In this part, we will present the implementation process of AskBot's architecture. To demonstrate the feasibility of our approach, we focused our work on the Machine Learning domain. Thus, we develop an inclusive chatbot able to handle repetitive and massive questions related to the Machine Learning domain. Furthermore, AskBot's architecture can easily perform in different contexts by applying the same implementation process.

In Fig. 3 we present the methodology adopted to train AskBot. As demonstrated in Fig. 3 there are seven main phases in the implementation process of AskBot, namely: (1) Data Collection, (2) Data Pre-processing, (3) Word embedding, (4) Data Splitting, (5) Intent Classification, (6) Similarity Measures and (7) Answer Generation. In this section, we will deeply outline each phase.

Fig. 3. Methodology adopted to develop AskBot.

1) *Data collection*: The proposed approach automatically collects pairs of Q&As from several online forums and educational sources providing reliable answers for ML

questions, including: Interview Bit¹, Simplilearn², Edureka³, Project Pro⁴, Guru99⁵, Coursera⁶, and Quora⁷. Specifically, the present work includes 10075 Q&As retrieved through the ParseHub data extraction tool. It scraps and handles large amounts of data from several sources. However, our solution excludes 8784 of the Quora retrieved Q&As since the chatbot requires direct and concise answers whereas most of Quora's answers are subjective (ideas, experiences, ...), too long, and indirect. Furthermore, this work includes Q&As shared in the Stack Exchange network, especially, 19876 pairs of Q&As are integrated from three reliable sources: Cross Validated, data science, and Artificial Intelligence. They enrich AskBot's KB to 21167 Q&As.

Besides ML questions, the present work integrates Q&As about general conversations (Small Talk) to improve the chatbot's ability to appropriately interact when it receives queries about topics other than technical ones. For that reason, the proposed chatbot integrates an open-source dataset, from the GitHub site. It contains general Q&As, regarding the following topics: greetings, AI, computers, emotion, food, gossip, health, history, humor, literature, money, movies, politics, psychology, science, sports, and stories. Thus, AskBot can imitate human capability to talk about general topics. Furthermore, the chatbot integrates DialogPT, a sizable pre-trained dialogue response-generating model, developed by MSR AI and the Microsoft Dynamics 365 AI Research team for small talk conversations. The model is created using 147M conversations from Reddit posts. The DialogPT project lays the groundwork for creating adaptable Open Domain chatbots, able to answer engagingly and naturally a wide range of conversational subjects, tasks, and information requests. Experience demonstrates that the response produced by DialogPT is comparable to the quality of human response (Zhang et al., 2019).

2) *Data preprocessing*: The present step focuses on applying a series of transformations to preprocess and clean the retrieved Q&As. Hence, successfully performing NLP models. As demonstrated in Fig. 4 there are six main steps in cleaning questions: (1) Remove duplicated rows (2) Delete numbers, and hashtags using the NeatText library (3) Replace punctuations with a space, except the dashes (- and _) since the dataset contains technical words separated by dashes such as the word "scikit-learn". In this case, replacing dashes leads to considering scikit and learn as two different words. The proposed solution is to concatenate these words rather than separate them (4) Remove stopwords: Many words in the English language, such as "I," "the," and "you," are used frequently in texts however they do not offer any significant

1 <https://www.interviewbit.com/>
2 <https://www.simplilearn.com/>
3 <https://www.edureka.co/>
4 <https://www.projectpro.io/>
5 <https://www.guru99.com/>
6 <https://www.coursera.org/>
7 <https://stackexchange.com/>

information for NLP operations and modeling. Since it is highly recommended to eliminate them, the proposed approach removes stopwords to increase the efficiency and robustness of the NLP model (5) Fix contractions: A contraction is a word or group of words that has had one or more letters removed and replaced with an apostrophe. The proposed solution replaces contractions with the complete version of the word; For example, “what’s” and “you’ve” become respectively “what is” and “you have”. (6) Lemmatization: in this step, the proposed solution consists of converting any kind of word to its base root mode. It is highly recommended to apply Lemmatization when the meaning of the word is important for the analysis.

The second part of the data processing step is to clean responses by removing special characters and HTML tags. In Fig. 5 we present the word cloud for all stored questions in the dataset. As shown in the word cloud, the word occurs in the text more frequently the bigger and bolder it is in the word cloud. Thus, we can ensure that all questions in the dataset are around the Machine Learning domain.

Fig. 4. Methodology adopted to preprocess the questions.

Fig. 5. Word cloud for all stored questions in the dataset.

3) *Word embedding*: The proposed approach focuses on four main word embedding techniques, especially:

- TF-IDF instead of Bag Of Words, because Bag of Words simply creates a set of vectors that contain the number of word occurrences in the document, while the TF-IDF model contains information about the most important and least important words as well. BOW vectors are easy to interpret. However, TF-IDF generally works better in machine-learning models (Pimpalkar and Raj, 2020).
- GloVe captures long-term interdependence by taking semantic meaning and word similarity into account during embedding (Chuah, 2022).

- Fasttext since it can consider the context in textual data and handle out-of-order words by n-gram models (Lestari and Setiawan, 2022).
- Word2vec has proven excellent performance in vectorizing words, and phrases, by producing one vector per word (Sharma and Kumar, 2023b).

Based on the Python Language, the proposed approach succeeds in (1) Developing the TF-IDF model able to vectorize Q&As in numerical vectors by following the TF-IDF process. (2) Developing the glove model by applying “Glove-wiki-Gigaword-50”: a pre-trained glove model with no casing, based on 2 billion tweets, 27 billion tokens, and 1.2 billion words. (3) Developing the Fasttext model through the pre-trained model called “Fasttext-wiki-news-subwords-300” which uses one million words vectors and is trained on the statmt.org news dataset, UMBC web-based corpus, and Wikipedia 2017 (16B tokens). (4) Applying the word2vec model by using the “word2vec-google-news-300” that was trained on 100 billion words. It includes three million words and phrases represented by 300-dimensional vectors.

4) *Data splitting*: In this step, the proposed approach automatically classifies questions' intents to group similar questions into the same class. The chatbot’s KB includes two types of questions: (1) WH-Questions starting with Wh words such as: what, how, when, why, which, who, and where. They represent almost 27.5% of the KB (2) “Non-Wh-Questions” beginning with different words, they represent almost 72.5% of the KB because most learners prefer asking their questions freely without starting with wh-words. Fig. 6 presents the distribution of WH-Questions and Non-WH-Questions in the KB.

Our work proposes a novel approach to analyze both Wh-Questions and Non-Wh-Questions. The chatbot’s KB is divided into two main parts, and each part will be analyzed separately: (1) Dataset for Wh-Questions to automatically classify their intents since all questions start with "WH-words" and (2) Dataset for "Non-Wh Questions": because it is challenging to automatically classify them since they begin with unpredictable words.

Fig. 6. Distribution of WH-questions and No-WH-questions in Q&As dataset.

5) *Intent classification*: Our proposed approach automatically classifies WH-Questions by developing a python script based on the following conditions:

- If the question starts with "what", the intent class will be: "Defintion_or_asking_for_information", since we noticed that the questions that start with "what", ask for either a definition or a piece of information. Example: what is supervised learning?
- If it starts with "why", the intent class will be "Reason". Example: Why does overfitting occur?
- If it starts with "How", the intent class will be "Method ". Example: How is the f1 score used?
- If it starts with "Who", the class will be "Person". Example: Who invented the concept of overfitting?
- If it starts with "Which ", the intent class will be "Choice ". Example: which is better lstm or gru?
- If it starts with "Where", the intent class will be "Source_or_case", since the questions that contain where ask for either a source or an explanation about a specific case. Example: Where do predictions depend on?
- If it starts with "When", the intent class will be "Situation_to_use_or_to_happen", since the questions start with when asking when to use a situation and when it occurs. Example: When to use graph Learning?

As demonstrated by the distribution of intent classes (Fig. 7) the dataset of WH-Questions is unbalanced. Histograms show that most questions fall into two classes: "Method" with 2944 questions and "Definition or asking for information" with 2092 questions. In addition to that, 260 questions refer to "Situation to use or to happen," 387 questions pertain to "Choice," and 873 questions refer to "Reason." However, just a few questions from the class "Source or case" with 51 questions and "Person" with four questions.

Fig. 7. Distribution of intent classes.

The intent classification step aims to predict the intent of new wh-questions. For that reason, our approach includes a predictive model to forecast the appropriate intent class for a given wh-question. Especially, there are various models to perform the intent classification task, such as K nearest neighbors, Naïve Bayes, Support Vector Machine, Decision Tree, Random Forest, etc. Our proposed architecture adopts Neural network algorithm (NN) because of two main reasons claimed by [35] : (1) it needs less formal statistical training (2)

it has a high capacity to detect complex nonlinear relationships between dependent and independent variables, in our case, independent variables refer to wh-questions and the intent class is the dependent variable. The first task is to vectorize wh-questions by using word embedding techniques. Then, develop the neural network (NNs) model that predicts the corresponding intent class in WH-Questions. For that reason, we divide the Wh-Question dataset into two parts: The first one is training data (80% of the dataset) to train the NNs model and the second one is testing data to test the pre-trained model and evaluate its accuracy (20% of the dataset). Then, we use the confusion matrix to evaluate the performance of the NNs model. As demonstrated in Fig. 8 the confusion matrix resumes the intents classification task. Predictions are distinguished by classes and contrasted with real values. Good predictions are presented in the diagonal of the matrix. For example [Method, Method] = 569 which means that 569 questions in the test data present the method intent class, and they were well classified by the NNs model. As demonstrated by Fig. 8 a few questions were badly classified: For example [Reason, Method] = 2 which means that just two questions that present method class, have been classified as Reason class. Thus, we can conclude that the NNs model fits well the Q&As in the test dataset.

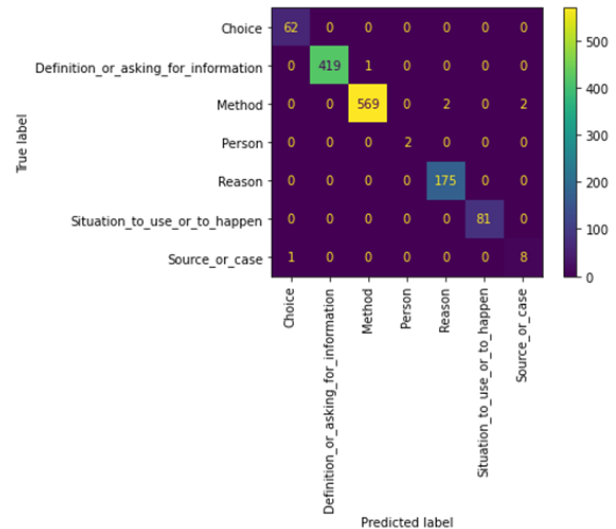

Fig. 8. Confusion matrix of NN model.

Additionally, we display the classification report as a performance evaluation metric to measure the model's performance. Especially, it presents the classification model's precision, recall, F1 score, and accuracy.

Recall for the class Definition = 1 (419 / 419). Only the classification of the definition intent is important for the recall of the class definition. This doesn't depend on how the other intents are classified. Even if the model mistakenly identified all other intents as definition, the recall will be 100% when it classifies all the definition intent questions as Definition. Precision for the class Definition = 0.9976 (419/420). Many incorrect (Or few correct) classifications for the Definition class lead to low precision. The precision for the Definition class shows how accurate the model is in identifying learners' questions related to the definition class.

Recall and precision are complementary; they measure the model's performance related to a specific intent. However, the model's performance related to all classes is measured through the accuracy or F1 score, they describe the model performance in forecasting questions' intents. Accuracy calculates the number of times the model was correct overall and (ii) F1 score assesses a model's performance by combining the model's precision and recall scores.

As demonstrated by Fig. 9 the classification report demonstrates that the model's accuracy and F1-Score are respectively equal to 0.995, 0.97. It means that our NNs model fits well the dataset of WH-Question, i.e., the model can distinguish well between the classes. Thus, we can conclude that the model is reliable; it is able to make good predictions.

		precision	recall	f1-score	support
	Choice	1.00	0.98	0.99	63
Definition_or_asking_for_information		1.00	1.00	1.00	419
	Method	0.99	1.00	1.00	570
	Person	1.00	1.00	1.00	2
	Reason	1.00	0.99	0.99	177
Situation_to_use_or_to_happen		1.00	1.00	1.00	81
	Source_or_case	0.89	0.80	0.84	10
	accuracy			1.00	1322
	macro avg	0.98	0.97	0.97	1322
	weighted avg	1.00	1.00	1.00	1322

accuracy: 0.9954614228877458

Fig. 9. Classification report of NN model.

6) *Similarity measures*: The proposed architecture calculates similarity measures to retrieve the most similar question. Then, send its response to the learner's question. In the case of WH-Question, AskBot vectorizes the learner's question through word embedding techniques, predicts the learner's intent, then applies cosine similarity. Regarding Non-Wh-Questions, it is difficult to classify the intent class because they start with unpredictable words. For that reason, the proposed solution uses the Soft Cosine Measure to find the appropriate answer directly without classifying their intentions. Soft Cosine Measure is most appropriate for Non-WH-Questions because it can find questions that are related even when they do not share any words. After evaluating several similarity scores, we find that the score of 0.6 has shown satisfactory results in extracting similar questions to the learners' questions. For that reason, we adopt that score as a threshold of similarity. When a user asks a question, we calculate the similarity between the user question and all questions in the local KB, if the similarity is greater than 0.6, then, we send the response of the similar question to the user. Specifically, we choose the question with the highest score of similarity.

7) *Evaluation process*: The proposed approach includes 100 pairs of Q&As related to the ML domain to evaluate each vectorization model. As presented in Fig. 10 for each question in the test dataset, we applied the preprocessing steps and the vectorization models. Then, there are two main cases: (1) Relating WH-question, the proposed solution is to predict the intent class by applying the NNs model, then applying cosine

similarity to retrieve the most similar question to the test question. And finally, retrieving the stored answer to the matched question. (2) Regarding the No-WH-Questions, the proposed approach is to apply the soft cosine similarity to retrieve the most similar question with its response.

The proposed approach includes 100 pairs of Q&As related to the ML domain to evaluate each vectorization model. Specifically, for each question in the test dataset, we applied the preprocessing steps and the vectorization models. Then, there are two main cases: (1) Relating WH-question, the proposed solution is to predict the intent class by applying the NN model, then applying cosine similarity to retrieve the most similar question to the test question. And finally, retrieving the stored answer to the similar question. (2) Regarding the Non-WH-Questions, the proposed approach is to apply the soft cosine similarity to retrieve the most similar question with its response.

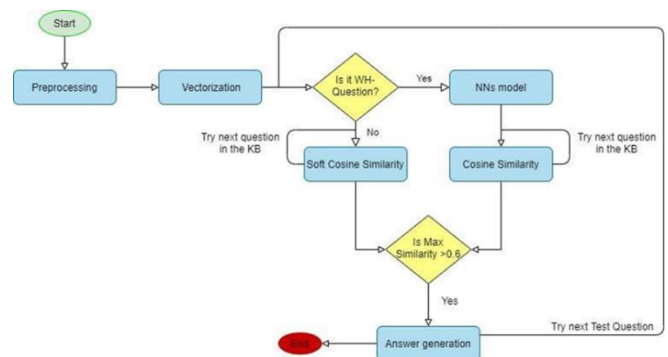

Fig. 10. Flowchart of the evaluation process.

In the evaluation process, we create a dataframe that summarizes the test results. Next, we evaluate the performance of the vectorization methods. Sometimes, even if the scores similarity is high, we find that questions are not very similar. Thus, we cannot automatically evaluate the test results based on the score similarity. Therefore, three team members examine the results to retrieve the number of correct answers in each vectorization method. Each member scores the generated answers by reporting 1 if the questions are similar and 0 otherwise. Since the dataset used in the evaluation process contains Wh and Non-Wh questions, we calculate the percentage of correctly answered questions for each type according to each vectorization technique.

As shown in Fig. 11 all vectorization techniques have demonstrated good results regarding WH-Questions. Specifically, TF-IDF succeeds in responding to 90% of WH-Questions. Based on Fig. 11 we considered TF-IDF as the most appropriate method for WH-Questions for two main reasons: (1) 90% of WH-Questions were well classified. (2) Just 10% of WH-Questions were badly classified, which demonstrates that there is a low chance to make bad classifications for new WH-Questions. Based on Fig. 12, both TF-IDF and Fasttext demonstrated good results in 70%, and 72% of questions respectively. Thus, we adopted Fasttext for Non-WH-Questions.

Fig. 11. Comparison between the performances of the vectorization methods in WH-Questions.

Fig. 12. Comparison between the performances of the vectorization methods in NO-WH-Questions.

C. Architecture's Components

In this section, we will present the main components of AskBot's architecture and the generated information flow to answer learners' questions. In Fig. 13 we present a flowchart that explains how the chatbot's components interact to answer a given question.

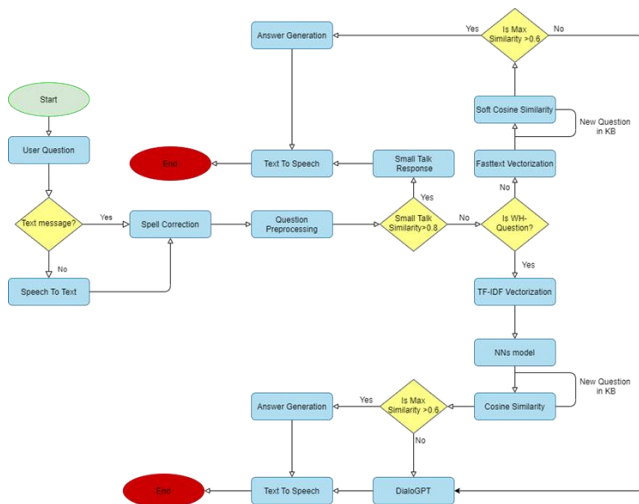

Fig. 13. Flowchart of the Askbot's architecture.

1) Back-end

a) *Spell Correction*: One common task in automatic NLP is spelling correction for many NLP applications, including Web search engines, text summarization, sentiment analysis, etc. When the user misspells search terms or the user's message differs from the spelling in the local KB, the Automatic Spelling Correction function enables search queries

to produce the intended results by correcting and rectifying misspelled words through a suggested set of terms that are the closest lexically to the incorrect ones (Hládek, Staš and Pleva, 2020). Python proposes a variety of modules and packages to carry out spell correction such as textblob, pyspellchecker, and JamSpell. However, these Python tools are not specifically designed for correcting technical words in the ML field. For that reason, our approach proposes the my_autocorrect Python function that takes a word as input and outputs a list of terms that are related to it.

First, we start by extracting 10068 keywords from Q&As in AskBot's KB, next, we store them in a python dictionary. Then, we check if a given word exists in the dictionary, thus, the word is correct. Otherwise, we calculated the similarity between the given word and all words in the dictionary. Specifically, after testing several similarity scores, we find that the score of 0.5 has shown good results in retrieving the most similar words. For that reason, we adopt that score as a threshold of similarity. We keep words with similarity scores higher than the threshold of 0.5. And finally, we replace the given word with the word that has the highest similarity score. In Fig. 14 we present two use cases of the developed function "my_autocorrect". In the first example: my_autocorrect('bagng'), the misspelled word 'bagng' will be replaced by the word "bagging" since it represents the highest score similarity (=0.571429). In the other example, the word 'classfer' will be replaced by "classifier" as the most similar word to 'classfer'.

my_autocorrect('bagng')				my_autocorrect('classfer')			
	Word	Prob	Similarity		Word	Prob	Similarity
2202	bagging	0.000133	0.571429	5525	classifier	0.000133	0.666667
3170	bag	0.000133	0.400000	6939	classifiers	0.000133	0.600000
67	laggy	0.000133	0.285714	420	class	0.000133	0.571429
187	bagof	0.000133	0.285714	953	classier	0.000133	0.555556
1104	engage	0.000133	0.250000	1307	perclass	0.000133	0.555556

Fig. 14. Spell correction function.

b) *Data Preprocessing*: It is the component responsible for cleaning the user's input to transform it into a structured format by applying the data preprocessing steps.

c) *Vectorization*: It is the component that vectorizes the user's input, it takes the output of the "Data Preprocessing component" and verifies if the user's question is a WH-Question, then, it applies TF-IDF to vectorize it. Otherwise, it applies Fasttext.

d) *Prediction Model NNs*: It is the model that predicts the intent class for WH-Questions asked by the user. It uses the output of the vectorization component to predict the user's intention.

e) *Similarity Measure*: It is the component responsible for generating the appropriate answer for a given question, it verifies the question's type. When the asked question is a WH-Question, then, it uses the intent class and the cosine similarity score to retrieve the most similar question to the user's

question, and finally, it sends the response of the similar question as the appropriate response. Otherwise, if the user's question is a NO-WH-Question, then, it applies the Soft Cosine Similarity to generate the answer.

f) *Small Talk Verification*: It is the component responsible for analyzing the user's message and verifying whether the message falls into small talk data or not. It aims to handle small talk conversation by applying the cosine similarity between the user and the small talk data. If the user's question is similar to a small talk question. (i.e the similarity between the user's question and questions in the small talk data is greater than 0.8). Then, the response will be extracted from small talk data (See Fig. 6) rather than searching in the local kb. We used a high score similarity to ensure that the user's question falls into general conversation and not a technical question.

g) *DialoGPT*: It is the component responsible for generating answers if the user's questions do not match with the stored Q&As in the local kb. After applying the similarity measures, if the similarity score between the user's question and the KB does not exceed the threshold of 0.6. Then, the answer is generated from the DialoGPT component. The small talk and DialoGPT components aim to make the chatbot richer and friendlier. It can interact with learners freely and respond to general questions beyond its local kb. Thus, enhancing the user experience.

h) *Speech Recognition*: It is the component responsible for interacting with voice messages. It aims to make the chatbot more inclusive. Thus, disabled learners can use it to find the information they need. There are two main tasks to perform speech recognition:(1) *Speech-To-Text (STT)*: It is an AI technology that converts voice content into text. It enables a computer program to take a human voice and convert it into text. (2) *Text-To-Speech (TTS)*: It is an AI technology that aims to convert text into voice. It provides the opposite of speech-to-text software's ability to turn voice content into text. The AskBot's architecture supports learners, especially those with disabilities, by efficiently handling their voice queries through *SpeechToText* and *TextToSpeech* techniques. Hence, our proposed chatbot is inclusive.

2) Front-end

a) *Graphical user Interface*: In order to facilitate the use of the chatbot, we developed a Graphical User Interface (G.U.I). Thus, learners can use it to interact with the chatbot by sending text/voice messages. We used the package "Tkinter" to develop the chatbot interface. It is a standard graphical library for Python to create a GUI-based application.

As demonstrated in Fig. 15 the interface includes a frame for conversation, an input field for the user to enter a message, and two buttons. The first one is labeled "send," to enable sending a message, and the second one enables the STT technology. Students can send messages through two methods: (1) Entering text messages in the input field. (2) Pressing on the "micro" icon to send voice messages.

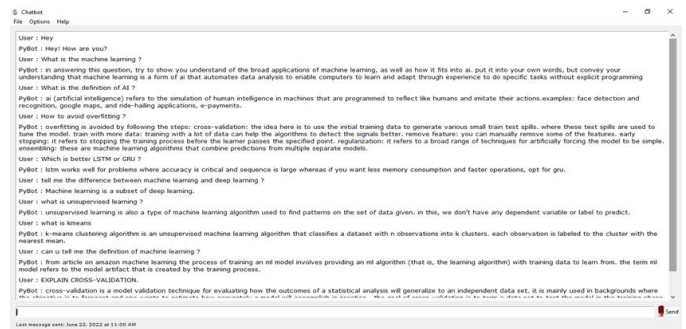

Fig. 15. Spell Use case of AskBot.

V. CONCLUSION

In this paper, we proposed an inclusive chatbot able to respond to users' questions about the Machine Learning field. It helps learners in their learning processes by providing reliable information the learners need without wasting time searching in many available sources. The present work proposes a smart learning architecture that supports various AI technologies and aims specially to automate answering massive and repetitive questions asked by learners. AskBot offloads tutors from doing repetitive tasks and helps them concentrate and focus their energies on tasks that need more concentration and effort. Furthermore, it converts text to speech and speech to text to facilitate the learning process. Thus, the designed chatbot is inclusive, it can be used by disabled students using speech recognition technology. Disabled students can easily ask their questions by sending vocal messages and receiving their responses in voice format. In addition to that, our chatbot can recognize small talk messages and handle general conversation by using small talk data and the DialoGPT model. Thus, the chatbot adapts its response according to the student's requests. Hence, it encourages learners to interact freely with it and makes them more engaged and motivated. Although this work provides valuable insights to save time and energy needed in chatbot's creation process, it is important to acknowledge some limitations that could be covered by other researchers. Especially, (1) the current version AskBot is not evolutive because the local KB is still limited to already stored knowledge. (2) More advanced models could be tested to all questions without separating them to Wh-Questions and No-Wh-Questions. In future works, we plan to address these limitations and add more advanced features such as (1) Sentiment analysis to recognize the learner's emotions and personalized the chatbot's responses. (2) Deep learning models to create generative chatbots and test their ability to answer students' questions. (3) Distributed storage for the chatbot kB to enhance the speed system and its performance (4) integrate AskBot in the existing Learning Management Systems (LMS).

Abstract—The research was oriented to the development of a knowledge management model for the generation of innovative capacities in the organizations that provide services. A systematic review of articles published in the Scopus, IEEE Explore and Google Scholar databases was carried out, where 67 articles and 24 models were selected, which were subsequently analyzed based on their theoretical foundation, strategies used for the generation and dissemination of knowledge, incorporation of the organizational culture and the use of Information and Communication Technology (ICT) in the generation and dissemination of knowledge. The proposed model, unlike the models evaluated, is oriented towards generating added value with a new strategic approach structured in the knowledge management and organizational memory macro-processes, which in turn are divided into 29 and 11 macro-activities respectively, which incorporate the organizational culture and allows guiding the organization to improve its functions through the incorporation of innovation and use of ICT in all processes of the organization and in each stage of the generation and management of knowledge; establishing the essential parameters for the generation of innovative capacities, generation of knowledge, intellectual capital and transfer of information to knowledge, which can be used within the organization. The proposed model, unlike the models evaluated, is aimed at directly strengthening interpersonal relationships between members of the organization and between them and their clients. In the same way, it incorporates a maturity model made up of five levels to measure the state in which the organization is in relation to knowledge management.

Keywords—Component; model; knowledge management; intellectual capital; information and communication technologies

I. INTRODUCTION

In a competitive world like today, marked by globalization and constant changes in the environment, it has generated the obligation in organizations not only to produce but also to innovate their processes and improve their products and/or services through the incorporation of new technologies, knowledge and information management, among other strategies. [1,2] In these new innovations impregnated with radical changes, knowledge-based work prevails [3,4]. From this point of view, it is proposed that those companies that offer products and services based on knowledge and that put the generation of added value through innovation first will become an intelligent company with a competitive advantage over its competitors. [5]. Under this context, the knowledge and

reflective capacity of people is the driving force for business and organizational performance [6,7], positioning itself as the essential element of an organization to achieve a competitive advantage over its competitors [8,9]. It is an element of high differential value in organizations, used as a competitive strategy to maximize the productivity of organizations [10].

Knowledge is recognized as a fundamental resource for modern society and organizations as it has unlimited potential for business growth [11], becoming the main source of competitive advantage for organizations [12,13]. In this sense, organizations in their search to stay current in competitive environments, must ensure continuous improvement in all their processes and make use of those concepts, tools, and models that make them faster than their competitors; one of these concepts is knowledge management [14]. Knowledge management has the purpose of collecting, organizing, distributing, sharing and using the intangible assets of an organization [15]. Knowledge management has emerged as the strategy companies need to adopt to manage and use organizational knowledge. [16,17], that is, it allows information to be managed among its stakeholders, to advance its process of wealth creation and value addition [18] positively impacting organizational innovation [19]

In this context, organizations are oriented to form high-performance work teams in such a way that it allows them to synchronize the knowledge applied in the available resources to be used optimally. In this same-dimensional scheme, knowledge, information, and communications are extremely key factors in the production or service generation processes. In this sense, managing knowledge in organizations will not be anything other than the process of creating, storing and applying knowledge in solving problems related to the processes that are part of the value chain. To achieve this task, it is necessary to have quality information technology services, which include highly qualified human capital, as well as financial and technological resources through planning, direction, and control.

In this order of ideas, the following research questions emerged: What are the theoretical and practical elements that should be considered as base descriptors in the construction of a knowledge management model? What are the knowledge management models that facilitate the generation of innovative capacities in organizations? In this sense, the present investigation was oriented to the development of a knowledge

management model that allows service provider organizations to manage the knowledge inherent to the activities carried out by the personnel that work in the organization. The established objectives were as follows: a) Establish the theoretical and practical elements of knowledge management b) Compare the knowledge management according to the established theoretical and practical elements and c) develop a knowledge management model for the generation of innovative capacities in service provider organizations.

This research is structured as follows: Section II highlights a brief theoretical description of the issue raised. Section III describes the methodology used to address the research and develop the proposal of the knowledge management model. Section IV provides the development of the knowledge management model proposal for the generation of innovative capacities and the detailed description of each of the macro activities that comprise it. Section V includes the comparison of the models studied and the discussion of the most outstanding findings of the investigation. Section VI concludes the paper and highlights future work.

II. THEORY

A. Knowledge

The triumph of new companies is based on learning, where the most important capital is man [20,21,22], who owns the most precious asset of this era and has the power to transform it through learning, its socialization and application [23]. In this regard [24] point out that the best source for obtaining lasting competitive advantages is knowledge. Knowledge is a flow in which experiences, important values, contextual information, and expert points of view are mixed [25, 18], which provide a framework for the evaluation and incorporation of new experiences and information [26, 27].

B. Knowledge Management and Innovation

Knowledge management is the ability of a company to generate knowledge for its subsequent dissemination and incorporation into its products or services [28]. It is the relationship between the employee and the company aimed at managing information; that is, identify it, select it, organize it and give it a use to generate competitive advantage. [29, 30, 31, 32]. Knowledge management is more than a process of accumulation of information, since the most important objective is to create new knowledge that contributes value and is a source of competitive advantages [33, 34, 35]. Through knowledge management, organizations manage to capture, preserve, generate, and transmit the knowledge necessary to obtain a competitive advantage, through the generation of value and the innovation of their processes [36, 37, 38, 39]. In this sense, we can affirm that knowledge management is one of the most important assets of the organization, being the engine of organizational innovation [31, 32, 40, 41].

III. METHODS

A systematic review of articles published in the Scopus, IEEE Explore, and Google Scholar databases was carried out applying criteria to filter information such as the definition of keywords, aimed at obtaining the information according to the intention of the analysis of the present investigation. The first

step was to select the knowledge management models present in scientific databases and scientific indexing services such as Scopus, IEEE Explore, and Google Scholar, where 46 knowledge management models were selected. In the second step, the models that did not meet the criteria were discarded and only 24 were selected that clearly established the foundation bases and the strategies used for knowledge management. The third step was to perform a search for articles related to knowledge management, and 625 related articles were reviewed. In the fourth step, articles that did not meet the requirements were discarded and 67 articles that fall within the knowledge areas of this study were selected. In the following, Fig. 1 shows the flow chart for the selection of models and reviewed articles.

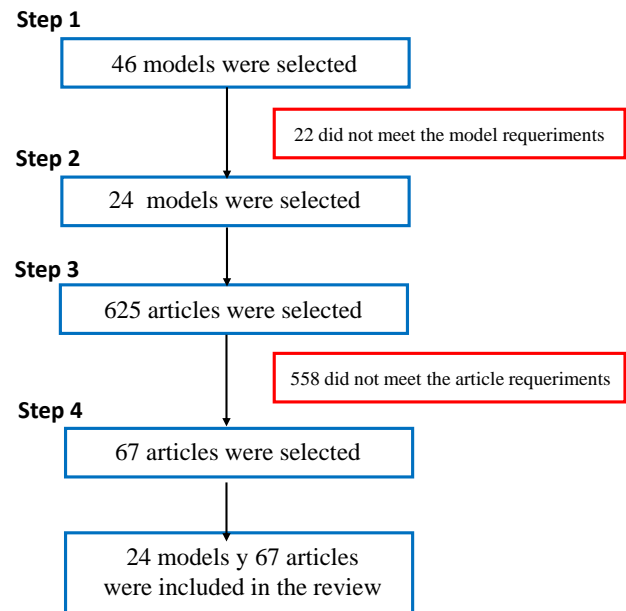

Fig. 1. Flow chart for the selection of models and reviewed articles.

The knowledge management models that were analyzed and that were the pillars of the proposed knowledge management model were: Wiig's knowledge management model. (Wiig, 1993), Nonaka and Takeuchi (1995), Technology Broker Model (Brooking, 1996), Canadian Imperial Bank Model (Hubert Saint-Onge, 1996), West Notary University Model (Bontis, 1996), Skandia Navigator Model (Leif and Malone, 1997), Intangible Assets Model (Sveiby, 1997), Intellect Model (Euroforum, 1998), Dow Chemical Model (Dow, 1998), Competitive Strategic Management Model: Intangible Capital (Bueno, 1998), Knowledge Practices Management Model (Tejedor and Aguirre, 1998), Nova Model. (Nova Care, 1999), Andersen model (Andersen, 1999), Knowledge Management Assessment Tool Model (Andersen and APQC, 1999), Cities Intellectual Capital Benchmarking System Model (CICBS, 2001), Operations Intellectual Capital Benchmarking System Model. (OICBS Viedma, 2001), Kerschberg technology integration model. (Kerschberg, 2001), Bustelo and Amarilla's knowledge management model (Bustelo and Amarilla, 2001), and Riesco's situational integrated model. (Riesco, 2004), Knowledge management model from a "humanist" vision (De Tena, 2004), Design of a knowledge management system in a school organization

(Durán, 2004), Paniagua technological knowledge management model and López (Paniagua and López, 2007), Holistic Model for knowledge management. (Angulo and Negrón, 2008), Knowledge management model for productivity and innovation centers. (Rivera, 2021); where fundamental aspects that give the nature of knowledge management models were evaluated, such as: the bases that support the models, intervention strategies for the generation, sharing, dissemination and internalization of knowledge, organizational culture and the role of technologies in knowledge management.

IV. RESULTS

A. Construction of the Knowledge Management Model

Based on the results obtained from the analysis of the 24 knowledge management models mentioned above and the analysis of the 67 articles related to the research topic that were selected as input for this research, a knowledge management

model was developed for the generation of innovative capacities in organizations that provide technological services, supported by various strategic actions that are in turn grouped according to the processes considered important for the correct generation and dissemination of knowledge.

In the model that is going to be presented, there are two macro processes such as Knowledge Management and Corporate Memory. In turn, from the Knowledge Management macro-process, two processes emerge, such as: Knowledge Management and Organizational Culture with their respective subprocesses: Intellectual Capital, Knowledge Transfer, Organizational Development, Organizational Learning, Organizational Commitment, and Competency Development. Each thread has its respective strategic actions to guarantee the harmonious functioning of the processes. Next, in Fig. 2, the Knowledge Management Model for the Generation of Innovation Capabilities in organizations that provide services.

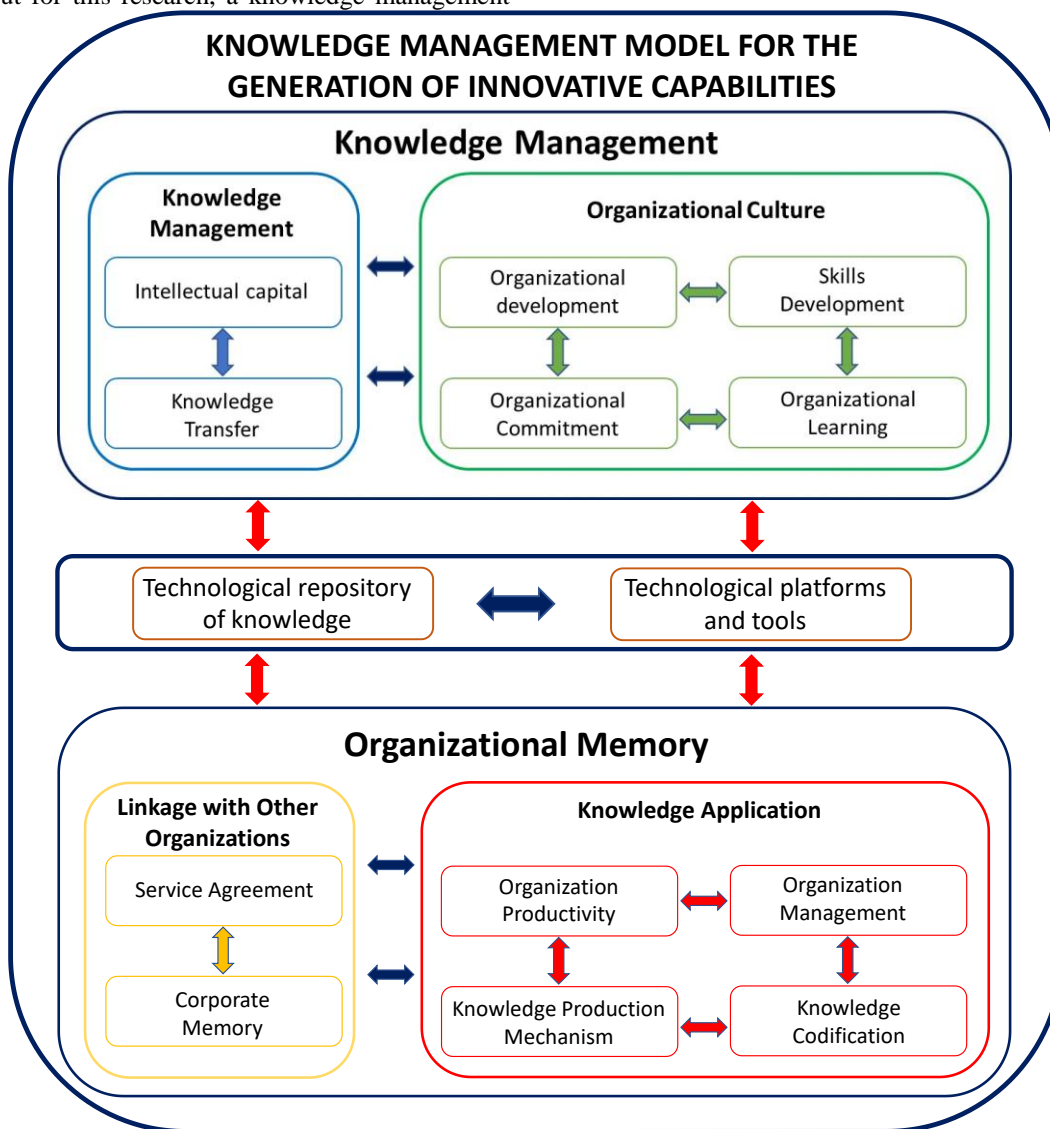

Fig. 2. Knowledge management model for the generation of innovation capabilities in organizations that provide technological service.

Each of the processes with their respective sub-processes is described below:

- 1) Knowledge management macroprocess
 - a) *Process: Knowledge Management*

Sub-process: Intellectual Capital

The strategic actions required for this subprocess are mentioned below:

- 1) Increase individual capacities through the encouragement and support of their staff to carry out post-graduate studies and/or updates
- 2) Guide the generation of knowledge to the needs of the environment.
- 3) Use the investigations carried out by the personnel who work within the organization.
- 4) Guide the production of knowledge to the solution of customer problems.
- 5) Establish knowledge-exchange relationships with other institutions in the area.
- 6) Establish policies for knowledge management.
- 7) Relate knowledge management to the organization's exchange strategies.
- 8) Guide the generation of tacit and explicit knowledge in the creation and capture of the same.
- 9) Establish the generation of knowledge due to the functions of the personnel that make it up .
- 10) Establish the order of knowledge in the organization that generates it.
- 11) Classify knowledge according to its content.

Sub-process: Knowledge Transfer

The strategic actions required for this sub-process are mentioned below:

- 1) Spread knowledge both internally and externally.
- 2) Share the knowledge produced to improve professional practice.
- 3) Establish the dissemination of knowledge generated by the staff working in the organization.

b) *Process: Organizational Culture*

Sub-process: Organizational Development

- 1) Relate the shared values with the management philosophy of your clients.
- 2) Operationalize shared values through productivity.
- 3) Guide the self-development of workers in relation to the needs of their clients.
- 4) Guide the self-development of workers in relation to personal skills.

Sub-process: Organizational learning

- 1) Link competencies related to knowing how to know with individual expectations.
- 2) Recognize the importance of organizational learning for knowledge management.

- 3) Spread knowledge and share best practices through workers

- 4) Relate the exchange strategies of the organization with knowledge management.

Sub-process: Corporate commitment

- 1) Develop a training plan aimed at organizational development and knowledge management.
- 2) Establish common protocols and standards for the production of knowledge
- 3) Evidence the organizational commitments in the production of knowledge.
- 4) Show individual commitments in the production of knowledge.

Sub-process: Competence development

- 1) Link the competences related to know-how with the capacities of the personnel, for the correct generation of knowledge.
- 2) Orient the competences related to know-how towards the ideal performance.
- 3) Link the competencies related to knowing how to know with the requirements of a particular situation.

Likewise, from the organizational memory macroprocess, two (2) processes emerge, such as: Application of knowledge and Linkage with Other Organizations. The Knowledge Application Process through the Management of the organization under study, was made up of the sub-processes (with their respective strategic actions): Productivity, Organization Management, Knowledge Production Mechanism, and Knowledge Codification. The Linkage process with other organizations was made up of the sub-process: Services agreement and Corporate Memory. Each of the strategic actions grouped into the corresponding sub-processes is described below:

- 2) Organizational memory macroprocess

a) *Process: Application of Knowledge*

Sub-process: Productivity of the Organization

- 1) Guide operational processes through the management responsible for knowledge management.
- 2) Include knowledge delivery mechanisms in the organization responsible for knowledge generation.

Sub-process: Organization Management

- 1) Add value to processes and results through the generation of innovative knowledge.
- 2) Promote and maintain cooperation with public and private institutions involved in national development.

Sub-process: Knowledge Production Mechanism

- 1) Establish an administrative structure for the registration of knowledge production.
- 2) Include knowledge production mechanisms in the different processes that make up the organization.

Sub-process: Codification of Knowledge

1) Codify the knowledge generated based on each product or service provided.

Sub-process: Investigation

1) Develop an adequate inventory of the knowledge production of the different processes that make up the organization.

2) Establish a human resource training process for Management based on the priorities of its clients.

b) Process: Linkage with Other Organizations

Sub-process: Acuerdo de Servicios

1) Establish cooperation agreements for the transfer of knowledge

Sub-process: Memoria Corporativa

1) Incorporate ICT for the storage and management of knowledge

The model embodied considers the technological platform as a fundamental pillar for the correct management of knowledge. The model is part of the contribution of IT in each process that makes up the organization under study, which will allow knowledge to be generated due to the functions of the members of the organization under study, for which standard processes are required for their management, which is specified in: capturing and creating knowledge; classify, order and encode to transfer, disseminate, and share it in a common language; thus, it is possible to objectify it, separate it and group it according to common characteristics of the organization.

In relation to the Organizational Culture for knowledge management, priority should be given to the characteristics of people and organizations such as: self-development, values, learning and sharing skills, as well as knowing, knowing how to do, and organizational exchange strategies; likewise, to the human asset, organizational development and organizational learning.

The Knowledge Management and Organizational Culture components are derived from the proposed Knowledge Management model, and both components interact with the possibility of being improved and affected. This is because knowledge management is an organizational process of intellectual capital, which is made up of human, structural, and referential capital.

The effectiveness of the knowledge put into action by the Management of the organization under study must be oriented by reason of the organization's mission. For the quality of knowledge, emphasis should be placed on the following: staff training regarding the social reality of the industry and the country and thus achieve a rational use of knowledge, have a standard structure and a system of indicators to measure and evaluate the added value of the knowledge managed by the Management.

B. Proposed Knowledge Management Maturity Model

For the implementation of the proposed model, a maturity model for knowledge management was developed, which is made up of five levels, as can be seen in Fig. 3. Each level reflects the state in which the organization is with related to knowledge management.

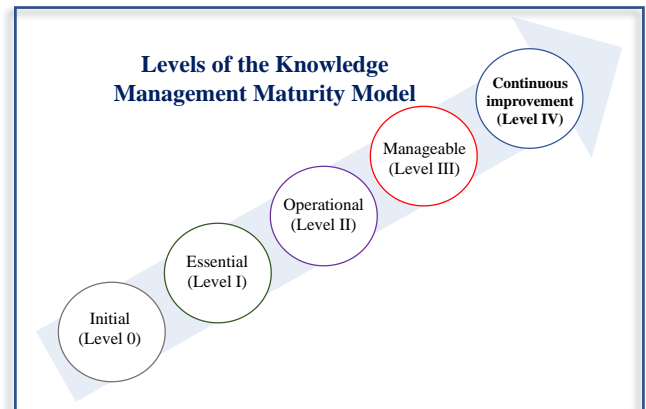

Fig. 3. Levels of the proposed maturity model for knowledge management. Adapted from Ronceros and Arias (2022).

Each stage reflects a state of maturity that is manifested through a set of characteristics (see Table I), which define the scale of the organization, which is visible through a process of evaluation and feedback as progress is made in its implementation.

TABLE I. MATURITY LEVELS

Maturity levels		
Level	Name	Features
I	Initial	There are no defined standard processes or methodologies for knowledge management.
		Knowledge management processes are not used or are used very little.
II	Essential	Fundamental processes for knowledge management defined and implemented.
		Tools implemented for the generation and dissemination of knowledge.
		Defined Roles and Responsibilities.
III	Operational	Establishment of a standard communication scheme.
		Defined, documented and integrated standard processes for knowledge management.
		Establishment of methodologies for the generation of knowledge
		Using the standard communication scheme.
		Quality Assurance in the generation and dissemination of knowledge.
		Processes for the generation of knowledge used by most of the organization's personnel.
IV	Manageable	Training process based on the career plan
		Particular management for corrective actions.
		Standardized and configured processes for the generation of knowledge.
		Historical database structure with

Maturity levels		
Level	Name	Features
		information on the different processes, lessons learned and metrics available to the entire organization.
		Evaluation of the processes involved in the generation and management of knowledge.
		Knowledge management tools integrated with corporate systems
		Identification, definition and documentation of critical success factors known by all members of the organization
V	Continuous improvement	Permanent evaluations and improvements in knowledge management
		Review and update of staff training plans
		Improvement of the instrument for measuring the maturity of knowledge management
		Evaluations and implementation of improvements to the methods and tools used for the generation and management of knowledge

V. DISCUSSION

The selected models were compared on the basis of their operation, intervention strategies for the generation, sharing, dissemination and internalization of knowledge. The comparative analysis of the knowledge management models and the selected learning models was carried out based on the descriptors base or foundation, Strategies for the generation and dissemination of knowledge, Organizational culture, participants and use of technologies; on which the following findings were obtained:

- **Base or foundation:** some models are based on the conversion of tacit knowledge and organizational knowledge on individual knowledge; others establish their operation in the culture of the organization and the commitment of the people who are part of it; another model is based on understanding different learning strategies by planning learning strategies to achieve learning conditions and objectives, in order to apply their knowledge and conceptual understanding to organizational problems.
- **Strategies for the generation and dissemination of knowledge:** the intervention strategies used in the different models for the generation, sharing, dissemination, and internalization of knowledge were evaluated. Saint-Onge (1996), bases his strategy on the fulfillment of corporate objectives through intellectual capital. Leif and Malone (1997) propose the creation of knowledge from the integration of human capital, structural capital, and client capital. Sveiby (1997) focuses on the cause and effect relationships between human capital, structural capital and relational capital. Bueno (1998), focuses on aligning the intellectual capital of the organization with the company's strategy. Tejedor and Aguirre (1998), the model guides its strategies in the strategic direction through competencies. Andersen (1999), the model establishes its strategies aimed at the measurement and

management of intellectual capital in organizations. Andersen and APQC (1999) are based on facilitating the flow of knowledge from individuals to the organization and back to individuals. Nonaka and Takeuchi (1999) proposed the creation of knowledge maps for the generation of tacit knowledge. Molina (2002), establishes learning communities and good practices for the generation of knowledge, assistance meetings, and help among the participants. Duran (2004) established the creation of forums for debates, meetings, and seminars among the participants to facilitate the generation of knowledge. Stallis and Jones (2002) and De Tena (2004) are based on the generation of knowledge maps for the creation of knowledge based on knowledge communities. Arciénaga et al. (2018) propose the creation of combined knowledge, through cooperative, learning, and work-based strategies.

- **Organizational culture:** Participation of the organizational culture in the processes of knowledge creation and management. The models proposed by Saint-Onge (1996), Leif and Malone (1997), Sveiby (1997), Bueno (1998), Tejedor and Aguirre (1998), Andersen (1999), and Andersen and APQC (1999), Stallis and Jones (2002), do not consider organizational culture in their model. Nonaka and Takeuchi (1995), De Tena (2004), Molina (2002), and Duran (2004), require for their operation that the culture of the organization pro-motes the sharing of knowledge among its members. Arciénaga et al. (2018) consider culture as a central point and a systemic factor in any discussion about the development of new knowledge or innovation.
- **Participants:** The different models consider the members of the organization responsible for the generation and development of knowledge creation and management systems.
- **Use of Technologies:** the role of technology in each of the evaluated models is slightly present in management, but is not present in the generation of knowledge. The Arciénaga et al. (2018) model establishes the use of ICTs for the generation and transfer of knowledge that allows innovation.

The models analyzed above mention that they use strategies for knowledge management, one group uses strategies that are oriented towards the identification and location of organizational knowledge, and another group uses strategies aimed at generating, disseminating and internalizing the knowledge that exists within the organization. each individual who works in the organization, however none of the models detail the strategies used or indicate the activities that involve these strategies, that is, they do not have a detailed scheme for the execution of the model unlike the proposed model where it is proposed a strategic structure that includes an execution scheme of the macro activities that make up each sub-process which in turn make up the macro processes of the model, in which 40 macro activities are involved.

Less than 30% of the models analyzed consider organizational culture as a fundamental basis for knowledge

management. However, it is not reflected in the model schematic. The organizational culture is a fundamental basis in the generation and management of knowledge, which is why in the proposed model it is considered as a process made up of four macro activities, being a main link of the model. In order to guarantee the alignment of the organizational culture to the proposal of knowledge management, the proposal of the maturity model of knowledge management composed of five levels was developed, in order to obtain a diagnosis of the state or level in which the organization is located. organization in relation to knowledge management in order to make the corresponding adjustments to the organizational culture to facilitate the success of the implementation of the knowledge management model. In this order of ideas, less than 40% of the models analyzed mention information technology for the transfer of knowledge and less than a third of this percentage indicates it in their scheme. However, the use of information technologies is not considered in the stages prior to the transfer of knowledge, which could be considered a weakness of these models. The proposed model considers the use of technologies in each of the phases of knowledge generation and management in organizations.

VI. CONCLUSION

Knowledge Management should be understood as the process within the organization aimed at creating a culture of sharing knowledge that has been acquired outside of it or that has been generated within it, with the purpose of being used by all members of the organization. organization, in order to encourage it to be more competitive through the generation of innovative processes, products and/or services. In this context, the proposed model:

- Generates value through knowledge management in all processes that are part of the organization, supported by communication as a process where the receiver is of great importance in the development of knowledge and its dissemination to its collaborators and clients.
- It is supported by concepts such as intellectual capital, knowledge management and organizational culture. Therefore, it translates into the need to develop the intellectual capital of the organization under study.
- It is a strategic process since it contributes to the generation, recruitment, organization, dissemination and use of intellectual capital, which allows the creation of a sustainable competitive advantage in organizations.
- Provides a new approach to guide the organization to improve its function; establishing the essential parameters for the generation, treatment and transfer of knowledge, which can later be used within the organization.
- It allows establishing the framework on which the organization can improve the work performance of the workers, as well as safeguard all the necessary knowledge for the full operation of the organization, strengthening the work groups that are in charge of solving problems and preserving the information.

- It allows contributing to the constitution of teams or working groups for the transfer of information and problem solving, directly strengthening the interpersonal relationships between the members of the organization and between them and their clients.
- It allows organizations to improve organizational performance, since its application directly contributes to the performance of the organization, which translates into more efficient employees and therefore a more profitable company.
- It provides a maturity model made up of five levels that allow measuring the relationship level of knowledge management within the organization, important information for the application of any knowledge management model.
- The proposed model is oriented to organizations that provide services; however, it could be considered to be implemented in other types of organizations. In this sense, the authors consider its implementation in a production organization for further studies to measure its level of effectiveness and its impact on knowledge management.

Recognition of Lung Nodules in Computerized Tomography Lung Images using a Hybrid Method with Class Imbalance Reduction

Yingqiang Wang, Honggang Wang, Erqiang Dong*

School of Electronic Information Engineering, Xi'an Siyuan University
Xi'an 710038, Shaanxi, China

Abstract—Lung cancer is among the deadly diseases affecting millions globally every year. Physicians' and radiologists' manual detection of lung nodules has low efficiency due to the variety of shapes and nodule locations. The paper aims to recognize the lung nodules in computerized tomography (CT) lung images utilizing a hybrid method to reduce the problem space at every step. First, the suggested method uses the fast and robust fuzzy c-means clustering method (FRFCM) algorithm to segment CT images and extract two lungs, followed by a convolutional neural network (CNN) to identify the sick lung for use in the next step. Then, the adaptive thresholding method detects the suspected regions of interest (ROIs) among all available objects in the sick lung. Next, some statistical features are selected from every ROI, and then a restricted Boltzmann machine (RBM) is considered a feature extractor that extracts rich features among the selected features. After that, an artificial neural network (ANN) is employed to classify ROIs and determine whether the ROI includes nodules or non-nodules. Finally, cancerous ROIs are localized by the Otsu thresholding algorithm. Naturally, sick ROIs are more than healthy ones, leading to a class imbalance that substantially decreases ANN ability. To solve this problem, a reinforcement learning (RL)-based algorithm is used, in which the states are sampled. The agent receives a larger reward/penalty for correct/incorrect classification of the examples related to the minority class. The proposed model is compared with state-of-the-art methods on the lung image database consortium image collection (LIDC-IDRI) dataset and standard performance metrics. The results of the experiments demonstrate that the proposed model outperforms its rivals.

Keywords—Lung cancer; artificial neural network; fuzzy c-means clustering method; reinforcement learning; restricted boltzmann machine

I. INTRODUCTION

Lung cancer is a dangerous and deadly disease, causing millions of deaths worldwide each year. The chances of surviving for five years with lung cancer are only 14% [1, 2]. CT imaging is the most popular method for screening lung nodules and has reduced lung cancer mortality by 20% [3]. CT provides valuable information for the diagnosis of lung cancer, but as the number of images increases, accurate evaluation becomes more challenging and poses risks to radiologists [4]. Therefore, it has become necessary to assist physicians in making faster and more accurate decisions than CT images [5].

Various methods are used for lung segmentation, including supervised, unsupervised, and semi-supervised learning

approaches. Supervised learning techniques such as ANN require training data to provide good performance for segmentation [6]. Deep neural networks are becoming popular but require large training datasets and huge computational costs [7]. Unsupervised learning approaches, such as clustering-based methods, rely on the entire image and operate based on the acquired pixel distances. Partitional and hierarchical clustering techniques are primary examples of cluster analysis, with crisp and fuzzy clustering procedures as subcategories [8]. The fuzzy c-means (FCM) algorithm is superior to other clustering algorithms because it is more tolerant of ambiguity and retains more of the image, but it struggles to segment images containing complex textures and backgrounds. Boosted clustering algorithms have been employed to segment lung nodules, but they suffer from sensitivity to noise and require a lot of repetition for convergence. The FRFCM segmentation algorithm [9] is suggested to segment nodules from lung CT images with strategic views of robustness against noise and more rapid but precise segmentation performance. The FRFCM algorithm defines a spatial function by combining the similarity of the gray pixel value and the membership to update the membership function in each iteration. The FRFCM algorithm can provide suitable segmentation results for all images with low computational cost and high accuracy.

Esfandiari et al. [10] conducted a systematic review of medical studies and found that categorization is the most time-consuming aspect of data mining approaches in medical fields such as diagnosis, therapy, and screening. Meanwhile, Lee et al. [11] studied methods for identifying lung nodules and found that most of them relied on the classification of nodule candidates, which reduces workload by removing undesirable portions from CT images. Adaptive thresholding-based methods are considered the most effective for identifying lung nodule candidates, although various other methods have been utilized [12]. The most successful image classification models, including medical ones, are CNNs. However, using CNNs for nodule candidate classification cannot achieve high performance since they are not suitable for extracting features from images with low dimensions [13].

RBMs [14] are a variety of neural networks with stochastic processing units coupled bi-directionally. Two classes of neurons are visible and hidden in an RBM. A group of neurons has no connection between its nodes, yet it must nonetheless form a bipartite network with symmetric connections between

*Corresponding Author.

its visible and hidden units. RBMs can be trained using more effective algorithms than unrestricted Boltzmann machines. In classification applications, RBMs are frequently used for feature extraction [15].

Data imbalance, which can significantly reduce performance, is a major challenge to medical image classification, as negative instances are much smaller than positive ones. Measures that could be implemented to contend with class imbalance are separated into algorithm-level and data-level methods. The data-level strategy uses under-sampling, over-sampling, or a combination of the two to lessen the negative consequences of imbalanced classification [16]. Algorithm-level approaches increase the weight of the minority class [17]. Furthermore, deep-learning approaches could be employed to address the issue of imbalanced classification [18]. Over recent years, various domains, such as computer games, robots' control, and recommendation systems, have successfully employed deep reinforcement learning (DRL). DRL enhances the performance of classification problems by eliminating noisy data and discovering better features. Notwithstanding, few works have applied DRL to classify imbalanced data. DRL is eminently suitable for classifying imbalanced data because of its learning approach. It employs a reward function that discriminates between classes by imposing heavier penalties on minority classes or giving higher rewards to them.

The paper presents a hierarchical lung nodule detection model established on the FRFCM clustering algorithm, an RBM, and an ANN boosted by a RL-based algorithm. The proposed model includes five steps, which is shown in Fig. 1: 1) Patient lung extractor: The FRFCM algorithm is used to segment CT images into two right and left lungs, followed by the utilization of a CNN to identify sick lungs. 2) Nodule candidate detection: In this step, an adaptive thresholding algorithm is employed to recognize the suspected region of interest (ROI). 3) Feature extraction: Some standard features are selected from every ROI, and then the RBM is considered as a feature extractor that extracts rich features among the standard features. 4) Classification: The features extracted by RBM are entered into an ANN to classify ROIs as healthy or sick areas. Due to many healthy areas than sick ones, ANN becomes imbalanced. RL is used to solve this issue and describe classification as a guessing game with sequential decision-making steps. At each stage, the agent uses a training instance to represent the environmental state and then, guided by a policy, performs a three-class classification operation. The classifier will accept a positive reward if the operation is completed; a negative reward will be given. The minority class receives higher compensation than the majority class. The agent's objective is to categorize the samples as precisely as possible to earn the most cumulative rewards, and 5) Localization of nodules: The Otsu thresholding algorithm is used to localize the nodule.

The contributions of the suggested model can be summed up as follows: 1) A hybrid model is presented that contains some steps that try to decrease the problem space in every step, 2) The FRFCM algorithm is considered for segmentation, which is one developed model with low computational cost and high accuracy, 3) A DRL model is offered for the classification

problem of ROIs to address imbalanced classification, and 4) The effectiveness of each component, including lung segmentation, classification, and nodule identification, is examined through studies, and its performance is evaluated in comparison to other approaches.

The remaining sections of the article are structured as follows: In Section II, a review of the literature for analyzing the lung nodule is provided. In Section III, the suggested approach is presented in further depth. Section IV presents the experimental findings and necessary analyses. Section V presents the discussion. Finally, the conclusion of the paper is presented in Section VI.

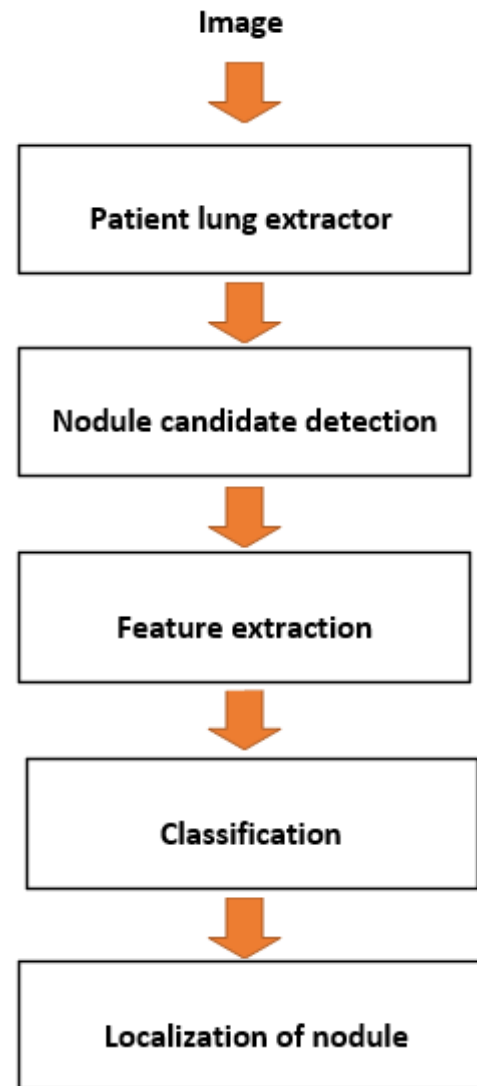

Fig. 1. Steps of the proposed algorithm.

II. RELATED WORK

Due to the small size of nodules, interpreting the CT images by the radiologist becomes difficult, so the task of accurate diagnosis is in trouble [19]. On the other hand, early detection of nodules is essential to achieve the best treatment plan and increase the survivability rate [20]. So far, many types of machine learning and deep learning approaches have been

introduced, focusing on detecting and localizing lung nodules, some of which are reviewed in this section.

A. Machine Learning

Ozekes and Camurcu [21] presented an automatic approach for pulmonary nodule detection using traditional machine learning methods like template matching. Wu, Sun, Wang, Li, Wang, Huo, Lv, He, Wang and Guo [22] designed an ANN architecture to distinguish malignant from benign samples. Texture and radiologist features were extracted and combined for classification in this work. Kuruvilla and Gunavathi [23] presented a computer-aided design (CAD) system comprising segmentation and classification stages for CT images. First, segmentation was done, then extracting features from the segmented area. Finally, an ANN was hired for classification. This work considered conventional features such as mean, SD, and skewness. Farahani, Ahmadi and Zarandi [24] founded a CAD system to diagnose pulmonary nodules in CT images. Their algorithm included three steps. First, a new segmentation algorithm was proposed based on FCM and KFCM algorithms that achieved acceptable results for lung segmentation. Second, they manually analyzed features and selected the best one for nodules classification. Finally, an ensemble of classifiers was applied for classification. Khan, Rubab, Kashif, Sharif, Muhammad, Shah, Zhang and Satapathy [25] combined pre-processing step with an ensemble approach for localized lung cancer. They showed that contrast stretching integrated with the discriminative classical features and the ensemble classifier could achieve high performance.

The inflexibility of feature extraction strategy is a major challenge in machine learning, particularly in deep learning. The lack of flexibility makes it difficult to learn high-level representations that generalize well to new and unseen data. This is particularly problematic when working with complex and heterogeneous datasets, where feature extraction is often a time-consuming and computationally expensive process. In addition, inflexible feature extraction strategies can also lead to overfitting, where the model becomes too specialized to the training data and performs poorly on new data.

B. Deep Learning

With the advent of deep learning algorithms in many applications [26-38], many researchers used them for nodule detection tasks [39, 40]. With its layered structure, deep learning can learn high-level features with high accuracy [41, 42]. Zhang, Yang, Gong, Jiang and Wang [43] introduced fusion feature vectors that integrated CNN, LBP, and HOG features to characterize the nodule area better. They used deep learning as a feature extraction module, in which the final feature vector was passed to a GBM classifier. The proposed method employed hybrid features for lung nodule classification. Hu et al. [61] combined the K-means algorithm kernel with the Mask R-CNN deep segmentation technique. This study had the greatest results, with a segmentation accuracy of 97% and an average runtime of 11s. Blanc et al. [44] offered a method to classify pulmonary nodules into two classes depending on whether their volume is greater than 100 mm³ or not. Zhang et al. [45] presented a multi-level CNN method to extract the essential features of any image. They optimize the values of meta-parameters using a non-stationary

kernel-based Gaussian surrogate model. Mobiny and Van Nguyen [46] developed an algorithm based on capsule networks for 3D lung nodules. The authors have shown that their algorithm performs well when a small dataset size. However, the prediction accuracy decreases when the dataset becomes too large. Kim et al. [47] designed a method based on the multi-scale gradual integration CNN, which used multi-scale inputs with different levels for classification. The proposed classification method suffers from data imbalance. Ozdemir et al. [48] suggested a two-step Bayesian CNN structure to take advantage of the segmentation predictions and uncertainties. In the first one, segmentation algorithms were performed on 2D axial CT slices. The original image combines segmentation predictive mean and standard deviation maps to create a 3-channel composite image fed into a 3D Bayesian CNN for nodule detection. Zhu et al. [49] combined expectation maximization (EM) to make a new 3D CNN method, whose purpose was to extract poorly supervised labels for nodule detection. In this algorithm, the Faster RCNN algorithm completed the nodule suggestion generation. Moreover, Logistic regression and the Half-Gaussian model were used for the central lobe location slice. Dou et al. [50] incorporated a group of 3D CNNs with diverse receptive field sizes to use multi-level contextual data around nodules. There are three different 3D CNNs designed for different-sized cropped cubes. Jiang et al. [51] suggested employing multi-group patches extracted from lung scans as a method for lung nodule detection. Frangi-filters were first utilized to remove the vessel-like formations. A slope analysis method was created to remove the nodules from the lung by enhancing the juxta-pleural nodules. Eventually, a CNN using multi-crop (MC) pooling was created to understand the specifics of radiologists using original CT images and their binarization. Dodia et al. [52] developed a new deep-learning-based method to detect lung nodules with decreased false positives. Their work employs a receptive regularization on the convolution and deconvolution layers of a decoder block in the V-Net. Huang et al. [53] proposed a CAD-based method that utilizes a 3D CNN [54] to detect lung nodules in low-dose CTs. The proposed method merges a priori intensity and geometrical knowledge about nodules and complicates anatomical structures with features and classifiers. Wu et al. [55] presented an interpretable method for pulmonary nodule segmentation, which supplies high-level semantic attributes and the areas of detected nodules. Huang et al. [56] introduced a fast and fully-automated end-to-end approach that automatically segments the exact nodule contours from the raw CT images with few FPs. Maqsood et al. [57] conducted a segmentation method using U-Net for lung nodule segmentation. Their technique increased the view of filters without reducing the loss and scope of data by integrating compactly and densely linked useful convolutional blocks with Atrous convolution blocks. Shen et al. [58] proposed a methodology called MC-CNN, which automatically obtains important nodule information by employing a multi-crop pooling strategy, cropping different regions from convolutional feature maps, and then repeatedly utilizing max-pooling.

Although deep models benefit from some properties, including extracting automatic features, they suffer from several difficulties. In the case of lung segmentation, an

extensive training dataset and huge computational costs are required for deep learning models. In nodule detection, they extract some suspicious ROIs and then classify them using CNN-based methods. Even though CNN can extract rich features, they fail in extracting features from small areas, i.e., ROIs.

III. ARCHITECTURE OF THE PROPOSED APPROACH

The paper offers a hybrid model containing steps that decrease problem space at every step. The proposed model consists of five steps: Patient lung extractor, Nodule candidate detection, Feature extraction, Classification, and Extraction of nodule area. First, CT images are segmented by the FRFCM algorithm that extracts two lungs, and then the lung containing the nodule for the next steps is identified by a CNN. In the second step, the adaptive thresholding method is hired to recognize ROIs from the suspicious lung. In the third step, some standard features from every ROI are selected, and then an RBM is considered to extract rich features from the standard ones. After that, the features extracted by RBM into an ANN to classify ROIs as healthy or sick areas. The proposed ANN benefits from an RL-based algorithm to handle class imbalance. Finally, the Otsu thresholding algorithm is used to localize the nodule. The overall architecture of the suggested model is given in Fig. 2; the next section provides further specifics.

A. Patient Lung Extractor

This step aims to segment the lungs of a CT image to reduce the search space by removing backgrounds and noises. The literature survey has proposed many preliminary segmentation methods for lung segmentation, but most fail to remove the noise from the image and segmentation quickly. To improve the weakness of the FCM-related algorithms, which are sensitive to noise, the FRFCM algorithm was proposed by combining local spatial data into the FCM algorithm to get better precision results. The objective function of the FCM algorithm with local information is provided by

$$J_m = \sum_{i=1}^N \sum_{k=1}^c u_{ki}^m ||x_i - v_k||^2 + \sum_{i=1}^N \sum_{j=1}^c G_{ki} \quad (1)$$

where $f = \{x_1, x_2, \dots, x_N\}$ illustrates a grayscale image, where x_i stands for the gray level of the i -th pixel. N shows the total number of pixels in image f , and c displays the number of clusters. m indicates a weighting exponent on each fuzzy membership, determining the amount of fuzziness of the resultant classification. $U = [u_{ki}]$ and G_{ki} denote the membership partition matrix and fuzzy factor provided as

$$G_{ki} = \sum_{\substack{r \in N_i \\ i \neq r}} \frac{1}{d_{ir} + 1} (1 - u_{kr})^m ||x_r - v_k||^2 \quad (2)$$

$$u_{ki} = \frac{1}{\sum_{j=1}^c \left(\frac{||x_i - v_k||^2 + G_{ki}}{||x_i - v_j||^2 + G_{ji}} \right)^{\frac{1}{m-1}}} \quad (3)$$

where v_k describes the prototype value of the k -th cluster, computed as

$$v_k = \frac{\sum_{i=1}^N u_{ki}^m x_i}{\sum_{i=1}^N u_{ki}^m} \quad (4)$$

Additionally, regarding morphological reconstruction (MR), the reconstruction of an image is shown as d and provided by

$$\varepsilon_p = R_e^c(f) \quad (5)$$

where $R_e^c(\cdot)$ is the morphological closing reconstruction, which is calculated as

$$R_e^c(f) = R_{R_f^\beta(\tau(f))}^\tau(\beta(R_f^\beta(\tau(f)))) \quad (6)$$

where τ and β stand for the erosion and dilation operation, respectively. Finally, considering morphological closing reconstruction, the objective function of FRFCM is computed as

$$J_m = \sum_{k=1}^c \sum_{p=1}^q [u_{kp}^m (||\varepsilon_p - v_k||)^2] + \sum_{k=1}^c \sum_{p=1}^q G_{kp} \quad (7)$$

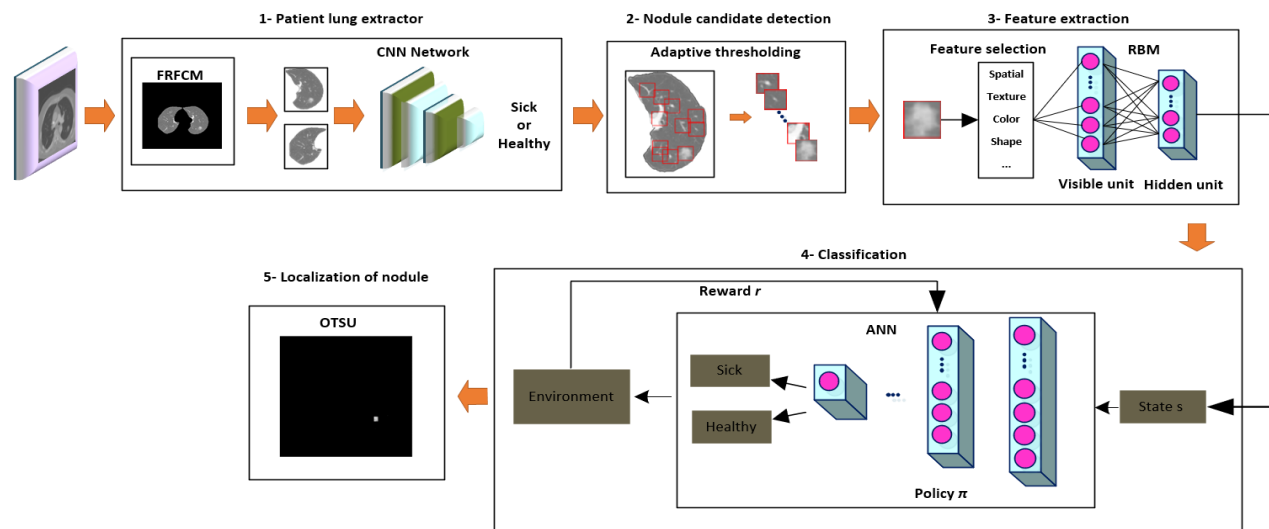

Fig. 2. Overall architecture of the proposed model.

A CNN is used to identify the lung containing nodules to decrease the search space further. Specifically, the only purpose of using CNN is to determine which lung in the CT image has the nodule, regardless of the nodule position.

B. Nodule Candidate Detection

The presence of any pulmonary nodules must be determined after the ill lung has been located using CT scans. However, finding nodules is difficult because pulmonary nodules are predominantly linked to the pleura or blood vessels. Moreover, various structural structures, such as blood arteries, airways, bronchioles, and alveoli, are present in both lungs and may have a comparable gray level to the nodules. Therefore, a transition step is needed to avoid missing nodules in CT images to specify a set of possible nodule candidates from ROIs [59]. This paper applies the adaptive thresholding method [61], one of the most valuable and efficient thresholding techniques, to select pulmonary nodule candidates for segmented lung images. This algorithm selects pixels less than a threshold value (TV) as the background, and those higher than the TV are chosen as the nodule candidate areas. In this method, the TV of each pixel is established on the values of the adjacent pixel intensity. The output of this step is different regions where the nodule is likely to be present. In this article, the bounding box, which has the most intersection of union (IOU) [60] with the actual location of the nodule, is identified as the patient area. Furthermore, two bounding boxes with IoU = 0 are randomly selected as non-nodule regions.

C. Feature Extraction

After detecting the nodule candidates from the sick lungs, the following stage selects a comprehensive feature vector for

each ROI to distinguish them as nodule or non-nodule. Indeed, ROIs and other structures are classified on such feature vectors. Although CNNs can select and extract automatically, they suffer from the classification of low dimensions, i.e., ROIs [61]. In this study, six classes of statistical features are used [62]: 1) Spatial including Entropy, Mean, Kurtosis, Skewness, Histogram of Oriented Gradients (Hog), 2) Texture including Haralick, Local Binary Pattern (LBP), Gray Level Co-occurrence Matrix (GLCM), Oriented FAST and Rotated BRIEF (ORB), 3) Color including Min Intensity, Max Intensity, Mean Intensity, Weighted Intensity, 4) Shape containing Area, Perimeter, Extent, Solidity, 5) Transform including Orientation, and 6) Edge including Corner Harries. These features are the most important ones that paraphrase an area appropriately. Fig. 3 shows the placement of these features in a vector for the next step.

It is possible that some features selected may be irrelevant and redundant, so a feature extraction step seems necessary. Many medical applications, particularly classification, depend on feature extraction [63]. It extracts the most relevant features and preserves the important information of the original image by removing unrelated and repetitious information [64]. An RBM is used that extracts efficient features and reduces the feature vector for this goal. Structurally, RBM is a deep architecture consisting of two layers of stochastic units called visible and hidden. Each element in the unit is connected indirectly with all pairs of another unit. There are no connections from visible to visible or hidden to hidden nodes in an RBM.

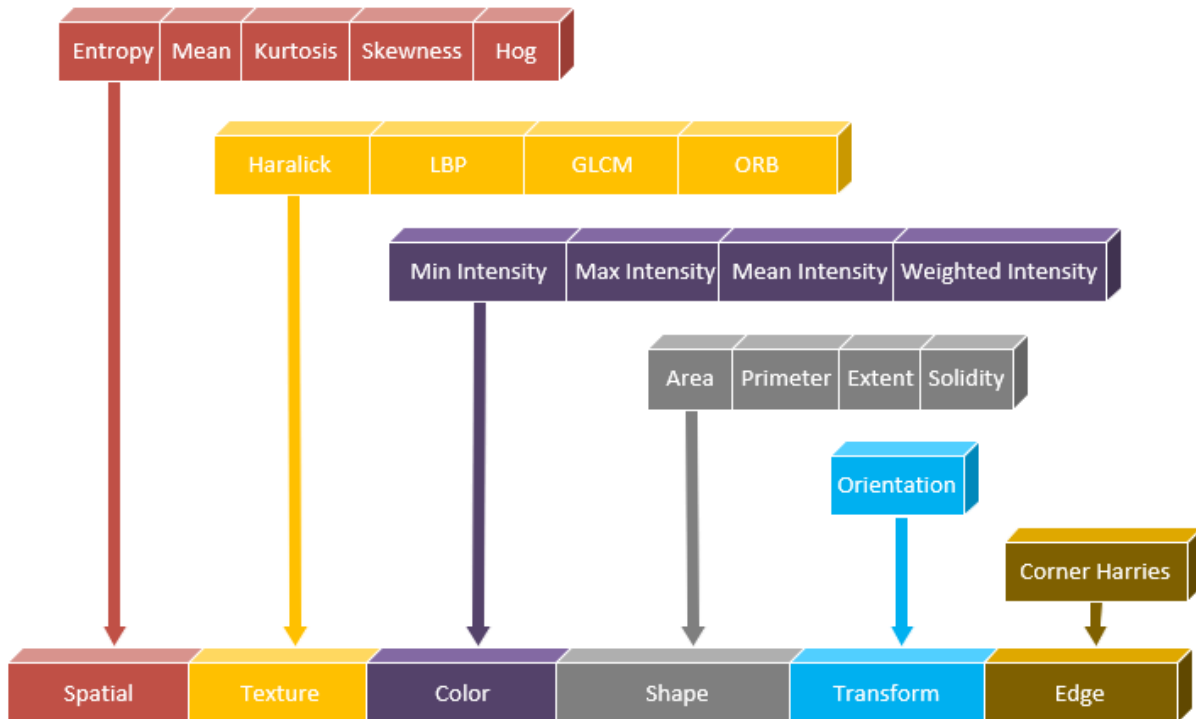

Fig. 3. Placement of features in a vector.

D. Classification

This step employs an ANN to classify ROIs as nodules or non-nodule areas. A classification imbalance issue exists due to the difference in the amount of data between non-nodule areas and nodule ones. The imbalanced classification Markov decision process (ICMDP) method is utilized to formulate a decision-making process that is sequential in nature, in order to deal with the problem of imbalanced classification. RL involves an agent attempting to achieve a high score by taking actions within an environment that lead to an optimal policy. For the suggested model, the agent receives a dataset sample and performs a classification task at each time step. Then, the agent receives the instant feedback from the environment. A correct classification results in a positive score, while an incorrect classification yields a negative score. The optimal policy can be achieved by maximizing the cumulative rewards in the algorithm of RL. Let a set of N samples with corresponding labels be given, denoted as $D = \{(x_1, y_1), (x_2, y_2), (x_3, y_3), \dots, (x_N, y_N)\}$, where x_i is the i -th sample and y_i is its label. The following describes the intended configurations:

- Policy π_θ : Policy π is a function that maps states (S) to actions (A), where $\pi_\theta(s_t)$ represents the action performed in a state s_t . The classifier model with weights θ is referred to as π_θ .
- State s_t : A sample x_t from the dataset D is mapped to each state s_t . The initial state s_1 is represented by the first data x_1 . In order to prevent the model from learning a specific sequence, D is randomized in each episode.
- Action a_t : The action a_t is executed to make a prediction about the label x_t , where the classification is binary, and the possible values of a_t are either 0 or 1. Here, 0 denotes the minority class, while 1 represents the majority class.
- Reward r_t : The reward is based on the performance of the action taken. If the agent performs the correct classification, it receives a positive reward; otherwise, it receives a negative reward. The bonus amount should differ for each class. Calibrated rewards can greatly enhance the model's performance by ensuring that the level of reward is aligned with the action taken. This work specifies the prize for an action using the subsequent formula:

$$r(s_t, a_t, l_t) = \begin{cases} +1, a_t = l_t \text{ and } s_t \in D_P \\ -1, a_t \neq l_t \text{ and } s_t \in D_P \\ \lambda, a_t = l_t \text{ and } s_t \in D_N \\ -\lambda, a_t \neq l_t \text{ and } s_t \in D_N \end{cases} \quad (8)$$

where D_P and D_N show the majority class and minority class. Correctly/incorrectly classifying a sample from the majority class yields a reward of $+\lambda/-\lambda$, where $0 < \lambda < 1$.

- Terminal E: In each training episode, the training process ends at various terminal states. A sequence of state-action pairs $\{(s_1, a_1, y_1), (s_2, a_2, y_2), (s_3, a_3, y_3), \dots, (s_t, a_t, y_t)\}$ from an initial state to a final state is

referred to as an episode. In the suggested model, the end of an episode is determined by either classifying all the training data or by incorrectly classifying a sample from the minority class.

- Transition probability P: The next state, s_{t+1} , is reached by the agent from the current state, s_t , according to the sequence of the data read. The probability of transition is represented as $p(s_{t+1}|s_t, a_t)$.

In deep Q-learning, the agent aims to choose actions to maximize the expected future rewards. Future rewards are worth γ times less in each subsequent time step:

$$R_t = \sum_{t'=t}^T \gamma^{t'-t} r_{t'} \quad (9)$$

where T shows the last time-step of the episode. An episode ends when either all the samples have been classified. Q values, measures of state-action quality, are defined as the expected return of the following strategy π , after seeing state s and taking action a :

$$Q^\pi(s, a) = E[R_t | s_t = s, a_t = a, \pi] \quad (10)$$

The maximum expected reward across all strategies after observing state s and taking action a is the best action-value function:

$$Q^*(s, a) = \max_{\pi} E[R_t | s_t = s, a_t = a, \pi] \quad (11)$$

This function satisfies the Bellman equation, which expresses that the optimal expected return for a given action is equal to the sum of the rewards from the current action and the maximum expected return from future actions at the following time:

$$Q^*(s, a) = E[r + \gamma \max_{a'} Q^*(s', a') | s_t = s, a_t = a] \quad (12)$$

The best action-value function is estimated iteratively utilizing the Bellman equation:

$$Q_{i+1}(s, a) = E[r + \gamma \max_{a'} Q_i(s', a') | s_t = s, a_t = a] \quad (13)$$

During training, after a state s is shown to the network, the network outputs an action a for that state while the environment returns a reward r , and the next state becomes s' . These parameters are embodied in a tuple (s, a, r, s') that is saved into the replay memory, M . Minibatches B of these tuples are selected from the replay memory to perform gradient descent. The loss function is expressed as:

$$L_i(\theta_i) = \sum_{(s, a, r, s') \in B} (y - Q(s, a; \theta_i))^2 \quad (14)$$

where θ indicates the model's weight, and y , shows the estimated target for the Q function. The latter is equal to the reward for the state-action combination plus the discounted maximum future Q value:

$$y = r + \gamma \max_{a'} Q(s', a'; \theta_{k-1}) \quad (15)$$

Of note, the Q value for the terminal state equals zero. The gradient value for the loss function at step i is calculated as follows:

$$\nabla_{\theta_i} L(\theta_i) = -2 \sum_{(s,a,r,s') \in B} (y - Q(s, a; \theta_i)) \nabla_{\theta_i} Q(s, a; \theta_i) \quad (16)$$

By performing a gradient descent step on the loss function, the model weights must be updated to minimize the error:

$$\theta_{i+1} = \theta_i + \alpha \nabla_{\theta_i} Q(s, a; \theta_i) \quad (17)$$

where α represents the learning rate.

E. Localization of Nodule

In the proposed method, sick ROIs, which ANN identifies, are localized by the Otsu thresholding algorithm [65]. Otsu is generally used for segmentation and localization applications [66, 67]. Otsu calculates and evaluates their between-class variation to determine the optimal threshold value. The Otsu shows that maximizing the between-class variance of the segmented classes is equivalent to minimizing the within-class variance. The Otsu segmentation level is acquired by reducing intra-class pixel power or gradually increasing inter-class variance. The inter-class variable specifies the mean between the pixels or classes of pixels [68].

IV. RESULTS AND DISCUSSION

A. Dataset

The Lung Image Database Consortium image collection (LIDC-IDRI) [69] was made by the Foundation for the National Institutes of Health (FNIH) and the Food and Drug Administration (FDA). In this dataset, a thoracic CT scan and a corresponding XML file, including the annotated results done by four radiologists, are included in 1,018 CT scans of 1,010 patients registered. The annotation procedure comprises two stages and seeks to recall all nodules in every CT scan as accurately as possible. In the first step, called the blinded-read step, every radiologist examined scans alone and observed lesions, including “nodule <3 mm” and “non-nodule ≥ 3 mm”. In the second unblinded-read stage, each radiologist checked their marks and decided to be aware of the anonymous marks of different radiologists. In the dataset, 7,371 lesions have been classified as nodules by at least one radiologist; 2,669 of these lesions received at least one “nodule 3 mm” designation from four radiologists, and 928 received four. These 2,669 lesions were given intellectual nodule characteristic ratings and nodule outlines.

B. Results

For this project, Python and the PyTorch framework were used, and the codes were written in a Jupyter notebook. The best model for the LIDC-IDRI dataset was obtained after 50 epochs, and the entire training process lasted for 3.5 hours. The optimal performance of the proposed model hinges on determining the best values for its hyperparameters. This task is not a straightforward one, as it entails exploring a vast search space of potential hyperparameter combinations and conducting numerous experiments to assess their efficacy. It demands significant effort and expertise in designing an

effective search strategy to identify the optimal values for each parameter. To achieve the optimal values, we conducted multiple experiments. A list of the most important parameters used in suggested model is shown in Table I.

The suggested algorithm effectiveness can be determined by comparing the suspicious areas that ANN identified with the real bounding box. For this goal, five algorithms are selected, namely 3D CNN [53], PN-SAMP-M [55], R-CNN [56], DA-Net [57], and MC-CNN [58], for comparison. The evaluation results obtained for the Intersection over Union (IoU) [60] and Hausdorff distance (HD) [70] criteria for the LIDC-IDRI dataset are depicted in Table II. According to the analysis, much research has improved nodule detection performance and achieved relatively excellent results. The IoU value of the MC-CNN model was 0.682, and the 3D CNN model later significantly enhanced it. The offered PN-SAMP-M model achieved an IoU score of 0.711, about 18% better than the previous model. Recent work was on the DA-Net model, which got an IoU score of 0.759. However, the proposed model outperformed the leading algorithm, DA-Net, with an IoU score of 0.825, or by around 20%. Fig. 4 shows examples of nodule detection by these methods. From the figure, the mask bounding box in the proposed model is more matched to that of the ground truth bounding box.

TABLE I. PARAMETER SETTING

Parameter	Value
Number of convolution layers	3
Convolution filters	32, 16, 8
Convolution padding	3 * 3
Convolution stride	2 * 2
Convolution kernel Size	1 * 1

MC-CNN [58]	0.770	1.472
Proposed	0.826	1.618

Fig. 4. Examples of nodule detection for methods.

1) *Examples of localizing nodules:* In the proposed algorithm, the suspicious regions detected by the ANN network are given to the Otsu algorithm to extract the localized nodule. Table III shows the results of ten samples of test images with the main images of the lung, single lungs, and localized nodules. Considering all these results shows that the Otsu algorithm localized the nodules well.

2) *Analyze of classifier:* The proposed ANN classifies nodule candidate areas and is a key element in the proposed model's performance. To investigate ANN performance, four models, namely HOUSES-UCB [45], CapsNet [46], MGI-CNN [47], and RFR V-Net [52], were employed for comparison on the LIDC-IDRI dataset. The evaluation criteria utilized are Accuracy, Sensitivity, Precision, F-measure,

Specificity, and G-mean. G-mean and F-measure are valuable metrics for evaluating the effectiveness of imbalanced classification algorithms [71]. G-mean is the geometric mean of sensitivity and precision, and F-measure represents a harmonic mean between recall and precision. As the G-mean and F-measure get a higher score, better performance of the algorithm would be reached. The performance of the proposed ANN, along with RL and the three-deep learning-based models, are compared in Table IV. The ANN model is a classifier that does not use RL for classification, and CNN is a model used instead of ANN. As the results reveal, the ANN+RL model has a more acceptable performance than the rest, which reduces errors by more than 45% in all criteria.

TABLE III. EXAMPLES OF NODULES LOCALIZED BY THE OTSU ALGORITHM

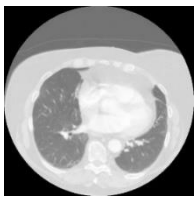

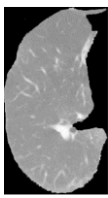

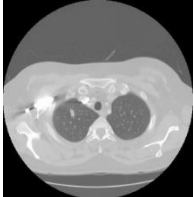

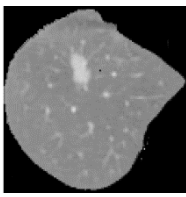

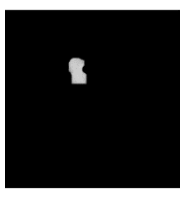

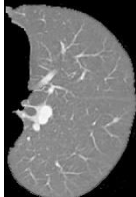

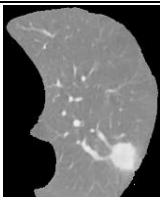

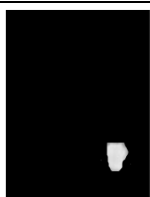

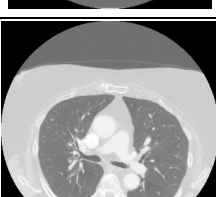

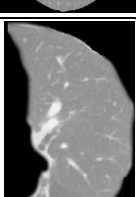

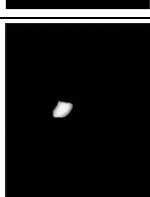

Original Image	Single Lung	localized nodule
		
		
		
		
		

TABLE IV. PERFORMANCE OF VARIOUS CLASSIFIERS

Method	Accuracy	Sensitivity	Precision	F-measure	Specificity	G-mean
HOUSES-UCB	79.11	80.85	90.72	91.52	87.26	82.75
CapsNet	83.00	83.63	91.33	92.35	88.45	83.40
MGI-CNN	85.33	85.71	92.49	93.40	90.02	84.45
RFR V-Net	89.40	90.28	94.72	95.50	91.02	88.48
CNN	84.12	86.23	91.03	91.25	89.15	85.47
ANN	88.13	93.61	95.65	94.61	92.15	86.53
ANN+RL	94.94	96.82	97.91	96.89	95.15	92.90

TABLE V. RESULTS OBTAINED FOR FUZZY ALGORITHMS

Method	IoU	HD
FCM	0.67	1.02
KFCM	0.76	1.56
SAFCM	0.72	1.81
FLICM	0.78	2.01
FRFCM	0.88	2.65

Furthermore, the maximum value of all measures in deep models is relatively different from ANN+RL. For example, by comparing ANN+RL and the second-best model, i.e., RFR V-Net, the difference is about 11% and 10% for the two criteria of F-measure and Recall. The comparison of ANN with ANN+RL shows that the RL trick improved the model by approximately 50%.

3) *Comparison of segmentation methods:* In this section, a comparison of the FRFCM algorithm with other fuzzy-based algorithms is intended. For this purpose, four algorithms, namely FCM [72], KFCM [73], SAFCM [74], and FLICM [75], were selected. The metrics IoU and HD, which are the most widely used for segmentation tasks, were used for evaluation. Table V shows the evaluation results of these methods. FCM had the weakest performance with values of 0.67 and 1.02 for IoU and HD, respectively. The developed algorithms, KFCM and SAFCM, had more power than FCM. Overall, fuzzy methods performed weaker than FRFCM, which outperformed the second-best algorithm, FLICM, with an improvement of roughly 36% for the IoU metric.

To investigate the execution time of algorithms, 20 test data samples were selected and the time spent on them was measured. Table VI shows the average time for these 20 samples. As expected, the time average of the FRFCM algorithm is less than others. Fig. 5 indicates a sample of CT images to highlight the superiority of FRFCM over others. As can be seen, the FCM algorithm did not correctly extract the nodule areas inside the lungs, which severely reduces the system performance since the proposed model's next steps depend on correctly extracting nodules in the segmentation step. Although KFCM performs better, they are unable to extract nodules. FRFCM is the most robust algorithm among the rest.

4) *Exploration of the loss function:* Data imbalances can also be handled using conventional methods, including tweaking data augmentation and loss functions. Among these techniques, the loss function is more important as it can emphasize the minority class. Five functions Balanced Cross-Entropy (BCE), Weighted Cross-Entropy (WCE), Dice Loss (DL), Tversky Loss (TL), and Focal Loss (FL) [76] were chosen to test the effectiveness of the loss functions in the proposed model. In the BCE and WCE loss functions, the positive and negative examples are given equal weight. The FL function can benefit applications using unbalanced data, which helps the model concentrate more on learning complex samples by underweighting the contribution of simple

examples [139]. Table VII displays the evaluation outcomes of these loss functions for the datasets. The FL function outperforms the others as expected, and as a result, it is around 51.16% better than the other loss functions. However, the FL function performs 34% worse than reinforcement learning.

Fig. 5. Examples of lung segmentation by fuzzy algorithms.

TABLE VI. COMPARISON OF EXECUTION TIMES OF METHODS (IN MILLISECOND)

Method	Time
FCM	810
KFCM	405
SAFCM	374
FLICM	328
FRFCM	219

TABLE VII. EFFECTIVENESS OF THE SUGGESTED ANN FOR VARIOUS LOSS FUNCTIONS

Method	Accuracy	Sensitivity	Precision	F-measure	Specificity	G-mean
WCE	83.78	84.25	86.48	86.40	85.03	82.79
BCE	84.47	85.85	87.02	87.79	86.14	83.71
DL	87.09	90.74	90.82	89.63	88.10	85.89
TL	88.25	91.43	92.79	90.20	90.96	87.06
FL	90.55	93.15	94.09	93.19	92.48	89.79

5) *Impact of the reward function:* In the proposed model, rewards of +1 /-1, and $+λ/-λ$ are assigned for correct/incorrect classifications to the majority and minority classes, respectively. $λ$ depends on the relative proportions of the majority to minority samples: the optimal value of $λ$ is expected to decrease as the ratio increases. To investigate the impact of $λ$, the model performance is evaluated with $λ$ initialized using a value from incremental values $\{0,0.1,0.2,0.3,0.4,0.5,0.6,0.7,0.8,0.9,1\}$, while keeping the majority class bonus constant (Fig. 6). At $λ = 0$, the impact of the majority class becomes zeroized; and at $λ = 1$, the relative impacts of both majority and minor classes are equal. Model performance across all metrics peaks at a $λ$ value of 0.3 (increasing from 0 to 0.4, and decreasing from 0.3 to 1. As such, while the effect of the majority class needs to be attenuated by adjusting $λ$, the overall model performance can be degraded by using too low of a value.

6) *Analysis of features extracted by RBM:* The hidden unit in the RBM network fed to ANN is a practical tool containing the compressed data of nodule candidate areas. The additional information is entered into the ANN by increasing the hidden size, which is practically useless. On the other hand, a small hidden size may not be able to hold all the information. To check the effect of the hidden size on the proposed model, six values $\{50, 80, 120, 150, 180, 210\}$ were tried as the hidden size on the model. Fig. 7 displays the results for these metrics. For all metrics, when the hidden size takes the values from the interval $[50, 120]$, the chart moves upward, and from $(120, 210]$, it has a descending movement. Accordingly, the best value for the hidden size is found to be 120.

C. Discussion

This section looks at why the suggested approach produces superior outcomes to other approaches. First of all, suggested model inherits from the hierarchical structure. Although these models may increase the time of diagnosis, they are relatively accurate as they provide each section's analysis process separately.

The proposed model consisted of several parts, each designed for a specific purpose. Two lungs needed to be extracted to reduce the entrance space, and despite the many segmentation methods available, FRFCM was found to be the best option. FRFCM was selected due to its short implementation time and acceptable results obtained in other articles, and its superiority over other algorithms was confirmed in Tables V and VI. Additionally, unlike different algorithms, FRFCM completely extracted all the holes in terms of schematic output, demonstrating its stability against various noise and other image disturbances (see Fig. 5). In the following steps, it was unnecessary to utilize a lung that did not include a nodule. Among deep learning structures for classification, CNN was the best architecture, which required little pre-processing compared to others. Whereas, in previous designs, filters were typically hand-engineered, CNN learned these filters firmly. Therefore, the first stage alone could diagnose lung diseases that might be hidden from the physician.

Fig. 6. Performance metrics plotted vs. the value of $λ$ in the reward function.

Fig. 7. Performance metrics plotted vs. the hidden size in RBM.

To reduce the input space further, the adaptive thresholding method was chosen as the best algorithm to select ROIs that are more likely to be nodules. This algorithm works well because it compares a pixel with the pixels around the contrast lines and prevents soft gradient changes. Moreover, another advantage is that only one image pass is needed.

One of the proposed algorithm's steps was selecting and extracting ROIs for classification. Although CNNs are one of the best models for classification, they cannot be helpful for tiny areas. In the experiments, CNN is used with various architectures as a classifier and reported the best result in Table IV. As can be seen, it works weaker than ANN. On the other hand, due to the nature of deep learning, the leading network is multi-layered, so some features are lost during the extraction and transfer process to the lower layer. In particular, overfitting may occur due to the extraction of many features. These problems are exacerbated if the amount of data is small. Therefore, the traditional feature selection process can be one of the critical options for selecting basic features with little data and achieving high accuracy. But the presence of unrelated and redundant features reduces the performance of machine learning models. For this purpose, an RBM that can encode any distribution and is computationally efficient was applied. Moreover, activations of the hidden layer can be used as input

in deeper models. The performance of the model is also affected by the size of the hidden layer, for which there is generally no rule for the number of hidden layers and accuracy. As shown in Fig. 7, better performance was obtained by setting the size to 120.

