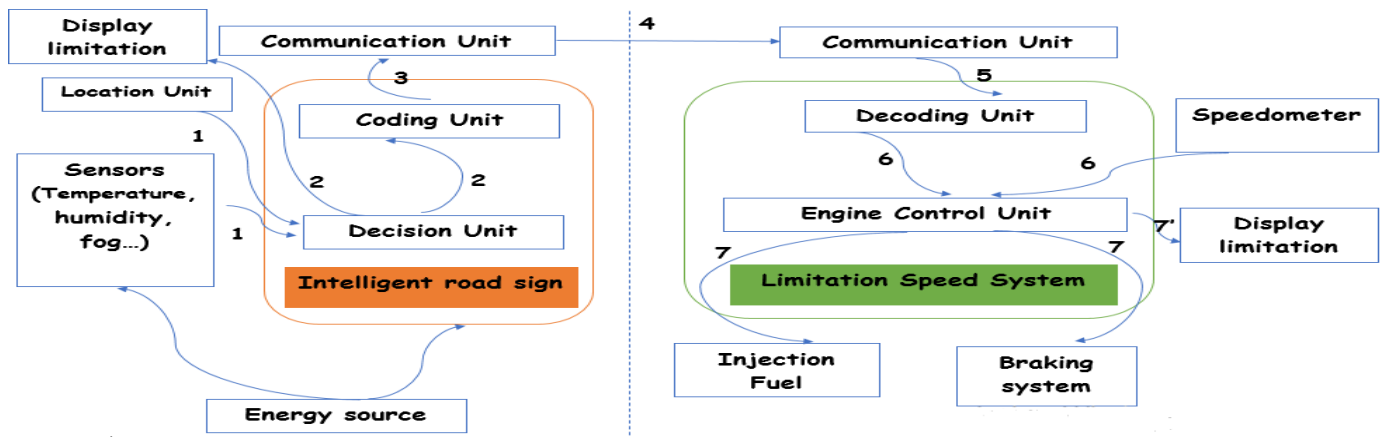

Fig. 1. Proposed system's components and communication.

Information is displayed in real-time on the vehicle's console (Screen LCD) and a beep sound will be played to alert the driver (arrows 7).

C. General Functioning

1) *Operating scenarios on vehicles:* Before implementing the proposed system, we surveyed to know people's opinions about autonomous vehicles and especially voluntary and obligatory ISA systems.

On a population of 820 Algerians, we obtained these results summarised by the histogram shown in Fig. 2.

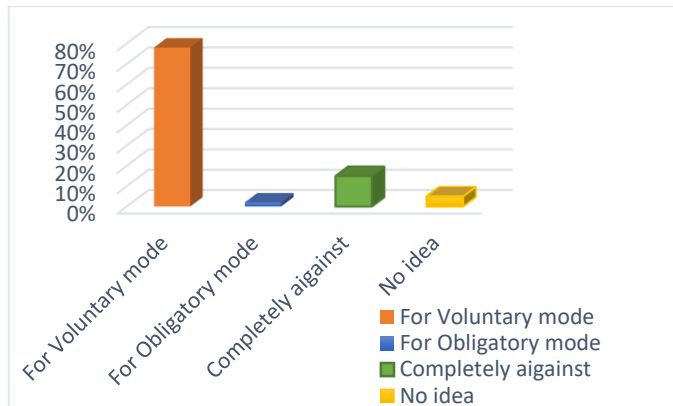

Fig. 2. Histogram representing survey results.

- Based on the survey results, we proposed two operating processes: the half-automatic mode which is an informative mode. It is used to alert the driver by a sonar or luminous signal if the maximum authorized speed is exceeded, and the limiter mode which plays the role of a reducing speed device that prevents vehicles from exceeding the authorized speed.
- So once the system is started, the half-automatic mode is required by default since it is a familiar mode with the usual operation of the vehicle and it is controllable by the driver, who can change the mode constantly and at any time.
- Once we are in the half-automatic mode, if the speed is higher than the road regulation by 10 km/h, the system will automatically switch to automatic mode (forced

deceleration) to decrease the risk factors of serious accidents. This decision was taken based on the following findings: 50% of the drivers operate above the authorized speed limit [29]. Generally, the drivers exceed the speed limit lower than 20 km/h, and a number of them exceed the limits of more than 20 km/h, which does not measure the incurred serious risks at all, nor the consequences caused by these excesses. Consequently, it is estimated that approximately 10% of the victims could be prevented if most motorists who usually drive at speeds higher than 10 km/h were encouraged to respect limitations. Approximately 20% of the victims could be prevented if all the vehicles respected the speed regulations.

- we have also taken into consideration the scenarios that may encounter our system, which include:
- First scenario: (highways, tunnel):
- At the entrance of a tunnel or on the exit of a highway, we generally notice the presence of an indication for a specific way (Fig. 3). So, to support this specificity we can use a directional antenna at the entrance of the tunnel at the exit of the highway.

Fig. 3. Specific way limited by 80 km/h.

- Second scenario: (intersections):
- We locate the presence of an intersection by the presence of directional signs or priority of a street sign, pedestrian crossings, and traffic lights. So, the sign read transmits the relative information to the taken road. It carries also information about nearby crossroads.
- Fig. 4 illustrates an intersection, where the driver can continue on the same path, or change direction. It is supposed that the white car is on the way which RW320 A, the red car is on the way to RN48B and the yellow one is on RN48A. The four panels carry information about the roadways of the intersection: if the white car turns left through the detection's sensors to determine the direction of the path, the system saves information RN48B and ignores the others.
- The vehicle can change directions by updating its information with those received from the panel.

Fig. 4. An intersection.

- Third scenario: (different speed limit according to the class of vehicle):
- Fig. 5 illustrates the situation. In this case, we add information containing the class range of the vehicle (example: A: for motorcycles, B: for light vehicles, and C: for heavy vehicles), we also include the same class range information of the vehicle in the signal code for the speed limit.
- When the vehicle receives data, the system compares the category and decides which one concerns it.

Fig. 5. Different speed limits according to the vehicle category.

2) *Operating scenarios on infrastructures:* In this subsection, we are going to present the architecture of the proposed decision unit, including the different components involved in its functioning: We suggest using a hybridized CBR method to the AHP method to get an optimal limitation by using the approach described in [30], the decision can be improved by adding an order of priority to the determining factors. we first apply the CBR process during the calculation of the similarity value after, we add the weights and then, we apply AHP to have a more reliable decision.

The different proposed speeds in studied cases are proposed according to Algerian norms.

IV. RESULTS, ANALYSIS, AND DISCUSSION

This work can be divided into two main parts:

The first clarified the process of detecting the optimum speed taking into consideration: the geometry of the road, the road surface, the weather conditions, the road traffic situation.

The figure below (Fig. 6) illustrates and summarizes the detection of the optimal speed process.

Fig. 6. Process to have the optimal speed.

Initially, we ensure that the panel is placed accurately by utilizing GPS technology, which provided us with the Latitude and Longitude coordinates, we have used Google Static Maps API to capture a personalized image of the geographical map of the location.

The card is retrieved in general, and to determine its type and style. For this, we have used the following types of cards, see Fig. 7:

- Terrain which specifies a physical relief map image, displaying topography and vegetation, this type of map was used to detect whether the location is a built-up area.
- Roadmap which specifies a standard road map image to detect the type of the road (a turn, a straight road).

Fig. 7. Terrain (left) and roadmap (right).

- After retrieving the necessary images, we proceed to the image processing phase:
- The Terrain type image: it is a two-color image where one color is for space and the other one is for man-made structures. After the indexing of the image, we obtain a matrix of 300x300 which contains two possible values 0 or F.
- 0 for the structures and F in hexadecimal for the void if the count of pixels containing the value 0 in the matrix exceeds a certain threshold, the location is then located in an Agglomeration zone, otherwise, it is considered to be located outside the built-up area.
- The Roadmap type image: it is a two-color image. A color for the void, and another for the roads, after the indexing of the image we obtain a matrix of 300x300 which contains two possible values: 0 for the roads and F in hexadecimal for the void. (Step 1. A).

To determine the shape of the road a form recognition is necessary. To expedite this process, we have created a database of 200 images containing roads, each with the appropriate speed according to Algerian regulations. Then we calculated the distance between the indexing matrix of the Roadmap type image and the matrices of our pre-indexed images stored in the database (Step1.B).

The recognition of the shape of the road is done by calculating the distance (color/location) between each image in the base and the image retrieved from the road.

The base image that has the smallest distance from the retrieved image represents the closest image. Each image in the base has an associated proposed speed, which is applied to the

road that has the smallest distance from the base image; it is called the preliminary speed (Step1.D).

After completing the image processing phase by calculating the preliminary Speed as a result of the previous phase, the next step is to calculate the optimal speed. This is achieved by using the values obtained from sensors and environment by applying the hybridized algorithm CBR-AHP (Step 2. A). At the end of this step, we have the optimum speed.

The second main part focuses on how the vehicle receives the final optimal speed, as shown in Fig. 8. The process involves transmitting the speed from a transmission antenna to a receiving antenna on the vehicle. Once received, the speed is limited by a speed limiter system integrated into the car, the steps mentioned above are carried out by information processing software systems. The next figure summarises the process.

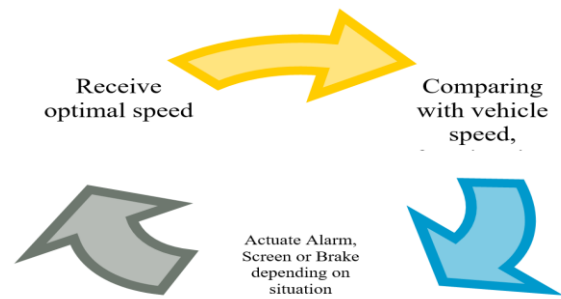

Fig. 8. Process to actuate screen, alarm, or brake depending on the situation.

To validate our approach, we opted for a simulation with SUMO (Simulation of Urban Mobility), which is a widely used traffic simulation software that enables the modeling and analysis of transportation systems in urban areas. By utilizing SUMO, researchers, and transportation planners can simulate real-world scenarios and assess the impact of different factors on urban transportation systems [31].

The following figure (Fig. 9) is an extract of Annaba's street roads in Algeria. The cars in green are vehicles respecting the limitation, those in light blue operate under the semi-automatic mode, while those in dark blue do not comply with the law, therefore the automatic mode activates automatically.

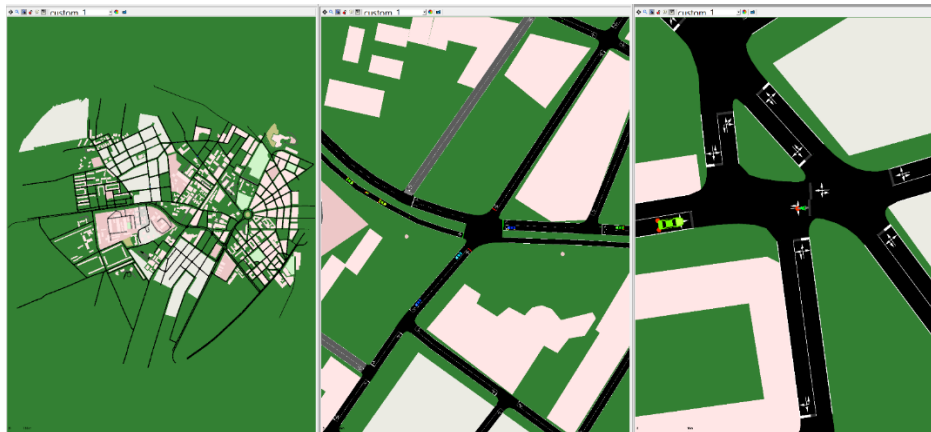

Fig. 9. Annaba's street roads-Algeria from SUMO simulator.

To check our method once again, we opted for a simulation of the same environment with the same conditions, and the same number of vehicles and pedestrians twice. The first time, the vehicles circulate in a random way not subjecting to any regulation obligatorily (like the actual situation in Algeria). However, in the second simulation, vehicles were forced to submit to the principle previously proposed and described by this article.

The results of the collisions that occurred during the two simulation runs are summarized in Table I.

Based on the obtained results, it is evident to notice that a significant decrease in the number of crashes has been observed, with the rate dropping from 33.01% during the first simulation to 19.23% in the second one. This remarkable drop can be mainly attributed to the change in the method of vehicle circulation, where, they were forced to respect the regulations, which seems encouraging. The findings prompted us to create a prototype with Arduino cards, implementing the functionalities of our desired system, to prove its feasibility.

The next illustrations represent the realized prototype. For this, we used several modules including Driver motor L293D, which is used to activate the rotation motor, Bluetooth HC-05 module, which is used to assure the communication between the panel and the vehicle.

Fig. 10 illustrates the prototype produced, part A represents the vehicle equipped with an LCD screen to display the speed and the operating mode; a Bluetooth to receive the speed of the panel.

Part B illustrates the smart panel equipped with several sensors and electronic components such as GPS, water sensor, light sensor, and temperature sensor. It describes the external conditions that can play a role in the decision process for example day or night, sunny or rainy.

The realized prototype controls the speed under the two modes described above.

In summary, despite being in the modeling and prototyping stage, the approach described in this paper has a lot of potential and yields encouraging results.

The originality of this work lies in the creation of a complete speed control system that encompasses both traffic signs and vehicle's speed limiter. This distinguishes it from previous works on smart panels in many aspects. First, it is more comprehensive, incorporating all the Algerian traffic standards (Each country can adapt the model according to its standards) as well as all the environmental factors leading to the change in speed. Without forgetting to mention that this hardware solution shows great potential compared to software solutions (such as a method with multi-agent systems) since ultimately it is a critical system that does not support a long waiting time.

TABLE I. RESULTS OF SIMULATION

	FISRT SIMULATION	SECOND SIMULATION
Pedestrians number	99	99
Vehicle number (Cars, Bus, Motorcycles, Bicycle)	1522	1522
Vehicle collision with pedestrians	12	7
Vehicle collision with another vehicle	318	192
Percentage of collisions with pedestrians	12,12%	7,07%
Percentage collisions with another vehicle	20,89%	12,16%
Total percentage collision	33,01%	19,23%

Fig. 10. Prototype with arduino cards.

Second, all existing ISA systems are based on the knowledge of the authentic speed limit often determined using GPS technology as we mentioned previously in Section II, which is due to its low cost and widespread availability. However, despite the popularity and functionality of GPS, there are fundamental problems with this system, most of which are related to the accuracy of the determined GPS has inherent inaccuracies due to uncertainties in satellite ephemeris, propagation errors, timing errors, multiple signal propagation paths, and reception noise, which can be particularly problematic in areas with a high-speed road adjacent to lower-speed residential streets. Additionally, GPS signals can be completely blocked in tunnels or under large structures. Updating the database with new road works data also presents a significant challenge. These issues highlight the need for a more comprehensive and robust speed control system, which the proposed hardware solution aims to address.

This work offers a mechanical solution that addresses the challenges faced by existing methods combining two subsystems; it provides a flexible, intelligent, and complete system that effectively addresses the problem of speeding. This new approach overcomes the limitations of existing methods, such as the inaccuracies and constraints of GPS, and offers a more reliable and adaptable solution. Overall, this work promises to provide a coherent and effective solution to the problem of speeding on the road.

TABLE II. COMPARISON WITH RELATED WORKS ON ISA SYSTEMS

Solution	Advantages	Disadvantages
GPS	<ul style="list-style-type: none"> - Access to precise and global positioning data. - Wide availability of map data. 	<ul style="list-style-type: none"> - Dependency on a stable GPS signal. - Limited accuracy in dense urban areas.
RFID	<ul style="list-style-type: none"> - Access to specific information from traffic signs. - Precise use of speed limits on specific road segments. 	<ul style="list-style-type: none"> - Difficult to collect and process data in real-time for vehicles traveling at high speed. - Vehicle must be close to the transmitter
Image processing	<ul style="list-style-type: none"> - Utilization of onboard cameras or existing sensors. - Adaptability to different types of traffic signs. 	<ul style="list-style-type: none"> - Dependency on visibility conditions and image quality. - Requirement for sufficient computational power for real-time image processing.
Dead reckoning	<ul style="list-style-type: none"> - Less dependency on external signals. 	<ul style="list-style-type: none"> - Limited accuracy over time and distance traveled. - Accumulation of measurement errors. - Need for regular calibration and recalibration of sensors to maintain accuracy.
Antenna communication	<ul style="list-style-type: none"> - Improved precision of speed limit information. - Real-time responsiveness for speed limit updates. - Adaptability to temporary changes in speed limits. 	<ul style="list-style-type: none"> - Dependency on reliable wireless communication. - Need for integration with existing traffic signs.

TABLE III. COMPARISON WITH EXISTING WORKS ON PANELS

Solution	Deep learning	Google Street Map	multiagent system	hardware-based
Real-time capabilities	Limited	Limited	Limited	Strong
Speed of processing	Fast	Fast	Fast	Fast
Adaptability	Moderate	Moderate	Moderate	High
Accuracy	High	High	Moderate	High
Robustness	Moderate	High	High	High

For better readability and by comparing the method used here with the existing ones, the tables (Table II and III) summarize the advantages and disadvantages of all approaches and techniques in the two subsystems.

V. CONCLUSION

This work falls under the continuity of seeking works to improve road traffic and reduce the amount of mortality. We are mainly interested in the problem of traffic accidents due to speeding. Despite this scourge that touches thousands of Algerian families every year, no radical solution has so far been introduced, therefore this work lays the foundation stone for the improvement of transport and the significant reduction in deaths on our roads. Based on a new system ISA, which communicates directly with the smart road signs, the proposed system has been simulated with SUMO, and a prototype is realized with Arduino to prove its validity.

Several perspectives could be considered to extend this work. We cite without limitation, the realization of a physical system, which will highlight our expectations and estimations.

Additionally, integrating radar functionality into the smart panel could increase its productivity and effectiveness, ultimately leading to a solution for addressing speeding drivers.

Experimentation on Iterated Local Search Hyper-heuristics for Combinatorial Optimization Problems

Stephen A. Adubi¹, Olufunke O. Oladipupo², Oludayo O. Olugbara³

Computer and Information Sciences Covenant University, Ota 112104, Ogun State, Nigeria^{1,2}
MICT SETA 4IR Center of Excellence, Durban University of Technology, Durban 4001, South Africa³

Abstract—Designing effective algorithms to solve cross-domain combinatorial optimization problems is an important goal for which manifold search methods have been extensively investigated. However, finding an optimal combination of perturbation operations for solving cross-domain optimization problems is hard because of the different characteristics of each problem and the discrepancies in the strengths of perturbation operations. The algorithm that works effectively for one problem domain may completely falter in the instances of other optimization problems. The objectives of this study are to describe three categories of a hyper-heuristic that combine low-level heuristics with an acceptance mechanism for solving cross-domain optimization problems, compare the three hyper-heuristic categories against the existing benchmark algorithms and experimentally determine the effects of low-level heuristic categorization on the standard optimization problems from the hyper-heuristic flexible framework. The hyper-heuristic categories are based on the methods of Thompson sampling and iterated local search to control the perturbation behavior of the iterated local search. The performances of the perturbation configurations in a hyper-heuristic were experimentally tested against the existing benchmark algorithms on standard optimization problems from the hyper-heuristic flexible framework. Study findings have suggested the most effective hyper-heuristic with improved performance when compared to the existing hyper-heuristics investigated for solving cross-domain optimization problems to be the one with a good balance between “single shaking” and “double shaking” strategies. The findings not only provide a foundation for establishing comparisons with other hyper-heuristics but also demonstrate a flexible alternative to investigate effective hyper-heuristics for solving complex combinatorial optimization problems.

Keywords—Combinatorial optimization; heuristic algorithm; heuristic categorization; local search; Thompson sampling

I. INTRODUCTION

Combinatorial optimization problems (COPs) are practically challenging because of the different characteristics of each problem domain and multiple conflicting constrictions to be adequately resolved. They are intrinsically non-deterministic polynomial-time hard problems with no single method that can generally outperform others across varying problem instances [1]. Due to the intrinsic hiccups of the earlier heuristic, and meta-heuristic methodologies, hyper-heuristic has emerged as a feasible search methodology for solving multifarious COPs occurring in varying practical

applications [2]. It has been effectively applied in multiple application domains, including scheduling [3], [4], timetabling [5], routing [6]–[8], software engineering [9], [10], and manufacturing [11]. In general, hyper-heuristics provide two different types of search space, which are low-level heuristics (LLHs) and acceptance mechanisms. However, how to select LLHs and combine them with an acceptance mechanism to realize an effective strategy for solving different COPs is particularly challenging.

In recent times, different methods, including machine learning have been investigated to improve the performance of hyper-heuristic optimization strategies. In this paragraph, we briefly review some related works that have attempted to improve the performance of hyper-heuristics. The Q-learning was utilized to select LLHs for a multi-objective route planning problem [12] and to choose an action in solving the interaction testing problem [9]. Deep Q-network [6] was applied as a heuristic selection mechanism to solve two routing problems from the library of hyper-heuristics flexible (HyFlex) [13]. In addition, Q-learning was applied to solve six problems from the HyFlex library by learning the pair of selection and acceptance mechanisms that are most suitable for an instance of a given problem [14]. Thompson sampling (TS) learning based on the selection of LLHs was recently introduced for solving COPs [15]–[17]. Moreover, TS has been applied to automatically configure the perturbation behavior of iterated local search (ILS) to solve six HyFlex COPs [18]. The evolutionary-based ILS hyper-heuristic was recently designed and tested on the extended HyFlex COPs to provide further evidence of the necessity for more categories of algorithms with improved perturbation strength [19].

A new perturbation strategy for ILS was proposed in [20] to solve the problems of pseudo-Boolean optimization where decision variables are perturbed to improve a local search strategy by maximizing the distance between solutions and maximizing the fitness similarity. An ILS algorithm was proposed in [21] for solving the problem of aircraft landing based on a search methodology that successively invokes a local search procedure to find a local optimum solution. The authors used a perturbation operator to modify the current solution to escape from the local optimum and provide a new solution for the local search procedure. The fair-share iterated local search (FS-ILS) [22] is a simple state-of-the-art selection hyper-heuristic that uses a conservative restart condition to prevent restarts, and only restart when a method is stuck and

enough time is available to attain a solution of similar quality. The work [23] presented an efficient algorithm for solving the problem of aircraft landing based on a mechanism that hybridizes the ILS and simulated annealing (SA) algorithms to find a feasible aircraft scheduling solution within the range of target time. The sequence-based selection hyper-heuristic inspired by a hidden Markov model was proposed in [24] as a general purpose hyper-heuristic for solving cross-domain COPs. However, the authors conceded that the performance of a selection hyper-heuristic may vary depending on the choice of the LLHs and that not all the heuristics contribute to the improvement of a candidate solution during the search process unless they are applied in a combination with sequences of heuristics.

Despite myriads of research publications on hyper-heuristics, the published results on cross-domain optimization algorithms still need further improvement. The confines shown by the existing algorithms for solving different COPs have provided a unique opportunity to improve the performance of a hyper-heuristic across different problem domains. The findings from the literature have generally suggested that identifying the right intensity of perturbation operations in ILS is challenging but warrants further investigation [20]. The focus of the present work is to extensively experiment with three categories of the TS-ILS hyper-heuristic [18] imbued with different perturbation behaviors and compare their performances against the existing benchmark algorithms on HyFlex COPs. The testing of a hyper-heuristic algorithm on standard problems with varying characteristics will enable a meticulous comparison of its generalization capability. Since an ILS-based hyper-heuristic is potentially targeted toward solving numerous COPs, an efficient strategy for determining its proper perturbation behavior on a specific problem is paramount to the success of ILS methodology [7], [21].

The overarching objectives of the present work are threefold. To describe three categories of the TS-ILS hyper-heuristic that combine low-level heuristics with an acceptance mechanism for solving standard HyFlex COPs. To experimentally compare the three categories of the TS-ILS hyper-heuristic against the existing benchmark algorithms on the standard HyFlex COPs. To experimentally determine the effects of LLHs categorization on the standard HyFlex COPs. The remaining parts of the paper are fleetingly organized as follows. Section II describes the TS-ILS hyper-heuristic with three categorizations of LLHs. Section III presents the experimental results of comparing the three categories of the TS-ILS hyper-heuristic against the existing benchmark algorithms on the standard HyFlex COPs. Section IV examines the effects of LLHs categorization on the standard HyFlex COPs. Section V discusses the study results and highlights the potential areas for further improvement. The paper is ultimately concluded in Section VI by explicating the category of the TS-ILS hyper-heuristic that recorded a good balance between “single shaking” and “double shaking” configurations.

II. THOMPSON SAMPLING ITERATED LOCAL SEARCH

Thompson sampling iterated local search (TS-ILS) hyper-heuristic is a probabilistic learning of profitable perturbation operations for a problem instance [19]. The hyper-heuristic augments the functional capabilities of TS and ILS to control the perturbation behavior of ILS. It selects LLHs and accepts or rejects a solution using the FS-ILS [22]. The local search phase of the hyper-heuristic is triggered after a perturbation process to improve the solution obtained from the perturbation stage, while the resultant solution is then considered for acceptance. There are six configurations in the $\text{config} = \{0, 1, 2, 3, 4, 5\}$ set and each one is an integer representation of a perturbation operation. Table I defines each element of a perturbation configuration set of length n , where the value of n was taken to be 6 in the present work.

TABLE I. PERTURBATION OPERATIONS OF THE TS-ILS HYPER-HEURISTIC

Value	Operation
0	Perturb with Mutation LLH + Mutation LLH (Mut + Mut)
1	Perturb with Mutation LLH + Ruin-Recreate LLH (Mut + RR)
2	Perturb with Ruin-Recreate LLH + Mutation LLH (RR + Mut)
3	Perturb with Ruin-Recreate LLH + Ruin-Recreate LLH (RR + RR)
4	Perturb with Mutation LLH only (Mut)
5	Perturb with Ruin-Recreate LLH only (RR)

The TS-ILS hyper-heuristic algorithm learns promising perturbation operations for the ILS by splitting the mutation (Mut) and ruin-recreate (RR) heuristics into two distinct entities as in the first two lines of Algorithm 1. The two vectors α and β are respectively representing the success and failure tallies for the perturbation configurations in the config set. The pair of elements in the two vectors at the same corresponding positions respectively correspond to the success and failure counts of the options in the config set. The initial solution for the problem instance being solved is generated. The resultant solution is then used to initialize the current solution S_0 and the best solution found so far (S_b). The Thompson sampling procedure generates the utility values for the elements of the config set based on tallies that are stored in the vectors α and β by sampling from a Beta distribution. This phase of the TS-ILS hyper-heuristic algorithm decides which of the perturbation operations that are represented in the config set is to be invoked. These perturbation operations can be seen as the alternative operators to be selected in the bandit problem. The corresponding first element, α_0 and β_0 of the α and β vectors are respectively passed as parameters to the sampling module to generate the utility value for the first element in the config set. The pseudocode for the TS-ILS hyper-heuristic algorithm is given by the following **Algorithm 1**.

Algorithm 1: TS-ILS Hyper-heuristic

```
 $M \leftarrow \{m_1, m_2, \dots, m_j\}$   
 $R \leftarrow \{r_1, r_2, \dots, r_k\}$   
config  $\leftarrow \{c_1, c_2, \dots, c_n\}$  ▷ Line 3  
 $\alpha \leftarrow \{0, \dots, 0\}$   
 $\beta \leftarrow \{0, \dots, 0\}$   
 $S_0 \leftarrow \text{generateInitialSolution}()$   
 $S_b \leftarrow S_0$   
while ( $\neg$ stopping_condition) do  
     $\Phi = \{\phi_1, \dots, \phi_i\} \leftarrow \text{generateUtilityValues}()$   
    select i from config:  $\phi_i$  maximizes  $\Phi$   
     $S' \leftarrow \text{perturb}(S_0, i)$   
     $S'' \leftarrow \text{localSearch}()$   
    if ( $S''$  is accepted) then  
         $S_0 \leftarrow S''$   
    end  
    if ( $S'' < S_b$ ) then  
         $\alpha_i \leftarrow \alpha_i + 1$   
        updateLS()  
        updateParam()  
    else  
         $\beta_i \leftarrow \beta_i + 1$   
    end  
    updateLLH()  
end
```

Studying the effects of LLHs categorization on the standard HyFlex COPs is paramount to the present work to determine the most appropriate algorithm for solving cross-domain COPs. Thus, TS-ILS1, TS-ILS2, and TS-ILS3 hyper-heuristics constitute three categories of the TS-ILS hyper-heuristic algorithm. The TS-ILS1 uses the subset {4, 5} and perturbs a solution once before intensification. The TS-ILS2 uses the subset {1, 2, 4, 5} and has been featured in the previous study [18]. The TS-ILS3 uses the entire set {0, 1, 2, 3, 4, 5} and all the options presented in Table I during the perturbation stage. The TS-ILS1 can only perturb a solution once before the intensification (single shaking) phase while the last two categories can perturb a resolution twice before the intensification (double shaking) phase. These differences are enforced by line 3 of Algorithm 1 [18] which has been extended in this study to any set of perturbation configurations. The categorizations have significantly affected the TS-ILS hyper-heuristic for solving diverse COPs. This is because the different perturbation strengths determine the effectiveness of the ILS-based hyper-heuristics [7], [20], [23].

The element of the set config that maximizes the utility values in Φ is selected, and the corresponding perturbation operation is carried out as designated in the next two lines. During the perturbation phase, the *speedNew* selection mechanism [14], [22] is employed to choose a given candidate LLH selected by the TS procedure. For example, if the selected configuration is 2, the selection mechanism chooses a perturbative LLH from the ruin-recreate set and applies it to a solution. The resultant solution is further perturbed by selecting and applying a perturbative LLH from the mutation set. The intensity of mutation and the depth of search are two parameter

archetypes in the HyFlex framework for parameterizing the use of LLHs [13]. A parameter value is chosen within the {0.0, 0.1, ..., 1.0} set of 11 values using a roulette-wheel procedure for the selected LLH to be analogously parameterized as in [24]. The local search module of the TS-ILS hyper-heuristic [18], [19] is triggered on the resultant solution to produce another solution (S''). The next operation decides if S'' is to be accepted to replace the current solution S_0 based on the accept probabilistic worse (APW) acceptance mechanism [14], [22].

The success tally (α_i) of the i element of the config set invoked in the current iteration is incremented only if the solution generated is strictly better than the best solution (S_b) found so far, otherwise, the value of β_i is incremented. This update scheme has enabled the TS-based probabilistic learning algorithm to adjust its preference according to the observed rewards of the alternative actions to be taken at every iteration. The function updateLLH() updates the parameters of the perturbative LLHs applied based on the speedNew selection mechanism. This update scheme does not apply to the local search heuristics and further details of how it is carried out can be found in [22]. The function updateLS() updates the data structures of the local search heuristics employed for the local search phase of the ILS hyper-heuristic. Finally, the function updateParam() updates the utility matrix used by the parameters of parameterized LLHs from the local search, mutation, and ruin-recreate operations. The entry for the parameter value selected by a roulette wheel procedure is updated after the iteration. The selection and update of values for the parameterized LLHs are analogous to the implementation in [24].

III. EXPERIMENTAL RESULTS

Three categories of the TS-ILS hyper-heuristic were implemented on an Intel i5-3340M CPU computer with random access memory of 8 gigabytes and a 2.70 gigahertz clock speed. The TS-ILS1, TS-ILS2, and TS-ILS3 hyper-heuristics were tested on the problem instances of Boolean satisfiability (SAT), Bin packing (BP), Personnel scheduling (PS), Permutation flow-shop (PFS), Travelling salesman problem (TSP), and Vehicle routing problem (VRP) reported in HyFlex v1.0. The testing was also performed on the ten instances of the Knapsack problem (KP), Quadratic assignment problem (QAP), and Maximum cut (MAC) problem reported in HyFlex v2.0. The execution time returned by a benchmark program on the computer machine is 507 seconds, which is the equivalent of 600 seconds on a standard testing machine according to the organizers of the cross-domain heuristic search challenge (CHeSC) in 2011.

The comparison of the different algorithms is based on the metrics of median objective function values (ofvs), formula one, μ -norm, and boxplot visualization as subsequently illustrated. The performances of the three categories of the TS-ILS hyper-heuristic were compared using the ofvs across nine HyFlex COPs. In addition, the performances of TS-ILS1, TS-ILS2, and TS-ILS3 were compared with those of the FS-ILS, NR-FS-ILS, AdapHH, EPH, SR-IE, SR-AM, and SSHH benchmark algorithms [25], [26] across eight HyFlex COPs. The results obtained for the PS problem by the existing algorithms could not be compared with those computed by TS-

ILS1, TS-ILS2, and TS-ILS3 because of the differences in the updated Java library used in the present work. The updated library has fixed a bug in the previous library that was used to produce the results [26]. The overall comparison of the algorithms will be prejudicial if an attempt is made to incorporate the results obtained for the PS problem. The data used for testing the existing algorithms, excluding the SSHH on HyFlex problems, were obtained online (<https://github.com/Steven-Adriaensen/hyflex>). The ofvs of the results computed by the SSHH algorithm can be found in [25]. In total, 60 instances of HyFlex COPs were tested for each of the three categories of TS-ILS hyper-heuristic based on the median ofvs. Moreover, 55 instances of the HyFlex COPs were tested separately for each of the three categories of the

TS-ILS hyper-heuristic. The three categories were also compared with seven benchmark algorithms based on the formula one, μ -norm, and boxplot visualization of median ofvs.

A. Comparison based on Median ofvs

Tables II and III highlight the performances of the TS-ILS categories in terms of the median ofvs obtained across the benchmark instances of the HyFlex COPs. The KP, QAP, and MAC problems of HyFlex v2.0 have ten benchmark instances which are five more than the first six problems of SAT, BP, PS, PFS, TSP, and VRP in HyFlex v1.0. The values in bold font denote the median ofv of the hyper-heuristic that reported the best performance for a problem instance.

TABLE II. MEDIAN OFVS OBTAINED BY CATEGORIES OF TS-ILS HYPER-HEURISTIC ON SIX HYFLEX V1.0 PROBLEMS

B. Comparison based on Formula One

The formula one scoring system has inspired one of the well-known metrics for evaluating hyper-heuristics [2]. Competing hyper-heuristics are assigned points based on the ofvs of their median best solutions obtained after 31 trials for each problem instance in the given test suite. The scores of 10, 8, 6, 5, 4, 3, 2, and 1 are respectively awarded to the best performing hyper-heuristic down to the eight-best one for a problem instance. Ties are handled by averaging the points that would have been given to one hyper-heuristic if there was no tie and assigning each of the hyper-heuristics the average score. In the rating system, the higher the score, the better the performance of a hyper-heuristic relative to the median results obtained by other hyper-heuristics.

The results of comparing eight hyper-heuristics on HyFlex COPs using formula one scores are presented in Table IV. The overall score in the table is the sum of scores obtained by a

given hyper-heuristic across problem instances. The categories of the TS-ILS hyper-heuristic can be observed to emerge as the most dominant hyper-heuristics across the HyFlex COPs considered. The overall performance of the categories of the TS-ILS hyper-heuristic on HyFlex v2.0 COPs was found to be superior to the performances of the other hyper-heuristics. The maximum score for each HyFlex v2.0 problem domain is 100 with the highest score of 10 for each problem instance. It can be inferred that the top three hyper-heuristics on HyFlex v1.0 problem based on the formula one scoring are TS-ILS2 with 162.8 points, followed by TS-ILS3 with 148.8 points, and TS-ILS1 with 146.9 points. The order of performances of the algorithms on HyFlex v2.0 problem instances is TS-ILS2 with 215.8 points, followed by TS-ILS1 with 214.8 points, and TS-ILS3 with 203.3 points. It is noticeable that there is a close race performance among the three categories of the TS-ILS hyper-heuristic on HyFlex v2.0, while TS-ILS2 outperformed the other categories on HyFlex v1.0. problems.

TABLE IV. FORMULA ONE RANKING OF CATEGORIES OF TS-ILS HYPER-HEURISTIC ON EIGHT HYFLEX PROBLEMS, EXCLUDING PS

Problem	AdapHH	EPH	FS-ILS	NR-FS-ILS	SR-AM	SR-IE	SSHH	TS-ILS1	TS-ILS2	TS-ILS3
SAT	21.00	10.00	34.85	23.35	0.00	5.00		35.10	34.85	30.85
BP	18.00	19.00	11.00	18.00	0.00	18.00		29.00	44.00	38.00
PFS	19.50	11.50	25.00	27.50	5.00	0.00		47.00	32.50	27.00

MAC	28.50	5.00	14.50	20.00	36.50	1.00	68.50	61.50	79.50	75.00
Overall	127.73	80.33	52.21	71.71	76.36	8.83	118.83	214.83	215.83	203.33

C. Comparison based on μ -norm Metric

This section compares the performances of ten hyper-heuristics across eight HyFlex COPs based on the μ -norm scores [25], [26]. The μ -norm is the average normalized evaluation function value. It is a more robust evaluation metric than the formula one scoring because it evaluates the performance of a hyper-heuristic based on the quality of the 31 solutions obtained over 31 trials on a problem instance. The μ -norm metric enables all the obtained ofvs to be normalized within the range [0, 1], where 0 means a hyper-heuristic outperforms other hyper-heuristics on all the tested instances, and a value of 1 connotes the opposite.

Table V provides comparative results of the categories of TS-ILS hyper-heuristics against the existing ones using the μ -norm scores. The data for the existing hyper-heuristics on the problem domains presented in Table V were taken from the paper [26]. The categories of the TS-ILS hyper-heuristic jointly

won seven out of the eight HyFlex problems. They outperformed the other hyper-heuristics on the PFS, KP, and QAP. The only problem domain where none of the categories of the TS-ILS hyper-heuristic recorded the best μ -norm value is SAT, where FS-ILS emerged as the best hyper-heuristic. The AdapHH is the closest challenger to the top algorithm (TS-ILS1) on the Knapsack problem. The three categories of the TS-ILS hyper-heuristic dominated all others on the QAP and MAC problems because they all constituted the top three successful algorithms across the problem domains. The EPH and SR-IE algorithms obtained the worst results on the MAC problem. The overall performance in Table V further consolidates the observation that the three categories of the TS-ILS hyper-heuristic are general in their applications to HyFlex v2.0 problems. Overall, the next best algorithms based on the μ -norm score, after the three categories of the TS-ILS hyper-heuristic, are AdapHH and FS-ILS, while the SR-AM algorithm delivered the worst performance.

TABLE V. COMPARATIVE RESULTS USING μ -NORM ON EIGHT HYFLEX PROBLEMS, EXCLUDING PS

D. Comparison based on Boxplot Visualization of Median ofvs

Fig. 1 presents the boxplots of the normalized ofvs of ten hyper-heuristics in Table IV. The minimum–maximum normalization scheme was applied to obtain the normalized median ofv of a hyper-heuristic on a particular instance of a problem domain [25]. The performances of the categories of the TS-ILS hyper-heuristic were benchmarked against the existing hyper-heuristics on HyFlex problems [26].

KP, The median score of the TS-ILS2 appears to be closest to the base of the plot in Fig. 1(a) to indicate good performance. A similar phenomenon can be observed for the TS-ILS1 and TS-ILS3 categories. The TS-ILS2 and TS-ILS3 have smaller boxes than the TS-ILS1 category. The three categories performed better than any of the other algorithms on the HyFlex v1.0 problems. The gap in the performance of the categories of the TS-ILS hyper-heuristic and other hyper-heuristics is more glaring for the QAP, and MAC HyFlex v2.0 problems.

Fig. 1. Boxplots of the overall normalized median of fvs obtained by the hyper-heuristics in Table IV.

The sizes of the boxes in Fig. 1(b) support the dominance of the categories of the TS-ILS hyper-heuristic. The interquartile range of the boxplots of each of the three categories of the TS-ILS hyper-heuristic is a minimal value, denoting low variability in their data. Combining the interquartile range with the proximity of the boxes to the minimum score means that the categories have enjoyed dominance over other algorithms on almost all problem instances of Knapsack, Quadratic Assignment, and Maximum-Cut. The categories can be observed to generalize well across eight HyFlex problem domains in sharp contrast to the other standard ILS hyper-heuristics, like FS-ILS and NR-FS-ILS.

IV. EFFECTS OF LOW-LEVEL HEURISTICS CATEGORIZATION ON HYFLEX PROBLEMS

The effects of LLHs on HyFlex problems have been investigated in this work. The first TS-ILS1 hyper-heuristic does not employ the double shaking strategy, but the other two categories that respectively implemented four and six perturbation configurations do. The problem domains of Bin packing, Permutation flow-shop, Knapsack, Maximum cut, Vehicle routing, and Quadratic assignment were chosen to demonstrate the differences among the three categories of the TS-ILS hyper-heuristic. The values in the config set have been defined according to the entries in Table I. The parameter C1 represents the first option that applied two mutation heuristics in succession before the application of the intensification heuristic. The parameter C6 represents the application of only one ruin-recreate heuristic before applying the intensification heuristic. The heuristic calls were recorded throughout the problem-solving process to obtain the boxplots. In addition, the perturbation configurations applied at each iteration were recorded accordingly. If a successful iteration of the best new solution is produced, the selected tally of a configuration was recorded. The log files of the top three runs for each problem domain were congregated for each category of the TS-ILS hyper-heuristic as shown in Fig. 2 to 4.

It is important to explain Fig. 2 to 4 to provide more clarity before interpreting the results provided by the figures. The multiple bar charts provide the success rates of the six different perturbation configurations (C1 to C6) for the three TS-ILS categories of TS-ILS1 (red), TS-ILS2 (blue), and TS-ILS3 (black). TS-ILS1 is a single shaking variant that utilizes the two configurations of mutation only (C5) and ruin-recreate only (C6) and therefore, it explains why only two red bars appear in each of the charts. Similarly, TS-ILS2 utilizes four configurations (C2, C3, C5, and C6) and it explains why only a maximum of four blue bars can be seen on each chart. The most successful configuration for both the TS-ILS2 and TS-ILS3 is C6 using the BP9 instance of Fig. 2 as an example, while the most successful configuration for TS-ILS1 is C4. This means that the application of only the ruin-recreate heuristic (C6) has found more best new solutions than any other configuration during the run of TS-ILS1 and TS-ILS2. However, for TS-ILS3, the application of two ruin-recreate heuristics in succession before the intensification (C4) was found to be the most productive option. Consequently, because TS-ILS2 outperformed TS-ILS3 on the multiple trials on the BP9 instance, it could be said that TS-ILS3 having so many configurations (six) slowed down its performance on the BP9 instance when compared to the performance of TS-IL2. Finally, the presence of the double shaking configuration (C2) in both TS-IL2 and TS-ILS3 has made them superior solvers than TS-ILS1 on the BP9 instance because the configuration has contributed to almost 40% of the best solutions found during the runs of TS-ILS2 and TS-LS3.

Most successful iterations were achieved with the application of ruin-recreate heuristics for the TS-ILS1 on the BP problem domain. This can be seen in the C6 column of the TS-ILS1 which has the highest bar for all instances. The TS-ILS2 and TS-ILS3 are better algorithms for solving the BP problem. They utilize more pairing of heuristics, especially with the pairing of Mut and RR (C2). Though, an exception is observed in the BP10 instance, where a single application of

RR is the most rewarding strategy. This phenomenon explains why the TS-ILS1 category, which is the weakest algorithm on the BP problem, outperformed its counterparts on the BP10 instance. The reason is that it could easily focus on the RR among only two options with the second option of Mut (C5) being a bad choice. The overall comparison of the performances of the hyper-heuristics on the BP problem domain has shown in Table II that the TS-ILS2 and TS-ILS3 are better than the TS-ILS1 across four of the five problem instances. This can be traced to their heavy reliance on C2, which cannot be observed for the TS-ILS1 category.

The single application of perturbation heuristics from the Mut is the best strategy for solving the instances of the PFS problem as evidenced in the plots of PFS3, PFS8, PFS10, and PFS11. It is not surprising that the TS-ILS1 outperformed the TS-ILS2 and TS-ILS3 categories. The six options available to the TS-ILS3 have appeared to be noisy. The reason is that it would take a considerable number of epochs for the TS procedure to converge using only the Mut strategy (C5) while solving the instances of the PFS problem. The double shaking options available to the TS-ILS2 and TS-ILS3 somewhat mired them from performing at a higher level for most instances of KP2, KP5, and KP6 of the knapsack problem. Interestingly, the four instances of KP1, KP2, KP5, and KP6 perfectly present the TS-ILS2 with four options as the most balanced based on the number of perturbation configurations. Observing the behavior of the TS-ILS3 on the MAC problem instances, none of the double shaking options of Mut + RR, RR + Mut, RR + RR, and Mut + Mut have a lower bar than the single perturbation options. This observation implies the importance

of pairing heuristics for solving these instances, and it explains why the TS-ILS2 and TS-ILS3 outperformed the TS-ILS1 on the problem. More interestingly, the performance of the TS-ILS2 on the MAC problem diverges from the performance of the other categories. Comparing their median ofvs across the ten problem instances, the TS-ILS2 obtained a lower (better) value across five problem instances while the TS-ILS3 managed to achieve the same feat in only three problem instances. This means that the two double-shaking options available to it are sufficient to make it excel in solving the MAC problem instances.

The mutation heuristics are more appropriate for the VRP problem because the column for the application of mutation heuristics is way longer than the application of ruin-recreate heuristics for the three categories of the TS-ILS hyper-heuristic. It is innocuous to generally conclude that the TS-ILS3 is a better solver of the VRP problem instances. This assertion can be justified by comparing the figures for the TS-ILS1, TS-ILS2, and TS-ILS3 on the VRP problem with their median ofvs in Table II. The top two perturbation configurations of the TS-ILS hyper-heuristic are the application of Mut and Mut + Mut (Fig. 4). The latter may be why the TS-ILS3 has performed better than the TS-ILS1 and TS-ILS2 on the VRP problem according to the values presented in Table V. This is because only the TS-ILS3 possesses the Mut + Mut option. The TS-ILS1 effectively leveraged the effectiveness of mutation heuristics on the QAP, while the plot for the TS-ILS2 and TS-ILS3 have demonstrated their partial reliance on the Mut option only.

V. DISCUSSION OF RESULTS

In this section, an extensive discussion of the results computed by the three categories of the TS-ILS hyper-heuristic

is provided. The study results generally indicate why the TS-ILS algorithm is effective using a component-based analysis of the hyper-heuristic. In addition, a few areas where further

improvement of the TS-ILS hyper-heuristic is required are highlighted in this section. The TS-ILS hyper-heuristics share similarities with existing ILS-based hyper-heuristics like FS-ILS [22]. The FS-ILS selects a single LLH heuristic during the perturbation stage by engaging a heuristic selection metric based on the ratio of the number of improvements made on an incumbent solution by an LLH to the total amount of its execution time when invoked. The TS-ILS hyper-heuristics use the same procedure to select LLHs, but the perturbation actions are governed by a Thompson sampling layer procedure that is featured in Algorithm 1.

Experimentation was set up to study the perturbation behavior of FS-ILS, TS-ILS1, TS-ILS2, and TS-ILS3 to reinforce the claim made in Section I about the need to control the depth of a perturbation. The experimentation profiles how these four hyper-heuristics solve cross-domain optimization problems, with results showing the weakness of some algorithms like FS-ILS, and why the successful categories of TS-ILS hyper-heuristics have overcome this weakness by varying perturbation control mechanisms. In the experimentation, three instances BP9, KP1, and MAC6 from three different problem domains were selected. The selected instances were taken from the problem domains where FS-ILS struggled to obtain good results to study if the perturbation control mechanisms of TS-ILS algorithms were responsible for their success. The four algorithms were run wherein each trial lasted for 279 secs, and the starting solution of each hyper-heuristics was initialized using the same seed. Tables VI, VII, and VIII present the results of the experiments for BP9, KP1, and MAC6 respectively.

There are seven trials for each algorithm, and the entries for the second trial of BP9 can be seen in the row “BP9-2”. This convention is used in all the tables for easy understanding. The average values obtained for the four algorithms in the order of appearance in the tables on the BP9 instance are captured in the following set {0.01247419, 0.00565258, **0.00137980**, 0.00400226}. Likewise, the average values for the KP1 instance are {-1235575.0, **-1256610.9**, -1249428.4, -1250803.0} and finally, for MAC6, it is {-1330.3, -1348.3, **-1354.9**, -1350.6}. Each entry in the last six columns (“Mut + Mut” to “RR”) represents the number of times a configuration was used during the run of a hyper-heuristic. For example, FS-ILS invoked 8,834 ruin-recreate heuristics and 7,324 mutation heuristics during its first trial as in row BP9-1 of Table VI.

The evaluation of the results presented in Table VI shows a huge discrepancy in the perturbation behavior of the FS-ILS

and TS-ILS algorithms. It can be observed that while the TS-ILS algorithms choose to use more ruin-recreate heuristics, FS-ILS did not discriminate amongst the two categories of perturbative heuristics, although it did slightly favor the ruin-recreate heuristics. This explains why FS-ILS did not perform well on Bin packing problems. The poor performance of FS-ILS for the trials on the instance of KP1 can be blamed on the issue that plagued it. Its relatively lower number of perturbation-intensification cycles (sum of the invocations of the number of perturbation and ruin-recreate heuristics) when compared with the TS-ILS algorithms. For the first three trials on KP1, FS-ILS completed an average of 173.3 cycles as opposed to 1,019.7 cycles for TS-ILS, 1,074 cycles for TS-ILS2, and 1,150 cycles for TS-ILS3. This means that FS-ILS did not have enough opportunity to search the heuristic space (and ultimately the solution space) unlike the TS-ILS variants. The main reason for this problem of FS-ILS is its excessive invocations of local search heuristics during the intensification phase, as reported in a previous study [19]. Finally, on the MAC6 instance, although the number of cycles completed by FS-ILS is not too far from that of TS-ILS2 and TS-ILS3, it still fell short in relative performance, as shown by its reported ofv per trial in Table VIII. The other algorithms concentrated their best perturbation efforts on invoking two perturbative heuristics in succession before entering the intensification phase. For example, the following phenomenon can be observed in the behavior of TS-ILS2 during the last three trials of Table VIII. The invocation of double shaking (Mut + RR or RR + Mut) was more favored (71.8% of the time) than the single shaking strategy.

The experiments performed in this work have shed more light on why the strategies of TS-ILS algorithms are effective. Moreover, it has provided a deeper understanding of the shortcomings of the previous ILS-based algorithms that do not affect the TS-ILS algorithms. The ability of TS-ILS to automate its perturbation behavior and utilize a local search module that is mindful of excessive invocations of local search heuristics elevated its performance and offered its better generalization ability across the nine problem domains from the extended HyFlex library. In future works, TS-ILS2 should be used in conjunction with tabu search, hidden Markov, and other adaptive perturbation strategies for performance improvement. In addition, investigating the variations of TS-ILS2 such as TS-ILS3 for different applications is an attractive venture. In particular, it should be exciting to apply The S-ILS2 algorithm in the field of evolutionary dynamic optimization, where perturbation strategy can assume an influential role.

VI. CONCLUSION

The objectives of the present work have been achieved through the description of three categories of the TS-ILS hyper-heuristic, experimentally comparing the three categories against the existing benchmark algorithms and the determination of the effects of LLHs categorization on HyFlex COPs. The TS-ILS2 with {1, 2, 4, 5} subset configuration has edged out the other categories across eight HyFlex problems. It can be observed with a further granularity that the TS-ILS1 has struggled to effectively solve the instances of the Bin packing problem according to the comparison based on the μ -norm scores. This observation can be ascribed to the lack of double shaking or a stronger perturbation feature in its composition because it uses only {4, 5} configuration subset. Although the TS-ILS1 outshone the other categories on the problems of Permutation flow-shop, Knapsack, and Quadratic assignment, its weakness was badly exposed when it was applied to solve the Bin packing problem. This eventually had a strong effect on its overall performance when compared to the other categories. The overall performances of the algorithms on the HyFlex v2.0 problems suggest a close race among the three categories after TS-ILS2 emerged as the overall best algorithm based on formula one and μ -norm scores.

The comparative results show that the TS-ILS3 recorded the best performance on three problem domains while the TS-ILS2 gave the best performance on the remaining problems. The uncanny fact is that the TS-ILS2 outperformed the TS-ILS3 on all but one of the problem domains. The TS-ILS2 recorded a better performance than the TS-ILS3 on the KP and MAC problems according to the formula one score, while the TS-ILS3 fared better than TS-ILS2 on the same problem domains based on the μ -norm scores. The reasonable explanation for this scenario is that the TS-ILS3 with more strategy options can sometimes obtain poor runs because of the convergence of the Thompson sampling module on the sub-optimal selection. Hence, this will affect its median ofv on the problem domains, but it has failed to perform better than TS-ILS2 in certain situations. In conclusion, the TS-ILS2 has a good balance between “single shaking” and “double shaking” configurations and emerged as the best hyper-heuristic algorithm for solving COPs.

Serious Game Design Principles for Children with Autism to Facilitate the Development of Emotion Regulation

Nor Farah Naquiah Mohamad Daud^{1*}, Muhammad Haziq Lim Abdullah², Mohd Hafiz Zakaria³

Center for Advanced Computing Technology (C-ACT)-Fakulti Teknologi Maklumat dan Komunikasi (FTMK), Universiti Teknikal, Malaysia, Melaka (UTeM)*

Abstract—Autism spectrum disorder (ASD) is a deficit-driven neurodevelopmental condition in three areas, which are social interactions, communication, and the presence of restricted interests and repetitive behaviours. Children with autism mainly suffer from emotional disturbance that emerges as meltdowns, tantrums, and aggression, increasing the risk of developing mental health issues. Several studies have assessed the use of serious games in helping children with autism enhance their communication, learning, and social skills. Significantly, these serious games focus on the strengths and weaknesses of the disorder to establish a comfortable and controlled environment that is able to support children with autism. However, there is still a lack of evidence in studies exploring the use of serious games for children with autism to facilitate the development of emotion regulation. The aim of this study is to consolidate and propose a new serious game design principle for children with autism to facilitate the development of emotion regulation. The target age of the children involved in this study ranged between 6 and 12. A review of previous literature on serious game design principles was conducted. More than 70 articles related to serious games for children with autism were analysed using thematic analysis. This study found 16 elements that influenced the designing and developing process of creating a serious game for children with autism. It has been organised and categorised into five attributes (user, game objectives, game elements, game aesthetics, and player experience). Certainly, this study demonstrates the needs and requirements of children with autism when designing serious games.

Keywords—Autism spectrum disorders; serious game; emotion regulation; serious game design principles

I. INTRODUCTION

Autism spectrum disorder (ASD) is one of the world's fastest-growing diseases. It is no longer considered an uncommon disorder in Malaysia but rather a developmental impairment that requires immediate assistance and understanding from all levels of society. Autism is a long-term neurodevelopmental condition distinguished by difficulties in interpersonal communication and social interactions, along with restricted, repetitive behaviour and interests [1-3]. Additionally, autism is referred to as a 'spectrum' disorder due to the wide range of symptoms that individuals experience. Presently, there is no known medical solution for autism, and researchers are still trying to figure out what causes it [4].

It is estimated that there are roughly 12,800 instances of autism in Malaysia, which is equivalent to 1 out of every 600

children [5]. Thus, the number of people diagnosed with ASD requesting services from the National Autism Society of Malaysia (NASOM) has increased by 30% across all age groups in recent years [6]. Besides that, males are more likely to have autism [7, 8] despite the fact that a recent meta-analysis found that the actual male-to-female ratio is closer to 3:1 than the previously reported 4:1; even though this study did not use the DSM-5 criteria [9].

Several studies have revealed that the majority of children with autism experience behavioural challenges, and certain characteristics of autistic children can be concerning to parents. Emotion regulation (ER) deficits were discovered to be a salient predictor of social and behavioural issues in children with autism [10] since they often exhibit excessive emotional reactivity or an emotional deficit compared to children with typical development [11]. Some children with autism who have limited verbal or nonverbal communication often face difficulties expressing themselves when they are frustrated or stressed [12]. As a result, children with autism are more likely to experience emotional disturbances such as meltdowns, tantrums, and aggression, which are risk factors for developing mental health disorders [13]. Besides that, disappointment induced by dysregulated emotions in children with autism may result in increased anxiety, despair, poor anger management, low frustration tolerance, impatience, despair, violence, mood dysregulation, and physical health implications [14, 15].

Conventional methods, such as paper-based and various therapeutic approaches have been suggested to support ER training for children with autism. However, paper-based aids are resource-intensive due to the need to craft the materials and intense instructions for children with autism [10], making them challenging for caregivers, teachers, and parents to utilise. Additionally, Sadka and Antle [16] also stated that the average delay in treatment for various mental health disorders surpasses ten years as a consequence of failure to notice symptoms, a lack of health care literacy, personal or social stigma associated with mental health care, and a lack of access to mental health therapy. Therefore, serious games have been shown to facilitate and support children with autism in acquiring academic, communication, job, and leisure skills [17]. Moreover, serious games bridge the gap between the tremendous demand for evidence-based interventions and the limited availability of professional autism services [18].

Despite the variety of technology-based interventions for children with autism, usability and uptake remain low. It is not surprising that there are few studies on serious game technology that may simulate the daily routine of children with autism to support emotion regulation [14, 19]. In fact, most of the existing studies fall into the social skills subcategory [20] focusing on facial expression [10, 21], or point to some aspects of the serious game, such as behavioural interventions and training methods [22, 23] without discussing in-depth analysis in the literature on serious games to develop emotion regulation [24] or promoting conventional emotion regulation training through serious games [25].

This study aims to better understand the user's needs and requirements to facilitate children with autism with their development of emotion regulation, such as recognising, interpreting, and generalising six basic emotions. The objective of this study is to consolidate and propose new serious game design principles for children with autism, focusing on the development of emotion regulation. Besides that, this study is driven to address the research question, which is: What are the appropriate serious game design principles for children with autism to facilitate their development of emotion regulation in their daily life activities? Significantly, this study focuses on filling the gap in the existing studies on facilitating the development of emotion regulation among children with autism using serious games.

II. RELATED WORKS

A. Autism Spectrum Disorder and Emotion Regulation

The term 'emotion' usually refers to a subjective state of being that is referred to as 'feelings' by most people. Emotions are an essential component of cognition and are closely tied to it [26]. Aside from that, emotions are generally thought to be actively felt and deliberate, whereas mood refers to a protracted, less intense affective state unrelated to whatever an individual encounters. Consequently, emotion recognition is considered a crucial skill that underpins more complicated emotional understanding and social abilities [27]. Additionally, emotion regulation is influenced by biology and through interactions with people in the environment [28].

Emotion regulation (ER) is defined as the voluntary management and modulation of emotional reactions through cognitive processes to regulate affective states in order to attain a goal [29]. Furthermore, emotions are also intertwined with an individual's daily life and have an impact on a variety of areas of human functioning, particularly communication and socialisation. As cited by Jinnah, et al. [30], it is mentioned that normally, typical infants begin to employ emotional expressions for social referencing between the ages of eight and ten months. However, children with autism may demonstrate little or no imitation of others' behaviour [1]. As a result, children with autism struggle to communicate, socialise, and maintain relationships with others [31].

Therefore, emotion regulation is a crucial skill that children with autism need in their lives. Certainly, emotion regulation has ended up as one of the critically highlighted issues in numerous areas, including Human Computer

Interaction (HCI). In addition, as cited by Sharma, et al. [32], emotion is crucial to understanding motivation in classroom interactions since teachers' instructional and interpersonal responses to children are often influenced by emotions. Thus, early intervention and evaluation of social and emotional skills in children with autism may help explain their observed traits [33].

B. Serious Games for Children with Autism to Facilitate Emotion Regulation

The most straightforward definition of 'video game' is interactive digital entertainment that is played on a computer, game console, or smartphone. It is also more commonly known as an electronic game that requires user interaction through a user interface that generates visual feedback. Furthermore, video games can be employed in a variety of sectors, including in the education field for people with special needs, despite being generalised as a source of entertainment only. Also, special education teachers are increasingly using technology-based interventions such as serious games to provide training to children with autism to enhance their social skills and quality of life [34]. Thereby, it should be noted that games have been employed as an additional tool for teaching and learning since the early nineteenth century.

According to Kokkalia, et al. [35], games in education are common because teachers frequently use games to create a more dynamic and creative learning experience. Besides that, video games and serious games have demonstrated that they can help children develop their cognitive and physical abilities owing to the consistent strategies for activity motivation and the feeling of personal pleasure gained from accomplishments [36]. Moreover, serious games have the ability to generate an emotional connection for people with special needs who are undergoing therapy or rehabilitation. In addition, previous studies claimed that games can be a joyful and pleasurable way for children to improve their skills [37]. Thus, several scholars believe that active exploration and immersion in games are able to enhance constructive, situational, and experienced learning [38].

Moreover, games have shown enormous potential as an intervention for children with ASD due to their ability to integrate attentively designed features with naturally occurring situations (i.e., having fun together) [39]. It is because game-based intervention is able to create a predictable environment to encourage attention and lessen the frustration of children with autism [40, 41]. For instance, a study found that training using virtual reality (VR) game approaches is able to improve the emotional and social skills of children with autism [42]. Additionally, game-based intervention is advantageous because it is predictable, repetitive, and devoid of stressful social demands, which are preferred by children with autism.

For instance, a previous study found that a game called FaceSay has successfully helped children with autism recognise facial expressions and feelings through the assistance of a realistic avatar [43]. Moreover, the visualisation of gaze in video games aids in the development of social attention and emotional abilities in children with autism [44]. Shams, et al. [45] also highlighted how the cosy and appealing aspects of serious games showed their ability to

improve emotion control in children with autism. Therefore, serious games are believed to have the potential to help children with autism improve their social communication skills and enhance their capacity to perceive and express emotions.

C. Designing Serious Games for Children with Autism

Game technology has been evolving with features and functions that defy expectations. Particularly, games have proven to be beneficial in a variety of fields, including the military, healthcare, and education. In fact, serious games have a lot of potential because they can foster relationships in a range of settings and contexts, such as realistic simulation games [46]. To emphasise, the usage of games in education has made learning more engaging and dynamic [47]. Therefore, game technology can be a promising tool for helping children with autism meet their needs by facilitating their therapy and skill development. In fact, games have the ability to capture the attention of children, including children with autism [48].

A large number of studies suggest that games can permanently prepare children physically and cognitively while also increasing their creativity, critical thinking, and sense of possibility. Additionally, studies have shown that ICTS is able to increase the interest and motivation of children with autism and support their social skills and social emotional domain skills development in a safe environment by using virtual environments that can replicate real-world situations [49]. Lee, et al. [50] also concede that animation, sound, and interface in technology-based intervention may reinforce and inspire children with autism.

As a result, a lot of guidelines and design principles have been produced to serve as a guide for designing and developing an appropriate game for a specified group, considering gameplay design, game mechanics, level design, reward systems, and other game aspects. Basically, the components that may be addressed in designing serious games include storylines, targeted skills, level progressions, feedback, and rewards [22, 51-53].

III. METHODOLOGY

This section describes the method used in this study. A comprehensive literature review on serious game design principles was conducted to retrieve and gather all the studies related to autistic people. A comprehensive literature analysis on serious game design principles was conducted to acquire and compile all studies that are relevant in facilitating children with autism with their development of emotion regulation. The children are aged between 6 and 12.

There are three stages of filtering and analysis used in the literature review stage. In the first stage, articles were extracted from Google Scholar, Science Direct, ACM Digital Library, IEEE Xplore, Scopus, Research Gate, and Springer Link between 2006 and 2021 using the key search criteria.

The primary search keywords were ‘Serious Games for Children with Autism Spectrum Disorder’, ‘Serious Games to promote Emotion Regulation of Children with Autism Spectrum Disorder’, and ‘Designing Serious Game for Children with Autism Spectrum Disorder’. In addition, search terms such as ‘Autism Spectrum Disorder’, ‘serious games’, ‘design principles’ and ‘emotion regulation’ were used to find additional articles. The keywords were gathered from academic journals, textbooks, technical reports, websites, and conference proceedings.

The first 70 articles in the search engine result were studied, and those that seemed relevant in terms of game-based interventions, serious games, and autism spectrum disorders (ASD) were chosen. In the first stage, the studies proposing serious games in the context of children with autism and review articles were accepted. Next, in the second stage, the articles were reduced to 48, which were discovered to be significant for analysis based on the suggested criteria related to the study. Then, these 48 articles were analysed in-depth to investigate the application design and existing guidelines in the third stage. The inclusion and exclusion criteria were described further in Table I. Iteratively, the analysed articles were taken into consideration and revisited, with a focus on serious game design principles for children with autism. In total, 24 articles were selected for critical examination and made it to the result table.

TABLE I. INCLUSION AND EXCLUSION CRITERIA

Inclusion Criteria	Exclusion Criteria
Studies from 2016 to 2022	Older than 2016
Serious Game, Game-Based Technology.	Any other computer-based intervention or assistive technology.
Focusing on designing games for autism spectrum disorder.	Studies that were not explained in literature or working paper.
Serious games that were tested on enough samples and in-game performance were validated.	Not enough studies and in +game performance were not validated.

After that, the 24 articles that were chosen were analysed and examined thoroughly, and the design principles were extracted using card sorting and thematic analysis. Prior to the complete system design, the card sorting technique was found to be very effective and an important way of getting the user’s input [54]. In addition, thematic analysis was used to extract the design principles. Thematic analysis is a technique for methodically detecting, organising, and interpreting patterns of meaning in a dataset. Besides, thematic analysis is a more divergent, compatible, and flexible research tool [55]. Thereby, the data were clustered thematically from the literature review.

In the first analysis, as shown in Fig. 1, the data was thematically clustered into five themes: user (green), game objectives (yellow), game aesthetics (pink), game elements (blue), and player experience (purple). Table II further explains the description for each theme.

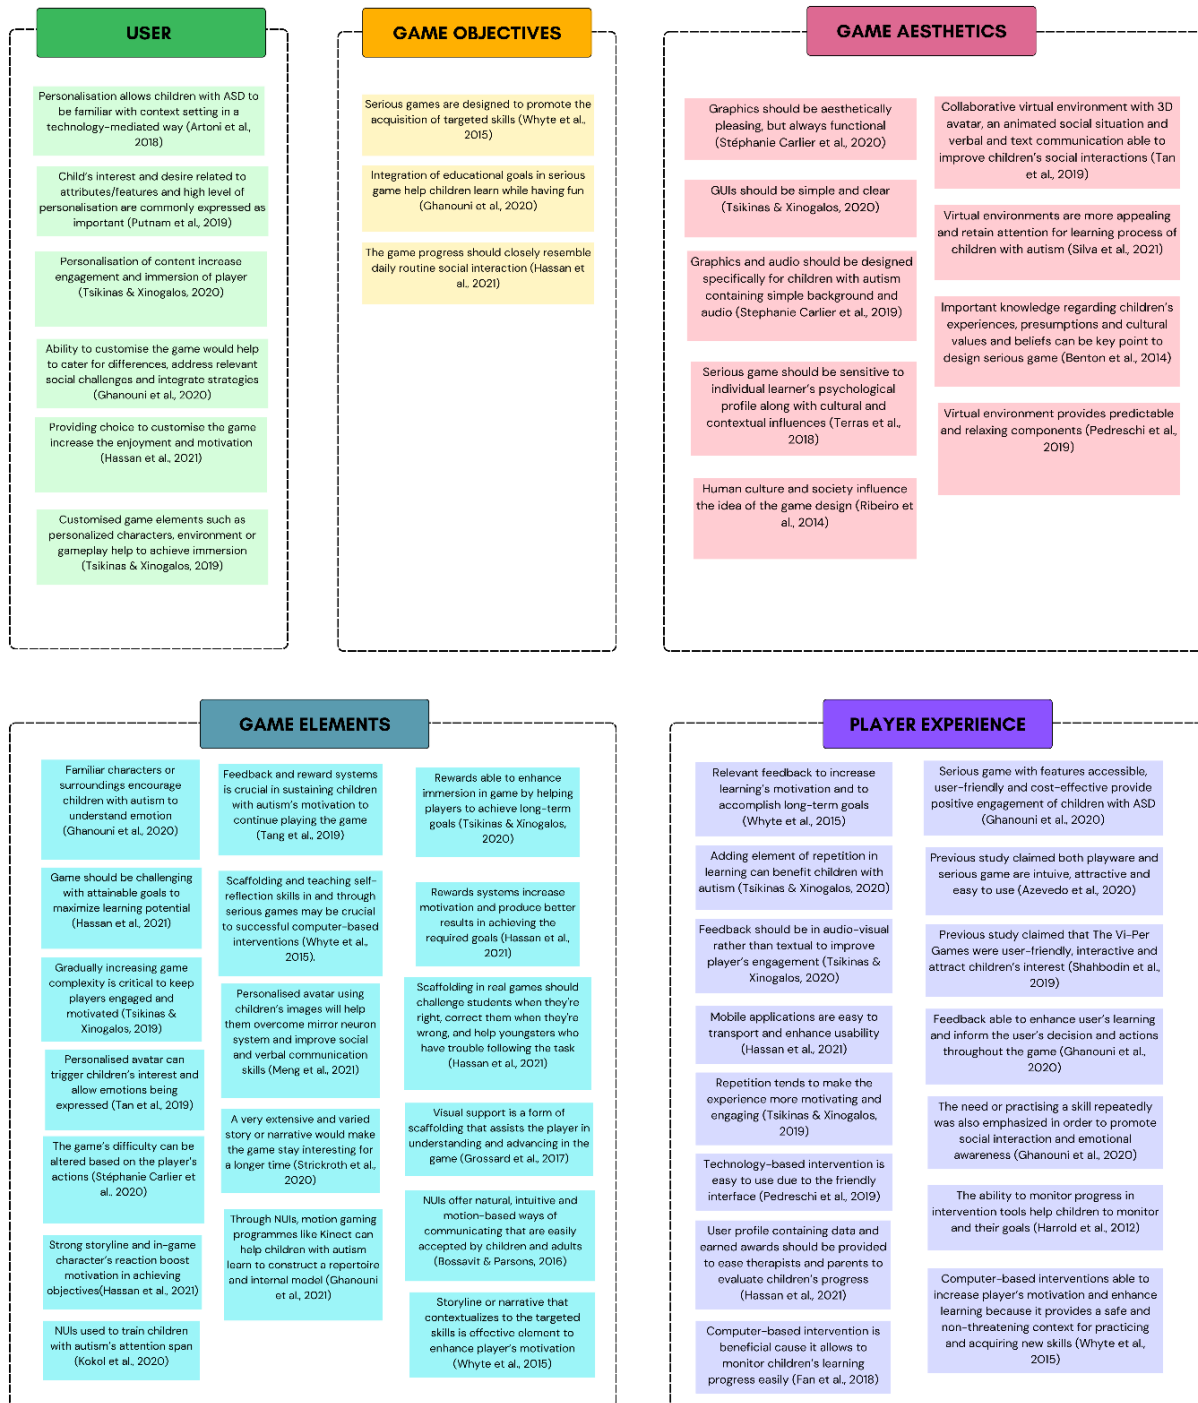

Fig. 1. First analysis: An iterative process in developing themes: user (green), game objectives (yellow), game aesthetics (pink), game elements (blue), and player experience (purple).

TABLE II. DESCRIPTION OF FIVE THEMES

Themes	Description	Colour coded
User	Represents the player profile.	Green
Game Objectives	Something that the player tries to achieve.	Yellow
Game Aesthetics	Sensory phenomena that the player encounters in the game/ Generalisation about art.	Pink

Game Elements	Components that make up the game.	Blue
Player Experience	Represents what the player goes through when playing the game.	Purple

In the second analysis, the themes were thoroughly examined to discover any possibilities for expanded sub-themes. As shown in Fig. 2, the User theme was refined to personalisation and customisation, the Game Objectives theme focused on the Individual Education Plan (IEP) goal of

children with autism, and the Game Aesthetics theme was narrowed to a graphical user interface, context settings, and virtual environment. The user was refined to personalisation and customisation in order to create a profile for children with autism, while the game objectives were refined to the individual education plan (IEP) goal since children with

autism have specific IEP goals to achieve. Meanwhile, the game aesthetics theme was refined to include a graphical user interface (GUI), virtual environment, and context settings that are able to ensure the game can provide comfortable environments and resemble the daily life activities of children with autism.

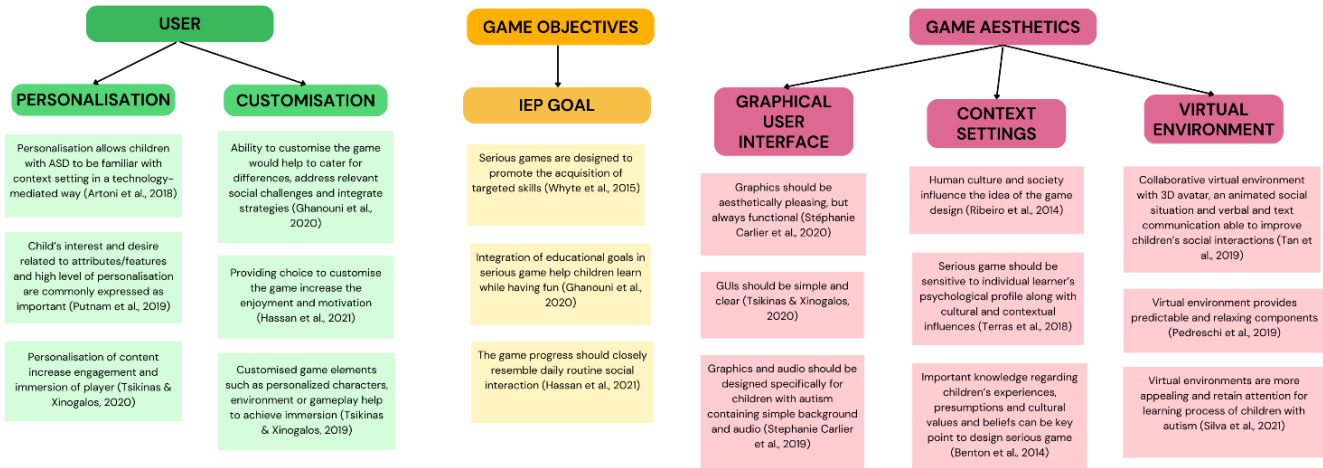

Fig. 2. Sub-themes for user, game objectives and game aesthetics.

Furthermore, in Fig. 3, the Player Experience theme was refined to feedback, repetition, usability, and monitoring in order to provide good responsive feedback and experience for children with autism when they interact with the game. Meanwhile, the Game Elements theme was clustered into

level progression, character, interaction, rewards, storyline, and scaffolding, which refer to the components that fulfil the design principles of serious games. Thereby, Table III shows the expanded themes with more sub-themes.

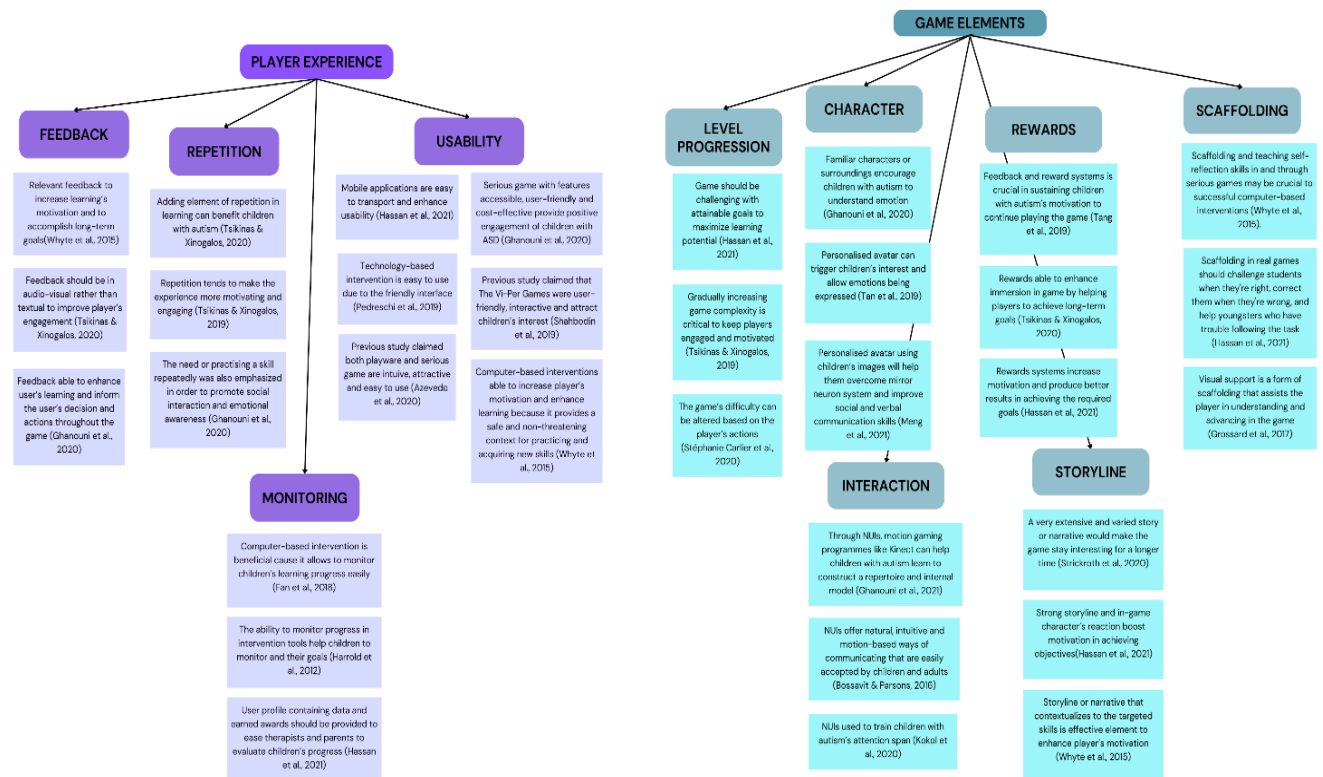

Fig. 3. Sub-themes for player experience and game elements.

TABLE III. RESULT OF SECOND ANALYSIS

Themes	Sub-themes
User	<ul style="list-style-type: none"> Personalisation Customisation
Game Objectives	<ul style="list-style-type: none"> IEP Goal
Game Elements	<ul style="list-style-type: none"> Level progression Character Interaction Rewards Storyline Scaffolding
Game Aesthetics	<ul style="list-style-type: none"> Graphical user interface (GUI) Virtual environment Context settings
Player Experience	<ul style="list-style-type: none"> Feedback Repetition Usability Monitoring

IV. RESULTS AND DISCUSSION

Through the comprehensive literature review on serious games for children with autism, Table IV is tabulated and presents the list of design principles for each of the components. There were 16 elements in the sub-themes found in this study, and they are clustered and organised into five attributes: (1) user, (2) game objectives, (3) game elements, (4) game aesthetics, and (5) player experience. This section briefly explains the five attributes of serious game design principles for children with autism.

TABLE IV. SERIOUS GAME DESIGN PRINCIPLES FOR CHILDREN WITH AUTISM

Attributes	Component	References
User	Personalisation	Allow content personalisation according to the needs [56-58].
	Customisation	Allow customising game elements to boost enjoyment and motivation [22, 52, 59].
Game Objectives	Individual education plan (IEP) goal	Specific targeted skills for children with autism to achieve that align with classroom activities [51, 53, 58].
Game Elements	Level progression	The game progression should gradually increase to motivate players [22, 52, 53].
	Character	Familiar and personalised character trigger children's interest [59-61]
	Interaction	Interactions should be natural and intuitive [59, 62, 63].
	Rewards	Player motivators [22, 23, 58].
	Storyline	Immersive, social-based stories and narratives [53, 64, 65].
	Scaffolding	Assist the player without controlling them through playing the game [22, 53, 66].
Game Aesthetics	Graphical user interface (GUI)	Visualisation should be clear, simple, and minimalist [12, 52, 67].
	Virtual environment	Provide immersive, relaxing, and attractive feelings by including animation, verbal, and text communication [61, 68, 69].
	Context settings	Culture and contextual influences should be considered [70-72].
Player Experience	Feedback	Relevant and responsive feedback should be considered to provide good engagement [52, 59, 65].
	Repetition	Repetition is needed to allow players to practise the targeted skills [58, 59, 73].
	Usability	The game should be easy to understand, safe, and child-friendly [53, 59, 68].

	Monitoring	Provide user profile containing data to monitor the progress [10, 22, 74].
--	------------	--

A. User

A user is considered a person who uses or operates the video game. In this case, children with autism are considered the users of the serious games. Since children with autism have difficulty processing inputs and social signals, they struggle to recognise emotions in social interactions [75]. Thus, personalisation and customisation are found to enable prioritising the child's needs.

Personalisation is important for children with autism, as parents or teachers can personalise the game according to the child's capabilities. Moreover, personalisation features in the games should be familiar and relate to children's interest and desire to increase their engagement and immersion experiences. According to Artoni, et al. [56], personalisation allows children with autism to become familiar with context in a technology-mediated way. Additionally, personalisation of both technology accessibility [76], content [58, 77], and the child's interest [57] is a critical key point when developing serious games for children with autism to increase engagement and immersion. Hence, game designers must have specific requirements to develop serious games that meet the autistic child's needs, especially focusing on facilitating the development of emotion regulation.

Customisation is also one of the important elements in the user category because games should provide the ability to customise certain game elements to increase enjoyment and motivation as well as cater to the children's needs. According to end-users, such as parents and therapists, customisation should be considered to ensure that children with autism properly provide feedback patterns [21]. Certainly, the ability to customise the game would aid in accommodating diversity, relevant social challenges, and integrating strategies [59]. Moreover, the ability to customise the characters, environment, or gameplay helps to achieve immersion and enhance the perception of uniqueness [22, 52].

It is important to consider personalisation and customisation when designing and developing games for children with autism to allow teachers and parents to personalise and customise the game according to the targeted skills. In fact, personalisation and customisation in games would also give flexibility to children with autism.

B. Game Objectives

Usually, any video game would have specific contents or objectives that would keep the game enjoyable to explore. This study found that serious games should have specific targeted skills and certain goals to be achieved or improved. Hence, a serious game for children with autism should have clear goals based on the individual education program (IEP) goals that teachers and parents want the child to achieve. Significantly, it is a critical component in designing serious games for children with autism because it requires specific content that aligns with the IEP goal, especially in facilitating the development of emotion regulation.

According to Hassan, et al. [22], when designing a serious game, the game content should closely reflect daily life

activities to ensure that children with autism are able to apply the skills in real-life scenarios. Besides, Tang, et al. [65] and Whyte, et al. [53] concede that the game objectives should be clear and must be classified as medium-term or long-term goals to ensure that players display greater intrinsic motivation when playing the game. Moreover, a game should have specific and clear objectives that are aligned with classroom activities or the curriculum [58]. Therefore, game designers should consider to using the IEP goals of children with autism to ensure the learning and training process is engaging and the targeted skills are achievable.

C. Game Elements

Game element is a term that refers to anything that is utilised and included in designing and developing a video game. Moreover, game elements are also known as the components that make up a game, which are called game attributes. Through the analysis, this study highlights six elements that have a good impact on designing serious games for children with autism.

Level progression is a crucial element in delivering the necessary content at every moment, and it reinforces progress for the player through a game's systems and mechanics. Level progression in games should not be too easy to avoid amotivation and frustration for the player. Hassan, et al. [22] emphasised that games should be challenging with attainable goals to maximise learning potential. In fact, the complexity of the game should gradually increase to keep players engaged and motivated [52]. Simply put, serious games cannot be so difficult that players become frustrated or so easy that they never learn new abilities [53].

Aside from that, character is also an important element to be considered when developing serious games for children with autism because characters can retain the child's attention as the game continues [73]. This is because familiar characters or surroundings encourage children with autism to get immersed in the game, especially in understanding the emotion [59]. In fact, Papoutsis, et al. [78] concede that familiar characters also make the user feel more at ease and improve the learning process. For instance, a mobile game application demonstrated that the use of a personalised avatar based on children's own pictures may elicit their emotions when they participate and engage in the activity [61]. Moreover, Meng, et al. [60] emphasised that children with autism can overcome the mirror neuron system and improve social and verbal communications with a personalised avatar. To summarise, character creation is an important element in designing serious games because it helps the player feel more immersed and interested to keep playing the game.

Besides that, interactions in games such as natural user interface (NUIs) enable children with autism who have sensitivity to interacting with technology intervention to benefit because NUIs provide a natural feeling using modalities such as touch, gestures, or voices. In fact, current Human Computer Interaction (HCI) paradigms indicate that interfaces should be natural and intuitive, leveraging motion-based touchless interactions known as NUIs [79]. According to Ghanouni, et al. [80], motion gaming programmes like Kinect are able to facilitate children with autism in learning to

create a repertoire of internal models through NUIs. For example, combining RGB cameras, depth detection, and careful user interface design in the Kinect visual sensor would provide better gaming and enjoyment experiences [62]. As a result, this study found that interactions play an important role in catering to the needs of children with autism.

This study also found that rewards provide a meaningful experience for children with autism since they can help motivate them to continue playing the game. Indeed, reward systems may be perceived as either motivators for players or as a means of mitigating disappointment [81]. In fact, Hassan, et al. [22] and Tsikinas and Xinogalos [58] concede that reward systems increase motivation and immersion in achieving medium-term and long-term goals. Additionally, Jouen, et al. [23] emphasised that gaming platforms offer a flexible and customisable manner of rewarding the player for achieving the objective, encapsulating the spirit of reward-based interventions. Eventually, when designing serious games for children with autism, designers should consider rewarding the player and the rewards should bring positivity to avoid frustration and give up.

Moreover, storylines in games are found to have a positive impact on children with autism by enhancing their motivation, attention, and interest in learning because they provide an interactive and immersive experience with a social-based context. Hassan, et al. [22] believe that a strong storyline and in-game characters' reactions are able to boost the player's motivation to achieve the objectives. In addition, a very extensive and varied narrative would keep the game interesting for a longer time [64]. A previous study also emphasised the importance of designing serious games underpinned by a motivating storyline to encourage players to keep playing [53, 65]. Therefore, this study concedes that a strong storyline with a social-based context is able to enhance social skills, foster intrinsic motivation to learn, and encourage them to pay attention.

Scaffolding is one of the strategies used in developmental learning and teaching. This is because scaffolding provides just enough assistance to ensure the children are successful in completing the given tasks on their own. This is why scaffolding can be an important element in designing serious games for children with autism. In fact, the affordances created by movement-driven avatars may have provided the best context for scaffolding engagement in autistic children [82]. Furthermore, Whyte, et al. [53] concede that scaffolding elements in serious games play an important role in successful game-based interventions as they intrinsically enhance the children's motivation to keep playing and learning. Certainly, scaffolding in games is a form of assistance to the player through playing the game by challenging them and correcting them in completing the tasks [22, 66]. Therefore, the game should include scaffolding elements to initiate engagement and interaction between player and game or player and peer, aside from assisting them through the game's progress.

D. Game Aesthetics

The sensory phenomena that players encounter in the games, such as visual, auditory, haptic, or embodied, are referred to as game aesthetics. Game aesthetics are an

expression of the game because the game itself needs precise degrees of interaction to function properly. Annetta [83] mentioned that visualisation is a powerful cognitive approach, and researchers have recognised it as an essential problem-solving strategy.

This study found that in designing serious games for children with autism, it is important to ensure the graphical user interface (GUI) is simple, clear, and minimalist. Subsequently, by improving the GUI design, higher usability and acceptance are able to be achieved [67]. In fact, children with autism may be overwhelmed and abandon the game or be distracted if the GUIs are complex, so the GUIs should be simple, clear, and appropriate [58]. In addition, to make the experience more user-friendly, researchers use basic and clear images with clear font text, huge navigation buttons presented clearly, and simple virtual reality aspects to avoid player distraction [52]. Carlier, et al. [12] concede that graphics and audio should be aesthetically pleasing but always functional. Hence, the GUIs in serious games for children with autism should be displayed clearly, not overlapped, and the use of colour should be minimised.

Immersion and engagement are important to attract the attention of children with autism, increase their attention span, and motivate them to keep playing. Thus, this study found that a virtual environment is able to teach children with autism to adapt to different situations in a safe way due to its feasibility. Additionally, children with autism can enhance their social interactions and comprehension by using collaborative virtual environments that include a 3D expressive avatar, an animated social setting, and verbal and text communication [61]. In fact, virtual environments are considered autistic-friendly because they provide predictable and relaxing feelings [68]. Moreover, virtual environments are appealing and able to retain the attention of children with autism in the learning process [69]. Hence, the simulated real world with 3D representations in a virtual environment is able to elicit interaction, the feeling of immersion, and the imagination of children with autism.

Other than that, context settings, localities, and cultural elements have been found to be considered when designing serious games for children with autism. This is because cultural and contextual settings would influence positive engagement. Ribeiro, et al. [71] concede that human culture and society influence the idea of game design. Besides that, important knowledge regarding children's experiences, presumptions, and cultural values and beliefs can be key points in designing serious games [70]. Additionally, developers should be sensitive to an individual learner's psychological profiles along with cultural and contextual influences when designing games [72]. Thus, the game elements should be integrated with cultural and contextual settings to provide familiarity to children with autism.

E. Player Experience

Serious games will be useless if the user finds them no longer engaging and entertaining, which means that a poor implementation would make it impossible to develop a game with a solid theoretical foundation. Moreover, immersion and exciting feelings in games entail more than just enjoying the game's storyline, graphics, and other game elements.

Therefore, in designing a serious game, especially for children with special needs such as autism, player experience should be contemplated.

This study found that feedback is important to provide a response between the player and the game through playing sessions. Indeed, it is also able to increase learning motivation and accomplish long-term goals [53]. Furthermore, feedback is needed in the game to inform the user's decision and action throughout the game, besides enhancing the user's learning [59]. Tang, et al. [65] emphasised that feedback in the game should be natural and provided through visual feedback such as text or animation. Additionally, Abirached, et al. [21] and Tsikinas and Xinogalos [58] concede that feedback in serious games for children with autism should be in an audio-visual format rather than textual to improve the player's motivation and maintain a high level of engagement. For instance, a previous study mentioned that the utilisation of appropriate immediate feedback in a serious game environment can lead to a state of flow or total engagement and immersion [84]. Thus, the feedback provided in the game should be audible or visual to maintain engagement, sustain motivation, and assist the players in game progress and performance.

Repetition, also known as repeatability, is the extent to which a player might want to play the game again after completing it once or more. In designing serious games for children with autism, it is crucial to allow repetition as the game progresses. This is because repetition tends to make the experience more motivating and engaging, which would benefit children with autism in acquiring certain skills [58]. This is supported by Ghanouni, et al. [59], where the value of repeated practice skills was beneficial to foster the development of social interaction and emotion recognition for children with autism. Repetition features in serious games for children are considered important because they can determine the player's mastery level and also make it possible to anticipate the following task [73]. Thus, repetition is a must because children with autism might want to repeat the game even though they accomplished it, possibly due to huge interest.

Besides that, usability is found to be another element that should be highlighted when designing serious games for children with autism to ensure the game is user-friendly, easy to use, and safe for the children. Technology-based intervention, such as mobile applications, web applications, or serious games, is easy to use due to the friendly interface that consists of interactive features that are able to attract children's interest [22, 68]. Importantly, serious games with accessible features, user-friendly, and cost-effective bring positive engagement from children with autism [59]. In addition, it is also able to increase the player's motivation and enhance the learning process as it provides a safe and non-threatening context to practice and acquire new skills [53]. In fact, the rise of toddler-friendly touch screens has had a positive effect on educational approaches for autism [85]. Then, developers should consider the usability of serious games when designing for children with autism.

Additionally, monitoring features have been found to be a crucial element in designing serious games for children with

autism because they provide accessibility, not only for the children but also for their parents, teachers, and therapists. It allows them to monitor the developmental progress of children with autism. Fan, et al. [10] mentioned that computer-based intervention is beneficial for parents and teachers because it can allow easy monitoring of the children's learning progress. This is why developers should consider having user profiles containing data and earned awards in the game to ease the teachers, therapists, and parents evaluation of the children's progress [22]. Moreover, the ability to monitor progress using intervention tools would help teachers and parents facilitate and support the child in developing their skills [74]. Thereby, monitoring progress is important in designing serious games for children with autism to allow teachers and parents to evaluate the developmental progress of the children's skills.

V. CONCLUSION

In conclusion, serious games show promising outcomes in many approaches to facilitating and supporting children with autism by enhancing a range of abilities. Significantly, serious games have shown to be quite beneficial in facilitating autistic people in enhancing their social and emotional domains, such as emotion regulation. This is because the player's emotions can be awakened to attain the game goals, accept challenges, follow game rules, engage with the game world, respond to feedback, or comprehend the game narrative.

Therefore, this study highlights the serious game design principles that should be included when designing a serious game for children with autism to develop their skills, especially emotion regulation skills. This study shows a significant presence of more appropriate design principles for developing serious games for children with autism by deeply understanding their needs and requirements. Therefore, a summary of the serious game design principles is presented in Table V.

TABLE V. A SUMMARY OF SERIOUS GAME DESIGN PRINCIPLES FOR CHILDREN WITH AUTISM

Design Principles	Recommendations
User <ul style="list-style-type: none">● Personalisation● Customisation	The game should be able to be customised and personalised according to the abilities of children with autism.
Game Objectives <ul style="list-style-type: none">● Individual education plan (IEP) goal	The game should have specific targeted skills that are aligned with each child's IEP goal or classroom activity.
Game Elements <ul style="list-style-type: none">● Level progression● Character● Interactions● Rewards● Storyline● Scaffolding	The game elements should make the children feel connected to the game and increase their motivation to keep playing the game.
Game Aesthetics <ul style="list-style-type: none">● Graphical user interface (GUI)● Virtual environment● Context settings	The game aesthetics should be simple and minimalist, especially for children with autism, to avoid distraction.
Player Experience <ul style="list-style-type: none">● Feedback● Repetition● Usability● Monitoring	The game should be responsive to player engagement and immediately respond to the player's interaction.

Besides that, the proposed serious game design principles that have been elicited from the existing study would undergo a validation process by experts, including special education teachers, academicians, and serious game experts who are experienced in developing serious games for special needs. A focus group discussion will be conducted to validate the proposed serious game design principles that have been identified in this study as suitable for designing serious games for children with autism. The feedback and suggestions from teachers and experts will be used to strengthen the serious game design principles for children with autism.

On the other hand, it is anticipated that these findings will serve as a guide for future researchers and future game developers who are interested in developing serious games for children with autism to facilitate their development skills, especially in supporting the development of emotion regulation. Following that, after the validation process in the focus group discussion, a prototype will be developed and tested with children with autism to identify the engagement and effect on their skill development.

ACKNOWLEDGMENT

The study is funded by Ministry of Higher Education (MOHE) of Malaysia through the Fundamental Research Grant Scheme (FRGS), No: FRGS/1/2021/FTMK/F00482. The authors also would like to thank Human Centered Computing and Information System Labs (HCC-ISL), Fakulti Teknologi Maklumat dan Komunikasi, Universiti Teknikal Malaysia Melaka for all the support and encouragement for this research.

Abstract—An automatic environment control systems for greenhouses are turning to be very significant because of food demand, and rise in temperature and population of the world. This article proposes to design and implement a low cost, robust and water efficient autonomous smart internet of things (IoT) system to monitor and control the temperature, and humidity of an outdoor oyster mushroom growing unit. The IoT-based control system involves DHT22 sensors, ESP32 controller and actuators (water pump and cooling fan) to facilitate the adequate amount of air for circulation to maintain temperature and water to maintain humidity inside an outdoor oyster mushroom growing unit as per its requirement. A real working prototype is developed and implemented on integrating fuzzy inference system (FIS) in ESP32 controller using Arduino C with the help of its integrated design environment. The FIS is designed to calculate the switching on/off time of water pump and cooling fan on sensing current temperature, and humidity inside oyster mushroom unit with respect to ambient temperature, and humidity respectively. The prototype provides inside temperature, humidity, ambient temperature, ambient humidity, water pump time and fan time on Thing-speak platform in real time. Furthermore, the data is used for design and simulation of Adaptive Neuro Fuzzy Inference Controller for an outdoor oyster mushroom growing unit in MATLAB/Simulink to improve the performance of the system. The practical applicability of the proposed ANFIS controller over FIS Controller and industrial PID Controller is shown by simulation findings with use of experimental data. The system reduces water use as well as an extremely extraordinary administration required for monitoring the mushroom unit. In addition, it increases robustness of the system.

Keywords—Precision agriculture; adaptive neuro fuzzy inference system; fuzzy inference system; oyster mushroom cultivation; internet of things

I. INTRODUCTION

Agricultural practices are utmost essential ways of subsistence over the period of human evolution. Henceforth, human beings depend on broad scale of agricultural goods in nearly every facet of life. However, today the changes in climatic conditions are affecting the growth of greenhouses drastically. In addition, increase in food demand with increasing world population, the traditional agricultural practices are transforming into artificial and smart practices. This study aims to address the problem of controlling the environment conditions in an oyster mushroom crop and

watering it without contamination, by providing sensor and actuators based smart autonomous controller, thereby removing much of efforts required by farmer.

The advent of new species of mushrooms for commercial growing during the past two decades has caused the mushroom industry worldwide to expand very quickly. Despite having a plenty of agricultural waste, and a rich fungal biodiversity, India's rise has received only unresponsive support. Presently, 0.13 million tons of mushrooms are produced in India [1]. From 2010 to 2017, the Indian mushroom market experienced an average annual growth of 4.3% (www.indiastat.com). This shows that the mushroom industry is expanding day by day and has potential to generate more money in the future. Since maintaining essential environmental conditions is necessary for mushroom growth, the key challenge is how to add value to the mushroom cultivation process. In order to link data to productivity gains, the Internet of Things (IoT) era is essential to the information technology revolution. The use of the IoT has the potential to help farmers to overcome a number of challenges, such as water shortages, a lack of adequate land for plantations, maintaining crucial parameter for crop growth, difficulty in managing costs, and meeting the global demand for food resources [2]. In order to help farmers to improve the quality, quantity, sustainability, and cost-effectiveness of agricultural production, smart agriculture uses IoT applications.

Oyster Mushroom has many advantages, including being high in proteins and having medicinal uses. These mushrooms can only grow in upland regions with specific humidity and temperature levels. Because it is more economical than other agricultural practices, the government encourages farmers to grow oyster mushrooms in lowland areas. Misting oyster mushrooms with clean water will keep them at the right humidity and temperature. It can develop normally in controlled environments where the temperature ranges from 24 to 27°C and the relative humidity ranges from 70 to 85% [3]. However, because it requires a significant financial commitment, farmers typically find it challenging to build air-conditioned farms. When growing mushrooms manually, humidity is maintained by hanging coir mats or gunny sheets along the walls, and it is kept moist by periodic watering during the cropping phase. It is also more difficult to maintain the proper humidity and moisture in the substrate during the summer because more water is lost due to evaporation. Watering the mushrooms extensively twice or three times a day is the solution, but this has the drawback of making the

mushrooms overly wet and producing unusable, low-quality product. Therefore, proper controlling mechanism is needed.

A smart oyster mushroom growing unit is an enclosed structure that offers mushrooms an environment that is properly controlled using IoT and Soft computing technology Fuzzy Inference System (FIS) to regulate mushroom growing conditions, to lower production costs and increase the revenues. The IoT-based control system involves DHT22 sensors, ESP32 controller and actuators water pump and cooling fan to facilitate the adequate amount of air for circulation to maintain the temperature and water to maintain the humidity inside the oyster mushroom growing unit as per its requirement. The real working prototype is developed and implemented on integrating FIS in ESP32 controller using Arduino C, and its integrated design environment. The FIS is designed to calculate the switching on/off time of water pump and cooling fan on sensing current temperature and humidity inside oyster mushroom unit with respect to ambient temperature and humidity respectively. The prototype provides inside temperature, humidity, ambient temperature, ambient humidity, water pump time and fan time on Thing-speak platform in real time. Furthermore, the data is used for design and simulation of Adaptive Neuro Fuzzy Inference Controller for an outdoor oyster mushroom growing unit in MATLAB/Simulink.

This research examines the modelling and controlling of inside temperature and humidity for an outdoor oyster mushroom growing unit with respect to ambient temperature and humidity. In addition, Proportional Derivative and Integrated (PID), Fuzzy logic control (FLC), and ANFIS are the control techniques that are discussed, compared and validated. The remainder of this article is presented as follows: literature review is discussed in Section II, all three controllers modelling are covered in Section III, a real time implementation of IoT prototype using FIS controller and all three controllers Simulink modelling is covered in Section IV, the experimental findings and discussions are included in Section V, and the conclusion of the work and future scope are covered in Section VI.

II. LITERATURE REVIEW

The adaptive neuro-fuzzy inference system (ANFIS) combines the concepts of neural networks and fuzzy logic. It is frequently used to solve engineering problems when traditional methods are unable to provide a quick and reliable solution [4]. Numerous academics have focused on the control design of the climate of smart mushroom houses over the last decade. A smart mushroom house environment was developed using a smart controller by MSA Mahmud et al [5] Thong-un, N. et al. [6], Ariffin, M. A. M. et al. [7], Sihombing, P. et al. [8], Chiochan, O. et al. [9], Marzuki, A. et al. [10], and Yin, H. et al. [11].

For controlling various green houses, a fuzzy system and neural network techniques were used by researchers Koutb, M. et al. [12], Lafont, F. et al. [13], Marquez-Vera et al. [14], Mote, T et al. [15], Revathi, S et al. [16], Xu, F. et al. [17], Fourati, F. et al. [18], Coelho, J. [19], Mohamed, S. et al. [20], Atia, D. M. et al. [21], Oubehar, H. et al. [22], Hernández-

Salazar et al. [23], Qiuying, Z. et al. [24], Khuntia, S. R. et al. [25], and Hamidane, H. et al. [26].

The significant contribution of the presented work is as follows:

- Designing of FIS system in MATLAB as per oyster mushroom cultivation requirement, includes input and output variable membership function design, setting fuzzy inference rules, and choosing a suitable defuzzification method.
- Design and implementing a low cost, autonomous IoT based monitoring, controlling FIS integrated system prototype that controls inside temperature and humidity of an outdoor oyster mushroom growing unit.
- Design and simulating an ANFIS controller in Simulink using real time data collected by IoT prototype.

III. PROPOSED AUTOMATIC ENVIRONEMNT CONTROLLERS FOR AN OUTDOOR MUSHROOM GROWING UNIT

A. Fuzzy Inference System

Fuzzy inference system (FIS) has three steps, fuzzification, inference engine and defuzzification. In fuzzification, the membership functions (MFs) are designed for input and output values. MFs are used to convert crisp value into fuzzy values. Trapezoidal MF is designed for input variables temperature, as shown in Fig. 1. The range of temperature considered is 0 to 50°C and the membership values are decided as Cold, Suitable, and Hot. Another input variable is humidity varying from 0 to 100%. Its membership values are considered as Dry, Suitable, and Wet with trapezoidal MF as shown in Fig. 2. The triangular MFs are designed for output variables water pump time, as well as fan time. Their range is considered from 0 to 60 seconds with Off, Slow, Medium, and Long membership values as shown in Fig. 3 and Fig. 4. The inference engine is the set of if-then rules, designed using expert suggestion and trial and error method as shown in Table I. In defuzzification, the fuzzy value is converted back into crisp value using center of gravity method.

Fig. 1. Membership function for input temperature.

Fig. 2. Membership function for input humidity.

Fig. 3. Membership function for water pump time.

Fig. 4. Membership function for fan time.

TABLE I. FUZZY RULE BASE

Rule	Input Variables				Output Variables	
	Temperature		Humidity		Water Pump Time	Fan Time
1	Cold	AND	Dry	THEN	Short	Short
2	Suitable	AND	Dry	THEN	Medium	Medium
3	Hot	AND	Dry	THEN	Long	Long
4	Cold	AND	Suitable	THEN	Off	Off
5	Suitable	AND	Suitable	THEN	Off	Off
6	Hot	AND	Suitable	THEN	Off	Medium
7	Cold	AND	Wet	THEN	Off	Off
8	Suitable	AND	Wet	THEN	Off	Off
9	Hot	AND	Wet	THEN	Short	Short

The designing of FIS is done in MATLAB/Simulink to generate .fis file. It is converted into Arduino C code to upload into ESP32 controller of IoT prototype for real time implementation.

B. Adaptive Neuro Fuzzy Inference System

ANFIS is an adaptive network consisting of fuzzy logic and neural network. The fuzzy controllers developed by Takagi-Sugeno are simulated using an adaptive network. With a given input/output data set, ANFIS modifies all the parameters using the back propagation gradient descent methodology for non-linear parameters and the least squares kind of method for linear parameters. This section presents the five-layered ANFIS architecture and the learning process for the neural fuzzy network.

- Layer 1: Each node i in first layer is functional adaptive.

$$O_i^1 = \mu_{A_i}(x) = \frac{1}{1 + \left(\frac{x - c_i}{a_i}\right)^{2b_i}}, \quad i = 1, 2, \dots, 17 \quad (1)$$

Where, x is the input to adaptive node i , A_i is the fuzzy variable associated with node i . O_i^1 is the membership function provides the degree of membership to which A_i given x satisfy the quantifier A_i . The $\{a_i, b_i, c_i\}$ are the parameter set with changing values to get best bell-shaped function.

- Layer 2: Every node in this layer is a circle node labeled Π , which multiplies the incoming signals and sends the product out. For an instance,

$$w_i = \mu_{A_i}(x) * \mu_{A_i}(y), \quad i = 1, 2, \dots, 17 \quad (2)$$

- Layer 3: Each node in this layer is a circle node labeled N . The i^{th} node calculates the ratio of the i^{th} rule is firing strength to the sum of all rules firing strengths.

$$\bar{w} = \frac{w_i}{w_1 + \dots + w_{17}}, \quad i = 1, \dots, 17 \quad (3)$$

- Layer 4: Every node in this layer is a square node with a node function.

$$O_i^4 = \bar{w}_i f = \bar{w}(p_i x + q_i + r_i) \quad (4)$$

Where w_i is the output of layer 3, and $\{p_i, q_i, r_i\}$ is the parameter set. Parameters in this layer will be referred to as consequent parameters.

- Layer 5: The single node in this layer is a circle node labeled Σ that computes the overall output as the summation of all incoming signals.

$$O_1^5 = \sum \bar{w}_i f = \frac{\sum_i w_i f}{\sum_i w_i} \quad (5)$$

C. PID Controller

To validate the performance of the study, we compared ANFIS, FIS with a standard industrial controller Proportional, Integral, and Derivative (PID) control system. We have used an Ideal PID controller using the equation (6) [27].

$$\mu(t) = K_p e(t) + K_i \int_0^t e(t) dt + K_d \frac{d e(t)}{dt} \quad (6)$$

Here K_p is the proportional gain, K_i is the integral gain and K_d is the derivative gain along with time t . The values of K_p and K_i are tuned using self-tuning App in Simulink and K_d is adjusted to zero initially.

IV. IMPLEMENTATION OF AUTOMATIC ENVIRONEMNT CONTROLLERS FOR AN OUTDOOR OYSTER MUSHROOM GROWING UNIT

A. Experimental Setup

The studied smart autonomous outdoor oyster mushroom growing unit is illustrated in Fig. 5. It is a small outdoor unit with dimensions 6 x 4 x 6 feet and designed and implemented at the Mushroom Lab, Indian Institute of Horticulture Research, ICAR, Hessaraghatta Lake Post, Bengaluru, India. It is loaded with 70 oyster mushroom bags each of weight 1kg and spawned with 50g of oyster mushroom spawns. It is covered with two layers of gunny sheets, which must be wet to keep the required climate inside the mushroom unit.

A smart IoT based climate control system is designed, implemented and deployed in an outdoor oyster mushroom

growing unit. It has two parts, an applied environment system and an internet of things (IoT) node as shown in Fig. 6. An applied environment system consist of AC cooling fan, a DC water pump and 6 mm diameter plastic pipe with length 25m. The water pump flows the water through the plastic pipe, which is positioned around gunny sheets to sprinkle water on it to maintain humidity inside the unit. The other part of system is an IoT node as shown in Fig. 7. It consists of two DHT22 sensors, ESP32 controller, and two relays. DHT22 sensors used to sense inside and outside temperature and humidity of the unit. The ESP32 controller is used to control the inside temperature and humidity on actuating water pump and cooling fans using FIS system. FIS is integrated with the ESP32 controller and used to calculate the water pump and cooling fan times. It helps ESP32 controller to trigger the actuator relays to turn them on and off. A built in Wi-Fi module of ESP32 controller is used to collect data in ThingSpeak platform after every 30 seconds. The data is collected from 17th, January 2023 to 31st, January 2023. The platform logs the temperature, ambient temperature, humidity, ambient humidity, water pump time, and cooling fan time. This experimental data is utilized for further implementation of ANFIS controller to control temperature and humidity of an outdoor oyster mushroom growing unit.

B. Implementation of ANFIS Controller

The ANFIS approach creates a FIS using a collected primary data. A backpropagation algorithm either alone or in conjunction with a least squares approach is used to tune (change) the membership function parameters. The FIS structure works alike a neural network that converts inputs into outputs by first mapping input membership functions and associated parameters to outputs.

As ANFIS is multiple input single output (MISO), two ANFIS models are generated. ANFIS-1 predicts the water pump time and ANFIS-2 predicts fan time. In both models, humidity and temperature are the input variables. In this study, the five-layered ANFIS simulates the operation of a fuzzy inference system as shown in Fig. 8. The input and output linguistic variables are represented by the fuzzy nodes in layer one and four, respectively. The term nodes in second layer serve as membership functions for input variables. The third layer's neurons represent a fuzzy rule, with input connections standing in for its prerequisites and output connections for its results. All of these layers are initially fully connected, signifying every potential rule.

The membership functions assigned to two input variables temperature and humidity is Gaussian as shown in Fig. 9 and Fig 10. The closed-loop control mechanism in the ANFIS model is dependent on the prior expert data. In this system, the humidity, temperature, and water pump time training data (with data points 14668) are used to train the ANFIS to obtain the membership function (MFs), which enables the ANFIS to estimate an accurate correlation between inputs and outputs. The expert data is used in the system input-output trial to design the controller with the least degree of error. Throughout 1,000 epochs, the training error is reduced until it is less than 1.9986. This implies that the ANFIS-1 system output is close to the desired training values.

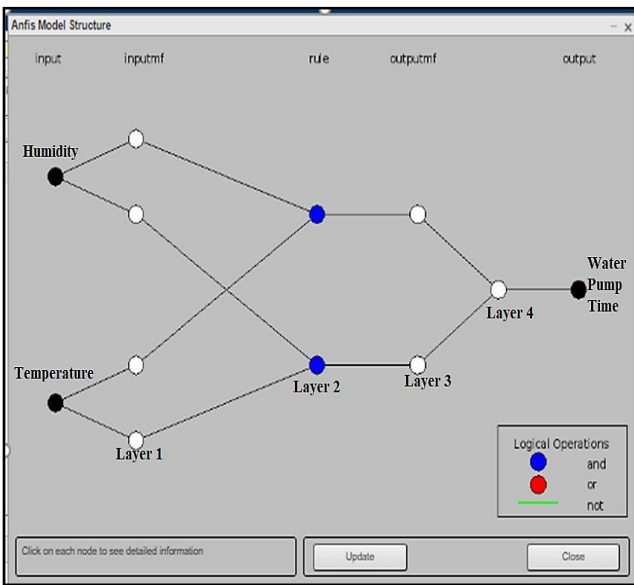

Fig. 8. ANFIS-1 architecture to predict water pump time.

Fig. 9. ANFIS-1 membership function for input temperature.

Similarly, ANFIS-2 is implemented in the same way as ANFIS-1, with an expert dataset (with data points 14668) containing temperature, humidity, and fan time. The training error is reduced throughout 1,000 epochs until it is less than

2.28817. This implies that the ANFIS-2 system output is close to the desired training values.

C. Simulink Models for FIS, ANFIS and PID Controller

The dynamic models of PID, FIS and ANFIS controllers are designed in MATLAB/Simulink environment to control inside temperature and humidity of an oyster mushroom growing unit, as shown in Fig. 11. A primary dataset is collected while experimenting IoT prototype to control its temperature and humidity in real time. It is consisting of temperature, humidity, water pump time and fan time. It is used as an input to all Simulink models. In Simulink, first, the FIS Simulink model is implemented as per the required design details discussed. Secondly, the ANFIS Simulink model is implemented as discussed in previous section. Thirdly, PID Simulink model is implemented as per equation (6).

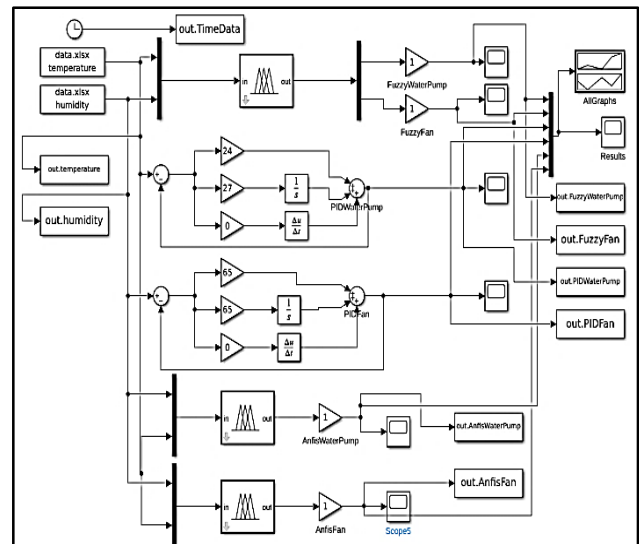

Fig. 11. Simulink models for FIS, ANFIS and PID Controller.

V. RESULTS AND DISCUSSION

In this section, firstly the results are presented and discussed for IoT based real time FIS controller, secondly the comparative study of FIS controller, ANFIS controller, and PID controller is discussed and presented, and lastly the cost analysis of IoT prototype is presented.

A. FIS Experimental Results and Discussion

The experimental results are obtained on implementing the IoT based prototype in an outdoor mushroom growing unit. To show the viability of the suggested FIS System, several experiments were carried out. The outcomes are the outputs of DHT22 sensor reading for temperature, humidity, ambient temperature, ambient humidity, and FIS calculated water pump time and fan time, transferred and updated on the website, www.thingspeak.com as shown in Fig. 12, Fig. 13, and Fig. 14. The date and timestamp for reading showed on website for user information. The real time results show the robustness of FIS based IoT prototype, which is able to maintain the required temperature, and humidity in an outdoor mushroom growing unit.

Fig. 12. Online visualization of humidity, and ambient humidity against time.

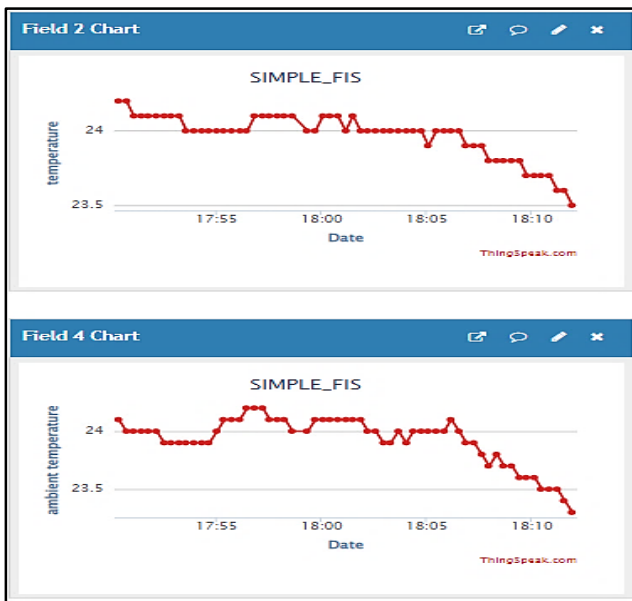

Fig. 13. Online visualization of temperature, ambient temperature against time.

Fig. 15 illustrates the calibrated humidity and ambient humidity sensor reading along with water pump time values of applied prototype obtained from the website, www.thingspeak.com in real time. It shows that, when humidity is below 70%, the water pump and fan switches ON, on the other hand when humidity rises above 70%, both remains off mode. This shows the water is used on requirement and playing a vital role in improving the water use as well. Similarly, Fig. 16 illustrates the calibrated temperature and ambient temperature sensor reading along with fan time values of applied prototype obtained from the website, www.thingspeak.com in real time. It shows that when temperature of an outdoor mushroom growing unit is not in range (above 27°C), then the FIS controller switches on the fan, until it comes in range. In addition when temperature is below 27°C, fan remains in switched off mode. This proves the robustness of the system.

Fig. 14. Online visualization of water pump time, fan time against time.

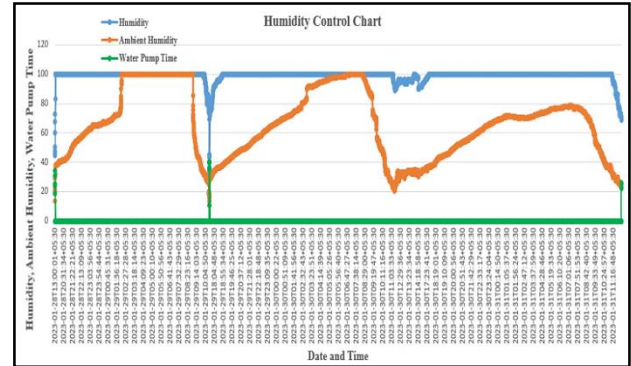

Fig. 15. Calibrated humidity and ambient humidity sensor reading along with water pump time values.

Fig. 16. Calibrated temperature and ambient temperature sensor reading along with fan time values.

B. Performance Evaluation of Simulink Models

ANFIS controller has the capability that can deal with nonlinear systems on the self-learning data. It is compared with FIS designed with human expertise knowledge and with a standard industrial PID controller with same system parameters. In PID controller there are only three parameters to adjust, whereas FLC has a lot of parameters to select like membership functions and its parameters, correct choice of rule base. The ANIFS controller self learns the data and designing neuro fuzzy system on training the data. The input data used is experimental data collected on implementing the IoT prototype for an outdoor oyster mushroom growing unit. It has timestamp, inside temperature and humidity value fields. The output of all Simulink models is water pump time and fan time, plotted in the graph shown in Fig 17.

Fig. 17. Output of Simulink models.

All three Simulink models are compared and evaluated using four performance matrices, transient time, settling time, overshoot and peak time. The transient time is the output characteristic of a control system. After applying an input to the control system, the output takes a specific time to reach a steady state. Transient time is the length of time that the control system must respond in order for the transient state to stabilize. While calculating transient time, the parameters considered are settling time, maximum overshoot, and peak time, rise time [28]. Table II and III shows that ANFIS controller has performed better than the FIS and PID controller in terms of transient time, settling time, maximum overshoot and peak time on achieving optimum values.

TABLE II. PERFORMANCE EVALUATION FOR FIS, ANFIS AND PID CONTROLLER FOR WATER PUMP TIME

Performance Parameters	Parameter Values		
	FLC Controller	ANFIS Controller	PID Controller
Transient Time	2.9693	2.9441	7.2451
Settling Time	19.917	16.3742	19.5115
Settling Min	19.0171	14.9875	19.1456
Settling Max	20.8169	17.7610	19.8772
Overshoot	9.4640	8.5054	23.8212
Peak	20.8169	17.7610	19.8772

TABLE III. PERFORMANCE EVALUATION FOR FIS, ANFIS AND PID CONTROLLER FOR FAN TIME

Performance Parameters	Parameter Values		
	FLC Controller	ANFIS Controller	PID Controller
Transient Time	2.9693	8.7821	2.9441
Settling Time	19.917	37.0608	16.3742
Settling Min	19.0171	35.1824	14.9875
Settling Max	20.8169	38.9393	17.7610
Overshoot	9.4640	20	8.5054
Peak	20.8169	38.9393	17.7610

C. Cost Analysis

The list of components and their descriptions used in implementing the IoT prototype are shown in Table IV. Dollars are used to express the cost analysis. Because of variation in the exchange rate of the world market, these cost patterns may change time-to-time. It includes the cost of labor, value added tax, or delivery cost. It can be seen that the full prototype cost 40.46\$. This suggests an inexpensive gadget that can be used by farmers with minimum, available resources efficiently [29].

TABLE IV. COST ANALYSIS OF IMPLEMENTED DEVICE PROTOTYPE

Sr. No.	Component Name	Specifications	Quality	Price per Item	Total Price
1	ESP32	DC Power Source, built in Wi-Fi & Bluetooth	1	4.62\$	4.62\$
2	DHT22 Sensor	Operating Voltage- 5V, Temperature, Range: -40 to 80 °C error: +0.5°C, Humidity Range: 0 to 100% error: +-2%	2	2.42\$	4.84\$
3	Relay Optocoupler	Operating Voltage: 5 to 12V, 1 channel with optical coupler	2	2.42\$	4.84\$
4	FAN	7 inch diameter AC 230 V Fan	1	8.51\$	8.51\$
5	PMDC Diaphragm Motor	Operating Voltage: 12V to 24V, RPM: 40 to 3000rpm, Inlet PSI:20, Nominal Flow>=2 LPM, Working pressure: 100PSI, Power:80 Watt.	1	20.06\$	20.06\$
6	White Pipe	Plastic material, diameter=6mm	1	0.36\$	2.19\$
7	4 Elbow connectors	Plastic material	4	0.073\$	0.29\$
8	T connector	Plastic material	1	0.073\$	0.073\$
Total Price of IoT Prototype in Dollars				40.46\$	

VI. CONCLUSION

A novel Internet of Things-based smart environment monitoring and control system for an outdoor oyster mushroom growing unit is presented in this paper along with a low-cost autonomous sensor prototype. A real working prototype was developed using fuzzy inference system (FIS). The purpose of this effort was to empower farmers to monitor and control temperature and humidity automatically for an oyster mushroom, to increase its yield. The applied prototype used two DHT22 sensors to measure inside and outside temperature and humidity of unit, a water pump to sprinkle the adequate amount of water to maintain humidity, a cooling fan to maintain temperature, and a Wi-Fi module to make internet access to the collected data. The data, collected on the web server, were thoroughly observed and analyzed. The FIS controller is reliable and robust. The data is used to design and implement adaptive neuro fuzzy inference system (ANFIS) in MATLAB/Simulink to improve the performance of controller.

The ANFIS controller is compared with FIS and PID controller in MATLAB/Simulink. The performance evaluation results of ANFIS controller is better than FIS and PID controller in terms of transient time, settling time, maximum overshoot and peak time. In future, the applied low-cost system can be studied, observed, and analyzed with ANFIS controller design. In addition, the presented study focused on small-scale mushroom cultivation, the proposed ANFIS controller can be studied for large-scale mushroom production.

Hybrid Particle Swarm Optimization-based Modeling of Wireless Sensor Network Coverage Optimization

Guangyue Kou*, Guoheng Wei

Department of Information Security, Naval University of Engineering, Hubei 430000, Wuhan, China

Abstract—To address the problem of insufficient coverage of WSN and poor network coverage in obstacle environments, the study proposes an improved particle swarm optimization (PSO) combined with a hybrid grey wolf algorithm. The speed and position of the PSO particle's search for superiority are enhanced through the guiding nature of the superior wolf in the grey wolf optimization (GWO), thus the convergence speed and search precision are improved. Based on this, the study applies the improved PSO to a wireless sensor networks (WSN) coverage optimization model and uses model comparison to test the effectiveness and superiority of the algorithm. According to the results, the node network coverage of PSO, genetic algorithm (GA), data envelopment analysis (DEA), GWO, and grey wolf particle swarm optimization (GWPSO) reach 85.97%, 87.24%, 88.76%, 89.31%, and 91.05% respectively in the trapezoidal obstacle environment. And the node network coverage of the research-designed GWPSO algorithm reaches the highest value of its kind. This shows that the research-designed GWPSO has superior performance in the optimization control of sensor coverage deployment compared with similar algorithms. The design provides a new path for optimizing wireless sensor node network coverage.

Keywords—Particle swarm optimization; wireless sensor networks; network coverage; grey wolf optimization; grey wolf particle swarm optimization

I. INTRODUCTION

As a communication transmission technology under the development of modern network technology, wireless sensor networks (WSN) can freely connect and combine a large number of sensor nodes through wireless communication, forming a communication network. It integrates three information functions through information collection module, information transmission module, and information processing module to achieve coverage and integrated information processing [1-3]. So far, in order to improve the coverage effect of wireless sensor networks, a variety of different types of intelligent algorithms have been used as optimization tools. Among them, the particle swarm optimization algorithm, as an algorithm with strong practicability and robustness, has also received many adaptive improvements in application [4-5]. However, particle swarm optimization (PSO) itself has certain flaws. PSO has the problem of local optimal solutions, which is easily affected by initial values, resulting in inaccurate search; PSO is sensitive to parameter settings and requires multiple experiments to obtain suitable parameter combinations, making parameter tuning difficult; The current research is mostly limited to the improvement of PS itself, lacking research on the combination of PSO algorithm and

other optimization algorithms. Therefore, it is necessary to introduce other algorithms to improve the PSO algorithm and enhance its practicality in WSN coverage optimization [6-8]. By introducing the grey wolf optimization (GWO) and combining it with the PSO for wireless sensor network coverage optimization, it can effectively avoid the local optimal solution problem of the PSO algorithm and improve the accuracy and stability of the search. The research will design and implement an adaptive algorithm for wireless sensor network coverage optimization based on GWO and PSO, effectively improving its optimization effect in practical application scenarios. At the same time, experimental verification will be conducted to further enhance its effectiveness and practicality.

II. RELATED WORK

The hybrid PSO model, an improvement of the particle swarm algorithm, has been gaining ground in various fields in recent years. Şenel F A's team proposes a hybrid model that combines the PSO with GWO, which uses the particles of GWO to replace the relatively underperforming particles of PSO, and then applies the model to leather nested industrial technology problems. After evaluation by the researchers, this model has a performance advantage, being able to obtain the optimal solution faster with fewer iterations than its swarm and social spider counterparts [9]. Chen S's team proposes a new hybrid PSO algorithm model to predict pollutant concentration in air pollution detection. This model combines PSO with a support vector machine (SVM) and uses the pollutant influencing factors as the main model input variables. This hybrid PSO model has superior performance compared to similar models with the same variable elements [10]. Corazza M's team proposes a particle swarm hybrid heuristic algorithm for the portfolio decision problem, which uses a penalty function to redefine the portfolio problem as an unconstrained problem and uses adaptive updates in the optimization process of the unconstrained penalty parameters. This algorithm performs superior to PSO with constant penalty parameters and is more efficient overall [11]. In their study of lateral loading problems for pile-like structures, Khari M et al. proposed a hybrid PSO model that integrates artificial neural networks with particle swarm algorithms, which can effectively predict the lateral deflection of pile-like structures. The results of 183 simulations conducted by the researchers show that the model has higher accuracy in predicting the lateral deflection of pile-like structures compared to similar models, while the systematic error is smaller and it shows higher performance on both the training and test sets.[12] The Sohoul A N team combined the particle swarm algorithm with

a genetic algorithm to form a new evolutionary hybrid PSO and applied the algorithm to the modeling of geological models. This algorithm is applied to the modeling of geological models and geological exploration. The method uses a particle swarm algorithm for magnetic data improvement and a genetic algorithm for model parameter estimation. The algorithm can offer valuable results for estimating model parameters under a 25% noise level [13].

Khalaf O I applied the honeybee algorithm to wireless sensor coverage optimization and compared the results with those of a genetic algorithm. The results show that compared to the genetic algorithm, the honeybee-based wireless sensor coverage optimization has better optimal coverage and consumes fewer resources in the computing process [14]. Cao L et al. proposed a WSN coverage strategy based on the social spider optimization algorithm, which decomposes the combined optimization problem by building and WSN model. The insufficient search capability and convergence speed of the social spider algorithm are improved and finally combined to form an optimization model. The results show that the model is effective in preventing blind spots and redundant spots in the network coverage [15]. Hoffmann R's team proposes a meta-cellular automata approach that solves the optimal wireless sensor coverage problem with smaller sensor tiles to achieve a 2D spatial coverage, which in turn forms a sensor-centered pixel envelope. The results show that the model rules formed by this method can evolve to a more stable optimal coverage state and allow more time for model evolution after the optimal coverage is found.[16]. Li Q's team developed a mathematical model to improve the low overall coverage of wireless sensors and designed a mobile node scheme to improve the coverage optimization of the target area, which can effectively enhance the optimal coverage problem in the detection area. The results show that the strategy designed in the study can effectively enhance the network coverage and prolong the network service time [17]. ZainEldin H's team proposed a dynamic deployment technology based on a genetic algorithm and applied it to the optimization of WSN coverage, which is used to reduce the overlapping area between adjacent nodes by optimizing the minimum quantity of nodes, thus forming the coverage effect. The results of the study show that the designed method is compatible with the proposed method. The results of the study show that the method designed in the study has higher stability compared to other methods [18].

III. WSN COVERAGE OPTIMIZATION MODEL CONSTRUCTION BASED ON GWPSO HYBRID ALGORITHM

A. PSO Optimization based on the Standard GWO

WSN is a distributed large-scale network, mainly composed of micro-nodes that can sense and process information and communication capabilities, and through a decentralized and self-organizing form of network, its network structure mainly consists of aggregation nodes, sensors, networks, etc. WSN on the target environment, such as temperature, humidity, and image information is collected and processed, and transmitted to the sensor terminal device, for the need of information. The WSN collects and processes information such as temperature, humidity, and images from

the target environment and transmits it to the sensor terminals to serve the users who need the information. Multiple sensor nodes are placed in the target area, which collects temperature, humidity, and image information and sends it to the gateway or aggregation node via multi-hop routing. The WSN architecture is shown in Fig. 1.

Fig. 1. WSN STRUCTURE.

Typically, a WSN node consists of a sensing unit, an energy unit, a processing unit, and a communication device, all of which work together to sense, collect and transmit target data. The sensing unit is responsible for converting the sensed analogue signal into a digital signal, which consists of sensors and A/D converters; the processing unit processes and compresses the collected data; the communication unit is responsible for data transmission and exchange of control information in the network; and the energy unit is responsible for providing energy to the other units, which are usually powered by micro batteries. The WSN node structure is shown in Fig. 2.

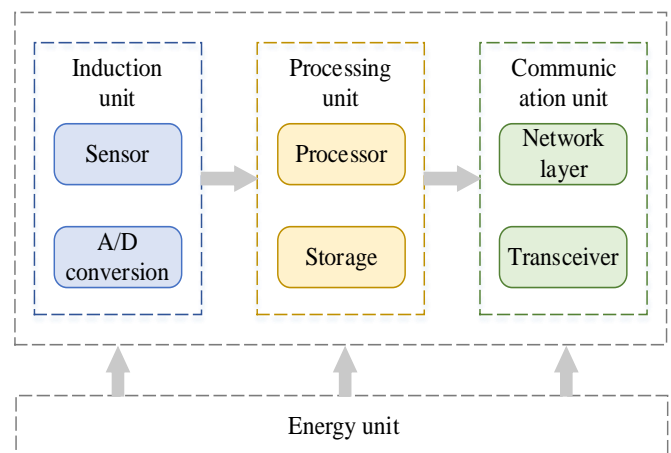

Fig. 2. WSN NODE STRUCTURE.

Suppose there are n sensor nodes in WSN, and the set is $S = \{s_1, s_2, \dots, s_i, \dots, s_n\}$, these nodes are identical and all have a radius of r , and the target detection area is a rectangle with an area of Z m². This grid monitoring area is transformed into Z a small rectangular grid of equal size whose geometric centre represents the monitoring position of the wireless sensor node in the target area. A monitoring action

is successful when the range between the target point and any node shall not be greater than the monitoring radius of the node. The set of monitoring target points is $M = \{m_1, m_2, \dots, m_j, \dots, m_Z\}$, the two-dimensional spatial coordinates of s_i in the set are (x_i, y_i) , the two-dimensional spatial coordinates of m_j are (x_j, y_j) , and the Euclidean distance between two nodes is shown in equation (1).

$$d(s_i, m_j) = \sqrt{(x_i - x_j)^2 + (y_i - y_j)^2} \quad (1)$$

The joint probability of all sensor nodes denoted as s_{all}, s_{all} to the target monitoring node m_j is shown in equation (2).

$$C_p(s_{all}, m_j) = 1 - \prod_{i=1}^n (1 - p_{cov}(s_i, m_j)) \quad (2)$$

In equation (2), P_{cov} represents the probability of a node sensing a target monitoring point s_i, m_j . Calculate the joint sensing probability of all target points, and the altogether joint sensing probability of target points is the coverage area, and the coverage rate C_r is as in equation (3).

$$C_r = \frac{\sum_{j=1}^Z C_p(s_{all}, m_j)}{Z} \quad (3)$$

A prerequisite for the self-organisation of sensor nodes to form a WSN is that the network remains connected. The nodes in the study have a sensing radius of r and a maximum communication distance of $2r$. When the range between nodes s_i and s_j does not exceed the sensing length, the two nodes are adjacent and the edge between nodes is 1. When the range between s_i and s_j exceeds the sensing radius, the two nodes are not adjacent and the edge between nodes is 0. Accordingly, the nodes' corresponding adjacency matrix AM is constructed and the connectivity of the network is judged using AM . The matrix N is shown in equation (4).

$$N = AM + AM^2 + \dots + AM^{n-1} \quad (4)$$

In equation (4), n represents the number of sensors, determining whether the elements in this matrix are all 1, if yes, the network is connected, otherwise the network is not connected.

The GWO imitates the hunting mechanism of grey wolves and has the advantage of being plain, flexible, and scalable, and uses fewer parameters in the algorithm. The mathematical

model of the algorithm simulates a wolf pack divided into four classes α, β, δ and ω , with a structure similar to that of a pyramid, as shown in Fig. 3.

Fig. 3. RANKING STRUCTURE OF WOLVES.

The wolves are ranked according to the fitness value of individual grey wolves, and the top three grey wolves in the pack are ranked in the α, β and δ levels respectively. α has the highest rank and indicates the current optimal solution. ω The grey wolf individuals with the highest rank are the candidate in this group. ω In the iteration of the algorithm, the grey wolves in the first three levels are responsible for guiding the grey wolves in the ω level to search for prey, and the grey wolves in the ω level improve their fitness value by searching for prey. Assuming that the actual location of the prey is unknown to individual grey wolves during the hunting process, the wolves with the highest to lowest ranks of α, β and δ are closest to the prey, so the wolves in the ω layer can surround the prey according to the positions of the wolves in the α, β and δ layers, and keep approaching the prey and finally find the prey. ω The distances between the wolves in the, and α, β, δ layers are shown in equation (5).

$$\begin{cases} D_\alpha = C_1 * X_\alpha(t) - X_\omega(t) \\ D_\beta = C_2 * X_\beta(t) - X_\omega(t) \\ D_\delta = C_3 * X_\delta(t) - X_\omega(t) \end{cases} \quad (5)$$

In equation (5), D_α, D_β and D_δ represent the distances between α, β and δ and ω respectively, $X_\alpha(t), X_\beta(t), X_\delta(t)$ and $X_\omega(t)$ are the positions of α, β, δ and respectively, and C_1, C_2 and C_3 represent the orientation variables of ω when the layer wolves move towards α, β and respectively. δ, ω After calculating the distance between the layer wolves

and the positions of the α , β and δ layer wolves during the hunt, the layer wolves kept approaching them in certain steps respectively and finally reached the predetermined position. The position of the ω wolf was updated as shown in equation (6).

$$\begin{cases} X_1 = X_\alpha - A_1 * D_\alpha \\ X_2 = X_\beta - A_2 * D_\beta \\ X_3 = X_\delta - A_3 * D_\delta \end{cases} \quad (6)$$

In equation (6), X_1 , X_2 and X_3 indicate the position of the wolf in the ω layer when it is guided by the wolves in the α , β and δ layers, respectively, and t indicates the current iterations. A_1 , A_2 , A_3 indicate the step length of the ω layer wolf as it approaches the prey under the guidance of the α , β and δ layers, respectively. When, $|A_1| < 1$ ω wolves will conduct a fine search around the prey, and when $|A_1| > 1$, ω wolves will expand their search around the prey. A_1 The formulae for A_2 and A_3 are shown in equation (7).

$$\begin{cases} A_1 = 2a * rand - a \\ A_2 = 2a * rand - a \\ A_3 = 2a * rand - a \end{cases} \quad (7)$$

In equation (7), a is the convergence factor, which represents the iterative process of decreasing from 2 to 0. The convergence factor a is calculated by equation (8).

$$a = 2 - 2 \left(\frac{t}{t_{\max}} \right) \quad (8)$$

t_{\max} The GWO algorithm generates the initial wolf pack, divides the pack into four classes: α , β , δ and ω , gauges the range between individual grey wolves and their prey, then updates their respective positions according to the measured lengths, with each individual grey wolf in the pack representing a solution that is continuously updated during the search process. The GWO process is shown in Fig. 4.

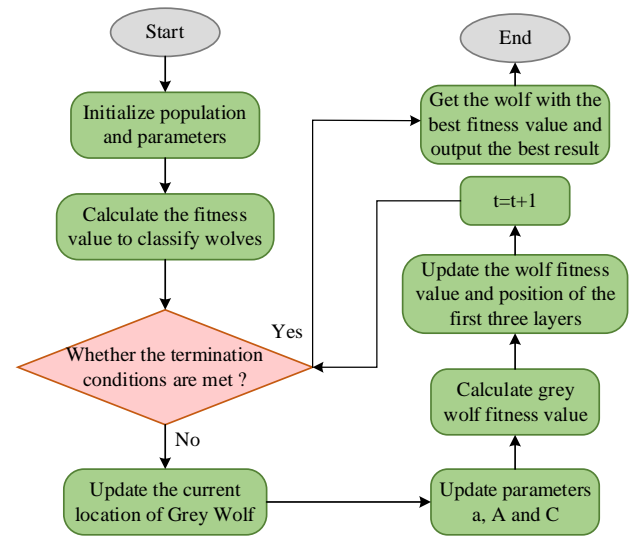

Fig. 4. FLOW OF GWO.

B. WSN Coverage Optimization Model for the GWPSO Hybrid Optimization Algorithm

The PSO always moves in the direction of the optimal individual's position, so its convergence velocity is relatively fast but the ability to balance the global search is still deficient, which leads to the inability of the algorithm to precisely seek the global optimal solution when solving complex optimization problems; GWO does not learn from the experience of others when searching for the optimal solution, so it is easy to ripe untimely. To address the shortcomings of both algorithms, the DEA algorithm is incorporated into PSO, and at the beginning, the chaos multi-way learning strategy is used to improve the population variance, and the convergence factor is dynamically adjusted to consider the global and local optimization. The properties of chaotic mapping can be able to properly enrich the variety of the initial population so that the particles can find the optimal solution, and the study uses Tent mapping to create the initial population [19-20]. Multi-way learning strategy can generate corresponding solutions by evaluating upper and lower-bound solutions and original solutions; the optimal solution of fitness value is selected from these solutions. The improved differential evolution PSO uses a mixed multidirectional learning strategy, according to which a multidirectional population is generated, the individuals of the generated multidirectional chaotic population are compared with the individuals of the original chaotic population in terms of their fitness values, and the individuals with the best fitness values are set as the initial population.

Assuming that the population size is N and the spatial dimension of it is D , a chaotic sequence is generated in the space using the Tent chaos

$$W = \{W_j, j = 1, 2, \dots, D\}$$

mapping

and $W_j = \{W_{i,j}, i = 1, 2, \dots, N\}$. The Tent chaos mapping function is shown in equation (9).

$$W_{i+1,j} = \begin{cases} Z_{i,j} / 0.65, & Z_{i,j} < 0.65 \\ (1 - W_{i,j}) / 0.35, & Z_{i,j} \geq 0.65 \end{cases} \quad (9)$$

$$a = -2 * \frac{\delta^2}{\delta_{\max}^2} \cos\left(\frac{\pi t}{2t_{\max}}\right) \quad (12)$$

The chaotic sequence generated by the chaotic mapping is mapped to the solution space to obtain the population

$$Y_j = \{Y_i, i = 1, 2, \dots, N\}$$

, $Y_i = \{Y_{i,j}, j = 1, 2, \dots, D\}$, and the population

individuals $Y_{i,j}$ denoted as shown in equation (10).

$$Y_{i,j} = Y_{\min,j} + Y_{i,j} (Y_{\max,j} - Y_{\min,j}) \quad (10)$$

In equation (10), $Y_{\min,j}$ and $Y_{\max,j}$ are the bounds on the particle finding solution, and $Y_{i,j}$ is the value of the i th particle in the space corresponding to the j th dimension. The multidirectional populations OY_j and OY_i , MY_j and MY_i are calculated as shown in equation (11).

$$\begin{cases} OY_{i,j} = Y_{\min,j} + Y_{\max,j} - Y_{i,j} \\ MY_{i,j} = Y_{\max,j} - Y_{\min,j} + Y_{i,j} \end{cases} \quad (11)$$

The fitness values of the primitive population and the multi-way population individuals are further calculated, and the particles with more favourable positions are selected from the population individuals based on the fitness values. The value of the coefficient A changes with the distance control parameter a during the iterative process, so setting the distance control parameter a to a reasonable value can effectively provide a solution to the balance between the speed of particle population search and the accuracy of particle local search. In the particle search process, the distance control parameter a needs to be set to a larger value in the first stage to expand the search range, which is beneficial to the particle search. In the later stage, the distance control parameter a needs to be set to a smaller value to concentrate the particle population around the optimal solution for fine searching. The linearly decreasing distance control parameter a cannot be adapted to the actual solving situation. To address this drawback, a cosine convergence factor strategy incorporating state coefficients is proposed to effectively take into account the overall optimization efficiency of the algorithm. Under this strategy, the distance control parameter a is non-linearly decreasing and its value is dynamically adjusted according to the properties of the random variables. With this strategy, the algorithm will search more vigorously at the initial stage of the iteration, and at the final stage of the iteration the particles will focus on the fine search around the optimal value, increasing the probability of finding the global optimum. The dynamic adjustment strategy for the convergence factor is shown in equation (12).

In equation (12), δ denotes the particle state coefficient, t

is the current iteration and t_{\max} is the maximum iteration. The study combines the convergence factor adjustment strategy of state coefficients and cosine transform, which effectively improves the speed of global particle search. The smaller change in the convergence factor at the end of the iteration is beneficial to the local fine search of the particle, thus improving the accuracy of the optimal solution. The GWO algorithm mainly adjusts its own position by combining the obtained position of individual grey wolves with the relationship between the first three levels of optimal solutions in the pack, enabling the exchange of information between the two. By introducing the idea of updating the position information in the GWO algorithm, the PSO's search capability is optimized so that the particles in space can expand the search space and enhance the search effort, thus finding the optimal solution more efficiently and accurately

[21]. The updated formula for the particles V_{ij} and X_{ij} after the introduction of the GWO idea is shown in equation (13).

$$\begin{cases} V_{ij}(t+1) = \omega V_{ij}(t) + c_1 r_1 (\omega_1 X_1(t) + \omega_2 X_2(t) + \omega_3 X_3(t)) \\ \quad + c_2 r_2 (p_{best}(t) - X_{ij}(t)) \\ X_{ij}(t+1) = X_{ij}(t) + V_{ij}(t+1) \end{cases} \quad (13)$$

In equation (13), c_1 represents the cognitive learning factor, which describes how much the finding of an optimal solution by an individual particle affects the finding of an

optimal solution by all particles in the space; c_2 represents the social learning factor, which describes how much the finding of an optimal solution by a population of particles affects the algorithm. c_1 Larger values indicate that particles are more

likely to concentrate locally, and larger values of c_2 indicate that particles are more likely to find a locally optimal solution

early and converge on that solution. r_1 and r_2 are random

numbers in the range [0,1]. ω_1 , ω_2 and ω_3 denote the inertia weight coefficients of the grey wolf. To take into account the global and local optimality finding capacity of the particles, the grey wolf inertia coefficients are improved as in equation (14).

$$\begin{cases} \omega_1 = \frac{|X_1|}{|X_1 + X_2 + X_3|} \\ \omega_2 = \frac{|X_2|}{|X_1 + X_2 + X_3|} \\ \omega_3 = \frac{|X_3|}{|X_1 + X_2 + X_3|} \end{cases} \quad (14)$$

When searching for the optimal value, the particle will learn from the current global optimum. When the difference between the current value and the global optimum is large, the learning of the particle will lead to an error and the particle will sink into the local optimum. If the global historical optimal solution approaches the current optimal solution, using the perturbation strategy will increase the range between the particle and the optimal solution, so the perturbation strategy should be used for particles that fall into the local optimum or perform poorly. As the 'early' particles are located closer to the optimal solution in some dimensions of space, external forces are applied to these particles to move them from their current position and proceed with the search. To address the problem of large fluctuations in the particle

population, the perturbation strategy is used to limit the perturbation operation to a distance of no more than 20%. The formula for updating the position of a particle after the perturbation is shown in equation (15).

$$X_{ij}(t+1) = r_1 V_{ij}(t+1) + (1 - 0.2r_2) X_{ij}(t) \quad (15)$$

In equation (15) r_1 and r_2 are random numbers in the range [-1,1]. Applying GWPSO hybrid optimization algorithm to the optimal deployment of node coverage in WSN, by using the coverage function as the fitness value of the algorithm. The beginning of the algorithm introduces a chaotic multi-way learning strategy to initialize the population and combines the state coefficients to improve the convergence factor using the cosine variation principle, thus enabling the algorithm to gain an improvement in its optimization-seeking capability. The inertia weight coefficients of the grey wolf are improved to update the position and speed of the particles, and finally, the speed and position of them are perturbed to improve the population diversity and thus the search accuracy of the particles, which effectively improves its search capability. The optimal fitness value at the end of the algorithm iteration is the global optimal solution. The flow of the algorithm is shown in Fig. 5.

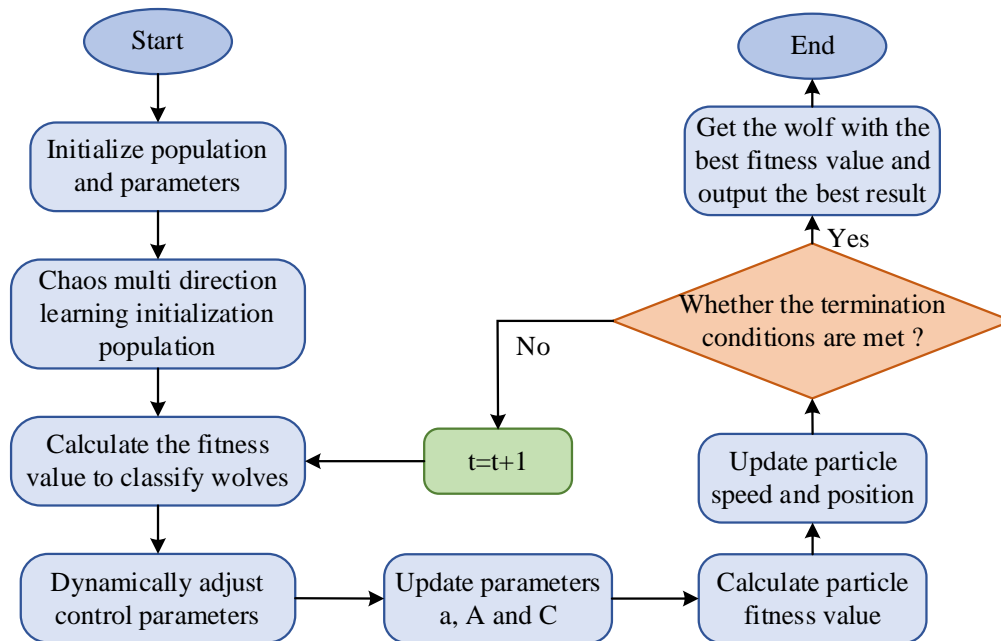

Fig. 5. FLOW OF GWPSO.

IV. ANALYSIS OF WSN COVERAGE OPTIMIZATION RESULTS BASED ON THE GWPSO HYBRID OPTIMIZATION ALGORITHM

The superiority of the GWPSO algorithm was demonstrated through simulation experiments in the MATLAB R2016a environment. Three different unimodal benchmark test functions and three different multimodal benchmark test functions were selected to test the convergence of the five algorithms. The population size in the test was 30, with 500 iterations. Any test function was independently run 50 times to record its average value. The study demonstrates the performance of the GWPSO hybrid optimization algorithm and its advantages through simulation experiments. Six functions are used to test the convergence function of the algorithm and to compare the performance with PSO, GA, DEA, and GWO algorithms. The four algorithms are used to optimise the deployment of WSN node coverage in an obstacle-free environment and a trapezoidal obstacle environment respectively, and finally, the results obtained are analysed. There are three single-peak-based test functions and three multi-peak-based test functions among the six selected test functions, and the optimal values in the GWPSO test theory are all 0. The test functions are shown in Table I.

The study compares the convergence of the PSO, GA, DEA, and GWO algorithms and the study's proposed GWPSO hybrid optimization algorithm under the test functions, and the algorithm's convergence under F1, F2, F3 and F4 is compared

as shown in Fig. 6.

In Fig. 6, the five algorithms converge gradually with an increasing number of iterations on the four functions, with the PSO, DEA, and GA algorithms showing poor convergence performance and the GWPSO algorithm showing the best convergence on the four functions. The convergence of the algorithms on F5 and F6 is shown in Fig. 7.

The advantageous convergence function of the GWPSO owing to the chaotic multidirectional learning strategy that improves the initial population space dynamically adjusts the control parameters, and uses the optimization-seeking property of the GWO algorithm to expand the particle's global search range in the pre-optimization phase. The use of the perturbation strategy effectively prevents the particles from sinking into the local optimum and significantly enhances the search precision of the particles, thus effectively improving the particle search capability. Thirty-five WSN nodes were deployed in a 50m x 50m square region with a sensing radius of 5m and a communication radius of 10m, $N = 50$ and $t = 30$. After the initial locations of the nodes were deployed, the nodes were unequally spread, and there was a large amount of coverage redundancy as the initial locations were randomly selected. Five algorithms were used to optimise the node coverage deployment and the coverage results are shown in Fig. 8.

TABLE I. TEST FUNCTION

ID	Function	Expression	Type
F1	Sphere	$f(x) = \sum_{i=1}^D x_i^2$	Unimodal
F2	Schwefel2.22	$f(x) = \sum_{i=1}^D x_i + \prod_{i=1}^D x_i $	Unimodal
F3	Rosenbrock	$f(x) = \sum_{i=1}^{n-1} \left(100(x_{i+1} - x_i^2)^2 + (x_i - 1)^2 \right)$	Unimodal
F4	Rastrigin	$f(x) = \sum_{i=1}^D \left[x_i^2 - 10 \cos(2\pi x_i) + 10 \right]$	Multimodal
F5	Griewank	$f(x) = \frac{1}{4000} \sum_{i=1}^D x_i^2 - \prod_{i=1}^D \cos\left(\frac{x_i}{\sqrt{i}}\right) + 1$	Multimodal
F6	Ackley	$f(x) = -20 \exp\left(-0.2 \sqrt{\frac{1}{D} \sum_{i=1}^D x_i^2}\right) - \exp\left(\frac{1}{D} \sum_{i=1}^D \cos(2\pi x_i)\right) + 20 + e$	Multimodal

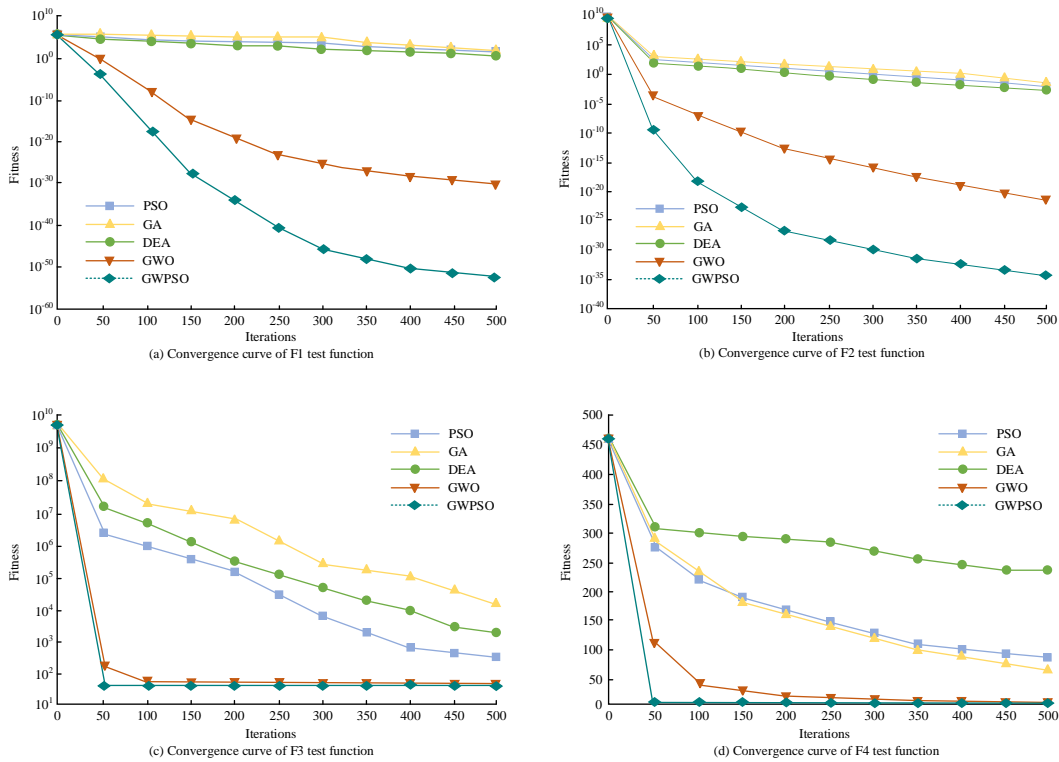

Fig. 6. CONVERGENCE CURVE OF F1, F2, F3 AND F4 TEST FUNCTIONS.

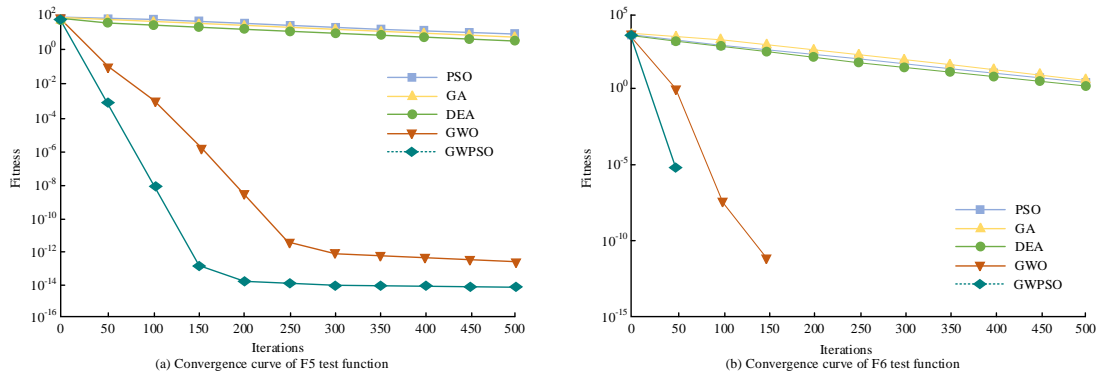

Fig. 7. CONVERGENCE CURVE OF F5 AND F6 TEST FUNCTIONS.

In Fig. 8, the network coverage was all improved after the node coverage deployment was optimized by the algorithms. The node network coverage after optimization by the PSO, GA, DEA, GWO, and GWPSO algorithms reached 86.75%, 88.24%, 89.54%, 90.48%, and 94.62% respectively. The node network coverage after optimization by the GWPSO algorithm was the highest among all algorithms and its optimization of node network coverage was the best, resulting in a significant coverage improvement. To further validate its availability, the study placed a trapezoidal obstacle in a 50m x 50m square monitoring area, which has an area of 500m². A population size of 50 was set and 25 sensing nodes were deployed, of which 2 were fixed nodes and the rest were mobile nodes. The maximum sensing radius of the mobile nodes is 5m and the maximum communication range is 10m, while the maximum sensing radius of the fixed nodes is 7.5m and the maximum communication range is 15m. Five algorithms were used to

optimize the coverage of the sensing nodes in the region, and the results are shown in Fig. 9.

Fig. 8. COVERAGE RESULTS IN BARRIER-FREE ENVIRONMENT.

VI. CONCLUSION

To solve the problems of insufficient coverage of WSN and poor coverage in obstacle environments, the study combines the GWO with the PSO algorithm, which in turn forms an optimization search algorithm with higher search accuracy and faster convergence. The study adopts the algorithm in an applicative design, applies it to a wireless sensor network coverage optimization model, and finally analyses the application of the model by way of model comparison and application validation. Five experimental models have been used for the optimization of WSN. The results demonstrate that the five algorithms tested converge gradually with an increasing number of iterations on six functions, and the GWPSO algorithm converges best on all functions. In the comparison of network coverage optimization results, the PSO, GA, DEA, GWO, and GWPSO algorithms achieved 86.75%, 88.24%, 89.54%, 90.48%, and 94.62% of node network coverage after optimization, respectively. The GWPSO algorithm had the highest optimized network coverage. In the obstacle environment, the node network coverage of PSO, GA, DEA, GWO, and GWPSO algorithms reached 85.97%, 87.24%, 88.76%, 89.31%, and 91.05% respectively. The optimized network coverage of the GWPSO algorithm was also the highest. This shows that the GWPSO network coverage optimization algorithm designed in the study has a superior performance and is more practical for the optimal control of sensor coverage deployment.

Fig. 9. COVERAGE RESULTS IN A TRAPEZOIDAL OBSTACLE ENVIRONMENT.

In Fig. 9, the network coverage in the trapezoidal obstacle environment was all improved after the algorithm was optimized for node coverage deployment. The node network coverage in the trapezoidal obstacle environment reached 85.97%, 87.24%, 88.76%, 89.31%, and 91.05% after optimization by the PSO, GA, DEA, GWO, and GWPSO algorithms respectively. The node network coverage after optimization by the GWPSO algorithm was the highest among all algorithms and its optimization of node network coverage was the best, resulting in marked upgradation in coverage. Because the number of sensor nodes in the trapezoidal obstacle environment was 10 less than the number of sensors in the barrier-free environment, the overall node network coverage after algorithm optimization was worse than that in the barrier-free environment, and the algorithm's optimization of node network coverage was also worse than that in the barrier-free environment. The results demonstrate that the GWPSO algorithm has the most significant optimization effect among all algorithms in both the obstacle-free and trapezoidal obstacle environments, fully verifying that the algorithm has superior performance in the optimal control of sensor coverage deployment, and providing an effective path for the optimization of WSN node network coverage.

V. DISCUSSION

The research aims to solve the problem of insufficient coverage of wireless sensor networks and poor coverage effect in obstacle environments. By combining the Grey Wolf algorithm and PSO algorithm, this study designed a GWPSO wireless sensor network coverage optimization algorithm and applied it to the sensor network coverage optimization model. The research results show that the GWPSO algorithm has the best convergence performance on all functions, and it achieves the best results in optimizing node network coverage, and also has the best coverage effect in obstacle environments. This shows that the GWPSO algorithm has better search accuracy and convergence speed, and has a significant application effect in the coverage optimization model of wireless sensor networks, with higher practicability. This research result provides effective algorithm support for the deployment and optimization of future wireless sensor networks, and can better adapt to complex real application scenarios. Future research based on this algorithm can further optimize its performance and enhance its applicability in application fields.

Abstract—Flexible AC Transmission Systems (FACTS) play a vital role in minimizing the power losses and improving voltage profile in power transmission system. These increase the real power transfer capacity of the system. However, optimal location of sizing of the FACTS devices determines the extent of benefits provided by the FACTS devices to the transmission system. Non-optimal solution in terms of the location and sizing may possibly lead to under-compensation or over-compensation phenomena. Thus, a robust optimization is a priori for optimal solution achievement. This paper presents a study on the effect on multi static VAR compensators (SVC) installation for loss control in power system using evolutionary programming (EP), artificial immune system (AIS) and immune evolutionary programming (IEP). The objective is to minimize the real power loss transmission and improve the voltage profile of the transmission power system. The study reveals that installation of multi-units SVC significantly reduces the power loss and increases the voltage profile of the system, validated on the IEEE 30-Bus Reliability Test System (RTS).

I. INTRODUCTION

The world electricity demand has been steadily increasing over the past few decades due to various factors such as population growth, urbanization, economic development, and technological advancements [1]. Conventional approach such as construction of new power plant and transmission lines to meet the increasing demand of electricity is not a feasible option due to many reasons such as high cost, environmental concerns, technical and time constraints. One of the vital ways to optimize the current system is by reducing the loss in the power system which can be achieved by injecting or retrieving the reactive power with the assistance of FACTS. Installation of FACTS devices can be one of the popular initiatives.

The concept of FACTS was first introduced by Hingorani in 1998 [2]. The working principle of FACTS is to enable the system electric parameters to change fast and flexibly while maintaining the security, stability and reliability of power system; thus, optimizing the existing resources in reducing power loss and cost, while improving the efficiency of the power grid operation [3]. It is important to understand that

FACTS devices confined several compensation devices such as unified power flow controller (UPFC), static VAR compensator (SVC), thyristor-controlled series compensator (TCSC), and static synchronous compensator (STATCOM). SVC is considered as a popular compensating device in power system. SVC is a parallel connected device which can act as variable capacitor or variable inductor.

The important uses of SVC are voltage stabilization of weak networks, reducing transmission losses, increasing power transfer capacity, increasing the small disturbance damping, improving voltage stability and removing power fluctuations [4]. SVC is chosen in this work based on its functionality. Optimal placement and sizing remain as a challenge in application of SVCs in voltage stability enhancement [5],[6]. Several optimization techniques have been invented to achieve the optimal solution for SVC installation for the purpose of minimizing the loss in power system or controlling the voltage level in a system within the acceptable limit determined by IEEE or IET standards. Otherwise, a power system will operate under low voltage level which in turn affecting the life time of a transmission cable in the system.

Heuristic optimization techniques have become an important approach in solving complex which is difficult to be solved using traditional approach [6],[7]. Heuristic optimization technique has been adopted in determining the optimization of FACTS devices for power system performance improvement. EP was used to optimize the size of SVC for minimization of loss and voltage profile improvement [8]. EP and AIS were used for SVC location and sizing optimization in IEEE 30-Bus RTS [9]. This application indicates that both EP and AIS is robust in achieving the optimal solution for SVC installation in power system.

On the other hand, improved version of traditional optimization techniques has also been proposed. Among the important techniques that can be highlighted, is a novel improved differential evolutionary (IDE) algorithm which is applied to optimize SVC and TCSC location and sizing for reactive power management in IEEE Bus-30 RTS, IEEE-57 RTS and IEEE-118 RTS [10]. Improved particle swarm in [11] is successfully applied in solving multi-objectives problems. However, the application dealt with the available transfer capability (ATC) study. Other important work that can be highlighted is the work conducted [12] where SVC and

The authors appreciate the support given by the Ministry of Higher Education and Universiti Kebangsaan Malaysia for the operational and financial support to this project under Project Codes GUP-2022-010 and RHB-UKM-2021-002.

TCSC were used as the compensating devices. Gravitational search algorithm (GSA) is proposed for the loadability enhancement of the power system under different loading conditions by determining the optimal placement of different TCSC and SVC [13]. Another work conducted using whale optimization technique in [14] can be considered useful involving SVC and TCSC installation. Thus, a critical review may lead to an efficient decision in any compensation effort in power system.

This paper presents effects of multi-SVC installation for loss control in power system using multi-computational techniques. In this study, EP, AIS and Immune EP (IEP) were applied to identify the locations and sizing of SVC installation in controlling the transmission loss in power system. Controlling transmission loss in power systems is important as it enables optimal voltage control, reactive power compensation, and power flow regulation. By strategically placing SVCs, voltage stability is maintained, transmission losses are minimized, and system efficiency is improved, leading to reliable and secure operation. Results validated on the IEEE 30-Bus RTS revealed that all the techniques are comparable for loss control scheme in power system.

This paper is organized as follows. The objectives and problem formulations are established in Section II. Section III describes the optimization techniques used in detail. Section IV presents the test system used in the work. Section V presents the simulation results and discussions. Finally, Section VI concludes the paper with recommendations.

II. OBJECTIVE AND PROBLEM FORMULATION

Loss minimization is a vital remedial action applied in power system planning and operation. Transmission loss is proportionally translated to monetary loss as not all electricity generated is delivered to the customers. Compensation scheme such as installation of SVC can greatly reduce losses in the system. This research holds significant importance as its main objective is to study the effect of installing multi SVCs for loss control in power system using multi-computational intelligence techniques. The optimization of SVC location and sizing plays a crucial role in achieving this objective. By formulating the problem in terms of power loss minimization, this study addresses a critical aspect of enhancing power system efficiency and sustainability, thereby contributing to the advancement of power grid operations and control strategies.

The objective function, (OF) of this work is to minimize total loss in a transmission power system, which is mathematically represented by:

$$OF = \min \sum_{i=1}^n P_{Loss,i} \quad (1)$$

where n is number of buses in the system, and $P_{Loss,i}$ is power loss for line i which can be determined using (2), (3) and (4).

$$P_{Loss} = \sum_{i=1}^n \sum_{j=1}^n [\alpha_{ij}(P_i P_j + Q_i Q_j) + \beta_{ij}(Q_i P_j + P_i Q_j)] \quad (2)$$

$$\alpha_{ij} = \frac{r_{ij}}{v_i v_j} \cos(\delta_i - \delta_j) \quad (3)$$

$$\beta_{ij} = \frac{r_{ij}}{v_i v_j} \sin(\delta_i - \delta_j) \quad (4)$$

where

r_{ij} = line resistance between bus i and bus j

P_i and P_j = active power at bus i and bus j

Q_i and Q_j = reactive power at bus i and bus j

V_i and V_j = voltage magnitude

δ_i and δ_j = voltage angles

α_{ij} = active power loss factor

β_{ij} = reactive power loss factor

The objective function is subjected to voltage constraints and SVC location and sizing during the optimization process. The minimum voltage must be kept within the specified limits during the optimization process as indicated in (5).

$$0.95 \text{ p.u.} \leq V_i \leq 1.05 \text{ p.u.} \quad (5)$$

Electrical utilities maintain the voltage level to be in the range ± 5 from the nominal voltage level. SVC can be located at load bus only.

The sizing of the SVC is subjected to constraint as shown in (6).

$$0 \text{ MVar} \leq Q_{SVC} \leq 100 \text{ MVar} \quad (6)$$

Loss reduction percentage (LRP) and V_{\min} improvement percentage (VIP) are used for comparison. LRP and VIP are computed based on (7) and (8).

$$LRP = \frac{P_{Loss}(\text{pre_SVC}) - P_{Loss}(\text{post_SVC})}{P_{Loss}(\text{pre_SVC})} \quad (7)$$

$$VIP = \frac{V_{\min}(\text{post_SVC}) - V_{\min}(\text{pre_SVC})}{V_{\min}(\text{pre_SVC})} \quad (8)$$

III. OPTIMIZATION TECHNIQUES

Optimization technique is a collection of mathematical principles and methods used in solving a quantitative problem. Optimization technique is one of the most preferred and widely used techniques to solve SVC location and sizing optimization for minimization of transmission loss. In this study, three promising and evolving optimization techniques are applied, namely EP, AIS, IEP for location and sizing optimization of SVC for power loss reduction.

A. Evolutionary Programming

Evolutionary Programming (EP) is an artificial intelligence method inspired from natural selection process to find the global optimum of a complex problem. It was first invented by Lawrence J. Fogel in the US in 1960 [15]. The mechanics of EP algorithm is illustrated in Fig. 1.

Step 1: Initialization

The initialization process of EP begins with generating the control variables for optimal location and sizing of SVC using a uniformly distributed random number generator. 20

individuals (parents) are generated based on the control variables for the first iteration. In this case, the control variables will represent the locations and sizing of the SVC units. Apparently, the number of control variables or decision variables will be doubled of the number of SVC units to be installed into the system. During initialization, parameters such as: number of individuals, mutation step size and maximum number of iterations are specified. The total loss of the system before optimization, $P_{Loss (pre_SVC)}$ is calculated as the reference value. The individuals that violate the requirements and constraints are subsequently exterminated from the population pool.

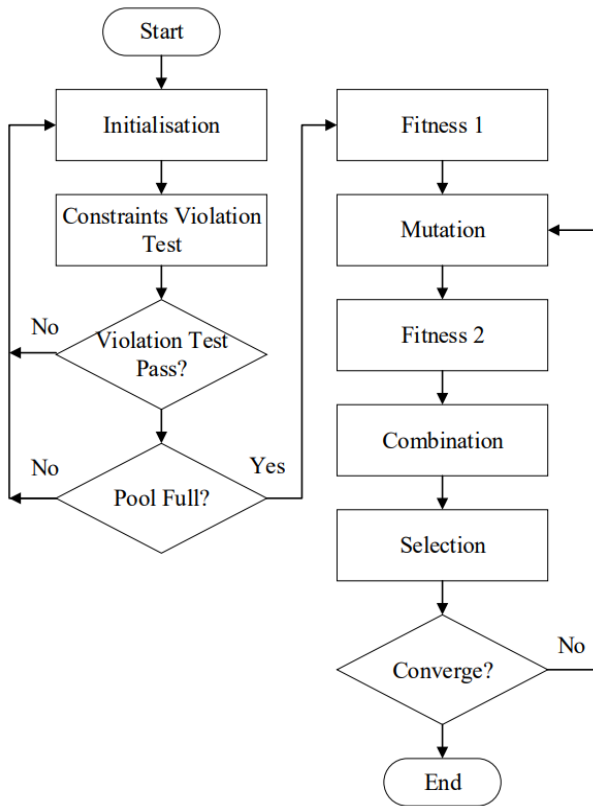

Fig. 1. Flow chart of EP algorithm.

Step 2: Fitness 1 Calculation

Load flow programs are performed to calculate the fitness value which is the real power loss, $P_{Loss (post_SVC)}$. If $P_{Loss (post_SVC)} < P_{Loss (pre_SVC)}$, and fulfils the other constraints specified, they will be accepted into the initial population pool. The general matrix for the initial population, X is given by (9).

$$X = \begin{bmatrix} x_{11} & x_{12} & \dots & x_{1q} & f_1 \\ x_{21} & x_{22} & \dots & x_{2q} & f_2 \\ \vdots & \vdots & \dots & \vdots & \vdots \\ x_{p1} & x_{p2} & \dots & x_{pq} & f_p \end{bmatrix} \quad (9)$$

where:

p = population size

q = no. of variable

f = fitness of the individual (parent)

Step 3: Mutation

Mutation is a process to breed offspring. The individuals (parents) in the population pool are mutated to breed offspring using the Gaussian mutation operator [16]–[18]. The Gaussian mutation equation is given in (10).

$$x_{i+m,j} = x_{i,j} + N \left(0, \beta (x_{jmax} - x_{jmin}) \left(\frac{f_i}{f_{max}} \right) \right) \quad (10)$$

where

$x_{i+m,j}$ = offspring (mutated parent)

$x_{i,j}$ = parent

N = Gaussian random variable

β = mutation scale $0 < \beta < 1$

x_{jmax} = maximum value of parent

x_{jmin} = minimum value of parent

f_i = fitness of the i^{th} random number

f_{max} = maximum fitness

Step 4: Fitness 2 Calculation

Fitness 2 calculation is performed by running the load flow again, using the offsprings bred during the mutation process. The matrix for the offspring population, X_{off} is given by (11).

$$X_{off} = \begin{bmatrix} \alpha_{11} & \alpha_{12} & \dots & \alpha_{1q} & F_1 \\ \alpha_{21} & \alpha_{22} & \dots & \alpha_{2q} & F_2 \\ \vdots & \vdots & \dots & \vdots & \vdots \\ \alpha_{p1} & \alpha_{p2} & \dots & \alpha_{pq} & F_n \end{bmatrix} \quad (11)$$

where

n = population size

m = no. of variable

F = fitness of the offspring

Step 5: Combination Process

The parent matrix and the offspring matrix are then combined in a cascaded form as in (12).

$$X_{combined} = \begin{bmatrix} X \\ X_{off} \end{bmatrix} \quad (12)$$

Step 6: Selection Process and Convergence Test

The individuals in matrix $X_{combined}$ is ranked in ascending order based on fitness value. 20 best individuals from matrix $X_{combined}$ are selected for the next iteration. New individuals are identified for the next iteration process. In this case, the new individuals will be equipped together with the corresponding fitness value for the next iteration or evolution. However, if the new individuals do not bring together the corresponding fitness values, Fitness 1 calculation needs to be conducted. A convergence test is used to check if the optimal solution has been achieved. Otherwise, Step 2 through Step 4

will be repeated until the convergence criterion is met or the iteration cycle reaches the maximum value set. EP algorithm converges when the difference between the maximum and minimum fitness values is 0.00001 presented mathematically in (13).

$$P_{Loss(max)} - P_{Loss(min)} \leq 0.00001 \quad (13)$$

That ends the EP process.

B. Artificial Immune System

Artificial Immune System (AIS) technique is inspired by biological immune system and has been used for computational models in solving complex real-world problems. The algorithms in artificial immune system adapt the immune system features of learning and memory to solve a problem. The evolution of AIS has its roots from the work of Farmer, Packard and Perelson [19]. The AIS flowchart is presented in Fig. 2.

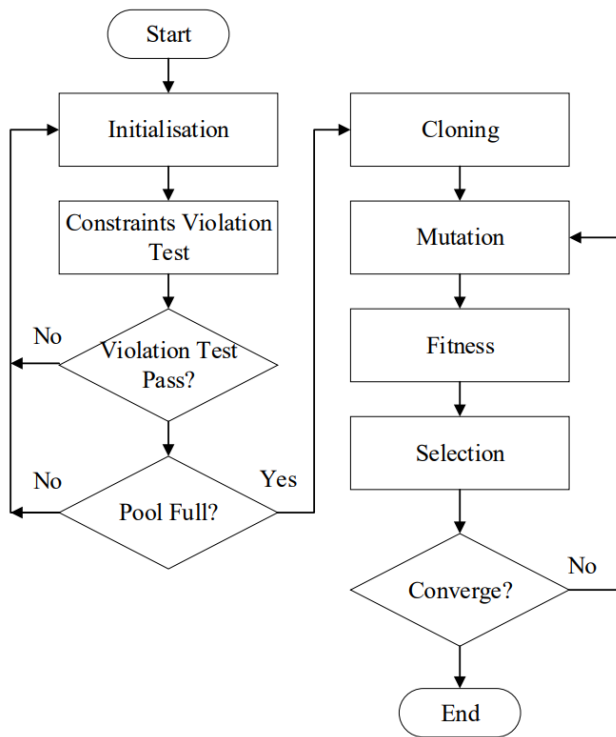

Fig. 2. Flowchart of AIS algorithm.

Step 1: Initialization

The initialization process of AIS begins with generating the control variables for optimal SVC using a uniformly distributed random number generator. 20 individuals (parents) are initially generated based on the control variables for the first iteration. During initialization, parameters such as: number of individuals, mutation step size and maximum number of iterations were to be specified. The total loss of the system before optimization, $P_{Loss(pre_SVC)}$ is calculated as the reference value. The individuals that violate the requirements and constraints are subsequently exterminated from the population.

Step 2: Parent Fitness Calculation

Load flow programs is performed to calculate the fitness value which is real power loss, $P_{Loss(post_SVC)}$. If $P_{Loss(post_SVC)} < P_{Loss(pre_SVC)}$, and fulfils the other constraints specified, they are accepted into the initial population pool. The general matrix for the initial population, X is given by (9).

Step 3: Cloning Process

The individuals in the initial pool, which are referred as parents, are cloned with a factor of 10 as suggested [20], [21]. The population size increases 10 folds after cloning. The general cloned matrix is given in (14) where k is the cloning factor.

$$X_{clone} = \begin{bmatrix} \begin{bmatrix} x_{11} & x_{12} & \dots & x_{1q} & f_1 \\ x_{21} & x_{22} & \dots & x_{2q} & f_2 \\ \vdots & \vdots & \dots & \vdots & \vdots \\ x_{p1} & x_{p2} & \dots & x_{pq} & f_p \end{bmatrix} \\ \vdots \\ \begin{bmatrix} x_{11} & x_{12} & \dots & x_{1m} & f_1 \\ x_{21} & x_{22} & \dots & x_{2q} & f_2 \\ \vdots & \vdots & \dots & \vdots & \vdots \\ x_{p1} & x_{p2} & \dots & x_{pq} & f_p \end{bmatrix} \end{bmatrix} \quad (14)$$

Step 4: Mutation

Mutation is a process to produce offspring. The individuals of the cloned population, X_{clone} are mutated to breed offspring. Mutation equation in (10) is adapted.

Step 5: Offspring Fitness Calculation

Then, load flow analysis is performed to determine the fitness of the offspring. The matrix for the offspring population, X_{cloned_off} is given by (15).

$$X_{cloned_off} = \begin{bmatrix} \begin{bmatrix} \alpha_{11} & \alpha_{12} & \dots & \alpha_{1q} & F_1 \\ \alpha_{21} & \alpha_{22} & \dots & \alpha_{2q} & F_2 \\ \vdots & \vdots & \dots & \vdots & \vdots \\ \alpha_{p1} & \alpha_{p2} & \dots & \alpha_{pq} & F_p \end{bmatrix} \\ \vdots \\ \begin{bmatrix} \alpha_{11} & \alpha_{12} & \dots & \alpha_{1q} & F_1 \\ \alpha_{21} & \alpha_{22} & \dots & \alpha_{2q} & F_2 \\ \vdots & \vdots & \dots & \vdots & \vdots \\ \alpha_{p1} & \alpha_{p2} & \dots & \alpha_{pq} & F_p \end{bmatrix} \end{bmatrix} \quad (15)$$

where

p = population size

q = no. of variable

F = fitness of the offspring

k = cloning factor

Step 6: Selection Process and Convergence Test

Selection process is conducted to identify the survivors among the fittest. In this case, the individuals in matrix X_{cloned_off} are ranked in ascending order based on fitness value. For this study, the individuals are ranked based on the lowest fitness value since the objective function is

minimization of total transmission loss. 20 best individuals from the matrix X_{cloned_off} are selected for the next iteration. A convergence test is used to check if the optimal solution has been achieved. Otherwise, Step 2 through Step 5 will be repeated until the convergence criterion is met or the iteration cycle reaches the maximum value set. AIS algorithm converges when the difference between the maximum and minimum fitness values is 0.00001 as presented in (13). That ends the AIS process.

C. Immune Evolutionary Programming

Immune Evolutionary Programming (IEP) is derived by integrating the traditional EP and AIS. The IEP flowchart is presented in Fig. 3.

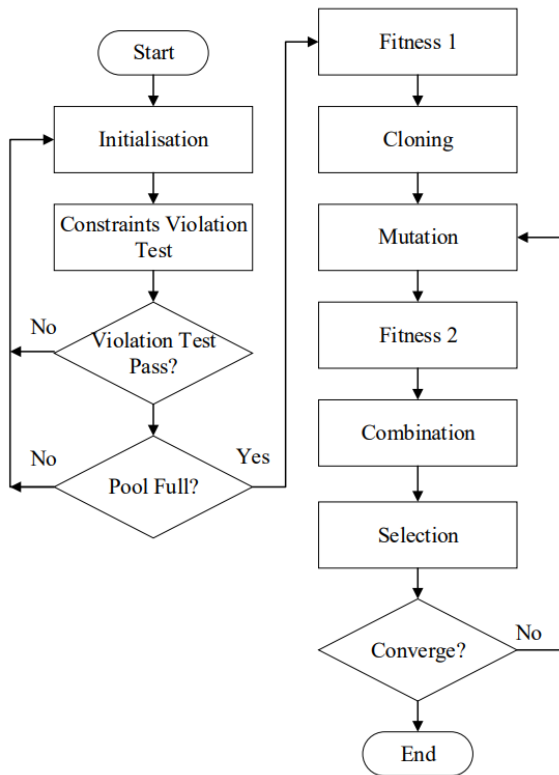

Fig. 3. Flowchart of IEP algorithm.

Step 1: Initialization

The initialization process of EP begins with generating the control variables for optimal SVC using a uniformly distributed random number generator. 20 individuals (parents) are generated based on the control variables first iteration. During initialization, parameters such as: number of individuals, mutation step size and maximum number of iterations were to be specified. The total loss of the system before optimization, $P_{Loss(pre_SVC)}$ is calculated as the reference value. The individuals that violate the requirements and constraints are subsequently exterminated from the population.

Step 2: Fitness 1 Calculation

Load flow programs are run to calculate the fitness value which is real power loss, $P_{Loss(post_SVC)}$. If $P_{Loss(post_SVC)} < P_{Loss(pre_SVC)}$, and fulfils the other constraints specified, they will be accepted into the initial population pool. The general matrix for the initial population, X is given by (9).

Step 3: Cloning

The individuals in the initial pool which are referred as parents are cloned with a factor of k as in (14).

Step 4: Mutation

Mutation is a process to produce offspring. The individuals in the cloned population pool are mutated to breed offspring. The Gaussian mutation equation in (10) is adapted.

Step 5: Fitness 2 Calculation

Then, load flow analysis is performed to determine the fitness of the offspring. The matrix for the offspring population, X_{cloned_off} is obtained as shown in (15).

Step 6: Combination Process

The parent matrix and the offspring matrix are then combined in a cascaded form. If the parent matrix and the offspring matrix are represented by (9) and (15), respectively, then the combined matrix, C , has the form as in (16).

$$X_{combined} = \begin{bmatrix} X \\ X_{cloned_off} \end{bmatrix} \quad (16)$$

Step 7: Selection Process and Convergence Test

The individuals in matrix $X_{combined}$ are ranked in ascending order based on fitness value. 20 best individuals from matrix $X_{combined}$ are selected for the next iteration. A convergence test is used to check if the optimal solution has been achieved. Otherwise, Step 2 through Step 4 will be repeated until the convergence criterion is met or the iteration cycle reaches the maximum value set. IEP algorithm converges when the difference between the maximum and minimum fitness values is 0.00001 as presented in (13).

That ends the IEP process.

IV. TEST SYSTEM

The single line diagram of IEEE 30-Bus RTS used in this study [22] is shown Fig. 4, depicts the configuration of the power system. This system consists of five generators located at Bus 2, Bus 5, Bus 8, Bus 11, and Bus 13. There is a slack bus located at Bus 1 which serves as the reference point for voltage and frequency. There are 24 load buses in the system. The system is interconnected through a total of 41 bus interconnecting lines, forming a complex network. This power system topology is used for identifying and analyzing optimum location and sizing of SVC installation in controlling the transmission loss in power system.

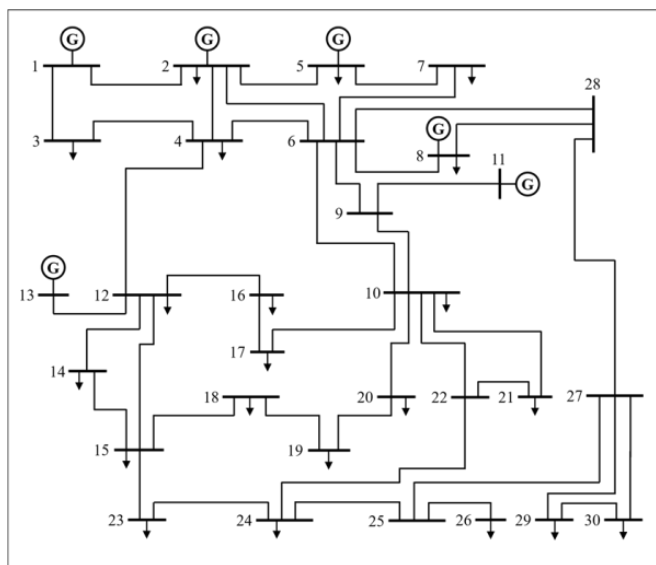

Fig. 4. IEEE 30-Bus reliability test system.

V. RESULTS AND DISCUSSIONS

This section presents the results of multi-SVC installation for loss control in power system using multi-computational techniques.

A. Bus Category Identification

Test was performed on IEEE 30-Bus RTS to identify the weak and strong buses of this system. An increasing reactive power load, Q_d was subjected to each of the load bus in the system and the corresponding voltage at the bus is recorded until the system collapsed. The results are presented in Fig. 1. From the figure, buses 26, 29 and 30 are identified as the weak buses indicated by their low maximum loadability value, $Q_{d,max}$ of each bus. For instance, the $Q_{d,max}$ for Bus 26 is 30 MVAR with its corresponding voltage 0.6997 p.u.. Other weak buses can be referred to the same figure. The identified strong buses for this system are buses 6, 4 and 3 due to maximum loadability of each bus. The $Q_{d,max}$ for all the three strong buses are 200 MVAR. The summary of all the details of weak and strong buses are tabulated in Table I.

B. Multi SVCs Installation

In this study, EP, AIS and IEP are validated on IEEE 30-Bus RTS to determine the effect of SVC installation on power loss and voltage profile of the system. In this study, three scenarios have been considered as follows:

- Scenario 1: Single SVC installation.
- Scenario 2: 2 units of SVC installation.
- Scenario 3: 3 units of SVC installation.

Error! Reference source not found. TABLE 2 tabulates the implementation scope of the multi-SVC installation on IEEE 30-Bus RTS. These are the scenarios studied to evaluate

the proposed optimization algorithm in finding the optimal location and sizing of SVCs.

1) *Scenario 1: Single SVC installation:* This section discusses the optimization results of single SVC installation in the attempt to minimize the P_{Loss} of the system. All together 6 buses were subjected to reactive power load; 3 weak buses (Bus 26, 29, 30) and 3 strong buses (Bus 6, 4, 3).

III presents the results for single SVC installation involving weak buses at Buses 26, 29 and 30 and strong buses involving Buses 6, 4 and 3. In general, all techniques managed to reduce the power loss in the system. For instance, when Bus 26 was subjected to 10 MVAR, the installation of single SVC managed to reduce the loss from 18.230 MW to 17.820 MW, solved using EP. The LRP is 2.249%. When the load is increased to 30 MVar, loss was reduced from 26.109 MW to 17.542, where the LRP is 32.815%. AIS and IEP also managed to achieve these results, which imply that all the three techniques are comparable. Generally, the values of LRP increase as the reactive power loading is increased regardless of any optimization technique. The details can be referred to the same table.

Table IV presents V_{min} and VIP before and after the single SVC installation. When Bus 26 was subjected to 10 MVAR, the installation of single SVC managed to increase the V_{min} of IEEE 30-Bus RTS from 0.940 p.u. to 0.957 p.u., solved using EP. The VIP is 1.841%.

When the load is increased to 30 MVAR, the V_{min} increased from 0.691 p.u. to 0.973 p.u., where the VIP is 40.799%. AIS and IEP also managed to achieve these results. Generally, the values of VIP increase as the reactive power loading is increased regardless of any optimization technique. More details can be referred to the same table.

Fig. 5. Minimum voltage profile of IEEE 30-Bus RTS with load variation.

TABLE I. SUMMARY OF 3 WEAKEST AND 3 STRONGEST BUSES IN IEEE 30-BUS RTS

Bus category	Bus Number	Reactive Load (MVar)	Voltage at loaded bus(p.u.)
Weak	26	30	0.6907
	30	35	0.5274
	29	35	0.6733
Strong	6	200	0.9286
	4	200	0.8963
	3	200	0.8602

TABLE II. IMPLEMENTATION SCOPE

Scenario	SVC	Bus Category	Bus Subjected to Q_d Load
1	1	Weak	26, 29 ,30
	1	Strong	6,4,3
2	2	Weak	26, 29 ,30
	2	Strong	6,4,3
3	3	Weak	26, 29 ,30
	3	Strong	6,4,3

2) *Scenario 2: 2 SVCs installation:* Table V presents the results for 2 SVCs installation involving weak buses and strong buses. In general, all techniques managed to reduce the power loss in the system with 2 SVCs installation. For instance, when Bus 26 was subjected to 30 MVAR, the installation of 2 SVCs managed to reduce the loss from 26.109 MW to 17.663 MW, solved using EP. The LRP is 32.352%. AIS and IEP also managed to achieve similar results. On the other hand, when strong buses (Bus 6, 4, 3) were subjected to 50 MVAR, the installation of 2SVCs managed to reduce the losses, solved using all the three techniques. However, the LRP in the range of 2.5% to 5% only. This implies that SVC installation reduces the loss in the power system greatly when weak buses are subjected to reactive power load compared to strong buses.

Tale VI presents V_{min} and VIP before and after the 2 SVCs installation. Overall, 2 SVCs installation increases the V_{min} in both weak buses and strong buses regardless the optimization techniques applied. For instance, when Bus 30 is subjected to 30 MVAR, V_{min} is increased from 0.707 p.u. to 1.010 p.u., solved using EP. The VIP is 42.877%. AIS and IEP also managed to achieve VIP in the similar range. Details on other buses can be referred to Table VI.

3) *Scenario 3: 3 SVCs installation:* Table VII presents the results for 3 SVCs installation involving weak buses and strong buses. 3 SVCs installation reduced loss in the system regardless the techniques applied. When Bus 30 is subjected to 30 MVAR, the loss was reduced from 26.109 MW to 19.140 MW which implies a LRP of 26.695% solving with EP. For the same scenario the LRP was 32.815% for single SVC installation and 32.352% for 2 SVCs installation. Similar results were observed with AIS and IEP. These results indicate, installation of multi-SVC not necessarily further reduces the loss of the power system. Based on the results, a maximum of 2 SVCs installation is recommended. However, other constraints of the power system need to considered. The details can be referred Table VII.

Table VIII presents V_{min} and VIP before and after the 3 SVCs installation. Overall, 3 SVCs installation increases the V_{min} in both weak buses and strong buses regardless of the optimization techniques applied. The best VIP was recorded when Bus 30 was subjected to 30 MVAR. The V_{min} was increased from 0.691 p.u. to 1.010 p.u. solving using EP. The VIP is 46.228%. AIS and IEP also managed to achieve same results. Results for other buses can be referred to Table VIII.

C. Location and Sizing of SVCs

The installation of SVCs into the system as the initiative to reduce the total power loss will require the optimal locations and sizing. The multi-SVC locations and sizing details for all the three scenarios are tabulated in Tables IX to XI.

Scenario 1: Location and sizing of single SVC: The results for Scenario 1 are tabulated in Table IX. Only location and sizing of single SVC for $Q_{d,max}$ for each bus are shown to simplify the results. For instance, when Bus 26 is subjected to 30 MVAR, the single SVC to be installed at Bus 26 of a 31.161 MVAR for a LRP of 32.815%, solved by EP. AIS and IEP also solved the same location for SVC installation and same range of SVC sizing, which implies that all the three techniques are comparable. Details of single SVC location and sizing when other buses are subjected to $Q_{d,max}$ can be referred to Table IX.

1) Scenario 2: Location and sizing of 2 SVCs: The results for Scenario 2 are tabulated in Table X. Only location and sizing of 2 SVCs for $Q_{d,max}$ for each bus are shown for simplification purpose. For instance, when Bus 26 is subjected to 30 MVAR, the 2 SVCs to be installed are at Bus 28 (27.535 MVAR) and Bus 26 (27.893 MVAR) for a LRP of 32.352%, solved by EP. The total SVC sizing was 55.428 MVAR. AIS and IEP also solved the same location for SVC installation and

same range of SVC sizing, which implies that all the three techniques are comparable.

However, it was observed the sizing of single SVC is much lower for the same scenario compared to total SVC sizing when 2 SVCs installation was opted. In this case, single SVC and 2 SVCs installations has same range of LRP. This implies, multi-SVC is not always an option to reduce loss in the system. Other factors such as installation cost, maintenance cost and accessibility need to be considered before opting for multi-SVC installation. Details of 2 SVCs location and sizing when other buses are subjected to $Q_{d,max}$ can be referred to Table X.

2) Scenario 3: Location and sizing of 3 SVCs: The results for Scenario 3 are tabulated in Table XI. Only location and sizing of 3 SVCs for $Q_{d,max}$ for each bus are shown for simplification purpose. For instance, when Bus 26 is subjected to 30 MVAR, the 3 SVCs to be installed are at Bus 10 (35.094 MVAR), Bus 16 (59.106 MVAR) and Bus 26 (41.203 MVAR) for a LRP of 26.695%, solved by EP. The total SVC sizing was 135.403 MVAR. IEP also solved the same location and sizing while AIS solved different location and sizing as shown in the same table.

TABLE X. LOCATION AND SIZING OF 2 SVCs INSTALLATION

Bus	Q_d (MVar) Max	OT	2 SVCs Installation					
			Location 1	Sizing 1 (MVar)	Location 2	Sizing 2 (MVar)	Total Sizing (MVar)	LRP (%)
26	30	EP	28	27.535	26	27.893	55.428	32.352
		AIS	28	27.534	26	27.891	55.425	32.352
		IEP	28	27.535	26	27.893	55.428	32.352

		IEP	28	27.535	26	27.893	55.428	32.352

TABLE XI. LOCATION AND SIZING OF 3 SVCs INSTALLATION

Bus	Q_d (MVar) Max	OT	3 SVCs Installation							
			Location 1	Sizing 1	Location 2	Sizing 2	Location 3	Sizing 3	Total Sizing	LRP
26	30	EP	10	35.094	16	59.106	26	41.203	135.403	26.695
		AIS	4	51.876	2	56.146	26	51.689	159.710	28.162
		IEP	10	35.099	16	59.109	26	41.206	135.414	26.693
29	30	EP	3	92.551	29	46.659	9	46.018	185.228	17.327
		AIS	3	44.277	29	46.771	11	44.591	135.639	20.303
		IEP	3	92.558	29	46.664	9	46.023	185.244	17.326
30	30	EP	22	5.1940	27	7.1640	30	26.992	39.349	25.237
		AIS	30	24.403	25	13.642	13	60.099	98.143	24.692
		IEP	22	5.1940	27	7.1640	30	26.992	39.349	25.237
6	150	EP	4	84.149	12	42.380	10	71.345	197.874	10.629
		AIS	6	82.832	6	98.791	8	23.357	204.980	14.727
		IEP	4	84.155	12	42.386	10	71.351	197.892	10.629
4	150	EP	4	94.776	3	50.071	12	27.708	172.555	20.629
		AIS	4	94.774	3	50.068	12	27.706	172.548	20.629
		IEP	4	94.776	3	50.071	12	27.708	172.555	20.629
3	150	EP	4	80.912	28	4.5520	3	82.972	168.437	25.705
		AIS	6	53.351	3	99.870	23	12.220	165.441	25.221
		IEP	4	80.912	28	4.5520	3	82.972	168.437	25.705

On the other hand, it was observed the sizing of single SVC and 2 SVCs are much lower for the same scenario compared to total SVC sizing when 3 SVCs installation was opted. In this case, single SVC and 2 SVCs installations have higher LRP compared to 3 SVCs. This implies, multi-SVC is not necessarily an option to obtain the highest LRP in the system. Based on the results, installation of 3 SVCs is not recommended as the LRP achieved is lower compared to single SVC and 2 SVCs. Other factors such as installation cost, maintenance cost and accessibility need to be considered before opting for multi-SVC installation. Details of 3 SVCs location and sizing when other buses are subjected to $Q_{d,max}$ can be referred to Table XI.

VI. CONCLUSION

Based on the key findings of this study, it can be concluded that the three optimization techniques, namely EP, AIS and IEP are effective solutions for addressing the complex task of optimal location and sizing of multi-SVC installation in the IEEE 30-Bus RTS power system. The work successfully explored the optimal positions, sizes, and number of SVCs while considering network operational constraints and SVC limitations, ultimately aiming to reduce total active power loss.

Findings of this study have broader implications for the field of power system optimization and control. It contributes to advancing the understanding of SVC installation for enhancing power system performance using multi-computational intelligence techniques. It also showcases the effectiveness of EP, AIS and IEP in tackling large-scale technical challenges and highlights their potential for addressing similar optimization problems in other power system scenarios.

In summary, this work demonstrates the efficacy of EP, AIS, and IEP in solving the optimal location and sizing problem of multi-SVC allocation. These results provide valuable insights for power system optimization and have broader implications for improving power grid performance, reliability, and efficiency.

ACKNOWLEDGMENT

The authors appreciate the support given by the Ministry of Higher Education and the Universiti Kebangsaan Malaysia for the operational and financial support to this project under Project Codes GUP-2022-010 and RHB-UKM-2021-002.

Economic Development Efficiency Based on Tobit Model: Guided by Sustainable Development

Ming Liu

Department of Business and Accounting, Henan Open University, Zhengzhou, 450000, China

Abstract—At present, in resource-based regions in China, it has been seriously restricted in the harmonious growth of green economy (GE) and environment. To find and solve the problems that affect the quality of regional GE development, the study took Xinjiang, a resource-based province, as the research object. With the data of 14 prefectures and cities in Xinjiang from 2017 to 2022, an evaluation model for the efficiency of GE development based on DEA-Tobit was constructed. Data envelopment analysis (DEA) measures the spatial autocorrelation and distribution characteristics of GE development efficiency in various prefectures and cities in Xinjiang. The influencing factors were analyzed by using Tobit model. From the empirical results, there are obvious differences in the spatial distribution of GE development among various prefectures and cities in Xinjiang. The average value is 0.7289, the highest value is 1, and the lowest value is 0.3684, with a difference of 0.6316. The efficiency values of GE in the seven regions R1, R2, R4, R6, R7, R9, and R13 have reached 1, and DEA is effective. Based on the global and local Moran index, it can be seen that there is no obvious spatial correlation between the development efficiency of green economy in the cities and cities of Xinjiang, and the absolute value of its coefficient is not more than 0.5. From the results of the Tobit model, there are still areas for raising the efficiency of GE development in most regions of Xinjiang. Based on the established DEA-Tobit GE development efficiency evaluation model, this study proposes targeted development strategies for improving the efficiency of GE development in Xinjiang.

Keywords—Tobit model; DEA; economic development efficiency; Moran index

I. INTRODUCTION

The coordination and win-win situation of "economic growth" and "resources and environment" is the essence of green development. Improving the quality of economic development and enhancing the GE efficiency is the way to achieve that. [1]. Currently, green development is promising direction of development. The proposal of this concept can not only solve the relationship between humans and nature, but also apply the concept to people's daily lives. This has played a positive role in establishing a resource saving and environmental friendly society. This has achieved the harmonious development of the economy, society, and ecological environment [2]. Along with the sustained and rapid growth of economy, the ecological environment has also deteriorated. This has restricted the harmonious development of the economy and environment in countries, especially in resource-based regions. However, in the current researches, there are few systematic researches on the efficiency of GE development in specific provinces. In the northwest frontier of China is Xinjiang, a province with harsh natural environmental

conditions and a low economic development. Ecological and environmental problems occur consequently. This has restricted the high-quality development of Xinjiang's economy [3,4]. Therefore, achieving green transformation and development in Xinjiang is an inevitable requirement for achieving sustainable development. Since there are few research results on green economy development efficiency in Xinjiang, taking it as the main body of research and carrying out detailed research from prefecture-prefecture level can enrich the field of green economy development efficiency in this region. Based on the double carbon background, this study applies the green related theory to the reality of green economy development in Xinjiang, which can expand the research ideas in this field. In addition, the research mainly constructs two empirical models. They are the DEA model of non-expected output and the Tobit spatial measurement model respectively; and the representative indicators of Xinjiang region are selected. This experiment not only measured the development efficiency of green economy in this region, but also innovatively conducted a further comparative analysis of its spatial distribution characteristics. The research combines measurement methods, spatial distribution rules and influencing factors to make the research results more convincing. Since the improvement of the development efficiency of green economy is a long-term development process, its input and output have a certain lag, which will also have a certain impact on the measurement results. This is what future research needs to improve as much as possible.

This study takes the green development of various states in Xinjiang as the research object, including five parts. At the beginning of the article, the first part mainly introduces the research background, significance, current situation and methods of the development efficiency of green economy. The second part describes the theoretical basis of green economy development and literature review. Respectively from the foreign and domestic two levels to comb and summarize. The third part is the method design of economic development efficiency measurement. It is mainly divided into two sections. The first section is to preliminarily screen the evaluation indicators of green economic development efficiency and establish a DEA model to calculate the corresponding green development efficiency value. The second section further extracts the effective indicators and constructs the evaluation model of green economy development efficiency based on Tobit. The fourth part is the empirical analysis of green economy development efficiency in Xinjiang from 2017 to 2019. The corresponding data were collected, and the spatial panel Tobit regression model was established to analyze the influence degree of the seven indicators on the green

development efficiency in Xinjiang. The last part is based on the empirical analysis results, and puts forward specific suggestions for the green development of Xinjiang.

II. RELATED WORKS

With the economic development and living standard improvement, natural environmental pollution is also increasing. Therefore, the GE has gradually become the hot issue of many researchers at home and abroad, and has been studied in various aspects. Scholars such as Ohene Arsare have evaluated the energy efficiency of African countries and its determinants through bootstrap truncated regression. The study showed that economic development and technological progress had a positive influence on energy efficiency in African countries [5]. Researchers such as Mikhno analyzed environmental impact factors on other quality of life indicators and the main trends and issues that had emerged since the introduction of the "GE". Research has proven that with the extensive development of the economy, the per capita GDP has significantly decreased [6]. Wang et al. constructed a coupling coordination degree evaluation method with entropy weight. Quantitative analysis was conducted on the sustainable development trend and subsystem coupling of regional GE. Research has shown that the model is feasible for the development of regional GE [7]. A heterogeneous stochastic frontier model was used to measure China's GE efficiency by researchers such as Qin. The GE efficiency in China was unsatisfactory, and regional heterogeneity was significant [8]. GE efficiency and regional differences of 11 cities in Zhejiang were measured with the non-radial DEA model of the Malmquist index by Lu et al. From the research, the main factors affecting the urban GE efficiency in Zhejiang were industrial structure, environment, and urbanization degree [9].

Scholars such as Zhao measured the air pollution control by adopting the proportion of air pollutant emissions to GDP. This study has effectively verified the relevance among air pollution, technology, investment, and GE development [10]. Zheng and other researchers based on the super-efficient DEA framework. It incorporated non expected output into the measurement index of regional economic development with a non-radial distance function. This study showed that the influence of financial aggregation on local GE had a non-linear threshold feature [11]. Lebedeva et al. compared existing GE assessment methods. The study found that current methods were mainly used to measure the "greening" of the economy [12]. To raise the efficiency of urban GE planning, researchers such as Liu have constructed a model based on an improved genetic algorithm. From the research results, the model has a high calculation accuracy and can be adopted in the design of urban greening planning [13]. Rutskiy and other experts have constructed a regression model based on empirical correlation. This model defined the impact of GE factors on manufacturing productivity. The research results showed that pollution control equipment and factory investment had a significant positive impact on the GE manufacturing industry [14].

To sum up, predecessors usually compare efficiency measurements based on a single structured data indicator system, while there are few researches on the major reasons influencing the efficiency of GE development. In addition, the

systematic and comprehensive efficiency analysis for specific provinces is also absent. Therefore, this study is aimed at specific provinces and regions, using Tobit model and DEA to measure the reasons influencing the efficiency of GE development in the province, thereby providing practical suggestions for these factors.

III. ECONOMIC DEVELOPMENT EFFICIENCY BASED ON TOBIT MODEL

A. Preliminary Selection of Evaluation Indicators for the Efficiency of GE Development

The term "GE" was proposed by the famous British economist Pearce. It believes that the GE is an economic development model that both human and nature can bear [15]. Moreover, this model will not cause ecological and social imbalances due to economic growth, nor will it restrict the constant growth of economy due to the depletion of natural resources. With the introduction of GE, many methods have been developed to measure the efficiency. However, there is currently no complete indicator system for the efficiency of GE development. Based on massive relevant achievements on green development, combined with the actual situation and data of various states and cities, the study screened the issues that affecting the efficiency of GE. For the establishment of an indicator system, it is first necessary to follow the principles shown in Fig. 1.

Fig. 1. Principles of establishing GE development efficiency index system.

In Fig. 1, the selection of this indicator requires four principles in order. The first is the principle of feasibility. The foundation of model implementation is data. When selecting indicators, it is necessary to consider whether the statistical data is complete, the difficulty of data collection, the proficiency in using models, and the feasibility of the results. The second is the systematic principle. The evaluation of the efficiency of the GE development involves multiple aspects such as resources, environment, and economy. Therefore, when selecting indicators, it is necessary to ensure that they are comprehensive, rich, and multidimensional. To make the calculation results more objective and reasonable, different indicators should be selected from multiple aspects to avoid interference with the evaluation results. Then there is the regional principle. When constructing an indicator system, it is needed to select GE development efficiency indicators that can represent different regions based on the economic level, cultural and geographical environment, and other conditions of different regions. Finally, there is the principle of scientificity. In constructing an indicator system, science should be taken as the basis. The selected indicators should be able to reflect the

relationship between the evaluated things, while ensuring the rationality of the evaluation results of the model. With the principle of indicator selection, the research preliminarily

divides the efficiency of GE development into three categories of indicators, as shown in Fig. 2.

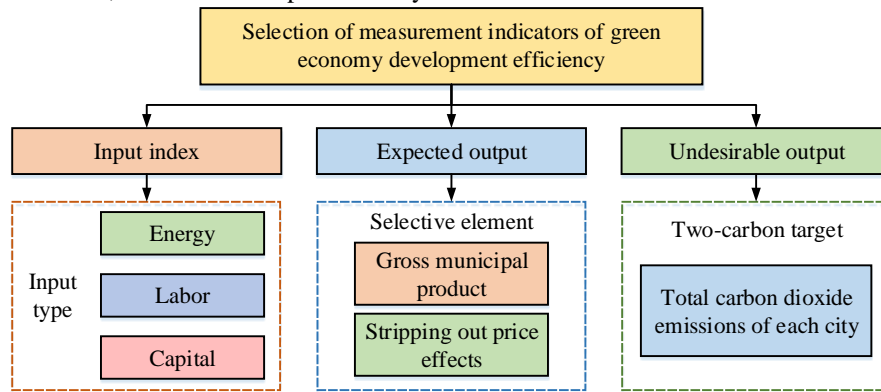

Fig. 2. Selection of measurement indicators of GE development efficiency.

In Fig. 2, the selection of investment indicators generally focuses on capital, labor, and energy inputs. Based on the availability and scientificity of data, capital investment is usually the amount of fixed assets investment of the whole society in each city. Energy input refers to the consumption of energy by enterprises or industries above designated size. Labor input is the total population of each city. In the current government work report, it is mentioned that efforts should be made to achieve the dual carbon goal and optimize the industrial and energy structure [16]. Therefore, the research takes the CO₂ emissions of each city as an unexpected output.

DEA is a relatively effective method for measuring efficiency values [17]. Measurement models consist of two broad categories, namely radial and non-radial, and angular and non-angular. Due to the fact that traditional DEA models do not take into account the slack issues caused by inputs and outputs, there may be a certain degree of calculation bias due to the existence of unexpected outputs when measuring efficiency values. Non-radial and non-angular DEA-SBM models were put forward to solve this issue [18]. The model considers the problem of relaxation variables and improves the accuracy of efficiency. The study compared various models and data collection, and ultimately selected the DEA model with unexpected outputs. The calculation expression of the DEA model for undesired outputs is shown in Equation (1).

$$\rho^* = \min \frac{1 - \frac{1}{w} \sum_{i=1}^w \frac{s_i^-}{x_{i0}}}{1 + \frac{1}{s_1 + s_2} \left(\sum_{r=1}^{s_1} \frac{s_r^g}{y_{r0}^g} + \sum_{r=1}^{s_2} \frac{s_r^b}{y_{r0}^b} \right)} \quad (1)$$

In Equation (1), ρ^* represents the efficiency value of GE development s_1, w, s_2 represents the total of elements of expected output, input, and undesired output, respectively. s^-, s^g, s^b are the relaxation variables of expected output, non-expected output, and input, respectively. x, y^g, y^b is input value, expected output value, and non-expected output value, and their respective calculation expressions are shown in Equation (2).

$$s.t. = \begin{cases} x_0 = X\lambda + s^- \\ y_0^g = Y^g\lambda - s^g \\ y_0^b = Y^b\lambda + s^b \\ s^- \geq 0, s^g \geq 0, s^b \geq 0, \lambda \geq 0 \end{cases} \quad (2)$$

In Equation (2), λ represents the weight vector. X, Y^g, Y^b represents a matrix composed of unexpected outputs, inputs, and expected outputs, respectively. The spatial autocorrelation test can reflect the overall distribution among regions. The spatial distribution characteristics of natural and ecological factors and their interrelationships can be measured by the spatial autocorrelation coefficient [19]. Moran's I coefficient and Geary's c coefficient are main indices for spatial autocorrelation analysis [20]. The global and the local Moran index are used to organise a spatial analysis of the GE development efficiency of each city, and judges whether the northern objects have a certain degree of agglomeration in space. The spatial correlation between a region and all regions can be reflected by the global Moran index. And it also can be applied to test the spatial dependence, spatial patchiness, and the degree of dispersion of gradients among all elements of the space as a whole. The calculation expression is expressed in Equation (3).

$$I = \frac{n \sum_{a=1}^n \sum_{b=1}^n \varpi_{ab} (x_a - \bar{x})(x_b - \bar{x})}{n \sum_{a=1}^n \sum_{b=1}^n \varpi_{ab} (x_a - \bar{x})(x_b - \bar{x})} = \frac{n \sum_{a=1}^n \sum_{b=1}^n \varpi_{ab} (x_a - \bar{x})(x_b - \bar{x})}{s^2 n \sum_{a=1}^n \sum_{b=1}^n \varpi_{ab}} \quad (3)$$

In Equation (3), x_a, x_b represents the observed values of a, b respectively. \bar{x} represents the average value observed in all regions. The spatial weight is ϖ , and n represents the number of samples. When Moran index $I > 0$, it indicates that the development efficiency of GE has a positive spatial correlation, and the greater the I value, the stronger the correlation. When the Moran index is $I = 0$, it indicates that the efficiency value is randomly distributed in space. The significance test of its spatial autocorrelation is performed

using the standardized statistic $Z(I)$, and its calculation expression is shown in Equation (4).

$$Z(I) = \frac{I - E(I)}{\sqrt{VAR(I)}} \quad (4)$$

In Equation (4), $E(I), VAR(I)$ represents the variance and expected value of the global Moran index, respectively. The local spatial autocorrelation analysis is performed using the local Moran index to reflect the relevance between a certain area and its surroundings. The calculation expression is shown in Equation (5).

$$I_i = \frac{x_a - \bar{x}}{s^2} \sum_{b=1}^n \omega_{ab} (x_b - \bar{x}) \quad (5)$$

The parameter meaning in Equation (5) is the same as the global Moran index, and the significance level is also tested using $Z(I)$.

B. Construction of Evaluation Model for GE Development Efficiency Based on Tobit

After preliminary screening of evaluation indicators for the efficiency of GE development, it is also necessary to focus on the actual GE development in the study area, guided by sustainable development, and conduct in-depth research on its various influencing factors. Based on the preliminary indicator selection of GE development, the study expanded it, and combined with the actual green development situation in Xinjiang, the specific indicators selected are shown in Fig. 3.

Fig. 3. Selection of influencing factors of GE development efficiency.

In Fig. 3, the study selected seven representative indicators as specific evaluation indicators for the standard of green development in Xinjiang. These include government support, economic development level, current industrial structure, tourism development level, average education level, foreign trade level, and energy consumption level that play an important role in Xinjiang's development. Tobit model is a generalization of Probit regression model proposed by economist James Tobin. It refers to an econometric model with hidden variables, although continuously distributed at positive values, still contain a portion of observations with a positive value of 0 [21]. The model uses the maximum likelihood method for estimation. In parameter estimation, this can better avoid bias or inconsistency issues. The model expression is shown in Equation (6).

$$r_i = \begin{cases} v_i \beta + \varepsilon, & r_i > 0 \\ 0, & r_i \leq 0 \end{cases} \quad (6)$$

In Equation (6), v_i represents the explanatory variable. r_i is the interpreted variable. β represents a regression parameter. ε represents a random perturbation term. Before figuring out the issues influencing the efficiency of GE development in various cities in Xinjiang, it was clear that the explained variable value was in the range of 0-1, so the Tobit model was used as the analysis method in the study. The efficiency of GE development is used as the explanatory variable, and the statistical yearbooks or bulletins of different cities in Xinjiang are used as the data source for studying the explanatory variable. According to the Tobit model, the resulting regression equation is constructed as shown in Equation (7).

$$Y_{gh} = \beta_1 X_{1gh} + \beta_2 X_{2gh} + \beta_3 X_{3gh} + \beta_4 X_{4gh} + \beta_5 X_{5gh} + \beta_6 X_{6gh} + \beta_7 X_{7gh} + \varepsilon \quad (7)$$

In Equation (7), $\beta_1, \beta_2, \beta_3, \beta_4, \beta_5, \beta_6, \beta_7$ represents the parameter to be evaluated. g represents the city of Xinjiang, and h represents the year. The explanatory variables and the interpreted variables are expressed in Table I.

TABLE I. EXPLAINED VARIABLE VERSUS INTERPRETED VARIABLE

Statistical variable	Index name	Variable	Meaning
Explained variable	Efficiency of GE development	Y	Efficiency of GE development
Interpreted variable	Government support	X_1	Share of General Public Budget expenditure in GDP (%)
	Level of economic development	X_2	Per capita gross regional product (yuan)
	Current situation of industrial structure	X_3	Proportion of output value of secondary industry in GDP (%)
	Tourism development level	X_4	Share of tourism revenue in GDP (%)
	Average educational attainment	X_5	Proportion of the total number of students in school to the total population of the District (%)
	Level of foreign trade	X_6	Total imports and exports as a percentage of GDP
	Degree of energy consumption	X_7	Energy consumption per unit of GDP (10,000 tons of standard coal / 10,000 yuan)

There are contradictions and incompatibilities among various factors in the indicator system, so the study conducts dimensionless quantitative processing on the values of the original indicators. Since most of the indicators are benefit based, the linear standardization method is used for processing. Equation is the standardized calculation of positive indicators (8).

$$X_{ij} = \frac{x_{ij} - m_j}{M_j - m_j} \quad (8)$$

In Equation (8), j represents the selected indicators. i represents each city. X_{ij} is the value of the j indicator i region after standardization. x_{ij} represents the original value. M_j, m_j represents the maximum and minimum values of the j index during the sample period. The standardized calculation of inverse indicators is expressed in Equation (9).

$$X'_{ij} = \frac{M_j - x_{ij}}{M_j - m_j} \quad (9)$$

Then, each indicator is weighted. Entropy method can avoid the interference of subjective factors and the importance of indicators is taken as the basis for weighting. Therefore, the research mainly uses entropy method to work out the proportion of specific indicators in the indicator system. It assumes that there is an indicator data matrix composed of m evaluation objects and n evaluation indicators. The higher the degree of dispersion of data, the lower the value of information entropy, and the greater the corresponding weight. Due to the standardization of some indicator values, the data may be small or even negative. Therefore, to ensure convenient and uniform calculation, its standardized values will be translated. The calculation expression is shown in Equation (10).

$$x'_{ij} = H + x_{ij} \quad (10)$$

In Equation (10), H represents the magnitude of the indicator shift, typically taking a value of 1. The weight of an indicator can be determined with entropy method. It represents a measure of uncertainty, and a smaller value indicates a higher

degree of variation. The more information offered by that, the more the weight it occupies. The calculation expression of the ratio of the market value of the i land under the j th indicator in this indicator is shown in Equation (11).

$$p_{ij} = x'_{ij} / \sum_{i=1}^n x'_{ij} \quad (11)$$

In Equation (11), p_{ij} represents the proportion of x'_{ij} . However, after the indicator is standardized, a value of 0 may appear during processing. Therefore, the study shifted the entire processed data to the right by 0.0001 units to make the 0 value after standardization meaningful. Then determine the information entropy value of the j index, as shown in Equation (12).

$$a_j = -k \sum_{i=1}^n y_{ij} \ln p_{ij} \quad (12)$$

In Equation (12), a_j represents the information entropy value of each indicator. n represents the sample number of each indicator. k represents a constant, which is related to the number of samples n , as shown in Equation (13).

$$k = 1 / \ln n \quad (13)$$

Information entropy a_j can be used to measure the information utility value of the j th indicator. When the information is completely out of order, $a_j = 1$. At this time, the utility value d_j of the indicator of a_j for comprehensive evaluation is 0. The relationship between the information usage value a_j of the indicator and the information entropy d_j of the indicator is expressed in Equation (14).

$$d_j = 1 - a_j \quad (14)$$

In Equation (14), $j = 1, 2, \dots, p$. When using the entropy to calculate the weight of each evaluation index, the higher the coefficient in the evaluation, the greater the importance of the evaluation. On the contrary, the importance of evaluation will

be smaller. The weight expression of the j index is obtained in Equation (15).

$$w_j = d_j / \sum_{j=1}^n d_j \quad (15)$$

According to the weights of various indicators, it needs to build corresponding for the standardized values of various indicators of data, and then the linear weighting method is used to calculate the sum of efficiency values.

IV. AN EMPIRICAL ANALYSIS OF THE EFFICIENCY OF GE DEVELOPMENT

After preprocessing the collected data, based on the non-expected output DEA model proposed in the study, the GE development efficiency of four prefecture-level cities, five regions, and five autonomous prefectures in Xinjiang were measured by MATLAB R2017b software. In the experiment, these 14 prefectures and cities in Xinjiang were named R1-R14. Their calculation results are shown in Fig. 4.