But the most important and innovative part of the proposed method was the classification of ROIs with ANN, which was an imbalanced problem due to a large amount of majority class data. From the results, it was confirmed that reinforcement learning applied to the classification could essentially solve it. On the other hand, it is hypothesized that the reinforcement learning method used in this study can be utilized by all classifiers experiencing imbalance to address this issue.

One potential limitation of the proposed model is its computational intensity, which may be due to the use of multiple algorithms, such as FRFCM, CNN, adaptive thresholding, RBM, ANN, and Otsu thresholding. As a result, the processing time required for analyzing a large number of CT images may increase. Another limitation is the possibility of class imbalance, as sick ROIs are less common than healthy ones, which may decrease the performance of the ANN. Although the reinforcement learning-based algorithm is used to address this issue, it may not always be fully effective. Furthermore, the accuracy of the proposed model may be dependent on the quality of the CT images used for analysis. The model's accuracy may decrease if the images have poor resolution or are affected by image artifacts or noise. Lastly, the proposed model was evaluated using the LIDC-IDRI dataset, and its performance may vary when applied to other datasets or in clinical settings. Therefore, further testing and validation are necessary to determine the model's robustness and generalizability.

V. CONCLUSION

This paper presented a hybrid method to recognize the pulmonary nodules in CT lung images. The proposed method's structure was composed of five different steps. First, the FRFCM algorithm is applied, which developed fast and robust to segment CT images, followed by a CNN to identify the sick lung. Then, the adaptive thresholding algorithm is performed to detect suspected ROIs from sick lungs identified by CNN. Next, some statistical features are determined from every ROI, and then an RBM is hired as a feature extractor that extracts wealthy features. After that, an ANN is utilized to classify ROIs as nodule or non-nodule areas. Finally, sick ROIs are localized by the Otsu thresholding algorithm. Naturally, sick ROIs are less than healthy ones, resulting in an imbalanced classification that reduces ANN performance. To shield this problem, RL is applied, which frames the training process as a sequential decision-making step. At each stage, the agent gets an example and categorizes it. The agent gets a reward from the environment for each categorization act in which the minority class receives a larger reward than the majority class. Finally, the agent discovers an optimal policy with a specific reward function and a supportive learning environment. Several experiments are designed to investigate the parts of the suggested model on the LIDC-IDRI dataset and standard performance metrics. Experimental findings showed that the suggested model performs better than other competitors.

In future work, it is planned to use 3D processing instead of 2D, which may increase the effectiveness of the proposed solution. Additionally, focus will be given to feature selection or extraction to improve the speed and accuracy of the suggested method.

Faculty of Ocean Engineering Technology and Informatics, Universiti Malaysia Terengganu, 21030 Kuala Nerus, Terengganu, Malaysia⁶

Abstract—Folk dance (FD) is a type of traditional dance that has been handed down through a culture or group from generation to generation. It is crucial to preserve and safeguard this type of cultural legacy since it can reflect the history and identity of particular nations. However, due to ineffective preservation and conservation techniques, the survival of FDs is being negatively impacted more and more. Its extinction may be caused by ignorance about and disregard for preservation and conservation efforts. The most efficient method for digitizing intangible cultural property, including FDs, is motion capture (MoCap). MoCap enables the conversion of real-time movement into digital performance to produce motion templates. This paper aims to provide suggestions and guidelines in conducting research to generate motion templates of FDs. Several key approaches are presented and discussed in detail, including acquaintance meetings, procedures and approval, interviews and experiments, and the framework. The proposed framework includes models for MoCap, skeleton generation, skeleton refinement, and evaluation. By implementing the proposed framework, the motion templates for FDs can be created. The generated motion templates will preserve and conserve FDs and guarantee their originality and authenticity.

Keywords—Motion capture; folk dance; motion template

I. INTRODUCTION

Since cultural heritage reflects the history and identity of certain countries, it is important to preserve and conserve it. Cultural heritage refers to the inherited beliefs, values, customs, practices, and artifacts that define a group or society [1]. It includes both tangible and intangible elements that have been passed down from generation to generation. The National Heritage Act of 2016 defines intangible cultural heritage as a human action or movement that can be observed, felt, tasted, smelled, or heard when performed or present, but cannot be appreciated when lost or disappeared [2]. This includes performing arts, customs and culture, oral traditions, fine arts or crafts, knowledge and practice, and living heritage.

Folk dance (FD) is considered a ritual among people that is a characteristic of the common inhabitants of a country or region that is passed down from generation to generation [3]. By performing such rituals for many years, people have gathered and performed such rituals to develop bonds with each other and connect with the space where they spend or spent their daily lives [2]. Dance is a performing art and consists of various movement sequences [4]. It can have different messages depending on the context due to their close relation to the culture and heritage of a place or nation [5].

Moreover, each dance creates a meaning, a story with the help of music, costumes, and dance movements [6]. In Malaysia, FD has been registered and categorized as performing arts under Intangible Cultural Heritage. Performing arts is a form of stage performance that is performed directly or immediately for the audience or spectators and involves four basic elements, namely time, space, and the relationship between performer and audience [2]. Examples of the most popular FDs in Malaysia are Tarian Gamelan, Tarian Piring, Tarian Zapin, Tarian Mak Yong, Tarian Sumazau, Tarian Ngajat, Tarian Kipas, Tarian Kathak, Tarian Kuda Kepang and others [7,8].

However, this kind of heritage can easily die out over time if it is not a tangible heritage. This is because the younger generation is not interested in passing on the cultural heritage and because of the changes in traditions (the transition to modernity) [2]. These reasons have significant impacts in the form of loss, neglect, extinction, and destruction. In addition, current methods for teaching, learning, and assessing FDs focus on human demonstration, text documentation, and video [9]. Human instructors such as teachers and coaches are usually involved to give commands or demonstrations about the dance movement [10]. Santos [11] described three limitations when a person attempts to provide feedback: The person cannot maintain the same level of attention and concentration for an extended period of time; they are unable to observe all the important physiological and biomechanical variables that characterise the movement, either at the same time or with high precision; and they are unlikely to provide extended simultaneous feedback. The use of text documents is suitable for presenting information about dance and its cultural significance, but it cannot present movements and different dance styles accurately [10]. When using videos, the movements of dances can be easily presented, but it is static (2D) and difficult to present additional information about each dance [10]. The existing framework from previous research is not sufficient to create the motion templates of FDs from scratch. Therefore, there must be a stable mechanism to preserve and maintain this kind of valuable intangible cultural heritage.

Digitization and visualization of FDs is an increasingly active research area in computer science. With the advent of rapidly advancing technologies, new ways of learning folk dances are being explored that enable the digitization and visualization of various FDs for learning purposes using different tools [10]. One of the methods for such purposes is

Wan Rizhan's DPU1.0 Research Grant (Project Code: R0309, Ref. No: UniSZA/2021/DPU1.0/05)

motion capture. Motion capture (MoCap) is one of the most effective methods for digitizing intangible cultural heritage, including FDs [6]. This is because MoCap enables the translation of live motion into a digital performance [12,13,14]. Mocap can also be used to recreate dances in three dimensions and display them in a 3D environment [15]. In other words, MoCap can be used to create motion templates. The use of motion templates in FDs has gained popularity in recent years due to the numerous advantages they offer. Motion templates are predefined movements or poses that are captured using motion capture technology and can serve as a reference for dancers to learn and perform choreography [16].

In this paper, a theoretical framework for creating motion templates of FDs using MoCap is proposed and presented. Different techniques and approaches for data acquisition and analysis are discussed in detail. In addition, the importance and processes of digitizing FDs with MoCap are highlighted to preserve and maintain folk dances by creating movement templates. This paper covers materials and methods in Section II, data collection and analysis in Section III, expected results and discussion in Section IV, and the last Section touches on the conclusion.

II. MATERIALS AND METHODS

To ensure the success of preserving and conserving FDs through digitization, various formal and informal research approaches can be used. These approaches include conducting acquaintance meetings, procedures and approval, interviews, and conducting experiments. The results of these approaches are important in obtaining the needed information and proposing the framework shown in Fig. 1. The framework includes the acquaintance meetings, procedures and approvals, interviews, experiments, and workflows.

Fig. 1. Proposed framework for creating motion templates of FDs using MoCap.

A. Acquaintance Meeting

The main purpose of acquaintance meetings is to gather information about the FD present in certain areas. Therefore, meetings with FD experts from the State Tourism Department and the Centre for Arts and Heritage at the local Institute of Higher Learning (IHL) are crucial to gather the information. The results of the acquaintance meetings can take the form of the following:

- Documentation of local FDs such as forms, articles, journals, policies, and guidelines.
- Identification of experts/founders of the local FDs
- Clarification of history and background of local FDs
- Explaining the movement styles and types of FDs

The knowledge gained from the acquaintance meetings can be used for the next steps; procedures and approval.

B. Procedures and Approval

To further investigate the local FDs, the procedures and approval related to laws and their procedures can be applied and implemented. These are listed below:

1) *Letter of intent for conducting the research at the potential sites/locations:* The potential sites/locations usually result from the previous acquaintance meetings. This letter is important to obtain the consent and cooperation of the potential sites for the study of the corresponding FDs. The content of this letter must address the need and importance of researching the local FDs, in addition to explaining the research team and the use of current technology to digitise the FDs. The need for teachers, experts or trainers to participate should also be mentioned in this letter.

2) *Invitation letter for conducting the fieldwork:* Once the consent and cooperation of the potential sites have been obtained, this letter should indicate the need for recording the movements of the masters, teachers, experts or trainers in the target sites. This fieldwork typically involves recording the movements of teachers or trainers using specific MoCap devices. The recorded movement data can be used as motion templates. The content of the letter should include an explanation of the type of MoCap devices used in the fieldwork and the results obtained when using the recorded movement data to create the movement templates.

3) *Request for Verification of Motion Templates:* The purpose of this letter is to request expert assistance in verifying the motion templates developed using the captured motion data. This step is important to ensure the authenticity of the local FDs under investigation. The letter must include the need for multiple experts among the masters, teachers, or instructors to be present at a specific date, time, and location.

4) *Application for copyright:* Copyright may be requested for any movement template created by FDs. The rights that creators have over their literary and artistic creations are critical to describing the copyrights in the created movement templates. The letter can be forwarded to potential

parties that can assist in funding and managing the publication of copyrights, such as the Intellectual Properties Corporation, the Division of Research and Development in certain IHLs.

These procedures and approvals step must occur in order for the research to be conducted effectively, especially when laws and confidential issues are involved.

C. Interviews

Interviewing is one of the most important methods to obtain and collect information about the FD under study and to verify the validity of the information. The interview can be conducted in a variety of formats including structured, semi-structured, and unstructured interviews [17] to meet the experts on FDs such as masters, teachers, trainers, etc. The frequency of interviews depends on whether the information collected is satisfactory and sufficient.

The results of the interviews are usually overviews of the type of FDs under study such as background, history, founders, and types of movements. In addition, the experts can be educated about the purpose of the study and the experiments to be conducted.

D. Experiments

The experiments are proposed to implement the methods planned in the research such as the proposed workflow and the collection of data from MoCap. The experiments usually involve the FDs experts and trainees in two different phases (development and evaluation), especially in collecting and recording their movements with MoCap devices. The development phase focuses on creating motion templates for FDs to use as benchmarks and reference sources. FD experts among teachers and trainers are involved in this phase. Later, the motion templates produced will be used as benchmarks in the dance evaluation phase by comparing the dancers' physical movements with the recorded movements in the motion template.

Therefore, explaining the experimental procedure is crucial to achieve the desired results. This includes the frequency of repetitions of the movements to be performed during recording with MoCap, the position and distance between the dancers and the MoCap device, the types of FDs to be implemented, and the types of actions to start and stop the movements.

E. Proposed Workflow

To generate the motion templates of FDs, the workflow in Fig. 2 is proposed. The workflow includes MoCap, skeleton generation, refined skeleton, and evaluation models. This workflow is used in the development phase.

Fig. 2. Proposed workflow for creating motion templates of FDs using MoCap.

1) *MoCap*: The MoCap model is used to capture motion data using specific MoCap techniques. MoCap techniques can be divided into marker-based and markerless MoCap. Both techniques have their own advantage in terms of performance, accuracy and cost. Examples of marker-based MoCap devices Optical Motion Capture System Qualisys, Vicon, Peak Performance Motion Capture System, Optoelectronic Motion Analyser, Eagle-Hawk System, and MAC3D Motion Capture System, while markerless MoCap devices are Kinect, PrimeSense Sensor, Sony PlayStation Eye, and Intel's Creative Camera [18].

The selection and use of these sensor devices usually depends on the provision of research funding and the complexity of the captured motion [19]. The marker-based MoCap techniques can guarantee high accuracy in capturing and tracking the human movements. However, attaching markers to a performer's body can restrict the performer's movements, which may affect the quality of the performance [20]. Moreover, marker-based MoCap techniques are usually developed in specialised and static studios. The cost of developing such studios is high. In contrast, the markerless MoCap techniques offer more freedom in movements and performance, as well as affordable prices, since no markers are attached to the performer's body, and no specialised studios are needed.

2) *Skeleton generation*: The skeleton generation model is used to project the skeleton for body movements. The data obtained from the motion recording is considered accurate. The skeleton is a set of systematically linked joints. The skeleton data is converted to specific file formats such as SKL, FBX, BVH, and CSV so that it can be used to enhance the data.

The skeleton file format (SKL) contains motion capture information, i.e., the spatial locations of points on the human body called joints. The SKL file format can be used and supported in Kinect Studio, Gesture Description Language Studio (GDL), and OpenNI [21,22]. In addition, the SKL file format can be found in the documentation for the 3D modeling software MilkShape 3D. According to the documentation, SKL files are "skeleton files that contain the bone hierarchy of the model and the positions and orientations of the bones in each frame of the animation" [23]. This file format is also used to capture motion data from human subjects during various exercises [24].

The FBX file format is created using the Autodesk FBX program. This file format can be created and modified in a variety of modeling programs such as Maya, 3ds Max, and Blender. FBX files can contain a variety of data types, including mesh, material, texture, and skeletal motion information. Animation data in FBX files is typically stored in keyframe format, with the position, rotation, and scale of each joint stored for each frame of animation [25]. They are therefore ideal for use in video games and computer graphics. In addition, FBX files can be imported into other software programs that accept the FBX format from Autodesk software programs [26].

Biovision Hierarchy (BVH) file format a file format commonly used in motion capture to store skeletal data [27]. This file format consists of ASCII text with a time-framed sequence of different specifications for subsequent poses. The first part of the ASCII text specifies the initial pose of a human skeleton. The hip joint is designated as ROOT in the first section of a BVH file, preceded by the keyword HIERARCHY, indicating that it has no progenitor joints. It serves as the parent joint and as the child joint of a nested construction [28,29].

Comma-Separated Values (CSV) is a file format used to store tabular data [30]. In the context of motion capture, CSV files can be used to store motion data in a format that can be easily imported into 3D animation software. CSV files typically contain a series of rows, with each row representing a frame of the animation and each column representing the position, rotation, or scale of a particular joint in the skeletal structure. The data in each row of the file contain three columns (X, Y and Z coordinates) separated by commas. The name of this file format is derived from the fact that the fields are separated by commas. In most cases, the data is simply entered into a text file as ASCII numeric values separated by commas [31].

3) *Refined skeleton*: The refined skeleton model is used to correct or refine certain minor motion errors by adjusting the keyframes for each joint in the skeleton. This process can be done using certain 3D programs such as Autodesk Maya, Blender, 3D Studio Max, ZBrush, Adobe Dimension, Cinema 4D, Sense, Houdini etc.

Knowledge of human anatomy is crucial in this process so that the joints of the skeleton can be adjusted as desired. Moreover, keyframing, graph editor for animation and rigging techniques like Euler filter, Butterworth and noise reduction are also important to minimize the anomalies in the skeleton.

Maya is a 3D modeling, animation, and rendering software developed by Autodesk [32]. It is widely used in the film and television industry for creating complex visual effects and character animation. Maya provides a wide range of tools and features for modeling, animation, texturing, and rendering, including support for advanced shading and lighting techniques such as physically based rendering (PBR) and high dynamic range (HDR) imaging.

Blender is a free and open source 3D software known for its versatility and ease of use [33]. It offers a similar range of tools and features as Maya, including support for advanced shading and lighting techniques. Blender is widely used in the gaming industry for asset and environment creation, and in the film and television industry for visual effects and animation.

3D Studio Max is a 3D modeling, animation, and rendering software developed by Autodesk [34]. It is similar to Maya in terms of tool selection and features, but is more focused on architectural and engineering visualization, as well as product design and prototyping. 3D Studio Max also provides support for advanced shading and lighting techniques and is commonly used in the architecture and engineering industries to create 3D visualizations of buildings and other structures.

Other popular 3D software packages include Cinema 4D, Houdini, and ZBrush, all of which have their own strengths and weaknesses depending on the specific needs of the user. In conclusion, the choice of 3D software largely depends on the specific requirements of the project and the skill level of the user. Maya, Blender and 3D Studio Max are all popular programs with their own unique features and capabilities.

4) *Evaluation*: a heuristic evaluation is proposed to evaluate the review of the created motion templates. Heuristic evaluation is one of the usability engineering techniques used to identify usability problems in user interface design so that they can be fixed during an iterative design process. The goal of heuristic evaluation is to identify usability problems in a user interface design so that they can be fixed during an iterative design process. It is the most widely used inspection method; it is inexpensive, intuitive, and easy to use compared to other evaluation methods, and it does not require pre-planning [35]. In heuristic evaluation, the interface is examined by a small group of evaluators and checked for compliance with established usability guidelines. According to Nielsen [36], the recommendation for a heuristic evaluation is three to five people. A heuristic evaluation session for a single evaluator typically takes one to two hours. For larger or more complex interfaces with a significant number of dialogue pieces, longer evaluation sessions may be required; however, it would be preferable to break the evaluation into numerous smaller sessions, each focusing on a different aspect of the interface. The main goal of heuristic evaluation is to identify usability problems in user interface design using ten (10) established heuristic principles [37].

Heuristic evaluation is a testing method based on the characteristics of reusability of the system in terms of user interface design, which enables fast and effective problem solving and decision making. Heuristic evaluation is an approach used in this case to identify a set of usability criteria of the motion templates and 3D model for FDs, for example, in cases where the criteria do not meet user requirements. The heuristic evaluation is used to successfully improve the design. By having the design perform a series of activities, the evaluator can assess how well it meets the standards for each stage [38]. In the testing in this application, heuristic evaluation is performed in accordance with the ten Nielsen principles, which include visibility of system state, consistency with the real world, user control and freedom, consistency and standards, error prevention, recognition, flexibility and efficiency of use, aesthetic and minimalist design, helping users detect, diagnose, and fix errors, and help and documentation. The authors plan to evaluate the application using heuristics, which is supported by the above description.

The goal of the heuristic evaluation is to identify as many usability issues as possible in the development of the motion templates and 3D model character for FDs. The feedback from the experts is important to design and develop good motion templates and 3D model characters for FDs. To achieve this, a heuristic evaluation procedure is performed in this step:

a) Distribute an online questionnaire and video clip via email before conducting a testing session.

b) Schedule a 2-hour appointment with the experts to conduct the assessment.

c) The experts provide their feedback via online questionnaires.

d) The results obtained are analysed and used to develop a framework and prototype.

In summary, heuristic evaluation is the most widely used inspection methodology; it is inexpensive, intuitive, and easy to use compared to other evaluation methods, and does not require advance planning [35].

III. DATA COLLECTION AND ANALYSIS

MoCap can generate raw FD motion data based on expert movements. The trajectories of the motion data can be collected and analyzed in a variety of file formats such as FBX, SKL, BVH, CSV, etc., which can be used in 3D software. Observing the keyframes for each motion is critical to ensure that the motion data is rendered as accurately as possible with few anomalies. Having the correct and accurate motion data is important for creating motion templates that can be used in a variety of areas.

Once the motion templates are created, the verification analysis of the created motion templates can be performed to maintain the level of efficiency, accuracy and satisfaction. The appropriate tool or procedure to verify the created motion templates is heuristic evaluation. The data collected by the FDs experts can be analyzed to verify the created motion templates.

In order to use the motion templates in certain platforms such as virtual reality, augmented reality, animation, simulation, games, etc., verification analysis must be performed for FDs motion templates with 3D characters.

The evaluation of VR, AR, animation, simulation, and game platforms can also be tested using the Technology Acceptance Model (TAM) and the Unified Theory of Acceptance and Use of Technology (UTAUT). TAM and UTAUT are both widely used models in the field of technology acceptance and adoption.

TAM is a theoretical model that explains how users perceive and adopt new technologies [39]. The model was originally proposed by Davis in 1989 and later modified by Venkatesh and Davis in 2000. According to TAM, two main factors influence user acceptance of technology: perceived usefulness (PU) and perceived ease of use (PEOU) [40]. PU refers to the extent to which a user believes that using the technology will improve his/her job performance, while PEOU refers to the extent to which a user believes that using the technology will be easy and effortless. The model suggests that PU and PEOU are the most important determinants of a user's attitude toward technology, which in turn affects his or her intention to use it [41].

UTAUT is a model that explains the factors that influence user acceptance and use of technologies [39]. The model was developed by Venkatesh et al. in 2003 [42] and is based on

four key factors: performance expectancy (PE), effort expectancy (EE), social influence (SI), and facilitating conditions (FC). PE refers to the extent to which a user believes that using the technology will improve his or her job performance, while EE refers to the extent to which a user believes that using the technology will be easy and effortless. SI refers to the extent to which a user believes that influential people in his or her life believe that he or she should use the technology, while FC refers to the extent to which a user believes that he/ she has the resources and support necessary to use the technology [42].

IV. EXPECTED RESULTS AND DISCUSSION

By implementing the approaches proposed in this research, the expected results can be presented and discussed in detail.

Using the proposed framework, the digitization of different types of FDs can be implemented using MoCap. MoCap technology captures movements with high precision, allowing detailed analysis of the specific body movements and gestures characteristic of FDs. This information can be used to create templates for movement patterns that can be used as references by dancers, choreographers, and researchers [16]. The proposed framework provides suggestions and guidelines for conducting research to create movement templates for FDs.

Moreover, the creation of motion templates for FDs is very important for the future generation. With the motion templates, this kind of valuable intangible cultural heritage can be preserved, conserved, and bequeathed to future generations [43]. Preservation, conservation, and inheritance can be done through various platforms such as virtual reality, augmented reality, simulation, film, animation, games, e-learning, etc. The representation of FDs on these platforms may be able to attract people and introduce them to FDs.

The movement templates can also be used to standardize the teaching and performance of folk dances. By creating movement templates that represent the correct movements and gestures, dancers can learn the dances more efficiently and accurately. This can also help maintain consistency in performances by ensuring that the dances are presented in the same way each time they are performed [16].

At the same time, the movement templates of local FDs can be copyrighted to formally register them as local intangible cultural heritage. This is because the appearance of the motion templates shows their uniqueness and innovativeness compared to the existing local FDs.

It may also be associated with collaboration and cooperation with other third parties. In many cases of local FDs, the experts are outsiders or come from different organizations. In addition, the movement templates created may themselves attract the creative content industry. This may provide an opportunity for commercialization of the created movement templates.

V. CONCLUSION

This paper presents and discusses in detail the framework proposed in this study for the creation of movement templates

of FDs with MoCap for the preservation and conservation of intangible cultural heritage. This framework includes conducting acquaintance meetings, procedures and approval, interviews and implementing experiments and proposed workflow. The findings from this framework are important and inter-relevant to obtaining the desired information.

The acquaintance meetings can be in the form of documentation and identification of experts that are important to gather the information about the local FDs present in certain areas. Letter of intent for conducting the research at the potential sites/locations, Invitation letter for conducting the fieldwork, Request for Verification of Motion Templates and Application for copyright are important to ensure the eligibility of the research conducted especially when law and confidential issues are involved. Meanwhile, the interviews are also important to get an overview of the types of FDs studied such as background, history, founders, and types of movements. Clarification of the purpose of the study and the experiments to be conducted can also be discussed with the experts. The workflow proposed in this study includes MoCap, skeleton generation, refined skeleton, and evaluation models.

For future work, this study is willing to apply the research approaches proposed in this paper to build the motion templates for local FDs in Malaysia. In Malaysia, FD has been registered and categorized as a performing art under Intangible Cultural Heritage. There are many FDs in Malaysia such as Tarian Gamelan, Tarian Piring, Tarian Zapin, Tarian Mak Yong, Tarian Sumazau, Tarian Ngajat, Tarian Kipas, Tarian Kathak, Tarian Kuda Kepang and others. It is expected that the implementation of the familiarization meetings, procedures and approval, interviews, experiments, and framework will fulfill the goals of facilitating the digitization of FDs and the preservation and conservation of this type of valuable intangible cultural heritage.

ACKNOWLEDGMENT

The author would like to acknowledge the Ministry of Higher Education (MoHE) and Center for Research Excellence and Incubation Management (CREIM), Universiti Sultan Zainal Abidin for the financial support through DPU1.0 research grant (Project Code: R0309, Ref. No: UniSZA/2021/DPU1.0/05) as well as Terengganu State Tourism Department for the shown interest and future collaboration in this study.

Abstract—Due to the growing need to use devices with low hardware resources in everyday life, the likelihood of their susceptibility to various cyber-attacks increases. In this regard, one of the methods to ensure the security of information circulating in these devices is encryption. For devices with small hardware resources, the most applicable is low-resource (lightweight) cryptography. This article introduces a new lightweight encryption algorithm, ISL-LWS (Information Security Laboratory – lightweight system), designed to protect data on resource-constrained devices. The encryption algorithm is implemented in the C++ programming language. The paper presents the statistical properties of ciphertexts obtained using the developed algorithm. For the experimental testing for statistical security, the sets of statistical tests by NIST and D. Knuth were used. Separately, the ISL-LWS algorithm was tested for avalanche effect properties. The obtained results of statistical tests were compared with the Present and Speck modern lightweight algorithms. The study and comparative analysis of the speed of encryption and key generation of the three algorithms were carried out on the Arduino Uno R3 board.

Keywords—Lightweight block cipher; S-box; linear transformation; avalanche effect; IoT devices; RFID tags; null hypothesis; NIST tests; D. knuth tests

I. INTRODUCTION

The main directions of the development of cryptography are largely associated with the development of communications and information technology. It is the progress in these areas that has made possible the widespread use of compact devices with low computing power that have access to the Internet and implement the concept of the Internet of Things (IoT) [1][2]. Examples of such devices are radio frequency tags (RFID), automated process control systems (SCADA), wireless sensors, electronic personal identification tools, etc. [3].

Lightweight ciphers are often less secure than traditional ciphers such as AES. This is because lightweight ciphers are optimized for high speed and low power consumption, not maximum security.

As defined by the US National Institute of Standards and Technology (NIST), lightweight cryptography is a subcategory of cryptography that aims to provide solutions for high-growth applications that make extensive use of low-power smart devices [4][5]. Modern cryptographic algorithms can work well on computers, servers, and some mobile phones, but IoT devices, smart cards, and RFID tags require the use of lightweight cryptographic algorithms [6].

When building lightweight block encryption algorithms, the following architectural solutions are used [7]:

- Reduction of the block size from 128 bits to 64 bits;
- Use of keys 64, 80, and 128 bits long;
- Use of 4-bit S-boxes instead of 8-bit ones;
- Use of a simplified key schedule.

Designing algorithms based on well-studied and widely used operations that perform elementary linear/nonlinear transformations.

When creating lightweight block ciphers, the following structures are used [8]:

- Feistel network;
- Substitution-permutation network (SP-network) using substitution boxes of small length;
- LRX-structure (logical operations, rotate left (right) shift, and addition modulo 2);
- ARX-structure (addition modulo 2^n , rotate left (right) shift, and addition modulo 2).

One of the main issues in lightweight cryptography is achieving a balance between security, efficiency, and cost. Obviously, optimizing a lightweight cipher to achieve high speed can weaken some of its security properties, and the algorithm will be more vulnerable to some attacks. Therefore, when developing a lightweight cipher, the first step is to determine the requirements for its security and limited resources, taking into account the scope of its application. When developing the encryption algorithm, the authors tried to balance security and speed.

This article presents a new lightweight symmetric block cipher algorithm ISL-LWS and its statistical analysis. The scientific novelty of the proposed algorithm is the SP transformation, which is performed in parallel by linear (P-box) and non-linear (S-box) cryptographic primitives, where two S-boxes are used simultaneously. This procedure makes it possible to increase the degree of non-linearity and data confusion in fewer rounds. An overview of related work is presented in the next Section II. Section III presents the developed algorithm, which is designed according to the Feistel network and includes linear and non-linear transformations that provide a high level of diffusion and confusion. The round key schedule algorithm is also presented

here. The results and discussion of the statistical tests are presented in Section IV. In addition, this section describes data on the hardware-software implementation of the algorithm and comparative performance analysis. Section V presents the conclusion, where the results of the work are indicated.

II. RELATED WORK

To date, a fairly large number of lightweight block encryption algorithms based on SP networks and Feistel networks are known [9]. Both approaches have their advantages and disadvantages in the context of constructing algorithms in conditions of limited resources. Lightweight block ciphers are represented by the following algorithms: Present [10][11], Clefia [12], Katan [13], Simon [14], Speck [15], Secure IoT (SIT) [16], etc.

A study by Xinxin Fan et al. (Fan et al. 2013) introduced a lightweight WG-8 encryption algorithm of the Welch-Gong family of stream ciphers, adapted for devices with low hardware resources [17]. Typically, some of them have been improved and developed by simplifying block ciphers to improve their performance. For example, DESL which is also known as lightweight DES, is a variant of classic DES. The main difference between the DESL cipher and the DES algorithm is that the former uses one S-box instead of eight ones, which reduces the ROM requirements for storing tables by eight times.

The lightweight encryption algorithm Present [18] is described in the article by L.K. Babenko, D.A. Bespalov, O.B. Makarevich, R.D. Chesnokov, and Ya.A. Trubnikov. The authors of this article have developed a software implementation and synthesized it into a hardware unit for a system on a chip within the framework of the requirements for low-resource cryptography, having obtained a sufficiently effective solution for its application in devices. In 2012, the ISO and IEC organizations included the Present algorithm in the international standard for lightweight encryption ISO/IEC 29192-2:2012.

Speck is a block lightweight encryption algorithm developed by the US National Security Agency. Speck is one of the fastest in lightweight cipher benchmarks, but its performance is highly dependent on architecture. Speck supports several block and key sizes. The block length can be 32, 48, 64, 96, and 128 bits. The key length depends on the block size. The range of key sizes is 64, 72, 96, 128, 144, 192, and 256 bits. The number of encryption rounds depends on the block size and the key. The range of rounds is 22, 23, 26, 27, 28, 29, 32, 33, and 34. Speck is standardized by ISO within the RFID air interface standard [15].

In a study by Muhammad Usman et al. 64-bit block lightweight encryption algorithm SIT [16] with a key length of 64 bits is considered. The architecture of the algorithm is a mixture of a Feistel network and an SP network. Conducted studies show that the algorithm provides significant security after five rounds of encryption.

Thus, R&D on the development and study of lightweight encryption algorithms is relevant.

III. LIGHTWEIGHT ENCRYPTION ALGORITHM ISL-LWC

The block diagram of the proposed ISL-LWC lightweight block encryption algorithm is shown in Fig. 1.

The main parameters of the algorithm:

- block length – 64 bits;
- key length – 80 bits;
- number of encryption rounds - 16.

The algorithm uses SP transformation, modulo 2 addition (XOR operation), rotate shift, and non-linear transformations in the form of S-boxes (S).

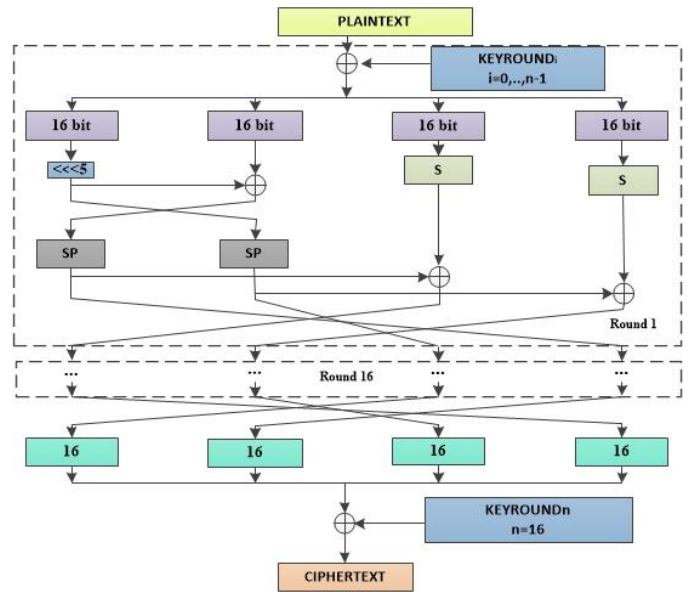

Fig. 1 Scheme of the encryption algorithm.

The encryption process consists of 4 stages:

Stage 1. A 64-bit plaintext block is added to the round key modulo 2 (XOR operation). Next, the resulting 64-bit block is divided into 4 subblocks of 16 bits each (the subblocks are numbered from left to right).

Stage 2. The 1st input subblock is rotated by 5, then the obtained value of the 1st input block is summed (XOR operation) with the 2nd subblock, and the resulting values are swapped in accordance with the scheme and go through SP transformations.

Stage 3. The 3rd and 4th sub-blocks go through the transformation S and then are added (XOR operation) with the results obtained at Stage 2 according to the scheme.

Stage 4. The results of Stages 2 and 3 are swapped according to the scheme of the encryption algorithm.

1) *SP transformation*: The SP transformation (Fig. 2) consists of non-linear 4-bit substitutions S-box1 and S-box2 (Tables I, II) and a linear bit permutation P-box (Table III). The methods for obtaining S-box1 and S-box2 are shown in [19]. The transformations above make it possible to perform confusion and diffusion.

Fig. 2 SP transformation scheme.

2) *S transformation*; Input 16 bits are represented as $a_0a_1a_2a_3a_4a_5a_6a_7a_8a_9a_{10}a_{11}a_{12}a_{13}a_{14}a_{15}$ of which every sequential 4 bits are represented as $m_i, i = 0, 3$. $m_0 = a_0a_1a_2a_3$, $m_1 = a_4a_5a_6a_7$, $m_2 = a_8a_9a_{10}a_{11}$, $m_3 = a_{12}a_{13}a_{14}a_{15}$. The values m_0, m_2 and m_1, m_3 are passed through 4-bit S-box1 and S-box2 and then swapped according to Fig. 3.

Fig. 3 S-box transformation process.

Round subkeys are generated on the basis of an 80-bit base key, which is divided into five sub-blocks of 16 bits each (sub-blocks are numbered from left to right) (Fig. 4). The cryptographic transformations used are the 4-bit S-box and addition modulo 2 raised to the power of the word length.

Fig. 4 Algorithm for generating round keys.

IV. STATISTICAL ANALYSIS OF CIPHERTEXTS

One of the main ways to test a block encryption algorithm for security is to conduct statistical analysis since most cryptographic attacks are based on the search for statistical vulnerabilities in the ciphertext.

To test sequences for randomness, there are a large number of algorithms, and for the convenience of checking sequences, software products have already been implemented that contain some sets of tests. Among them, the most common are the tests proposed by NIST, DIEHARD, CRYPT-X, D. Knuth, and others [20].

For statistical analysis of ciphertexts obtained using the ISL-LWC, Present, and Speck encryption algorithms, the NIST and D. Knuth test sets were used.

1) *NIST statistical tests*: NIST has developed a number of statistical tests which are based on the task of calculating a statistic that characterizes a certain property of a sequence compared with a reference statistic. Reference statistics are obtained mathematically, which is the subject of many theorems and scientific papers on cryptography, probability theory, and number theory. NIST tests have already been used to study the output sequences of cryptographic systems [21]. The tests are based on the concept of the null hypothesis. The null hypothesis is the assumption that there is some relationship between the occurrence of numbers. In other words, the null hypothesis is the assumption that the sequence is truly random (the symbols of which appear equally likely and independently of each other). Therefore, if such a hypothesis is true, then the encryption algorithm will perform well statistically.

To obtain the results of testing ciphers 15 NIST statistical tests were used: frequency bit test, frequency block test, test for a sequence of identical bits, test for the longest sequence of ones in a block, test for binary matrix ranks, spectral test, test for matching non-overlapping patterns, overlapping pattern matching test, Maurer's universal statistical test, linear complexity test, periodicity test, approximate entropy test, cumulative sums test, arbitrary variance test, and another arbitrary variance test [22].

Fig. 5 Comparative analysis of successfully passed NIST tests.

To study the statistical security of the ISL-LWC, Present, and Speck encryption algorithms using NIST tests, each algorithm encrypted 20 files, differing in size, on five different keys. As a result, 100 files were encrypted with each algorithm. The number of successfully passed NIST tests and a comparative analysis of the ISL-LWC, Present, and Speck encryption algorithms are shown in Fig. 5.

In each test, a so-called P-value is calculated, which indicates the level of randomness. If the P-value = 1, then the sequence is perfectly random, and if it is zero, then the sequence is completely predictable. Next, the P-value is compared with the threshold level of randomness α , and if it is greater than α , then the null hypothesis is accepted and the sequence is recognized as random, otherwise, it is recognized as non-random.

In the tests, $\alpha = 0.01$ is assumed. Therefore:

- If the P-value ≥ 0.01 , then the sequence is considered random with a confidence level of 99%;
- If the P-value < 0.01 , then the sequence is considered non-random with a confidence level of 99%.

As a result of the study and comparative analysis of the three encryption algorithms according to NIST tests, it was found that the percentage of successfully passed tests by algorithms is: ISL-LWC – 99%, Present – 97.5%, Speck – 97%. From the obtained results, we can conclude that the ISL-LWC algorithm satisfies the statistical security criteria.

2) *Statistical tests by D. Knuth*: One of the first sets of statistical tests was proposed by D. Knuth in 1969 and described in his classic work "The Art of Computer Programming". D. Knuth's set contains such tests as the serial test, gap test, poker test, coupon collector test, permutation test, monotonicity test, and correlation test. The tests are based on the chi-square (χ^2) statistical test. The calculated value of the χ^2 statistic is compared with the tabular results and, depending on the probability of occurrence of such a statistic, a conclusion is made about its quality [23]. Among the advantages of these tests are their small number and the existence of fast execution algorithms. The disadvantage is the uncertainty in the interpretation of the results [24].

To study the statistical security of the ISL-LWC, Present, and Speck encryption algorithms using the D. Knuth tests, we encrypted with each algorithm the same 100 files that were checked using the NIST tests. The number of successfully passed tests by D. Knuth and a comparative analysis of the ISL-LWC, Present, and Speck encryption algorithms are shown in Fig. 6.

As a result of the study on the tests of D. Knuth and a comparative analysis of the three encryption algorithms, it was found that the percentage of successfully passed tests by the algorithms is 93.5% for ISL-LWC, 99% for Present, and 99% for Speck. From the obtained results, we can conclude that the ISL-LWC algorithm satisfies the statistical security criteria.

Fig. 6 Comparative analysis of successfully passed tests by D. Knuth.

3) Study of statistical security indicators: For the study of statistical security, the following indicators were considered:

- average number of output bits that change when one input bit changes (avalanche effect);
- degree of completeness (d_c);
- degree of avalanche effect (d_a);
- degree of strict avalanche criterion (d_{sa}).

They are considered for various numbers of cycles and randomly taken encryption keys. The definition of the above indicators is presented in [25].

The essence of the experiment is to evaluate the depth of the avalanche effect of the ISL-LWC encryption algorithm, which is determined by the number of encryption rounds. The experiment was carried out on 100, 1000, and 10,000 blocks of ciphertext obtained using the ISL-LWC algorithm. Table IV presents the results of the assessment of the statistical security indicators of the ISL-LWC cipher.

TABLE IV RESULTS OF THE ASSESSMENT OF STATISTICAL SECURITY INDICATORS OF THE ISL-LWC CIPHER

Round number	D_{min}	D_{max}	d_w	M_{min}	M_{max}	m_w	d_c	d_a	d_{sa}

15	14,6191	16,4813	15,5504	30,6261	33,2589	31,9425	1	0,9899	0,9225
16	14,8984	16,7601	15,8293	30,6467	33,2795	31,9631	1	0,9894	0,9202

In Table IV, the following designations are used:

- M_{min} is the minimum value of the mathematical expectation of the number of changed bits for some bit at the input;
- M_{max} is the maximum value of the mathematical expectation of the number of changed bits for some bit at the input;
- D_{min} and D_{max} are the variances of the number of changed bits in the bitwise estimation of the minima and maxima of the mean values;

m_w is the average number of changed bits:

$$m_w = \frac{M_{min} + M_{max}}{2} \quad (1)$$

Analyzing the data obtained in Table IV, we can conclude that with an increase in the number of blocks for encryption, more accurate values of d_a and d_{sa} , are obtained, i.e. they approach value 1 faster in the fourth and subsequent rounds. As a result of the study, it was found that at the 4th round of encryption of the ISL-LWC algorithm, the input sequence is completely confused.

Results of the study and comparative analysis of the time of encryption and key generation on the Arduino Uno R3 board.

Encryption time testing for three encryption algorithms Speck, Present, and ISL-LWC was carried out on the Arduino Uno R3 board (Fig. 7).

- main features of Arduino Uno R3;
- microcontroller - ATmega328;
- clock frequency - 16 MHz;
- operating voltage - 5 V;
- flash memory - 32 MB;
- RAM - 2 Kb.

Fig. 7 Arduino Uno R3 board.

In [25] Arduino IDE version 2.0.0-rc3 was used to compile and upload the source code of lightweight encryption algorithms to the Arduino Uno R3 board (Fig. 8).

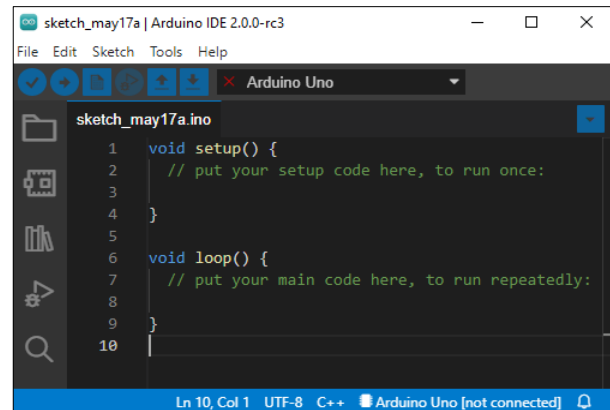

Fig. 8 Arduino IDE.

The three encryption algorithms (Speck, Present, and ISL-LWC) were implemented by the staff of the Information Security Laboratory of the Institute of Information and Computational Technologies of the Committee of Science of the Ministry of Science and Higher Education of the Republic of Kazakhstan (RK MSHE CS ICT ISL) in the high-level programming language C++.

The tests were carried out on open-source software platforms developed by the US National Institute of Standards and Technology in order to unify, simplify, and speed up the testing of lightweight cryptographic algorithms.

The results of the study and comparative analysis of the Present, Speck, and ISL-LWC algorithms are shown in Table V.

TABLE V COMPARATIVE ANALYSIS OF THE ALGORITHMS BY THE TIME OF ENCRYPTION AND KEY GENERATION

Encryption algorithm	Key size, bits	Plaintext block size, bits	Encryption time, μ s	Key setting time, μ s
Present	80	64	2111.56	1541.31
Speck	96		16.90	1320.69
ISL-LWC	80		108.59	275.12

As a result of a comparative analysis of Table V, it was found that the proposed encryption algorithm works faster than Present, and when scheduling round keys, it is 6 and 5 times faster than the algorithms under consideration, respectively.

V. CONCLUSION

Lightweight encryption algorithms are considered a relatively new direction in the development of symmetric cryptography. This need arose as a result of the emergence of a large number of devices with little computing power and memory. Therefore, there was a need to develop algorithms that can provide a sufficient level of security with minimal use of resources.

This paper provides a brief literature review of existing lightweight encryption algorithms. A new lightweight block encryption algorithm ISL-LWC, developed by the staff of the RK MSHE CS IICT ISL, is presented.

The cryptographic properties of the developed algorithm were studied using the evaluation of the "avalanche effect" and statistical tests. Based on the work carried out, it was found that the proposed encryption algorithm is effective in providing a good avalanche effect, and the encrypted data is close to random and is statistically safe.

The developed algorithm is implemented in software and hardware on the Arduino Uno R3 board. A study and comparative analysis of the encryption and key generation time with the well-known lightweight algorithms Present and Speck have been carried out.

The obtained test results allow us to conclude that the ISL-LWC cipher is generally not inferior to these two well-known lightweight algorithms. Further study of the cryptographic properties of this algorithm by other methods, such as linear and differential cryptanalysis, etc., will be continued. The results will be presented in subsequent papers and used to improve the proposed algorithm.

ACKNOWLEDGMENT

The work was performed within the framework of the grant funding project AP09259570 "Development and study of a domestic lightweight encryption algorithm with limited resources" of the RK MSHE CS.

An Investigation of Asthma Experiences in Arabic Communities Through Twitter Discourse

Mohammed Alotaibi^{1*}, Ahmed Omar²

Artificial Intelligence and Sensing Technologies (AIST) Research Center, University of Tabuk, Tabuk 71491, Saudi Arabia¹
Department of Computer Science-Faculty of Science, Minia University, Minia, Egypt, University Street, El-Minia 1666, Egypt²

Abstract—Artificial intelligence technologies can effectively analyze the public opinions from social-media platforms like twitter. This study aims to employ the AI technology and big data to explore and discuss the common issues of asthma that patients share on Twitter platform in Arabic communities. The data was acquired using the Twitter API version 2. Latent Dirichlet Allocation was used for grouping data into two clusters which provide information and tips about the treatment and prevention of asthma and personal experiences with asthma, including symptoms, diagnosis, and the negative impact of asthma on the quality of life. Sentiment analysis and data frequency distribution techniques were used to analyze the data in both clusters. The data analysis of first indicated that individuals are interested in learning about different ways to treat asthma and potentially finding a permanent solution. The data analysis of second cluster indicated the existence of negative sentiments about asthma, which also included religious expressions for improving the condition. The study also discussed the differences in expressions among Arabic communities and other communities.

Keywords—Asthma; twitter; semantic analysis; LDA; Arab; communities

I. INTRODUCTION

More than 350 million people worldwide suffer from asthma, which is one of the serious public health concerns [1]. Due to changes in the environment and in people's lifestyles, its prevalence and consequences are growing in urban areas and increasing around the world. It is the most prevalent chronic childhood condition as well as one of the most expensive healthcare expenditures.

One of the most prevalent forms of reactive airway disease is asthma, which is also associated with a higher risk of death and permanent impairment [1]. Atopic dermatitis and genetic predisposition mix with eosinophilic inflammation and ongoing exposure to environmental factors, particularly molds and pollution can cause progressive lung dysfunction. Also, due to greater understanding of the biology of the disease and therapeutic advancements, asthma-related mortality has decreased over the past few decades; nonetheless, more research and efforts are required to lower asthma-related death and disability. Also, it's estimated that asthma killed more than 1000 individuals worldwide [1].

The design and delivery of healthcare systems for the management and understanding of various chronic diseases like obesity [2-4], diabetes [5-8], and asthma have been accelerated by the rapid growth of technologies, smart mobile

devices, robotics, and social networks in telecommunications and the internet. A new virtual world was created as a result of the technological revolution; social networks now allow users to contact with friends and other people regardless of where they are in the world (geographically, politically, or economically). Globally, over 4.7 billion people use social networks, according to Statista [9], and this number is only anticipated to grow as mobile device use and mobile social networks gain popularity.

Twitter is one of the most commonly used social networks worldwide. It currently ranks as one of the leading social networks worldwide based on active users, according to recent social media industry statistics [9]. Twitter had 347.3 million monetizable daily active users worldwide as of the fourth quarter of 2020 [9]. Registered users can read and post tweets via the update feed, as well as follow other users [9]. This huge volume of posts on twitter platform provides billions of raw data that can be used for many purposes like research and business.

Big data is a term used to describe the enormous volume of both structured and unstructured data that regularly inundates a business [10]. Social networks in general are known as the most well-liked sources of big data. For example, each tweet posted on by a Twitter account includes multitude data input [Twitter account Id, Number of followers, Number of retweets, and Number of favorites etc.], all of which could be collected for each tweet, generating a huge volume of data in short time as the stream of data increase rapidly within seconds. Recently, artificial intelligence [AI] technology that uses huge volume of raw data has become one of the useful sources of information regarding people impressions/opinions about many events such as politics, social developments, pandemic etc.

AI technologies aid in the analysis of huge data, assisting decision-makers in their commercial decisions or governments in gaining insight into the views of the populace in their nation regarding a social, political, or economic issues. Sentiment analysis is a type of contextual text mining that can identify and extract subjective knowledge from various sources of information [11]. By monitoring online conversations, it assists a business in understanding the social perceptions of its brand, product, or service. As a result, the health sector participates in this virtual society as some patients share their experiences with the diseases they have and as some doctors have social media accounts and share clinical information with the public.

Using AI technologies for analyzing twitter conversations can be observed in healthcare research in different contexts.

For instance, twitter data was analyzed in [12] to understand the Covid-19 vaccine hesitancy; and the results revealed that potential side effects and vaccine safety were identified to be the major concerns among the public. Similarly, BERT-based supervised learning approach was used for analyzing over 31 million Covid-19 related tweets for self-disclosure in [13]. The study [13] found that users intentionally self-disclose and associate with similarly disclosing users for social rewards. Similarly, by analyzing HIV-related tweets [14] and diabetes-related tweets [15], recent research indicated that twitter discussions analysis can help in understanding nuanced public opinions, beliefs, and sentiments; and therefore, the decision-makers need to proactively use Twitter and other social media for understanding public health concerns. This is evident from a study conducted in Australia in 2019 [16]. A thunderstorm asthma outbreak in Melbourne, Australia, in 2016 led to over 8,000 hospital admissions in a matter of hours, which is a typical acute illness occurrence. A strategy based on the amount of time between events was suggested in this study since the time to respond to acute disease events is limited. Out of 18 experiment combinations, the results showed that three were able to identify the thunderstorm asthma outbreak up to nine hours ahead of the time specified in the official report, and five were able to identify it before the initial news report. The results of these studies [12-18] show the significance of Twitter monitoring and discuss conversational trends and prevailing attitudes that predominate in online social networks during a health crisis. In relation to twitter analysis of Asthma, previous studies [19-21] suggested the need for extensive research on using big data the asthma's contents in different contexts. To the best of authors' knowledge, there is no study about asthma issues in Arabic communities. Therefore, this study aims to employ the AI technology and big data to explore and discuss the common issues of asthma that patients share on Twitter platform in Arabic communities.

The remainder of the paper is organized as follows. Section II includes a review of related work. Section III describes the used methodology to develop the study. Section IV illustrates the outcomes and studies the results; and Section V discusses the results achieved while Section VI summarizes findings and outlines direction for future work.

II. RELATED WORKS

Asthma is one of the most common chronic health problems that have a significant negative influence on both society and an individual's well-being [1]. To create an epidemiological framework that can depict the condition's prevalence and patients' perceptions of that condition across multiple geographies, it is essential to integrate various large-scale data sources. Moreover, the number of social media applications has substantially increased over the last decade [20]. Twitter is a critical interactive venue for research information because statistics show that more than 80% of internet users look for health information online [9]. Social media is now being used by both patients and carers for support and information. They rely on social media for information and feedback from others to get the latest news and information on medications and treatments. Some even create and join online groups to provide support to each other.

In the contemporary era, Twitter was utilized in the health sectors, for example, to track and predict the spread of influenza [23-26]. It's also used to keep track of pharmaceutical side effects and understand the well-being of military populations [27], as well as to monitor the side effects of pharmaceuticals [28, 29]. These studies indicate the importance of social media data in public health, refining the target hypothesis' query lexicon and lowering the amount of noise in the extracted data. Despite the potential benefits, it is believed the following challenges explain why prior social media sensing experiments in public health have been short-lived or limited in scope. For example, [24] and [25] track influenza throughout a one- and two-month period, respectively. Moreover, the study in [27] investigates the harmful effects of medication over a six-month period. In terms of geographical coverage, just a few cities are examined in [24], and the transmission of influenza is studied at the national level rather than at the state or county level in [25]. Moreover, a study developed in 2013 [19] aimed to present Natural Language Processing-based Content Analysis research to aid with Asthma syndromic surveillance on Twitter. They used the Twitter API to get a big number of Tweets. Asthma and various misspellings of that word were among the search results, as were phrases for common medical devices linked with Asthma, such as "inhaler" and "nebulizer," as well as names of prescription medicines used to treat the illness, such as "albuterol" and "Singulair". Annotating the content of a randomly selected subset of these Tweets [N=3511] was done using an annotation scheme that coded for the following elements: the Asthma Symptom Experiencer [Self, Family, Friend, Named Other, Unidentified, and All-Non-Self, which was the union of these last four categories]; aspects of the type of information being conveyed by each Tweet [Medication, Triggers, Physical Activity, Contacting of a Medical Practitioner]. With the unigram model, SVM with 10-fold cross-validation achieved the highest prediction accuracy. Non-English, Self, All-Non-Self, Medication, Symptoms, and Spam were the categories with the highest reduction in classification error when utilizing the unigram model. For the unigram model, most of these categories demonstrated very high Precision and very high Recall. Surprisingly, the Unigram model performed significantly better than the bigram model, implying that individual words in these Tweets were more reliably predictive of content than pairs of words, which were less common. Authors concluded that using social media, such as Twitter, to undertake surveillance for chronic illnesses like Asthma is a promising method.

Moreover, another recent study [20] looked at the digital footprints [or "sociomes"] of asthma stakeholders on Twitter to see how they communicated online. Symplur Signals were used to collect tweets containing the word "asthma" and the hashtag #asthma. The characteristics of usage and tweets were examined between the words "asthma" and the hashtag #asthma, and then between four stakeholder groups: clinicians, patients, healthcare organizations, and industry. Authors found that with fewer people and tweets each month, the #asthma sociome was substantially smaller than the "asthma" sociome. The #asthma sociome, on the other hand, had a better correlation with asthma seasons and was less vulnerable to profanity and viral memes. Consequently, between April 2015

and November 2018, 308,370 individuals tweeted 695,980 times for the #asthma sociome. Clinicians accounted for 16% of tweets, patients for 9%, healthcare organizations for 22%, and industry for 0.3 percent. However, authors recommended that further research could aid in improving health-care communication and guiding patient and provide education.

In a different context, a recent study [21] focused on analyzing the most popular tweets and the quality of the links posted, and to determine what factors influence the debate about asthma on Twitter. The authors used Symplur Signals to extract data from Twitter, analyzing the top 100 most shared tweets and the top 50 most shared links with the hashtag #asthma. Each website's content was evaluated using an Asthma Content score, as well as validated DISCERN ratings and HONCode standards. They found out that the top 100 asthma-related tweets received 16,044 likes and were shared 10,169 times. Non-healthcare individuals accounted for 20 of the top 100 tweets, non-healthcare organizations accounted for 16, and doctors accounted for 14. There were 62 educational tweets among the top 100, 11 research-related tweets, ten political tweets, and 15 promotional tweets among the top 100. Moreover, the top 50 links were shared a total of 6009 times [median number of shares 92 (range 60-710)]. The most prevalent type of link was found to be instructional content (42%), followed by research papers (24%), promotional websites (22%), and political websites (12%). The Asthma Content ratings of educational links were higher than those of other links ($p=0.005$, $p<.05$). For all sorts of linkages, all three scores were poor. Only 34% of sites passed the HONCode criteria, and only 14% were found to be of good quality by the DISCERN score. The authors concluded that majority of tweets with the hashtag #asthma was educational. However, most top Twitter links rated low in terms of asthma content, quality, and trustworthiness.

A recent study [30] the impact of socio-cognitive factors on adherence to asthma medication using traditional mixed methods (interviews and twitter content analysis) and machine learning, found that some perceptions are more freely expressed on social media such as Twitter, than in the laboratory setting. Therefore, twitter data may be more reliable for understanding of public perceptions of asthma and its relevant factors compared to laboratory/hospital data in few instances. It should be noted that all studies refer to main role of tweets contents on understanding more about asthma while some studies recommend to do more search about the tweets contents towards asthma. However, this study is an attempt to contribute in adding a value to the understanding of tweets contents about asthma in Arabic communities.

III. METHODS

The study method occurred in the following phases, as shown in Fig. 1: data collection, data preprocessing (cleaning), sentiment analysis, and frequency distribution.

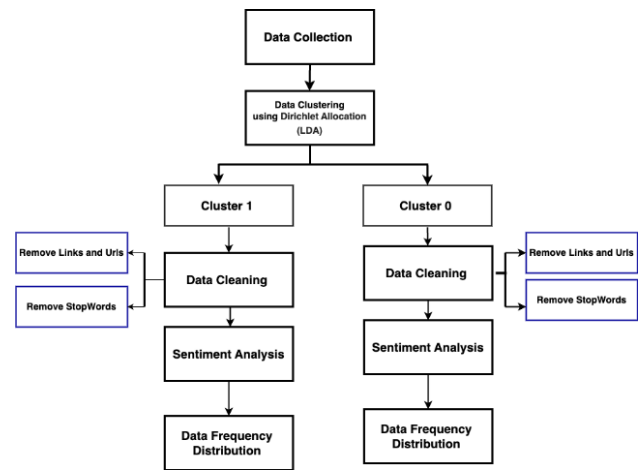

Fig. 1. Study methodology flowchart.

A. Data Collections

The data was acquired using the Twitter API version 2, premium version, which offers several additional features above the regular API version. The premium version of the Twitter API allows users to collect data from the previous 30 days. However, to enable the collection of data in excel sheet format, a python script was created. As search keywords, two separate terms [Asthma, asthmatic] were utilized. These hashtags were picked because they are popular on Twitter. User ID, user location, tweets, account followers, favorites, and retweets are all collected and kept in an excel sheet for further statistical research. One hundred thirty thousand (130,000) tweets including words asthma or asthmatic have been collected.

B. Data Clustering using Latent Dirichlet Allocation [LDA]

A statistical modeling technique called topic modeling can be used to identify the general "themes" that appear in a group of texts. A topic model such as Latent Dirichlet Allocation [LDA] is used to categorize text in a document to a certain topic. It creates a topic per document model and a words per topic model using Dirichlet distributions as the modeling framework.

C. Data Processing and Cleaning

In order to make the data clear, the following steps are followed: (1) personal interview, authors review all tweets and remove tweets that have no relation to asthma. (2) Python scripts were used to remove all tweets that include links or URLs because some of those tweets refer to another reference or for advertisement of a product etc. (3) another Python script was used to remove the stopwords in Arabic language from the tweets' contents. (4) a python script was used to tokenize tweets. Tokenization is one of the most fundamental yet crucial procedures in text analysis. Tokenization divides a stream of text into smaller pieces called tokens, which are frequently words or sentences. While this is a well-known issue with various ready-to-use solutions from popular libraries, Twitter data presents significant issues due to the language's nature.

E. Sentiment Analysis

One of the most beneficial applications of natural language processing is sentiment analysis (SA). We used "Mazajak" which is an Arabic SA system on the internet. The system is built on a deep learning model that produces cutting-edge results on a variety of datasets for Arabic dialects, including SemEval 2017 and ASTD. The existence of such a system ought to be helpful for numerous applications and fields of study that use sentiment analysis as a tool [31].

F. Data Frequency Distribution

As it is known in every language, some words are widespread. Notably, their use in the language is crucial; they don't usually convey a particular meaning, especially if taken out of context. Therefore, in this case of data frequency distribution, stop words were removed from each tweet using python scripts; also, removing the URL was performed.

G. Anonymity and Privacy

The data (preferred as tweets) utilized in this research is freely available on the internet. However, we decided to respect the privacy of the tweet senders. As a result, the User ID of all records were removed. Perceptions were defined as socio-cognitive elements such as opinions, beliefs, and feelings in this study, and this was also the definition of perceptions employed.

IV. RESULTS

We used LDA topic modeling to group the collected tweets into two clusters. The first cluster [cluster 0] contains tweets that provide information and tips about the treatment and prevention of asthma, including natural remedies, inhalation therapy, and the use of specific products. In contrast, the second cluster [cluster 1] contains tweets that discuss personal experiences with asthma, including symptoms, diagnosis, and the negative impact of asthma on the quality of life. There are also some tweets in this cluster that express frustration and negative feelings about asthma. In the following section we will presents and display some distributions of each cluster.

A. Cluster 0

Fig. 2 shows the distribution of sentiment in the first cluster. We can see that most of the tweets are labeled as neutral [62,366], followed by negative [32,913] and positive [6,412].

Fig. 2. Sentiment distribution in Cluster 0.

Fig. 3. Shows tweets length [number of characters] distribution.

Fig. 4. Shows word count tweets distribution.

Fig. 3 shows tweets length [number of characters] distribution while Fig. 4 shows the word count tweets distribution. Top 20 words [including stop words] frequency distribution before removing stop words is shown in Fig. 5.

Fig. 5. Frequency distribution of top 20 words in Cluster 0 before removing stop words.

The data shows that the word "الربو" [asthma] has the highest frequency with 108450 occurrences, followed by "من" [from] with 52865 occurrences, and "في" [in] with 38052 occurrences.

Further analysis of the distribution reveals that the words "علاج" [treatment], "مرض" [disease], and "مرضى" [patients] are also highly frequent, which suggests that the text or corpus is likely related to medical or health topics.

It is important to note that the distribution includes some common prepositions such as "على" [on] and "مع" [with], which may not carry significant meaning on their own but contribute to the overall frequency count.

Fig. 6 represents top 20 words frequency distribution after removing stop words. In the new distribution, the word "الربو" [asthma] still has the highest frequency with 109379 occurrences, but the words "علاج" [treatment] and "مرض" [disease] have increased in frequency, suggesting that the text or corpus may be more focused on medical treatments and

conditions. Additionally, words such as " لمرضى " [for patients] and " للاطفال " [children] have been replaced with " لمرضاي " [for my patients] and " للأطفال " [kids], respectively, indicating a slight difference in phrasing.

Fig. 6. Frequency distribution of top 20 words in Cluster 0 after removing stop words.

Fig. 7 shows the top 20 bigrams frequency distribution before removing stop words.

Fig. 7. Frequency distribution of top 20 bigrams in Cluster 0 before removing stop words.

Fig. 8. Frequency distribution of top 20 bigrams in Cluster 0 after removing stop words.

The provided data is a bigram frequency distribution, which lists the frequency of two-word phrases occurring in the text or corpus. In this case, the bigrams are not filtered for stop words. The most frequent bigram is " و " [asthma disease] with 10200 occurrences, followed by " مرضى الربو " [asthma patients] with 7110 occurrences, and " لمرضى الربو " [for asthma patients] with 6067 occurrences.

When compared to the previous distribution with stop words, it is evident that the bigrams in the current distribution are more specific and related to the topic of asthma and its treatment. The bigrams also provide more context and information about the text or corpus, such as the prevalence of asthma patients and the use of inhalers as a treatment.

However, it is important to note that the inclusion of stop words in the bigrams may result in some noise and redundancy, as some common phrases that do not carry significant meaning may also appear frequently. Therefore, filtering for stop words may help to reduce noise and highlight the most meaningful bigrams which is presented in Fig. 8.

After removing stop words (Fig. 8), the bigram frequency distribution shows that " مرض الربو " [asthma disease] is still the most frequent bigram with 10366 occurrences, followed by " مرضى الربو " [asthma patients] with 7330 occurrences, and " لمرضى الربو " [for asthma patients] with 6315 occurrences.

Compared to the distribution with stop words, the current distribution has fewer occurrences of bigrams, indicating that filtering for stop words has removed noise and redundancy. The bigrams in the current distribution are more specific and related to asthma and its treatment, such as " علاج الربو " [asthma treatment] and " بخاخ الربو " [asthma inhaler].

Fig. 9 shows the top 20 trigrams frequency distribution before removing stop words.

Fig. 9. Frequency distribution of top 20 trigrams in Cluster 0 before removing stop words.

Fig. 10. Frequency distribution of top 20 triigrams in Cluster 0 after removing stop words.

The previous distribution is a frequency distribution of the top 20 trigrams related to the topic of asthma treatment. It appears that the most frequent trigrams are those related to the treatment of asthma, with " علاج مرض الربو " [treatment of asthma] being the most frequent trigram, followed closely by " الربو بشكل نهائي " [asthma permanently]. This indicates that individuals are interested in learning about different ways to treat asthma and

potentially finding a permanent solution. Other trigrams in the list include " في علاج الربو " [in the treatment of asthma], " عن " [about asthma], and " شفاء مرض الربو " [cure of asthma]. These trigrams suggest that people are looking for information on various aspects of asthma treatment, including the effectiveness of different treatments, information on the condition itself, and potential cures.

Furthermore, the frequency of " يعانون من الربو " [suffer from asthma] indicates that many individuals are affected by this condition and are actively seeking ways to manage or treat it. Overall, the distribution provides insights into what people are interested in learning about regarding asthma treatment, with a particular emphasis on finding effective treatments and potentially a cure. In contrast, the trigram distribution focuses more on treatments for asthma, with " علاج مرض الربو " [treatment of asthma] being the most frequent trigram, and " علاج الربو " [asthma treatment] and " لعلاج مرض الربو " [for asthma treatment] also appearing in the list.

The distribution of the top 20 trigrams after removing stop words (Fig. 10) is different from the one without removing stop words. In this distribution, the trigrams related to asthma treatment are still present, with " علاج مرض الربو " [treatment of asthma] being the most frequent trigram. However, " مرض الربو " [asthma in a way] and " مرض الربو بشكل " [asthma permanently] are replaced by " الربو نهائيًا " [asthma final] and " الربو لاحتوائه " [asthma for containing]. This suggests that people are interested in learning about the final stage of asthma and its contents.

The trigrams related to " تكسب دعوة تتجيك " [winning a prayer saves you] and " تكسب دعوة نهائي " [final, you win a prayer] indicate that most of the target population are believers and they are looking for a prayer that God [Allah] will help them and be cures from asthma. The trigrams related to " تساعد نبتة الكوسة " [helps zucchini plant] and " الكوسة شفاء مرض " [zucchini is a cure for asthma] suggest that people may be looking for natural remedies or alternative forms of treatment for asthma. The trigrams related to " مضاد قوي للأكسدة " [powerful antioxidant] and " مضاد خاص للالتهاب " [anti-inflammatory properties] indicate that people may be interested in learning about the potential benefits of antioxidants and anti-inflammatory substances in managing or treating asthma.

Overall, the distribution after removing stop words provides a different perspective on what people are interested in learning about regarding asthma treatment. While the focus on finding effective treatments and potentially a cure remains, there is also interest in the final stage of asthma, natural remedies, and potential benefits of antioxidants and anti-inflammatory substances. The word cloud for the cluster 0 is presented in Fig. 11.

Fig. 11. Word cloud for Cluster 0.

B. Cluster 1

Fig. 12 shows the distribution of sentiment in the second cluster. We can see that a majority of negative sentiment [68945] followed by neutral sentiment [23815], and a minority of positive sentiment [19013]. Compared to the first cluster, this cluster has a significantly higher proportion of negative sentiment, while the proportion of positive sentiment is also higher than the previous clusters. The majority of the sentiment being negative suggests that the text in this cluster contains a lot of negative or critical opinions, about personal experiences with asthma.

Fig. 12. Sentiment distribution in Cluster 1.

Fig. 13 shows tweets length [number of characters] distribution.

Fig. 13. Tweets length in Cluster 1.

Fig. 14. Tweets distribution in Cluster 1.

Fig. 14 depicts the tweets distribution in cluster 1. Top 20 words [including stop words] frequency distribution before removing stop words is shown in Fig. 15.

Fig. 15. Frequency distribution of top 20 words in Cluster 1 before removing stop words.

The data shows that the most frequent word in the text is "الربو" [asthma] with a count of 112579, followed by The words "من" [from], "الله" [God], "في" [in], and "على" [on] with 52701, 27797, 21798, 11715 occurrences respectively. The word "ما" [what] appears in the list with a count of 11285, which suggests that the text may contain questions or inquiries related to asthma.

In the new distribution, the word "الربو" [asthma] still has the highest frequency with 109379 occurrences, but the words "علاج" [treatment] and "مرض" [disease] have increased in frequency, suggesting that the text or corpus may be more focused on medical treatments and conditions. Additionally, words such as "لمرضى" [for patients] and "الأطفال" [children] have been replaced with "لمرضائي" [for my patients] and "الأطفال" [kids], respectively, indicating a slight difference in phrasing.

Fig. 16 shows the top 20 words frequency distribution after removing stop words. The most frequent word in the text is still "الربو" [asthma], The word "لمرضي" [my illness] appears in the list with a count of 9408, which suggests that the tweets may include personal experiences of people with asthma. The word "الغبار" [dust] appears in the list with a count of 5667, which confirms that the text may be discussing asthma triggers, including environmental triggers like dust. The words "يا رب" [Oh God] and "اللهم" [O Allah] appear in the list with counts of 4724 and 4356, respectively, which suggests that some of the tweets may contain expressions of religious faith or appeals to a higher power for help with asthma management.

Fig. 16. Frequency distribution of top 20 words in Cluster 1 after removing stop words.

Fig. 17 shows the top 20 bigrams frequency distribution before removing stop words.

Fig. 17. Frequency distribution of top 20 bigrams in Cluster 1 before removing stop words.

Fig. 18. Frequency distribution of top 20 bigrams in Cluster 1 after removing stop words.

The most frequent bigram is "من الربو" [because of asthma] with a count of 12014, followed by the bigram "مرضى الربو" [asthmatic patients] that appears in the list with a count of 7919, which confirms that the text is discussing asthma and may contain personal experiences of people with asthma. The bigram "يعاني من" [suffers from] appears in the list with a count of 2803, which suggests that the tweets may include discussions about the challenges and difficulties of living with asthma. The bigram "يعين الله" [God help] appears in the list with a count of 2428, which suggests that some of the tweets may contain expressions of religious faith or appeals to a higher power for help with asthma management. filtering for stop words may help to reduce noise and highlight the most meaningful bigrams which is presented in Fig. 18.

After removing stop words (Fig. 18), looking at the distribution, we can see that the most frequent bigram is "مرضى" [asthmatic patients]

الربو " ["my asthma" in English] with a frequency of 8394, followed by "بخاخ الربو" ["asthma inhaler"] with a frequency of 6590. These two bigrams are related to managing the symptoms of asthma and suggest that people are sharing their personal experiences with using inhalers to control their symptoms. The third most frequent bigram is "مرض الربو" ["asthma disease"] with a frequency of 4521, followed by "الربو والحساسية" ["asthma and allergy"] with a frequency of 4029. These bigrams suggest that people are sharing their personal experiences with the diagnosis of asthma and its relationship to allergies.

Other common bigrams in the distribution include "يعاني الربو" ["suffers from asthma"], "ضيق التنفس" ["shortness of breath"], and "مشكلة مرض" ["disease problem"]. These bigrams indicate that people are sharing their personal experiences with the negative impact of asthma on their quality of life and the challenges they face in managing their symptoms.

Overall, the distribution indicates that people are sharing their personal experiences with asthma, including symptoms, diagnosis, and the negative impact of the disease on their lives. This information can be useful for healthcare providers and researchers in understanding the lived experiences of people with asthma and developing interventions to improve their quality of life.

Fig. 19 shows the top 20 trigrams frequency distribution before removing stop words.

Fig. 19. Frequency distribution of top 20 trigrams in Cluster 1 before removing stop words.

Fig. 20. Frequency distribution of top 20 trigrams in Cluster 1 after removing stop words.

Looking at the trigram distribution, we can see that the most frequent trigram is "يعاني من الربو" ["suffers from asthma"] with a frequency of 1746, followed closely by "يعانون من الربو" ["they suffer from asthma"] with a frequency of 1616. These trigrams suggest that people are sharing their personal experiences with asthma and the challenges they face in managing their symptoms.

The third most frequent trigram is "الربو بشكل نهائي" ["asthma finally"] with a frequency of 1603, followed by "مرض الربو بشكل" ["asthma disease in the form of"] with a frequency of 1579. These trigrams suggest that people are discussing the long-term impact of asthma on their lives and the challenges they face in managing the disease.

Other common trigrams in the distribution include "مشكلة" ["asthma disease problem"], "لو تعاني من" ["if you suffer from"], and "حل مشكلة المرض" ["solve the problem of disease"]. These trigrams suggest that people are sharing their personal experiences with the negative impact of asthma on their quality of life and seeking solutions to manage the disease.

Interestingly, the trigram "الله يأخذ الربو" ["God takes away asthma"] appears in the distribution with a frequency of 741. This trigram reflects a religious or cultural belief that asthma can be cured through divine intervention.

After removing the stop words (Fig. 20), the trigram distribution seems to be more focused on specific topics related to asthma. The most common trigrams are "مرض الربو نهائيا" [asthma is final], "مشكلة مرض الربو" [the problem of asthma], and "الربو وحساسية الصدر" [asthma and chest allergy]. These trigrams indicate that this cluster is more focused on discussing the negative impact of asthma on patients' lives and the difficulties associated with managing the disease.

The trigram "بخاخ الربو يفطر" [asthma inhaler breaks the fast] appears in the distribution, indicating that this cluster includes discussions related to religious practices during the month of Ramadan. This suggests that this cluster may include personal experiences and discussions from individuals living in Islamic countries where Ramadan is observed.

Overall, the trigram distribution after removing stop words indicates that the cluster focuses on discussing the negative impact of asthma on patients' lives, including the challenges associated with managing the disease and the impact on religious practices during the month of Ramadan. The word cloud for the first cluster is viewed in the Fig. 21.

Fig. 21. Word cloud for Cluster 1.

It is clear that this cluster focuses on personal experiences with asthma, including symptoms, diagnosis, and the negative impact of asthma on the quality of life.

V. DISCUSSION

LDA topic modeling was utilized to group tweets related to asthma into two clusters. The first cluster contained tweets that provided information and tips about the treatment and prevention of asthma. The second cluster contained tweets that discussed personal experiences with asthma and the negative impact on quality of life. Further analysis revealed that the text or corpus is related to medical or health topics, with the most frequent word being "asthma." Filtering stop words resulted in more specific and related bigrams and trigrams to asthma and its treatment. The data analysis of cluster 0 indicates that individuals are interested in learning about different ways to treat asthma and potentially finding a permanent solution. It is evident that most used phrases referred to the information on asthma, its treatments for patients and kids; with a focus on natural therapy and inhalation therapy. Similar results can be observed from [19], where it was found that most referred tweets reflected inhalation, use of nebulizer, and self-medication/ management procedures, indicating the informational content. In [20,21], it was identified that most of the tweets belonged to physicians and healthcare organizations presenting the educational and awareness information. Therefore, in similar other studies [19,20,21], the analysis of data from cluster 0 indicated that the social media platforms like twitter could be a useful platform for disseminating health information for creating awareness about asthma treatment and prevention practices, especially self-management procedures. Overall, the findings from cluster 0 could provide insights for healthcare professionals and researchers to develop better strategies and interventions for creating awareness in order to manage asthma.

In regard to cluster 1, the analysis of the sentiment, length, word count, and n-gram frequency distributions of the tweets related to asthma reveals important insights into the experiences and perceptions of people with asthma. Most of the sentiment in the second cluster is negative, indicating that this cluster contains a lot of critical opinions about personal experiences with asthma. The top words and bigrams suggest that people are sharing their personal experiences with asthma symptoms, diagnosis, and the negative impact of the disease on their lives. Filtering out stop words helps to identify the most meaningful bigrams and trigrams related to managing asthma symptoms and personal experiences of people with asthma. The analysis also highlights the prevalence of religious expressions by referring to God in the tweets related to asthma.

These findings indicate that people openly express negative sentiments about asthma and place significance importance on religion, indicating the impact of socio-cultural and religious factors among Arabic communities. However, analyzing the tweets in similar studies but in geographically different locations in previous studies [12-16,30], there were no references to the religion or god in asthma related tweets. Therefore, it is important to consider cultures in using the tweets for analyzing public perceptions related to healthcare services and disease management in order to formulate effective strategies for managing various conditions. In addition, analyzing twitter data can also be useful for assessing the public opinions related to the treatments, as in [12] vaccine hesitancy was highlighted for Covid-19. Similarly, the

reactions to asthma treatment and prevention procedures can be assessed from tweets analysis among the public in order to effectively manage the condition. In [30], it was observed that public can more freely express their opinions on social media platforms than on DHP's in relation to their health conditions. Furthermore, in [13], it was observed that public express their opinions on social media to gain social rewards. This is evident from the results from cluster 1 analysis, where people in Arabic communities openly expressed their religious references and beliefs; and also, the negative impacts on their quality of life. These openly expressed views can be an important source of information for healthcare decision-makers and governments during health crisis, where an outbreak can be effectively monitored, tracked, and controlled within the time as suggested in [16]. Furthermore, the twitter data analysis can also be effectively used in other critical conditions by analyzing disease specific tweets [14,15]. Furthermore, the studies [13-25,30] discussed in this article reflected varying results at different geographical locations, while few results are similar and few contrasted with the findings in this study. Therefore, the public perceptions related to asthma challenges, its management, treatment and prevention practices may differ across the regions, and it is also to be highlighted that there could be a cultural impact on these factors as observed in this study. Therefore, it is necessary for research practitioners to frequently analyze public perceptions about asthma at regular intervals at different locations to better manage the disease. Overall, the findings from cluster 1 analysis can be useful for healthcare providers and researchers in understanding the lived experiences of people with asthma and developing interventions to improve their quality of life.

VI. CONCLUSION

This study has addressed the research gaps by discussing the public opinions of asthma in Arabic communities, thus contributing to the knowledge, which can have various practical and theoretical implications. These findings can support healthcare decision-makers in Arabic communities to better understand the asthma patients' opinions about their conditions and aid them in formulating patient-centered strategies for managing asthma. Furthermore, this study acts as a foundation or reference for future researchers in using AI technologies for analyzing public health data, especially in Arabic communities.

In conclusion, it can be observed that neutral sentiment existed in relation to asthma related information, its prevention and treatment; and negative sentiments existed on its impact on the quality of life among the Arabic communities. Although, religious/cultural influence existed in expressing the opinions and managing the conditions, it is also observed that twitter could be an effective platform for not only monitoring and controlling the disease but also to educate and create awareness among the asthma patients.

ACKNOWLEDGMENT

The authors extend their appreciation to the Deputyship for Research & Innovation, Ministry of Education in Saudi Arabia for funding this research work through the project number (S-1442-0049).

Faculty of Computing and Information Technology, King Abdulaziz University, Jeddah, Saudi Arabia^{1,2,3}

Abstract—An accurate drug response prediction for each patient is critical in personalized medicine. However, numerous studies that relied on single-omics datasets continue to have limitations. In addition, the curse of dimensionality considers a challenge to drug response prediction. Deep learning has remarkable prediction effectiveness compared to traditional machine learning, but it requires enormous amounts of training data which is a limitation because the nature of most biological data is small-scale. This paper presents an approach that combines Bayesian Ridge Regression with Deep Forest. BRR relies on the Bayesian approach, in which linear model estimation occurs based on probability distributions rather than point estimates. It was utilized to integrate multi-omics, a feature selection that calculates the coefficient as the feature importance. DF reduces the computational cost and hyper-parameter tuning cost. The Cancer Cell Line Encyclopedia CCLE was used as a dataset to integrate the gene expression, copy number variant, and single nucleotide variant. Root Mean Square Error, Pearson Correlation Coefficient, and the coefficient of determination were used as the evaluation metrics. The obtained findings show that the proposed model outperforms Random Forest and Convolutional Neural Network regarding regression performance; it achieved 0.175 for RMSE, 0.842 for PCC, and 0.708 for R2.

Keywords—Bayesian ridge regression; deep forest; deep learning; drug response prediction; machine learning; multi-omics data

I. INTRODUCTION

Personalized medicine is a cancer therapy method that aims to find the most effective therapeutic solutions for each patient. The combination of genetic and drug-sensitivity data and the subsequent creation of drug-response associations allows for this discovery [1]. While personalized medicine is not yet utilized as a regular treatment, it is possible for most cancer patients due to the progress made in multi-omics features and drug-sensitivity testing [2]. Personalized treatment regimens based on genetics are one of the primary aims of systems medicine [3]. For the development of individualized cancer therapy treatments with a projected efficacy much above existing standard-of-care methods, the inferred models' ability to correctly forecast a tumor's responsiveness to a medicine or drug combination might benefit that process [3]. However, there has been a lack of progress in cancer treatment based on single-omics datasets such as those generated by the Human Genome Project and the early genomic profiling of the Cancer Genome Atlas (TCGA) projects [4]. The multi-omics analysis that has gained prominence in cancer research over the last several decades

may be the only way to get a comprehensive view of cancer behavior and uncover new therapeutic vulnerabilities [5].

Moreover, the "curse of dimensionality" or large p , small n , is one of the most challenging issues in drug response prediction and when dealing with omics data in general [6] in other words, having many features p . However, only a few available data instances n create a particular barrier to using early concatenation in multi-omics integration. For instance, the human genome has more than 20,000 protein-coding genes, a significant number. As a result of this integration, multi-omics datasets may easily contain more than 50,000 attributes when the genome, proteome, and transcriptome are all included. Regarding cancer data, the number of available tumor samples in a dataset is usually restricted, with cancer cohorts typically consisting of only a few hundred patient samples [5]. As a result, the features must be reduced through feature selection [7]. Feature selection works to identify the relevance of features and selects a collection of features or attributes based on a particular assessment criterion [8].

Despite the power of deep neural networks power, it appears to have drawbacks [9]. To begin with, it is noted that deep neural networks require enormous amounts (large-scale data) of training data are often needed, making them inapplicable to jobs having only small-scale data. Due to the high cost of class annotation, many real-world tasks currently lack adequate labeled data [9], [10], resulting in the poor effectiveness of deep neural networks in relation to those tasks [11]. Additionally, the success of deep learning is strongly dependent on carefully tuning several hyper-parameters [12]. Consequently, Zhou [11] introduced gcForest or Deep Forest (DF), which integrates multi-Grained and Cascade Forest as a deep learning alternative. gcForest is a new decision tree ensemble technique approach that outperforms deep learning across various applications.

This paper introduced a method that combines Bayesian Ridge Regression (BRR) with Deep Forest (DF) called (BRR-DF). BRR was used to integrate multi-omics which was utilized as a feature selection method that calculates the coefficient to determine the feature importance score. BRR relies on the Bayesian approach, in which linear model estimation occurs based on probability distributions rather than point estimates. In addition to the model parameters also coming from the distribution, the response is also generated from the probability distribution. The training inputs and outputs affect the posterior probability of the model parameters.

Furthermore, Ridge was embedded with Bayesian regression to reduce model complexity and multicollinearity by shrinking the coefficients. Most omics data is considered to be small-scale data; therefore, Bayesian is suitable for these cases. It integrates the prior knowledge of the parameter (prior parameter distribution) with the observed data. DF integrates Multi-Grained and Cascade Forest, which effectively capture the local features. The cascade forests utilize a network structure inspired by a multi-layer artificial neural network to continuously improve results. DF was suggested as a deep learning alternative to reduce complexity time in hyper-parameter tuning that otherwise causes a computational cost in deep learning models.

The contribution of the proposed method can be summarized in the following two points:

- Using BRR as a feature selection method for integrating gene expression, copy number variant, and single nucleotide variant to improve drug response prediction. BRR can handle inadequate data or skewed distributed data by modeling linear regression models using probability distributions. By utilizing BRR, we aim to identify the most informative features from multiple genomic data sources and improve the accuracy of drug response prediction.
- Using DF to reduce the computational cost of hyper-parameter tuning; also, when the inputs have a high degree of complexity or dimensionality, DF can boost its representational learning capabilities to improve prediction.

The rest of this paper is organized as follows. Section 2 introduced the related work. Section 3 presented the methods and materials used in this study including datasets, framework of BBR-DP, and evaluation metrics. Section 4 elaborated results and discussion. In Section 5, the conclusion and future work were presented.

II. RELATED WORK

The current studies have introduced various machine learning techniques for predicting drug sensitivity and discovering biomarkers affecting drug response. Examples of these techniques are Support Vector Machines (SVMs) [13], Graph Networks [14], [15], Bayesian multitask multiple kernel learning [16], [17], Random Forest (RF) [19–22], and Neural Network [22] models. However, there is still a significant opportunity to improve prediction effectiveness and model generalizability regarding these computational models. Deep Learning (DL) has also been employed successfully in other drug discovery-related tasks. The prediction effectiveness of Deep Learning algorithms is comparable to, if not better, than that of the approaches for the bulk of these tasks [23]. Numerous deep learning-based techniques for drug response prediction have been proven to be successful, including DeepProfile [24], CDRscan [25], DeepCDR [14], DeepDSC [26], and GraphDPR [15].

A Bayesian ridge regression-based approach (B-GEX) was developed by Wenjian et al. [27] to infer the gene expression profiles of various organs from blood gene expression

profiles. A low-dimensional feature vector was derived from the complete blood gene expression profile using feature selection for each gene in a tissue. To train the inference models to capture the cross-tissue expression correlations between each target gene in tissue and its preselected feature genes in peripheral blood, they used The Genotype-Tissue Expression (GTEx) RNA sequencing (RNA-seq) data of 16 tissues.

Velten and Huber [28] proposed a method for guiding penalization in regression using information from external covariates. Their method penalizes the feature groups defined by the covariates differentially and adjusts the relative power of penalization according to the information content of each group. Their procedure combines shrinkage with feature selection and provides a scalable optimization scheme using techniques from the Bayesian tool set. The method accurately retrieves each feature group's accurate effect sizes and sparsity patterns in simulations. They evaluated the performance of their method for drug response prediction using leukemia data. Prediction performance improves when the groups' dynamic ranges differ significantly.

Sharifi-Noghabi et al. [29] utilized deep learning to develop a method called MOLI (multi-omics late integration). MOLI integrates gene expression data, copy number alterations, and somatic mutation. Their model learns features for each omics data type by encoding subnetworks particular to it. MOLI is the first end-to-end late integration approach using deep learning that combines a "triplet loss function" and a "binary cross-entropy" to improve this representation. Responder cell lines are more comparable and distinct from non-responder cell lines, while the half maximal inhibitory concentration (IC50) values predicted by this depiction are more accurate.

Malik et al. [30] proposed a late multi-omics integration framework for robustly quantifying survival and drug response in breast cancer patients, emphasizing the relative predictive ability of the available omics datatypes. A supervised feature selection algorithm, neighborhood component analysis (NCA), was used to select the relevant features from the multi-omics datasets retrieved from The Cancer Genome Atlas (TCGA) and Genomics of Drug Sensitivity in Cancer (GDSC) databases.

A Deep Forest architecture, first presented by Zhou [31], was used by Su et al. [32] to develop the Deep-Resp-Forest anti-cancer drug response prediction model, which classifies the anti-cancer drug response as either sensitive or resistant. In Zhou et al.'s work, the Deep Forest, known as gcForest, was a cascade of forests. Su et al. achieved remarkable results when their model was tested against the Cancer Cell Line Encyclopedia (CCLE) and the Genomics of Drug Sensitivity in Cancer (GDSC). As they mentioned, regression is preferred for more accurate results.

Table I shows some recent studies that were focused on applying ML and DL methods in drug response prediction by focusing on methods/techniques, contributions/advantages, and limitations/disadvantages.

TABLE I. SUMMARY OF SOME RECENT STUDIES IN DRUG RESPONSE PREDICTION AND THEIR CONTRIBUTIONS AND LIMITATIONS

Resource and Year	Methods/Techniques	Merits, Contribution Advantages	Demerits and limitations Disadvantages	Datasets
Sharifi-Noghabi et al. [29], 2019	DNN Ridge regression	They indicated that MOLI outperforms early integration multi-omics and single-omics techniques. They mentioned it was the first strategy to employ pan-drug transfer learning for targeted drugs, and it improved prediction effectiveness relative to drug-specific inputs.	Although their research only employed DNA mutation, CNA, and gene expression profile, MOLI may be expanded to include other omics information and drug chemical structure. While they only explored the triplet loss for improving the concatenated representation, they observed that similar losses such as the contrastive loss function employed in the Siamese network [33] can be utilized instead. All utilized datasets have substantially skewed or imbalanced class distributions due to the few number of respondents' vs non-responders. They solved that by oversampling minorities. However, this method typically leads to overfitting, especially for deep neural networks.	GDSC PDX TCGA
Liu et al. [14], 2020	UGCN CNN	Insufficient or imbalanced training examples can be supplemented with the proposed UGCN by random selection of multiple complementary graphs for each medication. In the classification task, they randomized the feature matrix, connected complementary networks at random, and positive training examples were augmented five times. DeepCDR may be utilized with molecular generation processes. Existing chemical generation models based on the Recurrent neural network (RNN) technique[66], generative adversarial networks (GANs) [34] and deep reinforcement learning [35] Concentrate on broad chemicals while ignoring the characteristics of specific cancer cells. Methods for cancer-specific or disease-specific innovative drug design may be presented by employing DeepCDR predicted CDR as prior knowledge or a reward score for driving chemical production.	Top DL algorithms like DeepCDR and GraphDPR [15] perform better. For a drug-blind test, the examined deep learning approaches do not act as well as the SRMF, a matrix factorization-based method. To improve DL methods for predicting drug reactions, obtaining differentiating information from drug profiles is critical. Either create novel drug target fingerprint systems or use sophisticated "graph neural networks" to extract latent properties from drug data [36]. In future work, researchers can use huge amounts of omics data analyzed before and after treatment to determine how the tested drugs affect their molecular profiles.	GDSC CCLE TCGA
Jia et al. [37], 2021	VAE Elastic Net PCC PCA	Accurate drug sensitivity data prediction in cancer samples would allow recapitalization of recognized and new biomarkers, which are commonly missing owing to cell line methods or limitation of sample size. Their categorization of chemicals by reaction profiles showed distinct groupings and signatures. Using TCGA data, they discovered a link between medicines and TMB that was previously infeasible using cell line models. To find pan-cancer genomic markers, they explored DNA mutations, CNVs, and gene expression. The positive correlations between AZD6244 and the earlier published 18-gene signature demonstrated how their results are robust.	For some drugs, including LBW242, couldn't enhance prediction accuracy by fitting models. The model-fitting parameters of VAE-based models could not compete with PCA methods for several drugs (in-sample PCC and holdout R2). However, given insufficient data, the PCA-based model for paclitaxel failed to distinguish between pCR and non-pCR patients. So future validation is necessary to validate these prediction models. Moreover, while certain drugs had good prediction results in the cell line method, their response in cancer examples was variable. So studying drug response in cancer samples is substantially more difficult and involves various contexts and variables.	GDSC CCLE TCGA
Pouryahya et al. [38], 2022	Wasserstein distance Spearman's correlation PCC Hierarchical clustering Random forest regression	Using the optimal mass transport (OMT) theory and unsupervised and supervised ML models in conjunction with the CDCN model, they were able to show that random forest approaches in the consequent distinct pairs of cell-line and drug clusters can deliver more satisfactory predictive ability than the CDCN model used in previous studies. Using Wasserstein distances, which are calculated between invariant measurements of gene expression patterns, the researchers discovered that cell lines that were comparable in terms of Wasserstein distances responded similarly to (structurally identical) medicines.	In the clustering of drugs, unsupervised removal of strongly correlated cheminformatic features while maintaining non-redundant informative features. Despite the elimination of this feature, their strategy outperformed other approaches in terms of predictive power. Using mutation, CNV, and hyper-methylation data may enhance prediction results or provide new findings.	GDSC HPRD CCLP PubChem OncoKB
Wang et al. [39] 2023	GCNs AEs	In order to overcome some of the shortcomings of recent studies, including ignoring the correlation between drug cell line pairs (DCPs), the GADRP was developed. Additionally, the issue of over-smoothing, in which the representation of each node becomes more similar as the number of layers grows, was not considered in recent research that used GCNs. So they built a sparse drug cell line pair (DCP) network incorporating data on drug, cell line, and DCP similarity before using a stacked deep AE to extract low-dimensional representations from cell line attributes. Later, to learn DCP features, initial residual and layer attention based GCN (ILGCN), which can resolve over-smoothing issues, was used. Finally, the prediction was performed using a fully connected network.	First, ILGCN can only be regulated within five levels due to the scale of the DCP network and the constraints of computer storage capacity. Second, the GADRP deep learning model lacks biological entities like targets and disorders, which contribute to its level of inexplicability. Consideration should be given to including more entities and associations in cancer medication response prediction. Additionally, despite GADRP's potent prediction capabilities, its use in the clinic remains a significant issue because it is trained using in vitro data.	PubChem PRISM CCLE

Therefore, the drug response methods showed remarkable results when multi-omics were integrated. However, integration causes a curse of dimensionality which negatively affects prediction. In addition, multi-omics data is small-scale data, which needs a method to handle inadequate data or skewed distribution.

III. METHODS AND MATERIALS

The proposed solution works to reduce dimensionality and integrate the three omics, before using Deep Forest to improve the drug response prediction. The solution consists of four phases: datasets preparation, integrating multi-omics using Bayesian Ridge Regression, the Deep Forest phase, and the evaluation phase. The general framework is shown in Fig. 1; more details for each phase are discussed in the following points. Each single omics was processed independently; Bayesian Ridge Regression was utilized for each single data type.

A. Datasets

More than 1000 human cancer cell lines were gathered and molecularly described in the Cancer Cell Line Encyclopedia (CCLE) project [40] that has acquired and molecularly characterized over 1000 human cancer cell lines. The investigation discovered 24 anti-cancer drug sensitivity profiles among 504 cell lines. The CCEL [21], [40] dataset was used in this research. The half-maximal inhibitory concentration IC50 was used as the drug response for cell lines across the drugs (denoted by $y_{res,c}$) c for a cell line. Three omics were used, including single-nucleotide mutation (denoted by $x_{snv,g}$) g for gene, gene expression (denoted by $x_{exp,g}$), and copy number alteration/variation (denoted by

$x_{cnv,g}$) Gene expression and copy number alteration are real values, the single-nucleotide mutation use binary values, "1" used for mutation and "0" for wild type. There are no missing values in the gene expression data. For copy number alteration and single-nucleotide mutation, rows with more than half of the cells missing values were removed. The mean weight approach was used to compensate for the missing values for the remaining cell lines.

The distance was calculated to select the nearest k , which was used to impute the gene expression missing value, defined as follows:

$$dis(c, k) = \|x_{exp,c} - x_{exp,k}\|_2^2 \quad (1)$$

where c is the cell line, k is the nearest cell line, and x is the gene expression value for each cell line.

The mean value of the nearest cell lines was used to impute the missing value of cell line c in copy number alteration of genes g .

$$misCNV(c, g) = \sum_{k=1}^K \frac{dis(c, c_k)}{\sum_{k=1}^K dis(c, c_k)} misCNV(c_k, g) \quad (2)$$

The values of the single-nucleotide mutation features are binary, with 1 indicating mutation and 0 indicating wild type. The mean feature value for cell line c among the k -nearest cell lines was used to compensate for the missing SNV (single-nucleotide mutation or variation) value of gene g as follows:

$$\begin{cases} misSNV(c, g) = 1 & \text{if } (\sum_{k=1}^K misSNV(c_k, g) > \sum_{k=1}^K (1 - misSNV(c_k, g))) \\ 0 & \text{otherwise} \end{cases} \quad (3)$$

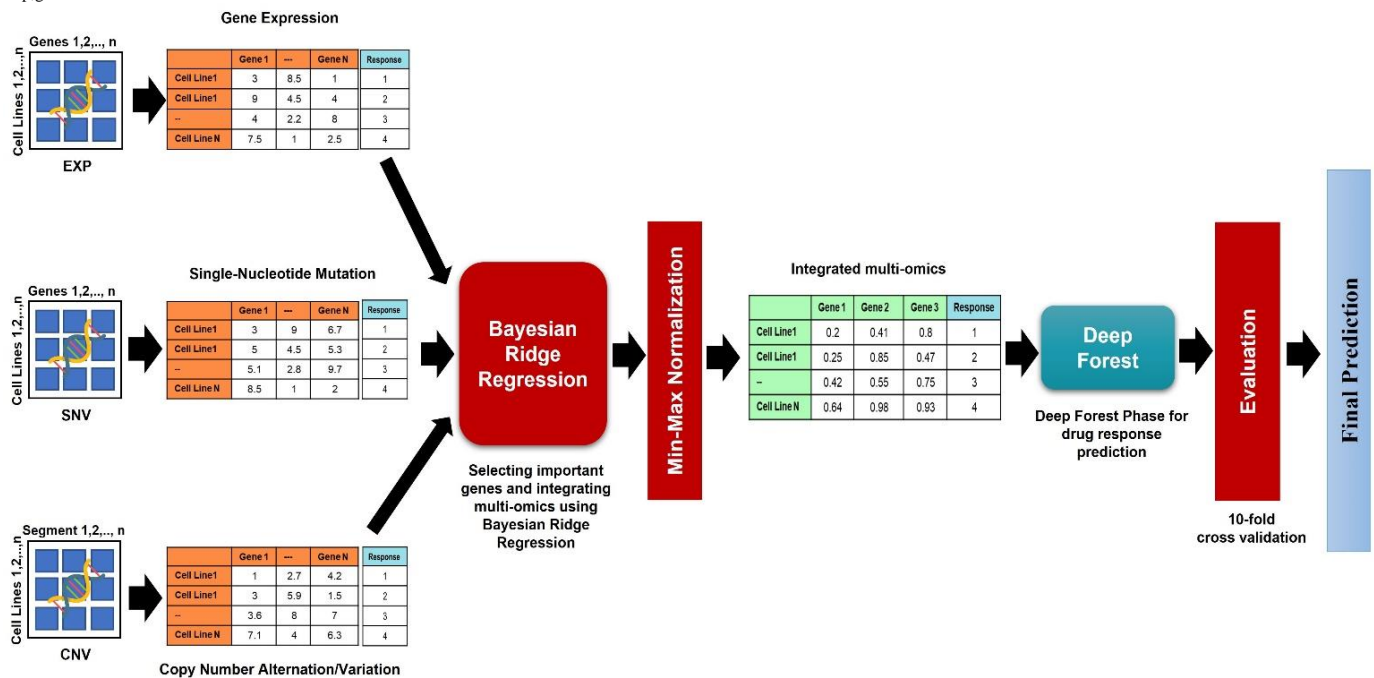

Fig. 1. The framework of BBR-DP to integrate multi-omics data for predicting drug response.