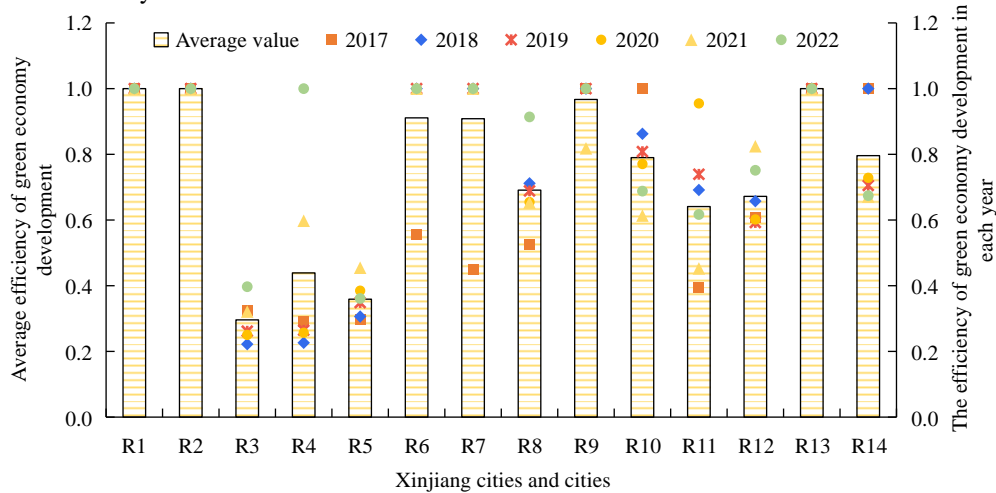

Fig. 4. GE development efficiency of 14 prefectures and cities in Xinjiang from 2017-2022.

From Fig. 4 it is clear that the spatial distribution of GE development in various prefectures and cities in Xinjiang varied greatly. The average value was 0.7289; the highest and the lowest value was 1 and 0.3684, respectively, with a difference of 0.6316. From the measurement results, the GE efficiency values of the seven regions R1, R2, R4, R6, R7, R9, and R13 had reached 1, and their DEAs were effective. In

2017-2019, only four regions, R1, R2, R9, and R13, achieved an average value of GE development above 0.9. The average value of GE development efficiency in northern, southern, eastern, and entire Xinjiang based on the measured GE development efficiency of each prefecture and city in Xinjiang are calculated and expressed in Fig. 5.

Fig. 5. Change trend of GE efficiency in Xinjiang as a whole and sub-region during 2017-2022.

From Fig. 5 it is clear that the overall efficiency of GE development in Northern Xinjiang was on the rise, with an average value of about 0.7796. The fluctuation trend of the efficiency of GE development in Southern Xinjiang was obvious, with an average value of about 0.7783, which was at a relatively stable medium to high stage. The efficiency of GE development in Eastern Xinjiang continued to rise after 2020,

with an average value of 0.4272. From 2019 to 2022, the efficiency of GE development in the entire Xinjiang region had a relatively stable trend of change, with a slow upward trend. This indicates that optimization has been done in industrial organization and the transformation of its development mode has been effective. In the experiment, Eviews software was used to obtain the GE development efficiency values of 14

prefectures and cities in Xinjiang in 2022, and a broken line chart reflecting their fluctuation trend was obtained, as shown

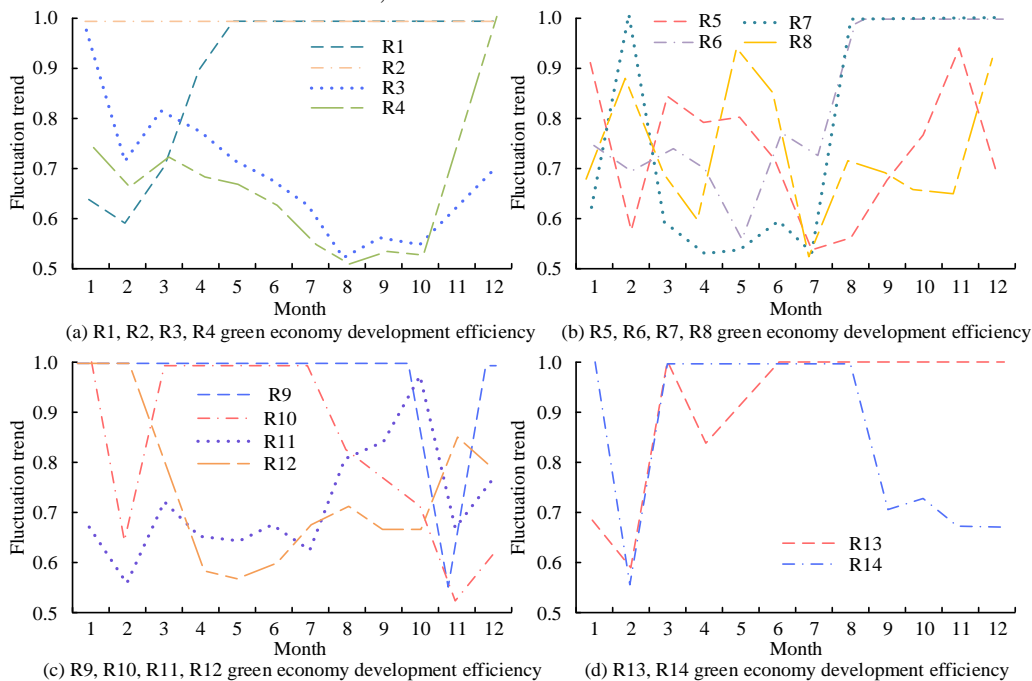

Fig. 6. Trend types of GE development efficiency in Xinjiang cities and cities in 2022.

From Fig. 6(a), GE development efficiency of R1 was of a fluctuating and rising type. That of R2 was stable. That of R3 and R4 was continuously fluctuating. From Fig. 6(b), GE development efficiency of R5, R6, R7, and R8 were the type of first decreasing and then increasing, fluctuating and rising, continuously fluctuating, and first decreasing and then increasing, respectively. From Fig. 6(c), GE development efficiency of R9, R10, R11, and R12 were respectively stable, fluctuating, decreasing first, then rising, and continuously fluctuating. From Fig. 6(c), GE development efficiency of R13 and R14 were respectively fluctuating upward type and fluctuating downward type. Among them, the development of resources, economy, and environment in stable regions was relatively balanced. However, fluctuating and declining regions were due to excessive urging of economic development, leading to resource waste and environmental pollution. This has led to a slide in the overall efficiency of the region's GE. The experiment used Stata15 software and combined with calculations to obtain the global Moran index measurement results of GE development efficiency in various states and cities in Xinjiang, see Table II.

TABLE II. MORAN INDEX AND TTS TEST IN XINJIANG FROM 2017 TO 2022

Year	I	$sd(I)$	z	$p-value^*$
2017	-0.113	0.181	-0.199	0.421
2018	0.320	0.174	2.287	0.011
2019	0.294	0.175	2.115	0.017
2020	0.319	0.175	2.264	0.012
2021	0.089	0.178	0.932	0.176

in Fig. 6.

2022	-0.044	0.173	0.187	0.426
------	--------	-------	-------	-------

From Table II, in 2018, 2019, and 2020, the GE development efficiency of various prefectures and cities in Xinjiang showed a relatively strong positive correlation. The correlation I was 0.320, 0.294, and 0.319, respectively. The spatial correlation in other years was significant. Through calculation, the local Moran index of GE development efficiency in various prefectures and cities in Xinjiang can be obtained. As shown in Fig. 7, the local Moran index test results and scatter plot for 2022 are shown.

Fig. 7. Scatter plot of local Moran index in 2022.

From Fig. 7, in 2022, most of the autocorrelations of the 14 prefectures and cities in Xinjiang did not pass the assist test, and only a few regions had significant local spatial correlations. Based on the overall and local Moran indexes, there is no significant spatial correlation between the efficiency of GE development in various prefectures and cities in Xinjiang. The experiment conducted statistical processing on seven specific evaluation index data of GE development

efficiency in Xinjiang from 2017 to 2022, and the results are shown in Figure 8.

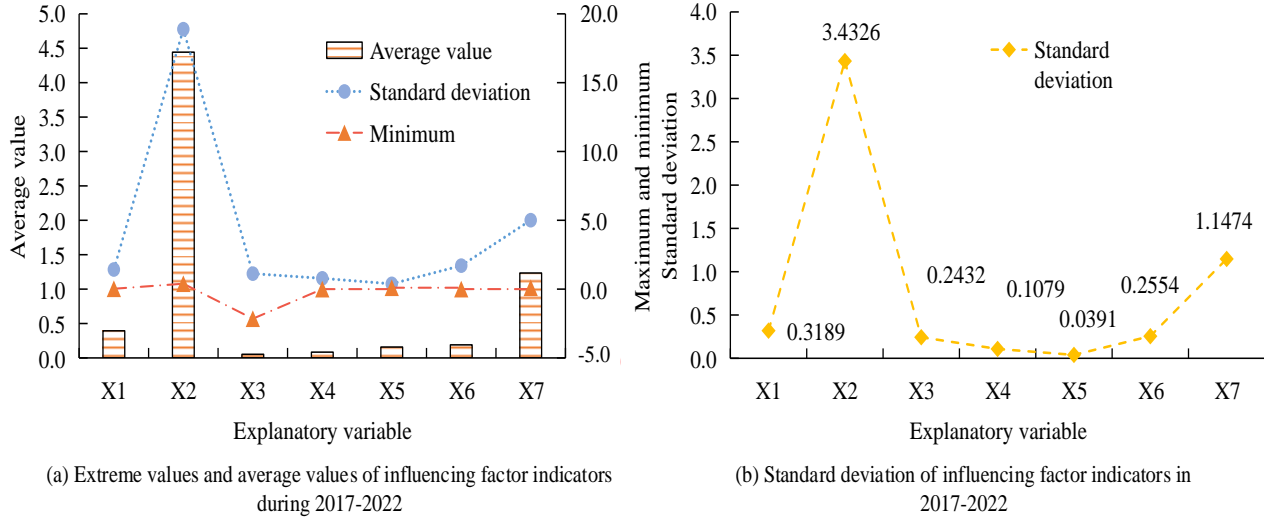

Fig. 8. Statistics of influencing factors of Xinjiang GE development efficiency from 2017-2022.

From Fig. 8 (a), among the seven GE development efficiency evaluation indicators, the average value of X_2 was the largest. This indicates that the contribution rate of GDP per capita is the highest, at 4.44. The average value of X_3 was the smallest, 0.0527, and its minimum value was negative. From Fig. 8(b), X_2 had the largest standard deviation of

3.4326. The standard deviation of DD was the smallest, 0.0391. Before conducting regression analysis on the data of the above indicators, correlation analysis and correlation significance test shall be conducted for each explanatory variable. This can avoid multiple collinearity problems between variables, as shown in Table III.

TABLE III. CORRELATION COEFFICIENTS OF EACH VARIABLE

Variable	X_1	X_2	X_3	X_4	X_5	X_6	X_7
X_1	1.000	0.186*	0.002	0.011*	0.220*	-0.012	-0.459*
X_2	0.186*	1.000	-0.010**	-0.058**	0.162*	0.025**	-0.195*
X_3	0.002	-0.010**	1.000	-0.098**	0.024	0.074*	0.103
X_4	0.011*	-0.058**	-0.098**	1.000	-0.101	0.013*	-0.036**
X_5	0.220*	0.162*	0.024	-0.101	1.000	-0.140*	0.096
X_6	-0.012	0.025**	0.074*	0.013*	-0.140*	1.000	-0.050*
X_7	-0.459*	-0.195*	0.103	-0.036**	0.096	-0.050*	1.000

Note: * and ** mean a significance level of 5% and 10%, respectively.

From Table III, even though the correlation between the two variables was significant, the correlation coefficient between each explanatory variable was small, and the absolute value of the coefficient was below 0.5. This implies that the probability of causing multicollinearity problems among

various explanatory variables is low. The experiment used Eviews 8.0 software to establish a Tobit model based on the relevant data of GE development efficiency indicators in Xinjiang and various regions from 2017 to 2022. Table IV is the regression results.

TABLE IV. REGRESSION RESULTS OF TOBIT MODEL

Explanatory variable	Northern Xinjiang	Southern Xinjiang	Eastern Xinjiang	Whole Xinjiang
ε	0.6993*	0.8480*	0.9368*	0.7741*
X_1	-0.3992	-0.1383**	-1.7892*	-0.1283**
X_2	-0.0108	0.0035	0.5073*	-0.0032
X_3	-0.3552	0.1578*	0.0376	0.0054
X_4	0.0913	1.2268	0.0239	-0.2882**
X_5	2.3485*	0.0184	-0.3553	0.8976**
X_6	0.0192	0.2973	-2.9941*	0.1227**
X_7	-0.0864*	-0.1238*	-0.0463	-0.0987*

Note: * and ** mean a significance level of 5% and 10%, respectively.

In Table IV, based on the analysis of the entire Xinjiang region, there was a significant correlation between the GE development efficiency and X_1 , X_4 , X_5 , X_6 , X_7 . The correlation values were -0.1283 **, -0.2882 **, 0.8976 **, 0.1227 **, -0.0987 *. Among them, there was a negative correlation with X_1 , X_4 , and X_7 . This indicates that government support, tourism development level, and energy consumption level have restrained the efficiency of Xinjiang's GE development. Average education level and foreign trade level promote the efficiency of GE development. From a regional perspective, the value of GE development in northern Xinjiang was significantly positively correlated with X_5 , and significantly negatively correlated with X_7 . The value of GE development in South Xinjiang was significantly positively correlated with X_3 , and negatively correlated with X_1 and X_7 . The value of GE development in Eastern Xinjiang was significantly positively correlated with X_2 , and significantly negatively correlated with X_1 and X_6 . Overall, there is significant room for improving the efficiency of GE development in most regions of Xinjiang.

V. CONCLUSION

This study took Xinjiang, a typical resource rich province, as the research object, and built a GE development efficiency evaluation index model based on DEA-Tobit to achieve sustainable green development of economy, resources and environment. The study used this model to calculate the efficiency of GE development in 14 prefectures and cities in Xinjiang from 2017 to 2020. At the same time, the autocorrelation relationship and spatial distribution characteristics were analyzed in depth. The research showed that there were obvious differences in the spatial distribution of GE development among various prefectures and cities in Xinjiang. The average value was 0.7289; the highest value was 1; the lowest value is 0.3684, with a difference of 0.6316. The GE efficiency value of the seven regions R1, R2, R4, R6, R7, R9, and R13 has reached 1, and their DEA were effective. Based on the overall and local Moran indexes, there was no obvious spatial correlation between the efficiency of GE development in various prefectures and cities in Xinjiang. The absolute values of their coefficients did not exceed 0.5.

According to the regression results obtained from the Tobit model, X_5 and X_6 had a great promoting effect on the efficiency of GE development in Xinjiang. X_1 has not played a positive role in the efficiency of Xinjiang's GE development, indicating that the relevant policies of the government were lagging behind. X_4 had an inhibitory influence on the efficiency of Xinjiang's GE development. This indicates that during its development, it has caused a certain degree of ecological damage. X_7 would inhibit the rise of the efficiency of GE development. Based on the results of the study, it is recommended to first increase the support of the local government in Xinjiang, optimize the industrial structure of Xinjiang as soon as possible, and promote energy development efficiency. In addition, it is necessary to strengthen investment in education in Xinjiang, do a good job in energy saving and emission reduction, and promote the overall efficiency of GE development in Xinjiang according to local conditions.

A Proposed Approach for Motif Finding Problem Solved on Heterogeneous Cluster with Best Scheduling Algorithm

Abdullah Barghash, Ahmed Harbaoui

Department of Computer Science, King Abdulaziz University, Jeddah, KSA

Abstract—The Motif Finding Problem (MFP) is the problem of finding patterns in sequences of DNA. This paper discusses and presents an enhanced scheduling approach to solve the motif problem on the Heterogeneous Cluster by making a comparison between exact algorithms. The method that was followed is to analyze several exact algorithms, compare them within specific points to measure, and improve performance by comparing the number of devices and peripheral units used in every situation and running time in every method. Our experimental results show that the use of the scheduling approach that use different algorithms on Heterogeneous Cluster make a significant difference in the speed of completing the problem and in a shorter record time with less resources, and that this proposed approach is more effective than the traditional method of distributing tasks to solve the motif problem.

Keywords—Motif finding problem; scheduling algorithm; heterogeneous; high-performance computing

I. INTRODUCTION

Motif finding is a well-known problem in bioinformatics that involves identifying patterns or motifs within a set of DNA or protein sequences [1]. These motifs, which can be as short as a few base pairs or amino acids, can provide important insights into the function and regulation of genes and proteins [2]. The motif finding problem is computationally intensive, as it requires analyzing large datasets and generating many potential motif candidates. To accelerate the motif finding process, researchers have increasingly turned to high-performance computing (HPC) techniques, which involve the use of specialized hardware and software tools to distribute and parallelize the computational workload [3]. Within this paper, we present our proposed approach, which not only improves time performance but also requires fewer resources, making it a valuable contribution to the field.

HPC clusters can be constructed with a variety of computing resources, including Central Processing Units (CPUs), Graphics Processing Units (GPUs), Many Integrated Core (MIC) Architecture, and other computing resources. As the domain of processors continues to evolve, that will lead to more heterogeneity among them.

One HPC approach for solving the motif finding problem is the use of CPUs and GPUs [4, 5]. By using CPUs and GPUs in combination, researchers can harness the power of both types of processing units to analyze large datasets and search more efficiently for motifs.

Das and Dai [6] proposed another HPC approach where the use of many integrated core (MIC) architectures, such as Intel's

Xeon Phi. MIC architectures are designed to provide high levels of parallelism and are well-suited for tasks that can be easily parallelized, such as motif finding. Zymbler and Kraeva [7] explained that by using MIC architectures, researchers can further increase the computational power available for solving the motif finding problem by following the proposed algorithm which showed high scalability, especially in the case of high computational load due to greater motif length.

Durbin et al. [8] found that effective use of HPC techniques for motif finding requires the implementation of appropriate scheduling strategies. Scheduling strategies determine how the computational workload is distributed among the available processing units and can significantly impact the efficiency of the motif finding process. For example, a scheduling strategy may involve dividing the dataset into smaller chunks and distributing them among the available CPUs, GPUs and MICs for parallel processing. Alternatively, Jones and Pevzner [9] determined that scheduling strategy may involve using machine learning techniques to optimize the allocation of computational resources.

HPC users may not always fully utilize the resources available to them on a cluster. This can be due to a variety of factors, including a lack of knowledge about the cluster's capabilities, the complexity of the HPC environment, limited time and resources, insufficient data, incorrect configuration, and inefficient algorithms. To overcome these challenges and fully utilize a cluster in their experiments, HPC users can seek support from experts, optimize their algorithms and data processing pipelines, and allocate sufficient resources. Additionally, HPC users can take advantage of cluster management tools and techniques, such as job scheduling and resource allocation, to better utilize the cluster's resources and improve the efficiency of their experiments. By addressing these challenges, HPC users can effectively leverage the power of HPC to solve complex problems and advance their research. Due to the difficulty of installing programs, as most software packages are not available by default for this environment, and the programs must be improved to take advantage of the capabilities of this device and match its high specifications, the same problems and challenges may be present through the administrator's view of the high-performance computer system. But, as software engineering advances, these problems are overcome by allowing software to optimize how it operates in a HPC environment. Another problem that is encountered from the point of view of the system administrator is that most users use by default one type of available resource, and this leads to a long waiting time in the queue for it to be released

for use by another user. This problem can be overcome by enabling scheduling algorithm that will direct users through different channels from resources to reduce waiting time in queue.

The effectiveness of using various types of resources in a heterogeneous environment depends on the parallel approaches chosen by the developer. The implementation of a scheduling strategy is a crucial aspect of performance. However, HPC users often utilize only one computing resource at a time for their experiments due to their expectations and behaviors. This paper presents a modified scheduling strategy for the planted motif finding problem that can achieve significant performance while using fewer computational resources.

II. MOTIF FINDING PROBLEM AND ALGORITHMS

The Motif-Finding problem (MFP) is the problem of finding patterns in sequences of DNA. Finding the common patterns in sequences is challenging as the DNA is a huge set [10]. This common pattern is called Motif and is usually a short segment that occurs frequently, see Fig. 1. These patterns considered a scientific interest in bioinformatics domain and those Motifs can be correspond to sequences of DNA that control the activation of specific genes [11]. MFP discovery algorithms can be classified into three categories based on its variants as Simple Motifs Search (SMS), Edited Motif Search (EMS) and Planted (l,d)-Motif Search (PMS)[12, 13]. This paper will consider (PMS) exact algorithms due to its high complexity [12] which makes it suitable to be solved on HPC systems as MFP is well known to be computationally intensive problem [14]. To detect a Motif of length L with allowed mutation d and all possible L -mers (4^L) is compared for all possible Motifs of length L and a sequence with size N we will get $(N - L + 1)$ using Brute-Force Algorithm. We will present our parameters same as used in [14, 15] and for such intensive resources computations could be implemented using heterogeneous platforms [4], [16]-[21] and for our experiment it will be conducted on a cluster containing CPUs, GPUs and MIC. The DNA constructed of nucleotides which is cytosine [C], guanine [G], adenine [A] or thymine [T] and can be represented using the regular expression in (1). The length L and its possible L -mers represented in (2). The sequence set on (3) and the *match* function used to compare Motifs A and B each of them has a size L represented on (4) the i _{th} position is represented where $A_i B_i$ for A and B Motifs. The counting of existence of L -mer in T sequences done by using *score* function shown in (5).

Motif finding problem can be solved in many algorithms that researchers have investigated in the past two decades [12, 13] and these algorithms are influenced by the length and the allowed mutations [6]. Some techniques are using variants of brute force algorithm that requires hundreds of hours. Faheem et al. [15] proposed an algorithm that can benefit from different architectures to split the MFP into smaller sub problems that can be solved on heterogeneous architectures with minimal communications. They proposed a speed-based scheduling algorithm to split the work and they proved that the problem is a data parallel problem given that they are using only brute force algorithm which may not be the most suitable algorithm for such problem; also it's hard to for a normal user to reserve a full cluster due to the fact that most of HPC centers

are a shared resource and they apply some resource limitation per user.

A Brute Force Algorithm solves this problem by considering all possible sets all 4^l possible l -mers. Compute the total distance of each l -mer in that set from all other l -mers in all t sequences. The correct Motif is the one with the smallest distances along all other l -mers. The running time of this algorithm is $O(4^l nt)$. To find a motif of $l = 11$ is about 5 hours and longer motifs cannot be processed in a reasonable amount of time [4]. Although the execution time of the brute force algorithm is clearly too long to solve the challenge problem, but it's of the exact algorithms that never fail to find the motif [4, 12].

The original Brute Force can be improved to be an upgraded version of Brute-Force algorithm called "SKIP Brute-Force" (SKIP BF) [4, 5, 22] as proven by Faheem [4] by using a grid computing and the enhanced version of Skip Brute Force has better execution time. This approach can be implemented in parallel on different compute resources as done by M. Al-Qutt et al. [5]. They implement the Skip Brute Force and solve MFP on CPU, GPU and MIC and the parallel version of their solution has significant execution time. The core enhancement on this SKIP BF Algorithm (Fig. 2) is to skip all iterations that won't lead to a correct solution. The algorithm behaves as Brute-Force algorithm by generating all possible 4^l l -mers then a generated l -mer of length L with d permitted mutations is considered matched if at least $(L - d) + 1$ identical positions at both are matched. Then the algorithm starts looking to the next sequence and excludes any unmatched l -mers from the search for the next sequence [5, 23]. SKIP BF leads to a better running time against the original Brute-Force Algorithm by skipping those irrelevant iterations and it's shown a high speedup performance on hardware accelerators like FPGA and shown a good chance for parallelization due to its fact of repetitive nature [22]. The complexity of this algorithm is $O(4^l nt)$ at its worst case [4].

The other algorithm to solve MFP was proposed by [3] called Recursive Brute Force Algorithm (RBF) and simply considered a searching technique that aims to search among the highest occurrence of the patterns of length L in set of characters and in some cases this algorithm allow us to accept the result of allowed mutation which means a non-exact match which is valid for MFP. RBF shown good time performance but its required a huge memory to be implemented using parallel methods as shown by Marwa Radad et al. [16, 25]. Memory allocation for recursive algorithms is major point and for RBF proposed by [24] they use the static memory allocation technique to avoid memory management and it was implemented in two phases- the initialization phase begins with candidate initialization as shown in Fig. 4; then test the candidate's list to search for possible candidates. Then extend the target for a good Motif and all motifs that have grater mutations than d are called bad candidates. The second phase is candidate generation phase and the extension and addition phase. RBF algorithm use a parallelization layer and distribute the workload using parallel paradigms MPI (Fig. 3). The search is finished in (level 1) with no expansion in time of $O(4^l nt)$. It has same complexity as the original Brute Force Algorithm [16].

Nikolaos et al. [28] introduced a parallel algorithm aimed at

efficient Top-k Motif Discovery in Weighted Networks. Their approach demonstrated commendable scalability and speedup, especially with an increase in the number of CPU cores. In a separate study, Theepalakshmi et al. [29] developed an enhanced solution for planted motif by applying the Freezing FireFly (FFF) algorithm. Their method outperformed existing state-of-the-art optimization algorithms in terms of time efficiency. Despite these advancements, this paper will primarily concentrate on the work referenced as [4], [5], [15], [16] given that the same platform was used for our experimental procedures.

III. PERFORMANCE ANALYSIS OF MOTIF FINDING ALGORITHMS ON DIFFERENT ARCHITECTURES

To evaluate the performance of HPC for solving planted motif finding problems, we conducted a series of experiments using CPUs, GPUs, and MIC architectures. The experiments were designed to compare the performance of different algorithms on each type of resource. We used three different exact algorithms for solving the planted motif finding problem: Brute Force (BF), Skip Brute Force (SBF) and Recursive Brute Force (RBF).

```

1. for L = 0 to 4L_motifSize - 1 do % examine all possible l-mers
2.     for Ti = 1 to t_sequences do % loop on all t sequences
3.         motif_found = 0;
4.         current_score = d_mutations;
5.         for W = 1 to n_seqSize-l_motifSize+1 do % loop on
           all windows
6.             dist = compute_distance ( L , W);
7.             if dist <= current_score
8.                 solution.motif = Li; % this can be the motif
9.                 solution.posit(Ti) = W; % save its position
10.                motif_found = 1; % a suspected motif was
                    found
11.                current_score = dist;
12.                if Ti = t_sequences % we reached the
                    last sequence
13.                    solution_found = 1;
14.                end

22.    if solution_found
23.        break;
24.    end
25. end
    
```

Fig. 2. Pseudo code algorithm for SBF.

For the experiments, we used a Synthetic DNA sequences [13] as database with a data parameters that proposed by Pevzner [14] for Planted (l, d) Motif where the input sequences of size $N = 600$ each from the set of alphabets (1) and a motif M of size $l = 15$ and $d = 4$ allowed mutation.

For the CPU experiments, we used a cluster that with a limited recourses per user of eight nodes, each equipped with two Intel Xeon processors. For the GPU experiments, we used a cluster of 2 nodes, each equipped with one NVIDIA GPGPU K20 graphics card. For the MIC experiments, we used a cluster of two nodes, each equipped with one Intel Xeon Phi 7250 processor. We measured the performance of the algorithms by running time in seconds that reflected the time required to complete the planted motif finding process.

Examining the results in Table I gives an indication of the improvement in total run time with different algorithms. For instance, implementing the three algorithms using one regular node with OpenMP will reduce the run time from 11368 seconds for brute force algorithm on a single regular node to 2343 seconds for skip brute force algorithm with a speedup factor of 4.8 and recursive brute force algorithm run time 420 seconds that's comes with a speed factor of 28.2 to the original brute force algorithm run time while using eight regular nodes, will reduce the run time for brute force algorithm from 1416 seconds on pure 8 regular nodes to 73 seconds for skip brute force algorithm with a speedup factor of 19.3 and recursive brute force algorithm run time 40 seconds that's comes with a speed factor of 35.4 to the original brute force algorithm run time. For MIC and GPU, architectures are designed to

TABLE I. MFP RESULTS WITH DIFFERENT ARCHITECTURES

that can be easily parallelized. They are not well-suited for tasks that require sequential execution or complex control flow that use recursive function calls. Therefore, parallel recursive algorithms are generally not supported on MIC architectures or GPUs while results show that skip brute force algorithm has better running time than original brute force algorithm with speed up factor 5.9 to GPU and 20.8 for MIC.

The results of the experiments showed that the performance of the algorithms varied significantly depending on the type of resource and the algorithm deployed on each one of them. Overall, the GPU and MIC architectures outperformed the CPU architecture in terms of running time in some algorithms while CPU has better running time for recursive brute force algorithm, these results will provide valuable insights into the performance of different algorithms on different types of resources and will help to identify the most effective algorithm for each architecture and generate the assign map Table II. We will be able to optimize the use of computational resources in Table I and II to improve the scheduling strategy efficiency of the motif finding process in detail in the coming section.

IV. SCHEDULING STRATEGY AND PROPOSED APPROACH

A scheduling strategy is a plan or approach for distributing computational tasks among the available resources in a HPC environment. In the context of motif finding, a scheduling strategy involve dividing the dataset into smaller chunks and distributing them among the available CPUs, GPUs, and MICs for parallel processing. There are several approaches that can be used to develop a scheduling strategy for solving motif finding problems on HPC systems that have different types of computing nodes.

HPC systems are typically shared resources among multiple users, each with their own research goals and computational needs. In this context, it is often the case that one user cannot fully utilize the entire cluster for their own use and must share the resources with other users. This can lead to a lack of access to the resources that a user needs for their research, or to longer wait times for access to the resources. Furthermore, HPC users often rely on only one type of computing resource, such as CPU or GPU, for their experiments which can lead to underutilization of other resources and less efficient use of the available resources.

provide high levels of parallelism and well-suited for tasks

A scheduling strategy can help to mitigate these issues by more efficiently allocating the resources of the HPC system among the different users and their tasks. By using a scheduling strategy that takes into account the characteristics of the tasks and the available resources, it is possible to improve the overall performance of the HPC system and increase the number of users that can be accommodated on the system.

We use a Task-based scheduling strategy that assigns tasks to the computing node that is most suitable for solving them based on the best performed algorithm from previous results. These types of strategies are often used to optimize the performance of HPC systems by ensuring that tasks are executed on the most appropriate computing resources [26].

We have developed a scheduling strategy that can be used to divide tasks based on the best-performed algorithm for solving the motif finding problem on CPUs, GPUs, and MICs with similar approach described in [15], [27]. The PBS script used to construct the scheduler and designed to optimize the performance of HPC systems by selecting the best algorithm for each task on each type of resource based on its performance, then will divide the workload among other computing resources as shown in Fig. 5. The scheduler can help to ensure that tasks are executed efficiently and accurately, improving the overall performance of the system. In addition, the PBS script can be easily modified to support new algorithms or to adapt to changes in the characteristics of the data, making it a flexible and versatile tool for solving the motif finding problem on HPC systems with different types of resources.

V. EXPERIMENT RESULTS AND VALIDATION

After running the scheduler on a heterogeneous cluster consisting of CPUs, GPUs, and MICs, we obtained the following results.

TABLE III. RESULTS OF THE PREVIOUS PAPERS

Platform	CPU Ratio %	CUDA Ratio %	MIC Ratio %	Results
1 Regular Node+ 1 CUDA+1 MIC	40.321	29.867	29.812	2330.11
2 Regular Node+ 1 CUDA+1 MIC	69.250	15.389	15.361	1978.20
4 Regular Node+ 1 CUDA+1 MIC	79.427	10.296	10.277	1533.72
8 Regular Node+ 1 CUDA+1 MIC	86.549	6.732	6.719	1056.87

TABLE IV. RESULTS OF THE PROPOSED APPROACH

Platform	CPU Ratio %	CUDA Ratio %	MIC Ratio %	Result
1 Regular Node+ 1 CUDA+1 MIC	40.321	29.867	29.812	363
2 Regular Node+ 1 CUDA+1 MIC	69.250	15.389	15.361	182
4 Regular Node+ 1 CUDA+1 MIC	79.427	10.296	10.277	121
8 Regular Node+ 1 CUDA+1 MIC	86.549	6.732	6.719	77

The scheduler was able to effectively divide the tasks based on the best-performed algorithm for each type of resource, resulting in an overall improvement in the performance of the system. With more resources that selected the more workload, is assigned as the case for CPU as shown in Table I.

```

1. PROGRAM MotifScheduler
2. Input : S[1, ..., T]
3. Input : L
4. Input : d
5. Input : Matrix M
6. BEGIN
7.  $t[t_1, \dots, t_p] \leftarrow$  load single task execution time for architectures
8.  $t_{min} \leftarrow \text{MIN}_{i=1}^p (t_i) * 4^L$ ; find the smallest run time
9. Assign smallest run time to the best performed algorithm from Matrix M
10. FOR  $i=1$  to  $p$ 
11.   IF  $t_i \leq t_{min}$  THEN
12.      $R_i \leftarrow 4^L / t_i$ ; find the weight of each architecture
13.   ELSE
14.      $R_i \leftarrow 0$ ; this architecture is very slow and will be ignored
15.   END
16. END
17.  $R_{total} \leftarrow R_1 + R_2 + \dots + R_p$ ; sum the weights
18.  $R_u \leftarrow 4^L / R_{total}$ ; find the tasks assigned to each weight unit
   offset = 0
   start $_i$  = 0
19. FOR  $i = 1$  to  $p$ 
20.    $C_i = R_i * R_u$ ; tasks assigned to architecture
   start $_i = \text{start}_i + \text{offset}$ ; determine the start index of tasks
   end $_i = \text{start}_i + C_i - 1$ ; determine the end index of tasks
   offset =  $C_i$ 
21.   Score $_i \leftarrow \text{SPAWN Algorithm}_i(S, L, d, C_i, \text{start}_i, \text{end}_i)$ 
22. END
23. return  $\text{MAX}_{i=1}^p (\text{Score}_i)$ ; find the motif of highest occurrence
24. END

```

Fig. 5. Pseudo code of scheduling algorithm to assign workload to architecture.

TABLE V. COMPARISON BETWEEN RESULTS

Platform	Previous Results	Our Results	Speed up
1 Regular Node+ 1 CUDA+1 MIC	2330.11	363	6.42
2 Regular Node+ 1 CUDA+1 MIC	1978.20	182	10.87
4 Regular Node+ 1 CUDA+1 MIC	1533.72	121	12.68
8 Regular Node+ 1 CUDA+1 MIC	1056.87	77	13.73

By comparing our results with Table III from [15] that use the same cluster we can see with one Regular Node, one CUDA and one MIC, our approach managed to finish in 363 second instead of 2330 seconds with speedup factor 6.4 and by using 8 Regular Node, 1 CUDA and 1 MIC, as this is the maximum user limitation for the user in the cluster we gain a speedup factor 13.7 in total time of 77 seconds while in Table III its required full capacity that consist of 265 Regular Node to gain total performance of 54.91 seconds.

A comparison of our results in Table IV with those presented in Table III from study [15] shows that our approach was able to achieve a significant improvement in performance. Using a configuration of one Regular Node, one CUDA Node, and one MIC Node, our approach was able to complete the planted motif finding problem in 363 seconds, compared to

2330 seconds in Table III. This resulted in a speedup factor of 6.4. Additionally, by using a configuration of 8 Regular Node, 1 CUDA Node, and 1 MIC Node, which is the maximum user limitation for our cluster, we were able to achieve a speedup factor of 13.7 in a total time of 77 seconds as shown in Table V. This is compared to the full capacity configuration of 265 Regular Node in Table III which took 54.91 seconds. The chart in the Fig. 6 illustrates a comparison between previous studies and the proposed approach.

Fig. 6. Comparison between previous studies and the proposed approach.

These results demonstrate the effectiveness of our approach in achieving improved performance in motif finding problem on heterogeneous cluster. Hence, it can be seen that the waiting time has become significantly less, because the distribution of users by placing them in different channels to use the resources makes the available resources larger and does not require a large launch time to make them available to the new user.

VI. CONCLUSION

In this paper, we propose a scheduling algorithm to make better use of the heterogeneous cluster. It is based on the idea of dividing tasks on multiple types of resources available on the HPC. The results of this algorithm were compared with previous results, but they were using only one type of resource, which caused a burden and took a longer time to solve the problem.

Overall, the use of the scheduler resulted in a significant improvement in the performance of the system for solving the motif finding problem on a heterogeneous cluster with different algorithms. The scheduler was able to effectively select the best-performed algorithm for each type of resource, resulting in an efficient and accurate solution to the problem with much more less resources.

Fruit Classification using Colorized Depth Images

Dhong Fhel K. Gom-os
Department of Computer Science
University of the Philippines Cebu
Cebu, Philippines 6000

Abstract—Fruit classification is a computer vision task that aims to classify fruit classes correctly, given an image. Nearly all fruit classification studies have used RGB color images as inputs, a few have used costly hyperspectral images, and a few classical ML-based have used colorized depth images. Depth images have apparent benefits such as invariance to lighting, less storage requirement, better foreground-background separation, and more pronounced curvature details and object edge discontinuities. However, the use of depth images in CNN-based fruit classification remains unexplored. The purpose of this study is to investigate the use of colorized depth images in fruit classification with four CNN models, namely, AlexNet, GoogleNet, ResNet101, and VGG16, and compare their performance and computational efficiency, as well as the impact of transfer learning. Depth images of apple, orange, mango, banana and rambutan (*Nephelium Lappaceum*) were manually collected using a depth sensor with sub-millimeter accuracy and subjected to jet, uniform, and inverse colorization to produce three sets of dataset. Results show that depth images can be used to train CNN models for fruit classification with ResNet101 achieving the best accuracy of 96% on the inverse dataset. It achieved 100% accuracy after transfer learning. GoogleNet showed the most significant improvement after transfer learning on the uniform dataset, at 12.27%. It also exhibited the lowest training and inference times. The results show the potential use of depth images for fruit classification and similar computer vision tasks.

Keywords—Fruit classification; depth image; depth colorization; CNN; transfer learning

I. INTRODUCTION

The depth output of a depth sensor is converted into a three-dimensional RGB image to provide a colorized depth image. To create colorized images, specific colorization procedures are used to the depth data. A colorized depth image stores the depth information per pixel as opposed to a color image, which typically stores red, green, and blue intensity values per pixel. As a result, in a colorized depth image, the intensity of each pixel indicates how far an object is from the camera. Depth image is also known as range image.

The use of colorized depth images has continuously gained attention in the research community. They are used in soybean canopy analysis through 3D point clouds [1], action recognition [2], human posture analysis [3], 3D semantic segmentation [4], object recognition [5], and kangaroo detection [6]. In these studies, depth images were used either exclusively or in combination with RGB through fusion. These studies have shown that colorized depth images are helpful for solving complex computer vision problems.

Certain colorized depth-image characteristics are beneficial for both simple and complex computer-vision problems. For example, depth images are good at separating 3D objects from

the horizontal plane [4], which is beneficial for object detection. They can provide an outline of the strong discontinuities at the edges of an object, which is advantageous for object classification [5]. Curvature information is also more prevalent in depth images than in color images [5]. In addition, they require less storage than colored images (see Table II). They are more useful in edge cases of machine learning problems [7], such as differentiating between a hotdog food and a hotdog balloon. They are also invariant to extreme variations in lighting conditions and scale [7]. However, it is widely known that depth images require a lot of pre-processing as opposed to color images because of their tendency to contain missing depths [5], as well as their low contrast property [6]. Additional processing is required to improve the contrast and accuracy in highly complex and wide-area applications.

For less complex and more constrained applications such as fruit image classification, the benefits of using depth images can be leveraged. Fruit image classification is a computer vision task in which fruit images are classified according to their class. Here, it is assumed that the images do not contain more than one class of fruit. Applications for fruit image classification include supermarket self-checkouts and fruit sorting in factories.

Several studies on fruit image classification have been conducted. However, most of these studies used color images as inputs. Only a few studies have explored the use of depth images for fruit classification. In particular, one study [8] trained six machine learning algorithms, including Sequential Minimum Optimization (SMO), k-nearest neighbors (KNN), bagging based on REPTree, Decision Trees (DT), and Random Forests (RF) in the Waikato Environment for Knowledge Analysis (Weka) using visual features from color images and object shape representations from depth images. The shape descriptors extracted from the depth images include compactness, symmetry, local convexity, smoothness, and image moments. The results showed that RF trained on a combination of scalable color and edge histogram descriptors yielded the best performance at 99% accuracy. The problem with this classical approach is the need to perform segmentation in color images and manually extract features from the depth images. Depth images cannot be processed without their corresponding color images.

Another study [9] used depth images to render a 3D point cloud of fruits for classification. Similar to [8], [9] developed a multi-feature classification framework utilizing both color and depth images. It uses a color layout descriptor, viewpoint feature histogram, and point feature histogram as descriptors in the classification problem. Similarly, this approach is labor intensive and requires manual extraction of features from

images.

Based on [8] and [9], depth images can be beneficial for fruit-image classification. However, no study has explored the use of depth images yet, particularly in CNN-based fruit classification. Therefore, the goal of this study is to explore the use of purely depth images based on simple colorization techniques in fruit classification using CNN. The researcher used three different types of depth images, namely color-jet, uniform, and inverse hue colorization, and compared the performance of each type in four CNN models, namely, AlexNet, GoogleNet, ResNet101 and VGG16. The effect of transfer learning on the type of depth image with the lowest error rate in each CNN model was also investigated. Because depth sensors are gaining popularity in the sensor market, it would be beneficial to explore the use of depth images in computer vision problems, particularly in fruit classification.

The remainder of this paper is organized as follows. After the introduction, Section II discusses the background of the study. Section III discusses the methodology of the study. The findings are presented in Section IV followed by future work and conclusions in Sections V and VI, respectively.

II. BACKGROUND

A. Fruit Classification

Fruit image classification is the process of identifying a specific type of fruit in an image. This task is typically performed using convolutional neural networks (CNNs), a type of deep learning model that has become dominant in various computer vision tasks. CNNs are trained on large datasets of labeled images and learn to recognize features that are relevant to the task of fruit classification. The trained model can then be used to classify new images of fruits based on learned features.

Almost all studies tackling fruit classification using CNN use RGB color images as their dataset, except for a few that use hyper-spectral images. Hyperspectral images are captured using expensive hyper-spectral imaging which is a technique that collects and processes information from across the electromagnetic spectrum to obtain the spectrum for each pixel in an image of a scene. Table I shows a summary of the dataset types used in training the CNN models for fruit classification from 2015. [10] summarized the CNN-based fruit classification studies conducted from 2015 to 2020. This summary was manually checked by the researcher, and the outcome was plotted in the table mentioned above. For 2021-2023, the researcher manually searched the Scopus database using the keyword "fruit classification" for relevant papers. As shown in Table I, there is only one paper [11] that used the other type of dataset, i.e. hyper-spectral, from 2015-2020 and another one [12] in 2022. Evidently, the research community on fruit classification has extensively used RGB color images, and has not substantially explored other image types, including depth images.

The most popular benchmarks used for fruit classification are ImageNet, VegFru [13] and Fruit 360 [14]. ImageNet is a large visual database designed for use in visual object recognition software. It contains over 14 million images that have been hand-annotated to indicate what objects are pictured, and bounding boxes are provided in at least one million

TABLE I. NUMBER OF CNN-BASED FRUIT CLASSIFICATION STUDIES PER DATA TYPE

Year	Color (RGB)	Other (Hyper-spectral)
2015-2020	20	1
2021	27	0
2022	29	1
2023*	5	0

images. VegFru is a domain-specific dataset for fine-grained visual categorization of vegetables and fruits based on their eating characteristics. Each image in the dataset contained at least one edible part of vegetables or fruits with the same cooking usage, and all images were labeled hierarchically. It is closely related to the daily lives of people and is aimed at domestic cooking and food management. Fruit 360 is a dataset of images containing fruits. It is a high-quality dataset that includes 131 fruits and vegetables. The images are color (RGB) and 100 pixels \times 100 pixels in size, with three values for each pixel. It contains a total of 90,380 images, with 67,692 images in the training dataset and 22,688 images in the test dataset.

Similar to other computer vision tasks, fruit classification tasks extensively use color images, perhaps because of ubiquitous color sensors. However, RGB images obtained from color sensors have issues when used in fruit classification. There is a high rate of misclassification of fruits that are of similar colors, such as avocado and watermelon, banana and papaya, orange and carrot, as shown in [15]; passion fruit and blackberries, red grapes and passion fruits in [16]; and peach and apple red, pear and apple green, and pomegranate and apple in [14]. It was also found in [17] that shape feature also resulted in high misclassification between apples and oranges. A similar result was found in [18] which suggested that the color feature alone does not provide a good classification outcome. One very recent study [19] used MobileNetV2 with attention module in the classification. The attention module worked well in non-smoothed fruits but provided low precision in smoothed fruits like orange (at 81.75%). The researcher argues that it might be beneficial to explore other types of images for fruit classification, one that is independent of color. This is especially because fruit classification task is constrained and not complex, where special imaging sensors such as a depth sensor can easily be set up.

B. Depth Sensing

Depth sensing refers to the process of measuring the distance between a device and an object. Depth-sensing cameras are used for this purpose, and they automatically detect the presence and measure the distance of an object within its field of view. There are three types of depth-sensing cameras based on their method of calculating depth: (a) structured light and coded light, (b) stereo depth, and (c) time of flight and LIDAR [20].

(a) is a type of technology that uses projected light, usually infrared light, in the scene for a sensor to obtain its pattern and estimate its depth. This type of technology is the best indoors and within a short range. However, it is vulnerable to interference from nearby devices that emit infrared light. As opposed to (a), which uses projected light, (b) uses any light to

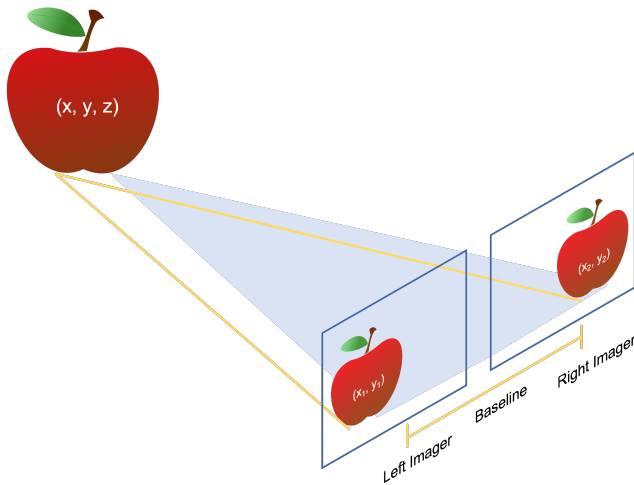

Fig. 1. Basic principle of stereo vision.

estimate depth but uses two sensors at a small distance apart. This technology works well both indoors and outdoor. Fig. 1 shows the basic operation of the stereo vision system. Similar to (a), (c) also emits light in the scene and calculates the time it returns to the sensor by which the depth is computed. As in (a), it is vulnerable to interference and is not ideal for outdoor conditions. The most common depth sensor uses a stereo vision mechanism for depth sensing. The depth sensor used in this study was a stereo-vision camera.

C. Depth Colorization

Depth colorization is a subset of image colorization [21] which is the process of estimating RGB colors for grayscale images to enhance perceptual quality. In the context of depth images, a grayscale image is a 2D depth map, where each pixel contains depth measurements from the depth sensor. Depth colorization is a method that adds colors to a depth map. This involves compression and coding [22]. It is not yet as developed as in compression and encoding in color images, but the ultimate goal is essentially the same: efficient storage, reduced artifacts, and reduced system bandwidth. To achieve this goal, various approaches have been developed. [23] suggested that there are two primary categories of representing colorized depth images, namely, hand-crafted depth colorization and ML-based depth colorization.

Some hand-crafted approaches include depth-to-surface normals [5], geocentric embedding (a.k.a. HHA encoding) [24], rendered mesh [25], quadtree decomposition & plane approximation [26], color-jet [27], and uniform and inverse colorization [22].

The surface normals [5] approach uses two cross-multiplied orthogonal tangent vectors and is normalized using the Euclidean norm, but introduces a recursive median filter to estimate the missing depth values and a bilateral filter to reduce noise. The geometric embedding approach encodes the height above ground and the angle with gravity for each pixel on top of the horizontal disparity [24]. The rendered mesh approach [25] first performs tabletop segmentation to extract the relevant depth map, missing depth values are filled in,

the mesh is extracted from the point cloud, and the mesh is re-projected to a canonical camera pose. All the three approaches are computationally expensive. Despite this, they only result in minimal to no improvement in some benchmarks for object recognition tasks. The quadtree decomposition and plane approximation approaches [26] achieved a low bit rate. However, this approach requires proprietary software for encoding and decoding and does not take advantage of the hardware acceleration modules present in modern computers.

A more advanced colorization technique, ML-based depth colorization, was developed in [23]. It uses a CNN architecture that is pre-trained on ImageNet. However, despite the use of neural networks, the results show that the model did not significantly improve the classification accuracy compared to color-jet and surface normals [27]. In fact, it performs worse in some models and benchmarks. It can be deduced from [23] that the encoding used does not significantly impact performance and high accuracy in computer vision tasks is still achievable even with a simple colorization approach.

It is for this reason that simple colorization approaches have been adopted in this study, namely, color-jet [27], uniform and inverse colorization [22].

1) *Color-Jet*: This is a common approach in depth colorization [27] where depth data is applied with a jet colormap to transform it from a single channel to a three-channel 2D depth image. This approach was found to be effective and computationally inexpensive and was shown to outperform HHA for object recognition. In this approach, the depth values are first normalized between 0 and 255, and then a jet color map is applied to the one-channel image to make it a three-channel image. A jet is a colormap [28] used for data visualization. It is a rainbow map that is commonly used to create false color images. Typically, the depth image is derived for each pixel (i, j) by mapping the distance to color values ranging from red (near) over green to blue (far). Sometimes, this mapping is reversed, i.e., blue is near, which is the case in this study.

2) *Uniform and Inverse Colorization*: [22] also developed a similar approach to [27] which uses the Hue colorspace with 6 gradations and 1529 discrete levels. It has two variations: uniform and inverse. The former directly encodes the depth value whereas the latter encodes the disparity value (reciprocal of the depth value). The latter is suitable for closer distances because it can capture finer details and information. The equations below show the mapping between the normalized depth (d_n) to the Red (p_r), Green (p_g) and Blue (p_b) channels respectively in case of uniform colorization.

$$d_n = \frac{d - d_{min}}{d_{max} - d_{min}}$$

$$p_r = \begin{cases} 255, & 0 \leq d_n \leq 255 \cup 1275 < d_n \leq 1529 \\ 255 - d_n, & 255 < d_n \leq 510 \\ 0, & 510 < d_n \leq 1020 \\ d_n - 1020, & 1020 < d_n < 1275 \end{cases}$$

$$p_g = \begin{cases} d_n, & 0 < d_n \leq 255 \\ 255, & 255 < d_n \leq 510 \\ 765 - d_n, & 510 < d_n \leq 765 \\ 0, & 765 < d_n \leq 1529 \end{cases}$$

$$p_b = \begin{cases} d_n, & 0 < d_n \leq 765 \\ d_n - 765, & 765 < d_n \leq 1020 \\ 255, & 510 < 1020 \leq 1275 \\ 1529 - d_n, & 1275 < d_n \leq 1529 \end{cases}$$

In case of inverse colorization, the mapping is done on the disparity value ($disp$) which is the reciprocal of depth.

$$disp = \frac{1}{d}, disp_{min} = \frac{1}{d_{min}}, disp_{max} = \frac{1}{d_{max}}$$

$$d_n = \frac{disp - disp_{min}}{disp_{max} - disp_{min}}$$

It is imperative that a simple and computationally efficient colorization approach be employed especially for real-time classification.

D. CNN Models

Convolutional neural networks (CNNs) is a deep learning network that automatically learns from visual data. In contrast to classical machine learning algorithms, CNN offers end-to-end model development without the need to manually extract features. CNN models learn patterns from input data via the convolution and pooling of multidimensional matrices. Four common models were considered in this study: AlexNet, VGG16, GoogleNet, and ResNet101.

1) *AlexNet*: AlexNet [29] is a convolutional neural network (CNN) architecture that was introduced in 2012 by Alex Krizhevsky, Ilya Sutskever, and Geoffrey Hinton. It was designed to compete in the ImageNet Large-Scale Visual Recognition Challenge (ILSVRC) and achieved a significant improvement in accuracy over previous methods. AlexNet consists of five convolutional layers and three fully connected layers, with multiple convolutional kernels extracting features from the images. The architecture also includes max-pooling layers and ReLU activation functions to improve performance. AlexNet's success in ILSVRC helped popularize deep learning and CNNs, leading to many more papers and applications in computer vision.

2) *GoogleNet*: GoogleNet [30], also known as Inception v1, is a convolutional neural network architecture that was introduced in 2014 by researchers at Google. The architecture was designed to improve the performance of neural networks by making them deeper while avoiding the complications that arise with an increasing number of layers. GoogleNet uses a unique architecture called the inception module that consists of multiple convolutional layers with different filter sizes and pooling operations. The Inception module allows the network to capture features at different scales and resolutions, thereby improving its ability to recognize objects in images. GoogleNet also includes auxiliary classifiers that help combat the vanishing gradient problem and improve training performance.

Fig. 2. General CNN architecture with depth image input.

3) *ResNet101*: ResNet101 [31] is a convolutional neural network architecture that was introduced in 2015 by researchers in Microsoft. The architecture is 101 layers deep and includes a unique feature called the “identity shortcut connection,” which allows the model to skip one or more layers. This approach helps to combat the vanishing gradient problem and allows the network to be deeper without sacrificing its performance. ResNet101 was designed to improve the accuracy of image classification tasks and it achieved high performance on the ImageNet dataset at the time of its introduction. The architecture has since been widely used and studied in the field of computer vision.

4) *VGG16*: VGG16 [32] is a convolutional neural network architecture introduced in 2014 by researchers at the University of Oxford. The architecture is unique in that it has only 16 layers with weights, as opposed to relying on a large number of hyper-parameters. VGG16 was designed to improve the accuracy of image recognition tasks and it achieved high performance on the ImageNet dataset at the time of its introduction. The architecture consists of five blocks of convolutional layers, each followed by a max-pooling layer, and three fully connected layers. The convolutional layers use small 3×3 filters, which help to reduce the number of parameters in the model.

E. Transfer Learning

Transfer learning is a machine learning technique that involves reusing a pre-trained model as the starting point for a new model on a different task. The pre-trained model has already been trained on a large dataset and has learned to recognize a wide range of features. By using the pre-trained model as a starting point, we can save time and computational resources that would otherwise be required to train a new model from scratch. Transfer learning is particularly useful when we have limited data for the new task, as the pre-trained model can provide a good starting point for learning the new task. Transfer learning has become a popular technique in deep learning, and it has been used in a wide range of applications, including image classification, object detection, and natural language processing. By leveraging the knowledge learned from pre-trained models, we can improve the performance of our models and reduce the time and resources required for training.

III. MATERIALS AND METHODS

The general architecture of the CNN model in this study is illustrated in Fig. 2.

Fig. 3. Dataset samples: (left-right) RGB, jet (D1), uniform (D2), inverse (D3).

A. Dataset

In this study, there was a need to gather depth images of fruits from scratch. A depth camera based on stereo vision matching, Intel RealSense D405, was used to collect depth images in an indoor environment at an 848×480 resolution (30 fps). This depth camera is ideal for close-range applications, providing sub-millimeter accuracy to capture small features in an object that is suitable for this study. It was attached to a tripod ~ 10 cm from the platform, and the surroundings were artificially lit with a 14 W LED ring light at 1600 lumens. The camera was placed in the middle of the ring light for even lighting. Fig. 3 shows a set of dataset samples with RGB and depth images in three colorization: jet, uniform and inverse.

One important aspect of this study is the choice of colorization for the depth images. Based on [23], there is no significant benefit from using computationally expensive approaches, as there is no evidence that this translates to high performance. Therefore, three simple colorization approaches were used. The researcher refers to these as D1, D2, and D3 for the color-jet, uniform, and inverse colorization, respectively. These datasets have one-on-one correspondence in samples, i.e., each sample in each dataset was taken at the same time, with the same fruit object and resolution, just a different colorization. In this way, we can also make fair comparisons of the performance of the three colorization methods.

The fruits considered in this study were apple, orange, mango, banana, and rambutan (*Nephelium Lappaceum*). These fruits were selected for the following reasons: (a) apples and oranges are different in color and similar in shape; (b) mangoes and bananas are similar in color and different in shape, and apples and rambutans are similar in color and have different shapes and textures.

B. Post-Processing Filters

To improve the depth quality and accuracy, the depth data from the depth camera underwent a series of post-processing filters before colorization, except for jet. Both the uniform and inverse colorized depth images underwent a series of filters, namely, decimation, spatial, temporal, and hole filling. Depth-to-disparity transformation and vice versa are required for certain filters.

Fig. 4 presents a summary of the post-processing filters used for each dataset. A decimation filter was used to minimize

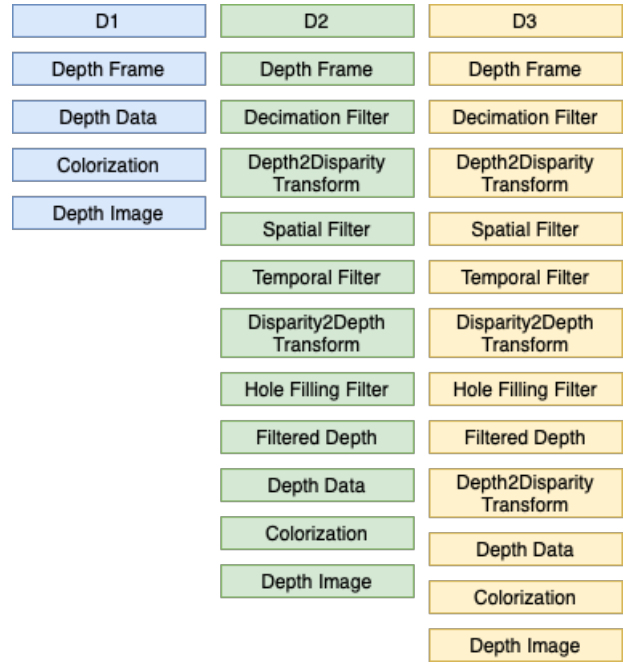

Fig. 4. The post-processing pipeline for each dataset.

TABLE II. FILE SIZE STATISTICS (IN BYTES)

	Min/Max	Mean	Median	Mode
D1	111,255/187,947	153,930	162,560	152,809
D2	76,041/111,565	96,124	99,273	93,907
D3	68,367/110,659	88,971	90,198	89,373
RGB	659,071/836,928	759,140	762,023	722,643

depth scene complexity. This was achieved by running an $N \times N$ median filter. A spatial filter was used to perform a 1D edge-preserving filter using a high-order domain transform in both the horizontal and vertical directions. A temporal filter was applied to enhance the persistence of depth data by pixel value manipulation over a number of previous frames. This is done by implementing a single pass on the data and updating the depth values while keeping track of the historical values. The hole-filling filter is intended to complete missing depth values and is performed by selecting neighborhood pixels to replace the missing depth.

After colorization, the depth images were saved using the PNG format, a type of lossless compression. Table II summarizes the statistics of the sizes of the different depth images, including their corresponding RGB color images in bytes. As shown, the inverse colorization requires the least storage among the three datasets used in this study. Generally, depth images require less storage than RGB images do. The RGB color image was almost 10 times the size of the inverse depth image. This is one benefit of using depth images over color images in computer vision tasks.

C. Experimental Flow

The activities of this study include data preprocessing, data augmentation, data splitting, training and validation, and performance evaluation as shown in Fig. 5. Each step is described in the following subsections.

Fig. 5. Flowchart of data processing and analysis.

TABLE III. DATASET DISTRIBUTION PER CLASS IN EACH DATASET TYPE

	Raw	Cleaned	Augmented	Cleaned + Augmented
apple	1,068	456	1,368	1,824
banana	1,057	534	1,068	1,602
mango	1,075	861	861	1,722
orange	1,077	301	1,204	1,505
rambutan	1,066	882	882	1,764
	5,343	3,034	5,383	8,417

1) *Data Pre-processing*: A total of 5,343 depth images were collected for each dataset type. However, all these cannot be used because some are extremely noisy such as images with large regions with missing depths. To clean the dataset, a MATLAB program was developed to display and manually check each image in color and depth formats. As a result of the cleaning process, there are only 3,034 valid samples in the dataset, as shown in Table III. Orange and mango produced the most and least number of invalid samples, respectively.

After the dataset was cleaned, the images were cropped ~ 80 pixels from the left border because of invalid depth [33]. Consequently, the dimensions of the image were reduced. This is a known issue for stereo vision algorithms that utilize the left imager as a reference because of the non-overlapping region in the camera's field of view.

2) *Data Augmentation*: Because the resulting dataset was reduced after cleaning, there was a need to perform data augmentation to increase the sample size. Transformations used in data augmentation include rotation, translation, scaling, and reflection. It is important to note that exactly the same augmentation was performed on the same depth image of each type to ensure uniformity across the different dataset. For instance, the same transformation is applied to sample image X across D1, D2, and D3. This ensures uniform transformation across depth images and provides fairer performance comparisons later. The dataset (both the cleaned and augmented) now totals 8,417 per type, i.e., 25,251 depth images across all three datasets.

3) *Data Split*: To avoid possible overfitting in model training, the dataset was augmented and divided into 70% training, 15% validation, and 15% testing. To provide better and fairer comparisons across types, the split was performed uniformly across types and evenly between the cleaned and augmented samples, i.e., each split contained a proportional distribution of cleaned and augmented samples. To do this, each sample in the cleaned and augmented dataset was numbered sequentially, and a MATLAB program was developed to uniformly and evenly divide the dataset.

4) *Training and Validation*: Model training was performed after the dataset was processed and split. The CNN models used in the training were AlexNet, VGG16, GoogleNet, and ResNet101, with a batch size of 32 and an epoch of 20. The Adam optimizer was used, and the loss type was the categorical cross-entropy. The training was run using the TensorFlow framework on Macbook Pro M2 with 16GB memory, 8 CPU, and 10 GPU cores. Prior to training, the images were rescaled between 0 and 1 and resized to 224×224 for AlexNet and 227×227 for the rest. In addition, a random seed was set, and TensorFlow op was enabled for deterministic output. A total of 12 training sessions were performed, i.e., four models were trained for each dataset. Retraining of the best-performing dataset per model was performed to determine the effect of transfer learning.

5) *Performance Metrics and Evaluation*: To evaluate the performance of the trained model, we ran the trained models on the test dataset and utilized standard performance measures. The metrics used in this study were the average per-class accuracy (A), precision (P), recall (R), macro-average F1-score ($F1_M$), weighted-average F1-score ($F1_\mu$), Kappa score (k), training time, and inference time. A confusion matrix was derived from each model after testing to compute the metrics.

$$A = \frac{\sum_{a=1}^L \frac{tp_a + tn_a}{tp_a + tn_a + fp_a + fn_a}}{L}$$

$$P = \frac{\sum_{a=1}^L \frac{tp_a}{tp_a + fp_a}}{L}$$

$$R = \frac{\sum_{a=1}^L \frac{tp_a}{tp_a + fn_a}}{L}$$

where tp_a , tn_a , fp_a , and fn_a represent true positive, true negative, false positive and false negative for class a .

$$F1_M = \frac{1}{|L|} \sum_{a \in L} F1_a$$

$$F1_\mu = \frac{1}{\sum_{a \in L} Supp(a)} \sum F1_a \times Supp(a)$$

where $Supp(a)$ denotes the number of samples in class a , and $F1_a$ is the F1-score of class a

$$F1_a = 2 \times \frac{P_a \times R_a}{P_a + R_a}$$

where P_a and R_a are precision and recall for class a respectively.

$$k = \frac{p_0 - p_e}{1 - p_e}$$

where p_0 is the observed agreement ratio and p_e is the hypothetical probability of change agreement. k is a statistical measure of inter-rater agreement for categorical data.

Training and inference times are the times required for the model to train and test, respectively. These are important metrics for verifying the calculation efficiency of models trained on depth images.

IV. RESULTS AND DISCUSSION

This section presents and discusses the findings of this study. Here, the researcher aims to demonstrate the performance of the models trained using different datasets. First, the performance by model with the use of the three datasets during training and validation is discussed, followed by the performance of each model by dataset. Subsequently, the performance of each trained model on the test dataset is presented. The calculation efficiency of each model is also discussed. Finally, the effect of transfer learning on model performance is presented.

A. Comparison of Performance during Training and Validation

In this section, the performances of the model in terms of training and validation accuracy and loss are compared. A desirable CNN model should rapidly improve accuracy and maintain stability as the number of epochs increases. Fig. 6 shows the training and validation performance of each model on the three datasets. With AlexNet, the training performance for all datasets showed a rapid and stable trend. This was also evident from the training loss trend of the model. Its validation accuracy was slightly lower than that of D2, showing an early increase as opposed to D1 and D3. Both D1 and D3 tended to oscillate in their validation performances during the early epochs. GoogleNet had a slower increase in training accuracy compared to AlexNet in all three datasets, although it stabilized well in later epochs. Its validation performance was more stable than that of AlexNet, even at earlier epochs. Compared with GoogleNet, ResNet101 showed a more rapid increase in training accuracy, but was still slower than AlexNet. It also exhibited a stable trend as the number of epochs increased. However, it showed very unstable validation performance across the three datasets. VGG16 has a better training performance than GoogleNet, particularly for D1. Its validation performance is comparable to that of GoogleNet, which registered high validation at earlier epochs and stabilized onwards. It showed the most stable validation performance for all datasets among all models.

Next, we look at the performance of the models by dataset as shown in Fig. 7. On D1, we can see that the quickest to rapidly increase in training accuracy is AlexNet followed by VGG16 and ResNet101. GoogleNet is the slowest. Both GoogleNet and VGG16 performs well in the validation set with more stability compared with the other two. ResNet101 is the worst to perform in the validation set with very unstable trend. Only VGG16 has stable trend in the validation loss compared to the rest with ResNet101 being the worst. In terms of D2, AlexNet still leads in terms of rapid increase in training accuracy with GoogleNet still trailing behind the rest. ResNet101 still has the worst validation performance. The validation loss of GoogleNet tend to be more stable in D2. In terms of D3, AlexNet still is the quickest to rapidly increase in training accuracy still with GoogleNet the worst. The trend of validation accuracy of ResNet101 still oscillate. We can say

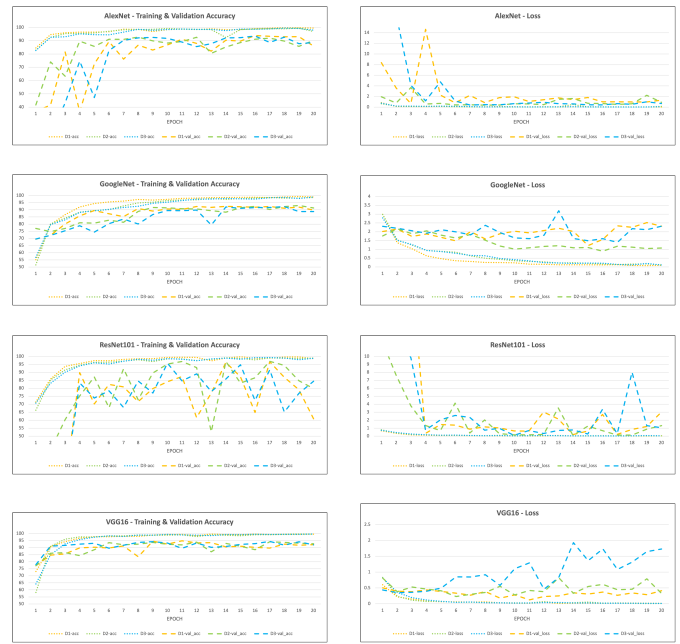

Fig. 6. Training & validation accuracy and loss by model.

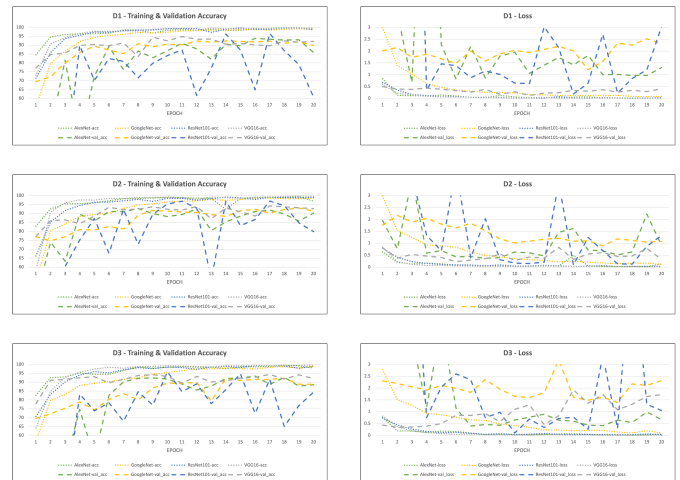

Fig. 7. Training & validation accuracy and loss by dataset.

that all models perform well in the training set across the three datasets but the validation performance of ResNet101 which is quite unstable.

B. Comparison of Performance on the Test Dataset

In this section, the performances of the models on the test datasets are presented. Table IV summarizes the performance measures for each model using different datasets. It can be observed that ResNet101 has the best performance across the three datasets and in all performance metrics. It had the highest accuracy, precision, recall, kappa-score, $F1_M$ and $F1_\mu$ on D3, followed by D2 and D1. On D1, it was followed by VGG16 and GoogleNet with AlexNet, with the poorest performance in all metrics. It has the lowest performance, with an average per-class accuracy of 0.76 and k of 0.7. Note that D1 did not

pass through the post-processing pipeline, which may have contributed to this result. In terms of D2, ResNet101 was followed by VGG16 and AlexNet, with GoogleNet performing the worst. It should be noted that AlexNet and GoogleNet had the same accuracy, precision, and recall values. They only differ in terms of k , $F1_M$ and $F1_\mu$ with AlexNet higher by 0.01 only. In terms of D3, next to ResNet101 are VGG16 and AlexNet, with GoogleNet trailing behind. It can be seen that VGG16 performs the second best overall with ResNet101. Overall, all models performed well in the three test datasets, except for AlexNet on D1, which registered $< 80\%$ across all metrics. The top dataset is D3, which is based on inverse colorization and registered 96% accuracy using ResNet101.

C. Training and Inference Duration

In this section, the computational efficiency of these models is discussed. The number of CNN parameters and the computational complexity are vital for the development of deep-learning applications. These variables contribute to the training and inference durations of the CNN models. An ideal CNN model is one that is less complex, yet produces good results at low training and inference times.

The number of layers and parameters in each CNN model, including the FLOPs, is listed in Table V. These variables define a complex CNN structure. The deeper the layers in a network, the more complex image processing properties that it can perform. Consequently, the hardware requirements for processing are greater. In essence, computational efficiency is determined by the amount of layers in the network and the training time, whereas computational difficulty is evaluated by the number of network parameters and FLOPs. The training and inference times of the models were also presented.

The AlexNet model has only 11 layers, which is the smallest among all the models considered in this study. It also had the lowest number of FLOPs. However, it did not have the lowest training time. It was only next to GoogleNet across all three datasets. This is due to the number of parameters, which is 60M compared with 6.8M of GoogleNet. Notably, VGG16 had the longest training time compared to ResNet101. Both also had approximately the same inference time. This can be attributed to the number of parameters VGG16 has including its massive amount of FLOPs. Among all three datasets, D3 requires the least amount of computation using GoogleNet in both training and inference with 41.07 and 0.53 minutes for training and inference, respectively. Note that D3 required the least storage which may have contributed to this outcome.

D. Transfer Learning

The researcher compared the accuracy of the four models with and without transfer learning. Only the dataset with the best accuracy during training from scratch for each model was chosen for the transfer learning experiment. D2 was used for AlexNet, GoogleNet, and VGG16, whereas D3 was used for ResNet101. The weights of the four models trained on ImageNet dataset were used.

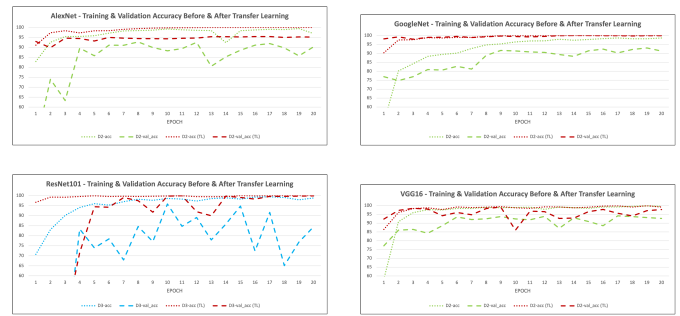

Fig. 8. Training & validation accuracy before and after transfer learning.

Fig. 8 shows the accuracy trend of each of the four models with and without transfer learning. The red lines indicate the accuracy of the model with transfer learning, and the other color indicates the accuracy without transfer learning. It is evident that the training accuracy of each model rapidly increased at earlier epochs with transfer learning compared to the accuracy without transfer learning. It also has a more stable rate than without transfer learning. It can be observed that the training accuracy is considerably higher with transfer learning, particularly for AlexNet, GoogleNet, and ResNet101. The training accuracy for VGG16 remained unchanged in later epochs.

In terms of validation accuracy, Fig. 8 shows a better overall performance in all models. Of note is ResNet101, which registered a more stable validation performance with fewer oscillations compared with no transfer learning. Both AlexNet and GoogleNet had very stable validation performances compared with no transfer learning and even with transfer learning for the ResNet101 and VGG16 models. Remarkably, GoogleNet's validation accuracy with transfer learning surpassed its training accuracy without transfer learning. These results indicate that transfer learning substantially increases both the training and validation accuracy of the CNN models. The extent of improvement varied from model to model.

To understand the effect of transfer learning on the four CNN models, the researcher gathered statistics on the training, validation, and testing performance of these models. The results are listed in Table VI. Here, the difference in accuracy is between the best accuracy with and without transfer learning. The increment, on the other hand, is the ratio between the accuracy difference and the accuracy of the CNN model without transfer learning. This measures the improvement provided by the use of transfer learning.

As shown in Table VI, GoogleNet exhibited the highest improvement in all aspects, including training, validation, and testing. It had the highest improvement in testing and the lowest improvement in training. This indicates that the novel GoogleNet architecture is suitable for applying transfer learning using depth images. It should be noted that its training accuracy has already reached 100% with the use of transfer learning. VGG16 was next to GoogleNet, with the highest improvement in the test dataset. This is despite having the lowest increase in training accuracy. It should be noted that VGG16 already has a high accuracy rate, even without transfer

TABLE IV. PERFORMANCE OF THE DIFFERENT CNN MODELS ON THE THREE DATASETS

	D1						D2						D3					
	A	P	R	k	$F1_M$	$F1_\mu$	A	P	R	k	$F1_M$	$F1_\mu$	A	P	R	k	$F1_M$	$F1_\mu$

TABLE VI. EFFECT ON MODEL ACCURACY BEFORE AND AFTER TRANSFER LEARNING

	Dataset	Training Accuracy Difference (%)	Validation Accuracy Difference (%)	Test Accuracy Difference (%)	Training Increment (%)	Validation Increment (%)	Test Increment (%)
AlexNet	D2	0.56	2.70	3.46	0.56	2.91	3.89
GoogleNet	D2	1.37	6.98	10.92	1.39	7.50	12.27
ResNet101	D3	0.66	4.13	4.00	0.66	4.31	4.17
VGG16	D2	0.03	5.00	8.13	0.03	5.31	8.93

learning. AlexNet registered the least improvement in both validation and test datasets. This is an indication that the traditional CNN structure has no significant effect in testing accuracy. In addition, its architecture was less affected by transfer learning. AlexNet, GoogleNet, and ResNet101 achieved 100% training accuracy with transfer learning. These findings are consistent with the belief that the two nonlinear structures of GoogleNet and ResNet are more suitable for certain classes of inputs, i.e., the accuracy increases as the image classes change. On the other hand, the single-channel classic CNN architectures of AlexNet and VGG16 are thought to be costlier for varying inputs.

The different CNN models respond differently to transfer learning due to their diverse structures. In addition, there is a large difference in terms of the dataset used to train the parameters of these models for transfer learning, i.e., ImageNet, and the actual dataset used in the classification problem, i.e. colored depth images. Overall, it was shown that transfer learning can significantly affect the classification accuracy of colored depth images of fruits. This is despite the fact that the pre-trained models were not previously trained on depth images. The extent of improvement depended on the model structure.

V. LIMITATIONS AND FUTURE WORK

This study has shown that it is possible to use colored depth images in fruit classification with a high rate of accuracy, aided by CNN and transfer learning. However, this study is limited in multiple aspects, such as the dataset used and CNN models considered. The dataset used in this study was limited, with only five classes. In future work, this can be increased to include other types of fruits, including those that are very similar in form, shape, color, and texture. Only four CNN models are used in this study. Future work could include other models, such as MobileNetV2, as well as other colorization approaches. It is also useful to explore the fusion of RGB and colored depth images in fruit classification problems.

VI. CONCLUSION

In this study, the researcher investigated the use of colored depth images in CNN-based fruit classification using AlexNet, GoogleNet, ResNet101 and VGG16 and examined their performance and the impact of transfer learning application. The primary findings are as follows: (1) All four models performed well during training and validation with both GoogleNet and VGG16 having desirable trends in all of the three datasets. ResNet101 is the least ideal. (2) ResNet101 exhibited the best test accuracy with 96% rate on D3, 95% on D2 and 91% on D1. AlexNet performed the least on D1 at 76%. (3) The post-processing filters applied to D2 and D3 contributed to the performance of the models. (4) Transfer learning considerably improved the performance of the models with GoogleNet registering the largest increase on the test set at 12.27%. (5) Transfer learning could provide better validation performance in ResNet101 whose validation performance was very unstable without transfer learning.

ACKNOWLEDGMENT

The researcher would like to thank the University of the Philippines Cebu Central Visayas Studies Center for the 2022 Research Grant and for Kaye and Gabby for the inspiration. To God be the glory!

From Phishing Behavior Analysis and Feature Selection to Enhance Prediction Rate in Phishing Detection

Asmaa Reda Omar, Shereen Taie, Masoud E. Shaheen
Computer Science Department,
Faculty of Computers and Information,
Fayoum University, Fayoum 63514, Egypt

Abstract—Phishing incidents have captured the attention of security experts and end users in recent years as they have become more frequent, widespread, and sophisticated. The researchers offered a variety of strategies for detecting phishing attacks. Over time, these approaches suffer from insufficient performance and the inability to identify zero attacks. One of the limitations with these methods is that phishing techniques are constantly evolving, and the proposed methods are not keeping up, making it a hard nut to crack. The objective of this research is to develop a URL phishing detection model that can demonstrate its robustness against constantly changing attacks. One of the most significant contributions of this paper is the selection of a novel combination of features based on literal and recent phishing behavior analysis. This makes the model competent sufficient to recognize zero attacks and able to adjust to changes in phishing attacks. Furthermore, eleven machine learning classification techniques are utilized for classification tasks and comparative objectives. Moreover, three datasets with different instance distributions were constructed at different times for the model's initial construction and evaluation. Several experiments were carried out to investigate and evaluate the proposed model's performance, effectiveness, and robustness. The experiments' findings demonstrated that the GaussianNB method is the most durable, capable of maintaining performance even in the absence of retraining. Additionally, the LightGBM, Random Forest, and GradientBoost algorithms had the highest levels of performance, which they were able to maintain by routinely retraining the model with newer types of attacks. Models that employed these three suggested algorithms outperformed other current detection models with an average accuracy of about 99.7%, making them promising.

Keywords—Gradient boosting; light GBM; machine learning; phishing; phishing URL; random forest

I. INTRODUCTION

Phishing is a crime to steal personal data and financial account credentials by employing social engineering and technical deception. This type of attack leads victims to deal with counterfeit websites and fool them into believing that they are legitimate and trusted ones by using deceptive e-messages with deceptive e-addresses. These sites trick recipients into revealing extensive financial and personal information, leading to significant aggregate identity theft and financial losses. These attacks could also instill malware onto victims' computers to directly steal credentials, often using systems that intercept victims' account data, user names, and passwords, or misdirect consumers to counterfeit websites [9]. Phishing is a significant

threat to Internet users. It also causes pecuniary loss and reputational impairment to the targets, like universities, companies, charities, and government entities. The first phishing attack was on E-Gold in June 2001 [25]. Although it was not considered successful, it planted a vital seed, and it established the basics of how phishers would operate going forward and still do, in large part, today. Phishers in late 2003 registered many domains that looked like legitimate sites such as eBay and PayPal. By the beginning of 2004, they were achieving considerable success that included attacks on banking sites. Since then, they have improved their methods to be more sophisticated, but they all still work on the same basic concept, which has proven to be quite effective. Phishing attacks result in a colossal loss of sensitive/personal information and even funds whose total amount could be billions of dollars in one year [31].

Since the beginning of 2020, the Anti-Phishing Working Group¹ (APWG) was tracking between 68,000 and 94,000 attacks each month. In the fourth quarter of 2021, APWG saw 888,585 attacks, which was the previous high. March 2022 had the highest monthly total in APWG's reporting history with 384,291 attacks. APWG recorded a total of 1,025,968 phishing attacks in the first quarter of 2022. This quarter's phishing activity was the worst that the APWG has ever recorded, and it was also the first time that the quarterly total exceeded one million. The number of phishing attacks has more than tripled every year.[8] According to studies on the user experiences of phishing attacks [33], [20], computer users are susceptible to phishing for the following reasons: Users improve their confidence and vulnerability as a result of decreasing their chances of falling victim to a phishing attack. Additionally, they lack a thorough understanding of URLs, are unaware of trustworthy websites, and are unable to view the complete URL of a web page because of redirectors or hidden URLs. They do not have much time to check the URL or access certain online pages mistakenly. They are unable to discriminate between legitimate and phishing web pages. Regardless of how important caution and experience are to the user, it is not entirely possible to prevent users from being caught in phishing attacks using their expertise. Technological advancement has provided phishers with better tools to launch dangerous and sophisticated attacks, making even the savviest internet users vulnerable. [18] For instance, Examining URLs carefully and avoiding sites that do not have

¹<https://apwg.org/>

an SSL certificate have been one of the main recommendations for avoiding phishing sites for many years. A website that has "HTTPS" in the URL is one that is secured by the HTTPS encryption protocol and has an SSL certificate. This method, however, is no longer effective for identifying suspicious websites. According to APWG's report [9], SSL was used by 84 percent of the phishing sites that were examined in the fourth quarter of 2020. This with quarterly increases of about 3%. To increase the success of phishing attacks, attackers have considered end-user personality traits, particularly the ability to deceive experienced users. A spear phishing attack is one that targets a specific organization, business, or individual. This type of attack is not typically carried out by random attackers, but rather by criminals seeking financial gain, trade secrets, or military information. Furthermore, some active attackers constantly innovate and learn how to circumvent new defensive methods, causing attacks to evolve on a daily basis and luring victims into gaining access to their accounts and financial information.

Since 2004, researchers have been working to combat phishing, which has become such a severe menace that it has caused significant damage. As the term 'phishing' revealed on DBLP² (Digital Bibliography & Library Project), the number of research articles released about detecting phishing attacks increases year after year. Phishing attacks exploit human users' weaknesses, and attackers are always devising new strategies to avoid detection. As a result, additional assistance systems are required to secure the systems/users. As decision support tools for users, software-based approaches are preferred. These approaches are classified as list-based, search engine-based, visual similarity-based, and machine learning-based. In dealing with phishing attacks, the machine learning-based strategy is the most successful. All researchers work for the same objectives: high detection accuracy, detection stability, fast detection, zero-day detection, language independence, and real-time detection. There are however some drawbacks that researchers must contend with, such as restricted datasets and the requirement for up-to-date information as phishing strategies evolve; additional features are difficult to obtain, slow, third-party dependant, and time consuming. As a result, certain machine learning systems need a significant amount of computing to acquire and calculate the features of diverse sources. In addition, the solution must be constantly improved to deal with changes in attack technique.[18] On the attacker's side, the technologies' support to attackers allows them to effortlessly deceive the victims. Consequently, phishing is one of the most persistent and rapidly growing online threats; identifying phishing attacks is one of the ongoing issues, and the hunt for a better solution continues.

This paper proposes new models for detecting URL phishing using a new set of fourteen robustness features. These features were chosen after observing the most recent and previous phishing attacks and focusing on URL phishing detection models and the literature features in order to consider the most important features and build a robust classification model that can deal with ever-evolving attacks. Furthermore, three new datasets were created at various points in time, one for building the model and the others for testing and measuring the model's performance and robustness. Eleven different

machine learning algorithms were evaluated to determine the model's best classification performance. Several experiments were carried out in order to assess the models. The main contributions of this paper are as follows:

- Introducing a novel combination of phishing URL detection features based on observations of old and recent phishing attacks. To the best of our knowledge, this is the first paper to analyze such criteria while constructing a feature set for the phishing detection system. The main objective of this approach is to ascertain how the phishing feature set can be sufficiently integrated into an effective countermeasure that can handle constantly changing attacks.
- Implementing a phishing URL detection model that is difficult for attackers to avoid and outperform other existing detection models. The proposed model could maintain its performance and detect any phishing URL whether it came from the pretrained or new datasets, even if the trained dataset was outdated, making it a promising solution for the phishing detection problem.
- Developing a robustness test utilizing three new URL datasets (phishing / genuine) gathered at different times over a three-year period to assess the performance of the proposed model.
- Examining the effect of retraining on model performance to emphasize the importance of regular model retraining for newer types of attacks, as well as having a robustness feature for dealing with constantly evolving attacks.

The remainder of this paper is organized as follows; the next section provides a literature review. Our methodology is proposed in Section III. Section IV highlights the experiments and evaluations of our proposed model. Section V concludes this paper, along with future work and directions.

II. RELATED WORK

Various methods and approaches have been investigated in order to understand and address phishing attacks. There are two types of phishing attack detection methods: user education-based and software-based. User education-based approaches try to improve users' ability to detect phishing attacks. These approaches teach people how to distinguish between authentic and phishing websites and emails. Software-based approaches are preferred as decision support systems for the user; these approaches are further classified into four types: blacklisting, visual similarity, machine learning, and hybrid methods. The widely used approaches to detect phishing websites is those based on machine learning. Classification, one of the primary areas of machine learning algorithms, is a widely used strategy for detecting phishing websites. The four stages of classification are typically preprocessing, feature generation, feature selection, and classification. The primary issue of classification algorithms is improving accuracy. Improving each categorization process may result in increased overall accuracy. In this section, we will concentrate on the most relevant and significant publications, as well as the existing methodologies for detecting phishing attacks that have been proposed in the literature.

²<https://dblp.org/>

Authors at [10] examined three important machine learning classifiers, Artificial Neuron Network (ANN), K-Nearest Neighbor (K-NN), and Decision Tree (C4.5), to cast with Random Forest Classifiers (RFC) in order to present a prototype for detecting phishing attacks on a website using the machine learning algorithm. According to the study, RFC outperforms other classifiers in terms of detection accuracy, scoring 97.33%. 4898 legitimate and 6157 phished websites were used in the experiment, and the researchers came to the conclusion that adding more variables to the process will increase the detection accuracy.

In this research [32], the authors employ a machine learning technique to handle the phishing problem, producing a model that uses 30 different features for phishing identification with three different algorithms: Random Forest RF, Support Vector Machine SVM, and classification tree CT. They create five alternative classification situations, including each algorithm alone, the combination of AND Techniques, and the combination of OR Techniques. The experiment results reveal that the Classification Trees technique has the most effectiveness in predicting whether a URL is secure or not, with an accuracy of 90% across a set of website links.

Authors at [21] examine different machine learning algorithms, including K-Nearest Neighbors (KNN), Decision Tree (DT), Support Vector Machines (SVM), Logistic Regression (LR), Random Forest (RF), and Extra Trees, to determine the best technique for detecting phishing websites. After comparing all of these techniques, authors decided that the Random Forest Classifier is the best for Phishing Website Detection. The authors at [27] compared the use of Random Forest, probabilistic neural networks, and XGBOOST in detecting Phishing and discovered that XGBOOST produced the best results in terms of MCC, F.score, and accuracy. This research [22] examines hyperlinks in HTML source code to detect phishing websites. Authors present a novel phishing detection approach that is client-side, language-independent, and achieves more than 98.4% accuracy when the Logistic Regression algorithm is used.

Authors at [7] propose a machine learning-based detection model and compare various algorithms. They also used various feature selection tools to select the most valuable features in 20 of the 48 features. According to their conclusion, Random Forest is the most effective classifier to use because it detected a phishing attack with 98.11 accuracy in 2.44 seconds. Fifteen features from various classes were chosen in this paper [34]. Five machine learning classifiers were tested, and it was discovered that random forest had the highest detection accuracy (94.79%). This study investigates the importance of each feature class and all potential combinations of feature classes. Authors in this research [19] created a phishing detection approach that only requires nine lexical features to detect phishing attacks. Their dataset contains 11964 instances of legitimate and phishing URLs. They tested their approach on various machine learning classifiers, including Random Forest, k-Nearest-Neighbor, support vector machine, and logistic regression, and found that the Random Forest algorithm had the highest accuracy of 99.57%. The authors claim that their approach's main contributions are third-party independence, real-time detection, detection of new websites, and use of limited features.

The authors of this paper [29] show that a machine learning model trained on old datasets can perform well when tested on those same old datasets, but when tested on new datasets, using the same features in both cases, its performance noticeably degrades. They also show that SVM is the most resistant to the new tactics employed by the current phishing attacks among the widely used machine learning algorithms. With the newly created dataset, their experimental findings revealed that Random Forest is the most effective strategy among all methods that were tested, including Support Vector Machines (SVM), k-Nearest Neighbors (kNN), Naive Bayes (NB), and Logistic Regression (LR).

Authors at [11] identify an effective machine learning approach for phishing URLs detection based on precision, false-positive rate, and false-negative rate. To ascertain the classification accuracy in phishing detection, different classifiers including Random Forest, Linear SVM, SVM Polynomial Kernel, and SVM Sigmoid Kernel were used. With an accuracy of about 97.42%, the result showed that Random Forest outperformed the other three machine learning algorithms. For similar purposes, six distinct machine learning classification techniques are used to identify phishing websites in this study [23]. The Gradient Boost Classifier had the best possible accuracy of 94.75%, while the Random Forest Classifier got the highest possible accuracy of 97.17%. Provisioning accuracy for the Decision Tree classifier is 94.69%. In contrast, SVM has a provisioning accuracy of 56.04%, KNN has a provisioning accuracy of 60.45%, and Logistic Regression has a provisioning accuracy of 92.76%.

Authors of [6] investigated the predictive performance of a number of machine learning techniques, such as Random Forests (RF), Logistic Regression (LR), Classification and Regression Trees (CART), Neural Networks (NNet), Support Vector Machines (SVM), Bayesian Additive Regression Trees (BART), and other models of AI algorithm. Based on their comparison results, the Gradient Boosting Classifier and Random Forest Classifier had the highest accuracy. Using a dataset from a phishing website called "phishing.csv," authors in this article [14] examined the accuracy of XGBoost Classifier, Decision Tree Classifier, Random Forest Classifier, SVM Classifier, KNN Model, Logistic Regression Model, and AdaBoost Classifier methods. XGBoost Classifier & Random Forest Classifier had better accuracy according to their results, even after applying SMOTE and PCA Techniques to the dataset to account for accuracy discrepancies.

This study [16] suggests a hybrid feature-based anti-phishing technique that only uses client-side URL and hyperlink data to extract features. In order to conduct experiments utilizing well-known machine learning classification algorithms, they also create a new dataset. Their test results demonstrate that the suggested phishing detection method is superior than conventional methods, with a detection accuracy of 99.17% using the XG Boost technique. Random Forest, Decision Tree, Light GBM, Logistic Regression, and Support Vector Machine methods are compared in this study [5] to evaluate and choose the best classification algorithm for the phishing problem. Their findings demonstrate that the Light GBM algorithm delivered the greatest results.

Considering the feature selection, the authors of this research [30] discuss the efficacy of two feature selection

methods, Omitting Redundant (FSOR) and Filtering Method (FSFM), in detecting Phishing Websites and compare the efficacy of three different machine learning algorithms: Naive Bayes (NB), Multilayer Perceptron (MLP), and Random Forest (RF). According to their empirical data, the optimized Random Forest (RFPT) classifier with feature selection by the FSFM outperforms all other strategies. Moreover, a framework for feature selection was described by the authors at [13], [12]. They presented an empirical hybrid framework with two stages that takes into account the filter and wrapper method. Those researches involve applying models with optimized (hyperparameter) parameters, such as Artificial Neural Network, XGBoost Classifier, and Random Forest Classifier, on two phishing datasets. The outcomes demonstrated that the XGBoost Classifier performed better than other classifiers.

Authors In this paper [26], proposed a strategy to identify the critical features by combining correlation and recursive feature elimination. The first scenario combines power predictive score correlation and recursive feature elimination, and the second scenario combines the maximal information coefficient correlation and recursive feature deletion. The third scenario combines recursive feature removal and Spearman correlation. According to their experimental findings, even with the lowest feature subset, all three scenarios from the combined findings of the offered approaches reach a high level of accuracy. Additionally, they discovered that Random Forest (RF) performs more accurately in identifying phishing websites.

A systematic review of phishing detection systems based on machine learning was carried out at [17]. The authors noted that studies that include more features have higher performance findings, studies that contain more features are more often used, and runtime performance was overlooked by most systems. In [15], the authors conducted a similar systematic review on machine learning-based phishing detection systems. They ranked classifiers based on the number of studies that used them. However, their conclusion is based solely on the statistical analysis of the studies under consideration. Moreover, the authors of [4] provide a systematic review of existing studies concentrating on Machine Learning and Deep Learning based phishing website detection in order to identify the major gaps and provide appropriate solutions. Their findings show that the imbalanced dataset use, issues with appropriate feature selection techniques, source selection, train-test split ratios, dataset size, inclusion and exclusion of website features, and run-time analysis are the main contributors to these flaws. Moreover, the results show that Random Forest, in the vast majority of peer-reviewed research articles, has the best overall accuracy.

In summary, the majority of the studies reviewed in this paper concentrate on the classification phase. Well-known machine learning algorithms like KNN, SVM, XGBoost Classifier, Decision Tree, Logistic Regression (LR), and Random Forest were used in the majority of the research. The Random Forest and the XGBoost Classifier algorithms are consistently yielding the best performance results when they were compared to other algorithms. The other part of the previous works is worked on feature selection phase through evolutionary and metaheuristic algorithms, and also some authors proposed hybrid feature selection models. The feature

set can be derived from a variety of sources, including the page source, search engine, URL, website traffic, and DNS. High detection accuracy, detection stability, quick detection, zero-day detection, language independence, and real-time detection are the universal goals shared by all researchers.

Additionally, these methods have a number of limitations that must be addressed in order to detect phishing URLs. To begin, the limited datasets and the requirement for updated datasets as phishing techniques develop; the majority of the work has employed preclassified and smaller datasets, which do not produce exact efficiency and precision when applied to great and real-world datasets. Additionally these approaches suffer from insufficient performance and the inability to identify zero attacks over time; as phishing techniques are always evolving, and the proposed methods are not keeping up. Second, the previously extracted features are comprehensive, with the limitation that such extraction requires a significant amount of time. Third, certain approaches used statistical methods to choose relevant features, while others proposed their own features; researchers often did not consider how their features can be defeated. Although these strategies have been effectively implemented in various approaches, they generate inaccurate results when domain knowledge is not amplified. Fourth, the previous methodologies offered lack advanced evaluation measures; the majority of the offered solutions don't concentrate at robustness and accuracy over time. To improve the classification accuracy of phishing websites, our suggested methodology concentrated on the feature selection phase as well as the classification phase. Furthermore, various datasets gathered over time and various experiments are used to test the model's performance and robustness.

Phishing incurs significant financial costs and can harm a company's, government entity's, or university's reputation. It also harms the systems of web hosts, email providers who must protect users from phishing spam, and responders tasked with defending networks and users. The number of phishing attacks discovered is constantly increasing. Phishing remains one of the most persistent and rapidly evolving online threats. As a result, the search for a better solution to overcome the limitations of existing solutions continues.

III. METHODOLOGY

A. Datasets

There are no benchmark datasets for detecting phishing websites. This is due to the limited lifespan of phishing websites and the inability of content-based analysis to exploit dead URLs. Furthermore, the majority of datasets are restricted to experimental feature values with no URL references. This prevents datasets from being reproduced or tested with different features. Moreover, the authors of this study [18] noticed a decline in performance when previous methods were evaluated on a current dataset, even after retraining. This drop in performance highlights the necessity of using a broad, high-quality, and up-to-date dataset when creating models. It is critical to have a robust model that can deal with constantly shifting attacks. Training classification algorithms on one dataset and then testing on a different recent one is one strategy to assess the robustness of the detection model.

As a result, three URL datasets (phishing and legitimate URLs) were collected over a three-year period. The first dataset (24,200 URLs) was collected in June 2020 for use in model building (training and initial testing), followed by the second (16,028 URLs) and the third (15,974 URLs) in October 2021 and January 2022, respectively. Both datasets will be used later to test the model’s robustness without and with retraining. The classification of these datasets is displayed in Tables I, II, III.

Legitimate webpage URLs are gathered from Alexa³, University of New Brunswick open databases⁴, and Mendeley Data repository⁵. For Alexa it only recommends top-ranked domains without mentioning sub-domains or paths. As a result, for the diversity of URLs, those lists cannot be used directly, especially when features such as subdomains and paths are used. To address this issue and provide a realistic dataset, the collected domains are used as seeds for crawling 10 URLs per domain. It was then processed through to remove duplicate and domain-only URLs, allowing for more representative samples. Phishtank is used to collect phishing URLs. All duplicate and defunct URLs are deleted during preprocessing of the collected URLs, and a maximum of 10 URLs with the same domain name are preserved.

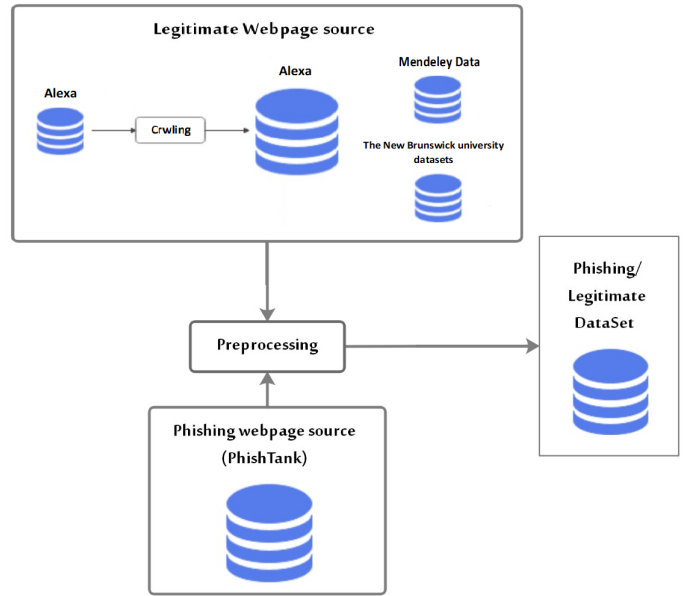

Fig. 1. Dataset construction process.

TABLE I. DATASET 1 (24,200 URLs) JUNE 2020

Database	Number of instances	Phishing/legitimate
PhishTank dataset	4,010 out of 6,233	Phishing
Alexa top-ranked websites	2,019 ended with 20,190	Legitimate

TABLE II. DATASET 2 (16,028 URLs) OCTOBER 2021

Database	Number of instances	Phishing/legitimate
PhishTank dataset	2,652 out of 4,862	Phishing
Alexa top-ranked websites	1,000 ended with 10,000	Legitimate
Mendeley data	3367	Legitimate

TABLE III. DATASET 3 (15,974 URLs) JANUARY 2022

Database	Number of instances	Phishing/legitimate
PhishTank dataset	2,659 out of 4,312	Phishing
the New Brunswick university datasets	2315	Legitimate
Alexa top-ranked websites	1,100 ended 11,000	Legitimate

B. Preprocessing

After collecting each dataset, it must be prepared for the feature extraction procedure. As soon as the dataset is collected, the preparation procedure begins. Three datasets and three distinct preparation processes have been completed. After gathering the dataset, the next stage is data preprocessing, which involves:

1. Eliminating redundant URLs and ensuring there are no intersections between the URLs in the three datasets.
2. Filtering all URLs to avoid broken URLs to ensure that the required accurate features are extracted during the feature extraction procedure.

It is important to note that using a fresh dataset is necessary because the majority of URLs provided by PhishTank or other providers won’t likely be active for three months or less. The collected phishing URLs were 4,010 out of 6,233 in the first dataset, 2,659 out of 4,312 in the second dataset, and 2,652 out of 4,862 in the third dataset. For the legitimate URLs, to ensure there are no redundancies, the URLs were collected with different ranking values. As a result, we obtained three distinct datasets. The general procedure used to create the dataset is shown in Fig. 1. The dataset is now ready for the next stage.

C. Feature Selection

The process of feature selection is crucial because correctly chosen features can improve classifier performance, while poorly chosen features can have the opposite effect. Feature selection is frequently accomplished by extracting as many features as possible and weighting them statistically in order to select the most weighted and vital aspects. This procedure generates dataset-dependent features that result in the best model performance. This performance, however, is not permanent because the features gradually lose significance and weight with time and a use of new datasets. This method of selection is one of the primary causes of the reduction in performance observed by prior works when their models were tested on new datasets. As a result, selecting robust features is a key goal to ensure that the classification model’s performance is maintained over time. A feature or collection of features

³<https://www.alexa.com/>

⁴<https://www.unb.ca/cic/datasets/url-2016.html>

⁵<https://data.mendeley.com/datasets/c2gw7fy2j4/3>

is considered robust if a phisher is unable to readily build a phishing website with features that mimic those of a reliable website.

In the next subsection, a phishing newest behavior is evaluated to serve as a guide in the selection process in order to identify a robust feature collection and efficiently detect phishing attacks. It is based on the most recent APWG reports as well as the most recent annual study of the scope and distribution of phishing by Interisel Consulting Group⁶. This part aims to increase understanding of the rate at which phishing is evolving, gather and assess the most recent phishing attack characteristics, and pinpoint which characteristics suggest more effective ways to combat phishing. Furthermore, it recommends which vulnerable features should be changed or ignored, as well as which additional phishing features are necessary.

1) Phishing Behaviour: In regard to phishing and how it has evolved, phishers always develop and vary their methods and approaches in order to avoid being detected and enticing victims. Thus, phishing is a significant hazard to millions of consumers, and it remains one of the most rapidly growing and persistent online threats confronting today's businesses. [1] So, staying up to date on the latest phishing strategies and phisher habits will keep us one step ahead of phishing attacks.

According to the authors of this report [28], the average lifetime of a phishing attack from start to the last victim is only 21 hours. Moreover, the Anti-Phishing Working Group's Global Phishing Survey [3], indicates that when victims begin accessing phishing sites, antiphishing entities take an average of 8 hours and 44 minutes to detect the attack. During this time, 63% of victims are exploited before the attack is detected and stopped. Therefore, in order to detect zero phishing attacks, you must not rely only on phishing blacklists. Additionally, you must work with a fresh dataset to ensure that you have the necessary features before the URL expires.

According to the data in [1], many phishing sites go undiscovered for days, if not months, allowing them to carry out their attacks. Around 78% of malicious sites were identified during the first year of registration, and 22% of phishing domains were older than a year. According to the authors of [1], the majority of malicious domains are used for phishing within the first three days of registration, while some domains are used within 14 days. Phishers typically employ them quickly to escape discovery. Some phishers recently waited more than 90 days after registering their domains to move out of the new domain status, which earns low reputation scores from security and anti-spam firms. According to their findings, 17% of maliciously registered domains were not used within 90 days of registration. **In this instance, the "Domain age" feature is still a good option from this standpoint.**

According to [24], 42% of phishing domains are compromised, and 58% of them have malicious registrations. Furthermore, the authors of [1] showed that 61% of the 99,412 domains utilized for phishing during their study period were maliciously registered, with the remaining 39% classed as compromised. In contrast to phishing that occurs on compromised (hacked) domains held by innocent parties, maliciously

registered domains are domain names registered by phishers to conduct phishing sites. According to the authors of a recent Interisel Consulting Group analysis [2], phishers hosted more attacks on compromised sites than malicious domains (a 53:47 ratio). This is consistent with the idea that hacked hostnames are appealing to phishers since they are more difficult to detect.

Many malicious domains have distinguishing features that may be utilized to rapidly and accurately detect them. In the event of hacked domains, however, it has legitimate features that will result in a high percentage of false-negative rates. To address this issue, we must distinguish between hacked and legitimate domains. We have principally based on three aspects, from the most recent common and best practices in the field: **1. A WHOIS-based feature (the domain's age), 2. An engine-based feature (web traffic), and 3. A feature based on HTML (if it has fake forms, broken hyperlinks, or foreign hyperlinks). All of these factors can be used to distinguish between legitimate and compromised domains.**

The majority of phishing attacks target just a few domain registries, domain registrars, and hosting companies.[24] About 9% of Phishing happens at a small number of providers that provide subdomain services [1]. As a member of the APWG, RiskIQ continuously analyzes the domain name system for instances of phishing. They discovered that out of the 6,153 distinct phishing URLs submitted to the APWG's eCrime Exchange in Q4 2020, 3,598 were hosted on unique second-level domains and 15 more were hosted on unique IP addresses without domains.[9]

In addition, Axur (an APWG member company) discovered that 63 percent of phishing domain names lacked a catchy keyword or contained or imitated brand names (like "accountupdate" or "sale"). In Q2 of 2020, it was 58%, while in 2019, it was 33%. To be clear, phishers aim to escape detection by utilizing generic terms instead of brand names in their selected domain names since telltale words in domain names are easier for defenders to locate.[9] Instead, phishers attempt to fool Internet users by taking advantage of the fact that characters in different language scripts may be virtually (or entirely) identical, allowing the phisher to impersonate a brand name. Phishers do employ them on occasion, though, since they can mislead the human eye and avoid detection by security tools that do not identify the words they are designed to represent [8].

In certain situations, **lexically-based characteristics, such as equal or hexadecimal in the URL and digits in the domain name**, might be used as a warning sign for phisher deceit. Moreover, a good signal for a phishing URL may be found in **the WHOIS-based feature; Registrar Name**, which phishers hide to avoid being blacklisted. Furthermore, the usage of subdomains that lead to phishing URLs is also indicated by **URL-based characteristics including URL length, host length, path length, and the number of dots in the URL.**

According to [9] several deception strategies phishers use to deceive consumers include encryption designed. In Q4 2020, 84 percent of phishing sites used SSL/TLS certificates, up 3 percent quarter over quarter, and 10% year over year. Furthermore, they discovered that 89 percent of the certificates used in phishing were Domain Valid "DV" certificates; these are routinely offered for free, and because they do not need

⁶<https://www.interisle.net/index.html>

human authentication, simply the domain name being used, they provide the lowest type of certificate validation. **In this case, the https/http check is not a sign of a phishing attack.** however, with a little motivation, we can still take use of this feature and try to leverage this clue to provide a low false-positive rate.

Based on these indications, fourteen features are in a great position to detect and prevent the bulk of phishing that occurs on maliciously and compromised domains. The structure, content, behavior, and URL of phishing websites have been considered. The selection of these features is one of the paper's main contributions. A novel fourteen-feature combination was presented to improve the detection accuracy of phishing URLs and verify resilience to deal with ever-evolving attacks.

D. Feature Extraction

This phase extracts features from the URL dataset. The extracted features are categorized as HTML-Based, URL-Based, Lexical-Based, WHOIS-Based, and Engine-Based Features, for a total of 14 features.

A data collector script was created. APIs are used for features that rely on a third party, such as WHOIS and Engine function. HTML parsing was necessary for the HTML features. Other features, such as URL and Lexical, were extracted quickly. Next the extraction and storage of these features for each URL, literature-based heuristics were employed to construct the feature vector, as illustrated below. To produce the labeled dataset, each URL needs its own feature vector. The feature vector corresponding to each URL is specified as $F = F1, F2, F3, \dots, F14$. Each attribute generates a value in the form of 1 or 0, with 1 indicating phishing and 0 indicating legitimate. Finally, the feature vectors were stored by the script into the database to be used later in the classification stage.

URL-BASED FEATURES:

- Feature 1 (F1): URL length
Although some phishers employ the accessible URL shortening tool, others continue to use the lengthy URL in the address bar to conceal the brand or company name. Legitimate URLs are often short in order to be easily remembered. Many phishing URLs, on the other hand, are lengthier since they rely on clicking on the phishing URL, and the phisher usually hides the redirected information in that long URL. URLs that are longer than 54 characters are given 1 (phishing), otherwise 0 (legitimate).
- Feature 2 (F2): Sub-domain
The URL of the majority of phishing websites has more than two subdomains. Each domain is separated by a dot (.), and it is uncommon to see more than one subdomain in the URL of a legitimate site. So, URLs with more than three dots are assigned 1 (phishing), otherwise 0 (legitimate).
- Feature 3 (F3): Secure Connection
Although it is simple to obtain a free SSL certificate from free sources such as Let's Encrypt, some phishers continue to avoid utilizing the HTTPS protocol. With a little drive, we can still make use of this feature. A

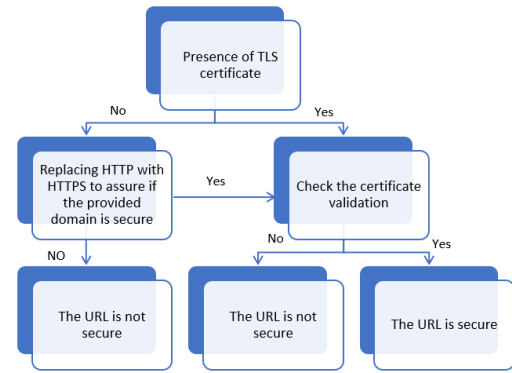

Fig. 2. Flowchart for secure connection check.

flowchart for the security check was shown in Fig. 2. Simultaneously, the vast majority of trustworthy websites are secure. Furthermore, even if the supplied URL is not secure, the URL is tested after replacing HTTP with HTTPS to determine whether the provided domain is safe or not, resulting in a more accurate extraction by lowering the false-positive and false-negative rate. Furthermore, for each domain having a certificate, we validate the certificate. Depending on whether the certificate is genuine, the value assigned to this feature is 1 (phishing) or 0 (legitimate).

- Feature 4 (F4): Host Length
Like URL length, genuine URLs are frequently short in order to be easily remembered and swiftly published, but phishing URLs are longer in order to conceal the identity of the site. So, URLs with host length more than 20 characters are allocated 1 (phishing), else 0 (legitimate).
- Feature 5 (F5): Path Length
The same as URL and host length, should not be too lengthy to ensure that the whole URL is not too long as a result. So, URLs with path length more than 35 characters are assigned 1 (phishing), otherwise 0 (legitimate).

HTML-BASED FEATURES:

- Feature 6 (F6): Fake Form
Following HTML processing, look for the page form. Assume the page has forms with external actions. In such instances, it is a fake form since it is most likely a phishing form that takes data and transmits it to an external processing website. So, depending on whether the page contains external form activities or not, the value assigned to this feature is 1 (phishing) or 0 (Legitimate).
- Feature 7 (F7): Broken Hyperlinks
The majority of phishers are just interested in one page that they are releasing. Most likely, most of the hyperlinks on the website are broken, thus if we discover that the majority of the hyperlinks are broken, it is an indication that the URL may be a phishing

URL. So, if the percentage of broken hyperlinks is greater than 25%, the feature is assigned 1 (phishing), otherwise it is assigned 0. (Legitimate).

- Feature 8 (F8): Foreign Hyperlinks
To prevent having broken hyperlinks on the website, most phishing pages use external functional URLs. So, if we discover that the majority of the hyperlinks are foreign, it is a strong sign that the URL is a phishing URL. If the percentage of foreign hyperlinks is more than 50%, the characteristic is assigned 1 (phishing), otherwise it is assigned 0. (Legitimate).

LEXICAL-BASED FEATURES:

- Feature 9 (F9): Equal
Because “=” is utilized to obtain input from the end-user, most professional websites are no longer used due to the risk of data sniffing. It is preferable to avoid URLs with this complex and hazardous lexical character by assigning 1 (phishing) to URLs with “=” else 0 (Legitimate).
- Feature10 (F10): Hexadecimal
Because URL encoding substitutes unsafe ASCII characters with “%” followed by two hexadecimal numbers, it is best to avoid using “%” in URLs such that URLs containing “%” symbols have a value of 1 (phishing) otherwise 0. (Legitimate).
- Feature11 (F11): Digit
Domains with numerals are perplexing. Furthermore, professional websites do not use domain names that include digits, and many phishers utilize numbers to fool end-users, such as naming the domain apple.com instead of apple.com. If the IP address is present in the URL, it is a malicious URL, and it will be allocated 1; otherwise, it is a genuine URL, and it will be assigned 0.

WHOIS-BASED FEATURES:

- Feature12 (F12): Host Age
The normal procedure for registering a domain is to register domain and then construct the website as rich as possible, which will take some time. The founder begins to declare and publicize the URL, or does not announce at all and instead relies on search engines such as Google to do so. On the contrary, most phishers register a domain and utilize it rapidly in order to evade discovery. As a result, it is preferable to avoid domains with an age of less than 90 days by assigning it 1 (phishing) else 0 (Legitimate).
- Feature13 (F13): Registrar Name
The registrar is the entity where the domain name is registered. According to the Internet Corporation for Assigned Names and Numbers (ICANN), there were over a thousand ICANN-accredited registrars globally by the middle of 2017, with the number steadily rising. Unless they hide it for any reason, we can determine who owns most domains. If you get a URL as an announcement with an unknown registrant name, it is most likely a phishing URL and will be assigned 1 (phishing), else 0 (no phishing) (Legitimate).

ENGINE-BASED FEATURES:

- Feature14 (F14): Web traffic
The web traffic, which can be collected from the Alexa database, is the total number of users who have visited a URL or webpage. Assume the website is among the top 500 thousand. In such instances, unless it is hacked to be used as a phishing website, it is difficult to be a phishing website. The likelihood of a phishing website growing as its popularity decreases. As a result, URLs with a rank more than 500 thousand are allocated 1 (phishing), while others are assigned 0. (Legitimate).

E. Classification Phase

In this phase, eleven classification algorithms; which were found to be the most adaptable in phishing websites detection, including Random Forest (RF), Gradient Boosting (GBoost), LightGBM (LGBM), Support Vector Machines (SVM), Logistic Regression (LR), k-nearest neighbors (KNN), Gaussian Naive Bayes(GaussianNB), CatBoost, Decision Tree (DT), Linear Discriminant Analysis (LDA), and Quadratic Discriminant Analysis (QDA), are used for classification activities and comparison purposes.

IV. EXPERIMENTAL AND EVALUATION

A. Evaluation Criteria

To evaluate the effectiveness of the proposed model, there are numerous assessment tools available. Calculating the accuracy rates will be accurate and efficient due to the used binary datasets. In order to assess how accurate our model is, we pay attention to its correctness.

Accuracy (A): It measures the overall percentage of predictions that come true as in Eq. (1).

$$Accuracy(A) = \frac{TP + TN}{TP + TN + FP + FN} \quad (1)$$

Properly identified cases are denoted by the letters TP, correctly rejected instances by the letters TN, incorrectly identified instances by the letter FP, and wrongly rejected instances by the letters FN.

Moreover, security is paramount in the world of cybersecurity since phishing attempts can cause significant harm to end users. Therefore, the key goal is to protect users from phishing attacks and drastically reduce misclassification to avoid any challenges faced by the user when utilizing services. Consequently, we include Precision, Recall, and F1-Score in our evaluation.

Precision evaluates the proportion of occurrences properly identified as phishing compared to all instances identified as phishing as in Eq. (2).

$$Precision = \frac{TP}{TP + FP} \quad (2)$$

Recall: It measures the proportion of phishing incidents that are accurately identified compared to all phishing incidents as in Eq. (3).

$$Recall = \frac{TP}{TP + FN} \quad (3)$$

F1-Score: It is a weighted average of Precision and Recall as in (4).

$$F1_Score = \frac{2 * Precision * Recall}{Precision + Recall} \quad (4)$$

B. Experiments and Results

Two stages of the experiments were carried out. The first step is to assess the classifiers and choose the algorithm that performs the best. The robustness and generalizability of the proposed models are evaluated in the second stage by training the model on recent datasets without retraining it. It also conducts additional experiments to investigate the impact of retraining on model performance by testing the model with a recent dataset after retraining. Each of these stages will be thoroughly illustrated in the following subsections.

1) *Releasing the Best Classification Algorithm:* These experiments aim to determine the classification process' best performing algorithm. Random Forest (RF), Gradient Boosting (GBoost), LightGBM (LGBM), Support Vector Machines (SVM), Logistic Regression (LR), k-nearest neighbors (KNN), Gaussian Naive Bayes(GaussianNB), CatBoost, Decision Tree, Linear Discriminant Analysis (LDA), and Quadratic Discriminant Analysis (QDA) algorithms are trained and tested on the first dataset; 24,200 phishing and legitimate URLs, as shown in Table II. The dataset is randomly split into 90% and 10% of the samples for the training set and testing set, respectively. On the training set, a randomized cross-validation (10-fold) search was performed with a maximum of 1000 iterations. These algorithms' classification results after 10, 100, and 1000 iterations are shown in Table IV. All algorithms

TABLE IV. PERFORMANCE OF THE CLASSIFIERS USING 10, 100, AND 1000 ITERATIONS

Algorithm	10 iterations	100 iterations	1000 iterations
RF	99.63	99.71	99.79
GBoost	99.42	99.67	99.84
LGBM	99.67	99.84	99.84
SVM	96.66	96.87	96.99
LR	96.28	96.82	97.07
KNN	99.42	99.42	99.59
GaussianNB	98.06	98.47	98.76
CatBoost	95.83	96.49	96.82
DT	96.16	96.61	96.61
LDA	95.87	96.32	96.94
QDA	83.80	84.88	85.95

improved in performance as the number of iterations increased, as can be shown. The best performance for the LightGBM and Decision Tree algorithms was achieved after 100 iterations and

TABLE V. THE BEST PERFORMANCE OF THE CLASSIFIERS

Algorithm	Accuracy	Precision	Recall	F1-score
RF	99.79	1.00	1.00	1.00
GBoost	99.84	1.00	1.00	1.00
LGBM	99.84	1.00	0.99	1.00
SVM	96.99	0.94	0.95	0.94
LR	97.07	0.95	0.92	0.94
KNN	99.59	1.00	0.99	0.99
GaussianNB	98.76	0.97	0.90	0.98
CatBoost	96.82	0.95	0.93	0.94
DT	96.61	0.94	0.93	0.94
LDA	96.94	0.96	0.91	0.94
QDA	85.95	0.43	0.50	0.46

remained constant after 1000 iterations. The results also show a performance competition among RF, LGBM, and GBoost classifiers. To the best of our knowledge, they outperform currently available state-of-the-art phishing detection systems designed and reach the best performance with nearly identical results. The highest accuracy of the classifiers is shown in Table V, and Fig. 3.

Fig. 3. The best classifier's accuracy.

2) *Future Attacks:* The goal of these experiments is to ensure that we have a robust model that can deal with ever-changing attacks. One method is to train the model on one dataset and then test it on a different, more recent one. As a result, two new datasets were used in these experiments. As shown in Tables II and III, we referred to them as the second and the third datasets.

These experiments were carried out in three steps:

- 1- Measuring model performance with new attacks.
- 2- Investigating the impact of retraining on model performance.
- 3- Emphasizing the significance of the model's regular retraining.

a) *Measuring Model Performance with New Attacks:* The first stage is to evaluate the model's performance with the new attacks, which is done by evaluating the suggested models with the second and third datasets, using all models demonstrated in the prior section. Table VI present the findings. According to the results, most of the classifiers' performance is slightly lower than in the previous experiment, with the exception of the CatBoost and DT algorithms, which both have slightly higher performance. Given that these datasets were not used in the training set, that each dataset is unique with no common URLs, and they were gathered over a three-year period, these findings could be considered good. Furthermore, the results show a decrease in performance for both the KNN and LightGBM algorithms. In terms of best performance, the second dataset indicated a competition amongst three classifiers: Gaussian NB, Random Forest, and Gradient Boost. Furthermore, the Gaussian NB classifier performs better with

TABLE VI. PERFORMANCE OF CLASSIFIERS ON THE SECOND, AND THE THIRD DATASETS

Algorithm	On the second dataset	On the third dataset
RF	98.5	98
GBoost	98.51	97.9
LGBM	95.7	83.5
SVM	95.8	95.7
LR	95.98	96.3
KNN	93.795	91
GaussianNB	98.5	98.67
CatBoost	97	97.1
DT	97	97.1
LDA	96	95.5
QDA	83.4	83.5

the third dataset. Random Forest and Gradient Boost are placed second and third in terms of performance, respectively.

The model’s efficacy and robustness are ensured by the features and classification technique used. This experiment highlights the value of the features chosen for the classification models, demonstrating that they were more resilient to new attacks and that active phishers are unable to overcome them. It also shows that the Gaussian NB algorithm’s performance has held steady over time, implying that it is the most resilient to fresh phishing attack strategies. In a close race for second place, the Random Forest and Gradient Boost algorithms both performed well.

b) Investigating the Impact of Retraining on Model Performance: The second step in these experiments is to investigate the effect of retraining on the model performance, which is accomplished by testing the models again after they’ve been retrained with the new phishing attacks. The second dataset was divided into two parts: train and test. The model was then retrained with the new training set (90% of the second dataset), with the same set of features, and tested using the new testing set (the remaining 10% of the second dataset) and the third dataset. Table VII shows the classification results.

For the new testing set (the remaining 10% of the second dataset), all of the classifiers’ performance increased and was very near to the first findings released from the initial model, emphasizing the need of retraining operations in order to preserve model performance over time. LightGBM was the most significantly improved algorithm, with its performance dropping from 99.84% accuracy to 95.68% when tested on the new dataset without retraining and returning to 99.78% accuracy when tested again but after retraining on fresh phishing attacks. For the third dataset, most classifiers’ performance increased when compared to the results of the prior test with the same dataset without retraining, as shown in Table VI. LightGBM benefitted the most after retraining, increasing its accuracy from 83.5% to 95.57%, although it was not the best accuracy classifiers received. In terms of greatest accuracy, the GaussianNB Algorithm ranks first with around 98.46%, followed by both GradientBoost and Random Forest in second place with approximately 98.3%. Despite the modest decline in performance, the GaussianNB Algorithm maintained its performance from the start of the experiments. After retraining, the performance of the CatBoost, QDA, and DT algorithms all decreased.

This experiment emphasizes the need of retraining for algorithms like LightGBM, which lose performance while

TABLE VII. PERFORMANCE OF THE RETRAINED MODELS

Algorithm	On the new testing dataset	On the third dataset

QDA	84.77

dealing with fresh datasets without retraining. Algorithms such as Random Forest and GradientBoost can deal with new attacks with a minor reduction in performance; this is regarded a satisfactory outcome if they do not regularly retrain with fresh datasets, but they are able to retain performance after retraining. The GaussianNB algorithm is the most immune to new phishing attacks without retraining and can even function effectively while being retrained.

c) Emphasizing the Significance of the Model’s Regular Retraining: The third phase emphasizes the importance of continual model retraining for more current attack types. As indicated in previous findings; Table VII, the classifiers’ performance was as excellent as it was for the first model due to retraining the model using recent attacks from the same time period as the test set. To ensure this, the third dataset is separated into train and test sets. The model was then retrained with the new training set. The new testing set is then used to test it. The classification result is shown in Table VIII below. The performance of most classifiers has improved once again, like in the prior experiment. LightGBM classifier returns to top place in terms of accuracy, followed by Random Forest and GradientBoost at the second level. The third and fourth levels are occupied by KNN and GaussianNB, respectively.

When these results were compared to the previous test results for the third dataset without any retraining, it was discovered that all algorithms outperformed their previous performance with the exception of GaussianNB, CatBoost, and DecisionTree algorithms, whose performance had a slight slip after retraining. The same result was observed while testing the third dataset after retraining the model using a portion of the second dataset, except that DecisionTree method performance rose after retraining the model with recent attacks from the same time period. Fig. 4, 5 compare models performance with and without retraining.

Fig. 4. The models performance on the second dataset with and without retraining.

Fig. 5. The models performance on the third dataset with and without retraining.

These studies illustrate the need of having a diverse set of characteristics that can counter ever changing attacks. It also underlines the need of selecting a classification method that performs well with both previously trained and fresh datasets. Furthermore, to safeguard the model's performance, it should be retrained on a regular basis for newer sorts of attacks. Furthermore, these experiments demonstrated that the LightGBM, Random Forest, and GradientBoost algorithms performed the best and maintained their performance with regular retraining of the model with newer types of attacks. Furthermore, the GaussianNB method is the most resilient algorithm, capable of maintaining its performance even without retraining, and its performance is considered good in comparison to current best and common practices used in the field. These four proposed models demonstrate that it is tough for attackers to avoid, since it is capable of dealing with the ever-changing nature of phishing attacks. Furthermore, they outperform the other detection models currently available. To the best of our knowledge, these are the first detection models that have demonstrated their resilience and generalization by being assessed with fresh up-to-date datasets without and with retraining and indicating that they can sustain and continue to perform well.

V. CONCLUSION AND FUTURE WORK

Based on the observation of historical and contemporary phishing attacks, this article developed a unique combination of phishing URL detecting features which offered novel

detection models that used the proposed features in concert with a machine learning algorithm. Eleven alternative machine learning algorithms were examined for classification tasks and comparative objectives. For the initial model creation and the model evaluation, three datasets were created. These datasets were gathered over a three-year interval to guarantee the model's generalizability and resilience to new datasets and phishing attacks.

Through a variety of experiments, beginning with assessing the classifiers to pick the best-performing algorithm and ending with emphasizing the relevance of the model's frequent retraining, the model performance, generalization, and robustness were evaluated using appropriate evaluation metrics. Based on the experimental data, the key conclusion is that the suggested models; which utilize LightGBM, Random Forest, or GradientBoost algorithms, have the best performance with an average accuracy rate of 99.7%, outperforming all other model in the literature. Furthermore, when evaluated with newer datasets, Random Forest, and GradientBoost models comes in the second level after the GaussianNB model which is the most durable without retraining. Additionally, it demonstrated that these models are able to maintain its performance with regular retraining with newer types of attacks and with the same set of features, which is regarded an extraordinary achievement and a step forward in phishing detection technologies. Adapting various parallel processing approaches to lower the time necessary to extract the features is one potential future attempt. Furthermore, we intend to employ deep learning algorithms in a performance evaluation. Moreover, we plan to expand our work on social media platforms such as Facebook, Instagram, and others.

Ensemble of Deep Learning Models for Multi-plant Disease Classification in Smart Farming

Hoang-Tu Vo, Luyl-Da Quach, Hoang Tran Ngoc
Software Engineering Department
FPT University, Cantho city, Vietnam

Abstract—Plant disease identification at an early stage plays a crucial role in ensuring efficient management of the diseases and crop protection. The occurrence of plant ailments can result in substantial reductions in both crop yield and quality, which may cause financial setbacks for farmers and lead to food shortages for consumers. Traditional methods of disease detection rely on visual observation, which can consume a significant amount of time, be a labor-intensive, and often be inaccurate. Automated disease detection systems, based on techniques for machine learning have the potential to greatly improve the precision and speed of disease detection. This article presents a model for classifying plant diseases that combines the output of two transfer learning models, EfficientNetB0 and MobileNetV2, to improve disease classification accuracy. The PlantVillage Dataset was used to train and test the model under consideration, which contains 54,305 photos of 38 different plant disease classes, achieving an accuracy rate of 99.77% in disease classification. The use of an ensemble of deep learning models in this study shows promising results, indicating that the technique can enhance the accuracy of plant disease classification. Besides, this study contributes to the development of accurate and reliable automated disease detection systems, thereby supporting sustainable agriculture and global food security.

Keywords—Ensemble learning; automated disease detection systems; transfer learning models; plant diseases

I. INTRODUCTION

Plants are susceptible to a variety of diseases, and this is particularly true in the Mekong Delta region of Vietnam and across the world. There are numerous factors that contribute to the development and spread of plant diseases, including weather conditions, soil health, and the presence of pests and pathogens [3]. The Mekong Delta, situated in the southwest of Vietnam, is also referred to as the Western Region, the humid and warm climate provides ideal conditions for the growth of many plant diseases, which can have significant economic and environmental impacts on local farmers and communities [41]. Similarly, in other parts of the world, plant diseases can be a major challenge for agriculture and food security, affecting yields and quality of crops. Therefore, it is crucial to monitor and manage plant diseases to prevent their spread and minimize their impact on plant health and food production. In recent times, there has been a growing interest in using machine learning (ML) and deep learning (DL) techniques to improve the early diagnosis of plant diseases. This involves developing algorithms that can analyze large datasets of plant images and detect early signs of disease, such as changes in leaf color or texture. These algorithms can be trained using labeled datasets of healthy and diseased plants, allowing them to identify

patterns and make accurate predictions about the health of a plant. By using these advanced techniques, researchers hope to enhance the precision and quickness of disease diagnosis, which could help farmers to take preventive measures and minimize crop losses. The study's primary contribution is to introduce a model for classifying plant diseases that combines the output of two transfer learning models, EfficientNetB0 and MobileNetV2, to improve disease classification accuracy.

II. RELATED WORKS

Numerous research studies have investigated the use of both traditional classification algorithms and advanced deep learning models in classifying plant leaf diseases. This indicates that there is an ongoing effort to develop more accurate and efficient methods for identifying and diagnosing diseases that affect plant leaves. The article [30] proposes ANN and SVM classifiers to identify and classify fungal diseases with an accuracy of 87% and 91.16%, respectively. This study [14] utilizes the Support Vector Machine (SVM) classifier for disease recognition, achieving an accuracy rate exceeding 90%. In the research [28] employs the SVM classification technique and involves the extraction of color and texture features, resulting in a classification accuracy of 88.89%. Through the extraction of features such as color, shape, and texture from images of healthy and unhealthy tomato plants and feeding them to a classification tree, the study [36] achieved a classification accuracy of 97.3% for six types of tomato images. The study [20] combines convolution neural networks (CNNs) and SVM method to extract features and classify rice leaf disease images, respectively. The research achieves a classification accuracy of 96.8%. The study [12] presents a fresh model for identifying plant leaf diseases, which employs a Deep CNN trained with an open dataset comprising 39 classes of images of plant leaves and their backgrounds. The research attains a classification accuracy of 96.46%. The paper [44] discusses the practicality of using CNN for classifying plant diseases in leaf images, resulting in an accuracy rate of 99.32%. The study [25] introduces a new approach to identifying rice diseases that utilizes deep CNN techniques, achieving an accuracy rate of 95.48%. The paper [48] presents a novel approach to classifying tomato leaf diseases using a deep CNN that incorporates an attention mechanism, achieving an accuracy rate of 99.24% on the tomato leaf diseases dataset. A compact CNN is suggested in this research [27] for the Tomato Disease identification task, achieving an F1 score of 99.70%. [43] The tomato diseases are accurately defined and classified using Convolutional Neural Network (CNN), achieving a success rate of 98.49%. In recent times,

transfer learning has gained widespread popularity and has been successful in solving several problems with significant achievements. Agriculture imaging tasks [32], [5], [26], [33], [31]; Medical imaging tasks [34], [2], [47], etc. To utilize the pretrained model for identifying plant diseases, this paper [49] presents the identification of apple leaf diseases with an accuracy of 93.71% using DenseNet-121. The study [16], the VGG16 deep learning model has been employed to achieve a 90% accuracy in identifying diseases in tea leaves. In this paper [45] employs the VGG16 model to identify diseased apple leaves with an accuracy of 90.4%. The identification of haploid and diploid maize seeds is achieved with an accuracy of 94.22% in this study [1] using the VGG-19 model. The classification of Tomato crop diseases is achieved in this paper [35] with an accuracy of 97.29% using VGG16 and 97.49% using AlexNet. The study [21] employed transfer learning with the plant village dataset to retrain the EfficientNet B7 deep architecture. Subsequently, down-sampling of collected features was performed using a Logistic Regression technique, which achieved a 98.7% accuracy. The research [13] involved tomato leaf disease detection, which was performed using Densenet-Xception, resulting in an accuracy of 97.10%. In this study [39], CNN models were employed to categorize diseases found in tomato plants, achieving an accuracy of 98.6% across 10 different disease classes. In the study [42], the success rate for tomato leaf disease recognition using VGG16, InceptionV3, and Resnet50 models were 99.62%, 99.75%, and 99.5%, respectively. The goal of this study [37] was for the purpose of diagnosing diseases present in tomato leaves by categorizing healthy and unhealthy tomato leaf photos using two pretrained CNNs, namely InceptionV3 and Inception ResNetV2. The study [22] achieved an accuracy of 99.22%. In this work, three CNN-based models (VGG-16, ResNet-152, and EfficientNet-B4) were proposed for the classification of tomato leaf diseases. The study found that the models reached accuracies of 93.75%, 97.27%, and 98%, respectively. With the utilization of a DenseNet model, the paper [6] achieved a classification accuracy of 99.9% in identifying tomato diseases. By leveraging MobileNetV2, the research [24] created an enhanced algorithm for recognizing apple leaf diseases and achieved an accuracy rate of 96.23%. In the research [4], the detection of tomato leaf diseases was performed using several models, with MobileNet achieving an accuracy rate of 94%, Xception at 95.32%, VGG16 at 93.35%, ResNet50 at 96.03%, DenseNet121 at 96.3%, and EfficientNetB5 at 99.07%.

III. TRANSFER LEARNING MODELS AND ENSEMBLE LEARNING

A. Transfer Learning Models

Transfer learning (TL) [29] is a technique in machine learning that improves the learning process by leveraging a pre-trained model for a new task. TL models are neural networks that have undergone training on a large dataset, typically used for tasks such as image recognition or natural language processing. These models are then adjusted and fine-tuned for a new task using a smaller dataset. The core principle behind transfer learning is based on the idea that a model capable of recognizing specific features in one domain can be repurposed to identify similar features in another domain. In recent times, various Deep Learning models, including EfficientNet, MobileNet, VGG, DenseNet, Xception, ResNet,

among others, have emerged victorious in the ILSVRC competitions. The ImageNet database, containing more than 1.4 million images for 1000 different classes, is the most widely utilized dataset for these competitions. The present research involves the combination of EfficientNetB0 and MobileNetV2 models for the classification of plant diseases.

B. Ensemble Learning

Ensemble learning (EL) [11] is a method that involves merging multiple separate models to achieve improved overall performance in terms of generalization. There are several types of ensemble models that can be used for this purpose, each with its own unique approach and set of advantages and disadvantages. One of the most common types of ensemble models is bagging [8], which stands for bootstrap aggregating. The Bagging technique consists of training multiple models on distinct subsets of data, followed by the amalgamation of their predictions through averaging or majority voting. This approach can diminish the variance of the models and enhance their general stability. Another popular ensemble method is boosting [10] [9], which involves sequentially training weak models and adjusting the weights of the training examples to focus on the most difficult cases. Boosting can be effective for improving the accuracy of the models and reducing bias. Stacking [46] is a more complex type of EL that involves training several models and then using another model, called a meta-model or a blender, to combine their predictions. Finally, decision fusion strategies based on deep ensemble models use deep learning methods to combine the results of several models, either in a hierarchical or parallel manner, to achieve better performance.

In our approach, we utilized two transfer Learning models (EfficientNetB0 [40] and MobileNetV2 [15] [38]) for the purpose of extracting deep features from the data provided. These deep features were then integrated together to form a single, high-dimensional feature vector. These features were then fed into a few dense layers for further processing and feature transformation. Finally, the resulting features were used to perform classification. This allowed us to leverage the complementary strengths of different deep networks and capture a richer representation of the input data compared to using a single deep network or traditional feature extraction methods. The outcomes demonstrate the proficiency of our method in leveraging the power of TL models for multi-plant disease classification.

IV. METHODOLOGY

A. Dataset and Data Preparation

The data set utilized in this research is PlantVillage dataset was first introduced at [17], [18]. The PlantVillage dataset comprises 54,305 images of leaves, both healthy and diseased, which have been categorized into 38 different groups based on their species and type of disease. The images include 14 types of crops and consist of 38 categories can be found in Table III. To train and evaluate the effectiveness of the suggested model, the dataset was divided into three separate groups, namely the training set, testing set, and validation set, in the proportion of 60:20:20. The distribution of the data set can be discovered in Fig. 1 and examples of plant disease

Fig. 1. A dataset distribution.

pictures from The PlantVillage dataset can be presented Fig. 2. Before the model training and evaluation, the datasets for training, validation, and testing will go through preprocessing techniques. These techniques consist of resizing the images to 224x224 and applying the image preprocessing function.

B. Proposed Model

In this research, we utilized two transfer Learning models (EfficientNetB0 [40] and MobileNetV2 [15] [38]) to extract deep features from the input data. These deep features were then concatenated together to create a feature vector. Then, these features were fed into a few dense layers for further processing and feature transformation. Finally, the resulting features were used to perform classification. The suggested model for plant disease classification can be seen in Fig. 3. The model has two main backbone networks, “EfficientNetB0” and “MobileNetV2,” both of which produce an output shape of (None, 1280). These output tensors are then processed by two separate batch normalization layers, and their outputs are concatenated together to form a (None, 2560) tensor. This concatenated tensor is then fed into a dense layer comprising of 256 units, followed by a dropout layer with a dropout rate of 0.5 to prevent overfitting. Finally, the output of the dropout layer is passed through another dense layer with 38 units, which produces the final output of the model. The overall count of parameters within the model is 6,983,177,

with 6,901,922 of them being trainable and the remaining 81,255 being non-trainable. The Architecture and Proposed model can be displayed in Fig. 4 and Table 1 showcases the representation of various information including layers of the model, the shape of each layer’s output, the count of trainable parameters in every layer, and the overall count of trainable parameters within the model. The proposed model also utilizes the technique of learning rate scheduling [23] during its training process. Learning rate scheduling is a technique that adjusts the learning rate, which controls the step size of the gradient descent optimization algorithm, during training. The purpose of this technique is to improve the convergence of the model by gradually reducing the learning rate over time. In this model, after two epochs, the learning rate has decreased by a factor of 0.5 to wait to adjust the learning rate if training accuracy does not improve. In order to address potential overfitting in the model, the regularization techniques used in this architecture assisting in avoiding overfitting and improve the model’s overall performance, which is important for many applications in the real world.

C. Model Evaluation Metrics

This study examined the effectiveness of DL models using a range of metrics, including Precision, Recall, F1-score, and Accuracy. Accuracy was employed to assess the overall performance of the models in predicting the target

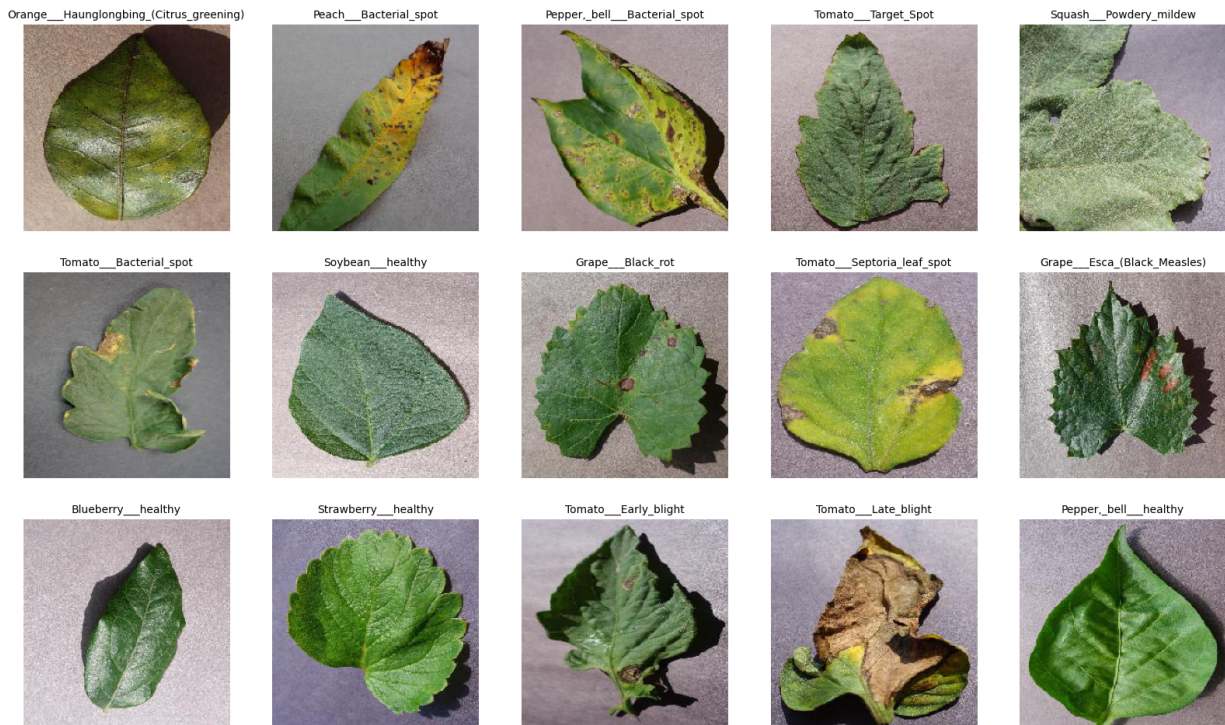

Fig. 2. Sample plant disease in plantVillage dataset.

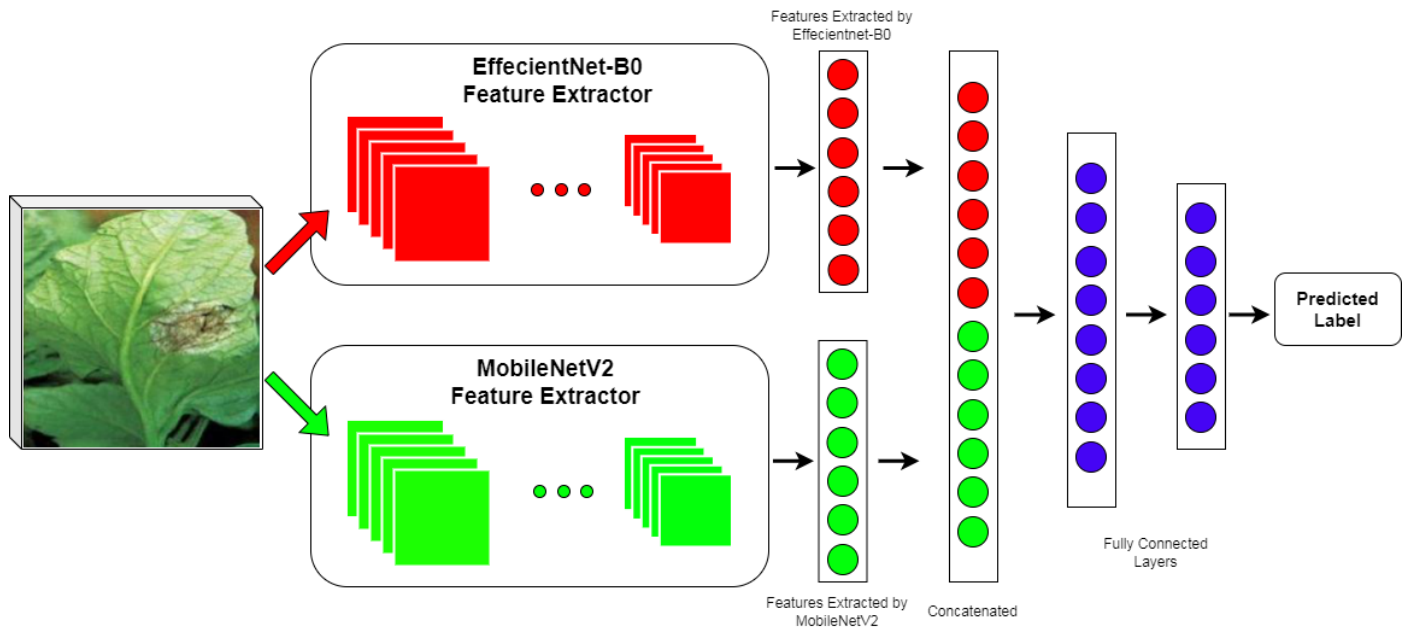

Fig. 3. Proposed model for plant disease classification.

variable. Precision measured the ratio of true positive results to all positive predictions, while recall measured the ratio of true positive predictions to all actual positive instances in the dataset. F1-score, which combines precision and recall, provided a balanced perspective on the model's performance, particularly in scenarios with imbalanced classes. By employing multiple evaluation metrics, we gained a comprehensive understanding of the model's performance and made well-

informed judgments regarding its effectiveness.

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (1)$$

$$Precision = \frac{TP}{TP + FP} \quad (2)$$

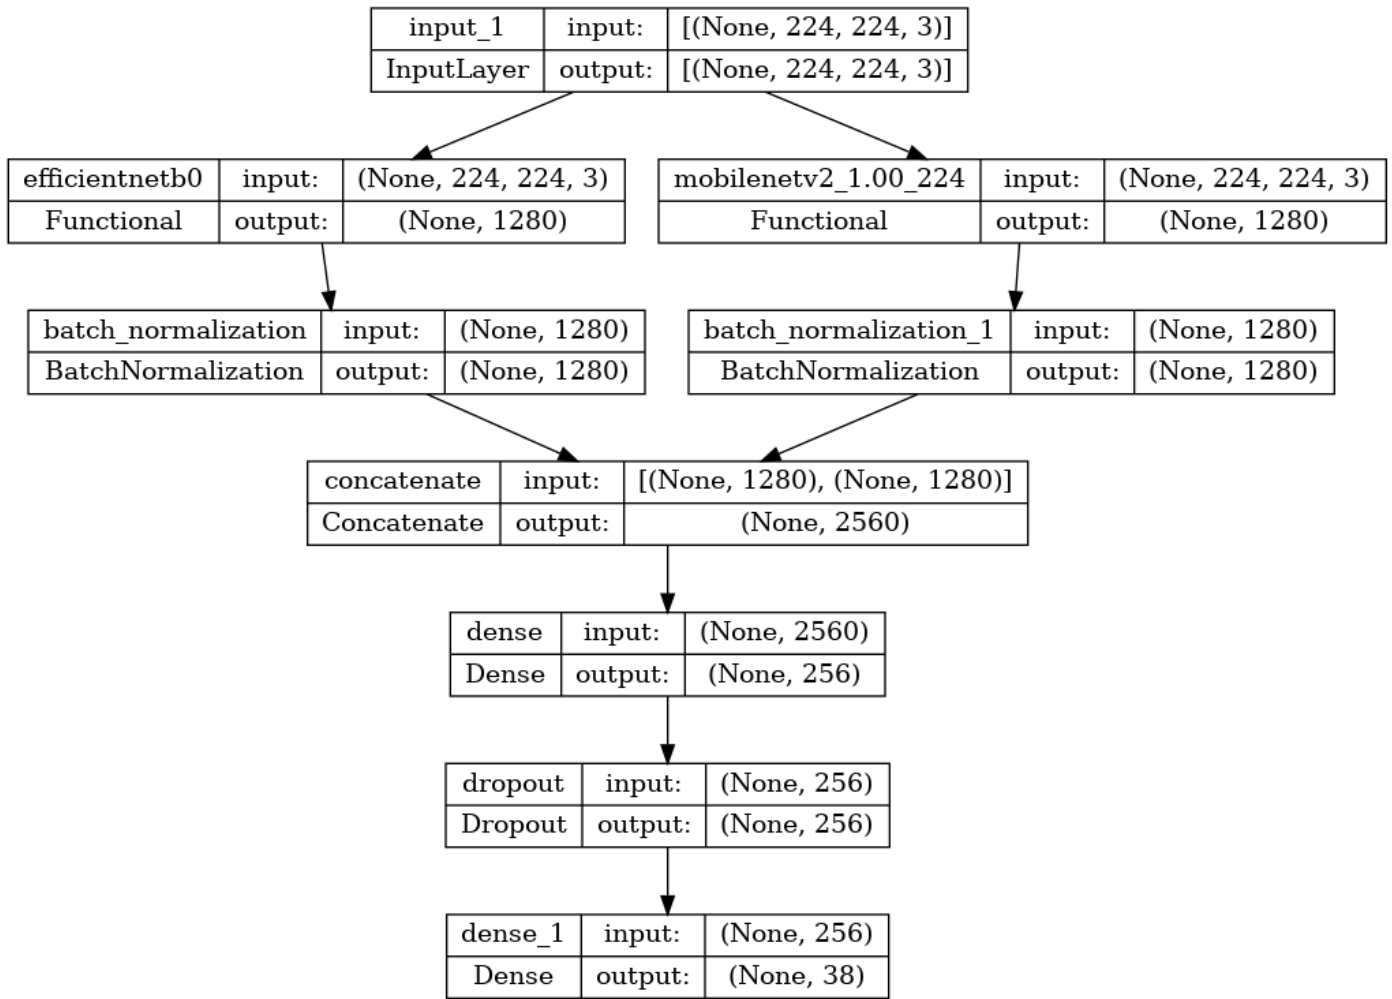

Fig. 4. The architecture of the suggested model is used in this study.

TABLE I. THE LAYERS OF PROPOSED MODEL

Layer (type)	Output Shape	Param #
input_1 (InputLayer)	[(None, 224, 224, 3)]	0
efficientnetb0 (Functional)	(None, 1280)	4049571
mobilenetv2_1.00_224 (Functional)	(None, 1280)	2257984
batch_normalization (BatchNormalization)	(None, 1280)	5120
batch_normalization_1 (BatchNormalization)	(None, 1280)	5120
concatenate (Concatenate)	(None, 2560)	0
dense (Dense)	(None, 256)	655616
dropout (Dropout)	(None, 256)	0
dense_1 (Dense)	(None, 38)	9766
Total params: 6,983,177		
Trainable params: 6,901,922		
Non-trainable params: 81,255		

$$Recall = \frac{TP}{TP + FN} \quad (3)$$

$$F_1 - Score = \frac{Precision * Recall}{Precision + Recall} \quad (4)$$

In which, TP: True Positive, TN: True Negative, FP: False Positive, FN: False Negative.

D. Results

Table II presents a comparative examination of the suggested model with modern methods on similar problems. The table includes the name of the plant, the quantity of categories, the number of pictures in the dataset, and the method used for detection along with the accuracy rate achieved. The PlantVillage dataset was used for both training and testing the recommended model, containing 54,305 photos of 38 different plant disease classes. According to the findings, the model that was suggested, which combines the output of two transfer learning models, EfficientNetB0, and MobileNetV2, achieved an accuracy rate of 99.77%, which outperformed all other methods listed in the table. According to the results, the suggested approach has the potential to substantially enhance the precision of plant disease classification and provide more reliable automated disease detection systems. The classification report presents the evaluation metrics for each class of plant disease, along with the support values for each class presented in Table III. The report shows that the model performs excellently, with most classes achieving perfect scores for evaluation metrics. The report provides useful insights into the model's capacity to identify and categorize various types of plant diseases. The confusion matrix of the suggested

model results is displayed in Fig. 5 and Fig. 6 presents the metrics that measure the proposed model's performance during both training and validation phases, which include loss and accuracy.

V. CONCLUSION

The presented study highlights the importance of timely identification of diseases that affect plants and the significant losses that can result from their unchecked spread. Traditional methods of disease detection are often inaccurate, time-consuming, and labor-intensive, making it difficult for farmers to efficiently manage their crops. The use of automated disease detection systems based on machine learning algorithms offers an excellent opportunity to improve the accuracy and speed of disease detection. The model for classifying plant diseases that have been suggested, which combines the outputs of two transfer learning models, EfficientNetB0 and MobileNetV2, has demonstrated an accuracy rate of 99.77% in disease classification, indicating its potential to provide more reliable automated disease detection systems.

Furthermore, this study's results offer promising indications that the use of an ensemble of DL models can significantly enhance the accuracy of plant disease classification. The development of more accurate and reliable automated disease detection systems is vital to support sustainable agriculture and global food security, making this study a valuable contribution to this field of research.

VI. FUTURE WORKS

There are several future works that can be pursued based on the findings of this study. First, the model can be tested on different datasets containing images of plant diseases to assess its robustness and generalizability. This will help to determine if the model can be applied to other crops and environments. Second, the model can be integrated into a real-time monitoring system to enable early detection and timely intervention. This will require the design of an easy-to-use interface that can be used by farmers and other stakeholders.

Primal-Optimal-Binding LPNet: Deep Learning Architecture to Predict Optimal Binding Constraints of a Linear Programming Problem

Natdanai Kafakthong, Krung Sinapiromsaran
Department of Mathematics and Computer Science
Chulalongkorn University
Bangkok, Thailand, 10330

Abstract—Identifying an optimal basis for a linear programming problem is a challenging learning task. Traditionally, an optimal basis is obtained via the iterative simplex method which improves from the current basic feasible solution to the adjacent one until it reaches optimal. The obtained result is the value of the optimal solution and the corresponding optimal basis. Even though learning the optimal value is hard but learning the optimal basis is possible via deep learning. This paper presents the primal-optimal-binding LPNet that learns from massive linear programming problems of various sizes casting as all-unit-row-except-first-unit-column matrices. During the training step, these matrices are fed to the special row-column convolutional layer followed by the state-of-the-art deep learning architecture and sent to two fully connected layers. The result is the probability vector of non-negativity constraints and the original linear programming constraints at the optimal basis. The experiment shows that this LPNet achieves 99% accuracy of predicting a single binding optimal constraint on unseen test problems and Netlib problems. It identifies correctly 80% LP problems having all optimal binding constraints and faster than cplex solution time.

Keywords—Deep learning; convolution neural network; linear programming; basic feasible solution; optimization

I. INTRODUCTION

Traditionally solving a linear programming (LP) problem. The authors in [17] requires an iterative simplex method [1] or an iterative interior point method [2]. The simplex method starts from an initial basic feasible solution (BFS) and pivots to the adjacent BFS with the objective improvement. It guarantees to reach the optimal BFS for nondegenerate and bounded LP with a nonempty feasible solution. While the interior point method starts at an interior point inside the feasible region and moves along an improved direction until it reaches the solution close to the optimal one.

The simplex method requires the feasibility of the current basic feasible solution. Since a general linear programming problem may not be feasible, it will need to be reformulated. Two classical artificial-variable techniques have been developed which are the two-phase simplex method [18] and the big-M method [17], [3]. Both techniques increase the dimension of the original problem by adding an artificial variable to each constraint causing more computational solution time.

In 2014, Boonperm, et al. [4] presented a non-acute constraint relaxation technique that eliminates the need for

artificial variables and reduces the start-up time to solve the initial relaxation problem. The algorithm reinserts the non-acute constraints back into the relaxation problem to guarantee the optimal solution or infeasibility or unboundedness of a linear programming problem. Moreover, there is a use case of angle measurement of LP constraints to control a jump direction in a metaheuristic algorithm to solve an LP problem that is introduced by Visuthirattanam [5]. In this paper, angle measurement between constraints is also considered as a part of preprocessing input of a deep learning model.

The deep learning concept mimics the computation from the biology of human brain cells to learn a task directly from numerical source data. It consists of multiple layers of interconnected nodes and arcs with weights and biases. The learning process adjusts weights that work together to recognize accurately and classify objects from data. An alternative method for solving an LP problem has been studied for centuries. Recently, the use of machine learning models such as a deep learning model is investigated. Instead of solving an LP problem every time a new problem is posted. Researchers investigate whether the machine learning model can be used to identify the optimal solution by learning from thousands of solved LP problems. With the appropriate form of the LP problem and the special deep learning architecture, the optimal basis of any linear programming problem can be obtained.

A. Contributions

This paper uses a deep learning model to solve a linear programming problem using only objective coefficients, the right-hand-sided values and the constraint coefficients avoid any iterative procedure that has been used for centuries. The concept is to use million solved linear programming problems as the training data with the appropriate matrix format as the all-unit-row-except-first-unit-column matrix and an additional row-column convolutional layer, which enables the deep learning model to identify the optimal binding constraints from linear programming problems of varying sizes.

The objective of this paper is the LPNet deep learning architecture that can solve a linear programming problem. It has the all-unit-row-except-first-unit column matrix as the input fed to the row-column convolutional layer. Then the output is sent to state-of-the-art deep learning model submitting to two fully connected layers before the last output layer.

In order to achieve the objective, this paper introduces a unit-vector normalization that simplifies the training process compared to the traditional normalization method. This method incorporates two key concepts - reordering constraints and scaling LP problems - to enhance the model's ability to learn effectively.

Finally, the LPNet architecture integrates all these processes together as illustrated in Fig. 1, and the trained model outperforms the benchmark LP datasets when compared to CLPEX [31], the state-of-the-art optimization LP solver.

The remainder of this paper is organized as follows. Section II provides a literature review. Section III covers the methodology of this paper. Section IV provides the analysis and results of the effective deep learning architecture. Section V is the conclusion of this paper, and the last section provides a discussion of this work.

II. LITERATURE REVIEW

Various deep-learning architectures have been proposed to learn different tasks via spatial relationships within the input data. A deep convolution neural network (DCNN) is one of the deep learning architectures which is suitable for computer vision tasks. Many state of the art architectures demonstrate high performance for an image classification task such as Resnet [20], MobileNet [6], EfficientNet [21], XceptionNet [22] and InceptionNet [23].

The study of Khade S. et al. [10], [12], [13] developed multiple DCNNs to identify iris liveness detection based on ResNet50 and EfficientNet for binary classifications. Moreover, the convolutional deep extreme learning machine method [14] can well recognize the pattern of a diabetic retinopathy image using DCNN architectures, that is ResNet, DenseNet [15], and GoogleNet [16]. This paper also developed DCNN with these architectures for multi-label classifications. Multi-label classifications [11] are more complex than binary classifications.

CNN with recurrent neural network (CNN-RNN) technique is utilized to detect and classify sarcasm [28]. In order to boost the detection outcomes of the CNN+RNN technique, a hyperparameter tuning process utilizing a teaching and learning-based optimization (TLBO) algorithm is employed in such a way that the classification performance gets increased.

The integration of a DCNN model to a multiparametric programming problem [24], [7] was demonstrated by Justin et al. [8]. Solving the parametric 0–1 LP problem by a DCNN model was proposed in 2022 [9]. The DCNN model for 0-1 LP learns from a histogram-like image representation.

Effati et al. [27] proposed two recurrent neural network models for solving linear and quadratic programming problems. The first model is derived from an unconstraint minimization reformulation of the program, while the second model is directly obtained from the optimality condition for an optimization problem. The paper compares the convergence of these models using the energy function and the duality gap. The paper also explores the existence and convergence of the trajectory and stability properties for the neural network models.

The use of a neural network as a solution bundle for solving ordinary differential equations (ODEs) for various initial states and system parameters is presented by Flamant et al. [26]. In 2023, Dawen Wu et al. [25] proposed a deep learning approach in the form of feedforward neural networks to solve linear programming (LP) problems. The approach models the LP problem by an ordinary differential equations (ODE) system, the state solution of which globally converges to the optimal solution of the LP problem. A neural network model is constructed as an approximate state solution to the ODE system, such that the neural network model contains the prediction of the LP problem.

III. METHODOLOGY

This paper proposed the deep convolutional neural network model, called LPNet, to learn from linear programming coefficients directly putting in the form of a general all-unit-row-except-first-unit-column matrix. This matrix contains the objective coefficients in the first row, normalized to one, the right-hand-side vector as the first column, and the rest are coefficients from constraints normalized to one. It then passes to the special row-column convolutional layer that is carefully designed with convolution filters for extracting the row-column components of the LP problems. After this layer, the result will pass to the state-of-the-art architectures. Then it will pass to two fully connected layers before connecting to the output layer. Each constraint will be marked as either it is one of the optimal basis or it is not in the output layer, see Fig. 1.

Fig. 1. Overview of an optimal binding prediction.

A. A Linear Programming Model

A linear programming model is an optimization model with a linear real-valued objective function ($c^T \tilde{x}$) and linear constraints ($A\tilde{x} \geq b, \tilde{x} \geq 0$). The optimal solution of this LP model is the feasible point that gives the smallest objective value for the minimization or the largest objective value for the maximization. It can be expressed in the following mathematical form.

$$\begin{aligned} \text{Min} \quad & c^T \tilde{x} \\ \text{s.t.} \quad & A\tilde{x} \geq b \\ & \tilde{x} \geq 0 \end{aligned} \quad (1)$$

where $c \in \mathbb{R}^n$, $A \in \mathbb{R}^{m \times n}$, $b \in \mathbb{R}^m$ and $\tilde{x} \in \mathbb{R}^n$. The optimal solution of the LP model can be solved using various iterative algorithms such as the two-phase simplex algorithm, the big-M algorithm, and the dual-simplex algorithm. Alternatively,

the optimal solution could be obtained if all optimal binding constraints are identified correctly. So learning to solve a linear programming problem can be cast as learning to identify the optimal binding constraint from a million linear programming problems.

For every LP problem, there is a corresponding dual LP problem. The original LP problem is called the primal LP problem. If one of these LP problems obtains an optimal solution then both problems will possess the optimal solution having the same optimal value and satisfying the complementary slackness. The non-zero value of any basic variable will cause the corresponding dual constraint to be binding. From equation (1), the dual LP problem is

$$\begin{aligned} \text{Max} \quad & \mathbf{b}^T \mathbf{y} \\ \text{s.t.} \quad & \mathbf{A}^T \mathbf{y} \leq \mathbf{c} \\ & \mathbf{y} \geq \mathbf{0} \end{aligned} \quad (2)$$

Note that the coefficients of the decision variable from a primal LP problem correspond to the row constraint for the dual LP problem. From the complementary slackness properties, [17] of the optimal conditions, the non-zero value of the dual basic variable will give rise to the corresponding primal constraint to be binding, i.e., if $y_i > 0$, for some $i \in \{1, \dots, m\}$ then the corresponding constraint in the LP primal problem will be binding. Similarly, the non-zero basic variable of the LP primal problem will give rise to the corresponding binding dual constraint. If $x_j > 0$, for some $j \in \{1, \dots, n\}$ then the corresponding constraint in the dual constraints will be binding. These optimal bindings can be predicted by LPNet which will be explained in detail in Section IV. The next section will cover the input design for this deep learning model from the coefficients of the primal LP problem.

B. Basic Feasible Solution

The LP problem from (1) can be converted to a standard form by subtracting non-negative surplus decision variables \mathbf{x}' as

$$\begin{aligned} \text{Min} \quad & \mathbf{c}^T \tilde{\mathbf{x}} + \mathbf{0}^T \mathbf{x}' \\ \text{s.t.} \quad & \mathbf{A} \tilde{\mathbf{x}} - \mathbf{I} \mathbf{x}' = \mathbf{b} \\ & \tilde{\mathbf{x}}, \mathbf{x}' \geq \mathbf{0} \end{aligned} \quad (3)$$

where \mathbf{I} is a $m \times m$ identity matrix, and \mathbf{x}' is $\{x_{n+1}, \dots, x_{m+n}\}$. So a new variable vector of the LP problem (3) is $\mathbf{x} = [x_1, x_2, \dots, x_{m+n}]^T$.

Definition 1: [19] For any nonsingular $m \times m$ submatrix \mathbf{A}_B of \mathbf{A} where $B \subset \{1, 2, \dots, m+n\}$ is the set of basic indices, $\mathbf{x} = [\mathbf{x}_B, \mathbf{0}]^T$ is called a basic solution with respect to the basis (\mathbf{A}_B) , where $\mathbf{0}$ in \mathbf{x} is the zero vector of all leftover components of \mathbf{x} associated with the $n-m$ non-basic variables of \mathbf{A} . From the constraint of the standard LP problem $\mathbf{A}\mathbf{x} = \mathbf{b}$, it can be rewritten as $\mathbf{A}_B \mathbf{x}_B = \mathbf{b}$. \mathbf{x}_B is called a vector of basic variables or basic variables in short.

Definition 2: [19] A vector \mathbf{x} satisfying the system $\mathbf{A}\mathbf{x} = \mathbf{b}, \mathbf{x} \geq \mathbf{0}$ is said to be a feasible solution for the system. A feasible solution with a known basis is called a basic feasible solution.

Theorem 3.1: [19] Given a standard LP problem (3) where \mathbf{A} is an $m \times n$ matrix of rank m ,

1. if the feasible region of the LP problem is nonempty and bounded, then there is a basic feasible solution.
2. if there is an optimal feasible solution, there is an optimal basic feasible solution.

This paper proposes a way to predict the optimal basic feasible solution from binding constraints of the LP problem using the target vector \mathbf{Y} corresponding to each constraint. If the element of \mathbf{Y} , Y_i is zero, then the constraint i will be binding and if the element of \mathbf{Y} , Y_j is one, then the constraint j is not binding and if the element of \mathbf{Y} , Y_k is two, then the constraint k does not exist from the original problem. It is just the padding constraint during the learning step of this deep learning architecture.

The next subsection will cover a theorem of scaling an LP problem which guarantees to have the same optimal basic \mathbf{A}_B . This theorem is designed to support an input form of LPNet in Section III.

C. Scaling LP Problems

Some LP problems may come from the same one with different multipliers to their constraints. Normalization of rows of LP problems helps identify duplicate samples during the training phase of LPNet. The following theorem shows that the scaled LP2 problem still has the same basic feasible solution as the LP1 problem. This implies that only one LP problem from all scaled LP problems is enough to be included in the training phase. This will help LPNet focus on one version of LP problems.

Theorem 3.2: Given LP1 has the optimal solution. For any positive scale α , a set of basic variables of LP1 will be the same as the basic variables of LP2(α). Moreover, the optimal basic indices in LP1 will be the same as the optimal basic indices in LP2(α)

$$\begin{array}{ll} \text{LP1} & \text{Min} \quad \mathbf{c}^T \mathbf{x} \\ & \text{s.t.} \quad \mathbf{A}\mathbf{x} \geq \mathbf{b} \\ & \quad \mathbf{x} \geq \mathbf{0} \end{array} \quad \text{LP2}(\alpha) \quad \begin{array}{ll} \text{Min} & \mathbf{c}^T \mathbf{x} \\ \text{s.t.} & \mathbf{A}\mathbf{x} \geq \frac{\mathbf{b}}{\alpha} \\ & \mathbf{x} \geq \mathbf{0} \end{array}$$

Proof: Assume LP1 has the optimal solution. Assume that the current basis is A_B with the set of basic indices B and let the set of the non-basic indices be N . It is easy to see that the optimal objective value

$$z^* = \mathbf{c}^T \mathbf{x}^* = \mathbf{c}_B^T \mathbf{x}_B^* + \mathbf{c}_N^T \mathbf{x}_N^* \quad \text{and} \quad \mathbf{A}_B \mathbf{x}_B^* + \mathbf{A}_N \mathbf{x}_N^* = \mathbf{b}.$$

Therefore $\mathbf{x}_B^* = \mathbf{A}_B^{-1} \mathbf{b} - \mathbf{A}_B^{-1} \mathbf{A}_N \mathbf{x}_N^*$ and

$$\begin{aligned} z^* &= \mathbf{c}_B^T (\mathbf{A}_B^{-1} \mathbf{b} - \mathbf{A}_B^{-1} \mathbf{A}_N \mathbf{x}_N^*) + \mathbf{c}_N^T \mathbf{x}_N^* \\ &= \mathbf{c}_B^T \mathbf{A}_B^{-1} \mathbf{b} + (\mathbf{c}_N^T - \mathbf{c}_B^T \mathbf{A}_B^{-1} \mathbf{A}_N) \mathbf{x}_N^*. \end{aligned}$$

Since z^* is the optimal objective value then

$$\mathbf{c}_N^T - \mathbf{c}_B^T \mathbf{A}_B^{-1} \mathbf{A}_N \geq \mathbf{0} \quad \text{and} \quad \mathbf{x}_N^* = \mathbf{0}.$$

Let $\alpha \in \mathbb{R}^+$ be such that

$$\begin{aligned} \mathbf{x}'_B &= \frac{\mathbf{x}^*_B}{\alpha} \\ &= \mathbf{A}_B^{-1} \frac{\mathbf{b}}{\alpha} - \mathbf{A}_B^{-1} \mathbf{A}_N \frac{\mathbf{x}^*_N}{\alpha} \\ &= \mathbf{A}_B^{-1} \frac{\mathbf{b}}{\alpha} - \mathbf{A}_B^{-1} \mathbf{A}_N \mathbf{x}'_N \\ &\geq 0 \end{aligned}$$

and

$$\begin{aligned} z' &= \frac{z^*}{\alpha} \\ &= \mathbf{c}_B^T \mathbf{A}_B^{-1} \frac{\mathbf{b}}{\alpha} + (\mathbf{c}_N^T - \mathbf{c}_B^T \mathbf{A}_B^{-1} \mathbf{A}_N) \frac{\mathbf{x}^*_N}{\alpha} \\ &= \mathbf{c}_B^T \mathbf{A}_B^{-1} \frac{\mathbf{b}}{\alpha} + (\mathbf{c}_N^T - \mathbf{c}_B^T \mathbf{A}_B^{-1} \mathbf{A}_N) \mathbf{x}'_N. \end{aligned}$$

That is $\mathbf{x}'_N = \frac{\mathbf{x}^*_N}{\alpha} = 0$, $\mathbf{x}'_B \geq \mathbf{0}$ and $\mathbf{c}_N^T - \mathbf{c}_B^T \mathbf{A}_B^{-1} \mathbf{A}_N \geq \mathbf{0}$. Therefore, the set of indices corresponding to \mathbf{x}' is the current basic feasible solution of LP2 with the same basis B . Similarly, if LP2 has an optimal basic feasible solution then LP1 has the same basic feasible solution.

In addition, the optimal basic indices in LP1 will correspond to the optimal basic indices in LP2(α). ■

D. All-Unit-Row-Except-First-Unit-Column Matrix

In the context of LPNet training, the normalization of inputs plays a crucial role in facilitating deep learning optimization to discover optimal parameters for learning optimal binding constraints. The process of normalization specifically addresses the numerical scaling of the rows within the constraint matrix of LP problems. To address this, the present research introduces a two-step data preprocessing approach for any LP problem prior to its utilization in the learning process.

The first step involves the reordering of all constraints based on the angles formed between the sum vector ($\mathbf{1}$) and the coefficient of each constraint equation. This reordering aims to enhance the structure of the input data for improved learning outcomes.

In the subsequent step, each constraint is individually rescaled to attain a unit norm. This normalization further aids in aligning the constraints on a consistent scale, enabling more effective learning and optimization processes.

By implementing these two preprocessing steps, this research enhances the overall effectiveness of LPNet training by ensuring that the input data is appropriately structured and scaled to facilitate the discovery of optimal binding constraints.

E. LP Constraint Ordering

The research findings demonstrate that the optimal binding constraints remain unchanged even when each row is interchanged with another in LP problems. In order to establish a suitable input format for deep learning, it becomes necessary to rearrange all constraints based on the angle between the gradient vector of primal LP constraints and the sum vector ($\mathbf{1}$), which represents a vector of ones with the appropriate size.

By rearranging the constraints in this manner, the input data is properly structured to align with the requirements of deep learning algorithms. This ensures that the crucial information captured by the gradient vector and the sum vector is effectively utilized, leading to more accurate and meaningful training results. Consequently, this approach enhances the overall effectiveness of the deep learning process in tackling LP problems and discovering optimal binding constraints.

Let \mathbf{a}_i be a gradient vector of the i^{th} constraint from \mathbf{A} . The angle between \mathbf{a}_i and $\mathbf{1}$ of size n is defined as

$$\theta_i^{row} = \arccos\left(\frac{\mathbf{a}_i^T \mathbf{1}}{\|\mathbf{a}_i\| \|\mathbf{1}\|}\right). \quad (4)$$

The primal constraints will be ordered from the smallest angle to the largest angle.

Similarly, the dual constraints corresponding to the column of \mathbf{A} will be rearranged by sorting the angle between the \mathbf{a}_j and $\mathbf{1}$ of size m ,

$$\theta_j^{column} = \arccos\left(\frac{\mathbf{a}_j^T \mathbf{1}}{\|\mathbf{a}_j\| \|\mathbf{1}\|}\right). \quad (5)$$

The next step is to rescale all constraints of the LP problem.

F. LP Scaling

The elimination of duplicate LP problems holds significant importance in the training of LPNet. In Figure 2, three distinct LP problems, namely LP1, LP2, and LP3, are depicted, all of which share the same basic feasible solution while differing only in scaling. In this study, LP1 serves as the normalized version for LP2 and LP3. By identifying the optimal binding constraints of LP1, it becomes possible to determine the optimal binding constraints for LP2 and LP3, as demonstrated in Theorem 2.

This approach of addressing duplicate LP problems streamlines the training process of LPNet. It leverages the knowledge gained from the normalized version (LP1) to efficiently identify the optimal binding constraints for the related LP problems (LP2 and LP3). By avoiding redundant computations, this methodology enhances the overall training efficiency and contributes to the improved performance of LPNet.

From Equation (1), coefficient vector \mathbf{c} , right-hand side vectors \mathbf{b} and matrix \mathbf{A} of the LP problem will be normalized into the unit vector format corresponding to \mathbf{c}' , \mathbf{b}' and \mathbf{A}' respectively. The coefficients of the objective function will be converted to $c'_j = \frac{c_j}{\|\mathbf{c}\|}$ for $j = 1, 2, \dots, n$, the coefficients of the constraint function $a'_{ij} = \frac{a_{ij}}{\|\mathbf{a}_i\|}$ for $i = 1, 2, \dots, m$ and $j = 1, 2, \dots, n$ and $b'_i = \frac{b_i}{\|\mathbf{a}_i\|}$ and $b''_i = \frac{b'_i}{\|\mathbf{b}'\|}$ for $i = 1, 2, \dots, m$. These normalized vectors will be stacked together to form the input matrix for the training and testing phases of LPNet. The label vector \mathbf{Y} will contain either 0 for the corresponding binding constraint, 1 for the corresponding non-binding constraint, and 2 for the padding constraint.

Fig. 2. An example of scaling LP problem of $\mathbf{x} \in \mathbb{R}^2$. Three corresponding LP problems, LP1 is the unit-vector normalization of both LP2 and LP3. These three LP problems are not the same problems but they have the same optimal basic variables. If the optimal binding constraints of LP 1 exist then other LP scales are immediately found. Then any LP sizes $\mathbf{x} \in \mathbb{R}^n$ will be scaled by the unit-vector normalization before entering to LPNet model.

$$\mathbf{X} = \begin{bmatrix} 0 & c'_1 & c'_2 & \dots & c'_n \\ b''_1 & a'_{11} & a'_{12} & \dots & a'_{1n} \\ b_2 & a_{21} & a_{22} & \dots & a_{2n} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ b''_m & a'_{m1} & a'_{m2} & \dots & a'_{mn} \end{bmatrix}$$

$$= \begin{bmatrix} 0 & \frac{c_1}{\|\mathbf{c}\|} & \frac{c_2}{\|\mathbf{c}\|} & \dots & \frac{c_n}{\|\mathbf{c}\|} \\ \frac{b_1}{\|\mathbf{a}_1\| \|\mathbf{b}'\|} & \frac{a_{11}}{\|\mathbf{a}_1\|} & \frac{a_{12}}{\|\mathbf{a}_1\|} & \dots & \frac{a_{1n}}{\|\mathbf{a}_1\|} \\ \frac{b_2}{\|\mathbf{a}_2\| \|\mathbf{b}'\|} & \frac{a_{21}}{\|\mathbf{a}_2\|} & \frac{a_{22}}{\|\mathbf{a}_2\|} & \dots & \frac{a_{2n}}{\|\mathbf{a}_2\|} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ \frac{b_m}{\|\mathbf{a}_m\| \|\mathbf{b}'\|} & \frac{a_{m1}}{\|\mathbf{a}_m\|} & \frac{a_{m2}}{\|\mathbf{a}_m\|} & \dots & \frac{a_{mn}}{\|\mathbf{a}_m\|} \end{bmatrix} \quad (6)$$

$$\mathbf{Y} = \begin{bmatrix} y_1 \\ y_2 \\ \vdots \\ y_m \\ y_{m+1} \\ \vdots \\ y_{m+n} \end{bmatrix} \quad (7)$$

To train LPNet with different LP problem sizes without recreating the specific input size of the deep learning model these inputs need to be embedded into the maximum matrix format. Assume that the maximum LP size is N constraints and N variables so \mathbf{Y} has $2N$ components. To set up a (m, n) input LP sample into the matrix of the maximum LP size (N, N) where $m \leq N$ and $n \leq N$, the small-sized (m, n) LP input matrix are padded with zero rows from the $m + 1$ row to the N row and zero columns from the $n + 1$ column to the N column. The corresponding label vector is assigned to 2, see the matrix below for the padding concept. An example of a $(2, 2)$ LP sample is added into (N, N) matrix \mathbf{X} with padding 2 in the \mathbf{Y} .

$$\mathbf{X} = \begin{bmatrix} 0 & c'_1 & c'_2 & 0 & \dots & 0 \\ b''_1 & a'_{11} & a'_{12} & 0 & \dots & 0 \\ b_2 & a_{21} & a_{22} & 0 & \dots & 0 \\ 0 & 0 & 0 & 0 & \dots & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & 0 & \dots & 0 \end{bmatrix}$$

$$= \begin{bmatrix} 0 & \frac{c_1}{\|\mathbf{c}\|} & \frac{c_2}{\|\mathbf{c}\|} & 0 & \dots & 0 \\ \frac{b_1}{\|\mathbf{a}_1\| \|\mathbf{b}'\|} & \frac{a_{11}}{\|\mathbf{a}_1\|} & \frac{a_{12}}{\|\mathbf{a}_1\|} & 0 & \dots & 0 \\ \frac{b_2}{\|\mathbf{a}_2\| \|\mathbf{b}'\|} & \frac{a_{21}}{\|\mathbf{a}_2\|} & \frac{a_{22}}{\|\mathbf{a}_2\|} & 0 & \dots & 0 \\ 0 & 0 & 0 & 0 & \dots & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & 0 & \dots & 0 \end{bmatrix}, \quad (8)$$

$$\mathbf{Y} = \begin{bmatrix} y_1 \\ y_2 \\ 2 \\ \vdots \\ 2 \\ y_{m+1} \\ y_{m+2} \\ 2 \\ \vdots \\ 2 \end{bmatrix} \quad (9)$$

The y_1 and y_2 in \mathbf{Y} are represented by the binding constraint status (0 or 1) of the constraints from non-negative variables $x_1, x_2 \geq 0$ respectively. The $N + 1$ and $N + 2$ components of \mathbf{Y} are $y_{N+1} = y_{m+1}$ and $y_{N+2} = y_{m+2}$ denoted by binding constraint status of the first and second constraints. By this concept, the LP model can be trained by many LP problem sizes simultaneously without recreating the CNN model for a specific LP size.

All LP problems will be converted to this all-unit-row-except-first-unit-column matrix as LPNet samples for the training and testing phases.

G. LPNet Architecture

The deep Learning model is an automated learning model that mimics the functioning of human neural networks in machine learning. It uses several layers of neurons arranged in sequential order. The target concept from training data will be learned by the weights and biases of all neurons.

Convolutional neural networks (CNNs) are specialized neural network structures capable of classifying image data much better than conventional neural networks. The main idea of CNN is to use a special type of layer called a convolutional layer that extracts parts of an image such as the borders of objects which is the spatial relation and sends to a pooling layer to extract only the information components from the multi-dimensional array. The proposed LPNet architecture needs a special convolutional layer to extract basic elements from the all-unit-row-except-first unit-column matrix of the LP problem in order to make the state-of-the-art CNN model (baseline model) efficiently be trained. The details of LPNet baseline model are shown in Table I which consists of three stages.

The first stage includes RConv layers that extract row and column features and transform them into spatial relations. To capture the spatial information of an LP problem, the special row-column convolutional layer is introduced, as explained in the following subsection. The second stage of the model is the baseline model, which incorporates a state-of-the-art CNN baseline model. Our results show that the best-performing baseline model for LPNet is MobileNet. The final stage of the model is the estimator, which includes fully connected layers. The last layers consist of 600 nodes, representing the optimal binding constraints status of LP problems with up to 300 constraints and 300 variables. Overall, the LPNet model is designed to effectively extract and utilize features from LP problems to identify optimal binding constraints and provide high-quality solutions.

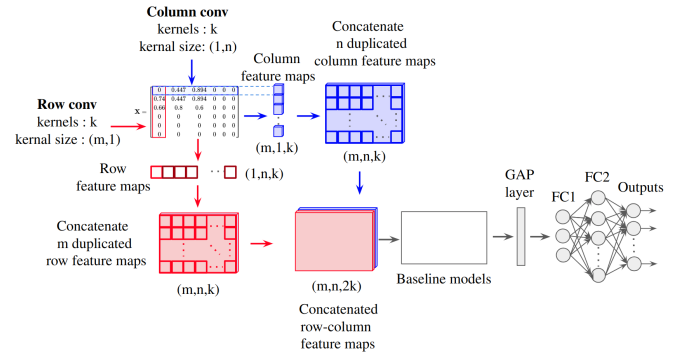

Fig. 3. The LPNet architecture.

H. Row-Column Convolutional Neural Network

In this research, CNN is used to extract features from the relationship between primal constraints and dual constraints using non-square kernels. A normalized input sample is convoluted over the column and the row to obtain row feature maps and column feature maps, respectively, see Fig. 3. Notice that, these row and column convolutional kernels will transform the row-column (primal-dual) information to spatial feature maps before passing to a state-of-the-art CNN architecture.

Primal constraints (rows of \mathbf{X}) will be convoluted by $(1, n)$ kernel size with k kernels for generating $(m, 1, k)$ column feature maps. Similarly, the dual constraints (columns of \mathbf{X}) will be convoluted by $(m, 1)$ row convolution with k kernels in order to create $(1, n, k)$ row feature maps. These feature maps will be duplicated m times for row feature maps and n times for columns feature maps. The duplicated row and column

feature maps will be concatenated to generate two $m \times n \times k$ spatial feature maps, called RConv. Finally, these features will be concatenated by depth to be an $(m, n, 2k)$ input of a baseline convolution architecture.

I. Baseline Convolution Architectures

CNN combines a convolution layer with other types of layers, such as a pooling layer, and then stacks such layer groups on top of each other. Some hyperparameters, such as the size of the kernel, the number of strides, and the number of padding are combined to become the architecture of CNN. There are many state-of-the-art CNN architectures such as ResNet50, MobileNetv1, EfficientNetB1, Xception, and Inceptionv1 which are famous deep models that are successfully learned to classify images. Resnet50 was the first to introduce a residual block concept that makes the model learn some residual features from the earlier layers. Later, the concept of residual blocks is improved using a depthwise convolution in order to reduce model parameters which are called mobilenet blocks. The depthwise separable convolution in the mobilenet blocks makes MobileNetv1 lighter than other baseline models. The mobilenet block concept is continually improved by searching for the best size of the height, width, and depth of convolutional filters from another deep learning model, and then it becomes EfficientNetB0-B7. This paper focuses on EfficientNetB1 which is suitable for LP samples. The idea of using multiple filters of different sizes on the same level is applied in the inception model. Then the inception model instead of having deep layers also has parallel layers thus making the model wider rather than making it deeper. A baseline model will be an engine for extracting features of LPNet after the LP sample is passed into the row-column convolutional layer. The details of the LPNet architecture with the mobilenet baseline convolution model are shown in the next section.

J. Global Average Pooling Layer and Fully Connected Layers

The feature maps from the baseline convolutional layers will be transformed into the spatial dimensions of feature maps by averaging the spatial features into vector features using a global average pooling layer. These vector features are fed to the first fully connected hidden layer. The first two hidden layers consist of 512 hidden nodes with a relu activation function following the batch normalization layer. Since this

paper aims to predict the maximum optimal binding constraints which are 300 constraints and 300 non-negative constraints of decision variables. Then the total number of constraints is about 600. So the last output layer contains 600 nodes with linear activation function in order to estimate the target vector in $\{0, 1, 2\}$, which is representing the optimal binding constraints. The next section will show the experimental results of LPNet models.

It is straightforward to train LPNet in supervised learning. Training LP samples will be transformed to all-unit-row-except-first-unit-column matrices (\mathbf{X}) from Eq. (8) and the optimal binding vectors (\mathbf{Y}) from Eq.(9). The transformed matrices allow the LPNet model to be trained in many LP problem sizes at the same time without reconstructing the individual input sizes. After the trained LPNet is completed then the next subsection shows the inference algorithm of the LPNet model.

K. LPNet Inference

The inference algorithm of LPNet is summarized as follows:

- 1) Compute angles between the gradient vectors of the primal constraints from Eq. (4).
- 2) Rearrange the order of primal constraints (\mathbf{a}_i and \mathbf{b}_i) by descending angles from 1).
- 3) Compute angles between the gradient vectors of the dual constraints from 2) using Eq. (5).
- 4) Rearrange the order of coefficient variables (\mathbf{a}_j and \mathbf{c}_j) from 2) by descending angles from 3).
- 5) Scale down the LP problem (c_j, b_i, a_{ij}) from 4) into (c'_j, b'_i, a'_{ij}) for $i \in \{1, 2, \dots, m\}$ and $j \in \{1, 2, \dots, n\}$.
- 6) If the LP problem size from 5) is the maximum size (m, n) = (N, N) then the input matrix for the LPNet model will be defined by Eq. (6) and then go to 8). Otherwise, go to 7).
- 7) The LP problem will be padded zeros by using Eq. (8) and then go to 8).
- 8) Take the input matrix from 6) or 7) into the trained LPNet model and the result will be a predicted optimal binding vector $\hat{\mathbf{Y}}$.

The experimental results of the row-column convolution layer plus given a baseline model followed by two fully connected layers and the output layer are presented in this section. About one million LP problems are randomly generated and solved for the training dataset and 500,000 LP problems for the testing dataset. Any small size LP problem is padded to have a matrix size of 300x300. All LP problems guarantee to have the optimal solution. The experiments are performed on Intel(R) Xeon(R) CPU @ 2.20GHz 25GB RAM GPU Tesla P100-PCIE on Ubuntu 18.04.5 LTS. It is implemented by Python programming language based on Tensorflow 2.8.0. [29].

IV. ANALYSIS AND RESULTS

A. Performance Measurement

Most deep learning models use the mean squared logarithmic error (MSLE) as the evaluation measure. It is often used in regression tasks for predicting a continuous value. The MSLE

loss function is defined as the mean of the squared logarithmic errors between the predicted values and the true values:

$$L(\mathbf{Y}, \hat{\mathbf{Y}}) = \frac{1}{m+n} \sum_{i=1}^{m+n} (\log(y_i + 1) - \log(\hat{y}_i + 1))^2,$$

where \hat{y}_i is the predicted value, y_i is the true value, and $n+m$ is the number of samples. The logarithmic transformation helps reduce the impact of large errors, which can be useful when working with skewed data or when there are a few extremely large errors that could dominate the loss. Notice that vector \mathbf{Y} contains a large number of 2's, an imbalance problem occurs during model training, and the error value for 2 is larger than the error from 0 and 1, so the trained model will predict 2 more accurately than 0 or 1. This situation is not reasonable for training the deep learning model for predicting binding and non-binding constraints. Therefore, it is necessary to change the scale of the data to a log scale.

Accuracy is a common metric used to evaluate the performance of a machine-learning model which is defined as the percentage of correct predictions made by the model on a dataset. It is often used to evaluate classification models, where the goal is to predict a class label for a given input. In this case, the model's predictions are compared to the true class labels for the inputs, and the percentage of correct predictions is calculated. This paper proposes two types of accuracy that are 0-1 accuracy and 0-1-2 accuracy. The 0-1-2 accuracy is the accuracy of all optimal binding statuses of \mathbf{Y} . $Y_i = 0$ represents an optimal binding constraint i that is $a_{ij}^T x^* = b_i$. $Y_i = 1$ indicates an optimal nonbinding constraint. $Y_i = 2$ shows an auxiliary constraint for padding zeros rows to an (m,n) LP problem as shown in Eq. (8).

$$Acc_{0-1-2}(\mathbf{Y}, \hat{\mathbf{Y}}) = \frac{\sum_{i=1}^N \beta_i}{N}$$

where

$$\beta_i = \begin{cases} 1 & \text{if } Y_i = \hat{Y}_i, \\ 0 & \text{if } Y_i \neq \hat{Y}_i. \end{cases}$$

The 0-1 accuracy is the accuracy without padding status $Y_i = 2$ of a (m, n) LP problem.

$$Acc_{0-1}(\mathbf{Y}, \hat{\mathbf{Y}}) = \frac{\sum_{i=1}^n \beta_i + \sum_{i=N+1}^{N+m} \beta_i}{m+n}$$

The following subsection will show the result of using the different normalizations with LPNet.

B. Normalization Experiment

All normalizations are applied to the row-column-conv MobileNet baseline model with the row-column arrangement of input samples. From Fig. 4, after 25000 iterations the unit-vector normalization can reduce loss values faster than other normalization methods.

As for the error value of the testing dataset shown in Fig. 5, both the min-max method and the standardization method fluctuated significantly more than the unit-vector method because the normalized input samples did not reduce the variation of the input LP samples. For the unit-vector method which

Fig. 4. Error of normalization methods of training dataset.

Fig. 5. Error of normalization methods of the testing dataset.

adjusts the problem to have the same scale, the loss value is more stable. Fig. 5 shows the lowest loss value of these normalization methods.

TABLE II. NORMALIZATION METHODS

Normalization	MSLE	0-1-2 acc	0-1 acc
Standardize	0.0078	0.983	0.957
Min-max	0.0068	0.987	0.967
Unit-vector	0.0034	0.996	0.990

C. Row-column Order Experiment

The lowest loss values of the three normalization methods are shown in Table II. The unit-vector normalization achieves the lowest loss value and gains the highest accuracy both the 0-1-2 accuracy and the 0-1 accuracy.

Table III shows MSLE of a different order of the all-unit-row-except-first-unit-column matrix. The original order column represents the order of rows and columns according to the given LP problem. The rearranged row order represents the order of all primal LP constraints according to the angle

TABLE III. THE AVERAGE MSLEs FROM THE ROW-COLUMN CONVOLUTION PLUS THREE STATE-OF-THE-ART CNNs

Models	MSLE		
	Original order	Rearrange row order	Rearrange row-column order
RCCConv ResNet50	0.0168	0.0213	0.0055
RCCConv MobileNetV1	0.0169	0.0061	0.0034
RCCConv EfficientNetB1	0.0164	0.0164	0.0151

between the row-coefficient vector and the sum vector. The rearranged row-column order represents the order of all primal LP constraints and dual LP constraints. Observe that the arrangement of rows and columns of the input samples shows superior performance over the original order and rearrange of row order only.

D. Baseline CNN Architecture Experiment

The validation dataset loss values of LPNet with different baseline models are displayed in Fig. 6. Our results indicate that the MobileNet model exhibits the most stable convergence compared to other baseline models. This suggests that the MobileNet model is a suitable choice for training LPNet and achieving consistent results.

TABLE IV. THE PERFORMANCE OF STATE-OF-THE-ART CNN ARCHITECTURES

Model	Parameters	MSLE	0-1-2 Acc	0-1 Acc
ResNet50	25,205,080	0.0072	0.986	0.966
MobileNetV1	4,327,640	0.0114	0.974	0.935
EfficientNetB0	5,279,415	0.0092	0.978	0.944
EfficientNetB1	7,805,083	0.0138	0.959	0.896
Xception	22,484,544	0.0070	0.990	0.976
InceptionV3	23,425,848	0.0136	0.962	0.902
RCCConv ResNet50	25,422,232	0.0055	0.992	0.981
RCCConv MobileNetV1	4,365,368	0.0034	0.996	0.990
RCCConv EfficientNetB0	5,317,269	0.0049	0.993	0.983
RCCConv EfficientNetB1	7,842,937	0.0151	0.954	0.882
RCCConv Xception	22,522,272	0.0049	0.992	0.982
RCCConv InceptionV3	23,463,576	0.0088	0.979	0.947

All experiments use the row-column arrangement of input samples. MSLEs of all architectures with RCCConv is smaller than the one without. Especially, the MobileNet baseline with RCCConv obtains the lowest loss and the best 0-1-2 accuracy as shown in Table IV.

The results of RCCConv MobileNetV1 in Fig. 7 show the average of all correctly optimal binding predictions (1.0 acc) with respect to many LP problem sizes. LP size ratios (d) are defined as the following conditions:

$$d(m, n) = \begin{cases} \frac{n-m}{n} & \text{if } n > m, \\ 0 & \text{if } n = m. \end{cases} \quad (10)$$

Fig. 7 shows the number of LP models that LPNet can predict all optimal constraints of different ratios of d . When d

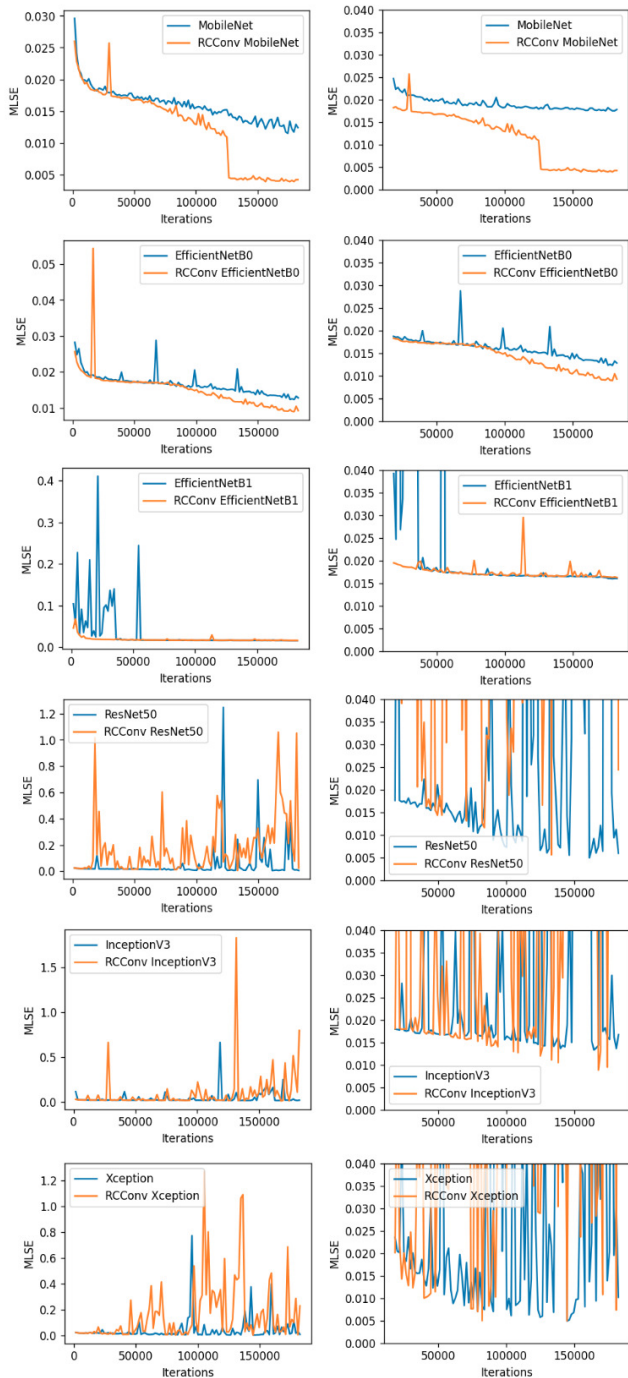

Fig. 6. Mean log square error of CNN baselines and RCConv CNN baselines of the validate dataset.

= 0, it means the number of constraints is equal to the number of decision variables. LPNet can predict all optimal binding constraints of LP problems over 80% when $0.2 \leq d \leq 0.3$. However, this model also suffers from an imbalance problem and many LP problems are infeasible if $m > m$ or $d > 0.8$. The next subsection shows the speed gain using LPNet to obtain the optimal solutions for LP problems.

From the above results, an optimal solution can be directly

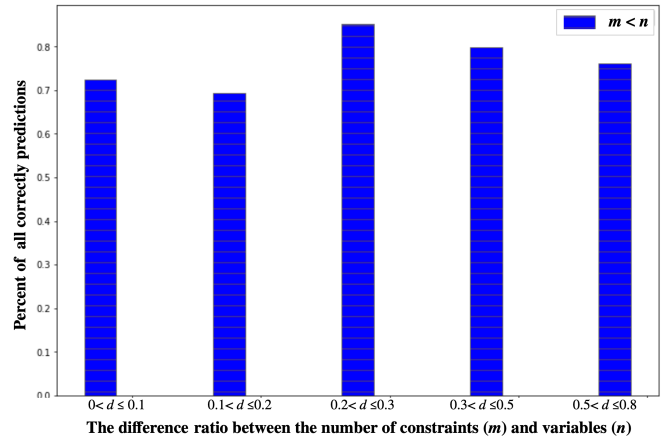

Fig. 7. The bar chart shows the average number of predicted optimal binding constraints that are correctly all components of Y depending on the LP problem ratios d .

obtained by solving the system of linear equations. There are n predicted constraints from $x_j \geq 0$ for $j \in \{1, \dots, n\}$ and $a_{ij}x_j \geq b_i$ for $i \in \{1, \dots, m\}$ that can be selected to solve the exact optimal solution. Fig. 8 shows the average total time for solving the LP problems where the number of constraints and variables are the same. The proposed LPNet algorithm saves a lot of time compared with the commercial solver Cplex [31]. The lowest solution time of the biggest LP size is 0.076 sec on GPU (Tesla-T4) using numpy.linalg solver. However, results are slightly longer on CPU (Xeon(R) 2.20GHz). Fig. 9 shows the average total time where $m < n$ and $n = 300$. LPNet GPU is also faster than LPNet CPU and the Cplex solver. LPNet GPU achieves 7.5 times faster than the cplex solution time.

Fig. 8. Total LP solution time for the number of constraints equal to variables.

E. Netlib Dataset

Netlib is a collection of mathematical software, algorithms, and databases that were widely used in the scientific and engineering communities during the 1980s and 1990s. The dataset contains software packages for optimization, linear algebra,

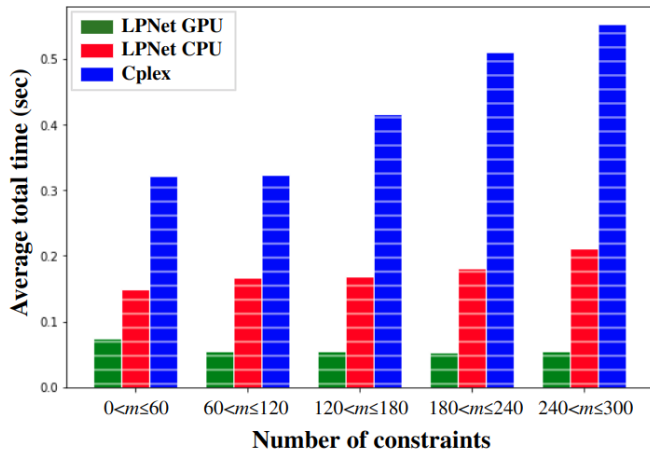

Fig. 9. Total LP solution time for the number of constraints with 300 variables.

differential equations, and other areas of scientific computing. It also includes benchmark datasets, including the Netlib LP dataset, which is a collection of linear programming problems commonly used to evaluate and compare the performance of optimization algorithms. Today, Netlib serves as an archive of legacy software and algorithms and is still widely used in academic research and education as a reference resource.

Table V lists selected LP problems from netlib having m and n less than 300. All of them can be directly sent to LPNet to identify the optimal solution.

F. Convolution Analysis

A visual explanation for explaining the relation between a target class and outputs of a CNN layer is introduced by Grad-CAM [30]. The main concept is to choose an interested target class in \mathbf{Y} and take a partial derivative from the output-predicted class with respect to output feature maps of the interested CNN layer for measuring a gradient size corresponding to the sensitive area of the CNN feature maps. The

output feature maps of each CNN layer can be localized maps highlighting important regions related to the target class.

Fig. 10. Output feature maps of convolutional layers of the RCConv MobileNet baseline.

Fig. 10 shows the gradCAM heatmaps of each layer of one of the test problems of size 292×292 from LPNet with the MobileNet baseline. The all-unit-row-except-first-unit-column matrix of the test problem is plotted at the top left of Fig. 10. The second sub-figure to the right comes from the row-column convolutional layers (RCConv) which combine spatial information of rows and columns. By the concept of padding 0, the pixels over the 292×292 rows and columns respectively generate the dark color. The conv1_relu layer will be convoluted and reduced dimensions by half to get a general concept that is related to the prediction $\mathbf{Y}_i = 0$ for $i \in \{0, \dots, 600\}$. MobileNet architecture has a lot of depthwise and pointwise convolutional layers for reducing many parameters compared with regular convolutional layers. Until the last pointwise CNN layer (conv_pw_13_relu), there are some feature maps that respond to the optimal binding prediction. Notice on the highlighted heatmap RCConv to conv_pw_5 layer, LPNet is extracting the sensitive area in terms of highlighted rows which corresponds to the optimal binding constraints. The higher layers will be convoluted and reduced dimensions in order to embed the important features as shown in the conv_pw_13_relu heatmap.

Further, three feature maps of all CNN layers can be localized by gradCAM for nonbinding constraints and padding constraints status in \mathbf{Y} as shown in Fig. 11. For the output layer of LPNet with the MobileNet baseline, the prediction gives three possible prediction statuses which are 0, 1, or 2.

Fig. 11. GradCAM heat maps of the last CNN layer (conv_pw_13_relu) depend on the specific classes in \mathbf{Y} .

The important area of the specific status related to the last convolution (Conv_pw_relu) is shown in Fig. 11. In order to investigate where are the optimal binding constraints, the heatmaps from the gradCAM technique will only consider the prediction at $\mathbf{Y}_i = 0$ for $i \in \{0, \dots, 600\}$ as shown in the left Fig. 11. The middle figure shows the heatmaps of nonbinding constraints that are $\mathbf{Y}_i = 1$ for $i \in \{0, \dots, 600\}$. The heatmaps of the right figure are represented by the padding status $\mathbf{Y}_i = 2$ for $i \in \{0, \dots, 600\}$. Moreover, this heatmap shows the separated area of binding constraints, non-binding constraints, and padding.

Fig. 12. Both heatmaps show the area highlight of the optimal binding constraints status ($0 \in \mathbf{Y}$) from non-negative variables and regular constraints, respectively.

Fig. 12 shows the localized heatmaps that are related to the non-negative constraints of variables from 1 to 300 and the original constraints from 301 to 600. It indicated that LPNet tried to capture the dual constraints see the left figure with highlight columns that relate to the non-negativity constraints and the right figure shows the highlight of heatmaps that affect the original constraints.

V. DISCUSSION

This LPNet model has a limitation that it works for any linear programming problem having sizes less than 300 rows and 300 columns due to the hardware limitation. To solve a linear programming problem of larger sizes, new training data must be synthesized and solved and weights of the state-of-the-art deep learning model must be retrained on large system resources.

For the perfect prediction of the optimal binding constraints, LPNet determines the optimal solution of a linear

programming problem algebraically, without the need of an iterative step. However, if the prediction is not 100%, some constraints are not the optimal binding constraints. The real optimal constraints must be reidentified. So this work can be extended using the iterative procedure after the optimal binding prediction. A complete linear programming solver utilizing the predicted optimal binding constraints could be created.

In 2023, [25] introduced a novel deep learning approach using feedforward neural networks to solve the LP problem. The approach models the LP problem by an ordinary differential equations (ODE) system, the state solution of which globally converges to the optimal solution of the LP problem. A neural network model is constructed as an approximate state solution to the ODE system, such that the neural network model contains the prediction of the LP problem. The neural network is extended by taking the parameter of LP problems as an input variable so that one neural network can solve multiple LP instances in a one-shot manner. However, it is important to note that the proposed method's performance has only been tested on a specific collection of small LP examples. Its efficacy on more complex or diverse LP problems remains uncertain.

Overall, LPNet provides a promising approach for identifying optimal binding constraints in LP problems, which can greatly reduce the computation time required for traditional iterative solvers. With further development of the algorithm, LPNet has the potential to become a powerful tool for solving complex LP problems in various fields.

VI. CONCLUSIONS

This paper presents the deep learning architecture for identifying the optimal binding constraints called LPNet. A linear programming problem must be cast as the all-unit-row-except-first-unit column matrix with row-column rearrangement before sending it to LPNet. LPNet is composed of the row-column convolutional layer followed by the state-of-the-art convolutional neural network models and two fully connected layers of neural networks and ends with the output layer. With RCCConv + MobileNetV1 + two fully connected layers + output layer, LPNet achieves 99.6% 0-1-2 accuracy from a million synthesized linear programming problems with finite optimal solutions.

The form of the all-unit-row-except-first-unit column has been studied to show the performance obtained for scaling to unit-vector over the max-min normalization and the standardization of rows. Moreover, the arrangement of rows and columns also helps reduce training loss.

LPNet is able to predict 80% of linear programming problems with all optimal binding constraints from generated linear programming problems and it correctly predicts 86% benchmark netlib problems of size smaller than 300 variables and 300 constraints. It can achieve the optimal solution faster than the cplex solver more than 6 times.

In general, any LP problem may not have an optimal solution. It will be very useful to design deep learning to categorize LP problems whether they are infeasible, unbounded optimal, or have a finite optimal solution. Moreover, LPNet weights can be used to accelerate the solution time of any commercial LP solver.

Abstract—According to the World Health Organization, epilepsy affects more than 50 million people in the world, and specifically, 80% of them live in developing countries. Therefore, epilepsy has become among the major public issue for many governments and deserves to be engaged. Epilepsy is characterized by uncontrollable seizures in the subject due to a sudden abnormal functionality of the brain. Recurrence of epilepsy attacks change people's lives and interferes with their daily activities. Although epilepsy has no cure, it could be mitigated with an appropriated diagnosis and medication. Usually, epilepsy diagnosis is based on the analysis of an electroencephalogram (EEG) of the patient. However, the process of searching for seizure patterns in a multichannel EEG recording is a visual demanding and time consuming task, even for experienced neurologists. Despite the recent progress in automatic recognition of epilepsy, the multichannel nature of EEG recordings still challenges current methods. In this work, a new method to detect epilepsy in multichannel EEG recordings is proposed. First, the method uses convolutions to perform channel fusion, and next, a self-attention network extracts temporal features to classify between interictal and ictal epilepsy states. The method was validated in the public CHB-MIT dataset using the k-fold cross-validation and achieved 99.74% of specificity and 99.15% of sensitivity, surpassing current approaches.

Keywords—Epilepsy; epilepsy detection; EEG; EEG channel fusion; convolutional neural network; self-attention

I. INTRODUCTION

Epilepsy is a neurological disease that disturbs the normal functionality of the brain [1]. Epilepsy provokes sudden seizures in the subject, which go from subtle loss of gaze to violent convulsions of the body and extremities, often jointly with fainting, salivation up to the subject's unconscious [2]. Epileptic seizures are produced by a sudden abnormal activity of neurons. The cause that fires such abnormality is still unknown [3]. Recurrence of seizures disrupt the patient's daily activity and damages his personal life, even acquiring additionally psychological illness, such as depression, anxiety, and schizophrenia [4]. Furthermore, patients with epilepsy are often excluded and stigmatized by society [5].

Epilepsy can affect any people without condition of age, gender, or race [6]. According to the World Health Organization (WHO) [7], there are more than 50 million of people suffering of epilepsy around the world, and 80% of patients

live in low income countries, facing difficulties in accessing medical services and treatments in order to alleviate the undesired symptoms of epilepsy [8]. As a results, epilepsy has become in a public health problem for many governments and it deserves to make efforts to improve the quality of life of millions of patients with epilepsy [9].

Since the invention of the electroencephalogram (EEG) in 1929, EEG has widely used to study the brain functionality and its associated diseases [10]. Thereby, EEG has become in the standard medical device to detect and diagnose epilepsy due to its easy to use, non-invasive nature, non-age restriction, and real-time sensing features [1]. An EEG records the electric potential generated by neurons while interacting with each others. To do that an EEG employs an array of electrodes which are tied to the head scalp. As a result, an EEG recording provides multiple time-varying signals, one signal for each electrode [1], [2], [11]. As illustration, Fig. 1 shows an EEG recording of three signals from three electrodes.

In order to diagnose epilepsy using EEG, the EEG recording of a patient is analyzed by the neurologist, who performs a visual exploration of signals and searching for spikes, sharp, and slow wave patters that characterize an epileptic seizure [12]. However, epileptic disease can vary widely and shows a wide range of symptoms in patients. As a result, the traditional visual analysis of EEG recordings to diagnose epilepsy is a time-consuming process and quite prone to misdiagnose [13], [14]. Misdiagnosis may lead to maltreatment with undesirable consequences for the patient [15]. Thus, a proper diagnosis of epilepsy is very important in order to provide proper treatment.

Over the past decade, many studies have been carried out with the aim of developing automatic systems for the detection of epilepsy [16], [17], [18] and towards the prediction of seizure episodes [19], [20], [21], [22]. Most studies exploit machine learning (ML) and deep learning (DL) algorithms to build classification models capable of detecting seizure patterns in EEG records. While ML employs hand-crafted features, DL has the capability to learn automatically a rich set of features from training data, offering a more flexible feature space for modeling [23].

Despite the recent advances, detecting epileptic seizures still defies current methods and there are still many unresolved problems. This work addressees two major questions that are

stated below:

- 1) An EEG device has several electrodes for more accurate medical diagnosis. Although there are methods for merging multiple EEG signals, the method that best suits for an optimal combination of EEG information coming from multiple electrodes is still undefined.
- 2) The epileptic seizure detection is an unbalanced classification problem in essence, with long hours of normal states (or non-seizure episodes) and a few seconds of abnormal states (seizure episodes). Most existing approaches use certain sampling criteria to balance the number of samples in the training and testing set; however, the effect of using the full dataset on classification performance remains unknown.

So, the main contribution of this study is twofold:

- 1) An improved EEG channel fusion method for an optimal combination of information from multiple EEG signals, while increasing the classification performance. The proposed classification model firstly uses convolutions to merge EEG channels and increase the representativeness of input signals. Next, a self-attention transformer extracts temporal features of the fused signal to improve the classification performance.
- 2) The use of a data augmentation method and a weighted loss function that enables the use of large and unbalanced EEG datasets, while improving classification performance.

The remainder of this paper is organized as follows. Section II exposes the background about epilepsy, as well as, the related work. Section III summarizes the methods employed to detect epileptic seizures. Section IV presents the results achieved and provides an analysis of the results compared to previous work. Finally, Section V enlists the findings of this work and the forthcoming investigations.

II. BACKGROUND

The EEG is the standard device to detect and diagnose epilepsy and other brain diseases [1]. An EEG records the electrical activity of the brain for a certain interval of time (minutes, hours, days) and results in a recording file for further visual analysis by the neurologist [24]. To overcome the time-consuming and visual demand process of the traditional analysis of EEG recordings, many automatic methods have been proposed; being the majority of current methods based on DL algorithms [16], [17], [18]. In this way, the detection of epileptic seizures is commonly stated as supervised classification problem of two classes or binary classification [25], [23].

In order to build a classification model, an enough EEG data should be available. However, typically, researchers do not use all EEG data to avoid unbalance between classes and to reduce the computational burden. Instead, they use specific segment of signals from an EEG recording as training. In such manner, it is common that selected segments correlate the phases of epilepsy experienced by the patient. According to the process of epileptogenesis [19], [26], [1], a patient faces

four phases of epilepsy: interictal, preictal, ictal, and postictal. The ictal phase is the seizure episode or attack episode, and the other phases are located in temporal reference to this state. Thereby, the interictal phase is the state a few hours away of a seizure and is considered as the normal state of the patient; the preictal phase is the state of the minutes preceding a seizure; and the postictal phase is the state of the minutes after a seizure. It is worth mentioning that there is still non-consensus in the duration of such stages due to the variability of the epilepsy disease, with the exception of the seizure state [27], [28], [29]. Fig. 1 shows the four phases of epilepsy in an EEG recording of three channels. Note that the seizure (ictal) phase duration is too short in the recording and this makes the EEG data very unbalanced. In addition, because of the diversity of epilepsy among patients, seizure patterns are too diverse and are the main challenge for learning algorithms. Fig. 2 illustrates the seizure segment which is red shaded, showing variability of the signals between EEG channels.

Fig. 1. Epilepsy phases in a long time EEG recording. For convenience, only three channels are plotted.

Fig. 2. The epilepsy seizure stage into an EEG recording. The seizure is red shaded, whereas the non-seizure parts are green shaded. For convenience, only three channels are plotted.

Aiming to build a classifier for seizure detection, most researchers use interictal and ictal signals as input data [26], [30], [31], [32], [33], and other investigators use preictal and ictal stages as input data [34], [35], which is also used for researchers that intend to predict a seizure attack [28], [22]. Either using interictal and ictal or preictal and ictal to develop a seizure detector, the classifier is trained to learn how to discriminate between normal and abnormal signals, or non-seizure and seizure segments. On the other hand, tanking into account the classification performance, although the authors

have reported high accuracies in their model performance, the majority of the results are not reproducible due to the lack of consensus on the selection of the portion of the signals used for model training and testing.

Dealing with the problem of epilepsy detection, another issue arises during data selection for training a model: the selected signals are too unbalanced because the patients stay many hours normally (interictal phase), but stay just a few seconds of a seizure (ictal phase) [36]. The high unbalance of classes often cripples any learning algorithm [25]. To overcome class imbalance, researchers have proposed undersampling the majority class, oversampling the minority class, and some data augmentation. It is common to find methods which combine majority class undersampling with increasing minority class data [18]. For data augmentation, the method of sliding a window with overlap has provided great results [37], [34], [31] when compared to the generation of new samples by a specialized model [36].

Another problem that hinders epilepsy detection is that EEG recordings are inherently multichannel data. This is because EEG employs an array of electrodes to record the brain activity in many different locations of the head at a given time. So, an EEG recording consists of spatio-temporal sample points recorded by each electrode. For medical diagnostics of epilepsy, EEG headsets with as many electrodes as possible are preferred in order to reach a higher performance in detection, e.g., an EEG with 19 electrodes arranged according to the international 10/20 system [38]. On the other hand, for non-medical applications, an EEG with fewer electrodes is enough [39], e.g. mental fatigue detection in drivers.

In medical diagnosis using EEG, simultaneous EEG signals increase the visual effort of the neurologist and make it prone to misdiagnosis. With the goal to develop robust automatic system for epilepsy detection, the multichannel issue, also named spatial filtering [40], should be addressed. While some researchers have searched for the most discriminative channel that allows the best classification, a few researchers have proposed a specific method to combine multichannel EEG signals. The former strategy consists of evaluating EEG channels, one by one, and selecting the channel that provides the best performance [20]. This procedure might be slow and the trained model relies heavily on the domain of application, e.g., epilepsy detection [41], [42], mental fatigue detection [43], and active brain computer interfaces (BCI) [40]. The latter strategy consists of designing a specific method that carries out the combination of multiple EEG signals. The main advantage of these methods is that they are more scalable and independent of the application domain [35].

More specifically, although the combination of EEG channels might be performed using learnable DL-based models, there are some mathematical transformations to merge multiple EEG channels into single channel, such as the common spatial pattern (CSP) [44] and the Choquet fuzzy integral [45]. Actually, the CSP is still widely used and actively studied to overcome the limitation of the original CSP [46], [47], [33].

On the other hand, some researchers have leveraged the latest developments in DL and have proposed methods to discriminate between non-seizure and seizure segments while combining multiple EEG channels. Usually, these methods are

based on convolutional neural networks (CNN) and long short-term memory (LSTM) neural networks, which are able to learn both spatial and temporal features from training data [48], [34], [35]. As a results, different DL-based models have been proposed for epilepsy detection, such as based only in CNN models [26], [31], only in LSTM models [35], or CNN-LSTM hybrid models [42], including the plethora of LSTM variations like the bidirectional-LSTM and nested-LSTM [49], [50], [51]. Recently, the self-attention transformer [52] has also been introduced to classify EEG signals due to its ability to capture long-term temporal dependencies analogously to the LSTM network [53]. In spite of recent advances, the question of how to combine several EEG signals whilst increasing classification performance remains unanswered.

Because our approach proposes to take advantage of recent advances in DL, this work has looked at the latest approaches focused on detecting epilepsy using DL and the largest EEG database CHB-MIT [54]. As follows, we sum up the most important related works which have established the current state of the art (SoA). Furthermore, this study takes into account the works that employ interictal and ictal signals as input data due to two reasons. First, interictal and ictal signals are used by the majority of studies as input data source. Second, interictal and ictal segments seem the correct way to discriminate between normal and abnormal states of an epileptic patient due to higher performance that it provides rather than other sources of data.

One of the first works that applied DL towards seizure detection is the work of Zhou et al. [26]. The authors use CNN to detect seizure at a level of patient. The model consists of a 2D convolution layer, an activation function, a 2D max-pooling, and followed by a fully connected (FC) layer for classification. The input data is extracted from the interictal and ictal signals of epilepsy, and next, they were split into time windows of 1 sec. Two experiments were carried out using two different data sources: using time-domain signals and using 2D-spectrogram. Spectrogram is computed using the fast Fourier transform (FFT) for each time window and its channels, and next, they are concatenated along the depth. Assessing the model performance in the CHB-MIT dataset, the use of spectrogram outperforms the time-domain input data, 97.5% against 62.3% of accuracy, respectively. However, because the model is too simple, the high gain may result from data preparation rather than from the data source used (e.g., spectrogram images are normalized between 0 and 1, while time-domain signals not). Also, no information is provided about the data selection process, neither about the treatment of unbalancing between interictal and ictal samples. In contrast, recent approaches mainly use time domain signals, but increasing the model complexity.

Then, Hossain et al. [34] proposed a specialized EEG channel fusion layer before temporal feature extraction for seizure detection. In a cross-patient scheme, input data belongs to preictal and ictal stages, which are split into time windows of 2 sec, 80% overlap. The model contains four CNN blocks. Each block consists of a convolution, an activation function, and a max-pooling. However, the first block is slightly different: first, a convolution operates along time, and next, a convolution operates along channels, both performing feature extraction, then an activation function is applied. Assessing

in the CHB-MIT dataset, the model achieved a sensitivity of 90%, a specificity of 91.65%, and an accuracy of accuracy of 98.05%. Despite the reported high performance, the data selection is unclear and number of seizures recognized is unknown.