In a similar way, the missing value of IC50 was imputed in the same way as the copy number alteration manner. The

mean value of the nearest cell lines was used to impute the missing value of cell line c .

$$misIC50(c, g) = \sum_{k=1}^K \frac{dis(c, c_k)}{\sum_{k=1}^K dis(c, c_k)} misIC50(c_k, g) \quad (4)$$

K=10 was selected for preparing the CCEL dataset.

The IC50 matrix was converted to a tabular form which had 8712 rows, then all of the drug responses of each cell line were grouped by the mean for each cell line to be considered as the drug response that needed to be predicted in a regression problem. The final total samples were 363 for the IC50 data. Table II shows the total number of samples for the CCEL data.

TABLE II. THE TOTAL NUMBER OF SAMPLES FOR THE CCEL DATA

Type	Raw Data	After Preprocessing
Cell Lines	1061	363
Drugs	24	24
Gene expression	20049 (1061)	19,389 (363)
Single-nucleotide mutation	1667 (1061)	1667 (363)
Copy number alteration	24960 (1061)	24960 (363)

B. Integrating Multi-Omics Bayesian Ridge Regression

Bayesian Ridge Regression (BRR) was used as the feature selection method to reduce dimensionality and integrate multi-omics. This method, which is based on a Bayesian approach, is concerned with selecting subsets of the independent variables in linear regression to predict a response variable. The response variable is first assigned a probability distribution via the specification of a family of prior distributions for the unknown parameters in the regression model. However, because the data influence this family's ultimate choice of the prior distribution, the independent variables are assumed to be distinct observables, and the corresponding regression coefficients are assigned independent prior distributions [41]. BRR fits a model where the weighted sum of the independent variables can predict the response variable. It works by determining a set of coefficients to utilize in the weighted sum to perform a prediction. These coefficients were used as feature importance scores to select the best features of each single omics data.

$$y = \beta_0 + \beta_1 * x_1 + \beta_2 * x_2 + \varepsilon \quad (5)$$

where y is the dependent variable (also known as the response variable) β is the coefficient or model parameter, x is the value of a predictor variable, and there is also an error term describing the effect of variables not included in a model or random sampling noise.

From a Bayesian perspective, probability distributions rather than point estimates are used to build linear regression. The response, y, should be chosen from a probability distribution rather than evaluated as a single number. The goal of Bayesian Linear Regression is to ascertain the posterior distribution for the model parameters rather than to identify the one 'best' value of the model parameters. In addition to the model parameters also coming from a distribution, the response is also generated from a probability distribution. The training inputs and outputs affect the posterior probability of

the model parameters [42], [43]. However, Ridge was embedded with Bayesian regression to reduce the model complexity and multicollinearity by shrinking the coefficients. Most omics data is considered to be small-scale; therefore, Bayesian is suitable for these kinds of cases. It integrates the prior knowledge of the parameter (prior parameter distribution) with the observed data.

The three omics Exp, SNV, and CNV were tested as a single item of data and integrated in different combinations as follows: 1) EXP, 2) SNV, 3) CNV, 4) EXP and SNV, 5) EXP and CNV, 6) SNV and CNV, 7) EXP, SNV, and CNV. In addition, three experiments were implemented to evaluate the proposed solution and to study the multi-omics in various scenarios.

In the first scenario, the Baseline, all features of each single/multi omics were included in the model. It was implemented to test how the three omics affect the drug response without feature selection methods. In the second scenario, BRR was utilized to select the essential features of each single-cell omic - integrating them with the other one. According to the literature review, as a common practice, the mean value of all coefficients was used as a threshold to select features with coefficients higher than or equal to the calculated mean [44]. Also, the coefficients computed by the BRR were used to select important features for each single/multi-omics. In this last scenario, the top 10% of coefficients higher than or equal to the calculated mean were selected as informative features. After implementing various experiments for the different ratios, the ratio of the top 10% was selected, and it was noted that this 10% achieved the best results. This ratio was also used to reduce the computational cost of the model.

C. Drug Response Prediction Using Deep Forest

Deep Forest is a new ensemble Random Forest or decision tree approach that integrates multi-Grained Cascade Forest. This approach utilizes a cascade ensemble to create a deep forest as an alternative to deep learning that supports representation learning in gcForest. When the inputs have a high degree of complexity or dimensionality, multi-grained scanning can boost its representational learning capabilities, possibly helping gcForest to be contextually or structurally knowledgeable [10], [31]. gcForest allows a model complexity to be automatically defined, it performs very well even on small-scale data, and the number of cascade stages may be adjusted adaptively. Additionally, the developers/researchers can tailor their training expenses to their available computing resources. While deep neural networks have many hyper-parameters, gcForest has just a few. Its performance is relatively stable according to the hyper-parameter settings, it can achieve remarkable performance in most scenarios, even across datasets from diverse domains, by utilizing the default option. Through the use of external neural networks, gcForest may be trained and the theoretical analysis made more straightforward. It is noted that ensemble methods or cascade trees are more accessible to analyze than deep learning [10], [45].

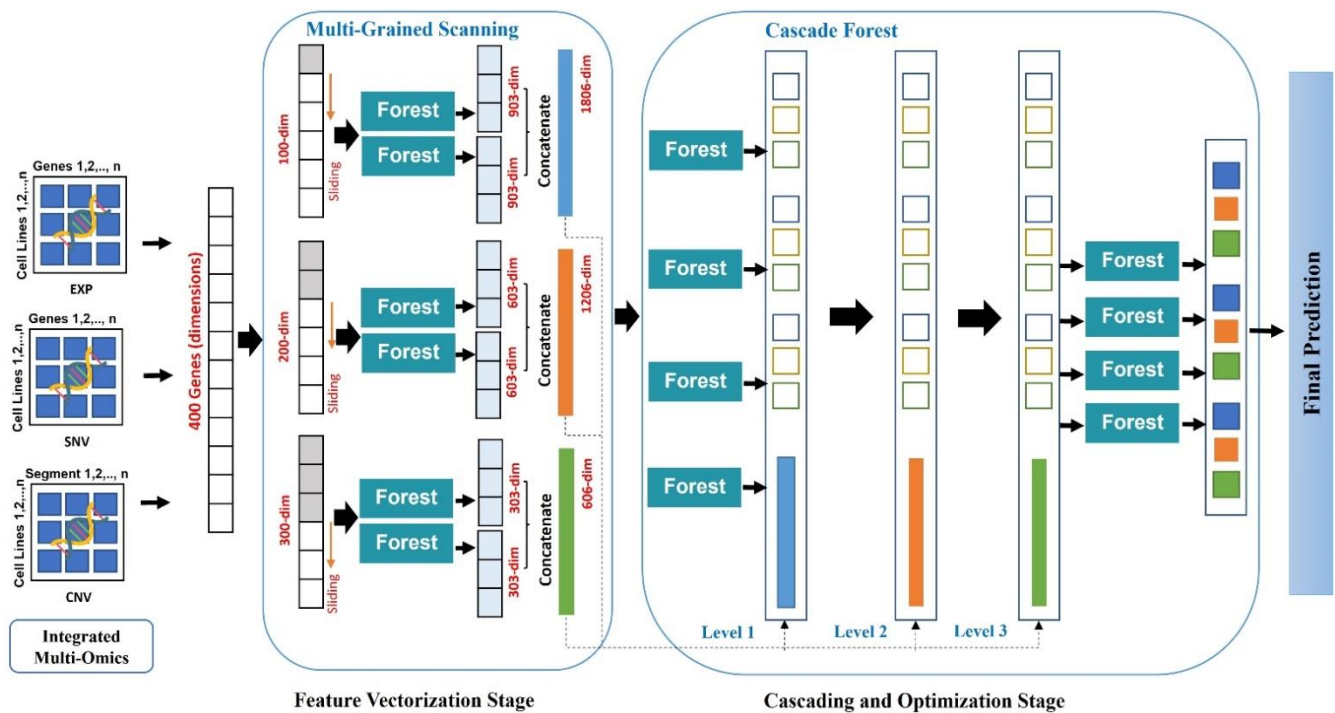

Fig. 2. The flowchart of BBR to integrate multi-omics data.

This phase consists of two stages, shown in Fig. 2: the Feature Vectorization Stage and Cascading and Optimization Stage. Deep Forest relies on multi-grained scanning, which effectively captures the local features. Also, the cascade forests utilize a network structure inspired by a multi-layer artificial neural network for continuously improving results.

1) *Feature vectorization stage*: Multi-grained scanning, motivated by the multi-convolution kernels used in Convolutional Neural Networks (CNNs), can discover and handle feature relationships in the subsequent cascade forests. the sliding window technique utilizes a scanning process to determine the local features and convert the raw data into a chain or set of low-dimensional local feature vectors [9], [31]. These low-dimensional vectors are then used to train a series of forests to get the class distributions for the input vectors.

Therefore, the raw features will be transformed into a high-dimensional feature vector using the multi-grained scanning, in this stage. Multi-Grained Scanning is utilized by sliding the windows to scan the original features and convert them into feature vectors. Suppose there is gene expression data as the sequence data; 400 raw features (dimensions) will be selected. Three sizes of sliding window will be used 100, 200, and 300. After scanning for a window size of 100 features, we will get 301 feature vectors according to this formula (total dimensions N_d - window size w) / the stride of the sliding $s + 1$. The distance the window moves in each step is named the stride. Therefore, $400 - 100 / 1 + 1 = 301$ feature vectors. A window with 100 dimensions will be generated, then 201 feature vectors will be processed for a window size of 200 and 101 feature vectors for a 300- dimensional. The final sample for training will be 903 instances for a window size of 100 features, one random forest, and three classes for

prediction, as an example. If there are two random forests, the total number of samples will be 1806 instances when they are concatenated [31], [46].

2) *Cascading and optimization stage*: Cascade forests employ a network structure similar to a multi-layer artificial neural network, with each layer connected to the layer before it in the network hierarchy. It may be thought of as a collection of randomly generated forests that have been joined together [31]. Several random forests are used to construct each layer, and each decision tree inside a particular forest produces a drug response prediction independent of the others. In the following step, an overall drug response vector for the forest is created by taking the average of the drug responses provided by the decision trees in the forest. In the process of decomposition, the representation vector can be used as an input for the next cascade level in the process of decomposition. Processing is carried out in stages per each layer of the cascade, with each layer sending its results to the next and the processing results being passed on layer by layer until the prediction performance in the next level of the cascade does not increase [10].

D. Evaluation Metrics

The 10-fold cross-validation approach was utilized to evaluate the performance of the proposed solution. The mean of 10 iterations was recorded as the final result. Three evaluation metrics were used in this research, Root Mean Squared Error (RMSE), Pearson Correlation Coefficient (PCC), and the coefficient of determination R-Squared (R^2).

RMSE [25], [26] was utilized to measure the error, which is the difference between the actual drug response values and the predicted values. It is defined as:

$$RMSE = \frac{\sqrt{\sum(y_i - \hat{y}_i)^2}}{N} \quad (6)$$

where y is the real value of drug response, \hat{y}_i is the predicted value of drug response, and N is the sample size.

The PCC [47] value was used to measure the degree of relationship or correlation between the drug response and predictors produced due to the multi-omics integration, defined as:

$$PCC = \frac{\sum(x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum(x_i - \bar{x})^2} \sqrt{\sum(y_i - \bar{y})^2}} \quad (7)$$

where x_i is the value of the predictors, y_i is the drug response value, and \bar{x} and \bar{y} indicate the mean of the values.

R^2 [48] was used to measure how much of the variability of drug response can be explained by its relationship to the other predictors which could be formulated as:

$$R^2 = 1 - \frac{\sum(y_i - \hat{y}_i)^2}{\sum(y_i - \bar{y})^2} \quad (8)$$

where y is the actual value of drug response, and \hat{y}_i is the predicted value of drug response.

E. Comparison Criteria

The proposed Deep Forest was compared to Random Forest (RF) as a traditional machine learning method and CNN as a deep learning method. In addition, RF showed remarkable results according to various studies [19], [21], [49]. Furthermore, these algorithms were selected because CNN and an ensemble RF inspired Deep Forest. Therefore, they were employed to study which algorithm affects the Deep Forest the most.

IV. RESULTS AND DISCUSSION

The performance of the proposed solution was demonstrated using three scenarios: baseline, coefficient higher than or equal to the mean, and the top 10% of coefficients higher than or equal to the mean.

A. Baseline Scenario

In this scenario, all features were included in the model. It was used as a baseline result for measuring the effectiveness of the suggested BRR method. Table III shows the results of the three methods for the baseline.

TABLE III. THE RESULTS OF THE BASELINE SCENARIO FOR THE CCEL DATA

Type	Features	RMSE	R ²	PCC	Time (Sec)
<i>Deep Forest (DF)</i>					
EXP	19389	0.196	0.639	0.8	204.6
SNV	1667	0.238	0.002	0.029	28.1
CNV	24960	0.221	0.161	0.398	242.4
EXP, SNV	21056	0.196	0.624	0.79	138
EXP, CNV	44349	0.198	0.588	0.767	447

SNV, CNV	26627	0.222	0.159	0.396	328.8
EXP, SNV, CNV	46016	0.198	0.587	0.766	550.2
<i>Random Forest (RF)</i>					
EXP	19389	0.184	0.547	0.74	25.6
SNV	1667	0.237	0.016	0.119	0.859
CNV	24960	0.23	0.071	0.261	38.6
EXP, SNV	21056	0.182	0.565	0.752	27.6
EXP, CNV	44349	0.189	0.474	0.688	61.8
SNV, CNV	26627	0.223	0.131	0.357	38
EXP, SNV, CNV	46016	0.187	0.519	0.72	63.6
<i>CNN</i>					
EXP	19389	0.212	0.329	0.572	186
SNV	1667	0.252	0.004	0.047	21.4
CNV	24960	0.243	0.032	0.168	240
EXP, SNV	21056	0.206	0.383	0.618	195
EXP, CNV	44349	0.244	0.297	0.544	426
SNV, CNV	26627	0.237	0.05	0.217	251.4
EXP, SNV, CNV	46016	0.24	0.407	0.637	443.4

In general, DF showed the highest computational cost. Regarding R^2 and PCC, DF achieved the best results, and CNN showed the worst results. RF showed the lowest results from the perspective of RMSE and computational time. When multi-omics were integrated, DF achieved no effect, with EXP having the highest score. RF displayed a 4% improvement ratio when EXP and SNV were integrated. Also, CNN showed a 24% improvement ratio when EXP, SNV, and CNV were integrated.

Fig. 3 to 5 show the differences between the R^2 training and testing results in the Baseline scenario. Those figures measure the differences between prediction results on training data compared to testing data in the term of R^2 . There was overfitting in the three models; this usually happens with small-scale data. The average ratio of overfitting for DF, RF, and CNN was 60%, 62%, and 72%, respectively. In which DF had the smallest differences between training and testing results and CNN showed the highest ratio. This means the models cannot be generalized and needs more data or other techniques to handle overfitting.

Fig. 3. R² results for the training and testing of the DF in the Baseline scenario.

Fig. 4. R² results for the training and testing of the RF in the Baseline scenario.

Fig. 5. R² results for the training and testing of the CNN in the Baseline scenario.

B. The Mean of Coefficients as a Threshold

In this scenario, the coefficients of each feature were calculated using BRR. Each feature was considered significant when its coefficient was higher than or equal to the mean of all coefficients. Table IV shows the results of this scenario.

TABLE IV. THE RESULTS OF THE MEAN OF COEFFICIENTS SCENARIO FOR THE CCEL DATA

Type	Features	RMSE	R ²	PCC	Time (Sec)
Deep Forest (DF)					
EXP	10204	0.199	0.594	0.771	89.4
SNV	783	0.241	0.012	-0.097	47.1
CNV	12538	0.226	0.095	0.304	130.8
EXP, SNV	10987	0.197	0.643	0.802	122.4
EXP, CNV	22742	0.201	0.526	0.725	211.2
SNV, CNV	13321	0.226	0.094	0.303	137.4
EXP, SNV, CNV	23525	0.201	0.53	0.728	370.2
Random Forest (RF)					
EXP	10204	0.192	0.479	0.692	13.4
SNV	783	0.258	0.021	-0.14	0.375

EXP, SNV, CNV	23525	0.196	0.468	0.683	32.2
CNN					
EXP	10204	0.171	0.664	0.814	85.2
SNV	783	0.234	0.067	0.258	13.5
CNV	12538	0.272	0.007	-0.069	122.4
EXP, SNV	10987	0.166	0.617	0.785	90
EXP, CNV	22742	0.184	0.519	0.72	204.6
SNV, CNV	13321	0.251	0.015	0.114	129.6
EXP, SNV, CNV	23525	0.206	0.595	0.771	208.8

CNN showed the best results in terms of RMSE, R², and PCC; it achieved 0.171, 0.664, and 0.814, respectively. Then DF came second best and finally RF. Both RF and CNN exhibited no effect when multi-omics were integrated because gene expression caused the highest results. DF presented an 8% improvement ratio when EXP and SNV were integrated. Exp played an essential factor in achieving remarkable results, CNV, and SNV.

Fig. 6. R² results for the training and testing of the DF in the Mean of Coefficients scenario.

Fig. 7. R² results for the training and testing of the RF in the Mean of Coefficients scenario.

Fig. 8. R² results for the training and testing of the CNN in the Mean of Coefficients scenario.

Fig. 6 to 8 show the differences between training and testing results in The Mean of Coefficients as a Threshold scenario. There is still overfitting even though feature selection, cross-validation, and Dropout were utilized. The average ratio of overfitting for DF, RF, and CNN was 63%, 69%, and 54%, respectively. CNN showed the lowest differences ratio between the R2 training and testing results. CNN overfitting ratio was reduced from 72% to 54% compared to the Baseline scenario. However, RF and DF did not show a positive effect of applying BBR.

C. The Top 10% of Coefficients

In this scenario, the coefficient of each feature was calculated using BRR. Then, the mean of all coefficients was used as a threshold, and the top 10% of features were selected from the features that passed the threshold. Table V shows the results of this scenario.

TABLE V. THE RESULTS OF THE TOP 10% OF COEFFICIENTS SCENARIO FOR THE CCEL DATA

Type	Features	RMSE	R ²	PCC	Time (Sec)
Deep Forest (DF)					
EXP	1020	0.176	0.706	0.84	47.5
SNV	78	0.227	0.087	0.289	23.2
CNV	1253	0.225	0.107	0.322	51.7
EXP, SNV	1098	0.175	0.708	0.842	45.1
EXP, CNV	2273	0.188	0.584	0.764	35
SNV, CNV	1331	0.222	0.127	0.352	66
EXP, SNV, CNV	2351	0.184	0.618	0.786	56
Random Forest (RF)					
EXP	1020	0.192	0.495	0.703	1.48
SNV	78	0.245	0.016	0.116	0.11
CNV	1253	0.234	0.067	0.256	1.88
EXP, SNV	1098	0.19	0.509	0.713	1.53
EXP, CNV	2273	0.193	0.469	0.685	3.01
SNV, CNV	1331	0.235	0.062	0.247	2
EXP, SNV, CNV	2351	0.183	0.583	0.763	3.02

CNN					
EXP	1020	0.171	0.544	0.737	15.5
SNV	78	0.234	0.035	0.182	6.53
CNV	1253	0.229	0.083	0.283	18
EXP, SNV	1098	0.194	0.495	0.703	16.4
EXP, CNV	2273	0.161	0.564	0.751	26.8
SNV, CNV	1331	0.217	0.167	0.407	18.7
EXP, SNV, CNV	2351	0.159	0.585	0.764	27.4

In this scenario, the highest results were noticed when multi-omics were integrated. DF achieved RMSE 0.175, R² 0.708, and PCC 0.842 because of combining EXP and SNV. RF and CNN displayed the best scores when the three omics were integrated. The lowest RMSE -0.159- was achieved by CNN.

Fig. 9 to 11 demonstrate the last scenario: The Top 10% of Coefficients. The average ratio of overfitting for DF, RF, and CNN was 54%, 64%, and 39%, respectively. In this scenario, the overfitting of the DF was reduced from 60% to 54% compared to the baseline and from 72% to 39% for CNN. RF had the highest difference between training and testing for all scenarios. Therefore, this scenario showed the best effect of utilizing BRR in the three models.

Fig. 9. R² results for the training and testing of the DF in the Top 10% of Coefficients scenario.

Fig. 10. R² results for the training and testing of the RF in the Top 10% of Coefficients scenario.

Fig. 11. R^2 results for the training and testing of the CNN in the Top 10% of Coefficients scenario.

D. Summary of the Scenarios and Algorithms

This section presents the comparisons when evaluating which algorithms performed better. The DF, RF, and CNN algorithms were compared in terms of R^2 and RMSE regardless of a specific scenario.

Fig. 12. R^2 results for the DF, RF, and CNN algorithms in all scenarios.

According to Fig. 12, the suggested algorithm Deep Forest (DF) has the best results as it achieved 39% for the average of the R^2 results of all scenarios. Both RF and CNN obtained 31% as the average of R^2 .

Fig. 13. RMSE results for the DF, RF, and CNN algorithms in all scenarios.

Regarding RMSE, DF obtained the lowest score, as shown in Fig. 13; it was 0.207 which is the average of all scenarios. RF obtained 0.210, and CNN obtained 0.213.

Therefore, the results and performance of the proposed method can be summarized by the following points:

- Bayesian Ridge Regression as a feature selection method for integrating multi-omics showed an 11% improvement ratio in terms of R^2 compared to the Baseline scenario. Also, the complexity time was reduced by 90%.
- The proposed method BRR-DF has the best results in terms of R^2 and RMSE in all three scenarios. The Top 10% scenario exhibited the best performance regardless of the specific algorithm.
- The drug response was mainly explained by the gene expression data more than the copy number and single nucleotide variants.
- Random Forest showed an 18% improvement when the three omics were integrated. Also, it was the fastest algorithm when dealing with these omics data.
- In Deep Forest, integrating gene expression and single nucleotide variant has a better result than integrating all three omics. Both Random Forest and CNN showed better results when all three omics were integrated.

E. Comparison with Related Studies

To evaluate the performance and robustness of the proposed model using the CCLE data, BRR-DF was compared with three state-of-the-art models as follows:

- WGRMF [50]: Weighted Graph Regularized Matrix Factorization is applied for predicting the anti-cancer drug response in cell lines. Their model used the CCLE, which contains 491 cell lines and 23 drugs with 10,870 known responses. WGRMF utilizes gene expression and drug fingerprints as the input for the model.
- DeepDSC [26]: Gene expression is employed to extract the features of cell lines using a stacked deep autoencoder, before the chemical structure is integrated with gene expression to predict the drug response. DeepDSC uses the CCLE, which contains 491 cell lines and 23 drugs with 10,870 known responses.
- SRMF [51]: A Similarity-Regularized Matrix Factorization model combining gene expression with chemical structures for drug response prediction. The CCLE, with 10,870 known responses, contains 491 cell lines and 23 drugs.

Table VI shows a comparison between the proposed method and the three models in the CCLE dataset.

TABLE VI. COMPARISON OF PERFORMANCES WITH OTHER RELATED MODELS

Model	RMSE	PCC	R^2
WGRMF	0.56	0.72	-
DeepDSC	0.23	-	0.78
SRMF	0.57	0.71	-
BBR-DF (Proposed)	0.17	0.84	0.70

The proposed model showed an improvement in terms of achieving the lowest RMSE and highest PCC compared with the other models. R^2 needs to be enhanced, and some of the limitations are discussed in the following section.

F. Effectiveness of Gene Expression in Drug Response

The main challenge in drug development research and clinical trials is the lack of understanding regarding how individuals respond to drugs, which can significantly impact their efficacy and tolerability [52]. The present study aimed to investigate this issue by analyzing gene expression data, copy number alterations (CNA), and single nucleotide variants (SNV) to determine their role in drug response. The results indicated that gene expression data was the most significant factor in describing drug response, as compared to CNA and SNV. To identify the genes that are most important in explaining drug response, the study utilized Bayesian Ridge Regression (BRR) to calculate a coefficient for each gene based on its mRNA expression data. Genes with high coefficients were considered potential candidates for explaining drug response. Table VII presents the top five genes based on their coefficient for 24 drugs, while the complete list of ranked genes for each drug is provided in the Supplementary Materials.

TABLE VII. THE TOP FIVE GENES SELECTED BY THE MODEL FOR 24 DRUGS IN CCLE

MT1E (Metallothionein 1E) appears as an important predictor for 4 drugs: AZD0530, Erlotinib, Lapatinib, and Vandetanib. It is a Protein Coding gene. Frontometaphyseal Dysplasia 1 and Bladder Cancer are some of the diseases that are associated with MT1E [53]. In addition, CLEC2B (C-Type Lectin Domain Family 2 Member B) has a high score as an informative gene for 3 drugs: AEW541, L-685458, and RAF265. Several cancers, such as pancreatic adenocarcinoma, melanoma, and clear cell renal cell carcinoma, have been linked to CLEC2B as a marker [54]. However, those genes and their effect on each drug need to be validated in the biological context, which is an essential point in our future work.

V. CONCLUSION

Bayesian Ridge Regression (BRR) was combined with Deep Forest (DF) to enhance drug response prediction by integrating multi-omics data. BRR was used to select informative features for every type based on the coefficient value before integrating it with the other omics. DF works effectively to capture the local features and utilizes a network structure inspired by CNN for continuous improvement. Three scenarios were implemented. In each scenario, three models were utilized to evaluate the proposed model: Deep Forest (proposed), Random Forest, and CNN. BRR-DF displayed an 11% improvement ratio in terms of R^2 compared to the Baseline scenario. Also, the complexity time was reduced by 90%. DF showed the best results in all three scenarios in which it obtained 0.175, 0.842, and 0.708 regarding RMSE, PCC, and R^2 , respectively. The Top 10% scenario exhibited the best performance regardless of the specific algorithm. In DF, integrating gene expression and a single nucleotide variant showed a better result than integrating all three omics. Both Random Forest and CNN exhibited better results when all three omics were integrated. Regarding the multi-omics that were used, the drug response was mainly explained by the gene expression data more than the copy number and single nucleotide variants.

There are some limitations to the proposed solution. Firstly: the experiments showed overfitting even though cross-validation and feature selection were utilized. Techniques such as bootstrapping, ensemble methods, and synthetic oversamples could be investigated. Secondly, we only focused on cell line data. Future work will utilize drug information such as chemical structure and the drug target. Thirdly, selecting the best features was implemented manually, in which the top 10% were chosen. However, an automatic method, such as a voting-based will be studied in future work.

Systematic Analysis on the Effectiveness of Covert Channel Data Transmission

Abdulrahman Alhelal, Mohammed Al-Khatib

Computer Science Department, Imam Mohammad Ibn Saud Islamic University, Riyadh, Saudi Arabia

Abstract—A covert channel is a communication channel that allows parties to communicate and transfer data indirectly. Covert channel types are storage, timing, and behavior channels. Covert channels can be used for malicious and benign applications. A covert channel is a mechanism for violating the communication security policy that was not anticipated by the system creator. Recently, covert channels are used to transfer text, video, and audio information between entities. This article, discusses studies related to the development of covert channels as well as the research works that focus on improving the performance/throughput of covert channels. Also, it analyzes the previous studies in terms of publication type, year of publication, article title, article purpose, transferring file format used in covert channel, coding technique, throughput performance, time needed to transfer files, and article limitations.

Keywords—Covert channel; transmission; limitations; file; encoding throughput; performance; time; audio; video; text

I. INTRODUCTION

A covert channel is a mechanism for violating the communication security policy, where it is employed for encoding and decoding [1, 2]. The most important channel types are storage, time, and behavior channels. Storage channels is created using disk, physical memory to be shared between entities during using covert channel. A timing channel is a communication channel that can send/receive data by altering an entity's timing behavior. Covert channel works by altering the behavior of an application. A covert channel is used in data transmission in order to send different types of data between entities. There are several restrictions in the transmission process, such as channel capacity in terms of throughput. This article concentrates on investigating and evaluating the covert channels utilized in data transmission. Then analyze the collected studies about covert channels to identify the mechanisms used to create covert channels. In addition to determine, the throughput needed to transfer files. A comparative survey of related works is done in terms of several dimensions: The technique used to create the channel, the purpose of the channel, data format, coding techniques, throughput performance, time needed to transfer files, and article limitations. The methodology for conducting a comparative analysis about covert channel studies, which concern in data transmission, is shown in Fig. 1.

The rest of the article is structured as follows: Section II provides background and basic knowledge about covert channels, covert channel and scenarios. Section III discusses and analyzes related work about the effectiveness of covert channel data transmission. Section IV discusses the comparative analysis for related works studies and article

recommendations. Section V concludes the article and lists future works.

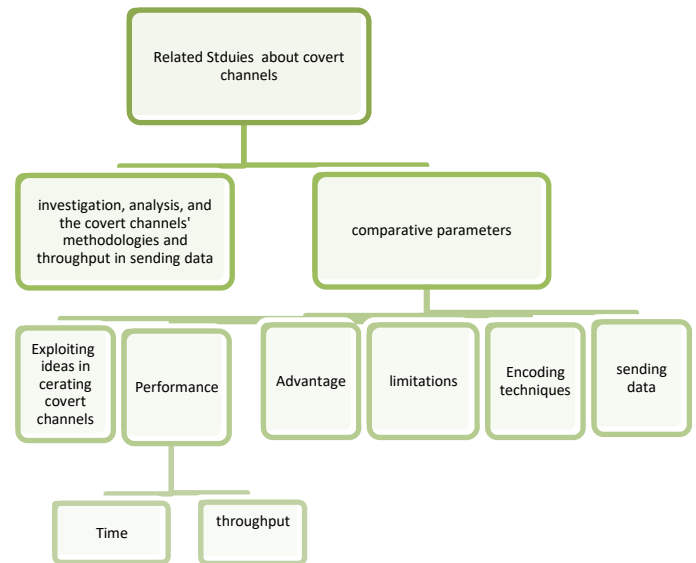

Fig. 1. Comparative survey methodology.

II. BACKGROUND OF COVERT CHANNEL

This section will cover the covert channel, its types, its scenarios, and covert channel applications.

A. Covert Channel

Lampson [3], first one that identifies a covert channel in a single machine computer environment in 1973 in his research titled "A Comment on the Confinement Problem". He describes a covert channel as a channel that is not intended for the transmission of data. Covert channel is a communication channel that allows parties to communicate and transfer data indirectly using per-agreement knowledge. As depicts in Fig. 2, the covert channel model uses to encode and decode the original messages. Covert channel is a mechanism for violating the communication security policy that was not anticipated by the system creator [1, 2, 3].

The sender and receiver (e.g.; Alice and Bob respectively) want to communicate covert message in spite of attacker existence (e.g.; Wendy). A covert channel is a type of secret channel. It sends secret data in an unseen manner by the monitoring system. Covert channel compromises the normal communication connection. Assume that Alice and Bob are connected through networked computers under the supervision of a network administrator.

Fig. 2. Covert channel model [2].

As a result, a network covert channel exists when Alice and Bob create a concealed communication channel that is undetectable by the network monitoring system. Alice and Bob must have pre-shared key called pre-agreement knowledge. So the channel is ordinal channel that has covert data from Alice to Bob. Secret data is agreed upon by the entities as pre-agreement knowledge that is used to encode and decode the original messages. For example, if the pre-agreement between client and server is that each word with an even number of letters is read as a 1 and each word with an odd number of letters is read as a 0. For example, if a client sends a message to the server, the "covert channel", the server will interpret it as a "10" [1, 2, 4].

In the communication process, the secure transmission of secret communications relates to two aspects: communication content security and communication connection security. The security of these two features can be improved by using network covert channels [5]. A covert channel can be either a standalone or a networked system. The covert information is exchanged between elements in the stand-alone system. The covert information is sent over the network in a network-based system [6]. Initially, researchers focus on local covert channels, in which two processes with differing levels of security might connect with one another to leak information. Typically, a process with a high security level leaks information to a process with a low security level. With the growth and rapid development of computer networks, the focus has switched to network covert channels, which can embed covert information into network protocols [7].

B. Covert Channel Types

The most important three categories of covert channels are storage covert channels, timing covert channels, and behavior-based covert channels [3, 8, 9, 10]. Fig. 3 shows the main three types of covert channels.

Fig. 3. Types of covert channel.

1) *Storage covert channels*: The sender and receiver create covert channel based on shared storage data agree on shared data. To embed covert data, storage channels primarily modify two characteristics of information.

a) *File names can be utilized* as entity attributes for storage channels. It can be altered by a single process. When any process performs a read operation, a message transfer between the processes occurs. It's also possible to change file attributes, which are properties of a file. Even though requesting a file that does not exist, the file system's feedback status can be used for storage channels [10, 11].

b) *Shared resources*: Storage channels can be made up of disk blocks, physical memory, I/O buffers, allocated I/O devices, and other queues for shared devices like printers and plotters. Storage channels are defined as a system feature that allows one system entity to signal information to another entity by writing to a storage location that is then read by the second entity directly or indirectly. It encrypts data and stores it on a medium that is shared by the endpoints. The shared resource was not made to transport data. A covert channel can be implemented in a networked system by utilizing reserved fields in various packet headers/footers or by hiding data in the payload. Attackers employ storage channels to encrypt information being transferred and then decode it afterwards. Some fields in TCP/IP stacks are left empty or unused. These vacant fields are used by attackers as storage conduits [10, 11].

2) *Timing channel*: A timing channel is a communication channel that can send data to a receiver/decoder by altering an entity's timing behavior. For example, packet delays between packet streams, packet reordering inside packet streams, or encoder resource access time. allows one system entity to communicate with another by manipulating its own use of a system resource in a way that affects the second entity's system response time. It changes the event time so that data can be shared between the endpoints. The main benefit is that the covert channel may be set up without affecting the transmission data stream. To this purpose, timing-based channels can be used with a variety of protocols because they are not affected by the network's packet syntax or semantics.

Attackers employ timing covert channels to modify system resources in order to deliver a message over time. The temporal delay between consecutive packet transfers is known as inter-packet delay. Timing-based covert channels are suitable for designing a complementary nonce synchronization channel that can improve robustness against message loss in existing authentication techniques, according to Vanderhallen et al. [11]. They tested this approach on top of an open-source authenticated CAN communication library, demonstrating that covert timing channels can improve communication robustness in benign situations while without compromising the security guarantees of the underlying authentication primitives when attacked.

3) *Behavior-based covert channels*: Behavior-based covert channels are described as a communication channel in which the sender or receiver's internal states are modulated by

purposefully selecting certain inputs to the systems. It works by altering the behavior of an application on purpose. The endpoints use this change to communicate. Covert channels based on behavior address the application level and are neither synchronized or dependent on a specific network protocol. As a result, they are more difficult to avoid and detect: identifying the message in a covert channel requires complete understanding of the application. Tamer Fatayer et al. [4, 9, 12], proposed behavior based channel through exploiting memory address in Linux operating system, where this channel change the behavior of using system calls and redirect the system call to malicious code implement by attacker to perform specific tasks.

C. Covert Channel Senarios

Zaider et al. [2] mention that that are different applications or usages (legitimate and illegitimate) for cover channel. Many covert channel applications are harmful or undesirable, which poses a severe danger to network security [2, 13, 14, 15, 16]. Malicious covert channel applications compromise network security. The Internet is the ideal high-bandwidth medium for covert communications because of the massive amount of information it contains as well as the enormous variety of data protocols. It is essential to comprehend current covert channel strategies while creating countermeasures. Identification, elimination, and capacity restriction of covert channels must be addressed to protect future computer networks, which is difficult. The current trend of covert channels is used in transforming secret information between entities [4, 9, 12, 17, 18, 19]. The researchers exploit network to transfer secret data (e.g., text, video, web, and audio) between entities. There are various covert channel scenarios:

1) *Storage channel scenarios*: Fatayer [12] developed a covert channel through developing table that is considered as pre-agreement data between entities. The covert channel-using table to transmit secure data that allows two entities to agree on a secret key using encryption to prevent an attacker from getting any information. Qiumin Xu et al. [20] a Trojan application can cause resource contention by altering the contents of a cache set to encode '1' and leaving the resource idle to encode '0'. On the other hand, the Spy application visits the cache and measures its access time in order to decode the transferred bit. Similarly, a Trojan application can cause contention by consuming a lot of execution units, warp schedulers, and instruction fetch units to encode '1' and then leaving those resources idle to encode '0,' which the spy can decode.

2) *Timing channel scenario*: Timing channels seek for TCP segments, which provide a finer range of information encoding options. For instance, steganography methods may take use of ACK/SYN sequences [21]. Information-containing segment patterns and artificial reordering. Following the same patterns as legal traffic and are immune to regularity testing. Active timing channels, on the other hand, create traffic and may easily maintain the form of the distribution, making them less susceptible to shape detection tests. However, they are

unable to maintain pattern recurrence and are easily detected using a regularity test.

3) *Behavior-based scenario*: Fatayer et al. [9] exploit buffer overflow vulnerability in C language on the Linux operating system to develop a covert channel. They exploit stack-overflow attacks vulnerability and address space layout randomization on Linux to transmit different file formats between entities. On entity tries to guess the randomization value that cause buffer overflow in Linux memory, while the other entity monitoring the count the guessing numbers till the success guess.

III. LITERATURE REVIEW ANALYSIS

This article will discuss studies that target covert channels utilized in data transmission between entities in this section. After that, we will analyze those studies to investigate the shortcomings and limitations of cover channel throughput during sending data by addressing these restrictions and limitations.

A. Covert Channels in Data Transmission

Channel in a wireless communication system with adaptive rate: They were able to effectively demonstrate a covert channel with a throughput of more than 150 Mbps that reliably delivered the hidden payload while minimizing the mistakes seen in the underlying communications system. Although the focus of this study was on IEEE 802.11ad, additional adaptive rate communication protocols should be able to benefit from using modulation and coding schemes selection to increase covert channel capacity. The selection of a cover object is limited to objects that can tolerate a certain amount of distortion (e.g., Audio and video), which is a significant flaw in this method. They don't used text or executable files. To minimize distortion on the underlying communications channel without compromising the covert channel's throughput, a modified embedding mechanism was developed.

Wendzel et al. [22] introduce a full survey covert channel that used to hide information inside network protocol. They investigated and analyzed around 109 techniques targeting covert channels that hide communication protocol. They classified a covert channel according to special pattern. They classify the covert channel according to eleven patterns which are Size Modulation, sequence of header/PDU elements to encode hidden information, add redundancy, PDU corruption/Loss pattern, random value pattern, value modulation pattern, reserved/unused pattern (a reserved or unused header/PDU element was used by the covert channel to encode data), inter-arrival time pattern, data rate of a traffic, PDU order patter, and retransmission pattern as depicts in Fig. 4.

In this survey we concerned with data rate of a traffic pattern, which allows covert channel sender alters the data rate of a traffic flow to the covert channel receiver. Using exception handling, we will construct a covert channel that we will utilize to deliver files to the server. Additionally, we employed a pattern called program flow pattern, which modifies program execution and transmits covert data to the receiver.

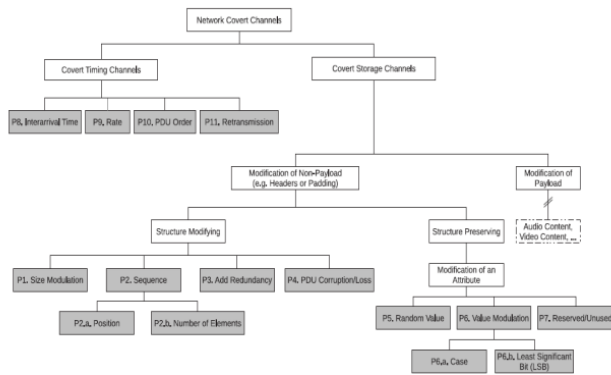

Fig. 4. Classification pattern of covert channel [22].

Zander et al. [22] presented a survey of developing network covert channels. The terms, adversary scenario, covert channel techniques, and countermeasures are all covered in this survey. Covert channels are used in sending information through network protocols. The survey showed the covert channel may use unused header bits, header extensions, padding, the IP Identifier and Fragment Offset, the TCP Initial Sequence Number (ISN), checksum fields, the time to live (TTL) field, the modulation of address fields and packet lengths, the modulation of timestamp fields, packet rate and timing, message sequence timing, packet loss and packet sorting, frame collisions, and ad hoc routing protocols. Also, they mention the counter measures techniques that used to detect and prevent covert channel. The following countermeasures are used such as:

- 1) Eliminate the channel including host security, Network security, traffic normalization.
- 2) Limit the bandwidth of the channel.

They introduced [22] an explanation of covert channel capacity, the amount of information that can be encoded in a resource's size (storage channels) or the speed at which it can be modulated (timing channels) can be used to estimate the covert channel capacity. Estimating the capacity in terms of bits per packet or bits per message sequence is simple for some channels. The amount of overt communication between covert sender and receiver or the amount of acceptable overt traffic accessible in the network determines capacity in bits per second. Therefore, it must modify the mechanisms for generating and producing covert channels in order to boost their capacity.

Schmidbauer et al. [18] present two covert channels that exploit nonce-based network authentication. First covert channel exploit key-based authentication and the second covert channel exploit hash-based authentication. These channels are used for sending encrypted information between parties. They investigated and exploited the challenge-response authentication with a nonce for transfer secret information. They evaluated their covert channel in terms of throughput rate. They increased the performance of the throughput by applying Compression and codebook techniques. They measure the throughput through number of attempt to achieve challenge-response authentication mechanism. Fig. 5 shows that using a compressed JS-Hex file requires 500 attempts to

communicate 4 bytes over Hash-based covert channel, whereas using an uncompressed JS-Hex file requires 3000 attempts.

Fig. 5. Throughput hash-based covert channel [18].

Fatayer [12] developed a storage covert channel through developing a storage memory to be a pre-agreement data store between entities. Data structures are utilized to establish the covert channel, which will be used to transfer secure data between entities. This covert channel enabled parties to agree on a secret key. This mechanism is flexible in generating key with different size. On the other hand, it cost more traffic overheads and time consuming.

Fatayer et al. [9] exploit stack-overflow attacks and address space layout randomization on Linux to transmit different file formats. The sender tries to guess the delta_mmap memory (length 16 bit). One entity wants to send Files indirectly to other entity through a server. They are located in the same machine. Client tries to guess the random memory offset of standard C-library (delta_mmap) of the vulnerable server, and Bob tracks Alice's guessing attempts by monitoring the server process. Information to be sent is encoded in the number of failed guesses before success. They transmitted text and audio files between entities. They achieve best throughput performance using hexadecimal coding as depicts in Table I.

TABLE I. COVERT CHANNEL PERFORMANCE DURING TRANSFERRING AUDIO FILES [9]

Audio file size	Optimization time	Without optimization
2.3 KB	.76 minute	1.01 minute
1.2 MB	91.9 minute	234 minute

They suggested researchers to use encoding techniques to enhance the throughput performance. Additionally, they will look into methods for boosting channel throughput by determining the ideal block size, ideal number of tables, and ideal region number encoding—possibly utilizing Huffman-code. This article contribution is stemmed from this point. This article will develop covert channel to send file with different format with coding mechanism such as Byte, Hexadecimal, Huffman, and base64 coding.

Elsadig et al. [17], introduce a full comprehensive survey about the usage of covert channels and their types. They mention several benign usages of the covert channel, where the author considers it a new direction in security. Previous works focus on developing covert channels that depend on a new idea and the advantages and disadvantages of existing covert channels. These researches mention that there is limitation in throughput performance. Few research works investigated the use of covert channels to send files with different formats. Moreover, the performance of such covert channels has not been adequately explored. Previous researches did not investigate the use of encoding algorithms to improve the throughput performance of covert channels as well.

Jens et al. [19] exploit VoIP communications as a technique to increase privacy in sending files. They suggested hiding traffic within VoIP conversations to prevent disclosure from blocking the ongoing exchange of information. They use the voice activity detection features which found in client interfaces to create phony quiet packets that may be utilized as a carrier for transferring secret data. Results show that the suggested method may be effective for enforcing privacy in practical use scenarios, particularly for file transfers. They leveraged VoIP traffic by developing a virtual network interface for tunneling protocols of the TCP/IP suite.

Privacy Enhancing Technology Voice Activity Detection (PETVAD) is slower than a direct access because HTTP is influenced by the TCP's subpar performance when there are significant delays. Part of results in [19] as depicted in Table II, which indicates that to send 1 MB webpage it cost 283 (KB/s) as throughput and 3.61 second in the existence of 100ms delays [19]. Throughput is measure through constructing local area and wide area network configurations. They used three webpages to be sent through the covert channel. Each page has 1, 10, and 100 inline objects, each of which is 1MB, 100 KB, and 10 KB in size.

Cumulative Distribution Functions (CDFs) that describe the probability distribution of random variables of transfer over times. As it is visible, the larger the size of the website, the higher the variations experienced by the users when retrieving a page as shown in Fig. 6. The low bandwidth may cause interactive services (like web surfing) to lag too much, hence some sort of optimization or content scaling may be advised in these situations.

TABLE II. TIME AND THROUGHPUT FOR DIRECT AND PETVAD COVERT CHANNELS [19]

web pages size	Time (second)	Rate (KB/s)	Techniques	Delay
1* 1MB	3.61	283	Direct	100 ms
10* 100K	4.98	205		
100 * 10 K	21.65	47		
1* 1MB	422.21	2.43	PETVAD	
10* 100K	442.53	2.31		
100 * 10 K	660.53	1.55		

Fig. 6. Using a VIOP covert channel to transfer web sites [19].

B. Analysis Summary

The covert channels utilized for data transfer between entities are the topic of this article. There are several methods for creating covert channels, each of which can be used to encode and decode information. There are several types of information that are sent through channels, such as text files, audio, video, and web pages. We analyze and evaluate the performance of the covert channel in terms of throughput. The term "throughput" in this article means the number of transmitted bits per second. We observed from related works that the covert channel has low throughput. The authors use several mechanisms to enhance the performance, such as using encoding techniques.

IV. DISCUSSION ANALYSIS AND RECOMMENDATION

A. Systemic Review Discussion

This article discusses and analyzes studies related to the development of covert channels as well as the research works that focus on improving the performance/throughput of covert channels. This article analyzes the previous studies in terms of publication type, year of publication, article title, article purpose, transferring file format used in covert channel, coding technique, throughput performance, time needed to transfer files, and article limitations. Then compare conventional and modern mechanisms for creating covert channels. Table III, shows that covert channel is used for transferring files between entities. There are several mechanisms for creating covert channels. Current trends for creating covert channel through exploiting: Networks protocol (e.g., TCP), System interfaces, and Programming language.

Table III, examines previous studies to investigate covert channel capacity, throughput, and data transfer time; a comparative survey of related work in terms of exploiting ideas to create covert channels, channel type (e.g., storage channel), creation purpose (malicious and benign), data transmission type (e.g., audio and video), measurement performance, optimization techniques, advantages, and drawbacks where it's clear that the covert channel can be used to send different type of data such as audio, video, webpages, and text. The covert channel must be supported with coding techniques to increase the channel throughput. The covert channel must authenticate

parties before using it to send data. Furthermore, one of the primary goals of the covert channel is to improve throughput performance.

TABLE III. COVERT CHANNELS OF PREVIOUS STUDIES

Terms	Collected research
Exploiting idea	Ideas of collected article [4, 18, 19, 22, 23, 24] exploits networks protocol (e.g., TCP), system interfaces
Channel Type	Storage channel, timing channel, program flow
Purposed	Most of article s target is attack purposes. Some of them used to send secret data.
File Type	Text file, webpages and voice [19],
Measurement performance	Articles measure throughput and time of sending files performance.
Coding Optimization	Hex-coding [12], compression and code book technique [18], without coding [19].
Advantage	Every article is consideration as a new idea for a covert channel. These article s serve as warnings about the threats against network and software.
Drawbacks	The throughput performance is still low and needed to be improved.

Evaluating and analyzing the previous related works is depicted in Table IV in terms of publication type (conference or journal), publication year, article title, main idea of generating a covert channel, type of data transmission, coding techniques used in generating data, throughput performance in sending data, time performance in sending data, and article covert channel limitations.

TABLE IV. (A). THE MAIN COMPARISON POINTS FOR PROPOSED COVERT CHANNEL AND PREVIOUS COLLECTED ARTICLES

article reference	Publication type/year	Article Name	Main idea	Data transfer type
[18]	Conference/ 2022	"Challenging channels: Encrypted covert channels within challenge-response authentication.	They investigated and exploited the challenge-response authentication with a nonce for transfer secret information	They mention JS hexadecimal, JS-string, JS-plain, And ASCII alphabet
[4, 9, 12]	Conference/ 2011	OverCovert: Using Stack Overflow Software Vulnerability to Create a Covert Channel	Exploiting stack memory to hacks Linux memory functions to create covert channel.	Text and audio file

[19]	Journal/ 2020	VoIP network covert channels to enhance privacy and information Sharing	Develop covert channel depends on using the voice activity detection features which found in client interfaces to create phony quiet packets that may be utilized as a carrier for transferring secret data	Web pages as Google YouTube
proposed	2022	Exploiting a program execution for developing a high throughput covert channel.	exploit program execution	Text, audio, video,

TABLE V. (B). THE MAIN COMPARISON POINTS FOR OUR PROPOSED COVERT CHANNEL AND PREVIOUS COLLECTED ARTICLES

article reference	Coding	Throughput Concept	Time	Limitation
[18]	compression and codebook techniques	Number of attempts Needs to achieve challenge-response authentication	Not computed	countermeasures that allow the limitation of bandwidth, for example the utilization of appropriate RSA keys, and the elimination of the CC through the deployment of application-level firewalls
[4, 9, 12]	Used just hexadecimal coding	Number of bit sending during time	Time for agreement time and time for sending different files	Throughput is still low and authors just used hexadecimal . They presumptively believe that a server program is monitored by a local program that resides on the server's computer. They presume that the server cooperate with two parties.
[19]	There no special coding it just using two networks	Number of object(KB) in web pages transmitted per second	Computed	content-rich web browsing may require further optimizations, such as operating in a text-only fashion

B. Recommendation

Through related works analysis and developing covert channel, the following recommendations are

1) To develop covert channel countermeasure, we must understand covert channel mechanisms in terms of identification, elimination, and the capacities.

2) Applications and scenarios for covert channels in computer networks are varied.

3) Increased channel capacity can be achieved by changing the processes used to create and develop covert channels.

4) Both beneficial and harmful purposes are carried out through the covert channel.

5) The researchers concentrate on the fact that the channel capacity has a gap, which has to be filled by future researchers.

6) Using coding techniques maybe increase the throughput of channel in sending data.

7) Sending information through covert channel need security issues (e.g., entities authentication) beside sending data covertly.

V. CONCLUSION

Covert channel has several types: storage, timing, and behavior channels. Covert channel has several applications including data transmission. In this article, we focused on investigating and assessing the covert channels that used in data transfer. We collected earlier studies to identify methods for creating covert channels and how they measured the throughput at which data was delivered between organizations. We do a comparative survey of related work in terms of exploiting ideas to create covert channels, channel type (e.g., storage channel), creation purpose (malicious and benign), data transmission type (e.g., audio and video), measurement performance, optimization techniques, advantages, and drawbacks. We determine recommendations based on conducted survey, including: Applications and scenarios of covert channels in computer networks are varied. Increased channel capacity can be achieved by changing the technique that used to create and develop covert channel. In covert channel, coding techniques increase throughput of channel in sending information through covert channel need security issues (e.g., entities authentication) besides sending data covertly. The covert channel must be supported with coding techniques to increase the channel throughput. The covert channel must authenticate parties before using it to send data. Furthermore, one of the primary goals of the covert channel is to improve throughput performance.

ACKNOWLEDGMENT

I am a student at Imam Mohammed Ibn Saud Islamic University. I extend my appreciation to the Deanship of Scientific Research at Imam Mohammed Ibn Saud Islamic University for funding and supporting this work through the graduate student research support program. I would like to express my sincere gratitude to my advisor, Prof. Mohammed Al-Khatib, for their invaluable guidance and support

throughout my master's program. Their expertise and encouragement helped me to complete this research.

Towards Analysis of Biblical Entities and Names using Deep Learning

Mikolaj Martinjak^{1*}, Davor Lauc², Ines Skelac³

Faculty of Philosophy and Religious Studies, University of Zagreb, Zagreb, Croatia^{1,3}
Faculty of Humanities and Social Sciences, University of Zagreb, Croatia²

Abstract—Scholars from various fields have studied the translations of the Bible in different languages to understand the changes that have occurred over time. Taking into account recent advances in deep learning, there is an opportunity to improve the understanding of these texts and conduct analyses that were previously unattainable. This study used deep learning techniques of NLP to analyze the distribution and appearance of names in the Polish, Croatian, and English translations of the Gospel of Mark. Within the scope of social network analysis (SNA), various centrality metrics were used to determine the importance of different entities (names) within the gospel. Degree Centrality, Closeness Centrality, and Betweenness Centrality were leveraged, given their capacity to provide unique insights into the network structure. The findings of this study demonstrate that deep learning could help uncover interesting connections between individuals who may have initially been considered less important. It also highlighted the critical role of onomastic sciences and the philosophy of language in analyzing the richness and importance of human and other proper names in biblical texts. Further research should be conducted to produce more relevant language resources, improve parallel multilingual corpora and annotated data sets for the major languages of the Bible, and develop an accurate end-to-end deep neural model that facilitates joint entity recognition and resolution.

Keywords—Bible; deep learning; gospel of mark; natural language processing; social network analysis

I. INTRODUCTION

The Bible is a significant religious text that has been translated into many languages and is one of the world's most widely studied ancient texts. However, the translations of the Bible exhibit substantial variation across the languages into which they have been translated, and these translations have undergone numerous revisions over the years. As a result, studying the translations of the Bible in different languages and understanding the changes that have taken place over time are essential for scholars in several fields, including theology, linguistics, religious studies, and history.

With recent advances in deep learning, there is an opportunity to improve understanding of these texts and conduct previously impossible analyses. Deep learning techniques are still not commonly used in this field of research, but they can help scholars analyze and interpret biblical text by enabling them to process large amounts of data and identify connections and information that cannot be identified using traditional methods. In this context, one application of deep learning is the use of natural language

processing (NLP) to analyze the language used in the text. Natural language processing can be used to identify patterns in the use of words and phrases, as well as in the syntax and grammar of the text.

Recent research has explored the use of SNA to study language and culture. Social network analysis is a useful tool for identifying patterns in large data sets, and has been applied to various domains, including linguistics, anthropology, and sociology. It is also a useful technique that can be used to uncover patterns and relationships between Bible translations by analyzing the frequency of words and phrases in different translations.

In this case study, the use of deep learning techniques is explored to analyze the distribution and appearance of names in the Polish, Croatian, and English translations of the Bible. For this research, data from the 100-language parallel corpora created by Christos Christodouloupoulos and Mark Steedman are used [1]. When multiple versions of the Bible were available, the creators of the corpora preferred to use the oldest translation available. For example, the King James Version was used for the English language.

Furthermore, this analysis uses the methodology of distant reading [2]. It aims to analyze large collections of texts using computational tools and techniques, as this allows for the generalization and identification of patterns that would otherwise be impossible to detect. The present case study uses SNA techniques to investigate the relationships and interactions within a network of entities in the selected book of the Bible. When SNA techniques are applied to large data sets of translations, insights can be gained into the relationships between translations and the religious and linguistic factors that influence the translation process.

This study aims to strengthen the robustness of biblical text analysis across multiple languages; therefore, it should be viewed as a first step or pilot research. As a starting point, the Gospel of Mark is chosen. The Gospel of Mark's Footprint will be expanded to other languages and subsequently to the entire New Testament and later to the entire Bible. The goal is to enhance understanding of the distribution of names in the biblical text and provide a framework for analyzing other interdisciplinary aspects, including theological, linguistic, and philosophical ones. Finally, during this analysis, different philosophical questions about the status of the names appeared and have been discussed using a framework from the analytical philosophical tradition.

In this paper, after the review of existing research and available language resources, the methods and results of entity recognition and resolution in a selected Gospel will be presented. Finally, the obtained results and the possibilities of future research will be discussed.

II. LITERATURE OVERVIEW

A. *About the Gospel of Mark*

The Gospel of Mark was written in the first century for a general audience of Christians, although scholars debate the exact audience and purpose of the gospel [3]. It is the shortest of the four canonical gospels and is believed to have been written between AD 65 and 70. Hence, it is one of the earliest written accounts of Jesus Christ's life and teachings.

In the Gospel of Mark, Jesus is presented as the Son of God and the long-awaited Messiah (Christ) of Jewish prophecy. Throughout the gospel, Jesus performs miracles and teaches with authority, attracting crowds of followers while challenging the religious and political authorities of his time. This gospel emphasizes Jesus' role as a suffering servant who will be rejected, betrayed, and crucified but will also rise from the dead and bring salvation to humanity. Specifically, Mark portrays Jesus as a human being with a divine mission who is uniquely qualified to fulfill the promises and prophecies of the Hebrew Bible. Jesus' identity is gradually revealed throughout the gospel as he heals the sick, forgives sins, calms storms, feeds the multitudes, and confronts demons. At Jesus' baptism, a voice from heaven proclaims, "...Thou art my beloved Son, in whom I am well pleased." (Mk 1:11) [4], confirming the divine identity of Jesus. Despite Jesus' powerful teachings and miraculous deeds, many people rejected him, including the religious leaders of his day, who saw him as a threat to their authority. This leads to Jesus' arrest, trial, and crucifixion, but also sets the stage for his ultimate triumph over death and evil powers.

The Gospel of Mark contains a distinctive theology that emphasizes certain key themes and ideas. There are a few theological themes found in this Gospel. For this research, the most prominent theme is the Messianic Secret. The Gospel of Mark portrays Jesus as the Messiah, while emphasizing that his identity is often hidden or a secret. This is because Jesus repeatedly commands those he has healed or exorcised to tell no one about what he has done, and he often speaks in parables that are difficult for his disciples and others to understand.

The reference for all names mentioned in the text is not obvious from the text. Sometimes it relates to our knowledge of the Bible, especially other synoptic gospels [5]. The Gospel of Mark gives us names such as Jesus, Simon, John, James, etc. However, who was James? It should be concluded that from the text itself. Another challenge is that there is more than one James, and, in some cases, it is not so evident to which person the text refers. The same thing happened with the name John, where it can distinguish at least John the Baptist and John the Apostle, and with the other names as well. The solution for distinguishing is mentioned in the Results and Discussion section.

B. *The Analysis of NLP Resources for Bible Studies*

There are various applications of NLP resources for Bible studies thus far. Natural language processing tools can be used to analyze the language and style of the Bible, which can provide insights into the authorship and composition of different biblical texts. However, using NLP tools for biblical studies has several challenges and limitations. For example, the complexity and diversity of biblical texts makes it difficult to create NLP resources that can capture all the nuances and subtleties of the language. In addition, the cultural and historical contexts in which the Bible was written can be difficult to capture using NLP tools alone and may require additional theological expertise. Therefore, NLP tools should be used in conjunction with other methods and expertise, not in place of close reading and interpretation of texts.

Büchler and Mellerin [6] discuss the use of NLP resources for Bible studies. This article provides an overview of several NLP tools and resources designed specifically for analyzing biblical texts, such as morphological analyzers, part-of-speech taggers, syntactic parsers, and named entity recognition systems. These tools enable scholars to identify patterns of language use, track the evolution of specific words and phrases, and uncover hidden connections between different parts of the Bible. The authors also discuss the potential benefits of using NLP tools for biblical studies. For example, they propose that NLP can help scholars identify allusions and quotations from other texts in the Bible, which can shed light on the cultural and historical contexts in which the Bible was written.

Another topic that can be investigated using NLP is authorship attribution. According to [7], attribution of authorship involves analyzing various linguistic features of a text to determine the probability that a given author wrote the text. The authors discuss challenges that arise when applying authorship attribution to the Bible, such as the use of pseudonyms and the difficulty of obtaining enough training data for accurate analysis and provide examples of how authorship attribution has been used to analyze different parts of the Bible, such as the Psalms and the Pauline epistles. Despite these challenges, authorship attribution can provide valuable insights into authorship and the historical context of biblical texts. Thus, by identifying the authors of different parts of the Bible, scholars and researchers could gain a deeper understanding of the historical and cultural contexts in which these texts were written.

In addition, several studies have been conducted to compare Bible translations in different languages. Using SNA techniques, a study examined the frequency of words in the English and German translations of the Bible. The study found that some words were used more frequently in one translation than in the other, which could be attributed to differences in language structure, culture, and translation choices [8]. By comparing translations in different languages, scholars can better understand the choices made by translators and the cultural and linguistic factors that influence those choices.

As stated previously, NLP tools are used for various analyses of the biblical text; however, none of the existing studies conducted a comparative analysis of personal names in

different languages. This analysis can have several outcomes: 1) It can show linguistic (phonetic) differences between Bible translation and different languages, allowing for a language distance analysis; 2) It can provide a parallel philosophical and theological perspective to the name analysis; 3) It can use SNA to show differences in social connections between different translations of the Bible, which can help in determining some ambiguous places in understanding personal relations in the Bible.

III. METHODS

A. Distant Learning Method of Literary Analysis

In recent years, distant reading, a literary analysis method that involves analyzing large bodies of texts using computational techniques, has been applied to biblical studies. This method has been used to identify patterns and trends in the use of language and themes across multiple biblical texts, shedding new light on the historical and cultural contexts in which these texts were written. One of the key aspects of distant reading is the use of quantitative methods to measure and compare literary phenomena. Moretti [2] suggests that we should examine the “big picture” of literary history by analyzing large data sets and mapping out the evolution of genres, themes, and styles over time. A general goal of distant reading is to uncover broad patterns and trends in literature that can reveal new insights and understandings about literary history, genres, and themes [9].

In doing so, patterns that may not be visible at the level of individual texts or authors can be identified. Another important aspect of distant reading is the use of computational tools to process and analyze textual data. Moretti argues that we should go beyond traditional methods of literary analysis, such as close reading and interpretation, and embrace the potential of digital technologies to handle large amounts of data [2]. By using tools such as text mining, topic modeling, and network analysis, hidden patterns and connections in the literature that would otherwise be impossible to discern can be uncovered.

However, distant reading also faces several challenges and limitations. One of the main criticisms of distant reading is that it prioritizes quantitative analysis over qualitative interpretation and reduces literary texts to mere data points. Despite this limitation in this study, the results obtained using this methodology are always discussed and verified using traditional theological and linguistic methodologies.

B. Construction of the Entity Graph

The entity graph is built in two phases. In the first phase, named entities are recognized and classified using the ByT5 neural model [10] fine-tuned in the relevant parts of the multilingual named entity recognition (NER) data set. The results were manually evaluated and corrected, and the data set will be used to fine-tune the NER model in the future. The second phase was manual disambiguation and classification of the recognized named entities. The graph (social network) was constructed based on counts of co-occurrence of the entities of type person in the verses.

C. Social Network Analysis Metrics

Within SNA, various centrality metrics are used to determine the importance of network entities. In this research, degree centrality, closeness centrality, and betweenness centrality were used, each providing unique insights into the structure of the network.

Degree Centrality is a simple metric that counts the number of direct connections (edges) an entity has with other entities in the graph. Higher-degree centrality values indicate a higher number of connections. This metric can be used to identify nodes that are well connected and potentially influential within the network. Closeness centrality measures how close a node is to all other nodes in the network. It is calculated by taking the inverse of the sum of the shortest path distances between a node and all other nodes in the network. A higher closeness centrality value indicates that an entity is more central and can reach other nodes in the graph more quickly. Betweenness centrality, a related metric, measures the extent to which an entity acts as a bridge to other entities. It indicates how often a node lies on the shortest path between pairs of other nodes [11].

IV. RESULTS

An entity graph (a social network) created by the described method reveals interesting insights into relationships among people mentioned in the gospel. The selected centrality measures – degree centrality (D), closeness centrality (C), and betweenness centrality (B) – for the English, Croatian, and Polish languages are presented in Table I.

The difference between languages and the apparent difference in numbers on individuals and their relationship or closeness demonstrated in Table I is in significant part due to the use of pronouns. Each language will use a different number of pronouns, corresponding to the development and flow of the language. SNA metrics show that Jesus is a central figure, but also give some surprising results, such as that Mary Magdalene is closer in a relationship and connections than Mary, mother of Jesus. Yet, it is also due to how the gospel was written.

Differences and similarities between centrality measures are easier to interpret when visualized using a spring graph layout, as shown in Fig. 1, Fig. 2, and Fig. 3.

The graphs in the three languages show that Jesus is a central figure of the gospel. Obviously, many connections led to Jesus, especially those closest to him – for example, John the Baptist, Simon Peter, John and James Zebedee, and others. When the names of Timaeus and Bartimaeus are looked at, it is noticed that they are closer to Jesus in the Croatian language than in others. In that sense, they are not directly connected to Jesus in English or Polish but are in the Croatian version of the graph. The main reason for this occurrence is that Jesus was specifically mentioned by name in the Croatian version of the text. Another intriguing part of the graph is the name of Simon, who is in the text distinguished as a Cyrenian and his two sons, who have no connection to Jesus in the graph. However, according to knowledge of other gospels and reading of the Gospel of Mark, it is known that Simon was the one who assisted Jesus in carrying his cross. Mary Magdalene,

Mary the mother of James and Joses, and Salome all experienced similar events. There are no direct connections to Jesus in the graphs, even though it is known from other resources and standard interpretations of the Bible that there is a connection. Aside from the obvious connections, it was interesting to see the link between Jesus, Barabbas, Pilate, and Joseph of Arimathea, who are all directly connected to Jesus. Note that Joseph is only identified by his first name in the Croatian and Polish versions of the graph.

In the King James version of the English translation, which is used in this analysis, the name James Zebedee is used, while in the Croatian and Polish translations, the name is Jakob or Jakov. In graphs, it is evident that the same person is in question, since there is a connection between him, his brother John, and his father (signed just as Zebedee). For some other figures, a 'new' or a bit untraditional method was used. For the research, the surnames that are not present in the gospel were added to distinguish similar names that refer to different people.

TABLE I. SELECTED SNA METRICS (D – DEGREE, C – CLOSENESS, B - BETWEENNESS) ORDERED BY THE BETWEENNESS CENTRALITY IN THE ENGLISH TRANSLATION

	ENTITY	ENGLISH			CROATIAN			POLISH		
		D	C	B	D	C	B	D	C	B

It is common for biblical names to be translated differently in different languages, depending on the linguistic and cultural traditions of each language. James has become a common English name and is often used to refer to the biblical figure. Many English-speaking readers may not recognize that the name Jacob refers to the same person. However, some English translations use the name Jacob instead of James, particularly in recent translations that seek to be more faithful to the original Hebrew and Greek texts.

V. DISCUSSION

A. Theological Perspective

During the manual evaluation and correction process, the greatest diversity came from the differences in the languages and the use of names in specific languages. Some Bible translations do not follow the phonetic development of an original name but instead use more common names that evolved over time and even morphed into different names. However, some names needed to be differentiated even more in the text itself. The first task was to distinguish between the names of places, towns, regions, and individuals. It was also necessary to differentiate between functions such as Caesar, Pharisee, etc., and individuals since the program recognized them as specific names of people rather than functions. In that sense, a boat (pol. *łódź*) was recognized as a proper name in the Polish version of the text, probably because there is a town with the same name in Poland.

Furthermore, the main challenge in identifying individuals in the Gospel is that the text provides only a first name, occasionally giving a last name or what we would call, in today's terms, a last name [12]. In biblical terms, they almost always represent a connection with a particular person in parent-child relationships. The name Bartimaeus, the son of Timaeus, is the most notable and precise connection between father and son (Mk 10:46-52) [4]. It is a Greek name that means "son of Timaeus." "There are no similar connections in other places of the gospel. Instead, one can see "son of Alphaeus," "son of Zebedee," or even "Son of David," which is sometimes applied to "Jesus". The problem emerged because those connections are not evident in the text unless manually marked. As a result, last names were required to make clearer distinctions. Moreover, the apostles James and John were given the surname Zebedee, but that did not resolve the issue, especially since there were other people named

James. One is known as “James Alphaeus” and is sometimes referred to as “the lesser”. Additionally, he is supposed to be Levi’s (Mathew) brother. The information on Levi as Mathew is reconstructed from other synoptic gospels and textual connections that are not obvious from a single reading of the story.

There is also a problem with the name Simon, which is given to Peter as he becomes a disciple, but it is also the same name of individuals who are difficult to distinguish. In some ways, one is unsure if those are two different people or if they are referred to differently, as in the case of Levi.

In our analysis of the text, it was important to differentiate Christ as a name from Christ as a reference to Jesus, as Ehrman concludes [13]. In other words, a problem emerged during the name analysis because it was necessary to distinguish between Christ as a name and Christ as a function. That is, in terms of theology, Ehrman’s work made sense to this. The concept of the Messianic secret in the Gospel of Mark has important implications for understanding the relationship between Jesus and his disciples, the apostles.

B. Philosophical Perspective

Except for the beginning of the Gospel of Mark, where the syntagm ‘Jesus Christ’ is used, it cannot be sure if Christ refers to Jesus in other places. However, it is clear in some places that it does not or can be questioned. This is a challenge for linguistic analysis because the question is: when Christ refers to Jesus, is it only when there is a syntagm Jesus Christ, and is it possible that Christ does not refer to any specific person in some places?

The famous location is (Mk 8: 29), where Jesus asks his disciples: “...But whom say ye that I am? And Peter answered and saith unto him, Thou art the Christ.” [4] As a result, the syntagm Jesus Christ is not the only place where Christ refers to Jesus.

For linguistic analysis, “Christ” can be interpreted as a function in Frege’s terms [14], with Jesus serving as the object that fulfills the function of being “Christ.” In the case of “Christ” in the Gospel of Mark, one could interpret it as a function that assigns the value of being the Messiah, the Savior, or some other similar role to a particular object. Depending on the context, the object that fulfills this function could be Jesus or another individual. However, the function would remain the same regardless of the specific object that performed it.

If Jesus is the only object that fulfills this function, then the function would have a unique value, and any use of the term “Christ” would necessarily refer to Jesus. However, Frege’s theory of functions allows for the possibility of multiple values that fulfil a function. The specific number and nature of these values would be determined by the context and interpretation of the term “Christ.”

If one wants to limit “being a Christ” to one person, then it is better to understand “Christ” as a name and not a function. According to Kripke [15], names are rigid designators; therefore, the meaning of a name is fixed and independent of any specific description or property of the individual. With

this definition, it can be said that Christ, as a rigid designator, has the same fixed meaning as the name Jesus when it is known that these two names refer to the same person (compare [16, 17]). This meaning, or the object of reference, could be Jesus or another figure, such as the Messiah or the Savior. Still, the name “Christ” would always refer to the same individual, regardless of the specific properties or descriptions used to describe them. Kripke’s theory also allows the possibility of reference failure, in which a name does not refer to any individual in the world. This could happen if the name is used in a context where no individual matches the description associated with it (for example, before Jesus was born) or if it is unknown that Christ has the same reference as Jesus. In the case of “Christ” in the Gospel of Mark, it is also possible that the name Christ does not refer to any specific individual in some contexts, either because it is used in a general sense or because there is ambiguity or uncertainty about its referent.

Therefore, “being a Christ” can be understood as a function in Frege’s terms. Kripke’s theory of reference provides a more useful framework for understanding how names refer to individuals in the world when this individual is unknown or uncertain.

VI. CONCLUSION

From a theological perspective, this study demonstrates that in some cases it is difficult to distinguish an individual from the mission or even from another individual. Almost everyone in the world knows who Jesus is and perhaps who Peter or Judas is. Still, this research showed that some interesting connections between individuals who seemed less important could be discovered through deep learning. Even with this small extract of the text and only a few languages, it will become even more prominent on a larger scale.

Given the importance and influence of Bible, the relative scarcity of available language resources is surprising. Therefore, our future research will initially focus on creating more relevant resources, starting with improving parallel multilingual corpora and annotated data sets for all the major languages of the Bible. These resources are necessary to train more accurate multilingual language models for named entity recognition and entity resolution. Based on these data sets, the intention is to develop an accurate end-to-end deep neural model for joint entity recognition and resolution, which would facilitate numerous other research projects in digital humanities, theology, and related fields.

Another unexpected early finding was that the newer NER models performed worse than older models on biblical texts, contrary to the standard benchmarks, which should be thoroughly researched and explained.

Further research using other metrics and techniques from SNA in studying the interaction of entities in the Bible and validating those findings against traditional research should yield interesting results.

Finally, given the richness and importance of human and other proper names in biblical texts, several interesting studies in onomastic sciences and sociolinguistics could be conducted, ranging from analyses of the similarity and differences of

biblical names across different languages to the creation of alternative similarity matrices among languages.

Deadline-aware Task Scheduling for Cloud Computing using Firefly Optimization Algorithm

BAI Ya-meng*, WANG Yang, WU Shen-shen

School of Information Engineering, Jiaozuo University, Jiaozuo 412000, China

Abstract—Task scheduling poses a major challenge for cloud computing environments. Task scheduling ensures cost-effective task execution and improved resource utilization. It is classified as a NP-hard problem due to its nondeterministic polynomial time nature. This characteristic motivates researchers to employ meta-heuristic algorithms. The number of cloud users and computing capabilities is leading to increased concerns about energy consumption in cloud data centers. In order to leverage cloud resources in the most energy-efficient manner while delivering real-time services to users, a viable cloud task scheduling solution is necessary. This study proposes a new deadline-aware task scheduling algorithm for cloud environments based on the Firefly Optimization Algorithm (FOA). The suggested scheduling algorithm achieves a higher level of efficiency in multiple parameters, including execution time, waiting time, resource utilization, the percentage of missed tasks, power consumption, and makespan. According to simulation results, the proposed algorithm is more effective and superior to the CSO algorithm under HP2CN and NASA workload archives.

Keywords—Cloud computing; energy efficiency; task scheduling; firefly algorithm

I. INTRODUCTION

In recent years, wireless and emerging technologies have undergone significant progress, particularly the Internet of Things (IoT) [1, 2], artificial intelligence [3], machine learning [4-6], smart grids [7], Blockchain [8], 5G connectivity [9], and cloud computing [10], resulting in a number of positive effects on society. Cloud computing offers convenient, flexible, and ubiquitous access to a set of configurable computing resources, such as servers, storage, applications, and services, which are delivered via the web and released instantly [11, 12]. It allows users to access computer resources without having to manage them actively [13]. In this regard, three types of services can be provided by a cloud: infrastructure, software, and platform [14]. The first service is infrastructure as a service (IaaS), which offers storage and computational resources [15]. In the second service, users can access the software remotely without installing it locally, which is called software as a service (SaaS) [16, 17]. The third service is the platform as a service (PaaS), which provides a platform on which clients can build applications [18]. Virtual Machines (VMs) are provided by cloud providers as computing resources. To improve the efficiency of cloud computing, optimal task scheduling is critical when numerous users demand services from the cloud [19].

To achieve the desired quality of service (QoS), efficient task scheduling allocates resources optimally across the desired tasks in a timely manner. Optimizing a given objective involves building a schedule of tasks to be allocated to VMs with consideration of some constraints [20]. Each cloud infrastructure relies on a task scheduling algorithm as a key component. The performance metrics used in scheduling procedures involve computation-based indicators, including response time, energy consumption, and makespan, and network-based indicators, including round trips, communication cost, and traffic volume [21]. There are three types of optimal task scheduling approaches in cloud computing: heuristic, meta-heuristic, and hybrid. Heuristic task scheduling algorithms offer ease of scheduling and deliver the best possible solution, but they do not guarantee optimal outcomes. A meta-heuristic approach can find optimal solutions to task scheduling problems in a polynomial amount of time. The hybrid task scheduling algorithm combines both the heuristic and meta-heuristic approaches [22, 23].

Although there are promising approaches to efficient task scheduling in the cloud, the problem of task scheduling remains NP-complete [24, 25]. This paper proposes and uses the Firefly Optimization Algorithm (FOA) in order to schedule a bag of tasks in a cloud environment, avoiding network communication and data transfer costs. In the experimental setup, the proposed algorithm is compared to the Highest Response Ratio Next (HRRN), Shortest Process Next (SPN), First Come First Served (FCFS), and PSO algorithms. The proposed method was tested using various distributions to gain insight into its performance trend. By optimizing both the time overhead and the energy consumption of the mobile device, the QoS for mobile users is enhanced by maximizing the overall system benefits. The main contributions of this paper are as follows:

- Defining the task scheduling problem and formulating mathematical models and the objective functions used to optimize the allocation of tasks to virtual machines.
- Analyzing the performance of the proposed algorithm in terms of execution time, makespan, and energy consumption.
- Verifying the experimental results by comparing them to CSO, FCFS, and PSO findings.

The remainder of the paper follows in the following order. A discussion of recent cloud task scheduling methods is presented in Section II. Section III describes and models the problem of task scheduling in a cloud computing environment, followed by an explanation of the proposed algorithm. Section IV discusses the simulation results. The paper concludes with Section V.

II. RELATED WORK

Yu and Su [26] proposed a system called Three Queues (TQ) that uses dynamic priorities and three queues in order to cope with the increasing heterogeneity of cloud computing clusters. Based on the priority of tasks, the algorithm places tasks in a waiting queue and then categorizes them based on the input amount, output amount, number of current tasks running on a node, completion time, and disk I/O rate of the Map phase. Hardware utilization is improved by placing jobs in corresponding queues. It has been demonstrated that this algorithm improves task scheduling performance in the presence of both CPU-intensive and I/O-intensive tasks and shortens task execution times. The genetic algorithm proposed by Sun, et al. [27] uses phagocytosis as a crossover operation, generates a sub-chromosomal individual by phagocytosing two mother chromosomes, produces a random third individual, and determines a new individual resulting from phagocytosis based on the load-balancing standard deviation and fitness factor, which results in a high percentage of high-quality individuals. An evolutionary genetic algorithm for multiple populations is then used that creates initial subpopulations using the Min-Min algorithm, and these subpopulations are evolved using an improved genetic algorithm. According to simulations, the proposed algorithm schedules cloud tasks efficiently.

Al-Maytami, et al. [28] developed a new scheduling algorithm using Directed Acyclic Graphs (DAG) and Prediction of Tasks Computation Time (PTCT). Furthermore, by reducing the Expected Time to Compute (ETC) matrix using Principle Components Analysis (PCA), the proposed algorithm significantly improves makespan and minimizes complexity and computation. According to simulation results, the algorithm outperforms other algorithms for heterogeneous systems regarding schedule length rate, response time, and efficiency. Prasanna Kumar and Kousalya [29] used the Crow Search Algorithm (CSA) to schedule cloud tasks. The CSA draws inspiration from the food-collecting behavior of crows. The crow keeps on searching for a better food source than its current food source as it keeps watching its mates. This paper uses the CSA to find suitable VMs and minimize the makespan. CloudSim is used to measure CSA's performance over ACO algorithms. Simulation results indicate that the CSA algorithm is superior to the ACO algorithms.

Panda and Jana [16] developed an energy-efficient task scheduling algorithm (ETSA) to resolve task scheduling problems. The algorithm considers and normalizes both the completion time and the total resource utilization of a task. ETSA was evaluated for its ability to measure energy efficiency and makespan in heterogeneous environments. ETSA was tested in a wide variety of heterogeneous environments, and the test results showed that it was able to achieve better energy efficiency and makespan than existing

algorithms. The algorithm also accounts for both completion time and resource utilization, which gives it an advantage over other scheduling algorithms. Na, et al. [30] propose a Squid operator and Nonlinear Inertia Weight PSO (SNW-PSO) algorithm to better meet the users' QoS requirements in cloud computing. Execution cost and execution time are optimized by the algorithm. As part of its optimization process, nonlinear inertia weights are introduced to prevent the algorithm from jumping from its local optimum. Furthermore, the squid operator allows for greater particle diversity and faster convergence to optimal positions within particle swarms. This algorithm compensates for the weaknesses of the traditional PSO algorithm, namely its ease of over-convergence and tendency towards the local optimum. The SNW-PSO algorithm converges more quickly than an LDIC-PSO algorithm and reduces both task completion time and cost when compared to a PSO algorithm with linearly decreasing inertia weight.

III. PROPOSED METHOD

In cloud computing, different quality of service parameters is optimized by scheduling tasks. The task scheduling problem entails allocating several tasks appropriate to a certain number of VMs. This section proposes an evolutionary task scheduling approach using FOA. Environmental dynamics, deadlines, and declining the entire task are the basis of the proposed method. The task scheduling problem is modeled based on the following assumptions:

- The VMs are heterogeneous in terms of processing power and power consumption;
- There is no migration of tasks between VMs;
- All submitted tasks are independent.

A. FOA Formulation for Task Scheduling Issue

The firefly algorithm is a novel technique based on fireflies' social behaviors in nature. They flash short lights rhythmically. Each one's flashing pattern is unique and different from the rest. They utilize the lights for the mate-attracting process and attract prey. Furthermore, these lights can function as a protective mechanism in favor of fireflies. The rhythmic light, flashing rate, and time interval between flashing signals cause the two sexes to get attracted to each other. Each parcel is a firefly which is updated according to a firefly's awareness of its neighbors in the multidimensional search space through attracting dynamically. The parameters of FOA are described in the following.

- Light intensity factor (I): In the firefly algorithm, the light intensity factor is defined by Eq. 1. In this equation, I_0 denotes the initial light, r is the distance between two fireflies, and I is the received light intensity.

$$I = \frac{I_0}{r^2} \quad (1)$$

- Attractiveness: The amount of a firefly's attractiveness corresponds to the light intensity that neighboring firefly witnesses and is defined by Eq. 2 and Eq. 3. The parameter β is used for measuring the attractiveness (attraction) between two fireflies.

$$\beta = \beta_0 \times e^{-\gamma r} \quad (2)$$

$$\beta = \frac{\beta_0}{1 + \gamma r^2} \quad (3)$$

- The distance between fireflies: Euclidean distance determines the distance between two fireflies, calculated as follows.

$$r_{ij} = \|x_i - x_j\| = \sqrt{(x_i - x_j)^2 + (y_i - y_j)^2} \quad (4)$$

- Luciferin release: Like other algorithms, the firefly algorithm starts with a randomly selected population. Therefore, the optimization begins randomly with a population of n fireflies in the search space. According to Eq. 5, the algorithm first updates the luciferin share of every firefly and then updates their position in every repetition.

$$l_j(t + 1) = (1 - \rho)l_j(t) + \gamma j_j(t + 1) \quad (5)$$

In each repetition, the luciferin amount for every firefly is determined according to the fitness of its position. It means, based on the amount of fitness, some luciferin is added to the previously available amount for every repetition. In the above equation, $j_j(t + 1)$ represents the fitness function (the fitness of the position) of the i -th firefly in t repetition of the algorithm, γ is the luciferin rise constant, and $(1 - \rho)l_j(t)$ is the amount of luciferin decrease.

- The probability of firefly selection: for every firefly i , the probability of turning toward the brighter neighbor j is expressed as follows. In Eq. 6, t denotes the time measure, $d_{i,j}(t)$ is the distance between two fireflies, $r_d^i(t)$ is the decision-making (intuitive) radius of a firefly, and $N(t)$ is the ensemble of neighboring fireflies of the firefly i at time t .

$$P_{ij}(t) = \frac{l_j(t) - l_i(t)}{\sum_{k \in N(t)} l_k(t) - l_i(t)} \quad j \in N(t), N(t) = \{j: d_{i,j}(t) < r_d^i(t), l_i(t) < l_j(t)\} \quad (6)$$

- Updating the firefly position (a novel solution): The time-district moving of a firefly could be presented as follows:

$$x_i(t + 1) = x_i(t) + s \left(\frac{x_j(t) - x_i(t)}{\|x_j(t) - x_i(t)\|} \right) \quad (7)$$

In the above equation, $x_i(t)$ refers to the m -dimension vector of the firefly i at time t , and s stands for the number of moving steps.

B. Task Scheduling Algorithm based on Discrete FOA

The original purpose of the firefly algorithm was to solve continuous optimization problems, so it may not be effectively employed for discrete optimization problems. Therefore, in this paper, the Smallest Position Value (SPV) rule proposed by Bean [31] is implemented for the discrete firefly algorithm. The implementation is as follows:

1) *Solution representation:* The search space has n dimensions corresponding to the tasks' number; thus, every dimension represents one task. The vector $x_i^t = (x_{i1}^t, x_{i2}^t, \dots, x_{in}^t)$ denotes the fireflies' positions in the search space. The SPV rule assigns tasks based on their positions. Fig. 1 illustrates an acyclic graph structure relevant to this research, consisting of six tasks. Table I presents the scheduling solutions. As dimension 4 in Table I has the smallest position value, it is the first task to be assigned, and dimension three is the second task, and so on. Initial population: Discrete firefly algorithms generate the initial population using a uniform distribution, similar to most meta-heuristic algorithms that generate the initial population randomly. The position values are also generated randomly by applying uniform random numbers to intervals of $[0, 1]$.

2) *Solutions update:* Every firefly is evaluated using this permutation to determine its fitness function value. Every firefly's fitness function value is influenced by light intensity. Dim fireflies are attracted to bright ones. The firefly's attractiveness is determined by Eq. 2 and Eq. 3. The distance between two fireflies is measured by Eq. 4, and tasks are assigned using the SPV rule. Every firefly's attractiveness is calculated and then based on this value, its movement is determined by Eq. 7. The mentioned steps are repeated until the completion term is met when all the fireflies are attracted. To calculate the number of missed tasks, the beginning time and deadline of tasks are taken into account. In task scheduling, the main goal is to minimize the total execution time and the number of missed tasks. Eq. 8 calculates the fitness value of the proposed method for reducing total task execution time and the number of missed tasks. The input parameters are also normalized using Eq. 9.

$$\text{Fitness} = w_1 \times \text{Makespan} + w_2 \times \text{Missed Task} \quad w_1 + w_2 = 1 \quad (8)$$

$$\text{Normalized}(m) = (m - M_{\min}) / (M_{\max} - M_{\min}) \quad (9)$$

Eq. 9 normalizes the parameter m between the largest and smallest values. Both cases were used in simulations to obtain the total execution time and the number of missed tasks. As shown in Eq. 10, the proposed method uses the tasks' completion times to determine the tasks' total execution times.

$$\text{Makespan} = \min(C_{\max}^{\{j_0\}}), \text{ where } C_{\max} > C_t, t = 1, 2, 3, \dots, n \quad (10)$$

Fig. 1. DAG graph for six tasks.

TABLE I. THE SOLUTION EXAMPLE FOR SIX TASKS

	1	2	3	4	5	6
x_{ik}^t	0.3	0.4	0.092	0.035	0.59	0.61
Tasks	T3	T4	T2	T1	T5	T6

In the equation, t denotes a task, cmax is the maximum time required to complete it, and ct is the completion time of the task t.

C. Solving an Example

In this subsection, the proposed method procedure is illustrated using an example of 6 VMs and 30 tasks whose durations are 100 and 200, and their deadlines are determined according to Table II. The completion time is 1.53 seconds, and the number of missed tasks' is 1. It should be noted that the initial attraction intensity for every firefly is randomly determined based on the Gaussian distribution and initial position of fireflies. Every firefly is assessed to calculate the fitness function value. The fitness function value for every firefly is associated with light intensity. Dim fireflies are

attracted to bright ones. The firefly's attractiveness is determined by Eq. 3, and the distance between two fireflies is measured by Eq. 4. Tasks are assigned using the SPV law. Every firefly's attractiveness is calculated, and then based on this value, its movement is determined by Eq. 7. The mentioned steps are repeated until the completion term is met when all the fireflies are attracted. The proposed method's way of assigning and scheduling tasks is presented in Fig. 2.

IV. EXPERIMENTAL RESULTS

Cloudsim is used to implement the proposed algorithm for task scheduling. The proposed method was simulated and compared to the available algorithms using the data in Table II [32]. In the proposed method, the entrance times of all tasks are equal, but the serving times, deadlines, and the tasks' interdependencies are considered according to Table II. For example, task 9 requires three units of time to get served, and its deadline to complete execution is 6. Also, tasks 1 and 7 should be completed prior to task 9. Table III presents the tasks' characteristics, Table IV contains the features of VMs, Table V outlines the features of data centers, and Table VI shows the parameters of the firefly algorithm.

A. First Experiment: Evaluation of the Proposed Method Compared to [32]

The experiment simulates eight cloud resources and creates and executes thirty tasks, as shown in Table II. The tasks are

designed to emulate real-world workloads and evaluate the performance of cloud resources. The experiment results are then used to analyze the performance of various cloud resource configurations. In order to examine the efficiency of the proposed algorithm, we compared it with HRRN, SPN, FCFS, and PSO algorithms. Fig. 3 to 6 illustrate that our method outperforms others in terms of overall execution time, average service time + waiting time, percentage of missed tasks, and resource utilization. The results show that our proposed algorithm can effectively optimize resource utilization and reduce the overall execution time of the cloud system. This is beneficial for cloud computing users, as it can reduce their costs and improve their performance. Furthermore, our proposed algorithm also provides more efficient scheduling and task assignment, resulting in better task scheduling, faster task completion, and higher resource utilization. This improved performance leads to better user experience and satisfaction.

B. First Experiment: Evaluation of the Proposed Method Compared to [33]

This experiment compares the proposed method with the method presented in [33] regarding makespan and power consumption. HPC2N and NASA workloads were evaluated using 500 physical machines, 200 virtual machines, and 100 to 1000 tasks. As shown in Fig. 6 to 9, our method provides better performance. The proposed scheduler outperforms the existing CSO algorithm by approximately 10% in terms of makespan under HPC2N workloads. When compared to the CSO algorithm, our algorithm improved the makespan by 8% under NASA workloads. Energy consumption is an important

parameter that impacts both the cloud provider and the cloud user. In the cloud computing paradigm, the goal is to minimize energy consumption by which cloud providers can effectively run tasks on virtual resources in the cloud by consuming a minimal amount of energy. The cloud user is also benefited from the availability of resources at a lower cost since resources are readily available. HPC2N and NASA workload archives were used to evaluate energy consumption. We compared our algorithm with the CSO algorithm under HPC2N workloads, and the results indicated a significant reduction in energy consumption, up to 10%. Compared to the CSO algorithm, our algorithm consumes up to 12% less energy under NASA workload archives.

V. CONCLUSION

Cloud computing allows users to access shared computing resources. Requests and demands are the basis of cloud computing, where users request resources from service providers and access them. Due to the dynamic nature of cloud environments and user requests changing over time, we need a scheduling method that can handle more tasks in less time. This paper proposed a new deadline-aware task-scheduling technique based on the firefly optimization algorithm. The experiments were conducted on different workloads. The experimental results proved that the proposed algorithm performed better than previous works concerning waiting time, execution time, missed tasks percentage, and resource utilization. Future work may examine the use of different heuristics to determine optimal initial conditions for FOA or other meta-heuristic algorithms. Our future plans include further exploring the time and space complexity of the proposed algorithm, examining the effective combination of artificial intelligence technology and task scheduling algorithm, and analyzing the energy consumption optimization of green cloud computing data centers.

Information Construction Office, Jilin Institute of Chemical Technology, Jilin, China¹
School of Information and Control Engineering, Jilin Institute of Chemical Technology, Jilin, China^{2,3}

Abstract—As network attacks are more and more frequent and network security is more and more serious, it is important to detect network intrusion accurately and efficiently. With the continuous development of deep learning, a lot of research achievements are applied to intrusion detection. Deep learning is more accurate than machine learning, but in the face of a large amount of data learning, the performance will be degraded due to data imbalance. In view of the serious imbalance of network traffic data sets at present, this paper proposes to process data expansion with GAN to solve data imbalance and detect network intrusion in combination with CNN and BiLSTM. In order to verify the efficiency of the model, the CIC-IDS 2017 data set is used for evaluation, and the model is compared with machine learning methods such as Random Forest and Decision Tree. The experiment shows that the performance of this model is significantly improved over other traditional models, and the GAN-CNN-BiLSTM model can improve the efficiency of intrusion detection, and its overall accuracy is improved compared with SVM, DBN, CNN, BiLSTM and other models.

Keywords—Intrusion detection; GAN; CNN; BiLSTM

I. INTRODUCTION

Technology is developing very fast these days, and the internet has become an indispensable tool in our daily lives. It brings great convenience to all walks of life. However, in today's network environment, a variety of new means of attacking the network continue to emerge, with increasingly larger impact scales and higher attack frequencies. As a result, network security has become a growing concern. The task of network intrusion detection is to find suspicious attacks and take appropriate protective measures to re-duce the possibility of subsequent attacks and minimize corresponding economic losses. Therefore, research on Intrusion Detection (ID) has become a major research direction in the field of network security [1-2].

The intrusion detection system is one of the most promising methods for quickly identifying and dealing with network intrusions. It can identify whether the system is being attacked or has been attacked, and can take preventive measures against possible network attacks. An intrusion detection system can detect and analyze network activities on a computer, thereby protecting sensitive information, preventing unauthorized user access, system misoperation, and malicious intrusion. However, in the current network traffic, the volume of normal data flow is much larger than that of abnormal data flow. This results in a serious imbalance in the proportion of data occupied by normal flow and abnormal flow, which

significantly reduces the learning performance and accuracy of the classifier.

Intrusion detection technology has developed rapidly over the years and has become a crucial aspect of network security. The main focus of intrusion detection is to detect any suspicious activity that may lead to network breaches and take appropriate measures to prevent them. There are two primary methods of intrusion detection - signature-based and anomaly-based. Signature-based intrusion detection is a rule-based method that compares incoming network traffic with a pre-defined set of signatures or patterns. While this method is highly accurate, it cannot detect new or unknown attacks and requires frequent updates of the signature database to maintain effectiveness [3]. On the other hand, anomaly-based intrusion detection works by identifying abnormal patterns in network traffic that deviate significantly from the expected behavior of the network. This method is useful for detecting unknown attacks that do not match any known signature, but it can also produce false positives by flagging normal behavior as suspicious. Anomaly-based intrusion detection can be achieved through various techniques such as machine learning, data mining, data statistics, and deep learning.

Machine learning algorithms can learn from labeled data sets and identify the patterns that distinguish normal and malicious traffic. Data mining techniques can be used to extract useful knowledge from large-scale network data sets and identify abnormal behaviors. Data statistics can help identify unusual changes in the network, while deep learning algorithms can analyze large amounts of data and identify complex patterns and correlations that are difficult to detect through other methods.

In conclusion, intrusion detection is critical for ensuring network security, and the choice of intrusion detection method depends on the specific needs of the network and the level of threat faced. Both signature-based and anomaly-based intrusion detection methods have their advantages and limitations, and the optimal approach often involves combining multiple techniques to achieve the best results.

At present, machine learning has been widely used in intrusion detection, but machine learning is mostly shallow learning, focusing on feature engineering and selection, and the accuracy will be degraded when dealing with a large volume of real network traffic data. Deep learning can deal with a large volume of data, and thus it is more accurate and effective in intrusion detection. Convolutional Neural Networks (CNN) and Bidirectional Long Short-Term Memory (BiLSTM) can

automatically learn feature representations from input data, while Random Forest, Decision Tree, and SVM require manual feature design or rely on feature engineering. This gives CNN and BiLSTM an advantage in handling complex data such as images, speech, and text. BiLSTM is specifically designed for handling sequential data and can capture long-term dependencies within sequences. In contrast, methods like Random Forest, Decision Tree, and SVM are not well-suited for modeling sequential data. CNN and BiLSTM have the property of parameter sharing and weight sharing, making the training of the models more efficient and allowing them to handle problems with a large number of parameters. On the other hand, Random Forest and Decision Tree require more parameters and computational resources. The generator in Generative Adversarial Networks (GANs) utilizes a CNN architecture, which exhibits excellent generation capabilities and can generate realistic synthetic data. CNN and BiLSTM can efficiently process large-scale data through mini-batch training, especially when accelerated by GPUs. In comparison, Random Forest and Decision Tree may face limitations in memory and computational resources when dealing with large-scale data. However, due to the imbalance of the data sets, the performance will be significantly degraded as the volume of abnormal data is much smaller than the volume of normal data. Therefore, this paper proposes to solve data imbalance via GAN, which has been widely and effectively used in speech and image fields. In this paper, GAN is used to create virtual data similar to the minority class for resampling to improve the efficiency and accuracy of intrusion detection. Moreover, it is found that the effect of using multi-model mixture is better than that of using single model. Therefore, this paper adopts the method of combining CNN and BiLSTM to conduct experiments. The main contributions of this paper are summarized as follows:

1) Proposed to use of GAN pairs to solve the problem of data imbalance, and add an attention mechanism to solve the problem of inaccurate model results caused by unreasonable convolution kernel settings.

2) Propose the design and implementation of an intrusion detection model based on CNN-BiLSTM, and combine CNN with BiLSTM to build the intrusion detection classification model. In addition, add a self-attention mechanism to BiLSTM to make the model more effective and more accurate.

3) Study the performance and effect of the data set in machine learning such as Naive Bayes, Random Forest and Decision Tree, and compare with the model in this paper. The experimental result shows that the performance of GAN-CNN-BiLSTM is higher than the traditional classification model, so the performance of the model proposed in this paper is higher than other traditional models, which can improve the efficiency of intrusion detection and the overall accuracy.

Starting from the data, this paper first uses GAN to balance the data, which lays a good foundation for the subsequent training of the classification model, improving the accuracy of intrusion detection. Then, it obtains the final model through continuous improvement. Moreover, the CIC-IDS-2017 data set is used for experimental verification, and compared with CNN, BiLSTM, SVM and other models. The experimental

result shows that the detection model proposed in this paper has a better effect and higher accuracy.

The proposed model in this paper can provide network security protection for the following:

1) Protection of critical infrastructure: It can be applied to critical infrastructure such as power grids, water supply systems, transportation systems, etc. It helps detect and prevent potential network attacks, hacker intrusions, and data breaches, ensuring the security and reliable operation of this infrastructure.

2) Security for companies and organizations: It can protect the network and information security of companies, organizations, and institutions. It helps identify malware, phishing attacks, data theft, and other security threats, providing real-time threat intelligence and defense measures.

3) Government agencies and military applications: It holds significant importance in government agencies and military sectors. It can be applied to network security and intelligence analysis, aiding in the discovery and prevention of cyber espionage, malicious attacks, and information warfare.