Later, Gao et al. [55] proposed to classify image spectrogram of EEG signals by using transfer learning. The authors stated a classification problem of four classes: interictal (selected from two hours away from the ictal), preictal I (selected from 30 min before the ictal), preictal II (chosen 10 min before the seizure), and ictal. First, only 11 patients were selected from the CHB-MIT dataset. Then, signals are cleaned using the discrete wavelet transform (DWT) and split into time windows of 4 sec. Next, time-domain signals are converted to spectrogram images. A data augmentation of ictal signals is employed using a sliding window with 50% overlap. The authors use three pretrained models from image classification task, Inception-ResNet-v2, Inception-v3, and ResNet152, whose outputs are fed to two FC layers of 1,024 and 512 neurons that are used for classification. Validation is performed in a hold-out cross-validation, 70:30, achieving a sensitivity of 95.8% and a specificity of 99.3% detecting the ictal state.

Then, Li et al. [30] proposed a hybrid architecture of CNN and nested LSTM networks. The model consists of three 1D-CNN layers and 100 nested cells of LSTM. Data was carefully selected from interictal and 135 seizures, which are split into time window of 4 sec. Each time window is reshaped in such a way that EEG channels are as features to be processed by the 1D-CNN, and then, after feature extraction, output features are fed to a FC layer of 50 neurons before classification. The model achieved 95.42% of sensitivity, 95.29% of specificity, and 95.29% of accuracy in a 10-fold cross validation. Although the achieved metrics are higher, this is because seizures to be detected have been carefully selected and reduced to 135.

Next, Wang et al. [31] proposed to classify interictal and ictal signals using only a 1D-CNN model. Selected signals is split into time windows of 2 sec and a data augmentation is applied just to ictal segments with 50% overlap. The model architecture consists of two CNN heads, like an ensemble, whose outputs are fed into two FC layers of 256 and 128 neurons before classification. The model validation is performed in a k-fold cross validation scheme, but at level of seizures in the dataset. Working with 145 seizures, the model achieved in average 88.14% of sensitivity, 99.62% of specificity, and 99.54% of accuracy. It is noticeable that 1D CNN alone does not provide a reliable sensitivity to detect epileptic seizures.

Later, Abdelhameed et al. [32] proposed a 2D autoencoder (AE), together with a LSTM network to classify interictal and ictal signals. Data from 16 patients are selected according to the age criterion within the CHB-MIT dataset. Next, the whole dataset is standardized at once, and later, data is split into time window of 4 sec. Then, each window is normalized to 0-1 to ensure reconstruction by the AE. The AE module consists of four layers of conventional 2D-CNN for encoding and decoding. The classification module employs the latent encoded vector as input data and consists of a LSTM network, followed by a FC layer of 256 neurons. The method was assessed in a 10-fold cross validation, achieving $98.72 \pm 0.77\%$ of sensitivity, $98.86 \pm 0.53\%$ of specificity, and $98.79 \pm 0.53\%$

of accuracy. Despite reported the performance is too high, the standardization of the whose dataset before data splitting is not according to ML practices [25].

As exposed above, CSP still is used for EEG channel fusion and the proposal of Li et al. [33] have reported recently high performances in 5-fold cross validation. The authors used the empirical mode decomposition (EMD) to increase the signal-to-noise ratio before to apply CSP. Next, a support vector machine (SVM) is trained using the variance of signals as input features. The method achieved in average, 97.34% of sensitivity, 97.50% of specificity, and 97.49% of accuracy. Despite the sensitivity is higher, the number of detected seizures is just 131, which have no explanation of their selection criteria.

More recently, the self-attention transformer has been introduced in many areas and is widely used for natural language processing (BERT, GPT-3), image classification (vision transformer-ViT), and others applications [56]. In this way, Pan et al. [53] proposed a transformer model to detect epilepsy. Dataset is prepared as non-epilepsy and epilepsy segments, and next, data is split into time windows of 4 sec, with 50% overlap. Also, to ensure balanced samples, an undersampling of the majority class is carried out. Finally, only three EEG channels are fed to the transformer encoder, whose outputs are send to a FC layer for classification. Evaluation in a 5-fold cross validation, the model achieved 94.96% of sensitivity, 93.97% of specificity, and 94.46% of accuracy. Despite the high performance, the authors do not provide sufficient information about what EEG channels are use as input data, and which phase of epilepsy is considered as non-epilepsy and how is trained the model with a fair five thousand samples of each class.

It should be mentioned that previous studies have used certain sampling criteria to balance the number of samples in each class, regardless of whether or not they have used any method of data augmentation. However, the joint use of data augmentation and weighted loss function methods has not been fully explored and remains also as an open question.

This work addresses two main issues outlined above: combining EEG channels as well as the joint use of data augmentation and weighted loss functions in order to increase the classification performance towards epileptic seizure detection.

III. OUR APPROACH

Fig. 3 presents the general pipeline to detect epileptic seizures in EEG recordings. First, a brief description of the dataset is furnished. Then, the preprocessing methods used are described. Next, the neural network model that performs EEG channels fusion and involves a transformer network is presented. Finally, the classification step is performed and the model performance is validated.

As follows, a deep description of each step of the pipeline is provided.

A. EEG Dataset

The EEG data used in this study comes from the CHB-MIT public dataset [54] and contains almost 980 hours of EEG recordings and 198 seizures. The dataset was collected from 23 pediatric patients with incurable epilepsy, 3–22 age. The

Fig. 3. The epileptic seizure detection pipeline.

recording chb21 was obtained 1.5 years later from the same patient chb01, and because seizure patterns are different, this is treated as a new patient’s recording.

Recordings are stored at the sampling frequency of 256 Hz and different EEG devices with different number of electrodes/channels were employed during recording of data, however, EEG recordings of 23 channels are the most common in the dataset. To release the dataset, longtime recordings were usually split into one hour long recording, and sometimes into two or four hours long recording. EEG recordings that contain seizures are referred to as seizure records; otherwise, non-seizure records. As ground truth (GT), the dataset provides the start and end for each seizure in the seizure record.

B. Preprocessing

In this stage, two main processes are performed: data selection and data windowing.

The former process, data selection, aims to select the EEG recordings and their signals to be used to train a model. In previous studies [16], [17], [18], researchers have found that interictal and ictal signals are the best ones to discriminate between NON-SEIZURE and SEIZURE sample data (see Fig. 1 to illustrate about these epilepsy phases). In addition, researchers have used recordings of 23 channels to overcome the diversity of EEG montages in the CHB-MIT dataset. In this work, we also use interictal and ictal signals among the EEG recordings of 23 channels which involve 181 seizures. Interictal data consist of signals two hours away of a seizure (we name non-seizure signals). On Further, ictal data consists of each seizure signals from all patients (we name seizure signals). Moreover, to reduce computations, signals were downsampled to 128 Hz because it does not affect the classification performance [57]. Moreover, no filtering technique is used as in previous studies [26], [32], [20].

The latter process, data windowing, aims to split the selected EEG segments into small processable time windows. A time window is the sampling unit and is used as input data of the model. This work uses a time window of 1 sec. Besides, in order to mitigate the unbalancing between non-seizure and seizure samples, data augmentation is applied to seizure signals. The data augmentation strategy consists in sliding a window with 80% overlap. Fig. 4 delineates the approach of data splitting and data augmentation employed in this work.

C. Neural Network Architecture

Fig. 5 depicts the proposed neural architecture for epilepsy detection. The neural model receives the time windows as input data. Input data is in time-domain window. Then, it performs

Fig. 4. Data windowing of non-seizure and seizure signals. The image in the top row illustrates the splitting of non-seizure data. The image in the bottom row shows the simultaneous splitting and augmentation of the seizure data.

EEG channel fusion and extracts features for classification. Finally, the model predicts outputs in the form of two categorical data: either non-seizure (interictal) or seizure (ictal) class.

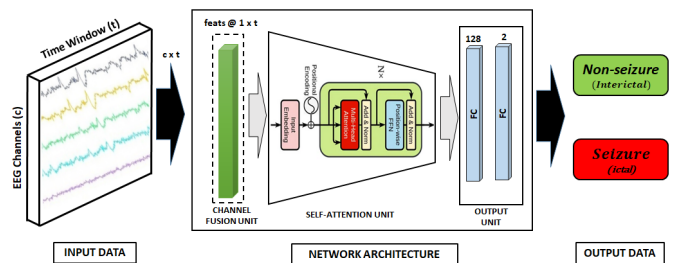

Fig. 5. The neural network architecture.

In brief, the neural network consists of three basic units. First, the Channel Fusion Unit fuses the information coming from different EEG channels into a single channel signal. Second, the Self-attention Unit extracts temporal features based on the previous single channel signal. Third, the Output Unit combines the learned representations for a successful classification.

In this work, the Channel Fusion Unit is inspired by the study of Hossain et al. [34], however, with a slight variation. In our case, once EEG channels are combined, two additional convolutions still refine the spatial features using a small kernel size to diminish the computation burden. The Self-attention Unit is based on the classical transformer architecture proposed by Vaswani et al. [52] and processes the enhanced single channel signal to learn long temporal dependencies of the signal. Ultimately, the Output Unit consists of two layers of fully connected neurons and performs classification.

Table I details the neural network architecture and its parameters. The input data consists of a 2D matrix $X^{c \times t}$, where c is the number of EEG channels (23) and t is the number of time points in the time window (128).

D. Classification

After model training, it is capable to classify non-seizure versus seizure sample units. To predict the label class, the latest layer of the model employs the Softmax activation function to estimate the probability distribution of the input data [25].

TABLE I. DETAILS OF THE PROPOSED NEURAL NETWORK.

Unit	Layer	Output size	Parameters
-	Input	23x128	-
Channel Fusion Unit	Conv 11	23x128x16	kernel 1x3, map 16, None

E. Experimental Design

In order to evaluate the feasibility of the proposed neural architecture and to compare its performance with related work, the model is validated using the k-fold cross validation (k=5). The k-fold cross validation was widely employed in previous studies to validate their model performance [16], [17], [18]. However, to ensure a fair assessment and comparison of model performance, in addition to the accuracy, the sensitivity, specificity, precision, and F1-score should be used as validation metrics, because detecting epilepsy is an extremely unbalanced classification problem [25].

IV. RESULTS AND DISCUSSION OF RESULTS

The proposed model is implemented in the Python 3.9 environment and the Pytorch 1.13 deep learning framework and runs in a computer desktop with a GPU NVIDIA GeForce RTX 2070 Super. The hyper-parameters used to train the model are: the Adam optimizer, the cross-entropy loss function which should use normalized weights depending on the proportion of samples from each class in the training set (the larger the number of samples of the class, the smaller the weight, and conversely), the batch size of 128, the learning rate of 1e-4, and 150 number of epochs for model training.

The model performance is assessed using the 5-fold cross validation, and the achieved results are shown in Table II. The results follow the format of the average plus/minus the standard deviation. The proposed model achieved 99.74 ± 0.08 of sensitivity and 99.15 ± 0.1 of specificity detecting epilepsy patterns, with high precision and great F1-score.

TABLE II. CLASSIFICATION PERFORMANCE OF THE PROPOSED MODEL USING 5-FOLD CROSS VALIDATION IN THE CHB-MIT DATASET.

Classifier	Sensitivity	Specificity	Precision	F1-score	Accuracy
This work	99.74 ± 0.08	99.15 ± 0.1	97.66 ± 0.71	98.4 ± 0.32	99.68 ± 0.06

To ensure an equitable and fair comparison of our achieved results against related work, we selected the most recent SoA methods that use interictal and ictal signals as input data and validate their results using the k-fold cross-validation scheme. Table III summarizes the performance reported by several SoA studies.

On the other hand, there are studies that have presented some specific EEG channel fusion approaches, like Hossain

et al. [34] and Chakrabarti et al. [35] for epilepsy detection using preictal and ictal signals, and the work of Gao et al. [58] for fatigue detection in drivers. Because the source of data to train and test their models differs from ours, we implemented such models and trained them using their own suggested hyperparameters for a fair comparison of performance. These studies are highlighted with an * in Table III.

After reviewing Table III, it can be seen that our model is significantly better than models that do not perform channel fusion, being the work of Abdelhameed et al. [32] the only one that comes close to our results, however, the authors just worked with 86 seizures from 16 subjects.

On the other hand, comparing our results against approaches that specifically perform EEG channel fusion, first, it is interesting to observe that the study of Li et al. [33] achieves a higher sensitivity and specificity of almost 97% working with 131 seizures. As this work uses CSP/EMD to fuse EEG channels, we can deduce from this that working with all EEG channels or searching for the best single channel is not good enough for the model, even using the most advanced transformer architecture like in the study of Pan et al. [53]. As a result, fusion of EEG channels before feature extraction can be quite advantageous.

Next, we compare our results against approaches that perform specialized EEG channel fusion based on neural networks. In this way, the study of Hossain et al. [34] implements the channel fusion before the feature extraction, whereas the study of Gao et al. [58] and Chakrabarti et al. [35] implement the channel fusion after feature extraction. Again, it is noted that channel fusion approaches work better than non-channel fusion approaches. Taking into account the achieved performances in descending order, they go from Chakrabarti et al. [35], Gao et al. [58], to Hossain et al. [34]. It seems that EEG channel fusion also is feasible before and after temporal feature extraction. However, our approach, that simultaneously fuses EEG channels and enhance spatial features at input data level before feature extraction, and next, leverages a simple self-attention transformer, outperforms all these approaches and provides the highest sensitivity and specificity to classify between non-seizure and seizure EEG signals.

V. CONCLUSION

In this work, a new approach to detect epileptic seizures has been described. The method is based on a specific channel fusion layer that optimally combines multiple EEG channels into a single channel and enhances spatial features. Then, a simple self-attention transformer is employed to extract temporal features in order to improve the classification performance.

The feasibility of the method was validated in the public CHB-MIT EEG dataset using 5-fold cross validation. In a highly unbalanced dataset and assessing 181 seizures from 24 patients, the proposed model achieved 99.74 ± 0.08 of specificity, 99.15 ± 0.1 of sensitivity, 97.66 ± 0.71 of precision, 98.4 ± 0.32 of F1-score, and 99.68 ± 0.06 of accuracy. Comparing with current SoA methods, the proposed method surpasses them considerably.

In the course of future work, further studies are still needed on new methods of merging EEG channels, especially those

of a linear nature, as they are easier to understand by humans. Furthermore, new data augmentation techniques are needed and generative neural networks may provide an improvement over existing ones.

Abstract—Light field (LF) imaging can obtain spatial and angular information of three-dimensional (3D) scene through a single shot, which enables a wide range of applications in the fields of 3D reconstruction, refocusing, virtual reality, *etc.* However, due to the inherent trade-off problem, the spatial resolution of acquired LF images is low, which hinders the widespread application of LF imaging technique. In order to relieve this issue, an end-to-end LF spatial super-resolution network is proposed by considering the multi-level perception and view reorganization. This method can fully explore the highly interwoven LF spatial and angular structure information. Specifically, a multi-feature fusion enhancement block is introduced that can fully perceive LF spatial, angular, and EPI information for LF spatial super-resolution. Furthermore, the angular coherence between LF views is exploited by reorganizing the LF sub-aperture images and constructing a multi-angular stack structure. Compared with other state-of-the-art methods, the proposed method achieves superior performance in both visual and quantitative terms.

Keywords—Light field image; spatial super-resolution; multi-level perception; view reorganization

I. INTRODUCTION

Light Field (LF) image with four-dimensional structure not only contains the intensities of light ray, but also records the directions of light ray. Compared with traditional 2D imaging which can only capture the spatial information of light ray, LF imaging technique has great potential in many fields, such as image refocusing [1], 3D reconstruction [2], and virtual reality [3], *etc.* However, due to the inherent trade-off problem between spatial and angular resolution in the imaging plane, low spatial resolution hinders the application of LF imaging. High-efficiency spatial super-resolution methods for LF imaging play a crucial role in advancing technological development and have wide-ranging applications in medical treatment, security monitoring, and related fields. The significance of these methods lies in their ability to enhance the resolution of LF data, enabling the reconstruction of high-quality images with greater detail and precision. Therefore, it is imperative to investigate and develop efficient LF super-resolution techniques to address the challenges posed by low spatial resolution of LF data and improve their usability in various applications.

LF image has several representations, such as lenslet image, Sub-Aperture Image (SAI) array and Pseudo Video Sequence (PVS), *et al.* For SAI (also called view) array representation, the adjacent SAIs records the same 3D scene information with a small disparity. This means that the SAI array is highly correlated, which benefits in enhancing the LF spatial super-resolution performance. SAI array representation is always adopted for LF spatial super-resolution task. Especially with the development of deep learning, the convolutional neural Network (CNN) has been widely used in LF image processing tasks with SAI array representation. However, due to the complex LF structure, and the interweaving of spatial and angular information in LF images, there are great challenges to further improve the super-resolution performance by using CNNs under SAI array representation. To solve this problem, most existing methods usually consider exploring the structure information of LF image or reducing the dimensionality of the LF image. Although these methods can reconstruct high spatial resolution LF images, their performance is limited. The reason lies in two aspects. One is that the LF structure information is under-explored. The other is that the rich angular information contained in LF image is under-used. Fully exploring LF structure and angular information is more conducive to improving LF super-resolution performance.

In order to mitigate these issues, in this paper, we propose a LF spatial super-resolution network via multi-level perception and view reorganization. By introducing the multi-feature fusion enhancement block, our network can adequately explore and fuse LF structure information, including spatial, angular, and Epipolar Plane Image (EPI) information, so as to recover more details, especially for some occlusion regions. In addition, in order to better mine the abundant angular information, we reorganize the LF SAIs in different angular directions. Specifically, we arrange the horizontal and vertical SAIs in the LF image array with the same angular coordinate element into a stack, and construct a Multi-Angular Stack (MAS) structure. The MAS structure can provide rich angular and spatial information for LF image spatial super-resolution. The main contributions of this paper are as follows:

- We propose a multi-feature fusion enhancement block

to fully perceive LF spatial, angular, and EPI information for LF spatial super-resolution.

- We construct a multi-angular stack structure to adequately explore LF angular information to enhance LF spatial super-resolution performance.
- Comprehensive experiments demonstrate the superiority of the proposed method than the other state-of-the-art approaches.

The rest of this paper will be organized in the following way. A brief review of related work will be provided in Section II. In Sections III, we present our approach. Section IV discusses the simulation results. Finally, the paper is concluded in Section V.

II. RELATED WORKS

LF spatial super-resolution aims to generate high spatial resolution LF images from densely sampled low spatial resolution one. To achieve this goal, two approaches can be used. One is to apply a single image super-resolution method [4] to super-resolve each SAI separately. The other is to build a mathematical model based on prior information to directly reconstruct high spatial resolution LF image. With the development of deep learning, researchers are more inclined to use CNN to realize the spatial resolution reconstruction of LF images, which can take full use of LF abundant structure information and improve the LF reconstruction performance. A brief reviews of single image super-resolution and LF image super-resolution are given in this section.

A. Single Image Super-resolution

Single image super-resolution does not involve multi-view tasks, for which the goal is only to generate a high-resolution 2D image from a low-resolution 2D image. Shi *et al.* [5] constructed a structure-aware single image super-resolution network to further generate structure and details of images. Song *et al.* [6] developed a criss-cross network to reduce the computation complexity for single image super-resolution task. In their method, few feature points were used to compute long-range dependencies. Hsu *et al.* [7] proposed a detail-enhanced wavelet residual network for single image super-resolution to resolve the details over smooth problem. Wang *et al.* [8] developed an end-to-end joint framework to super-resolve single image by considering the issue of no ground truth high resolution images and degradation models are available. Lan *et al.* [9] put forward a lightweight network for single image super-resolution, which can decrease computational burden by expressing multiscale feature and learning feature correlation.

Single image super-resolution method can reconstruct high spatial resolution LF image by super-resolve each SAI. However, the inherent structure information is under-explored in this kind of method, which limits the LF super-resolution performance.

B. Light Filed Super-resolution

Different from 2D image super-resolution, the pixel information required for LF super-resolution actually exists in each SAI. The four-dimensional information of the LF image

can be decomposed into many SAIs recording the scene, and there is a certain disparity between different SAIs, which has a strong correlation. Therefore, the SAIs of LF images are highly correlated, and the utilization of single view spatial information and angular correlation between different views is the key factor to improve the performance of LF image super-resolution.

Early studies followed the traditional paradigm by developing different models to achieve super-resolution in LF image space. Among them, LFBM5D [10] extends the BM3D [11] filtering to 5D to provide more prior information and thus improve the super-resolution performance. Mitra *et al.* [12] proposed a Gaussian mixture model for encoding the spatial structure of the LF to cope with noise and super-resolution issues. Farrugia *et al.* [13] used multivariate ridge regression to approximate the subspace linear projection method of the adjacent SAIs to the middle SAI. Rossi *et al.* [14] utilized the complementary information between different views to achieve spatial super-resolution through graph optimization based on regularized coupling of graphs. Although these models can encode the structure of the LF by establishing a mathematical model, they rely too much on the prior information of the image, resulting in limited super-resolution performance.

With the development of deep learning, researchers are more inclined to build different super-resolution networks to learn the mapping relationship between low-resolution and high-resolution LF images. For example, Yoon *et al.* [15] proposed a model for LF image super-resolution based on deep convolutional networks. Zhang *et al.* [16] divided the views into four groups, and used the residual information between adjacent views to cope with super-resolution tasks. They explored the correspondences between different viewpoints and divided the SAIs into multiple image stacks with a consistent sub-pixel offset. However, the complementary information between all views was not fully utilized, and the disparity consistency was not well maintained. In order to make full use of the high-dimensional features of LF data, Yeung *et al.* [17] alternately used convolutions to characterize the relationship between pixels in the 4D structural information of spatial domain and angular domain. However, the inherent disparity structure of LF images is ignored. Jin *et al.* [18] proposed an all-to-one light-field super-resolution strategy to strengthen the disparity structure. They explored the complementary information between the views to perform individual super-resolution for each SAI of LF image. Wang *et al.* [19] proposed a spatial-angular interaction strategy and designed different networks to extract spatial and angular features respectively. Wang *et al.* [20] further used separable convolutional networks to explore the spatial-angular information of LF. Although they explore the spatial-angular information to a certain extent, they do not effectively mine the high-dimensional information of the LF image. As a result, the LF super-resolution performance is affected to a certain extent. Liu *et al.* [21] extracted global view information and simultaneously modeled the correlation within each view to achieve better super-resolution performance. Although these methods have shown remarkable performance, there are still some problems that are not well addressed. One is that the high-dimensional information of LF images is not fully utilized, especially the complementary information between spatial angulars and the geometric consistency information of LF EPIs. The other is that the angular structure

between the LF views is not broken, and the angular correlation between the LF images is not explored enough.

Focusing on the above problems, we propose a novel network for LF spatial SR based on the content characteristics of LFs. We introduce two strategies to mitigate the above problems. Since the high-dimensional features of the LF image contain rich information, we fully explore the LF spatial information, LF angular information, and the geometric information of the LF EPIs, respectively. The information is interacted and the channel attention is increased to obtain the enhanced information after interaction. In order to further explore the angular correlation between the LF views, we break the angular structure of the LF array and rearrange it into multiple stacks, and super-resolve each horizontal view stack separately. The network makes full use of the content characteristics of LF images and further improves the performance of LF spatial resolution reconstruction by fully exploring the information of different dimensions of the LF and designing the cross-arrangement of views to mine the angular correlation between views. Experimental results on both real and synthetic datasets demonstrate the superiority of the proposed method.

III. PROPOSED METHOD

In the proposed method, the spatial information of the LF image, the angular information and the geometric information of the LF EPIs were used to interact with the multi-dimensional features of the LF and reorganize the array structure based on the content characteristics of the LF. The method makes full use of multi-dimensional information and angular correlation of LF images, and is composed of two main modules: multi-stream feature fusion enhancement module and structure reorganization module. The overall network structure is shown in Fig. 1. We formulate LF in terms of a four-dimensional tensor $L(u, v, x, y) \in \mathbb{R}^{U \times V \times X \times Y}$, where U and V denote the angular dimensions, and H and W denote the spatial dimensions. Specifically, the SAI of a $U \times V$ array represents the LF, and the resolution of each SAI is $H \times W$. The high-resolution LF image $L \in \mathbb{R}^{U \times V \times \alpha X \times \alpha Y}$ is reconstructed from the low-resolution LF image $L \in \mathbb{R}^{U \times V \times X \times Y}$, where α is the magnification factor. Following [16-19], we perform SR only on the Y channel to reduce the computational complexity. The Cb and Cr channels are upsampled using bicubic interpolation algorithms. Then the super-resolved Y, Cb and Cr channels are converted into an RGB image. The proposed reconstruction network can be written as

$$L_{HR}(u, v, \alpha x, \alpha y) = f(L_{LR}(u, v, x, y), \Theta),$$

$$\Theta^* = \arg \min_{\Theta} \|L_{GT}(u, v, \alpha x, \alpha y) - L_{HR}(u, v, \alpha x, \alpha y)\| \quad (1)$$

where $L_{HR}(u, v, \alpha x, \alpha y)$ is the reconstructed dense LF, $L_{GT}(u, v, \alpha x, \alpha y)$ is the ground truth, $f(\cdot)$ represents the mapping from low resolution LF image to high resolution LF image, Θ is the network parameter.

To achieve a high-quality dense LF reconstruction and obtain optimal network parameter Θ , we propose a multi-stream reconstruction network. To effectively extract distinctive information from various view images, we propose a novel approach that combines multiple features to enhance the representation of LF spatial, angular, and EPI information. Specifically, we present a multi-feature fusion enhancement

block that can accurately capture spatial and angular details contained in the LF data (See Sec. III-A). Moreover, we design a Structure-based Super-Resolution Module that utilizes the angular information present in the subaperture view array to perform super-resolution reconstruction, thus optimizing the quality of the reconstructed views (see Sec. III-B). To further enhance the geometric consistency between the reconstructed views and maintain the valuable disparity structure of the LF data, we propose a mixed loss function that incorporates both reconstruction loss and EPI gradient loss (see Sec. III-C). The network architecture is elaborated in the following subsections.

A. Multi-stream Feature Fusion Enhancement Module

To enhance the characteristics of decoupling, this paper proposes the addition of a channel information, $L \in \mathbb{R}^{U \times V \times X \times Y \times C}$, to the 5D data. Multiple representation methods of the LF image in various dimensions were utilized to explore its content characteristics and extract feature information. The fusion process of multi-stream feature, denoted as L_{MFFE} , is expressed as follows:

$$L_{MFFE} = f_{MFFE}(\text{CA}(\text{SFE} + \text{AFE}) + \text{CA}(\text{EPI}^H + \text{EPI}^V)) \quad (2)$$

Here, **SFE** stands for the spatial feature extraction module of subaperture view, **AFE** indicates the angular feature extraction module of subaperture view, **EPI^H** and **EPI^V** denote the feature extraction modules of the EPI in the vertical and horizontal directions (EPI-H and EPI-V), respectively, and **CA** represents the attention module. In what follows, we expound on each module of the Multi-stream Feature Fusion Enhancement Module.

Spatial Feature Extraction(SFE): We focus on the information of SAI in the dimension and reshape the 5D LF data with increased channel information $S^{lr} \in \mathbb{R}^{UV \times C \times X \times Y}$. The SFE module is used to extract the spatial features of the SAI. Specifically, SFE is a module composed of three convolutions with a kernel size of 3×3 , a step size of 1, a dilation rate of 2, and a Relu activation layer after each convolution layer. Since we focus on $H \times W$, the dimension information, SFE only includes the pixel information of the context in each SAI, which has a good refinement of the global features of each SAI and has rich texture information.

Angular Feature Extraction(AFE): In view of the multi-angular characteristics of LF, we centers on the $U \times V$ angular information. Similarly, we reshape the original 5D light field data $A^{lr} \in \mathbb{R}^{HW \times C \times U \times V}$. The AFE module is used to extract the angular feature from the pixel information of the same angular position of the SAI. Specifically, AFE is a module composed of three convolutions with a kernel size of 3×3 and a step size of 1. Each convolution layer is followed by a Relu activation layer. Different from SFE, AFE pays more attention to the correlation in angular, and different SAIs have strong correlation in the same pixel position, which can provide more pixel information for the occlusion area.

EPI Feature Extraction(EPI-H, EPI-V): EPI is the horizontal $E_H^{lr} \in \mathbb{R}^{VW \times C \times U \times H}$ or $E_W^{lr} \in \mathbb{R}^{UH \times C \times V \times W}$ vertical two-dimensional slice information of SAI by sampling angular coordinates and corresponding spatial coordinates in multi-dimensional data of LF. Acknowledging the effectiveness

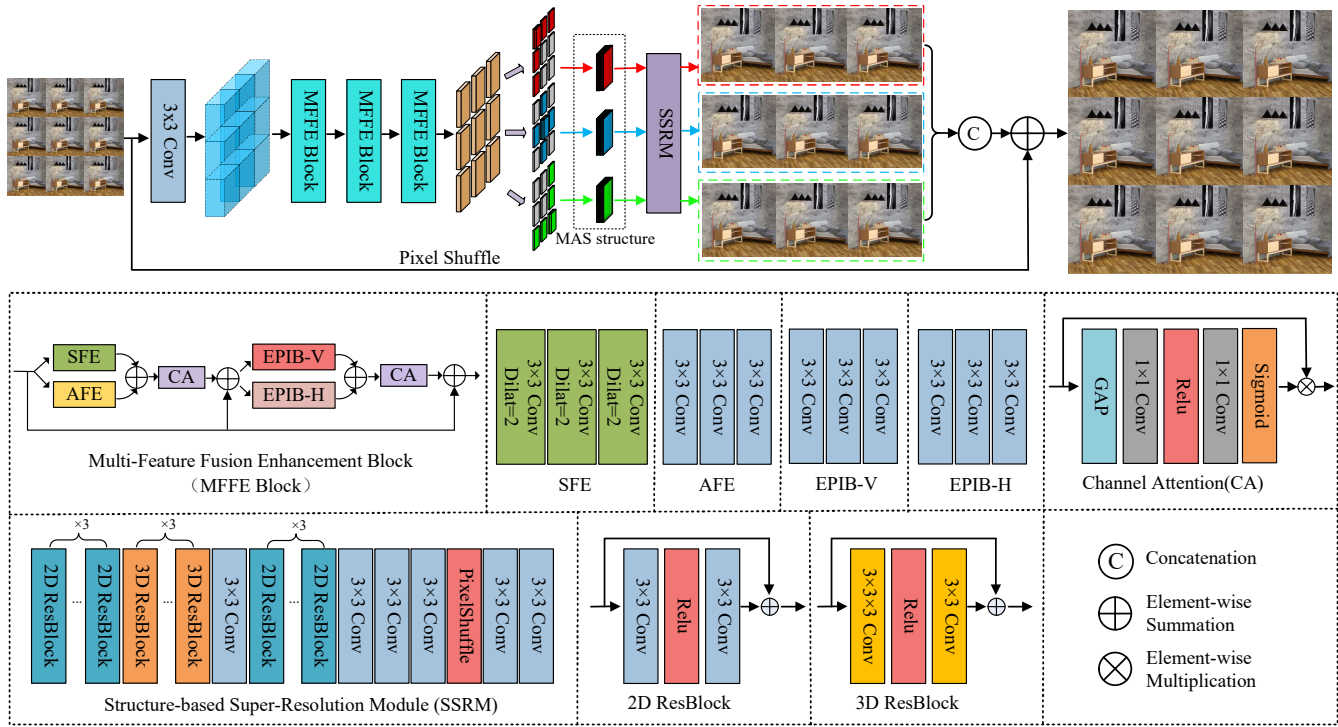

Fig. 1. The architecture of our light field spital reconstruction network.

of EPI in reflecting the geometrical consistency of LF, we delves into the analysis of LF geometric information, both horizontally and vertically. Specifically, EPI-H and EPI-V are modules composed of three convolutions with a kernel size of 3×3 and a step size of 1. Each convolution layer is followed by a relu activation layer. The EPI slices have a simple linear structure, which is basically a slanted straight line composed of homogeneous regions, and perform well for the analysis of features in the scene slices even for the rather complex shape and intensity variations in SAI.

Channel Attention(CA): Due to the local nature of convolutional operations, obtaining sufficient information to extract inter-channel relationships in LF imager can be challenging. To address this limitation, we integrate CA into our proposed architecture after the SFE and AFE fusion, as well as after the EPI-H and EPI-V fusion. The CA module compresses the feature map into a feature vector via global average pooling (GAP) to obtain a global description feature. Non-linear relationships between channels are then learned by compressing the channel count through 1×1 convolutions, using the rule activation layer, and subsequently amplifying the channel count via another 1×1 convolution layer. Finally, the weighting coefficients assigned to each channel by the sigmoid function enable effective cross-channel interaction and enhancement of fusion interaction amongst the information.

B. Structure-base Super-resolution Module

This paper proposes a novel approach to leverage the angular information contained in the subaperture view array for super-resolution reconstruction. Specifically, a cross-arrangement structure of the angular view and a reorganized

parallax structure of the view are proposed to enhance the utilization of angular information. Then, a multi-stream feature fusion module is introduced to extract rich and high-dimensional features, which are subsequently fed into the structure-based super-resolution module. The network structure can be expressed as:

$$L_{HR} = \text{Concat}(f_{SSRM}^1(MFFE^1), \dots, f_{SSRM}^i(MFFE^i)) \quad (3)$$

where $f_{SSRM}^i(\cdot)$ represents the Structure-base Super-resolution module, $MFFE^i$ represents the input information of the first row in the cross-arrangement structure of angulars and views, and i represents the number of rows, where the main scenario in this paper is $i = 5$. The designed super-resolution network comprises three 2D ResBlock convolutions, three 3D ResBlock convolutions, one 3×3 convolution, three 2D ResBlock convolutions, three 3×3 convolutions, one pixel shuffle layer, and two 3×3 convolutions. Different ResBlock convolutions are utilized to fuse rich information in both the spatial and angular domains, while the pixel shuffle layer achieves spatial super-resolution via upsampling.

C. Training Details

In this method, we adopt the $L1$ loss function to measure the reconstructed target LF $L_{HR}(u, v, \alpha x, \alpha y)$, and supervise our network by its ground truth value $L_{GT}(u, v, \alpha x, \alpha y)$, which is defined as:

$$loss_1 = \sum_{u,v,x,y} (|L_{GT}(u, v, \alpha x, \alpha y) - L_{HR}(u, v, \alpha x, \alpha y)|) \quad (4)$$

To further preserve the valuable disparity structure of the

LF and promote the geometric consistency between the reconstructed views, this paper refers to the EPI gradient loss function proposed by [22], which is defined as follows

$$\begin{aligned}
 loss_2 = & \sum_{y,v} (|E_{GT}^x(x,u) - E_{HR}^x(x,u)| \\
 & + |E_{GT}^u(x,u) - E_{HR}^u(x,u)|) \\
 & + \sum_{x,u} (|E_{GT}^y(y,v) - E_{HR}^y(y,v)| \\
 & + |E_{GT}^v(y,v) - E_{HR}^v(y,v)|)
 \end{aligned} \quad (5)$$

The training objective of our method is to minimize these two losses: $\min loss_1 + loss_2$.

IV. EXPERIMENTS

To confirm the efficacy of the proposed approach, a range of detailed experimental results have been presented, comprising ablation experiments and comparisons with the existing methods. Specifically, we follow [20] which utilize five publicly available LF datasets (namely EPFL, HCInew, HCIold, INRIA, STFgantry) during both the training and testing phases. The training and test sets follow the same partitioning as provided in [20]. The LFs within these datasets possess an angular resolution of 9×9 . During the training procedure, we downsample the SAI into LF patches of size 32×32 via bicubic downscaling. The optimization of our network utilizes both $L1$ and EPI loss functions and the Adam method. Our network is implemented in PyTorch, leveraging an RTX 5000 GPU. The learning rate is initially configured to 2×10^{-4} and subsequently reduced by a factor of 0.5 every 15 epochs. The performance of our proposed method is evaluated using objective measures, including Peak Signal-to-Noise Ratio (PSNR) and Structural Similarity (SSIM), while simultaneously conducting a subjective comparison of detail texture regions after SR.

A. Comparison With State-of-the-Art Methods

The proposed method is compared with several state-of-the-art methods, comprising three single-image SR techniques [7-9] and seven LF image SR methods [16,17,18,19,20,23,24].

To ensure a uniform training process, we retrained all these methods using the same dataset. **Quantitative Results:** Table I presents quantitative results for $2 \times$ SR and $4 \times$ SR. The proposed method significantly outperforms three single image super-resolution methods, VDSR[7], EDSR[8], and RCAN[9]. This improvement is mainly attributed to the complex texture details present in the comprehensive scene, which renders the reconstruction method of single image unsuitable for LF image reconstruction. Moreover, our approach attains the best overall performance compared to resLF[16], LFSSR[17], LF-ATO[18], LF-Internet[19], LF-DFnet[20], MEG-Net[23], and DPT[24]. Our proposed method outperforms the comparative methods in all five datasets for two primary reasons. Firstly, the comparative methods are less effective in fully exploiting the LF's rich angular information and handling complex scenes. resLF[16] constructs view stacks to explore LF information in five directions: horizontal, vertical, left, right, and tilt, fails to fully use complementary information among all views while maintaining disparity consistency. Similarly, though the LF-ATO[18] method proposes an all-to-one architecture that explores complementary information between views, the feature information between spatial and angular domains is not entirely fused. This deficiency affects the spatial super-resolution performance. Second, the comparative methods fail to exploit the LF's geometric structure information to its full potential. LF-Internet[19] utilized the spatial and angular interaction strategy and different networks to extract spatial and angular features while making use of the spatial and angular correlations. However, they neglected the EPI structure information and angular geometric information, which deteriorated the quality of LF spatial reconstruction. Similarly, although LFSSR[17] utilized convolution to characterize the relationship between pixels in a 4D information space in the spatial and angular domains, it ignored the inherent geometric structure of the LF and failed to fully utilize the angular geometric structure. Observing the evaluation metrics presented in Table I, we note that the proposed method outperforms the comparative methods significantly.

Qualitative Results: The qualitative results of the Bedroom in the HCInew scene and ISO_Chart_1_Decoded in EPFL scene reconstructed by different methods under task $2 \times$ SR and $4 \times$ SR is presented in Fig.2 and Fig.3, respectively.

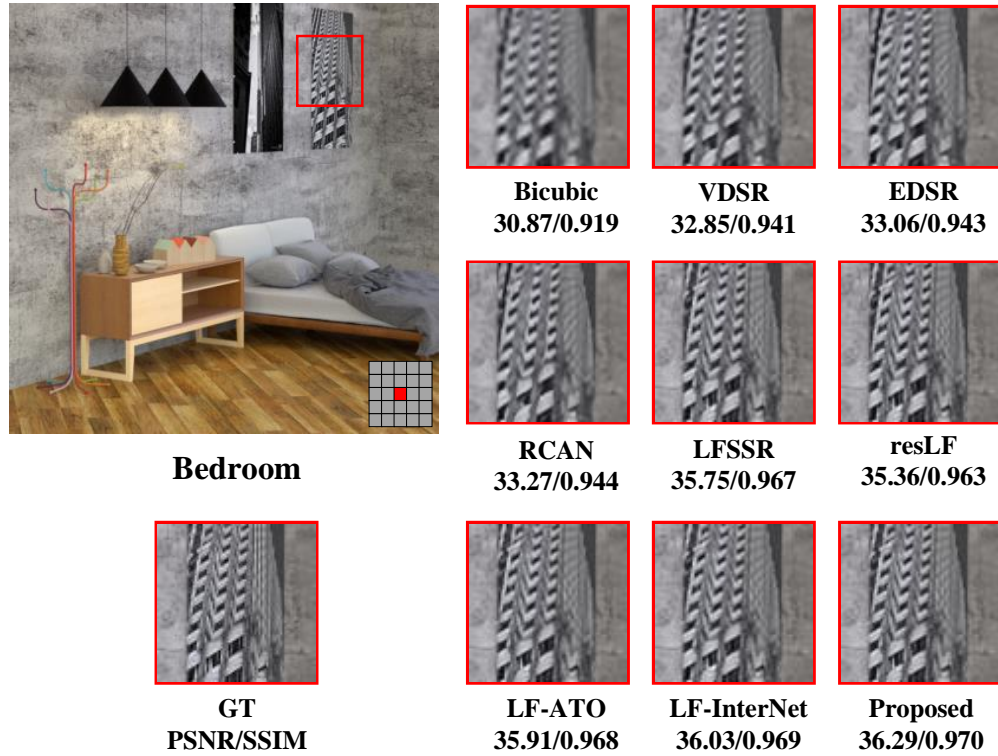

Fig. 2. Visual comparisons for $2\times$ SR. The super-resolved center view images are shown. The PSNR and SSIM scores achieved by different methods on the presented scenes are reported below the zoom-in regions.

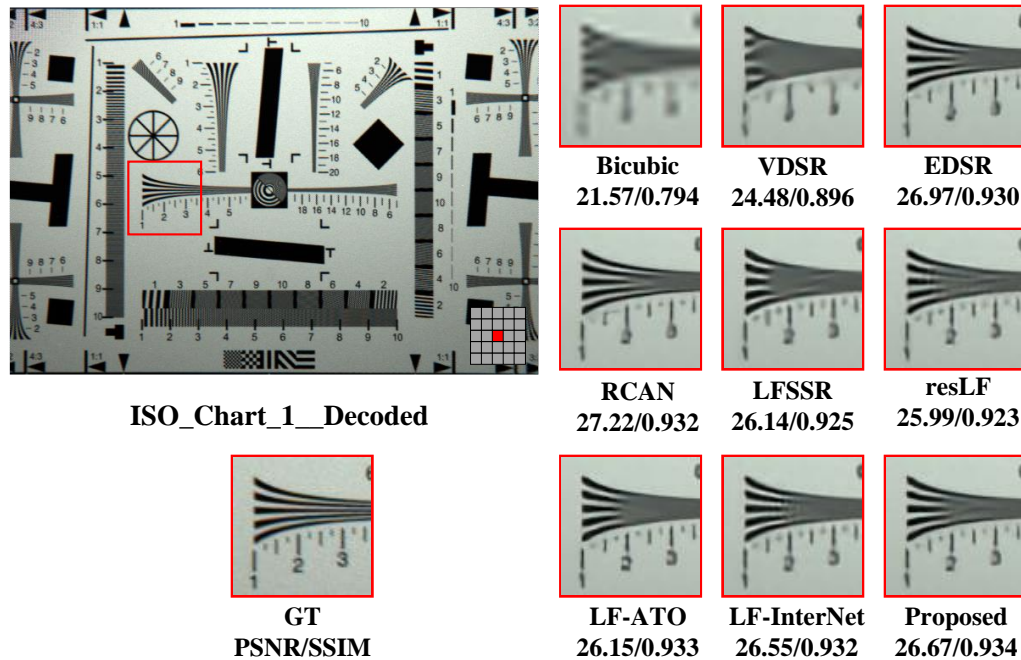

Fig. 3. Visual comparisons for $4\times$ SR. The super-resolved center view images are shown. The PSNR and SSIM scores achieved by different methods on the presented scenes are reported below the zoom-in regions.

The magnification of the local view of the reconstructed sub-aperture is shown in the red box. In Fig.2, although the Bedroom scene contains complex textures, which makes reconstruction challenging. Our method leverages high-dimensional features of the LF and combines spatial and angular domain with EPI information to recover more detailed information of the scene. It can be seen from the Fig.3, the scene is composed of numerous lines and gaps that are difficult to reconstruct. While the LF reconstruction method can capture more information, it still has limitations in such complex line scenes with small gaps. Instead, EDSR[8] and RCAN[9], two single image super-resolution methods, show better reconstruction performance on these scenes. This is because the real pixel information is insufficient at a higher super-resolution size, and the LF reconstruction method synthesizes more new pixel information, which is intertwined with each other and blocks the gaps between lines. Compared with current state-of-the-art SISR and LF image SR methods, our method produces images with more accurate details and fewer artifacts.

B. Ablation Experiments

To gain a deeper understanding of the proposed network’s properties, an ablation study was performed to demonstrate the efficacy of the feature fusion and angular view intersection arrangement structure for high-dimensional data in the LF context. The study involved removing various components from the network, including the channel attention module, EPI feature extraction module (EPI-H, EPI-V), angular feature extraction module, spatial feature extraction module, and structure-based super-resolution module. These were identified as the variants of the proposed network for the purposes of the study and are respectively denoted as “w/o CA”, “w/o EPI-H”, “w/o EPI-V”, “w/o AFE”, “w/o SFE” and “w/o the SSRM”. The comparison results (PSNR/SSIM) of the different variants of the proposed method for task 2×SR on five public datasets are presented in Table II. The results indicate that the proposed method significantly outperforms the other variants with the removal of any module leading to an adverse effect on the reconstruction performance.

Specifically, compared with “w/o CA”, the proposed

method has obvious advantages in PSNR. This can be attributed to the channel attention module, which analyzes the weight of each channel by fusing spatial and angular with horizontal and vertical information of the polar plane. It strengthens the channel weight coefficient that has a greater impact on reconstruction. In comparison to “w/o EPI-H” and “w/o EPI-V”, the proposed method attains higher PSNR and SSIM scores due to the EPI module’s ability to analyze the section information of the LF geometrically, resulting in better recovery of the structural information. The proposed method outperforms “w/o AFE” by achieving a 0.28 dB PSNR gain by using the angular information to improve the LF reconstruction performance significantly. The multi-stream feature fusion module extracts diverse structural information by analyzing multiple dimensions of the high-dimensional data of the LF, thereby enhancing spatial angular correlations. Thus, all modules in multi-stream feature fusion contribute positively to the reconstruction performance. Significantly, the proposed method achieves the best gain compared to “w/o SSRM”, with the PSNR value increasing from 34.21 dB to 34.56 dB for 2×SR. This is because the cross-arrangement of angular viewpoints offers geometric structure analysis of the angular correlation of the LF, leading to an improvement in reconstruction quality.

C. Extended Experiments

In this paper, we investigate the impact of angular resolution on the performance of our proposed method. We evaluate the super-resolution performance under different angular resolutions by extracting $A \times A$ sub-aperture views of the center from the input LF image, where A represents the number of views ($A = 3, 5, 7$). We train separate models for the 2× super-resolution task with each angular resolution setting. Our results, as shown in Table III, reveal that increasing the angular resolution from 3×3 to 7×7 improves the PSNR values. This improvement can be attributed to the richer angular information provided by additional views, which enhances the spatial super-resolution. However, we observe that the performance saturates for angular resolutions greater than 5×5 . This is because the information obtained from the 7×7 sub-

aperture views is already sufficient, and further increasing the angular resolution yields only marginal improvements in performance.

D. Discussions

This paper proposes a new method for learning LF spatial SR by interweaving LF spatial and angular structure information. Here, some discussions are presented. (1) Similar to previous literature, we adopt publicly available LF data to conduct detailed experiments. The qualitative and quantitative comparisons with the state-of-the-art SR methods demonstrate the superior performance of the proposed method. (2) Our ablation study highlights the effectiveness of multi-stream feature fusion by means of the integration and interlacing of high-dimensional data from diverse sources during the multi-stream feature fusion phase. This approach facilitates the extraction of comprehensive information, thereby enhancing reconstruction performance. Furthermore, the ablation experimental outcomes validate the effectiveness of both the proposed MFFE and SSRM. (4) Considering the quantitative results presented in Subsection IV, the performance of the proposed method for the narrow-baseline LF images is significantly better than that for the widebaseline LF images, mainly because the latter has a larger parallax range, posing greater challenges to feature extraction.

V. CONCLUSION

In this paper, we present a multi-stream feature fusion spatial reconstruction network with cross-arranged viewpoints. The network consists of two stages: multi-stream feature fusion and reconstruction based on cross-permutation of angular viewpoints. In the multi-stream feature fusion stage, we combine and interweave high-dimensional data from different sources to extract rich information that can be used to improve the reconstruction performance. Additionally, this stage allows us to fully explore the high-dimensional data of the LF and fuse different dimensional data. Then the rich information obtained in the multi-stream feature fusion stage is used to mine the LF information from the geometric structure level to improve the reconstruction performance. Through experiments on five public datasets, we demonstrate that our proposed method produces high-quality spatial reconstructions of LF images under both $2\times$ SR and $4\times$ SR reconstruction tasks. Furthermore, we analyze the influence of the input angular resolution on reconstruction performance. Our results show that our method significantly outperforms state-of-the-art approaches.

Enhancing Intrusion Detection Systems with XGBoost Feature Selection and Deep Learning Approaches

Khalid A.Binsaeed, Prof.Alaaeldin M. Hafez

College of Computer and Information Sciences, King Saud University, Riyadh, KSA

Abstract—As cyber-attacks evolve in complexity and frequency; the development of effective network intrusion detection systems (NIDS) has become increasingly important. This paper investigates the efficacy of the XGBoost algorithm for feature selection combined with deep learning (DL) techniques, such as ANN, 1DCNN, and BiLSTM, to create accurate intrusion detection systems (IDSs) and evaluating it against NSL-KDD, CIC-IDS2017, and UNSW-NB15 datasets. The high accuracy and low error rate of the classification models demonstrate the potential of the proposed approach in IDS design. The study applied the XGBoost feature extraction technique to obtain a reduced feature vector and addressed data imbalance using the synthetic minority oversampling technique (SMOTE), significantly improving the models' performance in terms of precision and recall for individual attack classes. The ANN + BiLSTM model combined with SMOTE consistently outperformed other models within this paper, emphasizing the importance of data balancing techniques and the effectiveness of integrating XGBoost and DL approaches for accurate IDSs. Future research can focus on implementing novel sampling techniques explicitly designed for IDSs to enhance minority class representation in public datasets during training.

Keywords—Intrusion detection system; deep learning (DL); XG-Boost; feature extraction; Bidirectional Long Short-Term Memory (BiLSTM); Artificial Neural Networks (ANN); 1D Convolutional Neural Network (1DCNN); Synthetic Minority Oversampling Technique (SMOTE); NSL-KDD dataset; CIC-IDS2017; UNSW-NB15

I. INTRODUCTION

As computer networks continue to play an increasingly important role in modern life, ensuring cybersecurity has become a crucial area of research. One method to protect against potential threats is using an Intrusion Detection System (IDS). By continuously monitoring the state of both software and hardware on a network, IDS plays a critical role in maintaining cybersecurity [1]. Many Intrusion Detection Systems (IDSs) generate alerts, even in low-threat situations, straining cybersecurity experts and increasing the risk of actual intrusions going undetected. The literature includes extensive research on the subject, and different approaches to IDSs have been developed. However, current IDSs still face difficulty detecting unknown or novel attacks due to the constantly evolving network configurations. Therefore, it is critical to continue the research on IDSs to identify and detect such attacks [2].

Attackers can initiate attacks by distributing malicious files to devices connected to a network, resulting in potential

damage to the device or theft of sensitive information [3]. Various technologies, such as firewalls, anti-virus software, email filters, and virtual private networks (VPN), protect networks from such threats. Intrusion Detection System (IDS) is another commonly used approach, where network traffic is monitored to detect any unusual activities. Network intrusion detection can be categorized into anomaly-based and signature-based [4]. Signature-based methods rely on predetermined criteria to identify attacks and categorize threats, while anomaly-based methods classify threats by studying regular traffic to develop profiles based on available data. Based on the given definitions, we can infer that Signature-based IDS are vulnerable to new undefined attacks as they solely depend on the current rules to generate their alerts. However, anomaly-based IDS are more effective when dealing with new threats as they do not base their alerts on existing rules [5] [6]. That does not mean that Signature-based IDS are less critical; it offers improved detection accuracy and reduced triggers of false alarms while identifying known threats. Although there is a high probability of false positives associated with anomaly detection IDS, the research community has widely accepted it due to its theoretical potential for identifying new threats [7].

A. Feature Engineering Challenges within NIDS

Creating a dependable and flexible NIDS that detects unknown future attacks presents two significant challenges. Selecting appropriate features from internet traffic collection for anomaly detection can present a noticeable challenge [7]. The features selected for one type of threat may not be practical for other attacks due to the ever-changing and evolving nature of attack scenarios. The literature has already proposed potential ways to address the challenge, the most common of which is the use of deep learning, a subset of machine learning techniques that uses hierarchical layers of data processing stages to learn features or representations and classify patterns [8]. Deep learning plays a crucial role in image categorization. It is also frequently utilized in natural language processing, speech recognition, audio, picture, video processing, graphical modeling, pattern identification, and language-related tasks. Improvements in learning algorithms can enhance IDS's ability to achieve a higher detection rate and lower false alarm rate. The use of deep learning-based techniques is anticipated to assist in overcoming the challenges of developing an effective NIDS [8].

Unlabeled network traffic data can be collected from various sources, and deep learning algorithms can be applied to generate a good feature representation of these datasets. These

characteristics can then be utilized for supervised classification on a small, labeled traffic dataset consisting of regular and anomalous traffic records. A spoofed, private, and isolated network environment can be used to collect the traffic data for the labeled dataset [9].

B. Aim and Objective

The study aims to provide a reliable and efficient approach for identifying different cyber-attack types using sequence modeling and deep learning by proposing the following:

Developing an effective intrusion detection model for detecting malicious traffic, leveraging SMOTE, BiLSTM, XGBoost, and 1DCNN/DNN for improved intrusion detection.

To achieve the aim of this study, the following objectives have been created:

- Identify all the model variations that need to be evaluated using SMOTE, BiLSTM, XGBoost, and 1DCNN/DNN.
- Evaluate the identified models against well-known IDS datasets from the literature (NSL-KDD [10], CIC-IDS2017 [11], and UNSW-NB15 [12]).

C. Problem Statement

The increasing use of interconnected computing systems has brought numerous benefits to daily activities and exposed us to vulnerabilities beyond human control. As a result, cybersecurity measures must be included in communication exchanges to ensure secure communication. However, with evolving security risks and threats, there is a constant need to improve security measures, including Intrusion Detection Systems (IDS). Despite the efforts of researchers to develop novel IDS systems, achieving high detection accuracy while reducing false alarm rates remains a challenge.

II. RESEARCH STRUCTURE

This paper is organized into seven sections, providing a comprehensive examination of the research topic:

- **Section 1: Introduction** - This initial section provides an overview of the paper's structure and objectives, setting the stage for the subsequent discussion and analysis.
- **Section 2: Background and Related Work** - This section explores key concepts and offers some background information to facilitate the understanding of the rest of the paper.
- **Section 3: Proposed Model (Methodology)** - This section explains the methodology of the proposed model and how it works.
- **Section 4: Results** - This section presents the results obtained by applying the newly proposed model to the experimental datasets.

- **Section 5: Evaluation** - This section compares different results using evaluation metrics such as precision and recall.
- **Section 6: Discussion** - This section provides a discussion of the results, offering insights and interpretations.
- **Section 7: Conclusion** - The final section concludes the paper, addressing the limitations encountered during the research and proposing potential directions for future work, aiming to expand upon and build on the current study.

III. BACKGROUND AND RELATED WORK

The field of intrusion detection systems (IDS) has been rapidly evolving in recent years, with a focus on improving the accuracy and efficiency of detection methods. Various techniques have been proposed in this paper, including, IDS data preprocessing (data cleansing - removal of null and duplicate values, data balancing using SMOTE, and data standardization using standard scalar techniques), feature engineering (using XGBoost), and data classification (One-dimensional CNN, DNN Models, and Bidirectional Long-Short-Term Memory (BiDLSTM)). These methods have demonstrated promising results in detecting various network intrusions, including Denial of Service (DoS) attacks, intrusion attempts, and unauthorized access attempts. Furthermore, DNN Models and BiDLSTM have emerged as powerful tools for identifying complex patterns in network traffic data, making them valuable additions to the IDS toolbox. This background section provides an overview of these topics, discussing their underlying principles.

A. Feature Engineering

In machine learning, feature engineering plays a vital role as it converts raw data into a more suitable format, which allows for a better representation of the underlying issue and enhances model performance. XGBoost, a gradient-boosted decision tree algorithm, is renowned for its effectiveness and efficiency in feature engineering. Introduced by Mounika and Rao [13] and embraced by numerous researchers [14] [15], XGBoost is part of the Community for Distributed Machine Learning and excels in optimizing memory and hardware utilization in tree-boosting algorithms. Kasongo and Sun [16] employed XGBoost in their intrusion detection research, using the UNSW-NB15 dataset for model training and evaluation. They implemented a filter-based feature reduction technique alongside the XGBoost algorithm and used specific machine-learning approaches for binary and multi-class classification scenarios. The study showed that the XGBoost-driven feature selection method increased test accuracy for binary classification from 88.13% to 90.85%, demonstrating its effectiveness in boosting the precision of ML-based models. Dhaliwal et al. [17] conducted another study, developing a model to assess various network data attributes such as precision, accuracy, and confusion matrix. They employed the NSL-KDD dataset and XGBoost to achieve their objectives. The primary goal was to better understand data integrity and enhance data detection accuracy. The researchers recommended further investigations to facilitate the deployment of intrusion detection models.

XGBoost supports gradient, regularized, and stochastic gradient boosting techniques and permits the incorporation and adjustment of regularization parameters [18]. The algorithm optimizes memory usage, significantly reduces computation time, and manages missing values. Its sparse-awareness allows for a unified framework in tree structures, improving the trained model with new data [19]. XGBoost constructs a sequential decision tree, assigning a weight to each data value, which influences the likelihood of a decision tree selecting it for analysis [20]. Although challenges exist in network data preprocessing, data classification, and labeling, XGBoost tackles issues such as high-level preprocessing, DDoS attack mitigation, false alarm rates, and semi-supervised techniques necessary for a dependable IDS model [21]. Due to its capability to address most problems encountered in feature selection, XGBoost serves as a potent instrument for developing efficient intrusion detection systems [22].

B. Deep Learning Classification

In this section, we will review the relevant literature on various deep learning classification techniques that have been employed in the proposed model. The methods discussed include XGBoost, BiLSTM, DNN, One-dimensional CNN and Long Short-Term Memory (LSTM). These techniques have been applied in a wide range of intrusion detection systems and have demonstrated their effectiveness in handling complex and large-scale data. We will explore the key aspects of each method, as well as their applications in the field of intrusion detection. By examining the current state looking into the background of these techniques, we aim to provide a functional understanding, ultimately informing the development of a robust and efficient intrusion detection model.

1) One-dimensional CNN and Long Short-Term Memory (LSTM): Recurrent Neural Networks (RNNs) are a class of neural networks that can generate cycles through links between nodes, allowing the output of certain nodes to influence their future input and enabling temporal dynamic behavior. RNNs, derived from feed-forward neural networks, use their internal state (memory) to handle input sequences of varying length, making them ideal for AI tasks such as speech and handwriting recognition [23]. Long Short-Term Memory (LSTM) networks, a specialized form of RNNs, were developed to address the vanishing gradient problem commonly encountered during the training of conventional RNNs [24]. LSTMs, equipped with memory cells and gating structures, can effectively store information across extended sequences. In one study, the authors of [25] used an RNN with LSTM to recognize threats and normal patterns within IoT traffic. They trained their model using the UMSW-NB15 dataset and found that the LSTM RNN-based IDS was efficient and could detect threats with high accuracy. However, they suggested that further verification with a larger dataset was necessary. Agrawal and Duvey [26] aimed to develop an intrusion detection system using deep learning technology to identify infiltration and malicious activities that could disrupt the network environment. They proposed a hybrid DL-driven method that employs one-dimensional CNN and LSTM to detect attacks on the KDD99 dataset. The proposed model's performance was evaluated on binary and multiclass classifications using the KDD99 datasets. In another study, Qazi et al. [27] proposed a deep learning architecture for network intrusion detection based on a one-dimensional

convolutional neural network. The study aimed to identify three types of network attacks, namely PortScan, DoS, and DDoS, using the CICIDS2017 dataset. The results showed an accuracy of 98.96%, but the authors suggested further analysis, such as using Principal Component Analysis (PCA), to investigate the reduction in input characteristics.

2) Bidirectional Long-Short-Term Memory (Bi-LSTM): Bidirectional Long Short-Term Memory (Bi-LSTM) is a variant of Recurrent Neural Network (RNN) that processes input sequences in both forward and backward directions using two hidden layers [28]. It predicts the order of elements based on prior and future context through two LSTMs operating simultaneously in opposite directions, generating a combined output that approximates the target signal. Imrana et al. [1] proposed a BiDLSTM-based intrusion detection system to address challenges faced by IDS. They used the NSL-KDD dataset for training and evaluating the model, a widely recognized dataset in IDS research. Experimental results demonstrated the effectiveness of the BiDLSTM approach, showing superior performance in accuracy, precision, recall, and F-score compared to conventional LSTM and other state-of-the-art models. The false positive rate was also significantly lower. The researchers studied integrated systems by combining cutting-edge feature selection approaches with conventional LSTM and BiDLSTM models. Traditional machine learning methods struggle to effectively identify complex and multidimensional intrusion data in real-world network application environments [29]. In contrast, deep learning-based Network Intrusion Detection Systems (NIDS) have gained interest due to their ability to handle large-scale data and extract essential traffic features. Research by Alghazzawi et al. [30] proposed a hybrid Deep Neural Network (DNN) model that outperformed traditional machine learning classifiers in network and host-level event monitoring. Sun et al. [31] developed the LuNet deep neural network architecture, using RNNs for temporal feature learning and CNNs for spatial characteristic extraction from traffic data. This approach reduced false positives and enhanced validation accuracy. Al-Omari et al. [32] developed an intrusion detection model by combining RNN and LSTM approaches, while Alwan et al. [33] created a Bi-LSTM network using the UNSW-NB15 dataset as a benchmark, achieving an accuracy above 95%. Yu et al. [34] proposed a session detection method using Bi-LSTM, leveraging advancements in Natural Language Processing (NLP) made by LSTMs to represent sessions in a specific language. They based their experiments on the ISCX IDS dataset, grouping packets by IP addresses to create sessions and encoding them using word embedding. They trained an LSTM model to predict anomalous sessions, utilizing a Bi-LSTM model to learn sequence properties in both directions.

In conclusion, deep learning techniques like Bi-LSTM, hybrid models incorporating CNNs and LSTMs, and LSTM-based approaches have shown considerable promise in intrusion detection systems. These methods outperform conventional machine learning approaches in terms of accuracy, recall, and F-score [35]. They provide effective solutions for intrusion detection in real-world network application environments due to their ability to process complex, large-scale data and extract fundamental features from traffic data. Their development and implementation have improved network intrusion detection systems' overall performance and

strengthened network security infrastructure.

3) *Deep Neural Network (DNN)*: Deep Neural Networks (DNNs) are a type of artificial neural network (ANN) that consist of multiple layers between their input and output layers. They are composed of biases, synapses, neurons, weights, and functions, which work together to mimic the human brain's processing capabilities. DNNs can be trained like any other machine learning algorithm, making them suitable for various artificial intelligence tasks, such as image and speech recognition [36]. In one study, Devan and Khare [37] proposed an XGBoost-DNN model for network intrusion detection. The XGBoost algorithm was employed for feature selection, while DNNs were used to classify network intrusions. During DNN training, the Adam optimizer was utilized to optimize the learning rate, and the Softmax classifier was employed to categorize network intrusions. To validate their proposed model, cross-validation was performed, and it was compared to other shallow machine learning techniques such as SVM, logistic regression, and naive Bayes. Classification assessment metrics, including accuracy, precision, recall, and F1-score, were computed and contrasted with the existing shallow approaches. In another study, Kumar et al. [38] investigated DNNs to develop a flexible and efficient intrusion detection system (IDS) for identifying and categorizing unanticipated cyber-attacks. The study thoroughly analyzes DNN and other traditional machine learning classifier studies on several freely accessible benchmark malware datasets. However, the study's limitation is that the complex DNN structures have a high computational cost, so they were not trained using benchmark IDS datasets. Other research includes Tang et al. [39], who devised a deep learning-based approach for intrusion detection in software-defined networking (SDN) architecture. Potluri et al. [40] adopted a deep neural technique to manage large volumes of network data for deep-category identification. Kang et al. [41] developed a potential intrusion detection system for vehicular networks using deep neural networks. These studies, among others, demonstrate the potential of DNNs in intrusion detection systems and their ability to effectively classify various types of network intrusions.

IV. PROPOSED MODEL (METHODOLOGY)

In this paper, we proposed BiLSTM and neural network models for classification and XGBoost for feature engineering. Moreover, in order to make the evaluation scientifically accurate, we will be using the datasets from the literature (NSL-KDD [10], CIC-IDS2017 [11], and UNSW-NB15 [12]). Unfortunately, these datasets suffer from significant class imbalance problems between the different categories. Prior researchers have not always addressed this issue, which presents a high risk of failing to detect the minority class target value. While the accuracy of these studies may be high due to the low number of candidates for some target classes, it is essential to note that accuracy alone can be misleading. To overcome this problem, we will incorporate oversampling techniques into the proposed algorithms to improve the detection of target classes in the imbalanced data. In addition to accuracy, we will also focus on precision and recall as performance metrics in this research. A. Modeling Process The proposed study will employ two main modeling processes to train the chosen dataset for intrusion detection. These two processes are combined:

- Xgboost + 1DCNN, BiLSTM
- Xgboost + DNN, BiLSTM.

Furthermore, the hyperparameter tuning process will be applied to both models to ensure the most accurate testing. B. Training and Testing This section will provide an overview of the four models utilized in this study. These models were created to evaluate and compare the performance of the proposed framework under varying circumstances. The defined models are as follows:

- Model 1: Using a standard dataset and applying [1D CNN + BiLSTM]
- Model 2: Using a standard dataset and applying [ANN + BiLSTM]
- Model 3: Using a balanced dataset (created with SMOTE) and applying [1D CNN + BiLSTM].
- Model 4: Using a balanced dataset (created with SMOTE) and applying [ANN + BiLSTM].

The split model framework is illustrated in Fig. 1.

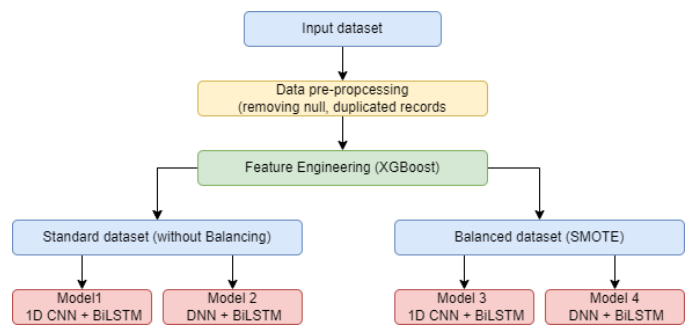

Fig. 1. Proposed model framework.

For this study, three datasets have been utilized, namely NSL-KDD, CIC-IDS2017, and UNSW-NB15. The dataset underwent several preprocessing steps, including removing null elements and duplicate rows, changing data types to use lower memory, and performing label encoding. The presence of any missing values in the selected dataset was analyzed, and the results are presented in Fig. 2.

```
print('total number of null elements present in the dataset : ', combined_data.isnull().sum().sum())
total number of null elements present in the dataset : 0
```

Fig. 2. Null elements.

A. Converting Data to Numerical Values

To utilize the categorical features in deep learning algorithms, the data needs to be converted into numerical values. One way to achieve this is through one hot encoding, a technique that represents categorical variables as numerical values in a machine learning model. One hot encoding offers several advantages, such as enabling categorical variables in models requiring numerical input and improving model performance by providing more information about the categorical variable. For this study, the categorical variables identified

in the features selection stage have been used, and one hot encoding is performed on these variables. An example of the resulting output is shown below using the NSL-KDD dataset after performing the one hot encoding function. The pre-processed data can now be used for training the deep learning models.

In their study, Mohammed [42] designed a fully connected network structure consisting of input, hidden, and output layers. To define these layers, the author utilized the Dense class, which allows them to specify the number of nodes or neurons in the layer as the first argument and the activation function to use the activation argument. In their architecture, the ReLU activation function was applied to the first two layers to introduce non-linearity. In contrast, the Sigmoid activation function was used in the output layer to ensure the network output is confined between 0 and 1. Moreover, the author implemented a dropout regularization technique to mitigate overfitting during training.

In the proposed model, one-hot encoding is crucial since both BiLSTM and XGBoost have been shown to work better with numerical values rather than categorical values [43], [44]. By applying one-hot encoding to categorical variables such as Protocol type, service, and Flag, a more appropriate input format is achieved for our machine learning algorithms. This approach ensures enhanced performance and more accurate results. One-hot encoding is applied to variables such as Protocol type, service, and Flag [44], as shown in Fig. 3 (before encoding) and Fig. 4 (after encoding).

protocol_type	service	flag
tcp	private	REJ
tcp	private	REJ
tcp	ftp_data	SF
icmp	eco_i	SF
tcp	telnet	RSTO

Fig. 3. Data before One Hot Encoding.

flag_REJ	flag_RSTO	flag_RSTO50	flag_RSTR	flag_50	flag_51	flag_52	flag_53	flag_SF	flag_SH
0	0	0	0	0	0	0	0	1	0
0	0	0	0	0	0	0	0	1	0
0	0	0	0	1	0	0	0	0	0
0	0	0	0	0	0	0	0	1	0
0	0	0	0	0	0	0	0	1	0

Fig. 4. Data after One Hot Encoding.

B. Data Standardization

To bring the numeric columns in the dataset to a standard scale without distorting their differences in ranges of values, the data needs to be standardized. Standardization is a process that rescales the distribution of values so that the mean of the observed values becomes 0 and the standard deviation becomes 1. To achieve this, the standard scalar method was used for standardization. A value is standardized as follows:

$$y = \frac{x - \text{mean}}{\text{standard_deviation}} \quad (1)$$

Where the mean is calculated as:

$$\text{mean} = \frac{\sum x}{\text{count}(x)} \quad (2)$$

And the standard deviation is calculated as:

$$\text{standard_deviation} = \sqrt{\frac{\sum (x - \text{mean})^2}{\text{count}(x)}} \quad (3)$$

C. Oversampling Technique

The data preprocessing and standardization steps are applied uniformly to all three datasets. However, since the datasets are highly imbalanced, it is necessary to use data-balancing techniques to improve performance. Imbalanced data refers to datasets in which the target class has an uneven distribution of observations, with one class label having a significantly higher number of observations than the other. To address this issue, we will use an oversampling technique called SMOTE (Synthetic Minority Oversampling Technique) to balance the data. The SMOTE technique uses a hybrid method called SMOTE+TOMEK [45] to remove overlapping data points for each class dispersed in the sample space. Once SMOTE has finished its oversampling, the class clusters may encroach on each other's space, causing the classifier model to overfit. The pairs of samples from opposing classes closely related are called Tomek linkages. Most of the class observations from these linkages are eliminated to improve class separation near decision boundaries. The links are applied to oversampled minority class samples from SMOTE to obtain better class clusters. Therefore, both class observations from the Tomek linkages are typically deleted, rather than just the observations from the majority class. In their study, Mohammed [42] designed a fully connected network structure consisting of input, hidden, and output layers. To define these layers, the author utilized the Dense class, which allows them to specify the number of nodes or neurons in the layer as the first argument and the activation function to use the activation argument. In their architecture, the ReLU activation function was applied to the first two layers to introduce non-linearity. In contrast, the Sigmoid activation function was used in the output layer to ensure the network output is confined between 0 and 1. Moreover, the author implemented a dropout regularization technique to mitigate overfitting during training. The hyper parameters for the four models were tuned based on their performance on selected performance metrics, which include accuracy, precision, recall, and F1 score. Tables 1 and 2 list the hyper parameters chosen for each model.

D. Feature Engineering and DL Classifications

The next step involves performing feature engineering to develop a deep learning model. In this study, XGBoost, an optimized gradient boosting algorithm, will be used for feature engineering as it performs better on numerical datasets for both Model 3 and Model 4. The top 20 essential features from the used dataset were identified using the XGBoost classifier algorithm to perform feature extraction. This was achieved by tuning hyperparameters such as the number of estimators, leaves, and the maximum depth of trees in the algorithm.

The literature describes that sequence modeling algorithms have shown promising results in handling numerical data in recent years. Various algorithms such as RNN, LSTM, MLP, DNN, and BiLSTM have been used as classification models for Intrusion detection problems. For instance, an unsupervised deep learning technique called Autoencoder takes a vector as input and produces the same dimension vector as output. The primary process involves taking input data, reducing its dimensionality, reconstructing it into a lower dimension, and then attempting to reconstruct it back to its original dimension. During this process, the noise in the data is removed, and only the essential features are retained as input data shape.

The hyper-parameters tuned for these four models are outlined in Tables I and II. These were selected based on the performance metrics chosen for evaluation. The considered performance metrics include Accuracy, Precision, Recall, and F1 Score.

TABLE I. HYPER PARAMETER USED FOR MODELS 1 AND 3

Hyper parameters	ID CNN (Model 1 and 3)
Epochs	150
Optimizer	Adam
Batch Size	128
# of Layers (1D)	2
Maxpooling Layers	3
Batch Normalization	3
BiLSTM Layers	2

TABLE II. HYPER-PARAMETER USED FOR MODELS 2 AND 4

Hyper parameters	DNN (Model 2 and 4)
Epochs	150
Optimizer	Adam
Batch Size	256
# of Layers (NN)	2
Maxpooling Layers	1
Batch Normalization	1
BiLSTM Layers	2

The dataset has been divided into training, and testing data using the Train Test Split function from Sci-Kit Learn to prepare for training the model. For the model an optimal ratio of 80% has been selected for training data and 20% for testing data.

V. RESULTS

this section present the results of the proposed module aimed at enhancing the performance of an Intrusion Detection System (IDS). After running the module, we have reached some critical conclusions regarding the efficacy of the proposed approach. Specifically, we have utilized four different models to assess the system's performance and determine which model performs better based on various metrics. In this section, we will discuss the results of the evaluations and highlight the strengths and weaknesses of each model.

Various performance metrics determine which of the four models performs better. The metrics used to evaluate the models include precision and recall. Precision measures the percentage of correctly predicted positive outcomes out of all the predicted positive outcomes. It can be expressed as the ratio of true positives (TP) to the sum of true and false

positives (TP + FP). Mathematically, precision can be defined as $TP / (TP + FP)$. Precision primarily focuses on the positive class rather than the negative class. Recall, also known as sensitivity, measures the percentage of correctly predicted positive outcomes out of all the actual positive outcomes. It can be expressed as the ratio of true positives (TP) to the sum of true positives and false negatives (TP + FN). Mathematically, recall can be defined as $TP / (TP + FN)$. The definitions of precision and recall are:

$$Precision = \frac{TP}{(TP + FP)}$$

Another metric is The F1-score, which is a weighted harmonic mean of precision and recall and measures the overall performance of a classifier model. The highest possible F1 score is 1.0, while the lowest is 0.0. As the F1-score is based on precision and recall, it is always lower than accuracy measures, which incorporate only one of these factors. The weighted average of F1-scores should be used to compare classifier models rather than a global accuracy measure.

$$F1 = \frac{2 \times (Precision \times Recall)}{(Precision + Recall)}$$

In this paper, we will explain how we implemented the four modules on the NSL-KDD datasets. The performance metrics described earlier were used to evaluate the three datasets using the four models previously defined. All four models were implemented for each dataset, and the results were compared to determine which model performed best. Subsequently, we will present a summarized table of the results obtained from the other two datasets without delving into the implementation details since we followed the same approach as the first dataset.

1) Model 1: imbalanced dataset: 1D CNN + BiLSTM:

In the case of the ND-L-KDD dataset, model 1 achieved better accuracy, which is noteworthy given the imbalance in the data. Specifically, the training accuracy was 98.3%, and the testing accuracy was 97.9%. The accuracy plot in Fig. 5 provides additional insight into the model's behavior and can be used to identify any inconsistencies that may have occurred during training.

Fig. 5. Model 1 accuracy-epoch.

Fig. 5 demonstrates a typical trend, with a gradual decrease in loss observed during the training phase and some fluctuations across all epochs for the testing dataset. These fluctuations are also visible in the accuracy plot, indicating that the model tries to learn from the loss experienced in the previous epoch.

TABLE III. MODEL 1: CONFUSION MATRIX

Attacks	Normal	Dos	Probe	R2L	U2R
Normal	10609	49	1	3	0
Dos	52	15208	97	167	6
Probe	4	64	2683	10	0
R2L	0	158	1	569	1
U2R	0	9	0	3	10

The confusion matrix in Table III indicates that the model performed exceptionally well for more class variables. In contrast, the last two classes, R2L and U2R, had very few correctly classified target variables. This could be due to the imbalance in the dataset, which contains only a few classes for these categories. Table 4 shows each class's false positive rate, recall, and F1 score to understand better which class had the lowest correct classification rate.

TABLE IV. MODEL 1: CLASSIFICATION REPORT

Attacks \ metrics	Precision	Recall	F1-Score	Support
Normal	0.99	1.00	0.99	10662
Dos	0.99	0.98	0.98	15530
Probe	0.96	0.97	0.97	2671
R2L	0.76	0.78	0.77	729
U2R	0.59	0.45	0.51	22

The output from the classification report in Table IV indicates that the U2R class has the lowest precision and recall values, with a precision value of 59%, recall of 45%, and F1 score of 51%. This is likely due to the imbalance in the dataset. However, the precision and recall values for the overall model are high, at 97.9% and 97.8%, respectively.

```
precision_score(y_eval,pred, average='weighted')
0.9790783062879445
```

Fig. 6. Model 1 precision score.

Although the total recall and precision values in Fig. 6 and 7 provide an overview of the model's performance, they do not fully capture the degree of imbalance in the data when classifying the testing dataset. To gain a more nuanced understanding of the model's performance, it is necessary to examine each class's precision and recall values separately.

```
recall_score(y_eval,pred, average='weighted')
0.9789590627524912
```

Fig. 7. Model 1 recall score.

2) Model 2: Imbalanced dataset: ANN + BILSTM: accuracy of nearly 99%. Fig. 8 show that accuracy has consistently increased with each epoch. However, some epochs have lower validation accuracy, possibly because the model encountered new images that it had not seen in previous epochs. The same trend is observed in the loss plot.

Fig. 8. Model 1 accuracy-epoch.

TABLE V. MODEL 2: CONFUSION MATRIX

Attacks	Normal	Dos	Probe	R2L	U2R
Normal	10583	36	8	0	0
Dos	64	15136	88	135	3
Probe	12	52	2805	10	0
R2L	2	182	2	557	1
U2R	1	12	0	4	11

The confusion matrix in Table V reveals that the normal class outperforms all other target classes. The U2R and R2L classes demonstrate the weakest performance in accurately classifying the test dataset, which may also be attributed to class imbalance in the dataset.

TABLE VI. MODEL 2: CLASSIFICATION REPORT

Attacks \ metrics	Precision	Recall	F1-Score	Support
Normal	0.99	1.00	0.99	10627
Dos	0.98	0.98	0.98	15426
Probe	0.97	0.97	0.97	2879
R2L	0.79	0.75	0.77	744
U2R	0.73	0.39	0.51	28

Examining the classification report in Table VI, it can be concluded that precision is improved for all classes when compared to Model 1. However, the recall for the U2R class in Model 2 is the lowest among all classes. This indicates that the ratio of correctly predicted positive elements to the total positive elements is low. As a result, the model struggles to predict the U2R class accurately and often misclassifies it as another class.

```
precision_score(y_eval,pred, average='weighted')
0.9790410957911807
```

Fig. 9. Model 2 precision score.

```
recall_score(y_eval,pred, average='weighted')
0.9793967142472394
```

Fig. 10. Model 2 recall score.

The precision and recall values for Model 2 shown in Fig. 9 and 10 are 97.9% and 97.9%, respectively. Although the overall performance of the model is quite remarkable, it is crucial to evaluate the model’s performance for individual classes, particularly those with fewer samples in the dataset. The U2R and R2L classes, for example, exhibit lower performance metrics, which could be ascribed to the class imbalance in the dataset. The total recall and precision do not fully reveal the extent of data imbalance when classifying the testing dataset. It is only by examining each class individually that one can fully understand the model’s performance.

3) *Model 3: Balanced dataset with SMOTE: 1D CNN + BILSTM*: For models 3 and 4, the dataset will be preprocessed using SMOTE to oversample the least represented target classes and increase their count to match the highest represented target classes. This oversampling process balances each category in the dataset and eliminates any class imbalance. The resulting model achieved an accuracy of 95%, indicating that it did not perform better than the first two models that used the imbalanced dataset. The accuracy plot for this model are shown in Fig. 11.

Fig. 11. Model 3 accuracy-epoch.

The confusion matrix presented in Table VII reveals that almost all the target classes have performed better than in the previous two models. The reason for the lower accuracy is that the number of incorrectly classified instances is higher,

as the dataset size increased due to the oversampling of the data. This increase in dataset size led to more opportunities for misclassification, resulting in a lower overall accuracy.

TABLE VII. MODEL 3: CONFUSION MATRIX

Attacks	Normal	Dos	Probe	R2L	U2R
Normal	15377	18	37	6	0
Dos	28	14255	115	814	180
Probe	1	32	15308	83	7
R2L	0	278	10	14972	144
U2R	0	206	0	1361	13870

TABLE VIII. MODEL 3: CLASSIFICATION REPORT

Attacks\metrics	Precision	Recall	F1-Score	Support
Normal	1.00	1.00	1.00	15438
Dos	0.96	0.93	0.94	15392
Probe	0.99	0.99	0.99	15431
R2L	0.87	0.97	0.92	15404
U2R	0.98	0.90	0.94	15437

The classification report in given in Table VIII. The precision and recall of Model 3 for all the target classes were better than those of the previous two models. When comparing these metrics for Models 1 and 2, the precision of the U2R class for Model 3 was 98%, while for the others, it was 73% and 59%. For the U2R class in recall, Model 3 had 90%, whereas Model 1 had 45% and Model 2 had 39%. This demonstrated that Model 3 performed significantly better than the other models and had a higher prediction rate for less frequent target classes. This performance improvement was solely due to the balancing of the data, which allowed the model to learn more about the less frequent target variable classes. The classification report was provided as well. The average weighted precision and recall values for Model 3 were 95.9% and 95.6%, respectively.

4) *Model 4: Balanced dataset with SMOTE: ANN + BILSTM*: The accuracy plot shown in Fig. 12 displays a significant amount of fluctuation in the validation dataset, which can be attributed to the fact that the model may have encountered a different set of data during testing on that epoch.

Fig. 12. Model 4 Accuracy-Epoch.

As seen in the confusion matrix in Table IX, the values appear similar to those of Model 3, with the ratio of correctly predicted classes remaining consistent between the two models. To gain a deeper understanding of the model's performance, it is necessary to examine the precision, recall, and F1 score mentioned in Table X. When compared to Model 3, Model 4 exhibits weaker performance, as the precision for the U2R class is lower, and the recall for the R2L class is significantly lower than the previous model. The precision and recall values obtained for this model are 95.3% and 94.8%, respectively.

TABLE IX. MODEL 4: CONFUSION MATRIX

Attacks	Normal	Dos	Probe	R2L	U2R

Probe	0.99	0.99	0.99	15431
R2L	0.95	0.83	0.89	15404
U2R	0.85	1.00	0.91	15437

VI. EVALUATION

A. Evaluation of the Models Against the NSL KDD Dataset

In the NSL-KDD dataset, when considering accuracy, Model 1 and Model 2 perform better than Model 3 and Model 4, achieving a high accuracy of approximately 99%. When taking average precision and recall into account, Models 1 and 2 still outperform Models 3 and 4. However, Models 1 and 2 predict poorly for two attack classes, namely R2L and U2R, which can be clearly observed in both the confusion matrix and classification report. The number of incorrect predictions is higher in Models 1 and 2 compared to Models 3 and 4.

In Models 3 and 4, the precision and recall for U2R and R2L are above 85%, and for other attack classes, they are above 93%. Model 3 demonstrates better precision and recall rate performance compared to Model 4, as Model 3 combines Bi-LSTM and 1D-CNN with balanced data, whereas Models 1 and 2 were trained on imbalanced data.

Additionally, Model 3 excels at correctly detecting most of the classes in the dataset. This model incorporates SMOTE for balancing data, XGBoost for feature engineering, and a combination of 1D-CNN and Bi-LSTM as the classification algorithm. Although the training and testing accuracy of Model 3 is lower than that of Models 1 and 2, this is due to the significantly smaller number of elements in the target classes with the least representation in Models 1 and 2 (U2R - 52, R2L - 995). Consequently, even if these classes were entirely misclassified, only 1,047 out of 125,973 would be incorrectly classified. However, if these classes were misclassified in real-time, they would be detected as normal or other attacks, undermining the goal of detecting intrusions.

To address this issue, precision and recall were calculated for each target class in the dataset. This approach allows to evaluate how well the model has predicted each target class individually, rather than. Models 1, 2, and 4 exhibit lower precision and recall for the U2R and R2L classes. In contrast, Model 3 demonstrates a precision of 98% for U2R and 87% for R2L, along with a recall of 90% for U2R and 97% for R2L. Table XI provide a summery of NSL-KDD dataset performance. While Table XII and XIII provides a comparison of the performance of the best model against similar research in the literature.

TABLE XI. SUMMARY OF THE NSL - KDD DATASET PERFORMANCE

Models	Precision	Recall
1	97.9	97.8
2	97.9	97.9
3	95.9	96.9
4	95.3	94.8

TABLE XII. PRECISION PERFORMANCE METRIC - COMPARISON OF OTHER PAPERS

Target class	Best model	Chongzhen	Mohammed	Yakubu Imrana
Normal	100%	71%	61%	75%
DoS	96%	96%	94%	97%
Probe	99%	86%	97%	84%
R2L	87%	81%	99%	98%
U2R	98%	73%	100%	77%

TABLE XIII. RECALL PERFORMANCE METRIC - COMPARISON OF OTHER PAPERS

Target class	Best model	Chongzhen	Mohammed	Yakubu Imrana
Normal	100%	71%	61%	75%
DoS	96%	96%	94%	97%
Probe	99%	86%	97%	84%
R2L	87%	81%	99%	98%
U2R	98%	73%	100%	77%

B. Evaluation of the models against the CIC-IDS2017 dataset

For the CIC-IDS2017 dataset, Model 1 exhibits better accuracy, considering the data imbalance, with a training accuracy of 97.4% and a testing accuracy of 97.3%. The confusion matrix and classification report can be found in Tables XIV and XV.

TABLE XIV. MODEL 1: CIC-IDS2017'S - CONFUSION MATRIX

Attacks	Benign	Port Scan	DDos	WEBattack	Bot
Benign	82423	35	1599	1	3
PortScan	64	12308	0	0	0
DDos	818	0	11340	0	0
Web Attack	120	0	0	64	0
Bot	194	0	0	0	13

TABLE XV. MODEL 1: CIC-IDS2017'S - CLASSIFICATION REPORT

Attacks/metrics	Precision	Recall	F1-Score	Support
Benign	0.99	0.98	0.98	84061
PortScan	1.00	0.99	1.00	12376
DDos	0.88	0.93	0.90	12158
Web Attack	0.81	0.06	0.12	207
Bot	0.98	0.35	0.52	185

Based on the confusion matrix in Table XIV, it is evident that the model performs exceptionally well for the classes with a higher number of instances. The last two classes, DDOS and Web Attack, have very few correctly classified target instances. This can be attributed to the imbalance in the dataset, as there are very few instances for those categories. To understand which class has performed the poorest in terms of correct classification, the false positive rate, recall, and F1 score of the model can be examined in Table XV.

TABLE XVI. MODEL 2: CIC-IDS2017's - CONFUSION MATRIX

Attacks	Benign	Web Attack	PortScan	DDos	Bot
Benign	83824	1	36	157	43
Web attack	127	58	0	0	0
PortScan	18	0	12358	0	0
DDos	114	0	9	12033	2
Bot	145	0	0	0	62

TABLE XVII. MODEL 2: CIC-IDS2017's - CLASSIFICATION REPORT

Attacks \ metrics	Precision	Recall	F1-Score	Support
Benign	1.00	1.00	1.00	84061
Web attack	0.98	0.31	0.48	185
PortScan	1.00	1.00	1.00	12376
DDos	0.99	0.99	0.99	12158
Bot	0.58	0.30	0.39	207

From the confusion matrix XVI, it can be observed that model 2 performs exceptionally well for the classes with a higher number of instances. Similar to Model 1, the last two classes, DDOS and Web Attack, have very few correctly classified target instances. This can be attributed to the imbalance in the dataset, as there are very few instances for those categories. The false positive rate, recall, and F1 score of the model can be seen in Table XVII to understand which class has performed the poorest in terms of correct classification.

For Models 3 and 4, a new dataset will be created using SMOTE, which over samples the least represented target classes and matches their count to that of the most represented target classes.

TABLE XVIII. MODEL 3: CIC-IDS2017's - CONFUSION MATRIX

Attacks	Benign	Web Attack	PortScan	DDos	Bot
Benign	23314	553	16	997	312
Web attack	24	25234	0	0	0
PortScan	395	0	24861	0	0
DDos	1	0	0	25176	21
Bot	2	0	0	6	25251

TABLE XIX. MODEL 3: CIC-IDS2017's - CLASSIFICATION REPORT

Attacks \ metrics	Precision	Recall	F1-Score	Support
Benign	0.98	0.93	0.95	25192
Web attack	0.98	1.00	0.99	25258
Port Scan	1.00	0.98	0.99	25256
DDoS	0.96	1.00	0.98	25198
Bot	0.99	1.00	0.99	25259

The confusion matrix in Table XVIII demonstrates that almost all the target classes in model 3 have performed better than in the previous two models. The lower accuracy can be

attributed to the increased number of mis-classifications due to the over-sampled data, which increased the dataset size.

The precision and recall of this model for all the target classes are better than the previous two models. For instance, the precision of the Web Attack class for Model 3 is 99%, while the other models have 81% and 58%. In terms of recall for the Web Attack class, Model 3 has 100%, whereas Model 1 has 6% and Model 2 has 30%. This indicates that Model 3 has performed significantly better than the other models and has a higher prediction rate for less frequent target classes. This performance improvement is primarily due to the balancing of the data, allowing the model to learn more about the underrepresented target classes. The classification report is provided in Table XIX. The weighted precision and recall values for this model are 98.1% and 98.1%.

TABLE XX. MODEL 4: CIC-IDS2017's - CONFUSION MATRIX

Attacks	Benign	Web Attack	PortScan	DDos	Bot
Benign	24550	470	2	70	100
Web attack	0	25258	0	0	0
PortScan	23	0	25233	0	0
DDos	21	0	0	25173	4
Bot	16	0	0	6	25237

TABLE XXI. MODEL 4: CIC-IDS2017's - CLASSIFICATION REPORT

Attacks \ metrics	Precision	Recall	F1-Score	Support
Benign	1.00	0.97	0.99	25192
Web attack	0.98	1.00	0.99	25258
PortScan	1.00	1.00	1.00	25256
DDos	1.00	1.00	1.00	25198
Bot	1.00	1.00	1.00	25259

In the CIC-IDS2017 dataset, and based on Tables XX and XXI. When evaluating average precision and recall for all models, each one performs well. However, when examining individual precision and recall, Models 1 and 2 under-perform in two classes, namely Web Attack and Bot, which might be due to the imbalance in the dataset. The number of incorrect predictions is higher in Models 1 and 2 compared to Models 3 and 4 for the attack classes. After balancing the data, Model 4 outperforms all other models we have built, with an accuracy of 99% and individual precision and recall for the two classes that performed poorly in Models 1 and 2. For these classes, Model 4 achieves a recall of 100% and precision of 99%.

TABLE XXII. SUMMARY OF THE CIC-IDS2017 DATASET PERFORMANCE

Models	Precision	Recall
1	97.4	97.3
2	99.3	99.3
3	98.2	98.2
4	99.4	99.4

Table XXII presents the precision and recall results of four different models for the CIC-IDS2017 dataset. Model 1 achieves a precision of 97.4% and a recall of 97.3%, indicating good performance, but not the best among the tested models. Model 2 performs exceptionally well, achieving a precision and recall of 99.3% each, which suggests a high degree of accuracy in identifying true positives and avoiding

false negatives. Model 3 shows slightly lower results, with a precision and recall

C. Evaluation of the Models Against the UNSW-NB15 Dataset

For the UNSW-NB15 dataset, Model 1 exhibits better accuracy considering the data imbalance, with a training accuracy of 94.6% and a testing accuracy of 94.5%. The confusion matrix and classification report can be found in Fig. 13 and 14

Attacks	Analysis	Backdoor	Dos	Exploits	Recon	generic	Normal	Fuzzers	Worm

Fig. 14. Model 1 -UNSW-NB15 - classification report.

Fig. 15 and 16 presents the confusion matrix and the classification report for Model 2 on the UNSW-NB15 dataset, showing precision, recall, F1-score, and support for each attack category. The best precision and recall scores of 1.00 are seen in the Generic and Normal classes, indicating perfect classification for these categories. Exploits and Reconnaissance classes also perform well, with precision scores of 0.88 and 0.88, and recall scores of 0.92 and 0.94, respectively. These scores suggest accurate and comprehensive classification in these categories. However, the Backdoor and Worm classes exhibit lower performance, with Backdoor having a precision of 0.38 and a recall of 0.21, and Worm having a precision of 0.50 and a recall of 0.26. The F1-scores for these classes

are also relatively low at 0.27 for Backdoor and 0.34 for Worm, indicating weaker classification performance for these categories.

Attacks	Analysis	Backdoor	Dos	Exploits	Recon	generic	Normal	Fuzzers	Worm
Analysis	88	0	2	28	00	0	0	0	0

Worm	0.50	0.26	0.34	19

Fig. 16. Model 2 -UNSW-NB15 - classification report.

The classification report for Model 3 in Fig. 17 includes metrics such as precision, recall, and F1-score for each class in the UNSW-NB15 dataset. These metrics allow us to assess how well the model is able to identify each individual class. The model shows remarkable performance for “Generic” and “Normal” classes, achieving nearly perfect precision, recall, and F1-scores. Additionally, “Analysis” and “Reconnaissance” classes exhibit strong performance with high precision and recall values resulting in impressive F1-scores. However, there are some classes that have weaker performance. For example, the “Backdoor” and “Exploits” classes have a notable discrepancy between their precision and recall values, leading to lower F1-scores. Additionally, the “Dos” class has balanced precision and recall values, but they are still lower than those of other

classes. The “Fuzzers” class has a low precision of 0.44 but a high recall of 0.94, resulting in a moderate F1-score. Lastly, the “Worm” class has a high precision of 0.89 but a low recall of 0.37, leading to a relatively low F1-score of 0.52.

The evaluation of Model 3’s classification report and confusion matrix shown in Fig. 19 and 18 weights revealed that the model can accurately identify positive instances for each class with a precision score of 84.15%. However, it is only able to capture 78.6% of the actual positive instances in the dataset, indicating room for improvement in recall performance. Despite the model’s varied performance across different classes, the higher precision score suggests that the model is relatively reliable when it makes predictions for a specific class. In summary, these results suggest that the model can benefit from further optimization to improve its overall performance, especially in the under performing classes.

Attacks/ metrics	Precision	Recall	F1-Score	Support
Analysis	0.93	0.98	0.95	7896
Backdoor	0.80	0.62	0.70	7865
Dos	0.74	0.74	0.74	7803
Exploits	0.84	0.62	0.71	7682
Reconnaissance	0.93	0.83	0.88	7885
Generic	1.00	0.99	0.99	7894
Normal	1.00	1.00	1.00	7899
Fuzzers	0.44	0.94	0.60	7717
Worm	0.89	0.37	0.52	7884

Fig. 19. Model 3 -UNSW-NB15 - classification report.

Model 4’s performance is similar to that of Model 3, with accuracy improving gradually with each epoch. However, there are some fluctuations in the validation accuracy that could be due to the model being exposed to new, unseen data during specific epochs. The same is true for the loss plot.

Fig. 18. Model 3 -UNSW-NB15 - confusion report (Part 2).

The classification report and confusion matrix for Model 4, presented in the Fig. 20 and 21 and 22, indicates that the model performs exceptionally well in most categories. Precision and recall scores are notably high for Analysis, Reconnaissance, Generic, Normal, and Worm attack types, with values near or at 1.00, indicating excellent performance. The performance for Backdoor, Dos, Exploits, and Fuzzers is also quite good, with precision and recall scores ranging between 0.85 and 0.99. Overall, the high scores across the board suggest that Model 4 is highly effective at identifying various attack types in the UNSW-NB15 dataset.

In the UNSW dataset, a total of nine attack classes have been used, with a higher number of attacks features present in Generic, Normal, and Exploits. Other attack classes have fewer rows, resulting in data imbalance. Models 1, 2, and 4 achieve an accuracy of around 95%, while Model 3 has an accuracy of 78%. This clearly demonstrates that Model 3

Attacks	Reconnaissance	generic	Normal	Fuzzers	Worm

Worm	0.98	0.99	0.98	7884

Fig. 22. Model 4 -UNSW-NB15 - classification report

significantly under performs compared to the other models. When examining the individual precision and recall of the attack classes in Models 1 and 2, only the classes with a higher number of data points perform well, while others, aside from Generic, Normal, and Exploits attack classes, perform poorly. The least performing class is Backdoor, where the recall in Model 2 is around 7%. After oversampling the dataset using SMOTE, Model 4 performs better than the other models, with an accuracy of 95% and improved individual precision and recall for each of the classes. Classes with fewer data points, such as Analysis, Backdoor, DoS, and Exploits, perform better in Model 4, which incorporates ANN + Bi-LSTM models after data balancing.

D. Evaluation Summary for the Three Datasets

In summary, for the NSL-KDD, CIC-IDS2017, and UNSW-NB15 datasets, Models 1 and 2 generally perform well in terms of accuracy, while Model 3 under performs. Model 4, which employs ANN + Bi-LSTM models after data balancing using SMOTE, consistently outperforms the other models, especially when considering individual precision and recall for each attack class. Model 4 improves performance for underrepresented attack classes, indicating that balancing

the dataset and using ANN + Bi-LSTM models contribute to better overall performance in intrusion detection. Table XXIII demonstrate the results of the best performing model.

TABLE XXIII. BEST MODEL (MODEL 4) - RESULTS

Dataset	Accuracy	Precision	Recall
NSL-KDD	95.8	95.3	94.8
CIC-IDS2017	99.0	99.3	99.3
UNSW-NB15	95.3	94.4	94.2

VII. DISCUSSION

The results presented in this study provide valuable insights into the performance of four different intrusion detection models across three distinct cybersecurity datasets. Through a rigorous evaluation process, we have demonstrated the effectiveness of the proposed model, which combines BiLSTM, XGBoost, and 1DCNN/DNN, in detecting intrusions across diverse cybersecurity environments.

The findings show that Model 4, which utilizes ANN + Bi-LSTM architecture with data balancing using SMOTE, consistently outperforms the other models in terms of precision and recall. This indicates the model's capability to effectively detect intrusion attempts, even in underrepresented attack classes. These results suggest that data balancing techniques combined with deep learning architectures offer a promising approach to improving the performance of intrusion detection models.

Additionally, the study shows that the proposed model is adaptable to different cybersecurity contexts, as demonstrated by its strong performance across the NSL-KDD, CIC-IDS2017, and UNSW-NB15 datasets. The diversity of these datasets highlights the need for intrusion detection models that can effectively handle varying cybersecurity landscapes. The results suggest that the proposed model has the potential to offer an effective solution to the ongoing challenge of intrusion detection in such environments.

It is worth noting that the study is not without limitations. While we have evaluated the proposed model across three distinct datasets, there exist many other cybersecurity datasets that could provide a more comprehensive evaluation of the model's performance. Additionally, the study has focused solely on the effectiveness of intrusion detection models and has not explored other potential applications of deep learning in cybersecurity, such as anomaly detection or threat intelligence.

Overall, our study provides evidence that combining deep learning architectures with data balancing techniques can lead to improved performance in intrusion detection. The proposed model's adaptability to diverse cybersecurity contexts offers promise for the development of effective and robust intrusion detection systems. Future research could explore the use of the proposed model on other cybersecurity datasets and investigate the potential applications of deep learning in other areas of cybersecurity.

VIII. CONCLUSION

This study investigated the effectiveness of using the XG-Boost algorithm for feature selection in combination with dif-

ferent deep learning (DL) approaches, such as ANN, 1DCNN, and BiLSTM, to build accurate intrusion detection systems (IDSs) in both binary and multiclass classification settings. Three datasets were used to evaluate the proposed methods: NSL-KDD, CIC-IDS2017, and UNSW-NB15. The results demonstrate the classification models' high accuracy and low error rate, indicating that the proposed methods are a viable and promising approach for designing IDS.

Initially, the suggested DL techniques were used to test the datasets across the entire feature space, followed by the implementation of the XGBoost feature extraction technique presented in this study to obtain a reduced feature vector. The study also analyzed the performance results of researchers who utilized various classifiers. The experimental results showed that using a reduced feature vector can help reduce the model's complexity while improving detection accuracy on test data.

The datasets used in this study all contained data imbalance, which can lead to biased models over the larger categorical class. This issue was observed in models 1 and 2 on all three datasets. The SMOTE data balancing technique was introduced to address this issue, resulting in better performance in models 3 and 4, as indicated by the individual class's precision and recall. Specifically, for the NSL-KDD dataset, models 1 and 2 had low U2R class performance, with precision and recall values of 59

Overall, the performance of Models 1 and 2 is generally good in terms of accuracy for the NSL-KDD, CIC-IDS2017, and UNSW-NB15 datasets, while Model 3 does not perform as well. However, Model 4, which involves the use of ANN + Bi-LSTM models after applying SMOTE for data balancing, consistently outperforms the other models, particularly when looking at the precision and recall of each individual attack class. By improving the performance of underrepresented attack classes, Model 4 suggests that balancing the dataset and utilizing ANN + Bi-LSTM models contribute to overall improvement in intrusion detection performance.

Therefore, future work could involve implementing a novel sampling technique designed explicitly for IDSs to boost the prevalence of the minority classes in other public datasets during the training phase. Overall, this study's findings highlight the importance of data balancing techniques in addressing data imbalance issues and the effectiveness of using XGBoost and DL approaches in building accurate IDSs.

ACKNOWLEDGMENT

We are appreciative of our colleagues and other researchers for their aid with editing, feedback meetings, and moral support. The university's research assistants and study participants, who impacted and inspired us should also be thanked.

QMX-BdSL49: An Efficient Recognition Approach for Bengali Sign Language with Quantize Modified Xception

Nasima Begum*, Saqib Sizan Khan, Rashik Rahman, Ashraful Haque, Nipa Khatun, Nusrat Jahan, Tanjina Helaly
Department of Computer Science and Engineering, University of Asia Pacific,
Dhaka, Bangladesh

Abstract—Sign language is developed to bridge the communication gap between individuals with and without hearing impairment or speech difficulties. Individuals with hearing and speech impairment typically rely on hand signs as a means of expressing themselves. However, people, in general, may not have sufficient knowledge of sign language, thus a sign language recognition system on an embedded device is most needed. Literature related to such systems on embedded devices is scarce as these recognition tasks are very complex and computationally expensive. The limited resources of embedded devices cannot execute complex algorithms like Convolutional Neural Network (CNN) properly. Therefore, in this paper, we propose a novel deep learning architecture based on default Xception architecture, named Quantized Modified Xception (QMX) to reduce the model's size and enhance the computational speed without compromising model accuracy. Moreover, the proposed QMX model is highly optimized due to the weight compression of model quantization. As a result, the footprint of the proposed QMX model is 11 times smaller than the Modified Xception (MX) model. To train the model, BDSL 49 dataset is utilized which includes approximately 14,700 images divided into 49 classes. The proposed QMX model achieves an overall F1 accuracy of 98%. In addition, a comprehensive analysis among QMX, Modified Xception Tiny (MXT), MX, and the default Xception model is provided in this research. Finally, the model has been implemented on Raspberry Pi 4 and a detailed evaluation of its performance has been conducted, including a comparison with existing state-of-the-art approaches in this domain. The results demonstrate that the proposed QMX model outperforms the prior work in terms of performance.

Keywords—Bengali sign language; CNN; computer vision; model quantization; Raspberry Pi 4; transfer learning; Tiny ML

I. INTRODUCTION

Disability is a crucial issue in terms of human rights because a person with an impairment is usually deprived of ordinary public welfare. Almost a billion of the world's population has some form of physical disability¹. Individuals with disabilities experience more negative socioeconomic consequences, resulting in a poorer standard of life. While over 430 million people worldwide suffer from hearing impairment², there are more than 1.7 million hearing and speaking impaired people in Bangladesh alone³. These impaired people belong to

the Bangladesh Deaf and Mute Community (BDMC). Due to their communication impediment, the BDMC, faces numerous obstacles while attempting to participate in education, work, social activities, and other aspects of everyday life.

Sign language employs the visual-manual paradigm to communicate meaning. Sign language is conveyed via hand and finger movements to create gestures. The only way to communicate with people with hearing or speaking disabilities is through sign language. Similar to every other language, the Bengali language has its own sign language, which is known as Bengali Sign Language (BdSL). The BDMC uses only BdSL to communicate with everyone, which restricts their ability to converse with society, as the majority of the society does not know sign language due to a lack of social awareness.

In the aforementioned scenario, communication between the BDMC and society requires a sign language interpreter. However, a skilled interpreter may not always be readily available, and in such circumstances, paying fair fees may be a serious worry. An automated recognition system for sign language can play a vital role in reducing the basic and social differences between society and BDMC. Therefore, sign language recognition is a popular area of study. Current research in this area focuses mostly on either sensor-based [1] or vision-based [2] systems.

Numerous studies have been conducted on BdSL recognition, and there are numerous benchmarking datasets [3], [4], [5], [6], [7] for BdSL recognition. However, these datasets are insufficient for training and evaluating deep learning models, and the majority are not open-source. CNN [8], [9] is a popular choice along with the transfer learning [10], [11], [12] model to recognize BdSL.

Several research implements the CNN model for recognizing BdSL. Hossain et al. [13] proposed a CNN-based sign language recognition model and achieved 98.75% accuracy. Islam et al. [14] also proposed a CNN-based model, and they evaluated their model using 10-fold cross-validation. They achieved 99.80% accuracy. Some research utilized CNN-based transfer learning models for recognition. Rafi et al. [4] utilized the VGG19 transfer learning model with 89.6% accuracy. To our knowledge, no prior work exists on constructing an efficient deep learning model that can be implemented in embedded or IoT devices via model quantization. The majority of recent work employed mainstream or pre-trained models. Therefore, these models cannot be implemented on devices with a low configuration.

²<https://www.who.int/news-room/fact-sheets/detail/deafness-and-hearing-loss>

³https://en.wikipedia.org/wiki/Deafness_in_Bangladesh

Therefore, this research proposes a BdSL recognition deep learning system in which the available default Xception [15] model has been extensively altered to obtain a new model with greater accuracy. In addition, the novel Modified Xception (MX) model has been quantized in order to be applied in embedded systems. Thus in this research, a novel Quantized Modified Xception (QMX) model is proposed. This paper also offers a comprehensive investigation of QMX, Modified Xception Tiny (MXT), Modified Xception (MX), and the default Xception model. Furthermore, the developed QMX model has been successfully implemented on an embedded device, namely the Raspberry Pi 4. The QMX recognition model is only 3.3MB in size and contains just 3,317,201 trainable parameters, making it an extremely lightweight model for embedded system implementation. To train and evaluate the model, an open-source benchmark dataset named BDSL 49 [16] that contains 14,700 images divided into 49 classes is utilized. The QMX model achieved an overall F1 accuracy of 98%.

The main contributions of this research are as follows:

- A quantization algorithm for the Modified Xception (MX) model.
- A Quantized Modified Xception (QMX) model has been proposed to recognize hand signs and predict the characters. The QMX model is 72 and 11 times lighter than the default Xception and Modified Xception (MX) models respectively. Moreover, it achieved an average F1-score of 98%.
- For IoT implementation, the proposed QMX model is deployed on an embedded system, which is Raspberry Pi 4 for evaluating the model efficiency and inference time.

The rest of the paper is structured as follows: Section II represents the literature review. The dataset description is provided in Section III. The proposed methodology is described in Section IV. Section V analyzes the results of the conducted experiments. Lastly, Section VI concludes the paper with some future works.

II. LITERATURE REVIEW

Recognition of sign language is a very intriguing area of study. Although research on BdSL recognition is abundant, few have managed to make it implementable and attainable in a practical situation; therefore, it remains unexplored. This section outlines the evolution of research regarding BdSL recognition.

Islam et al. [17] provided a Bengali sign language digit recognition system using deep learning, which delivers the output in text form. Using the Ishara-Lipi dataset, they developed the proposed model, which gained about 95% accuracy. However, they did not use RGB images during model training. Khan et al. [18] proposed a CNN and Region of Interest (ROI) segmentation-based BdSL translator device that can translate only five sign gestures. It has a 94% accuracy rate for recognizing signs in real-time. Due to the lack of available signs for different words, they built the device using five words only. The authors of [19], reviewed the research approaches of BdSL from 2002 to 2021 and discussed each work's contributions

and weaknesses. The Scale Invariant Feature Transform (SIFT) technique and CNN were used in the proposed system of [3] to detect one-handed gestures of 38 Bengali signs. However, they used grayscale images for training their proposed model. Using CNN, the authors of [13] achieved 98.75% accuracy in recognizing Bengali signs. However, they only used one-handed sign gestures. Shurid et al. [9], proposed a Bengali sign language recognition and sentence building CNN-based model and achieved 90% accuracy using their augmented dataset. However, their proposed model could not work properly to recognize critical sign gestures.