4) Security in the financial industry: It can be used in the financial industry to safeguard the network security of banks, payment systems, and financial institutions. It detects and prevents network fraud, credit card fraud, hacker attacks, and other financial crimes.

In Section II, a review of prior research and methods related to network intrusion detection is provided. Traditional intrusion detection techniques, as well as machine learning and deep learning-based approaches, are introduced, and their advantages and disadvantages are discussed. In Section III, the architecture and working principles of the proposed GAN-CNN-BiLSTM model are presented. The functionality and interactions of each component are explained, highlighting the model's strengths and innovations. Section IV describes the experimental setup designed and executed in this study, showcasing the experimental results and performance evaluation. A comparison is conducted between the proposed model and other methods, analyzing the reliability and effectiveness of the results. Finally, the main findings and contributions of the paper are summarized in Section V, and prospects for further research are outlined.

II. RELATED WORK

A. Related Study on Intrusion Detection Models

Intrusion detection generally consists of two steps: preprocessing and classification. Preprocessing technology, also known as feature selection technology, is a key technology in the process of intrusion detection. It can reduce the size of the original data, improve the training efficiency of the model and the accuracy of the classifier. According to whether feature selection is independent of classifier, feature selection methods can be divided into two categories: filtering and packaging. Filtering method is independent of classifier, and it carries out feature selection according to the statistical characteristics of original data. In traditional intrusion detection system, the original data needs to be sent to a classifier after preprocessing.

Because of the progress of artificial intelligence (AI) technology in intrusion detection system (IDS), detection methods based on AI, such as Decision Tree[4], Support Vector Machine (SVM)[5], CNN[6-8], Long Short-Term Memory (LSTM)[9-11] and Recurrent Neural Network (RNN)[12-13], are widely and effectively used in intrusion detection systems. Vinayakumar R et al. proposed an intrusion detection method in combination with CNN and LSTM, and the experimental result show that it performs better in all indicators than only using CNN or CNN-RNN [14]. Tetsushi Ohki, et al. proposed a dimensionality reduction technique in combination with information gain and principal component analysis (PCA), using support vector and other means to detect intrusions, and the experimental result shows that the mixed dimensionality reduction method is better than the single dimensionality reduction method[15]. Liu Yuefeng et al. proposed an intrusion detection method based on multi-scale CNN, which uses convolution kernel of different scales to extract the optimal features of data. This method not only converges quickly, but also improves detection accuracy [16]. Lirim Ashiku et al. used the DNN network for intrusion detection training, which is optimized on the basis of CNN and deepens the network structure to improve the detection accuracy [17]. Yin C L et al. proposed the use of RNN to build an IDS detection model for identification in consideration of the time series relationship for feature extraction, but for high-dimensional features, RNN is significantly incapable of feature extraction, resulting in poor model performance [18].

The research shows that these deep learning-based intrusion detection systems perform better when dealing with big data, but there are still some problems:

1) *Outdated data set*: Most of the previous intrusion detection research is based on KDD-CUP99 or NPL-KDD data set, which has a history of more than 20 years, and cannot reflect the current network situation well.

2) *The data samples are unbalanced*: Classification research usually pays more attention to improving the overall evaluation indicators of the model, such as accuracy, precision, etc., and ignores the classification of minority samples. But in the real network environment, these minority attacks will produce more damage and impact than the majority attacks. However, the current researches based on KDD-CUP99 and other datasets usually directly use the official training and testing samples, and few research works deal with the problem of data imbalance under the intrusion detection problem and the related solutions.

3) *Feature learning is not comprehensive most of the previous studies are based on a single neural network*: CNN can learn the spatial features in the data and extract the local features accurately, but it cannot learn the temporal features. RNN can extract temporal features in data and analyze long-term dependencies of information, but it cannot effectively extract spatial features. In addition, RNN can only learn the temporal characteristics of the data in a single direction, and does not fully consider the joint influence of the information before and after the traffic data on the current state.

Intrusion detection is being extensively studied because it is an important security guarantee not only for the traditional Internet, but also for the Internet of Things and other networks. However, most of the previous studies used traditional machine learning or simple deep learning, and the data sets used, such as KDD-CUP99 and NSL-KDD, are too old to reflect the current network traffic well, and it is difficult for traditional machine learning algorithms to deal with a large volume of data, therefore, this paper uses the large data set CIC-IDS 2017 containing the latest attacks to solve the problems in current research by a multiway method.

B. Related Study on Data Imbalance

Data imbalance means there are large quantitative gaps among different data categories. Deep learning algorithms can get the best result when there are similar quantities among categories, so data imbalance is one of the factors degrading the deep learning performance.

In order to solve the problem of imbalanced data, one idea is to start from the algorithm level, according to the defects of the algorithm in solving the imbalanced problem, combined with the characteristics of imbalanced data, the algorithm is improved to improve the ability of the algorithm to deal with imbalanced classification problems. The other is to start from the data level. Existing studies solve the problem of data imbalance mainly through random undersampling, random oversampling and SMOTE. Random oversampling will expand the data scale and prolong the training time, which is easy to fall into overfitting; random undersampling will blindly delete some data, influencing the classification accuracy; the samples generated by SMOTE have no diversity [19].

To improve the model performance by sampling and optimizing the data, Yan B, et al. used SMOTE technology to sample the NSL-KDD data sets, and compared the performance of the newly sampled data with some algorithms such as RF, SVM and Backpropagation Neural Network (BPNN) [20]. Min E X, et al. built a new network architecture on GAN to generate data against data imbalance [21]. However, it has been proven that GAN training may lead to gradient vanishing, making the generator output invalid and making the result poor.

Therefore, this paper proposes a method to solve the problem of data imbalance and generate higher-quality data sets via Generative Adversarial Networks (GAN), GAN is a new generative model, which learns the probability distribution of the target data sample to generate forged samples that are greatly similar to the target data sample. It is a new generative model that directly compares the distribution of forged samples and target samples for training and generation, and continuously generates forged samples that are as close as possible to the real sample by means of confrontation. It improves the generation quality of forged samples and effectively solves the problem of overfitting caused by the lack of training samples in the generation process of traditional generative models. Therefore, GAN has been applied to the generation of data in many fields and achieved good results, but it has not been applied to the imbalance problem of network intrusion detection data. Then, a classification model is built in combination with CNN and BiLSTM, and balanced

data sets are used for training to obtain a model which is more stable in training and gives better results.

III. INTRUSION DETECTION MODEL BASED ON GAN-CNN-BILSTM

Fig. 1 shows the structure of the GAN-CNN-BiLSTM model, as there is only a little abnormal data in intrusion detection, data distribution of the data sets used for intrusion detection is unbalanced. Thus this paper generates and expands the minor training samples with GAN to reduce the impact of imbalanced training samples on the detection accuracy. After the data set is balanced using GAN, the generated minor samples and the original data set are combined into a new data set with balanced sample distribution, and then the data set is normalized and other preprocessed. Finally, the data set is used to train the CNN-BiLSTM model and obtain the classified detection results.

A. Data Set Balance

Generative Adversarial Networks (GAN), a new regression generation model proposed by Goodfellow, et al in 2014, consists of Discriminative Network (D) and Generative Network (G), which are rivals, as Generative Network creates a new data instance while Discriminative Network evaluates the data authenticity, both try to outperform each other and thus gradually improve in this process [22]. GAN learns the probability distribution of the target data samples to generate fake samples highly similar to the target data samples, it is a generative model as it directly compares the distribution of the fake samples and the target samples to train and generate new ones, and fake samples which are as close as possible to real

samples are continuously generated by confronting, improving the generation quality of fake samples and solving the problem of overfitting caused by insufficient training samples in traditional generative models. Its structure is a two-person zero-sum game, where one's gain is the other's loss.

If the convolution kernel setting of GAN is too small, the dependency in the data will not be obvious, while if the convolution kernel setting is too large, the computational efficiency will be degraded. Therefore, this paper intends to introduce an attention mechanism, which sets different weights for different parts of these vectors according to their importance, so as to sort the importance of information and quickly extract the key feature information. It not only saves model computation and storage but also enables the model to judge more accurately.

Fig. 2 shows the structure diagram of a GAN model with added attention mechanism. Real data is the real data of the data set, and generated data is the data generated by G. Random noise can make the network random and generate distribution, so that it can be sampled. In the training process of GAN, G and D are continuously optimized and enhanced, as G is to make D unable to distinguish while D is to enhance its ability to judge the authenticity of the data through continuous improvement, and the principle can be expressed as formula (1):

$$\min_G \max_D V(D, G) = E_{x \sim P_{data}(x)} [\ln D(x)] + E_{z \sim P_z(z)} [\ln (1 - D(G(z)))] \quad (1)$$

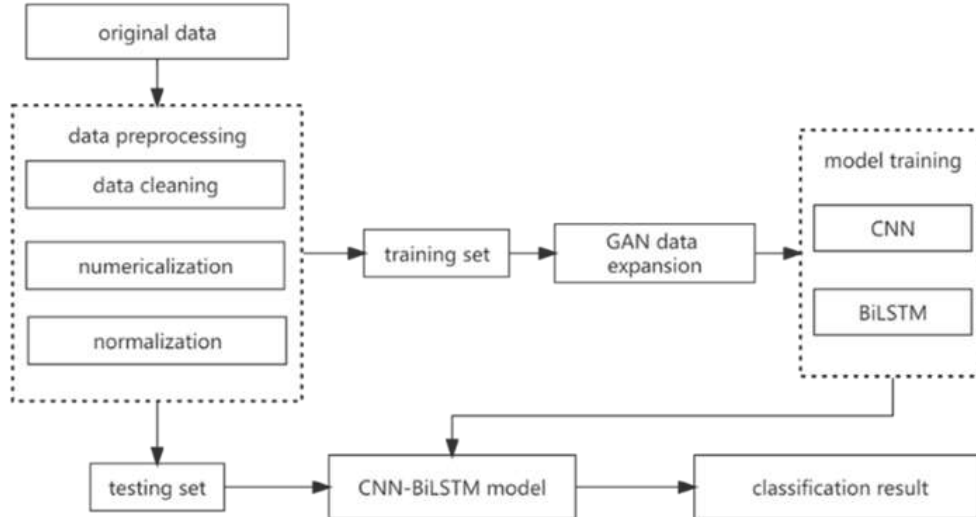

Fig. 1. Flow Chart of intrusion detection model based on GAN-CNN-BiLSTM.

Fig. 2. Structure diagram of a GAN model with added attention mechanism.

In the formula, $V(D, G)$ is the objective function, P_{data} is the real sample distribution, P_z is the generated sample distribution, $D(x)$ is the probability of x being the real sample, and $G(z)$ is the sample generated by model G based on the input z .

After the convolution processing in the attention mechanism module of the model, the resulting convolution feature vector X serves as input. The processing shown in formulas (2) to (4) is then applied to obtain $f(x)$, $g(x)$, and $h(x)$ with different output channel sizes, where W_f , W_g , and W represent weight matrices trained through different methods. Next, $f(x)$ is transposed and multiplied by $g(x)$ using formula (5). Finally, an attention map is obtained after Softmax processing.

$$f(x) = W_f x \quad (2)$$

$$g(x) = W_g x \quad (3)$$

$$h(x) = W x \quad (4)$$

$$s_{ij} = f(x_i)^T g(x_j) \quad (5)$$

Next, $h(x)$ is used to perform pixel-by-pixel multiplication with the obtained attention map, resulting in the feature map of adaptive attention. Eq. (6) is used to compute the attention weights, where $\beta_{j,i}$ represents the degree of influence of the model on the i th position when synthesizing the J TH region. Then, Eq. (7) is used to obtain the attention feature map. Finally, the feature map with attention mechanism is combined with the feature vector X using formula (8) to obtain the feature map with attention mechanism.

$$\beta_{j,i} = \frac{\exp(s_{ij})}{\sum_{i=1}^N \exp(s_{ij})} \quad (6)$$

$$o_j = \sum_{i=1}^N \beta_{j,i} h(x_i) \quad (7)$$

$$y_i = \gamma o_j + x_j \quad (8)$$

The main process of GAN model training is shown in Algorithm 1.

B. CNN-BiLSTM Model

Convolutional Neural Networks (CNN), belong to a multi-layer supervised learning neural network, consists of the input layer, the convolutional layer, the pooling layer, the fully connected layer and the output layer. A CNN model can be composed of multiple convolutional layers, pooling layers and fully connected layers, and the convolutional layer and the pooling layer generally appear alternately. The pooling layer is usually followed by the fully connected layer and the output layer is usually followed by the fully connected layer, or the classification layer in other words. Classification is realized by logistic regression, Softmax regression or even a SVM, and the features extracted by the CNN, which is the result of the classification, are classified and output by the output layer. The loss function takes the gradient descent to reversely regulate the weight parameters in the neural network layer by layer at minimum, and improves the accuracy of the network through continuous training. CNN can extract and classify features in the meantime, so that feature classification can effectively use feature extraction; weight sharing can effectively reduce the training parameters, making the neural network structure simpler and more adaptable, and Fig. 3 shows its structure.

For Bidirectional Long Short-Term Memory (BiLSTM), the Long Short-Term Memory (LSTM) is a variant of traditional RNN, but the structure of LSTM, which is more complex, can be divided into four parts for interpretation: forget gate, input gate, cell state and output gate. Compared with the classical RNN, the gate structure of LSTM can effectively capture the semantic correlation between long sequences and alleviate gradient disappearance or explosion. BiLSTM is composed of forward LSTM and backward LSTM, which enhances the LSTM and improves the performance of the model. It trains two LSTMs on the input data, the first LSTM is on the original data and the other is on the reversed data so that more features are added to the network, the result is obtained faster, and the defect of gradient vanishing is eliminated. Fig. 4 shows the structure of BiLSTM.

BiLSTM needs to calculate the output according to the time sequence, if the distance between the interdependent features is too far, it will take several time steps to accumulate information and connect the two, and with the increase of the distance, the possibility of capturing effective information will gradually decrease. However, the self-attention mechanism will connect any two words directly through a calculation result, which shortens the distance between long-distance dependent features and is conducive to the effective use of these features. Therefore, this paper adds a self-attention mechanism to BiLSTM to improve the efficiency of the model.

Fig. 3. Model of CNN.

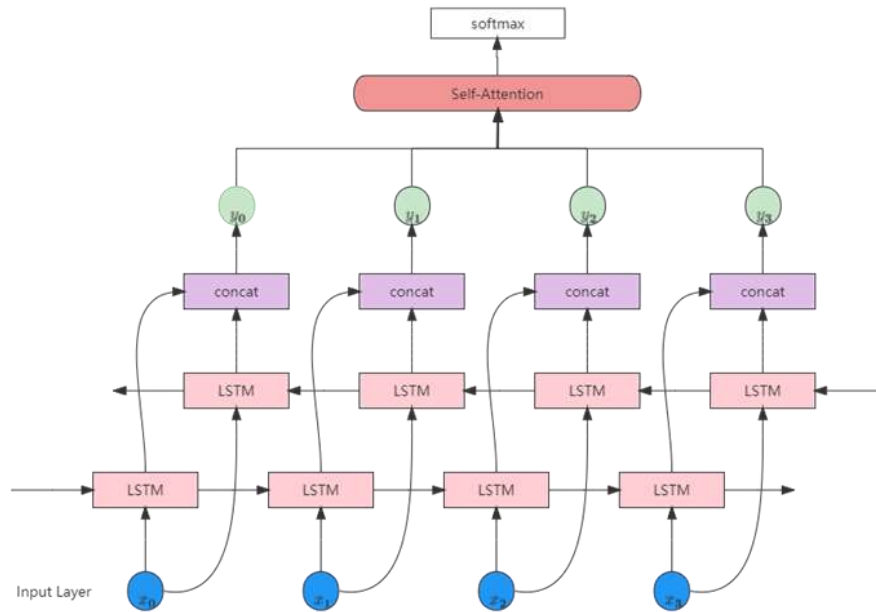

Fig. 4. Model of BiLSTM.

IV. EXPERIMENT AND RESULT ANALYSIS

A. Experimental Environment

In order to verify the intrusion detection model in this paper and build a simulation experiment environment, the Pytorch 10.2 deep learning framework is used to build the model in Pycharm, and data are processed by Python 3.6; the operating system is 64-bit Windows 10, the CPU is Intel core i5-7300HQ 2.50 GHz, and the memory is 16 GB DDR.

B. Data Set

The data set used in this paper is CIC-IDS-2017, which contains normal data similar to real data and the latest attacking data. The information of this data set, which contains a large number of network intrusion traffic data, can better reflect the current network environment, and the training set and test set are adjusted to improve the test result in the complex network environment at present, 80% was randomly selected as the training set and 20% as the test set. This data set contains benign and recent common attacks, similar to real-world data (PCAPs). It also includes the result of network traffic analysis by CICFlowMeter, using tagged flows based on timestamp, source and destination IP, source and destination port, protocol and attacks (CSV file), and a data set containing 15 class labels (1 normal label + 14 attack labels). Table I lists the volumes of various attack data:

TABLE I. CIC-IDS-2017 DATASET

Attack Type	Number of Instances
BENIGN	2359087
FTP-Patator	7938
SSH-Patator	5897
DDos	41835
Dos Hulk	231072
Dos GoldenEye	10293
Dos slowloris	5796
Dos Slowhttptest	5499
WebAttack-Brute Force	1507
Web Attack-XSS	652
WebAttack-SQL Injection	21
Bot	1966
Infiltration	36
PortScan	158930
Heartbleed	11

C. Data Preprocessing

1) *Data cleaning*: The missing values in this dataset all appear under the Flow Bytes/s feature. When dealing with the problem of missing data, methods such as deletion, completion and imputation are usually used. Since the dataset is very large and the missing ratio is small, this paper uses the tuple deletion method to delete the data rows with missing values. Infinite values exist under the features Flow Bytes/s and Flow Pkts/s. During data processing, the infinity value cannot be calculated properly. The infinite values of this data set basically appear in normal traffic and have no effect on classification. Therefore, the information lines containing infinite values are directly deleted. Duplicate data is hardly helpful to the training of intrusion detection system, therefore, only the first occurrence of data is kept and the duplicate data is removed. When the data set is recorded, the table header information is mistakenly written into the data multiple times, and it is directly deleted here to ensure that the data is comprehensive, clean, and error-free.

2) *Numericalization of character-type features*: Convert character attributes in the data set to binary features. This is a crucial step in many machine learning tasks as most algorithms cannot work directly with non-numeric data. In the context of intrusion detection, many datasets contain character-based features such as protocol types, service types, or flag values. These features are often categorical in nature, meaning that they take on a limited number of distinct values. To turn these categorical features into numerical ones, one common technique is to use binary encoding. By converting categorical features into binary features, we can ensure that all features in the dataset are numerical, which is necessary for most machine learning algorithms. This process also helps to reduce the impact of bias on the algorithm's results and increase the accuracy of the model. Overall, numericalization of character-type features is an important step in preprocessing data for intrusion detection and other machine learning tasks. It helps to ensure that the data is ready for use with a variety of algorithms and can improve the performance of the model.

3) *Normalization processing*: Normalization is an essential preprocessing step in machine learning, which involves scaling the features of a dataset to a standardized range. This is necessary because different features often have different scales or units, which can lead to biased predictions or overemphasis on certain features. In intrusion detection, normalization is particularly important due to the diverse nature of network traffic data. The min-max normalization method is a popular technique for scaling data to a standardized range. It involves scaling the values of each feature to a range of [-1, 1], based on the minimum and maximum values of that feature in the dataset. This normalization method preserves the relative distances between values within a feature and ensures that all features have equal influence on the learning process. The advantage of the min-max normalization method is that it is simple and easy to implement, and it maintains the original information and structure of the data. It also helps to prevent

the model from being overly influenced by outliers or extreme values. The min-max formula is shown in Eq. (2), where max represents the maximum value of each feature, and min represents the minimum value.

$$y_i = \frac{x_i - \text{Min}}{\text{Max} - \text{Min}} \quad (9)$$

D. Parameter Setting

In the model of this paper, the parameters of GAN were set as batch-size 50, epoch 500 and learning rate 0.001, the Relu function is selected as the activation function and the Adam optimizer is used for the model. The convolution layer and pooling layer of CNN have two layers respectively. The initial parameters of CNN include convolution kernel size set to 3, activation function set to the Relu function, pooling layer size set to 2 and fully connected layer size set to 16, and a Dropout layer is added to avoid overfitting. In the BiLSTM network of this paper, the output size is set to 10, the features extracted by CNN and BiLSTM are fused in parallel, the fused features are added into the self-attention layer, and different weights are assigned to different features.

E. Measurement Indicators

In this paper, Accuracy, Precision, Recall and F-score are mainly used to evaluate the models.

Accuracy: It represents the proportion of samples that are correctly predicted by the model, providing an overall measure of classification or prediction accuracy.

Precision and Recall: Precision and recall are commonly used in binary or multi-class classification problems. Precision measures the proportion of true positive predictions among all samples predicted as positive, while recall measures the proportion of true positive samples correctly identified by the model.

F1 Score: The F1 score is a metric that combines precision and recall, calculated as the harmonic mean of precision and recall. It provides a balanced measure of model performance, giving equal weight to precision and recall. It is particularly useful for imbalanced datasets and classification tasks.

So as to evaluate the detection performance of different models, as below:

$$\text{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN} \quad (10)$$

$$\text{Precision} = \frac{TP}{TP+FP} \quad (11)$$

$$\text{Recall} = \frac{TP}{FN+TP} \quad (12)$$

$$F - \text{score} = \frac{2TP}{2TP+FP+FN} \quad (13)$$

Where, TP is the quantity of correct traffic, TN is the quantity of normal traffic in correct judgment, FP is the quantity of normal traffic in incorrect judgment, and FN is the quantity of incorrect traffic in incorrect judgment.

F. Results

In order to analyze the influence of the expanded data set on the detection accuracy, GAN is used to expand the minor

classes in the training set in different percentages: 0%, 40%, 80% and 120%, and the results are shown in Table II, indicating that the accuracy rate is the highest when the expansion percentage is 80%, so the expansion percentage in this experiment is 80%.

In order to illustrate the effects of the models proposed in this paper, CIC-IDS-2017 data sets were selected for experiments, and CNN, RNN, BiLSTM and CNN-BiLSTM were used for comparative experiment. Common intrusion detection algorithms such as SVM, NBM, Decision Tree and Random Forest are applied to the data set in this experiment for comparison. The results are shown in Table III and Fig. 5 shows the accuracy of the deep learning algorithm

TABLE II. THE ACCURACY OF DIFFERENT EXPANSION RATIO

data expansion ratio	Web Attack-XSS (ACC)	Web Attack-SQL Injection (ACC)	Infiltration (ACC)	Heartbleed (ACC)	Total (ACC)
0%	62.08	63.57	60.26	58.49	92.15
40%	65.27	67.08	64.92	63.64	95.03
80%	67.25	68.74	66.21	68.49	96.53
120%	65.83	67.72	65.35	65.83	95.76

TABLE III. MODEL COMPARISON

Model	Evaluation Index (%)			
	Accuracy	Precision	Recall	F-score
CNN	93.74	92.52	93.47	92.45
RNN	83.65	81.73	82.77	82.76
SVM	61.37	61.21	60.75	61.46
NBM	79.85	83.36	78.52	77.94
Decision Tree	84.63	85.27	84.32	84.49
Random Forest	86.26	87.48	87.27	87.64
BiLSTM	93.06	91.75	92.52	93.26

GAN-CNN-BiLSTM	96.32	96.55	95.38	96.04

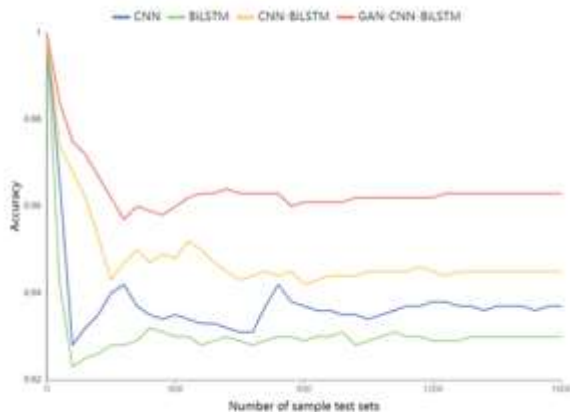

Fig. 5. Algorithm accuracy comparison.

The study compared the performance of the proposed GAN-based data expansion method with several common models such as CNN, BiLSTM, SVM, NBM, and Random Forest. The results indicated that the accuracy of the GAN-based model was significantly higher than that of CNN and BiLSTM by 2.58% and 3.26%, respectively. The accuracy of the GAN-based model was also 1.81% higher than that of CNN-BiLSTM. Additionally, the performance of some classic models such as SVM and NBM were not satisfactory, whereas the Random Forest model performed better than these models.

However, the GAN-based model outperformed all these models in terms of accuracy. The proposed model based on CNN-BiLSTM and GAN was able to solve the problem of imbalanced dataset and achieved an accuracy improvement of 10.06%. This improvement proved the effectiveness and innovation of the proposed model. Therefore, it can be concluded that the GAN-based data expansion method is a promising approach for improving the performance of intrusion detection systems. It is expected to have significant implications for the development of future intrusion detection techniques.

V. CONCLUSION

This paper proposes a novel model called GAN-CNN-BiLSTM, which aims to enhance the performance of intrusion detection. The main challenge in intrusion detection is the class imbalance problem, where the normal class dominates the data set, while the abnormal class is relatively small. To address this issue, GAN is introduced to expand the size of the abnormal class, CNN-BiLSTM is adopted for feature extraction and classification, and the CIC-IDS 2017 data set is utilized for evaluation. The proposed model is compared with other traditional models, and the experimental results demonstrate that GAN can effectively eliminate the class imbalance problem, and the CNN-BiLSTM model outperforms other models in terms of accuracy.

Although the proposed model uses a widely adopted data set, it has not been tested in a real network environment. Collecting large-scale, high-quality data and annotating it in real-world environments is a challenging task. Data privacy and security are crucial. Transferring models from the lab to real environments requires considering adaptability and generalization. Real-world data has greater variations and noise, requiring the model to maintain good performance. To overcome these challenges, reasonable data collection and processing methods are needed, ensuring dataset diversity and representativeness. Data privacy and security measures must be in place to protect the data. Model optimization is necessary, including fine-tuning, regularization, and parameter adjustment in real environments, to improve generalization. Future research will focus on exploring and improving the model by utilizing larger and more diverse data sets, and optimizing the intrusion detection model. This will enable the model to be tested in a real network environment, and validate its performance for real-world applications of network intrusion detection. The GAN-CNN-BiLSTM model's enhancements in intrusion detection bolster the identification and defense against network attacks. Its impact includes improved network security for critical infrastructure,

companies, and government institutions, minimizing risks and losses from threats. The study showcases the efficacy of multimodal data processing and deep learning in intrusion detection, providing valuable insights for future research. The integrated model's design and optimization offer new directions for further advancements in intrusion detection.

Abstract—This study aims to design and develop Wi-Fi tracker system that utilizes RSSI-based distance parameters for crowd-monitoring applications in indoor settings. The system consists of three main components, namely 1) an embedded node that runs on Raspberry-pi Zero W, 2) a real-time localization algorithm, and 3) a server system with an online dashboard. The embedded node scans and collects relevant information from Wi-Fi-connected smartphones, such as MAC data, RSSI, timestamps, etc. These data are then transmitted to the server system, where the localization algorithm passively determines the location of devices as long as Wi-Fi is enabled. The mentioned devices are smartphones, tablets, laptops, while the algorithm used is a Non-Linear System with Lavenberg–Marquart and Unscented Kalman Filter (UKF). The server and online dashboard (web-based application) have three functions, including displaying and recording device localization results, setting parameters, and visualizing analyzed data. The node hardware was designed for minimum size and portability, resulting in a consumer electronics product outlook. The system demonstration in this study was conducted to validate its functionality and performance.

Keywords—Wi-Fi tracker system; RSSI-based distance; crowd monitoring; Unscented Kalman Filter; indoor

I. INTRODUCTION

Wi-Fi tracking technology enables the detection of Wi-Fi signals emitted by individuals or objects, allowing for tracking their locations. This technology finds applications in indoor environments such as laboratories and nursing homes, where it can be beneficial for monitoring the health of the residents. [1]. Two primary types of Wi-Fi tracking system exist, including active and passive. Active tracking relies on individuals carrying a dedicated tracking device at all times, which can be inconvenient due to the constant need for device presence [1]. In contrast, passive Wi-Fi tracking does not require individuals to carry a tracking device but can only track the behavior of detected objects within the operational area [2].

Wi-Fi tracker system has garnered significant attention and found extensive applications in many cases. It has been employed for diverse purposes, including monitoring bus passenger volume, public transit ridership, human movement analytics, tourism mobility, tracking pets or wildlife, analyzing visitor behavior, tracking indoor pedestrian

movement, capturing shopper activities, detecting client positions, monitoring patients, and tracking attendance of officers, students, and teachers. [3]–[14]. System has also been successfully applied in various settings, such as museums, buildings, malls, campuses, schools, offices, airport areas, bus stations, theaters, etc. Wi-Fi tracking technology allows for the detection and tracking of smartphone locations using Wi-Fi probes [9], [15], [16]. This capability enables the analysis of device distributions, particularly in outdoor and indoor areas, providing insights into crowd levels and density [13], [17], including crowdedness levels [4].

The design and development of Wi-Fi tracking system involved conducting intensive preliminary study, which focused on studying the behavior of smartphones during connection. The evaluation was also carried out to determine the suitability of RSSI method for the tracking system [18]. The conducted experiments showed that system could collect important information such as RSSI (Wi-Fi signal strength) and MAC address of the smartphone. These two data are the required information that needs to be processed further. When Wi-Fi is enabled on a smartphone, it broadcasts packet request data containing the protocol, channel, and MAC address through Wi-Fi signal [18]. The initial step in implementing Wi-Fi tracking system using RSSI method involved sniffing these data packets and measuring the corresponding RSSI level at each node [19].

The use of RSSI method in Wi-Fi tracker system necessitates consideration of several factors. Firstly, RSSI value can exhibit instability [16]. Secondly, the interval time for broadcasting packet request data is variable and dependent on the state of the smartphones [20]. Thirdly, each smartphone emits a distinct initial power level [19]. Therefore, to address these challenges, a localization algorithm was developed to determine the location of the smartphone based on information gathered from all nodes. Study was conducted on digital filter design to enhance detection accuracy [21], [22]. Two candidate algorithms, namely the Intersection density algorithm and the Non-linear Least Square (NLS) algorithm, were evaluated in terms of their performance. The NLS algorithm was selected as the localization algorithm considering the issue of unstable RSSI values [22]. Unscented Kalman filter (UKF) algorithm was employed to reduce the noise value as well as enhance the detection accuracy. This

algorithm reduces noise and contributes to a more stable RSSI value, improving prediction accuracy [21], [23].

The ongoing study aims to develop Wi-Fi tracking system for indoor crowd-monitoring applications. This system enables the estimation and determination of the number of people in a room. It also acts as portable sensor because the nodes receive RSSI and capture Wi-Fi power emitted by Wi-Fi devices. The captured data is then transmitted using the Message Queue Telemetry Transport (MQTT) protocol and processed on the server. During the capturing process, the nodes collect data for duration of 5 seconds and store it locally in a circular file with up to five files stored in the active directory. The processor reads the third file in the active directory, parses and encapsulates the data in JSON format, and sends it to an available server.

According to the findings in study [18], when smartphones activate their Wi-Fi function and connect to an available Wi-Fi hotspot, they transmit a unique wireless signature known as MAC address. Additionally, the timestamp and RSSI values of smartphones vary depending on their types, models, and vendors. These data can be utilized as valuable references for constructing Wi-Fi tracking system. Fig. 1 shows the proposed architecture of Wi-Fi tracker system, comprising two main subsystems, including the node and server subsystem. The node subsystem is responsible for sniffing smartphone data transmitted at specific locations. Installing more than three nodes within the target area is advisable to ensure comprehensive coverage. The collected data from the nodes is then sent to the server for further processing. The server subsystem performs data computation using suitable algorithms and conducts analysis. The resulting data are summarized and presented on an online dashboard for visualization purposes.

Several steps need to be followed to operate system. Firstly, nodes are placed at desired locations within the target

area. Subsequently, when smartphones in proximity have their Wi-Fi switched to on/active, they will broadcast packet request data to the surrounding environment. Alternatively, smartphones can connect to nearby Access Points (AP), and system remains active as long as broadcast packet request data is continuously processed. Each node within the location then captures and sniffs smartphone packet data. To perform this function, the nodes must be configured in monitoring mode, and once captured, the nodes transmit the data to the server. However, before sending the data, it is encrypted using Transport Layer Security/Secure Sockets Layer (TLS/SSL) with 1024-RSA encryption to ensure compliance with data security requirements. This step is crucial as the data transmitted during communication are susceptible to vulnerabilities [[24], [25]]. Subsequently, the nodes establish a connection with Wi-Fi tracker AP and the collected data is finally transmitted to the server using MQTT protocol.

The server plays a crucial role in system by collecting data from all nodes. It achieves this by subscribing to MQTT broker based on the designed topic. Upon receiving the data, the server decrypts the packet data and organizes it based on MAC address information. This process results in a set of MAC address data along with their corresponding RSSI values from each node. By utilizing this data set, the server proceeds to compute the location of each device using two algorithms, including UKF and the NLS algorithm. The raw data, as well as the processed data containing the smartphones and their respective locations, are stored in the database. MongoDB was selected as the database system for Wi-Fi tracking system, while an online dashboard was developed to provide a user-friendly interface for accessing and visualizing the data. This dashboard is a web application running on the server, which also serves as a platform for basic system configuration and presents the results of the analyzed data.

Fig. 1. The architecture of the proposed Wi-Fi tracker system.

This study consists of six sections, namely introduction, system overview, embedded node (hardware and software), localization algorithm, server system, and online dashboard. The final section encompasses a functional test conducted through system demonstration. As the focus of this study is primarily on describing the structure of system, the proposed results are limited to system demo. Wi-Fi tracker system presented is a result of extensive study in the field of Wi-Fi tracking, and it has been successfully implemented on real hardware. The viability of the proposed concept has been carefully validated. Therefore, future study efforts should aim to evaluate the proposed system comprehensively. This evaluation should include assessing accuracy in relation to the number of smartphone entities, power consumption analysis, measuring actual access time with varying user numbers, testing against multiple attack scenarios to assess vulnerability, and conducting other relevant analyses.

II. RELATED WORKS

Wi-Fi Tracker system typically comprises two primary components, including the node and the server system. The node system acts as a sensor that scans smartphone information. The scan results obtained from the node system are then transmitted to the server for further processing using various algorithms. The server system performs computations using the collected data from multiple nodes to predict the location of the smartphones. Additionally, a dashboard, which can be a web-based or smartphone-based application, may be incorporated into system to configure the algorithms and display the results.

Numerous frameworks have been introduced to facilitate the prototyping of Wi-Fi tracker system. These include CrowdProbe [26], mD-Track [27], Widar [28], IndoTrack [29], Beanstalk [30], SenseFlow [31], ARIEL [32], Probr [33], MOBYWIT [34], etc. However, many of these studies lack comprehensive discussions on all aspects of Wi-Fi tracking system, including the hardware, software, algorithms, server system, web-based application, and system demonstration. To address this gap, the focus of this study is to provide a comprehensive design of Wi-Fi tracking system that offers a clearer understanding. The study aims to delve into the different components of system in greater detail compared to previous studies [[18-26]. It is expected to make it easier for readers to understand the whole system.

In comparison to previous studies [3]–[14], [26]–[33], this Wi-Fi tracking system offers additional components such as a server system and a user-friendly web-based application.

These additions enable real-time monitoring of passive smartphone positions based on RSSI values. The online dashboard included in system provides various features, including a heat map, time reports, and user identification based on MAC data. The server system plays a critical role in gathering all the scanned information from the nodes. It performs the localization algorithm and employs UKF for computation. The collected raw data, as well as the computation results, are stored in the database. Additionally, the database is used for a Graphical User Interface (GUI) to configure system, display the results, and present the analyzed data. Wi-Fi tracking system has been designed and packaged as a consumer electronics product. This aspect has a positive implication, as it ensures that system is well-suited for market deployment in the future [35].

III. METHODS

A. Embedded Node

The node system of Wi-Fi tracking system is developed on the Linux platform. Specifically, the current version of the node system is designed to run on Raspberry Pi Zero W, with Raspbian (Debian 9) as its operating system. A web application is created using the NodeJS framework to simplify system configuration process. The services of the node system are managed using pm2, allowing users to configure system via a local IP browser (<http://10.42.0.1>). Additionally, the node system can be controlled through a dashboard deployed on the server. Users can use the dashboard reboot button to reboot a specific node. The communication between the dashboard and the node system is facilitated through MQTT protocol. The node subscribes to the command topic while the dashboard publishes commands to the same topic. This enables seamless command exchange between the dashboard and the node system. The node system can be further divided into two main components, namely hardware, and software, which will be explained in detail as follows:

1) *Hardware part (Raspberry Pi)*: This embedded node hardware is designed to carry out the following tasks with optimal functionality: a) perform the main function, which is scanning, encrypting, storing, and sending the data, b) auto-connect to the network, c) provide node configuration system, d) supply backup power system, and e) be controlled remotely by the user. After the requirement has been defined carefully, tracker node hardware specification is decided, as shown in Table I.

TABLE I. HARDWARE SPECIFICATIONS

No.	Specification	Description
1	Power Input	Main DC 9V 1.5 A Back-up power: LI-ION bat 3.8V/ 4500mAh
2	Operating Temperature	Normal operation: -10°C ~ +60°C Storage operation: -20°C ~ +70°C
3	Feature	Remotely controlled (By internet and GSM module), it has a configuration system interface (web apps), Power back-up (up to 8 hours), LED indicator
4	Dimension	10 10 × 5 cm
5	Portability & Lightweight	11 Yes

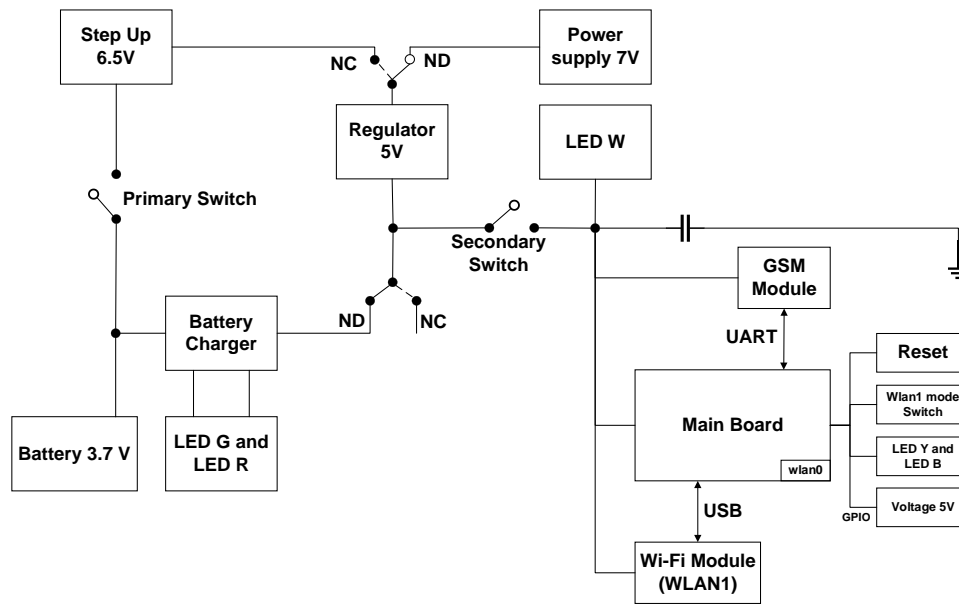

Fig. 2. Block diagram of node hardware.

The node system utilizes the Raspberry Pi Zero W, known as the mainboard, a compact and powerful development board running on the Linux platform. This mainboard provides excellent processing capability despite its small size. The functionality of the node is enhanced by connecting it to a complement board that integrates various components. These components include power management circuits, LED indicators, physics controls, GSM modules, and external antenna connectors. GSM module communicates with the mainboard using the UART Serial protocol, allowing efficient data transfer and communication. An external antenna is utilized, connected via a USB type B connector, and configured as wlan1 while the wlan0 is embedded in the mainboard.

Fig. 2 shows the structure of the node hardware, which is designed based on the requirements and functionality of the node. The main board is responsible for scanning/sniffing the packet request data through wlan1 and transmitting the data to the server through wlan0. The node hardware consists of two main power sources, including the main supply adaptor with a voltage of 7V and a backup supply in the form of a 3.7V battery. By default, when the main supply is available, the module draws power from it while the battery charge module charges the battery. Two LED indicators are provided, namely LED R and LED G indicating that the battery is charging and fully charged, respectively. When the main power is off, the relay switches from normally closed (NC) to normally open (NO), allowing the power supply to be sourced from the backup battery. The 5V regulator is necessary to ensure that the mainboard operates at its designated operating point. Additionally, a step-up module is used to ensure that the 3.7V battery voltage is appropriately boosted to drive the 5V regulator.

A capacitor bank is added to ensure a stable power supply during the switching process of the relay. It provides temporary power when the relay changes its state, and the main power becomes temporarily unavailable. Additionally, a

switch is incorporated to allow the user to manually turn on and off the node, serving as both a primary and secondary switch. GSM module is responsible for receiving Short Message Service (SMS) commands from the user. The data is sent to the mainboard for processing when an SMS is received. The mainboard verifies the validity of the command, and when it is valid, the node will be restarted. There are two options for GSM module, including SIM800L version 1 and SIM800L version 2. SIM800L version 1 operates at an operating point between 3.4V and 4.4V, while SIM800L version 2 operates at 5V. When SIM800L version 1 is chosen, an additional regulator is required to provide the correct voltage. However, since the hardware only provides a 5V power line, SIM800L version 2 can be used without needing an additional regulator to supply 4V. This means that SIM800L version 2 is selected for this system configuration.

Two LED indicators (LED B and LED Y) are connected to GPIO pins on the mainboard to provide visual indicators. These LEDs can be programmed to function according to specific requirements, such as light up when the node sniffs or sends packets. A reset button is also included to allow for external hard resetting of the mainboard. System also features a wlan1 mode switch, which allows for changing the mode of wlan1 between AP mode and monitoring mode. AP mode is used when the user wants to access and configure system node through web browsing. On the other hand, monitoring mode is utilized when the node is actively sniffing packet data.

The PCBs are designed with a focus on minimalism, ensuring that the electronic components can be integrated efficiently without adding unnecessary bulk to the case of the node. This design approach aligns with market demands for electronic devices that are lightweight, portable, modern, elegant, and simple. The hardware implementation of tracker node, based on the design shown in Fig. 2, is illustrated in Fig. 3. The casing of the node is made from Polylactic Acid (PLA), the same material used in other consumer-based product developed by Pusat Mikroelektronika ITB. Examples include

IR-based remote controllers [36], humidity and temperature sensor nodes [37], electronic transaction devices [38], and generic power sockets [39]. This material is suitable for a proper case because it is light, low-cost, solid, and resistant to dust particles & water.

Fig. 3. Photographs of trackernode hardware.

2) *Software part (Program node)*: Five programs running in the node include a) Main program (i.e., Sniffing, Encrypting, and Sending data), b) Sending node status, c) GSM module, d) Web control, and e) Web configuration. The description of each program is explained as follows:

a) *Sniff the packet data*: Fig. 4 illustrates the workflow of the program used to control Wi-Fi tracker and gather the required packet request data. It is crucial to consider the frequency at which devices broadcast packet request data as it directly impacts the accuracy and reliability of system. The more frequently devices send probe requests, the better the results can be achieved. During observations, several factors were identified that influence the frequency of packet requests, including the type of smartphones and the individual states. Different smartphone models may have varying time intervals for sending out packet requests, hence, to capture and analyze Wi-Fi data, Tshark, a packet sniffing tool, is utilized. The question of how Tshark analyzed the data was demonstrated in [18].

Smartphones with different chipsets and wireless adapters exhibit variations in their scanning behavior, which can be observed through the differences in scanning results. Several smartphones have a feature that enables power-saving mode, leading to slower probe request broadcasts than smartphones without this feature. Based on preliminary observations of various smartphone types, probe requests are sent at different intervals. The fastest observed interval between probe requests is approximately 3 seconds, while the slowest interval is around 60 seconds. The frequency of probe requests is higher in active scanning mode and lower during other smartphone activities such as web browsing, files downloading, or sleep mode.

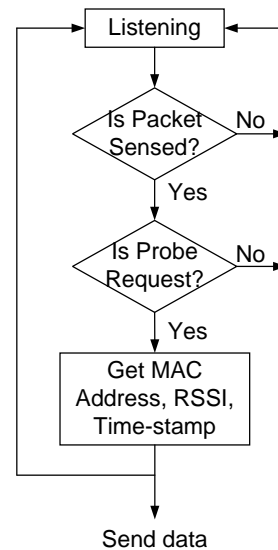

Fig. 4. Flowchart of scanning data for smartphone connected to Wi-Fi.

When considering smartphones, two scanning methods are used for active Wi-Fi AP as defined by [13], namely active and passive scanning. In passive scanning, the smartphone receiver is turned on to listen to each channel for the beacon. This scan is completely passive, and nothing is transmitted from the smartphone. While for active scanning, the smartphone will broadcast the packet on each channel. Probe requests are sent on the currently tuned channel to discover existing AP. The main focus of this system design is tracking the location of smartphones rather than AP. By setting the node to monitoring mode, no packet data is sent, thereby requiring smartphones to be in active scanning mode.

b) *Encryption*: As discussed in the previous chapter, security, and privacy issues are important concerns in the application due to the utilization of user information. MAC address emitted by smartphones has a considerably unique nature, allowing potential tracking of user whereabouts [11]. For example, unauthorized individuals can steal information stored in MAC address and use it to identify peoples' location and duration of stay in a building [24]. This raises significant safety and privacy concerns [25]. In this study, TLS/SSL is employed for MQTT communication to ensure secure transmission due to its ability to provide a secure communication channel between the client and server. TLS operates at the transport layer, enabling encryption without the need for application-layer encryption implementation. TLS/SSL consists of two main components, including securing the connection between the client and server using Certificate-Based Key Exchange and securing the sent messages using RSA encryption. The workflow of TLS/SSL in this system is shown in Fig. 5.

A certificate-based key exchange mechanism is employed to ensure a secure connection. The authorized user provides a certificate to both the server and node, which establish a connection assuming they possess the same certificate. The server generates private and public keys for encryption and decryption of information. The public key is then shared with the node using the certificate. The node, having the matching

certificate, can access and utilize the public key. The information is encrypted using the public key, employing the RSA method with a 1024-bit key in this study. All scanned data in the node, including the node status, will be encrypted. Similarly, the server, possessing the private key, is used to decrypt the encrypted information.

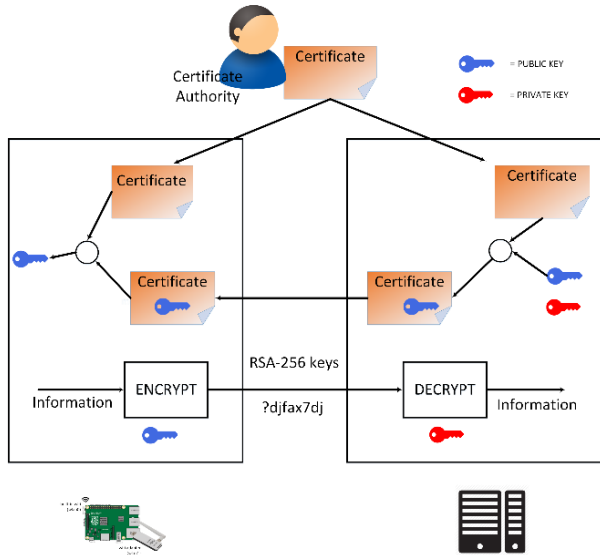

Fig. 5. TLS/SSL block diagram.

c) *Sending node status:* As described earlier, tracker node sends the captured data to the server using MQTT protocol, a client-server publish/subscribe messaging transport protocol. MQTT is widely known for its lightweight and efficient nature in terms of bandwidth usage. It is a popular choice for IoT platforms due to its low-power consumption and ease of implementation [40]. In system, small amounts of data are transmitted at frequent intervals, as opposed to sending large chunks of data less frequently [41]. MQTT protocol, with its support for the publish/subscribe scheme, was chosen for this purpose. Fig. 6 shows the data transmission process from the node to the server, utilizing the built-in Wi-Fi interface (wlan0) to connect to AP.

Fig. 6. Sending data from node.

MQTT protocol is utilized to send data in the form of a JSON object. The publisher (node) establishes two distinct topics, namely the main and the status topics. The main topic is responsible for transmitting the primary data whenever the device is scanned, while the status handles the status information of the node, which is sent every 10 seconds. The node status indicates the connectivity status with the server. An example of the main information JSON object, which has a data size of approximately 107 bytes, is provided below.

```
{
  "device_addr": "AA:BB:CC:DD:FF:GG,"
  "rssi_dbm": "-23",
  "time_epoch": "1493901414.065620"
}
```

An example of the node status JSON object, which has a data size of approximately 57 bytes, is provided below:

```
{
  "MAC_addr_node": "B8:27:EB:EB:D8:42"
}
```

d) *GSM module operation:* GSM/SMS service enables remote node control through GSM frequency by sending a message to a specific node phone number. The available remote-control actions include allowing the configuration to state/AP and rebooting the node. The commands can be found in a default configuration with only numbers listed under authorized phone numbers capable of controlling the node. GSM module receives an SMS representing the command to restart the node. First, the command is sent to the mainboard using a serial connection. Then the mainboard processes the node and executes the command (reset the board). This functionality proves useful when a specific program, such as the scanning mode, stops working and there is no internet connection available. Table II provides a list of some AT commands, while the port for GSM module is depicted in Fig. 7. The SIM800L module is a widely used GSM/GPRS module for serial communication. It is commonly employed in remote control projects, allowing smartphones with a Microsim-type SIM card to send messages for control purposes. This module utilizes the TTL serial port and features an LED indicator. The LED blinks slowly when the module is connected to a GSM network and blinks rapidly when there is no signal. Although the module provides 13 ports, only a few of them are utilized in this study. GSM hardware is initially connected to the Raspberry Pi for development purposes, as shown in Fig. 8. The experiment involved several components, including the Raspberry Pi, a computer running Python, the SIM800 module, and various jumpers. The connection was carefully made, considering the functions of each port (especially RX, TX, GND, and VCC) to ensure the program was successfully downloaded.

The flowchart shown in Fig. 9 illustrates the control process of GSM module using the mainboard (Raspberry Pi). The main board is responsible for four tasks, including setting up GSM module to SMS mode, extracting commands, making the decision to require a restart, and executing the reboot script. On the other hand, GSM module has four tasks, including listening to incoming SMS, deciding on incoming SMS, reading the SMS, and sending messages to the mainboard. UART communication is used between the two components. In the initial step, GSM module is set up in SMS mode by sending a sequence of AT commands from the mainboard to the module. When there are no errors, GSM module enters SMS mode and listens for incoming messages. When an SMS is received, GSM module will transmit it to the mainboard via UART. The mainboard will then verify the message and extract the content to determine whether it is a restart command to execute a reboot script to restart the node.

TABLE II. COMMANDS OF THE AT

Command	Description
AT+CMGF=1	Set module to operate at SMS/Text mode
AT+CMEE=1	Check whether SMS mode is supported or not
AT+CNMI	New SMS indication
AT+CMGR	Read an SMS

Fig. 7. GSM module SM800L port (top and bottom views).

Fig. 8. GSM hardware setup for development purposes.

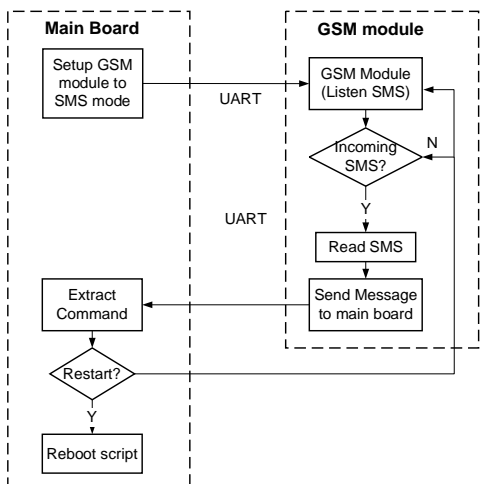

Fig. 9. Flowchart of GSM controller.

During the development process, a problem arose where the flowchart did not work correctly. The possible issue is related to the signal antenna GSM, serial communication (UART), or an incorrect AT command sequence. To resolve this problem, the code and commands were modified using the Python library. Eventually, the node was successfully tested and demonstrated the ability to receive commands from SMS and execute them.

e) *Web control system:* A GUI is provided in the dashboard, which includes a function to monitor the status of the nodes, whether they are sending data or not. The dashboard offers real-time data presentation with the following features: i) Basic map cartesian and dynamic configuration, the basic map will display the tracked device

location in cartesian mode, ii) The trajectory of the smartphone graph, iii) Node status monitoring and iv) Calibration page. The layout can be configured from the map setting container on the right side of the map, as shown in Fig. 10. The devices map menu is used to display the algorithm result in a real-time. The map setting is used to set into desired area/location because there is also a form of MAC address filter to display only specific MAC addresses. It is useful for testing the accuracy of the algorithm purpose.

Furthermore, additional features in the dashboard were implemented, as shown in Fig. 11. These include the node name, node status, and a reset command. The reset command menu is used to reset a specific node. The node name corresponds to MAC address of Wi-Fi module connected to Wi-Fi tracker AP. Each node name is published to a different topic, and the node subscribes to the topic based on its Wi-Fi MAC address (wlan0 interface). This allows the status of each node to be displayed in the dashboard.

In system specification, the remote-control functionality of the node was defined, but the web server lacks knowledge of the address, preventing direct command transmission. MQTT protocol was employed to address this, followed by a publish and subscribe scheme. Instead of directly sending commands to the node, they are published to MQTT broker using a known address. The node then subscribes to the relevant topics to receive and execute the commands, allowing it to restart the board. The illustration of the scheme is presented in Fig. 12. An online dashboard is developed using Node.js, a popular full-stack JavaScript web application framework, to enhance the user experience. The integration with Mongo and front-end development with Angular are also implemented.

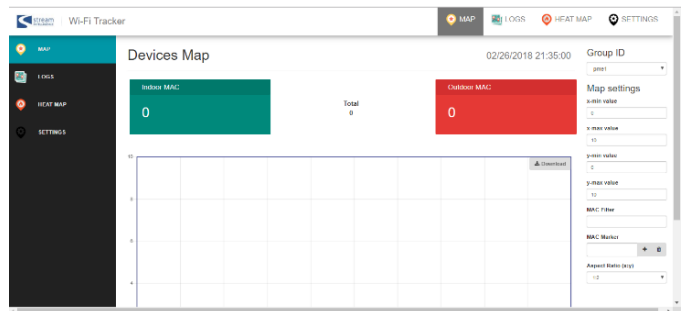

Fig. 10. Basic cartesian map, all detected devices/smartphones after the computation process is displayed in this map. Using MAC address, RSSI, and time stamp data, the location of devices can also be determined.

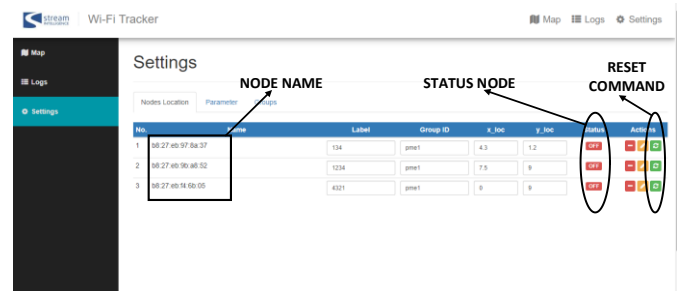

Fig. 11. Appearance of the dashboard for node status and controller.

Fig. 12. MQTT broker scheme.

B. Localization Algorithm

This section describes the localization algorithm applied in system. The algorithm predicts the location of devices based on previously obtained information. For this purpose, distance-based method is implemented, which is an RSSI-based localization algorithm. Based on the set of RSSI measurement results, the location of devices is predicted using the estimated distance between tracker nodes and smartphones. In addition, UKF is used to enhance system performance, consisting of three steps, namely modeling, predicting, and correcting, as summarized in Table III. The detailed derivation and simulation under MATLAB are explained in [21], [22]. The calculations are performed in the Apache Storm-based server, and the algorithms are written in Python script. The *NumPy* library is used to perform matrix computation in Python. The code includes a function to initialize the Kalman model used in this work. The prediction and correction steps of UKF are implemented to predict the next state value from the current state and store it in memory.

C. Server System Dashboard

1) *Brief description of system structure:* The server is deployed on the Debian 9.1 Linux platform and has two main functions, including collecting data from all nodes and estimating the location of detected devices. The data transport from nodes to the server is facilitated through three mechanisms, namely MQTT protocol, a message broker server for MQTT, and Apache Storm. Apache Storm enables distributed real-time computation with the NoSQL platform MongoDB used to store the data. The users can set the configuration and real-time localization from web apps deployed under the Nodejs platform.

The main processor of the server utilizes Apache Storm 1.1.0, which is built on the Java platform and enables distributed computation. Apache Storm is supervised and monitored by the Supervisor and ZooKeeper components. It follows a spout-bolt architecture, where the input data is received by the spout and processed by separate bolts. Python programming language (version 2.7) was chosen for the algorithm implementation due to its extensive library support, facilitating faster development. Apache Storm is implemented using the Streamparse framework, as shown in Fig. 13. This framework allows real-time visualization on the Map dashboard, although global grouping is not currently implemented in the framework.

Serializer Spout is the data flow gate subscribing to certain topics where nodes publish. In this Spout, serializer (message parsing) is conducted from JSON format to a tuple of the device address, timestamp, node ID, and RSSI. Finally, all parsed data are sent to InsertDeviceBolt to be stored in MongoDB as devices collection and BufferMsgBolt.

TABLE III. UKF ALGORITHM FOR THE PROPOSED SYSTEM

Model
$RSSI(t+1) = RSSI(t) - 10\alpha * v(t) * 10^{\frac{(Pinit(t)-RSSI(t))}{10\alpha}} * \Delta t$ $v(t+1) = v(t)$ $Pinit(t+1) = Pinit(t)$ $Z = [RSSI]$ $R = \left[\left(\frac{3.0 * RSSI + 340}{70} \right)^2 \right]$ $Q = \sigma^2 \begin{bmatrix} \Delta t^3/3 & \Delta t^2/2 & 0 \\ \Delta t^2/2 & \Delta t & 0 \\ 0 & 0 & 1 \end{bmatrix}$
Prediction Step
<ul style="list-style-type: none"> Calculate weight, sigma-point: $W_0^m = \frac{\lambda}{n + \lambda}$ $W_0^c = \frac{\lambda}{n + \lambda} + 1 - \alpha^2 + \beta$ $W_i^m, W_i^c = \frac{1}{2(n + \lambda)}, i = 1, 2, \dots, 2n$ $\lambda = \alpha^2 (n + k) - n$ $\chi_0 = \mu$ $\chi_i = \begin{cases} \mu + [\sqrt{(n + \lambda)\Sigma}]_i, & \text{for } i = 1, 2, \dots, n \\ \mu - [\sqrt{(n + \lambda)\Sigma}]_{i-n}, & \text{for } i = n + 1, \dots, 2n \end{cases}$ Unscented transform $\psi_i = f(\chi_i), z_i = h(\chi_i)$ Transition state: $\bar{y} = \sum_{i=0}^{2n} W_i^m \psi_i$ $P_{yy} = \sum_{i=0}^{2n} W_i^c (\bar{y} - \psi_i) (\bar{y} - \psi_i)^T + Q$
Correction Step
<ul style="list-style-type: none"> Kalman Gain: $\bar{z} = \sum_{i=0}^{2n} W_i^m z_i$ $P_{zz} = \sum_{i=0}^{2n} W_i^c (\bar{z} - z_i) (\bar{z} - z_i)^T + R$ $P_{yz} = \sum_{i=0}^{2n} W_i^c (\bar{y} - \psi_i) (\bar{z} - z_i)^T$ $K = P_{yz} * P_{zz}^{-1}$ Correct the prediction: $X_{k+1} = \bar{y} + K * (Z_k - \bar{z})$ $P_{k+1} = P_{yy} - K * P_{yz} * K^{-1}$

BufferMsgBolt receives the data from Serializer Spout and temporarily stores it until enough data from at least three nodes with the same device address are collected. In this stage, the data is filtered using UKF and stored as the maximum RSSI value. Afterward, the NLS algorithm is applied to compute the location of the device, and the result is sent to InsertDeviceLocBolt to be stored in the locations of MongoDB collection. System called heartbeat is implemented to maintain a constant stream of data in Storm, which keeps

system alive by checking the incoming stream data within a timeout range. Since the server has only one deployment, the service needs to run for a long time, which is served by a component called heartbeat_keeper.

Fig. 13. Storm implementation.

2) *Server system:* The server system performs data calculations using Apache Storm, a parallel streaming processor. Large companies widely use Apache Storm for processing big data in near-real time. It is an open-source distributed computation system that is free to use, simple, and compatible with various programming languages. In this implementation, Python was chosen as the programming language. The server system architecture is shown in Fig. 14, with a message broker employed to receive data from the nodes. Mosquito, a lightweight and straightforward MQTT broker framework in Python, is used for this purpose.

During the first phase of server system development, Cassandra was chosen as the database solution before MongoDB usage. Cassandra is renowned for its clustered architecture and high availability. However, later in the development process, the decision was made to switch to MongoDB for storing the computation results. MongoDB was preferred due to its document-based database flexibility and ease of querying and inserting data. It is important to note that for optimal performance in a clustered environment, the tables must be structured maturely and well-designed. As a proposed solution, a scenario can be devised where, once all executions and developments are stabilized, a migration back to Cassandra can be considered for further enhancements and improvements in the server system.

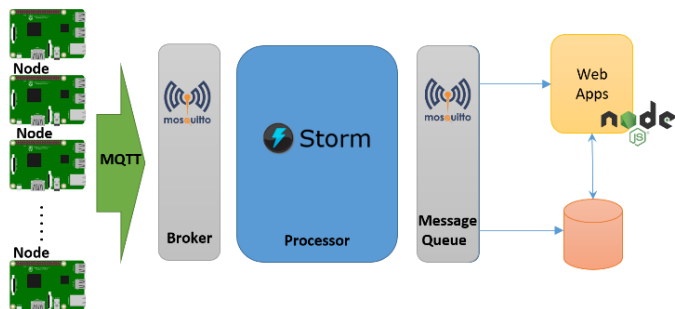

Fig. 14. Server system architecture.

3) *MQTT broker:* A broker is a message pool that manages where the message is delivered. When a broker receives a message on a particular topic, it broadcasts them to every subscriber who subscribes to the same topic. The broker concept for the proposed system is shown in Fig. 15. It illustrates that node 5 published a “Hi!” message in topic /hello/world/, and MQTT broker will broadcast to wherever node is subscribing to the same topic /hello/world/. Therefore, nodes 3 and 1 receive the message because they subscribe to the/hello/* topic. Meanwhile, node 4 will not receive the message due to different topics and node 2. This is because node 2 and 4 serves as a publisher. MQTT security is implemented by exchanging data in an SSL tunnel connection. The client, who acts as publisher or subscriber, needs to have certificates with username and password inputted before sending the message. In the server as a subscribe, the node sends data to the broker (publish mode) in a specific topic. Therefore, to receive data from nodes, the subscriber needs to subscribe to the same topic. For example, the server as a subscriber receives data in a topic: com. stream/track/Wi-Fi/device. The payload of this message is presented in the program as follows:

```

{
  "device_addr": "AA:BB:CC:DD:FF:GG", // uniqueID of device
  "rssi_dbm": "-23", // signal strength which read by Node
  "time_epoch": "1493901414.065620", // epoch time of data being sent
  "nodeID": "11:22:33:44:55:66" // uniqueID of the node which sends the data
}
  
```

In the server as a publisher, the result of computation needs to be pushed immediately to web apps to gain real-time experience. This feature is served by implementing a publisher which broadcasts the process to every web app. An example is in the program below, where the device is unique of the device, x_loc and y_loc denote the x and y positions of the device.

```

{
  "dev_in": 3, // amount of devices in the room
  "dev_out": 10, // amount of devices out of the room
  "devices": [ // list of devices
    { "device": "B3:B9", "x_loc": -0.19, "y_loc": -5.77 },
    { "device": "FD:78", "x_loc": 12.17, "y_loc": 14.51 }
  ]
}
  
```

Fig. 15. MQTT broker concept.

4) *Processor description in detail:* As discussed earlier, Apache Storm is utilized as a processor in the server. The Storm topology consists of Spouts, which receive the data, and Bolts, as micro-computations or processes. The Storm computation is based on micro-computation, so every computation needs to be distributed in Bolts. Every incoming message from *the broker* is serialized in *SerializerSpout* and turned into a tuple. These tuples are then forwarded to the *BufferMsgBolt*, where they are merged with messages from other nodes, which is processed by the algorithm. The computed result is stored in a database through the *RecordStreamBolt* and sent to the dashboard using the *ResultPubBolt*. The workflow of the processor is illustrated in Fig. 16. Meanwhile, in Fig. 17, the flowchart depicting the implementation of UKF algorithm is shown. Firstly, the algorithm parameters are initialized, such as the path-loss exponent, node location, room location, and other relevant parameters. The user configures these parameter values through the web interface, and the database stores these configured values. Finally, when the algorithm is executed, it retrieves the configured values from the database for processing.

The Table State and Table Device serve as temporary memory to store the previous state of UKF and the previous set of smartphone data, respectively. The Table State keeps track of the previous RSSI values and covariance matrix for all existing nodes and smartphones. On the other hand, the Table Device stores the previous information of the devices detected. The long Table State and Table Device were used to determine the time to live (TTL). The program regularly checks the tables and deletes any values that have expired. This approach addresses the issue that the node may not always be able to scan RSSI values from devices, allowing us to utilize the previous values. The TTL helps determine the validity duration for using the stored data.

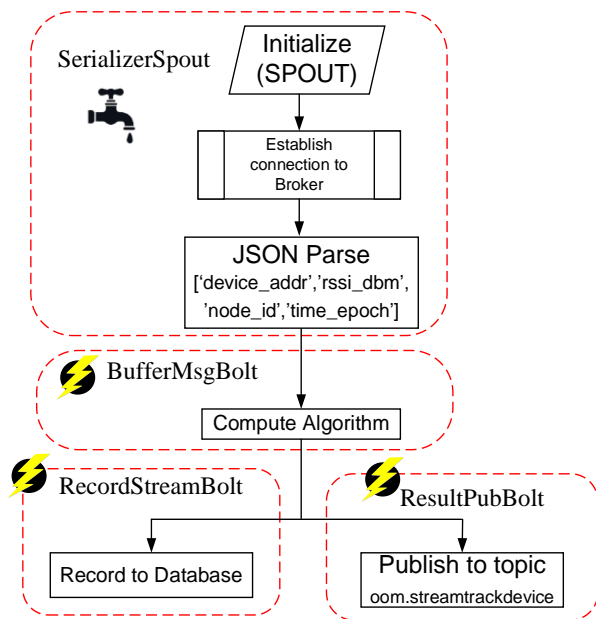

Fig. 16. Storm flowchart.

Fig. 17. Workflow of algorithm in general.

The program continuously checks the Table Device and performs the localization algorithm computation for all the available data stored. The resulting localization information is then saved in a database and sent to the dashboard for visualization. The data was modified for the algorithm by employing the NLS with initial power (NLS1). First, it will be used to decide whether the device is inside or not, followed by refining the detection using the NLS with power difference (NLS2). Fig. 18 is the flowchart of the NLS implementation.

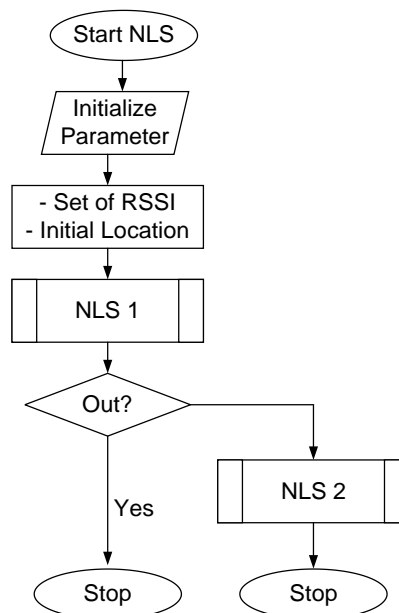

Fig. 18. The NLS algorithm flowchart.

5) *Database:* Data is stored in various collections with their respective data structures, which are shown in Table IV. Config collection contains display configurations and some parameters used in the algorithm. The Devices collection stores all raw data captured by the nodes. The Collections collection includes all the computation results (documents) of the devices, including their location and status. Finally, the Nodes collection contains information about all registered nodes. Database Structure.

TABLE IV. THE DATABASE STRUCTURE

Structure	Description
Configs	{ "_id" : ObjectId("5979a1c2e70bc538eba1b612"), "groupId" : "pme1", "_v" : 0, "mapConfig" : { "xmin" : 0, "xmax" : 10, "ymin" : 0, "ymax" : 10 }, "roomSize" : { "xmin" : 0, "xmax" : 10, "ymin" : 0, "ymax" : 10 }, "pathloss" : 23 }
Devices	{ "_id" : ObjectId("5976c272e28b3501e5bdef2c"), "timestamp" : "", "rssi_dbm" : 0, "node_id" : "", "device_id" : "SA:SD" }
Locations	{ "_id" : ObjectId("5979f740e28b350ff263b31a"), "status" : 0, "modified" : ISODate("2017-07-27T21:22:56.598Z"), "loc_z" : null, "loc_x" : -1.8633060346972499, "loc_y" : 2.9159220745415255, "device_id" : "DA:A1:19:99:84:A4" }
Nodes	{ "_id" : ObjectId("59788125287c9919e0295b0b"), "nodeId" : "C", "groupId" : "pme1", "locX" : 12, "locY" : 12, "_v" : 0, "modified" : ISODate("2017-07-26T03:37:29.433Z") }

Config fields:

- `_id`: id of document.
- `GroupId`: Id of a group of configurations. This will be used to group of nodes.
- `mapConfig`: configuration for display in cartesian
 - `xmin` : x min value of map
 - `xmax` : x max value of map
 - `ymin` : y min value of map
 - `ymax`: y max value of map.
- `roomSize`: the size of the room
 - `Pathloss`: Pathloss value of room of observation. This is used for calibration.
 - `xmin`: x min value of room
 - `xmax`: x max value of room
 - `ymin`: y min value of room
 - `ymax`: y max value of room

Devices fields:

- `_id`: id of document.
- `timestamp`: timestamp
- `rssi_dbm`: received signal strength in dbm
- `node_id`: uniqueID of the node where message comes from

Location fields:

- `_id`: id of document.
- `status`: define where the devices regarding room size config. 1 inside, 0 outside.
- `modified`: last updated record. Format: 2017-07-27T21:22:56.598Z
- `loc_z`: z location in cartesian. For current development, always null.
- `loc_x`: x location in cartesian
- `loc_y`: y location in cartesian.
- `device_id`: id of device

Nodes fields:

- `_id`: id of document.
- `nodeId`: uniqueID of node
- `groupId`: group Id of node
- `loc_z`: z location in cartesian. For current development, always null.
- `loc_x`: x location in cartesian
- `loc_y`: y location in cartesian.
- `Modified`: last updated record with the format as follows: 2017-07-27T21:22:56.598Z

6) *Data exchange*: This subsection provides a more detailed analysis of the data exchange mechanism in the server system. As previously stated, data are exchanged via MQTT protocol from the node to the server, where nodes publish the message to the topic (then denoted as "A"). The *SerializerSpout* subscribes to this topic, allowing it to receive messages from any nodes that send data to topic A. The received data is then processed and inserted into a database using Pymongo. The insertion is carried out by the *InsertDeviceBolt* and *InsertDeviceLocBolt*, which store the computation results in the locations and devices collections.

IV. RESULTS AND ANALYSIS

A. Setting at a Glance of System

This subsection provides a comprehensive explanation of how to utilize system. The process will be described step-by-step, starting from the initial hardware node setup and leading up to displaying the scanning results on an online dashboard. In order to implement system in the field, different user access levels were defined. System consists of two types of users, namely, admin and dashboard users. Admin users are Wi-Fi tracker developers responsible for setting up and configuring the node and server system, while dashboard users can adjust algorithm parameters and view the results. For indoor localizer environment (Wireless Sensor Network), a minimum of three nodes is required, although using at least four nodes is recommended for more accurate data collection. Distance between nodes should not exceed 20 meters. Positioning the nodes at elevated points, away from obstructions, and ensuring they are connected to Wi-Fi router is advisable. The chosen location used for the live demonstration of system follows the spot-point used in [18]. A glass wall surrounds the room and has a dimension of 30m x 10m, with two static obstacles (concrete pillars) located in the middle. Four tracker nodes are used for this test, with each node placed in a corner, as illustrated in Fig. 19.

Each tracker node is powered by an Adaptor 9V 2A, which serves as the main power and is backed up with a battery of 3.7V 4500mAh, switched with a physical switch relay. The node is configured by enabling AP mode, which is done by pressing the green button for approximately 5 seconds. Subsequently, the node enters AP mode when the configuration indicator turns on (blue light) and the active

indicator turns off (orange light). The configuration process can be carried out by connecting to the default SSID and password and accessing the specific local IP of the node through a web browser. The values that can be configured include the node connection, credentials account (e.g., secret-id, secret-key, and target host), phone number, and authorized phone numbers. While in the configuration state, the node does not capture data. Once the configuration is complete, the submit button should be clicked to apply the new settings, automatically rebooting the node. Finally, the node collects data and sends it to the server.

Fig. 19. Demonstration setup: (a) Map of the room for system demonstration; (b) Photographs of the room situation and placed tracknode.

In order to transmit data to the server, the node requires an internet connection. A web client interface has been created based on the NodeJs framework, operating on a node, and this interface supports real-time visualization. Messages are sent from the server (Apache storm - *Buffermsgbolt*) to the NodeJs using MQTT, with the NodeJs acting as a subscriber. A sockets connection is implemented in NodeJs to enable updates whenever new messages arrive. The UI for the angular server and communication with the REST API is implemented using the express framework. To access the website, users need to follow these steps: i) Activate the configuration mode of the node. ii) Open a web browser and navigate to <http://10.42.0.1>. iii) Enter the required credentials and configurations. iv) Fill out the available forms and initiate a reboot. Detailed instructions for these steps are provided in the subsequent section.

B. Detail Setting

The first step involves setting Wi-Fi interface into AP mode by activating a provided button. Instead, the wlan1 interface was utilized, and specifically designated for sniffing packet data, as previously explained. Once wlan1 is in AP mode, other computers or laptops can connect to the established AP. Users can then open a browser and enter the address 192.168.0.1 to access the configuration web interface. The node was restarted after making the necessary changes. The online dashboard will display a setting summary of the node, as shown in Fig. 20(a). Users can click the edit configuration button to view the surrounding APs detected by the node. To send data to the server, the wlan0 interface of the node will establish a connection with one of the detected APs, as illustrated in Fig. 20(b).

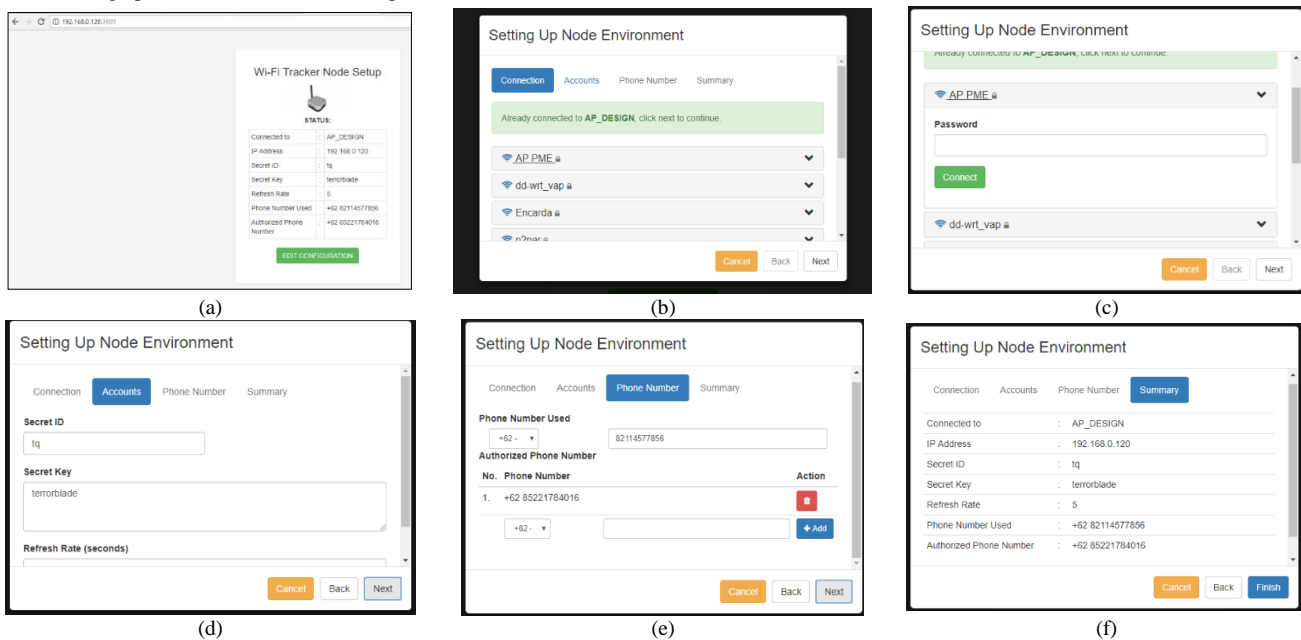

Fig. 20. Demonstration setting flow: (a) Summary of Wi-Fi tracker node setup, Informing the node status, Wi-Fi tracker AP, IP address, Secret ID, Secret key, Refresh rate, Phone number used, and Authorized phone number; (b) Setting up node environment in step I; (c) Select AP and insert password; (d) Setting up node environment in step II: user name and password setting for MQTT; (e) Setting up node environment in step III: GSM number setting used in node and list of authorized number; (f) Summary of the setting.

In the following steps, the user selects the name (SSID) of Wi-Fi network from the available connections list and clicks the connect button, as shown in Fig. 20 (c). Once the device is connected, the user proceeds by selecting the next button and enters the secret ID, secret key, and host obtained from the service provider. It is essential to keep this information private and not share it with others. Clicking the test button prompts a success message when the entered account details are correct. When the user encounters a failed message (Fig. 20d), they are encouraged to contact the provider for assistance. Upon completing a step, they can continue with the optional case by clicking the next button to activate the SMS Service. Next, the user is advised to input their phone number and authorized phone numbers. Finally, the submit button is selected, as shown in Fig. 20(e), to initiate a reboot of tracker node. The setting summary of the node is then displayed (Fig 20f). After clicking the finish button, the online dashboard is presented (Fig. 21). MAC field can be used to filter the displayed devices and leaving it empty will show all detected devices. Devices of interest can be marked in red using MAC marker. The aspect ratio setting determines the ratio of the x-axes and y-axes.

The configuration of each node location is performed in the menu section for node location settings, and all nodes have been placed in specific locations. This setting indicates the location of the node to the algorithm using the x_loc and y_loc coordinates. The menu also displays the status of the node, indicating whether it is available or not, in the status column. Additionally, any unregistered nodes are shown, allowing for the addition of their locations and saving them to the database. The nodes are monitored by being set in the settings menu (Fig. 22), and their status is updated every 1 minute. For system calibration, there is a parameter tab available in the settings. This tab allows for the adjustment of room size, map values, and path-loss of components (Fig. 23). The settings for room size and path-loss exponent can be found under the setting menu within the parameter tab. Path loss calibration is used to represent the surrounding conditions or barriers within the room for the algorithm. The room size parameter determines the observation space and helps consider whether the device is inside or outside the room.

Fig. 21. Node location setup.

Fig. 22. Node status and setup dashboard.

Fig. 23. Calibration and room setting dashboard.

C. Displaying other Data Analysis

The dashboard includes a real-time device monitoring feature on the map, as well as the percentage of people inside versus outside the observed room to enhance analysis. A marker has been added, which turns red when devices are outside and green when inside. Fig. 24 provides an example of data analysis during the field test, showing the number of smartphones inside the room (green), outside the room (red), and in a specific location (orange) for a day.

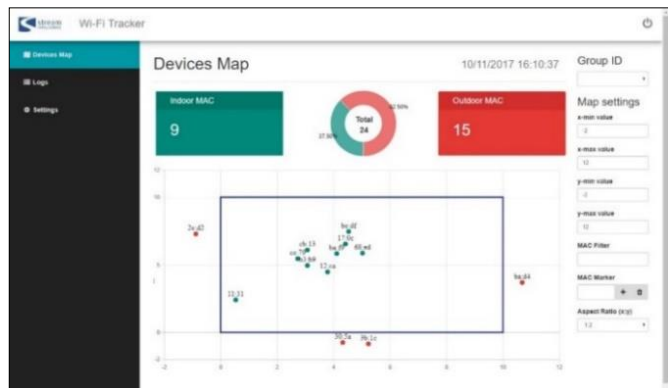

Fig. 24. Devices map on the online dashboard, red represents external devices by time, cyan represents inside, and yellow amount of device in a certain place.

The report can be accessed by daily inquiries on two pages, namely, Logs [34] and Heatmap [33]. The Logs page displays a report based on the access time parameter, while the Heatmap page displays a report based on the parameter of locations. Furthermore, the Logs page allows users to view crowd density in a room over time, with the option to select a specific date for more detailed information. The three categories in this menu are outside, inside, and certain places, with the need to define the latter before accessing system as shown in Fig. 25; it illustrates the volume of people in the test room over time, with data sampled every five seconds. The administrator can download the chart image of Logs (time reports) by clicking the calendar icon and submit button. On the other hand, CSV file containing the raw data of this day can also be downloaded smoothly by clicking CSV icon. The administrator can hide the need data to be analyzed by choosing menu as follows: outside, inside, and ranged devices. The Heatmap feature visually represents the activity density in the observed room throughout the day. By setting the desired date and submitting it, users can obtain the Heatmap, which is centered on the origin point of the room ($x = 0, y = 0$). Red indicates high activity, while grey represents low activity,

similar to a graph (Fig. 26). The Heatmap can be accessed daily by clicking the Heatmap page, automatically displaying the report of the day. A black square represents the room, and users can adjust the X and Y values to navigate the map. The maximum heat value can also be adjusted to define the intensity of activity. In conclusion, the dashboard enables crowd detection through the visualization of Heatmap data.

Wi-Fi tracking system should offer three important parameters, namely, device classification, user localization, and user profiling [35]. The proposed system is currently capable of defining only the location of the user. In future updates, additional services will be added to gain more benefits, such as user profiling and device classification based on RSSI signal emitted by the smartphones of users. Furthermore, system provides trajectories of devices, which can be accessed through the Logs bar. This feature displays the number of devices (smartphones) present inside or outside the room at specific times. It also allows monitoring of specific places, regardless of whether they are inside or outside the room. The Log bar is utilized to display the data analysis, allowing the user to observe the number of devices inside or outside the room at a particular time.

Fig. 25. Time reports.

Fig. 26. Heatmap reports.

D. Discussion

The popularity of smartphones as study objects in the computing field is increasing with Wi-Fi tracker system [31]. This is because wireless human sensing system can be carried out accurately and with far coverage. Smartphones can periodically send Wi-Fi request packets which tracker can detect by capturing the passive signal information of the smartphone, including MAC address and RSSI [4], [42]. In comparison to other technologies for human sensing, such as

infrared or video thermal cameras, which are less accurate in identifying indoor crowd density, Wi-Fi tracker offers greater accuracy and coverage. These alternative technologies have limitations in terms of a fixed location, angle, and limited range for detecting human presence in various indoor areas. Given the widespread use of smartphones with Wi-Fi connectivity, Wi-Fi tracker system attempts to extract information about human density in a room through smartphones. By utilizing RSSI parameter, system can determine the position of smartphones and their users in a specific area. While the current Wi-Fi tracker system is relatively simple and based on limited-scale trials, it can serve as a solution for monitoring crowd density, which is crucial in social activities. The applications of this system are diverse, such as tracking the number of daily visitors to a shopping center and identifying the most frequently visited stores. Conversely, it can also provide insights into the number of people present and working in a building. This human sensing information helps service providers understand patterns in public spaces within indoor areas. System can be implemented on campuses for various applications, including tracking occupancy in academic spaces such as offices, libraries, laboratories, lecture halls, meeting rooms, faculty rooms, and seminar auditoriums.

The proposed system has the potential to be implemented as a position-tracking and indoor crowd-monitoring solution, which is widely used in modern cell phones. This tracking methodology can be applied to monitor individuals in various indoor locations such as logistics warehouses, hospitals, or airports. Unlike GPS, which has limited accuracy, system utilizing RSSI level from Wi-Fi routers can provide higher accuracy. Wi-Fi routers are already installed in many places, resulting in a lower initial cost during system development by leveraging existing Wi-Fi infrastructure. Therefore, they offer an advantage over GPS. Wi-Fi tracking system, based on RSSI-based distance, can be implemented in indoor applications, such as campus areas, as demonstrated in this paper (i.e., ITB area). It is recommended to conduct further studies to assess the performance of system in real-world settings, as all the demonstrations were conducted in a controlled environment. The accuracy of system in tracking various elements in the real world also needs to be examined.

The demonstration results show the successful monitoring of crowdedness using the online dashboard. System effectively captures the volume of smartphones connected to Wi-Fi, as anticipated, and crowdedness data is displayed at five-second intervals. Furthermore, the online dashboard provides the ability to specify the location of smartphones, such as inside devices, outside devices, and within a specific range. This study does not include statistical analysis as it solely reports on system architecture and system demo. A previous study presented a similar framework, but it was specifically dedicated to outdoor applications in wide areas, particularly for smart city scenarios [34]. In contrast, this proposed system is intended for indoor areas. The scientific advancement highlighted by this system is the visualization purpose of the dashboard.

Future study will encompass the evaluation of other performance metrics and practical performance measurements,

as identified by Xia et al. These metrics include accuracy, precision, complexity, robustness, scalability, and costs [43]. Several existing RSSI-based localization methods can be incorporated to enhance the proposed system and achieve an optimal balance. These methods include fingerprinting, distance-based approaches, statistical techniques, machine learning, deep learning, etc. Exploring these algorithms will allow for the identification of the most suitable approach within system.

V. CONCLUSION AND FUTURE WORKS

A significant area of study in recent years has been the development of Wi-Fi tracking system driven by the increasing number of smartphone users. People tend to be constantly connected to the internet through various sources, including free Wi-Fi spots. Therefore, there is a growing interest in tracking individuals using the signals emitted by their smartphones. This study focuses on designing, implementing, and demonstrating Wi-Fi Tracker system specifically for indoor crowd monitoring. System comprises two main subsystems, namely, tracker node and the server. To utilize system, users must place a minimum of three tracker nodes in a specific location to establish wireless networks. These tracker nodes serve as wireless sensors that scan smartphone packet request data. Simultaneously, the server and an online dashboard must be prepared to display real-time data. System captures three crucial pieces of information, namely, Received Signal Strength Indicator (RSSI), Media Access Control (MAC) address, and timestamp of the smartphones. These data are then transmitted from tracker node to the server. Once received, the server performs computations on the data, including processing MAC address, timestamp, and RSSI. By implementing a localization algorithm configured through the web-based dashboard, system can predict the location of smartphones and analyze their distribution. The dashboard is accessible through a specific PC using a unique web address.

The primary significance of the described system lies in its ability to capture and analyze MAC addresses and RSSI instances. However, the challenge posed by MAC randomization is an important consideration for future work. Nowadays, most smartphones employ MAC randomization techniques to prevent Wi-Fi tracking. This behavior involves broadcasting a randomized MAC address instead of the actual one, making it challenging to track and identify devices accurately. In practice, this could result in an influx of fake users generated by the same smartphone, particularly in scenarios where two users are close. Addressing this issue and developing strategies to differentiate between genuine and fake users in real-world situations is essential.

ACKNOWLEDGMENT

A Knowledge Based Framework for Cardiovascular Disease Prediction

Abha Marathe, Dr. Virendra Shete, Dr. Dhananjay Upasani

Department of Electronics and Telecommunication Engineering, MIT School of Engineering and Sciences, Pune, India

Abstract—Cardiovascular disease has become more concern in the hectic and stressful life of modern era. Machine learning techniques are becoming reliable in medical treatment to help the doctors. But the ML algorithms are sensitive to data sets. Hence a Smart Robust Predictive System is almost essential which can work efficiently on all data sets. The study proposes ensemble classifier validating its performance on five different data sets- Cleveland, Hungarian, Long Beach, Statlog and Combined datasets. The developed model deals with missing values and outliers. Synthetic Minority Oversampling Technique (SMOTE) was used to resolve the class imbalance issue. In this study, performance of five individual classifiers – Support Vector Machine Radial (SVM-R), Logistic Regression (LR), Naïve Bayes (NB), Random Forest (RF) and XGBoost, was compared with five ensemble classifiers on five different data sets. On each data set the top three performers were identified and were combined to give ensemble classifiers. Thus, in all total 25 experimentation were done. The results have shown that out of all classifiers implemented, the proposed system outperforms on all the data sets. The performance was validated by 10-fold cross validation. The proposed system gives the highest accuracy and sensitivity of 87% and 86% respectively.

Keywords—Machine learning; ensemble classifier; cardiovascular disease; performance metrics; classifier techniques

I. INTRODUCTION

The urbanization of the population in the world resulted in the increase in the urban population from 37% in 1970 to the projected 61% in 2025[1]. One of the major impacts of such lifestyle is cardiovascular disease-CVD. According to WHO [2] 17.9 million people died in 2019 because of CVD which is nearly 32% of world-wide deaths. For predicting the CVD risk, different traditional risk calculators are used. They assign certain weights to the risk factors and calculate the risk scores. But these calculators have limitation that they are population specific as certain population was considered in the respective cohort study. Also, the risk factors considered are different for different calculators. The decisions given by these calculators differ on the same population [3], hence they are not consistent as well. Therefore, designing a robust system which is applicable for all type of population is the need of the hour. This can be done with the help of ever evolving and reliable sophisticated machine learning and deep learning approaches. Because of manual constraints, many modern age researchers moved towards these approaches. These algorithms are sensitive to data sets. The literature surveyed has revealed that for all different dataset different machine learning techniques were found to be different. The objective of the study is to propose a novel robust algorithm which works on diverse

dataset efficiently. This proposed algorithm is a uniquely developed ensemble classifier of three individual classifiers Random Forest, Support Vector Machine Radial and XGBoost. The performance was validated on five different datasets to prove its consistency.

The paper is divided into six sections. Besides Introduction, Section II discusses about the work done till date, Section III focuses on the proposed system, Section IV contains different evaluation parameters used for classifier performance, Section V reveals the results and their discussions and the last Section VI is the conclusion and future scope of the study.

II. RELATED WORK

In past few decades many Machine learning techniques have been used for prediction of heart disease. Many studies involved the comparison of traditional CVD risk calculators with different Machine learning algorithms. Many studies of heart disease prediction used cohort data set. The comparison of traditional CVD risk calculator models with different machine learning models[4] used nearly 30000 subjects from eastern China who were having high risk of CVD for 3-year risk assessment. Random forest was found to be the best with AUC of 0.787. Similarly, in the other study from Korea 4699 subjects were extracted from Korean National Health Insurance Service Health Screening Database. Out of all the 10 ML algorithms applied, XGBoost, Gradient Boost (GB) and RF with AUC nearly 0.81 performed even better than the existing risk models- Framingham and ACC/AHA American College of Cardiology /American Heart Association risk model [5]. Another cohort study based on same population compared the Pooled cohort equations, Framingham risk model and QRISK3 model with different machine learning algorithms. Neural network was found to have highest C-statistics of 0.751[6]. Another study from Athens, Greece which used 10 years of follow up compared the machine learning techniques with statistical approach of Hellenic Score. The Random Forest algorithm gave the best results [7]. One more study where electronically recorded data by UK National Health Service (NHS) was used. The performance was validated by Harrell's c-statistic. The traditional ACC/AHA model was compared with different ML algorithms like Random Forest, Logistic Regression, Gradient Boosting and Neural Networks. AUC-c statistics was found to be best for Neural network with 0.764 value.[8]. Another cohort study from UK compared the Framingham model, Cox proportional Hazard model and ML algorithms like SVM, RF, NN, AdaBoost, Gradient boosting and Auto prognosis-advanced Bayesian optimization technique to predict the

CVD. The missing values were addressed by Miss Forest algorithm. Auto prognosis performed best out of all the techniques compared [9]. Cohort study for CVD prediction was carried out in Northern California with 32192 patients. Atherosclerotic CVD i.e. ACVD patients were also included in the study. The machine learning algorithms like RF, GBM, XGBoost and logistic regression were compared. XGBoost demonstrated highest AUC 0.70 (95% CI 0.68 to 0.71) in the full CVD cohort and AUC 0.71 (95% CI 0.69 to 0.73) in patients with ASCVD, with comparable performance by GBM, RF and Regression [10]. Apart from cohort studies many researchers used the data sets which are directly provided by the data providers like Cleveland, Hungarian, long Beach, Switzerland, Statlog etc. These data sets are available on UC Irvine Machine learning Repository. There are 76 attributes out of which most relevant 14 attributes are provided by the data providers. Machine learning algorithms are very much sensitive to data sets. To get high efficiency and reliability the data sets need to be properly formed. Before implementing any algorithm, data preprocessing is a must. Data Preprocessing includes steps of data cleaning like addressing the missing values, identifying the outliers, checking for duplicate records etc. In many real-life problems data imbalance is a major challenge in front of the researchers. Specifically, for a medical study like disease detection the data points with one class i.e., normal, and healthy person is more as compared to the patient suffering from a particular disease. This results in class imbalance. Hence before application of any algorithm balancing the data by addressing this data skew becomes a need. Such data preprocessing seen in different studies often leads in better results. In [11] Cleveland data set which is most widely used data set was used for prediction of heart disease. The authors generated artificial records in 5%, 10%, 20% and 50%. They proposed a data duplicate finder algorithm which removes the duplicates in the record. The decision tree C5.0 was used as a classifier which gives the better results for the data set without duplicates as compared to with duplicates. Like the duplicate records, the missing values and outliers are very crucial to handle. These missing values can be either removed with no information loss or can be imputed. In [12], the missing values were imputed by Mean whereas the outliers were identified by Boxplot and were removed. The class imbalance problem was solved by SMOTE technique. Such imbalance in the data set of Framingham data set was balanced by Random Oversampling examples in [13]. The AUC was used as a performance metrics. It reported the maximum achieved AUC by SVM of 0.75. Like the imbalance data set where the number of instances is required to be balanced, the number and the relevance of the attributes is also very important in any predictive system. Addition of irrelevant features in the dataset may misguide the model, hence identification of important attributes and their inclusion in the model is very important. Ample studies are done where different techniques of feature selections and their role in improving the performance of the model are discussed. In [14] different classifiers like Linear Discriminant Analysis-LDA, Decision tree (DT), SVM, GB and RF were used. For feature selection sequential feature selection (SFS) was used. Use of SFS reduces the number of features and hence optimizes

computation time. It was found that for Hungary, Switzerland & Long Beach V and Heart Statlog Cleveland Hungary Datasets, Random Forest Classifier SFS and Decision Tree Classifier SFS achieved the highest accuracy ratings of 100%, 99.40% and 100%, 99.76% respectively. There are other feature selection methods like Fast Correlation-Based Filter Solution (FCBF), minimal redundancy maximal relevance (mRMR), Least Absolute Shrinkage and Selection operator (LASSO), and Relief which were used in [15]. It has used 10 ML algorithms and indicated the best algorithm for feature selection method. Extra tree (ET) classifier was found to be superior amongst all. Accuracy of top performer ET and GB found to be 92.09% and 91.34% when all attributes were considered. With relief feature selection algorithm, the accuracy of ET increased from 92.09% to 94.41% whereas for GB the increase was from 91.34% to 93.36% when FCBF feature selection was applied. Another study used the feature selection methods like Relief Feature selection technique and least absolute shrinkage and selection operator algorithm (LASSO) [16]. The data set contained 13 attributes out of which Random Forest bagging method (RFBM) identified most relevant 10 features and accuracy achieved with this was 99.05%. Addition to these traditional feature selection methods, [17] proposed fast conditional mutual information (FCMIM) technique which is based on selection of features on the basis of features mutual information. The combination of SVM-FCMIM gave the highest accuracy of 92.37%. In [18] the heart disease prediction was carried out by dimension reduction method. PCA and Chi-square analysis with Random Forest shown the best performer with 98.7% accuracy. When weak performers are combined, a strong predictive system can be generated. These are called as Ensembled classifiers. Researchers have experimented with different ensemble classifiers and comparison made with individual classifiers. Studies like [19] weighted majority voting ensemble was used. The weights assigned to the individual classifiers' votes were decided as per their AUC values. The results observed were that this ensembled classifier performed best with AUC value of 83.9 for with laboratory parameters and 83.1 without laboratory parameters. There are three different types of ensemble techniques, Bagging, Boosting and Stacking. In [20] all these techniques along with majority voting were used. With bagging technique, the accuracy improved by 6.92%, with boosting this improvement was found to be by 5.94%, with stacking it improved by 6.93% whereas the highest improvement was observed by majority voting which was 7.26%.

III. PROPOSED SYSTEM

This study proposes five different ensembled classifiers- E₁, E₂, E₃, E₄ and E₅. The composition of these ensembled classifiers is detailed later. The entire work done was divided into four main phases:

- Phase 1: Five different individual classifiers were trained, tested and validated by five different data sets.
- Phase 2: These classifiers were used to construct the five proposed ensemble classifiers.

- Phase 3: These ensembled classifiers were trained, tested and validated by all data sets.
- Phase 4: The individual and the ensembles were compared with different performance metrics and conclusions were drawn.

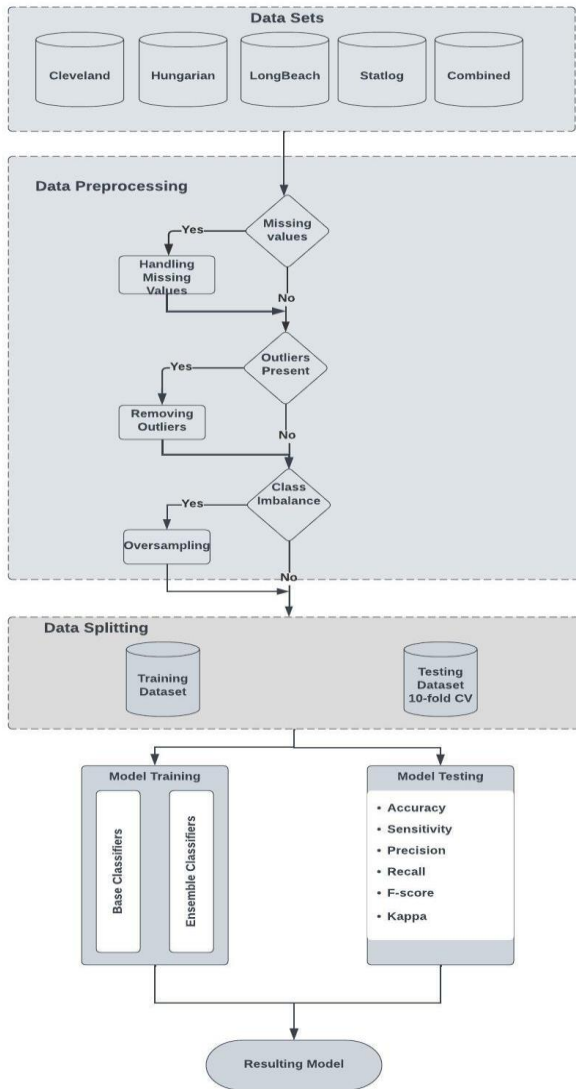

Fig. 1. Proposed system.

The entire system is depicted in Fig. 1. R programming language with R-studio as its IDE is used for this study.

A. Data Set Description

Five different datasets were used for this study-Cleveland, Hungarian, Long Beach, Statlog and Combined datasets taken from UCI Machine Learning repository [21,22]. The Cleveland data set is most used data set by all researchers working on heart diseases. In actual it consists of total 76 attributes, but out of them only 14 are more accurate and are widely used and given by data set provider. The number of instances is 303 with 13 predictors and one response variable. Here the target variable is represented as “num”, where 1

stand for presence of heart disease whereas 0 represents absence of heart disease. Similarly, the other data sets are Hungarian dataset with 294 instances, Long Beach Dataset with 200 instances, Statlog Data set contains 270 instances with same attributes and combination of all datasets with 797 instances.

B. Data Preprocessing

Data cleaning is an important task in any machine learning problem. The quality of data becomes more crucial in medicine area [23]. Data cleaning in this study was done by finding missing values, finding outliers and checking and class imbalance problem. The missing values were removed without loss of information. In second step the outliers were checked and were removed from the data set. Third step was for checking the class imbalance in data set. It happens if there are a greater number of samples belonging to one class as compared to other class which may result into biased classifier. Many methods are presented by different researchers to tackle this problem [24]. In this paper, this issue was addressed by Synthetic Minority Oversampling Technique, i.e., SMOTE.

C. Synthetic Minority Oversampling Technique-SMOTE.

In this method minority class is oversampled by creating Synthetic examples unlike oversampling which generates the duplicate data points [25]. It uses the KNN algorithm to generate these synthetic points. A random sample from minority class is selected. Then one sample from K neighbor is selected and the distance vector between this selected point and current data point is calculated and further multiplied by any random number between 0 to 1. This is then added to current point and synthetic data point is created. Class imbalance was found in Hungarian and Long Beach Data sets. SMOTE technique was used to solve this issue in these two data sets.

D. Proposed Ensemble Classifiers

The study proposes five different ensembled classifiers as discussed below:

E₁: It was designed by combining all the base classifiers. Majority voting scheme was used for the prediction. All the five classifiers were considered for voting with same importance. The class label w was predicted by the decision given by each classifier C_i for every feature vector x as given in (1). Mode indicates majority as per usual statistical meaning.

$$w = \text{mode}\{\text{decisions}(C_1(x), C_2(x), \dots, C_m(x))\} \quad (1)$$

E₂: This ensemble classifier was based on the baseline accuracy of individual classifier. The classifier with highest accuracy was assigned with more weight. This assigned value of weight was then used as a multiplier for the prediction probability of the respective classifier. For a given feature vector x , depending on the probability of the label class the final decision was taken. The weight of the individual classifier was calculated as given in (2).

$$W_i = \frac{A_i}{\sum_i^m A} \quad (2)$$

TABLE I. TOP THREE PERFORMERS

Data Sets	Classifiers				
	RF	NB	SVM-R	LR	XgBoost
Cleveland	✓		✓		✓
Hungarian	✓	✓			✓
Long Beach	✓		✓		✓
Statlog		✓	✓		✓
Combined	✓		✓		✓

Where

A_i : Accuracy of individual Classifier

m : Number of classifiers used

W_i : Weight of individual Classifier

The final prediction probability for each class label is calculated as in (3).

$$p = \sum_i^m (W_i * A_i) \quad (3)$$

The class label having highest probability for a given feature vector was assigned to that vector. All the classifiers are considered in this voting scheme.

Total datasets considered for this study are five. All five individual classifiers were applied to all five datasets. Thus total 25 individual experimentations were done. Then for each data set top three performing classifiers based on their accuracies were identified. The top three classifiers for individual datasets are given in Table I.

Thus, three following different unique combinations of classifiers emerge which were considered for further experimentation.

E_3 : It was the first combination RF+SVM-R+XgBoost. These three classifiers were used for majority voting. Label class w was assigned for a given feature vector given in (4).

$$w = mode\{Decisions(RF, SVM - R, XgBoost)\} \quad (4)$$

e.g., let for any feature vector x , the decisions are as- RF: Class 0, SVM-R: Class 0, XgBoost: Class1. Then the final decision was taken as in (5).

$$w = mode\{0,0,1\} \Rightarrow w = 0: Class 0 \quad (5)$$

E_4 : This was the second unique combination of RF+NB+XgBoost. These three classifiers were used for majority voting. Label class w was assigned for a given feature vector as shown in (6).

$$w = mode\{Decisions(RF, NB, XgBoost)\} \quad (6)$$

E_5 : This was the third unique combination of RF+SVM+XgBoost. These three classifiers were used for majority voting. Label class w was assigned for a given feature vector as in (7).

$$w = mode\{Decisions(NB, SVM, XgBoost)\} \quad (7)$$

The different ensembles are depicted in Fig. 2.

Fig. 2. Construction of ensemble classifier.

IV. EVALUATION PARAMETERS

The evaluation of performance of all the classifiers i.e., individual and ensemble were done by creating an error matrix or Confusion matrix specified in Table II. It shows four different notations True Positive TP these are the patients who are suffering from CVD and the algorithm also predicts the same. The number FN is False negative which shows that these many patients are suffering from disease but they are predicted as they are not suffering. This number needs to be less and costs more in medical studies. False positive FP indicates the number of patients not suffering from disease but identified as they are suffering. True negative refers to the true classification of normal patients. The performance of any classifier is characterized by values of FP and FN. These metrics are discussed below:

TABLE II. CONFUSION MATRIX

		Predicted	
		Positive	Negative
Actual	Positive	TP	FN
	Negative	FP	TN

Accuracy: It is the ratio of total true predictions to total number. It is given by (8)

$$Accuracy = \frac{(TP+TN)}{(TP+FP+FN+TN)} \quad (8)$$

Sensitivity: It is also called as true positive rate. It is the ratio of positive number classified correctly to the total positive instances. It is given by (9).

$$Sensitivity = \frac{(TP)}{(TP+FN)} \quad (9)$$

Specificity: It is defined as true negative rate. It is the ratio of measures of negative number classified correctly to the total negative instances. It is given by (10).

$$Specificity = \frac{(TN)}{(TN+FP)} \quad (10)$$

Precision: It is also known as positive predictive value. It is the ration of proportion of positive number classified correctly to total predicted positive. It is given by (11).

$$Precision = \frac{(TP)}{(TP+FP)} \quad (11)$$

F-measure: It is a measure of model performance that combines precision and recall into single number. It is given by (12).

$$Fmeasure = \frac{(2*Precision*Recall)}{(Recall+Precision)} \quad (12)$$

Kappa: It is the measure which accounts for correct classification due to chance

If $K > 0$: Classification is better than chance classification.

$K < 0$: Classification is not better than chance Classification.

$K = 1$: Perfect Classification.

$K = 0$: Pure chance classification.

V. RESULTS AND DISCUSSIONS

An elaborated discussion of the different results obtained for individual and ensemble classifiers is given below. The various performance metrics are compared and conclusions are drawn. The performance validation of all the models was done by 10-fold cross validation.

A. With Individual Models

The five different individual classifiers- RF, SVM, NB, LR and XGBoost were first applied on all the five data sets. For each data set the top performers based on different performance parameters were identified. On Cleveland data set, XGBoost was observed to be the best performer in terms of accuracy with 87.78% value, followed by RF and SVM-R with 84.44% and 83% of accuracy. Same is true for other performance metric like Specificity and Precision. Though the sensitivity of LR is highest amongst all, but it lags in the other parameters. Hence for Cleveland data set, the top three performers are considered as XGBoost, RF and SVM-R. The performance is given in Table III. For Hungarian data set, XGBoost, RF and NB comes out to be the top 3 performers with 91.26%, 90.29% and 86.41% of accuracy. These models also head in the important parameter i.e., Sensitivity with values 94.5%, 89.47% and 90.20%, Table IV shows the comparison. For the third data set which is Long Beach dataset, SVM Radial performs best with accuracy 88.64%. It also leads in the other parameters like Sensitivity, Specificity and Precision as well. The second topper is XGBoost and RF. Therefore, the top three identified classifiers for Long Beach Data Set are XGBoost, RF and SVM-RBF, shown in Table V. The next data set was Statlog data set. The findings depict that, XGBoost, SVM-R, NB and are top three classifiers. Their accuracy values are 86.42%, 86.42% and 85.19% respectively. The parameters are compared in Table VI.

The last data set considered was Combined data set. It was found that RF performed best from all models with highest accuracy of 89.06%. The next followers were observed as XGBoost and SVM-R. These three classifiers were toppers in the performance parameters like Sensitivity, Specificity and Precision as well apart from accuracy. This is shown in Table VII. Thus, for Cleveland, Hungarian and Statlog dataset it is XGBoost which is best performer in terms of accuracy whereas for Long Beach it is SVM-R and for Combined data set it is Random Forest. The performance parameters averaged on all dataset for all individual classifier is shown in Table VIII.

Fig. 3. Performance comparison of individual classifier.

Fig. 3 shows the performance of individual classifiers. The parameters taken for graphical representations are Accuracy, Sensitivity and F measure.

B. With Ensemble Classifiers

After applying individual models for all data sets, ensemble classifiers were designed based on Majority Voting and Weighted Voting. Firstly, all individual classifiers were considered for voting with same importance which forms Ensemble E1. Then the weighted voting was considered with all models with assigned weight as per the accuracy. This gave second ensemble E2. The next three ensemble were E3, E4 and E5, emerged as the top three performers for all five data sets. It was observed that out of all ensembles, E3 performs best with highest accuracy of 88.89% accuracy and 87.18% sensitivity on Cleveland data set and with 90.29% Accuracy and 89.47% Sensitivity for Hungarian Data set, refer Table IX and Table X respectively. Similarly, for Statlog data set as well, E3 is best performer with Accuracy 86.42% and Sensitivity 83.78%, as given in Table XI.

For Long Beach data set, E5 leads with 88.64% accuracy and sensitivity 90.48%. shown in Table XII. For Combined data set it is E4 which has highest accuracy of 86.88% and sensitivity of 85.62% amongst all ensembles shown in Table XIII. The values of different performance parameters of all ensembles averaged on all data sets are shown in Table XIV. Out of all ensembled classifier, the proposed ensemble classifier i.e., E3 is observed to have highest accuracy, sensitivity, F measure and Kappa values the best ensemble classifier. The graphical information in Fig 4, shows that E3 has highest Accuracy, Sensitivity and F-measure amongst all Ensembles. When all individual and all ensemble classifiers were compared on their average values of all data sets, proposed ensemble E3 was found to be the best amongst all with highest accuracy, sensitivity, F- measure, and high Kappa values as given in Fig 5.

VI. CONCLUSION AND FUTURE SCOPE

This article presents a reliable framework which can be used for predicting the cardiovascular disease. It deals with data cleaning by removing the noise from the data like outliers and missing values. For the Hungarian and Long Beach data to overcome the class imbalance, Synthetic Minority Oversampling Technique-SMOTE was used. Support Vector Machine Radial (SVM-R), Logistic Regression (LR), Naïve Bayes (NB), Random Forest (RF) and XGBoost were first implemented on all five data sets. Then five different ensembled classifiers were constructed. First ensemble classifier E₁ is designed considering all individual classifiers. Based on majority voting the final decision was taken for prediction. For second ensembled classifier E₂, all independent classifiers were considered but the prediction was done based on weighted majority voting. The weights to the classifiers were assigned depending on the accuracy of the classifier. For third, fourth and fifth ensembles, top three performers were identified on all five data sets. Out of these five different combinations of top performers, three unique combinations were selected. Hence, the third classifier E₃

consists of RF, SVM-R and XGBoost. The fourth ensembled E₄ is made up of RF, NB and XGBoost. The fifth one E₅ is constructed with NB, SVM-R and XGBoost. An exhaustive comparison of all individual classifier along with all ensembled classifiers was done. For any machine learning technique, the true classification rate is very important. Hence accuracy was given first importance. But at the same time for any medical study, the False Negative number is crucial. This number should be as less as possible. Therefore, sensitivity parameter is also focused. 10-fold cross validation was performed for validation. The results have shown that the amongst individual classifier XGBoost has performed the best on all data sets with average 86.7% accuracy, 85.3% sensitivity, 87.6% specificity, 86.1% Precision, 85.6% F-measure and 0.73 as Kappa value. The parameters were found to be improved with E₃ ensembled classifier as 87.6% accuracy, 86.0% Sensitivity, 89.0% Specificity, 87.8% Precision, 86.9% F-measure and 0.75 as Kappa value. Thus, SRPS proves out to be most reliable for CVD prediction amongst all discussed. The future endeavor of the study could be the use of subset of the data set in terms of the attributes. In this study, all features were used for diagnosis. The further improvement can be made by using different feature selection methods like Wrapper method, Correlation based feature selection method, etc. Also, Principal Component Analysis can be used to reduce the dimension. Further, this proposed ensembled classifier can be used for other disease prediction as well.

ACKNOWLEDGMENT

We would like to acknowledge the guidance and the support given by MIT ADT faculty, research colleagues during the development of manuscript and MIT ADT library for provision of various resources.

Unsupervised Bearing Fault Diagnosis via a Multi-Layer Subdomain Adaptation Network

Nguyen Duc Thuan, Nguyen Thi Hue, Hoang Si Hong*

School of Electrical and Electronic Engineering, Hanoi University of Science and Technology, Hanoi, Vietnam

Abstract—Bearings play a crucial role in the functioning of rotating machinery, making it essential to monitor their condition for maintaining system stability and dependability. In recent years, intelligent diagnostic techniques for bearing issues have made significant progress due to advancements in artificial intelligence. These methods rely heavily on data, requiring data collection and labeling to develop the learning model, which is often highly challenging and nearly infeasible in industrial settings. As a result, a domain adaptation-based transfer learning approach has been suggested. This approach aims to minimize the difference between the distribution of accessible data and the unlabeled real-world data, enabling the model trained on public data to function effectively with actual data. In this paper, we introduce a sophisticated subdomain adaptation technique for cross-machine bearing fault diagnosis using vibration, termed multi-layer subdomain adaptation. Verification experiments were conducted, and the findings indicate that the proposed approach offers relatively high accuracy up to 97.47% and excellent transferability. Comparative experiments revealed that the proposed method is a superior technique for bearing fault diagnosis and slightly outperforms other methods (3-5%) in both predictive and noise-ignore capabilities. Comprehensive validation experiments were conducted using the HUST dataset.

Keywords—Bearing fault; fault diagnosis; domain adaptation; transfer learning

I. INTRODUCTION

Bearings are an essential component in rotating machinery. Bearing-related failures account for up to 50% of total machine failures [1]. Precise detection of rolling element bearing faults is crucial for ensuring the reliable operation of rotating machinery. This is because any failure in the bearing could directly impact the functioning of the entire machine. Luckily, modern machine learning techniques have helped make significant progress in data-driven approaches to bearing fault diagnosis [1]. As a result, traditional methods that rely heavily on expert knowledge are no longer required. This has attracted considerable attention and is an area of extensive research [2].

The traditional data-driven approaches for fault diagnosis have been successful in achieving accurate results. However, this is only possible when sufficiently labeled samples or data are available (vibration, acoustic emission, current, etc.). To guarantee high accuracy in fault diagnosis, the testing data must match or is similar in probability distribution to the dataset used for training [3]. This is important because the fault diagnosis models need to be carefully trained and may be difficult to apply directly to different machines or operating conditions.

Transfer learning is a promising tool to overcome the limitations of traditional data-driven approaches for fault diagnosis. It involves transferring knowledge from one task to another, and one commonly utilized technique is domain adaptation [3]. To extract good feature representation across domains, various methods have been proposed, such as the deep adaptive network (DAN) introduced by Long et al. [4] and the hybrid distance-guided adversarial network (HDAN) proposed by Han et al. [5]. However, current domain adaptation methods are limited to diagnosing faults within the same equipment under varying conditions, making it difficult to obtain specific data to train the expected fault diagnosis model. Therefore, transfer fault diagnosis across different machines has become increasingly important. Song et al. [6] introduced a retraining strategy-based domain adaptation network, while Guo et al. [7] utilized a one-dimensional generation adversarial network (MLI-D-GAN) to jointly train generated and real damage data, enabling sufficient labeled data to overcome the limitation of existing models. Recently, Feng et al. [8] presented a domain adversarial similarity-based meta-learning network (DASMN) and Li et al. [9] developed an optimal ensemble deep transfer network (OEDTN) that utilized maximum mean discrepancy (MMD) with different kernels to construct multiple diverse DTNs.

Although transfer fault diagnosis across machines has been achieved with existing methods, there are still weaknesses in terms of fault diagnosis accuracy. The reason is that most of the mentioned methods are based on reducing the discrepancy in feature distribution. They may only adjust the overall distribution since the criteria function only accounts for the statistical parameters of the entire domain and not for each individual class/subdomain. Thus, to overcome this limitation and enhance the transfer fault diagnosis performance across different machines, we introduce a novel multi-layer adaptation network based on LMMD [10] criteria over layers in this article. The methodology is in Section II and experiments are in Section III. The main contributions of this paper are:

- We propose a novel multi-layer subdomain adaptation method that adjusts the domain distribution in each layer of the shared feature extraction module.
- We evaluate the performance of the proposed method on HUST bearing dataset and do comparative experiments to verify its ability to improve fault diagnosis accuracy across different bearings/machines.

II. METHODOLOGY

A. Problem Description

In this section, we start by discussing the issue of bearing fault diagnosis across machines. We begin by assuming that there is a rolling bearing monitoring dataset labeled from one (source) machine $D_s = \{(x_i^s, y_i^s)\}_{i=1}^{N_s}$, which we call the source domain data. The dataset contains N_s samples with labels y_i^s which belong to the labeled space Y_s . The samples x_i^s belong to the sample space X^s and are governed by the marginal probability distribution $P_s(X^s)$. We also have another rolling bearing monitoring dataset without labels from another (target) machine, called the target domain data $D_t = \{(x_i^t)\}_{i=1}^{N_t}$, which contains N_t samples and all samples are governed by the marginal probability distribution $P_t(X^t)$. Since the two datasets come from different machines, their marginal probability distributions are different, and we have $P_s \neq P_t$.

The main focus of this paper is on the transfer fault diagnosis of rolling bearings across different machines i.e., from the source to the target domain. Traditional data-driven methods rely solely on the source domain data with labels to train a classification neural network, which is a nonlinear mapping between the sample space X^s and the labeled space Y^s [11]. However, directly using the established nonlinear mapping/network to recognize the health status of unlabeled samples from the target domain will yield low fault diagnosis accuracy, as the two domains have different data distributions [12]. Thus, to improve the fault diagnosis accuracy, it is crucial to train the fault diagnosis model using not just labeled data from the source domain but also unlabeled data from the target domain. This presents the challenge of learning domain-invariant features by minimizing the data distribution discrepancy between the source and target domain data. As a

result, knowledge obtained from one machine can be used for fault diagnosis in another machine.

B. Proposed Method

In this study, a multi-layer subdomain adaptation model is developed to transfer fault diagnosis between different bearings. As shown in Fig. 1, our goal is to train a feature extractor that can accurately diagnose bearing faults for data in the target domain. The training process involves iteratively calculating the objective functions and updating the model parameters using the backpropagation algorithm. Afterwards, we obtain a trained model that can predict the label of new data in the target domain.

The training process is described as follows: the training data consists of labeled source data (x^s, y^s) and unlabeled target data (x^t) . Different domains use the same feature extractor, consisting of three one-dimensional convolutional layers and two fully connected layers (see Table I). The output of the feature extractor is the predicted label for the input data, used to calculate the objective functions based on the training objective. The training objective is to classify faults and minimize the distance of probability distribution between the outputs of different domains. Therefore, there are two objective functions: the objective function for classification (L_{cls}) and the objective function for adaptation (L_{ada}). The classification objective function is calculated based on the true label and predicted one of the data in the source domain. The adaptation objective function is calculated by sum of the distribution discrepancies (LMMD) between hidden features from different domains. This is a new and important aspect of this method, instead of relying solely on the distribution distance of features in the last layer. The important concept of computing the distribution discrepancy will be clarified in Section II C.

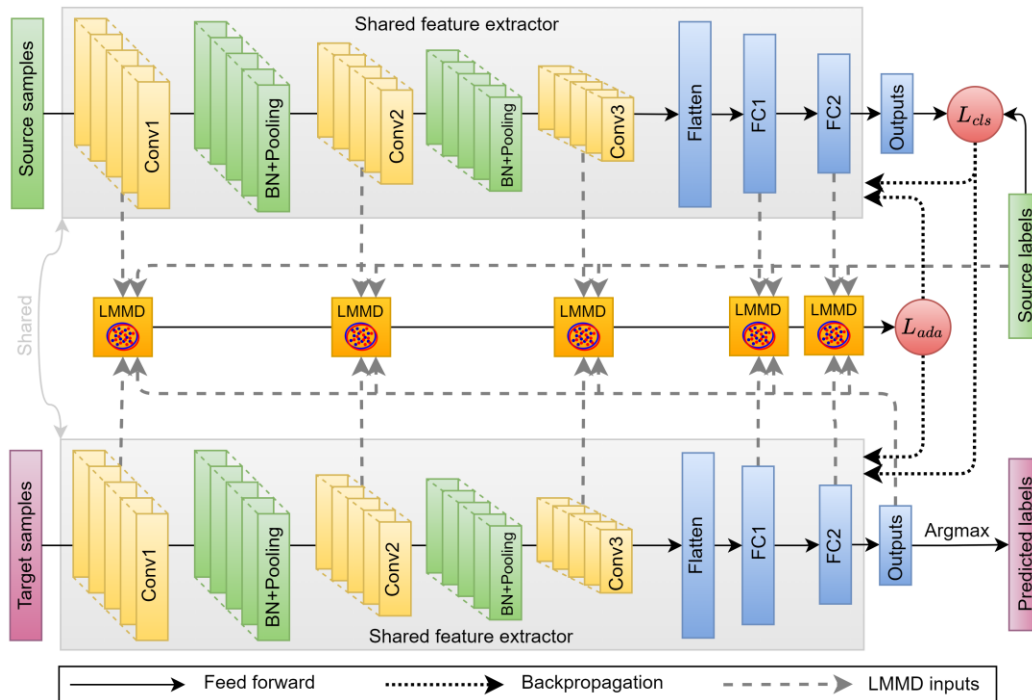

Fig. 1. Overview of the proposed method.

TABLE I. SPECIFICATION OF THE FEATURE EXTRACTOR

No.	Layer	Filter size	Output size	Activation function	BN/Pooling
0	Input	-	(4096, 1)	-	-
1	Conv1	(15, 1, 16)	(4096, 4)	ReLU	BN+Pooling
2	Conv2	(5, 16, 16)	(1024, 8)	ReLU	BN+Pooling
3	Conv3	(3, 32, 16)	(256, 16)	ReLU	-
-	Flatten	-	(4096, 1)	-	-
4	FC1	(4096, 512)	(512, 1)	ReLU	-
5	FC2	(512, 64)	(64, 1)	ReLU	-
6	Output	(64, 4)	(4, 1)	Softmax	-

BN: Batch Normalization

C. Loss Function

The objective of the model is fault classification and domain adaptation based on minimizing the distribution distance. For the classification objective function, it relies on the well-known cross-entropy function:

$$L_{cls} = - \sum_{i=1}^n y_i \log(\hat{y}_i) \quad (1)$$

where n is the number of classes, y_i is the ground-truth label, and \hat{y}_i is the softmax probability for the i -th class. As for the adaptation objective function, LMMD is an MMD-based criterion for measuring distribution discrepancy [10]. The MMD formula for calculating the distribution distance is described as follows:

$$MMD(P_s, P_t) \triangleq \|\mathbf{E}_{P_s}[\Phi(x^s)] - \mathbf{E}_{P_t}[\Phi(x^t)]\|_H^2 \quad (2)$$

where P_s, P_t denote the distribution of source and target domain; \mathbf{E} denotes the expectation; H denotes the reproducing kernel Hilbert space; $\Phi: X^{s,l}, X^{t,l} \rightarrow H$. In practice, an estimate of the MMD compares the square distance between the empirical kernel mean embeddings as:

$$MMD(P_s, P_t) \approx \frac{1}{N_s^2} \sum_{i=1}^{N_s} \sum_{j=1}^{N_s} k(x_i^s, x_j^s) + \frac{1}{N_t^2} \sum_{i=1}^{N_t} \sum_{j=1}^{N_t} k(x_i^t, x_j^t) \quad (3)$$

where N_s, N_t stand for the number of samples in source and target domain; the kernel k means $k(x_i, x_j) = \langle \Phi(x_i), \Phi(x_j) \rangle$. The MMD-based techniques primarily emphasized the alignment of overall distributions while disregarding the connections between subdomains within the same category. It is crucial to consider the relationships between these relevant subdomains and align their distributions between the source and target domains. To achieve this, we considered the Local Maximum Mean Discrepancy (LMMD) method in (4). In (4), the letter c denotes the class label. Eq. (4) is then estimated as (5). In (5), $\omega_i^{sc}, \omega_j^{tc}$ stand for the weight of x_i^s, x_j^t belonging to class c , are computed as (6). In (6), y_{ic} is the c -th entry of the output vector y_i with input x_i .

$$LMMD(P_s, P_t) \triangleq \mathbf{E}_c \|\mathbf{E}_{P_s^c}[\Phi(x^s)] - \mathbf{E}_{P_t^c}[\Phi(x^t)]\|_H^2 \quad (4)$$

$$LMMD \approx \frac{1}{C} \sum_{c=1}^C \left\| \sum_{i=1}^{N_s} \omega_i^{sc} \Phi(x_i^s) - \sum_{j=1}^t \omega_j^{tc} \Phi(x_j^t) \right\|_H^2 \quad (5)$$

$$\omega_i^c = \frac{y_{ic}}{\sum_{j=1}^N y_{jc}} \quad (6)$$

Afterward, the adaptation loss L_{ada} is computed as (7). It must be noted that for the convolution layer, the feature maps are flatted before calculating the LMMD. It means that layer number 3 and the next flatten layer utilize the same LMMD.

$$L_{ada} = \sum_{i=1}^5 LMMD \text{ at layer } i \quad (7)$$

Finally, the overall objective function in (8) is the sum of the two aforementioned objective functions. With this, the model can maintain its classification ability while also adjusting the embedding features to a common distribution.

$$L = L_{cls} + L_{ada} \quad (8)$$

III. EXPERIMENTS

A. HUST bearing Dataset

The verification experiments were conducted exclusively on the HUST bearing dataset as in our previous work [1]. What makes this dataset especially advantageous is that it contains fault signals from five bearings across different types of defects and working conditions. The data acquisition system is shown in Fig. 2. The data acquisition system includes a 1-HP induction motor, an accelerometer of PCB352C33 and a measurement module with torque and velocity sensors.

Because of this, we can assess the performance of our proposed method for various domain adaptation tasks across different bearings or machines. For the purpose of test analysis, we selected bearings of types 6205, 6206, and 6207 with a no-load shaft speed. Each type of bearing includes four health conditions: normal (N), inner race fault (I), outer race fault (O), and ball fault (B). The faults were generated using the wire-cutting method, which creates cracks with a size of 0.2 mm. The accelerometer captured the vibration signals at a sampling rate of 51,200 samples per second for 10 seconds. To augment training/test data, the raw vibration signal was truncated into segments with a length of 4096 with 75% overlap. Then we obtain 496 segments/class/bearing with each segment as an input of the model.

Fig. 2. HUST bearing data acquisition system [1].

The adaptation tasks are defined as S5-6, S5-7, S6-5, S6-7, S7-5, S7-6, M5, M6, and M7. Each task name includes 2 parts: the prefix (S: single-source | M: multiple-source), and the suffix to supplement information for the prefix (5: 6205 | 6: 6206 | 7: 6207). In detail, for single-source tasks, the suffix denotes the source bearing and the target one e.g., 5-6 means that the source bearing is 6205 and the target one is 6206. As for multiple-source tasks, the suffix number denotes the target bearing, while the source is the remaining two bearings. For each task, 80% source data and 80% target data are used to train the network, while the remaining 20% source data is used to validate and 20% target data is used to test/evaluate.

B. Experiments Setup

In this section, we describe the experimental setup. The first experiment is to evaluate the effectiveness of the proposed method in transferring knowledge to adaptive tasks defined in Section III A. The second experiment is an extension of the first experiment with added multi-level noise components in the training/testing data. The purpose of the second experiment is to assess the proposed method's performance in the presence of noise, which is common in real-world scenarios. Finally, the third experiment aims to compare the proposed method's performance with other methods to demonstrate its superiority in adaptability. All models were trained/evaluated on the same HUST bearing dataset to ensure fairness in comparison. The metrics for model evaluation are (overall) accuracy (9), precision (1), sensitivity (11), F1-score (12), confusion matrix, and t-SNE visualization to observe the feature distribution of source and target domains [13].

$$Accuracy = \frac{No. of correct predictions}{No. of all samples} \quad (9)$$

$$Precision = \frac{No. of true positive predictions}{No. of all positive predictions} \quad (10)$$

$$Sensitivity = \frac{No. of true positive predictions}{No. of all positive samples} \quad (11)$$

$$F1 - score = 2 \times \frac{Precision \times Sensitivity}{Precision + Sensitivity} \quad (12)$$

The verification experiments were conducted on a computer with the following specifications: an Intel i7 12700F CPU, 16 GB of RAM, and a 24GB Nvidia GeForce GTX 3090 GPU. These experiments were implemented utilizing the PyTorch framework from the source <https://github.com/ZhaoZhibin/UDTL> [14]. For the training process, the hyperparameters were configured as follows: the number of epochs was set to 100, the batch size at 64, the learning rate to 0.001, the momentum at 0.9, the optimizer was Adam, and the weight decay was 0.00001. To provide a reliable measure of accuracy, each model was re-trained 10 times, and the results were reported as mean and standard deviation values.

IV. RESULTS AND DISCUSSIONS

In the first experiment, we evaluated the performance of the proposed method across all tasks. Table II shows the overall accuracy, precision, sensitivity, and F1-score of the model with the test data in the target domain. It can be seen that the overall accuracy of the single-source tasks is quite good, ranging from 86% to 96%. Specifically, task S6-5 had the lowest accuracy of 86.62%, while task S6-7 had the highest accuracy of 96.46%. Furthermore, the inversely related tasks (e.g. S5-6 and S6-5) had similar accuracy. This reveals that the result of transfer learning depends on the relationship between domains and not on which domain is the source and which is the target.

Regarding other metrics for single-source tasks, we can see that precision, sensitivity, and F1-score are relatively consistent for each task. The magnitude of these metrics varies by no more than 1%. This is achieved by the class balance in the test data set.

TABLE II. TRANSFER FAULT DIAGNOSIS RESULTS WITH THE PROPOSED METHOD

Task	Overall accuracy (%)	Precision (%)	Sensitivity (%)	F1-score (%)
S5-6	88.38	89.43	88.38	88.90
S5-7	92.93	93.78	92.93	93.35
S6-5	86.62	87.91	86.62	87.26
S6-7	96.46	96.60	96.46	96.53
S7-5	89.14	90.27	89.14	89.70
S7-6	94.44	94.64	94.44	94.54
M5	92.42	92.75	92.42	92.59
M6	95.71	95.87	95.71	95.79
M7	97.47	97.54	97.47	97.51

In Table II, for multi-source tasks, it is easy to see that their performance is significantly improved compared to the single-source tasks. Task M5 achieved 92.42% accuracy, higher than Sx-5 tasks due to more contribution from the source domain. Tasks M6 and M7 both scored above 95% on all criteria. This superiority is achieved through an increase in source data, which can compensate for each other's deficiencies to help the model learn more effectively. From this, we can conclude that enhancing the source domain data will improve the model's diagnostic capabilities. Additionally, we can observe a trend where the accuracy of multi-source tasks depends on the shared target domain of the single-source tasks. This means that the Mx predictive ability will be a function of the Ma-x abilities.

Fig. 3 illustrates the confusion matrices corresponding to the considered tasks. Unlike overall accuracy, the confusion matrix provides a clearer explanation of the accuracy for each class, with the value in each cell being the number of instances. At a glance, we can see that the highest accuracy is concentrated on classes I and O in all tasks. We believe this is due to the clear defect patterns in these two classes, making

them easier to identify for the model. In the dataset, defects related to class B are difficult to predict accurately and are often confused with faults in class I. This phenomenon is seen from 6205-related tasks i.e., the fault characteristic of class I and B of bearing 6205 may be hard to distinguish (e.g., the fault frequency). For the case of the healthy bearing, tasks M6 and M7 achieve almost perfect accuracy, while tasks M5, S6-5, S7-5, S5-6, and S5-7 show worse accuracy. It can be speculated that there are issues with the N data for bearing 6205 (e.g., a small crack may exist). However, this is not as serious as misclassifying failures as non-failures.

Fig. 4 visualizes the distribution of features in the final layer of the neural network in the Descartes coordinate system using a visualization method called t-distributed stochastic neighbor embedding (t-SNE), which is a dimensionality reduction algorithm. We observe that the mispredictions in the classes occur due to the mismatch between the source and target class distributions of the data. To address this issue, some studies have proposed labeling some of the training data in the target domain, which can be further explored in [15].

Fig. 3. Confusion matrices for all tasks.

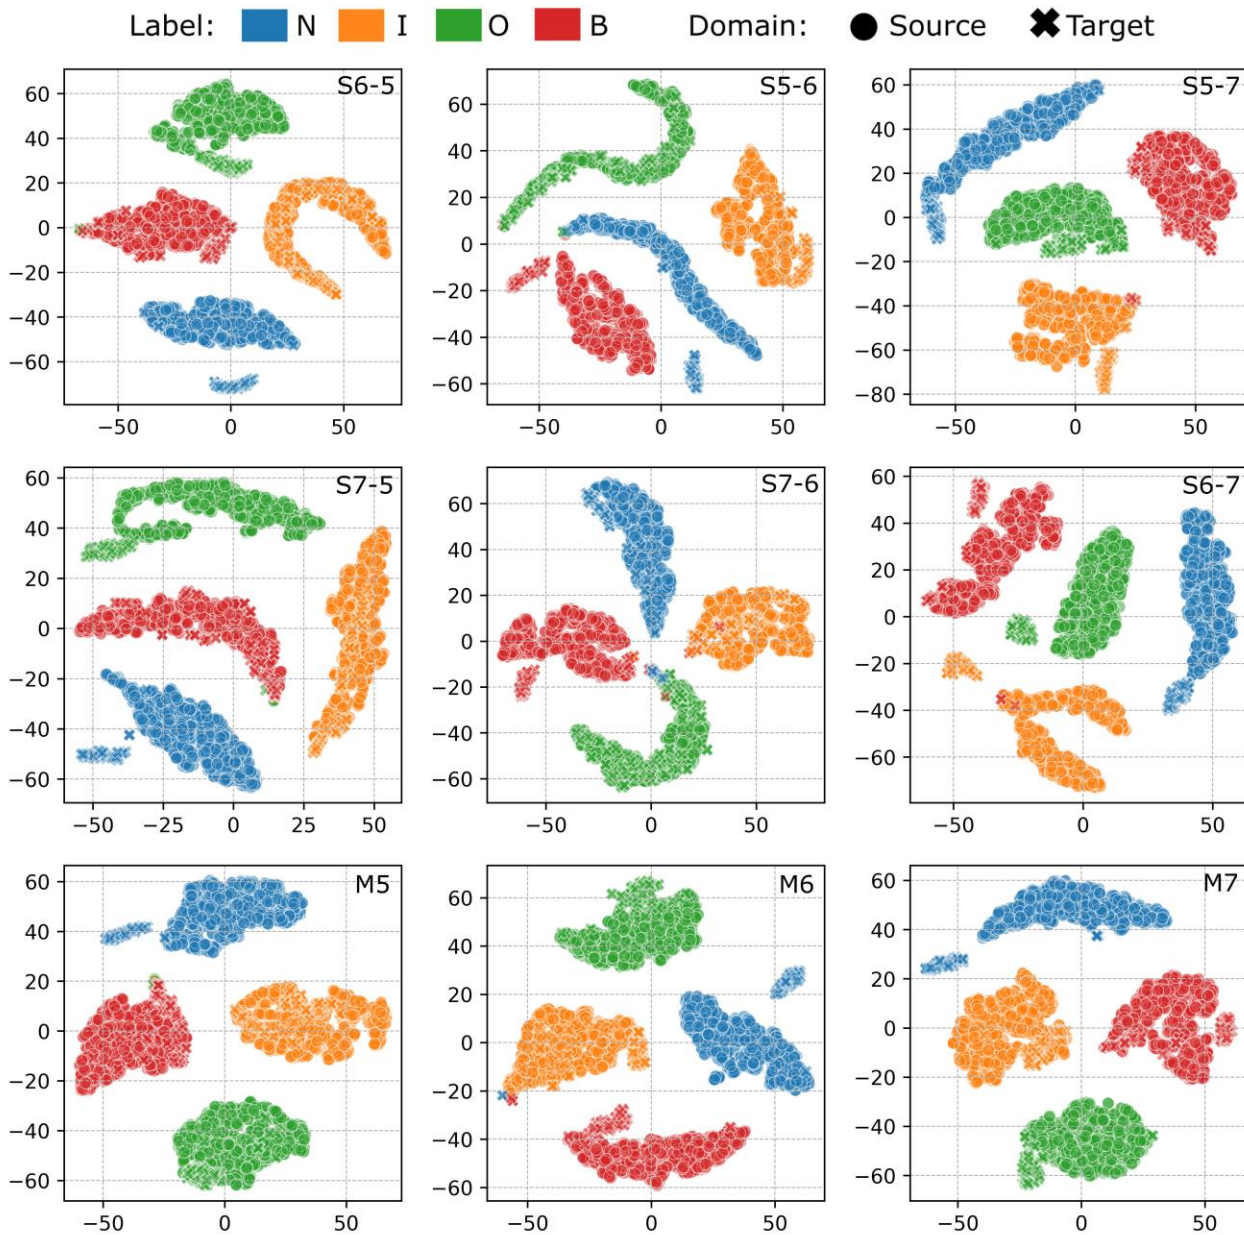

Fig. 4. t-SNE visualization of the last features in all tasks.

In the second experiment, we examined the performance of our proposed method in the presence of noise in the data. We added Gaussian white noise with a mean of 0 and a standard deviation of 1 to the training and test data. To vary the intensity of the noise, we scaled the amplitude by different coefficients ranging from 0 to 0.9 with a step of 0.3. In the third experiment, we compared our proposed method with other popular domain adaptation methods, including JMMD [16], MKMMD [17], CORAL [18], DANN [19], and CDAN [20], in the presence of noise. The effect of noise was also included to provide a comprehensive comparison. The results of the experiments demonstrated the effectiveness of our proposed method in the presence of noise. Our method outperformed the other popular domain adaptation methods, particularly as the

intensity of the noise increased. The results are presented in Fig. 5.

In Fig. 5, as the level of noise increases, all examined methods experience a decrease in performance. Multi-source tasks show a decrease from 92-97% to 89-93%, while single-source tasks experience a decrease from 86-96% to 81-92%. Notably, while the other methods experience a significant accuracy drop of up to 10%, our proposed method only experiences a slight decrease of around 5% for all tasks. This indicates that our method is less affected by noise, promising stability and high reliability. Regarding the correlation between the methods, it is truly difficult to distinguish because they differ slightly in their predictive capabilities.

Fig. 5. The performance of different methods under different levels of noise. Noise levels are: (a) 0; (b) 0.3; (c) 0.6; (d) 0.9.

Nonetheless, we still recognize the effectiveness of our proposed method because, in all cases, it slightly outperforms the other methods. Our success can be attributed to taking into account the varying distributions between classes (subdomains), which sets us apart from other approaches. Furthermore, our approach is reinforced by a thorough examination of all hidden layers, an aspect that has been overlooked by many previous studies. Going forward, we aim to explore algorithms that improve adaptability in scenarios where distributions cannot be homogenized.

V. CONCLUSION

This study introduces a new method based on transfer for fault diagnosis in bearings across various machines, named weighted multi-layer subdomain adaptation. Due to the weakness of traditional metrics as MMD for feature alignment between different domains, we inspired by LMMD to develop a new model architecture for the task of domain adaptation. This method is validated using HUST bearing dataset for nine transfer fault diagnosis tasks where labeling of target domain data is not required. Verification experiments were conducted, and the findings indicate that the proposed approach offers

relatively high accuracy up to 97.47% and excellent transferability. Comparative experiments revealed that the proposed method is a superior technique for bearing fault diagnosis and slightly outperforms other methods (3-5%) in both predictive and noise-ignore capabilities.

Abstract—The accurate and real-time detection of road lanes is crucial for the safe navigation of autonomous vehicles (AVs). This paper presents a novel approach to lane detection by leveraging the capabilities of the Mask Region-based Convolutional Neural Network (Mask R-CNN) model. Our method adapts Mask R-CNN to specifically address the challenges posed by diverse traffic scenarios and varying environmental conditions. We introduce a robust, efficient, and scalable architecture for lane detection, which segments the lane markings and generates precise boundaries for AVs to follow. We augment the model with a custom dataset, consisting of images collected from different geographical locations, weather conditions, and road types. This comprehensive dataset ensures the model's generalizability and adaptability to real-world conditions. We also introduce a multi-scale feature extraction technique, which improves the model's ability to detect lanes in both near and far fields of view. Our proposed method significantly outperforms existing state-of-the-art techniques in terms of accuracy, processing speed, and adaptability. Extensive experiments were conducted on public datasets and our custom dataset to validate the performance of the proposed method. Results demonstrate that our Mask R-CNN-based approach achieves high precision and recall rates, ensuring reliable lane detection even in complex traffic scenarios. Additionally, our model's real-time processing capabilities make it an ideal solution for implementation in AVs, enabling safer and more efficient navigation on roads.

I. INTRODUCTION

The rapid development of autonomous vehicles (AVs) has the potential to revolutionize the transportation industry by providing safer, more efficient, and more convenient means of transportation [1]. Central to the success of AVs is their ability to perceive and understand the environment around them. Among various perception tasks, the accurate and real-time detection of road lanes plays a critical role in ensuring the safe navigation of AVs. Lanes are used to guide the vehicles in maintaining their position on the road, adhere to traffic rules, and avoid collisions with other vehicles or obstacles [2].

Traditional lane detection methods, such as edge detection and Hough transform, have shown limited success due to their

sensitivity to noise, poor adaptability to varying environmental conditions, and inability to handle complex traffic scenarios [3-5]. With the advancement in deep learning, convolutional neural networks (CNNs) have demonstrated promising results in various computer vision tasks, including lane detection [6]. However, existing CNN-based lane detection methods still face challenges in terms of real-time processing, adaptability to diverse traffic scenarios, and robustness under varying environmental conditions.

Given the limitations of current lane detection techniques, there is a need for a more efficient, robust, and real-time solution that can address the challenges posed by diverse traffic scenarios and environmental conditions [7]. The Mask Region-based Convolutional Neural Network (Mask R-CNN) model, which was originally designed for object detection and segmentation, has demonstrated remarkable performance in various computer vision tasks [8]. Its ability to precisely localize and segment objects in images makes it a suitable candidate for lane detection. However, the application of Mask R-CNN in the context of lane detection has not been fully explored.

In this paper, we propose a novel approach to lane detection by adapting the Mask R-CNN model to specifically address the challenges associated with detecting lanes in real-world traffic scenarios. Our goal is to develop a robust, efficient, and scalable architecture for lane detection that can accurately segment the lane markings and generate precise boundaries for AVs to follow, even in complex traffic scenarios and varying environmental conditions.

The main contributions of this paper are as follows:

- 1) We propose a novel Mask R-CNN-based approach to real-time lane detection for autonomous vehicles, which addresses the challenges associated with existing lane detection techniques and provides a more efficient, robust, and adaptable solution.
- 2) We introduce a comprehensive custom dataset consisting of images collected from different geographical locations, weather conditions, and road types. This dataset ensures the model's generalizability and adaptability to real-

world conditions, which is crucial for the successful deployment of AVs.

3) We incorporate a multi-scale feature extraction technique in our proposed model, which improves its ability to detect lanes in both near and far fields of view, enabling more accurate and reliable lane detection across various scenarios.

4) We conduct extensive experiments on public datasets as well as our custom dataset to validate the performance of the proposed method. The results demonstrate that our Mask R-CNN-based approach significantly outperforms existing state-of-the-art techniques in terms of accuracy, processing speed, and adaptability.

The remainder of this paper is organized as follows: Section II provides a review of related work in the field of lane detection, highlighting the limitations of existing methods and the potential of Mask R-CNN for this task. Section III presents the details of our proposed Mask R-CNN-based approach to real-time lane detection, including the architecture, multi-scale feature extraction technique, and the custom dataset. Section IV describes the experimental setup, including the public datasets and evaluation metrics used to validate the performance of our method. Section V presents the results of our experiments, comparing the performance of our proposed method to existing state-of-the-art techniques, and discussing the implications of our findings. Finally, Section VI concludes the paper and provides directions for future research.

II. RELATED WORKS

Lane detection is a crucial component of perception systems for autonomous vehicles, as it ensures safe navigation and adherence to traffic rules. Over the years, various approaches have been proposed for different practical tasks and datasets ranging from traditional methods to deep learning-based techniques [9-11]. In this section, we review some of the key works in lane detection, considering traditional approaches, CNNs, RNNs, UNet, and other deep learning models (see Table I).

A. Traditional Approaches

Traditional lane detection methods primarily rely on hand-crafted features and geometric properties of lanes. Some of the most common techniques include edge detection, Hough transform, and lane fitting algorithms [12].

Edge detection techniques, such as Sobel and Canny operators, are used to identify the boundaries of lane markings in images [13]. While these methods can perform well in simple scenarios, they are sensitive to noise and may fail in complex traffic scenes or under varying environmental conditions.

Hough transform is another popular method for lane detection, which identifies lines in an image by converting the image space into a parameter space [14]. Although it is effective in detecting straight lines, the Hough transform struggles with curved lanes and requires additional preprocessing steps to address issues such as perspective distortion.

B. CNN-based Approaches

Convolutional Neural Networks (CNNs) have demonstrated great success in various computer vision tasks, including lane detection [15]. These networks learn hierarchical features from raw images, enabling them to automatically learn and adapt to different scenarios. Some notable works employing CNNs for lane detection are as follows:

1) *SCNN*: In this work, Pan et al. proposed a Spatial CNN (SCNN) for lane detection, which incorporates spatial information by extending the convolution operation to the vertical and horizontal directions [16]. This approach achieved state-of-the-art performance on public datasets and demonstrated robustness to varying lighting conditions and occlusions.

2) *LaneNet*: In LaneNet, Neven et al. employed an encoder-decoder architecture with a binary segmentation branch for lane detection [17]. The model also used an instance segmentation branch to differentiate between individual lanes, improving its ability to handle complex scenarios.

C. RNN-based Approaches

Recurrent Neural Networks (RNNs) have been used for lane detection tasks due to their ability to model temporal dependencies in sequences. Some works that employ RNNs for lane detection include:

1) *LSTMs*: Chen et al. proposed an approach combining LSTMs and CNNs to model temporal dependencies in consecutive video frames for lane detection [18]. This approach improved the robustness of the model to varying lighting conditions and occlusions.

Pan et al. (2018) presents an end-to-end lane detection approach using a fully convolutional neural network (FCN) and an RNN [19]. The FCN is used to generate lane boundary probability maps, which are fed into the RNN to predict the final lane boundaries. The approach is shown to be effective in detecting lanes in complex driving scenarios.

Li and Zhang (2017) propose a real-time lane detection algorithm based on an RNN [20]. The RNN is trained on a large dataset of road images to predict lane boundaries. The proposed algorithm achieves high accuracy in lane detection and real-time performance. Lee and Kim (2019) propose a real-time lane detection algorithm using a deep RNN [21]. The RNN is trained on a dataset of road images and is used to predict lane boundaries. The proposed algorithm achieves high accuracy in lane detection and real-time performance.

D. UNet-based Approaches

UNet is a popular encoder-decoder architecture for semantic segmentation tasks [22]. It has been employed in various lane detection works due to its ability to effectively capture both local and global context in images.

1) *SegNet*: Badrinarayanan et al. proposed SegNet, a UNet-like architecture for semantic segmentation [23]. SegNet has been used for lane detection tasks, demonstrating robust

performance in complex traffic scenes and under varying environmental conditions.

Liu et al. (2019) proposes a lane detection approach using a modified U-Net architecture. The modified U-Net includes multiple decoder paths to handle different scales of features, and skip connections are added to preserve spatial information. The approach is shown to be effective for detecting lanes in various driving scenarios.

Tahir et al. (2020) presents a lane detection and semantic segmentation approach using a U-Net architecture [24]. The proposed method combines lane detection and semantic segmentation to improve the accuracy of lane detection in complex driving scenarios. The approach is shown to be effective for detecting lanes in various lighting conditions and road types.

Yang et al. (2021) proposes a lane detection approach using a U-Net architecture and object detection [25]. The U-Net is used to detect lane boundaries, and object detection is used to remove false positives. The proposed algorithm achieves high accuracy in lane detection and reduces false positives. U-Nets have shown great potential for lane detection in autonomous vehicles due to their ability to learn high-level features and preserve spatial information [26]. The above mentioned works demonstrate that the application of U-Nets to lane detection can lead to effective and efficient autonomous driving systems.

E. Other Deep Learning Models

Apart from the approaches mentioned above, other deep learning models have also been applied to lane detection tasks.

1) *DeepLab*: DeepLab is a popular semantic segmentation model that employs atrous convolutions and fully connected conditional random fields (CRFs) for improved segmentation performance [27]. DeepLab has been used in various lane detection works, demonstrating robust performance across different scenarios.

2) *Mask R-CNN*: While originally designed for object detection and segmentation, Mask R-CNN has the potential to address lane detection challenges due to its ability to precisely localize and segment objects in images [28].

Thus, while traditional approaches for lane detection have shown limited success, deep learning-based techniques, including CNNs, RNNs, UNet, and other models, have demonstrated promising results in handling the challenges posed by diverse traffic scenarios and varying environmental conditions [29]. However, each approach has its own set of advantages and limitations, necessitating the development of more efficient, robust, and real-time solutions for lane detection in autonomous vehicles.

In this paper, we propose a novel Mask R-CNN-based approach to real-time lane detection, addressing the challenges associated with existing techniques and providing a more efficient, robust, and adaptable solution. By leveraging the capabilities of the Mask R-CNN model and incorporating a comprehensive custom dataset and a multi-scale feature

extraction technique, our proposed method aims to achieve superior performance in terms of accuracy, processing speed, and adaptability compared to existing state-of-the-art techniques.

TABLE I. COMPARISON OF DEEP LEARNING METHODS FOR LANE DETECTION

Approach	Pros	Cons
Detection	Simple implementation, effective in basic scenarios	Sensitive to noise, fails in complex scenes, does not handle curved lanes well
Hough Transform	Effective in detecting straight lines, handles perspective distortion	Struggles with curved lanes, requires additional preprocessing
SCNN	Incorporates spatial information, robust to lighting and occlusions	Limited to scenarios present in training data, may require large datasets
LaneNet	Encoder-decoder architecture, instance segmentation for individual lanes	Complex model, may be slower in real-time applications
LSTMs	Models temporal dependencies, robust to lighting and occlusions	Requires video input, may not perform well on single images
SegNet	Captures local and global context, robust in complex scenes and varying conditions	Relatively large model, may be computationally expensive
DeepLab	Atrous convolutions and CRFs for improved segmentation, robust across scenarios	Complex model, may require additional processing for instance segmentation
Mask R-CNN	Precise localization and segmentation, potential for real-time processing	Limited exploration in lane detection, may require adaptation for specific scenarios

III. PROPOSED METHOD

It was chosen to adopt the contemporary design of the Mask R-CNN convolutional network in order to simultaneously tackle the issue of crack detection and their pixel-by-pixel separation. This was done in order to save time. First, let us take a look at its internal makeup and analyze how it works. The Region-based Convolutional Neural Network (R-CNN), Fast R-CNN, and Faster R-CNN are the three architectures that came before the Mask R-CNN, all of which were based on the concept of processing tiny regions. Historically, the Mask R-CNN architecture has had the following number of predecessors. As we reviewed, deep learning models have been used in many areas from teaching sphere to sport, medicine, as well as autonomous vehicles [30].

Fig. 1 depicts the Mask R-CNN approach that we developed in order to solve the lane detection issue. The design of the Mask R-CNN is made up of several complicated blocks. First, an illustration is sent to the data of the model in order to point out the feature map. Commonly used model architectures include VGG-16, ResNet50, and ResNet101, both of which include eliminated several layers that are in charge of categorization.

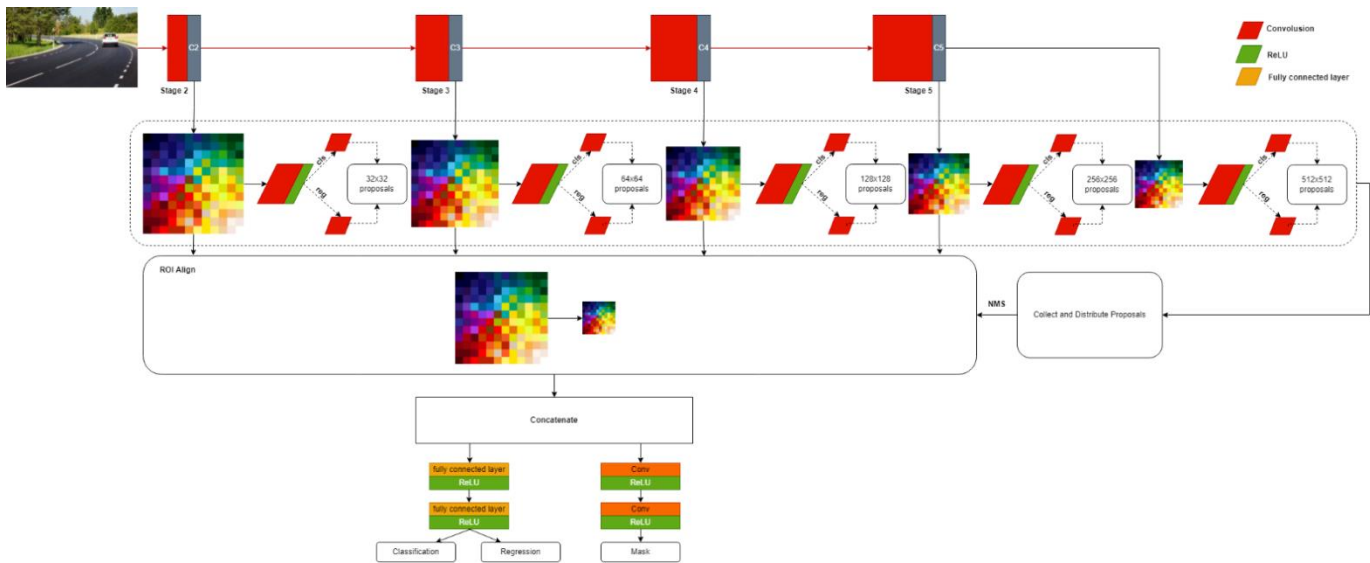

Fig. 1. The proposed system architecture.

The collected feature maps are processed RPN block, which has the duty of generating the supposed areas in the picture that contain objects based on the assumption that certain regions include objects. In order to accomplish this goal, a network with a 3x3 frame is moved across the feature map, and an outcome is created according to k anchors in place, which serve as the foundation for the size and position that are both supplied. RPN creates an estimate of the existence of a component for every anchor, as well as an improvement of the position of the boundaries of the item, if it has been found. This occurs only if the object has been found. At this level, we are going to focus on highlighting areas of interest that have the potential to contain items. Because of the functioning of non-maximum suppression, redundant regions are thrown out at the very end of the process.

Following that, the Region of Interest Align procedure is used to choose the values pertaining to the areas from the feature maps. These values are then scaled down to the same size. The last procedures of classification, refining of the dimensions of the box with boundaries, and forecasting the mask are carried out, as stated by them. The mask that is shown at the output has a significantly shrunk size yet displays true numbers. It is feasible to get an accuracy level that is satisfactory when the mask is sized to match the dimensions of the item that is being picked.

IV. EXPERIMENTAL RESULTS

A. Evaluation Parameters

The proposed model is evaluated using a number of different metrics, including the mean average precision (MaP) and the average recall (AR) at a number of different intersection over union (IoU) levels [31-33]. In classification issues involving localization and object identification, the ratio of the areas of the bounding boxes is most often employed as a metric to measure the reliability of the position of the bounding box. This is because the ratio of the areas of the bounding boxes is directly proportional to the accuracy of the location of the bounding box.

In deep learning based segmentation processes, accuracy is a crucial metric used to evaluate the quality of the segmentation. Accuracy refers to the extent to which the segmentation model's output matches the ground truth or the manual annotations provided by experts [34].

$$accuracy = \frac{TP + TN}{TP + FN + TN + FP}, \quad (1)$$

There are several measures of accuracy used in deep learning based segmentation processes, including pixel-wise accuracy, mean intersection over union (IoU), and dice coefficient [34-36]. Pixel-wise accuracy measures the percentage of correctly classified pixels in the segmentation output. Mean IoU calculates the similarity between the predicted segmentation mask and the ground truth, while the dice coefficient measures the overlap between the predicted and ground truth segmentation masks [35].

$$IoU = \frac{S(A \cap B)}{S(A \cup B)} \quad (2)$$

Specificity measures the proportion of true negative predictions made by the model. It is calculated as the ratio of correctly identified negative samples to the total number of actual negative samples. In segmentation tasks, specificity measures how well the model is able to correctly identify regions that do not belong to the target class or feature [36].

$$precision = \frac{TP}{TP + FP}, \quad (2)$$

Sensitivity, also known as recall, measures the proportion of true positive predictions made by the model. It is calculated as the ratio of correctly identified positive samples to the total number of actual positive samples. In segmentation tasks, sensitivity measures how well the model is able to detect the presence of the target class or feature in the input data [37].

$$recall = \frac{TP}{TP + FN}, \quad (3)$$

Both sensitivity and specificity are important metrics in deep learning based segmentation processes, as they provide a more complete understanding of the model's performance. A high sensitivity score indicates that the model is able to accurately detect the target feature or class, while a high specificity score indicates that the model is able to correctly identify regions that do not belong to the target class or feature.

To achieve high sensitivity and specificity scores in deep learning based segmentation processes, it is important to use appropriate training data and model architecture. The training data should be diverse and representative of the expected inputs, and the model architecture should be chosen to optimize the segmentation task at hand. Additionally, regularization techniques and hyperparameter tuning can be used to improve the model's performance and achieve higher sensitivity and specificity scores.

B. Results

In this section, we demonstrated the obtained results applying Mask R-CNN for road lane segmentation. Fig. 2 demonstrates lane detection and segmentation from the input images.

Fig. 3 and Fig. 4 demonstrate real-time lane detection process from the camera. Thus, the camera sends real-time video to the decision making system, in the result decision making system makes recommendations in real-time using the proposed Mask R-CNN model. It helps to tune the moving of the cars.

Fig. 2. Lane segmentation of the road.

Fig. 3. Lane detection process.

Fig. 4. Comparison of the obtained results for the real-time lane detection process from the camera.

Fig. 5. Comparison of the obtained results demonstrating several examples of applying the proposed framework in process.

Fig. 5 demonstrates several examples of applying the proposed framework in process. The proposed system can work in different weathers including sunny, rainy, cloudy or other weather condition. Moreover, it can work in daytime and nighttime. The proposed system can make a decision in real-time and can help to moving of autonomous vehicles.

Fig. 6. The proposed model accuracy in 100 learning epochs.

Fig. 6 demonstrates the proposed model accuracy in 100 learning epochs. The model achieved to 90% accuracy in lane detection problem in 60 learning epochs, and it achieved to 95%-98% in 100 learning epochs.

Fig. 7. The proposed model loss in 100 learning epochs.

Fig. 7 demonstrates the model loss in 100 learning epochs. Therefore, from the figure, we can say that, there are no sharp fluctuations, and depending on number of learning epochs, the model loss reduces.

V. DISCUSSION

The field of machine learning and deep learning has revolutionized the domain of autonomous vehicles by enabling them to detect, classify, and navigate their surroundings autonomously. In this paper, the authors propose a Mask R-CNN approach for real-time lane detection for autonomous vehicles. In this section, we analyze the advantages, disadvantages, challenges, and future perspectives of different machine learning and deep learning methods and indicate the advantages of the proposed Mask R-CNN approach.

Support Vector Machines (SVMs) have been widely used for object detection and image classification [38]. SVMs have shown promising results in various applications, but they are limited by their inability to handle large datasets and the need for feature extraction.

Deep learning models, such as Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs), have shown impressive results in various applications. One of the significant advantages of deep learning models is that they can learn features automatically, without the need for manual feature extraction. However, deep learning models require a large amount of data and computing resources to train, and they can be challenging to interpret.

The Mask R-CNN approach has been gaining significant attention in recent years for its ability to generate pixel-level masks for each detected object [39]. This approach extends the Faster R-CNN algorithm by adding a segmentation branch. The Mask R-CNN approach has shown promising results in various applications, including object detection, instance segmentation, and human pose estimation.

The proposed Mask R-CNN approach for real-time lane detection for autonomous vehicles has several advantages. First, it can detect lanes in real-time, making it suitable for autonomous vehicles. Second, it can generate pixel-level masks for each detected lane, which can provide more accurate information about the lanes' position and shape [40]. Third, the approach can handle complex scenarios, such as occlusions and lane merging, which can be challenging for traditional lane detection methods. Fourth, the approach does not require manual feature extraction, making it more efficient and less prone to errors.

However, there are some challenges associated with the Mask R-CNN approach. One of the significant challenges is the need for a large amount of annotated data to train the model [41]. Another challenge is the high computational cost of training the model, which can be a limiting factor for some applications. Additionally, the interpretation of the model's output can be challenging, as the approach is based on a complex neural network architecture.

In the future, the development of more efficient and interpretable deep learning models will be crucial for the continued advancement of autonomous vehicles. In particular, the integration of multiple sensor modalities, such as lidar, radar, and cameras, will enable more accurate and robust perception systems. Moreover, the development of more advanced algorithms for handling complex scenarios, such as crowded urban environments, will be necessary.

Thus, machine learning and deep learning have enabled significant advancements in the field of autonomous vehicles. The proposed Mask R-CNN approach for real-time lane detection has several advantages, including real-time detection, accurate lane position and shape information, the ability to handle complex scenarios, and efficient and automatic feature extraction. However, there are some challenges associated with this approach, including the need for a large amount of annotated data, high computational costs, and interpretability. The development of more efficient and interpretable deep

learning models and the integration of multiple sensor modalities will be essential for the continued advancement of autonomous vehicles.

VI. CONCLUSION

In this paper, we presented a novel Mask R-CNN-based approach for real-time lane detection in autonomous vehicles. Our method adapts the Mask R-CNN model to specifically address the challenges posed by diverse traffic scenarios and varying environmental conditions. We introduced a robust, efficient, and scalable architecture for lane detection, which segments the lane markings and generates precise boundaries for AVs to follow. To ensure the model's generalizability and adaptability, we also introduced a comprehensive custom dataset and a multi-scale feature extraction technique.

Extensive experiments were conducted on public datasets and our custom dataset, validating the performance of the proposed method. The results demonstrated that our Mask R-CNN-based approach significantly outperforms existing state-of-the-art techniques in terms of accuracy, processing speed, and adaptability. The real-time processing capabilities of our model make it an ideal solution for implementation in AVs, enabling safer and more efficient navigation on roads.

As part of our future work, we plan to extend the proposed method to handle more complex scenarios, such as detecting lanes in the presence of shadows, occlusions, and varying lighting conditions. Additionally, we will investigate the integration of our lane detection approach with other perception tasks, such as object detection and semantic segmentation, to develop a unified perception system for autonomous vehicles. This would further improve the safety and efficiency of AVs, ultimately bringing us closer to the widespread deployment of these vehicles on our roads.

Overall, the proposed Mask R-CNN-based approach to real-time lane detection for autonomous vehicles represents a significant step forward in the development of robust and reliable perception systems for AVs, paving the way for their safe and efficient operation in diverse traffic scenarios and under varying environmental conditions.

Abstract—The approach used in this study involves applying the Cournot model, which is initially based on the analysis of product quantities in the market. Building upon the obtained equilibrium, a second analysis is conducted to examine the impact of the open innovation integration rate, utilizing a dynamic model. The obtained results have demonstrated that multiple equilibria are possible, and under certain conditions, competing firms have a stake in carefully analyzing the integration rate of open innovation.

Keywords—Duopoly; open innovation; closed innovation; Cournot model

I. INTRODUCTION

The closed innovation model is a strategy that prioritizes the use of internal resources to optimize the innovation process, ultimately leading to the development of innovative products and services [1]. Essentially, companies focus on building and nurturing the necessary competencies in-house to become leaders in their respective markets. By keeping innovation activities in-house, companies can have more control over the entire innovation process, from ideation to product launch, and can better protect their intellectual property.

The primary goal of closed innovation is to ensure that the necessary resources are developed and improved to implement the innovation process effectively[2]. This approach facilitates the creation of new products and services while simultaneously minimizing risks and creating barriers to imitation by competitors. Closed innovation also allows companies to build a competitive advantage by cultivating in-house expertise and refining their innovation processes. By relying on internal resources, companies can optimize the innovation process, leading to more efficient product development, better quality products, and higher profits[3].

According to Chesbrough, the closed innovation model was effective for much of the 20th century. However, this approach to innovation faced two significant limitations. The first limitation was succinctly expressed by Bill Joy, the co-founder of Sun Microsystems, who noted that "No matter who you are, most of the smartest people work for someone else". In other words, relying solely on internal resources means missing the valuable expertise and ideas that exist beyond the organization.

However, Open innovation is viewed as a sustainable innovation approach that depends on international collaboration between companies and countries[4]. As companies seek to gain a competitive advantage through

innovation, open innovation has become increasingly popular among academics and practitioners. However, the current literature has mostly focused on the benefits of open innovation and overlooked its potential failures [5]. The integration of open innovation (OI) and the circular economy (CE) has the potential to contribute to a more sustainable economy.

However, there is a lack of understanding of how OI can be leveraged to promote the adoption of CE. As an important aspect of the economy, it is crucial to investigate the relationship between OI and CE and identify ways to overcome the barriers to CE adoption[6]. The second limitation is related to the high level of investment required to support the innovation process. Since closed innovation relies on internal resources, there is a higher level of investment needed to supply the innovation process. This investment also comes with a higher risk as developed ideas may not be supported by the organization, resulting in wasted resources and missed opportunities[7].

The concept of open innovation has been widely applied in various fields, particularly in innovation management for firms of different sizes. Its emphasis on sharing and collaboration has made it a popular topic of interest[8]. Numerous studies have highlighted the discovery of an inverted U-shaped relationship among open innovation, knowledge reorganization, and innovation performance. Moreover, it has been observed that knowledge reorganization and reuse play a mitigating role by alleviating the adverse effects of excessive open innovation on innovation performance[9]. Furthermore, the observed correlation among open innovation, generic strategies (cost-leadership and differentiation), and business performance indicates that the influence of open innovation on business performance is mediated by the adoption of cost-leadership and differentiation strategies[10][11].

Open Innovation has gained significant attention in both research and management practices[12]. As radical innovation and new business development often necessitate external technologies and commercialization methods, many companies have transitioned from a Closed to an Open Innovation model[13]. However, firms frequently encounter challenges during the implementation phase, with the focus primarily placed on external ideas, technologies, and identification processes, while cultural obstacles are often overlooked[14]. While the open innovation literature has extensively discussed strategies, processes, and business models, it has largely neglected the importance of the underlying innovation culture[15].

Researchers have conducted multiple studies to examine the differences between Open Innovation and Closed Innovation, with the objective of characterizing each type of innovation. These studies have revealed that Chesbrough's six principles of open innovation rely on a false dichotomy that necessarily opposes closed innovation to open innovation[13]. Within the same context, researchers have conducted studies to explore the implementation of inbound, outbound, and combined open innovation practices. These investigations have examined multiple factors such as organizational context, company structure, collaborative arrangements, the involvement of diverse actors, and the outcomes achieved, providing insights into the role and influence of these factors on the efficacy of open innovation practices in companies[16].

The dilemma between Open Innovation and Closed Innovation lies in the strategic choice that companies face regarding their approach to innovation. Closed Innovation is based on the principle that the company should internally control and develop its innovations, relying on its own resources and capabilities. On the other hand, Open Innovation takes a more open approach, seeking to integrate external ideas, knowledge, and resources through collaborations, partnerships, and leveraging the innovation ecosystem.

The challenge arises when companies are faced with the decision of selecting the optimal approach to embrace. Closed Innovation provides enhanced control and protection of internal knowledge; however, it may limit exposure to new ideas and opportunities[17]. Conversely, Open Innovation offers access to a broad spectrum of external knowledge and resources, fostering innovation, yet it entails risks such as potential intellectual property disclosure and difficulties in coordinating with external partners[18]. Therefore, companies must navigate between adopting a more secure and internally-focused approach or embracing a collaborative and open approach to innovation, carefully considering the benefits and drawbacks of each, as well as their unique organizational context and environment.

Various alternative approaches are being used to examine open innovation[19]. These include empirical studies, which involve collecting real-world data and analyzing its impact on firm performance through surveys, interviews, case studies, and quantitative analysis. Network analysis explores the structure and dynamics of innovation networks, investigating collaborations, partnerships, and knowledge flows to identify key actors and understand their influence on innovation outcomes. Qualitative research, such as ethnography and in-depth interviews, delves into the experiences, perspectives, and behaviours of individuals and organizations involved in open innovation. Technological platforms and data analytics leverage advanced technologies to analyze large-scale datasets, uncovering patterns, trends, and correlations relevant to open innovation. Simulation models simulate scenarios to understand the complexities, trade-offs, and uncertainties of open innovation, facilitating the testing of different strategies and policies. Comparative studies compare industries, sectors, or regions to identify variations in open innovation practices, outcomes, and contextual factors, providing insights into industry-specific challenges, best practices, and policy implications for promoting open innovation.

Game theory has proven to be a useful tool for modeling the interactions that take place in Open Innovation ecosystems. Specifically, the Cournot duopoly has emerged as a popular game theory model to simulate the strategic behavior of firms in Open Innovation[20]. For example, an Open Innovation process in a Cournot duopoly is analyzed using a differential game approach that incorporates knowledge spillover. The optimal licensing contract for a patentor with a quality improvement innovation in a Cournot duopoly market is analyzed in this paper. s are endogenously determined via the R&D process[21]. Another study examined the optimization of technology licensing contracts for quality improvement innovation in the context of Cournot competition[22]. A similar study has addressed the problem of patent licensing in a Cournot duopoly, where one of the firms acts as the innovator (patentee) and encounters capacity limitations. The focus of this study revolves around investigating the challenges associated with patent licensing within the context of a Cournot duopoly, where one firm holds the role of the patentee and faces capacity constraints[23]. Another study focused on a differentiated Cournot model and a differentiated Bertrand model, in which one of the firms engages in an R&D process resulting in an endogenous cost-reducing innovation[24]. The role of platform economics in facilitating open innovation while addressing the challenges of information stickiness and product diversification risks was studied in [25].

II. METHODOLOGY

A. Goals and Assumptions Underlying the Study

The purpose of this paper is to explore the adoption of open innovation versus closed innovation by a firm operating in a duopoly model, specifically using the Cournot model. The study incorporates an integration rate parameter to assess its impact on the firm's innovation strategy. It is important to mention that the analysis does not consider the specific activities of the competing firms. Additionally, this study builds upon and draws inspiration from several related works in the field. In this regard, the study considers the work on the complex dynamics of R&D competition with one-way spillover based on intellectual property protection[25].

This study specifically focuses on a dynamic two-stage model. Indeed, investigations on the two-stage model have increasingly captured the interest of economists. Whereas initially, many scholars were primarily focused on examining the properties of the static model. It is undeniable that the static model has its limitations. One of these limitations is its ability to only analyze the individual supply and demand equilibrium between firms. When the factors of supply and demand undergo changes, the corresponding supply relationship will also shift.

This research employs nonlinear dynamics theory to examine the evolutionary process within firms' games. Various scholars have conducted previous studies on this topic. The local and global dynamic properties of a two-stage oligopoly game model with an adaptive dynamic mechanism, highlighting its complex evolutionary behaviors was studied in [26]. Also, another paper investigated the properties of a dynamic Cournot duopoly game model with a nonlinear demand function[27]. Similar works can be found in [28].

Moreover, the economic dynamical system has shown significant interest in the dynamical two-stage game. For example, a dynamic model of a two-stage remanufacturing closed-loop supply chain was used to investigate how technological innovation, Big Data marketing, and overconfidence influence the decision-making process of supply chain members[29]. The stability of a two-stage duopoly Cournot game model, which incorporates a nonlinear inverse demand function and R&D spillover, is investigated. The results indicate that the final state of the system is influenced by its initial state[30].

B. Mathematical Model

To assess the effects of open innovation versus closed innovation, the Cournot duopoly model is used. The model assumes the presence of two companies, labeled i ($i=1,2$), in a market, offering identical products. Recognizing the value of innovation as a means of achieving a competitive edge, each firm adopts a strategy that enables it to emerge as the leader in the market.

Our model consists of two game stages that take into account the time required for innovation before introducing products to the market. In the first stage, the innovation parameter is considered, followed by the standard Cournot model where a balance is sought in relation to the quantities of products on the market. Differences in the levels of innovation integration (i.e., open innovation) between firms can result in differences in product quality. The industry is characterized by a linear inverse demand function expressed as:

$$p_i = a - bQ \quad (i = 1,2)$$

Where, $a > 0$ and $b \in [0,1]$,

Q is the total quantity in the market $Q = \sum_{i=1,2} q_i$, q_i is the outputs of the products producing by the firm i .

This work consider that the two firms decide to integrate the innovation in their strategies. In order to model the OI and CI, This paper introduce the parameter $\sigma_i \in [0,1]$ that corresponds to the OI integration rate. The effective marginal cost of firm i is represented as follow:

$$C_i(\sigma_i) = A + c \times (1 - \sigma_i), \quad i = 1,2 \quad (2)$$

According to this cost equation, if a firm i decides to outsource the innovation the marginal cost will be A , since the rate σ_i will be equal to one. However, if firm i decides to internalize, completely, the innovation, the marginal cost will be high since it will be equal to $A+c$.

Considering the gains that can be obtained from corporate innovation (CI), such as high-powered incentives, firm-owned property rights, and reuse cost, it can be hypothesized that as long as the firm perceives a decrease in these gains, its rate of Open innovation will diminish. Therefore, it represents losses generated by the massive use of Open innovation, charges for the firm and therefore an additional cost.

Furthermore, based on several works of duopolistic models[31], the expressions of a quadratic cost equation, loss of a firm i can be expressed as:

$$L(\sigma_i) = \gamma\sigma_i^2/2(i = 1,2), \quad (3)$$

Where γ is a spillover parameter.

C. Profit of each Firm

According to the propositions given above, the profit equations for the two firms

$$\begin{cases} \pi_1(q_1, q_2, \sigma_1, \sigma_2) = [p_1(q_1, q_2) - C_1(\sigma_1, \sigma_2)]q_1 - L(\sigma_1), \\ \pi_2(q_1, q_2, \sigma_1, \sigma_2) = [p_2(q_1, q_2) - C_2(\sigma_1, \sigma_2)]q_2 - L(\sigma_2). \end{cases} \quad (4)$$

Substituting Eq. (1) and (2) into Eq. (4), the expression of profit function for each firm is:

$$\begin{cases} \pi_1(q_1, q_2, \sigma_1, \sigma_2) = -bq_1^2 + (a - bq_2 - A - c(1 - \sigma_1))q_1 - \gamma\frac{1}{2}\sigma_1^2 \\ \pi_2(q_1, q_2, \sigma_1, \sigma_2) = -bq_2^2 + (a - bq_1 - A - c(1 - \sigma_2))q_2 - \gamma\frac{1}{2}\sigma_2^2 \end{cases} \quad (5)$$

Now, the marginal profits of these two firms are:

$$\begin{cases} \frac{\partial \pi_1}{\partial q_1} = -2bq_1 + (a - bq_2 - A - c(1 - \sigma_1)) \\ \frac{\partial \pi_2}{\partial q_2} = -2bq_2 + (a - bq_1 - A - c(1 - \sigma_2)) \end{cases} \quad (6)$$

The second-order conditions are met because

$$\frac{\partial^2 \pi_1}{\partial^2 q_1} = \frac{\partial^2 \pi_2}{\partial^2 q_2} = -2 < 0.$$

According to Eq. (6), the reaction function of the firm 1 and firm 2 by setting $\frac{\partial \pi_1}{\partial q_1} = 0, \frac{\partial \pi_2}{\partial q_2} = 0$ is as follow:

$$\begin{cases} R_1(q_2, \sigma_1) = q_2^* = \frac{(a - bq_1 - A - c(1 - \sigma_1))}{2b} \\ R_2(q_1, \sigma_2) = q_1^* = \frac{(a - bq_2 - A - c(1 - \sigma_2))}{2b} \end{cases} \quad (7)$$

$$\text{Let } U = \frac{(a - A - c)}{2b}$$

Cournot equilibrium can be expressed by replacing q_1^* and q_2^* in reaction's function.

$$\begin{cases} q_1^* = \frac{2}{3} \left(U - \frac{c}{2b} (\sigma_2 - \frac{1}{2}\sigma_1) \right) \\ q_2^* = \frac{2}{3} \left(U - \frac{c}{2b} (\sigma_1 - \frac{1}{2}\sigma_2) \right) \end{cases} \quad (8)$$

Provided that $\frac{2b}{c}U > (\sigma_2 - \frac{1}{2}\sigma_1)$ and $\frac{2b}{c}U > (\sigma_1 - \frac{1}{2}\sigma_2)$.

Therefore, in the subsequent scenario, it is assumed that a Cournot equilibrium exists.

D. First Stage of Equilibrium Analysis

According to this result, the rate of OI determines the production strategy of the quantities to be produced for each firm. Also, by subtracting q_2^* from q_1^* ,

$$\Delta Q = q_1^* - q_2^* = \frac{c}{3b} (\sigma_1 - \sigma_2) \quad (9)$$

According to ΔQ value, the equilibrium quantities depend on the innovation integration rates for each firm. Thus, assuming firm 1 chooses an OI approach ($\sigma_1=1$) and firm 2 chooses CI as an opposite approach ($\sigma_2=0$), $\Delta Q > 0$. Firm 1 must always deliver quantities greater than those of firm 2, since $\frac{c}{3b}$ is positive.

The profit function about innovation rate σ_i captured by taking Eq. (8) into Eq. (5) in reverse order can be obtained as:

$$\begin{cases} \pi_1(\sigma_1, \sigma_2) = \left(\frac{5c}{9b} - \frac{1}{2}\gamma\right)\sigma_1^2 + \frac{1}{9}\left(8U - \frac{c}{4} - \frac{5c}{18b}\sigma_2\right)\sigma_1 - \frac{1}{9}U(3-2b)\frac{c}{2b}\sigma_2 + \frac{1}{9}U^2(3-2b) \\ \pi_2(\sigma_1, \sigma_2) = \left(\frac{5c}{9b} - \frac{1}{2}\gamma\right)\sigma_2^2 + \frac{1}{9}\left(8U - \frac{c}{4} - \frac{5c}{9 \cdot 2b}\sigma_1\right)\sigma_2 - \frac{1}{9}U(3-2b)\frac{c}{2b}\sigma_1 + \frac{1}{9}U^2(3-2b) \end{cases} \quad (10)$$

The equation of the profits of the two firms makes it possible to calculate the maximum local profit according to the rates of integration of the IO.

For this, the derivative of the system of equation (10) give

$$\begin{cases} \frac{\partial \pi_1(\sigma_1, \sigma_2)}{\partial \sigma_1} = \left(\frac{5c}{18b} - \gamma\right)\sigma_1 + \frac{1}{9}\left(8U - \frac{c}{4} - \frac{5c}{18b}\sigma_2\right) \\ \frac{\partial \pi_2(\sigma_1, \sigma_2)}{\partial \sigma_2} = \left(\frac{5c}{18b} - \gamma\right)\sigma_2 + \frac{1}{9}\left(8U - \frac{c}{4} - \frac{5c}{9 \cdot 2b}\sigma_1\right) \end{cases} \quad (11)$$

Based on this approach, different expectations are assumed from the two firms. Indeed, supposing that firm 1 is rational in a bounded way and firm 2 is a local approximation. The limited rational actor 1 does not have complete knowledge of the market; hence, they try to use local information based on marginal profit.

E. Second Stage of Equilibrium Analysis

In this section, the impact of adjustment mechanisms on the competitive outcomes of enterprises, building on the work of Dixit is discussed. Dixit's research focuses on constructing a competitive model of two companies with an adjustment mechanism and estimating the marginal profit to describe the production evolution[32][33]. In this paper, two different scenarios are given: when two companies co-exist in the same market and when one company takes full control of the market after dislodging the other. The findings indicate that the adjustment mechanism is effective in reducing the output and profit gap between the companies, and in some cases, it can lead to the elimination of this difference and the attainment of Nash equilibrium[34].

Therefore, it is supposed that Firm 1 decides to proceed with the decisions concerning the rate of integration of the IO by either increasing or decreasing it. Thus, the dynamic adjustment mechanism can be modeled as follows:

$$\begin{cases} \sigma_1(t+1) = \sigma_1(t) + \vartheta_1 \sigma_1(t) \frac{\partial \pi_1(\sigma_1, \sigma_2)}{\partial \sigma_1} \\ \sigma_2(t+1) = \sigma_2(t) + \vartheta_2 \sigma_2(t) \frac{\partial \pi_2(\sigma_1, \sigma_2)}{\partial \sigma_2} \end{cases} \quad (12)$$

Where, ϑ_1, ϑ_2 are positive parameters, which represent respectively the speed of adjustment of firm 1 and firm 2.

By replacing the profit given in equation (11) in the equation, (12) system become:

$$\begin{cases} \sigma_1(t+1) = \sigma_1(t) + \vartheta_1 \sigma_1(t) \left(\left(\frac{5c}{18b} - \gamma\right)\sigma_1(t) + \frac{1}{9}\left(8U - \frac{c}{4} - \frac{5c}{18b}\sigma_2(t)\right) \right) \\ \sigma_2(t+1) = \sigma_2(t) + \vartheta_2 \sigma_2(t) \left(\left(\frac{5c}{18b} - \gamma\right)\sigma_2(t) + \frac{1}{9}\left(8U - \frac{c}{4} - \frac{5c}{9 \cdot 2b}\sigma_1(t)\right) \right) \end{cases} \quad (13)$$

III. EQUILIBRIUM POINTS AND LOCAL STABILITY

The system of Eq. (13) given is a set of coupled first-order nonlinear difference equations. To analyze the equilibrium and stability of the system, the fixed points of the system by setting $\sigma_1(t+1) = \sigma_1(t)$ and $\sigma_2(t+1) = \sigma_2(t)$.

Setting $\sigma_1(t+1) = \sigma_1(t)$ and $\sigma_2(t+1) = \sigma_2(t)$, the system become:

$$\begin{cases} \vartheta_1 \sigma_1(t) \left(\left(\frac{5c}{18b} - \gamma\right)\sigma_1(t) + \frac{1}{9}\left(8U - \frac{c}{4} - \frac{5c}{18b}\sigma_2(t)\right) \right) = 0 \\ \vartheta_2 \sigma_2(t) \left(\left(\frac{5c}{18b} - \gamma\right)\sigma_2(t) + \frac{1}{9}\left(8U - \frac{c}{4} - \frac{5c}{18b}\sigma_1(t)\right) \right) = 0 \end{cases} \quad (14)$$

After performing computational analysis, it was determined that the system given by Eq. (16) has four equilibrium points. These points are:

$$(\sigma_1, \sigma_2) = (0, 0)$$

$$(\sigma_1, \sigma_2) = \left(\left(\frac{16U - c}{\frac{5c}{9b} - 2\gamma} \right), 0 \right)$$

$$(\sigma_1, \sigma_2) = \left(0, \left(\frac{16U - c}{\frac{5c}{9b} - 2\gamma} \right) \right)$$

$$(\sigma_1, \sigma_2) = \left(\left(\frac{40U - 5c + 9\gamma \frac{c}{b}}{18b\gamma - 25c} \right), \left(\frac{40U - 5c + 9\gamma \frac{c}{b}}{18b\gamma - 25c} \right) \right)$$

To guarantee that all four equilibrium points of the system (10) are non-negative, the following conditions must be satisfied: $5c - 18b\gamma > 0$ and $U < \frac{c}{16}$. Additionally, it is important to note that the analysis assumes positive values for ϑ_1 and ϑ_2 .

$$J = \begin{bmatrix} 1 + \vartheta_1 \left(\left(\frac{5c}{18b} - \gamma\right)\sigma_1 + \frac{1}{9}\left(8U - \frac{c}{4} - \frac{5c}{18b}\sigma_2\right) \right) & -\frac{1}{9b}\vartheta_1 \sigma_1 \left(\frac{5c}{18b}\right) \\ -\frac{1}{9b}\vartheta_2 \sigma_2 \left(\frac{5c}{18b}\right) & 1 + \vartheta_2 \left(\left(\frac{5c}{18b} - \gamma\right)\sigma_2 + \frac{1}{9}\left(8U - \frac{c}{4} - \frac{5c}{18b}\sigma_1\right) \right) \end{bmatrix} \quad (15)$$

After identifying the four equilibrium points of the system given by Eq. (16), the next step is to study their stability. This is an important step as it helps us determine the behavior of the system around these equilibrium points. The stability of an equilibrium point can be classified as either stable, unstable, or semi-stable. A stable equilibrium point is one where any small disturbance from its position will cause the system to return to that point. An unstable equilibrium point, on the other hand, is one where any small disturbance will cause the system to move away from that point. Lastly, a semi-stable equilibrium point has one stable direction and one unstable direction. By analyzing the stability of each equilibrium point, insights can be gained into the behavior of the system and its evolution over time.

A. First Equilibrium Point:

The Jacobian matrix at the equilibrium point $(\sigma_1, \sigma_2) = (0, 0)$ is:

$$J(0,0) = \begin{bmatrix} 1 + \vartheta_1 \left(\frac{1}{9b} \left(8U - \frac{c}{4} \right) \right) & 0 \\ 0 & 1 + \vartheta_2 \left(\frac{1}{9b} \left(8U - \frac{c}{4} \right) \right) \end{bmatrix}$$

The eigenvalues are the solutions to this equation, which are:

$$\lambda_1 = 1 + \vartheta_1 \frac{(8U - \frac{c}{4})}{9b}$$

$$\lambda_2 = 1 + \vartheta_2 \frac{(8U - \frac{c}{4})}{9b}$$

Since ϑ_1 and ϑ_2 are positive, and that $\frac{c}{4} < 8U$, then both eigenvalues are positive. This means that the equilibrium point (0,0) is unstable node.

In terms of the physical interpretation of the system, this result suggests that the equilibrium point (0,0) is unstable when the gain parameters for the feedback loops, ϑ_1 and ϑ_2 , are positive and the net effect of the feedback loops on the system is positive, as represented by the positive value of $(8U - c/4)$.

B. Second Equilibrium Point

The Jacobian matrix at the equilibrium point

$$(\sigma_1, \sigma_2) = \left(\left(\frac{16U-c}{\frac{5c}{9b}-2\gamma} \right), 0 \right) \text{ is:}$$

$$J \left(\left(\frac{16U-c}{\frac{5c}{9b}-2\gamma} \right), 0 \right) = \begin{bmatrix} 1 + \vartheta_1 \left(\frac{40U-9c}{45b-18\gamma} \right) & -\vartheta_1 \frac{4U-c}{45b-18\gamma} \\ 0 & 1 + \vartheta_2 \left(\frac{40U-9c}{45b-18\gamma} \right) \end{bmatrix}$$

The Jacobian matrix is a diagonal matrix; thus, its corresponding distinct eigenvalues are:

$$J \left(\left(\frac{16U-c}{\frac{5c}{9b}-2\gamma} \right), 0 \right) = \begin{bmatrix} 1 + \vartheta_1 \left(\frac{40U-9c}{45b-18\gamma} \right) & -\vartheta_1 \frac{4U-c}{45b-18\gamma} \\ 0 & 1 + \vartheta_2 \left(\frac{40U-9c}{45b-18\gamma} \right) \end{bmatrix}$$

If $U > 9c/40$ and $b > 2\gamma/5$, the equilibrium point is an unstable node, meaning that the trajectories of the system move away from this point. This implies that the market will not reach a stable state and will continue to fluctuate. On the other hand, if $U > 9c/40$ or $b > 2\gamma/5$, the equilibrium point is a stable node, meaning that the system will move towards this point as time progresses. In other words, the market will reach a stable state, either with high U or high b values.

The stability analysis of the equilibrium point is crucial in understanding the behavior of the system. The results obtained suggest that the stability of the equilibrium point is influenced by the values of U and b. Therefore, firms can use this information to adjust their strategies and optimize their profits. By maintaining the optimal values of U and b, enterprises can stabilize their position in the market and achieve long-term success.

C. Third Equilibrium Point

The Jacobian matrix at the equilibrium point is:

$$J \left(0, \left(\frac{16U-c}{\frac{5c}{9b}-2\gamma} \right) \right) = \begin{bmatrix} 1 + \vartheta_1 \left(\frac{40U-9c}{45b-18\gamma} \right) & 0 \\ -\vartheta_1 \frac{4U-c}{45b-18\gamma} & 1 + \vartheta_2 \left(\frac{40U-9c}{45b-18\gamma} \right) \end{bmatrix}$$

The Jacobian matrix is a diagonal matrix; thus, its corresponding distinct eigenvalues are:

$$\lambda_1 = 1 + \frac{\vartheta_1(40U-9c)}{45b-18\gamma}$$

$$\lambda_2 = 1 + \frac{\vartheta_2(40U-9c)}{45b-18\gamma}$$

The types of the second equilibrium point are similar to the boundary equilibrium points. If $U > 9c/40$ and $b > 2\gamma/5$ then is the equilibrium point is unstable node. However if $U > 9c/40$ or $b > 2\gamma/5$ the equilibrium point is stable node.

In economic terms, the boundary equilibrium points signify a scenario where one of the two firms has exited the market.

Equilibrium points $(\sigma_1, \sigma_2) = \left(\left(\frac{16U-c}{\frac{5c}{9b}-2\gamma} \right), 0 \right)$ and $(\sigma_1, \sigma_2) =$

$\left(0, \left(\frac{16U-c}{\frac{5c}{9b}-2\gamma} \right) \right)$, on the other hand, it indicates that one of the

firms has taken the lead in the oligopoly market, resulting in a monopoly market. The local stability of equilibrium points reflects the short-term stability of the economic market. However, neither of these scenarios is desirable. It is only when both companies restrict each other that the market and the country can achieve stable development. This state is known as "Nash equilibrium," which is reached when both firms maximize their own profits while also ensuring the stable development of the market.

D. Fourth Equilibrium Point

The Jacobian matrix at the equilibrium point is:

$$J = \begin{bmatrix} 1 + \frac{c}{9b} \vartheta_1 \left(\frac{-65(8U-c+9\gamma\frac{c}{5b})}{(18b\gamma-25c)} + \frac{8U}{c} \right) & -\vartheta_1 \frac{c}{9b} \left(\frac{8U-c+9\gamma\frac{c}{5b}}{(18b\gamma-25c)} \right) \\ -\vartheta_2 \frac{c}{9b} \left(\frac{8U-c+9\gamma\frac{c}{5b}}{(18b\gamma-25c)} \right) & 1 + \frac{c}{9b} \vartheta_2 \left(\frac{-65(8U-c+9\gamma\frac{c}{5b})}{(18b\gamma-25c)} + \frac{8U}{c} \right) \end{bmatrix}$$

The trace of the given Jacobian matrix J is:

$$Tr(J) = 2 + \frac{c}{9b} (\vartheta_1 + \vartheta_2) \left(\frac{-65(8U-c+9\gamma\frac{c}{5b})}{(18b\gamma-25c)} + \frac{16U}{c} \right)$$

Therefore, the determinant of the given Jacobian matrix J is:

$$Det(J) = 1 + \frac{c}{9b} (\vartheta_1 + \vartheta_2) \left(\frac{-65(8U-c+9\gamma\frac{c}{5b})}{(18b\gamma-25c)} + \frac{8U}{c} \right) + \vartheta_1 \vartheta_2 \left(\frac{c}{9b} \right)^2 \left(\frac{8U-c+9\gamma\frac{c}{5b}}{(18b\gamma-25c)} \right)^2$$

The characteristic polynomial of matrix:

$$P(\lambda) = \lambda^2 - \text{Tr}(J) + \text{Det}(J) = 0$$

The discriminant of the characteristic polynomial is given by:

$$\Delta = \text{Tr}(J)^2 - 4\text{Det}(J)$$

Substituting the expressions for $\text{Tr}(J)$ and $\text{Det}(J)$,

$$\Delta = \left[2 + \frac{c}{9b}(\vartheta_1 + \vartheta_2) \left(\frac{-65(8U-c+9\gamma\frac{c}{5b})}{(18b\gamma-25c)} + \frac{16U}{c} \right) \right]^2 \left[1 + \frac{c}{9b}(\vartheta_1 + \vartheta_2) \left(\frac{-65(8U-c+9\gamma\frac{c}{5b})}{(18b\gamma-25c)} + \frac{8U}{c} \right) + \vartheta_1\vartheta_2 \left(\frac{c}{9b} \right)^2 \left(\frac{8U-c+9\gamma\frac{c}{5b}}{(18b\gamma-25c)^2} \right) \right]$$

Simplifying this expression may lead to a long and complicated expression, but it represents the discriminant of the characteristic polynomial which determines the stability of the equilibrium point.

The given equilibrium is a stable node if the following conditions are satisfied:

- $\text{Tr}(J) < 0$ and $\text{Det}(J) > 0$
- $\Delta > 0$ and $\text{Tr}(J) < 0$

Therefore, these conditions should be satisfied

$$(40U - 5c + 9\gamma c/b)^2 < \frac{(64\vartheta_1\vartheta_2U - 9c(\vartheta_1 + \vartheta_2) + 25\gamma c\vartheta_1\vartheta_2)}{18b}$$

$$\frac{(-65(8U - c + 9\gamma c/5b))}{(18b\gamma - 25c)} < 0$$

$$8U - c + 9\gamma c/5b > 0$$

$$\frac{(40U - 5c + 9\gamma c/b)}{(18b\gamma - 25c)} > 0$$

If these conditions hold, then the equilibrium point

$$(\sigma_1, \sigma_2) = \left(\left(\frac{40U-5c+9\gamma\frac{c}{b}}{18b\gamma-25c} \right), \left(\frac{40U-5c+9\gamma\frac{c}{b}}{18b\gamma-25c} \right) \right) \text{ is a stable node.}$$

IV. NUMERICAL ANALYSIS

This section of the article focuses on performing a numerical analysis to investigate stability studied in the previous section. The model used in this analysis assesses the effects of open innovation (OI) versus closed innovation (CI) using the Cournot duopoly model. The model assumes the presence of two companies in a market offering identical products, with the industry characterized by a linear inverse demand function. Each firm adopts a strategy that enables it to emerge as the leader in the market. Three equilibrium points will be studied, although the first equilibrium point will be omitted due to its non-stability. The aim is to demonstrate the impact of open innovation (OI) integration in the context of a Cournot duopoly.

The model consists of two game stages that take into account the time required for innovation before introducing products to the market. In the first stage, the innovation parameter, followed by the standard Cournot model, where seeking a balance in relation to the quantities of products on the market. The goal of the numerical analysis is to

demonstrate the impact of OI integration in the context of Cournot duopoly. Through this analysis, the objective is to gain insights into the stability of the equilibrium point under diverse scenarios and conditions. This endeavor aims to provide valuable information for decision-making and strategic planning. One important aspect of studying these systems is to determine their stability, which refers to how they behave over time under small perturbations.