Ishara-Lipi [6] is a commonly used dataset for BdSL recognition, though it consists of only 36 characters out of 49. "BenSignNet" a CNN and concatenated segmentation-based model, was proposed in [8] that only detects Bengali Sign Language alphabets using three different datasets. However, the model is computationally expensive as it used several image processing techniques. Ilias et al. [20] proposed a Sign Language Recognition Generative Adversarial Network (SLRGAN) using a Context-Aware Generative Adversarial Network architecture. The proposed model achieved 23.4%, 2.1%, and 2.26% word error rates for three primarily used datasets such as RWTH-Phoenix-Weather-2014, Chinese Sign Language (CSL), and Greek Sign Language (GSL). However, they considered only the contextual information of the sign language. A CNN-LSTM model was proposed to recognize both hands' lexical signs in Bangla [7]. However, the BdSL dataset has only 36 classes with 13,400 images and produced 90% training accuracy and 88.5% testing accuracy. Rafi et al. [4], proposed a VGG-19-based model to recognize 38 different classes of Bengali sign gestures and obtained 89.6% test accuracy. However, their dataset contains a low amount of sample images. In order to enhance inter-dataset performance, the research work [10] uses a variety of deep learning models and angular loss functions to highlight the significance of generalization in finger-spelled BdSL recognition. Due to a lack of diversity in the dataset, they achieved 55.93% and 47.81% test accuracy using the SphereFace loss function in the VGG-19 architecture. A pre-trained model called "MobileNet" was proposed in [11]. The authors proposed an approach for converting signs made in BdSL into their appropriate Bengali letters. They evaluated the model using the Ishara-Lipi dataset and achieved 95.71% accuracy. However, this model could not detect the hand signs in different backgrounds.

The authors of [21] presented a quantization method to estimate the floating-point calculations in a neural network using just integer arithmetic. The network quantization techniques are discussed by Garifulla et al. [22] which are used for disease diagnosis on portable medical devices to reduce the CNN models' size and inference time. The authors of [23] examined the mathematical properties of quantization parameters and assessed the choices made for a large variety of neural network models for various domains of application, such as voice, language, and vision. Koutayni [24] introduced a low-energy solution for depth camera-based hand posture estimation methods and compressed the deep neural network model using dynamic quantization approaches at various levels to gain maximum compression without sacrificing accuracy.

Most of the existing BdSL recognition models are trained with datasets, which are insufficient due to the lack of data

TABLE I. CLASSES LABEL AND NAME

2	240	60	128 x 128	RGB
...
48	240	60	128 x 128	RGB

samples in them. Furthermore, hardly any research focuses on the real-life implementation of BdSL recognition systems on low-end devices.

III. DATASET DESCRIPTION

The use of sign language is essential to communicate with persons with hearing disabilities or persons with speaking disabilities. A dataset is highly useful for an automated system to recognize the hand signs of Bengali Sign Language. For this research purpose, a dataset named BdSL 49 [16] is utilized with 49 classes. Each class represents a Bengali alphabet, numeric character, or special character (space, Hasantha). The dataset consists of 14,700 images organized into 49 categories. In Table I, 49 labels of the dataset referring to the naming of Bengali letters are listed. Fig. 1 illustrates sample images of each class.

Each sample image is labeled with the appropriate Bengali characters. Each class has approximately 300 images and is divided into two sections: one for training and the other for testing the model. 80% of the images for each class is considered for training, while the remaining 20% is considered for testing. Table II illustrates the data distribution between the train and the test set of the BdSL 49 dataset. As shown in Table II, there are 240 samples in the train set and 60 samples in the test set of each class. All images are in RGB format with a 128X128 pixel size.

IV. METHODOLOGY

This section discusses the proposed methodology. As the embedded low-end devices are unable to run computationally expensive models, thus a novel Modified Xception (MX)

model is proposed and described in subsection IV-A. However, when the MX model is implemented in an embedded device to perform in real-time, its footprint needs to be compressed further. Hence, in subsection IV-B, a quantization method is proposed that quantizes the MX model, and thus, the QMX model is achieved by converting the float 32-bit MX model into an int 8-bit QMX model. The QMX model is proposed to run the model specifically in a relatively low-configuration devices in real time environment.

Initially, some benchmark transfer learning models, namely Xception, InceptionV3, InceptionResNetV2, MobileNet, MobileNetV2, ResNet50V2, ResNet101V2, and ResNet152V2 are trained using the BdSL 49 dataset. Among these eight models, the Xception model performed comparatively well. However, it provides only 93% accuracy. Based on the performance analysis, Xception has the best level of accuracy. The Xception model architecture is chosen as a framework for developing the proposed QMX architecture. However, the Xception model size is around 240MB, which is very large. Therefore, to improve the model's performance and decrease the model's size, the Xception model's architecture is altered, and a novel MX model is proposed. Afterward, the MX model is quantized to implement it in embedded devices. Thus, the Quantized Modified Xception (QMX) model is attained. Finally, the QMX model is implemented on an embedded device, namely the Raspberry Pi 4, for inference.

A. Proposed Modified Xception Architecture

The proposed MX model is a highly comprehensive architectural model featuring 31 layers instead of the 71 layers of the original Xception model. The architecture of Xception is divided into three components. Initially, the data passed via the entry flow, then eight times repeated in the middle flow, and finally, passed through the exit flow. However, the precision of hand sign recognition is inadequate. Additionally, since Xception is a generalized architecture, it contains an extensive number of trainable parameters that are not optimal for all types of recognition. Hence, the purpose of our research is to design an effective architecture with the essence of the Xception model and achieve adequate precision for BdSL recognition.

The proposed MX model utilizes the Depthwise Separable Convolutional (DSC) layer which is a variant of the Separable Convolutional layer. The DSC layer partitions the process into two or more sub-processes. Upon the conclusion of each sub-process, the outcomes are integrated with the overarching result. Therefore, it reduces the multiplication costs resulting for a similar type of process. The utilization of Separable Convolution reduces the computational cost as well as the number of trainable parameters. The standard convolution operation incurs a substantial computational expense due to the simultaneous processing of all color channels, as indicated by the multiplication cost outlined in Eq. (1). In contrast, separable convolution is a technique that separates the color channels. Consequently, the multiplication of the number of kernels presented in Eq. (2) is performed on a single channel.

$$Conv2D = K^2 * d^2 * C * N \quad (1)$$

Fig. 1. Sample images from the dataset.

Fig. 2. Sample of the residual network.

$$SepConv2D = d^2 * 1 + 1^2 * N \quad (2)$$

Eq. (1) and Eq. (2) represents the complete multiplication costs for ordinary and separable convolution, respectively. The dimension K , as derived from the convolution process in Eq. (2), undergoes a transformation where it is multiplied by N after switching to a value of 1. Similarly, the variable d , which represents the size of the filter, is multiplied by 1 after undergoing a transformation and the variable C , representing the color channels in Eq. (2), is reduced to a value of 1. Finally, the variable N denotes the number of kernels. On the other hand, the neural network's architecture which comprises an excessive number of layers, may suffer from data loss resulting from a vanishing gradient. The MX model employs residual connections (a type of skip connection) which is illustrated in Fig. 2. The implementation of a residual layer mitigates this phenomenon and effectively incorporates various forms of data.

Fig. 3 illustrates the changes made to the default Xception architecture. Many layers are removed and a few layers are added in the Xception architecture in order to achieve an efficient architecture with sufficient precision. Changes in the architecture are classified in colors where “Green” signifies

the addition of a new layer or connections to the Xception architecture. “Blue” signifies a modification of the parameter values of any existing layer in the Xception which is known as fine-tuning. “Red” signifies the elimination of the layers from the default Xception model.

The starting layer of the MX architecture is a standard convolutional layer with the kernel size modified to 5×5 to avoid overfitting. It was only performed in the top two convolution layers. After the first Separable Convolution layer, several layers are further added to the structure. The new architectural layers include Depthwise Convolution, Batch normalization, and LeakyReLU activation function. The RGB images that are provided to the Depthwise Convolution undergoes a process of channel separation, convolution, and subsequent re-stacking, as demonstrated in Eq. 3. The Separable Convolution process corresponds to the Depthwise Convolution, with the exception of an additional step. The process of pointwise convolution involves an additional step. Following the stacking process, the features depicted in Eq. 2 are extracted through the utilization of a 1×1 filter.

$$DepthwiseConv2D = d^2 * 1(C1) + d^2 * 1(C2) + d^2 * 1(C3) \quad (3)$$

In the given context, the variable d denotes the dimensions of the filter, while the C variables correspond to the color channels. Each color channel is assigned a value of 1 and subsequently multiplied by d . Hence, the aforementioned methodology exhibits swifter and more effective outcomes in comparison to traditional convolution. Batch Normalization is employed subsequent to the Depthwise Convolution layer to expedite the training process and streamline the learning

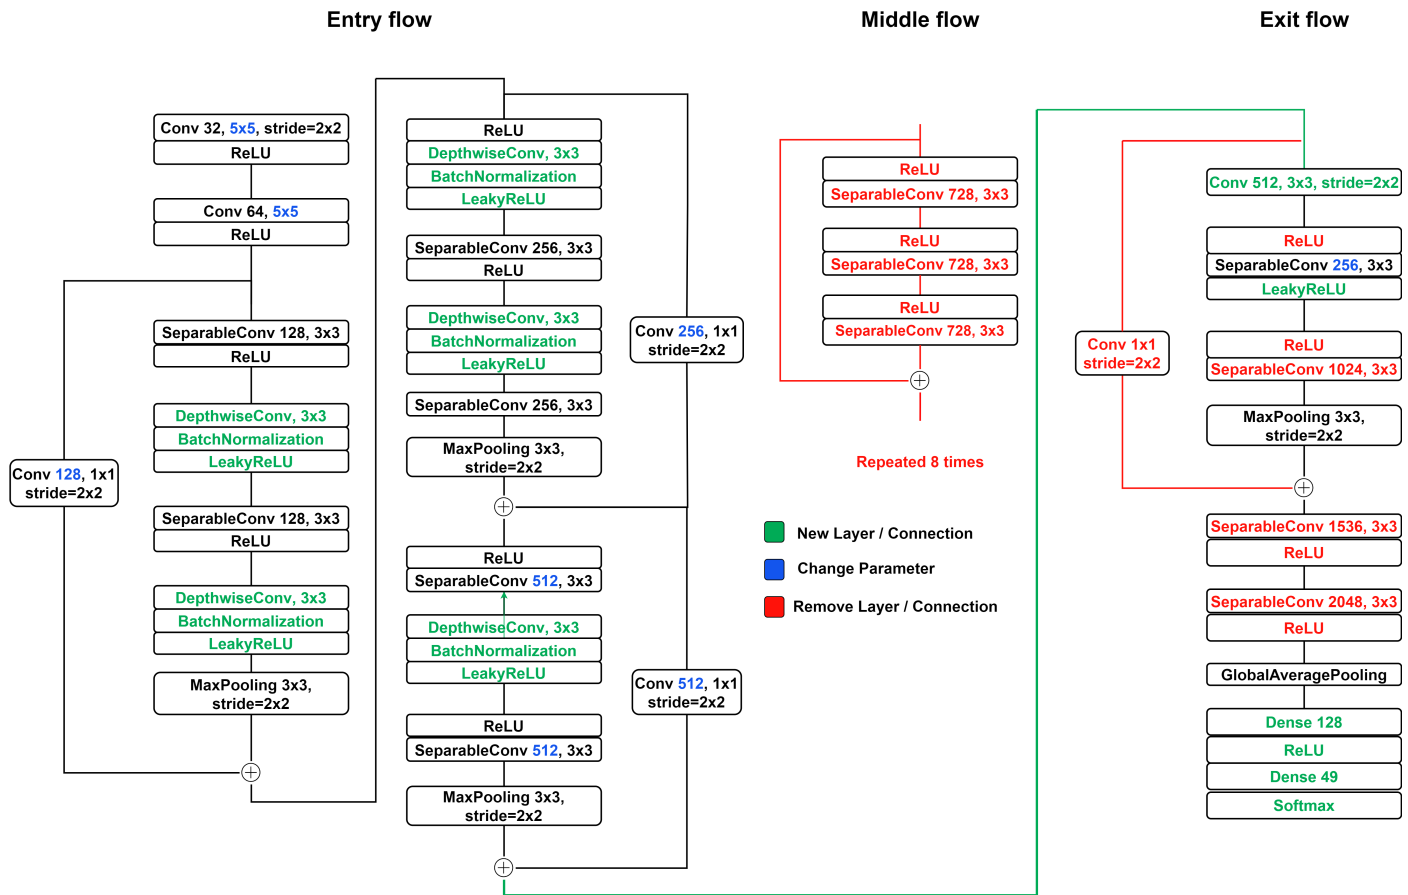

Fig. 3. Architectural modification of the Xception model.

procedure. Subsequently, the Leaky Rectified Linear Unit (LeakyReLU) activation function is employed. The Rectified Linear Unit (ReLU) activation function is triggered when the neurons within a neural network produce a positive value. In the absence of a positive value, the output of the function is zero. The LeakyReLU activation function is designed to mitigate the issue of “dead ReLU” that arises when the output of a ReLU is consistently negative. The system is capable of accepting certain numerical values that fall within the negative range and are in close proximity to zero. The LeakyReLU is mathematically represented by Eq. (4), where α is a constant parameter which is assigned a value of -0.01.

$$f(x) = \max(\alpha x, x) \quad (4)$$

The objective of utilizing Depthwise Convolution and LeakyReLU is to derive supplementary features from images. It improves the precision of the model. The “Entry Flow” architecture employs the Depthwise Convolution and Batch Normalization techniques, along with the LeakyReLU activation function, at multiple locations, as illustrated in Fig. 3. Additionally, the filter value of the final two separable convolution layers in the “Entry Flow” segment is reduced, and the parameters of the residual connection layers are modified. This makes the model more lightweight. To make the model lighter and more streamlined, the entirety of the “Middle Flow”

design is eliminated. This modification extensively reduces the computational cost of the model. An immediate connection between “Entry Flow” and “Exit Flow” is established. “Exit Flow” is also customized. A new convolution layer and LeakyReLU activation are added to this segment, and most of the separable convolution layers are omitted. The residual layer is also removed from this portion. After the GlobalAverage-Pooling layer, two fully connected layers are added with ReLU and Softmax activation functions respectively. An overview of the proposed MX model architecture is illustrated in Fig. 4.

B. Quantized Modified Xception (QMX)

Model Quantization is a well-known model compression approach that reduces the computational load and memory usage of the neural network models. The proposed quantization technique for the MX model is presented in this section. In this method, r represents the real number, q denotes the bit representation of the values, or quantized values. Most of the time, quantized networks are trained using floating point numbers, and then the weights are quantized. The before and after quantization of each of the convolutional layers are illustrated in Fig. 5, where (a) introduces 8-bit integers and 32-bit integer accumulator and (b) illustrates that the convolution layers are trained using simulated quantization. All variables and calculations utilize 32-bit floating-point arithmetic. To imitate the effects of variable quantization, the computation graph

Fig. 4. Proposed MX architecture.

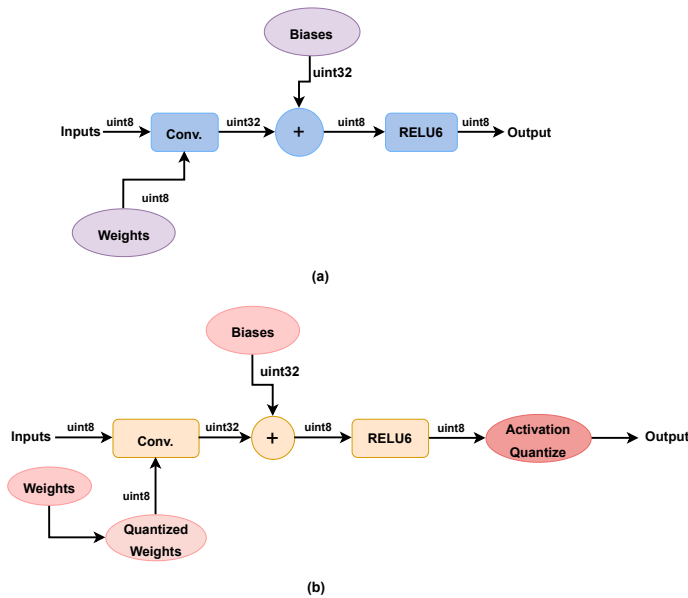

Fig. 5. Integer quantization in the convolution layer.

is infused with weight quantization and activation quantization endpoints. The resulting graph estimates the integer-only computation graph during training with standard optimization techniques for floating-point models.

A technique is provided during the forward pass of training for simulating quantization effects. The Backpropagation proceeds as usual, and floating point values are utilized for all weights and biases, allowing straightforward correction of minor values. Conversely, the forward propagation pass simulates quantized inference as implemented by the inference engine. The quantization technique's rounding behavior is integrated into floating-point arithmetic, such as: 1) The weights are quantized before convolving. The layer is normalized with batch normalization prior to quantization. The weights, \hat{w} are incorporated with the batch normalization parameters using Eq. (5), where γ is the batch normalization scale parameter. The symbol φ is a very small constant, and η is a moving average estimation of the variance of convolution results throughout the batch. 2) Activation functions are quantified where they arise during inference.

$$\hat{w} = \frac{\gamma \times w}{(\eta + \varphi)^{\frac{1}{2}}} \quad (5)$$

The point-wise quantization function q in Eq. (6) is used to perform quantization, which is controlled for each layer by the quantization level numbers and the clipping range.

$$clip(R; p, q) = \min(\max(x, p), q)$$

$$s(p, q, \kappa) = \frac{q - p}{\kappa - 1}$$

$$q(R; p, q, \kappa) = \lfloor \frac{clip(R, p, q) - p}{s(p, q, \kappa)} \rfloor * s(p, q, \kappa) + p \quad (6)$$

Here, R represents the real value that must be quantized and the notation for the quantization spectrum is p, q, κ indicates the number of quantization levels, while “ $\lfloor \cdot \rfloor$ ” indicates rounding to the nearest integer. The value of κ is set to 8 because, for 8-bit quantization, $\kappa = 2^8 = 256$ is utilized.

The quantized model's workflow is described by Algorithm 1. At first, the model receives the sign image and its corresponding labels as initial input. Following this, the MX floating point deep learning architecture shown in Fig. 4 is constructed (step 1). Following the development of the model, it is quantized to enable quantize-aware training (step 2). The quantized model is finally trained until it reaches convergence (step 3). The model is thus ready for inference, at which point, it can predict the desired output based on an input image (steps 4 and 5). Here, Quantization Aware Training (QAT) is used for compressing the proposed model. QAT is a model quantization technique where quantization operations are inserted before training the model. It enables the quantized weights and activation functions of the model to be adjusted.

C. Raspberry Pi Integration

The QMX model is implemented into Raspberry Pi 4 embedded system in order to evaluate the performance of the model in a real-world configuration. Python is utilized as the programming language for model implementation and TensorFlow 2.6 for inference. Initially, the input images or video frames are streamed by the device's camera module. Then, it predicts the corresponding signs. Finally, the output is displayed on a display screen connected to the device through

Algorithm 1 Training Steps of Quantization

Input: Sign images and corresponding labels.

Output: Recognize class name of sign images.

- 1: Create a training graph for a floating point model.
- 2: During training and inference, tensors will be reduced into fewer bits while inserting the quantization operations.
- 3: Train the quantized model using training data until convergence.
- 4: Perform the necessary improvements and build the inference graph for usage in a low-bit inference engine.
- 5: Use the quantized inference graph to draw conclusions from the data.

Fig. 6. Overview of raspberry pi 4 implementation.

its HDMI connector. Fig. 6 represents an overview of the Raspberry Pi 4 implementation.

D. Experimental Setup

The Google Colab Pro edition is utilized to execute the training procedure. A variety of Python packages are utilized for implementation. Pickle is used for data loading. Tensorflow serves as the backend to the Keras framework for model development. “Categorical Cross-Entropy” is chosen as a loss function for model compilation. Adaptive Moment Optimization (Adam) is utilized as an optimizer with a learning rate of 0.01. The Adam optimizer offers a quicker computation time and requires fewer training parameters. The gradient descent algorithm uses this approach by taking the gradients’ exponentially weighted average into account. Using averages accelerates the algorithm’s convergence towards minima. The batch size is set to 58 for 60 epochs and evaluates the model using the test dataset. The batch size of 58 is determined since the entire train sample is a factor of 58.

After the QMX model has been established, it is implemented on a Raspberry Pi 4 for inference. The original Xception, MX, and MXT models are also incorporated into the embedded device, enabling the examination of real-world performance. As a result of implementing all four models on Raspberry Pi 4, a quantitative analysis of the performance of these models in terms of model flash occupancy, inference time, and energy consumption is obtained. Energy consumption and inference time are important considerations

for evaluating real-world performance. The embedded device is a stand-alone device connected to a power bank, thus if the model is very efficient, then it consumes less power. Additionally, shorter estimation time indicates greater real-time accuracy.

V. RESULT ANALYSIS

In this section, experimental results and model assessments are quantitatively analyzed. The QMX model has been subjected to comparative analysis with several existing models. Besides, an estimation is conducted on the memory consumption, average operational duration, and average energy consumption of the MX, MXT, and QMX variants. The precision, recall, and F1 accuracy of the quantized model are also measured.

A. Evaluation Matrices

To evaluate the QMX model, five evaluation metrics are selected, namely precision, recall, F1-score, ROC-AUC curve, and confusion matrix. For an ideal classification model, both precision and recall tend to be one (1). The F1 score is determined by the weighted average of precision and recall. Therefore, this score takes into account both false positives and false negatives.

The confusion matrix is a prominent metric used in classification problems. It is applicable to both binary classification and multiclass classification problems. The comparison between the predicted outcome and the actual result can be derived using the confusion matrix. The AUC (Area under the ROC Curve) - ROC curve (Receiver Operating Characteristic curve) is a performance metric for classification problems with different threshold values.

B. Evaluation of the QMX Model

Fig. 7 illustrates the accuracy and loss graph of the QMX model while training. Here, the training score is represented by the blue line and the test score is represented by the yellow line during the training phase. From this figure, it is observed that the training score converges rapidly just within 10 epochs and remains constant for the rest of the epochs. On the contrary, the test score converges within 20 epochs after significant fluctuation. In addition, after convergence, the train and test scores become almost the same, the test score is slightly lower than the training score. Therefore, it can be concluded that the model exhibits a high degree of generalization.

Fig. 8 depicts the confusion matrix of the QMX model, revealing that the model is quite accurate at recognizing 49 distinct hand signs. Sixty images per class are used to evaluate the trained model. Approximately 59 to 60 images, and in some instances 57 or 58, are accurately predicted for each class.

Table III presents the classification report which contains evaluation metrics, namely precision, recall, and F1-score for each class of the MX, MXT, and QMX models. Although the average, macro average and mean average are the same for all three models, the QMX model is lighter, faster, and more efficient among these three. Moreover, embedded devices can utilize the QMX model better. Thus, the QMX model is

Fig. 11. Saliency map visualization.

better in terms of space and time complexity while maintaining accuracy.

Fig. 9 establishes that, compared to the original Xception, MX, and MXT models, the int8 QMX model consumes less flash memory and average inference time. The average inference time of these four models is calculated after 100 iterations using the Raspberry Pi 4. The QMX model's flash occupancy is 72, 11, and 3 times less than the original Xception, MX, and MXT models, respectively. Besides, the recognition performance of the QMX model is 12, 9, and 3 times faster than the original Xception, MX, and MXT models, respectively. In a nutshell, Fig. 9 displays the lightweight features of the QMX model, and these percentages imply a significant increase in the model's lightweight characteristics. In addition, the QMX model can process 25 frames per second, as demonstrated in Fig. 9; hence, the model can predict hand gestures in real-time.

The average F1-score is 0.98, which means the model's F1 accuracy is 98%. Fig. 10 represents the ROC and AUC graph. Here, the ROC threshold value is plotted for each class and then the AUC curve for each class is determined. For all classes, AUC lies between 0.96 and 1.00, making it a very generalized model that can perform well in real-life configurations.

C. Saliency Visualization

A saliency map is a visual representation of the area where viewers' attention tends to first focus [25]. It can be used to focus on the most prominent areas of a picture that are most likely to influence the model's prediction. By using Eq. (7) and (8), a saliency map can be visualized.

$$S_x(i) = w_x^T * i + b_x \quad (7)$$

$$w = \frac{\partial S_x}{\partial i} \quad (8)$$

Here, $S_x(i)$ represents the score of the predicted class x , the one-dimensional image vector is referred to by i , w indicates the weight and b represents the bias for the predicted class x . The gradient specifies how strongly each pixel of the image (i) can influence the outcome of the prediction (S). Knowing the weights (w ; using Eq. (8)) for each pixel allows us to display the information as a saliency map, where each pixel represents the strength with which it influences the outcome of the prediction. Fig. 11 reveals which pixels are crucial for predicting the signs. And it can be seen from this figure that the saliency map highlights the pixels of the hand signs, indicating that the QMX model takes into account the hand elements from the image to produce precise predictions.

To generate a saliency map, the first input images shown in Fig. 11(a) are fed to the model. Afterward, the corresponding class x is predicted by the model. A 2D matrix is constructed utilizing a Gaussian pyramid from an image vector, which is responsible for activating class x , by employing the established weights (w). This 2D matrix is shown in Fig. 11(b) and it depicts the important pixel areas of the images responsible for the prediction of class x . Furthermore, upon projecting the aforementioned 2D matrix onto the input image, it becomes apparent that the salient features of the image are distinctly emphasized, as illustrated in Fig. 11(c). Depending on the prediction score S_x , the important areas are strongly or weakly highlighted. Fig. 11(c) reveals that the areas of the hand signs are prominently highlighted and concentrated, indicating that the model considers the hand signs to be the most essential attribute for predicting the related signs.

D. Comparison with State of the Arts

The present investigation employs BDSL 49 for the purpose of training pre-existing architectures. Table IV presents a visual representation of the results obtained by various architectures on the BDSL 49 dataset. By recreating, training and testing the model of [14],[4],[3],[6] and [8] on the BDSL

TABLE IV. PERFORMANCE COMPARISON BETWEEN PROPOSED QMX MODEL WITH THE STATE-OF-THE-ART ARCHITECTURES WHEN TRAINED ON BDSL 49 DATASET

Research	Dataset	Classes	F1 Accuracy
Islalm et al. [14]	BDSL 49	49	92%
Rafi et al. [4]	BDSL 49	49	93%
Shanta et al. [3]	BDSL 49	49	93%
Islam et al. [6]	BDSL 49	49	94%
Miah et al. [8]	BDSL 49	49	77%
Proposed QMX Architecture	BDSL 49	49	98%

TABLE V. PERFORMANCE ANALYSIS OF PROPOSED QMX MODEL WHEN TRAINED ON OTHER AVAILABLE DATASETS

Dataset	Train Data	Test Data	Classes	F1 Accuracy
38 BdSL [14]	11061	1520	38	89%
KU-BdSL [26]	1200	300	30	99%
Ishara-Lipi [6]	3333	792	36	93%
BdSL 49 [16]	11774	2940	49	98%

49 dataset, the QMX model achieved an F1 accuracy of 92%, 93%, 93%, 94%, and 77%, respectively. The QMX model got the highest accuracy of 98% for the proposed QMX architecture. On the other hand, Table V shows the performance of the proposed QMX architecture using some benchmark datasets. For the proposed QMX architecture, it achieved 89%, 99%, and 93% respectively, using the datasets [14], [26] and [6]. Besides, utilizing BDSL 49 dataset the QMX model achieved an F1 accuracy of 98%. This comprehensive comparison indicates that the proposed QMX architecture is quite standard for BdSL recognition.

VI. CONCLUSION

Persons with hearing impairment may face challenges in interacting with those who primarily use verbal language for communication. On the other hand, the majority of people in society can not understand sign language, which creates a communication gap between them. Therefore, in order to address this concern, this research has devised a QMX framework for the identification of BdSL that can be implemented on an embedded system. The model under consideration has been trained on a large dataset, referred to as BdSL 49, which has been designed to closely resemble real-world scenarios. This has resulted in the development of a model that exhibits a high degree of accuracy. The dataset maintains the standard sign representation of Bengali Sign Language, containing 49 different classes. Furthermore, the proposed QMX model is efficient as it requires low resources and can run in real time on a low-end device or embedded system. Besides, it is 11 times smaller than the proposed MX model and achieves an overall accuracy of 98%. In order to alleviate the challenges faced by persons with hearing disabilities or persons with speaking disabilities, our proposed future research endeavors involve the development and implementation of a language model capable of generating text from video streaming.

ACKNOWLEDGMENT

We give special thanks to the Institute of Energy, Environment, Research, and Development (IEERD) and the University of Asia Pacific (UAP), for supporting this research project.

Abstract—The world's ecosystem and environment are rapidly deteriorating with an increase in the depletion of forest conditions due to forest fires. In recent past years, wildfire incidents in Sikkim have increased due to severe climatic changes such as turbulent rainfall, untimely summers, extreme droughts in winters, and a reduction in the percentage of yearly rainfall. Forest fires are one of the numerous kinds of disasters that impose disastrous changes on the entire environment and disrupt the complex correspondence of the flora and fauna. The research's goal is to examine the vegetation indices based on different climates to know why forest vegetation is decreasing day by day from 2000 to 2023. The frequent changes in forest vegetation are extensively studied by using satellite images. This data has been collected by three satellites Landsat-5, Landsat-8, and Landsat-9 on different vegetation indices NDVI, EVI, and NDWI. East Sikkim area is chosen to compute forest vegetation indices based on the heap's landmass this region is unexplored yet and also studied about the forest changes by using different spatial temporal indices in the range of the entire district in the future. The authors of this paper have used Landsat multi-spectral data to assess changes in the area of vegetation in a sub-tropical region like a dense forest region in east Sikkim. The analysis depicts space images, computes vegetation indices (NDVI, EVI, NDWI), and accomplishes mathematical computation of findings. The proposed method will be helpful to discuss the variance of vegetation in the entire East Sikkim region at the time span of 2000–2023. In the analysis, we find that mean and standard deviation values change over the years in all indices. Later, we also calculated changes by using a classification model and find a total 10% change in forest areas in approximately 22 years.

Keywords—Classification; change detection; vegetation indices; landsat; machine learning

I. INTRODUCTION

It is found that climate is very much affected by global warming throughout the world. Spectral Indices detected different factors like rainfall and temperature within 1 to 15 years [1]. Based on the increasing extremes caused by human-induced climate change, as well as the limited progress made towards finding climate change solutions, the National Academies of Science and Engineering recently recommended that the USA develop a trans-disciplinary research program into proposed climate intervention techniques [1]. Earth quacks also deteriorate the vegetation area because of their frequent occurrence as earlier we used to hear about earth quacks

occurring in 4 to 5 years but now every month it probably happens. Due to earthquakes lots of forest decaying problem arises like plant community shift, Species loss, and productivity reduction of alpine grasslands [2]. Flood is also one crucial factor to decrease the vegetation area but it is also found that initially, floods affected crops but later crop productivity and fertile land improved and resulted in dense vegetation area [3]. By mapping vegetation cover before and after floods, spacecraft images, rainfall data, a tool used for analyzing the geographical area, and a rain gauge were used to evaluate post-flood loss or benefit[3]. The deforestation and degradation of forests alone contribute between 20 and 25% of global greenhouse gas emissions [4]. District-wise Sikkim climate data is analyzed over the period 1901 to 2007 to predict rainfall, precipitation, and temperature followed by mean 17.82 mm per day, Standard Deviation 3.55 mm per day, Coefficient of Variation (C.V.) 20%, precipitation Trend is - 2.627mm per day/100 years, minimum temperature trend 2.86 0C/100 years and maximum temperature 0.730C/100 years. The environmental influence on vegetation increases as more regions of the world become forested. Inside the city limits, there are forests, which causes changes in the vegetation of the forests. Computing the quality of forest areas and the surrounding environment and making decisions to ensure the population's sanitary and environmental safety depends on understanding where these changes occur, in what quantities, and in response to what variables [5]. The dynamics of forest vegetation may be studied in great detail using satellite photos over Google Earth Engine [6]. Satellite photos enable us to get factual data about the temporal and spatial variations in vegetation. The commonly uses type of satellite data is Landsat, Sentinel, and MODIS from various very famous data archive providers like USGS, Copernicus Programme, NASA, etc. [7]. Landsat itself has various development, from Landsat 1 to Landsat 9. Sentinel also has various versions from Sentinel 1 to Sentinel 5.

A number of methods have been employed to determine the area occupied by vegetation [8]. These methods involve classifying the outcome based on supervised and unsupervised learning, automatic image processing, the generation of index pictures, as well as visual interpretation [9]. The dynamics of plant cover can be analyzed using spectral and temporal indices obtained from time-lapse images.

*Corresponding authors.

Two categories can be used to categorize these applications. The first category consists of universal systems, which help us analyze data obtained through remote sensing of the Earth and address a variety of issues [10]. The second category consists of software (tools) designed to handle extremely specific jobs. Such programs have the undeniable advantage of being made specifically to address a given practical issue. In these programs, the majority of the steps are automated. Upon examining the current approaches to evaluating vegetation changes within a forest agglomeration based on multi-temporal photographs, we decided that it would be beneficial to develop a tool for the evaluation of vegetation changes based on multi-temporal images [11].

To analyze satellite images, an algorithm was created. This application performed a number of functions, including the study of satellite images, the calculation of spectral indices, the evaluation of the cloud cover mask, and the statistic-based analysis of interpretation results. This algorithm categorizes multi-temporal images to detect the dynamics of land occupied by vegetation.

The research's goal is to use remote sensing data from the year 2000 to the year 2023 to examine the forest vegetation in the east Sikkim forest area. Principal research goals: (1) Building a database of Landsat satellite photos for the years 2000 to 2023; (2) Creating an algorithm along with software development acquired from several vegetation indices. (3) The identification of the primary mechanisms that brought about the observed alterations in the east Sikkim forest areas. A unique algorithm was developed for the detailed examination of Landsat remote sensing data in East Sikkim through which the originality of the proposed scientific research is explained. This is a feasibility study organized in the East Sikkim region. So far, no such studies have been conducted on forest cover changes in the East Sikkim region related to changes in social, economic, and political conditions. A more rigorous explanation of the novelty's position is required. Our own algorithm's development opens up various possibilities for its widespread practical application.

II. RELATED WORK

The most common origin for the remote sensing data of Earth for a variety of examinations is Landsat pictures. The benefit of Landsat data is related to the policy of free picture access and the continuity of observations over a 50-year period. As per the analysis of spatiotemporal characteristics, the moderate forest conquered approximately 46% in 1985 and 57% in 2005, and 58% of the total land is occupied by open forests which were a replacement for these [12]. In addition to this, we have analyzed spatial and temporal indices in the East Sikkim area. The majority of India's forests are degrading due to forest fires. In East Sikkim, forest fire is a frequent process as the water stress level is very high in the summers. It is a tedious task to figure out the statistical data on the occurrence of forest fires in a year, but statistics cleared that estimated that 33% of a few states and more than 90% of other states are exposed to forest fires annually [13]. The burnt areas could be easily seen in the SWIR band when using band(3 2 1), and band(4 3 1) [14]. The Sikkim Mountains, a crucial phytogeographical reserve for the nation, contain more than 26% of all blooming plants. Landsat data are

useful for tracking forest regions. Many different techniques are used for analyzing and monitoring the Landsat input data. Several image processing techniques created in remote sensing are used in extracting area-covering details with the help of satellite images. Using Landsat to map forests, presents a variety of challenges. Landsat images of forested areas typically include a combination of data about anthropogenic items and vegetation in their pixels. When recognizing forest areas, more vegetation cover from the image must be retrieved. To distinguish between forest and non-forest regions, one method uses spectral vegetation indices such as the Normalized Difference Vegetation Index and vegetation index sensitive to the water content of plants normalize difference water index. Another spectral technique makes the assumption that forest pixels are linear mixtures of the three common land cover, vegetation, impervious surface, and soil components (the so-called V-I-S model). In the paper, it is suggested that mapping of the forest area be done using a mix of spectral and spatial data. The technique comprises these two distinct categories of elementary coverage classes based on pixels and segments (segment-based).

III. STUDY AREA

Sikkim is one of the largest forest heaps in the northeast of India. Sikkim state covers a total area of 7096 sq Km. The geographical area we have targeted as the study area is the East Sikkim region, which is approximately 964 sq. km in size and located at 27.3084° N, 88.6724° E in Fig. 1. As per the Forest Management Department, 14.44% area of Sikkim is covered under scrub-(RF) and alpine pasture, and 29.5% area is occupied by perpetual snow cover. Remote Sensing Data for the year 1988 depicts that the vegetation area for crops which may be Terraced/Semi Terraced is 604.85 sq. km and this cropland is mixed with dense forest of capacity 603.34 sq. km. The district area is 173.19 sq km which is 2.44% of the total area. As stated by the Forest Survey of India (FSI), the reported Forest State covers an area of 5841.39 sq km which is equal to 82.32% and 0.8% of the whole nation's forest region. According to the State of Forest Report of the Forest Survey of India, Ministry of Environment & Forest, Government of India, the status of Forest cover evaluation is gradually increasing which was 2756 sq km in 1987 and 3262 sq km in 2003. In 2021, the number of trees and forests in India covered 80.9 million hectares, which is equal to 24.62% of the country's total land area. Areas that are part of a biosphere reserve's buffer zone are excluded from the Protected Area Network.

The amount of area covered by the protected Area Network of State is 2177.10 sq km. (i.e.30.68% of the entire geographical area) whereas the amount of land covered by the protected Area Network and biosphere reserve in the State is 3013.10 sq km (i.e.42.46% of the entire geographical area). There is mainly five types of forest present in East Sikkim: wet temperate forests find generally in hilly areas, subtropical or moist broad-leaf forests, which are areas of forests where half of the world species are living in different zones, moist mixed forests are types where greenery increases or decreases with the season these are also known as dry deciduous forest, other types of forest are conifer forest and sub-alpine forest, conifer forests are also deciduous forest but the property of these forests are these are always green but sub-alpine forests are primary factors of nature and environmental disturbance

Fig. 1. Location of study area.

these are basically prone to fire and 80% forest fire incident are happened due to these indices in India these are basically found at eastern middle Himalayas. Sikkim is India's greenest state but with time and change in climate and environmental conditions, we find that there are high changes are occur from one type of forest to another type of forest which also leads to deforestation.

IV. METHOD AND DATA

For analysis of change in East Sikkim, Fig. 2 we are google earth engine (GEE) satellite-based planetary tool [14], It has a collection of many satellites based real-time data sets like Landsat, Sentinel, and MODIS as well as provides users, a tool (code editor) for analyzing these data. Here we are using Landsat data for finding changes in the forest area as well as East Sikkim from the year 2000 to 2023. Landsat has a collection of data from 1972 to 2023. Landsat has different versions based on time of availability, spatial resolution, and wavelength. Till now USGS has launched nine versions of Landsat data sets from Landsat 1 to Landsat 9. We are using, data from the Landsat-5 (Thematic Mapper), Landsat-7 (Enhanced Thematic Mapper Plus), and Landsat-9 (Operational Land Imager-II) satellites to examine the dynamics of the study area's forest vegetation. Many scenes are present in the chosen location. The work uses five bands (Short Wave Infrared, Green, Red, Near Infrared and Blue), which have a spatial resolution of 30m. Landsat uses a worldwide reference system (WRS) that catalog Landsat data by path and row. Table I represent used datasets and band for analysis of change in the study area. Fig. 2 shows the technique used in research for the analysis of change using different data sets and vegetation indices. Later

for verification of the result, it also calculates changes in land cover areas of the study area, East Sikkim using the supervised classification model Random forest.

A. Vegetation Indices

Low vegetation and high vegetation land cover class contain all the land cover areas which having some greenery or dense forest, for proper differentiating between these two land cover classes we are using Normalize Difference Vegetation Index (NDVI) [15], [16], Normalized Difference Water Index (NDWI) [17] and Enhance Vegetation Index (EVI) [18]. After calculating the ground reference point we observed the study area and calculated its daily average temperature and rain and peak months as August to October rain goes above 90mm. From the observation, we find the average temperature is high in the month between May to July and the average rain is maximum in the month of August and September.

$$NDVI = \frac{NIR - Red}{NIR + Red} \quad (1)$$

The NIR and SWIR bands are used by NDBI to highlight man-made built-up regions. It is ratio-based to lessen the impact of variations in terrain illumination and atmospheric effects.

$$NDWI = \frac{Green - NIR}{Green + NIR} \quad (2)$$

In Landsat 8 and Landsat 9, Enhanced Vegetation Index is calculated as

$$EVI = \frac{2.5 * ((Band5 - Band4))}{(Band5 + 6 * Band4 - 7.5 * Band2 + 1)} \quad (3)$$

Fig. 2. Methodology used in research.

TABLE I. BAND USES FOR CALCULATING CHANGES IN FOREST COVER

Landsat Datasets	Blue	Green	Red	Near Infrared	SWIR 2
Landsat 5 TM (Band number: Wavelength)	B1: 0.45–0.52	B2: 0.52–0.60	B3: 0.63–0.69	B4: 0.76–0.90	B7: 2.08–2.35
LANDSAT 7 ETM+ (Band number: Wavelength)	B1: 0.45–0.52	B2: 0.52–0.60	B3: 0.63–0.69	B4: 0.77–0.90	B7: 2.08–2.35
Landsat 9 OLI (Band number: Wavelength)	B2: 0.45–0.51	B3: 0.53–0.59	B4: 0.64–0.67	B5: 0.85–0.88	B7: 2.11–2.29

V. RESULT

Vegetation Indices (VIs) combine surface reflectance at two or more wavelengths to emphasize a specific characteristic of vegetation. They are created using vegetation's reflective qualities. Each VI is intended to calculate a specific characteristic of the vegetation. Every VI needs accurate reflectance readings from multispectral or hyperspectral sensors. The spectral bands sampled in the input dataset dictate which VIs can be generated on that dataset. A VI is accessible for the dataset if it has all the spectral bands necessary for that index. Some place is used to calculate density by using the normalized difference vegetation index.

NDVI is frequently used in agriculture, forestry, and the environment to track the development and well-being of vegetation as well as to spot stressed or damaged areas. In addition to mapping and categorizing different vegetation types, NDVI values can be used to track changes in vegetation cover over time. Fig. 6 shows the change occurring in NDVI value on the study area over the period of time. Every time it is changed with time but in the year 2022- 2023, this data is changed more number times. Enhanced Vegetation Index (EVI) [19] is also a mechanism for measuring vegetation greenness that is similar to the Normalised Difference Vegetation Index (NDVI). EVI, on the other hand, compensates for some atmospheric

Land Cover Areas in East Sikkim in Year 2000

Fig. 3. Forest cover area of East Sikkim in the year 2000.

Land Cover Areas in East Sikkim in Year 2010

Fig. 4. Forest cover area of East Sikkim in the year 2010.

Land Cover Areas in East Sikkim in Year 2023

Fig. 5. Forest cover area of East Sikkim in the year 2023.

factors and background noise from the canopy and is more sensitive in regions with dense vegetation. EVI also provides producers the ability to precisely compare data and monitor changes. These comparisons are quick and simple thanks to the use of our vigor items scaled to an absolute standard. Fig. 7 provides a change in the study between the years 2000 to 2023. EVI values are changed rapidly between these years. Later for verification purposes, we calculate the change in the study area using the ensemble-based [20] classification algorithm random forest [21] and find nearly 10% of land cover classes are changing. Later we calculate the change in water content over vegetation in the study area using the normalized difference water index (NDWI) [22], [23]. The Near-Infrared (NIR) and Short Wave Infrared (SWIR) channels are used to create the Normalised Difference Water measure, which is a satellite-derived measure. While the NIR reflectance is influenced by changes in leaf internal structure and dry matter content but not water content, the SWIR reflectance reflects changes in both vegetation water content and the spongy mesophyll structure in vegetation canopies. The accuracy of determining the water content of vegetation is increased when the NIR and SWIR are combined because they eliminate changes brought on by the internal structure and dry matter content of leaves. The spectral reflectance in the SWIR region of the electromagnetic spectrum is substantially governed by the quantity of water present in the interior leaf structure. Therefore, leaf water content has a negative relationship with SWIR reflectance. Fig. 6, Fig. 7, and Fig. 8 show the change that arises over the study area Fig. 1 mainly in the forest region. From Fig. 3, 4 and 5, it is quite clear that deforestation happened over the study area. Still, due to good climate and environmental conditions, this deforestation is not converted into non-forest areas. From the calculation, we find about 10% of forest loss present over the study area. Fig. 9 shows the yearly forest in square meters from the year 2000 to the year 2022. Here if we focus on the output generated by vegetation indices, Fig. 6, 7 and 8, overall mean and standard deviation values are not changed but the pattern of these changes are frequent in the current year. By the above findings, it is figured out that moderate dense forest is higher in comparison to the non-forest area, dense forest area, open forest area, and scrub which is 42.3 %, 21.7 %, 16.09%, 10.3 %, and 8.8% in the year 2000, respectively and it is also analyzed that moderate dense forest area is decreasing year by year due to forest fire which is 42.5 % in the year 2010 which gradually decreasing after decades too. It became 41.3 % in 2023 and for other land areas transformation can also be seen. Dense forests were 16.9 % in the year 2000 which decreased by 15.70% in 2010 and 15.20 % in 2023. The non-forest area is decreasing by these fire incidents and it is clearly shown by the graph that it was 21.7 % in 2000 which increased to 22.20 % in 2010 and 23.10 in the year 2023. Open forest area is also increasing by the incident of forest fire while scrubs are continuously decreasing. By the Fig. 10, it is concluded that open forest area is gradually increasing i.e. 10.3% (2000), 13 % (2010), and 14.3 % (2023). In this proposed study area it is observed that we can generate land cover area loss or affected parameters by forest fire by using this developed tool or framework on any land with approximately similar spectral indices.

VI. CONCLUSION

The ability to perform high-frequency time series analyses using new-generation multi-spectral sensors aboard the Landsat 5, Landsat 8, and Landsat 9 satellite platforms opens up previously unheard-of possibilities for multi-temporal change detection studies on phenomena with significant dynamic behavior (for example, high-frequency mapping for disaster management) or on regions with recurring cloud cover issues. These new sensors' radiometric properties, while similar, are not equivalent, and this might result in noticeable variations in the radiometric amounts that are received. Forest changes are easily computed using these vegetation indices, and verified by using supervised classification results and global forest loss computation technique. Later our objective is to develop a GUI that calculates the change in vegetation indices. There are nearly more than 97 vegetation indices available that may be used for computing change in vegetation. These indices will be very help full for finding changes in climate conditions, environmental deterioration, Soil erosion, and many places.

Abstract—Mangoes are a great commercial fruit and are widely cultivated in tropical areas. In smart agriculture, the automatic quality inspection and grading application is essential to post-harvest processing, due to the laborious nature and inconsistencies of traditional manual visual grading. This paper presents a low-cost, efficient, and effective mango grading system based on image processing and machine learning methods to generate higher quality fruit sorting, quality maintenance, production, and cut back labor concentration. A novel database of classified mangoes was collected and built in An Giang province. Methodologies and algorithms that utilize digital image processing, content-predicated analysis, and statistical analysis are implemented to determine the grade of local mango production. On our collected dataset, the proposed system achieved overall with an overall accuracy of 88% for all mango grades. The system shows compromised results for higher-quality fruit sorting, quality maintenance, and production while reducing labor concentration.

Keywords—Smart agriculture; mango grading; image processing; machine learning methods

I. INTRODUCTION

Mango production is a major industry worldwide, contributing significantly to the economy of many countries. Asia is the dominant continent in terms of mango production, making up approximately 76% of the global industry [18]. In many mango planting areas, the level of automation and efficiency of post-harvest processing is far from satisfactory in terms of accuracy and throughput: Although mango is a quick-rotten and short-lived fruit, its post-harvest processing is still carried out manually via visual inspection [14]. Mango farmers may face significant expenses if mangoes are not sorted promptly after harvest. When it comes to marketing mangoes, external quality features play a vital role in their grading. Size, shape, ripeness, and the presence of surface defects are commonly used standards for assessing mangoes [15]. To facilitate this grading process, computer vision techniques have emerged as the most widely employed approach in modern systems, particularly in quality inspection and grading. These techniques enable the creation of a machine vision system that not only mimics the human grading process but also significantly accelerates it. As a result, there is a growing demand for efficient and effective solutions that allow enterprises and farmers to leverage these new technologies. Over the past two decades, the field of agriculture has witnessed a shift from traditional human grading to automated grading for fruits. Many companies have adopted automated grading for various crops, including peaches and oranges [?]. Notably, a researcher has developed an image analysis-based system for grading

apples. Their study involved training the system with numerous examples to enable it to become proficient in distinguishing fruit differences and creating a reliable reference dataset for the grading system [3]. To properly classify mangoes, it is important to be familiar with the mango grading standards. While color and size are significant criteria for fruit sorting, there is another crucial factor for sorting mangoes: the texture of their skin. Incorporating skin texture into the classification system can enhance the accuracy of sorting. Therefore, this study focuses on the processing and analysis of images to automate the grading and sorting process, which represents a crucial phase within the productive mango supply chain system.

II. RELATED WORKS

Grading and sorting fruits is a crucial stage in the agro-processing industry. Manual sorting of fruits is time-consuming, laborious, and prone to human error. Therefore, grading and sorting of fruits using image processing or computer vision techniques have gained significant attention in recent years. Various research studies have been conducted to develop automated systems for the grading and sorting of fruits. Regarding fruit grading and quality evaluation, the authors in [5] reviewed the basic process flow of fruit classification and grading. Feature extraction methods for color, size, shape, and texture are discussed with feature extraction algorithms used in computer vision and image processing such as Speeded Up Robust Features (SURF), Histogram of Oriented Gradient (HOG), and Local Binary Pattern (LBP). Additionally, this research briefly touches upon some popular machine learning algorithms like k-Nearest Neighbors (k-NN), Support vector machines (SVM), Artificial neural networks (ANN), and Convolutional neural networks (CNN). By presenting a theoretical foundation for the identification, classification, and grading of horticultural products, this study aims to facilitate the practical application of these methods in a real-world setting. The authors in [16] proposed an image processing algorithm combined with machine learning to detect and identify defects on the surface of mango skin. The algorithm consists of the main steps: extracting the area containing the mango fruit from the background and extracting the defective skin from the left region after improving the contrast of the left region from the input image. The researchers of [27] proposed a mobile visual-based system for food grading that involves three levels of image processing: low level for image acquisition and pre-processing, intermediate level for segmentation, representation, and description, and high level for recognition and interpretation. The study compared different classifiers,

including SVM, k-NN, Random Forest, and Naive Bayes, and found that SVM performed the best with an accuracy of 98.5% using the extracted feature vector. The system successfully graded bananas based on ripeness and overcame the challenge of identifying and outputting small defects on the fruit. To evaluate the quality of apples and gauge their level of maturity, the authors in [1] employed algorithms that utilized digital fuzzy image processing, statistical analysis, and content analysis. Along with a variety of filtering techniques for processing images, MATLAB's color-based segmentation method has been adopted to improve precision in finding the RGB component of a good apple and a ripened apple. By converting the image to grayscale, the system generated a histogram graph to analyze the results. The data confirmed that this automatic grading system was beneficial in reducing processing time and decreasing errors in assessment. In another work, this research [13] reported an automatic adjustable algorithm for sorting and grading apples using linear SVM and Otsu's thresholding method [17] for color image segmentation. It automatically adjusts the classification hyperplane with minimal training and time required. Additionally, it is not affected by changes in lighting or fruit color, making it an efficient and reliable option. This approach can effectively segment and sort apples in a multi-channel color space and can be adapted for other imaging-based agricultural applications. In terms of processing time efficiency, the authors in [21] introduced a split and merge approach that exhibits advantages over both Otsu's method and graph-based segmentation. This approach utilizes both local and global characteristics of color intensities in an image to improve blemish detection. The method first subdivides the image into a set of disjoint and arbitrary regions using the k-means clustering algorithm, which groups together pixels with similar feature vectors. The regions are then merged iteratively, and a graph called Region Adjacent Graph (RAG) is built to represent neighborhood relations among the segmented regions. The merging process continues until the regions satisfy the homogeneous condition or until no further merging is possible. To achieve citrus diameter detection, the researchers of [2] employed Canny edge for edge detection and DP algorithm for contour extraction to find the two points with the largest distance in the contour to achieve citrus diameter detection, which achieves a good balance between false detection and missed detection, and has a good edge detection performance. Furthermore, the RGB color space is converted into HSV color space, and the parameters of the H component are extracted to obtain the citrus coloring rate, thus realizing the citrus appearance quality grading system. By comparing manual and systematic tests, the study's authors achieved a measurement accuracy of 99%. This level of accuracy is practical for real-world applications. The article [7] proposes a method for estimating the size, volume, and mass of a Laba banana using just a single camera mounted on top of the fruit. This addresses the need to avoid setting up multiple 3D or camera projections to calculate the volume of the object for weight grading. The proposed method involves capturing top-view images of the banana, converting them to grayscale, and applying a traditional Otsu thresholding scheme for the GREEN channel of the images. The height and width of the banana are estimated from the resulting segmented image, which is then used to calculate the banana's weight using the product of the estimated volume and the average density of bananas.

In addition to the aforementioned studies, a number of studies have been undertaken to investigate the grading of mangoes through the utilization of image processing or computer vision approaches. For example, in a comprehensive review [24], an overview of the computer vision-based mango grading system was presented, which has been widely adopted in research works. The study identified image acquisition, image pre-processing, segmentation, background removal, feature extraction, and classification as fundamental steps in the mango classification process. A detailed analysis of appearance-based mango grading was conducted, and a parameter-wise survey was recommended. The authors concluded that the accuracy of ripeness analysis is better when using HSV, HSI, and CIELab color models rather than RGB color models. Furthermore, geometrical features such as area, major axis, and minor axis provide better size-based classification, while thresholding techniques are successful in segmenting defects, and Fourier descriptors can be best used for shape classification. Many machine learning models were examined for classification; however, Support Vector Machine (SVM) and Fuzzy classifiers were found to perform better. By using the image-extracted parameters for grading, accurate, reliable, and consistent mango grading can be achieved. The authors in [19] defined seven Hue moments for shape analysis and improved efficiency by using Green's formula for calculating the Hue contour. This reduces computation time and resources needed for Hue moment calculation. For this reason that applying Green's formula to the Hue vector field of an image allowed calculation of the Hue moment using only the boundary, or contour, of the image. Binarized images were used to detect defective skin, where pure skin was black and damaged areas were white. The developed system achieved 83.33% accuracy, correctly sorting 10 out of 12 mangoes into their respective categories. Methodologies and algorithms that utilize digital fuzzy image processing, content-predicated analysis, and statistical analysis to determine the grade of local mango production have been implemented in [22] for the purpose of contributing for a design and development of an efficient algorithm for detecting and sorting the mango at more than 80% accuracy in grading compared to human expert sorting. By making use of the Fuzzy Inference Rule, which is capable of dealing with the inherent ambiguity and vagueness in images, it becomes possible to conduct more flexible and intuitive image analysis. Besides, this approach can enhance the accuracy of image segmentation and reduce noise. It has proven to be effective in several applications such as image enhancement, edge detection, and object recognition. Specifically, in this context, putting in the Fuzzy Inference Rule to compute the grade of mango based on three parameters - size, color, and skin - led to the improvement of the scheme based on digital image processing techniques by selecting the best threshold scheme that produced an accurate result of classification. The authors in [10] offered a novel evaluation of the internal quality of mango based on its external features and weight, using four machine learning models - Random Forest (RF), Linear discriminant analysis (LDA), Support vector machines (SVM), and K-nearest neighbors (k-NN). The models take inputs such as length, width, defect, and weight, and output the mango classifications into different grades. The captured images and load-cell signals are converted to structured data using data normalization methods and elimination of outliers (DNEO) and normalization and outliers are eliminated to improve the dataset. Morphological

processing and different image processing algorithms including filtered noise, edge detection, and boundary trace are used to detect objects in binary images. The results show that this method is more effective than using external features or weight alone, and does not require expensive non-destructive measurements (NDT).

A growing body of research on image processing techniques for the quality grading of fruits highlights their potential, including for mangoes, as a non-destructive and automated alternative to traditional grading methods. Such techniques have the potential to improve the efficiency and accuracy of fruit grading. However, numerous techniques for sorting or evaluating mangoes have been studied both domestically and internationally, there is no universally effective approach due to the inconsistent standardization of mango grading. Because criteria used for grading mangoes may differ not only between regions and countries but also from the seller to seller. Consequently, it is worth noting that none of the discussed research on mango grading has explicitly focused on the local mangoes of An Giang province. And this shortage underscores the need for an intuitive grading system that meets the requirements of mango grading in this region. The aim of the image processing-based system for mango grading is to professionalize the grading process by utilizing computer vision techniques to enhance accuracy and efficiency. The main contributions of this paper include:

- Build a new comprehensive dataset of high-quality images of local mangoes in An Giang Province for training and evaluation of the system's machine-learning algorithms.
- Employ state-of-the-art image processing techniques to accurately and efficiently classify mangoes based on their size and blemishes, reducing human error and increasing the speed of the grading process.
- Create the groundwork for easy-to-use software that connects with the grading system, allowing users to upload images of mangoes and receive reliable and impartial grading results.
- Reduce the cost of manual grading by automating the grading process, thus reducing labor requirements, increasing throughput, and enhancing scalability.

III. MATERIALS AND METHODS

A. Overview of the Proposed System

The proposed mango grading methodology consists of five essential steps. These steps involve image acquisition, followed by image augmentation to improve the dataset's diversity. Next, the state-of-the-art Otsu method [17] is utilized to isolate the mangoes and segment them from the background. Then, the contour analysis is performed to measure the mangoes' circumference accurately. In the final step, the effectiveness of our proposed method is evaluated on our mango dataset. By following these steps, our system utilizes several image-processing methods to effectively isolate and segment the mangoes, accurately compute their size, and detect blemishes using Canny edge detection and contour detection techniques. We leverage these techniques to identify an extensive range of blemishes, such as brown or black spots and insect scars.

To evaluate the performance of our methodology, the Random Forest model is used to predict the mangoes' grades on the test set. We then calculate the F_1 score, along with accuracy, precision, and recall for each class, to evaluate the model's performance.

B. Data Collection and Preprocessing

Taiwanese mango is a popular mango variety due to its large, fleshy fruit, sweet flavor when the fruit is still green, origin in eastern India, and high-profit rates when exported to the Chinese market. Therefore, in this study, the Taiwan mango is used to acquire images and evaluate our proposed system. Our imaging system consisted of a Canon 1300D camera with a Canon 50mm f1.8 STM lens and a T660EX tripod to ensure stability. The camera was positioned 42 cm from the mango, with a TR120N1/40W.H bulb placed 63 cm above the mango to maintain consistent illumination. Multiple angles were captured for a comprehensive view of the mango. The mango is placed on a white background. Each fruit is captured at 5-6 different angles and the mango is rotated vertically along the stem. The complete experimental setup is illustrated in Fig. 1.

Fig. 1. Experimental setup for image collection.

Post-capture, each image is uniformly resized and their pixel values are normalized to adjust brightness and color. Additionally, the images are cropped to focus on the region of interest and remove any visible noise. However, having only 110 samples may not be sufficient for machine learning methodologies, as it can lead to overfitting. In order to improve the dataset, a multitude of data augmentation techniques was employed, including horizontal flipping, and rotation by 90 degrees both clockwise and counterclockwise, thereby augmenting the original dataset from 110 to 440 images. This augmentation process is visually depicted in Fig. 2. These augmentation techniques also help improve the generalizability of the model and avoid training overfitting, as well as the system will have more diverse instances to learn from the datasets [12], [23] (see Table I).

The images were categorized into three distinct groups based on the grading standards provided by local expert

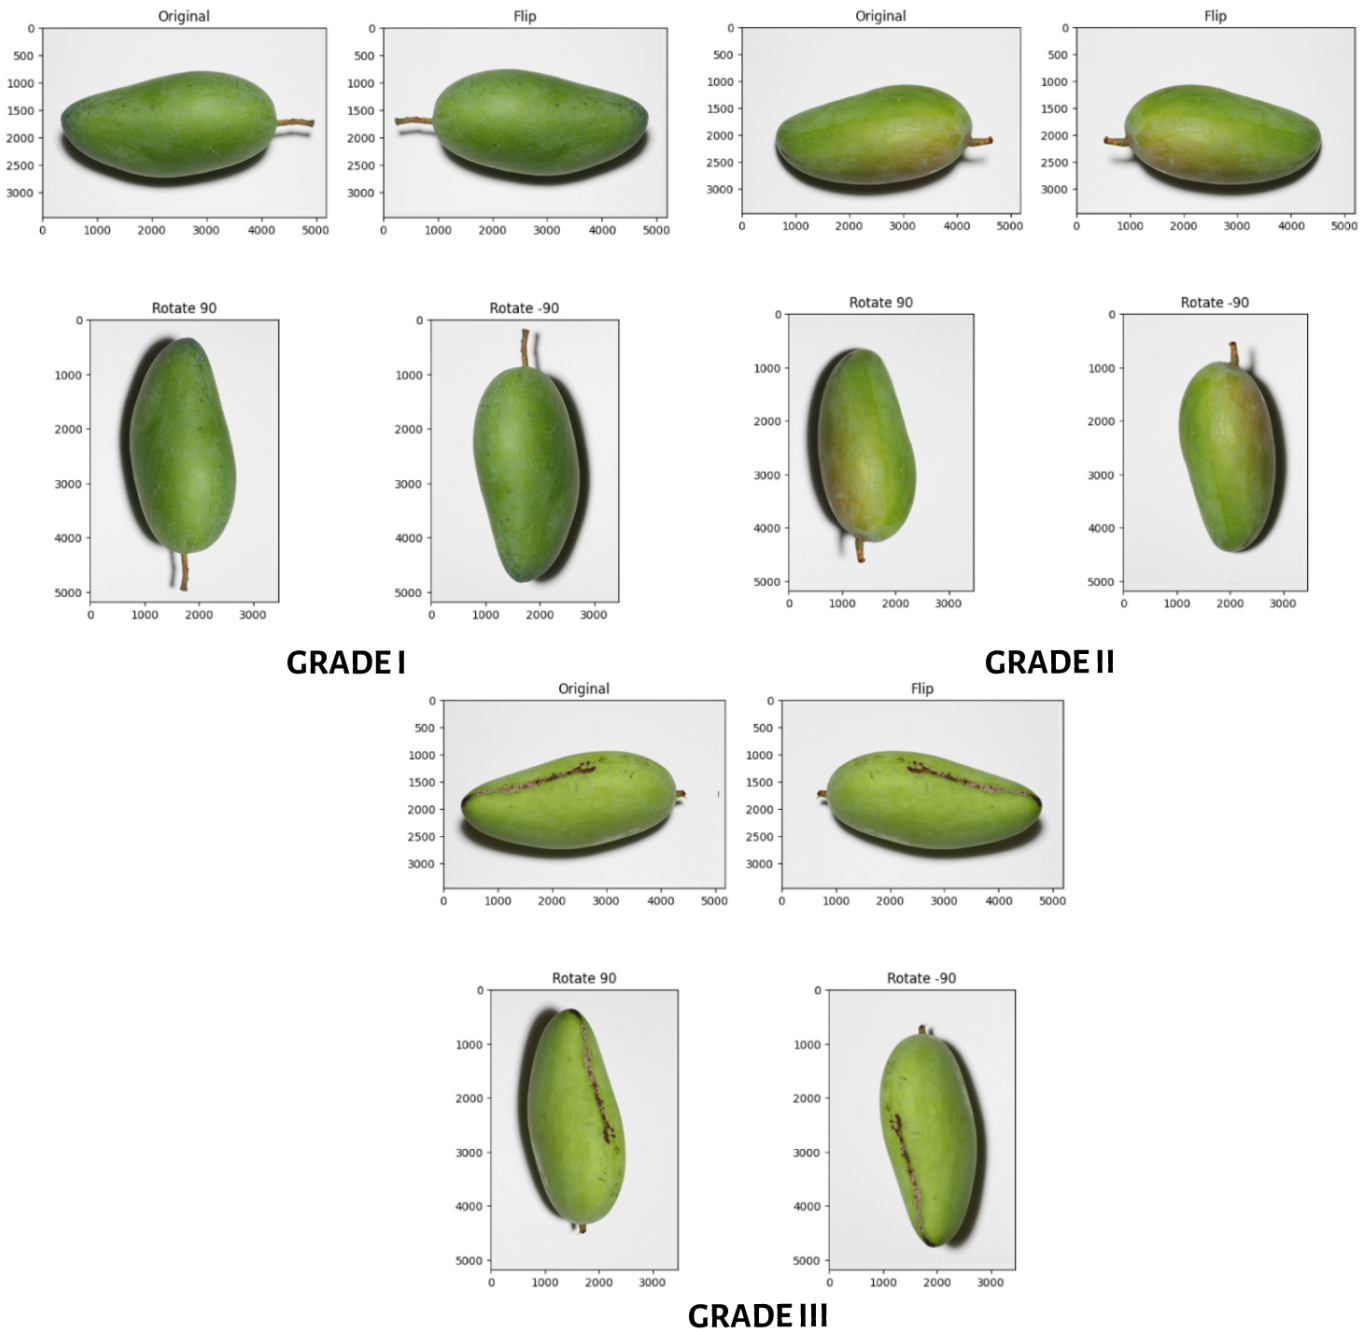

Fig. 2. Visual Representation of Data Augmentation Results.

TABLE I. THE TOTAL DATA SET AFTER DATA AUGMENTATION

Origin	Flipping	90° Rotation	-90° Rotation	Total
110	110	110	110	440

graders. These groups were Grade I, II, and III, and the details of these standards are shown in Table II. The dataset was then divided into a training set that contained 90% of the images. To evaluate the performance of image processing techniques on new and unseen data, 10% of the images were reserved for

future evaluation. The training set was further randomly split into training and validation sets in an 80:20 proportion. This separation is crucial for ensuring that the techniques are robust and can generalize well to new data, beyond merely performing well on the training data. Some representative samples from our mango dataset are shown in Fig. 3. The first line exhibits images of a grade I mango, which is the best quality. Images in the second row are of Grade II mango, while the images in the third row are of Grade III mango, which is the lowest quality. An overview of the dataset structure is illustrated in Fig. 4.

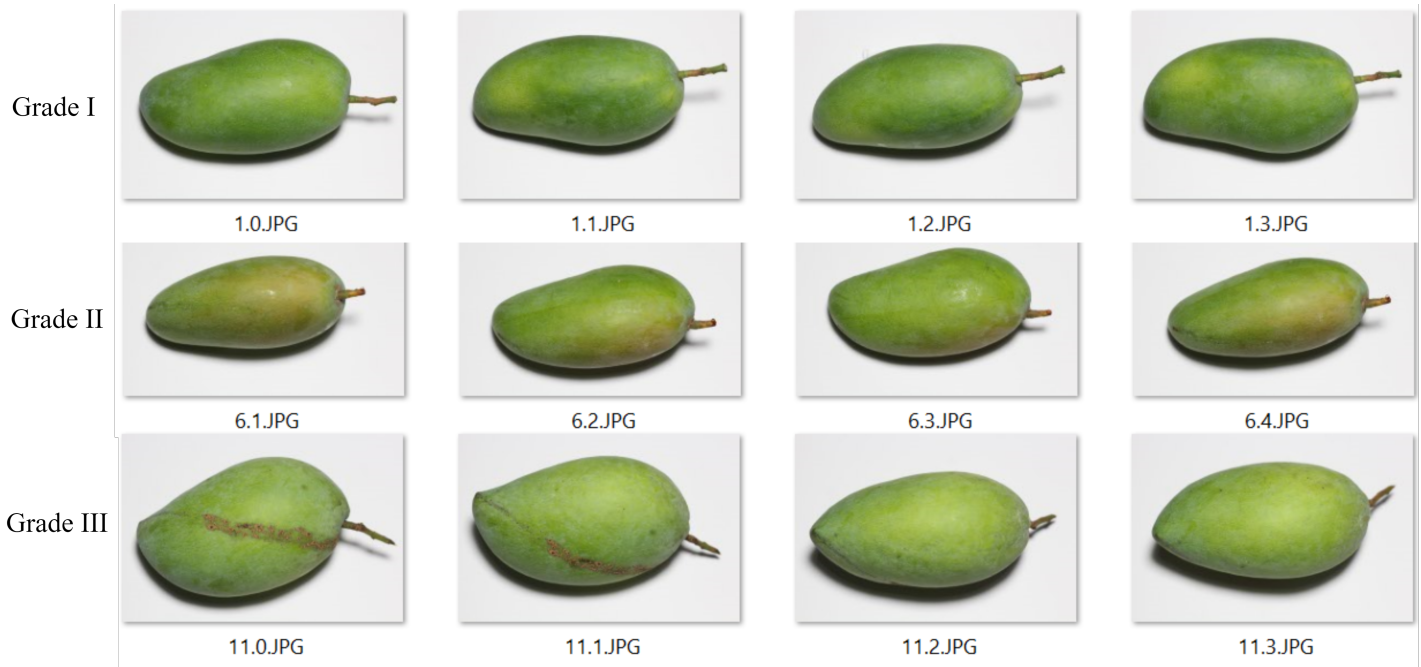

Fig. 3. Some representative samples from our mango dataset.

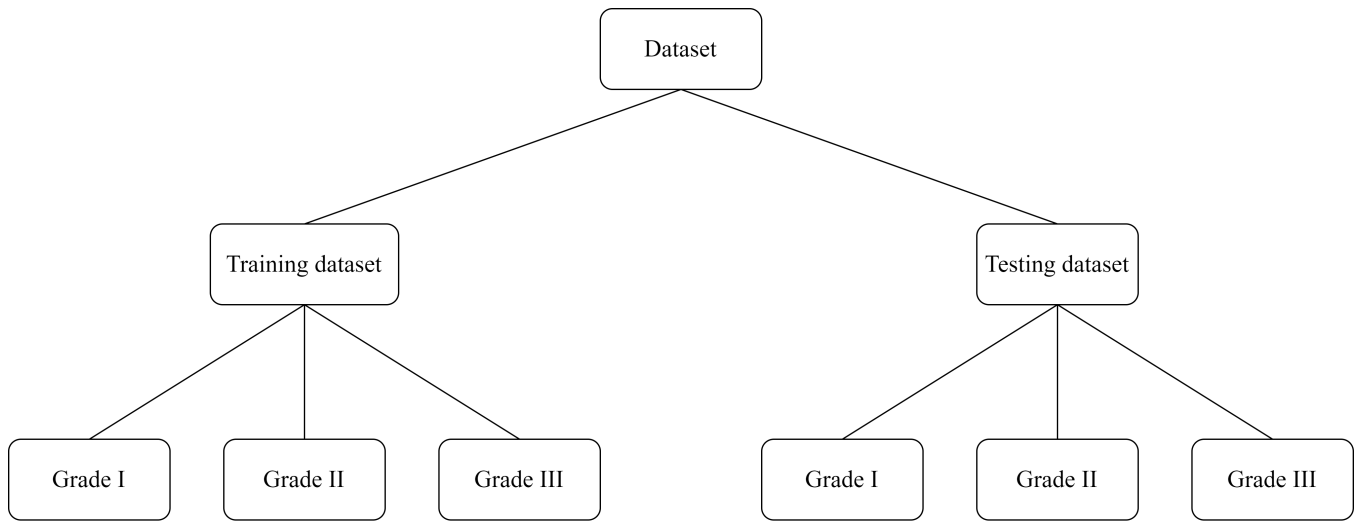

Fig. 4. Structure of mango dataset for image processing.

TABLE II. AN GIANG PROVINCE MANGO GRADING STANDARDS

Grade	Weight (g)	Blemishes	Description
I	> 620	Absent	Grade I mango has no dark spots, smooth, beautiful skin, is older, and weighs 620g or more.
II	500 - 620	Moderate	Grade II mango has few dark spots, flawless skin, and weighs 500-620gr.
III	< 500	Severe	Grade III mango is ripe, has dark spots, scars, and heavily soiled skin, and weighs 500g or less.

[17]. It can determine the optimal threshold value used to segment an image into foreground and background regions. In the case of our study, this approach would be particularly useful when the background of the mango image has varying intensities and the lighting is uneven.

Given the input image be denoted as I with size $M \times N$. The gray levels of the image range from 0 to $L - 1$, where L is the number of gray levels in the image. The histogram of the image is defined as (1):

$$H(k) = \frac{n_k}{N} \quad (1)$$

Where n_k is the number of pixels with gray level k and N is the total number of pixels in the image.

C. Image Segmentation using Otsu Method

The Otsu method is a popular technique characterized by its non-parametric and unsupervised nature of threshold selection

Let T be the threshold value, where $0 \leq T \leq L-1$, and let ω_0 and ω_1 be the weights of the background and foreground classes, respectively. The background class consists of pixels with a gray level less than or equal to T , while the foreground class consists of pixels with a gray level greater than T .

The mean intensity of the background class and foreground class is denoted as μ_0 and μ_1 , respectively. The between-class variance σ_B^2 is calculated as (2):

$$\sigma_B^2 = \omega_0 \times \omega_1 \times (\mu_0 - \mu_1)^2 \quad (2)$$

The within-class variance σ_W^2 is also calculated for each possible threshold value T :

$$\sigma_W^2 = \omega_0 \times \sigma_0^2 + \omega_1 \times \sigma_1^2 \quad (3)$$

Here, σ_0^2 and σ_1^2 are the variances of the background and foreground classes, respectively. The total within-class variance is:

$$\sigma_T^2 = \sigma_W^2 + \sigma_B^2 \quad (4)$$

The optimal threshold value T^* is selected by maximizing the between-class variance σ_B^2 :

$$T^* = \operatorname{argmax}_{0 \leq T \leq L-1} \sigma_B^2(T) \quad (5)$$

By applying the Otsu method to our mango images, we obtain binary images where the mango is represented with white pixels, and the background is represented with black pixels, as demonstrated in Fig. 5.

D. Contour Analysis for Finding Mango Circumference

The contour area is a critical feature for size grading agricultural produce. Its measurement allows for the identification of size distribution, sorting, and grading of fruits and vegetables for the market. In fact, contour area calculation is a powerful tool in image processing applications for accurate size grading. In light of this, this study focuses on the use of the *findContours* function in the OpenCV library, a cross-platform, lightweight, and open-source computer vision library, which supports various machine languages [8], to detect mango contours in images, which is a fundamental step in contour area calculation. To ensure high-accuracy results, we have skillfully employed Otsu-based techniques in image preprocessing, helping us to effectively separate the mango fruits from their backgrounds. The result obtained from contour detection is shown in Fig. 6

However, selecting appropriate parameters using the *findContours* function is central to obtaining precise image segmentation, unsuitable parameter configuration could lead to potential errors, inevitably reducing the overall accuracy of the system. Thus, we conducted experiments to evaluate the effectiveness of different retrieval modes and approximation techniques. In terms of retrieval modes, four hierarchical retrieval modes were investigated, including RETR_EXTERNAL, RETR_LIST, RETR_CCOMP, and RETR_TREE. While RETR_EXTERNAL retrieves only the exterior or outermost contours of the objects in the images and ignores any nested contours inside them, RETR_LIST returns all of the contours as a flat list. RETR_CCOMP organizes all of the contours into a two-level hierarchy, where external contours

come first, and boundaries of the holes reside on the second level. Finally, RETR_TREE reconstructs a complete hierarchy of nested contours. Each contour represents a node in a tree structure, and there exists a parent-child relationship between contours based on their nesting level. The RETR_EXTERNAL mode was found to be the optimal retrieval mode as it detected only the outer contours of the fruits.

In addition, our research has evaluated various approximation methods, including CHAIN_APPROX_NONE, CHAIN_APPROX_SIMPLE, and CHAIN_APPROX_TC89_L1. CHAIN_APPROX_NONE returns all the contours without removing any redundant points, making it the most precise representation of the contour. However, it is computationally expensive and less efficient due to the generation of a large number of points. CHAIN_APPROX_SIMPLE offers a balance between efficiency and accuracy; it only returns the endpoints of the contours, making it an ideal method for applications that require faster processing times. However, this method may lead to shape approximation errors and may not accurately represent curved contours. Conversely, CHAIN_APPROX_TC89_L1 provides a more precise representation of the original shape and is more accurate than CHAIN_APPROX_SIMPLE. However, it generates a large number of points and takes more time to process the contours. The outcomes of the experiments showed that CHAIN_APPROX_TC89_L1, a modified version of the Douglas-Peucker algorithm, produced the most desirable contour approximations.

In order to evaluate the efficacy of the contour detection technique, the circumferences of the fruits identified through this method were recorded and subsequently compared. The findings of this analysis have been reported in Table III.

TABLE III. CIRCUMFERENCE OF DETECTED MANGO FRUITS USING DIFFERENT COMBINATION OF RETRIEVAL MODE AND APPROXIMATION METHOD

Retrieval Mode	Approximation Method	Circumference (pixels)
RETR_EXTERNAL	CHAIN_APPROX_NONE	452
RETR_EXTERNAL	CHAIN_APPROX_TC89_L1	448
RETR_LIST	CHAIN_APPROX_NONE	1247
RETR_LIST	CHAIN_APPROX_SIMPLE	1298
RETR_LIST	CHAIN_APPROX_TC89_L1	1271
RETR_CCOMP	CHAIN_APPROX_NONE	1264
RETR_CCOMP	CHAIN_APPROX_SIMPLE	1279
RETR_CCOMP	CHAIN_APPROX_TC89_L1	1270
RETR_TREE	CHAIN_APPROX_NONE	1189
RETR_TREE	CHAIN_APPROX_SIMPLE	1227
RETR_TREE	CHAIN_APPROX_TC89_L1	1219

The results indicate that using the RETR_EXTERNAL retrieval mode combined with the CHAIN_APPROX_TC89_L1 approximation method resulted in the most accurate detection of mango fruits, with a circumference of 448 pixels. Although the CHAIN_APPROX_NONE method produced the most precise representation of the contour, it required considerable computational resources and generated a high number of points, which could eventually affect the overall processing and detection speed.

Upon completion of the contour-detection step, the results

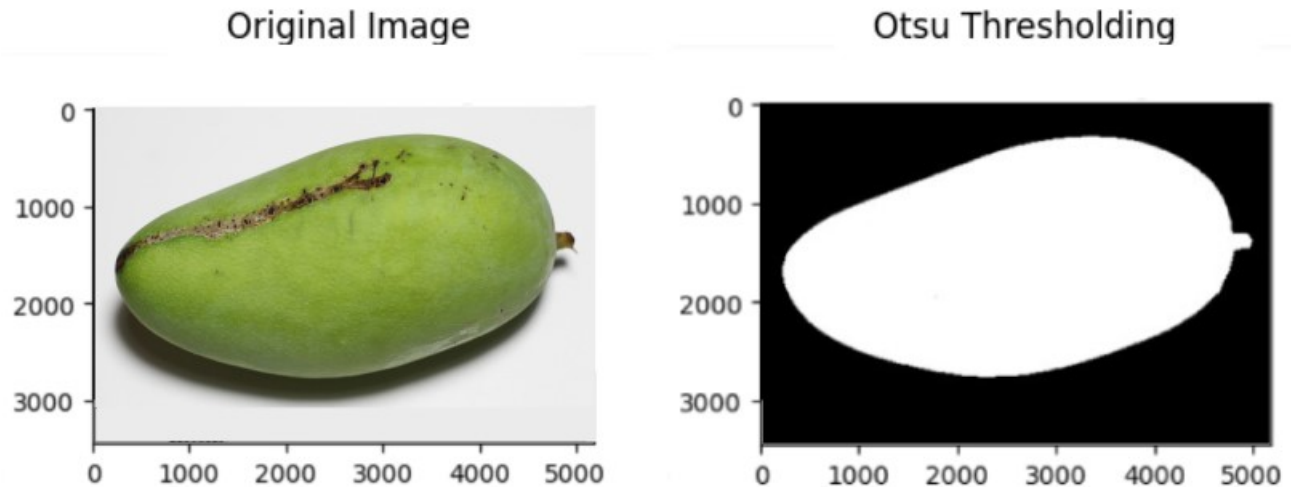

Fig. 5. Original and binary image of mango after Otsu thresholding for segmentation.

Fig. 6. Contour detected mango image.

were used for calculating the surface area by the *contourArea* function. The effectiveness of the contour area feature in mango size grading is evaluated by conducting several experiments. The results reveal that contour area is a highly effective feature in the mango size grading process, outperforming other commonly used features.

These exceptional results can be correlated with the capability of the contour area feature to capture the size and shape of the mango fruit accurately. Therefore, the implementation of contour area as a size grading feature is a robust and reliable approach that could be adopted in the industry to significantly enhance the grading process's accuracy and efficiency.

E. Blemish Detection

Blemish detection [9] is a crucial area of study in the context of mango grading, as it directly affects the overall quality and commercial value of the fruit. In recent years, there has been a considerable shift towards the use of image processing techniques for non-destructive and efficient evaluation of fruit quality [11]. One such technique that has

shown promising results in blemish detection is the use of edge detection algorithms coupled with contour detection.

Canny edge detection [4] is a popular edge detection algorithm known for its noise immunity and high accuracy. Specifically, it detects the intensity changes that occur at the edges of the object and produces a thin line that outlines the object boundary. Canny edge detection is particularly useful in highlighting blemishes present on the mango's surface. Contour detection, on the other hand, identifies smooth curves that outline objects, making it ideal for identifying fruit blemishes.

By leveraging advanced techniques such as Canny edge detection and contour detection, we are able to achieve a multitude of advantages when evaluating fruit quality. These methods exhibit a remarkable level of accuracy, which means that even minor flaws and imperfections can be accurately identified. Furthermore, they are efficient and non-destructive, allowing for quick and smooth evaluations. Through their use, we can eliminate subjective judgments and human errors that are common with conventional inspection methods. That ultimately leads to more objective results, making the assessments of the fruit quality more dependable and reliable. Fig. 7 displays the outcome of utilizing the Canny edge detection technique.

Once the edge detection process is completed, the resulting output is used as input for the contour detection algorithm to accurately identify and extract the contours of the mango blemishes. The contour detection algorithm traces the edges detected by the Canny algorithm and links them to form closed contours, thus enabling the identification of the blemish areas.

Analyzing these contours, the algorithm is able to output the boundary coordinates of the blemish contours on the surface of the mango. In terms of visualization, the contour of the mango's blemishes is displayed in Fig. 8.

Additionally, Table IV illustrates the efficacy of the blemish detection algorithm through a set of representative samples. In order to accurately represent the entire dataset, the table includes various examples with both large and small blemishes, different values for each column, and a few instances of

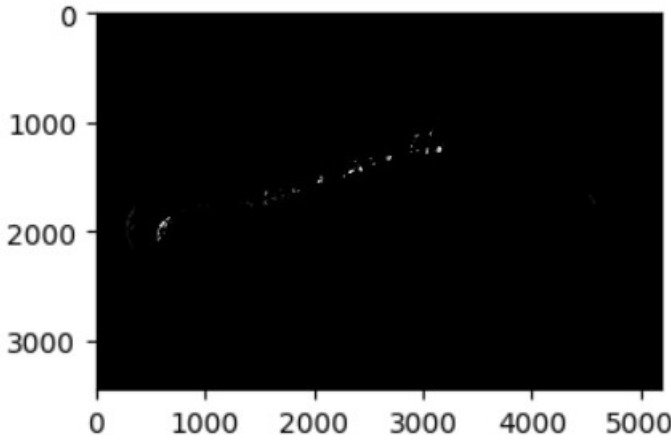

Fig. 7. Mango image obtained after canny edge detection.

Fig. 8. Contour detection following the canny edge detection algorithm.

duplicate values. The selection of rows has been made with utmost care to ensure that the table is an accurate reflection of the data in its entirety.

TABLE IV. BLEMISH DETECTION ALGORITHM RESULTS

Area	Perimeter	X	Y	Width	Height
16.5	17.071067690849304	1323	1656	5	7
12.5	21.899494767189026	1042	1689	4	9
19.0	24.14213538169861	1431	1666	9	7
47.0	38.14213538169861	1230	1677	12	10
13.0	14.828427076339722	1261	1659	5	5
16.0	18.485281229019165	1080	1685	6	7

29.0	32.14213538169861	1262	2991	8	12
99.5	84.1837653058624	1324	1654	21	19
21.5	28.727921843528748	1278	1665	11	6
15.0	20.485281229019165	1241	2789	5	9
12.0	23.313708305358887	1233	1663	10	6

To summarize, the use of Canny edge detection and contour detection for identifying mango blemishes proves to be a promising non-destructive technique that enhances grading accuracy through reliable and effective edge detection. This

approach also reduces inspection time and human errors, ultimately increasing grading efficiency.

F. Data Training with Random Forest Algorithm

The selection of an appropriate machine learning algorithm is critical for successful image processing. Decision Tree (DT) and Random Forest (RF) are commonly used due to their effectiveness in handling complex datasets and feature engineering. However, DT tends to overfit and require a large number of decision nodes, leading to slow and inaccurate predictions, while RF overcomes these limitations by using an ensemble of decision trees that randomly select feature and data subsets for training, resulting in higher accuracy [25].

The RF algorithm constructs a forest of decision trees by randomly selecting subsets of features and data samples from the training set [6]. The algorithm builds a decision tree on each selected subset, reduces variance, and improves accuracy by aggregating predictions of all decision trees. The RF comprises the following steps:

- Randomly select a subset of features and data samples from the training set.
- Build a decision tree on the selected subset.
- Repeat the above two steps multiple times to build a forest of decision trees.
- Predict the output by aggregating the predictions of all decision trees.

The RF algorithm uses a training dataset with N observations and M features to build T decision trees. For each tree t , a random subset of m features is selected, and a bootstrap sample of n observations is drawn. The algorithm builds a decision tree on this subset, and to obtain the final prediction for the i -th observation, the algorithm considers y_i as the true label of the i -th observation and $\hat{y}_{i,t}$ as the predicted label by the t -th decision tree. The final prediction is obtained by aggregating the predictions of all T decision trees in the forest using the formula:

$$\hat{y}_i = \text{aggregate}(\hat{y}_{i,1}, \hat{y}_{i,2}, \dots, \hat{y}_{i,T}) \quad (6)$$

To optimize the performance of the RF algorithm for a specific task, fine-tuning its parameters is necessary. The following RF parameters were fine-tuned:

- *n_estimators*: the number of decision trees in the forest. Increasing the number of trees can improve accuracy but also increases computation time. A value of 100 was chosen as it provided good results without significantly increasing computation time.
- *max_depth*: the maximum depth of each decision tree. A higher depth can increase model complexity and lead to overfitting, where the model memorizes the training data instead of learning general patterns. To prevent overfitting while still providing good results, a *max_depth* of 10 was chosen.
- *min_samples_split*: the minimum number of samples required to split a node. This parameter helps to

balance bias and variance in the model, and a value of 5 was selected.

- *min_samples_leaf*: the minimum number of samples required to be at a leaf node. This parameter reduces the complexity of decision trees and prevents overfitting. A value of 2 was chosen.
- *max_features*: the maximum number of features considered when splitting a node. This parameter can help prevent overfitting by reducing the number of irrelevant features used in the model. The value of *sqrt* was chosen, meaning that the maximum number of features considered at each split is the square root of the total number of features.

By fine-tuning these parameters and validating the results on a separate validation subset, the model's complexity and accuracy were balanced, and overfitting was prevented, ensuring that the model would generalize well to new data.

IV. RESULTS AND DISCUSSION

A. Experimental Setup

The experiment utilized Google Colab and the Python programming language to perform image processing techniques, while OpenCV was used to execute a variety of image processing operations such as Otsu thresholding, *findContour*, Canny edge detection, and contour detection for blemishes. The image dataset utilized in this study consisted of mango images with a uniform size of 640 pixels.

To assess the performance of the machine learning models, Scikit-learn (Sklearn) [20] was used to calculate various evaluation metrics such as accuracy, precision, recall, and *F₁score*. These metrics were computed for each grade of mangoes, including Grade I, Grade II, and Grade III, as well as for the overall performance of the models.

The experimental setup employed in the study ensured that the models were trained and evaluated using a standardized approach, thereby guaranteeing the validity and reliability of the results obtained.

B. Evaluation Metrics

Evaluation metrics play a crucial role in assessing the efficacy of image processing-based fruit grading methods. The selection of appropriate evaluation metrics is vital in determining the accuracy and reliability of the grading techniques employed. The *F₁score* is widely recognized as a key evaluation metric, as it offers a balanced measure of precision and recall, which are critical factors in fruit grading. The *F₁score* is a type of *Fscore*, commonly used in binary classification problems, which is calculated as the harmonic mean of *Precision* and *Recall* [26]. The *F₁score* is particularly useful when the dataset is imbalanced, a common scenario in fruit grading. The general formula (6) for the *Fscore* is:

$$Fscore = \frac{(1 + \beta^2) \cdot (Precision \cdot Recall)}{(\beta^2 \cdot Precision) + Recall} \quad (7)$$

Where β is a parameter that controls the relative weight of precision and recall. When β is set to 1, the formula reduces to the *F₁score*, which is often used as a default value.

In this study, the *F₁score* was selected as the primary metric and was calculated for each grade of mangoes by comparing the results of image processing techniques with the ground truth labels. Additionally, accuracy, precision, and recall were also computed to provide further insights into the performance of the image processing techniques. Accuracy measures the overall correctness of the predictions, while precision measures the proportion of true positives among all positive predictions, and recall measures the proportion of true positives that were correctly identified. To calculate accuracy, precision, and recall from the *F₁score*, the following formulas (8), (9), (10) were used:

$$Precision = \frac{TP}{TP + FP} \quad (8)$$

$$Recall = \frac{TP}{TP + FN} \quad (9)$$

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (10)$$

Where *TP* is true positive, *FP* is false positive, *TN* is true negative, and *FN* is false negative. These formulas can be used to provide additional insights into the performance of image processing techniques for fruit grading, along with the *F₁score*.

The *F₁score*, along with other evaluation metrics, provides a quantitative measure of the effectiveness of image processing techniques for grading mangoes. The use of appropriate evaluation metrics ensures that the grading techniques employed are accurate and reliable, providing insights into the potential of these techniques for streamlining the grading process and improving the accuracy and consistency of grading mangoes.

C. Numerical Results and Discussion

To evaluate the effectiveness of our mango grading methodology, we chose the Random Forest model, which is ideal for handling small datasets and making predictions on a test set for evaluation purposes. By utilizing this model, we obtained comprehensive evaluation results for our image processing techniques based on parameters such as Accuracy, Precision, Recall, and *F₁score*. The clear and compelling evidence of our methodology's ability to accurately grade mangoes is reflected in the numerical presentation of our findings in Table V, as well as their virtual representation in Fig. 9. The combination of these two forms of data visualization serves to underscore the robustness and reliability of our approach.

As shown in Table V and Fig. 9, the image processing techniques used in the study achieved a high level of accuracy, with an overall accuracy of 88%. Table V shown that the highest accuracy was achieved for Grade I, with a accuracy of 91.32%, indicating that the technique performed well in identifying the highest-quality mangoes. Grade II had a slightly

Fig. 9. Virtual evaluation results of mango grading model using image processing.

TABLE V. NUMERICAL EVALUATION RESULTS OF MANGO GRADING MODEL USING IMAGE PROCESSING

Grade	Accuracy	Precision	Recall	F1 Score
Grade I	91.32%	92.06%	93.87%	92.12%
Grade II	85.35%	87.66%	83.45%	85.03%
Grade III	88.76%	84.89%	91.05%	87.66%
Overall	88.25%	88.31%	88.05%	88.73%

lower accuracy of 85.35%, indicating that the technique was less successful in identifying the middle-quality mangoes. However, this accuracy score is still considered high and indicates that the technique is relatively robust. Grade III had an accuracy score of 88.76%, indicating that the technique performed well in identifying the lowest-quality mangoes.

The precision scores for the three mango grades were considerably elevated, with values between 84% and 92%. This signifies that the image processing technique accurately detected true positives, or the number of mangoes that were correctly identified for each grade while limiting the number of false positives, or the number of mangoes that were inaccurately identified. The highest precision score was observed for Grade I, indicating that the method was exceptionally precise in identifying the finest quality mangoes. Conversely, the lowest precision score was noted for Grade III, suggesting that the technique faced more difficulties in detecting the poorest quality mangoes.

Similarly, the recall scores for the three grades were also high, with values ranging from 83% to 93%. This implies that the technique was proficient in identifying all relevant occurrences, or the number of mangoes that were correctly identified for each grade while minimizing the number of false negatives, or the number of non-mangoes that were wrongly

identified as mangoes. The highest recall score was obtained for Grade I, indicating that the technique accurately identified the highest-quality mangoes. On the other hand, the lowest recall score was obtained for Grade II, suggesting that the technique faced more challenges in identifying middle-quality mangoes.

Moreover, the F_1 score for the three grades were also high, ranging from 85% to 92%. The F1 score is a measure of the harmonic mean of precision and recall, providing a balance between the two metrics. The highest F_1 score was achieved for Grade I, indicating that the technique was highly successful in identifying the highest quality mangoes with a balance between precision and recall. Conversely, the lowest F_1 score was observed for Grade II, implying that the technique experienced more difficulties in identifying middle-quality mangoes.

This study demonstrates the potential of image processing techniques to improve the precision and consistency of mango grading while streamlining the process. The implications of this study are noteworthy, as they imply that image processing techniques could be a reliable and effective means of grading mangoes. Furthermore, this study is in line with other research in the field, which also highlights the effectiveness of image-processing techniques for fruit grading. However, this study underscores the potential of utilizing a combination of techniques, such as Otsu thresholding, *findContour* of OpenCV, Canny edge detection, and contour detection for blemishes, to attain high levels of precision and consistency in grading mangoes. Therefore, this study provided valuable insights into the potential of image processing techniques for improving fruit grading's precision and consistency, and its implications could be instrumental in the fruit industry. The screenshot of the mango grading system is shown in Fig. 10.

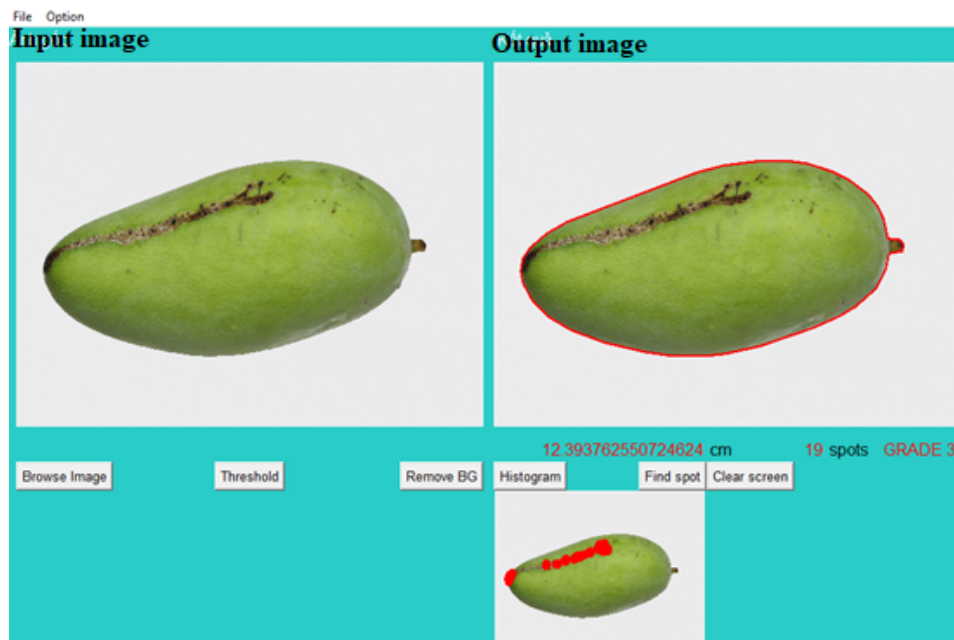

Fig. 10. The screenshot of the mango grading system.

V. CONCLUSIONS, LIMITATIONS, AND FUTURE RESEARCH

The proposed image processing system successfully has achieved the goal of automating the grading and sorting process of mangoes. By using the Otsu method for image segmentation and contour analysis for finding mango circumference, the system was able to accurately detect and classify mangoes based on their external quality features such as size, shape, and the presence of blemishes. The classification accuracy results showed that the proposed system is effective and efficient for grading mangoes, with an overall accuracy of 88%.

Despite the success of the proposed system, there are still some limitations and challenges that need to be addressed in future work. One of the limitations of the system is that it requires a controlled environment for image capturing, which can be challenging to achieve in real-world scenarios. Moreover, the system heavily relies on the quality of the input images, which can be affected by various factors such as lighting conditions and camera settings. Another challenge is the need for continuous updates and improvements to ensure the system's reliability and adaptability to new varieties of mangoes.

In future research, we aim to overcome the limitations and challenges outlined above and further enhance the accuracy and efficiency of the proposed system. To this end, research efforts should prioritize the development of more robust and precise image processing and analysis algorithms that can effectively handle variations in image quality, lighting, and camera calibration. Furthermore, we plan to explore various image segmentation and feature extraction techniques to augment the system's capacity to classify mangoes based on their quality features with greater accuracy. The use of advanced machine learning approaches, such as deep Convolutional neural networks, could also be explored to improve the grading

and sorting process's accuracy and efficiency. Additionally, we intend to investigate the feasibility of integrating the proposed system with other mango supply chain components, such as harvesting and packaging, to create a fully automated system. Lastly, it is crucial to consider the proposed system's potential impact on the livelihoods of small-scale mango farmers and ensure that the technology remains accessible and affordable for them. Therefore, future research should strive to develop solutions that can benefit all stakeholders in the mango supply chain, from farmers to processors and consumers.

ACKNOWLEDGMENT

Graduate School of Information Science and Engineering, Ritsumeikan University, Kusatsu, Shiga, Japan²

Abstract—Due to the immobility of devices in conventional intelligent spaces, the quality and quantity of their applications (i.e., services) are thus restricted. To provide better and more applications, the devices in the spaces must be able to move autonomously to ideal positions. To solve this issue, the concepts of reconfigurable intelligent space (R+iSpace) and mobile modules (MoMos) have been introduced. Each device in the R+iSpace is carried by one or more MoMos that can freely move on the ceiling and walls. Consequently, the R+iSpace has evolved into a user-centered intelligent space, where devices can move to the user to provide services instead of the user having to move to where the devices are. In this work, several promising applications are introduced as open research challenges for the R+iSpace and the MoMo. In fact, various wall-climbing robots have been developed, however, their speed and carrying capacity are insufficient for adoption for the MoMo and the R+iSpace. Therefore, the development of MoMo requires the creation of entirely new designs and mechanisms. In addition to introducing promising applications, this work provides an overview of all versions of the MoMo that have been developed to gradually make it deployable in a realistic R+iSpace.

Keywords—Climbing Robot; intelligent space; iSpace; mobile module; MoMo; reconfigurable intelligent space; R+iSpace; smart home; ubiquitous environment

I. INTRODUCTION

Recently, terms such as smart homes, ubiquitous environment, and intelligent space (iSpace) have become popular [1]–[3]. This type of space is no longer merely an abstract concept realized in sophisticated research centers; it is being widely implemented even in ordinary homes. The fundamental premise of these spaces is to increase the intelligence of the devices contained within, allowing them to provide users with more valuable information and services. However, the methods by which devices interact with the users vary according to the space. For example, in an iSpace [1], each device is treated as a distributed intelligent network device (DIND) and is connected to the same local network. Here, a DIND can be either an input device (e.g., a camera or microphone) or an output device (e.g., a projector, light, television, or speaker). An input DIND is used to capture the demands of the user or the current state of the space. Then, the captured data are transmitted to a server computer. After processing the data and determining an appropriate service, the server distributes this result to all DINDs. Finally, a single or multiple output DINDs, as specified by the server, provide service to the users.

However, these spaces are either static or semi-dynamic and are not entirely oriented toward the users. In a static space, the poses (i.e., their positions and orientations) of all devices (e.g., DINDs in an iSpace) are fixed and do not

Fig. 1. A conceptual reconfigurable intelligent space with mobile modules (MoMos).

automatically change. In contrast, in semi-dynamic space, the positions of devices are fixed but their orientations are variable. The simplest approach to transform a static device into a semi-dynamic state is attaching it to an actuator. Typically, the users must arrange devices in such spaces into optimal positions manually. Each time requesting a service, the user must consider the location of the device to obtain the most effective service. For instance, to watch television, the user must walk in front of a television. Furthermore, multiple devices are required to provide greater services to the users. For example, a home with multiple rooms needs multiple televisions, and detecting the users in any situation requires multiple cameras.

Due to the reasons stated above, fully dynamic spaces are required to provide higher quality and quantity of services. A fully dynamic space is known as a reconfigurable iSpace (R+iSpace). For an R+iSpace to be completely user-oriented, its devices must be able to move and rotate autonomously. This can be accomplished by mounting the devices using an on-ground robot or a wall-climbing robot. This eliminates the need for the user to move in order to watch television; rather, the television will move closer to the user. Moreover, by transforming a space into one that is fully dynamic, the number of devices required to provide valuable services is minimized

Fig. 2. Several promising applications of MoMo in the future.

[4], [5]. In an iSpace, for instance, only one television is required because it can be moved between rooms.

As previously mentioned, there are two methods to convert a space to an R+iSpace. The first is mounting the devices on on-ground robots. In this method, the devices move on the floor alongside the robots. On the ground, however, there are numerous obstacles, including humans. These obstacles are challenging for the robots to avoid, as they may be dynamic or frequently change. Consequently, the algorithm for robot movement becomes extremely complex. In addition, the robots may negatively impact the users by obstructing their movement. Remarkably, due to the limited height of a standard on-ground robot, devices such as cameras and lights cannot cover a large area when mounted on the robots. For these reasons, this approach was not adopted for the development of R+iSpace.

On the other hand, the second method is employing wall-climbing robots that are capable of carrying devices and moving along the ceiling and wall (hereafter referred to as the field). The greatest advantages of this method are that the robots and mounted devices do not occupy any floor space, do not need to avoid numerous obstacles, and do not impede the users. Thus, the movement algorithm for robots becomes simpler. Furthermore, the devices, such as cameras and lights, can be positioned anywhere, allowing them to monitor a larger area. In light of this, the second method was adopted for building the R+iSpace.

Numerous climbing robots have been developed previously [6]–[28]. These robots can be categorized based on their adhesion or movement techniques. According to the adhesion techniques, they can be classified into four types: magnetic force [6]–[11], suction force [12]–[18], use of adhesive material [19]–[24], and mechanical adhesion [25]–[28]. In contrast, they can be categorized based on three movement techniques: walking by raising each leg individually [6]–[8], [12]–[15], [19]–[21], [25], driving using wheels [9], [16]–[18], [22], [23], [28], and moving with crawlers [10], [11], [24], [26], [27]. These robots were experimentally demonstrated to be capable of moving across a field without falling. However, these robots have numerous limitations, including slow movement, energy expenditure during idle state, insufficient loading capacity, and difficulty in self-localization.

In order to establish the R+iSpace, a novel climbing robot must be developed. The new robot is called mobile module (MoMo), which can move on the field and to which a device can be mounted (Fig. 1). Nevertheless, developing such a robot is extremely challenging. The MoMo must move efficiently on the field, not fall off the field, have a sufficient moving speed, not consume electricity when in the idle mode, have a large loading capacity, and precisely and simply self-localize. In addition to introducing several promising applications of the R+iSpace, this work provides an overview of all developed MoMos.

Fig. 3. Previous versions of the MoMo.

II. PROMISING APPLICATIONS OF MOBILE MODULES (MoMos)

As mentioned in Section I, the MoMo is significantly important for creating a fully user-oriented R+iSpace. By proposing such an R+iSpace utilizing MoMos, numerous user-oriented applications can be provided in the future. Fig. 2 illustrates several of these anticipated applications.

A. Adaptive Layout Service

The first promising application of the MoMo is adaptively customizing the layout of the R+iSpace and the properties (e.g., location) of available devices within this space. For instance, by attaching partitions to multiple MoMos, users can change the design of a room at any time (Fig. 2a). Moreover, when a user enters the space, devices connected to the MoMos, such as cameras, projectors, lights, televisions, and wall clocks, can be repositioned optimally. Typically, cameras can be moved to situations where users and their requests can be easily detected and recognized. Similarly, the position, display size, and display resolution of a projector can be adjusted in response to the status of the user. During a conversation between two or more users, using the cameras to detect eye movements, the lights can be moved to appropriate positions that better emphasize the object on which the users

are focusing.

B. Indoor Delivery Service

Currently, conveyor belts and delivery robots are used in restaurants to deliver food and drinks directly from the kitchen to tables of customers. However, conveyor belts require space on the floor for installation. Moreover, delivery robots are predominantly ground-based. Such a robot must be capable of detecting humans, tables, and other obstacles placed on the ground to prevent collisions. Moreover, the appearance of such robots may annoy customers. Therefore, a robot that can move across the ceiling and walls without encountering obstacles to deliver food exhibits advantages such as ease of movement, conservation of floor space, and unobstructive operation. This robot can be developed using a single MoMo and an extendable robotic arm to pick up and drop off food (Fig. 2b).

C. Indoor Walking Assistance Service

The population in developed countries such as Japan is aging and declining. Consequently, many elderly people have problems with their spine, waist, or legs. These people have difficulty walking in everyday life and require devices to assist them in safely moving around. As a promising solution, a MoMo can be combined with an assistant module to aid elderly people in indoor environments (Fig. 2c). When compared to canes, crutches, walkers, and other walking mobility aids for older adults, a support device powered by MoMo will not require users to use their hands to control it. Sensors on the device can detect the direction of the user and transmit the acquired information to the MoMo. The MoMo then proceeds in this direction.

D. Indoor Transportation Service

Elevators and escalators are commonly used in commercial establishments, such as hotels, shopping centers, and high-rise structures. They are also used in private settings, such as private homes, particularly in homes with disabled residents. Given the size of a typical commercial space, the area required for an elevator or escalator is negligible. By contrast, individual locations are significantly smaller than commercial locations. Consequently, a relatively significant area is required to install a static elevator or escalator. Moreover, the installed devices are not as frequently used as they are in commercial spaces. Therefore, it is preferable to adopt a dynamic elevator in a private space rather than a fixed one. A dynamic elevator can be defined as a device that operates whenever users require it and frees the area in which it is located when not in use. As shown in Fig. 2d, two or more MoMos are utilized to construct such a flexible elevator. These MoMos carry a base plate on which the user can stand safely. With the ability of the MoMo to move on the field, the system can transport users in a manner similar to an elevator when in the active mode and move to the ceiling to free occupied space when in the inactive mode.

E. Workflow Monitoring Service in the Operating Room

For surveillance purposes, a minimal number of cameras can be attached to MoMos to allow them to move freely on the field (Fig. 2e). In this way, the camera system can monitor an R+iSpace, such as a private home, without encountering

TABLE I. PREVIOUS MOBILE MODULE (MoMo) SPECIFICATIONS

	MoMo 1	MoMo 2	MoMo 3	MoMo 4.1	MoMo 4.2

dead angles. Notably, such a system is more critical when monitoring the workflow in an operating room. For instance, the workflow monitoring systems in [4], [5], [29], [30] employed multiple cameras to capture every movement in the operating room. Then, the systems used these data to estimate the current workflow phase and detect unusual events that occurred during this phase. However, a surgical workflow is generally performed by a group of surgeons, with support staff gathered around a patient. Consequently, many dead angles may exist, and the critical motions that the cameras are unable to capture may be overlooked. By adopting MoMos in these situations, the attached cameras can be relocated to locations that provide a clearer view of both human and equipment movement.

III. PREVIOUS MoMo VERSIONS AND THEIR LIMITATIONS

Since 2012, the R+iSpace, specifically the MoMo, has been the subject of extensive research [31]–[35]. Consequently, four prototypes of the MoMo were developed, excluding the version introduced in this study (refer to Fig. 3 and Table 1). These MoMos were proposed according to the following six design requirements: they must be able to move on both the ceiling and wall, their fall must be prevented by using a fastening mechanism, they must move sufficiently quickly, they must consume no energy when fastened and idle, they must have a high loading capacity, and they must be accurate and straightforward in their self-localization, as discussed in Section I. Before delving into the details of the latest MoMo version, this section provides a brief overview of previous versions and their limitations.

A. Screw–nut Mechanism–based Four-legged MoMo 1

The first MoMo was a four-legged walking robot capable of moving across the field (Fig. 3a) [31]. Each leg was composed of two actuators. One, referred to as a pinning actuator, was used to fasten and unfasten a leg to and from the field. The

other, known as a panning actuator, was used to rotate the leg (gait steps 1, 2, 3, and 4) or the body (gait step 5) around the hip joint (refer to Fig. 4). This MoMo fastened and unfastened a leg to and from the field via a screw–nut mechanism controlled by the pinning actuator (Fig. 5). Each robot leg was equipped with a screw, and numerous nuts were evenly spaced across the vertical and horizontal axes of the field. The MoMo walked on the field by sequentially moving the four legs. Consequently, five gait steps were required to move from one position to the next, as illustrated in Fig. 4.