The stability of this system is investigated by analyzing the behavior of its trajectories for different parameter values. In particular, the values of ϑ_1 and ϑ_2 affect the stability of the system.

$$U = 5, c = 1, \gamma = 2, b = 4, \vartheta_1 = 3, \vartheta_2 = 2$$

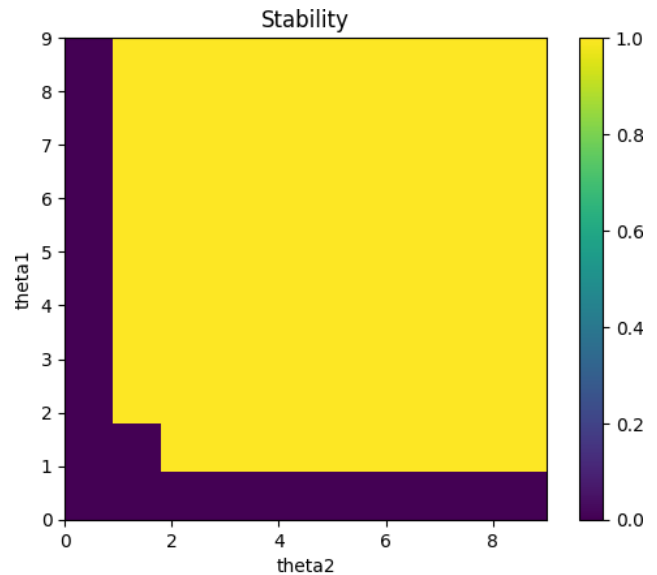

Fig. 1. Stability analysis for the last equilibrium point.

Based on the values of the parameters provided, the graph (Fig. 1) shows the stability of the system as a function of the variables ϑ_1 and ϑ_2 .

The stable region is represented by the purple shaded area, and it corresponds to the values of ϑ_1 and ϑ_2 for which the system is stable. The unstable region is represented by the yellow shaded area, and it corresponds to the values of ϑ_1 and ϑ_2 for which the system is unstable.

The stability boundary is represented by the black curve, and it separates the stable region from the unstable region. Points on this curve correspond to values of ϑ_1 and ϑ_2 for which the system is marginally stable, meaning that small perturbations can cause the system to become unstable.

Overall, this graph provides a visual representation of the stability of the system as a function of the variables ϑ_1 and ϑ_2 , which can be useful for understanding the behavior of the system and for making design decisions.

For the Second equilibrium given the following values, $U = 5, c = 1, \gamma = 2, b = 4, \vartheta_1 = 3, \vartheta_2 = 4$

This graph (Fig. 2) shows the behavior of the system at the equilibrium point (2, 2) as the parameters $U, c, \gamma, b, \vartheta_1$, and ϑ_2

are varied. The color of each point on the plot represents the type of stability of the equilibrium point at that parameter combination. The blue points represent a stable node, the red points represent an unstable node, and the white points represent a saddle point.

As the values of U , c , γ , b , ϑ_1 , and ϑ_2 are varied, the shapes of the stability regions change. In general, as U increases, the stability regions expand, and as c or γ increase, the stability regions contract. The positions of the stability regions depend on the values of b , ϑ_1 , and ϑ_2 .

Overall, this graph provides insight into the behavior of the system at the equilibrium point (2, 2) and how it changes as the parameters of the system are varied.

Fig. 2. Stability analysis for the second equilibrium point.

The graph shows the stability of the equilibrium point in a Cournot duopoly model with open innovation, where ϑ_1 and ϑ_2 represent the speed of adjustment for each firm, and σ_1 and σ_2 represent the ratio of open innovation for each firm.

The red line represents the stability boundary, where any points above the line correspond to a stable equilibrium, while points below the line correspond to an unstable equilibrium. The stability boundary is determined by the Jacobian matrix at the equilibrium point, which in this case is a diagonal matrix with distinct eigenvalues λ_1 and λ_2 .

The eigenvalues can be used to determine the stability of the equilibrium point. If both eigenvalues are negative, then the equilibrium point is stable; if both eigenvalues are positive, then the equilibrium point is unstable; if one eigenvalue is negative and one is positive, then the stability of the equilibrium point depends on the slope of the null clines.

In this case, the stability boundary is curved, which indicates that the stability of the equilibrium point depends on the values of ϑ_1 and ϑ_2 . When ϑ_1 is small and ϑ_2 is large, the equilibrium point is stable for a wide range of values. However, as ϑ_1 increases and ϑ_2 decreases, the stability region becomes smaller and shifts to the right.

The fact that the stability boundary is curved indicates that the duopoly model with open innovation is highly nonlinear,

and small changes in the values of the parameters can have significant effects on the stability of the equilibrium point. This suggests that firms should be careful in their strategic decision-making, and should take into account the potential effects of their actions on the stability of the market.

The graph (Fig. 3) shows the stability of the third equilibrium point in a Cournot duopoly model with open innovation. The model has four parameters: $U = 5.0$, $c = 2.0$, $b = 1.5$ and $\gamma = 0.5$. The equilibrium point is represented in the graph as a black dot at the origin (0, 0).

Fig. 3. Stability analysis for the third equilibrium point.

The arrows in the graph in Fig. 3 represent the direction of the trajectories of two firms in the duopoly as they adjust their speed of innovation, with one arrow representing the trajectory of the first firm (θ_1) and the other arrow representing the trajectory of the second firm (θ_2). The color of the arrows represents the magnitude of the eigenvalues of the Jacobian matrix at each point in the plane, with warmer colors (such as red and orange) indicating more positive eigenvalues and cooler colors (such as blue and purple) indicating more negative eigenvalues.

The graph shows that the equilibrium point at the origin is a saddle point, with one stable direction along the θ_2 axis and one unstable direction along the θ_1 axis. This means that the equilibrium is locally stable in the direction of the second firm's speed of innovation, but unstable in the direction of the first firm's speed of innovation.

Overall, the graph provides insight into the dynamics of the Cournot duopoly model with open innovation and shows how the stability of the equilibrium point depends on the firms' speed of innovation.

In economic terms, the third equilibrium point represents a scenario where both firms choose not to engage in open innovation, resulting in a monopolistic market. The stability of this equilibrium point reflects the short-term stability of the market. However, this scenario is not desirable in the long run, as it hinders innovation and can lead to market inefficiencies.

In economic terms, the third equilibrium point represents a scenario where one of the firms dominates the market with a monopoly position. This may be due to several factors, such as

technological advantages or economies of scale. However, this scenario is not desirable, as it leads to inefficiencies in the market and reduced consumer surplus. It is only when both firms compete and restrict each other's market power that the market can achieve stable development. This state is known as "Nash equilibrium," where both firms maximize their own profits while also ensuring the stable development of the market.

Overall, the graph provides a visual representation of the stability of the third equilibrium point in a duopoly Cournot model, highlighting the importance of competition and market regulation for achieving optimal market outcomes.

V. CONCLUSION

This study explored the use of the Cournot duopoly model to evaluate the impact of open innovation on competitive advantage. By incorporating the parameter of innovation into our model, the first stage of the game is studied, followed by the standard Cournot model to find a balance in the quantities of products on the market. Our analysis showed that the use of open innovation could lead to higher profits and market share for both firms compared to closed innovation. In addition, the speed of adjustment parameter plays a crucial role in the stability of the system, with a smaller value indicating greater stability. Overall, our study highlights the importance of considering open innovation strategies in a competitive market environment.

Our mathematical model demonstrates that under certain conditions, open innovation can lead to greater market share and profits for both firms, compared to a closed innovation approach. These findings have implications for firms operating in industries with high levels of technological change and innovation, and suggest that collaboration can be a powerful tool for achieving competitive advantage.

However, further research is needed to fully understand the dynamics of open innovation systems, and to explore the impact of different market structures, levels of OI investment, and intellectual property rights on firm performance and market outcomes. By further exploring these significant inquiries, a more nuanced comprehension of the intricate interplay among innovation, collaboration, and competition can be acquired. This, in turn, enables the development of strategies that optimize the advantages of open innovation for firms, consumers, and society.

Abstract—The convergence of farming with cutting-edge technologies, like the Internet of Things (IoT), has led to the emergence of a smart farming revolution. IoT facilitates the interconnection of numerous devices across different agricultural ecosystems, enabling automation and ultimately enhancing the efficiency and quality of production. However, the implementation of IoT entails an array of potential risks. The accelerated adoption of IoT in the domain of smart farming has amplified the existing cybersecurity concerns, specifically those pertaining to access control. In extensive IoT environments that require scalability, the conventional centralized access control system is insufficient. Therefore, to address these gaps, we propose a novel decentralized access control framework. The framework applies blockchain technology as the decentralization approach with smart contract application focuses on the application scenario in smart farming to protect and secure IoT devices from unauthorised access by anomalous entities. The proposed framework adopted attribute-based access control (ABAC) and role-based access control (RBAC) to establish access rules and access permissions for IoT. The framework is validated via simulation to determine the price of gas consumption when executing smart contracts to retrieve attributes, roles and access rules between three smart contracts and provide the baseline value for future research references. Thus, this paper offers valuable insight into ongoing research on decentralized access control for IoT security to protect and secure IoT resources in the smart farming environment.

Keywords—Access control; role-based access control; attribute-based access control; blockchain technology; internet of things; smart contract; smart farming

I. INTRODUCTION

The integration of the Internet of Things (IoT) technology into smart farming infrastructure has the potential to revolutionize the agricultural industry by enabling the collection and analysis of vast amounts of data from various sources such as sensors, drones, and cameras. IoT technology can provide real-time information on farm operations, allowing farmers to remotely monitor and control equipment and make data-driven decisions for fast response to issues, minimize impact and reduce costs [1]. However, the adoption of IoT devices in smart farming also presents several challenges that need to be addressed. One of the primary concerns is the risk of IoT security, which arises due to the use of numerous heterogeneous devices in the system. Another critical issue is the management of resources, which can become complex and require a high level of coordination and integration. Furthermore, as smart farming systems grow in

size and complexity, scalability becomes an increasingly important factor that must be considered[2],[3],[4]. Thus, to address the challenges posed by the adoption of IoT devices in smart farming, it is crucially needed for the enhancement of access control to ensure authorized access will be granted to legitimate devices while also being scalable to accommodate future expansion. An effective access control system can help mitigate the risks associated with IoT security and improve the overall scalability and management of resources in smart farming systems. Nevertheless, conventional centralised access control has brought about several problems and remains as a complicated issue since it includes single point of failure and incapability of addressing dynamic and diverse access control requirements for future IoT ecosystems [5] [6]. Therefore, the new framework must be designed with the aim of shifting from a centralised approach to a decentralised approach for eliminating trusted third parties in access control and achieving optimum management of IoT resources. Thus, this paper proposes a decentralisation approach using blockchain technology as a suitable solution since it provides an open, transparent and distributed ledger without the need for a third party [7]. It also has strong security features for securing IoT resources in the form of hashing ledger which guarantees high system reliability and integrity. This paper is structured as follows. Section II describes the background study including the IoT infrastructure, security issues, access control, blockchain smart contract and its application in smart farming. Section III highlights the related works to this study. Section IV discussed the proposed decentralised access control framework for IoT security enhancement using blockchain technology. Section V describes the evaluation procedure. Section VI presents the contribution for this work and Section VII discusses the conclusion for this study.

II. BACKGROUND STUDY

According to the United Nations (UN), population growth is steadily increasing along with food consumption and production demands, which are anticipated to increase up to 70% by 2050 [10]. To fulfil these demands, conventional agriculture must shift to smart farming which combines internet connection and modern technology like IoT. This will provide numerous benefits, including accurate data collection for data-assisted decision-making [11], [12]. Such a scenario will enable remote monitoring, thereby contributing to the reduction of production costs. This will lead to efficient and sustainable agricultural production that is more demand-oriented and resource-efficient.

A. IoT Architecture and Security Issues in Smart Farming

In smart farming, the integration of IoT sensors with any farm equipment and machinery for monitoring temperature, humidity, pressure, etc., will enable systematic data collection. The data can be remotely sent from different locations to a centre for monitoring and decision-making. These devices and sensors have their roles to play according to the different techniques used, their functionality and implementation, which can help farmers provide information in real-time. Farming techniques can be improved based on the collected information [13]. For instance, the roles include crop management, water management, soil management, livestock management, smart greenhouses and agriculture drones[11]. Smart irrigation systems, for instance, use temperature and soil sensors to maintain and control water wastage as well as to improve crop quality by monitoring the humidity of the soil and only watering at the right time. Thus, the management of heterogeneous IoT devices and sensors must be efficient and reliable.

The IoT architecture illustrated in Fig. 1 displays the key layers in smart farming, which are: the physical layer, the network layer, the edge or fog layer and the application layer. The physical layer can be any type of device (such as actuators and sensors) connected to the IoT network. The network layer is responsible for data transmission from the physical layer to the data processing system. The data transmission may use any wired or wireless device, such as a router, access points, 4G or 5G network, Wi-Fi, Bluetooth, etc. The network layer has a high possibility of security flaws if there is connectivity via the internet. The probable attacks (such as identity theft, bullying or controlling/hacking) can be countered by implementing identity management and encryption schemes [14]. The next layer is the edge or fog layer consisting of various resources with computer processing capabilities. This layer can store a small amount of data and process that data. It can also be used for decision-making and security features. The edge or fog layer includes the in-out interface and the gateway used to manage the entire collected data from the sensor without transmitting it to the cloud. The application layer is the communication protocol and interface that provide services to users and data visualisation from the sensor network.

It is important to protect and safeguard connected devices in the IoT environment [2]. According to [14], the security protocols that should be applied in smart farming IoT security solutions are access control, authentication, firewall, anomaly detection system and cryptography. However, before applying those security protocols, we must address the security issues and potential attacks in each layer of smart farming. Study [15] has developed various security protocols and arranged them into different categories (access control protocols, authentication protocols, key management protocols and intrusion detection protocols) to support various IoT applications that suffer from possible attacks.

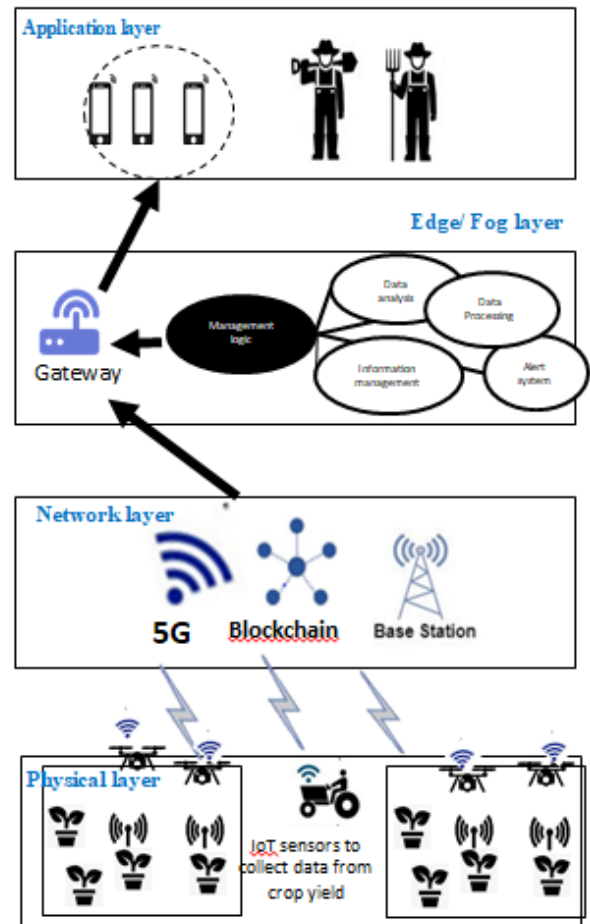

Fig. 1. Smart farming architecture.

Access control must be implemented to facilitate the process of data transfer in the physical layer. However, in IoT environment, security protocols (such as secure public key-based authentication and cryptography) are not suitable due to high computational power and storage capacity requirements [4]. Gupta et al. (2020) stated that edge layers may contain major security issues due to IoT devices and sensors that do not have their own security. This makes it easy for attackers to gain remote access to the system via unauthorised access, booting, flooding and signature wrapping. In the application layer, attacks have been categorised into two types: software attacks and encryption-based attacks. Software attacks generally use malicious software agents to acquire authentication credentials of users [14]. Encryption-based attacks apply extensive attacks to exploit the cryptographic protocols and mathematical models. Table I provides a summary of possible security attacks and issues in smart farming, along with the proposed countermeasure. In Table I, the type of attack is categorised according to the layers in the smart farming architecture.

TABLE I. SECURITY ATTACKS AND COUNTERMEASURES ACCORDING TO LAYERS

Layer	Security goals	Security attacks	Countermeasure
Application	Availability, Non-Repudiation, Privacy [17], Accountability and Integrity [2]	Data thefts, Sniffing, Access Control [4], [14] [17], Phishing attack, Malicious scripts, Deny services [4], reprogram attacks [17], Channel interference, DoS/DDoS, Cyberagroterrorism [2], Malicious Code Injection Attack, tempering privacy [14]	Access control, data encryption (cryptography and non-linear key encryption), Authentication, anti-virus, anti-spyware, firewall and ACLs [14]

B. Access Control in IoT

The basic element of access control is the ability of the subject and object to perform an action that includes interaction in the right manner [19]. In the IoT environment, access control plays a crucial role in ensuring that all resources, including actuators and devices, are protected using selective restrictions that control access to IoT devices [20]. The object is defined as the system resource that contains or stores information on IoT devices, sensors, directories, programs, etc. An object is secured by a set of access policies consisting of conditions and requirements for an object's access to be granted. The subject can be defined as an entity (users or systems) that is capable of accessing an object. A subject must prove that it satisfies an access policy of a requested object before access is granted.

According to [21], four design components must be addressed based on the current access control problem in the IoT environment. Meanwhile, several approaches have been proposed for managing access control and associated privilege according to their access level in IoT systems [22], [23], [24], [25],[26],[27]. Discretionary Access Control (DAC), Mandatory Access Control (MAC), ABAC and RBAC are the most conventional models used in smart farming. Based on the literature, two commonly employed access control mechanisms for IoT are RBAC and ABAC due to their strong features and flexibility in supporting the IoT environment [28], [29], [30], [31], [32], [33], [34], [35].

1) *Basic concepts, advantages and disadvantages of the ABAC model:* ABAC uses pre-defined policies for access permission. The policies consist of three attributes: subject, object and environment [8], [30]. The attributes are used to authorise access permission with specified access policies using a target function that determines whether or not sufficient privileges are present for access[36]. Specific access policies with selected attributes must have good management [32].

The advantages of ABAC include the flexibility of policies based on changing dynamic attributes, such as location and time. With its flexibility and scalability, the ABAC model is more suitable for access control in IoT [32], [34], [36], [37], [38]. In addition, the use of access control marker language (XACML) as an extension of ABAC can be expressed as logical-based policies to define valid authorised access [21]. However, the drawback of XACML is the extensible markup language (XML), which makes it unsuitable for constrained devices, such as IoT applications. In ABAC, all attributes that have been defined must be managed and distributed to the right user for effective access management [32]. It can be a problem for IoT devices with less storage and computing power when the number of attributes and the number of users increase.

2) *Basic concepts, advantages and disadvantages of the RBAC model:* In RBAC, access control is based on the roles of subjects within an organisation who give permission. By associating the user with its roles and access permissions (e.g., read, write and execute), the roles are set to be active. They

can be structured in hierarchal order where senior roles are more powerful and have more permission for access as compared to junior roles. Another important aspect of RBAC is constrained enforcement. A constraint can be applied at either the system level or the application level. Restrictions to RBAC states with or without being event triggered are known as invariant and precondition. These two restrictions are used as conditions when a role is assigned to a user in a user-role assignment and permission is assigned to a role in a permission-role assignment.

The advantages of RBAC are: a) the user can access resources based on the achieved tasks under suitable access mode and b) it is easier for the system administrator to redefine permissions for each user separately according to their roles [8]. The disadvantage of the RBAC mechanism is the inability to differentiate its role [28], leading to role-permission explosion problems in situations where the service-providing entities are unable to allow access permission to the user-role assignments of the role-providing entities due to a large number of objects [8]. Research [39] stated that service-providing entities must use an alternative to confirm if an unknown guest legitimately owns a certain role. The authors in [30] also noted that the disadvantages of the RBAC system are its lack of flexibility in adapting to changing users, maintain user-to-role assignment and role-to-permission assignments for dynamic applications or large-scale applications with a significant number of users or objects.

In summary, IoT has various limitations, including resource constraints, that prevent IoT from handling operations that require high computational power including managing complex access control [40], [41]. In [42], the authors use a combination of RBAC and ABAC models in the centralised environment. The authors proposed to divide the permissions assigned to a role according to their access actions. However, most research had proposed centralised decisions which can lead to the central point of failure and limited resources of IoT devices [43],[40]. Thus, the decentralised approach is more suitable for large-scale IoT environments.

C. Blockchain and Smart Contracts

Blockchain is formally described as a digital, decentralised and distributed ledger that communicates transactions or sensitive data without trusted third parties, removing centralised authority and intermediaries, and enabling two parties to communicate and conduct business quickly, securely and reliably [44]. This technology is different from the traditional system where the conventional approach is centralised. The structure of chain in blockchain is shown in Fig. 2.

In contrast, the blockchain system implements a decentralised system with many possible physically scattered nodes [45]. Blockchain also has strong security features for securing IoT resources in the form of hashing ledger which guarantees high system trustworthiness and integrity [32]. Based on the literature, blockchain has various unique characteristics such as decentralisation, transparency, autonomy, security, immutability, traceability, integrity and programmability [46]. Due to blockchain's characteristics, its application is relevant for access control in smart farming since complex approaches are required. In the meantime, for a successful transaction on a blockchain network, verification is required through a consensus algorithm to reach an agreement on the transaction or a smart contract between two parties. The adoption of a consensus mechanism is dependent on the types of networks and the roles of nodes. Blockchain networks can be public or private networks [47], and the roles can be permissionless and permissioned. In permissioned or private networks, only invited nodes can participate in the network. The nodes will be divided and assigned to their roles. Only the selector miner node can perform transactions [48].

Meanwhile, smart contracts are self-executing contracts in which the terms of an arrangement between two parties are expressed in computer codes. When the requirements of a smart contract are met, it will self-execute to a blockchain, removing the need for trusted third parties [49]. According to [50], smart contracts are one solution that responds to the transaction sent by a user. The transactions use code logic which is the Solidity language [51]. Once users agree to the agreement based on the contract, this code logic will be incorporated into the blockchain network and all users in the network will have copies of the contract.

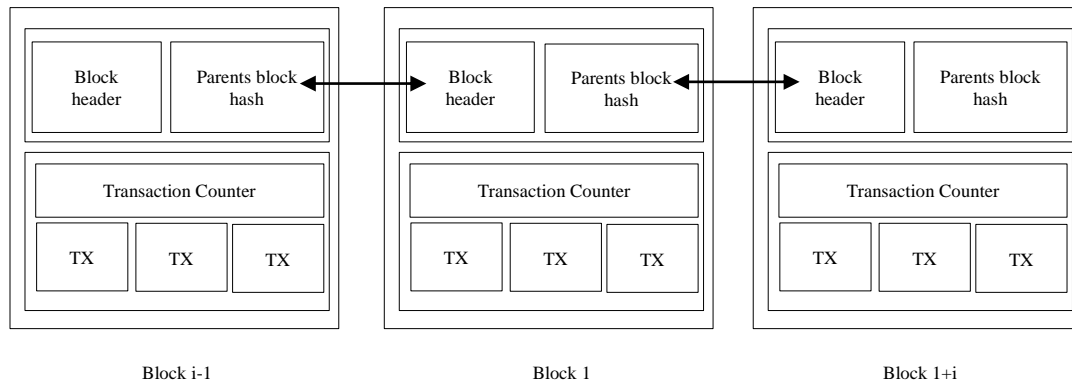

Fig. 2. The chain in blockchain.

III. RELATED WORKS

This section presents the most relevant literature related to our study and proposes a solution for access control in the IoT environment. Table II displays several existing solutions with a list of required elements for developing access control solutions in the IoT environment. The researchers in [52] proposed RBAC as a strategy for device management by considering the limited user access strategy and protecting the IoT network using Software-Defined Networking (SDN). The proposed study was able to manage network flow and provide dynamic access control when the access network rule needed to change. This proposal can overcome the problem of unauthorised device in the system by authenticating the server and providing information, such as a network device and network identification, to detect malicious activity. However, this proposal requires a system administrator to carefully manage user access control and network rule exposed to the risk of vulnerabilities due to careless configuration. The study [53] proposed a framework by using event-based solutions for access control mechanisms in an IoT environment. To handle the event process, the authors employed a processing module as a policy module for managing and controlling the movement of event operators and calculating data to prevent starvation of resources during the computation process.

Researchers also suggested combining the access control model and blockchain since blockchain has been widely used in several domains for promoting decentralisation, dynamic access control and tamper-proof [54]. ABAC was proposed to be the access control model with advantages such as scalability and flexibility for securing and protecting IoT resources with excellent features. The research [55] suggested a Policy chain integrated blockchain-based ABAC framework to address the problem of securing shared resources in decentralisation. In this framework, the authors utilised the JSON + Script format as the policy expression and devised new ways to apply policies using “script interpreter”. The interpreter was constructed according to three evaluations: evalScript, evalRule and evalPolicy as well as a consensus protocol for executing decisions faster. The research proposes that off-chain resources can be accessed by IoT devices using the pre-determined on-chain policy. The authors used consortium blockchain and two different nodes: full nodes and lightweight nodes. It was noted that the consensus algorithm can be used for validating and storing transactions in full nodes. The synchronisation of current state networks was accomplished in light nodes.

Similarly, [56] proposed an access control framework based on the blockchain technology suitable for heterogeneous IoT by evaluating attributes, operations and environments according to requests. In this proposal, the researchers used four smart contracts for executing access control mechanisms: access control contract (ACC), subject contract (SC), object contract (OC) and multiple policy contracts (PCs). They ensure security and flexible access control in the IoT environment. The authors also utilised trust management for detection and evaluation of malicious behaviour from other devices. The authors [34] stated that the protection of critical resources in IoT can be done by replacing conventional centralised access control, which is insufficient in large-scale IoT environments. They suggested the Attribute-Based Distributed Access Control (ADAC) with a smart contract system. ADAC was proposed to manage and access attributes of IoT devices by using three smart contracts: ACC, OC and multiple PC. ADAC development was inspired by the ABAC model which can determine authorised users based on subject attribute, object attribute, environment attribute and policies. The study [57] also offered to solve the single point of failure issue by combining Accountable Subgroup Multi-Signature (ASM) algorithm with the ABAC model and smart contract policy in order to achieve fine-grained and reliable data access control. This paper uses access policies to specify whether users with certain subject attributes are permitted to perform certain actions on data with certain object attributes in a certain environment. The access policies consist of Subject Attributes Policy (SAP), Object Attribute Policy (OAP), Attributes Authorise Policy (AAP), Environment Attributes Policy (EAP) and Result. For policies, evaluation is based on the required attributes that meet with policy, and the result consists of three elements: permit, deny and not applicable. ABAC model for IoT-integrated blockchain technology to tamper-proof, store the attribute and eliminate a single point of failure were utilised in a study. For accessing data, the author applied four smart contract mechanisms implemented on the Ethereum blockchain: ACC, object attribute management contract (OAMC), subject attribute management contract (SAMC) and policy management contract (PMC). They are responsible for storing and managing access policy information that consists of specified actions regarding the subject and object which must have their access request verified. However, the proposed framework lacks security and privacy protection of IoT data due to unauthenticated edge nodes which have no access decision at the edge. The researchers in [59] proposed the BorderChain application which allows IoT owners to authorise selective IoT services and devices that permit access at the IoT gateway before opening the endpoint to others via smart contracts. After the IoT owner grants access, an access token will be generated which can be used by legitimate IoT services and users to query IoT resources in IoT domains. This solution can convince IoT domain owners that the system will only authorise IoT requests that they approve. For scalability goals, the authors implemented off-chain (outside blockchain) which is cheaper and more efficient during the process of signature verification mechanism. The study [9] combined elements of access control methods, such as ABAC, RBAC and Capability-Based Access Control (CBAC), to establish fine-

grained policy decisions in the healthcare environment. This framework reduces the number of policies by using the attribute to define roles as well as capabilities to provide only single attribute expressions that can access multiple resources. However, this framework is partially decentralised and stores access policy in a single database server based on a policy language (XACML) as well as policies generated by administrators. The blockchain will only allow if it reaches an agreement in the smart contract/consensus algorithm. It was also noticed that the development of security policies in access control mechanisms can be achieved via smart contracts where all users in the blockchain network will acquire a copy of policies and store them in blockchain. Flexibility and scalability can be achieved when using the combined access control model in an IoT environment since it can be utilised in heterogeneous IoT devices, further reducing the use of storage capacity for storing access policies in IoT devices.

Based on the literature, we identified that there is significant advantage for decentralised access control with blockchain technology integrated with the RBAC and ABAC models. RBAC can provide strong security by conducting role hierarchy and constraints to give permission, whereas ABAC is very flexible in granting access permission based on the three attributes. Therefore, in this paper, for our framework development, we propose the use of blockchain technology as a decentralised solution for managing and storing access policy information of subject and object that must verify their access request. We also utilise smart contracts for the automation of access decisions. For access policy development, we propose to implement a combination of the RBAC and ABAC models as an access control strategy. Our proposed framework is aiming to close the gaps for the access control focusing on enhancement of security and resource management using decentralized IoT mechanism that also considers the scalability factor.

IV. DECENTRALIZED ACCESS CONTROL FRAMEWORK FOR IoT SECURITY ENHANCEMENT USING BLOCKCHAIN TECHNOLOGY IN SMART FARMING

This section discusses our proposed decentralised access control framework for IoT security enhancement using blockchain technology. First, we present an extensive overview of our proposed framework, as illustrated in Fig. 3. This framework was developed with the primary aim of achieving security, while also efficiently managing resources and ensuring scalability to cope with the increasing demands of smart farming. This framework was developed by adapting the FRABAC model where the combination of RBAC and ABAC models with user-role permission and attributes are employed for the user, admin and resource owner through smart contracts [8]. The integration of blockchain and access control models is the novel element that can reduce the redundancy of several roles and rules of permission. It has a unique access without creating or implementing special roles or rules reserved for each user/device. This framework can help address the role permission explosion or role-explosion problems, which have complex role structure (hierarchy) and a large number of roles. Most of them have the same access permissions. Our framework includes a blockchain-based smart contract and P-2-P network. The network consists of

IoT node owner, full nodes, lightweight nodes and extra lightweight nodes which have their own responsibilities based on the ability to execute access control according to computing power and storage capacity that considered based on smart farming scenario.

In this framework, we propose the adoption of smart contracts for access permission request, access control rule management and for verifying the permitted decision by fulfilling the requirement of access rules.

Smart contract is also responsible for updating attributes and roles. Access permission provides transparent access permission and traceability since all nodes have a copy of the smart contract. In FRABAC model there are Access Control Contract, Object-Rule Management Contract and Subject-Role Management Contract. These three concepts were adopted as IoT_ACC, IoT_ORMC and IoT_SRMC in our framework. In

the smart farming environment, to address heterogeneous IoT device authorisation matters, we propose that every device must authenticate itself by describing and identifying its own credentials including its attributes, such as address name, identification number, location and role. Thus, all authenticated devices must interact through smart contracts for access control execution which contributes to tamper-proof access rules. A set of rules was developed to define access permission that can be executed by a subject (IoT devices) to access the object (resources). This access decision is processed by checking the matching rule with the list of all attributes that meet the requirement. The rules consist of i) identifier role, ii) type of access request, iii) identifier access action and iv) the list of attributes. The attributes must have the same attribute values in the resource, rs, and the requestor, known as IoT devices, u. We defined V as value of attributes which can be presented as follows: $V_{rs}(r,att) = V_{u_i}(u,att)$.

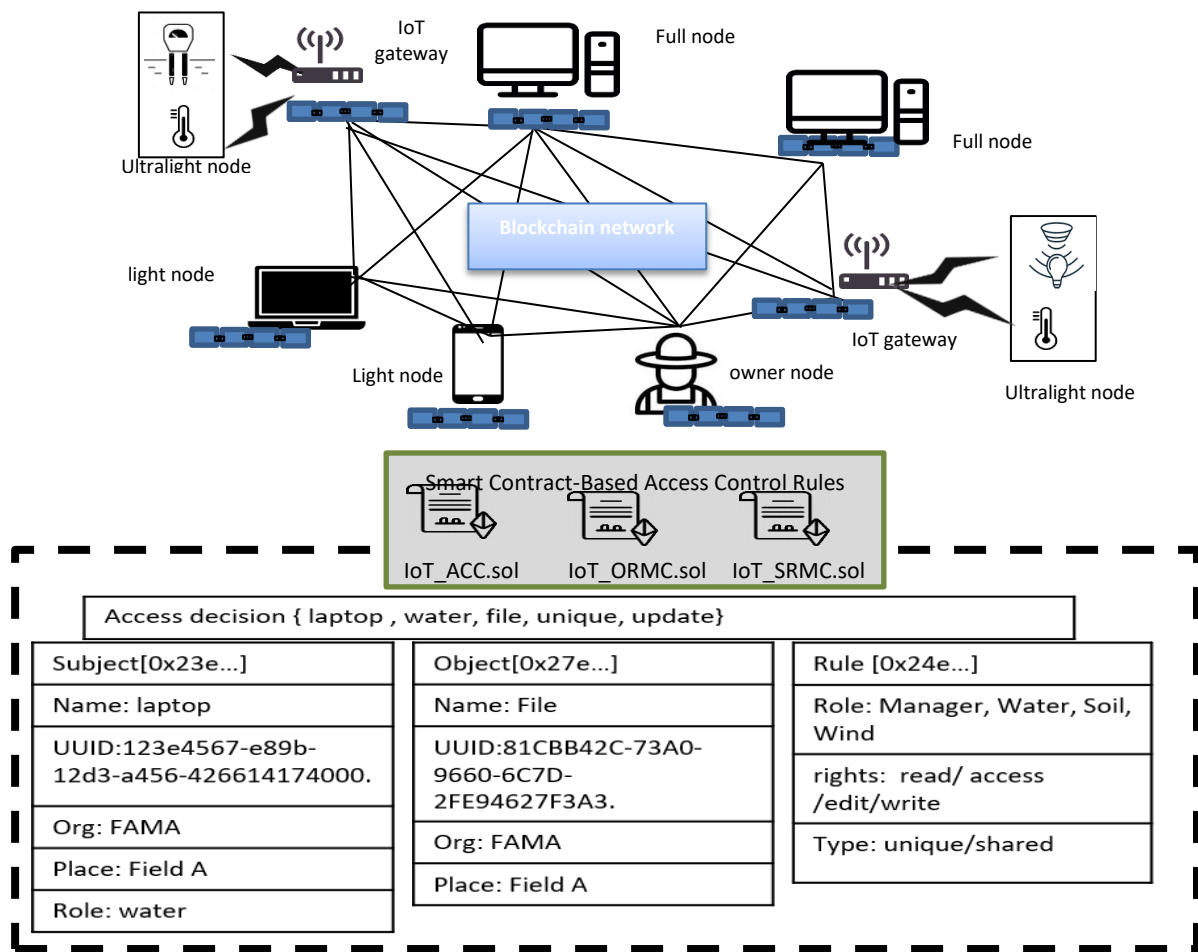

Fig. 3. Decentralized access control framework for IoT security enhancement using blockchain technology in smart farming.

The flow of access control in the proposed framework was described by illustrating the interaction of network nodes with smart contracts, as illustrated in Fig. 4. The IoT owner nodes are responsible for managing access rules. The access rules consist of four factors: type of access, role, access action and a matching list of all attributes. Once rules are mined, they will be stored in IoT_ORMC (step 0.1). The IoT owner node is also responsible for storing and managing all attributes that consist of three different nodes, including full nodes, light nodes and ultralight nodes. The IoT owner node must assign a role for each node based on its responsibility and it will be stored in IoT_SRMC (step 0.2). When IoT_ACC obtains a request from any node, such as light nodes (laptop), to access resources (step 1), the request will be evaluated by IoT_ACC. Evaluation is accomplished by obtaining the access rules from IoT_ORMC (step 2) and acquiring all attribute information as well as the roles from IoT_SRMC (step 3). Finally, IoT_ACC verifies the access request by matching the access rule in IoT_SRMC and the attribute in IoT_ORMC (step 4). If the request is sufficient for access privileges, the requestor (laptop) can access the resources based on its roles.

A. Blockchain Nodes

In this framework, public and permissioned blockchains are adopted where nodes will be added and removed from the network with their identity verification. Since every node has a role and permission, the blockchain nodes require more CPU processing power and memory requires significant storage

space to maintain the ledger copy [59]. We propose using four different nodes that allow heterogeneous IoT devices to access the blockchain network. Two nodes used for access control are categorised according to their capabilities, storage capacity and computing power [63]. The types of nodes and their responsibilities are categorised in the blockchain network, as follows:

- IoT requestor node is a requester that runs smart contracts for requesting access to resources. In the smart farming scenario, the requestor nodes are IoT devices or IoT sensors. Each node requestor is added and authenticated to the blockchain network by the IoT owner node before requesting access to resources. Requestor nodes represent three different nodes: full node, light node and ultralight node.

Full nodes are devices that have sufficient computing power and storage capabilities such as computers, laptops and servers that can perform full transactions. Light nodes are devices that have limited storage capabilities and computing power and can only store blockchain headers and support services for themselves. Mobile phone is one example of light nodes. Ultralight nodes are devices that have insufficient storage capabilities and computing power. Sensors and actuators are examples of ultralight nodes that require connection from the IoT gateway to P2P networks through communication technologies, such as Wi-Fi and ZigBee.

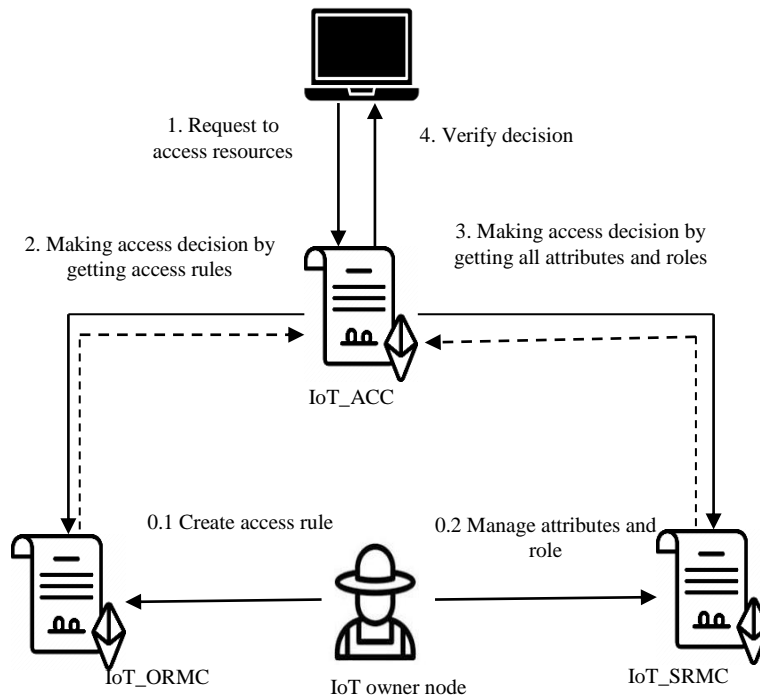

Fig. 4. The interaction between IoT requestor node with smart contracts to access a resource.

- IoT owner node represents the owner of the IoT resources and devices in smart farming. An IoT owner node defines and deploys access control rules and permits requestor devices to enter the network through smart contracts. It can also add new IoT devices, manage node attributes as well as assign their roles that represent their responsibility.

B. Smart Contract-based Access Control Rules

In this research, for the verification mechanism in the blockchain network, we designed smart contract-based access control rules where the admin has the privilege to register devices to the blockchain network for the first time. Afterwards, all devices that request access to the network will be self-authenticated. This is particularly significant since smart farming consists of heterogeneous sensors that require self-administration to obtain access to the system at any time. In our smart contract design, we propose three smart contracts to avoid complexity. The smart contracts are: IoT_ACC, IoT_SPMC and IoT_ORMC. IoT_ACC is responsible for enforcing rules and making access decisions, IoT_ORMC is responsible for managing and updating the rules and resource attributes and IoT_SPMC is responsible for managing and assigning device attributes and the role of IoT devices.

1) *Access Control Contract (IoT_ACC)*: IoT_ACC evaluates requests and provides access decisions made by access requests from IoT devices and sensors (subjects) to access resources (objects) in the system. This contract is executed by IoT devices when checking the pre-condition rules. The pre-condition rules will be matched based on the rules made from ORMC to the ACC to determine whether the subject has the right to perform actions on the object. To evaluate an access decision, this contract has two steps:

Step 1: Identification step

In this step, IoT_ACC will identify the type of request by IoT devices, either unique or multiple, and verify whether the IoT devices have sufficient requirements for acquiring access privileges. If the devices identified have access privileges, then the request will be saved and evaluated, otherwise, the request will be ignored. This step consists of two functions:

- `typeReq()`: used for the identification of type request. The request must have three things: user, `ui`, resources, `ri`, that want access and access action, `acci`. In this identification process, the user, `ui`, must contain identification, `userID`, that uses an Ethereum account and the list of user attributes, `userAtt` (e.g., location, time). Meanwhile, resource, `ri`, must have object identification, `objectID`, identification of resources belonging, `refer_to`, the list of resource attributes (e.g., location, type), `resourceAtt`, and access action, `acci`.
- `requestAction()`: used for deciding the type of request. The request `typeReq()` will pass value where a decision is made based on the object `refer_to` attribute.

Step 2: Evaluate the request

After successfully identifying the type of request, the evaluation process request is accomplished by retrieving precondition and evaluation constraints. To evaluate the access request, IoT_ACC must recognise whether or not the requestor is an active role and has rules. There are two functions in this step:

- `activeRole()`: to identify active role by checking the subject/IoT device via registering all attributes of subject/IoT devices in blockchain.
- `getRule()`: to retrieve rules that are specified in the form of tuple (rolei, typeAcci, accModei, attribute index list, attribute user, attribute resources). We determined rolei as the identifier of the role, while typeAcci represents the type of access. 1 represents shared access, while 0 represents private access. accModei is set as the identifier of access action, and the list of attribute index is defined as matching values of attributes in the resource, `ri`, and the user, `ui`. In tuple, the attribute user defines the values of attributes of the user. The attribute resources represent the attribute values of resources.

After evaluating the rules and active roles, IoT_ACC is conducted to evaluate three constraints defined in RBAC and ABAC.

- User resource constraints were used to check whether the attributes in the object and user are the same values. If the values of attributes are the same, it will pass the value to `currentRule()` in the form of a Boolean function which is a true value.
- User constraints were used to check if attributes in devices are equal or the same values as the access rule. If the value of attributes is the same, it will pass the value to `currentRule()` in the form of a Boolean function which is a true value.
- Object constraints were used to check if attributes in resources are equal or same values as the access rule. If the value of attributes is the same, it will pass the value to `currentRule()` in the form of a Boolean function which is a true value.

After successfully validating the access request through several steps, the subject (the IoT device) verifies the results.

2) *Object-Rule Management Contract (IoT_ORMC)*: IoT_ORMC specifies a policy by defining a set of access rules associated with each subject and resource based on two types of rules for resource access: shared access and private access, as shown in Fig. 5 the process of adding access rule. In this smart contract, only the IoT owner has the authority to execute the access rules. According to [8], these rules will be more efficient in reducing excessive permissions. Instead of checking user queries by using many rules, the model checks user queries by using only one rule. In this study, the set of access rules have four criteria: type of rule, access action, role and constraint, as shown in Table III.

Fig. 5. Process adding access rule function.

TABLE III. SET OF ACCESS CONTROL RULES FOR IoT_ORMC

Type of Rule	Access Action	Role	Constraint
unique	Update / write	Water	Extension rs: docx place rs: A type rs: water $V u(u,att) = V r(rs, att)$.
multiple	Read	Water	Extension rs: pdf place rs: A type rs: water $V u(u,att) = V r(rs, att)$.

- Type of rule: is the type to access resources. In this case, we divided access resources into two types: unique and multiple. Unique access is an editable resource, such as word (i.e., docx) and excel (i.e., xlsx). Multiple access is a non-editable source, such as portable document format (i.e., pdf), video (i.e., mp4, avi) and audio (i.e., wav, aif, mp3).
- Access action: is an action that performs by subject to access resources; for instance, read, write, view, control, etc.
- Role: is a character played by IoT devices (e.g., the device for watering plants is categorised under water group).
- Constraints: are access restrictions built on logical formula by donating the value function where the attribute value for the user is $V u(u,att)$ and the attribute value for the resource is $V r(rs, att)$. Constraints can also include other statements such as time or location which are environment attributes, $V u(u,att)$.

3) *Subject-role Management Contract (IoT_SRMC)*: In the process of access control, IoT devices can have their identity impersonated [64][64]. To address this security concern, IoT_SRMC is proposed to authenticate legitimate users who intend to access the IoT network by registering a new device in the IoT network. This contract adopts ABAC

and RBAC models as a strategy for accessing control. It determines all attributes of IoT devices that can be used as valuable information to assess resources and assign roles to IoT devices. Each IoT device has a unique identifier (Ethereum account address) and multiple attributes associated with its ID, including location and role. This contract has functions for managing subject attributes and roles, such as adding, deleting and updating, which can only be performed by the IoT owner. In Table IV, all information about the IoT device is shown.

TABLE IV. SUBJECT REGISTRATION TABLE

device	deviceID	deviceType	deviceRole	devicePlace
Device A	0xA128F8	laptop	water	field A
Sensor B	0xA134S8	temperature	water	field A
Gateway A	0xA122A8	gateway	soil	field A

C. Framework Flow

We present two types of form requests in this research. First part is the registration of new IoT devices and sensors; second part is the access request by IoT devices made through smart contracts. Fig. 6 illustrates the decentralised access control for IoT security enhancement. For the first part, the registration of new devices and sensors begin when an IoT owner issues a smart contract that implements a hybrid access control mechanism into the blockchain. Blockchain responds by issuing requests to the IoT owner and then creates a smart contract.

The IoT owner requests to register his own IoT devices and sensors, known as a subject, intended to authorise its device by providing all device and sensor attributes (i.e., name, location, identification, role, etc.). If no rule is made, the IoT owner must publish an access rule based on four criteria: i) types of access (shared, private), ii) role, iii) access action and iv) constraint. Lastly, after all access rules are complete, the transaction is stored in the blockchain.

For the second part, access is requested by IoT devices made through smart contracts where the IoT devices send a request for any service to access or update (i.e., data, file, storage unit) in the IoT network. Next, when the request of the subject is generated, IoT_ACC (main smart contract) is executed to control the overall access management. IoT_ACC will then obtain all information from IoT_ORMC and IoT_SRMC to match values between the access request, access rule and list of attributes to obtain the access decision for IoT devices. If all information shows the same values and authentication is successful, then access permission for IoT devices is complete. IoT_ACC then forwards back the return access result to IoT devices or corresponding objects. Finally, the result of access permission is stored in the blockchain network.

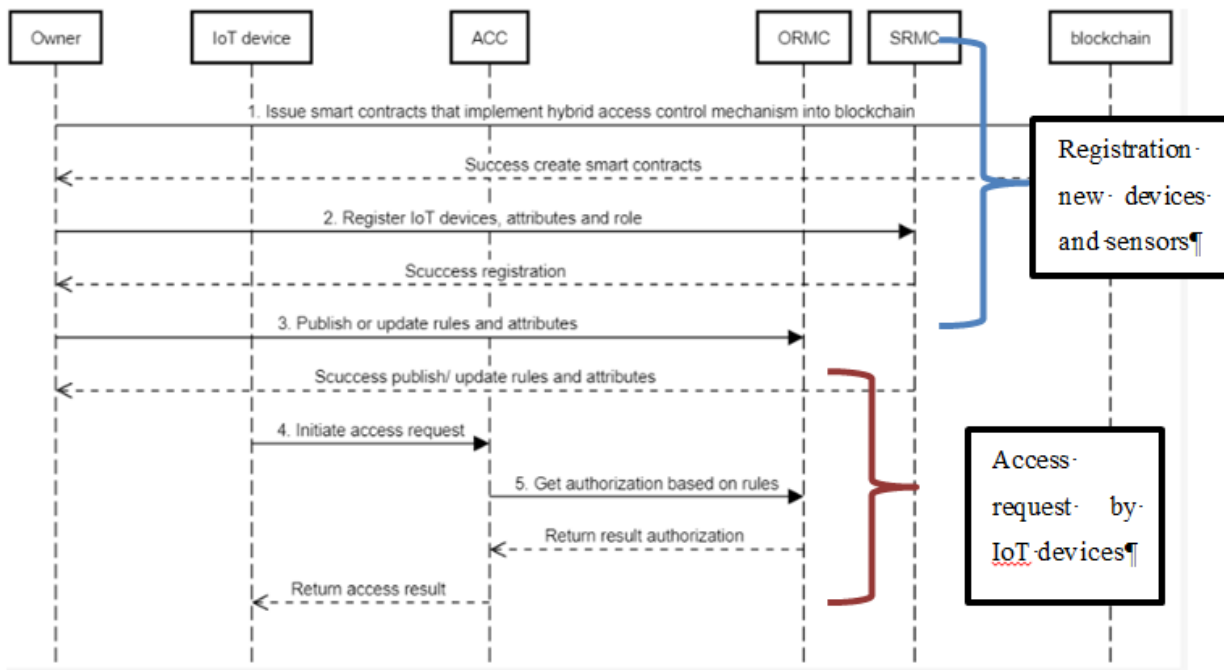

Fig. 6. Access control flow mechanism in smart farming.

V. EVALUATION

The main component of the proposed framework is the smart contracts that functioned as the verification mechanism. The deployment of smart contracts on the blockchain and the execution of associated contracts require payment of fees to the miner who mines the block. Thus, to evaluate our proposed framework, the smart contract cost consumption was measured by calculating the gas used for a transaction execution for the specific functions in smart contracts. The complexity of the task determines the quantity of gas consumed, with more gas being used for more complex tasks and the price of gas fluctuates over time. The fee required to perform a task is calculated by multiplying the consumed gas amount and the gas price. In this study, we run experiments for evaluation in the Ethereum network and the gas limit is set by the transaction initiator that determines the level of computational resources to be utilized in executing the transaction. In Ethereum, a unit called gas was employed to quantify the amount of work required to complete a task when deploying a smart contract. The initiator pays a fee for the gas used, which can vary depending on the gas limit set. The higher the amount paid, the easier the transaction will be executed [65] [66]. In this study, we determine cost per transaction by multiplying the gas price per unit with the gas limit (gasPrice X gasLimit) as per calculation in [51]. If the gas limit does not exceed the gas used, the execution of the transaction will be successful and it will be added or dropped in the blockchain network.

A. Simulation Setting

The experiments were conducted during the end of March 2023 when the value of 1 Ether is at the average of 1 eth ~ 1000000000 gwei. In this study, the simulation environment

was set up in two layers with the hardware setting and the software setting, as displayed in Tables V and VI, respectively.

TABLE V. HARDWARE SETTING

Items	Description
Operating system	Windows 10
Processor	AMD Ryzen 7 3700U with Radeon Vega Mobile Gfx 2.30 GHz
Memory	8 GB RAM

TABLE VI. SOFTWARE SETTING

Items	Description	Details
Language	Solidity	Used to build prototypes of smart contracts based on object-oriented programming language
Platform	Ethereum Network	Used as a public blockchain network in the virtual environment (EVM)
Compiler	Remix ide (version 0.5.17)	Used to compile smart contracts
Test network	goerli testnet	Used to test networks
Gas limit	3,000,000 units	Used to set the amount of gas initiator that will execute the transaction

B. Gas Usage and Cost per Operation in Smart Contracts

The costs and gas usage in different smart contract deployments of IoT_ACC, IoT_ORMC and IoT_SRMC are shown in Table VII. Deployment of IoT_ACC smart contract requires 1,487,367 gas units. The gas cost in IoT_ACC is less than other smart contracts since IoT_ACC smart contract is only used for enforcing access decisions. Meanwhile, in IoT_ORMC smart contract, 2,196,564 gas units are required to create access rules based on ABAC and RBAC that execute

the checking steps to determine if the role is a one-to-one relationship and active. In the meantime, to deploy IoT_SRMC smart contract, 1,677,746 gas units are required. Then, using the experiment's result, the cost of executing the IoT_ACC, IoT_ORMC and IoT_SRMC functions is calculated using Eq. (1).

$$TxFee = gas * gasPrice * 10^{-9} \quad (1)$$

where gas represents the amount of gas used by the transaction, gasPrice represents the price of each gas unit, and 10^{-9} is a conversion factor to convert the result into Ether. Hence, in this study, we determine that the cost value of executing each of the proposed smart contracts for IoT_ACC, IoT_ORMC and IoT_SRMC are 0.007212, 0.020180 and 0.019921 ether. This value serves as a benchmark for the cost operation for the proposed framework application in smart farming settings.

TABLE VII. GAS USAGE AND COST OF DIFFERENT SMART CONTRACT FUNCTIONS: IoT_ACC, IoT_IoT_RMC

Smart Contract Deployment	Description	Gas used	Cost (ether)
IoT_ACC Function	Responsible for enforcing rules and making access decisions	1,487,367	0.007212
IoT_ORMC Function	Responsible for managing and updating rules and resource attributes	2,196,564	0.020180
IoT_SRMC Function	Responsible for managing and assigning device attributes and the role of IoT devices	1,677,746	0.019921

VI. CONTRIBUTION

This paper proposes a novel decentralised access control framework for IoT security enhancement by adopting blockchain technology with the combination of ABAC and RBAC access control models. The aim of this proposed framework is to enhance the efficiency of access control management and secure IoT resources [8][9] with the scope of this study being smart farming. This framework aims to reduce the redundancy of permission required to authenticate devices to authorise and at the same time provide capacity for scalability. The pre-determined study objectives are as follows:

- We developed a decentralised access control framework embedded with blockchain technology to secure IoT resources from being accessed by unauthorised entities and scalable to cope with future expansion.
- We employed smart contracts as a fine-grained access control strategy to assign role-permission-based attributes that include object, subject and environment.
- We adopted two access control models (RBAC and ABAC) as an authentication element, including device attributes (name, location, type) and device roles in the smart farming environment.

- For validation, we applied Ethereum blockchain smart contract functionalities to issue, revoke or modify roles corresponding to a user, resource attributes and role permissions. The resource owner can further grant or deny access to resources.
- We conducted a simulation experiment to evaluate the framework component which is the smart contracts using gas cost measurements in the Ethereum network.

VII. CONCLUSION

The integration of IoT devices in smart farming facilitates the modernization of information and communication, resulting in increased productivity within the agricultural industry. To maintain the integrity of IoT resources and achieve security while also efficiently managing resources and ensuring scalability, a framework of decentralised access control using blockchain technology was developed in this study. The framework was developed based on findings from a detailed analysis published by researchers. Our proposed framework was developed by adopting blockchain technology to authenticate and authorize user and IoT device access while facilitating efficient resource management and scalability in IoT-enabled smart farming. The implementation of smart contracts is proposed to enhance the trust facilitated by the implementation of a ledger that is transparent and immutable. This study also suggests the implementation of the principle of role inheritance to reduce unnecessary user groups from access permission that can control the separation of duties, the list of privileges and confidentiality. In the framework, we proposed to combine blockchain technology as a decentralised approach with a hybrid access control model that consists of RBAC and ABAC. The proposed framework utilises a set of rules consisting of roles, access types, lists of attributes and actions that can be executed to obtain access permission by roles. The rules are divided into two types of access which are unique and multiple access. The proposed framework can resolve the challenge of role explosion, simplify management tasks, and reduce the complexity associated with traditional access control methods that rely on a centralized design. By doing so, the framework offers an effective solution to the limitations of current access control methods. It can enhance the overall security and resource management in decentralized IoT environments, thus improving the performance and efficiency of the access control mechanisms. The framework's main component which is the smart contracts was evaluated by measuring gas usage to determine cost operation using simulation. The finding can be used as a benchmark for comparison with the execution in the Mainnet network environment.

In future work, we will further evaluate the proposed framework using the measurement of the transaction throughput and network latency in blockchain by conducting more experiments. Also, an exploration towards a tokenised-based accelerating process for communication between smart contracts and IoT devices will be delivered to understand the effect of various attacks, such as DDOS attacks or man-in-the-middle attacks that compromise the integrity of data entry in smart farming.

Abstract—In recent years, occupational accidents have been increasing, and it has been suggested that this increase is related to poor or no supervision of personal protective equipment (PPE) use. This study proposes developing a system capable of identifying the use of PPEs using artificial intelligence through a neural network called YOLO. The results obtained from the development of the system suggest that automatic recognition of PPEs using artificial intelligence is possible with high precision. The recognition of gloves is the only critical object that can give false positives, but it can be addressed with a redundant system that performs two or more consecutive recognitions. This study also involved the preparation of a custom dataset for training the YOLO neural network. The dataset includes images of workers wearing different types of PPEs, such as helmets, gloves, and safety shoes. The system was trained using this dataset and achieved a precision of 98.13% and a recall of 86.78%. The high precision and recall values indicate that the system can accurately identify the use of PPEs in real-world scenarios, which can help prevent occupational accidents and ensure worker safety.

Keywords—Personal protective equipment (PPE); artificial intelligence (AI); YOLO (You Only Look Once); object detection; neural network; custom PPE dataset

I. INTRODUCTION

Workplace accidents pose a serious threat to the safety and well-being of workers worldwide. The human cost of such accidents is immeasurable, with the victims and their families often enduring long-term physical, emotional, and financial consequences. Besides, accidents at work can also have significant economic impacts, such as lost productivity, increased healthcare costs, and legal liabilities for employers. Thus, preventing and mitigating the risks of occupational accidents should be a top priority for governments, organizations, and individuals alike.

Unfortunately, recent statistics indicate that the frequency of occupational accidents has been on the rise, leading to an increase in injuries and fatalities. For instance, the Ministry of Labor and Employment Promotion reported a staggering 23.7% increase in accidents in April 2022 [1] compared to the same period the previous year. The report showed that Lima had the highest number of accidents, with 2,132 cases, of which six were fatal. The most common types of accidents were due to object strikes and falls, with tools being the leading cause. Fingers and eyes were the most affected body parts.

In a recent study, it was determined that, on average, 87% of workers do not use PPE properly, linking the lack of PPE usage to both fatal and non-fatal accidents [2]. Furthermore, the use of PPE is a legal right for workers, who are obligated to protect their health and lives [3].

To address this alarming trend, researchers and practitioners have been exploring various solutions to prevent or mitigate the risks of occupational accidents. One promising approach is the use of artificial intelligence systems to detect the use of personal protective equipment in work environments. PPEs are essential safety devices that protect workers from hazards, such as falling objects, sharp tools, chemicals, or radiation. However, the effectiveness of PPEs relies on their proper use and maintenance, which is only sometimes guaranteed in practice.

AI-based systems can help monitor and enforce the proper use of PPEs in real-time, thus reducing the risk of accidents and injuries. However, an adequate and relevant dataset is a significant challenge in developing such systems. The performance of AI algorithms depends heavily on the quality and quantity of data used to train them. Collecting and labeling large and diverse datasets of workers wearing different types of PPEs in various work environments can be costly and time-consuming, so a pre-trained neural network such as YOLO can help reduce time in training and deploying a model [4].

Researchers had to create a step-by-step dataset using internet images to overcome this limitation, using various techniques, such as web scraping, data augmentation, and transfer learning, to generate a large and diverse dataset of workers wearing different types of PPEs in various work environments. Researchers must ensure a balanced and representative dataset of the real-world distribution of PPEs and work environments.

With a custom dataset of images obtained from github's user [5], an innovative AI-based system was developed that uses advanced image processing techniques, specifically convolutional neural networks and object detection, to detect the use of PPEs in work environments. The system can recognize various types of PPEs, such as hard hats, safety glasses, vests, shoes, and gloves, and their proper use and placement on the worker's body.

One of the advantages of this system is its non-invasiveness. The system can be used on cameras installed in

the work environment to capture images of workers wearing PPEs, without requiring physical contact or interference with their daily activities [6]. This feature makes the system more acceptable and practical for workers and supervisors, as it does not disrupt their workflow or privacy.

In this paper, a review was conducted to determine which neural network would perform most efficiently. Section III details how a neural network can be trained in the cloud, thus avoiding the need for powerful hardware. Section IV presents the results regarding precision and recall to provide a comprehensive understanding of the system's performance. Finally, Section V shows the conclusions about the findings.

II. LITERATURE REVIEW

"Design of an artificial vision system to determine the quality of mandarins" is a thesis about the development of an algorithm that classifies mandarins based on their size, shape, and colour using digital image processing and region-based segmentation through a webcam using MATLAB and Arduino, achieving an accuracy of 93.3% in classification[7].

Another thesis mentions that techniques such as You Only Look Once, Region proposals + CNN, Single Shot Detector, among others, can be used to detect objects based on computer vision, and these techniques are associated with deep learning. The advantages and disadvantages of each technique mentioned above are also discussed [8].

It is possible to classify lemons, using artificial vision, based on their shape and dimensions. The development of the algorithm follows the phases of an artificial vision solution acquisition, pre-processing, segmentation, description and recognition and interpretation, and the efficiency achieved by the system is 83.9% in "Development of an artificial vision system to perform a uniform classification of lemons" [9].

An article named "Real-time Personal Protective Equipment Detection Using YOLOv4 and TensorFlow" consists of developing a mask and face shield detector as preventive measures for COVID-19 in real-time using YOLOv4, obtaining a system effectiveness of 79% [10].

A thesis called "Electronic system for quality control of chicken eggs using image processing" from the Universidad Técnica de Ambato (Ecuador), consists in a quality control system for chicken eggs using image processing in Python with the OpenCV library, concluding that two factors mainly determine the efficiency of the system, the software used and the ambient lighting [11].

"Design of a classifier system for apples by colour, using artificial vision, for the company Fresh & Natural C.I." from Andrea Aguilar, developed an apple classifier using artificial vision, capturing images from a webcam and using MATLAB as a processing interface, obtaining an effectiveness of 100% for a number of 18 apples [12].

III. PROPOSED SYSTEM

The following is a general description of the network's operation, an explanation of the dataset used, the criteria used to select the neural network, the hardware and software used during this work, and considerations that must be considered.

A. System Overview

As illustrated in Fig. 1, the system is founded upon the state-of-the-art Yolov5s architecture to train a neural network that can accurately identify personal protective equipment in real time. To ensure optimal performance, a custom dataset is prepared, employing detailed image segmentation and data augmentation techniques to triple the number of images. The trained model is then deployed to evaluate frames captured by a webcam, seamlessly detecting PPEs worn by individuals in real time.

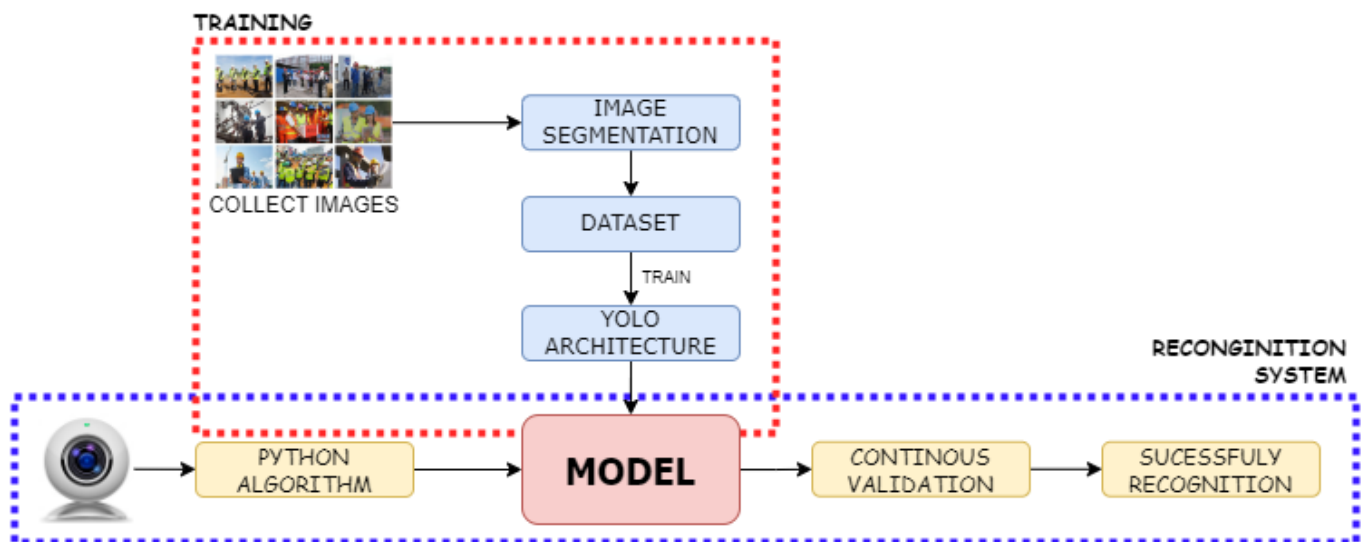

Fig. 1. Flowchart proposed system.

B. EPP Dataset

In this study, the classes to be recognized in the system were defined according to the Peruvian technical health standard for personal protective equipment, which is a ministerial resolution [13]. The classes were also defined based on the body parts involved in accidents. The classes to be detected were as follows: helmet, vest, goggles, gloves, shoes, and the person itself, resulting in six classes. This classification system was crucial for the training and testing of the deep learning model used in this study, as it allowed for accurate and reliable detection of the relevant personal protective equipment in real-time; in Fig. 2, the total object per class in the entire dataset is represented.

Fig. 2. Quantity objects per class.

C. Software and Hardware Selection

After a long comparative investigation of different open-access neural networks[14], it was chosen to use the YOLO v5 neural network, because it is easy to train, it can be used directly with video and webcam source and is lightweight than older YOLO's version. But in YOLOv5 there are some variants, because of that, two parameters were considered for selecting the neural network variant: the accuracy concerning a dataset called Common Objects in Context (COCO) and the processing speed in images per unit of time [15].

Below, in Table I, we show the different YOLOv5 variants with the established parameter data for comparison.

With a simple calculation, we can obtain ratings for each of the YOLO variants, shown in the following Table II, where a lower rating indicates a better relationship between processing time and system accuracy.

It is observed that v5n is the best option for a system where an optimal relationship between processing time and accuracy is desired, but in the present case, one used v5s because one wanted more accuracy, sacrificing some performance.

TABLE I. PROCESS TIME PER IMAGE YOLO

YOLO variant	COCO accuracy (%)	Process time (ms/image)
v5n	27.6	62.7
v5s	37.6	173.3
v5m,	45.0	427.0
v5l	49.0	857.4
v5x	50.7	1579.2

TABLE II. PROCESS TIME PER ACCURACY YOLO

YOLO variant	Process time (ms) / accuracy
v5n	2.27
v5s	4.61
v5m,	9.49
v5l	17.50
v5x	31.15

Python 3.9.7 was used for training and implementing the neural network, as it has active community support and is compatible with a wide range of existing Python libraries. A cloud service called Google Colab is used for training due to the intensive GPU usage required, which can be expensive. Google Colab offers free access to GPUs for a few hours per week, and it also allows users to connect with Google Drive to save progress and resume when more hours are available on Google Colab, all Software and Hardware used is shown in Table III.

TABLE III. EXPERIMENTAL SETUP

Hardware / Software	Description
Lenovo T430 i5 3320M	Computer specification
Microsoft Windows 10 Pro	Operating system
Google Colab	Web App for Neural Network training
Python 3.9.7	Python's version used
Roboflow	Web App for dataset creation
Generic Webcam	1080p 60fps

D. PPE Detector System

The YOLO source code has been analyzed, and it has been determined that the input image is resized to a resolution of 240 x 240 pixels, as per the information gleaned from the neural network's source code. Moreover, it has been observed that YOLO employs a 6x6 initial kernel, and uses a 3x3 kernel in the deeper layers, every kernel means a convolution and every convolution makes the image smaller. In the final stage of training, the layers were modified to predict six classes that align with the prepared dataset. A detailed breakdown of the neural network layers can be found in Fig. 3, providing further insights into its inner workings.

Conv means a convolutional layer, C3 means three convolutional layers with same parameters, Up Sampling is used to resize the image to its original size, NMS is to keep the bounding box of each class with the highest confidence score.

Using YOLOv5s, training the neural network can be accomplished through simple steps. Firstly, the YOLOv5 GitHub repository must be cloned. Next, the necessary libraries located in requirements.txt must be installed. Finally, the training steps can be followed using the following arguments: --data data.yaml --epochs 200 --weights yolov5s.pt --batch-size 40.

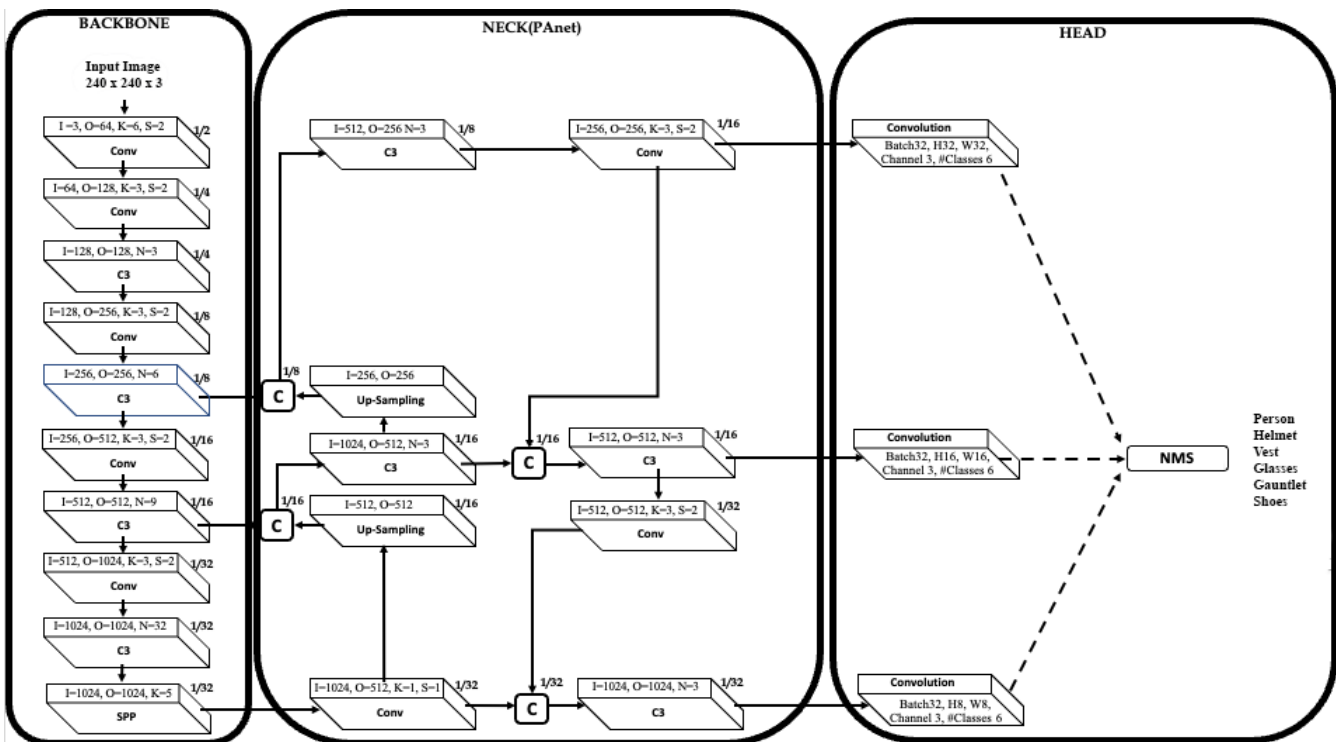

Fig. 3. YOLOv5s architecture.

IV. RESULTS AND EVALUATION

The results of a neural network system can be divided into two categories: training results and recognition results. Training results are observed during the training process and serve as an indicator of whether the neural network is performing well or not. Recognition results are custom metrics that allow us to evaluate the performance of the neural network.

A. Training Results

The system's accuracy and losses should be examined first when training a neural network. While these are not directly related, they provide insight into the system's overall behaviour shown in Fig. 4. System's global accuracy is 80%, or 0.8, this can be interpreted as image recognition, but since the system will be used in video, in section C, experimental results are shown, due multiple images in a second can be processed in video. This situation indicates that many PPEs are being recognized. On the other hand, losses are less than 10%. This result suggests that the system only misclassifies a small fraction of the PPEs it encounters, and confusion with other categories is minimal. While this indicates good system performance, it should be noted that these are general observations.

B. Evaluation Metrics

The widely adopted mean average precision will be used (mAP) metric to evaluate the object detection model. The mAP[16] metric is a comprehensive measure of the effectiveness of object detection models, which considers both the precision (1) and recall (2) of the model across different levels of confidence. It is calculated by averaging the precision values at different levels of recall, where precision is

the proportion of correctly classified objects among all objects classified at a certain level of confidence, and recall is the proportion of correctly classified objects among all objects that should have been classified:

$$\text{Precision} = \text{TP} / (\text{TP} + \text{FP}) \quad (1)$$

$$\text{Recall} = \text{TP} / (\text{TP} + \text{FN}) \quad (2)$$

Here, *TP* represents the number of true positives, which indicates the number of PPE objects correctly detected and classified by the model. *FP* represents the number of false positives, corresponding to the number of non-PPE objects incorrectly classified as PPE objects. *FN* represents the number of false negatives, which indicates the number of PPE objects that have been missed by the model and not detected.

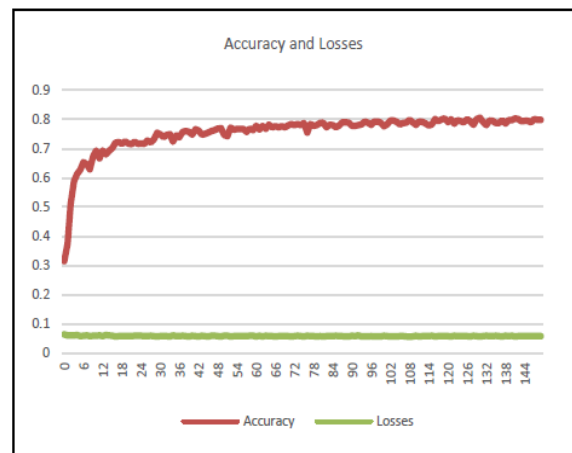

Fig. 4. Accuracy and losses of the proposed system per epoch trained.

The mAP metric is a comprehensive measure of the effectiveness of object detection models, which considers both the precision and recall of the model across different levels of confidence. It is calculated by averaging the precision values at different levels of recall, where precision is the proportion of correctly classified objects among all objects classified at a certain level of confidence, and recall is the proportion of correctly classified objects among all objects that should have been classified.

The mAP metric is widely used in many applications, including workplace safety monitoring and quality control in manufacturing, where the reliable detection and classification of PPE objects is crucial for ensuring worker safety and product quality. By utilizing the mAP metric, we can obtain a comprehensive and quantitative assessment of the performance of the object detection model, which is essential for ensuring the effectiveness and reliability of the system in real-world applications.

C. Result Analysis

Using a threshold of 0.5 for each class identification, using 1080p webcam input source and 600 x 400 output video, the object detection model achieved a precision of 0.98130841 and a recall of 0.8677686 in identifying PPE objects, including helmets, gloves, vests, shoes, safety glasses, and people. The precision value indicates that the model accurately classified 98.13% of the detected PPE objects, while the recall value indicates that 86.78% of all PPE objects in the images were successfully detected and classified. The model's ability to identify multiple types of PPE objects suggests various features for object recognition, although gloves were the most challenging object to recognize. A frame is processed in around 0.075 seconds that means 13 frames per second using YOLO V5s (refer Fig. 5).

The closest better version of YOLO is 2x slower according to Table II, it means 7 frames per second, it wouldn't have been optimal for real-time applications.

These results suggest that the model performs well in identifying PPE objects, but further optimization may be needed to improve its accuracy in detecting and classifying gloves. Monitoring and evaluating the model's performance will be necessary for ensuring its reliability and effectiveness in real-world applications.

Fig. 5. Result of system's prediction.

V. DISCUSSION

To improve the performance of the model, it is recommended to experiment with different threshold values for detecting personal protective equipment, as this can help fine-tune the algorithm for optimal sensitivity and specificity. Additionally, using metrics such as precision and recall can provide a more comprehensive evaluation of the model's performance and highlight areas for improvement. Expanding the dataset to include more diverse and challenging scenarios can enhance the model's robustness and generalizability. By implementing these recommendations, the model can be optimized for more accurate and reliable detection of personal protective equipment in various real-world applications.

VI. CONCLUSION

The YOLOv5s neural network is lightweight enough to be used in real-time scenarios, as demonstrated by its successful performance on relatively old hardware while achieving efficient results. However, to further improve the present work, it is suggested to have a better distribution of classes in the dataset, with roughly the same number of objects per class, to enhance recall, especially for challenging objects.

Using CNN with a video source or webcam offers advantages compared to its application on static images. This is because it is not necessary to recognize the object immediately or in the first video frame. Instead, the object can be recognized within a specific period, even if it only appears in a few frames, and it will still be considered valid. This temporal recognition capability allows for capturing and recognizing objects in a video sequence, which is beneficial for applications such as object tracking or real-time object analysis. By leveraging the contextual information provided by consecutive frames, the CNN can improve recognition accuracy and provide more robust results in dynamic environments.

By augmenting the dataset, the model is exposed to a greater variety of images, which can improve its ability to generalize to new, unseen data. When working with limited data, these results in a better-trained model with higher precision and lower losses are often necessary. Furthermore, data augmentation can also help to reduce overfitting, a common problem in deep learning where the model becomes too specialized to the training data and performs poorly on new data. Therefore, performing data augmentation on the dataset is crucial in developing robust and accurate computer vision models.

Department of Mathematics and Statistics-Faculty of Applied Science and Technology, Universiti Tun Hussein Onn Malaysia, Pagoh Education Hub, 84600 Pagoh, Johor, Malaysia⁴

Abstract—Lung cancer is the most prevalent cancer in the world, accounting for 12.2% of all newly diagnosed cases in 2020 and has the highest mortality rate due to its late diagnosis and poor symptom detection. Currently, there are 4,319 lung cancer deaths in Malaysia, representing 2.57 percent of all mortality in 2020. The late diagnosis of lung cancer is common, which makes survival more difficult. In Malaysia, however, most cases are detected when the tumors have become too large, or cancer has spread to other body areas that cannot be removed surgically. This is a frequent situation due to the lack of public awareness among Malaysians regarding cancer-related symptoms. Malaysians must be acknowledged the high-risk symptoms of lung cancer to enhance the survival rate and reduce the mortality rate. This study aims to use a fuzzy linear regression model with heights of triangular fuzzy by Tanaka (1982), H -value ranging from 0.0 to 1.0, to predict high-risk symptoms of lung cancer in Malaysia. The secondary data is analyzed using the fuzzy linear regression model by collecting data from patients with lung cancer at Al-Sultan Abdullah Hospital (UiTM Hospital), Selangor. The results found that haemoptysis and chest pain has been proven to be the highest risk, among other symptoms obtained from the data analysis. It has been discovered that the H -value of 0.0 has the least measurement error, with mean square error (MSE) and root mean square error (RMSE) values of 1.455 and 1.206, respectively.

Keywords—Lung cancer; high-risk symptom; fuzzy linear regression; H -value; mean square error

I. INTRODUCTION

Cancer is a disease caused by uncontrolled cell division. Lung cancer develops when cancer originates in the lungs and spreads to lymph nodes or other organs, such as the brain. Moreover, lung cancer may spread from other organs. Lung cancer includes four stages which in Stage I, cancer has not grown to lymph nodes or other parts of the body, whereas in Stage II, the tumors may be bigger and/or have begun to spread to nearby lymph nodes. When cancer has advanced to the lymph nodes of the mediastinum, a diagnosis of stage III can be determined (the chest area between the lungs). In Stage IV, the cancer has spread to the lining of the lungs or to other organs [1].

Lung cancer (small and non-small cell) is the second-leading cause of cancer in both men and women (excluding skin cancer) in 2020 [2]. This kind of cancer is on the rise in several countries, particularly in Asia, where the rate increased from 56 percent in 2012 to 58 percent in 2018 [3]. In the year of 2020, lung cancer is the top cause of cancer-related mortality with 1.80 million deaths, followed by colon and rectum cancer with 935 thousand deaths, and liver cancer with 850,000 deaths. Lung cancer has killed 4,319 lives in Malaysia, or 2.57 percent of all mortality based on the latest WHO data published in 2020. Malaysia ranks 77th in the world with a death rate of 15.25 per 100,000 population [4].

Malaysia continues to have the lowest 5-year lung cancer survival rate. Symptoms of lung cancer are unusually detected at an early stage, and more than half of lung cancer patients pass away within the first year after diagnosis. Currently, the main causes of lung cancer are unknown. Yet, certain risk factors and symptoms enhance the likelihood of a person developing lung cancer. There are also a few patients with lung cancer who exhibited no symptoms or identified risk factors [5]. Common lung cancer symptoms include persistent coughing, breathing difficulties, bloody coughing, and a sudden decrease in weight. All these symptoms may appear within one month after a lung cancer diagnosis [6].

This research presents a study on the prediction of high-risk symptoms of lung cancer in Malaysia using the fuzzy linear regression method. The primary goal of this study is to determine the highest-risk signs and symptoms of patients with early lung cancer detection to enhance the likelihood of diagnosing malignancy early and decrease lung cancer mortality. It is important for Malaysians to be aware and acknowledge the highest risk symptoms of lung cancer for them to get early treatment at early stages to increase the likelihood of survival. As for the proposed method, numerous researchers have utilized fuzzy modeling to investigate cases in various fields, including medicine, science, and engineering. Fuzzy modeling is typically used to evaluate more complex scenarios and is reliable. Since 1965, when Lotfi A. Zadeh devised the fuzzy set theory, numerous studies have utilized the fuzzy method. Fuzzy linear regression in 1982 is

recognized as the basic model for other fuzzy models. The model is conveyed as a dependable method since it does not need any assumptions to ensure the results obtained are applicable to society. Hence, the results will still be accurate even if the data of the sample is small.

The entirety of this article is structured as follows: Part II emphasizes significant studies on current challenges and ways to resolve them, while Section III outlines the research methodologies. Section IV includes the results and Section V presents the discussion. Section VI concludes the paper and proposes future work.

II. LITERATURE REVIEW

A. Lung Cancer in Malaysia

Lung cancer is the primary cause of cancer-related mortality globally and the most common cause of death in Malaysia, with males surpassing females regardless of the tumor's size, location, or dissemination. Lung cancer contributes to around 15.13 percent of cancer deaths [7]. The reported 1-year survival rate is only 35.5 percent however, the relative 5-year survival rate is only 11.0 percent. The survival rate of lung cancer patients in Malaysia at 1 and 5 years is one of the lowest compared to other types of cancer, as shown in Chart A. This survival rate is one of the lowest in the world. The one-year and five-year survival rates are shown per stage in Chart B [8]. Fig. 1 displays Chart A and Chart B.

There are two distinct diagnostic presentations for lung cancer patients: symptomatic and incidental. Most cases were inadvertently diagnosed through chest X-rays and CT scans. According to the Malaysian Health Technology Assessment Section, a CT scan known as low-dose computed tomography (LDCT) is currently used for lung cancer screening and improved lung cancer diagnosis. Unfortunately, it does not apply to lung cancer patients at high risk. Screening high-risk individuals through screening results is critical since it enhances the likelihood of early cancer detection and decreases lung cancer mortality [11].

While among symptomatic patients, the most often reported complaints that resulted in an imaging referral were the development of a new cough or the worsening of a previously expressed clinical picture suggestive of pneumonia and haemoptysis [12]. It has been proven that cough is the symptom that appears most frequently in lung cancer patients based on the results [13] which frequently reported lung cancer symptoms to include shortness of breath, cough, and anxiety. The study [14] also stressed that fever and cough were the most prominent early symptoms, and respiratory symptoms were prevalent among lung cancer patients. Research [15] reported that cough has the highest number which is 62.0% of patients, followed by chest pain (51.8%) was the most prevalent symptom present at the time of diagnosis. Studies [16] and [17] discovered that haemoptysis had the highest diagnostic value for lung cancer.

B. Background of Fuzzy Linear Regression

Regression analysis is a statistical technique used to determine the cause-and-effect relationship between two variables. Regression analysis is a potent method for comprehending (including forecasting and explaining) the causal factors underlying a population outcome [18]. However, regression models are particularly susceptible to outliers. An outlier is a data point that deviates significantly from most other observations. Variability in measurement may result in an experimental error, whereas an outlier in regression analysis may cause a significant issue. Although data are infrequently linearly separable, regression analysis methods also oversimplify real-world data and issues.

Fuzzy linear regression analysis on the other hand is a significant alternative to conventional regression methods based on statistics. In fuzzy linear regression analysis, a wide variety of fuzzy linear models can be used to approximate a linear dependence based on a set of observations. There are two types of fuzzy regression. The researchers in [19] created 'possibilistic' fuzzy regression, a linear programming method that aims to reduce the fuzziness of a system. The second approach is a fuzzy least-squares method that minimizes the distance between two fuzzy numbers. The approaches are designed to handle fuzzy data to satisfy a particular requirement [20].

In a fuzzy environment, a fuzzy regression model is applied to evaluate the functional relationship between the dependent and independent variables. In the literature, numerous fuzzy regression models and methods for estimating the fuzzy parameters of these models have been developed. The possibilistic approach and fuzzy least squares model are the

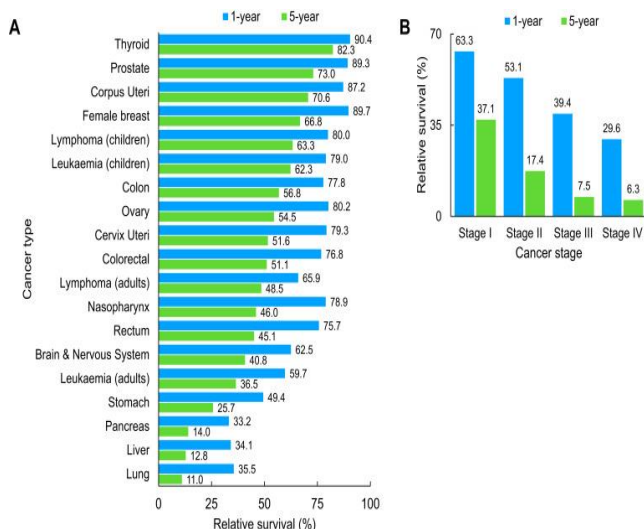

Fig. 1. Relative survival of cancer patients in Malaysia.

In Malaysia, the probability of getting lung cancer is approximately 1 in 60 for males and 1 in 138 for females, with patients often being diagnosed at the age of 70 or older (range 15 to 90 years). Nevertheless, most cases of lung cancer were not discovered until a very late stage, stage III or stage IV, which is above 90 percent for both sexes. Early-stage disease (I, II, and chosen IIIa) is amenable to curative surgery, which offers the best possibility of long-term cure and disease-free survival [9]. However, most patients (about 75 percent) are diagnosed with advanced cancer (stage III/IV). Despite significant advances in late-stage lung cancer oncological treatment in recent years, survival rates remain poor [10].

two most frequent methods for assessing fuzzy regression models [21]. Fuzzy methodology surpasses conventional regression methodology when it is required to predict an outcome variable based on many interrelated factors. Furthermore, it is proved that fuzzy linear regression is more effective relative to simple and multiple linear regression methods [22].

III. METHODOLOGY

Fuzzy sets can be used to account for data inaccuracy and ambiguity. For example, rather than just assigning a binary value to a symptom, such as "present" or "absent," a fuzzy set may be used to represent the degree to which a patient exhibits a specific symptom. This would be preferable to the traditional approach of assigning a binary value [23].

The fuzzy linear regression approach is simpler and more transparent to calculate than classical regression but does not significantly differ from classical regression. Furthermore, these results provide support for the concept of fuzzy linear regression prediction, especially when it comes to fuzzy data [24]. The high-risk symptoms of lung cancer can be detected with greater precision by using the fuzzy linear regression method, which provides a better prediction of imprecise data than regression analysis.

Statistical analysis is adaptable and useful to numerous domains, especially the linear regression technique. Several model elements are represented by fuzzy numbers in fuzzy linear regression, which is a kind of regression analysis. It has been demonstrated that fuzzy linear functions are a good strategy for unclear occurrences in linear regression models [25]. The data were analyzed using the statistical software Matlab and Microsoft Excel.

A. Fuzzy Linear Regression (Tanaka, 1982)

To formulate a fuzzy linear regression model, the following were assumed to hold (Tanaka, 1982):

- (1) The data can be represented by a fuzzy linear model:

$$Y_e^* = A_1^* x_{e1} + \dots + A_g^* x_{eg} \triangleq A^* x_e \quad (1)$$

Where,

Fuzzy parameter A_g

The variable of fuzzy parameter x_e

Equation of the fuzzy parameter Y_e^*

$$\mu_{Y_e^*}(y) = 1 - \frac{|y_e - x_e^T \alpha|}{\sum_f \zeta_f |x_{ef}|} \quad (2)$$

- (2) The degree of the fitting of the estimated fuzzy linear model $Y_e^* = A^* x_e$ to the given data $Y_e = (y_e, \varepsilon_e)$ was measured by the following index h_e , which maximizes h subject to $Y_e^h \subset Y_e^{*h}$, where:

$$Y_e^h = \{y | \mu_{Y_e}(y) \geq h\}$$

$$Y_e^* = \{y | \mu_{Y_e^*}(y) \geq h\} \quad (3)$$

Which are h -level sets. This index h_e is illustrated in Fig. 2. The degree of the fitting of the fuzzy linear model for all

data Y_1, \dots, Y_N is defined by $\min_f [h_f]$. Fig. 2 portrays the fitting degree of Y_e^* to a fuzzy data of Y_e .

Fig. 2. Degree of fitting of Y_e^* to a given fuzzy data Y_e .

- (3) The vagueness of the fuzzy linear model is defined by:

$$JJ = \zeta_1 + \dots + \zeta_g \quad (4)$$

The problem was elucidated by acquiring fuzzy parameters A^* which minimized JJ subject to $\bar{h}_e \geq H$ for all e , where H was selected by the decision maker as the degree of fit of the fuzzy linear model. The \bar{h}_e can be acquired by utilizing:

$$\bar{h}_e = 1 - \frac{|y_e - x_e^T \alpha|}{\sum_f \zeta_f |x_{ef}| - \varepsilon_e} \quad (5)$$

Tanaka (1982) model estimated the fuzzy parameter $A_e^* = (\alpha_e, \zeta_e)$, which are the solutions of the following linear programming problem:

$$\min_{\alpha, \zeta} = \zeta_1 + \dots + \zeta_g$$

Subject to $\zeta \geq 0$ and

$$\alpha^T x_e + (1 - H) \sum_f \zeta_f |x_{ef}| \geq y_e + (1 - H) \varepsilon_e$$

$$-\alpha^T x_e + (1 - H) \sum_f \zeta_f |x_{ef}| \geq -y_e + (1 - H) \varepsilon_e \quad (6)$$

The best fitting model for the given data may be obtained by solving the conventional linear programming problem in (6). The number of constraints, $2N$, was generally substantially greater than the number of variables, g . As a result, solving the dual problem of (6) was easier than solving the primal problem of (6).

The fuzzy linear regression model (FLRM) can be stated as:

$$Y = A_0(\alpha_0, \zeta_0) + A(\alpha, \zeta) x + \dots + A(\alpha, \zeta) x_g \quad (7)$$

IV. RESULTS

Hideo Tanaka presented a fuzzy approach for linear regression analysis in 1982. There is a fuzzy model in which human estimation and some systems play a role and must deal with a fuzzy structure. Tanaka's fuzzy linear regression was used in the study to estimate the size of lung cancer patients' tumors. In total, 124 patients were used. Gender, ethnic, age,

tumor size, cough, haemoptysis, weight loss, appetite loss, chest pain, comorbidities, smoking habit, and stage of cancer were the most key factors. The data were obtained using Microsoft Excel and MATLAB software. H-values ranging from 0.0 to 1.0 were utilised to calculate the center, a_i , and width, c_i , of each fuzzy parameter. a_i is the center of a fuzzy parameter, while c_i represents the parameter's fuzziness (width). The results of this H-value are shown in the Tables I.

TABLE I. FUZZY PARAMETER OF $H=0.0$

Variables	Fuzzy Parameter	
	Center a_i	Width c_i
Age	0.3332	0.6097
Ethic	3.3148	0
Cough (A_1^*)	2.3085	0
Haemoptysis (A_2^*)	14.5494	0
Weight loss (A_3^*)	5.3752	0
Appetite loss (A_4^*)	-6.6669	0
Chest pain (A_5^*)	10.6765	0
Smoking habit (A_6^*)	-0.0589	0
Comorbidity (A_7^*)	-4.8611	0

Table I displays the centre, a_i , and width, c_i values for the fuzzy parameters when $H = 0.0$. The values of the fuzzy parameter are displayed in Table I; the data was conducted using Matlab code and eleven variables were included. The dependent variable is the size of the tumor, and nine independent variables, lung cancer symptoms. The fuzzy mean tumor size (mm) can be represented by haemoptysis with a fuzzy parameter value of 14.5494. The second highest fuzzy parameter was chest pain equal to 10.6765. The fuzziness of the nine variables reflects the uncertainty of tumor size in millimeters. By this fuzziness parameter, the dispersion can be explained. In this context, the fuzziness of the parameter is $J = 0.6097$. In addition, the negative nature of A_4^* , A_6^* , and A_7^* is dependent upon the strong correlations between x_4 , x_6 , and x_7 . The tumor size of lung cancer (mm) is inversely proportional to appetite loss, smoking, and comorbidity.

The following is the estimated fuzzy linear regression model for lung cancer patients.

$$\hat{Y} = 0.6097 + (0.3332, 0.6097) \text{ age} + (3.3148, 0) \text{ ethnic} + (2.3085, 0) \text{ cough} + (14.5494, 0) \text{ haemoptysis} + (5.3752, 0) \text{ weight loss} - (6.6669, 0) \text{ loss of appetite} + (10.6765, 0) \text{ chest pain} - (0.0589, 0) \text{ smoking} - (4.8611, 0) \text{ comorbidity. $$\hat{Y} = 5.9810 + (0.3128, 5.9810) \text{ age} + (2.5509, 0) \text{ ethnic} + (4.1223, 0) \text{ cough} + (14.6450, 0) \text{ haemoptysis} + (4.0024, 0) \text{ weight loss} - (4.6237, 0) \text{ loss of appetite} + (9.6400, 0) \text{ chest pain} - (0.0315, 0) \text{ smoking} - (4.1034, 0) \text{ comorbidity}. \quad (18)$$

1) *Measuring mean square error (MSE)*: Table XII displays the mean square error (MSE) values for those H-values. The observed Y is determined by the responses of 124 patients with lung cancer. The H-value with the smallest MSE is 0.0. Since the MSE value of the H-value of 0.0 is the lowest when compared to other values, it has been concluded that this model is the most suited and effective model for predicting the high-risk symptoms of lung cancer.

TABLE XII. MEAN SQUARE ERROR VALUES

MSE Values	
H-values	Mean Square Error
0.0	1.455
0.1	1.467
0.2	1.481
0.3	1.497
0.4	1.517
0.5	1.549
0.6	1.592
0.7	1.657
0.8	1.774
0.9	2.101
1.0	2.138

2) *Measuring root mean square error (RMSE)*: Table XIII shows the root mean square error, which is computed by calculating the square root of the total mean square error to achieve the least error value. The models were tested using mean square error. H-values of 0.0 and 1.0 have RMSE values of 1.206 and 1.462, respectively. The fuzzy linear regression model with H-value of 0.0 proves to be the most precise model

for predicting the high-risk symptoms reported by lung cancer patients at Hospital Al-Sultan Abdullah (UiTM Hospital), given that its RMSE is the lowest among the other models.

TABLE XIII. ROOT MEAN SQUARE ERROR VALUES

RMSE Values	
H-values	Root mean square error
0.0	1.206
0.1	1.211
0.2	1.217
0.3	1.224
0.4	1.232
0.5	1.244
0.6	1.262
0.7	1.287
0.8	1.332
0.9	1.450
1.0	1.462

V. DISCUSSION

Fuzzy linear regression with an H-value of 0.0 is the best model for predicting high-risk lung cancer symptoms in patients at Al-Sultan Abdullah Hospital (UiTM Hospital). Fuzzy linear regression with an H-value of 0.0 has lowest mean square error (MSE) and root mean square error (RMSE) values compared to other H-values. H-value of 0.0 produced MSE and RMSE values of 1.455 and 1.206, while an H-value of 1.0 yielded MSE and RMSE values of 1.784 and 1.336, respectively. The optimal model has been proved to be the fuzzy linear regression of H-value with 0.0 as it has the smallest measurement error. The summary values of MSE and RMSE are displayed in Table XIV.

TABLE XIV. MSE AND RMSE VALUES OF THE MODELS

Summary of MSE and RMSE Values		
H-values	MSE	RMSE
0.0	1.455	1.206
0.1	1.467	1.211
0.2	1.481	1.217
0.3	1.497	1.224
0.4	1.517	1.232
0.5	1.549	1.244
0.6	1.592	1.262
0.7	1.657	1.287
0.8	1.774	1.332
0.9	2.101	1.450
1.0	2.138	1.462

The best parameter for fuzzy linear regression was discovered using the values of mean square error and root mean square error. This study found that haemoptysis was the most impactful symptom in diagnosing lung cancer high-risk symptoms, as it has the highest fuzzy mean parameter in the model with an H-value of 0.0 and a value of 14.5494, as shown in Table I. The findings similar to the [26] stated that individuals diagnosed with lung cancer showed a significantly greater prevalence of persistent haemoptysis. [27] and [28] also emphasized that haemoptysis is the most prevalent cause of lung cancer across all age groups. Chest pain is the second highest risk symptom of lung cancer as it has the value of fuzzy mean parameter of 10.6765 based on Table I. The results are also akin to the study by [29] found that the frequency of haemoptysis, cough, and chest pain was significantly higher than in other samples in all stages. According to [30] chest pain was the top five major complaints when it comes to lung cancer symptoms. Age, ethnicity, cough and weight loss are the other variables that are closely related to the high-risk symptoms of lung cancer as it has positive values of fuzzy mean parameter. In addition, the high-risk symptoms of lung cancer are inversely proportional to the female gender, Chinese ethnicity and other ethnicities, appetite loss, smoking habit, and the presence of other diseases (comorbidity) as it has negative values of fuzzy mean parameters. The lowest mean square error is 1.455, and the least root mean square error is 1.206.

The purpose of this study was to predict the high-risk symptoms of lung cancer in the early stage to initiate preventative measures for lung cancer patients. It was determined that haemoptysis and chest pain are high-risk symptoms for lung cancer patients at Hospital Al-Sultan Abdullah (UiTM Hospital). However, most of the patient data collected from Al-Sultan Abdullah hospital (UiTM Hospital) was from patients with advanced lung cancer (stages 3 and 4). It is difficult to detect symptoms for the earlier stage of lung cancer due to the tumor size in stages I and II is smaller in size since the small tumors convey less texture and shape information than those larger tumors in late stages [31]. It is stated that the bigger the diameter of the tumor size, the more advanced the stage of lung cancer, and the symptoms of lung cancer will begin to appear one by one such as haemoptysis and chest pain. Even though the symptoms are recognized at a late stage, the doctors or patients can still take the initiative or precautions at earlier stages for more particular symptoms as revealed by the results rather than any random symptoms.

VI. CONCLUSION

The aim of this study was to determine high-risk lung cancer symptoms in order to initiate preventative actions. It was concluded that haemoptysis and chest pain are high-risk symptoms for lung cancer patients at Hospital Al-Sultan Abdullah (UiTM Hospital). Both high-risk symptoms can be presented to medical doctors and nurses at the UiTM Hospital so that they can apply them to patients at an early stage. Extreme weight loss, loss of appetite, and comorbidity are the further lung cancer symptoms. Fuzzy linear regression with H-value of 0.0 is the best model for predicting the high-risk symptoms of lung cancer in patients at Hospital Al-Sultan Abdullah (UiTM Hospital) as it has the least measurement

error, with mean square error (MSE) and root mean square error (RMSE) values of 1.45 and 1.206, respectively.

In future studies, other researchers should resolve the issue of determining the stages of lung cancer among patients at Selangor's general hospitals. The study should be expanded to include other public hospitals in each state of Malaysia. In that scenario, the lung cancer study may be thoroughly explored in Malaysia and other countries.

Abstract—Distributed Denial of Service (DDoS) is a major attack carried out by attackers leveraging critical cloud computing technologies. DDoS attacks are carried out by flooding the victim servers with a massive volume of malicious traffic over a short period. Because of the enormous amount of malicious traffic, such assaults are easily detected. As a result, DDoS operations are increasingly appealing to attackers due to their stealth and low traffic rates. DDoS assaults with low traffic rates are also difficult to detect. In recent years, there has been a lot of focus on defense against low-rate DDoS attacks. This paper presents a two-phase detection technique for mitigating and reducing LRDDoS threats in a cloud environment. The proposed model includes two phases: one for calculating predicted packet size and entropy, and another for calculating the covariance vector. In this model, each cloud user accesses the cloud using the virtual machine, which has a unique session ID. This model identifies all LRDDoS assaults that take place by using different protocols (TCP, UDP, ICMP). The experiment's findings demonstrate, how the suggested data packet size, IP address, and flow behavior is used to identify attacks and prevent hostile users from using cloud services. The VM instances used by different users are controlled by this dynamic mitigation mechanism, which also upholds the cloud service quality. The results of the experiments reveal that the suggested method identifies LRDDoS attacks with excellent accuracy and scalability.

Keywords—LRDDoS attack; distance deviation; covariance vector; threshold

I. INTRODUCTION

As next-generation Internet technologies are devised and developed, distributed denial of service (DDoS) attacks on the internet have become exceedingly dangerous. The traditional technique of executing DDoS attack is to flood the network with a high number of packets, straining the server's bandwidth, computational power, memory and delaying legitimate users' access to resources. In 2001, Asta networks observed a new sort of assault on the internet backbone: a denial-of-service attack. Kuzmanovic and Knightly discussed the idea at the SIG conference in 2003 [1]. They assumed the attacks were conventional DoS attacks, which may significantly limit and restrict network traffic. Furthermore, the attacks are called "Shrew Attacks" because they cannot be detected by the methodologies. The attacks were known as Low Rate Distributed Denial of Service (LRDDoS) attacks by other researchers. [2]. Unlike classic assaults, LRDDoS attacks send intermittent high-volume queries and use weakness in the network protocol [3] to actively minimize resource requirements for normal users. The attacks have a substantial impact on network performance.

An average attack traffic, on the other hand, is quite minimal due to the short duration of each assault burst, which is remarkably comparable to the burst traffic generated by many conventional application services. LRDDoS attacks are difficult to identify and mitigate because of their stealth and destructiveness. If the device requires new functionalities, the new protocols or regulations must be redesigned. As a result, existing network detection mechanisms for LRDDoS assaults are often down.

DDoS assaults are classified by the network into two sorts based on their behaviour: "Low Rate DDoS" and "High Rate DDoS" (LRDDoS & HRDDoS attacks) [4][17]. The HRDDoS attack's goal is to block legitimate users from accessing services. These attacks are carried out by transferring a large volume of traffic in order to take advantage of network capacity. The fundamental weakness of the HRDDoS assault is its traffic characteristics, which is why the attackers prefer the LRDDoS approach [5]. LRDDoS attacks are difficult to detect since the assault traffic resembles normal traffic.

Instead of depleting network bandwidth and resources throughput, an LRDDoS attack targets protocol stack flaws. The attacker emits malicious packets at a low rate, because of which the security systems built on network-level are not able to detect the characteristics of the attack. The attacker's goal is basically degrading the "Quality-of-Service (QoS)" being experienced by a legal end user rather than disrupting the network services delivered to them. Many approaches to detecting DDoS attacks have been developed, including the Anomaly Detection System (ADS). However, LRDDoS attacks involve regular behavior as normal traffic deliberately, as a result of which, it is difficult to identify.

The goal of an LRDDoS attack is to continuously drain resources and bandwidth [4]. This form of assault generates adequate traffic in the network. Fig. 1 depicts the LRDDoS assault scenario. The network time duration (Δt), burst rate (br) and burst width (bw) are used to describe these assaults. LRDDoS attacks operate differently than traditional DDoS attacks. Since TCP vulnerabilities are the main targets of LRDDoS attacks, it can be difficult and complex to identify these attacks.

LRDDoS attacks differ significantly from traditional kinds of assault detected via anomaly detection techniques. This attack makes use of TCP congestion by transmitting malicious traffic in small bursts over a short period of time, known as a pulsing assault, or by sending packets at a steady pace, known as a constant attack. On average, present LRDDoS detection

algorithms can identify just a small percentage of attack packets. Because the difference between regular traffic and LRDDoS traffic is so small, it is extremely difficult to recognize and discriminate.

Fig. 1. LRDDoS attack traffic variations.

The present cloud security solutions are non-adaptive and insufficient for detecting LRDDoS attacks. To address this issue, a two-phase detection approach is used to distinguish between legitimate and malicious communication in the cloud computing environment. The suggested approach is independent of the assault pattern. It may achieve a significant distance barrier, leading to a low false positive rate.

The following is the contribution:

Examine the difference in packet size distribution between legitimate and malicious assaults.

A system that incorporates quick access to cloud services is recommended.

The suggested approach adapts to both internal and external network traffic, allowing for the detection of the attack and the reduction of LRDDoS recurrence in the future.

II. RELATED WORK

Wang et al. [6] introduced METER, an “enseMble discrEte wavelet Transform-based technique for detecting low-frequency DDoS assaults in SDN”. This model assists in identifying the assault by computing the wavelet coefficients matrix and the associated entropy. Yu et al. [7], devised a methodology to identify DDoS attack using dynamic resource allocation approach and queueing theory. Xiang et al. [8] used information metrics such as generalized entropy and information distance to network traffic-based algorithms to detect low-rate DDoS attacks.

A mathematical model for recognizing low-rate DDoS assaults was developed by Luo et al. [9] based on the congestion characteristics of victim TCPs. Wu et al. [10] also developed a mathematical model that combines the MF-DFA algorithm with the holder exponent to distinguish between malicious and non-malicious traffic in a low-rate DDoS assault.

Takahashi et al. [11] developed a method for detecting a shrew DDoS assault that has already been initiated in a home network setting employing a bottleneck connection with unknown bandwidth and buffer capacity. The proposed attack detection method reduces downstream traffic from targeting network to keep the quality, while keeping the attack traffic covert by increasing the pulse rate exploratorily and measure the attack effect by deploying bot nodes in the home network.

By monitoring the pace at which flow table rules are applied, Dhawan et al. [12] suggested a technique for identifying DoS assaults. The network is alerted that it may be attacked when the rate of flow rule installation rises over a certain threshold, and the defensive mechanism is then turned on.

H. Chen et al. [13] offer a hybrid approach for detecting LDoS attacks that incorporates trust evaluation with the Hilbert-Huang Transformation. An intrinsic mode function (IMF) is implemented using a hybrid method which includes the correlation and Kolmogorov-Smirnov values, and if these values are more than 0.4 and 0.3, respectively, and the static point shows a higher degree of confidence in the network, it will help in detecting LDoS assaults.

Kieu et al. [14] suggested a technique for detecting LDDoS attacks by estimating TCP throughput and using the TCP congestion window. Wu et al. [15] identify and filter out DDoS traffic using temporal frequency analysis. The filtering technique is developed as a system in the real world.

Florea et al. [16] advocated adopting a unified detection architecture to overcome the challenge of detection against low-rate DDoS attacks.

III. SYSTEM MODELING AND ASSUMPTIONS

The proposed model is a dynamic mitigation strategy for detecting LRDDoS attacks and optimizing QoS while working with constrained system resources. Both lawful packets and attack packets supplied by the legitimate user and the attacker may be easily sent to the current network detection system since the internet was created for openness and best effort transmission. In the event of an LRDDoS assault, when compared to lawful traffic, the attack packet shows several odd properties, such as the quantity of traffic flows and packets with unusual distributions or statistics [18]. LRDDoS packets have higher features than legitimate traffic since they are purposefully manufactured by prebuilt programme. As a result, the packet size in each request may be used to measure the distribution difference between regular traffic and malicious traffic [18]. While considering an LRDDoS attack, each and every packet transferred to the network is regarded a lawful request packet since all of the header information is acceptable. This helps the attacker to purposefully aggregate the packets and attack the victim’s server which leads to the display of abnormal deviations in its network [5].

The technique focuses on the differences between the distribution of packet sizes and between legitimate and attack packets. This measured difference allows for the identification of the traffic.

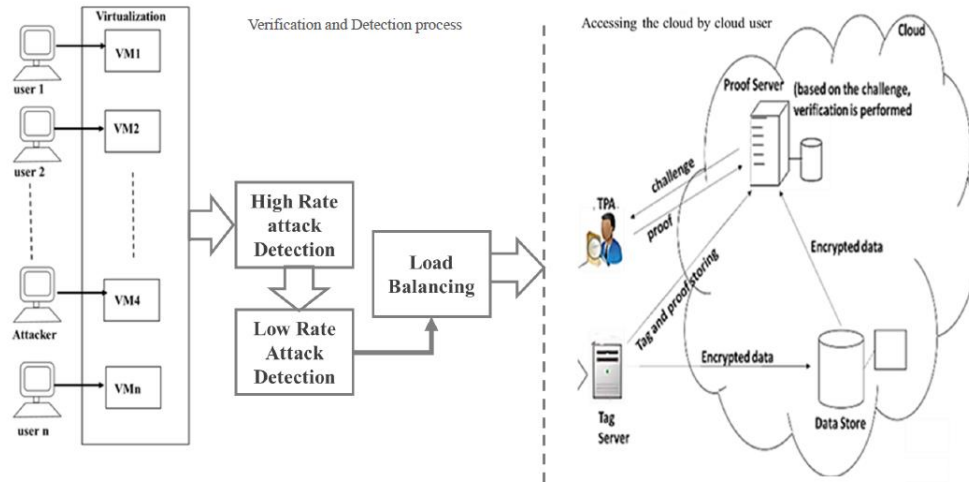

Fig. 2. Proposed model.

As seen in Fig. 2, each legal cloud user (cc_i) is given access to a virtual machine (VM_i). The cloud architecture is split into two portions, one to offer service and the other to verify and identify DDoS attacks. The cloud user's virtual machine (VM_i) is the source of the verification and detection process, where the LRDM algorithm is put and from which the predicted packet size of each traffic is calculated. The Low-rate detection method receives the network traffic from each virtual machine VM from which session ID S_{id_i} is retrieved.

A. PHASE I Algorithm

The LRDM method is split into two stages; the first stage examines the packet size and flags communication as malicious if it exceeds a certain threshold. Each user (cc_i) connects to the network and sends the (Rq_i) request packet to the cloud. Let $Rq_i(t)$ represent the collection of network flows in the cloud over the t interval.

$$Rq_i(t) = \{Rq_1(t), Rq_2(t), Rq_3(t), Rq_4(t), \dots \dots \dots Rq_n(t)\}$$

The cloud user CC_i sends a request Rq_i with a packet size PS_i for a particular time interval Δt . The maximum packet size that can be sent across the network is set to $PS_{max} = 1514$. As a result, the network flow at the moment Δt for each cloud user will be $Rq_i(\Delta t)$.

$$Rq_i(\Delta t) = \{Rq_1(PS_1), Rq_2(PS_2), \dots \dots \dots Rq_n(PS_n)\}$$

It should be remembered that the network protocol limits packet size. As a result, TCP traffic during an LRDDoS assault will enter a malicious series of drop-recovery-drop. In LRDDoS attack situations, TCP transmission becomes more discontinuous and unsteady as compared to TCP traffic in normal network settings. The packet size received should satisfy the range $60 \leq PS_k \leq 1514$. Each cloud user sends a N_i network request to the cloud server at Δt time interval.

In order to create a collection of packet size arrays $PA(\Delta t)$, the packet size is directly retrieved from the packet header,

$$PA_i(\Delta t) = \{PA_1, PA_2, \dots \dots \dots PA_n\}$$

The mean packet size is calculated for the network over a time interval (Δt).

$$\overline{MPA} = \frac{1}{N} \sum_{k=1}^{N_i} PA_i, \text{ such that } 60 \leq PA_k \leq 1514$$

The probability of occurrences of $Rq_i(\Delta t)$ is calculated as,

$$p(Rq_i(\Delta t)) = \frac{N_i}{\sum_{i=1}^N N_i}, \text{ where } p(Rq_i(\Delta t)) \geq 0 \text{ and } \sum p(Rq_i(\Delta t)) = 1$$

The packet size expected for each network flow of CC_i is calculated as,

$$Ep'(x) = \sum_{i=1}^N p(Rq_i(\Delta t)) * \overline{MPA}$$

Next, compute the distance deviation between the calculated packet size ($Ep'(x)$) and default packet size ($Ep'_t(x)$), this distance gap help to identify the inequality between the legitimate traffic and normal traffic.

$$\partial(\alpha, \Delta t) = Ep'(x) - Ep'_t(x)$$

Suppose $Rq = \{r'_1, r'_2, r'_3, r'_4\}$ is the ordered flow of traffic in the network at the sample time period Δt . Let the probability of each flow will be $P = \{p_1, p_2, p_3, p_4\}$. The mean packet size $\overline{MPA} = \{m_1, m_2, m_3, m_4\}$ for all value of Rq . The obtained and stored value of the normal expected packet size will show a loss of generality as,

$$Ep'\{r'_1, r'_2, r'_3, r'_4\} = Ep'\{r'_4, r'_3, r'_2, r'_1\}$$

The symmetry of the attack is independent of the arrival pattern and pulse pattern; therefore the accuracy will be overwhelmed by the distance deviation caused by the LRDDoS attack in the network.

$$Att_{flag} = \begin{cases} 1, & \partial(\alpha, \Delta t) \geq 0 \\ 0, & \partial(\alpha, \Delta t) < 0 \end{cases}$$

Fig. 3 depicts the flow diagram illustrating the Algorithm of phase 1.

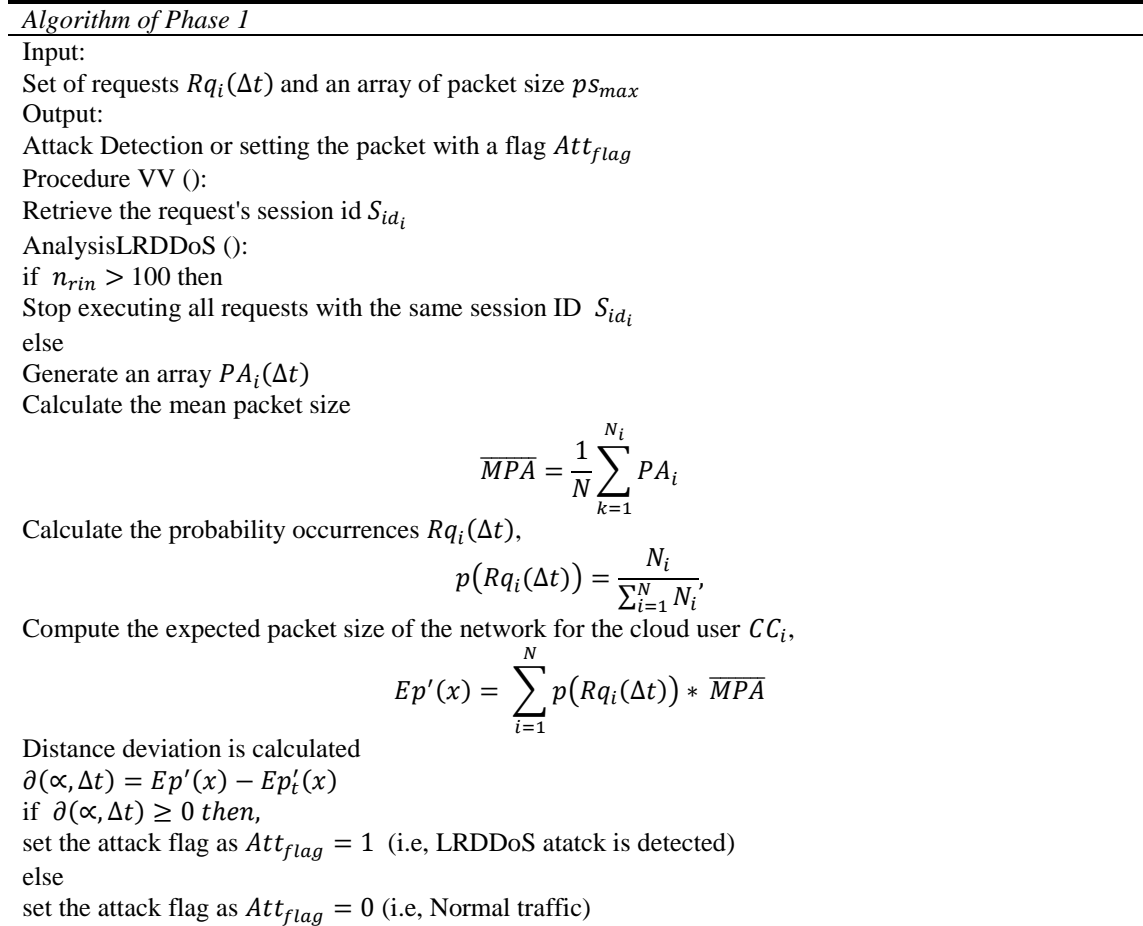

Fig. 3. Phase I flow algorithm.

B. PHASE II Algorithm

In this phase II process, a usage of covariance vector to identify LRDDoS assaults; if the LRDDoS assault pulse is perceived as a significant signal, the network background traffic acts as the sender's noise. During transmission, attack flows are masked by genuine traffic; nevertheless, covariance vector detection is used to identify attack flows at the receiving end.

1) *The covariance vector principle:* A random vector's covariance matrix is a square matrix that contains all of the covariances between the vector's entries. Consider the two vectors \hat{x} and \hat{y} which are used as random vector as,

$$\hat{x} = \{x_1, x_2, \dots, \dots, x_n\}^t$$

$$\hat{y} = \{y_1, y_2, \dots, \dots, y_n\}^t$$

$$cov[\hat{x}, \hat{y}] = E[(x_i - E[x_i'])(y_j - E[y_j'])]$$

$cov[\hat{x}, \hat{y}]$ is known as cross covariance vector. A cross-covariance matrix is one in which the element at the i, j positions represent the covariance between the i^{th} element of one random vector and the j^{th} element of another random vector variable with several dimensions. All of the scalar random variables in the vector are its elements. There is finite

or an infinite number of potential values for each element, as well as a finite or an unlimited number of values that may be experimentally observed. The cross-covariance matrix logically adds more dimensions to the idea of covariance. Typically, the cross-variance vector mean of the two vectors x and y is expressed as,

$$K_{xy} = cov[\hat{x}, \hat{y}] \stackrel{\text{def}}{=} Ep[[x_i - Ep(x_i')] - [y_i - Ep(y_i')]]^{\Delta t}$$

In the phase II algorithm, some initial vectors are used to perform the calculations for each request coming from the cloud user CC_i . A normal traffic vector is generated $\widehat{R}_{nor} = \{RN_1, RN_2, \dots, \dots, RN_n\}$, mean vector value of the normal traffic as M_{nor} and threshold value δ_{nor} . In this phase the covariance vector mean value is subtracted by predefined mean vector value and then compared with the 3-phase threshold and 4-phase threshold value to detect the LRDDoS attack in depth. The request (Rq_i) which is detected will be put on hold for a specific time period and the IP address (IP), protocol used(P), attack duration (D_i), attack period(Δt), attacking rate(r) is blacklisted which is indicated as B_{list} . Fig. 4 depicts the flow diagram illustrating the Algorithm of phase II.

<p>Algorithm of Phase II</p> <p>Input :</p> <p>Set of request $R_i(\Delta t)$</p> <p>\widehat{R}_{nor} mean vector value of the normal traffic as M_{nor}</p> <p>Threshold value δ_{nor}.</p> <p>Output:</p> <p>B_{list} and time of halt</p> <p>Procedure :</p> <p>Convert the request obtained from the network to a vector form \widehat{R}_{rec}</p> <p>Check the result obtained from the from the pahse I algorithm</p> <p>If $Att_{flag} = 1$</p> <p>Blacklist the request $R_i(\Delta t)$ in B_{list} file by capturing the information as IP address (IP), Protocol used(P), attack duration (D_i), attack period (Δt), attack rate (r) and halt the cloud user for $\frac{1}{2^n} \Delta t$.</p> <p>Otherwise</p> <p>Compute the covariance vector mean as,</p> $K_{rec} = E[[R_{inor} - E(R'_{inor})] - [R_{irec} - E(R'_{irec})]]^{\Delta t}$ <p>If $K_{rec} - M_{nor} \leq 3\delta_{nor}$ or $4\delta_{nor}$ then,</p> <p>Set $Att_{flag}=0$, consider as normal traffic</p> <p>Else</p> <p>Set $Att_{flag} = 1$ and Blacklist the request $R_i(\Delta t)$ in B_{list} file by capturing the information as IP address (IP), Protocol used(P), attack duration (D), attack period (Δt), attack rate (r). and halt the cloud user for $\frac{1}{2^n} \Delta t$</p>

Fig. 4. Phase II flow algorithm.

IV. EXPERIMENTAL OUTCOME AND ANALYSIS

The experiment is made by establishing some crucial criteria depending on the outcomes of available resources in order to assess how well the suggested system performs when subjected to an LRDDoS attack, identify the attack's features, and creates a blacklist of the attacker. The primary justification for looking into the assault is the design of the communication protocols, which enable successful end-to-end service delivery. The proposed system mitigates LRDDoS attacks in a cloud computing environment using a two-phase detection method. Attackers however, use the protocols to change how cloud services and apps are accessible. According to the suggested strategy, the three main flooding assaults are TCP SYN, UDP, and ICMP. In this case, the victim end of the attack experiences one-way attack traffic and disproportionately high levels of unauthorized resource use.

The experimental setup uses the following configuration. One server with $m + n$ virtual machines is used, where m stands for legitimate users and n stands for malicious users. The configuration includes Windows 10 operating system, Intel (R) Core (TM) i7-4790 CPU running at 3.60 GHz, 500 GB of storage, 16 GB of RAM for desktops and 72 GB for server. The scenarios of low-rate DDoS attacks and non-attack traffic are created for the experiment. In the absence of an attack, authorized users (m virtual system) contact the cloud

server to request access to services or files kept on the server. A malicious user (n virtual machine) sends attack packets to the cloud server in an attack scenario. In contrast, in an attack scenario, the cloud server will simultaneously receive requests from both legitimate users and malevolent users. To identify the LRDDoS attack sources per source IP throughout the observed period, the correlation 1 query is run on the input stream. By combining the source addresses that come from the user group ($m + n$ users), correlation is achieved. At the selected time interval, network flows are gathered. Attack packets are added to the Backlist B_{list} along with the session ID of the virtual machine source when the individual source IP crosses the threshold value.

The two-phase detection system captures the stream processing quite well. Data from the baseline profile are used to calculate the threshold value. The cloud's statistics and behavior while it is not under assault are examined. The baseline profiling is done for a period of time that varies from daily to weekly to monthly. The baseline is periodically updated to reflect any alterations to the cloud usage. The Slowloris attack tool is used to simulate low-rate attack situations. It is a DDoS attack programme that creates irregular HTTP connections using the Hyper Text Transfer Protocol (HTTP). By absorbing all connections of the server, the tool attempts to maintain HTTP connections for an

extended period of time while slowing down the cloud server (such as Apache and dhttpd). The Apache web server's timeout setting is 250 seconds by default; however, it can be changed depending on how the attack packets are transmitted.

Incomplete HTTP connections are opened by the Slowloris to launch low-volume assaults. It performs data requests and, once all connections have been used, resets the timeout counter value to 1. Using $x + y$ malicious nodes, the assault begins with the command `perl slowloris.pl -dns -s 192.169.60.1 - 250 www.abcexample.com - timeout 3 - num 60 - port 80`. By claiming to be IP addresses in the subnet from 192.169.60.1 to 192.169.60.250, the malicious nodes create 60 connections and maintain them by making data requests every 5 seconds. The low acquisition rate timeout of 5 seconds is selected. In low-rate attack scenarios, the legitimate nodes submit request packets to the cloud server concurrently with the malicious nodes. At the CC, the traffic is recorded for each scenario, and a matching Traffic flow behavior graph (TFBG) is created. In Fig. 5, the TFBGs are shown. Fig. 5(a) demonstrates the steady traffic flow that was present when there was no threat of assault, while Fig. 5(b) depicts the periodic and pulsating traffic streams seen during an LRDDoS assault.

The detection precision of each assault is displayed in Table I below. The total detection accuracy for a TCP SYN

flooding attack is stated to be 99.97% in a time window of 60 seconds. For different threshold values, such as 100, 1000, 5000, 10,000, and 15,000, the accuracy of the attack detection is accordingly 99.85%, 99.98%, 99.99%, 99.99%, and 99.99%. The overall detection accuracy for a UDP flooding attack is reported to be 99.96% during a time window of 60 seconds. Attack detection accuracy ranges from 99.81%, 99.98%, 99.99%, 99.99%, and 99.99% for threshold values of 100, 1000, 5000, 10,000 and 15,000, respectively. For an ICMP flooding assault, the total detection accuracy was 99.84% within a 60-second time window. The accuracy with which the assault is detected is 99.32%, 99.93%, 99.98%, 99.99% and 99.99% for various threshold values, such as 100, 1000, 5000, 10,000 and 15,000, respectively.

In accordance with the IP addresses, the received packets are counted. The non-attack scenario had an average flow count of 2982; the low-rate assault scenario had an average flow count of 610. Table II provides an overview of the values for the selected parameters. According to Fig. 6, legitimate requests in the system under the nonattack scenario last a little bit longer than malicious ones under the LRDDoS attack scenario. The resource isolation means that the LRDDoS assault won't have an effect on the container instances handling malicious requests that have been blacklisted. Fig. 6 demonstrates the flow of requests within the network, showcasing both normal traffic and malicious traffic.

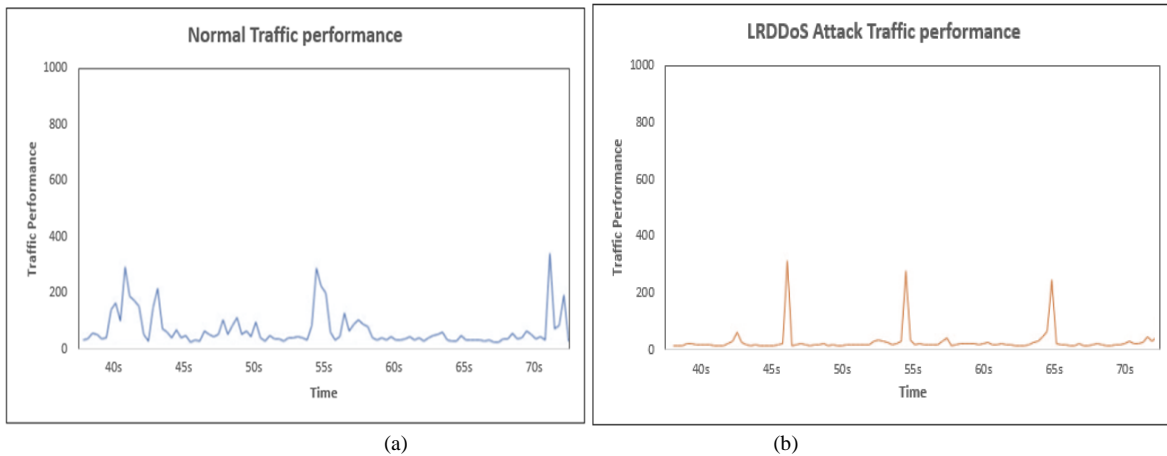

Fig. 5. Traffic flow behavior graph: (a) Normal traffic, (b) LRDDoS attack traffic.

TABLE I. LRDDoS ATTACK DETECTION PRECISION

Attack Source	Threshold	TCP SYN	UDP	ICMP
SET 1	100	99.85	99.81	99.32
	1000	99.98	99.98	99.93
	5000	99.99	99.99	99.98
	10000	99.99	99.99	99.99
	15000	99.99	99.99	99.99
Average		99.97%	99.96%	99.84%

TABLE II. PARAMETER EXPERIMENTAL VALUES

Traffic scenario			Behavior graph pattern	Average flow count	Response time
Normal Traffic			Uniform pattern	2982	60 seconds
LRDDoS attack traffic	Periodic and pulsing	610	60 seconds		

Fig. 6. Combined traffic flow behavior.

Table III provides a comparison of the suggested technique to the current approaches. When comparing approaches, it is taken into account how well they can identify DDoS attacks with low attack rates, as well as how quickly they can respond. To evaluate the correctness of the proposed technique, two metrics are used: True Negative Rate (TNR) and True Positive Rate (TPR), also known as specificity and sensitivity, respectively. TPR and TNR are calculated as follows:

$$TPR = \frac{x'}{x' + y'}$$

and

$$TNR = \frac{a'}{a' + b'}$$

where,

x' = signifies properly identifying malicious users.

y' = Unauthorized users .

a' = Accurately detected authorised users.

b' = Authorized users who were

mistakenly labelled malevolent.

The following metrics are used to assess the proposed method's accuracy:

$$Accuracy = \frac{x' + a'}{x' + y' + a' + b'}$$

The experiment was repeated multiple times with various combinations of reliable ($x + p$) and malicious ($y + q$) nodes selected from the set of 16, 32, 64, 128, 256, and 512 in order to evaluate performance. Table III displays the comparative analysis of the experimental outcomes. For a high number of nodes, there is only a little change in the flow count. Therefore, only the results for up to 128 nodes are displayed. Based on the response time, average flow count, and traffic flow behavior, the study is carried out. Based on the trials, 99.1% and 99.5%, respectively, are the average values for TPR and TNRs shown in Fig. 7. The proposed technique has a 99.4% total accuracy rate as shown in the below Table III.

TABLE III. COMPARISON OF PROPOSED SYSTEM WITH EXISTING SYSTEM

Methodology	Normal	LowRate	Response time	Accuracy
FR-Red [a]	Yes	Yes	(15.1-125.8) sec	98%
Queue based model[b]	Yes	Yes	Medium	99.1%
LORD [c]	Yes	Yes	75sec	99.1 %

V. CONCLUSION AND FUTURE RESEARCH PROSPECTS

This work proposes a simple and effective two-phase detection methodology for detecting LRDDoS attacks in a cloud domain. The suggested model incorporates the 3D Threshold and covariance vector notions as well as the packet size of each request and the network flow count. Based on the concept, a faulty LRDDoS attack in a network with restricted resources is possible. The model's performance demonstrates a 99.97%, 99.96%, and 99.84% accuracy in identifying the LRDDoS attack, which is carried out utilizing the TCP, UDP, and ICMP protocol. By establishing a variety of threshold values, the testing results show an average detection of 99.8%. Using this method, the cloud user's virtual machine may be optimized and system resources can be dynamically reassigned. The suggested approach entirely eliminates the effect of LRDDoS attack by blacklisting the user for a particular time period and increase the ability of the other user to utilize the service of cloud without get affected by the assault.

As part of future work, it is necessary to investigate strategies to counteract LRDDoS attacks on the assumption that virtual machines may expand with limitless resources. Furthermore, in the limitless resources scenario, an attempt is made to investigate pricing difficulties in a VM-based cloud system when defending against an LRDDoS assault.

Abstract—Abnormal detection of pig behaviors in pig farms is important for monitoring pig health and welfare. Pigs with health problems often have behavioral abnormalities. Observing pig behaviors can help detect pig health problems and take early treatment to prevent disease from spreading. This paper proposes a method using deep learning for automatically monitoring and detecting abnormalities in pig behaviors from cameras in pig farms based on pig behavior patterns comparison in activity periods. The approach consists of a pipeline of methods, including individual pig detection and localization, pig tracking, and behavioral abnormality analysis. From pig behaviors measured during the detection and tracking process, the behavior patterns of healthy pigs in different activity periods of the day, such as resting, eating, and playing periods, were built. Behavioral abnormalities can be detected if pigs behave differently from the normal patterns in the same activity period. The experiments showed that pig behavior patterns built in 30-minute time duration can help detect behavioral abnormalities with over 90% accuracy when applying the activity period-based approach.

Keywords—Deep learning; pig tracking; behavior patterns; pig health monitoring

I. INTRODUCTION

Pig tracking plays an important role in the early detection of problems in pig health and welfare. Traditionally, this job is done by workers on pig farms. This manual method has a number of disadvantages. Firstly, workers cannot monitor all pigs continuously and all the time, because they have many other jobs to do. Secondly, they lack the capability to remember and associate the behaviors of each individual pig over a long period of time to detect behavioral abnormalities. In addition, on large pig farms, this task requires a lot of labor.

Tracking pigs automatically not only reduces labor costs, but can also provide better performance since pig behaviors can be observed and associated over a longer period of time. By recording pig behavior measurements over a long period of time, the changes in behavior patterns of pigs can be detected, and these can be used as early signs of disease. If the decision can be made only at the observing time and can not be associated with other observations in the past, only serious clinical signs can be detected, which may result in a late intervention [1].

Pig tracking can be performed in groups or at the individual level. Although group behavior measurement has been proven to have usefulness in pig health and welfare monitoring, individual behavior detection and tracking has more

advantages as it can enable personalized abnormal detection and treatment [1]. Obviously, tracking individual pigs is a more challenging task than tracking group of pigs because of the potential errors in individual pig detection and identification. Recently, with improvements in object detection and tracking techniques, pig tracking has been focused on individual-level.

Tracking pigs from surveillance cameras is a widely used method due to its low cost and simplicity of installation when compared to wearable methods. Depth sensors such as 3D cameras have been used to measure the depth of pig images detected to identify if a pig is standing or lying [2, 3, 4, 5], but this kind of device is expensive, and this method cannot be used to identify other postures such as eating or drinking. Recently, deep learning approaches have been utilized to detect, track, and identify exact behaviors of individual pigs. Based on the convolutional neural network (CNN) architecture, a number of multi-object detection algorithms have been introduced, such as Faster R-CNN [6], SSD [7], YOLO [8]. These algorithms can help locate and classify objects in images, which can be used for pig localization and posture classification in video frames from surveillance cameras. This approach worked on inexpensive 2D RGB cameras and has the ability to identify various pig behaviors such as standing, lying, eating, drinking, foraging, etc. [4, 5, 9, 10, 11, 12, 13, 14] or identify moving, non-moving behaviors [1]. Non-moving behaviors can be identified in the detection phase by dividing pig classes of the detection model into sub-classes such as pig standing, pig lying, pig eating, etc. [1, 10, 11] or using an additional image classification model to classify the detected pig images into different behavior classes [13]. Moving behaviors, such as walking or running, can be identified in the tracking process by measuring the distance that a pig traveled between continuous frames [1, 13]. In addition to basic postures and behaviors, some researchers tried to identify more complex postures, such as sitting, lateral lying, sternal lying, etc. [11]. When the behaviors can be identified during the tracking process, changes in pig behaviors can be detected by considering the time for each behavior [10, 13] or time spent moving, being idle, and distance traveled [1].

One of the most challenging issues in pig tracking is identification errors caused by identity switching or changing problems during the multi-object tracking process. Some previous works have tried to improve this problem by using additional methods, such as a correlation filter-based tracker via a novel hierarchical data association algorithm [15] or trajectory processing and data association [16]. However, due to the natural conditions of commercial pig farms, such as high

pig density, low light, similar appearances of pigs, or wide covering area of cameras, tracking each individual pig for a long time with low identification error rate is still a difficult task.

In this paper, we propose a pipeline of methods, including detection, tracking, building healthy pig behavior patterns, and behavior abnormality detection based on comparison of new pig behaviors and healthy pig behavior patterns. We tried to reduce the impact of identification errors by calculating the behavior patterns in 30-minute-long videos. Moreover, to make the behavior patterns built in only a 30-minute time duration but still have capabilities for detecting behavioral abnormalities, we built different behavior patterns for each activity period in a day. According to our studies, pigs have typical behaviors during different activity periods in a day, such as resting time, eating time, playing time, and building different behavior patterns for each activity period can improve the behavioral abnormality detection performance.

In our method, videos from cameras installed on pig pens will be streamed to the Yolo v7 model [17] to detect pig locations and postures. In the detection phase, pigs detected will also be classified into different posture classes, such as standing, lying, and eating. Pig locations in continuous video frames will be used to identify the individual pigs and track their movements using the DeepSORT algorithm [18]. While lying and eating behaviors are identified in the detection phase, standing and moving behaviors need to be determined in the tracking phase. In the tracking phase, we can measure the distance between the locations of each individual pig in continuous frames. If the distance between locations of a pig is less than a threshold number in some continuous frames, the pig can be determined to be idle rather than moving. Based on the behaviors recognized in the detection and tracking processes, behavior patterns can be built for different activity periods of a day. The experiments showed that the behavior patterns, which were built from 30-minute time duration, could reduce the identification error but still show behavioral characteristics in each activity period.

The main contributions of our method are:

- Proposed an end-to-end method for detecting and tracking pigs individually, measuring their behaviors and building behavior patterns, detecting behavioral abnormalities.
- Proposed an approach for building healthy pig behavior patterns in different periods of time in a day, such as rest time, eating time, and playing time. With this approach, we can build behavior patterns in only 30 minutes to reduce the identification error. Based on the behavior patterns, abnormalities can be detected by calculating the difference between the tracked pig behavior set and the behavior patterns. We tested our approach on both healthy and sick pig datasets.

The rest of the paper will be structured into the following sections. Section II describes the materials and methods for pig detection, tracking, and behavior analysis. Section III describes the experiments and results. Section IV finalizes a conclusion.

II. MATERIALS AND METHODS

A. Datasets

The datasets used in this paper were collected from two pens on a commercial pig farm. One pen (Pen 1) contains healthy pigs, and the other one (Pen 2) contains sick pigs (which were collected from other pens for quarantine purposes). Videos from both pens were used to create the pig detection and tracking datasets. Videos from Pen 1 were used to build healthy pig behavior patterns, and videos from Pen 1 and Pen 2 were used to build test datasets for behavioral abnormality detection.

The video was recorded using one EZVIZ (resolution: 1920 x 1080, focal length: 4.0mm, max frame rate: 15 FPS) on pens containing 15-18 pigs with ages from 3 months to 4 months and weights from 40 kg to 50 kg.

The videos were recorded across different days and times to collect the data in different conditions. Fig. 1 shows the sample images from the experimental pens.

Fig. 1. Sample images from experimental pens.

From this raw dataset, we created pig detection, pig tracking, pig re-identification, and pig behavior analysis datasets for our experiments. The details of these datasets are described in the next sections.

1) *Detection dataset*: To create the detection dataset, we extracted image frames from captured videos and manually annotated them using the LabelImg tool [19]. Using this tool, we created a bounding box for each pig in the images and assigned it one of three classes: standing, lying, or eating (to annotate the eating behavior, we need to create a bounding box covering not only the pig but also the feeder as well, so

that the model can learn if it is eating food in the feeder trough or not).

Totally, 3,069 images were extracted from recorded videos and annotated for training and testing the detection model (48,522 annotations). The images were extracted from videos captured at different times in order to test the detection and tracking performance in various illumination and weather conditions.

2) *Tracking dataset*: To create the detection dataset, we just need to create a bounding box for each pig and assign it a behavior class, as mentioned above. But to create the tracking dataset, we need to assign each pig the same identification number (ID) from frame to frame.

The frames in the tracking dataset are selected in the order they appear in the video but don't need to be continuous because the frame rate of videos is very high. On average, we just selected and annotated one-fourth of the frames on each testing video. To test the tracking performance of both pens, we create two tracking subsets on videos from Pen 1 and Pen 2, as described in Table I. As mentioned above, the frames in a tracking subset must be put in order, so it can be seen as a sequence of frames.

TABLE I. SUMMARY OF TRACKING DATASET

	Sequence Length (seconds)	Number of frames
Sequence from Pen 1	300	247
Sequence from Pen 2	300	250

3) *Pig re-identification dataset*: The pig re-identification dataset contains individual pig images for the purpose of recognizing the individual pig without consideration for its behaviors. Therefore, it includes all the pig images in the pig behavior dataset plus other pig images we collected by using the detection model. Totally, we obtained 5,460 images for 30 pig identities for our pig re-identification dataset.

4) *Pig behavior analysis dataset*: This dataset includes 30-minute videos collected from both pens to build behavior patterns and test abnormality detection based on behavioral analysis. In particular, the dataset consists of the following videos:

- Nine videos collected from the healthy pig pen in three activity periods, as mentioned above. Three videos were collected randomly in each activity period to build the behavior pattern for that period.
- Three videos collected from the healthy pig pen in three activity periods for testing purposes.
- Three videos collected from the sick pig pen in three activity periods for testing purposes.

B. Method

In order to build the behavior patterns of pigs in a video, they first need to be detected in each video frame. The detections obtained in continuous video frames are used for tracking the pigs and identifying their behaviors. In our

method, the detections can be used to identify non-moving behaviors such as lying, standing, or eating with corresponding class labels. However, to determine the moving behavior, we need to consider the distance between pig locations in continuous frames during the tracking process.

Fig. 2 shows the overall architecture of our system. The methods applied in each module are described in the following sections.

1) *Pig detection*: In this phase, the YOLO v7 model was used to detect the pigs. The YOLO is a popular object detection algorithm and is widely used today due to its speed and accuracy. It is a single-state object detection scheme that divides images into a grid, in which each cell in the grid is responsible for detecting objects itself.

YOLO v7 is an object detection architecture entirely written in Pytorch with models pretrained on the COCO [20] dataset. We chose to use YOLO v7 because it is significantly faster and more accurate compared to the previous versions. We first pre-trained the model with the COCO dataset, and followed by our own dataset as a fine-tuning task. The pre-training step is necessary when training most CNNs for image classification or detection to obtain good initial weights on an extremely large dataset (millions of images).

In the following stage, we fine-tuned the model using our detection dataset. The purpose of the model is not only to detect the pigs but also to identify non-moving pig behaviors such as standing, lying, and eating.

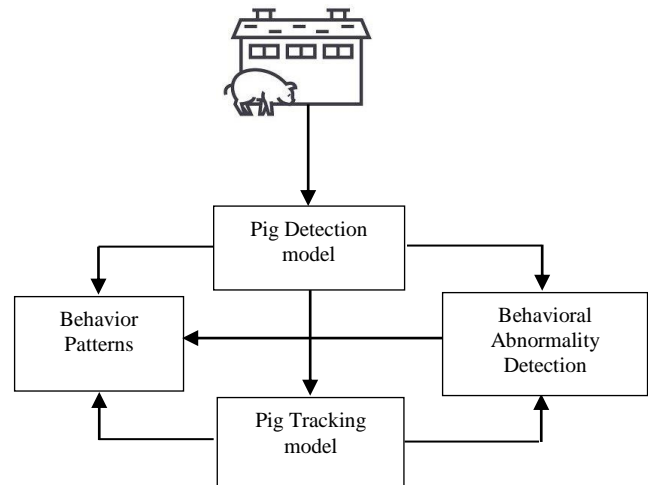

Fig. 2. Overall architecture of our method and system.

2) *Pig tracking*: From the locations of pigs detected in the frames, we employed DeepSORT, a multi-object tracking (MOT) technique, to track the pigs in videos. DeepSORT uses the Kalman filter [21] to track the objects detected in the frames in the previous step (using one of the object detection algorithms such as YOLO, R-CNN family, etc.). The Hungarian algorithm [22] will be used to match the tracked objects and detections in the next frame. DeepSORT not only uses the distance between tracks and detections as measurements of matching but also uses deep image similarity

as an additional metric. This greatly reduces the number of misidentified objects and can help re-identify the objects that have not been tracked in the previous frame (in the pig tracking task, this can be caused by the bad illumination conditions). To measure the image similarity, we used the OSNet (Omni-Scale Network) [23] model, pre-trained on the person re-identification dataset and followed by our own pig re-identification dataset.

The original DeepSORT was developed for a general multi-object tracking context in which the number of targets is unknown. When applying it to the group-housed pig tracking task where the number of pigs is stable, DeepSORT can assign a different ID to the same pig target as the video frames grow and the pig goes far from camera or changes the behavior. This will cause the identification switch errors and increase the ID beyond the real pig's numbers, making the behavior extraction task for individual pigs not stable. To solve this problem, we employed the improved DeepSORT algorithm proposed by S. Tu et al. [16], in which we added an additional re-matching step for lost and new tracks using both trajectory and data association processing. This remarkably improves the tracking performance and reduce the identification errors as described in the tracking results section.

3) *Behavioral abnormality analysis*: In this phase, we used the results of the detection and tracking phases to determine the behaviors of each individual pig. In particular, if the posture of a pig recognized in the detection phase is lying or eating, its behavior is determined to be the same. If the posture of a pig recognized in the detection phase is standing, the change in its position in the tracking phase (if any) will be used to determine if it is standing or moving. We set a threshold for the distance between positions of the pig in continuous frames. If the distance is greater than the threshold, the pig is determined to be moving; otherwise it is standing.

Based on that scheme, all four behaviors of pigs will be identified during the detection and tracking phases. From the behaviors identified in the frame sequences, the total amount of time for each behavior will be calculated over a period of time to build the behavior patterns of pigs in each activity period. In this research, we introduce the term "activity period", which implies a period of time in a day that the pigs mainly perform some typical behaviors. In our experiment, we set the time for each activity period as in Table II. Please note that the times for activity periods may vary on different farms. But in commercial settings, farm owners can set the times for them, and system can collect data and build the behavior patterns accordingly.

TABLE II. TIME FOR ACTIVITY PERIODS

Activity Periods	Time	Description
Resting period	0h-7h, 8h-10h, 14h-16h, 18h-24h	Pigs mostly spend time for resting, sleeping
Eating period	7h-8h, 13h-14h, 17h-18h	Pigs mostly spend time for eating
Playing period	6h-7h, 16-17h	Pigs mostly spend time for playing, looking for food

We chose the time duration to build behavior patterns is 30 minutes and the behavior patterns will be calculated for three activity periods in a day, as mentioned above. The 30-minute time duration was chosen to balance the identification errors and the abnormality detection abilities of behavioral patterns. If the time duration is shorter, identification errors can be reduced, but the behavior patterns may not be sufficient to represent the activity periods. While a longer time duration may produce a better behavior pattern, identification errors will increase. Since the current farm's natural conditions do not guarantee accurate long-term tracking, a 30-minute time duration for building behavior patterns is a reasonable choice.

The healthy pig behavior patterns in each activity period will be calculated as follows:

- Calculating the time for each behavior of each individual pig in each 30 minutes.
- Building the behavior patterns of healthy pigs by averaging the time for each behavior in the same activity period.
- Building the daily behavior patterns of healthy pigs by averaging the 30-minute behavior patterns in the same activity period.
- Behavior patterns will be calculated for three activity periods, as mentioned above.

Behavior patterns will be built and updated on a daily basis. The behaviors of tracked pigs will be calculated using the same formula and compared to the behavior patterns. The difference between them will be calculated using the Euclidean distance, and a threshold will be set for abnormality detection.

During the tracking process, some tracks may be lost and reappear, and their behaviors will not be recorded during that time. To make the behavior patterns and extracted behavior set have a consistent time, we assign the behaviors in lost time according to the previous and subsequent behaviors (half of time for the previous and half of time for the subsequent). Therefore, the total time for all behaviors in behavior patterns and behavior sets is always 30 minutes.

III. RESULTS AND DISCUSSION

A. Evaluation Metric

1) *Detection evaluation*: To evaluate the performance of the detection model, we used the mAP (mean Average Precision) metric, which is a standard metric to evaluate the performance of most common object detection methods. We first compute the IoU of the ground-truth bounding boxes with detected boxes as in Eq. (1).

$$IoU = \frac{\text{Area of Overlap}}{\text{Area of Union}} \quad (1)$$

From the IoU metric of each bounding box pair, we computed the AP (Average Precision) metric for each class, and mAP is the mean of all APs as in Eq. (2) and (3).

$$AP(c) = \frac{TP(c)}{TP(c)+FP(c)} \quad (2)$$

$$mAP = \frac{1}{\text{classes}} \sum_{\text{classes}} AP(c) \quad (3)$$

Where $TP(c)$, $FP(c)$ are True Positive, False Positive, respectively and $AP(c)$ is the AP score of class c .

2) *Tracking evaluation*: The tracking performance metric used in our experiments is MOTA (Multi-Object Tracking Accuracy) [24]. This metric is calculated based on three types of errors: FN (False Negative), FP (False Positive), and IDSW (Identity Switch) as in Eq. (4).

$$MOTA = 1 - \frac{\sum_i FN_i + FP_i + IDSW_i}{\sum_i GT_i} \quad (4)$$

Where FN_i is a real object but the tracker for it was not generated, FP_i is a non-existing object in ground truth but the tracker for it was generated wrongly, $IDSW_i$ is a mismatch, and GT_i is ground truth.

We also used $IDF1$ as a second metric to evaluate the tracking model. This metric focuses on the identity switch, which evaluates the ability to track identities.

$$IDF_1 = \frac{2IDTP}{2IDTP + IDFP + IDFN} \quad (5)$$

Where $IDTP$, $IDFP$, $IDFN$ are True Positive, False Positive, False Negative on identity switches.

3) *Behavioral abnormality detection evaluation*: Each pig tracked will be assigned a unique identification (ID) with four behavior metrics, which are the time for each behavior in 30 minutes. These metrics will be compared to the behavior pattern in the same activity period using Euclidean distance as in Eq. (6).

$$d(Y, \hat{Y}) = \sqrt{\sum_{i=1}^n (Y_i - \hat{Y}_i)^2} \quad (6)$$

Where Y is the behavior pattern and \hat{Y} is the behavior set of the tracked pig.

If the distance is greater than the threshold number, a behavioral abnormality is detected. In the testing process, if an abnormality is detected in a sick pig, the prediction is correct, and vice versa. The performance of behavioral abnormality detection can be evaluated by dividing the number of correct predictions by the total prediction number (Accuracy score).

B. Detection Results

The results of the detection phase are shown in Table III. Please note that besides mAP, we also reported the Precision and Recall scores for the detection model.

TABLE III. RESULTS OF PIG DETECTION MODEL

Class	mAP	Precision (%)	Recall (%)
Stand	99.3	98.3	98.5
Lie	99.6	98.6	99.1
Eat	98.9	97.0	97.0
All	99.3	97.9	98.2

The reported detection results are very good in all metrics, considering the natural conditions of the commercial pig farm in our dataset. The cameras do not have a good viewing angle

due to the low ceiling of pens, which was designed for human monitoring and also for saving purposes. For this reason, some pigs are overlapped in videos when they stay close to each other and far from the camera. If pens are designed to support the automatic tracking task with a higher ceiling, the detection results will be better. Fig. 3 shows a case where a pig was hidden by the feeder due to the low camera viewing angle and could not be detected.

Fig. 3. Sample image for a detection errors when a pig was hidden by the feeder due to the low camera viewing angle.

C. Tracking Results

Table IV shows the results of the tracking model in MOTA and IDF1 scores. We also reported the number of identity switches (IDS), which calculates the times when trackers swap from one to another. This metric is also important because it shows the number of identification errors during the tracking process.

TABLE IV. RESULTS OF PIG TRACKING MODEL

Validation set	Original DeepSORT			Improved DeepSORT		
	MOTA (%)	IDF1 (%)	IDS	MOTA (%)	IDF1 (%)	IDS
Sequence 1	91.5	93.4	13	92.8	95.6	10
Sequence 2	92.5	94.0	10	94.3	96.1	8
Avg.	92.0	93.7	11.5	93.6	95.9	9

The overall MOTA (93.6 %) and IDF1 (95.9 %) are satisfactory. Results for Sequence 2 are slightly higher because it was collected from the sick pig pen, where pigs move less than in the healthy pig pen.

The average number of IDS is 9, meaning that each pig changed its identification only about 0.4 times on average during the tracking process. In our object tracking algorithm, the objects are tracked not only based on their trajectory but also on their visual similarity. And the object in the current frame will be associated with the object in some frames before it. Therefore, even though the pigs in the previous frames and the current frame are predicted to have different class labels, they will be assigned the same ID. This is important for the tracking process because it will not cause identification errors.

Fig. 4 illustrates the cases where pigs change behaviors during the tracking process but their IDs remain unchanged.

Fig. 4. Sample frames for tracking results when pig 9 was approaching the feeder with the recognized behavior “Standing” (above), then changed to “Eating” (below), but the ID was not changed. Similarly, the pig 4 changed behavior from “Lying” to “Standing” but the ID is the same.

D. Behavioral Abnormality Detection Results

Based on the pig behavior analysis datasets, the experimental process of behavior analysis and abnormality detection is as follows:

- Building healthy pig behavior patterns: Nine videos from the healthy pig pen for behavior pattern building purposes are fed through the detection and tracking models. The time for behaviors of individual pigs in these videos is calculated and averaged to build three behavior patterns of healthy pigs in three activity periods in a day. Please note that in commercial settings, the behavior patterns can be built using more 30-minute videos collected from tracking cameras. We just used three videos for each activity period for experiment purposes.
- Testing on the videos collected for testing purposes: Six videos from the healthy pig pen and sick pig pen (two for each activity period) are fed through the detection and tracking models. The behavior of each individual pig will be calculated and compared to the healthy pig behavior pattern in the same period built in the previous step using the Euclidean distance formula.

Table V shows the healthy pig behavior patterns built from videos.

TABLE V. HEALTHY PIG BEHAVIOR PATTERNS

Activity period	Moving Time	Standing Time	Lying Time	Eating Time	Total
Resting	0.4	0.4	29.2	0	30
Eating	5.3	5.2	0.5	19.0	30
Playing	23.1	4.5	1.8	0.5	30

From the behavior patterns shown in the above table, we can see the typical behaviors of healthy pigs during each activity period of a day. For example, in the resting period, pigs spend most of their time lying while in the playing time, they mostly move around the pen (for playing or searching for food).

Table VI shows the time of each behavior for each pig in testing videos and the Euclidean distance between each pig behavior set and the healthy pig behavior pattern in the same activity period.

TABLE VI. BEHAVIOR TIME FOR PIGS IN TESTING VIDEOS

A) RESULTS ON A HEALTHY PIG VIDEO IN THE RESTING PERIOD

14	21	4.5	4.5	0	3.4
15	20	8.5	1.5	0	5.1
16	19	9	0	2	6.5

As shown in Tables VI(A) and VI(B), pigs spend almost all of their time lying in both healthy and sick pig videos in resting period. Therefore, it is difficult to detect behavioral abnormalities in this period. We may only detect the pigs infected with a disease that makes them excited and move or run continuously, even in the resting period. However, there is no pig with that kind of disease in our datasets, so we cannot draw conclusions about that case.

The detection of behavioral abnormalities is much better in the two remaining activity periods. Results from Tables VI(C) and VI(D) showed that the healthy pigs spent most of their time eating, but the sick pigs also spent a considerable amount of time lying during the eating period. Therefore, if we set a threshold for Euclidean distance to 9, we can detect behavioral abnormalities with accuracy around 90% on average (15/16 are correct predictions for healthy pigs and 12/14 are correct predictions for sick pigs). Similarly, if we set the Euclidean distance threshold to 12 in the playing period, the accuracy on average is around 93% (15/16 correct predictions for healthy pigs and 14/15 correct predictions for sick pigs).

In our experiments, due to the regulations in the livestock sector, we had difficulties infecting the healthy pigs with the viruses to make them sick. Instead, we used the sick pigs collected from other pens to collect data for testing. Therefore, the pigs in sick pig videos are different from the pigs in healthy pig videos, which are used to build behavior patterns. The abnormality detection performance for sick pigs will be better if behavior patterns are built on the same pigs that are tracked. This is feasible in commercial settings, in which behavior patterns are built in the same pen with tracked pigs (abnormality detection for pigs today can use the behavior patterns built yesterday).

IV. CONCLUSION

We proposed a method for pig behavior detection, tracking, and behavioral abnormality analysis based on behavior patterns built from 30-minute videos in different activity periods under the natural conditions of pig farms using deep learning. We conducted various experiments to illustrate our method on our own datasets collected from a commercial pig farm, including healthy pig and sick pig datasets.

The experiment results showed that the behavior patterns built using the activity period-based approach can capture the typical characteristics of pigs in each activity period and can be used to detect behavioral abnormalities in pigs.

The activity period-based approach also has a lot of potential for future improvements. For example, more activity periods can be studied and used rather than only three, or weights can be assigned for behavior metrics to indicate the importance of typical behaviors in each activity period. We can also add more metrics to the behavior patterns and develop a more sophisticated method for abnormality detection based on the behavior patterns.

Abstract—Food is an essential ingredient needed by humans. In addition to being consumed, it can also be a valuable commodity for economic purposes through productivity of food crops. Therefore, this study aims to model the forecasting of maize productivity in Indonesia using Production and Operations Management-Quantitative Method (POM-QM) software. The data collected on productivity of corn commodities in Indonesia between 1980-2019 shows fluctuations, with both deficit and surplus periods. This study uses a time series data-based forecasting model consisting of three methods, namely Double Moving Average (DMA), Weighted Moving Average (WMA), and Single Exponential Smoothing (SES). The selection of the best model was conducted based on the Mean Absolute Deviation (MAD), Mean Square Error (MSE), and Mean Absolute Percent Error (MAPE). SES emerged as the most preferred, with a lower MAPE value of 4.913%. The predicted productivity of corn in Indonesia is estimated at 5.28 tons/ha/year, sufficient to meet consumers' demand. Therefore, governments are recommended to use this information in predicting corn productivity to meet the national demand in the future.

Keywords—Forecasting model; productivity; corn commodity; POM-QM

I. INTRODUCTION

Food security is a vital issue in Indonesia. Furthermore, it is essential to make sufficient food available to meet the population's needs, to avoid prolonged political and social turmoil. Food security is also an indicator of a country's economic growth and can reflect prosperity and a benchmark for the level of welfare, especially in terms of people's productivity and consumption [1]. Therefore, to optimize the utilization of natural resources in each region, it is imperative to implement management strategies tailored to each region's unique characteristics [2-6].

The government's commitment to addressing food security is evidenced by recognizing food as a human right for Indonesian citizens, as stipulated in Law Number 18 of 2012. This aligns with the first and second goals of the Sustainable Development Goals (SDGs), which aim to end poverty worldwide and achieve food security and improved nutrition while promoting sustainable agriculture.

The commodity corn (*Zea mays* L.) is an alternative staple food and a grain plant from the grass family (Graminaceae). In Indonesia, the main maize-producing regions include Central Java, West Java, East Java, Madura, Special Region of Yogyakarta, East Nusa Tenggara, North Sulawesi, South

Sulawesi, and Maluku. Especially in East Java and Madura, corn plants are cultivated intensively due to the favorable soil and climate conditions that support their growth [7].

Corn is a food commodity that plays an essential and strategic role in national development [8], and its contribution to the Gross Domestic Product (GDP) continues to increase yearly, even during an economic crisis [9]. It is one of the most important staple foods in Indonesia. Furthermore, this crop, alongside two other commodities, namely rice and soybeans, is the main target of the Ministry of Agriculture in achieving food self-sufficiency.

Corn is also widely used for multiple purposes, including as a food and feed ingredient. It is being adopted as an alternative fuel source domestically and internationally [8]. However, the demand for this crop remains high since it serves as an ingredient for animal feed companies and other food processing industries [10]. The Ministry of Agriculture considers five commodities such as corn, rice, soybeans, sugar, and beef, as the main food items [11].

As the second most produced food after rice, corn's high demand as animal feed and for industrial purposes poses challenges such as depletion of natural resources and the impact of climate change. Cooperation and collaboration are required to support the development of sustainable corn commodities [12]. However, the problem of land-carrying capacity is a constraint for Indonesian agriculture. As the population increases, more land is needed to meet housing demands, leading to the conversion of agricultural land and affecting corn productivity in the country. Despite a fluctuating rise in production in Indonesia between 1980 and 2019, the overall increase was only 3.98 tons/ha/year or 0.102% per year [11]. There are high fluctuations in productivity of corn commodities. This fluctuation is attributed to internal and external factors such as climate, weather, and government policies.

Thirty years ago, maize was primarily consumed as food. However, with the development of the poultry industry in the early 1970s, corn began to be used as an energy source for modern poultry feed [13]. Before 1990, it was shown that 86% of this crop in Indonesia was consumed directly, and only about 6% was used in the feed industry. Despite this, the adoption of maize in the food industry remains low, accounting for only 7.5% [6]. The availability of this commodity is wider in the rainy than dry season [14]. This

crop is typically cultivated on dry land and planted during the rainy season. The limited harvest area during the dry season results in the low availability of corn to meet the domestic industry's needs [9].

According to Purwanto [14], from 1989-2002, there was a shift in the use of maize, with a continued dominance for direct consumption. After 2002, a greater proportion was employed to meet the demand of the feed industry. The use of this commodity in the food industry has also been on the rise. This change has transformed maize from a staple food commodity into an industrial raw material [15]. The demand for the commodity continues to grow yearly with the increasing population and industry [14]. Additionally, rising oil prices also impact its dynamic demand. The increase in the use of maize as an alternative energy and raw material for the feed and food industries is expected to persist. Furthermore, the rise in per capita income causes an increase in demand for corn commodity derivative products [9].

Forecasting involves estimating future requirements, including the quality of goods, time, and location needed to meet demand [16]. It is the art and science of predicting events yet to occur by always using data from the past [17-18]. According to [19-20], as a crucial component of decision-making, forecasting requires predicting future events to inform effective decisions. Inaccurate forecasting results pose a persistent challenge [16].

Time series analysis and forecasting are active study areas [21]. The accuracy of time series forecasting plays a crucial role in the decision-making process. The several method used in prediction include the time series method, which is grouped into the average (Single Moving Average (SMA) and Double Moving Average (DMA)), the smoothing (Single Exponential Smoothing (SES), double exponential smoothing from Brown and Holt), and the regression method, namely time series regression [22-23-24].

Method used in forecasting vary widely but are adapted to the pattern of data. Generally, there are three types of method to determining the level of the error. These include MAD, MSE, and MAPE, which calculate the average absolute difference, average difference in rank, and average absolute difference percentage, respectively [25]. In utilizing the time series method, it is important to identify the data pattern type, which includes trend, cyclical, seasonal, and horizontal [26].

The availability of several statistical softwares supports the selection of forecasting method. Various study analysts have conducted forecasting models using software assistance to facilitate calculations [27]. For instance, POM-QM software has been studied for product sales forecasting [28]. Furthermore, this method provides module options for mathematical calculations. Its forecasting model has several method, including Naive, Moving Average, Weighted Moving Average (WMA), Exponential Smoothing, Trend Analysis (regression over time), Linear Regression/Least Square, Multiplicative Decomposition (seasonal), and Additive Decomposition (seasonal). Given these considerations, it is necessary to have a model to predict productivity of corn commodities. Therefore, this study aims to establish a forecasting model for corn commodity productivity in

Indonesia using Production and Operation Management-Quantitative Method (POM-QM) software.

II. MATERIALS AND METHOD

The variable used was the harvested area of corn per year from 1980-2019. Secondary data in the form of time series sourced from the data and information center (Pusdatin) under the Ministry of Agriculture and the Central Bureau of Statistics (BPS) were used in this study. The population consists of information on productivity of corn commodities from 1980-2019. A saturated sampling method was employed, where all population members were used as samples.

Forecasting model for corn commodity productivity in Indonesia:

A. Forecasting Model of Corn Commodity Productivity with DMA

Double-moving average is used to forecast time series data with a linear trend [26]. Multiple moving averages, also known as linear moving averages, deal with time series data with patterns that tend to experience a linear trend. Furthermore, the double-moving average is a method that simultaneously uses single-moving average data with adjustments between the first and second moving averages and trend adjustments [29].

DMA is a method in which the first and second moving average groups are calculated. It is symbolized by $(k \times k)$, meaning that the moving average is calculated using the k periods [23]. The moving average method has no objective basis for determining the number of moving average orders [30].

Many methods can be used in forecasting, including DMA. The data used for calculations do not have elements of trend or seasonal factors. DMA is a forecasting method performed on past data for two periods with an average pattern [31], which is suitable for long-term data [32]. The mathematical equation of DMA is presented in Equation 1:

$$F_{t+1} = X_1 + X_2 + \dots + X_T \quad (1)$$

Information:

F_{t+1} = Forecast for period t+1

X_T = True value of t period

T = Timeframe of moving average

The process data analysis in forecasting model for corn commodity productivity using DMA involve several steps, including (a) identify time series data patterns, (b) determine the value of the first moving average, (c) determine the value of the second moving average, (d) determine the value of the constant (at), (e) determine the value of the trend coefficient (bt), (f) select the best model based on the criteria for forecasting accuracy, and (g) determine forecast results for future periods. The data analysis was performed using the help of POM-QM software to facilitate the computation process.

B. Forecasting Model of Corn Commodity Productivity with WMA

WMA forecasting method develops the moving average method with additional weights in the calculation. It is calculated by assigning greater influence to certain values in a data set based on their attributes. In contrast, the average is determined by giving weights. WMA forecasting method is an advanced version of the moving average method in which each time series is given a certain and different weight [33]. In simple terms, WMA is a moving average given weight in each data [34].

Determination of weight is subjective, depending on the experience and opinion of the data analyst. For instance, the analyst may give more weight to the last observation or vice versa. The weighted factor will be greater in the final period than in the early period when the weighting opportunity is higher in the previous observation. The longer the period specified, the greater the weighting given to the most recent data, and the number of weighted opportunities equals one [35]. Finally, the formula used in forecasting model of corn commodity productivity with WMA is presented in Equation 2.

$$WMA_{t+1} = \frac{kX_1 + (k-1)X_{t-1} + \dots + X_{t-(n-1)}}{k + (k-1) + \dots + 1} \quad (2)$$

Information:

k number of periods or ranges of forecasting numbers,

X_t is the time series data value at point t.

C. Forecasting Model for Corn Commodity Productivity with SES

SES is a simple method that requires estimating a single parameter. It assigns Exponential Moving Average (EMA) weights to all historical data. The exponential smoothing forecasting method is an iterative procedure of repeating calculations that improves the forecast (smoothing) by calculating the average of past values in a time series in an exponential manner [36-37-38]. SES is appropriate for data without extreme trends and is usually for forecasting one period in the future. The goal is to estimate the current level and use it to forecast preceding values. Forecasting model for corn productivity with SES employs the formula in equation 3 [39].

$$F_{t+1} = \alpha \cdot X_t + (1 - \alpha) F_t \quad (3)$$

Information:

F_{t+1} is the forecast for the next period, α is the smoothing constant, X_t is the t-th data or observation, and F_t is the t-th period data. The F_{t+1} forecast is based on the weighting of the latest X_t data with a weight of α and the newest forecasting weighting of F_t with a weight of $1-\alpha$. By repeating this process and replacing F_{t+1} and F_{t+2} with their components, the result in Equation 4 is obtained:

$$\begin{aligned} F_{t+1} &= \alpha \cdot X_t + (1 - \alpha) F_t \quad (4) \\ &= \alpha \cdot X_t + (1 - \alpha) [\alpha \cdot X_{t+1} + (1 - \alpha) F_{t+1}] \\ &= \alpha \cdot X_t + \alpha(1 - \alpha)X_{t+1} + (1 - \alpha)^2 F_{t+1} \end{aligned}$$

$$= \alpha \cdot X_t + \alpha(1 - \alpha)X_{t+1} + \alpha(1 - \alpha)^2 F_{t+1}$$

Therefore, F_{t+1} is WMA of all historical data. As t increases, the value of $(1-\alpha)^2$ decreases, leading to a smaller contribution from $F(1)$. Since $F(1)$ is not known, the initial value can be estimated. For volatile initial data, one method is to set the first forecast equal to the first observation, $F_1=y_1$. Furthermore, for initial data that is quite constant, the average of the first five or six data points can be used as the first forecast $F_1=MA(5)$ or $F_1=MA(6)$. The exponential smoothing equation can be rewritten in a form that describes the role of the weighting factor α , as shown in Equation 5:

$$F_{t+1} = F_t + \alpha(X_t - F_t) \quad (5)$$

Exponential smoothing is used to adjust a previous forecast (F_t) by incorporating adjustments for errors. The value of α , which ranges between 0 and 1, cannot be equal to 0 or 1. To obtain a stable forecast with random smoothing, a small α value should be used for data that does not fluctuate too much. In contrast, a large α value is more appropriate for data that fluctuates significantly and requires a fast response to changes. To determine the optimal α value, one can estimate it using trial and error, testing values of 0.1, 0.2, 0.3, ..., 0.9, and selecting the value with the smallest MSE for the next forecast.

Selection of the best model for forecasting productivity of corn commodities

The accuracy of calculations in the forecasting method is often subject to variations in data patterns. Therefore, selecting the right method is imperative to minimize errors in the forecasting results [40]. Each method has its level of accuracy that needs to be considered. As a result, it is essential to choose a method that can minimize forecasting errors. According to [41-42], forecast facts are expected to have small values and errors. The error value is inversely proportional to the accuracy of the prediction result.

The selection of the best forecasting model depends on the resulting error. Some of the criteria that are often used to calculate the accuracy of the model forecasting time series include: (a) Mean Absolute Deviation (MAD), (b) Mean Square Error (MSE), and (c) Mean Absolute Percent Error (MAPE). The smaller the criterion value, the better the prediction results obtained [43-45].

1) MAD: Method for determining the overall forecast error is MAD, which is obtained by dividing the sum of the absolute values of each error by the sample size (number of forecast periods) [43-44]. Finally, the mathematical formula of MAD is presented in Equation 6:

$$MAD = \frac{\sum_t^n (A_t - F_t)}{n} \quad (6)$$

information:

A_t = Actual demand in period t

F_t = Forecasting demand in period t

n = Number of forecasting periods involved

2) *MSE*: MSE is calculated by adding the squares of all errors in each period and dividing them by the number of forecasting periods [43-44]. The mathematical expression of MSE is presented in Equation 7:

$$MSE = \frac{\sum_{t=1}^n |A_t - F_t|^2}{n} \quad (7)$$

Information:

A_t = Actual demand in period t

F_t = Forecasting demand in period t

n = Number of forecasting periods involved

3) *MAPE*: MAPE is an evaluation calculation used to measure the accuracy of prediction [45-46-47]. It [48-49] was chosen as the performance metric and was employed to assess forecasting method accurately. Furthermore, MAPE is not influenced by the predicted time series magnitude [50-51]. Also, it is frequently used in practice [52], independent of scale, and easy to interpret, which makes it popular among industry practitioners [53-54]. MAPE measures the average of absolute errors as a percentage of the average absolute error rate of the actual data period. The mathematical expression is shown in Equation 8:

$$MAPE = \frac{(100)}{n} \sum_{t=1}^n \frac{|A_t - F_t|}{|A_t|} \quad (8)$$

Information:

A_t = Actual demand in period t

F_t = Forecasting demand in period t

n = Number of forecasting periods involved

MAPE measures the average of absolute errors as a percentage of the average value total error rate of the actual data period. Its criteria explain that the smaller the MAPE value, the better the accuracy. Table I shows the score criteria [55].

TABLE I. MAPE VALUE CRITERIA

MAPE value	Criteria
< 10	Very good
10 - 20	Well
20 - 50	Enough
>50	Bad

Productivity data processing of corn commodities is carried out using POM-QM software.

The subsequent stage involves describing and processing data on productivity of corn commodities. The POM-QM software application was employed to process corn commodity productivity data from 1980-2019. Several forecasting method in the POM-QM application were utilized, resulting in the generation of anticipated forecast outcomes.

To apply the POM-QM software in forecasting productivity of corn commodities, the steps to be followed include: (a) run the QM program and select the module-forecasting; (b) select the menu File-New-Time series Analysis and a dialogue box titled “Create data set for Forecasting/Time-series Analysis” will appear (c) in the dialog box, provide the title of the forecast, "Productivity of corn commodities," along with the number of time series data periods to be used as training data, starting from 1980-2019. Specify the name that will appear for each row period name, either using numbers, letters, or months. After completing the above steps, press the OK button. The data settings in QM for Windows are shown in Fig. 1.

Fig. 1. Data settings in QM for windows.

Forecasting is crucial for companies as it aids in managing productivity, inventory, and planning decisions [56]. According to [57], relying on a single forecasting model is insufficient. Several choices of forecasting models should be considered to arrive at the most accurate prediction. The forecasting results for productivity of corn from each method are then collected and analyzed for accuracy. Therefore, it is important to choose the appropriate forecasting method, as using an inappropriate one may reduce the forecast's accuracy.

III. RESULTS AND DISCUSSION

A. Forecasting Model of Corn Commodity Productivity with DMA

DMA is a forecasting method conducted by adding corn commodity productivity data in the two previous periods and dividing the sum by two. It can also be performed by calculating the average of corn commodity productivity data in the two previous periods. The results of moving average forecasting are shown in Table II.

TABLE II. CALCULATION OF THE DOUBLE MOVING AVERAGE FORECAST AT CORN COMMODITY PRODUCTIVITY

Measure	Value
Error Measures	
Bias (Mean Error)	.154
MAD (Mean Absolute Deviation)	.154
MSE (Mean Squared Error)	.037
Standard Error (denom=n-2=35)	.199
MAPE (Mean Absolute Percent Error)	4.913%
Forecast	
next period	5.28

Based on DMA applied to forecast corn commodity productivity, Table II presents the results of the bias or average error, which are 0.154. MAD is also 0.154, while MSE (Mean Squared Error) is 0.037. Fig. 2 shows the forecasting graph of productivity of corn commodities using this method.

Fig. 2. Forecasting graph with the double moving average method on productivity commodity corn.

Fig. 2 shows that the forecasting results for corn commodity productivity from DMA appear different from the actual data. This is because the standard error of this method is 0.199 deviations.

B. Forecasting Model for Productivity of Corn Commodity with WMA

WMA 2 is performed by assigning weight to corn commodity productivity data for the last two years. The forecasting of corn commodity productivity began in 1980-2019. The calculation process of this forecasting method is presented in Table III.

TABLE III. FORECASTING THE WEIGHTED MOVING AVERAGE ON PRODUCTIVITY COMMODITY CORN

Measure	Value
Error Measures	
Bias (Mean Error)	.205
MAD (Mean Absolute Deviation)	.205
MSE (Mean Squared Error)	.065
Standard Error (denom=n-2=35)	.261
MAPE (Mean Absolute Percent Error)	6.517%
Forecast	
next period	5.23

Based on WMA applied to forecast corn commodity productivity, Table III present the results of the bias or average error, which are are 0.205. MAD is also 0.205, while MSE is 0.65. Fig. 3 shows the forecasting Graph with WMA for productivity of corn commodities.

According to Fig. 3, the forecasting results for corn commodity productivity using WMA display a slight increase towards the end of the period in comparison to DMA. However, it should be noted that this increase is attributed to the standard error of 0.261 deviation, as evidenced by the actual data.

Fig. 3. Forecasting graph with the weighted moving average method at corn commodity productivity.

C. Forecasting Model of Corn Commodity Productivity with SES

To calculate the forecasting of corn commodity productivity using SES, the α coefficient is first determined. This is performed by multiplying α by the actual demand. Afterwards, the result is added with the outcome of 1 minus α multiplied by corn commodity productivity forecast in the previous period. The value of α is assumed to be 0.5 in this model. The forecasting process using SES is presented in Table IV.

TABLE IV. FORECASTING SINGLE EXPONENTIAL SMOOTHING AT CORN COMMODITY PRODUCTIVITY

Measure	Value
Error Measures	
Bias (Mean Error)	.2
MAD (Mean Absolute Deviation)	.2
MSE (Mean Squared Error)	.056
Standard Error (denom=n-2=36)	.244
MAPE (Mean Absolute Percent Error)	6.356%
Forecast	
next period	5.263

Table IV shows that from the results of forecasting productivity of corn commodities using SES, the bias or average error of this forecast are 0.2. MAD is also 0.2, while MSE is 0.056. Fig. 4 shows the forecasting Graph of SES.

Fig. 4 shows that the forecasting results for corn commodity productivity from WMA appears to be more stable than SES. This is because the standard error of this method is 0.244 deviations.

Fig. 4. Forecasting graph with the single exponential smoothing method on corn commodity productivity.

Table V presents the forecasted corn commodity productivity using method such as (a) DMA, (b) WMA, and (c) SES in the next (year). The data used in the analysis consist of 39 years productivity, spanning from 1980-2019.

TABLE V. THE VALUE OF THE SIZE OF THE ERROR IN THE FORECASTING MODEL FOR THE PRODUCTIVITY OF CORN COMMODITIES

Method	Value Measurement Error			
	MAD	MSE	SEE	MAPE
Double Moving Average	0.154	0.037	0.199	4.913%
Weighted Moving Average	0.205	0.065	0.261	6.517%
Singel Exponential Smoothing	0.2	0.056	0.244	6.356%

The analysis in Table V compares the error rates of the three different methods for forecasting corn productivity. Based on the results, DMA outperforms the other method with an MAPE value of 4.913%, which is very close to zero. Therefore, DMA is chosen for forecasting corn commodity productivity. The forecasting values for the upcoming period are presented in Table VI.

TABLE VI. VALUE OF CORN COMMODITY PRODUCTIVITY FORECASTING SIZE NEXT PERIOD

Method	Forecasting Next Period's Measurement Value
Double Moving Average	5.28
Weighted Moving Average	5.23
Singel Exponential Smoothing	5.263

Table VI indicates that the forecasted corn commodity productivity for the next period is 5.28 tons/ha/year. This implies that corn commodity production in Indonesia is expected to satisfy the entire consumer demand.

IV. CONCLUSIONS

Forecasting results of corn commodity productivity, using the following methods: (a) Double Moving Average, (b) Weighted Moving Average, and (c) Single Exponential Smoothing in the next (year), from 1980 – 2019: Forecasting model for corn commodity productivity The selected method, namely the Single Exponential Smoothing method, has a lower error rate than other forecasting models, the MAPE value is 4.913%. The forecasting model for corn commodity productivity is 5.28 ton/ha/year, meaning that corn commodity productivity in Indonesia is expected to meet all consumer demands for corn commodities. The results of this study are expected to assist the government in predicting the amount of corn commodity productivity in the next period by national corn needs.

Abstract—In today's digital environment, recommendation systems are essential as they provide personalised content to users, increasing user engagement and enhancing user satisfaction. This paper proposes a double ensemble recommendation model that combines two collaborative filtering algorithms, K Nearest Neighbour (KNN) and Matrix Factorization (MF). KNN is a neighbourhood-based algorithm that uses the similarity between users or items to make recommendations. At the same time, MF is a model-based algorithm that decomposes the user-item rating matrix into lower-dimensional matrices representing the latent user and item factors. The proposed double ensemble model uses KNN and MF to predict missing ratings matrix and combines their predictions using stacking. To evaluate the performance of the proposed ensemble model, we conducted experiments on three datasets i.e. Movielense, BookCrossing dataset and Hindi Movie dataset and compared the results with those of single algorithm approaches. The experimental results demonstrate that the double ensemble model outperforms the single algorithm approaches regarding accuracy metrics such as Mean Square Error (MSE), Root Mean Squared Error (RMSE), Mean Absolute Error (MAE). The results indicate that stacked KNN and MF lead to a more robust and more accurate recommendation system.

Keywords—Recommendation system; k nearest neighbour; matrix factorization; predictions using stacking; ensemble model

I. INTRODUCTION

A recommendation system is essential in everyone's life since it allows people to choose from all available possibilities. A recommendation system is an integral component of machine learning algorithms that provides meaningful recommendations to users. There are two popular types of recommendation systems:

- Content-based.
- Collaborative Filtering.

Content-based recommendations are insufficient since they evaluate the user's history when making suggestions. A collaborative filtering strategy is being utilised to address such issues, in which it seeks comparable groups of users to make judgments. The content based recommendation system is a supervised machine learning technique, which is used to induce a classifier to discriminate between interesting and uninteresting items for the customer.

Filtering is estimating a consumer's interest by recognising predilections and information from a huge number of users. This is done by using strategies that need cooperation between

several data sources, agents, etc., for data filtering to fetch information or patterns. According to the central tenet of collaborative Filtering, two clients, X and Y, may have similar choices in one product if they have a similar option in other products.

Examples of collaborative filtering algorithms:

- YouTube content suggestion to users — It proposes videos to you based on other users who have followed or viewed similar videos as you.
- Coursera course recommendation — It proposes courses based on the completion of existing courses by others.

The collaborative filtering focus on past experience, past knowledge and user behaviour. The collaborative filtering recommends items based on similarity measures between users and items. The basic purpose of such approach is to identify users with similar interests or common preferences about any product or item. The collaborative filtering approach's main advantage is its extensive coverage. The objective of any recommendation system is to make user-relevant product recommendations. Understanding item content is not always necessary; for instance, a movie's genre does not always contain the complete story. No cold-start issue allows us to predict item ratings without prior information about that item and without waiting for a user to purchase. It displays how user preferences have changed over time. Latent factor models, which capture minor intrinsic qualities if most customers buy two unrelated, are particularly susceptible to Filtering.

The main weakness of this strategy is that it is unfriendly for suggesting new things because there is no item interaction with it. Memory-based approaches are infamous for having poor performance on highly sparse datasets.

The cold-start problem is caused by collaborative filtering systems' reliance on the utilisation of publicly available data from similar users. If you were creating a brand-new recommendation system, you wouldn't have any helpful information. Scalability problems of the algorithm arise as the number of users increases. We would have to build a sparse matrix with tons of elements if we had millions of clients and many thousands of films.

Lack of reliable; Input data may not always be accurate because human rating performance is not always dependable.

Ratings are not as crucial as user participation. Item-based suggestions provide a superior answer in this case.

In this paper, we have presented a double ensemble model for recommendation using KNN and MF. Overall, the proposed double ensemble recommendation model provides a promising approach for improving the accuracy of recommendation systems by combining different algorithms. This model can be applied to various domains, including e-commerce, social networks, and multimedia.

The organisation of this paper is as follows :

Section II throws light on work already being done in the field. Section III represents the proposed work. The experiment setup and result is discussed in Section IV. Section V concludes with future directions.

II. RELATED WORK

Lots of work has been done in the last decade in the field of recommendation systems. We have considered the recent work of the previous 5-6 years.

Wu et al. present a novel deep learning-based collaborative filtering (CF) approach that utilises a marginalised denoising auto-encoder (MDAE) to capture high-order interactions among users and items. They have experimented on three real-world datasets to demonstrate that the proposed method outperforms several state-of-the-art CF methods[1].

A novel CF approach based on Recurrent Neural Networks (RNNs) is presented by Hidasi et al., which can model sequential user behaviour. The proposed method outperforms traditional CF methods on two benchmark datasets and also shows promising results on a real-world dataset[2].

Tan and Wang proposed a new factorisation machine-based CF approach that utilises funnel-structured embeddings to capture both the sequential and holistic user behaviour information for the session-based recommendation. Experimental results on three real-world datasets show that the proposed method outperforms several state-of-the-art approaches[3].

Kaur and Singh presented a comprehensive survey of neighbourhood-based CF methods, which are the most commonly used CF methods in practice. The paper provides a detailed overview of the existing methods, their variants, and their strengths and weaknesses[4].

A novel CF approach is presented by Zhou et al. for implicit feedback datasets that utilise adaptive regularisation to handle the sparsity and noise of the data. Experimental results on three real-world datasets demonstrate the superiority of their method.[5].

Yuan et al. propose a novel CF approach incorporating temporal dynamics into the recommendation process. The proposed method uses a recurrent neural network (RNN) to model the temporal patterns of user-item interactions and achieves better performance on two datasets[6].

A deep Bayesian CF approach is presented by Wang et al. that can handle cross-domain recommendations. The proposed method uses a hierarchical Bayesian model to capture the

relationships between different domains and performs better than several other CF methods on different datasets [7].

Wang et al. propose a deep learning-based clustering method to improve the performance of CF. The proposed method utilises a neural network to learn user and item representations and then performs clustering on these representations to group similar users and items. Experimental results on two datasets show that the proposed method leads to better results than others [8].

Ma et al. presented a joint embedding method for CF that uses orthogonal regularisation to improve the quality of user and item representations. The proposed method achieves state-of-the-art performance on two benchmark datasets[9].

Jia et al. proposed a hybrid CF model that combines reinforcement learning with traditional CF methods to improve personalised recommendations. Experimental results on a real-world dataset show that the proposed method outperforms several state-of-the-art CF methods[10].

In this paper, Chen et al. propose a user modelling method for recurrent neural network (RNN) based CF, which uses a hierarchical attention network to capture the user preferences and generates personalised user representations for better recommendation accuracy[11].

Hu et al. presented an Attentional factorisation machine-based CF approach for a session-based recommendation. The proposed method uses attention mechanisms to capture the importance of different items in a session and performs better on two considered datasets[12].

Li et al. presented a multi-relational graph convolutional network-based CF approach for a cross-domain recommendation. The proposed method uses graph convolutional networks to learn user and item representations across multiple domains and achieves better performance than several state-of-the-art CF methods on a real-world dataset[13].

Li et al. presented a neural collaborative filtering (NCF) approach using long-term and short-term user representations to capture user preferences. The proposed method achieves better accuracy when tested with two datasets[14].

Wu et al. provide a comprehensive survey of the literature on bias and fairness in recommendation systems in this paper. It discusses the various types of bias in such systems, the methods used to detect and mitigate bias, and the ethical and legal considerations associated with fair recommendation [15].

Zhang et al. proposed a graph neural network-based recommendation algorithm that uses graph convolutional networks to model user-item interactions. The authors evaluated their approach on several benchmark datasets and showed that it outperforms several state-of-the-art recommendation algorithms[16].

Ricci et al. wrote a recommender system handbook covering various aspects of recommendation, including algorithms, evaluation, and applications[17].

We can conclude that ensemble models can improve the performance of recommendation systems. KNN and MF approach combining can perform better.

III. PROPOSED METHOD

This study developed a CF technique based on KNN and SVD. Generally, SVD provides a more accurate prediction compared with KNN. KNN method is based on k nearest neighbour users or items followed by top K users, and items are chosen. The accuracy depends on the source of the data and the target objective. Usually, KNN is better in data sets with low missing data proportions. SVD is better in massive-size data sets.

This research attempted to go beyond traditional ensemble learning by investigating multi-level ensemble learning concerning recommender systems. We concentrated on stacking generalisation when developing the Recommender System. We tried to examine the impact of the shift from single-level to multi-level ensemble learning on overall accuracy. We used the three datasets and three ensemble approaches based on Collaborative Filtering to evaluate accuracy. The results reveal that 2-level stacking outperforms single-level stacking and any individual recommender system.

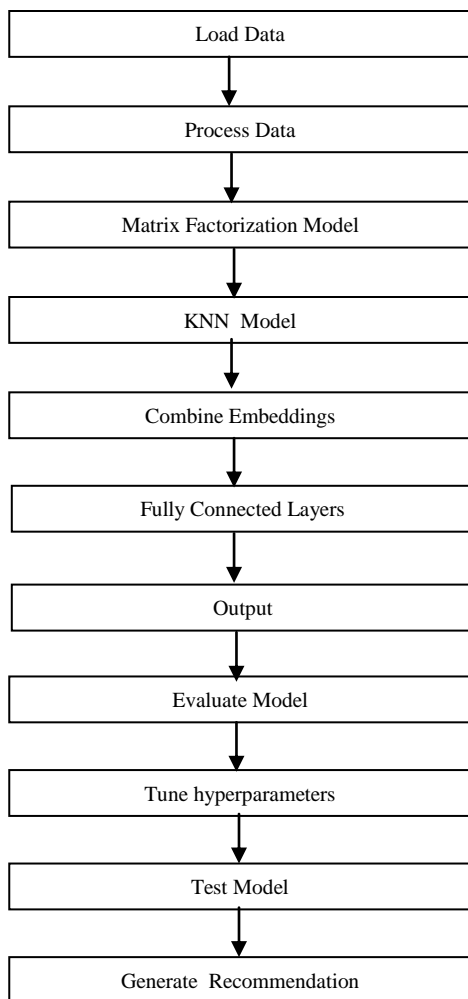

Fig. 1. Flow chart of the proposed work.

This proposed work uses KNN and Matrix Factorization (MF) as reference models. We have first implemented KNN and computed the results for various configurations like change in K etc. After taking multiple configurations, we have performed self ensemble model of KNN. We call it self-ensemble because we have considered the single base model and ensemble its variations for better performance. After this, we considered the Matrix factorisation model and computed the results on its variations like SVD. Similar to the previous one here, we also perform self-ensemble for MF. Now finally, we have proposed the double ensemble hybrid model. Hybrid as it uses both KNN and MF. We are here stacking both these models, so we named it Double ensemble. The proposed model is applied to three popular datasets. Experiment results show the proposed model's superiority.

Bagging, Boosting, Stacking, and other models are included in ensemble learning. Stacking will be the primary topic of this article. However, the recommendations mentioned above suggest a particular aspect and do not recognise the recommendation of specific movies submitted by individual users, causing the recommended material to stray from users' needs and impacting the user experience. Compared to the traditional CF-based algorithms on KNN and MF, the proposed method can realise the recommendation of specific movie input by particular users, make more personalised recommendations, and deal with the issue of cold start and sparse matrix processing to some extent.

We must train a broad set of learners to create an effective ensemble model. We used Collaborative filtering models such as KNN and MF in our scenario. Each student uniquely manipulates the dataset and makes errors based on their personal biases. We trained these models on a subset of the dataset and assessed their accuracy and diversity on the remainder. Initially, we divided the total dataset 80:20 into training and test datasets. The individual learners were then trained on the training dataset, and predictions were generated on the test dataset. We calculated accuracy using the MSE, RMSE and MAE value and diversity using the Pearson correlation coefficient. We have implemented 3 Algorithms and evaluated all three algorithms on 3 Datasets, explained in detail in the next section.

This work integrates the approaches mentioned earlier and presents three ensemble recommendation algorithms:

- 1) Ensemble K-Nearest Neighbors (E-KNN).
- 2) Ensemble Matrix Factorization(E-MF).
- 3) Stacked Nearest Neighbors- Matrix Factorization (S-KNNMF).

Algorithm 1: E-KNN (Ensemble K Nearest Neighbour Algorithm)

We have implemented the vanilla KNN algorithm and then taken its three variants by varying the parameters like K and distance. After that, through stacking, we made self ensemble model of KNN. The flowchart of the proposed work is given in Fig. 1. The steps are as follows:

Step 1: Input Datasets

The input of this algorithm is recommendation datasets. We have considered three datasets. The three datasets are taken to check the coverage and better performance check.

Step 2: Determine Similarity Using the Distance Function.

We have to take distance as a Euclidean distance, and another is Manhattan distance. There are different distance functions, but Euclidean is the most often used. It is most commonly utilised when the data is continuous. For continuous variables, the Manhattan distance is also quite popular.

Euclidean distance =

$$d(x, y) = \sqrt{\sum_{i=1}^m (x_i - y_i)^2 \dots \dots \dots i}$$

Manhattan distance =

$$d(x, y) = \sum_{i=1}^m |x_i - y_i| \dots \dots \dots ii$$

Step 3: Determining the Best K value.

The lower value of K is sensitive to outliers; at the same time, a higher K-value is more immune to outliers since it considers more votes when projecting. Cross-validation is an effective method for determining the best K value. It calculates the validation error rate by excluding a subset of the training data from the model construction process. Cross-validation (say, 10-fold validation) entails randomly splitting the training set into ten groups, or folds, of about similar size. 90% of the data is utilised for training the model, with the remaining 10% used to validate it. Based on the 10% validation data, the misclassification rate is calculated. This method is repeated ten times. Every ten times, a different collection of observations is handled as a validation set. It yields ten validation error estimates, which are then averaged out.

Step 4: Ensemble of the KNN Model

For the ensemble, we have used the stacking method. The primary distinction between voting and stacking is how the final aggregate is accomplished. In voting, user-specified weights aggregate the classifiers, whereas stacking uses a blender/meta classifier to do this aggregation. As we have used the self-ensemble model, we have used stacking for the ensemble.

Step 5: Assessing the Model Performance.

We have evaluated model performance on the error terms MSE, RMSE, and MAE.

Step 6: Final Output is Prediction

Finally, we would want to make predictions using the proposed model. We have considered the three variants of KNN and ensemble them using the stacking method. We have

applied three different datasets to evaluate the performance of this model.

Fig. 2 represents the block diagram showing the ensemble of KNN using the stacking approach.

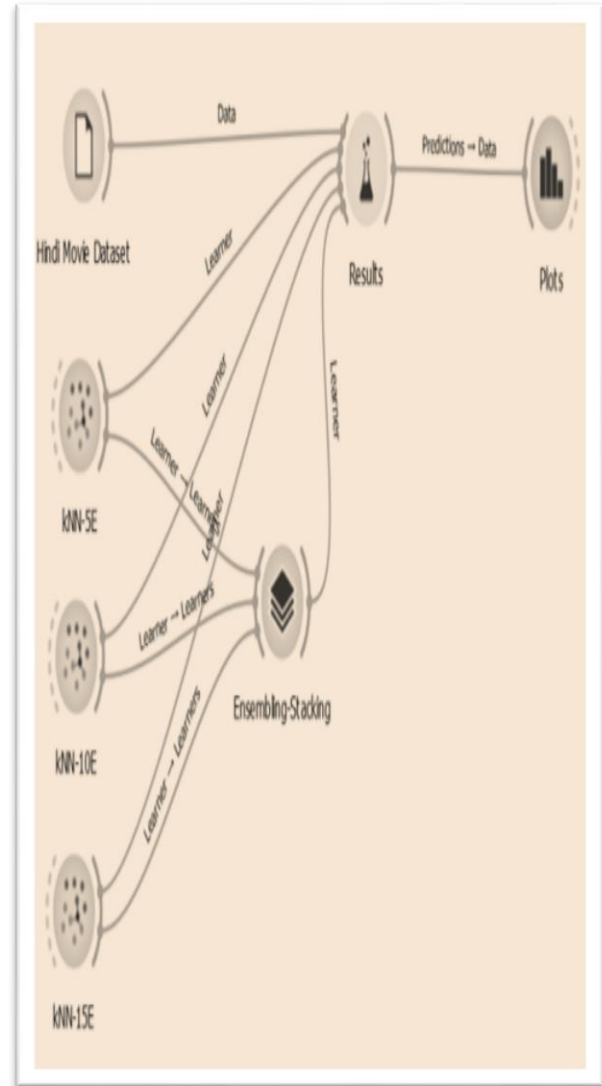

Fig. 2. E-KNN model on hindi movie dataset.

Algorithm 2: E-MF(Ensemble Matrix Factorization Algorithm)

We have implemented the Various Matrix algorithms. We have considered the three variants of matrix factorisation NMF, SVD and SVD++. After that, we made a self-ensemble model of MF through stacking.

E-MF algorithm for a stacking ensemble model that combines NMF, SVD, and SVD++ models for recommendation:

Step 1 Split the user-item rating matrix into training and validation sets.

Step 2 Train an NMF model on the training set using gradient descent to minimise the reconstruction

error between the actual ratings and the low-rank approximation of the matrix.

- Step 3** Train an SVD model on the training set using gradient descent to minimise the MSE between the actual ratings and the predictions of the model.
- Step 4** Train an SVD++ model on the training set using gradient descent to minimise the MSE between the actual ratings and the predictions of the model.
- Step 5** Use the NMF, SVD, and SVD++ models to generate predictions for the validation set.
- Step 6** Combine the predictions of all models using stacking ensemble method.
- Step 7** Calculate the MSE between the actual ratings and the combined predictions for the validation set.
- Step 8** Choose the best ensemble model based on the validation MSE.
- Step 9** Use the chosen ensemble model to generate predictions for new users or items.

Fig. 3. Block diagram of E-MF model.

Algorithm 3: Proposed Double Ensemble Algorithm Based on KNN and MF

We have taken KNN and MF as reference models in this proposed work. Firstly we have implemented KNN and computed the results for various configurations like change in K etc. After taking multiple configurations, we have performed self ensemble model of KNN. We call it self-ensemble because we have considered the single base model and ensemble its variations for better performance.

After this, we considered the Matrix factorisation model and computed the results on its variations like SVD and SVD++. Similar to the previous one here, we also perform self-ensemble for MF. Now finally, we have proposed the double ensemble hybrid model. Hybrid as it uses both KNN and MF. We are here stacking both these models, so we named it Double ensemble.

The KNN-MF-based double ensemble recommendation system is a double ensemble MF algorithm variation that combines matrix factorisation with KNN for better recommendation accuracy. Here are the steps of the algorithm:

Input:

- User-item interaction matrix (R), where each element r_{ij} represents the rating or preference of user i for item j .
- Number of factors (k) to use for matrix factorisation.
- Number of matrix factorisation algorithms to use (m).
- Number of ensemble methods to use (n).
- Number of neighbors (K) to use for KNN.