By adopting the screw–nut mechanism to fasten at least three of the four legs while in motion, the first MoMo was able to move on the field and effectively avoid falling. Additionally, once the robot tightened its screws into the nuts, it required no energy to maintain that position. This implies that the MoMo had zero energy consumption during any period of inactivity. Moreover, as each nut on the field had a fixed distance from the surrounding ones and the movement of each robot was restricted to this distance, the current location of the robot was measured quickly and accurately.

However, the first MoMo has several problems. The first and major limitation was the moving speed. In an experiment, it took 46 s for the robot to move 15 cm (approximately 0.33 cm/s) to the next position. This speed was insufficient for use in the R+iSpace. There are two possible explanations for this slow speed. The first and foremost reason was that the robot spent an inordinate amount of time fastening and unfastening the leg as a result of the screw–nut mechanism. The second reason was the length of time required to move the legs sequentially. The second limitation of the first MoMo was that the friction between a screw and a nut during fastening was experimentally shown to occasionally result in movement failure. The third was the high cost associated with the use of eight actuators.

Fig. 6. Gait steps of MoMo 2.

B. Screw–nut Mechanism–based Two-legged MoMo 2

A second version was introduced to address the moving speed issue of the initial version (Fig. 3-b) [32]. Specifically, the number of legs was reduced to two. Each leg, similar to the legs in the first version, was equipped with two actuators called pinning and panning actuators. The screw–nut mechanism was also used in this version. Because of the limited number of legs in this robot, three screws in a triangular shape were attached to each leg to ensure that the robot had sufficient hinge force to free one leg and rotate its body around the other leg (gait step 2 in Fig. 6). The pinning actuator on each leg fastened or unfastened the screws simultaneously. The arrangement of the nuts on the field was thus altered to accommodate the screw structure. This MoMo added an additional component for mounting the device. A built-in actuator moved the component and device near one leg (gait step 1) before unfastening the other leg and rotating the body (gait step 2). Thus, the moment of inertia decreased dramatically with the rotation of the body. Consequently, MoMo 2 required only two gait steps to complete a movement (Fig. 6).

This version of the MoMo inherited all the advantages of MoMo 1, i.e., mobility without falling from the field, energy-free operation in the idle state, and efficient and precise localization. Moreover, by reducing the number of legs from four to two, the number of gait steps was reduced from five to two. Thus, the movement speed of the robot increased more than sixfold, from 0.33 cm/s to 2.05 cm/s. Additionally, this version utilized only five actuators, when compared to the eight required in MoMo 1, resulting in a decrease in the cost of the robot.

Although the movement speed of MoMo 2 was improved, it was extremely slow when deployed in practical applications. Apart from the reduction in speed caused by the screw–nut mechanism, the movement of the extra component between the two legs during gait step 1 also reduced the speed. Moreover, this version of MoMo lacked a device (e.g., a sensor) for tracking the location of screws on the legs in relation to nuts in the field. Experimentally, it was observed that a marginal error in positioning gradually resulted in screw abrasion. Consequently, incomplete leg fastening due to screw abrasion occurred occasionally. The incomplete fastening yielded a gap between the robot and the field. This gap led to an inability to

Fig. 7. Pin-lock mechanism in MoMo 3.

Fig. 8. Gait steps of MoMo 3.

fasten the other leg in the next gait step.

C. Pin-lock Mechanism–based Two-legged MoMo 3

The third version of the MoMo was developed to overcome the issues raised in the second version (Fig. 3c) [33]. Two significant changes from the second MoMo were observed in this version. First, the screw–nut mechanism was replaced with a new one called pin-lock, as shown in Fig. 7. Specifically, the three screws were replaced with three pins on each robot leg. Each pin had a larger end and a smaller body. Moreover, the nut on the field was replaced with a hole formed by two circles of varying sizes. The fundamental concept of the pin-lock mechanism was to use the pinning actuator on a leg to simultaneously push three pins into the larger circles of the holes and then use the panning actuator to rotate them into the smaller circles to lock (i.e., fasten) the leg. The unlocking (i.e., unfastening) procedure was performed in the reverse order. Thus, the panning actuator served two roles in MoMo 3: rotating the body around one leg (similar to MoMo 2) and rotating the pins from the larger circle into the smaller one. Owing to the larger diameter of the end of the pin in comparison with the smaller diameter of the hole, the MoMo could avoid falling out of the field when locked. Second, the extra movable component where the device was attached was eliminated. Instead, the device was positioned at the center of the MoMo. Thus, the number of gait steps was reduced from two to one (Fig. 8). However, the removal of the extra component increased the moment of inertia of the robot during body rotation. To adapt to this, MoMo 3 replaced the panning actuator with one that had a higher torque than that used in MoMo 2.

By substituting the screw–nut mechanism with the new pin-lock mechanism and omitting the extra movable component to reduce one gait step, the moving speed of this MoMo was increased significantly from 2.05 to 2.8 cm/s. Moreover, the extra component necessitated the use of an actuator to

Fig. 9. Barb-spring mechanism in MoMo 4.

translate between the two legs. Consequently, by eliminating this component, the required number of actuators was reduced from five to four, resulting in a reduction in the cost of the robot. Moreover, by ensuring that the larger circle of the hole has a diameter greater than the end of the pin, the MoMo could handle misalignment between the pin and hole caused by marginal positioning errors during the movement of the robot without the use of additional sensors. Thus, movement failure that occasionally occurred in the first and second MoMos was thoroughly overcome experimentally.

Nevertheless, several issues from the previous MoMos persisted. For example, although MoMo 3 could move faster than the previous two, its speed remained insufficient for adoption in the R+iSpace. Intuitively, the robot required approximately 3 min to move to a position 5 m away from the current one. Moreover, as previously stated, the panning actuator was replaced with a higher torque to accommodate the expansion in the moment of inertia. However, this replacement was insufficient to cope with the considerable torque generated by a heavy device (e.g., a television) attached to the robot.

D. Barb-spring Mechanism-based Two-legged MoMo 4

The fourth version of the MoMo was developed to further improve the speed of movement [34]. This version of the MoMo has two subversions (Fig. 3-d and 3-e). The first subversion (MoMo 4.1) was nearly identical to MoMo 3, except for the addition of a new barb-spring mechanism in place of the pin-lock mechanism (Fig. 9). The panning actuator was retained to enable rotation of the body of the MoMo around one leg. Conversely, the second subversion (MoMo 4.2) retained the barb-spring mechanism used in MoMo 4.1 but omitted the panning actuators of the two legs. Instead, it employed a wheel mechanism comprising an omni wheel that was controlled by an actuator. The wheel mechanism was attached between the two legs to allow the body of the robot to rotate around one leg. This reduced the number of required actuators. However, the gravity force acting on the robot caused a small gap between the robot and the field during its body rotation. Hence, a compressed spring was incorporated into the wheel mechanism to ensure that the wheel was always in contact with the field. Both subversions were equipped with the newly developed barb-spring mechanism, which accelerated the fastening and unfastening processes.

As mentioned previously, MoMo 3 rotated the pinning and panning actuators sequentially to push the pins on the leg into the larger circles and then rotated the pins into the smaller circles. These sequential actions, combined with the

Fig. 10. Gait steps of MoMo 4.

slow rotation of the actuator, resulted in low-speed fastening and unfastening processes. To address this, the barb-spring mechanism in MoMo 4 utilized compressed springs inside the pins to immediately push (by bigger springs) and lock (by smaller springs) the pins into the holes without the need for the effort of an actuator. However, the pinning actuator was required to unlock the pins and their barbs from the holes and compress the springs inside the pins. During the rotation of the body of the robot, the compressive state of the springs was naturally maintained by the resistive force from the field. Once the pins reached the holes, the resistive force was lost, and the pins were pushed into the holes automatically. Both robot subversions moved on the field by repeating a single gait step, similar to the third robot (Fig. 10). However, the gait step required fewer actions, and each action was significantly faster than that of MoMo 3.

As mentioned earlier, although MoMo 4 required only one gait step, the speed of the gait step was significantly faster than in the previous version. Consequently, there was a nearly threefold increase in the moving speed of the MoMo. Experimentally, MoMo 4.1 that used the omni wheel to rotate the body and MoMo 4.2 that used the panning actuator achieved speeds of 7.91 and 6.82 cm/s, respectively. In comparison, MoMo 3 had a speed of only 2.8 cm/s. It was observed that substituting the panning actuator with the omni wheel resulted in a faster speed. Additionally, by adopting the barb-spring mechanism rather than the pin-lock mechanism, the legs could be automatically fastened without the assistance of an actuator. Therefore, the roles of each actuator were reduced, resulting in energy savings.

However, several issues remain unresolved or resurfaced in this version. First, the loadable weight of the MoMo remained small and constrained owing to the elimination of the extra movable component. Second, because the pin used two barbs to lock it to the field, the body of the pin was required to have a diameter that corresponded to the diameter of the hole in the field (Fig. 9). Consequently, any misalignment between the pin and the hole could result in a fastening failure. This implies that the movement failure issue that was resolved in MoMo 3 reappeared in MoMo 4. Third, the primary reason for replacing two panning actuators with an omni wheel controlled by an actuator in MoMo 4.2 was to reduce the number of actuators required. However, the aforementioned movement failure occurred more frequently in MoMo 4.2 than in MoMo 4.1. This can be explained as follows. The compressed spring within the wheel mechanism generates a pushing force that acts on the field. By contrast, a reaction force of equal magnitude acted on the robot. Moreover, one leg was fastened, and the other was left free during body rotation. As a result of the reaction force, the gap between the robot and the field became

more significant, and misalignment between the pins and holes occurred more frequently.

IV. CONCLUSION

Several future applications of R+iSpace and MoMo are presented in this paper to demonstrate that R+iSpace and MoMo research is extremely promising. Moreover, an overview of all developed MoMo versions was included. The developed MoMos satisfied four of the six design requirements. The robots were able to move on the field without collapsing. In addition, they required no electrical power to remain stationary in the field. Furthermore, they were able to precisely pinpoint their locations. However, the remaining two requirements (i.e., sufficient movement speed and large carrying capacity) were not met. Although the upgrade from the third to the fourth version of the MoMo significantly increased its speed, a faster MoMo was required for practical applications in the R+iSpace. Moreover, all versions of the MoMo were developed with the primary objective of increasing the speed of movement. The loading capacity was not taken into account during design or testing. None of the MoMos investigated the capacity of carrying weight. Additionally, movement failure due to pin-hole misalignment was a significant issue in these MoMos. These problems are open research questions for the future.

Blockchain-enabled Secure Privacy-preserving System for Public Health-center Data

Md. Shohidul Islam, Mohamed Ariff Bin Ameen, Husnul Ajra, Zahian Binti Ismail*
Faculty of Computing, Universiti Malaysia Pahang, Kuantan, Malaysia

Abstract—Health center data implicates a large scale of individual health records and is immensely concealment sensory. In the virtual era of large-size data, the increasingly different health informatization causes it important that health data needs to be stored precisely and securely. However, daily health data transactions carry the risk of privacy leaks that make sharing difficult. Moreover, the recently permitted blockchain applications suffer from deficient performance and lack of privacy. This study presents a privacy-preserving and secure sharing and storage system for public health centers based on the blockchain method to dispose of these issues. This system utilizes a hash-256-based access controller and transaction signature with the consensus policy and provides security to share and store health data in the blockchain. In this approach, blockchain guarantees scalability, privacy, integrity, and availability for data retention. Also, this paper measures the performance of transactions with supporting confidentiality-preserving and shows the average transaction time and acceptable latency when accessing health data.

Keywords—Blockchain; data; health; public; secure transaction

I. INTRODUCTION

Blockchain is currently inclining extensive importance and remarkable investment policy of shareholders across an exhaustive range of different initiatives [1]: sharing economy, digital currency, energy trades, financial security, copyright defense, and e-government. Blockchain, as a security defense technology, is evolving into a critical enabling approach for various organizations to create and deploy different decentralized applications and perform many digital sharing [2]. In order to make high-grade services to users, transactions in such applications must be high-speed, less latency, safe, and robust. In this regard, the integration of several emerging technologies in the health industry makes the processing of health information growingly knowledge [3], which defines the health record as the most creative and shareable resource. Nowadays, the medical records generated in the global health sector are growing explosively.

As the level of health information in health centers is increasing day by day, information systems are becoming increasingly complex, and the importance of information security and privacy [4] is increasing incredibly. Nowadays, the traditional paper-based health records of health sectors and their data management systems face serious risks to the privacy and integrity of storing patients' health information. Furthermore, as most health centers are sequestered from each other, long-term storage, sharing, and maintenance of health information are not facilitative to better treatment and counseling. As a result, there is potential for wastage of medical equipment and

key data in the healthcare sector. Furthermore, there has been some work on the security of data transactions in the health industry. This sector has some common work and authentication process issues that ignore health resource-controlled transactions and performance. Due to some conceptual issues, such as a lack of trusted transactions, data security, integrity, scalability, etc. The application development based on many technologies in the health sector for digital transactions is fairly slow. For these reasons, it is challenging to find a standard approach to preserve and manage humane and rational services on a large scale.

Fortunately, the recent rise of blockchain technology could open up new horizons for the secure data repository in the healthcare sector [5]. The blockchain approach can provide a trustworthy solution to health management as a rich database with features of decentralization, integrity, security, privacy, and transparency. The emergence of blockchain-based data management in the health sector has motivated the advancement of a rich data platform instead of traditional health record systems that revolutionizes the processing of health information privacy and integrity in health centers. The foremost intent of this paper is to design a secrecy-conserving and secure data storage system for health centers using blockchain [6]. Blockchain-based healthcare platform adds a timestamp to guarantee data immutability during data transactions, and user nodes access data through approved blockchains. Specifically, PoW consensus can accomplish entire decentralization in this design. All transaction records are imitated to all nodes over the blockchain [7] network.

Fig. 1. General functions of public health center.

In Fig. 1, an operative scenario of the public health center exhibits how to conduct secure data transactions in the blockchain-enabled health center system. Authorized health practitioners and consultants can access public health centers and provide necessary health advice using health data. This system will ensure security, scalability, privacy, and integrity while storing and making health records accessible through blockchain technology [8]. Blockchain executes computational tasks and data mining through smart contracts on the chain

*Corresponding Authors.

using the consensus algorithm. All instructions, block size, and block confirmation precisely restrains the space resources available and time for the smart contract. Each node collects public health records and performs data transactions sequentially. The verifiable data is stored in the chain of systems that support privacy-preserving, including high performance. In this way, health records can be stored on the blockchain by a medical practitioner or user, improving the interoperability issues of current health record systems. With this blockchain-based framework, health records can be protected from malicious misuse and tampering. Hence, the applicability of health data and various use cases, blockchain can produce tamper-proof records while maintaining data privacy.

The key contributions of this study can be synopsised as follows:

- This paper provides a health center data repository and sharing system based on blockchain technology.
- This paper equips a system workflow to develop the proposed system and provides sequence diagram.
- This paper designs an evaluation measurement setting and demonstrates the performance of the proposed system.

The leftover of this study is as follows. In Section II, this study introduces the related work. Section III discusses the entire proposed model with design. In Section IV, this paper confers the results and discussion of the experimental appraisal of the proposed model. Lastly, Section V concludes the presented work with the conclusion of this paper.

II. EXISTING RELATED WORK

This segment briefly discusses the current studies related to the present work. This paper here surveys existing blockchain-based safe data storage and secure record-sharing issues. Typically, in healthcare resources, traditional systems suffer from some complications when storing and exchanging data to securely integrate interconnected networks. A lot of scholars have suggested various approaches to health record information sharing where in some cases, access control, secure storage, confidentiality, scalability, and integrity of information have not been considered or are deficient.

Through its decentralized standards in the healthcare sector, blockchain can accurately formulate medical functionality to monitor primary clinical data of human life, share secure patient data, and protect data storage [9]. Yang and Li [10] suggested a blockchain-based EHR construction. This construction controls the misuse and tampering of Electronic Health Records by pursuing entire circumstances in the blockchain network. Bowman et al. [11] demonstrated an approach called Private Data Object (PDO) that facilitates reciprocally unreliable groups to conduct intelligent contracts on personal information employing Intel SGX. PDO uses the interpreter enclave, and it executes an intelligent agreement composed in the structure. Cheng et al. [12] presented a system named Ekiden that incorporates secrecy-preserving contracts into a blockchain-enabled Trusted Execution Environment (TEE) as a common framework. By exploiting a Proof-of-Publication protocol, Ekiden can sustain blockchain designs, including indecisive consensus that depends on authorized timers. In this

case, such a system may add certain runtime overhead, induce security concerns and indicate an outsized attack surface.

Kushch et al. [13] introduced a particular data structure as a blockchain tree for reserving health records in the blockchain. The blockchain tree is designed by one or additional patient identity records and a sub-chain. As the primary blocks of the sub-chain, this sub-chain holds more critical facts and blocks. Tanzila Saba et al. [14] proposed a protected and energy-efficient Internet of Medical Things (IoMT) framework for e-healthcare over a wireless body area network in clinics. Through this, necessary actions can be taken by tracing the health of remote patients and required monitoring of the data. Moreover, sensitive health records are likely to be disclosed due to biased energy-efficient data transfer and limited sensor capabilities. Ashutosh Sharma et al. [15] described a blockchain-based IoMT scheme with smart contracts for e-healthcare management, which is based on the preset code short script that will enrich agreement execution and eliminate intermediaries for delivering trust, security, and certification among its stakeholders.

D'Arienzo et al. [16] and Yu et al. [17] discoursed the benchmarking scheme named BLOCKBENCH for assessing the execution of private blockchain on behalf of required information processing workloads. This technique works on energy-efficient persistent data security and fault-tolerant storage systems. Zhang et al. [18] introduced a scheme named OpTrak that concentrated extensively on employing blockchain to deal with the U.S. opioid concern. The intent of this system was to permit direct control of records in an access control method for the prescription database to prevent overprescription. Fan et al. [19] offered a secure radio frequency identification (RFID) system based on a lightweight cloud authentication framework for IoT-based ecosystems. The system is constructed to perform at less computational power. Liu et al. [20] introduced a cloud-based scheme called CloudDTH constructed on digital twin medical care prescriptions. The scheme is developed to encourage the convergence and interaction of the digital twin in the medical sector based on various clinical procedures.

According to the aforementioned context, research in this sector has some general and authentication process problems which ignore resource-controlled transactions and the performance of health tasks. This paper offers possible solutions to maintain secure transactions and healthy data integrity. The proposed architecture can deliver optimal transaction times and low latency for different user nodes.

III. MATERIALS AND METHODS

This section presents a proposed determination based on blockchain technology to overcome the current complexity of storing sensitive records of public health centers, especially guaranteeing a safe healthcare process. It illustrates the coordination process of healthcare activities, sequence diagrams, and block-generated flow results.

A. Public Health Center Modeling using Blockchain

In this portion, this paper mainly presents a framework to enhance system performance for health centers to support the privacy, integrity, verifiability, and security of authorized health records, and it also introduces the workflow of the scheme.

Fig. 2 depicts a secure storage architecture for the health center using blockchain. The functions and methods used in a health center data security storage scheme based on blockchain and access control are expressed here. Constructing such a new blockchain-based secure data cloud architecture for any health center can meet the goals of executing high-performance, privacy, and integrity authorization frameworks. The security and scalability of health information in this model can produce satisfaction and rightfulness of data services among any clinic's stakeholders. This system will build stakeholders' confidence in the need to use blockchain-based secure and professional services in this sector. The key design concept and functions of this platform are based on the health data user or consultant, health center controller, and secure data repository.

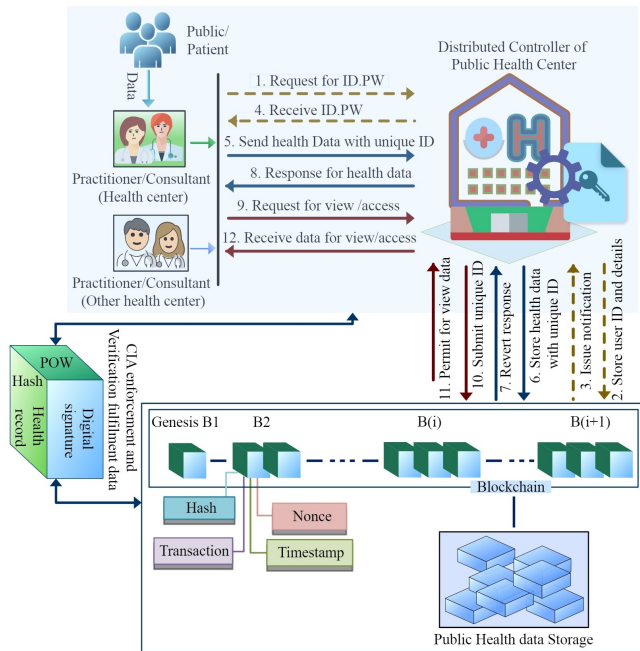

Fig. 2. Blockchain-based public health center model.

The functionality of the data user or consultant of the blockchain-based health center model is operated by the health center controller. The respective users or consultants perform the health care functions existing on this platform as data privacy-keepers. In this scheme, only relevant users or consultants can individually access health data and create or update health data smart contracts on the blockchain. Health data users or consultants collect all health information from patients or individuals under treatment and record it in the blockchain by generating public keys. Consultants can generate a set of private keys for each patient or individual's unique health record.

In this scheme, the health center controller initially allows respective health data users or consultants to generate their own unique identity to register. Then for registration at a health center, the controller issues a unique digital ID with a password individually to users or consultants through this framework. In this case, the Bcrypt algorithm is used to create the digital identity of users or consultants. All this information is stored in data storage. Then, registered authorized health

information users or consultants can access the blockchain network using their unique digital keys. In this case, verification and authentication processes must be followed to access the blockchain network. This framework can create a unique data identity for each patient or individual's unique health record. In a blockchain-based secure framework, accessing data from the database, such as adding, viewing, or sharing data, must communicate with the blockchain to ensure system confidentiality, security, and availability.

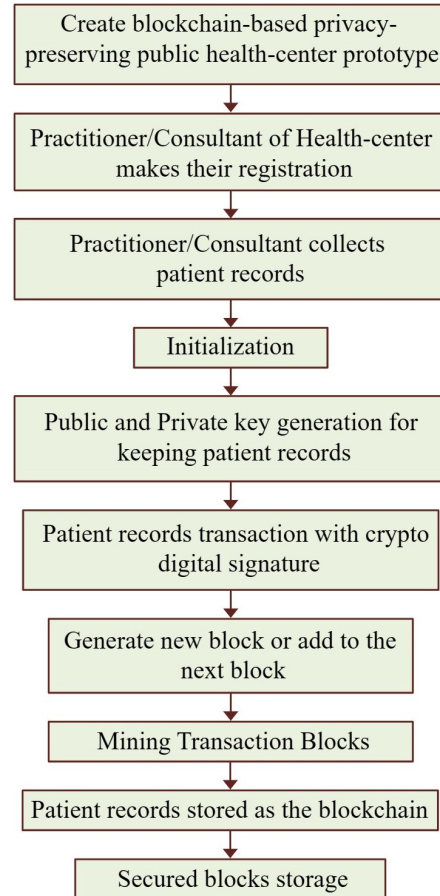

Fig. 3. Workflow for blockchain-based public health center system.

The blockchain network ensures the preservation, accuracy, and security of health records in the storage system through trusted and authorized user or consultant nodes. In this platform, health data is uploaded to the blockchain for immutable storage based on transaction signatures. Entire data is cross-referenced by generating the SHA-256 hash to securely store health data under integrity and confidentiality. PoW consensus policy is executed to conduct the full decentralization of health data in this blockchain network. Sequencing of each SHA256 hash inspects and verifies any tampering of transaction data by hash, nonce, timestamp, and encoding value. Transaction block history is effectively verified by miners. Otherwise, the data chain will logically be declared invalid if any kind of interruption is encountered.

The process of transmitting and receiving records is mentioned in public health center model. Users or consultants need to provide valid Identity (ID) and Password (PW) to access

the scheme of the health center. Through authentication, they can request the controller of the health center to access the blockchain storage. In this case, they can send encrypted health data to storage for accumulating purposes. If necessary, they can receive data from blockchain storage. When encrypted health data is stored in the block, a unique data identity (DID) will be generated for each patient or person under treatment. The controller supports storing or retrieving patient data in the database through DID. The workflow of the proposed system based on the blockchain technique is presented in Fig. 3. Each process and operation of building the approved blockchain-based health center model is manipulated. Based on this workflow, various functional interactions and functions of the user or consultant are programmed with the blockchain.

B. Coordination Process

As indicated by the proposed model, the distributed controller of the public health centers allows medical practitioners or consultants to access health data on the blockchain. It comprises practitioners or consultants as the user, distributed controller as the registration process and access task, and a blockchain ledger. Here the blockchain governs the highly distributed ledger to store various information about the health of the public or patients and to conduct timely transactions, to which only authorized participants to have access or permission. Participating network nodes are engaged in inputting, storing, viewing, and verifying different health data. The sequence diagram of the proposed model for user activities is illustrated in Fig. 4. This sequence diagram is designed to show the sequence of activities of the proposed model. The performing operations of this framework are briefly introduced as follows.

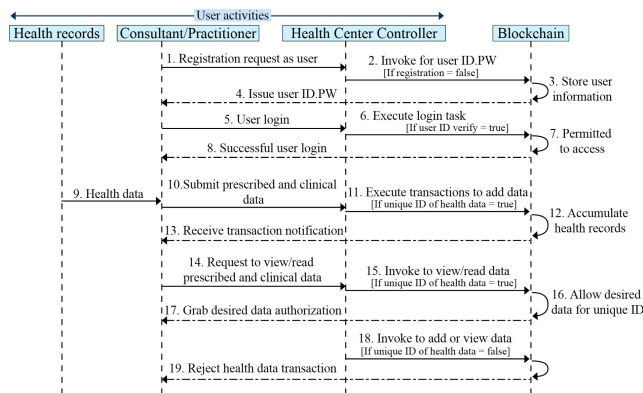

Fig. 4. Sequence diagram of user activities for blockchain-based public health center.

Step1: In this case, each medical practitioner or consultant sends a request for registration to the public health center controller with all their information. The health center controller receives all the information and verifies whether the doctors or consultants have already registered in the system. After verification, it takes the registration decision and invokes storing all user information in the blockchain. After storing the information of the doctors or consultants, the blockchain user login credentials and issues them a unique identity with a password through the distributed controller for login. Consultants

can successfully login into the system at any time through verification and get data access.

Step2: After login, each medical practitioners or consultant collects information from the public or patients and submits the prescribed and clinical data to the health center controller. The health center controller calls for creating unique identities of individual health information in the context of public or patient health information received from consultants. Blockchain produces and accumulates unique identities with hash-based values of individual health records. Only those consultants or doctors who have been permitted access rights to this blockchain platform can add or transact patient medical records. After publishing the health record in the blockchain, participants receive the confirmation notification of the data transaction.

Step3: Each medical doctor or consultant can interact with the blockchain through the health center controller to at look public health records. If each medical doctor or consultant wishes to view and read the prior health data from the blockchain, first, they need to login into the system using their unique identity with a password through the distributed controller. In this case, they must have unique identities of individual health information of their prescribed people or patient. Then, they use the unique identities of patients to request access to the public health center’s controller to view prior prescribing and clinical data. The health center controller receives their requests and verifies whether the unique identities of patients are already generated in the system. After verification, it allows to visit and read the pre-prescribed health information of the unique identity of those people from the blockchain. Finally, medical doctors or consultants get the opportunity and authorization to view and read the prior prescribed health information. The medical doctor can monitor the current health data along with the previous health information of the prescribed patient to make new prescriptions and add them to the data block of the system. But in this case, the blockchain system will reject the transaction to view the health data if it is found to be incorrect/false while verifying the unique identity of the patients collected by the doctors or consultants.

The various activities that take place between different actors for health data processing within the proposed platform, authorize combining blockchain technology with public health data. The sequence diagram norms of blockchain transaction process are depicted in Fig. 5. The sequence diagram of blockchain transaction process consists of medical practitioners or consultants, security enforcement and blockchain process. Medical doctors or consultants collect public or patient health records and interact with the blockchain to complete the transaction. Separate public key and private key pairs are generated by employing key generation algorithms to able health data processing within the proposed platform. This system randomly generates these keys.

The blockchain process includes hashing and signing algorithms to enforce robust security on health data. When a medical practitioner or consultant shares a patient’s health records with another, no assets are actually being sent to anyone. In this case, instead of sending data, the customer has to announce new data allocation by reallocating an amount of data to the blockchain. To reassign data, each data transaction

Fig. 5. Sequence diagram of blockchain transaction process.

must be signed by the sender's private key and verifiable using the sender's public key. Hash-256 function is used for data processing operations in this network. It retrieves health data by making a unique hash value while accessing health records through URLs in the web system.

Fig. 6. Consequence of block generated flow.

In addition, it allows user nodes to process health data within the platform to sign their transactions with private keys, and it can assure the integrity of stored data through verification to make secure share between the participants. As a PoW consensus algorithm, nodes select miners for the next block generation of the system and ensure continuity by synchronizing data. Due to the presence of this consensus procedure, the blockchain network achieves block record verification and reliability and establishes trust during data distribution. The consequence of block generated flow for data transactions on the blockchain after the mining process in this system are shown in Fig. 6. In this case, implementing RSA and SHA-256 in the system ensures the health data confidentiality of the blockchain storage and protects the published records. It also

delivers timely data to the blockchain repository and ensures maximum availability.

In the proposed model, it shows the process of generating the cryptographic hash SHA-256 associated with the data structure of the blockchain, which is an explicit means of enforcing data integrity. Blockchain's data structure forms a hierarchical set of blocks for secure access where the current block accumulates values such as hash, block transaction, timestamp, nonce, blockchain address, and so on. The blockchain's header holds the block number, and then the previous block's hash value provides the reliability of the transaction data chain. In this case, the block body can incorporate one or more transactions of health data.

Algorithm 1 Generate transaction key-pair

```

1: if health data user start transaction then
2:   procedure set(transactionKeyGenerate)
3:   RNG ← generate random(cryptographic value)
4:   Kpr ← generate(RSA(1024, RNG))
5:   Kpb ← Kpr · Kpb(i)
6:   decode in PEM, ascii (Kpr, Kpb)
7:   get Kpr, Kpb
8: else
9:   do nothing
10: end if
11: end procedure

```

The asymmetric cryptographic algorithm RSA PKCS is operated for digital signatures and transactional matters from a provable security perspective with the aim of establishing trust between users and cloud servers. Also, digital signature verifiability is checked using the Elliptic Curve Digital Signature Algorithm (ECDSA) from both the user side and server side for data security. Failing this verification on tampering and altered data values will automatically discard the adversary message. Due to two-party verifiability, the selected transaction is unable to forge signatures on the data and will not be authenticated as a legitimate user. The process facts of the generated transaction signatures relative to the user nodes are shown in the sequence diagram of the blockchain transaction process mentioned.

Algorithm 2 Digital signature generation for health data transaction

```

1: procedure signature(transaction)
2: if health data user Uh requests transaction T over BC then
3:   T ← makes T exclude sender's Kpr
4:   Kpr ← create RSA.key(sender's Kpr)
5:   Tsigner ← create crypto-sign.new(Kpr)
6:   H ← compute hash.encode(standard value)
7:   return Tsigner.sign(H).decode(ascii)
8: else
9:   not creating signature for T
10: end if
11: end procedure

```

When health practitioners and consultants desire to initiate public health data transactions in this platform, a key pair as a public key (K_{pb}) and a private key (K_{pr}) is generated, which is illustrated in Algorithm 1. Accordingly, the RSA technique is

utilized for public health data encryption or data decryption, and the PEM method is mapped with ASCII to decode the transactions. The process of digital signature generation during health data transactions is shown in Algorithm 2, which will ensure confidentiality while accessing data on the network.

Algorithm 3 Creating and Adding a new block for hash-based health data transactions

```
1: procedure createNewBlock(health data)
2: Initialize health transaction (empty set)
3: set in  $block \leftarrow (block_n, healthtransaction, nonce, timestamp, prehash)$ ;
4: if  $block_n \leftarrow len(chain) + 1$  then
5:   append the  $block$  for a new health transaction in  $chain$ ;
6:   re-set regarding the running  $transaction$ ;
7:   add health  $blocks$  to  $chain$ ;
8: end if
9: if  $block_s \leftarrow json.block.encode(standard\ value)$  as a file then
10:   $hash256 \leftarrow hash.new(SHA256)$ 
11:  update  $hash256.block_s$ 
12:  return encoded  $hash256$  in hexadecimal
13: else
14:  do nothing;
15: end if
16: end procedure
```

Algorithm 4 Append node to health blockchain network

```
1: procedure registration request(node)
2: if health data user request for a node then
3:   create a registration node
4: end if
5: Initialize parameters: ( $healthtransaction, chain, nodes, genesis_{block}$ )
6:  $urlNodeparse \leftarrow parse.urlNode$ 
7: if sets  $urlNodeparse.Netloc$  and  $urlNodeparse.path$ . then
8:   add  $urlNodeparse.Netloc$  and  $urlNodeparse.path$  to  $nodes$ ;
9:   append a new node to  $nodes$ ;
10: else
11:   not make to append;
12: end if
13: end procedure
```

The process of creating and adding a new block for hash-based health data transactions is exhibited in Algorithm 3. Here, block data transaction contains blockn, health transaction data, nonce, timestamp, and hash value which are important to ensure the integrity and immutability of public health records. In the blockchain-based public health center network, the process of adding the new node is introduced in Algorithm 4. This framework allows new nodes to be added to ensure transactions in a distributed or decentralized network. The procedure of accumulating and accessing public health-center data over the blockchain is ascertained in Algorithm 5. In this case, the digital signature process in the transactional health data is employed and verified by defining the PKCS1 standard based on the RSA technique. The Proof of Work method is performed to accomplish the valid proof conditions of mining requirements, and the health transaction records are validated

to share or access from one network node to another network node. The consensus Proof of Work process in the blockchain-based public health center system network will automatically adjust the number of new participating nodes and maintain the scalability of the network by speeding up the data transaction process. Finally, this model publishes the transactional data blocks of public health centers on the healthcare blockchain ledger.

Algorithm 5 Accumulating and accessing public health-center data over blockchain

```
1: procedure accumulating and publishing
2: Initialize transaction parameters for health data
3: generate health transaction block
4: verify digital transaction signature
5:  $K_{pb} \leftarrow RSA.sender's\ K_{pb}$ 
6:  $signverifier \leftarrow PKCS1.new(K_{pb})$ 
7:  $hash = SHA.new(health\ transaction.encode(utf8))$ 
8: verify( $hash$ , hex transaction Signature)
9: perform proof-of-work method
10: accomplish mining valid proof conditions
11: synchronise blockchain's nodes
12: check the health transaction blockchain is valid
13: transmit health data to transaction chain array
14: if verify transaction signature then
15:   transaction or share from one node to another node
16:   access health data
17: end if
18: end procedure
```

IV. RESULTS AND DISCUSSIONS

In this segment, this paper evaluates the performance of the presented secure storage management system with respect to user nodes for health centers using blockchain. The performance evaluation of this framework supports achieving the safety goals of the scheme. Experimental arrangement and qualitative analysis of this framework have been carried out to achieve data privacy and security objectives. It has been set a procedure evaluation environment to assemble the system demonstration and investigation using an Intel(R) Pentium(R) N5000 laptop (CPU -1.10GHz), x64-based processor, Windows 10, 4 GB RAM, 64-bit operating system. In the evaluation method, data access user or consultant node and blockchain node are embedded to investigate the underlying operations of the health scheme. To design the proposed model, it has been employed Python 3.9.0 (64-bit), Flask 1.1.1, and DevTools, including the web server gateway interface.

In order to evaluate and exhibit the health center's performance, multiple user or consultant nodes communicate with the blockchain server in this architecture. In this case, the average transaction time in milliseconds (ms) and latency in ms are evaluated for several data transactions on the blockchain by user nodes. In this case, the performance of each node is recorded by performing different data transmissions of this proposed system. In this scheme, it has been set nodes 1 to 5 to execute transactions. User nodes mine all transmitted blocks containing 1, 5, 10, and 15 transactions (T1, T5, T10, and T15) and propagate them to the blockchain-based public health center system. The specific results of the average transaction

Fig. 7. Average transaction time for different user nodes.

time for different user nodes are shown in Fig. 7. As this test demonstration, by user or consultant node1, the health center scheme reaches 36.31 ms for T1 and 82.7 ms for T15. Again accordingly, by user node 5, the health center scheme reaches 81.11 ms for T1 and gradually reaches a maximum of 275.76 ms for T15. The corresponding average transaction time across network nodes is expected in this system for different block transactions.

Fig. 8. Latency for different number of user nodes.

Next, it has been measured various transaction-based latencies across the setup nodes in this scheme. For this scheme, the precise consequences of latency for the different numbers of user nodes are shown in Fig. 8. As the work demonstration, it measures the latency of 16.42 ms through the user or consultant node1 for T1 to transmit and receive data block to the blockchain server. It also measures a latency of 26.21 ms for T15 using node 1. Moreover, for a capacity of user node5, the system observes a latency of 25.18 ms for T1 and a maximum latency of 43.35 ms for T15.

Finally, the overall performance induced by this scheme is analyzed by comparing the latency of several nodes. In this case, it sends and receives a data block for 10 transactions to each node in the blockchain server. It measures system latency under different nodes as a benchmark performance. The observation analysis of Latency per client node for publishing transactions between the native blockchain [21] and the proposed work is shown in Fig. 9. According to the exposition of this analysis, the latency of the proposed system compared

to the native blockchain is 23.7 ms for node 1. Accordingly, the latency of the proposed system is found to be 48.7 ms compared to the native blockchain for node 8. It can be observed that the proposed system exhibits the most promising consequences in terms of latency than the native blockchain. Therefore, it exposes relatively good scalability in health center data transactions.

Fig. 9. Comparative analysis of latency per client node for publishing transaction.

This paper exhibits the functionalities comparison of the presented scheme with some other existing works on blockchain-based data storage in Table 1. For this comparison, by using available (✓) and not available (×), This paper includes some different technical functionalities such as availability (A), Confidentiality (C), Integrity (I), server-side verifiability (SSV), and user-side verifiability (USV). However, most relevant schemes lack many other significant technical features that are not committed to securely storing health data. The comparison consequences exhibit that the mentioned structure accomplishes better than the recent systems and hence can afford an optimistic determination for enhancing existing health data storage applications.

V. CONCLUSION

Encouraged by the demand for health center digitalization, this paper designed a secure storage system for data management by deploying a privacy-preserving and performance-enhanced blockchain. In this study, a trusted access control strategy based on blockchain is designed to control user access to confirm secure and efficient health record sharing. The proposed system specifies functional units and follows a systematic process for blockchain-enabled decentralized data

repository and record sharing. This scheme may allow consultants or users to store data more securely than conventional schemes, particularly by ensuring confidentiality, availability, scalability, and integrity. Then, this work has exhibited the performance evaluation of the system by measuring the publishing transaction time cost and its latency on the blockchain employing different user nodes. Compared to traditional schemes, the presented framework can be a reliable and promising determinant in the health center industry towards efficient and secure management of health records. It may consume a significant amount of energy during data transactions and storage in the system, which is enough to raise environmental concerns and can be considered a system limitation. In future work, this work will extend and study this scheme toward auditing the metadata of the cloud storage.

National School of Applied Sciences, Ibn Zohr University, Agadir 80000, Morocco

Abstract—Monitoring a driver’s heart rate is an important determinant to his health condition. The monitoring system must be accurate and non restrictive to the user’s actions. Estimating the driver’s change in his usual heart beat pattern can prevent undesirable outcomes. Several methods exist to estimate heart rate without any contact. In this paper, we are focusing on a method that uses remote photoplethysmography (rPPG). rPPG is a technique where heart rate is extracted from a PPG signal. The signal is extracted from the changes in blood flow that corresponds to the color variations recorded through an RGB camera. In this work, a different study that was based on an existing algorithm is presented to determine its processing time. The algorithm we proposed was divided into different global blocks and each block into different functional blocks (FBs). Though evaluating all the blocks’ processing time, it was possible to determine the most time consuming functional blocks. The results are implemented on different architectures: Desktop, Odroid XU4 and Jetson Nano to provide a higher performance.

Keywords—Heart rate; driver; photoplethysmography; non-contact; embedded architectures

I. INTRODUCTION

Monitoring Vital signs can be life saving. When it comes to driving, it could save the driver’s life as well as anyone who could be affected by a potential accident. People suffering from cardiovascular diseases (CVD), like cardiomyopathy or coronary heart disease (CHD), can become a danger to themselves and any passerby. A rapid heart rate and palpitations can also be caused by a low blood sugar. It can indicate a hypoglycemia for example. Therefore, heart rate is an indicator of several health conditions as it is the first response of the body to a threat. According to the world health organization, an estimated of 17.9 million people died from CVDs in 2019, representing 32% of all global deaths. Heart attacks and strokes were responsible for 85% of these deaths [1]. The death of a driver due to a disease attack is a reasonably common cause of death on the road [2]. As reported by the Center for Disease Control and Prevention (CDC), 1.35 million people are killed every year on the road around the world. Injuries on the road is the eight leading cause of death globally [3]. Therefore, a continuous heart rate monitoring in this context is of great importance as it can save lives.

Measuring heart rate usually requires an ECG that records the electrical heart activity caused by the repolarization and depolarization of the muscle [4], [5]. Different methods exist to estimate heart rate in vehicles. They can be divided into five types depending on what kind of system is used. There is the heart rate monitor integrated into the steering wheel, the seat, the rear-view mirror or the seat-belt or a heart rate monitor

using a camera. As an example, J. Priya et al. 2020 used a pulse sensor, GPS and GSM modules are combined to the steering wheel to assess the driver’s pulse rate in real time [6]. Using also a steering wheel, Arakawa et al. 2018 developed a system that measures heart rate through a transmitter and a red LED as a receiver [7]. S. Mitani 2018 developed an in-vehicle pulse sensor using the microwave sensor where the sensor is in the driver’s seat [8]. Texas instruments developed in 2019 the AWR1642 sensor placed on the rear-view mirror that estimates the heart rate of all the passengers [9]. There are also devices situated in the seat-belt as in the HARKEN concept [10]. Another method is to extract heart rate from the changes of hemoglobin concentration on the surface of the face captured by an RGB camera [11]. Y. lee et al. 2018 used Impulse-Radio Ultra-Wideband (IR-UWB) Radar Technology to monitor vital signs [12]. W. Lv et al. 2021 also used radar technology. They used a frequency-modulated continuous-wave (FMCW) Millimeter Wave Radar in the 120 GHz band [13].

In our work, we propose an algorithm that estimates heart rate through an RGB camera. It is divided into four parts. The first part focuses on the face detection and the forehead extraction. We used the box blurring filter, the edge sobel edge detection technique and morphological operations for face detection and the extraction of the region of interest. The second part extracts the raw signal by calculating the average of each of the channels (red, green and blue). The third part uses only the green channel of the image to estimate the final signal. The result is obtained by normalizing and denoising the signal and also using a detrending filter and a moving average filter. Finally, the fourth part calculates the heart rate based on a frequency analysis. The three latter parts were based on the work of P. rouast et al. 2016 [14]. The summary of our contribution is as follows:

- The proposition of a new algorithm for face detection and forehead extraction.
- The examination of the temporal constraints based on a Hardware/Software Co-Design approach.
- The evaluation of the algorithm on different embedded architectures.

The algorithm based on C/C++ was validated then was accelerated using OpenMP, MPI and CUDA. We chose a hybrid implementation of OpenMP or MPI and CUDA due to the requirements of the algorithm. CUDA uses NVIDIA’s Graphics Processing Unit (GPU) to achieve a higher performance time-wise. Using parallel programming gives better results than the naive implementation. We first tested the algorithm on a desktop, but the desktop is not adequate to monitor heart

rate when driving because of its size and power consumption. Therefore, we tried implementing the algorithm on embedded architectures such as Odroid XU4 and Jetson Nano.

This paper is structured as follows: Section I describes the recent works on contactless heart rate monitoring. Section II describes our methodology. Then, Section III highlights the results obtained by implementing the algorithm on different architectures. Finally, a conclusion summarizes this work and gives some future perspectives.

II. RELATED WORK

Various studies were made to estimate heart rate from an RGB camera. It was possible to monitor heart rate by monitoring the variation of the RGB colors of an image induced by the changes of blood flow in the capillaries. The signal extracted from those variations is known as a photoplethysmography (PPG) signal. The human skin is illuminated with a light source and a camera captures the variations of color [15]. The skin's RGB values change with time and are estimated through the reflection of the light [16]. There are two types of reflection: specular and diffuse as shown in Fig. 1. The reflection of a skin pixel is defined in Eq. 1 [16].

$$C_k(t) = I(t) \cdot (v_s(t) + v_d(t) + v_n(t)) \quad (1)$$

Where k is the k th pixel, $I(t)$ is the luminance intensity, $v_s(t)$ is the specular reflection that occurs on the surface, $v_d(t)$ is the diffuse reflection on the blood vessels and $v_n(t)$ is the noise.

The specular reflection is a mirror-like reflection and does not contain information of the pulse. It can be expressed in Eq. 2 [16].

$$v_s(t) = u_s \cdot (s_0 + s(t)) \quad (2)$$

Where u_s is the unit color vector of the light spectrum and s_0 and $s(t)$ are the stationary and changing parts of the specular reflection.

The diffuse reflection is related to the absorption of the light. It is defined in Eq. 3 [16].

$$v_d(t) = u_d \cdot d_0 + u_p \cdot p(t) \quad (3)$$

Where u_d is the unit color vector of the skin, d_0 is the stationary reflection, u_p is the relative strength of the pulse in the channels and $p(t)$ is the signal.

Fig. 1. Reflection of the light on the skin [16].

Different methods were proposed to extract the PPG signal like the green spectrum method where the signal is extracted

from the G channel only [17], the Blind source Separation-based (BSS) methods that uses all three channels [18], the CHROM technique that is chrominance-based [19], the Plane-Orthogonal-To-Skin (POS) that defines an orthogonal plane to a normalized skin [16] and the Spatial Subspace Rotation (2SR or SSR) that measures the rotation of the spatial subspace of the pixels [20].

H. Rahman et al. 2016 used an RGB camera to monitor heart rate [21]. They used an Independent Component Analysis (ICA) to extract the PPG signal and the Fast Fourier Transform to convert the signal to the frequency domain. M. A. Hassan et al. 2016 also used an RGB camera using only the green spectrum [22]. V. Jeanne et al. 2013 used an infrared camera instead of a regular RGB camera that requires certain light conditions [23]. Other methods for non-contact heart rate monitoring include radar systems. K. J. Lee et al. 2016 used continuous-wave Doppler Radar to estimation a driver's heart rate. The radar is installed in the seat. The emitted signal gets reflected and contains information about the heart activity. The spectral peak of the reflected signal represents the value of the heart rate. Instead of using a Fast Fourier Transform (FFT), they proposed a method using multiple signal classification (MUSIC) because the contamination of the signal caused by movement of the driver and the vehicle [24]. H. Xu et al. 2021 also used radar technology to estimate heart rate. They used an ultra-wideband (UWB) radar with a mean absolute error (MAE) of 1.32 [25].

This work focuses on the algorithm proposed by P. Rouast et al. 2016 [14]. They used the green spectrum method. The face is detected using the Viola-Jones algorithm as the first method and a deep neural network (dnn) as the second method. Then, it is captured by a camera in order to determine facial landmarks. After that, the forehead, where most of the blood vessels are concentrated, is selected as the region of interest. The average of each pixel color (Red, Green, Blue) of the region is measured over time to extract the PPG signal. Afterwards, the signal is filtered and its peaks are detected to estimate the heart rate. However, the processing time of their work is significant and needs improving. Furthermore, the face detection part is the most time consuming.

III. METHODOLOGY

Estimating heart rate is defined in this paper as a four steps methodology: face detection, raw signal extraction, signal filtering and heart rate estimation. Each step represents a block and every block is going to be divided into different functional blocks (FBs).

A. Face Detection

In this work, heart rate is being extracted from the face. The face is the most visible part on the body when a person is captured by a camera. And since the forehead is a surface that has a visible subcutaneous vascular structure, the forehead is the region of interest. Therefore, face detection is an important phase of the algorithm. Different methods exists to detect and track the face. The most used in contactless monitoring are machine learning based methods. They are capable of recognizing facial features through comparing them with an existing database. The main issue with these kind of methods

is that they are time-consuming. Consequently, we propose a different approach for face detection.

1) *Original approach:* The original algorithm on which this work was based used the Viola-Jones algorithm to detect the face. It's a haar classifier that is trained to detect faces. The OpenCV cascade classifier was used. Once the face is detected, the region of interest (ROI), known as the forehead, is selected. The algorithm can track faces and that means that it works when there is movement but it takes an important amount of time to be executed, approximately 1s. The Haar cascade uses Haar-like features represented by rectangles. Each rectangle is used to detect a region of the face [26]. These features help identifying where pixel intensity suddenly changes. The darker areas have a pixel value of 1 and the lighter areas have a pixel value of 0. When the difference of the sum of the first area's pixels and the sum of the second area's pixels is close to 1, then an edge was detected.

2) *First method:* The problem encountered in the beginning of this work is that a trained haar classifier cannot be accelerated using parallel computing to reduce its processing time as it is an OpenCV function. The first approach to this problem was to use a sequence of images instead of a video. The processing time decreased but was still significant. The second approach was to use a sequence of images, but instead of detecting the face for each images the region of interest is defined manually. The face is static and so is the ROI. If the ROI's emplacement in the image is known, it can be extracted without going through a trained classifier. The processing time of the ROI extraction using this method was 0,02 ms instead of 1s with a haar classifier.

3) *Second method:* The second method was proposed because of how limited is the previous one is. Even if the processing time is significantly low, it is not practical to manually set the ROI each time. This method works through three steps: image preprocessing, face identification and forehead extraction.

Fig. 2 represents the ROI extraction algorithm. The algorithm that represents the first block is divided into different functional blocks. In the first functional block, the RGB image is converted to grayscale and a box blurring filter is applied in order to apply to sobel filter. In the second functional block, the resulting image is converted to a binary image to be able to detect the contours. Once the contours are detected, in the third functional block, inside the contours is filled in white and morphological operations are applied. After that, in the last functional block the new contours are found to determine the top extreme point that represents the top of the head.

a) *Preprocessing:* In this step, the colored image is turned into a gray scale image because the edge detection technique works with gray scale images only. Then, the image is blurred. Fig. 3 represents the original image and Fig. 4 represents the grayscale image.

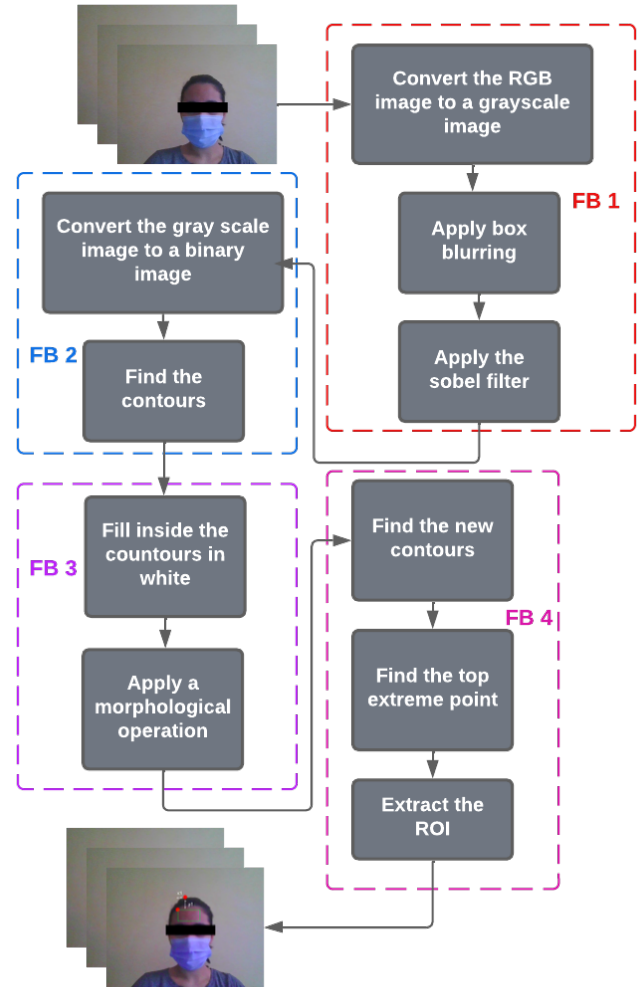

Fig. 2. ROI extraction (Block 1).

Fig. 3. Original image.

Fig. 4. Gray scale image.

Box blurring is a low-pass filter where an image's pixel has a value close to the average value of the pixels surrounding it. It allows the suppression of as much noise as possible. A 3x3 matrix K is applied on the image to blur it. The convolution technique is shown in Eq. 5. The center of matrix K corresponds in the image to the pixel's value that's going to change. The value is calculated by adding the product of each

neighboring value with the corresponding kernel's value.

$$K = \frac{1}{3 \times 3} \begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix} \quad (4)$$

$$B = A \oplus K \quad (5)$$

Where A is the input image and B is the blurred image. The blurred image is obtained using Eq. 6 [27].

$$B(i, j) = A(i, j) \oplus K(i, j) = \sum_{m=0}^2 \sum_{n=0}^2 A(2, 2) F(i - m, j - n) \quad (6)$$

Where $0 \leq i, m \leq 2$ and $0 \leq j, n \leq 2$

b) Face identification: In order to detect the face, the sobel filter is used to detect the edges of the face by calculating the gradient of the image. According to Himani et al. 2020, the sobel filter is more precise and time-efficient than the canny filter [28]. The filter highlights the edges. It uses two 3x3 matrix Sx and Sy also known as convolution kernels or masks.

$$Sx = \begin{bmatrix} -1 & 0 & +1 \\ -2 & 0 & +2 \\ -1 & 0 & +1 \end{bmatrix} \quad (7)$$

$$Sy = \begin{bmatrix} +1 & +2 & +1 \\ 0 & 0 & 0 \\ -1 & -2 & -1 \end{bmatrix} \quad (8)$$

Sx is the horizontal mask used for the changes in the horizontal direction and Sy is the vertical mask used for the changes in the vertical direction. Sy is a rotation of the second kernel Sx by 90°. The kernels are applied separately on the image to produce separate calculations of the gradient component in each orientation [29].

$$Gx = Sx \oplus A \quad (9)$$

$$Gy = Sy \oplus A \quad (10)$$

Where A is the input image.

The separate gradients are combined to produce one image using Eq. 11.

$$G = \sqrt{Gx^2 + Gy^2} \quad (11)$$

An approximation of the combined gradients is given by Eq. 12.

$$G = Gx + Gy \quad (12)$$

The edges obtained are shown in Fig. 5.

Fig. 5. Image filtered using sobel edge filter.

After using the sobel edge filter, a thresholding is applied on the filtered image. It converts the image from a gray scale one to a binary image. It's an OpenCV technique where a pixel's value becomes 0 if the initial value is smaller than the threshold, otherwise it becomes 255 which is the maximum value a pixel can have. It turns the edges completely white while the rest is black. This technique thickens the edges and make them more visible. Fig. 6 represents the image after using the thresholding technique.

Fig. 6. Image after using the thresholding technique.

Algorithm 1 describes how the sobel edge filter is performed.

Algorithm 1 Box blurring and sobel edge filter (FB1)

Input: Image

Output: Image after using the sobel filter

Function cvtcolor:

| GrayImage \leftarrow 0.299.R + 0.587.G + 0.114.B

Function blur:

| Create a 3x3 kernel

| Apply the kernel to the image

Create the horizontal mask Sx

Function filter2D:

| Compute correlation between Sx and the GrayImage

| Get Gx

Create the vertical mask Sy

Function filter2D:

| Compute correlation between Sy and the GrayImage

| Get Gy

G \leftarrow Gx + Gy

c) Forehead extraction: The first step to detect the forehead is to find the coordinates of the contours. They are found using the OpenCV function: findcontours. The function detects the sudden changes in the image's color. Once the change is detected, the coordinate are retrieved. The function implements an algorithm introduced in 1985 by S. Suzuki et al. [30].

When the contours are retrieved, it becomes possible to color the face in white with the OpenCV function fillpoly. Now, we want to delete the forms left on the background but also leave only the upper part of the face. For this purpose, a mathematical operation, known as an opening, is applied on the filled image to make the image more clear. The image contains small white filled forms that need to be removed, hence darkened. An opening is the process of applying erosion followed by dilatation on an image [31]. These two operations are achieved by using a 5x5 structuring element x on an image A as shown in the following formula.

$$B = (A \ominus x) \oplus x \quad (13)$$

Where the first operation represents the erosion and the second represents the dilatation.

The dilatation and erosion give a new binary image. In the dilatation, the pixel's value of image A is set to 1 when any of the neighboring pixels is equal to 1. Whereas in the erosion, the pixel's value of A is set to 0 when any of the neighboring pixels is equal to 0.

Now that only some parts of the image are left and the forehead is very visible, it is possible to detect the forehead by finding the top extreme point on the image which is the top of the head.

In order to find the coordinates of the top extreme point, we apply the OpenCV function findcontours. The use of this function for a second time gives us the new contour's values because the image have been modified. Then, a loop is used to compare between all the new coordinates of the contours to find the top point. Algorithm 2 describes these steps.

Algorithm 2 Finding the top extreme point (FB4).

```

Input: Image after using the opening operation
Output: The Top extreme point
Function findcontours:
| Retrieve the contours from the image
Create a point Top
for  $i = 0$  to  $Contours.size()$  do
| Create a point P
| Create a vector NewContours
|  $NewContours \leftarrow Contours[i]$ 
| for  $j = 0$  to  $NewContours.size()$  do
| | Create a point CurrentP
| |  $CurrentP \leftarrow NewContours[j]$ 
| | if  $y$  coordinate of  $CurrentP$  ;  $y$  coordinate of  $P$  then
| | |  $P \leftarrow CurrentP$ 
| | end
| end
|  $Top \leftarrow P$ 
end
    
```

The top extreme point is represented in red in Fig. 7. The last step is to subtract a value $x1$ to the x coordinate of the top point and add a value $y1$ to the y coordinate. It allows us to get an ROI that starts from these new coordinates a little below the top of the head where the forehead is situated. Fig. 8 represents this step.

Fig. 7. The Top extreme point on the original image

Fig. 8. Roi extraction.

B. Raw Signal Extraction

The raw signal is extracted from the image by using a function that calculates the average of each channel's pixels. An image contains 3 channels: red, green and blue. The average of each channel is added to the signal. And, for every frame, new values are added to it. At this stage, the signal represents the changes of the pixel's values from one frame to another. Fig. 9 represents the raw signal extraction algorithm.

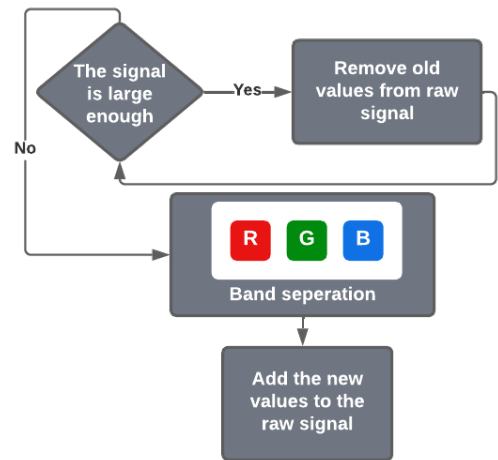

Fig. 9. Raw signal extraction (Block 2).

C. Signal Filtering

Different methods exist to obtain the final signal. After extracting the average of each channel, only the green channel is left. W. Verkruyssen et al. 2008 explained that the green channel contains the most information about a PPG signal. The main reason for that is the better absorption of green light than red and blue by hemoglobin [32]. Fig. 10 represents the signal filtering algorithm which represents the second block of the algorithm.

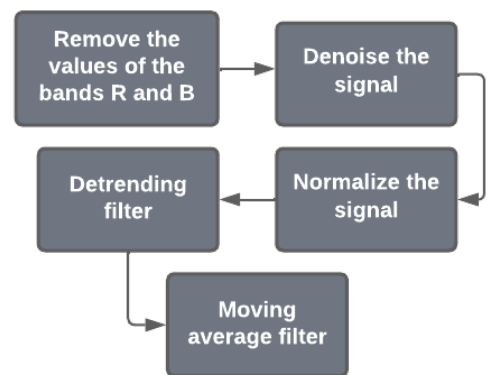

Fig. 10. Signal filtering (Block 3).

This block is executed only if the signal is large enough. There is enough data after exactly 35 frames. The block, represented in Fig. 11, contains four steps. First, a filter is used to remove unwanted spikes from the signal. Then, normalize the signal and apply a high pass and a low pass filter to cut off low and high frequencies corresponding to 0.7 and 3 Hz [33]. These frequencies are generally caused by noise and sudden light change. P. rouast et al. 2016 used detrending filter as an equivalent to the high pass filter and a moving average filter as an equivalent to the low pass filter.

D. Heart Rate Estimation

The HR is measured using a frequency analysis. This block remained the same as the original algorithm and is executed only if the signal is large enough. In this case, the discrete Fourier transform (DFT) is used. The heart rate is calculated with Eq. 14.

$$BPM = (MaxFr * fps * 60) / Size \quad (14)$$

Where:

MaxFr is the maximum frequency

fps is the number of frames per second

Size is the size of the signal

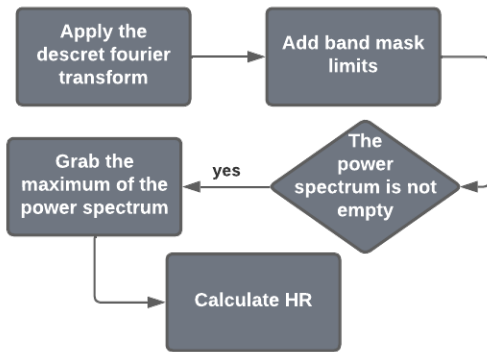

Fig. 11. Heart rate estimation (Block 4).

IV. HARDWARE AND SOFTWARE RESULTS

The algorithm was first validated using the C/C++ language. Then, in order to achieve better results in term of time consumption, we separated the algorithm into four blocks, each with a specific function. This step was essential to estimate the processing time of the blocks and to determine the blocks that consume the most. The first block is for face detection and forehead extraction, the second is for the raw signal extraction, the third is for signal filtering and finally the fourth block calculates the heart rate. In our case, the first block was the most consuming, hence its separation into four functional blocks. The second temporal evaluation on the algorithm revealed that the first functional block (FB1) takes most of the block's processing time.

A. System Specification

This work was implemented on an Intel i7-1165G7 desktop that has a NVIDIA GeForce MX330 GPU based on a Pascal architecture and that supports CUDA. It was also implemented on two different embedded architectures: Odroid XU4 and NVIDIA Jetson Nano. The Odroid XU4 has an exynos 5422 processor, an ARM A15 CPU with 2 Ghz and an ARM A7 with 1.4 Ghz. Finally, the NVIDIA Jetson Nano has an ARM A57 CPU with 1.43 Ghz and a Maxwell based GPU. Table I represents the systems' specifications.

TABLE I. SPECIFICATION OF THE SYSTEMS USED

Type	Desktop	Odroid XU4	Jetson Nano
Processor	11th Gen Intel Core™	Exynos 5422	Tegra SoC
CPU	Intel i7	ARM Cortex A15/A7	ARM A57
GPU	NVIDIA GeForce MX330	Advanced Mali	Nvidia Maxwell
Support language	C/MPI/OpenMP/Cuda/OpenCL	C/MPI/OpenMP/OpenCL	C/MPI/OpenMP/Cuda
Frequency	2.8GHz	2GHz/1.4GHz	1.43Ghz
Weight	1,78kg	60g	136G
Energy	90W	5W	10W

B. Sequential Implementation of the Algorithm

The algorithm was implemented on each of the different architectures based on the C/C++ language. It contains four blocks and the processing time of each block was calculated. Table II summarizes the time evaluation.

TABLE II. PROCESSING TIME OF EACH BLOCK

Blocks	Desktop	Odroid XU4	Jetson Nano
B1	50,41 ms	503,21 ms	16,56 ms
B2	0.51 ms	0.52 ms	0.033 ms
B3	0.86 ms	2.22 ms	0.1 ms
B4	0.52 ms	0.5 ms	0.07 ms
Total	52.3 ms	506.45 ms	17.39 ms

The time evaluation in Table II shows that the Jetson Nano consumes the less when compared to the other architectures with a global processing time of 16.76 ms. The desktop consumes 52.3 ms and the Odroid XU4 consumes 506.45 ms. Fig. 12 to 15 represent the processing time of block 1 to block 4 respectively on three different architectures. The Jetson Nano has a lower processing time for all blocks. Block 1 consumes the most for all architectures. For that reason, the functional blocks of Block 1 are going to be evaluated. Block 1 is about 50.41 ms for the desktop, 503.21 ms for the Odroid XU4 and 16.56 ms for the Jetson Nano. The next step is to evaluate

the processing time of the functional blocks of B1 and use OpenMP, MPI and CUDA in order to accelerate the global processing time of the algorithm.

Fig. 12. Processing Time of Block 1.

Fig. 13. Processing Time of Block 2.

Fig. 14. Processing Time of Block 3.

Fig. 15. Processing Time of Block 4.

C. OpenMP and MPI based Implementation

In this, we are going to use both OpenMP and MPI to accelerate the algorithm and determine which one gives better results. However, the main issue we encountered is the difficulty of accelerating the first block using directives. The reason for that is the fact that Block 1 contains mainly OpenCV functions, we couldn't reduce its processing time using OpenMP and MPI. OpenMP and MPI directives wouldn't be effective. On the contrary the processing time increased. Therefore, the implementation of the algorithm using OpenMP and MPI was done only on Blocks 2, 3 and 4. Table III represents the processing time of blocks 2, 3 and 4 with OpenMP and MPI.

The temporal evaluation in Fig. 16 represents the processing time of Block 2, Block 3 and Block 4 with C/C++, OpenMP and MPI implemented on the desktop. It shows better results with MPI as the time is significantly lower than with OpenMP and even more when compared with C/C++. MPI is 6.2 times faster than OpenMP for Block 2, 2.2 times faster for Block 3 and Block 4. Fig. 17 and 18 represent the comparison between the processing time of same blocks using C/C++, OpenMP and MPI but implemented on Odroid XU4 and Jetson Nano.

TABLE III. PROCESSING TIME OF EACH BLOCK WITH OPENMP AND MPI

Blocks	Desktop	Odroid XU4	Jetson Nano
OpenMP			
B2	0.42 ms	0.52 ms	0.03 ms
B3	0.28 ms	1.55 ms	0.092 ms
B4	0.27 ms	0.31 ms	0.067 ms
Total	1.24 ms	2.38 ms	0.19 ms
MPI			
B2	0.069 ms	0.59 ms	0.03 ms
B3	0.12 ms	2.037 ms	0.093 ms
B4	0.12 ms	0.34 ms	0.067 ms
Total	0.31 ms	2.97 ms	0.19 ms

For the Odroid XU4, the results show a nearly same processing time for Block 2. OpenMP was found to be 1.4 times faster for Block 3 and 1.6 times faster for Block 4. MPI was found to be 1.1 times faster for Block 3 and 1.4 times faster for Block 4. This concludes that OpenMP shows a better result than MPI on XU4 with an improvement in global processing time of all the blocks of x1.4 for OpenMP and x1.1 for MPI. In regards to the Jetson Nano, the results show the same results for OpenMP and MPI. However, MPI shows a better result on the desktop with an improvement in global processing time of x6 when OpenMP shows an improvement of x2.

Fig. 16. Improved processing time on desktop.

Fig. 17. Improved processing time on Odroid XU4.

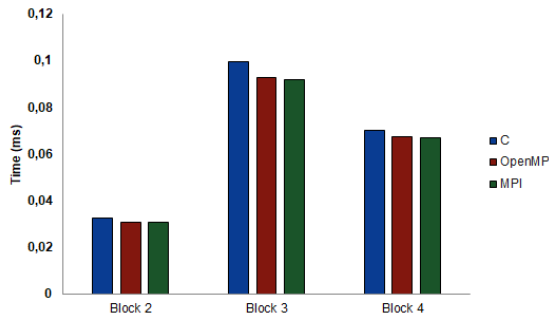

Fig. 18. Improved processing time on Jetson Nano.

D. Cuda based Implementation

In this part, we focused only on the first block. Block 1 was divided into five functional blocks (FBs) as previously shown in Fig. 2. Since we couldn't improve its processing time using OpenMP or MPI, we opted for CUDA to exploit the advantages of a GPU. Table IV represents the processing time of the four different functional blocks of Block 1 on the desktop and the Jetson Nano.

TABLE IV. PROCESSING TIME OF B1'S FUNCTIONAL BLOCKS

Blocks	Desktop	Jetson Nano
FB1	23,21 ms	7,56 ms
FB2	9,8 ms	2,47 ms
FB3	7,41 ms	5,23 ms
FB4	3,07 ms	1,18 ms

For both the desktop and the Jetson Nano, the first functional block is the most consuming. FB1 consumes a time of 23,21 ms for the desktop and 7,56 ms for the Jetson Nano. Consequently, FB1 will be accelerated using CUDA. Fig. 19 summarizes the processing times of the different functional blocks.

Fig. 19. Processing time of the different functional blocks of B1 in desktop and Jetson Nano.

FB1 contains three sub-blocks (SBs). The first one converts an image from RGB to grayscale, it takes an average of 5.12 ms for the desktop and 1.25 ms for the Jetson Nano. The second applies a blurring filter with an average of 3.6 ms for the desktop and 1 ms for the Jetson Nano. The last sub-block filters the image using a sobel filter and takes 14.49 ms for

the desktop and 5.3 ms for the Jetson Nano. We then opted to accelerate the first and the last sub-blocks as shown in Fig. 20 for both architectures.

Fig. 20. CPU-GPU implementation based on CUDA.

Fig. 21. Improved global processing time on desktop.

Fig. 21 shows the improved global processing of the algorithm on the desktop and Fig. 22 shows the improved global processing on the Jetson Nano. We obtained an average improved time 35.54 ms for the desktop, hence an overall improvement of x 1.5. For the Jetson Nano, we achieved an improved time of 12.7 ms which is 1.32 times faster. We

used a hybrid implementation of CUDA for the first block and OpenMP/MPI for the other three blocks.

Fig. 22. Improved global processing time on Jetson Nano.

V. CONCLUSION

In this paper, a non contact heart rate monitoring algorithm is proposed to measure the driver's heart rate. The algorithm was studied to be implemented on different architectures such as Odroid XU4 and Jetson Nano. The time evaluation of the C/C++ implementation showed better results on the Jetson Nano than the other architectures. We were able to exploit the advantages that presents a Nvidia GPU in CPU-GPU architectures by using CUDA. A hardware/software co-design approach was implemented and showed that the Jetson Nano remains the best choice. The sequential implementation consumes a lot of time. Hence, it is not real-time. For this reason, an acceleration of the algorithm was proposed. The acceleration is based on OpenMP, MPI and CUDA on the different architectures used. Future works consist of improving the face detection algorithm when there is movement and further accelerating the algorithm based on CUDA.

ACKNOWLEDGMENT

We owe a debt of gratitude to the National Center for Scientific and Technical Research of Morocco (CNRST) for their financial support (grant number: 27UIZ2022) and for the financial support of the project Cov/2020/109.

Abstract—Effective public health responses to unexpected epidemiological hazards or disasters need rapid and reliable monitoring. But, monitoring fast-changing situations and acquiring timely, accurate, and cross-national statistics to address short-term mortality fluctuations due to these hazards is very challenging. Estimating weekly excess deaths is the most solid and accurate way to measure the mortality burden caused by short-term risk factors. The Short-term Mortality Fluctuations (STMF) data series is one of the significant collections of the Human Mortality Database (HMD) that provides the weekly death counts and rates by age and sex of a country. Sometimes, the data collected from the sources are not always represented in specific age groups rather represented by the the total number of individual death records per week. However, the researchers reclassified their dataset based on the ranges of age and sex distributions of every country so that one can easily find out how many people died in per week of each country based on an equation and earlier distribution data. The paper focuses on the implementation of multi-output regression models such as logistic regression, decision tree, random forest, k nearest neighbors, lasso, support vector regressor, artificial neural network, and recurrent neural network to correctly predict death counts for specific age groups. According to the results, random forest delivered the highest performance with an R squared coefficient value of 0.9975, root mean square error of 43.2263, and mean absolute error of 16.4069.

Keywords—Multi-output regression model; short-term mortality fluctuations; machine learning; deep learning

I. INTRODUCTION

In the past few years, there have been many outbreaks of natural or man-made hazards which eventually turned into a pandemic situation. For instance, influenza outbreaks in 2014–15, 2016–17, and 2017–18, as well as the recent COVID-19 pandemic. These hazards induced significant increases in short-term mortality in several countries [1]. Accurate and statistical data is important to analyze the mortality rates and to provide an immediate response to short-term health concerns for reducing life loss. However, the recent COVID-19 pandemic pointed out the scarcity of reliable, accurate, and comparable international data required to track the spread of epidemics [2]. In May 2020, the Human Mortality Database (HMD, [3]) team released the Short-term Mortality Fluctuations (STMF) data series to meet the increasing need for such

data. The information on how many people died in a calendar year has been kept in this dataset on a weekly basis. However, the researchers built their dataset on age-specific deaths in each country so that one can find out how many children, youth, or adults die in each country per week. In many cases, researchers have already stated that they cannot get accurate data into different ranges of ages but they can get the total death number of a city, a country, or a state. To mitigate these problems, researchers normally use the below Eq. 1 for distributing the total number of deaths to age-specific numbers. They use the equation 1 and use the earlier distribution that they already deposited into the database. However, the observed or forecasted death counts from annual age-specific groups are then converted to standard age groups using the following formula:

$$\hat{M}_b^s(x, x+m) = M_b^s(x, x+n) * \frac{M_b(x, x+m)}{M_b(x, x+n)} \quad (1)$$

In the above equation, $M_b^s(x, x+n)$ indicates the number of death according to the original data in the interval of age $[x, x+n]$ in s week of year b and n is the age interval length of original data. On the other hand, $\hat{M}_b^s(x, x+m)$ indicates the predicted number of death in the interval of age $[x, x+m]$ in s week of b year and m is the age interval length of estimated data. $M_b(x, x+m)$ and $M_b(x, x+n)$ represents the number of death in the whole year b .

Similar to the age specific distributions, they have calculated the specific groups based on sex by using the annual data stated in the following Eq. 2 when the age-specific sex group data is unavailable.

$$\hat{M}_b^{s,males}(x, x+m) = M_b^{s,total}(x, x+m) * \frac{M_b^{males}(x, x+m)}{M_b^{total}(x, x+m)} \quad (2)$$

The death rate according to the age groups has been estimated using total number of death in s week of b year and total population $P_b(x, x+m)$ of specific age groups using the following Eq. 3:

$$R_b^s(x, x + m) = \frac{M_b^s(x, x + m)}{P_b(x, x + m)/52} \quad (3)$$

However, The accuracy of the prediction of weekly age or sex group specific data from the combined data using the above distribution equation is not calculated or proved. As an efficient and easy alternative to the equation to solve the problem, we have proposed a system that uses several multi-output regression models. Compared to developing separate five single-output models for predicting five output features, multi-output regression has multiple advantages. Multi-output regression provides reduced training time, a unified prediction rule, and improved predictive generalization. As a result, much more complicated decision-making problems can be solved easily [4]. In this work, the prime objective of this research is to propose a model using multioutput regression to correctly perform the prediction of mortality data based on combined weekly mortality data. After collecting the dataset, we applied six ML models as well as two DL models named Linear Regression (LR), Decision Tree (DT), Random Forest (RF), K-nearest Neighbour (KNN), Least Absolute Shrinkage and Selection Operator (LASSO), Support Vector Regressor (SVR), Artificial Neural Network (ANN) and Recurrent Neural Network (RNN). After then, we have compared the output of each model. Finally, we have explored the best-performing model for the problem.

The remainder part of the paper is organized as follows: the recent relevant works is shown on Section II, the materials and methods is described on Section III, the result of the experiment is shown on Section IV, discussion is demonstrated on Section V and finally the conclusion and future works on Section VI.

II. RELATED WORKS

Some researchers already exploited the benefit of multi-output regression in their work. For example, in [5], Cui et al. jointly predicted two healthcare resource utilization measures such as length of stay and cost using multi-output regression models. They used four regression models such as NN, DT, RF, and multi-task Lasso for the prediction. They have achieved best performance with RF model when features generated through skip-gram feature vectors according to the R^2 coefficient, RMSE, Mean-Absolute error (MAE), Median Absolute Error (Median-AE) among the uninterpretable methods. Boumezoued et al. [6] utilized linear regression and neural network model to the correction of the mortality data while birth by month data is not available. They worked on the database of human mortality. In [7], Shahid et al. used seven regression models including decision tree, random forest, linear regression, support vector regression, ridge regression, gradient boosting, and multi-layer perceptron to efficiently forecast road traffic flow. Before implementing the models, they have utilized five dimensionality reduction methods. Han et al. [8] applied multi-output least square support vector regressor (M-LSSVM) to predict the levels of gas in a multi-tank LDG system in real time. It encompasses both the individual fitting errors as well as the combined ones for each output. Tuia et al. [9] employed an multioutput support vector regressor

(MSVR) model to estimate biophysical parameters such as fractional vegetation cover, chlorophyll content, and leaf area index from remote sensing images in a simultaneous manner. The study demonstrated that M-SVR is a viable substitute for nonparametric estimation of biophysical parameters and model inversion, compared to the single-output regression method. Li et al. [10] developed a system that utilizes multi-target regression models to predict the time series value of blood-drug efficacy in traditional chinese medicine datasets. The proposed system utilized the correlation between targets to enhance the performance of four learning techniques such as LR, Partial Least Squares, SVR, and ANN. SVR exhibits the best performance among the applied models. Meyer et al. [11] investigated the use of multi-target machine learning models for wind turbine normal behavior monitoring. The authors assessed 6 multi-target models such as DT, RF, KNN, MLP, CNN, and LSTM in a wind turbine case study and found that these models offer benefits over single-target modeling. Specifically, multi-target models can significantly decrease the effort required for the lifecycle management of normal behavior models while maintaining model accuracy. Kucuk et al. [12] predicted soil moisture through applying nine multi-output regression models such as LR, ridge regression, Lasso, RF, adaptive boosting, extreme gradient boosting, gradient boosting, histogram-based gradient boosting and extra tree regressor (ETR). They have shown that ETR delivers best performance with 0.81 r-squared coefficient value.

III. METHODOLOGY

The whole procedure has been subdivided into several parts such as dataset description, data preprocessing, implementation of multi-output regression models and finally the comparison of the performance of the algorithms. The conceptual flow of the procedure has been demonstrated on Fig. 1. At first, we have gathered the dataset in csv format. The data values has been scrubbed with the necessary features, and the final dataset has the features named Country Code, Year, Week, Sex, D_Total, D0_14, D15_64, D65_74, D75_84, and D85p. To handle multiple target features, we have utilized several regression models that perform better in multi-output regression problems such as LR, DT, RF, KNN, Lasso, SVR, ANN, and RNN. All the implementation were performed on python. Finally, the the performance of the model has been evaluated based on performance metrics.

A. Dataset Description

The STMF data series, a part of HMD, contains the records of human mortality rate according to every week of a year. The data has been stored both in the csv and excel file formats. There are total 19 features in the dataset such as CountryCode, Year, Week, Sex, next five features (5-9) includes death counts by age group (0-14, 15-64, 65-74, 75-84, 85+), total death counts through combining all age groups, next five features (11-15) such as death rates by age group (0-14, 15-64, 65-74, 75-84, 85+), total death rates through combining all sex groups, finally 17-19 attributes are explanatory indicators such as split, splitsex and forecast (see Table I). The four columns of the dataset are country in ISO-3 code format, year, week, sex of the the people who has died. It maintains the guidelines of ISO 8601-2004 to arrange the week. Generally, a year is

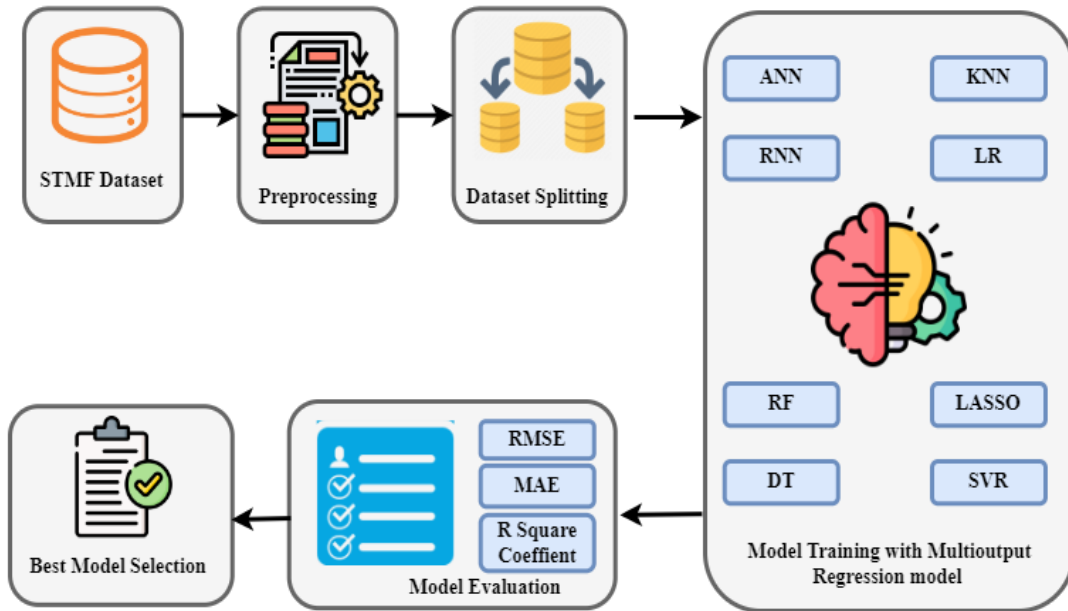

Fig. 1. Conceptual flow of the proposed model.

divided to 52 weeks except for some years of 53 weeks like 1992, 1998, 2004, 2009, 2015, and 2020. However, this paper focuses on the dataset with ten features where the five features such as country code, year, week, sex, D_Total were used as independent features and the five features such as D0_14, D15_64, D65_74, D75_84, and D85p were used as dependent features. On the other hand, there are 107211 records in the table.

B. Data Preprocessing

Data preprocessing is performed to remove any abnormalities in the dataset, identifying missing values as well as to prepare the data for further analysis. In this work, the dataset was checked whether it has any null values or not and it was replaced with zero using the fillna() option of python. After that, the character values changed using the encoder of python as the character or word data cannot be used for the application.

C. Multi-output Regression Models

Multi-output regression involves concurrently predicting multivariate output feature space from a given multivariate input feature space [13], [14]. Suppose $a \in R^u$ is a u -dimensional input feature space and $b \in R^v$ is a v -dimensional output feature space. So, multi-output regression can be stated as mapping from R^u to R^v [15]. In this work, we simultaneously predicted five output features using multi-output regression models. We have implemented eight different regression models namely ANN, RNN, LR, DT, RF, KNN, Lasso, and SVR to the data.

1) *Artificial Neural Network (ANN)*: ANN [16] is a computational network, which is motivated by the structure and function of biological neural networks in the brain [17]. The neural networks have several's neurons that are interconnected to each layer named as nodes similar to biological neural networks. The basic objective is to simulate the neural network that makes up the human brain so that computers can be capable of comprehending information and making decisions in the same way humans do. There are major three layers of ANN.

- **Input Layer**: The input layers receive input in various formats from multiple sources provided by researchers. Inputs are provided in the form of a pattern and vector from those external sources.
- **Hidden Layer**: The hidden layer lies in the middle of the input and output layers. This layer extracts all hidden features and patterns based on a given weight.
- **Output Layer**: Each input is multiplied by its associated weight. If the summed-up weighted input is zero then a bias is added to make a non-zero or different output. After that an activation function is applied to the summed-up weighted inputs to get the desired output. The Eq. 4 displays the standard format of a transfer function.

$$y = \sum_{i=1}^n W_i * X_i + c \quad (4)$$

Here, the variable y represents the weighted sum, where X_i represents the input values, W_i represents their respective

TABLE I. DIFFERENT ATTRIBUTES OF THE DATASETS

S.N.	Attributes	Type of Attribute	Attribute Value
1	CountryCode	Nominal	Australia, Austria, Belgium, Bulgaria, Croatia, Czech Republic, Denmark, England and Wales, Estonia, Finland, France, Germany, Greece, Hungary, Iceland, Israel, Italy, Latvia, Lithuania, Luxembourg, Netherlands, Norway, Poland, Portugal, Russia, Scotland, Slovenia, Slovakia, Spain, Switzerland, Sweden, USA
2	Year	Numerical	1990-2022
3	Week	Numerical	1-53
4	Sex	Nominal	Male(m), Female(f), Both(b)
5	Death counts by age group (0-14), D0_14	Numerical	Mean: 24.48840206
6	Death counts by age group (15-64), D15_64	Numerical	Mean: 741.2852896
7	Death counts by age group (65-74), D65_74	Numerical	Mean: 574.2379793
8	Death counts by age group (75-84), D75_84	Numerical	Mean: 860.7234414
9	Death counts by age group (84+), D85p	Numerical	Mean: 874.3757614
10	The total death counts of all ages combined, DTotal	Numerical	Mean: 3075.110874
11	Death rates by age group (0-14), R0_14	Numerical	Mean: 0.000410215
12	Death rates by age group (15-64), R15_64	Numerical	Mean: 0.003046857
13	Death rates by age group (65-74), R65_74	Numerical	Mean: 0.020856924
14	Death rates by age group (75-84), R75_84	Numerical	Mean: 0.055437482
15	Death rates by age group (84+), R85p	Numerical	Mean: 0.166329407
16	The total death rates of all ages combined, RTTotal	Numerical	Mean: 0.009862773
17	Split	Nominal	0,1
18	SplitSex	Nominal	0,1
19	Forecast	Nominal	0,1

weights, and c represents the bias term. The output is then produced by passing the weighted total through an activation function. The training of the model has been performed in 100 epochs with relu activation function as well as Adam optimizer.

2) *Recurrent Neural Network (RNN)*: RNN is a type of artificial neural network in which the output from one phase is fed back as input for the subsequent phase. It possesses hidden layers that utilize RNN memory to preserve information from prior computations, thereby facilitating the extraction of significant information for the purpose of sequential data processing. Thus, many applications with sequential data such as speech recognition [18], language translation [19], and human activity recognition can be benefited from RNNs. RNN converts independent activations into dependent ones by giving each layer the same amount of weights and biases. This reduces the complexity of increasing parameters and helps to memorize each previous output, which will be used as input for the subsequent hidden layer. After then, each set of three layers can be connected to form a single recurrent layer. The Eq. 5 represents the formula for determining the current state:

$$S_t = f(S_{t-1}, X_t) \quad (5)$$

Here, S_t denotes the present state, S_{t-1} denotes the preceding state, and X_t denotes the input state. The Eq. 6 represents the formula for using the activation function:

$$S_t = f(W_{ss}S_{t-1} + W_{sx}X_t) \quad (6)$$

Here f is the activation function, W_{ss} represents the weight assigned to the recurrent neuron, and W_{sx} represents the weight assigned to the input neuron. The Eq. 7 represents the formula to determine output:

$$Y_t = W_{sy}S_t \quad (7)$$

Here Y_t represents the output and W_{sy} represents the weight assigned to the output layer.

3) *Linear Regression (LR)*: LR is one of the widely used machine learning methods which estimates the linear relationship between dependent and independent variables. It demonstrates how the value of the dependent variable changes based on the value of the independent variable. Basically, it is employed in predictive analysis. It forecasts factors that are real or numerical, such as birthday, sales, salary, age, and product price. The main goal of linear regression is to determine the best-fitting linear equation that reduces the disparity between the anticipated and actual values of the dependent variable. The Eq. 8 represents the formula of the model.

$$y = b_0 + b_1x_1 + b_2x_2 \dots b_nx_n \quad (8)$$

Here y denotes the dependent variable, also termed as target variable, $x_1, x_2 \dots x_n$ denotes the independent variables, which are known as predictor variables. $b_0, b_1, b_2 \dots b_n$ denotes the coefficients associated with each independent variable. b_0 is the line's intercept, and a_1 is the linear regression coefficient.

4) *Decision Tree (DT)*: DT is a supervised learning algorithm applied to both classification and regression problems. It is a tree-like structured approach where the internal nodes indicate input features or attributes, branches indicate the decision-making process that is based on those features, and leaf nodes indicate the output or prediction of the model. The algorithm starts at the root node of the tree and at every decision node, the algorithm selects the branch to pursue by evaluating the present record's values with associated decision node values. Based on this comparison, the algorithm follows the corresponding branch to the next node. One of the main issues in DT algorithms is to determine the best attribute for the root node and subsequent sub-nodes. An attribute selection measure (ASM) can be used to find solutions to these issues. There are two widely used ASM techniques that are described in the following sections.

- **Information Gain**: After dividing the data depending on an attribute, it calculates the reduction in entropy or uncertainty in the target variable. The splitting attribute is selected based on the attribute that has the highest information gain. The Eq. 9 represents the formula to calculate Information Gain (IG).

$$IG = Entropy(s) - \sum \frac{|S_v|}{|S|} * Entropy(S_v) \quad (9)$$

Here, $Entropy(s)$ represents the entropy of the original dataset S . $|S_v|$ represents the instance number in S that have the value v for attribute, $|S|$ represents the total instance number in S , and $Entropy(S_v)$ is the entropy of the subset S_v after splitting the data based on the attribute value v .

- Gini Index: Gini index quantifies the impurity or dissimilarity of a dataset's value while creating a decision tree. The objective of the Gini index is to reduce impurities from the root nodes to the leaf nodes. The attribute with the lowest Gini index should be chosen as the splitting attribute. Gini index can be calculated using the below formula stated in Eq. 10.

$$GI(S) = 1 - \sum p_i^2 \quad (10)$$

Here, p_i is the proportion of instances in S that belong to class i .

5) *Random Forest (RF)*: RF is another popular supervised algorithm that integrates the power of decision trees and ensemble learning for solving classification and regression problems [20]. It functions by randomly choosing subsets of the training data and features known as bootstrap samples from the original dataset. Each decision tree is then created independently using these subsets through a recursive process. During prediction, each tree generates an independent prediction and the final prediction is then determined by taking the average prediction of all the trees. There should be a chance that certain decision trees may generate incorrect predictions, but when all the trees are combined, it provides an accurate prediction. RF also provides several other benefits, including the ability to handle nonlinear relationships, capture complex interactions among features, and improved accuracy, and robustness against outliers and noise compared to individual decision trees [21].

6) *K Nearest Neighbour (KNN)*: KNN is one of the simplest yet versatile algorithms applied to both classification and regression tasks [22]. This algorithm is non-parametric, instance-based, and makes no assumptions on the distribution of the underlying data. KNN algorithm assigns labels to previously unlabeled data based on the features and labels of its K nearest neighbors in the training data. The process involves computing the distance between the new unseen input data and each training sample using a certain distance metric such as Euclidean distance, Minkowski distance, Manhattan distance, hamming distance. In the classification process, KNNs are used to assigning labels to a new data point based on the dominant class label among the neighbors. In regression, the predicted value is calculated by averaging the target values of K 's nearest neighbors. The choice of K may have impact on the algorithm's performance. If the value of K is smaller, it may lead to a potentially more flexible and noisier prediction and if the value of K is larger, it may lead to potentially smoother but biased predictions. In order to identify the K nearest neighbors, Euclidean distance is used most of the time as a distance metric. The Eq. 11 represents the formula to determine the nearest neighbors between two data sets, p and q .

$$d(p, q) = \sqrt{\sum_{i=1}^n (q_i - p_i)^2} \quad (11)$$

Here, p and q denote the coordinates of data points in each dimension, and n represents the total number of dimensions or features.

7) *Least Absolute Shrinkage and Selection Operator (LASSO)*: LASSO is a type of linear regression model that employs shrinkage to select the variables. It is beneficial in analyzing datasets with high dimensions, specifically those with many features and fewer observations [23]. During prediction, the linear regression model provides equal importance to all features. However, when there are many features, including irrelevant or redundant ones, the model may become complicated and overfit the training data, which results in poor generalization of new data. Lasso Regression addresses this problem by adding an L1 penalty term to the cost function. The L1 penalty promotes sparsity and facilitates efficient feature selection by shrinking the coefficients of irrelevant features toward zero, thereby eliminating the corresponding features from the model. The generic form of the cost function in LASSO regression is presented on Eq. 12.

$$J = \frac{1}{m} \sum_{i=1}^m \left(y^{(i)} - h \left(x^{(i)} \right) \right)^2 + \lambda \sum_{j=1}^n |w_j| \quad (12)$$

Here, the variable m denotes the count of training examples. The variable $y^{(i)}$ represents the target variable's value for the i -th training example. The expression $h(x^{(i)})$ denotes the hypothesis function's for prediction, while n denotes the total number of features. The weight assigned to the j th feature is represented by w_j .

8) *Support Vector Regression (SVR)*: SVR is a supervised learning algorithm used for classification and regression problems [24], [25], [26]. It is an expansion of the Support Vector Machine (SVM) algorithm. The aim of SVR is to select a hyperplane with a maximum margin while allowing a certain level of error (epsilon) for data points that lie within that margin. The SVR algorithm tries to identify the optimal hyperplane by solving an optimization problem that minimizes the training data error and maximizes the margin. In the prediction phase, SVR applies the learned hyperplane to predict the values for new data points. The predicted values are defined by the position of the data points with respect to the hyperplane. SVR can handle non-linear relationships and high-dimensional data effectively with the help of kernel functions. Kernel functions are applied to convert the input data into a higher-dimensional space, where it can find a linear regression function. The selection of the kernel function depends on the type of data and the problem at hand. The three kernels that SVM most frequently uses are.

- Linear kernel: It deals with large sparse data and is used in text categorization. It measures the linearity between the input data and the target variable.
- Polynomial kernel: This kernel, known as a polynomial kernel, introduces polynomial features to capture nonlinear relationships.

- Radial Basis Function (RBF): It maps the input data into an infinite-dimensional feature space applying Gaussian functions.

D. Performance Metric

The purpose of accuracy metrics is to determine the performance of any model. In this section, we used three evaluation metrics such as R Square coefficient, RMSE, and MAE to measure the prediction accuracy of the regression models.

1) *R Square Coefficient*: R square coefficient is an evaluation metric that measures the fitness of a regression model [7]. It can be expressed as using Eq. 13.

$$R^2 = 1 - \frac{\sum_i (x_i - \hat{x}_i)^2}{\sum_i (x_i - \bar{x})^2} \quad (13)$$

Where, x_i and \hat{x}_i are the actual and predicted output of i -th sample respectively, \bar{x} is the average output. The highest value of R^2 is 1, indicating that the closer the value to 1 the better fitted the model is.

2) *Root Mean Square Error(RMSE)*: RMSE is a general-purpose error metric used to measure the performance of a model according to prediction accuracy [27]. The smaller the RMSE value the higher the prediction accuracy. It can be expressed as the square root of the mean squared error. The equation to calculate MSE and RMSE for multi-output regression model is provided in Eq. 14 and 15, respectively.

$$MSE = \frac{1}{m} \frac{\sum_i (x_i - \hat{x}_i)^2}{N} \quad (14)$$

$$RMSE = \sqrt{MSE} \quad (15)$$

In the above equation stated in 14, N denotes the number of samples.

3) *Mean Absolute Error(MAE)*: MAE calculates the difference between actual output and predicted output. MAE for multi-output regression model expressed in the Eq. 16.

$$MAE = \frac{1}{m} \frac{1}{n} \sum_{i=1}^n |(x_i - \hat{x}_i)| \quad (16)$$

IV. EXPERIMENTAL RESULTS

The main objective of the proposed model is to predict the weekly death count based on age-specific user group. To perform the task, we have implemented several regression models. The dataset was divided into 80% to 20% where 80% data is used for training and 20% data for testing purposes. All the experiments were performed in Python. The performance of these models is evaluated based on three different metrics such as MSE, MAE and R squared coefficient. The higher value of the R squared coefficient is found with RF algorithm (0.9975), which is followed by DT (0.9958), RNN (0.9529), KNN (0.9430), ANN (0.9427), LR (0.8937), Lasso (0.8937), SVR (0.8438) which is shown on Table II. The higher value of the R squared coefficient, the lower value of RMSE and MAE indicates good fitted model for the task. It is evident that the value of MAE is lower with RF (16.4069) that is

TABLE II. COMPARISON AMONG THE REGRESSION MODELS BASED ON RMSE, MAE AND R SQUARED COEFFICIENT

	RMSE	MAE	R Squared
RF	43.2263	16.4069	0.9975
DT	56.4134	21.7217	0.9958
RNN	333.8810	124.3763	0.9529
KNN	386.2374	106.2851	0.9430
ANN	389.7136	114.8771	0.9427
LR	525.6425	212.0527	0.8937
Lasso	525.6477	211.7925	0.8937
SVR	656.4845	245.8620	0.8438

followed by DT (21.7217), KNN (106.2851), ANN (114.8771), RNN (124.3763), Lasso (211.7925), LR (212.0527) and SVR (245.8620). The lowest RMSE value is found on RF with 43.2263 which is followed by DT, RNN, KNN, ANN, LR, Lasso, and SVR. Therefore, it can be concluded that RF is the best-performing model for the task and after then DT showed almost similar types of prediction.

V. DISCUSSION

In this research, we figured out that, instead of using the distribution equation, the construction of a model with random forest and decision tree algorithms to perform the count of mortality in absence of age specific data from the total count of all ages is much easier and better solution. It is evident that the use of the multi-output regression model has proved its efficiency to perform the prediction. To the best of our knowledge, this work is the first attempt to propose a multi-output regression model as a solution to the distribution problem on the mentioned dataset. It can be summarised that ML techniques provide better output for multi-output regression than DL methods. Among the classifiers, RF showed the best performance based on RMSE, MAE, and R squared coefficient.

However, the performance of several algorithms can further be improved through tuning the hyper-parameters of the model. In addition, the utilization of these regression models can be applied to the similar domains through extending their potentiality.

VI. CONCLUSION

STMF data series is one of the most valuable data series of HMD. Various types of analysis can be performed using the weekly records according to the information of their age group and gender. However, the data that are collected from various countries sometimes lack the weekly death information. Currently, researchers used the distribution equation to calculate the age-specific weekly data. Multi output regression models are getting popularity in prediction related problems over the last few years. In this work, we have implemented such regression models because of the benefits over single output model. In this work, RF is selected as the best performing model based on R-square coefficient, RMSE and MAE.

Opportunities in Real Time Fraud Detection: An Explainable Artificial Intelligence (XAI) Research Agenda

Eleanor Mill, Wolfgang Garn, Nick Ryman-Tubb, Chris Turner
Surrey Business School, University of Surrey, Guildford, GU2 7XH

Abstract—Regulatory and technological changes have recently transformed the digital footprint of credit card transactions, providing at least ten times the amount of data available for fraud detection practices that were previously available for analysis. This newly enhanced dataset challenges the scalability of traditional rule-based fraud detection methods and creates an opportunity for wider adoption of artificial intelligence (AI) techniques. However, the opacity of AI models, combined with the high stakes involved in the finance industry, means practitioners have been slow to adapt. In response, this paper argues for more researchers to engage with investigations into the use of Explainable Artificial Intelligence (XAI) techniques for credit card fraud detection. Firstly, it sheds light on recent regulatory changes which are pivotal in driving the adoption of new machine learning (ML) techniques. Secondly, it examines the operating environment for credit card transactions, an understanding of which is crucial for the ability to operationalise solutions. Finally, it proposes a research agenda comprised of four key areas of investigation for XAI, arguing that further work would contribute towards a step-change in fraud detection practices.

Keywords—Artificial intelligence; explainable AI; machine learning; credit card fraud

I. INTRODUCTION

Europol's Serious and Organised Crime Threat Assessment identifies non-cash payment fraud as one of the most concerning criminal activities in the European Union [1]. In the UK alone, fraud losses on UK issued cards totalled £567 million in 2020 [2]. UK losses, however, are dwarfed in comparison to global losses which were estimated to be \$32.39 billion in 2020, extending to over \$40 billion by 2027 [3]. It is argued that as the use of non-cash payment cards increases year on year, perpetrators of these frauds are likely to see a continual increase in their illegal funding unless industry and academics can come together to create a significant step-change in the way in which fraudulent transactions are intercepted.

A. Changing Landscape

The volumes and velocity of credit card transactions means that financial institutions cannot rely on human expertise alone to identify fraudulent transactions. Fraud Management Systems (FMS) complement other internal processes to help automate fraud detection and decision-making. FMSs are traditionally rule based, meaning every single transaction is checked against a catalogue of pre-determined rules. This is an approach favoured by industry fraud experts because of the ease with which they can understand the inputs, modify the rules and interpret the results. However, whilst the relative simplicity of

rule-based systems ensures the results are easily understood, this fixed approach does not scale well and limits the ability of the FMS to recognise or adapt to evolving patterns of fraud. Moreover, recent regulatory and technological developments threaten the effectiveness of traditional rule-based fraud management systems. As a consequence the payments industry, and therefore payment card fraud detection, is facing a once-in-a-generation need for radical change.

1) *Regulatory developments:* As part of the Payment Services Directive 2 (PSD2) regulation, Strong Customer Authentication (SCA) has recently been enforced in Europe and the United Kingdom [4]. SCA employs new Regulatory Technical Standards (implemented through an initiative called 3-D Secure 2.0) which enhance the current practices of processing customer transaction data. One of the pre-SCA challenges for issuers in fraud detection was the limited amount of data they received from the retailer – typically less than 10 variables per transaction. In contrast, the new Regulatory Technical Standards describe “Authentication Enrichment” data that a retailer should now provide to an issuer in addition to the usual transaction data. The Authentication Enrichment data increases the original 10 variables to over 100 variables (known as “security features”) [5], [6] as shown in Fig. 1 .

The ten-fold increase in the security features necessitates a step-change in traditional rule-based fraud detection methodologies. Whilst rule-based engines will continue to perform initial screening of transactions to eliminate the most common fraud approaches, machine learning (ML) will be required to perform the majority of the analysis. Synergistically, the results of those ML models must be easily translated by the fraud analysts and management teams in order to interpret and act upon any newly derived insights.

Additionally, the Regulatory Technical Standards dictate the need to perform the analysis of transactions using these data points in real-time. The adoption of Authentication Enrichment data and enforcement of real-time analysis makes improvements to the automated processing of transactions increasingly urgent: It is claimed that “Approximately 80% of issuers plan to invest in machine-learning (ML) and rule-based engines to facilitate SCA processes by the end of 2021” [7].

2) *Technology developments:* Technology is revolutionising the way society pays for its goods and services. Contactless technology has become mainstream [8] and digital wallets such as Apple Pay, Google Pay or Samsung Pay have significantly increased their user base, especially in the younger generations

Fig. 1. Additional security features to be provided from the merchant (retailer) to the issuer as a result of new SCA regulatory technical standards (implemented through an initiative called 3-D Secure 2.0) [6].

[9]. Using this technology, payments can now be made through physical cards, mobile phones and even jewellery such as rings or watches which use Near Field Communication (NFC) technology. In addition, Open Banking has facilitated the entrance of a myriad of new payments service providers and the introduction of account-to-account payments [10].

These innovations not only transform the footprint of a traditional payment transaction but also highlight the flexibility needed to address the future transaction landscape. Traditional rule-based fraud detection methodologies which rely on a user's consistent and repetitive behaviours are less effective when payments can be made through any device, piece of clothing or jewellery in any location and at any time. Similarly, changes to the way payments are conducted means a re-evaluation of a retailer's payment infrastructure [11] which, in turn, will also affect their traditional fraud detection methodologies.

Finally, recent advances in technology enable fraudsters to work en masse, causing disruption at an ever faster pace. In [12], Dvorsky reported on the already-present ability of criminals to launch AI-based attacks, enabling much faster and more widespread disruption than previous human manual led strikes. Fraudsters are agile. They do not have the restraints of customer privacy, regulation and legacy applications to accommodate. In a recent industry report [13], Mike Haley, CIFAS CEO said "fraud is ever evolving, and criminals continue to collaborate. As a community, we must do the same".

Hence the need for the FMS to be able to adapt at pace becomes even more critical. Rule-based systems may have been sufficiently refined over the past 30 years to effectively seek out known fraud patterns or traits, yet it is suggested that they are no match for the dynamics of this modern fraud landscape. As a consequence, the accuracy of the traditional FMS over the medium-to-long term will decline.

B. Current Status

To address the challenges of escalating transaction volumes, changes in regulation, technological advancements and a more sophisticated and technology-savvy criminal fraternity, researchers are exploring the opportunities of employing ML techniques in credit card fraud detection. However, adoption

of ML techniques in financial settings have been slow to materialise [14]. The running hypothesis is that organisations perceive ML techniques as "black box" solutions which lack transparency and are therefore difficult to trust. Some domains, for example movie recommendation engines, are able to tolerate the opacity which accompanies black box solutions since the consequences of an incorrect outcome (for example a poor movie recommendation), whilst potentially irritating, present a low risk to the user.

In financial domains the consequences of an incorrect decision on a data subject are more impactful. In the case of credit card fraud detection, a consumer is likely to have the transaction rejected, and potentially the credit card subsequently withheld or cancelled. At the very least this will result in annoyance or embarrassment, but it may also impact the consumer's ability to buy groceries or keep up with payments on more substantial items. The existence of these risks places a much stronger onus on practitioners to ensure they can trust in the outputs of these ML models. For the finance industry, the inability to understand or justify the outcomes of the black box ML models has consequentially become a strong barrier to change.

To counter this challenge, scholars have begun investigating ways in which ML techniques can be leveraged whilst simultaneously providing transparency to engender trust in the models and therefore encourage more ubiquitous adoption. An emerging and increasingly popular technique to create this transparency is Explainable Artificial Intelligence (XAI).

C. Terminology

Scholarly research of nascent fields often begins with the difficulty of achieving a consensus on normative terminology. This is especially pertinent for the discourse surrounding XAI. As noted by both [15] and [16], many authors avoid committing themselves to a definition of an XAI system. This may be because, as a nascent field, the community have yet to come together to agree upon a clear definition. Yet without open discussion, how can consensus be reached? Those same authors suggest that this avoidance exposes the discipline to criticism that the field lacks rigour, noting that the community cannot justify claims of delivering XAI without agreement as to what XAI is.

To complicate matters further, there is also discord between authors regarding use of the terms "explainable" (usually followed by "artificial intelligence" and denoted XAI) and "interpretable" (usually followed by "machine learning" and denoted IML) with some authors considering the two terms analogous [17], [18] and other authors seeing a clear distinction between them.

One suggestion [19] is that the term "explainable" should be considered an umbrella term which has the goal to "... summarise the reasons for neural network behaviour, gain the trust of users, or produce insights about the causes of their decisions". The authors then perceive interpretability as a sub-goal to shed light on "what a model did or might have done" – answering the question of "how" the system came to its conclusion, yet stopping short of providing the complete response which a system audit may require. An explainable model is therefore, by definition, inherently interpretable yet

the reverse is not true – an interpretable model does not necessarily satisfy all the requirements of being explainable.

Similarly, [20] provide an holistic definition of XAI as “AI systems that can explain their rationale to a human user, characterize their strengths and weaknesses, and convey an understanding of how they will behave in the future.” Their concept of interpretability, analogous with the perspective of [19], is also subservient to the concept of being explainable. However the authors are more precise in their description, suggesting that “Interpretable models are machine learning techniques that learn more structured, interpretable, or causal models.”

This concept of interpretability representing models that can be decomposed by an appropriately skilled audience is becoming more widely recognised amongst contemporary authors. Specifically, authors identify linear models, decision trees, rule-based models and constrained variants of black-box models as interpretable models [21]–[25]. Such models are often referred to as “inherently” interpretable [22], [23], [26], [27] or “intrinsic” [28], with the advantage that they are able to provide accurate and undistorted [26] explanations for the model output.

In contrast, black box models are often defined as models which are not interpretable, that is their complexity is so acute that the intended audience are unable to unravel their inner workings. When presented with such a model, it is increasingly commonplace for those seeking an explanation of the output to implement a subsequent interpretable model in a post-hoc fashion, the purpose of which is to find an approximate and human-understandable explanation to the original model’s output. Obscuring the holistic definitions of both [19] and [20], authors frequently refer to these post-hoc models as explainable models [15], [22], [29] or explainable AI [23], [27], although others employ the term post-hoc interpretability [21], [30].

In an effort to reconcile the discourse, this paper leverages the holistic perspectives of both [19] and [20] to suggest XAI should be considered as an umbrella term. Specifically, it adopts the definition put forward by [20] (see above) which emphasises the importance of producing an explanation that is human-understandable, including transparency of the working parameters of the system. Where necessary, it differentiates XAI models through use of the terms “intrinsic” and “post-hoc”. The former term describes models that are inherently interpretable. Decision trees and linear regressions are well studied examples of intrinsic models. Section III-B discusses intrinsic models in more detail and highlights some of their perceived challenges. Other models are built to prioritise alternative desiderata such as precision, accuracy or speed. In that circumstance, explanations are obtained “post-hoc”, i.e. derived as part of an additional process after the model has delivered the outcome.

D. Scholarly Focus

Despite the ongoing debate as to the exact terminology and definitions pertaining to XAI, many scholars are undeterred in their investigations. XAI models are an increasingly popular research topic within the ML community (see Fig. 2a), and the techniques to develop, present and categorise the explanations

(a) Web of science core collection articles or proceedings papers focusing on XAI 2000 to 2021.

(b) Web of science core collection articles or proceedings papers focusing on credit card fraud 2000 to 2021.

Fig. 2. Scholarly focus for XAI and credit card fraud 2000 to 2021.

are many and varied. Likewise, investigations into credit card fraud detection are enjoying renewed attention (Fig. 2b). However, analysis of this joint population reveals just one paper published over the past 21 years which specifically investigates the application of XAI within a credit card fraud context [31].

Within that paper the authors initially propose a black box solution to distinguish between fraudulent and legitimate transactions. They subsequently acknowledge the difficulty that a human being would have in understanding the resulting output and propose an overlay to translate the results into human-understandable format. The explanation is therefore positioned as an afterthought, rather than central to the paper.

One additional paper of note explores the ability to extract generalised rules from a neural network within the domain of credit card fraud [32]. Despite no specific reference to XAI, it makes an early contribution to the field by introducing SOAR (Sparse Oracle-based Adaptive Rule extraction) which makes complex rule-sets more comprehensible by exploiting key decision boundaries.

Hence fraud – XAI cross-disciplinary research has so far lacked focus. This paper seeks to address the gap by arguing that techniques attributed to the field of XAI have the ability to accelerate a step-change in the detection of fraud in the credit card industry. This research agenda suggests ways in which XAI can improve the adoption of complex models, such as neural networks, in credit card fraud detection. Section II begins with a discussion of the credit card fraud operating landscape and key challenges which must be overcome for

successful model adoption. Section III then lists four significant focus areas which would benefit from increased scholarly attention. Finally, Section IV provides concluding remarks.

II. FUNDAMENTAL CONCEPTS AND BACKGROUND

A. Credit Card Operating Environment

Credit card transactions are bifurcated into Cardholder Present (CP) and Cardholder Not Present (CNP) transactions. For CP transactions the customer is physically present at the purchase point and offers a physical card to the retailer for payment. For CNP transactions the purchase is carried out remotely, for example over an e-commerce website. It is this latter scenario which will be the focus of this paper.

The speed and simplicity with which an individual can execute a credit card transaction disguises the complexity of its operating environment. There are multiple key organisations which have to interact seamlessly to deliver a smooth consumer experience. Fig. 3 shows the five key parties involved and the general timings used to execute and settle a credit card transaction.

The customer initiates the process by providing credit card payment details to the retailer in exchange for a product or service (step (1)). In real-time, the retailer requests permission from the issuer through both the acquirer and the payment card association [steps (2) to (4)] and receives an authorisation code back [steps (5) to (7)], at which point the transaction is either authorised or declined. Readers will be familiar with this entire request and response process being completed in a matter of seconds.

Following the transaction approval, the retailer receives funds from the issuer up to three days later [steps (8) to (13)]. The issuer then places the transaction on the credit card statement and issues the statement up to thirty days post transaction [step (14)]. The cardholder then has up to another thirty days to settle the bill either in full or through the use of a credit facility [step (15)].

Real-time fraud analysis focuses on confirming the authenticity of a single credit card transaction before the transaction is completed (see step (1) to step (7) in Fig. 3). The retailer, acquirer, card association and issuer all have roles to play. They perform similar types of analyses in order to ensure they are comfortable with the validity of the transaction, yet their fraud detection datasets are substantially different (Table I), enabling a multi-dimensional view of both the transaction and the context within which the transaction is being executed [33].

TABLE I. ORGANISATIONS AND THEIR CREDIT CARD FRAUD DETECTION DATASETS

Organisation	Fraud Dataset
Retailer	Previous customers and purchases
Acquirer	Transactions from all retailers who bank with them
Card Association	Transactions using the card association brand
Issuer	Transactions from all customers using issuer cards

To minimise repetition, this paper will assume the perspective of the retailer / e-commerce gateway in its discussions of fraud identification strategies and where XAI can improve the status quo. However, the strategies discussed are equally as relevant to acquirers, card associations and issuers in the real-time environment.

B. Key Challenges

FMS which enable the retailer's detection of illegitimate credit card transactions are hindered by four key challenges which will be described below. These challenges complicate the fraud identification process yet must be catered for in order to provide an operationally effective solution. Since intrinsic XAI models need to incorporate both the underlying ML algorithm and the explanation, any intrinsic XAI model will have to accommodate for all of these challenges in order to deliver an effective fraud detection explanation. In contrast, the first challenge is the only challenge relevant for a post-hoc XAI model, since its underlying AI model should operationally satisfy all key challenges.

1) *Real-time analysis*: Modern technology allows for the accumulation of hundreds of security features to provide information about the legitimacy of a transaction, as illustrated in Fig. 1. However, to ensure adherence to new regulations, deliver a smooth checkout experience for the customer and to minimise losses at the e-Commerce gateway those security features also need to be processed in real time. The real-time credit card transaction process illustrated by points (1) to (7) in Fig. 3 typically takes less than two seconds [34].

The foremost concern for the retailer is the provision of a seamless checkout experience for all legitimate transactions. A recent survey indicated that almost 20% of online shopping cart abandonment experiences were as a result of a "sticky" checkout experience [35]. The negative experience also reduces the likelihood of individuals visiting the store in the future thereby also impacting future sales revenue. Retailers' determination to protect their seamless checkout process is one of the key drivers behind the slow adoption of 3D Secure¹ checkouts [36].

2) *Concept drift*: A further advantage of real-time fraud analysis and explanation is the ability to detect emerging fraud trends and enable timely decision-making. Historically, the behaviour of fraudsters has been moderately consistent, enabling the cataloguing of fraud vectors which allows for rule-based analysis [37]. However, recent technological advances have enabled a more sophisticated and agile offender. *Concept drift* is the term used to describe this changing circumstance. Unforeseen, changing patterns in the fraud vectors results in the rules catalogue becoming either outdated or unmanageably large as more rules are added to try to keep pace with the new patterns of fraud. As a consequence, the fraud identification becomes less effective.

Examples of XAI models addressing concept drift in the domain of financial fraud are scant. However, the field could benefit from advances made in other fields. In particular, recent years have cemented the importance of addressing concept drift in the medical field of pandemic / epidemic response. In this field, authors have proposed various explainable models to support a real-time decision support model. Notably, [38] analyse Covid-19 symptomatic data using their DeepCOVID post-hoc XAI model. The result is a real-time graphical representation

¹3D Secure (3DS) requires customers to complete an additional verification step with the card issuer when paying, for example being directed to an authentication page on their bank's website, where they enter a password associated with the card or a code sent to their phone.

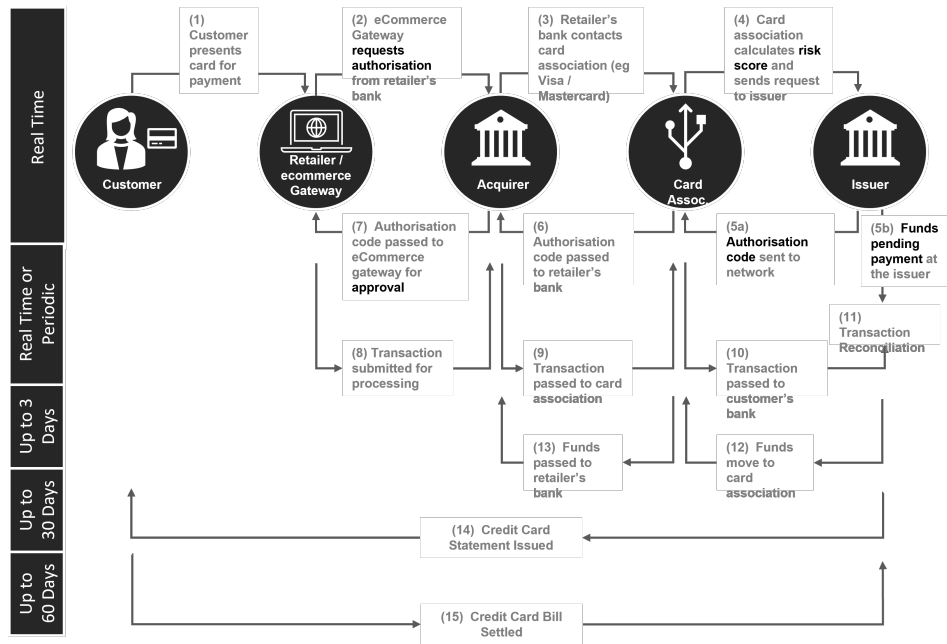

Fig. 3. CNP Credit card transaction life-cycle.

of the variables providing the most significant contributions to the prediction of Covid-19 diagnosis.

3) *Minimising false positives:* A model will sometimes incorrectly indicate a positive (e.g. fraudulent) result. This is known as a false positive result. Maximising the opportunities for a seamless checkout experience requires fraud investigators to minimise the occurrence of false positives when identifying fraudulent transactions.

False positives create friction in the process by either slowing down the real-time approval whilst manual assessment is required or cancelling the valid transaction altogether. In the latter case, the retailer loses both the goodwill of the customer and the value of the sale [39]. In addition to the negative experience of the customer, the occurrence of false positives creates further expense for the retailer as manual intervention is required to investigate the queried transactions. In an empirical survey of contemporaneous neural networks applied in credit card fraud detection, [14] suggested all but eight of the fifty-one (51%) ML methods in their literature population would be operationally ineffective. This is due to the high numbers of false positives in the results, requiring costly and inefficient manual oversight.

Whilst obtaining the proportion of false positive results on a test dataset helps to understand the efficacy of an AI model, it does little to provide transparency as to why incorrect predictions are being made. In contrast, XAI solutions have the advantage of being able to provide transparency to explain the reasoning for a false positive result. Saliency plots, for example, have been used by researchers to understand why an image-processing model was mistaking the picture of a husky for a wolf on a test dataset despite working with good accuracy on the training dataset [21].

4) *Dealing with class imbalance:* Fraudulent transactions are anomalous data points which exist within a large popula-

tion of genuine transactions. Mark Nelson, Visa's Senior Vice President of Risk Products and Business Intelligence, reports that Visa operates at a fraud rate of 0.1% of transactions [40]. Having an unbalanced dataset such as this creates difficulties for training ML models with the data since many algorithms assume an equal distribution of each class. When the minority class is the most important class, as it is in fraud detection, it typically results in a poor predictive performance.

A variety of approaches are available to scholars working with class imbalance. One option is to employ a weighted loss function which penalises the misclassification of the minority class thereby boosting its performance. Other popular approaches involve either undersampling the majority class or oversampling the minority class. Undersampling involves removing a proportion of the majority class in order to create a more balanced population. This is either done through random sampling or in a more structured way, often using nearest neighbour techniques. In contrast, oversampling the minority class increases the occurrence of the minority class in the dataset. This can either be done through making copies of existing minority transactions or creating additional synthetic transactions. SMOTE (Synthetic Minority Oversampling Technique) [41] remains a popular oversampling approach which has spawned an array of derivative oversampling techniques.

C. Fraud Risk Scoring

Fig. 1 illustrates the many data points which are available to the retailer for the purposes of performing a transaction fraud assessment. These data points are employed in a number of AI profiling algorithms to be used as inputs to generate an aggregated risk score. Fig. 4 represents a drill-down into the fraud detection process for a retailer / e-commerce gateway and highlights some of the most common inputs to the risk score such as product profiling, customer profiling, geo-location profiling and analysis of spending patterns [42]. The aggregated

fraud risk score is then compared to a fraud risk threshold determined by the retailer. Scores over the threshold identify transactions which the retailer considers worthy of challenge.

1) *Product profiling*: When retailers list a product for sale, they make an assessment of how appealing the product is likely to be to a fraudster. Typically, fraudsters steal products which are high value and high demand and can easily be resold on a secondary market. Retailers would identify these products in their portfolio as “High-Risk” and therefore apply a high-risk score to any sale of this product. The risk score is magnified when the number of high-risk products in a single transaction increase. In a recent survey of over 1,000 retail fraud professionals, the product profile (also referred to as the “Order Content”) was the key fraud indicator for 34% of survey respondents [42].

Shopping trends are in constant flux, depending upon the availability of new technology releases, changes due to seasonal trends, product availability and even media or social media influences. Consequently, it is difficult to implement an effective rule-based solution for determining high-risk products. However, ML provides retailers with an ability to adapt to new trends in a timely manner. Analogous with the discussion on *concept drift* in the paragraphs above, XAI solutions will provide real-time transparency of emerging trends enabling a retailer to understand why specific products are designated as high-risk. Graph Convolutional Networks are a popular tool in the detection of emerging trends due to their interpretability, enhanced performance and flexibility [43].

2) *Customer profiling*: It is important that retailers know their customer. This is not only relevant from a loyalty perspective, building a strong customer-retailer relationship, but it also provides useful knowledge in the fight against fraud. The above mentioned survey [42] identified the customer profile as the second most important fraud indicator for the survey respondents.

In respect of CNP transactions, the retailer needs to have confidence that the customer is genuine, and that they are dispatching the product to the right person at the correct address. This is much easier if they already have a prior transaction history with the customer, and far more difficult if the customer is new onto their platform. In order to establish a customer profile, they reference a number of key pieces of information which includes, but is not restricted to:

- Name and delivery address
- Usual mode of ordering (e.g. mobile or desktop)
- Frequently used IP Addresses
- Frequently used payment details
- History of returns or disputes
- Email address
- Email account history

Changes to any of the above profile factors can increase the customer’s risk score.

The lowest risk for the retailer is a customer with whom they have a regular transaction history, no reported disputes,

consistent behavioural patterns (e.g. mode of ordering and use of IP Address) and delivery to the same dispatch address. Any transactions with a customer in this category would be given a low-risk score for their customer profiling.

The highest risk for the retailer is a new customer. In this case they have no prior relationship data to build a customer profile. Instead, they leverage existing banking protocols alongside using other available data. At a minimum they ensure the shipping address reconciles with the billing address provided at checkout. Any deviations further increase the risk score of the customer profile. Other tactics involve ensuring the email address is not duplicated across their systems and looking at the account history of the email address.

The author in [44] explored user profiling to detect fraudulent cellular usage. Their work used an intrinsic XAI rule-learning technique to determine whether or not a customer was making a phone call from a cloned or genuine account. However, the flexibility and adaptability of clustering and classification ML algorithms have become increasingly popular in recent profiling studies. In particular, [45] demonstrated the effectiveness of the WIBL (Weighted Instance Based Learning) algorithm compared to more traditional clustering methods. WIBL improves explainability over existing clustering methods by using weighted features to indicate feature importance.

3) *Geo-location profiling*: The IP address also enables the retailer to access location details from where the order originates. This information is useful to the retailer in a number of ways. First, there may be certain locations which the retailer knows from prior experience have high risk of fraudulent activity. Retailers are able to use rule-based filters to exclude sales to those areas if they wish. Second, the location given by the IP address can be reconciled against the shipping and billing addresses. Although not a conclusive assessment, incongruence may indicate a higher risk of fraudulent activity.

4) *Spending patterns*: Finally, the retailer can also look for unusual or tell-tale spending patterns. They do this both at an individual customer level, and also holistically across their customer base. As above, this is much easier at an individual level if they have an established relationship with the customer. In that case they may be concerned with behaviours such as cancellations of orders followed by purchases of high-risk items, large volumes of high-risk products in a single transaction or unusual purchases for the customer profile, for example, an 80-year-old suddenly purchasing five flat-screen televisions. Looking across their customer base, they may see an unusual volume of high-risk products being purchased by different people but delivered to the same address, a common tactic when using “mules” to disguise fraudulent purchases.

III. RESEARCH AGENDA

The sections above articulate the motivation for change and describe the challenges encountered so far in the improvement of credit card fraud detection. In particular, Section II provides details regarding the context within which an effective fraud detection solution must operate. In this section we introduce a number of key concepts and developments within XAI that the authors argue would contribute towards a step-change in its adoption for credit card fraud investigations.

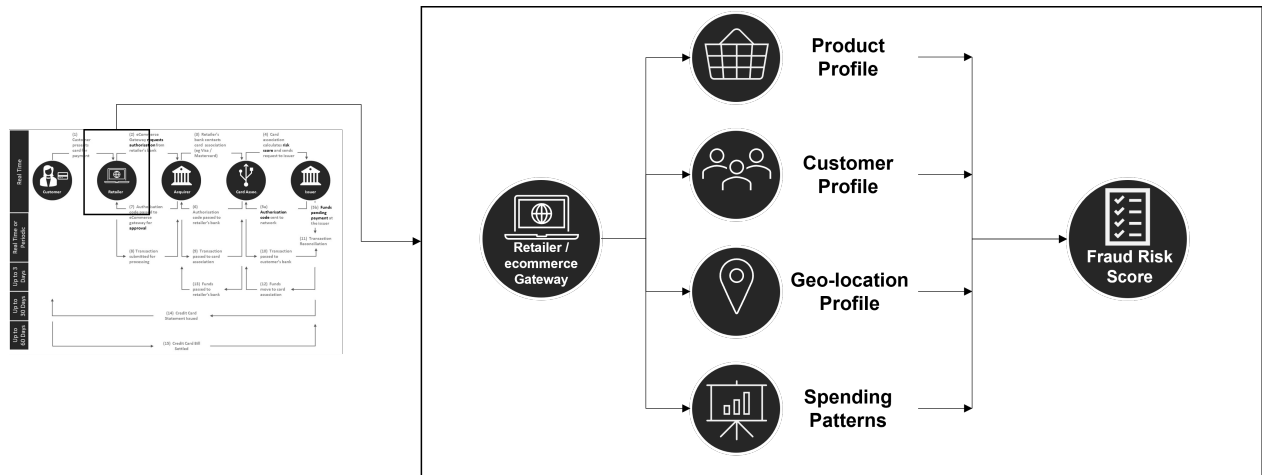

Fig. 4. Drill-down into the Retailer / e-commerce gateway process for fraud risk scoring.

To ascertain current trends in this domain, the Scopus database was employed as a primary source for gathering literature. A query identified computer science articles which were written in English and used the phrase "credit card fraud" in their key words. The resulting population of 181 articles were then filtered using reviews of the (1) title (2) abstract and (3) textual detail to focus on papers that are specifically concerned with the implementation of models in the domain of credit card fraud detection. In particular, papers which primarily focused on the generic development of models, only using a credit card fraud dataset as illustration of their techniques, were excluded from the survey. This filtering process resulted in a population of fifty-three papers, which subsequently grew to fifty-six following the addition of three papers identified by means of a snowballing technique.

Table II provides a selection of papers extracted from the full dataset. These papers consider at least two of the aforementioned operational challenges in their work. For completeness, the full table can be made available by contacting the authors of this paper. The table is complemented by Fig. 5a and 5b which summarise the full dataset.

A. Explanations within a Specific Context

Section II-B introduces the practical constraints of real-time analysis, managing unbalanced data and concept drift and minimising false positives which need to be considered in order for a model to be operationalisable. These contextual requirements of credit card fraud detection are perhaps more complex and multi-faceted than many fields. Additionally, Section II-C highlights a variety of fraud investigation approaches which provide transparency on the root causes of the fraud detection. Unfortunately, it is rare for scholars to acknowledge or clarify the timing and perspective within which their model is intended to operate, and the field of credit card fraud detection is no exception.

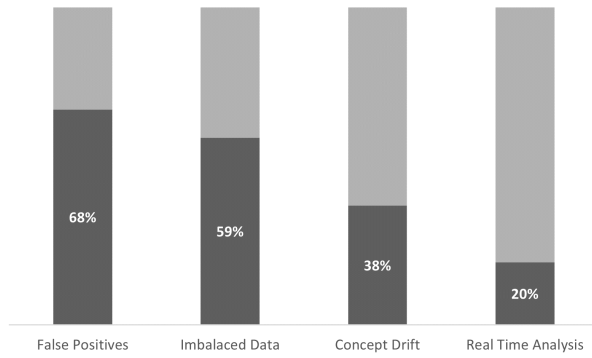

Fig. 5a and 5b show the resulting analysis of the literature population, with a view to understanding the extent of its coverage of the real world challenges discussed in Section II-B. Scholars demonstrate a strong awareness for incorporating the challenges of false positives and imbalanced data in their

papers (Fig. 5a) yet the majority fail to account for the difficulties brought about by the need to consider concept drift and real time analysis.

Fig. 5b particularly draws attention to the fact that the literature has so far failed to address any of these challenges, or even combinations of these challenges, in a consistent manner. In fact, five papers within the literature corpus failed to recog-

Fig. 5. Literature coverage of real world credit card fraud challenges.

nise any of the aforementioned challenges, whilst professing to deliver an implementable solution. In contrast, only two papers addressed all four of the aforementioned challenges [46], [47], with forty-two papers (75%) acknowledging two or fewer than two of them.

This analysis supports the argument that the current population of literature fails to take the contextual requirements of the credit card fraud operating environment into account when designing AI solutions. To encourage more ubiquitous adoption, scholars need to demonstrate an understanding of operational challenges and incorporate innovative solutions into their models. Authors also suggest that more rigour can be achieved by partnering with practitioners to deliver a testing strategy that mimics the operational environment [16].

Whilst scholars seeking to apply ML techniques in this domain might choose to specialise on a single challenge such as having unbalanced data or concept drift, demonstrating that the model is implementable in an operational environment (i.e. meets *usability* requirements) is key to achieving rigour and therefore ensuring more widespread acceptance [16].

Just as the contextual considerations of ML models are necessary for improving organisational adoption, the overarching consensus for XAI is that explanations are also contextual [82]. That is, in order for an agent to deliver a successful explanation, the context of the question must first be determined, and then addressed within the explanation itself. But what is meant by context, in the field of XAI, and how can it be achieved?

Whilst the literature contains a panoply of papers suggesting frameworks for the context of an explanation [18], [83]–[86], few provide an initial definition of what context means in the domain of XAI. Yet it is clear that the domain would benefit from a common vocabulary in order to move forward [15], [16]. In the absence of a normative definition, this paper proposes the following:

Context in XAI is any information needed by the explanation system to satisfy the explanation goals, trust and usability expectations of the audience.

This definition brings together four key elements of context frequently discussed in the literature. First it leverages the centrality of the audience [25], [87]–[90] since it is the audience who determines whether the explanation is a good one or not [16]. Second it captures the importance of understanding the goals of the audience, [85], [91] since it is the goals that drive the ML model design [85], [91], [92]. Third it recognises the value of ensuring trust in the explanation [17], [21], [93] since trust enables the audience to decide whether or not to have confidence in the results [21], [22]. Finally, by acknowledging the importance of usability [15], [82], [94], [95] the definition ensures that the system is more likely to be successful in an operational context [16], [94], [96].

Hence, the first recommendation for contributing towards a step-change in credit card fraud is to ensure that XAI models are designed with the context in mind. Demonstrating adherence to usability constraints such as real-time delivery, minimising false positives and supporting concept drift will encourage practitioners to see the potential rewards that XAI can bring over extant rule-based methods. An understanding of the audience goals will help scholars to develop XAI models that target practitioner desiderata and reflect the needs of real problems.

B. Increase Focus on Intrinsic Models

Section I-C introduces the concepts of intrinsic and post-hoc XAI models. For credit card fraud, the determination of fraudulent transactions can have a significant impact on a person's life and well-being. A false positive result could cause emotional distress such as shame or embarrassment as well as practical difficulties such as being unable to purchase goods. On the other hand, a false negative result fails to identify a transaction as fraudulent and results in financial consequences for the credit card holder, retailer or issuer. The serious consequences that could arise as a result of the fraud detection model forces the need for absolute trust that the explanation correctly interprets the decision-making within the model. Some authors suggest that models used for high stakes circumstances such as these should employ an intrinsic rather than post-hoc design [23].

Arguments supporting the use of intrinsic models leverage their ability to overcome the difficulties associated with black box models and their post-hoc explanations. The overriding challenge of black box models is their inherent opacity which undermines the ability of an individual to decide whether or not they can trust the model’s output. Moreover, the layering of a post-hoc explanation over the black box model introduces additional trust challenges. Since the post-hoc model, by definition, cannot provide a true 100% explanation of its underlying black box model, then there must be an element of uncertainty as to whether or not the explanation is correct. An individual faced with a black box model and post-hoc explanation therefore has two trust challenges to overcome:

- 1) Can the model be trusted to produce an accurate output?
- 2) Can the explanation be trusted to be faithful to the model?

In contrast, intrinsic models are sufficiently transparent that an individual can understand not only the most influential variables in the dataset, but also how those variables interact with other variables. Furthermore, the explanation, by design, directly reflects the model machinations, thereby enabling an easier decision as to whether or not to trust the output.

Unfortunately, there is a strong bias in the extant literature against the development of intrinsic models, meaning that focus is not forthcoming. Analysis of Guidotti’s [97] comprehensive survey of explainability methods identifies a slim population of 10 papers devoted to this approach, compared to 130 using post-hoc methods. Those findings are consistent with the analysis of literature conducted in this survey. Only seven of the fifty-six papers focus on the development of models which are inherently interpretable. The remaining forty-nine either propose black box models, or complex ensemble models without any attempt to explain the resulting outcomes.

There may be many reasons for this. Some authors suggest intrinsic models sacrifice accuracy for interpretability, [20], although other authors vehemently contest the notion [23]. Perhaps some scholars take pride in the complexity of black-box models ignoring the practical advantages that a transparent model would bring. Alternatively, authors designing models without a specific use-case in mind may prefer the advantages of flexibility that accompany a post-hoc, model-agnostic design.

Despite the cloak of simplicity that accompanies intrinsic models, they have many operational challenges that would benefit from scholarly focus [23]. It is not the intention of this discourse to argue a preference for intrinsic models over post-hoc techniques but to highlight that the field would benefit from increased focus and visibility. More work needs to be done to investigate the opportunities of intrinsic models in the fields of high-stakes decision-making where faithfulness to the underlying model has both an academic and moral imperative.

1) *Interpretable scoring systems:* A noteworthy subgroup of intrinsic models are interpretable scoring systems, used in decision-making and risk evaluation. Decision-making typically involves the careful evaluation of a number of diverse facts in order to arrive at a balanced decision. For example, medical professionals often weigh-up a number of discrete

Physiological parameter	Score						
	3	2	1	0	1	2	3
Respiration rate (per minute)	≤8		9–11	12–20		21–24	≥25
SpO ₂ Scale 1 (%)	≤91	92–93	94–95	≥96			
SpO ₂ Scale 2 (%)	≤83	84–85	86–87	88–92 ≥93 on air	93–94 on oxygen	95–96 on oxygen	≥97 on oxygen
Air or oxygen?		Oxygen		Air			
Systolic blood pressure (mmHg)	≤90	91–100	101–110	111–219			≥220
Pulse (per minute)	≤40		41–50	51–90	91–110	111–130	≥131
Consciousness				Alert			CVPU
Temperature (°C)	≤35.0		35.1–36.0	36.1–38.0	38.1–39.0	≥39.1	

NEW score	Clinical risk	Response
Aggregate score 0–4	Low	Ward-based response
Red score Score of 3 in any individual parameter	Low-medium	Urgent ward-based response*
Aggregate score 5–6	Medium	Key threshold for urgent response*
Aggregate score 7 or more	High	Urgent or emergency response**

Fig. 6. National Early Warning Scores (NEWS2) for assessing and responding to acute illness severity in the NHS [100].

facts about a patient before suggesting or even investigating a potential medical diagnosis, or finance professionals might weigh-up a number of different factors about a client before deciding on whether or not to offer them a loan. The accumulation and evaluation of these discrete facts are synonymous with domains requiring expert judgment. Heuristics are established through experience and expertise with simple techniques such as linear regression often being used to establish relationships between these pre-defined features and their classifier.

These aforementioned heuristics are known as “scoring systems”. Their popularity stems from the fact that decision-makers find them easy to understand and interpret [98]. Moreover, the input variables can easily be flexed to reveal the consequential impact on the predictor variable, and the model presents a common language for standardisation of reporting and comparison of results. Fig. 6 shows the scoring system mandated by NHS England for the assessment of patients presenting to, or being monitored in hospital. The lower table indicates the response that a patient should receive depending upon the medical staff’s assessment of the eight key variables in the upper table.

The transparency and uniformity of this approach has the added incentive of enabling the model to be transferable to other similar circumstances, as shown by [99] who demonstrated its effectiveness at also predicting short-term mortality as a result of Covid-19. However, the challenge of employing expert-led heuristic risk scores lies in the lack of a *formal guarantee* [101] that the heuristics are the right ones.

Recent experiences in AI demonstrate that oftentimes it is beneficial to ignore human experiences and instincts, and to instead be open to new discoveries and findings. One such example is the application of reinforcement learning to playing strategy games such as chess and Go. The initial approach was to use supervised learning techniques to “teach” the AI the strategies which had been learned by generations

of experts, but this only resulted in minimal improvements upon human levels of expertise. The step-change occurred when reinforcement learning techniques allowed the AI to learn for itself without human interference [102], resulting in significantly improved performance and the discovery of some novel game-winning strategies.

With this in mind, [103] introduce RiskSLIM (Risk-calibrated Supersparse Linear Integer Model) which learns from data, rather than experience and heuristics, to deliver a risk scoring system. The model not only works efficiently but is also able to be sensitive to organisational constraints such as minimising false positive results. Meanwhile it retains interpretability and enables expert decision-makers to flex the model prior to concluding on the overall risk assessment.

There are clear parallels to be drawn between the domains of medical risk assessment and credit card fraud detection. Both domains suffer from issues with unbalanced data, need to prioritise model efficiency and minimise false positives. Moreover, they require experts to have a full understanding of the drivers influencing the risk assessment.

Section II-C describes the four key dimensions which contribute to the holistic picture of a credit card transaction. Each dimension would be expected to have a risk score of its own and then be accumulated to produce an overall transaction risk score, in a similar manner to that presented in Fig. 6 [55], [57]. From the surveyed articles, six papers proposed a risk score as a decision-making tool as opposed to a binary classification approach. These papers were also more likely to have collaborated with industrial partners in their research, demonstrating the validity of risk scores being more aligned to a real-world perspective.

The survey also shows evidence that authors are increasingly looking beyond the single dimension of transaction spending patterns. Of the fifty-six surveyed papers, twenty-two of them incorporated customer profiling within their work. However, the inclusion of product profiles and geo-location profiles remains elusive.

Unfortunately, research into risk scoring systems which learn for themselves is scant. There are very few competitors to RiskSLIM to enable a sufficiently rigorous discourse. This is despite the successful practical applications which have been achieved by contemporary authors in the medical domain. For example, [104] collaborated with the World Health Organisation (WHO) to demonstrate its effectiveness in screening for adult attention-deficit/hyperactivity disorder and more recently [105] showed its effectiveness in screening for seizures in hospitalised patients. Given the ubiquity of scoring systems in use across multiple industries, and specifically their aforementioned relevance in fraud detection, the domain would benefit from more attention from scholars. In particular, it would be beneficial to explore applications for RiskSLIM outside of the medical domain, in addition to the development of alternative models to challenge the hegemony of RiskSLIM as a self-learning risk scoring system.

C. Measure the Faithfulness of Explanations

Assuming a researcher chooses to engage in the development of a post-hoc explanation technique, then common

sense dictates that the explanation must accurately represent the reasoning process behind the model's prediction. This close relationship between the explanation and the underlying reasoning process is often referred to as faithfulness [19], [21], [106] or fidelity [97].

It has been shown that without some measure of faithfulness of an explanation, an audience may be prone to over-trust and misuse explanation tools. This circumstance was exemplified by [107] who performed a contextual inquiry and survey of data scientists using the InterpretML implementation of Generalised Additive Models (GAMs) and the SHAP Python software package. Their investigation found that some users were using the tool to rationalise suspicious observations instead of just understanding the underlying model. Others were taking the visualisations at face value instead of using them to identify issues with the dataset. Moreover, the open-source nature of both tools led individuals to trust the explanations without fully understanding them.

Efforts to measure faithfulness are nascent, with few works in publication more than five years ago. In [108] the authors used a Natural Language Processing (NLP) model called NILE (Natural language Inference over Label-specific Explanations) to demonstrate that model faithfulness and model accuracy can co-exist. Their paper used a sensitivity analysis to evidence the faithfulness of their model. Building on that concept, [109] suggest that sensitivity should be accompanied by stability to determine whether or not an explanation is faithful.

In an effort to extract consistency from the diverse literature, [106] perform a review of faithfulness works. They identify (but do not necessarily endorse) three assumptions that they say researchers are making in order to determine faithfulness:

- 1) **The model assumption** Two models will make the same prediction if and only if they use the same reasoning process.
- 2) **The prediction assumption** On similar inputs, the model makes similar decisions if and only if it provides different interpretations for similar inputs and outputs.
- 3) **The linearity assumption** Certain parts of the input are more important to the model reasoning than others. Moreover, the contributions of different parts of the input are independent from each other.

In their discourse, [106] argue that the binary approach to determining faithfulness is fraught with difficulty since counter-examples will likely always exist. Instead, they suggest that authors should consider degrees of faithfulness to give an indication of how close an explanation is to the reasoning process of the underlying model.

Section III-B suggests there are two trust challenges that need to be overcome in order to be comfortable with the output of a black box model and its explanation. The issue of faithfulness is central to the second trust challenge. Nowhere is that trust more necessary than in high-stakes industries where the consequences of an incorrect or mis-interpreted explanation can be highly damaging. Whilst explanations may only be required under certain circumstances (for example in the event of an unexpected model outcome), there exists a moral

obligation to associate an explainable model in high stakes decision-making with some measure regarding the expected accuracy of the explanation to the ground truth.

D. Human Interaction with Explanations

In a recent call for closer integration between the Human-Computer Interaction (HCI) and ML communities, [90] cites the advantages to intelligible machine learning of leveraging the well-established human-centered research community. The cornerstone of HCI philosophy begins with understanding the needs of the audience, recognising that different audiences may have different requirements of the same system.

In the context of fraudulent transactions this paper adapts the work of [86] to suggest there are three key audiences for the explanation system:

- 1) The operator / executor i.e., the fraud analysts, whose role it is to determine the validity of the positive “red flag” transactions identified as potentially fraudulent.
- 2) The creator i.e., the technical support responsible for the internal operation of the system.
- 3) The examiners i.e., the senior management teams, who are focused on both the changing trends of fraud patterns and the integrity of the fraud identification process.

Critically, in the event of a transaction being deemed to be likely fraud, the cardholder should not be informed of the entire explanation without operator oversight, hence the omission of decision-subjects and data-subjects. This is because organisations within this process must take care not to advise fraudsters of the parameters in place to detect fraudulent transactions. It would therefore be incorrect to consider the cardholder as one of the parties requiring the direct explanation.

For the fraud analyst, the explanation is in place to ensure they fully understand, and agree with, the reasoning for the FMS to identify the transaction as fraudulent. They are detecting and looking for causal reasoning of an event which has already occurred. Hence their dialogue centres around local, causal explanations and the fitness of the attributes contributing towards each individual “red flag”.

Technical specialists meanwhile are interested in “how”, rather than “why” [110]. Their role is to ensure the system is operating effectively, for which they need transparency of the process rather than justification of an outcome. These teams will therefore look towards a causal attribution explanation in order to understand the internal workings of the explanation agent.

On the other hand, senior management teams are interested in fraud preventative measures [111]; explanations which shed light on predictive patterns. They may be searching for insight on emerging trends of fraud, in order to support future decision-making. Alternatively, they may be interested in validation that the models treat all data subjects equitably. Hence they need both local and global explanations; local to explain specific predictions and global to understand the model as a whole.

Identifying such diverse audiences and their corresponding perspectives provides a wealth of opportunities for researchers

to explore a variety of targeted explanations in fraud detection. Yet the HCI community, and increasingly the ML community too, suggest that scholars should go a step further in their quest to satisfy audience desiderata. In particular, the explanation should also reflect contemporary understandings of how an audience engages with an explanation [87].

Miller’s [87] seminal paper makes the case for ensuring researchers design explanations with an appreciation of human cognition in mind. It builds upon an earlier paper [82] which articulates the importance of comprehension in order to ensure the explanation is useful to the intended user in a practical setting. This view is widely held [16], [17], [93], [112].

Cognitive scientists claim that prior knowledge is widely recognised to have a profound influence on understanding new concepts [113]. Hence for an effective explanation, the explainer must first understand the audience’s initial level of existing knowledge. Any subsequent new information then builds upon that baseline [114], [115], incrementally constructing a bridge to a new knowledge state. This individualised layering of new knowledge on old becomes synonymous with explanation as a dialogue, wherein the audience repeatedly questions the explanation agent until a point of understanding is reached.

However, building knowledge in this way only allows for the audience to learn from the explanation agent. In fields such as fraud detection, there are also likely to be instances where experts have more knowledge than the explainer, resulting in them outperforming the system-generated explanation [116]. In this circumstance, explanations should therefore be a two-way concept. Whilst we look to XAI to communicate unknown patterns and influences extracted from the prescribed data, the expert audience adds breadth, supplementing the explanation with their own peripheral knowledge and undocumented experiences. Hence in expert systems, designing explanation with an interactive dialogue in mind allows for the development of a “learning loop”, which ultimately enhances the performance of both the XAI agent and the audience [116].

IV. CONCLUSION

Credit card fraud is widely acknowledged as a key contributor to the persistence of organised crime in the European Union. Moreover, the recent Covid-19 pandemic has accelerated the switch to digital payments and revealed the potential of a future cashless global society. As the use of payment cards continues to overtake the use of cash in our economy, the ability of payments providers to reduce the value and volume of fraudulent transactions becomes ever more crucial.

Regulators acknowledge this danger and are working to introduce increasingly stringent legislation to counteract the trend. In particular, they are leveraging the vast quantities of data available in our modern society to encourage more effective financial defences. As part of the PSD2 regulation, SCA has recently been enforced in Europe and the United Kingdom. SCA mandates real-time data analysis and the introduction of authentication enrichment data, both of which combine with recent developments in open banking and payment technologies to create an urgent need for change in the detection of fraudulent credit card transactions.

The overarching consensus is that established rule-based fraud detection methodologies are no longer scalable to the extent that modern society needs them to be. Moreover, they struggle to provide the flexibility or agility to adapt to either the rapidly changing operating environment or dynamic modus operandi of modern fraudsters. ML models have the ability to provide a solution to these challenges, yet their opacity has impeded their adoption in this domain.

In response, this paper argues for more researchers to engage with investigations into the use of XAI techniques for credit card fraud detection. It contributes to the discourse in three key ways:

- 1) It sheds light on recent regulatory changes which are pivotal in driving the adoption of new ML techniques.
- 2) It examines the operating environment pertaining to CNP credit card transactions, an understanding of which is crucial for the ability to operationalise ML solutions.
- 3) Using a survey of contemporary literature, it sets out a research agenda, arguing that further work would contribute towards a step-change in the adoption of ML into this industry.

The research agenda first suggests that the current literature fails to consistently accommodate the key contextual challenges of real-time analysis, concept drift, minimising false positives and dealing with class imbalance. These omissions lead to solutions which are not operationalisable, thereby undermining the relevancy of the work. Incorporating context fully into an XAI solution would support more wider adoption, yet recent papers in XAI have struggled to articulate the full meaning of context in this field. The first agenda point therefore provides a novel definition of the term "context" in relation to XAI and goes on to suggest that researchers should always design XAI models with context in mind.

Second, it recommends that more work should be done to examine the utility of intrinsic models and in particular focus on the under-researched area of self-learning risk scoring systems. Contemporary literature generally demonstrates a bias towards the development of post-hoc rather than intrinsic models. A popular argument suggests this is because black box models are more accurate than their interpretable counterparts. Yet this statement remains controversial for some authors, especially in light of the need for trust and transparency in high-stakes decision-making. Increased attention from scholars will help to progress this debate and may help to challenge the hegemony of incumbent risk scoring systems.

Third, it recognises that authors should consider implementing measures of faithfulness to give an indication of how close an explanation is to the reasoning process of the underlying model, and thereby help to establish trust in the explanation. Previous authors have demonstrated the tendency for an audience to over-trust and mis-use explanation tools without some measure of faithfulness. Its inclusion as an evaluation tool is particularly pertinent in the field of high-stakes decision-making such as fraud detection, where the consequences of an incorrect decision can be damaging to multiple parties.

Finally, it suggests recognising the value of human expert knowledge in this domain and incorporating an ability

to provide a "learning loop" which ultimately enhances the performance of both the XAI agent and the audience. The current corpus of literature recommends that explanations should not only be designed with the audience in mind, but also recognise the nuances of human cognition in order to deliver an explanation that is useful to the intended user in a practical setting. The explanation should subsequently evolve into a dialogue, wherein the audience can repeatedly question the explanation agent until a point of understanding is reached, and likewise contribute expert knowledge into the model to enhance mutual understanding.

ACKNOWLEDGMENT

The authors would like to thank the reviewers for their valuable feedback.

This research received no specific grant from any funding agency in the public, commercial or not-for-profit sectors.

Detecting Pneumonia with a Deep Learning Model and Random Data Augmentation Techniques

Tawfik Guesmi

Department of Electrical Engineering, College of Engineering University of Ha'il
Ha'il 2240, Saudi Arabia

Abstract—This research paper presents an investigation into the detection of pneumonia using deep learning models and data augmentation techniques. The study compares and evaluates the performance of different models based on experimental results. The proposed model consists of multiple convolutional layers and maxpooling layers. Extensive experiments were conducted on a dataset, and the results demonstrate the efficiency and accuracy of our approach. The findings highlight the potential of deep learning in pneumonia detection and contribute to the existing body of knowledge in this field. The implications of this research can have a significant impact on improving diagnostic accuracy and patient outcomes. Future research directions could explore further enhancements in the model architecture, investigate additional data augmentation techniques, and consider larger datasets for more comprehensive evaluations.

Keywords—Deep learning; pneumonia detection; convolutional neural network; random data augmentation

I. INTRODUCTION

The capabilities of e-health tools have been recently boosted and improved by advances in artificial intelligence (AI) that allows the detection and diagnosis of diseases. Artificial intelligence is not a newly-invented technique. In fact, it was prefigured in a chess computer program that was generated by Alan Turing in 1950 [1]. The health sector has not been deprived of these technological advances. Indeed, there has been considerable and growing interest in this health sector and especially in the automatic detection of diseases from medical images. As a subdomain of AI, machine learning makes use of algorithms so as to parse data, gain an understanding from the results, and apply the learning to make decisions and predictions. Thanks to the rise in computing power and the availability of huge datasets, researchers have proposed many new approaches of smart healthcare disease diagnosis and patient management by using machine learning and especially deep learning algorithms. We note that machine learning algorithms have been developed to detect objects or faces, to assist in healthcare, traffic prediction, natural disasters prediction, etc. In our research work, we are focused on the healthcare services by incorporating AI through disease detection and prediction using machine learning and deep learning. The proposed approach harnesses the benefits of AI-based systems in the medical diagnosis field by replicating human brain function for simple tasks and providing innovative solutions for more complex ones. Towards reaching our objective, we recommend implementing AI-based solutions. Our primary algorithmic approach includes machine learning, particularly deep learning algorithms, which provide computational models for learning data representations. We note that these algorithms have greatly

improved previous disease detection and recognition efforts [2].

Deep learning reveals a complex structure in high-dimensional data such as images and videos by using the back-propagation algorithm. The goal is to help a machine regulate its internal parameters to enable it to generate a configuration in each layer from the previous one. Being the most representative model of deep learning, CNN has been broadly put in application in many research areas, such as image classification, face recognition and object detection. It's composed of the input layer, hidden layers (at least one), and an output layer. Constructing a typical CNN takes some steps. The starting phase involves two types of layers: convolutional layers and pooling layers. In the proposed approach, a convolutional layer contains filters characterized with parameters that should be learned. Thus, the filters' height and weight tend to be inferior to those of the input volume. Then an activation map based on neurons is computed by convolving each filter with the input volume. The concluding phase consists in obtaining the convolutional layer's output volume. This is achieved by stacking all filters' activation maps along the depth dimension [3].

The proposed CNN architecture, along with the well-known pre-trained models DenseNet and MobileNet, is evaluated and compared in terms of their matching performance and computational cost. Furthermore, the incorporation of random data augmentation techniques enhances the model's ability to generalize to new and unseen images, improving its robustness and reducing the risk of overfitting. The experimental results demonstrate that the proposed CNN model outperforms the existing models in terms of accuracy and provides a promising solution for accurate and efficient pneumonia detection. By highlighting the value of this paper, we contribute to the advancement of AI-based systems in medical diagnosis, specifically in the detection and diagnosis of pneumonia, which can lead to improved healthcare outcomes, more timely treatments, and ultimately, saving lives.

The main objective of the proposed approach is to detect pneumonia from chest X-ray datasets. Convolutional neural networks (CNNs) are effective tools for image understanding and are widely used in medical image analysis. For these reasons, we have used two very well known and very successful CNNs which are: DenseNet and MobileNet in order to test them to detect pneumonia disease. The results obtained were compared to our CNN model. For this, we used four different datasets to validate the results. Note that we have used different data augmentation techniques to overcome the problem of limited datasets [4]. In many computer vision tasks,

the original dataset may be limited in size and may not reflect the variability of the real-world scenarios. For example, in an image classification task, the model may only see pictures of dogs taken from one angle and with a specific resolution. This lack of diversity in the training data can lead to poor performance when the model encounters new, unseen data. The main contribution and results are:

- The proposed CNN model, DenseNet and MobileNet showed performance improvements on augmented datasets.
- Our CNN model performed better than the other models.
- The results were validated on four different datasets. A comparative table has been drawn up for this purpose.
- We used random data augmentation techniques such as randomly flipping, zooming, shifting, and rotating images which can be highly beneficial for training image processing and computer vision models. These techniques can help to artificially increase the size of the training dataset and expose the model to a wider variety of image variations. It improves the model's ability to generalize to new images, making it more robust and less prone to overfitting.

In fact, using the classic techniques of data augmentation can be less beneficial as the model will be exposed only to the flipped version and it may not generalize well to the original version of the image in the case of the flipping technique. However, randomly flipping images can be more beneficial. It is important to expose the model to a diverse set of training data. Randomly flipping images horizontally or vertically can be a way to artificially increase the diversity of the training dataset by creating new images from existing ones. By randomly flipping images, the model is exposed to both the original image and its flipped version, which can help it learn to recognize objects regardless of their orientation.

Previous research in pneumonia detection has primarily focused on traditional machine learning algorithms and a limited set of image features. These approaches often struggle to capture the complex patterns and variations present in chest X-ray images, resulting in suboptimal performance and limited generalization capabilities. Furthermore, the use of pre-trained convolutional neural networks (CNNs) in this domain has been limited, and their potential for pneumonia detection remains underexplored. In this paper, we aim to address the gap between the existing approaches and the potential for leveraging deep learning techniques, specifically CNNs, for improved pneumonia detection. Our proposed work presents a detailed review of various CNN architectures, including well-known models such as DenseNet and MobileNet, and their characteristics. We then introduce an efficient CNN architecture for pneumonia detection using X-ray images, incorporating random data augmentation techniques. By leveraging the power of deep learning and exploring the potential of CNN models, we aim to overcome the limitations of existing approaches and achieve enhanced performance in pneumonia detection.

This paper is organized as follows: Section II explores the related research done in the same field. In Section III,

there is a brief description of the two deep convolutional neural networks: DenseNet and MobileNet. In Section IV, the description of the applied methodology and the proposed CNN architecture. Section V presents the experimental result and performance analysis. Finally, Section VI shows the results and discussion and Section VII concludes this paper.

II. RELATED WORKS

In recent years, deep learning has opened up horizons for researchers in the field of medical sciences. Published research is promising. These studies were done to test the detection, prediction and diagnosis of disease. Today, the enormous progress and advances of CNNs have attracted the attention of researchers to apply them in many fields. Medical research is one of the most sought-after fields. All the details and features in a medical image are of high importance in the machine learning pipeline. The problem is that most known ML algorithms used classical features to develop detection and recognition systems [5]–[7]. In contrast, the use of deep learning (DL) models, in particular convolutional neural networks (CNN), has demonstrated a strong ability to extract relevant features in the image classification framework [8], [9]. Image classification can be significantly improved if we have a very rich set of extracted features. Indeed, the availability of pre-trained CNN models like MobileNet [10], AlexNet [11], ResNet [12] and DenseNet [13] speeds up and improves the relevant feature extraction procedure. Several interesting research papers on the disease of pneumonia have been published with the aim of classifying chest X-ray images [14]–[19]. In [20], authors implemented a deep convolution neural network on more than 100 thousand x-ray images of approximately 32,000 in order to analyze and recognize pulmonary infection and its subtypes. In [21], Amit Kumar et al. implemented a Mask-RCNN which performed a combination of pulmonary image segmentation and an image augmentation. They started by testing known detection techniques such as YOLO 3 and U-Net but the results were not motivating. They then proposed their own model based on Mask-RCNN and showed in the experimental results that the proposed identification model achieves better performance.

In order to take advantage of the characteristics of the Inception V3 model, authors, in [22], have implemented a CNN model based on Inception V3. The authors were able to successfully classify various types of pneumonia infections on pediatric patients. They developed a new CNN model not only to classify images into class of sick people and non-sick people but also to classify images showing pneumonia disease into two categories: pneumonia caused by bacteria and pneumonia caused by a virus.

A novel approach for automatic detection of pneumonia was proposed by Anuja Kumar et al. in [23]. In fact, they proposed a deep Siamese neural network by analyzing the amount of white substance presence on both the right and the left chest of X-ray image. In their approach, Paras et al. [24] were inspired by pre-trained AlexNet and GoogleNet data models as well as data augmentation. The authors in [25], developed numerous models in order to validate an accurate result in detecting pneumonia. They trained AlexNet, LeNet, GoogleNet, ResNet, and VGGNet on a dataset of over 26 thousand images of a resolution of 1024x1024. Vikash et

al. proposed a novel approach for detection of pneumonia based on transfer learning and ImageNet model [26]. In [27], pneumonia was one of 14 different diseases that were detected using a 121-layer CNN on chest x-rays. In [28], authors developed an automated diagnosis of pneumonia by classifying X-ray images using deep CNN. They showed that the proposed model reached 91% of accuracy. In [29], authors proposed a novel deep convolutional neural network architecture to extract relevant features from chest X-ray images and classify them into two classes. They also studied in their paper, the influence of the size of the dataset on the performance of the model. They used the original dataset as well as its augmented version.

III. DEEP CONVOLUTIONAL NEURAL NETWORKS

A Convolutional Neural Network (CNN) is composed of neurons with varying weights and biases. These neurons receive inputs from preceding layers, producing a fast and precise algorithm [30], [31]. CNNs have proven to outperform traditional neural networks in detection and classification tasks, as seen in their successful classification of well-known image databases such as MNIST [32], [33] and CIFAR 10 [34], [35].

A. Convolution Layer

A convolution layer in deep learning is a layer in a neural network that performs a mathematical operation called convolution on the input data. The convolution operation involves sliding a small matrix (the "filter" or "kernel") over the input data and computing a dot product at each position, producing a feature map that represents important information from the input. This operation is repeated with multiple filters, effectively learning different features at different scales, and allowing the network to learn complex representations of the data. Convolution layers are commonly used in computer vision tasks, such as image classification and object detection. The formula for computing a single output element in a convolution operation is given as follows.

$$O_{i,j} = \sum_{m=0}^{k-1} \sum_{n=0}^{k-1} I_{i+m,j+n} \cdot F_{m,n} \quad (1)$$

where $O_{i,j}$ is the (i, j) th element of the output feature map, $I_{i,j}$ is the (i, j) th element of the input feature map, $F_{m,n}$ is the (m, n) th element of the filter (also called kernel) matrix and k is the size of the filter. This formula is applied element-wise for each position of the filter over the input feature map, with the result being a new output feature map that represents the filtered version of the input.

B. Activation Function

An activation function in deep learning is a non-linear function applied to the output of each neuron in a neural network. The activation function is used to introduce non-linearity into the model, allowing it to model complex relationships in the data. There are several commonly used activation functions, including (Fig. 1):

- Sigmoid: $f(x) = \frac{1}{1+e^{-x}}$
- Tanh: $f(x) = \tanh(x)$
- ReLU (Rectified Linear Unit): $f(x) = \max(0, x)$

- Leaky ReLU: $f(x) = \max(0.01x, x)$
- Softmax: used for multiclass classification, maps inputs to a probability distribution over the classes.

C. DenseNet

DenseNet is a network architecture characterized by the fact that each layer is directly connected to all the others. Feature maps from all layers that precede another are treated as separate inputs. On the other hand, the layers following any layer, are fed by its own feature maps. This connectivity model gives state-of-the-art accuracies on CIFAR10/100 (with or without data augmentation) [13], [36]. It's architecture is detailed in Table I.

TABLE I. DENSENET ARCHITECTURE

Layers	Output Size
Convolution	112x112
Pooling	56x56
DenseBlock (1)	56x56
Transition Layer (1)	56x56—28x28
Dense Block (2)	28x28
Transition Layer (2)	28x28—14x14
Dense Block (3)	14x14
Transition Layer (3)	14x14—7x7
Dense Block (4)	7x7
Classification Layer	1x1

D. MobileNet

MobileNet is a CNN architecture that is among the first CNN models that aims to be deployed on mobile applications. The main innovation is that the convolutions are separable according to the depth. A separable convolution transforms a classical convolution kernel into two separate kernels. For example, a 4x4 kernel turns into a 4x1 kernel and a 1x4 kernel. The objective behind this separation is to minimize the number of operations needed to perform the convolution. Therefore, the model becomes more efficient. This model is, today, a reference for object detection, face detection, and for object classification. MobileNet model has 27 Convolution layers which includes 13 depthwise Convolution, 1 Average Pool layer, 1 Fully Connected layer and 1 Softmax Layer. This model was developed by Andrew G. Howard and other researchers from Google [10]. It's architecture is detailed in Fig. 2.

IV. THE PROPOSED CNN ARCHITECTURE

A. Layers Description

a new approach of drawing a CNN model has been proposed in order to classify chest X-ray images. The goal is to classify images into two classes: Normal X-ray image and X-ray image with pneumonia. The CNN architecture is based on:

- Convolutional layers
- Maxpooling layers

The resulting image after the last convolution/maxpooling layer is first flattened and then inserted into a dense layer.

Fig. 1. Activation functions.

Type (Stride)	Filter Shape	Input Size
Conv (s2)	3 x 3 x 3 x 32	224 x 224 x 3
Conv dw(s1)	3 x 3 x 32 dw	112 x 112 x 32
Conv (s1)	1 x 1 x 32 x 64	112 x 112 x 32
Conv dw(s1)	3 x 3 x 64 dw	112 x 112 x 64
Conv (s1)	1 x 1 x 64 x 128	56 x 56 x 64
Conv dw (s1)	3 x 3 x 128 dw	56 x 56 x 128
Conv (s1)	1 x 1 x 128 x 128	56 x 56 x 128
Conv dw (s2)	3 x 3 x 128 dw	56 x 56 x 128
Conv (s1)	1 x 1 x 128 x 256	28 x 28 x 128
Conv dw (s1)	3 x 3 x 256 dw	28 x 28 x 256
Conv (s1)	1 x 1 x 256 x 256	28 x 28 x 256
Conv dw (s2)	3 x 3 x 256 dw	28 x 28 x 256
Conv (s1)	1 x 1 x 256 x 512	14 x 14 x 256
	3 x 3 x 512 dw	14 x 14 x 512
5X	1 x 1 x 512 x 512	14 x 14 x 512
Conv dw (s2)	3 x 3 x 512 dw	14 x 14 x 512
Conv (s1)	1 x 1 x 512 x 1024	7 x 7 x 512
Conv dw (s2)	3 x 3 x 1024 dw	7 x 7 x 1024
Conv (s1)	1 x 1 x 1024 x 1024	7 x 7 x 1024
Avg Pool (s1)	Pool 7 x 7	7 x 7 x 1024
FC (s1)	1024 x 1000	1 x 1 x 1024
Softmax (s1)	Classifier	1 x 1 x 1000

Fig. 2. The detailed MobileNet architecture.

The sigmoid function is used to activate the layer where the output was introduced. Note also that the sigmoid function was used in the last layer since the classification is binary. Fig. 3 illustrates the architecture of the proposed CNN. The architecture of the proposed CNN is carefully designed to learn and classify pneumonia patterns in chest X-ray images effectively. It utilizes the hierarchical structure of convolutional and pooling layers to capture both local and global features, enabling accurate and robust predictions. The combination of convolutional and dense layers allows the network to learn complex relationships and make informed decisions based on the extracted features. Overall, the proposed CNN architecture offers a powerful tool for pneumonia detection and showcases

promising potential in medical image analysis.

Initially, the image is resized to the size of (150x150). It is then integrated into a first layer (3x3x16) of sixteen filters and dimensions (3x3). The convolutional layer is then used to decompose the image to have new dimensions of (75x75x32). The latter is integrated into the Maxpooling layer having a window size of (2x2). We finally have an image with a new size. Different layers are listed below.

- The image crosses the second dimension convolutional layer (3x3x32). We will have as output of this layer an image (38x38x64). Shape Maxpooling layer (2x2) is introduced and gives as output an image with a new shape.
- The resulting image is passed through another convolutional layer of the same dimension and which has the same shape as the previous one. In order to detect more relevant details of the image, the latter is again processed by the convolutional layer. Thus, the image reaches a new shape of (19x19x128) and it is introduced through a Maxpooling layer of dimension (2x2).
- 64 filters make up the final layer which is of the shape of (3x3x64). The resulting image has the shape (5x5x256) and will once again be introduced into the maxpooling layer. The end result is a set of finer instances of the image which will help in better classification.

In the following, we move on to the description of the second phase: the deep neural network. After passing through the last layer, the output is flattened and inserted into the Deep Neural Network (DNN). Then, it is introduced into a 128 neurons layer in order to detect the key data of the image and its relevant characteristics. The ReLU function is used as an activation function. The last dense layer of the DNN is a single output neuron. The aim is to classify the chest X-ray images into two classes: images with pneumonia and images without pneumonia.

B. Summary of the CNN Model

The proposed CNN model is summarized as follows:

- Four convolutional layers.

TABLE II. DESCRIPTION OF THE CNN MODEL.

Layer	Filter	Kernel Size	Strid	Size of feautre Maps
Input	-	3 x 3	-	150 x 150 x 3
Conv(1)	64	3 x 3	1 x 1	150 x 150 x 3
Conv (2)	64	3 x 3	3 x 3	150 x 150 x 3
Batch normalization	-	-	-	150 x 150 x 3
Pooling	-	2 x 2	2 x 2	75 x 75 x 3
Conv(3)	64	3 x 3	1	75 x 75 x 3
Dropout	-	-	-	75 x 75 x 3
Batch normalization	-	-	-	75 x 75 x 3
pooling	-	2 x 2	2 x 2	38 x 38 x 3
Conv(4)	128	3 x 3	1 x 1	38 x 38 x 3
Batch normalization	-	-	-	38 x 38 x 3
pooling	-	2 x 2	2 x 2	19 x 19 x 3
Conv(5)	128	3 x 3	3 x 3	19 x 19 x 3
dropout	-	-	-	19 x 19 x 3
Batch normalization	-	-	-	19 x 19 x 3
pooling	-	2 x 2	2 x 2	10 x 10 x 3
Conv(6)	256	3 x 3	3 x 3	10 x 10 x 3
Dropout	-	-	-	10 x 10 x 3
Batch normalization	-	-	-	10 x 10 x 3
pooling	-	2 x 2	2 x 2	5x 5 x 3

- Four Maxpooling layers.
- flattened layer of zero parameters.
- Dense layers of about 819328 parameters.
- The total number of parameters that can be trained in the network is 1,246,401 parameters.

Our model is based on the CNN model described in Table II and its architecture is detailed in Fig. 3.

C. Random Data Augmentation

In order to properly implement a CNN, a large dataset is required. In case we have a limited amount of data, we can use random data augmentation techniques which are a solution to artificially increase the amount of existing data. In the case of medical image datasets, the data is not available in large quantities. Random data augmentation is often considered to be better than classic data augmentation because it can increase the diversity of the training data in a more controlled manner. In classic data augmentation, the same transformation is applied to all instances of the data, which can lead to overfitting to the augmented data and decreased performance on the original data. On the other hand, in random data augmentation, different transformations are randomly applied to each instance of the data. This increases the diversity of the training data in a more controlled manner and can help prevent overfitting to the augmented data. By applying different transformations to different instances of the data, random data augmentation can help the model learn to recognize objects regardless of their orientation, scale, and deformation. This can improve the model's generalization ability and increase its robustness to changes in the input data. This is why we applied the data augmentation technique on our training data set. An example of random data augmentation is shown in Fig. 4, 5, 6 and 7. In fact, we added changes to our images by making minor changes, such as:

- Random rotating data: it consists of applying random rotations to images in a dataset in order to increase the diversity of the training data and reduce overfitting. This can be done by specifying a range of rotation

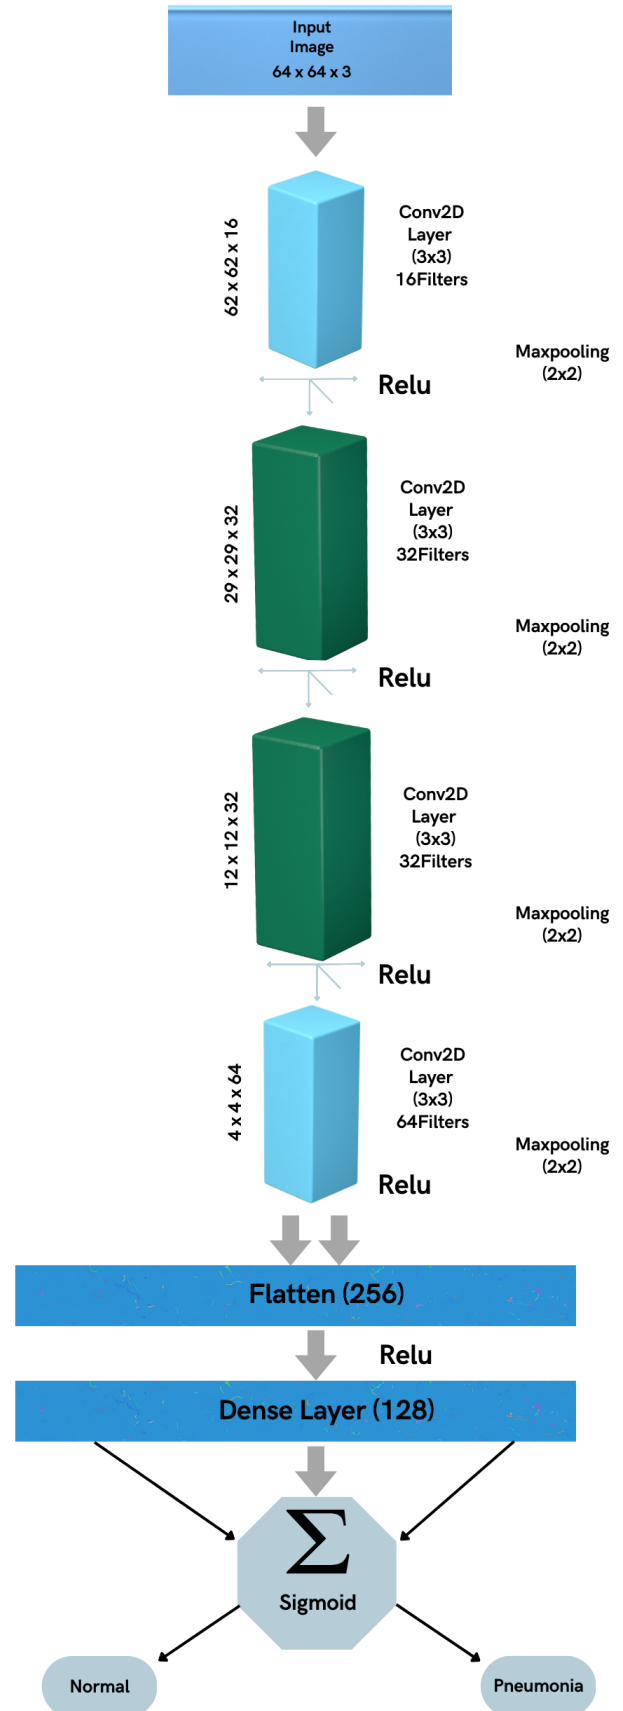

Fig. 3. Architecture of the CNN model.

angles, and then applying a random rotation within that range to each image in the dataset before it is used for training. This technique can be useful for image classification tasks, as it allows the model to learn to recognize objects in different orientations.

- **Random Zoom:** it involves randomly zooming in or out of an image by a certain percentage, while maintaining the aspect ratio of the original image. This technique can help increase the diversity of the training data and improve the robustness of the model by exposing it to different scales and perspectives of the same object. It can also help to prevent overfitting by making the model more generalizable to new images.
- **Random shifting images horizontally or vertically:** it consists of randomly shifting the position of an image by a certain number of pixels horizontally or vertically. This technique is used to simulate the effect of objects being slightly misaligned or translated in real-world scenarios. In such scenarios, a model trained on perfectly aligned images may not perform well when presented with images that are not perfectly aligned. However, by training the model on images that have been randomly shifted, the model can learn to be more robust to small changes in position and handle misalignment better.
- **Random flipping images horizontally:** the left and right sides of the image are switched. This can be done by reflecting the image across a vertical axis. The idea behind this technique is to artificially increase the diversity of the training data by exposing the model to both the original image and its flipped version. Flipping images horizontally can also be useful when the model needs to recognize objects that are symmetric across a vertical axis. For example, in object detection tasks, flipping the image horizontally and training the model on both the original and the flipped images can make the model more robust to detect the object in the image regardless of its orientation.
- **Random cropping:** the basic idea is to randomly select a rectangular region of an image, and then crop the image to that region. The cropped region is then resized to the original size of the image. We randomly select the starting and ending coordinates of the cropped region within the original image's dimensions. The cropped region is then resized to the original size of the image using interpolation to avoid distorting the image. the cropping parameters such as the size of the cropped region and the aspect ratio can be adjusted. For example, if the model is trained for object detection, the cropping area should be adjusted to keep the object of interest within the crop area. Also, when using random cropping, it is important to make sure that the entire image is covered by the crop area, otherwise important information may be lost.

We note that some data augmentation techniques are domain-specific, for example, in medical images rotating images can be harmful. In general, using a combination of different data augmentation techniques can be more effective

than using a single technique, as it can provide the model with a more diverse set of training data. This will increase the size of our training data and our model will consider each of these small changes as a separate picture. In our work we applied the data augmentation Algorithm 1.

Algorithm 1: Random Data Augmentation

```
Input : Training dataset  
Output: Augmented dataset  
Procedure  
| DataAugmentation  
end  
for each image  $x$  in the training dataset do  
|  $r \leftarrow \text{Random}(0, 1)$ ;  
| if  $r < p_{rotate}$  then  
| |  $x \leftarrow \text{Rotate}(x, \text{angle})$ ;  
| end  
| if  $r < p_{zoom}$  then  
| |  $x \leftarrow \text{Zoom}(x, \text{zoom})$ ;  
| end  
| if  $r < p_{h\_shift}$  then  
| |  $x \leftarrow \text{Shift}(x, h\_shift \times \text{width})$ ;  
| end  
| if  $r < p_{v\_shift}$  then  
| |  $x \leftarrow \text{Shift}(x, v\_shift \times \text{height})$ ;  
| end  
| if  $r < p_{flip}$  then  
| |  $x \leftarrow \text{Flip}(x)$ ;  
| end  
end  
Model.fit(Dataset);
```

In this work, we selected four different datasets where in each one we find a train folder, test folder and validation folder. Table III lists the number of images in each dataset. The datasets were selected from Guangzhou Women and Children's Medical Center [37] and they are images from pediatric patients of one to five years old.

V. EXPERIMENTAL RESULTS AND PERFORMANCE OF THE CNN MODEL

A. Hyperparameter Optimization (HPO)

To search for optimal hyperparameters of the model, random search was performed [38]. It is a method for searching for optimal hyperparameters of a training model that involves randomly sampling hyperparameter combinations from a pre-defined search space. The search space is defined by specifying a range or distribution for each hyperparameter. The outline of the algorithm for random search is as follows.

- Define the hyperparameter search space: it consists of specifying the range or distribution of possible values

TABLE III. DIFFERENT DATASETS OF CHEST X-RAY IMAGES

Data	Number of images	Training	Testing	Validation
Dataset 1	5872	4770	551	551
Dataset 2	5856	4762	612	482
Dataset 3	6896	5532	720	644
Dataset 4	4665	3672	474	519

Fig. 4. Images without augmentation.

Fig. 5. Image augmented by random translation technique.

Fig. 6. Image augmented by random flipping technique.

Fig. 7. Image augmented by random rotation technique.

for each hyperparameter.

- Initialize the random search object by creating an instance of the random search function, such as `RandomizedSearchCV` in `scikit-learn`, and specifying the model, the hyperparameter search space, the number of iterations, and other parameters such as the number of cross-validation folds.
- Generate random samples of hyperparameters by randomly sampling hyperparameter combinations from the defined search space. The number of samples is controlled by the number of iterations specified in step 2.
- Train the model with each sample of hyperparameters: For each generated sample of hyperparameters, train the model using the corresponding sample of hyperparameters and evaluate its performance using a performance metric such as accuracy or F1-score on

the validation set.

- Select the best set of hyperparameters by selecting the set of hyperparameters that results in the best performance on the validation set as the best set of hyperparameters.
- Validate the model on unseen data by using the best set of hyperparameters to train a final model and evaluate its performance on unseen data.

Hyperparameters obtained by the random search of the model were as follows. The model was trained using a batch size of 32, where 32 data samples are used to update the model's parameters in each iteration. The training process continued for 12 iterations. The early stopping technique was used to avoid overfitting, where the training process is stopped if the validation loss does not decrease for 7 consecutive iterations. This is done to ensure that the model generalizes well on unseen data.

B. Evaluation and Results

The training accuracy of a model is a measure of how well the model is able to predict the correct labels for the training data. The validation accuracy is a measure of how well the model is able to predict the correct labels for the validation data, which is a subset of the data that is held out from the training process and used to evaluate the model's performance. In general, the training accuracy of a model will be higher than the validation accuracy, because the model has seen the training data during the training process and has learned to predict the labels for those data points accurately. The validation accuracy is a more realistic measure of the model's performance, because it reflects the model's ability to generalize to unseen data. In order to determine the performance of the proposed method, we examined the accuracy, precision, recall, and F1 score. Accuracy is the proportion of correctly classified instances (True Positives and True Negatives) out of all instances. It is computed as follows:

$$Accuracy = (TP + TN) / (TP + TN + FP + FN) \quad (2)$$

Where True Positives (TP) are the number of instances where the model correctly predicted the positive class, True Negatives (TN) are the number of instances where the model correctly predicted the negative class, False Positives (FP) are the number of instances where the model incorrectly predicted the positive class and False Negatives (FN) are the number of instances where the model incorrectly predicted the negative class. Precision is the proportion of correctly classified positive instances out of all positive instances predicted by the model. It is calculated as:

$$Precision = TP / (TP + FP) \quad (3)$$

Recall is the proportion of correctly classified positive instances out of all actual positive instances. It is calculated as follows:

$$Recall = TP / (TP + FN) \quad (4)$$

F1 Score is the harmonic mean of precision and recall. It is calculated as follows:

$$F1-score = \frac{2 \cdot TP}{2 \cdot TP + (FP + FN)} \quad (5)$$

All values of accuracy, precision, recall and F1 score are listed in Table IV.

In order to assess the influence of the size of the dataset on the performance of the CNN model, we plotted the curves of Training accuracy/Validation accuracy and Training loss/Validation loss. The tests were carried out, first, on four original datasets. Fig. 8 show that the training and validation accuracy varies with the epoch count. In fact, the model is learning efficiently, the training and validation accuracy reach a plateau after the end of the 20th epoch indicating that the model has reached its maximum performance. The Training accuracy curve demonstrates the progression of the model's accuracy on the training set over successive epochs. As the training progresses, the accuracy steadily increases, indicating that the model is effectively learning the patterns and features of the pneumonia dataset. The upward trend in the curve signifies the successful optimization of the model's parameters, leading to improved classification accuracy. Similarly, the

Training loss curve illustrates the decline in the loss function during the training phase. The loss function measures the discrepancy between the predicted and actual values, and the decreasing trend of the curve indicates that the model is converging towards a better approximation of the ground truth labels. A lower loss value indicates that the model is becoming more proficient at minimizing errors and making more precise predictions. The Validation accuracy and loss curves provide insights into the model's generalization performance on unseen data. The Validation accuracy curve tracks the accuracy of the model on a separate validation dataset that was not used for training. A rising validation accuracy curve indicates that the model is not overfitting and can generalize well to new data.

Fig. 8. Training and validation accuracy/loss curves of our CNN model applied on dataset 1.

A comparison of the obtained metrics our solution with those of known models has been summarized in the Table V.

VI. RESULTS AND DISCUSSION

Note that the proposed model comprises four convolutional layers accompanied by four additional Maxpooling layers. The flattened layer of zero parameters and dense layers of about 819328 parameters come next. We thus have a total number of parameters which amounts to 1,246,401 parameters. We used two well-known and very powerful models to test the effectiveness of the proposed model. The CNN model was able to accomplish good values of Accuracy. After the augmentation of data, there was a clear improvement in the performance of all models and especially our CNN model (Table VI).

Four Chest X-ray images datasets served as the basis for our experiment. The datasets is publicly available on Kaggle, a shared data platform, and consists of 23289 real images

TABLE IV. PERFORMANCE OF THE PROPOSED METHOD

Model	Accuracy	Precision	Recall	F1-score
Our model	0.92	0.92	0.91	0.91

TABLE V. COMPARISON TABLE BETWEEN DIFFERENT MODELS

Model	Accuracy	Precision	Recall	F1-score

DenseNet121	0.49	0.50	0.48	0.49
Our model	0.92	0.92	0.91	0.91

TABLE VI. COMPARISON OF ACCURACY VALUES BETWEEN DIFFERENT MODELS

Data/Model	CNN		MobileNet		DenseNet	
	With aug	Without aug	With aug	Without aug	With aug	Without aug
Data1	97.88	80.64	99.99	62.50	80.76	80.76
Data2	95.34	80.41	97.11	62.50	87.78	78.39
Data3	95.04	81.02	96.05	61.18	87.78	79.89
Data4	94.99	80.70	98.26	61.18	87.78	79.89

developed by radiologists using data from real affected patients. We split our data into training, validation, and testing. First, data augmentation is done to enhance our dataset by doing minor changes in our images. We trained the models for 15 epochs with a batch size of 32 and a learning rate equal to 0.01. Our model showed a considerable improvement of performance between the basic and augmented images. We evaluated also the MobileNet and DenseNet models on data without and with augmentation and we find that augmenting data gives good results and enhanced the accuracy of different models. By applying data augmentation techniques, such as random cropping, flipping, rotation, and scaling, a larger and more diverse training dataset can be created from the original data. This increased diversity in the training data can lead to improved performance of the model on the test set, as it has seen similar variations during training. Additionally, data augmentation can also act as a regularization technique, preventing the model from overfitting to the training data. However, it's important to note that too much data augmentation can lead to overfitting to the augmented data and decreased performance on the original data. It's also important to find the right balance between the degree of augmentation and the quality of the augmented data to prevent information loss or degradation. In general, it's a good practice to experiment with different augmentation techniques and evaluate their effect on the model's performance. The results indicated that random data augmentation can be considered better than classic data augmentation because it increases the diversity of the training data in a more controlled manner, preventing overfitting to the augmented data and increasing the generalization ability of the model.

VII. CONCLUSIONS

This paper presents a comparative study of Deep Learning Models for the detection of Pneumonia, incorporating data augmentation techniques. The experimental results validate the effectiveness and accuracy of our proposed model. It

showed good results compared to MobileNet and DenseNet. A remarkable improvement was noticed after applying the data augmentation techniques on the different datasets. Data augmentation can be a powerful technique for improving the performance of deep learning models. By artificially increasing the size and diversity of the training data, data augmentation can prevent overfitting and increase the generalization ability of the model. This can lead to enhanced results on the test set, and improved performance in real-world scenarios.

While our research has presented valuable insights into the detection of pneumonia using deep learning models and data augmentation techniques, there are a few aspects that merit further consideration. Firstly, it is important to acknowledge the limitations of our study, such as the reliance on a specific dataset and the need for further validation on larger and more diverse datasets. Additionally, exploring the impact of different data augmentation strategies and their effects on model performance could be an interesting avenue for future investigation. Moreover, investigating the generalizability of our proposed model to other medical imaging tasks and assessing its performance in real-world clinical settings could provide valuable insights. Lastly, incorporating interpretability techniques to understand the model's decision-making process and exploring ways to address any potential biases are important directions for future research. By addressing these questions and focusing on these areas, we believe that further advancements can be made in the field of pneumonia detection using deep learning techniques.

Cross-age Face Image Similarity Measurement Based on Deep Learning Algorithms

Jing Zhang*, Ningyu Hu

Computer Department, Xinzhou Normal University, Xinzhou, 034000, China

Abstract—In this study, a multi-feature fusion and decoupling solution based on the RNN is proposed from a discriminative perspective. This method can address the identity and age information extraction losses in cross-age face recognition. This method not only constrains the correlation between identity and age using correlation loss but also optimizes identity feature restoration using feature decoupling. The model was trained and simulated in CACD and CACD-VS datasets. The single-task learning model stabilized after 125 iterations of training, while the multi-task learning model reached a stable and convergent state after 75 iterations. In terms of performance analysis, the DE-RNN model had the highest recognition accuracy with a mAP of 92.4%. The Human Voting model had a value of 90.2%. The mAP of the Human Average model was 81.8%, whereas the mAP of the DAL model was the lowest at 78.1%. Experiments proved that the model constructed in this study has effective recognition and application value in the cross-age face recognition scenario.

Keywords—Cross-age; image recognition; RNN; feature fusion; decoupling; loss function

I. INTRODUCTION

Nowadays, the universal facial recognition technology, which refers to facial recognition performed at small age intervals, has reached or even surpassed human performance. However, in specific scenarios such as cross age facial recognition across larger age intervals, the performance of universal facial recognition technology is limited because as individuals age, the facial features, including textures, bones, etc., gradually change. The facial feature changes with age seriously affect the performance of face recognition, resulting in unrecognizability or recognition errors. How to suppress age factors and extract age invariant facial features are the keys to cross age face recognition. The studies of cross age facial recognition algorithms not only compensate for the performance shortcomings of general facial recognition algorithms in large age interval facial recognition, but also has practical significance in criminal investigation, document and other scenarios. Scholar Ali et al. [1] emphasized the main applications, challenges, and trends of facial recognition systems in social and scientific fields in their research. At the same time, this article summarizes recent facial recognition technologies and introduces the future aspects of facial recognition technology and its potential significance in the upcoming digital society. Jin et al. [2] conducted facial image recognition analysis from RGB-D technology, proposing a pseudo RGB-D facial recognition framework and providing a data-driven method for generating depth maps from 2D facial images. The research results indicate that with image fusion

technology cooperating, the accuracy of facial recognition is significantly improved. Andrejevic and Selwyn [3] considered applying facial recognition technology to campus safety and emotion detection. And they analyzed the positive and negative impacts of this technology in campus applications. To provide a new approach for current cross age facial recognition and help face recognition overcome the information loss during feature fusion and decoupling, a feature fusion and feature decoupling model based on RNN is proposed.

This study proposes the application of RNN based feature fusion and feature decoupling models in cross age facial recognition. To further separate the age and identity features obtained from the decoupling process, this article also utilizes correlation loss to constrain the correlation between the two. And to ensure the effective identity features restoration during the feature decoupling, this article further designs feature restoration losses, so that the restored features can effectively represent the identity information of the face.

II. RELATED WORK

Chen and Lau [4] proposed an identity-level angle triplet loss and used Euclidean distance to calculate similarity for cross-age FR. They also adopted a moderately positive mining strategy. The results on FR datasets showed the effectiveness of this method. Bahmani and Schuckers [5] studied the impact of short-term changes in children facial features on recognition. They used a quality-aware face matcher (MagFace) to analyze the decay relationship between age gaps and matching performance. This study demonstrated that the accuracy of children's FR was 98% within 6 months. And the accuracy only dropped to 94% within 36 months, indicating that this method had high accuracy in children's FR within three years. Sajid et al. [6] evaluated different backbone structures of deep convolutional neural networks in FR at different age stages. This method used fine-tuning models for face image feature extraction and transfer learning for matching. Experiments showed that this method had application value. Rizwan et al. [7] combined facial expression and age recognition to develop a recognition system. This system not only considered indoor and outdoor applications but also used landmark positioning to avoid the obstruction of FR by masks. The experiment showed that the system had superior performance in recognition accuracy and computation time. Riaz et al. [8] proposed a 3D aging FR model for facial age-related factors such as line and wrinkle changes. This model also paid attention to gender differentiation, and dataset verification showed that this model had high recognition performance with an accuracy of 83.89% in simulation experiments. Kavita and Chhillar [9] analyzed the application of various technologies in face detection, FR, facial

expression, and age estimation. And they investigated the application background of FR technology in recent years. Based on the survey results, they summarized the research directions and future trends of FR technology.

Apart from the RNN used in this study, Long Short-Term Memory (LSTM) is also capable of memorizing sequential information. Therefore, Sepas-Moghaddam et al. [10] applied it in the context of FR, and also conducted multi-task learning using different frameworks. The application scenario was multi-view light field image FR. The experiment showed that the LSTM cell structure had higher accuracy in FR than the existing light field recognition methods. Dubey and Jain [11] used an improved VGG16 model for facial expression recognition and matched facial features by using transfer learning. In the simulation experiment, the recognition rate of this method on the validation dataset reached 93.7%, and the facial expression recognition accuracy was higher. Liu et al. [12] used Markov decision and attention control methods to model unordered images and process FR. Meanwhile, pose-guided methods were used for image recognition optimization. In simulation experiments, the model was proven to be effective. Zhang et al. [13] found that regional differences in facial features and environmental differences had an impact on feature extraction in FR. Therefore, they proposed a model that combined deep CNN network and reinforced attention mechanism for FR. After training the model, this method showed high recognition accuracy in mainstream FR scenarios.

In summary, as more and more researchers have focused on cross-age FR and proposed many solutions, cross-age FR has achieved certain results. However, there are still some issues. How to propose an effective solution that preserves not only facial identity information but also has relatively little correlation with age factors is still a challenging problem. Therefore, this study uses feature fusion and feature decoupling to constrain the correlation between facial identity and age feature information. It is hoped to compensate for the cross-age FR technology shortcomings in specific application scenarios.

III. MULTI-FEATURE FUSION AND DECOUPLING METHOD FOR CROSS AGE FR

A. Cross Age Facial Feature Fusion based on RNN

Cross-age FR is one of the important research branches of general FR. Similar to general FR tasks, it can also be divided into two sub-tasks: cross-age face identification and cross-age face verification. The cross-age face identification task involves inputting a given face query image, and then comparing each image in the database with the input query image, one by one, to determine whether they are the same person. It is worth noting that some images in the database may have a large age gap with the query image, which poses a challenge to the general FR algorithm. In the cross-age face identification task, cross-age face verification involves comparing each image with the query image and then determining whether they are the same person. The cross-age face detection and recognition is shown in Fig. 1.

Fig. 1. Process of cross age face detection and recognition.

As shown in Fig. 1, cross-age face detection and recognition usually includes the following steps: face detection, face alignment, face feature extraction, and face matching. Face detection and face alignment are preprocessing steps in FR, which are similar in both general FR algorithms and discriminative-based cross-age FR algorithms. However, the differences are as follows. Firstly, the cross-age FR model uses a cross-age face dataset for training. Secondly, the face features extracted by the discriminative-based cross-age FR algorithm need to have strong anti-interference ability to age factors, that is, only the face features related to the identity need to be extracted. Based on the above steps, each face image can be represented as a feature vector. Face matching is based on the similarity measurement of the extracted face feature vectors, with 1:1 or 1:N matching. And the more similar or exceeding the set threshold, the more likely it is the same person. In face matching, cosine similarity is commonly used. And this study also uses cosine similarity to represent the face similarity. The calculation for cosine similarity is shown in Formula (1).

$$\cos(A, B) = \frac{A \cdot B}{\|A\|_2 \cdot \|B\|_2} \quad (1)$$

In Formula (1), A and B represent the feature vectors of two face images, while $\|A\|_2$ and $\|B\|_2$ represent the Euclidean norms of the feature vectors. Deep learning is an important branch of machine learning, which has received widespread attention from researchers in recent years and has made significant progress in applications such as speech recognition, natural language processing, and computer vision [14, 15]. In this study, recurrent neural networks (RNN) in deep learning algorithms are used for feature fusion in cross-age FR. Unlike traditional neural networks, RNN utilizes sequential information within the network. It not only considers the input from the previous moment, but also has a memory of the previous content. So the current sequence output is also related to the previous output. This feature is very important in many application scenarios, as the embedded structure in the data sequence can transmit useful knowledge information. RNN can be regarded as a short-term memory unit including input layer, hidden layer and output layer. And the nodes between hidden layers are no longer connected. The value of hidden layer depends not only on the input at the current time but also on the output value of the hidden layer at the previous time. When training the RNN network for face feature fusion, given that there can be several facial images for each individual in the sample datasets, depicting different ages yet sharing the same identity, such images are initially organized into a sequence of faces, represented by Formula (2).

$$\{F_1^p, F_2^p, \dots, F_l^p\} \in \{F_1^p, F_2^p, \dots, F_l^p, \dots, F_N^p\} \quad (2)$$

In Formula (2), F denotes a face image, l denotes an identity number, P denotes the face sequence length, and N denotes all face images of this identity in a data set. Formula (2) indicates that the sampling strategy for the face sequence is continuous and uninterrupted sampling. The initial face features are extracted from the face images using the RNN backbone network, as shown in Formula (3).

$$x_i^p = G(F_i^p), i \in \{1, 2, \dots, l\} \quad (3)$$

In Formula (3), x_i^p denotes the feature extracted from the face image, and G denotes the backbone network of RNN. The RNN network not only considers the input at the previous moment but also has the memory ability for input content. With this characteristic, we treat the face feature sequence of the same identity as a sequence of facial appearance changes with age. And we stack the face feature sequence length and use it as input to the RNN. In order to give different attentions, the attention mechanism of RNN is used to weight the each time step's outcome. The process of RNN face feature fusion is shown in Fig. 2.

Fig. 2. RNN face feature fusion process.

As shown in Fig. 2, RNN is used to remember features from multiple time periods. X represents the fused face image feature while x_1 , x_2 , and x_3 represent feature extraction of images at different age stages. This scheme fuses the facial features of the same person at different age stages, thereby achieving feature fusion and making the fused face features have strong robustness against age interference.

B. Optimization Research on Cross Age Face Feature Fusion and Decoupling

Due to the influence of age, a same individual's face is very different at different ages. On occasions, the similarity gap between subjects of the same class surpasses that from different classes [16, 17]. If only the extracted face features are used for cross-age FR, a good performance is hard to obtain. It is necessary to eliminate the age factors influence on FR. Therefore, in this study, feature decoupling is used to optimize the feature fusion. The facial feature decomposition is represented by Formula (4).

$$x^p = x_{age}^p + x_{id}^p \quad (4)$$

In Formula (4), x_{age}^p represents the age feature, while x_{id}^p represents the face identity features. In facial feature decomposition, given the face feature x^p , the RNN fully connected layer is first linearly transformed to obtain age-

related features x_{age}^p . In order to reduce the identity information loss in the feature decomposition, this study projects the age-related features in the direction of x^p to obtain the corresponding age projection features, which are used as the final age features, as shown in Formula (5).

$$x_{proj}^p = \frac{x^p x_{r-age}^p}{\|x^p\|_2} \quad (5)$$

In Formula (5), x_{proj}^p represents the age projection feature in the direction of x^p , while x_{r-age}^p represents the age-related feature. Even after simple feature decoupling, the identity and age feature obtained may still have implicit correlations. Through the above feature decoupling, the study could acquire the features. In order to avoid the recognition degradation caused by the correlation of identity and age features, this study evaluates the correlation between identity and age features, and designs a loss function to minimize the correlation between them, achieving accurate constraint of feature decoupling, as shown in Formula (6).

$$\varphi = \frac{\left\| \frac{1}{m} \sum_{i=1}^m (Y_{age}^i - \mu_{age})(Y_{id}^i - \mu_{id}) \right\|}{\sqrt{\sigma_{age}^2 + \varepsilon} \sqrt{\sigma_{id}^2 + \varepsilon}} \quad (6)$$

In Formula (6), φ represents the correlation, μ_{age} and σ_{age}^2 are the mean and variance of Y_{age}^i . μ_{id} and σ_{id}^2 are the mean and variance of Y_{id}^i . ε represents a constant used to ensure numerical stability. Y_{age}^i and Y_{id}^i represent identity variables and age variables, respectively, and their definitions are given in Formula (7).

$$\begin{cases} Y_{age} = w_{age}^T x_{age} \\ Y_{id} = w_{id}^T x_{id} \end{cases} \quad (7)$$

In Formula (7), w represents trainable parameters, x_{age} and x_{id} represent age features and identity features, respectively. Therefore, the correlation loss function between them is represented by $L_c = \exp(|p|)$. FR based on discriminant cross-age is actually a multitask learning method. So besides correlation loss function, this study also needs to construct identity loss function and age loss function for RNN multi-feature fusion and decoupling cross-age FR. The approach taken in this study involves utilizing CosFace Loss as the primary identity loss function, which guides the model in learning essential identity-related information. The calculation is shown in Formula (8).

$$L_{id} = -\frac{1}{N} \sum_i \log \left(\frac{e^{s(\cos(\theta_{s,i})-c)}}{e^{s(\cos(\theta_{s,i})-c)} + \sum_{j \neq y_i} e^{s \cos(\theta_{j,i})}} \right) \quad (8)$$

Fig. 3. Facial image feature decoupling and feature restoration.

From Fig. 3, the face features fused by RNN are first reshaped into a feature map. In order to enhance the fitting ability of feature decoupling, this study uses convolution combined with ReLU activation to optimize the decoupling. When decoupling, further recovering the identity feature from the age feature is equivalent to further decomposing the identity-related feature and identity-unrelated feature, which is the final age feature. This process is represented by Formula (10).

$$\begin{cases} \tilde{x}_{id}^p = kx_{age}^p \\ \tilde{x}_{age}^p = x_{age}^p - kx_{age}^p \end{cases} \quad (10)$$

In Formula (8), N represents the samples number in the training set, while $\cos(\theta_{j,i}) = W_j^T x_{id,i}$ represents the classes number. W represents the weight vector corresponding classifier category j . $x_{id,i}$ represents the identity feature vector corresponding to the face identity label y_i , while $\theta_{j,i}$ represents the angle between the weight vector and the identity feature vector. c, s represent the hyper parameters of the CosFace Loss function. Therefore, this identity loss function improves the model's identity recognition ability by maximizing the inter-class difference and minimizing the intra-class difference. The age loss function is constructed by using the cross-entropy loss function and its calculation is shown in Formula (9).

$$L_{age} = -\log \left(\frac{e^{t^p}}{\sum_{j=1}^m e^{t^j}} \right) \quad (9)$$

In Formula (9), m represents the categories for age labels, and e^{t^p} and e^{t^j} respectively represent the i -th and j -th term values output by the classifier. Finally, combining the correlation loss function, identity loss function, and age loss function, this study constructs the overall objective function of the supervised learning. It is defined as $L = L_{id} + \alpha L_{age} + \beta L_c$, where α and β are hyper parameters that balance the three loss functions. Finally, to reduce the information loss caused by the feature decoupling process, this study adds the lost face identity information back to the decoupled identity feature. The process of feature recovery is shown in Fig. 3.

In Formula (10), \tilde{x}_{age}^p and \tilde{x}_{id}^p are the features obtained after decoupling. k represents a learnable vector with a range of 0-1. The calculation of this vector is shown in Formula (11).

$$k = g(\omega_2 f(\omega_1 \text{GAP}(x_{age}^p))) \quad (11)$$

In Formula (11), g represents the sigmoid activation function. ω_2 and ω_1 represent the parameters of the fully connected layer. f represents the ReLU activation function. GAP represents global average pooling. The identity-related features extracted from the age feature to the decoupled identity feature are added, and the final recovered identity feature is available, as shown in Formula (12).

$$\hat{x}_{id}^p = x_{id}^p + \tilde{x}_{id}^p \quad (12)$$

The algorithm flow of the face image recognition model constructed in this study is shown in Fig. 4.

Fig. 4. RNN feature fusion decoupling optimized cross age FR model process.

As shown in Fig. 4, the cross-age face feature fusion and decoupling optimization model constructed in this study mainly uses the RNN and loss function for optimization. The model inputs a sequence of face images obtained by sampling (i.e., face images of the same person at different ages), as well as corresponding identity labels and age labels. Then, the backbone network is used to perform initial feature extraction on the face image sequence to obtain the face feature sequence. After obtaining the face feature sequence, it is fed into the feature fusion module to ensure that the fused face features can contain the adults' identity information to a certain extent.

Although the fused features contain rich face identity information, feature decoupling is still necessary to obtain age-related and identity-related features. Finally, the identity recognition loss function is used to supervise the identity feature, the age estimation loss function is used to supervise the age feature. And the correlation loss function is used to constrain the correlation between the age feature and the identity feature.

IV. APPLICATION SIMULATION ANALYSIS OF CROSS AGE FR MODEL UNDER RNN FUSION FEATURE DECONSTRUCTION OPTIMIZATION

A. Parameter and Training Analysis of IDE-RNN Model

This study used RNN network feature fusion and feature decoupling, as well as related constraint functions optimization, to perform cross-age FR and construct the DE-RNN model. To verify the model, the CACD (Cross Age Celebrity Dataset) and its subset, CACD-VS, were used for simulation validation in this study. The CACD data set is a large-scale face aging data set for cross-age FR tasks. The collected images vary with changes in age, lighting, makeup, and other factors, which improves the simulation. The CACD-VS subset is meticulously annotated by cross-referencing associated images and web content. As for the face verification, each fold of the data set comprises of 200 positive sample pairs and 200 negative sample pairs. In the experiment, the hybrid matrix index and mean Average Precision (mAP) index were used. First, the parameters of the model constructed in this study were set as shown in Table I, and the model was simulated trained on the PyTorch platform.

TABLE I. DE-RNN MODEL PARAMETER SETTINGS AND TRAINING PARAMETERS

Parameter name	Character	Value
Length of face sequence	l	3
CosFace Loss Hyperparameter	c	0.35
	s	64
Loss function equilibrium coefficient	α	0.3
	β	0.3
Pytorch Batch size	/	64
Maximum number of workouts	/	200

After obtaining the above model parameters, this study verified the effectiveness of the proposed method on both cross-age and general face datasets. When testing, Principal Component Analysis (PCA) was used in this study to obtain feature vectors with high discriminability for classification. Cosine distance was used to measure face similarity. The comprehensive loss function during the training process is shown in Fig. 5.

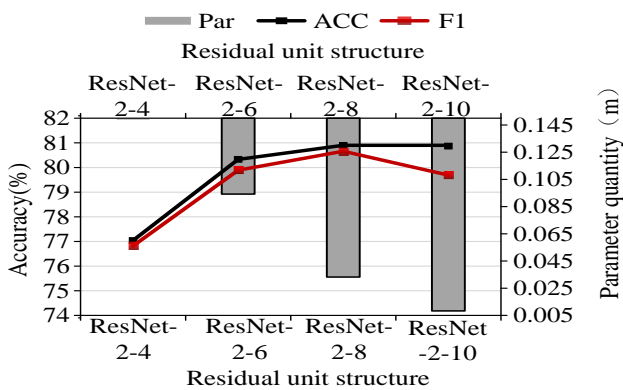

(a)Single-task damage identification model

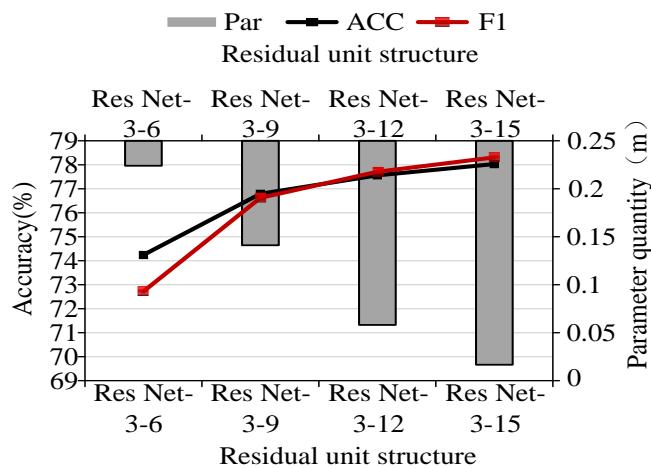

(b)Multi-task damage identification model

Fig. 5. Iterative comparison between single-task model and multi-task learning model.

The training curves in Fig. 5 include the age feature recognition accuracy and identity feature recognition for face matching, represented by acc and ID acc, respectively. From the training curves in Fig. 5, it can be observed that the single-task face image recognition model reaches full convergence after 125 iterations. While the single-task face identity recognition model has not yet reached full convergence. The multi-task learning model reaches a stable convergence state after 75 iterations. It can be seen that by utilizing multi-task learning to simultaneously optimize multiple tasks, the learning efficiency of the model is improved greatly, and the convergence speed of the model is significantly accelerated.

(a)2 Accumulation layer training results

(b)3 Accumulation layer training results

Fig. 6. Effect of different stack layer structure parameters on residual element performance.

In this study, the RNN backbone network was a residual network structure. The simulation tests were conducted to compare the face image recognition capabilities of different residual structures. Fig. 6 shows the effect of the residual blocks on the residual units with 2 and 3 layers of residual network stacks. As shown in Fig. 6, regardless of whether the residual network stack has 2 or 3 layers, the overall performance of the residual unit motion detection accuracy exhibits an increasing trend as the number of residual blocks increases. However, the overall accuracy in the residual network stack with three layers is lower than that in the stack with two layers. The average accuracy and F1 value in the two-layer stack structure were 79.785% and 79.265%, respectively. And in the three-layer structure, they were 76.555% and 76.34%, respectively. In terms of parameter calculation, the computing time of the residual network is negatively correlated with residual blocks. The residual blocks are more, the computation parameters are less. The average parameter for the two-layer stack structure was 0.0711 m, while that for the three-layer structure was 0.109 m. Therefore, the optimal number of residual network stack layers is two. And the best detection performance in the two-layer structure is the unit structure with four residual blocks, with accuracy and F1 values of 80.9% and 80.66%, respectively, which is higher than other structures. The experiment shows that the optimal value for parameter iteration of the RNN backbone network structure is the four residual blocks in the stack with 2 layers. After obtaining the parameters of the locally error-correcting joint residual network algorithm, this study compared the recognition accuracy and training time of 5 traditional CNN network structures. The experimental test data set selected the publicly available CACD data set, and the experimental results are shown in Table II.

TABLE III. TRAINING ACCURACY PERFORMANCE AND TRAINING TIME OF DIFFERENT ALGORITHMS IN CACD DATASET

Network structure	Accuracy (%)	Training time
LeNet5	60.21	50 m 12 s
AlexNet	72.83	47 m 34 s
Vgg16	78.36	24 m 20 s
GoogleNet	82.94	24 m 12 s
ResNet	88.82	22 m 10 s
DE-RNN	91.93	20 m 34 s

The table shows that LeNet5, AlexNet, Vgg16 are classic CNN network structures for image recognition, GoogleNet is the original basic network, ResNet is a single residual network, and DE-RNN is the proposed feature fusion and decoupling RNN model in this study. As shown in the table, the motion image recognition detection accuracy of individual classical CNN networks is decreasing, with accuracy below 80%. The recognition accuracies of GoogleNet and single residual network were 82.94% and 88.82%, respectively. While the proposed algorithm model had a higher accuracy of 91.93% compared to the first five CNN network structures. Moreover, its training time was the shortest, taking only 20 minutes and 34 seconds to train 500 image data.

B. Performance Analysis Parameters and Training Analysis of Cross Age FR using DE-RNN based on IDE-RNN Model

This study analyzed the performance of the DE-RNN cross age FR model on the CACD and CACD-VS datasets. Firstly, this study will compare other face verification methods and use a ten fold cross validation method to report ACC and AUC indicators. The specific experimental results are shown in Table III.

TABLE IV. ANALYSIS OF ACC AND AUC METRICS FOR DIFFERENT CROSS AGE FR MODELS IN CACD-VS DATASET

Methods	ACC	AUC
High-Dimensional LBplia	81.60%	88.80%
HFA	84.40%	91.70%
CARC	87.60%	94.20%
CAN	92.30%	N/A
Center Loss	97.50%	N/A
DAL	99.40%	99.60%
Human Average	85.70%	94.60%
Human Voting	94.20%	99.00%
DE-RNN	97.80%	99.60%

From Table III, the model proposed in this chapter is still competitive compared to other methods. In ACC indicators, DE-RNN performs better, but is lower than DAL. Among the AUC indicators, the AUC value of the DE-RNN model is 99.60%, higher than other algorithm models. In this study, four models with the highest AUC value will be selected for further

performance analysis. First, the mAP indicators of the model will be evaluated. The specific results are shown in Fig. 7.

Fig. 7. Comparative analysis of different algorithms for map.

In Fig. 7, a, b, c, and d represent the Human Average model, DAL, the Human Voting model, and the proposed DE-RNN model, respectively. It can be observed from Fig. 6 that the mAP of different models is positively correlated with the number of iterations. When the number of iterations for the test sample was 70, the DE-RNN model had the highest recognition accuracy, with a mAP of 92.4%. The Human Voting model had the second highest recognition accuracy, with a value of 90.2%. The mAP of the Human Average model was 81.8%, while the mAP value of the DAL model was the lowest, at 78.1%. Therefore, in the following experiments, the DAL model will not be considered due to its low mAP value below 80%.

(a) Cross age identification of CACD dataset

(b) Cross age identification of CACD-VS dataset

Fig. 8. Application of MTL-1DCNN model for damage identification of double-storey buildings.

This experiment aimed to validate the FR performance of different algorithms for different age groups in the CACD and CACD-VS datasets. The images of different age groups, 0-20, 20-30, 30-45, 45-60, and over 60 years old, in the datasets were used to verify the recognition accuracy. The specific experimental results are shown in Fig. 8, where the horizontal axis represents the age classification, numbered 1-5 from the lowest to the highest. The number of validation samples in both datasets was 200. From Fig. 8, it can be seen that in the face image recognition of the first stage, age 0-20, in the CACD-VS dataset, the DE-RNN model had an accuracy of 96%, higher than other algorithms. In the second stage, age 20-30 of FR in the CACD dataset, the accuracy of the DE-RNN model reached 98%, higher than that of the Human Voting model. Regarding the comparative methods, the Human Average model had better performance than the Human Voting model but was inferior to the DE-RNN model built in this study.

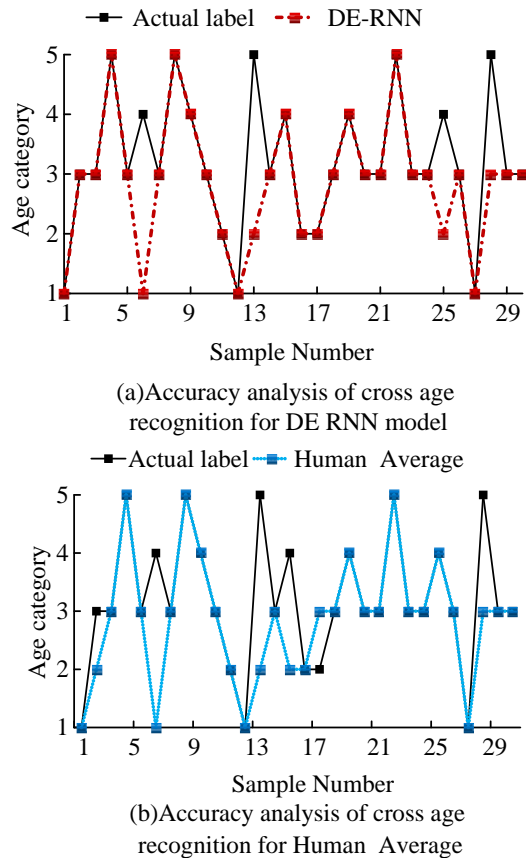

Fig. 9. Accuracy of cross age FR using different methods.

Finally, this study combined the CACD and CACD-VS datasets to compare the cross-age face image recognition performance of the two methods in the integrated data set. As shown in Fig. 9, out of the 30 training samples, the model built in this study only had four recognition errors, while the Human Average model had six misjudgments.

V. RESULT AND DISCUSSION

The technology that brings the most convenience to people's daily lives in artificial intelligence is facial recognition technology. As one of the representative artificial intelligence

technologies, facial recognition technology has naturally attracted a large number of researchers to conduct research. Since face includes a lot of useful semantic information, such as face, gender, expression, age and identity, face recognition also includes many research directions: face identity recognition, face age estimation, face expression recognition, etc.

In cross age facial recognition, feature fusion and feature decoupling can filter out age independent information in images. Yan et al. [18] proposed a new multi feature fusion and decomposition (MFD) framework for age invariant facial recognition. Based on facial time series, this method could combine feature decomposition and fusion to ensure that the final age independent features effectively represent the face identity information. And it has stronger robustness to the aging process. Huang et al. [19] first utilized attention mechanisms to divide the fused facial information into two parts: identity and age information. Then, they used methods such as multitasking learning and continuous domain adjustment to de correlate the two parts. Unlike conventional single Hot codes, the study aims to use a new identity state model to complete the identity state, and enhances the age smoothness of combined faces through a weighted allocation mechanism. The existing discrimination methods for cross age facial recognition mainly focus on decomposing facial features in images into age related and independent identity features, and then performing facial recognition. In fact, it is inevitable that facial identity information will be lost when feature decoupling. To address this issue, this article first proposes a cross age facial recognition framework based on multi feature fusion and decoupling, which fully learns facial feature representations with high discrimination ability, thereby alleviating intra class differences in cross age facial recognition [20, 21]. Therefore, this study also adopted this approach to optimize the face cross age recognition technology of RNN models. And CACD and CACD-VS datasets are used for validation analysis. In the experiment, it was found that the single task facial image recognition model reached a complete convergence state after 125 iterations. While the multi task learning training model reached a stable convergence state after 75 iterations. Therefore, the multi task optimization project proposed in this study is effective. In addition, through experiments, the research determines the RNN backbone network structure. That is, the best detection performance is the unit structure with two layers of stacked four residual blocks, whose precision and F1 value are 80.9% and 80.66% respectively, higher than other structures.

In performance analysis, the experimental results of facial image recognition between the ages of 0 and 20 in the first stage of CACD-VS data set show that the accuracy of the DE-RNN model is 96%, which is higher than other algorithms. In the second stage of facial recognition between the ages of 20 and 30 in CACD, the accuracy of the DE-RNN model is 98%, which is higher than the Human Voting model. At the same time, this study synthesized CACD and CACD-VS into a data set. And the performance of two methods in cross age facial image recognition was compared in the comprehensive data set. The results showed that out of 30 training samples, the model constructed in the study had only four recognition

errors, while the Human Average model had six judgment errors. The experiment shows that the improved recurrent neural network facial cross age recognition model proposed in this study has excellent accuracy and recognition speed.

VI. CONCLUSION

In this study, RNN network was used to construct a face cross-age recognition model with feature fusion and decoupling. The parameters and performance of the model were analyzed on a simulation platform. The experimental results show that the single-task learning model reached convergence after 125 iterations, while the multi-task model built in this study stabilized at 75 iterations. Meanwhile, in the data set analysis, the performance and structure of the backbone networks were compared. And the DE-RNN model had the highest accuracy of 91.93% and the shortest training time, which was 20 minutes and 34 seconds to train 500 image data. Regarding performance analysis, the DE-RNN model had the highest recognition accuracy, with a mAP of 92.4%, followed by the Human Voting model, with a value of 90.2%, and the Human Average model had a mAP of 81.8%. The performance of the three algorithms was compared and analyzed. In the first face image recognition stage, age 0-20, in the CACD-VS dataset, the accuracy of the DE-RNN model was 96%, higher than other algorithms. In the second stage, age 20-30 of FR in the CACD data set, the accuracy of the DE-RNN model reached 98%, higher than that of the Human Voting model. Regarding the integrated data set comparison, out of 30 training samples, the model built in this study only had four recognition errors, while the Human Average model had six misjudgments. The experimental data shows that the model built in this study has superior recognition performance and cross-age face image classification ability. However, the limitation of this study is that the sample classification is based on age stage labels, which still have some noise. For the multi feature fusion in this article, it is necessary to first sample a facial sequence and then fuse the features of the facial sequence. Therefore, this process increases model training and inference time. Therefore, in future experiments, the feature extraction optimization of age attributes will be considered.

ACKNOWLEDGMENT

The research is supported by: Research on virus propagation modeling and optimal control based on node security classification in the Internet of Things environment (No.: 202203021211116).