Output:

A set of recommendations for each user.

Steps:

1. Split the data into training and test sets.
2. For each matrix factorization algorithm ($i = 1$ to m):
 - a. Apply matrix factorisation to the training data using algorithm i to generate a set of recommendations (R_i).
 - b. Compute the prediction error of R_i on the test set using a suitable evaluation metric (e.g., RMSE, MAE).
3. For each ensemble method ($j = 1$ to n):
 - a. Combine the recommendations from all matrix factorisation algorithms using ensemble method j to generate a set of ensemble recommendations (R_j).
 - b. Compute the prediction error of R_j on the test set using the same evaluation metric as step 2.
4. Choose the combination of the matrix factorisation algorithm and ensemble method that produces the lowest prediction error on the test set.
5. For each user:
 - a. Compute the K nearest neighbours based on the user's rating history using a suitable similarity measure (e.g., cosine similarity, Pearson correlation).
 - b. For each item not yet rated by the user, predict a rating using a weighted average of the ratings of the K nearest neighbours.

- c. Combine the KNN predictions with the predictions from the chosen combination of matrix factorisation algorithm and ensemble method using stacking.
- d. Use the final set of combined predictions as the recommendations for each user.

Matrix factorisation, ensemble methods, and evaluation metrics are the same as described in the Double Ensemble Matrix Factorization algorithm. The KNN component adds a neighbourhood-based approach to the recommendation process, which can capture local and non-linear patterns in the data and improve the accuracy of recommendations, especially for cold-start users.

Fig. 3 shows the block diagram of our proposed S-KNNMF algorithm.

The proposed model performs better than the other two considered ensemble models.

IV. EXPERIMENTAL SETUP

The experiment was conducted on a 64-bit Windows 8 machine with 8 GB RAM and an Intel Core i5-4200M processor with a 2.50 GHz clock speed. Algorithms were implemented in python using Anaconda. For visualisation, various tools are used that are part of the Anaconda. In a few cases, Google-Colab is also used for running our models.

A. Datasets

We have used three datasets to test our proposed algorithms' performance in this work. The reason for taking multiple datasets is that it will cover all possible dependencies of the dataset's nature, like biased, sparsity, etc. They are as follows:

- 1) Hindi Movie.
- 2) Book Cross.
- 3) Movielens.

B. Results

We have taken three datasets for comparative analysis. We have evaluated the performance of our proposed model based on the error scores, namely MSE, RMSE and MAE. We have compared all three models, i.e. ensemble KNN, ensemble matrix factorisation, and stacked KNN-MF model. Table I represents the evaluation result on Hindi Movie datasets.

The table shows that our proposed method gives better results than the other two ensemble models. Fig. 4 graphically represents the comparative analysis of all three considered models.

Table II represents the evaluation result of the Book-Crossing Dataset. It also shows our proposed algorithm's superiority over other considered algorithms.

TABLE I. COMPARATIVE ANALYSIS OF THE HINDI MOVIE DATASET

Model	MSE	RMSE	MAE
E-KNN	0.900161946	0.948769	0.719056
E-MF	0.827225923	0.90952	0.700481
S-KNNMF	0.65895524	0.811761	0.624495

Fig. 4. Comparative graph for hindi movie dataset.

TABLE II. COMPARATIVE ANALYSIS OF THE BOOK-CROSSING DATASET

Model	MSE	RMSE	MAE
E-KNN	0.859679	0.927189	0.70268
E-MF	0.829634	0.910843	0.696308
S-KNNMF	0.789674	0.888636	0.681319

Table II shows our proposed method's superiority over the other two ensemble models. Fig. 4 graphically represents the comparative analysis of all three considered models for better representation.

Fig. 5. Comparative graph for book-crossing dataset.

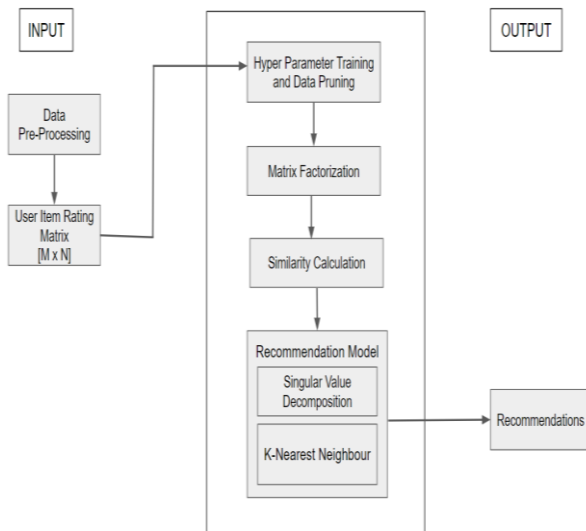

Fig. 6. Block diagram of an ensemble model.

Fig. 5 graphically represents the comparative analysis of all three approaches using Bookcrossing dataset. The Movielens dataset is very popular for performance analysis of recommendation systems. We have also used it for the evaluation of our proposed model. Fig. 6 is representing a block diagram of KNN and MF approaches. Table III represents the evaluation results of all considered algorithms on the Movielens dataset.

TABLE III. COMPARATIVE ANALYSIS FOR MOVIE-LENS DATASET

Model	MSE	RMSE	MAE
E-KNN	0.729304	0.853993	0.652247
E-MF	0.719795	0.848408	0.648123
S-KNNMF	0.658955	0.811761	0.624495

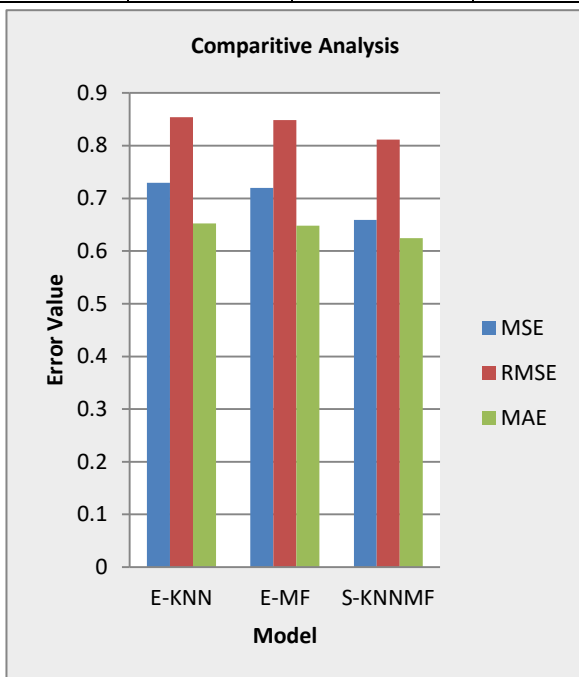

Fig. 7. Comparative graph for movielens dataset.

Table III supports our proposed method’s superiority over the other two ensemble models. Fig. 7 is representing the ensemble model of KNN and MF approaches for better representation of recommendation.

It is clear from Tables I to III that the Ensemble model performs better than the normal models. Double ensemble further improves the performance of the model. Our proposed model gives a minimum error value when evaluated based on MSE, RMSE, and MAE.

V. CONCLUSION AND FUTURE DIRECTION

Double ensemble recommendation models that combine collaborative filtering methods like K-Nearest Neighbors (KNN) and matrix factorisation (MF) can offer improved accuracy and diversity in the recommended items.

KNN is a user-based collaborative filtering technique that recommends items based on user similarity. It suffers from the sparsity problem and is less effective for cold start problems. Conversely, MF is a matrix-based technique that learns latent factors for users and items and can address the sparsity problem. However, it may struggle with long-tail recommendations.

Combining KNN and MF can address the limitations of both techniques, leading to better performance. By leveraging the strengths of both models, the double ensemble approach can generate more diverse and accurate recommendations, especially for cold-start scenarios and long-tail items.

Overall the double ensemble approach of KNN and MF is a promising solution for improving the accuracy and diversity of recommendation systems. In the future, NN-based algorithms are also combined to get better performance. Other ensemble methods can also be applied.

CONFLICTS OF INTEREST

The authors declare no conflict of interest.

Integrating Regression Models and Climatological Data for Improved Precipitation Forecast in Southern India

J. Subha¹, S. Saudia²

Centre for Information Technology and Engineering, Manonmaniam Sundaranar University, Tirunelveli-12,
Tamil Nadu, India^{1, 2}

Abstract—Modern technologies like Artificial Intelligence (AI) and Machine Learning (ML) replicate intelligent human behavior and offer solutions in all domains, especially for human protection and disaster management. Nowadays, in both rural and urban areas, flood control is a serious issue to overcome the vast disaster to life and property. The work proposes to identify an appropriate ML based precipitation forecast model for the flood-prone southern states of India namely Tamil Nadu, Karnataka, and Kerala which receive most precipitation using the climatological information obtained from the NASA POWER platform. The work investigates the effectiveness of ML forecasting models: Multiple Linear Regression (MLR), Support Vector Regression (SVR), Decision Tree Regression (DTR), Random Forest Regression (RFR) and Ensemble (E) learning approaches of E-MLR-SVR, E-MLR-DTR, E-MLR-RFR, E-SVR-DTR, E-SVR-RFR, E-DTR-RFR, E-MLR-SVR-DTR, E-MLR-SVR-RFR, E-MLR-DTR-RFR and E-SVR-DTR-RFR in forecasting precipitation. The E-MLR-RFR model produces improved and most precise precipitation forecast in terms of Mean Absolute Error (MAE), Mean Square Error (MSE), Root Mean Square Error (RMSE) and R^2 values. A higher precipitation forecast can be used to provide early warning about the possible flood in any region.

Keywords—Ensemble models; machine learning models; rainfall precipitation forecast; R-squared value

I. INTRODUCTION

Flood control is an important matter of concern to confront casualties and rehabilitation [1]-[2]. Even though many advanced techniques have been utilized to control flood, concerned authorities still struggle to safeguard citizens and to quickly update estimates of the damage caused by floods. The incidents which happened in Chennai, Kerala, Assam and Bangalore due to continuous heavy rainfall during the monsoon season [3]-[7] show that protecting all lives and physical resources is a critical matter. In India, monsoon rainfall accounts for 80% of annual precipitation [8]-[9]. Floods which occurred in Kerala in the years 2018, 2019 and 2020 led to death of around 483, 121 and 104 people respectively and immersion of many villages [10]-[11]. The majority of people were then stranded in their houses without access to enough food and water.

Also, such flood hazards have affected most other countries like Bangladesh, Nepal, Pakistan, Afghanistan, Saudi Arabia and Iran [43]-[44]. Among the notable causes of

flood, sudden and enduring heavy rain is the most important cause in all countries [12]. Forecast models published in [13]-[16], [19] are helpful to safeguard citizens, manage floods, operating reservoirs at critical situations by predicting floods and disseminating flood alerts. Hitherto, most flood forecasting systems relied either on monitored data or those retrieved from satellites [17]-[18], [20]-[21]. In [21]-[22], precipitation forecast is performed by interpreting such dynamically changing atmospheric data such as temperature, rainfall, humidity and wind direction. Predicting rainfall/precipitation from this large volume of unstructured weather data [22] is not a facile task. So, the work proposes to identify suitable climatological data pre-processing stages and ML models for an automated warning of flood to the public and authorities based on a precipitation forecast. ML models are producing remarkable solutions in the domain of weather forecast and disaster management [45]-[48].

So, the paper proposes a study to identify stand-alone and ensemble Machine Learning models, MLR, SVR, DTR, RFR, E-MLR-SVR, E-MLR-DTR, E-MLR-RFR, E-SVR-DTR, E-SVR-RFR, E-DTR-RFR, E-MLR-SVR-DTR, E-MLR-SVR-RFR, E-MLR-DTR-RFR and E-SVR-DTR-RFR towards flood prediction via heavy precipitation forecast for the flood-prone south Indian states like Tamil Nadu, Karnataka and Kerala. These states which receive most heavy rainfall have been prone to major floods [8]-[9], [11]. This proposed work focuses on identifying a precipitation forecasting system for the states by integrating climatological data in the ML framework. The climatological data of the highest precipitation receiving geo-spatial locations of those states are captured from the NASA POWER platform [30]. The work also analyses the results of ML based flood/precipitation forecasting models in literature prior to the selection of stand-alone ML models MLR, SVR, DTR, RFR and ensemble ML models, E-MLR-SVR, E-MLR-DTR, E-MLR-RFR, E-SVR-DTR, E-SVR-RFR, E-DTR-RFR, E-MLR-SVR-DTR, E-MLR-SVR-RFR, E-MLR-DTR-RFR and E-SVR-DTR-RFR to work with the climatological data for precipitation forecast. It also attempts the effectiveness of pairwise correlation for feature selection before selecting the independent features for training the ML models. The ensemble model, E-MLR-RFR produces the improved and highest R^2 -value to precipitation forecast.

This paper is organized in five sections. Section II outlines the literature in terms of related climatological datasets,

models and results predicted. Section III elaborates the data pre-processing, feature selection stages and the ML algorithms used for precipitation forecast. Section IV presents the results and discussion upon results and Section V concludes the paper.

II. RELATED WORKS

ML based papers, studies published by researchers to increase the accuracy of precipitation/ flood forecast are discussed in this section. Barrera-Animas, A.Y., et al. [23] presented a comparison of rainfall forecast models based on ML and Deep Learning (DL) architectures, Long-Short Term Memory (LSTM), Stacked-LSTM, Bidirectional-LSTM Networks, Extreme Gradient Boost (XGBoost), an ensemble of Gradient Boosting Regressor, Linear Support Vector Regression, and an Extra-trees Regressor to project hourly rainfall volumes using time-series data from five major cities of the United Kingdom (UK). The performance of the models is assessed using the assessment metrics, Root Mean Squared Error, Mean Absolute Error, and Root Mean Squared Logarithmic Error to identify the bidirectional-LSTM Network as a best rainfall forecast model out of all the models examined. Aftab, S., et al [24] used data mining approaches by identifying hidden patterns within the available elements of historical weather data to estimate the amount of rainfall. Velasco, L. C., et al. [25] forecasted the rainfall of Iligan city in Southern Philippines using Support Vector Regression Machine (SVRM) based on a 4-year and 17-month rainfall dataset collected using an Automated Rain Gauge (ARG). The forecasting model demonstrated a Mean Square Error (MSE) of 3.46. Khan, T. A., et al. (2019) [26] made classifier and regression models for the investigation of flash floods based on data gathered from the Kund Malir seashore by sensors. For forecasting, the dataset was subjected to Logistic Regression, Quadratic Support Vector Machine, K-Nearest Neighbors (K-NN), Exponential Gaussian Process Regression (GPR) and Ensemble Bagged Tree. The GPR outperformed all other methods with a minimal RMSE of 0.0002 and a prediction speed of 35000 observations per second. Abdullah, A. S., et.al. (2021) [28] used Seasonal Autoregressive Integrated Moving Average (SARIMA) and SVM for rainfall/precipitation forecast in Bogor City, Indonesia. The SVM delivered an accurate result with a minimal Mean Absolute Percentage Error (MAPE) for predicting rainfall. Sreehari, E., et. al. (2018) [29] used MLR to forecast the amount of rainfall using the dataset from the Nellore district of Andhra Pradesh, India. The MLR approach produced more accurate findings for the amount of rainfall than Simple Linear Regression (SLR). De Castro, J.T., et al. (2013) [31] developed a technique for a flash flood warning system using Short Message Service (SMS) with improved warning information based on rising water level and water velocity. The regression equation was created based on velocity and water level data that was collected over a seven-day period since they were thought to be flash-flood causes. In order to provide registered users with an early warning, the system computes the present and future risk of flooding based on the model. Rezaeianzadeh, M., et al. (2014) [32] did flood flow forecasting at the outlet of the Khosrow Shirin watershed in the Fars Province of Iran using Artificial Neural Networks

(ANN), Adaptive Neuro-Fuzzy Inference Systems (ANFIS), MLR, and Multiple Nonlinear Regression (MNLR). The MNLR models outperformed the ANN, ANFIS, and MLR models with smaller RMSE values. Saha, A., et al. (2021) [33] assessed the performance of flood susceptibility (FS) mapping predictions in the Koiya River basin in Eastern India. Eight flood conditioning variables based on the topography and hydro-climatological conditions were used to create a flood inventory map using the novel ensemble approach of Hyperpipes (HP) [47] and Support Vector Regression (SVR). The ensemble technique produced a higher accuracy of 0.915. The summary of the related works in terms of ML models, precipitation and watershed datasets used and prediction results in terms of MAE/ MSE/ RMSE/ Accuracy is presented in Table I.

From Table I, it is clear that knowing and evaluating variations in rainfall is essential for forecasting flood calamities. So, this paper proposes to use climatological data gathered from the NASAPOWER dataset [30] for the years from 2001 to 2020 in identifying a better ML based model to forecast precipitation in various flood-prone geographic areas across the southern states of the country namely Tamil Nadu,

Karnataka and Kerala. The work also investigates the improvement in precipitation forecast via pairwise correlation in the feature selection stage of the ML workflow. An accurate forecast precipitation can be used to alarm associated flood and plan relevant precautionary measures.

III. PROPOSED SYSTEM

The focus of this paper includes (i) gathering climatological data from the platform <https://power.larc.nasa.gov/> [30] (ii) utilization of ML models in predicting the weather data-based day-wise and month-wise precipitation and (iii) evaluation of results. For the purpose of making an early flood warning from precipitation forecast in a southern region of India, the daily and monthly based climatological features are used in this work. Relevant climatological features are scaled using Standardization to the range from 0 to 1. Following this process, relevant independent features in the dataset are identified using pairwise correlation [52] and then subjected to ML regression models and ensemble models to forecast precipitation. Methodology of the work as illustrated in Fig. 1 is explained in upcoming sub-sections.

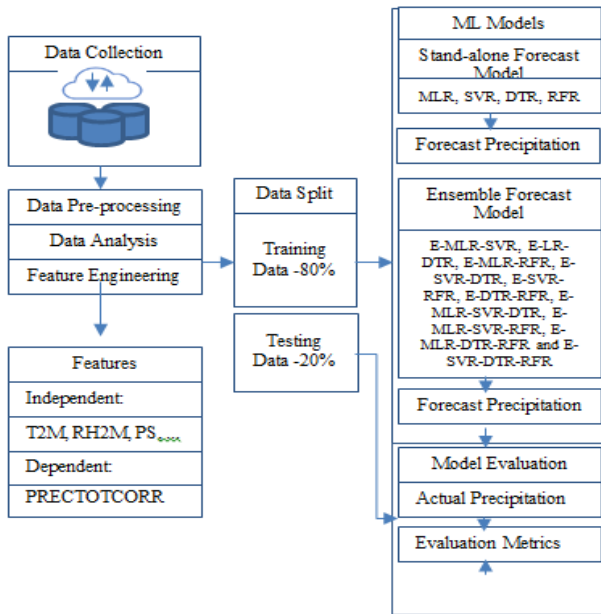

Fig. 1. Methodology of the proposed work.

A. Data Collection

The climatological data is acquired from the website, <https://power.larc.nasa.gov/> [30] to forecast precipitation using the ML functions in scikit learn package of Python. This site provides solar and meteorological data sets from satellite observations for renewable energy and agricultural needs. For user-selected grids, the solar and meteorological characteristics are offered in monthly and daily basis. This climatological dataset is gathered for the three distinct southern Indian states, Tamil Nadu, Karnataka and Kerala of India. The day-wise and month-wise precipitation data is collected for the years from 2001 to 2020 in this region in Comma Separated Values [CSV] file format. The dataset for

each region consists of 7305 records and 21 features. The details of the features in the dataset are mentioned in Table II.

TABLE II. ATTRIBUTES IN DATASETS

Features Name	Description	Units	Range
YEAR	Year	Integer	2001-2020
DOY	Month/ Day of Year	Integer	1-366
PS	Surface pressure	(kPa)	15.81-31.98
TS	Earth skin temperature	C	0.92-22.95
T2M	Temperature at 2 meters	C	14.68-34.80
QV2M	Specific humidity at 2 meters	(g/kg)	1.82-22.40
RH2M	Relative humidity at 2 meters	%	21.54-41.12
WD2M	Wind direction at 2 meters	(degrees) ⁰	8.83-25.23
WS2M	Wind speed at 2 meters	(m/s)	298.38-414.70
WD10M	Wind direction at 10 meters	(degrees) ⁰	4.15-18.92
WS10M	Wind speed at 10 meters	(m/s)	21.75-95.88
T2MDEW	Dew/Frost point at 2 meters	C	92.53-94.27
T2M_MAX	Temperature at 2 meters maximum	C	0.48-7.52
T2M_MIN	Temperature at 2 meters minimum	C	0.78-9.41
WS2M_MAX	Wind speed at 2 meters maximum	(m/s)	0.60-3.90
WS2M_MIN	Wind speed at 2 meters minimum	(m/s)	20.94-336.88
T2M_RANGE	Temperature at 2 meters range	C	0.74-10.76
WS10M_MAX	Wind speed at 10 meters maximum	m/s	1.2-13.03
WS10M_MIN	Wind speed at 10 meters minimum	m/s	0.02-9.22
ALLSKY_SFC_LW_DWN	All sky surface longwave downward Irradiance	(w/m ²)	21.62-336.19
PRECOTCORR	Precipitation corrected	(mm/day)	0-88.46

B. Data Pre-Processing

After data acquisition, data pre-processing is carried out to remove any null, empty or outlier data and to restore them with appropriate data for Machine Learning. Outliers are extreme data values which are out of observation ranges. The outliers/ missing values are rectified/ filled out to remove data irregularities and finally the entire data is transformed to the required format.

The climatological data obtained for the southern states, Tamil Nadu, Karnataka, and Kerala from [30] are devoid of missing values and outliers and so no pre-processing steps were necessary. The dataset is subjected to Data analysis and Feature Engineering to identify more relevant climatological features for training the different ML algorithms for forecasting rainfall. The later data analysis and feature engineering stages are detailed in the upcoming sub-sections.

C. Data Analysis

The climatological dataset used in the work is a high-resolution climatological data for a period of 20 years from 2001 to 2020. It is analyzed prior feature engineering using visualization tools of Python packages namely seaborn and matplotlib. The mean precipitation of Tamil Nadu, Karnataka, and Kerala over a period of time from 2016 to 2020 is shown in Fig. 2(a) to 2(c).

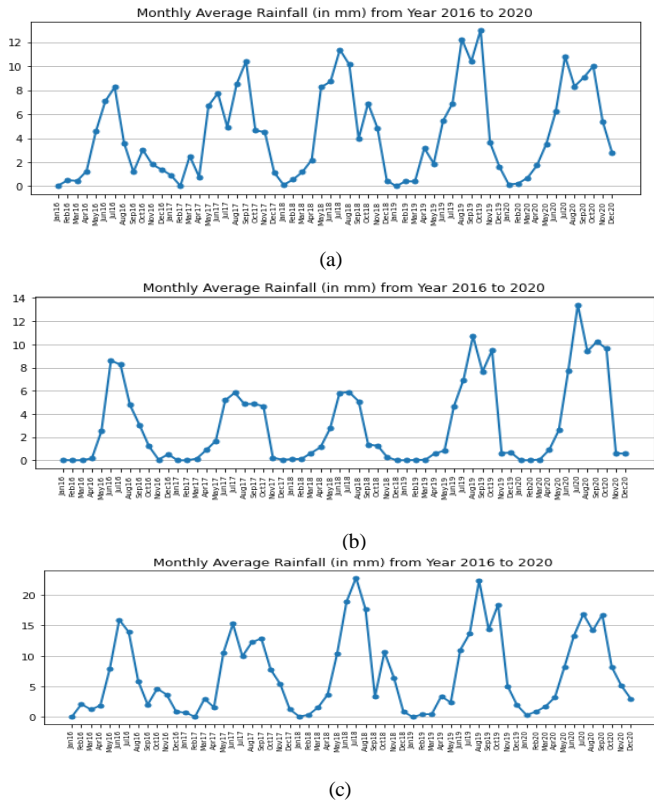

Fig. 2. Line plots showing average monthly precipitation from 2016 to 2020 (a) Tamil Nadu (b) Karnataka (c) Kerala.

The Fig. 2(a) clearly shows nine peak points from the climatological data of Tamil Nadu for the months July 2016, June 2017, September 2017, July 2018, October 2018, August 2019, October 2019, July 2020 and October 2020. Fig. 2(b) shows seven rainfall peak points of Karnataka which occurred in the months June 2016, July 2017 and 2018, August 2019, October 2019, July 2020 and September 2020.

Fig. 2(c) clearly shows ten peak precipitation points of Kerala in June and October of 2016, June and September of 2017, July and October of 2018, August and October of 2019 and July and September of 2020. Fig. 2(a) to (c) clearly indicate that there is maximum probability of precipitation and hence flood in monsoon season. Floods in these states have occurred during these high precipitation months [10], [66]-[67]. So, these months need special flood attention.

D. Feature Engineering

The goal of feature engineering in ML is to identify relevant independent features to make the models perform better. Scaling is one of the main goals of feature engineering which identifies the most pertinent quartiles of the data. In this work, the independent features in the respective ranges as shown in Table II are scaled using Standardization [49] to the range from 0 to 1. The scaling operation used to find the new independent feature value, x_{new} is shown mathematically in Eq. (1).

$$x_{new} = \frac{x - \mu}{\sigma} \quad (1)$$

where x is the independent feature, $\mu = \frac{1}{N} \sum_{i=1}^N (x_i)$ is the mean of the N values of the independent feature x_i and σ is the standard deviation represented mathematically as $\sqrt{\frac{1}{N} \sum_{i=1}^N (x_i - \mu)^2}$.

Correlation analysis helps to collect essential features from the dataset. First, the correlation coefficients between independent features are determined and recorded in a table called a correlation matrix. The correlation between two features is represented in each cell of the correlation table from -1 to 1. If the value is positive, then there is a normal correlation; while bigger positive values indicate a stronger correlation between features.

There is an inverse correlation when the matrix values are negative. Relationship between feature pairs in a dataset is determined using the `corr()` function in python as a heat map in Fig. 3. The correlation heat map for Tamil Nadu state is shown in Fig. 3. It clearly demonstrates correlations between independent features with same cell colour and value. The feature T2M is highly correlated with TS, T2M_MAX. Also, the feature T2M_DEW is highly correlated with TS, T2M_RANGE, T2M_MIN, QV2M, RH2M ALLSKY_SFC_LW_DWN etc.

The range of correlation from 1 to -1 is shown by the colour intensity variations from green to blue. An independent feature is chosen from each pairwise correlated group to be included in model design phase [52]. This helps to reduce the number of features in the dataset which in turn can improve the performance of ML modeling [49] - [53]. The effectiveness and interpretability of model can be increased by the new collection of uncorrelated features.

Following the feature selection stage, the dataset for Tamil Nadu state has the features: RH2M, PS, WS10M_MAX, ALLSKY_SFC_LW_DWN and WD10M. The feature engineered dataset with the relevant set of independent and dependent features as shown in Table III is subjected to the model building stage.

TABLE III. FEATURES OBTAINED FROM THE FEATURE ENGINEERING STAGE

State	Tamil Nadu	Karnataka	Kerala
Independent Features	RH2M, PS, WS10M_MIN, ALLSKY_SFC_LW_DWN, WD10M	RH2M, PS, WD2M, WS10M_MIN, WD10M	T2M_MIN, QV2M, RH2M, PS, WS10M_MAX, WS10M_MIN, WD10M

E. Model Building

This work proposes to identify the effectiveness of the standalone ML models: MLR, SVR, DTR, RFR and ensemble ML models: E-MLR-SVR, E-MLR-DTR, E-MLR-RFR, E-SVR-DTR, E-SVR-RFR, E-DTR-RFR, E-MLR-SVR-DTR, E-MLR-SVR-RFR, E-MLR-DTR-RFR and E-SVR-DTR-RFR in forecasting precipitation using the independent features obtained from the NASAPOW dataset for the flood-prone south Indian states of Tamil Nadu, Karnataka and Kerala. The dataset with features as in Table III is split into training and testing datasets in the ratio, 8:2 and the training dataset is subjected to the training phases of the above mentioned standalone and ensemble ML models [36]-[37]. In ensemble models, the final prediction is made by averaging the results of all the base models. General training phase of these ML and ensemble algorithms are briefed as follows:

1) Machine learning models: Machine Learning (ML) [38]-[41] is the science of creating regression/ classification models using algorithms that can draw knowledge from prior instances. The general data flow diagram of a ML based regression algorithm for forecasting rainfall is as shown in Fig. 4. Fig. 4 depicts the typical data flow diagram of the regression algorithm where the independent features from the dataset in Table III are subjected to the training phase of the ML algorithms, both stand-alone algorithms: MLR, SVR, DTR, RFR and ensemble algorithms: E-MLR-SVR, E-MLR-DTR, E-MLR-RFR, E-SVR-DTR, E-SVR-RFR, E-DTR-RFR, E-MLR-SVR-DTR, E-MLR-SVR-RFR, E-MLR-DTR-RFR and E-SVR-DTR-RFR to produce the model to forecast precipitation. The precipitation forecast is obtained from these models using the test data. The working of different ML and ensemble algorithms are briefed in sub-sections below.

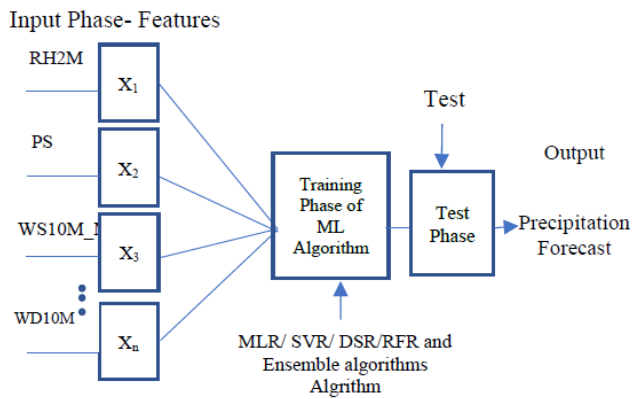

Fig. 4. General data flow diagram of regression algorithm.

2) *Multi linear regression*: Multiple Linear Regression [6], [41] determines the relation between dependent feature and many independent features to forecast the values of the continuous dependent feature. In MLR, the relationship between the independent features, x and dependent feature, y is modeled in the training phase as a linear equation shown in Eq. (2) by minimizing the sum of squares of error between the actual and predicted dependent feature values or residuals using Least Squares optimization [54]-[55].

$$y_{pi} = b_0 + b_1x_1 + b_2x_2 + \dots + b_nx_n \quad (2)$$

Here the indices $1,2,3, \dots, n$ correspond to the 'n' independent features, y_{pi} is the dependent feature, b_0 is the y-intercept, and b_1, b_2, \dots, b_n are the coefficients of the independent features x_1, x_2, \dots, x_n respectively. The illustration is shown in Fig. 5. In this work, MLR is trained using the training set Tamil Nadu, Karnataka and Kerala states and the model is used to forecast daily and monthly precipitation.

Fig. 5. General diagram for MLR [56].

3) *Support vector regression*: Support Vector Regression identifies a hyperplane in an n-dimensional space of the

independent features, x in the training dataset as a model to predict the values of the dependent feature, y_{pi} . The hyperplane model obtained after training as shown in Eq. (3) has the largest margin between the support vectors, ξ and ξ^* around a marginalized ' ϵ ' space. The ' ϵ ' space is $+\epsilon$ and $-\epsilon$ from the hyperplane.

$$y_{pi} = f(x) = bx + c = \sum_{i=1}^N (\alpha_i - \alpha_i^*) . K(x_i, x) + c \quad (3)$$

Here b is the weight vector corresponding to the independent feature x in terms of the Lagrange multipliers α_i, α_i^* and c is the bias term which are obtained in the training phase by minimizing the objective function, $\frac{1}{2} ||b||^2 + C \sum_{i=1}^N (\xi_i + \xi_i^*)$ using quadratic optimization [57]-[59]. K is the Kernel function which transforms x to higher dimension and C is the penalty parameter of the model and N is the size of the training dataset. The illustration of the parameters are shown in Fig. 6. In this work, the SVR model is used for predicting continuous values of precipitation for Tamil Nadu, Karnataka and Kerala on a daily and monthly basis.

Fig. 6. General diagram for SVR [59].

4) *Decision tree regression*: Regression issues can be solved using the Decision Tree Regressor (DTR) as shown in Fig. 7 [60], [63]. Starting with the root node with all the records in the training dataset, a decision tree is built. The tree divides into left and right child nodes based on a condition check on an independent feature values with least Mean Square Error to contain subsets of the training dataset. Mean Square Error is the difference between the predicted values of the dependent feature and its original target value.

The child nodes are further subdivided into their children nodes and thus become the parent nodes of next level. Each branch denotes the outcome of a test and each leaf node denotes the final outcome. The set of all conditions until different leaf nodes corresponds to the regression model. The predicted output is obtained as the average of the dependent feature values of all records in the leaf node. DTR model trained using the training set from Tamil Nadu state to forecast daily precipitation is shown in Fig. 7.

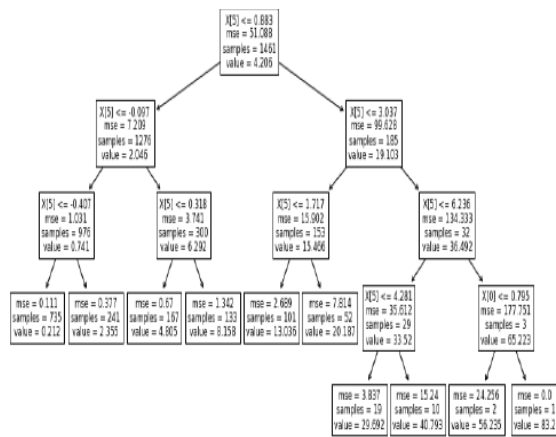

Fig. 7. Sample DTR with five levels drawn from climatological day-wise precipitation data of Tamil Nadu state.

5) *Random forest regression:* Random Forest Regressor (RFR) as shown in Fig. 8 has a large number of decision tree regressors trained from the subsets of the training dataset [65][27]. It is a bagging ensemble approach which employs aggregated decision trees that operate concurrently without interacting with one another and produces the regression output as the average of outputs from all decision tree regressors [61], [64]. One out of ten DTRs used in the RFR model trained using the training set from Tamil Nadu state to forecast daily precipitation is shown in Fig. 9.

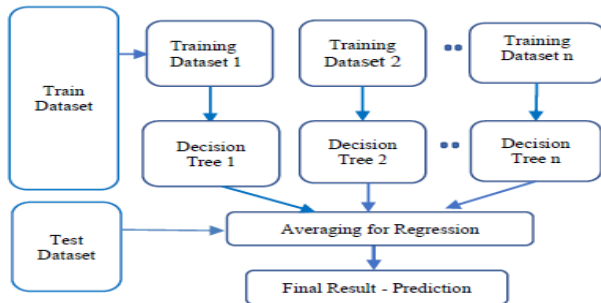

Fig. 8. The random forest regression ensemble.

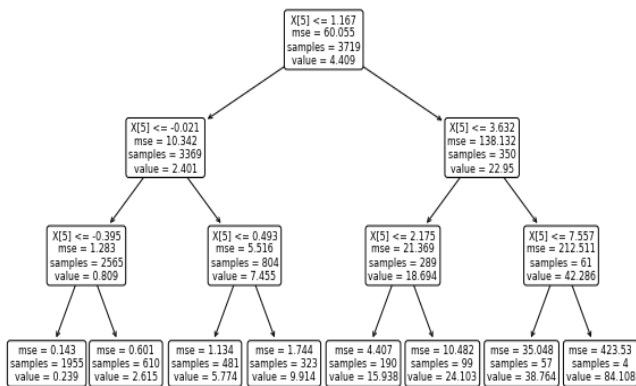

Fig. 9. One sample DTRs of RFR drawn from climatological data for Tamil Nadu state.

F. Ensemble Models

In Machine Learning (ML), the use of multiple models or algorithms to increase prediction reliability is referred to as ensemble learning [61]. The fundamental idea behind ensemble approaches is to achieve improved results using Eq. (4) by integrating results from many models than from a single model [61]-[62]. The average of results from the numerous regression models is the final prediction. In this work, the ensemble techniques, E-MLR-SVR, E-MLR-DTR, E-MLR-RFR, E-SVR-DTR, E-SVR-RFR, E-DTR-RFR, E-MLR-SVR-DTR, E-MLR-SVR-RFR, E-MLR-DTR-RFR and E-SVR-DTR-RFR are used to forecast precipitation.

$$Final\ Prediction = \frac{\sum_{j=1}^m (Prediction\ from\ Model\ j)}{m} \quad (4)$$

where $j = 1$ to m and m is the number of models.

The ensemble approaches used in this work are bagging/averaging approaches where arbitrary subsets of the training data are trained in several base algorithms: MLR, SVR, DTR, RFR and the predictions from each model are combined to get a final prediction. In the ensemble approach, E-MLR-SVR, the outputs of the basic regressors, MLR and SVR are combined to get the final output. Integrating stand-alone models yields better outcomes than using a stand-alone model. The climatological datasets from Tamil Nadu, Karnataka and Kerala are trained using the stand-alone ML algorithms and ensemble learning approaches to predict daily and monthly rainfall in the states of Tamil Nadu, Karnataka and Kerala. The performance of these models are assessed in terms of MAE, MSE, RMSE and R^2 values. Section IV analyses the results of these models in terms of regression metrics.

IV. EXPERIMENTAL RESULTS AND ANALYSIS

The performance evaluation metrics, Mean Absolute Error (MAE), Mean Squared Error (MSE), Root Mean Square Error (RMSE) and R^2 (R-squared) values are used to assess precipitation forecasting models [34]-[35]. MAE refers to the average of the absolute error difference between predicted value, y_{pi} and actual value, y_i as defined in Eq. (5). RMSE defined in Eq. (6) is the square root of the mean square error (MSE). The percentage of the dependent feature's fluctuation that can be predicted from the independent feature is known as R^2 value. It is defined in Eq. (7).

$$MAE = \frac{\sum_{i=1}^N |y_i - y_{pi}|}{N} \quad (5)$$

$$RMSE = \sqrt{\frac{1}{N} \sum_{i=1}^N (y_i - y_{pi})^2} \quad (6)$$

where $MSE = \frac{1}{N} \sum_{i=1}^N (y_i - y_{pi})^2$, N is the total number of observations/rows in the test data.

$$R^2 = 1 - \frac{\sum_{i=1}^N (y_i - y_{pi})^2}{\sum_{i=1}^N (y_i - \bar{y}_{pi})^2} \quad (7)$$

where y_i is actual value of i^{th} observation, y_{pi} is predicted value of i^{th} observation, \bar{y}_{pi} is the average of predicted values and N is the number of observations/rows.

A. Results and Analysis

The testing experiments are conducted on the test dataset obtained from the 20% climatological data of Tamil Nadu, Kerala and Karnataka states in an Intel Core™ i7-7500 CPU with 2.70 GHZ speed and 16GB RAM using the numerical and ML packages of Python. The results obtained in terms of MAE, MSE, RMSE and R2 values from the stand-alone ML algorithms: MLR, SVR, DTR, RFR and ensemble algorithms: E-MLR-SVR, E-MLR-DTR, E-MLR-RFR, E-SVR-DTR, E-SVR-RFR, E-DTR-RFR, E-MLR-SVR-DTR, E-MLR-SVR-RFR, E-MLR-DTR-RFR and E-SVR-DTR-RFR are tabulated in the Tables IV and V for day-wise and month-wise predictions. It is found from Tables IV and V that E-MLR-RFR produces improved precipitation forecast than other models in terms of MAE, MSE, RMSE and R2 values for Tamil Nadu, Karnataka and Kerala states and also than the models in [25], [28] and [32] in Table I. The minimal RMSE

and maximal R2 value for day-wise precipitation forecast from the E-MLR-RFR model are 0.11, 0.2, 0.1 and 0.9997, 0.999, 0.999 for Tamil Nadu, Karnataka and Kerala states respectively. Also the minimal RMSE and maximal R2 value for month-wise precipitation forecast from the E-MLR-RFR model are 0.06, 0.08, 0.31 and 0.9996, 0.999, 0.999 for Tamil Nadu, Karnataka and Kerala states respectively. The performance comparisons of the precipitation predictions made by different models: stand-alone algorithms: MLR, SVR, DTR, RFR and ensemble algorithms: E-MLR-SVR, E-MLR-DTR, E-MLR-RFR, E-SVR-DTR, E-SVR-RFR, E-DTR-RFR, E-MLR-SVR-DTR, E-MLR-SVR-RFR, E-MLR-DTR-RFR and E-SVR-DTR-RFR are respectively shown in the line diagrams from Fig. 10 to Fig. 12 for Karnataka state. Minimal error is noted from all the line plots in terms of predicted and actual monthly precipitation.

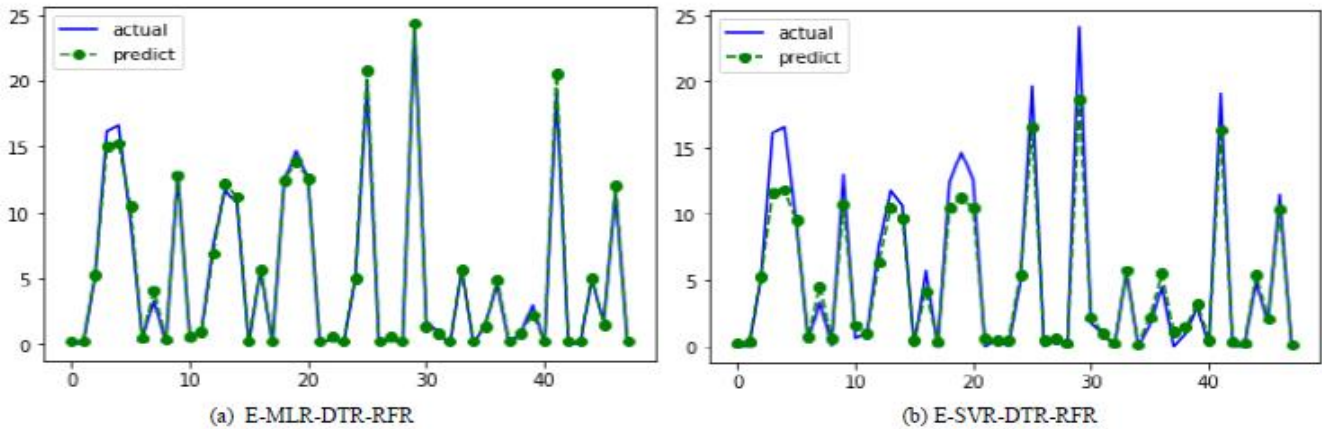

Fig. 12. Line plots showing actual and predicted monthly precipitation of Karnataka (a) E-MLR-DTR-RFR (b) E-SVR-DTR-RFR.

Fig. 13. Comparison of (a) MAE (b) MSE (c) RMSE (d) R^2 -values for Tamil Nadu (TN), Karnataka (KA) and Kerala (KL).

A barplot comparison of the evaluation metrics, MAE, MSE, RMSE and R^2 -values is also made between the states of Tamil Nadu, Karnataka and Kerala in Fig. 13. The ensemble model E-MLR-RFR fared better than other models. Also, the climatological data from Karnataka produces lesser error

when compared to the data from Kerala and Tamil Nadu for all models in the comparative study.

Heavy rainfall is one of the main reasons for flooding. A buildup of water in low-lying places can result in rivers overflowing their banks when rainfall surpasses a specific threshold, often 35.6 mm or more as reported in [42] and

shown in Table VI. So, the heavy rainfall predictions made from the best model, E-MLR-RFR proposed from the work to provide flood warnings in a specific location to reduce serious damage to both the environment and human societies.

TABLE VI. RAINFALL RANGE-FLOOD RANGE IS HIGHLIGHTED BOL

Description	Rainfall amount (mm/day)
Very Light Rain	0.1 -2.4
Light Rain	2.5 - 7.5
Moderate Rain	7.6- 35.5
Rather Heavy Rain	35.6-64.4
Heavy Rain	64.5 - 124.4
Very Heavy Rain	124.5 - 244.4
Extremely Heavy Rain	>244.4

V. CONCLUSION

The work has identified an appropriate ML based precipitation forecast model for the flood-prone southern states of India namely Tamil Nadu, Karnataka, Kerala which receive most precipitation using climatological data obtained from the NASA POWER platform. The precipitation forecast is proposed to alarm flood. The work investigated the effectiveness of ML forecasting models: Multiple Linear Regression (MLR), Support Vector Regression (SVR), Decision Tree Regression (DTR), Random Forest Regression (RFR) and ensemble approaches E-MLR-SVR, E-MLR-DTR, E-MLR-RFR, E-SVR-DTR, E-SVR-RFR, E-DTR-RFR, E-MLR-SVR-DTR, E-MLR-SVR-RFR, E-MLR-DTR-RFR and E-SVR-DTR-RFR in forecasting precipitation. The E-MLR-RFR model has produced improved and precise precipitation in terms of Mean Absolute Error (MAE), Mean Square Error (MSE), Root Mean Square Error (RMSE) and R² values. The higher precipitation forecast from E-MLR-RFR can be used to provide early warning about the possible flood in any region.

Department of Computer Science and Engineering, Acharya Nagarjuna University, Guntur, Andhra Pradesh, India¹

Department of Electronics and Communication Engineering, Acharya Nagarjuna University, Guntur, Andhra Pradesh, India²

Abstract—The World Health Organization (WHO) has released a report warning of the worldwide epidemic of heart disease, which is reaching worrisome proportions among adults aged 40 and high. Heart problems can be detected and diagnosed by a variety of methods and procedures. Scientists are striving to find multiple approaches that meet the required accuracy standards. Finding the heart issue in the waveform is what an Electrocardiogram (ECG) is all about. Feature-based deep learning algorithms have been essential in the medical sciences for decades, centralising data in the cloud and making it available to researchers around the world. To promptly detect irregularities in the cardiac rhythm, manual analysis of the ECG signal is insufficient. ECGs play a crucial role in the evaluation of cardiac arrhythmias in the context of daily clinical practice. In this research, a deep learning-based Convolution Neural Network (CNN) framework is adapted from its original classification task to automatically diagnose arrhythmias in ECGs. A deep convolution network that has been used for training with most relevant feature subset is used for accurate classification. The primary goal of this research is to classify arrhythmia using a deep learning method that is straightforward, accurate, and easily deployable. This research proposes a Recurrent Ascendancy Feature Subset Training model using Deep CNN model for arrhythmia Classification (RAFST-DCNN-AC). The suggested framework is tested on ECG waveform circumstances taken from the MIT-BIH arrhythmia database. The proposed model when contrasted with the existing models exhibit better classification rate.

Keywords—Feature selection; arrhythmia classification; convolution neural network; deep learning; electrocardiograms

I. INTRODUCTION

Many international health groups, including the World Health Organization, have concluded that cardiovascular diseases are the leading cause of death around the world. More people die each year from cardiovascular disease than from any other single cause [1]. Both strokes and heart attacks account for 88% of all cardiovascular diseases. Majority of cardiac deaths worldwide occur in regions with lower or moderate incomes [2]. Untreated cardiac arrhythmias and their long-term consequences are a leading cause of deadly cardiovascular diseases. Arrhythmia is the medical term for irregular heartbeats [3]. Arrhythmias play a pivotal role in ECG abnormalities, as this is essentially a rhythm conduction problem. Electrocardiography can detect potentially fatal heart arrhythmias and other problems. During this procedure, an

electrode is positioned on the patient's chest to record the rhythm of their heart's electrical activity. ECG sessions are typically used for long-term data recording and analysis by physicians and doctors to evaluate the presence or absence of a cardiac abnormality and the patient's risk for developing this condition. Time is a major factor in this undertaking. Therefore, it is crucial for doctors and medical professionals to be able to diagnose heart arrhythmia [4].

People are concerned about the global health as the prevalence of congenital heart defects increases over time. Up to this point, ECG signals have shown to be the most reliable method of determining cardiac dysfunction and abnormalities [5]. ECG and its associated terms P wave, QRS complex, T wave, and QT interval show normal heart activity [6]. By analysing these characteristics or electrical waves, the abnormality can be identified with the help of expert medical expertise. The heart diseases that affect heart rate were successfully observed using deep learning techniques [7]. It is possible that the irregular heart rate is the result of the faulty signal being too slow, too rapid, or completely unexpected. Lack of therapy can result in a heart attack or heart failure. The Normal Sinus Rhythm (NSR) represents a healthy, normal heartbeat on an electrocardiogram [8]. Congestive heart failure (CHF) represents the opposite type, a chronic condition in which the heart's ability to pump blood is impaired. Inadequate blood flow causes the heart to weaken and frequently disrupts its ability to operate [9].

Medical researchers have been motivated by the state-of-the-art uses of deep learning in the fields of pattern and image recognition. Though electrocardiograms (ECGs) are excellent at monitoring heart activity, only individuals with specialised training can read and understand the resulting tracings [10]. The distinction between symptomatic and asymptomatic arrhythmias is crucial because some potentially deadly arrhythmias can be present with no symptoms at all. Patients with symptomatic arrhythmias may experience dizziness, difficulty breathing, and an irregular heartbeat, all of which may be caused by emotional stress [11]. Extremely high blood sugar, mental stress, excessive smoking, hypertension, and other environmental and behavioural variables have all been linked to arrhythmias. A sluggish heartbeat is possible even in healthy persons, and is not always indicative of any underlying health concern [12]. Categorization results are helpful for diagnosing the risk of arrhythmias or sudden deaths, and can reveal information such as the presence of

non-sustained sustained ventricular tachycardia and ventricular premature beats.

In recent years, cardiac arrhythmia data has grown to an unprecedented degree, stifling advancements in feature-extraction outcomes. This is why Deep Learning (DL) has brought about crucial outcomes in the field of arrhythmia detection. Because of their ability to automatically detect and extract features to produce clear and precise findings, deep neural networks have gained popularity in the field of heartbeat classification [13]. In order to maximise the benefits of automated feature detection and extraction, a wide variety of methods and techniques have been integrated with cutting-edge deep-learning algorithms [14]. These methods can be grounded in a variety of frameworks, including those for multiple models and hybridization. In order to incorporate multi-level features and their transformation, a deep neural network is typically designed with a hierarchical layered structure [15].

In modern medicine, the diagnosis of potentially fatal cardiac arrhythmias requires the meticulous analysis of the ECG by board-certified cardiologists. Automated cardiac arrhythmia categorization, on the other hand, has the potential to speed up diagnosis while also providing cardiologists with more objective data [16]. To classify a system automatically into one of several categories is the goal of pattern recognition [17]. An experienced cardiologist can tell only by looking at the ECG waveforms printout what kind of cardiac arrhythmia their patient has. While advanced ECG analyzers can sometimes outperform a human cardiologist, there is still a subset of ECG waveforms that cannot be reliably identified by computers at this time [18]. The purpose of this research is to lay the groundwork for the creation of a computer-aided diagnostic system that will aid specialised cardiologists in the diagnosis of ECG arrhythmias in a way that is both smart and efficient in terms of both money and time. This is done by applying state-of-the-art deep learning approaches to the problem of ECG arrhythmia pattern detection alongside more traditional methods of ECG data processing [19].

In addition, this structure aids in the improvement of feature refinement. The limitations of traditional machine-learning strategies, such as the need for manual and inaccurate feature selection, which can have undesirable effects in the context of the aforementioned applications, are being overcome by integrating neural networks such as Recurrent Neural Networks (RNN) [20], Long Short-Term Memory (LSTM), Convolutional Neural Networks (CNN), and hybrid models, etc. Because accurate categorization of heartbeats and arrhythmia detection necessitates a large quantity of data to work with, the downsides of hybrid techniques build as the cost and lack of quality datasets [21], which may be regarded trivial in some viable scenarios, increase over time. This research offers a deep neural network ensemble to tackle these problems head-on, with the design and merging of two networks, then training the combined model all happening in one continuous process [22]. The innovative features centre on the utilisation of a multi-model framework that combines the capability to blend different ML/DL models and generate a robust result. The suggested methodology outperforms state-of-the-art studies in heartbeat detection and categorization.

This research proposes a Recurrent Ascendancy Feature Subset Training model using Deep CNN model for arrhythmia classification with better classification rate.

II. LITERATURE SURVEY

ECG tracing and arrhythmia classification methodology is presented by Tang et al. [2]. The suggested system includes a front-end IC, an FPGA-based delineation technique, and an arrhythmia classification technique. The inclination of the incoming analogue ECG signal is measured by a ternary second-order Delta modulator in the front-end circuit. Without regard to the instantaneous amplitude, the circuit transforms the analogue inputs into a pulse density modified bitstream whose pulse density is proportionate to the slope variation of the input analogue signal. Within a timing inaccuracy of 3 ms, the front-end chip can detect a slope variation as small as 3.2 mV/ms². Fabricated to use a 180 nm CMOS technology, the 0.25 mm² front-end IC uses just 151 nW of power at 1 kS/s sampling rate. An ECG waveform's fiducial spots can be located using a delineation technique that is informed by the slope variation received from the front-end circuit. A Spartan-6 FPGA was used to test the demarcation algorithm. The delineation system can determine 22 aspects about the QRS/PT waves based on their intervals, slopes, and shape. This information is used to classify arrhythmias such as ventricular ectopic beat (VEB), supraventricular ectopic beat (SVEB), and sinus node originated heartbeats using a rotational linear kernel support vector machine (SVM) for each individual patient.

An ECG is a non-invasive diagnostic tool for identifying heart rhythm disturbances. The literature reports numerous methods for classifying arrhythmias using a wide variety of ECG parameters. Accurate recognition and categorization of arrhythmias is proposed in this work by Zhang et al. [4] using a new approach in conjunction with a novel morphological feature. Events in the ECG signals are first identified. Then, certain sections of an ECG are extracted in order to measure their amplitude, interval, and duration, which are all parametric aspects of ECG morphology. Finally, a new clustering-based extracting features approach is proposed, along with a novel feature for assessing QRS complex morphological changes as visual patterns. At last, the feature vectors are fed into a neural network, a support vector machine, and a K-nearest neighbours classifier so that an automatic diagnosis can be made. Using the MIT-BIH arrhythmia database, which includes all fifteen heartbeat types recommended by the Association for the Advancement of Medical Instrumentation, the proposed method was evaluated, and with the help of the combined parameterized and visual pattern features of ECG Morphology, it achieved the best accuracy rate of 97.70% based on KNN.

An automatic method of detecting arrhythmias from a 12-lead ECG signal is a vital tool in the early detection and prevention of cardiovascular disorders. Previous research on automatic arrhythmia diagnosis often involved combining data from 12 ECG leads into a matrix, which was then fed into a number of feature extractors or deep neural networks. As the data from each lead of a 12-lead ECG interacts with one another during training, these approaches were able to extract

comprehensive properties of the full ECG. Poor information acquisition for 12-lead ECG was the result of ignoring the diversity of lead-specific properties across those leads. The information fusion of extensive features with consistency and lead-specific characteristics with variety should be considered to maximise the information learning of multi-lead ECG. In this paper, Wang et al.[5] presented a new Multi-Lead-Branch Fusion Network (MLBF-Net) architecture for arrhythmia classification by jointly learning the variety and integrity of multi-lead ECG through the use of multi-loss optimization. There are three parts to the MLBF-Net system: It consists of three parts: multiple lead-specific branches for learning the variety of multi-lead ECG; cross-lead features blending by appending the output feature maps of all branches for learning the integrity of multi-lead ECG; and multi-loss co-optimization for all the different branches and the concatenated network.

The ECG is the gold standard for diagnosing heart conditions. However, due to the volume of patient ECG data, human interpretation is laborious and time-consuming. Since there is a severe scarcity of medical personnel, intelligent ECG recognition technology is crucial. For the first time, this research provides an arrhythmia classification algorithm that makes use of ECG data fragments that each contain information on three whole cardiac processes across several ECG leads. Using the MIT-BIH arrhythmia database as training examples, the THML ECG data pre-processing algorithm is developed. To get the best possible integrated classification effect, Tang et al. [7] build four arrhythmia classification models using a 1D-CNN and a priority model integrated voting technique. Ablation trials demonstrate the viability and efficacy of THML ECG data, and the experiments were conducted using the inter-patient system proposed by the Association for the Advancement of Medical Instrumentation (AAMI).

Arrhythmia is a life-threatening kind of cardiovascular disease. ECG analysis using artificial intelligence is a powerful tool for the detection, diagnosis, and treatment of arrhythmia in its earliest stages. Commonly, many types of arrhythmia will be diagnosed in a single patient based on their ECG waveform. Despite this, the focus of the majority of the research done now is on multiclass approaches for dealing with the multi-label problem, which leads to information loss by disregarding the links between diseases. Therefore, Singh et al. [10] proposed an ECG-based multi-label feature selection method (MS-ECG) designed an evaluation criterion of ECG features based on kernelized fuzzy rough sets in order to select the best feature subset and maximise the ECG feature space. The author developed a multi-objective optimization model and proposed a multi-label classification algorithm for arrhythmia based on ECG. To reliably and automatically assign various labels to a single ECG signal, this sparsity-constrained method investigates the relationships between different arrhythmia disorders and examines the mapping link between ECG features and arrhythmia diseases.

Deaths from cardiovascular disease (CVD) now outnumber all others. ECG monitoring is currently included in wearable devices and is a common approach for diagnosing CVD. An ECG delineation and arrhythmia classification

(EDAC) system prototype for wearable ECG biosensors is presented in this research by Sohail, et al. [12]. The system is made up of a Delta-modulator-based analog-to-feature converter (AFC), a linear kernel support vector machine (SVM) classifier, an automated gain controller (AGC) block, and an algorithm for detecting, delineating, and extracting features from an ECG. In order to recognise QRS complexes, localise fiducial sites, and extract feature vectors for each pulse in the DDF block, the AFC digitises the slope and slope variation of the input analogue signal. On the basis of the detected QRS complex, the AGC then sends a gain control signal to the front-end amplifier. Finally, arrhythmia classification is handled by the SVM block. The MIT-BIH arrhythmia database is used to assess the efficacy of the EDAC system.

Qian et al. [15] introduced a low-overhead method for extracting key characteristics from ECG signals. Additionally, real-time algorithms are proposed to categorise arrhythmias based on these features. Two delta-sigma modulators with a 250 Hz sampling rate and three wave detection algorithms are the basis of the proposed feature extraction system. Essential information about each heartbeat is extracted and encoded into 68 bits of data, which is only 1.48 percent as much as other comparable approaches. Random forests are used as classifiers, and they are trained to distinguish between two common categories of arrhythmias. There are two types of ectopic beats: supraventricular (SVEB) and ventricular (VEB). Comparable to state-of-the-art approaches, the arrhythmia classification achieves F1 scores of 81.05% for SVEB and 97.07% for VEB. This technique offers a dependable and precise means of analysing ECG readings.

Performing an ECG signal analysis is a process that can be laborious, time-consuming, and prone to human error. That's why it's about time Pławiak et al. [16] had an automated study to help cardiologists spot issues in the heart faster and more reliably. While deep learning (DL) models have made remarkable strides and demonstrated impressive arrhythmia classification capabilities recently, their "black-box" nature makes it difficult to employ them in the medical field. This article presents a strong explainability approach to help explain how deep neural networks (DNNs) make decisions and to give feedback on biases that may be used to better train DNNs. In order to accomplish these goals, a DL model is first trained and tested using the MIT-BIH Arrhythmia Database. Post-hoc explanation techniques like SHapley Additive exPlanations (SHAP), local interpretable model-agnostic explanations (LIME), and gradient-weighted class activation mapping (Grad-CAM) are used to make sense of the classification results by deciphering the decision-making process. Several limitations are identified after evaluating these methods for ECG arrhythmia classification, including a lack of ability to identify the significance of a feature when that feature occurs multiple times in a signal and the fact that SHAP and LIME perform random perturbations, which can lead to unreliable explanations. Therefore, a unique K-GradCam approach is proposed to address the limitations of conventional post-hoc explainability techniques for time-series data.

Suitable for low-quality ECG data, Wang et al. [17] proposed a rapid and accurate denoising and classification method. In order to accomplish this, the author proposed a novel attention-based convolutional denoising autoencoder (ACDAE) model that uses a skip-layer and attention module to reliably reconstruct ECG signals from high-noise environments. A lightweight, efficient channel attention (ECA) module is used to efficiently update key characteristics obtained through cross-channel interaction, and skip-layer connections are used to reduce information loss while reconstructing the original signal. Four public databases are used for training and testing the model. Additive white Gaussian noise (AWGN) with amplitudes between 20 and 20 dB is used to evaluate the signals, along with noise from the MIT-Beth Israel Hospital Noise Stress Test Database (NSTDB) with amplitudes between 6 and 24 dB.

III. PROPOSED MODEL

The electrical activity of the heart can be measured and recorded with the use of ECG. The interpretation of ECG signals is vitally important for the diagnosis of arrhythmias. Cardiologists typically employ visual recognition to diagnose and detect various arrhythmias based on brief ECG data [23]. The QRS complexes will show any irregularities in the electrical signal. Detailed information about the signal's nature can be gleaned from the QRS complexes from the ECG signal. When it comes to categorizing ECG signals [24], feature extraction presents a substantial challenge. Most techniques based on deep learning for autonomous categorization of cardiac arrhythmia can be broken down into two categories: feature engineering and classification. To be more specific, researchers first manually retrieved a significant number of medically relevant ECG components, such as wavelet features. Integrated performance of P, Q, R, and S, plus T, a statistical feature of HRV, morphological features and a statistical feature of higher order mathematical techniques such as enhanced principal component analysis are used to reduce the dimensions of an ECG and thereby extract its features [25]. Artificial features are analysed using deep learning methods, self-organizing maps, and clustering, following feature engineering to yield a prediction result. Deep learning has several potential uses in the classification of cardiac arrhythmias for scientific research, however some issues remain to be resolved [26]. For instance, feature engineering that relies on subjective considerations can result in the removal of potentially relevant features, which in turn can have an impact on the overall classification performance.

The accuracy of ECG-based diagnostics for cardiovascular diseases has been shown to be improved with the help of deep learning models. They lead to steadily better neural networks by leveraging the cascade of mixed layers of neural networks to extract progressively higher-level features. In many applications of AI algorithms, deep neural networks have finally reached their full potential. This research proposes a unique framework for ECG analysis and classification, one that can represent the signal in a form that is portable between tasks. In order for this to occur, a deep neural network design is proposed that provides high abilities to learn such representations. Since this network has indeed been trained to identify arrhythmias, it is reasonable to presume that the

model has picked up all the relevant features information about the ECG's structure.

A CNN is the first model that this framework supports. It has three hidden layers, one flattening layer, two dense layers, and a batch normalization layer. A n1 matrix is what the CNN expects to see when it starts up. Additionally, a convolution layer and a pooling layer make up all hidden layers. Data type and quantity inform the best pooling strategy selection among options like min-pool, max-pool, and average-pool. Both the average and the maxpool methods are commonly employed for heartbeat categorization. With this goal in mind, max-pooling is used in the deployed CNN, which takes the item in the list from each unit of the feature map. The proposed model framework is shown in Fig. 1.

Fig. 1. Proposed model framework.

All of the convolution layers here are one-dimensionally applying convolution in time, and each of those layers has 32 kernels of size 3. Furthermore, all pooling layers employ

maximum pooling with a pool size of 5, and a stride of 3. Output class probabilities are predicted by a predictor network made up of five residual blocks, two fully-connected layers of 32 neurons each, and a softmax layer. First, an ECG signal is segmented into 15-second windows, and then one of those windows is chosen. Scaling all amplitude values to fall between 0 and 1. The next step is to identify all local maxima using zero-crossings of the first derivative. Then using a 0.9 threshold on the normalized value of the local maxima, identify a set of potential R-peak locations in an electrocardiogram. Using the middle value of R-R intervals as the window's standard heart rate, pick a section of the signal with a length of 1T for each R-peak. Adding leading zeros to each segment chosen until their total length is the same as some fixed value as set. In particular, the proposed beat extraction technique is simple to apply and produces reliable results when applied to signals of varying morphologies, making it ideal for use in applications requiring the extraction of R-R intervals. This research proposes a Recurrent Ascendancy Feature Subset Training model using Deep CNN model for Arrhythmia Classification.

Algorithm RAFST-DCNN-AC

{

Input: Feature Set {F_{set}}

Output: Arrhythmia Classification Set {AC_{set}}

Step-1: The feature set is considered and the features are analyzed for processing for accurate classification. The feature vector generation is performed based on the independent attribute correlation range. The feature vector generation of independent feature set is generated as

$$\begin{aligned}
 & FVset(Fset(M)) \\
 &= \sum_{f=1}^M \left(getattr(Fset(f)) + \frac{\max(Fset(f+1))}{\text{len}(Fset(f))} + \text{avg}(f, f+1) \right. \\
 & \quad \left. - \min(getattr(Fset(f))) \right)
 \end{aligned}$$

Here f is the feature considered and f+1 is the neighbor dependant feature.

Step-2: Hidden layer is situated between the input and output layers. An activation function is used to convert a set of weighted sources into an output. Since it is neither the input nor the output layer, this layer is referred to as the hidden layer. The processing layer called hidden layer is where everything actually occurs. The feature processing using hidden layers is performed for removing the irrelevant features still and to update the feature vector for better

classification rate. The process of hidden layer process is performed as

$$\begin{aligned}
 & HiddLayer(f, f+1, M) \\
 &= \sum_{f=1}^M FSet(sim(f, f+1)) \\
 & \quad + \frac{\min(Rec(j, i)) + \max(Fset(f))}{\sum_{f=1}^M \text{actv}F(\max(f+1), \min(f))}
 \end{aligned}$$

Step-3: After feature processing is done, Recurrent Ascendancy Feature Subset Training is performed to train the model with the processed feature vector for accurate Arrhythmia Classification that is performed as

$$FTrain(Fset(M)) = \sum_{f=1}^M \frac{\max(HiddLayer(f)) + \sum_{f=1}^M \maxrange(HiddLayer(f+1, f))}{\text{sizeof}(HiddLayer(M))}$$

Step-4: The updated feature set is generated and then the test data processing will be done for Arrhythmia Classification that is used for accurately classifying the disease or not as multiple sets. The Arrhythmia Classification is performed as

$$\begin{aligned}
 & ArClassupdate(Fset(M)) = \sum_{f=1}^M \sum_{f=i}^{\text{len}(FTrain)} FTrain(f) + \\
 & \sum_{f=1}^M \frac{G(\max(Ftrain(f)))}{\lambda}
 \end{aligned}$$

Here G is the function that identifies the similarity of the feature attribute comparison. λ is the threshold value considered for comparison.

Step-5: The classification set is generated and maintained for further identification of grade of the disease and the process of classification set generation is performed as

$$\begin{aligned}
 & ClaSet(ArClassupdate(f)) = \sum_{f=1}^M \text{getrange}(f, f+1) - \\
 & \min(ArClassupdate(f)) + \frac{\sum_{f=1}^{M-f} \max(FTrain(f+1))}{\max(FTrain(f))}
 \end{aligned}$$

IV. RESULTS

The significance of ECG classification is quite high important due to many contemporary clinical applications in which this problem can be expressed. The analysis and classification of ECG data is currently supported by a plethora of machine learning methods. The primary drawbacks of these ML outcomes, however, are the shallow feature learning

architectures and the reliance on heuristic hand-crafted or manipulated features. The difficulty stems from the fact that it is possible that the best features for this ECG classification problem will not be found. One proposed solution is to employ deep learning architectures in which the initial layers of convolutional neurons operate as feature extractors and the last layers of fully-connected neurons are used to decide between ECG classes. In order to categorize cardiac arrhythmias, this research work makes use of freely available dataset from kaggle available in the link <https://www.kaggle.com/datasets/shavanfazeli/heartbeat>. The MIT-BIH Arrhythmia Dataset and the PTB Diagnostic ECG Database are two well-known sources of heartbeat signals that were used to compile this dataset. Both datasets have sufficient sample sizes for use in deep learning network training. Deep neural network architectures for heartbeat classification have been investigated and the possibilities of transfer learning have been observed utilising this dataset. Electrocardiogram (ECG) waveforms of heartbeats (in both the normal case and the instances affected by various arrhythmias and myocardial infarction) are reflected in the signals. Each segment of these signals represents a single heartbeat during preprocessing. There are 87554 samples in all, and 10 features to analyse. The dataset is divided into 80% and 20% ratios, used for training and testing.

There are ECG recordings from multiple people included in the dataset. The dataset collects its own unique collection of features, and these differences have been taken into account independently of one another in the training and testing. This research proposes a Recurrent Ascendancy Feature Subset Training model using Deep CNN model for Arrhythmia Classification (RAFST-DCNN-AC). The proposed model is compared with the traditional ECG Delineation and Arrhythmia Classification System Using Slope Variation Measurement by Ternary Second-Order Delta Modulators (DACS-SVM-TSDM) model. The proposed model exhibits better performance in accurate classification when contrasted with the traditional models.

The technical hurdle for applications like speech recognition, image classification, strategy games, and medical diagnosis has been dramatically raised in recent years because to DNNs' powerful feature extraction capabilities and incremental learning methodologies. Since DNNs can recognise patterns and acquire important features from raw input data without requiring considerable human intervention in the form of custom rules and feature engineering, they are well-suited for decoding ECG data as opposed to standard machine learning approaches. Some studies have looked into the feasibility of using DNNs for automatic classification of cardiac arrhythmia using a single or multiple lead ECG.

ECG arrhythmia diagnosis using computers relies heavily on feature extraction. To this end, feature selection seeks out the most informative characteristics that can be used to distinguish between groups. The goal of feature extraction is to generate fewer features from the same dataset. When this new set of streamlined features is used, it should be able to effectively summarize the original set of features' worth of data. By combining the original features in this way, a condensed version of the full set can be made. The feature

extraction accuracy rate of the proposed and existing models are shown in Fig. 2.

Fig. 2. Feature extraction accuracy rate.

The process of reducing the number of dimensions that a dataset occupies involves a number of steps, one of which is feature extraction. As a result, processing will be less of a hassle. A key feature of these massive datasets is the abundance of variables they contain. Extensive computational resources are needed to process these variables. By selecting and merging variables into features, feature extraction aids in getting the best features from those large data sets. The proposed model in less time generates the feature vector. The feature vector generation time levels of the proposed and existing models are shown in Fig. 3 and the accuracy levels of the feature vector generation is shown in Fig. 4.

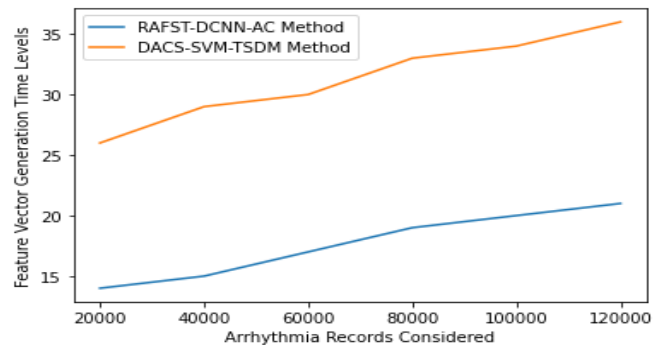

Fig. 3. Feature vector generation time levels.

Fig. 4. Feature vector generation accuracy levels.

Hidden layers in a CNN typically include convolutional layers, pooling layers, fully connected layers, and normalization layers. In this case, it simply implies that convolutional and pooling functions are utilised as activation functions rather than the conventional activation functions stated above. CNNs typically have convolutional layers, max pooling, fully connected layers, and normalising layers as their hidden layers. In this case, it just implies that users not utilising the standard activation functions specified earlier, but rather convolution and pooling functions. The hidden layer processing time levels of the proposed and existing models are shown in Fig. 5.

Fig. 5. Hidden layer processing time levels.

An activation function is used as the output of a neural network, which has a hidden layer in between its input and output. The function applies weights to the inputs. In a nutshell, the hidden layers alter the network's inputs in a nonlinear way. The number of hidden layers and the weights assigned to those levels can change based on the task being performed by the neural network. In a nutshell, hidden layers are a series of mathematical operations with the same goal in mind but different inputs. Squash functions are an example of a type of hidden layer. These functions take an input and return a value between zero and one, the range for defining probability, making them handy when the algorithm's expected result is a probability. The hidden layer processing accuracy levels of the proposed and existing models are shown in Fig. 6.

Fig. 6. Hidden layer processing accuracy levels.

There are two main types of arrhythmia, both of which are characterised by the patient's heart rate: bradyarrhythmias and tachyarrhythmias. They are further classified by their aetiology, mode of transmission, and resulting clinical symptoms. The ECG is a crucial tool in the detection of cardiac disorders. Arrhythmias, which include Atrial Fibrillation, Ventricular Tachycardia, Ventricular Fibrillation, and so on, are irregular rhythms in the ECG signal. The primary goal of this research is to identify and categorise patients with cardio-vascular arrhythmias. The Arrhythmia Classification Time Levels of the existing and proposed models are shown in Fig. 7.

Fig. 7. Arrhythmia classification time levels.

Too fast or too slow heart rates are examples of arrhythmias, often known as cardiac arrhythmias, heart arrhythmias, or dysrhythmias. It is possible for arrhythmias to present themselves with no warning signs at all. One possible symptom is experiencing a palpitation or a halt in heartbeats. In severe circumstances, users may experience dizziness, fainting, difficulty breathing, or chest pain. While most instances of arrhythmia are not life-threatening, certain types might put a person at risk for significant complications including a stroke or heart failure. Critical cardiac diseases can be helped greatly by automatic identification and classification of potentially fatal arrhythmias. The Arrhythmia Classification Accuracy Levels of the existing and proposed models are shown in Table I and Fig. 8.

TABLE I. ARRHYTHMIA CLASSIFICATION ACCURACY LEVELS

Records Considered	Models Considered	
	RAFST-DCNN-AC	DACS-SVM-TSDM
20000	91	81
40000	93	85
60000	95	86
80000	96	87
100000	97	91
120000	98	93

Fig. 8. Arrhythmia classification accuracy levels.

V. CONCLUSION

Diagnosis of arrhythmia typically involves the use of ECG because of its ease of use, lack of invasiveness, and high accuracy. Many deep neural network-based models have recently been successfully implemented for autonomous categorization of cardiac arrhythmia. However, most models, during training, separately extract the internal properties of each lead in the 12-lead ECG, leading to a deficiency in inter-lead features. The ECG is a reliable diagnostic tool for heart conditions because it measures electrical signals associated with heart muscle function. ECGs can be used to diagnose cardiac issues. Arrhythmia is a leading cause of sudden cardiac death. Heart disease, most often coronary artery disease, is the leading cause of death for persons older than 35. Today, multi-lead electrocardiogram (ECG) signals constitute the gold standard for computer-automated arrhythmia identification using deep learning models. However, due to the amplitudes of the input signals, these models supply too many parameters for practical use. In this research, we present a strategy for bridging the gap between the arrhythmia classification algorithm with multi-lead ECG signals and the arrhythmia classification algorithm with single-lead ECG signals using deep learning model to reduce the performance loss. This research proposes a Recurrent Ascendancy Feature Subset Training model using Deep CNN model for Arrhythmia Classification. The purpose of this research was to determine how little of a performance hit would result from shifting from arrhythmia classification based on multi-lead ECG signals to classification based on single-lead ECG signals. The intention was to take advantage of the high precision approaches based on multi-lead ECG signals in order to give the low computational cost offered by the approaches based on single-lead ECG signals. In future feature dimensionality reduction can be applied to reduce the feature vector size and also to use hybrid models integrated with optimization techniques for enhancing the classification rate.

Abstract—Machine learning (ML) algorithms are being integrated into several disciplines. Ophthalmology is one field of health sector that has benefited from the advantages and capacities of ML in processing of different types of data. In a large number of studies, the detection and classification of various diseases, such as keratoconus, was carried out by analyzing corneal characteristics, in different data types (images, measurements, etc.), using ML tools. The main objective of this study was to conduct a rigorous systematic review of the use of ML techniques in the detection and classification of keratoconus. Papers considered in this study were selected carefully from Scopus and Web of Science digital databases, according to their content and to the adoption of ML methods in the classification of keratoconus. The selected studies were reviewed to identify different ML techniques implemented and the data types handled in the diagnosis of keratoconus. A total of 38 articles, published between 2005 and 2022, were retained for review and discussion of their content.

Keywords—Ophthalmology; corneal disease; keratoconus classification; machine learning

I. INTRODUCTION

Keratoconus is a non-inflammatory bilateral corneal disease, characterized by a progressive deformation of the cornea which takes the shape of a cone [1]. The common symptoms of keratoconus are usually abnormally progressive myopia and astigmatism, vision poorly corrected by glasses, difficulty adapting to lenses, visual fatigue, and headaches. Other specific symptoms may be associated with each stage of keratoconus. The prevalence of keratoconus can range from 0.2 to 4.790 per 100 000 people [2]. Keratoconus can affect only one eye or both eyes at the same time, with different degrees of evolution, and repetitive eye rubbing is considered the most involved factor in the progression of this disease [3]. The diagnosis of keratoconus is generally made by examining the topography of the cornea as well as analyzing certain biomechanical characteristics of the cornea [4].

The detection of keratoconus, especially in its early stage, is a task that is not obvious in the absence of a set of uniform criteria describing this keratoconus stage. Considering the importance of the diagnosis of keratoconus, many contributions that aim at the classification of keratoconus have been published. The authors of a significant number of research works have opted for the adoption of ML techniques in their keratoconus classification systems, with the aim of achieving a good level of precision in the discrimination of this disease and assisting clinicians in patient diagnosis.

Generally, the diagnosis of keratoconus is done manually by specialists, who must analyze the different corneal characteristics to collect sufficient information to confirm the presence of keratoconus. However, to better support specialists in keratoconus detection task, many researchers have adopted ML algorithms to consolidate the decisions of ophthalmologists regarding the presence of keratoconus in patients [5]. The combination of the specialists' expertise and the advantages of ML, in processing different types of data, will certainly allow to detect keratoconus, particularly in its subclinical stage, with a high level of confidence and accuracy [6], to offer patients more choice of treatments and to avoid surgical interventions.

This paper proposes a systematic review concerning the use of ML techniques in the detection and classification of keratoconus. The main objective of this systematic review is to identify and evaluate the previous scientific literature relating to the classification of keratoconus using ML techniques, thus enabling researchers to learn about the state of research in this field. Moreover, this study will identify the commonly ML techniques used for the classification of keratoconus, the data types most used by ML-based systems in keratoconus classification and the corneal features most used in keratoconus classification.

II. RELATED WORKS

The detection of early or even preclinical forms of keratoconus will allow appropriate patient care and anticipate vision problems. Some research teams have focused on producing systematic reviews to present the latest advances in research concerning keratoconus disease to researchers. The Authors of systematic review [7] aimed to survey and critically evaluate the literature on the algorithmic detection of subclinical keratoconus. Measured parameters and the design of the machine learning algorithms reported in 26 papers were compared following PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) recommendations. As conclusion, authors reported that ML can potentially improve the detection of subclinical or early keratoconus. In the review [8], authors conducted the study to determine the prevalence and risk factors for keratoconus worldwide, including eye rubbing, family history of keratoconus, atopy, allergy, asthma, eczema, diabetes type I and type II, and sex. In this review 29 articles included 7 158 241 participants from 15 countries were analyzed. Results showed that the prevalence of keratoconus in the whole population was 1.38 per 1000 population and eye rubbing, family history of keratoconus, allergy, asthma, and eczema were the most important risk factors for keratoconus

according to the available evidence. Authors in [9] presented a systematic review to discuss new approaches to the early detection of keratoconus and recent investigations regarding the nature of its pathophysiology. Authors in this study reviewed the evidence for keratoconus complex genetics and evaluate the identified genes/loci and potential candidate gene/loci. Generally, there is a remarkable lack of reviews highlighting the different uses of ML techniques for the classification of keratoconus.

III. METHOD

This systematic review was conducted in Scopus and Web of science scientific databases, adhering to PRISMA guidelines in its most recent version 2020. For the proper conduct of this review, a list of research questions (RQ), that the Systematic Literature Review (SLR) should answer, has been listed in Table I. The collection of works studied in this systematic review aims to select as much as possible of related scientific papers, on detection and classification of keratoconus using ML tools, while excluding irrelevant studies that do not provide enough information related, thus aiming for high precision. In order to achieve the objectives, already cited, of this systematic review with good levels of precision, a well-extended search strategy is therefore necessary.

The terms considered in the selection of studies in this systematic review are “Keratoconus” and “Machine learning”. The research query used in this study is structured as follows:

Research query = (TITLE-ABS-KEY (keratoconus) AND TITLE-ABS-KEY (machine AND learning)).

TABLE I. RESEARCH QUESTIONS OF THE STUDY

No.	Research Question (RQ)
RQ1	What are the main objectives of using ML techniques in the classification of keratoconus?
RQ2	What are the ML techniques used in the classification of Keratoconus?
RQ3	What are the data types used by the different classifiers for the classification of keratoconus?
RQ4	What are the most used corneal features in keratoconus classification by the different ML models?
RQ5	What is the impact of ML use on the classification accuracy of keratoconus compared to traditional techniques?
RQ6	What is the number of keratoconus classes retained for each study included in this review?
RQ7	What are the limitations of the current literature and the opportunities for future research?

To produce a relevant systematic review, regarding the use of ML algorithms in keratoconus classification, a set of inclusion criteria (IC) and exclusion criteria (EC) was adopted in the process of selection of the considered documents. Included studies are the original articles, published between 2005 and 2022, which contributed on keratoconus detection using ML techniques. Selected works must use ML algorithms, trained and tested in different datasets, with a distribution of the data in training and testing datasets using different techniques such as cross-validation. In addition, the full text of the selected papers must be available, and only studies published in English were considered. Conference papers, conference reviews, letters, books, book chapters and editorials

were excluded from this study. The inclusion and exclusion criteria are summarized in the Table II below.

TABLE II. INCLUSION CRITERIA (IC) AND EXCLUSION CRITERIA (EC)

No.	Criteria
IC1	Papers published in a peer reviewed scientific journal.
IC2	Works published in English.
IC3	Testing of algorithms on test datasets.
EC1	Reviews, conference papers, conference reviews, letters, books, book chapters and editorials.
EC2	Works that do not provide enough information on the methodology adopted and that do not report results in a clear way.
EC3	Articles whose full text is not available.

According to the previous research query, a total of 175 documents were identified from Scopus and Web of science databases. After eliminating Reviews, conference papers, conference reviews, letters, books, book chapters and editorials, this number is reduced to 110 scientific articles. Among these 110 papers, 47 duplicate documents were removed. After reading titles and abstracts of different papers, 17 articles were excluded, 3 of which were not written in English and 14 others were not related to the classification of keratoconus using ML techniques. The other inclusion and exclusion criteria were applied on a total of 46 articles, of which two documents did not clearly detail the adopted methodology and did not report obtained results, and six other articles are not relevant, since they do not focus on the use of ML in keratoconus classification. The final number of articles included in this systematic review is 38 articles as shown in Fig. 1 below.

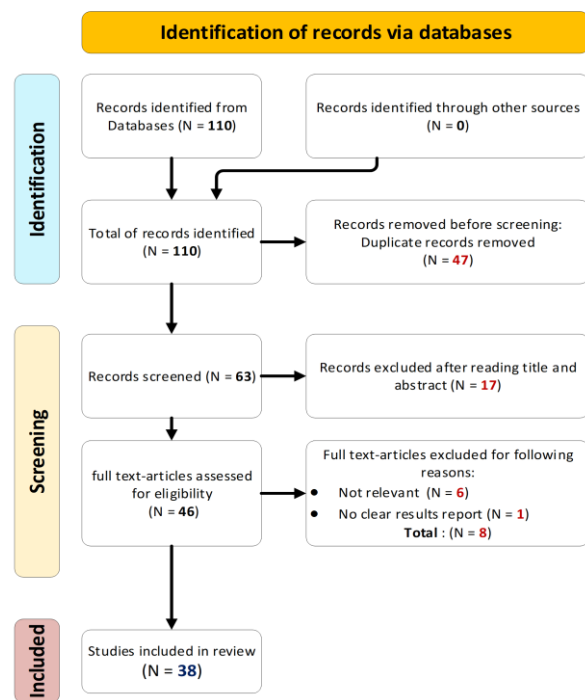

Fig. 1. PRISMA flow chart of the process of papers collection.

Once the articles were selected, based on the different inclusion and exclusion criteria already mentioned, an in-depth analysis of the selected articles was carried out. A set of information was extracted including the year of publication of each paper, the ML techniques used in the classification step of keratoconus, the number of inputs used by each technique and the technique performance in terms of accuracy, precision, recall, f1-score, sensitivity, specificity and area under the curve ROC. For the datasets, retained information represented the types of data used by different methods, the size of the dataset and the number of corneal classes considered during the classification process.

IV. RESULTS

Retained articles, related to keratoconus classification using ML tools, were published from 22 different countries. The countries representing the origin of the greatest number of publications are Belgium with 5 articles, followed by China and Spain with 4 articles each country, followed by USA and Romania with 3 articles each country. Belgium, China, Spain,

USA, and Romania represent the origin of 50% of the papers included in this study with a total of 19 papers. Fig. 2 below shows the distribution of included works by countries of publication and Table III reports the Literature Review Matrix (LRM) of reviewed articles.

Fig. 2. Distribution of selected papers by countries.

TABLE III. DETAILS OF STUDIES INCLUDED IN THE CURRENT SYSTEMATIC REVIEW

Ref.	Year	Technique	Data type	Dataset size	Classes number	Inputs number	Performance
[10]	2022	Five-layer feedforward network	Biomechanical parameters calculated from corneal raw videos	276 samples	2 classes	4 biomechanical characteristics	Accuracy: 98.7%, Sensitivity: 97.4% Specificity: 100% Precision: 100%
[11]	2022	FcNN, XGBoost & TabNet (Voting)	Corneal parameters	2613 samples	3 classes	18 variables	Accuracy: 90.6% to 95.6% Sensitivity: 67.6% to 90.5% Specificity: 90.9% to 97.9%
[12]	2022	SVM Classifier applied to selected features, extracted using AlexNet & TabNet	Corneal topographic images	682 images	2 classes	1x1000 features	Accuracy: 98.53% Sensitivity: 98.06% Specificity: 99.01%
[13]	2022	GoogLeNet Classifier applied to segmented image using PSO, DPSO & FPSO	Corneal topographic images	1500 images	3 classes	224x244x3 images	Accuracy: 95.9% Sensitivity: 94.1% Specificity: 97%
[14]	2021	Random Forest & decision tree	Pentacam topographic Corvis biomechanical variables	80 eyes	2 classes	27 parameters	Accuracy: 89% Sensitivity: 86% Specificity: 93%
[15]	2021	VGG-16	Corneal topographic images	1926 images	2 classes	224x224 corneal maps	Accuracy: 97.85 % Sensitivity: 98.46 % Specificity: 90% AUC: 94.23%
[16]	2021	Multilayer perceptron (MLP), neurofuzzy & Naïve Bayes	Pentacam measurements	450 eyes	4 classes	19 parameters	Accuracy: 98.2% Sensitivity: 98.5% Specificity: 99.4%
[17]	2021	Linear discriminant analysis (LDA) & random forest (RF)	Corneal tomography DCR & pachymetric parameters	434 cases	4 classes	11 parameters for RF. 6 parameters for LDA.	LDA Accuracy: 71% RF Accuracy: 78%
[18]	2021	Time delay neural network	Pentacam data	743 patients	2 classes	6 features	Sensitivity: 70.8% Specificity: 80.6%
[19]	2021	Convolutional neural Network (CNN)	Corneal frontal and lateral images	450 images	4 classes	Two 2D images	Accuracy: 97.8% Sensitivity: 98.45% Specificity: 96%
[20]	2021	Logistic regression, decision tree, random forest, MLP, Fast-Large Margin, KNN & Naïve Bayes	Images	Iraq base: 448 images. Europe base: 692 images.	2 classes	140 vectors of 400 dimensions	Accuracy: 91.33% Sensitivity: 88.58% Specificity: 94.39%
[21]	2021	RF, SVM, KNN, DT, NB, LR & LDA on selected features	Corneal parameters	3162 rows Harvard Dataverse Keratoconus dataset	2 classes 4 classes	10 variables 420 variables	Accuracy: 4 classes: 95.32% 2 classes: 98.1% AUC: 100% (4 classes)
[22]	2021	RF using PCA for	Pentacam parameters	267 eyes		267 parameters	Accuracy: 98%

		dimensionality reduction			2 classes	from 1692 parameters	Sensitivity: 97% Specificity: 98%
[23]	2021	24 machine learning models	Pentacam measurements	3 datasets of 5881 samples	5 classes 3 classes 2 classes	Elevation dataset: 5 features from 18	AUC (SVM): 5 classes: 88% 3 classes: 96% 2 classes: 99%
[24]	2021	Quadratic discriminant Analysis (QDA)	Pentacam data	12647 rows	6 classes	7 parameters	AUC: 95% to 100%
[25]	2020	CNN	Corneal tomography images	3218 images	3 classes	Images of 256x256 pixels	Accuracy: 95.8%
[26]	2020	Logistic regression	Demographic, optical & geometric data	178 eyes	3 classes	5 variables	Accuracy: 73%
[27]	2020	Logistic regression	Demographic, optical, pachymetric & geometrical parameters	169 samples	6 classes	17 variables	Accuracy: 69.8%
[28]	2020	RF, SVM, KNN, LR, LDA, Lasso Regression, DT & MLP	Corneal parameters	88 eyes	2 classes	11 parameters	Accuracy: 87% (RF) Sensitivity: 92% (SVM) Specificity: 88% (KNN) Precision: 89% (RF) AUC: 96% (RF)
[29]	2020	LR & Artificial Neural Network (ANN)	Corneal morphological features using Scheimpflug camera and UHROCT	121 eyes	3 classes	49 parameters	Sensitivity: 95.1% (LR), 98.5% (ANN) 1-Specificity: 94.8% (LR), 94.7% (ANN) AUC: 90% (LR), 93% (ANN)
[30]	2020	Feedforward Neural Network (FNN)	Anterior and posterior corneal elevations & minimum pachymetry value	812 subjects	5 classes	2 vectors of 46 anterior and 46 posterior parameters	Accuracy: 99.9%
[31]	2020	InceptionResNetV2	Corneal topographic images	6465 images	5 classes	Images of axial curvature, front and back elevation & corneal thickness	Accuracy: 95% Sensitivity: 91.9% Specificity: 98.7% AUC: 99.3%
[32]	2020	CNN	Raw data of the Pentacam HR system	854 samples	3 classes	Five matrices, each of a size 141x141	Accuracy: 94.74% Recall: 93.71% Precision: 94.1% F1-score: 93.89%
[33]	2020	CNN based on ResNet with fewer hidden layers and 4 input channels	Corneal topographic images	3000 images	3 classes	56x56x4 matrix	Accuracy: 99.3%
[34]	2020	25 machine learning models	Corneal parameters	3151 samples	2 classes 3 classes	8 features	Accuracy (Cubic SVM) : 2 classes: 94.0% 3 classes: 62%
[35]	2019	CNN	Corneal topographic images	3000 images	2 classes	180x240x3 pixels	Accuracy: 99.33%
[36]	2019	ResNet-18	Corneal topographic maps using anterior segment optical coherence tomography (AS-OCT)	543 images	5 classes	224x224 corneal maps	Accuracy: 87.4%
[37]	2019	Conditional linear Gaussian Bayesian network	Topographic indices, calculated from the Placido ring images	60 eyes	2 classes	16 parameters	Sensibility: 100% Specificity: 100%
[38]	2019	Feedforward neural network, Grossberg-Runge Kutta	Topographic data	851 subjects	4 classes	1x117 features	Accuracy : 99.58% Sensitivity: 99.91% Specificity: 99.90% Precision: 99.90%
[39]	2019	SVM & DT	Corneal Topographic images	40 cases	2 classes	16 features	Accuracy (SVM): 90% Accuracy (DT): 87.5%
[5]	2019	Density-based clustering	Corneal parameters	3156 eyes	4 classes	420 corneal parameters	Specificity: 94.1% Sensitivity: 97.7%
[40]	2017	SVM	Pentacam parameters	131 eyes	5 classes	25 parameters	Accuracy: 88.8%
[41]	2016	SVM	Pentacam data	860 eyes	5 classes	22 parameters	Accuracy: 88.8% Sensitivity: 89% Specificity: 95.2%
[42]	2016	MLP	Tomographic data, topographic data & keratoconus indices	135 eyes	3 classes	15 parameters	AUC: Unilateral: 88% Bilateral: 96%
[43]	2014	LDA & ANN	Maps of the corneal epithelial and stromal	204 subjects	5 classes	6 variables	Sensitivity: 94.6% (LDA), 98.9% (ANN)

			thickness				Specificity: 99.2%(LDA), 99.5%(ANN)
[44]	2013	DT	Corneal Topographic images	372 eyes	2 classes	55 features	Sensitivity: 100% Specificity: 99.5%
[45]	2010	SVM, MLP & Radial Basis Function Neural Network (RBFNN)	Corneal topographic maps using OrbscanII	318 maps	4 classes	11 variables	SVM & MLP: AUC: 99% Sensitivity: 100% Specificity: 100% RBFNN: AUC: 98% Sensitivity: 98% Specificity: 98%
[46]	2005	DT C4.5	Videokeratography data	244 eyes	2 classes	4 Zernike polynomial coefficients	Accuracy: 92% AUC: 97%

Considering publication dates of selected articles, a large part of the retained documents was published during the period 2019 to 2022, with a total of 31 papers; the seven remaining articles were published in the period from 2005 to 2017. Fig. 3 below represents the curve of the publication's evolution per years between 2005 and 2022.

Fig. 3. Number of articles by years of publication.

A. *RQ1. What are the Main Objectives of using ML Techniques in the Classification of Keratoconus?*

The early diagnosis of keratoconus is very meaningful to avoid heavy treatments or surgical interventions that can cause further damage to the cornea. Many technologies allow showing different aspects of the cornea, such as biomechanical features, wavefront aberrations, elevation maps and pachymetry [47]. To determine accurately keratoconus presence, ophthalmologists must be up to date and able to analyze, combine and interpret indices and information obtained by all these different technologies as diagnosis result. However, ML tools have shown great capacity in the analysis and processing of heterogeneous data, such as measurements, videos, images, etc. It is for these advantages that ML techniques have been used in systems of keratoconus classification. The main objectives of using ML in keratoconus classification are the optimization of keratoconus diagnosis process as much as possible by its early identification, the assurance of better care for patients and their follow-up, the proposal of adequate medical actions according to the identified stage, and the confirmation of the diagnosis carried out by specialists, by combining their expertise with the capacities of ML techniques. Moreover, ML is used in keratoconus classification to fix the limitations of existing diagnostic methods, including qualitative rather than

quantitative evaluations of parameters, coefficients, and observer bias [5].

B. *RQ2. What are the ML Techniques used in the Classification of Keratoconus?*

Various ML techniques were used for keratoconus classification in studied works. The unsupervised ML is represented in this review by the Density-Based Clustering technique which was used as keratoconus classifier.

For supervised ML, different methods were implemented in the contributions included in this review. Many works have adopted simple ML algorithms such as Support Vector Machine (SVM), K-Nearest Neighbors (KNN), Random Forest (RF), Linear Discriminant Analysis (LDA) or other algorithms [21]. Other studies have implemented some techniques, such as ensemble learning, based on Bagging, Boosting, Stacking,..., etc., allowing the combination of several machine learning algorithms to improve the performance of predictive systems in terms of classification accuracy [16]. Other techniques, such as DL were adopted in several works for classification of keratoconus. Generally, the different ML techniques commonly used in the studies included in this review are:

1) *Naive bayes (NB)*: The Naïve Bayes is a probabilistic classifier well suited to high dimensional datasets. Despite its simplicity, the NB algorithm can outperform other more efficient classifiers [37].

2) *K-Nearest neighbors (KNN)*: KNN method is a ML technique that classifies new observations, assigning them to the class most present in the neighbors of this observation based on similarity functions, such as distance functions [21], [28].

3) *Logistic regression (LR)*: LR is a probabilistic supervised ML algorithm using the sigmoid function as a decision rule, providing a probability of producing an event with values between 0 and 1 [21], [48].

4) *Linear discriminant analysis (LDA)*: It is a technique belonging to competitive machine learning methods, which is used for dimensionality reduction [49]. The idea behind LDA is to find a linear combination of variables that best separates different classes [50].

5) *Decision tree (DT)*: DT is a classifier algorithm of a tree structure. The nodes of the DT represent the evaluation tests of the observations attributes, while the arcs represent the responses to the tests associated with the nodes, and the leaves

correspond to the different classes [21]. Different variants of DT, such as Chi-square automatic interaction detection (CHAID) and classification and regression tree (CART), have been implemented for the discrimination of keratoconus [51].

6) *Artificial neural networks (ANN)*: It is a computational imitation of the way neurons work in the human brain, an ANN consists of three layers, input, hidden and output. Each neuron of a given layer is interconnected with the neurons of the next layer, and each connection has a weight which is used for the calculation of the output [52].

7) *Convolutional neural networks (CNN)*: Initially designed to process images more efficiently [53], CNNs are a particular type of ANN belonging to such a broad category of methods called DL. CNNs are designed using multiple building blocks, such as convolution layers, pooling layers, and fully connected layers. Deep learning techniques are based on the CNN architecture [35], [54].

8) *Ensemble learning*: Ensemble learning is a technique that consists of combining several individual ML classifiers to build a predictive system while improving the prediction

performance of the overall system. Random Forest is an example of ensemble learning techniques based on the bagging principle [28].

9) *Density-based clustering (DBC)*: It is an unsupervised ML technique based on local cluster criterion method, such as density connected points [5]. For this technique, the data points in the region separated by two clusters of low point density are considered as noise.

The emergence of the use of ML techniques in the medical field will undoubtedly impact the practice of health professionals, this diversity of ML algorithms used in the diagnosis of keratoconus, reflects the great interest of researchers in this disease and its treatment and management. However, it should be noted that the purpose of using ML in the medical field, ophthalmology in particular, is not to replace health professionals with automated systems, but rather to support them in the analysis and interpretation of voluminous and heterogeneous data collected, in order to make the right decisions by reducing the margin of error for specialists. Fig. 4 below represents different ML techniques identified in the papers included in the current review.

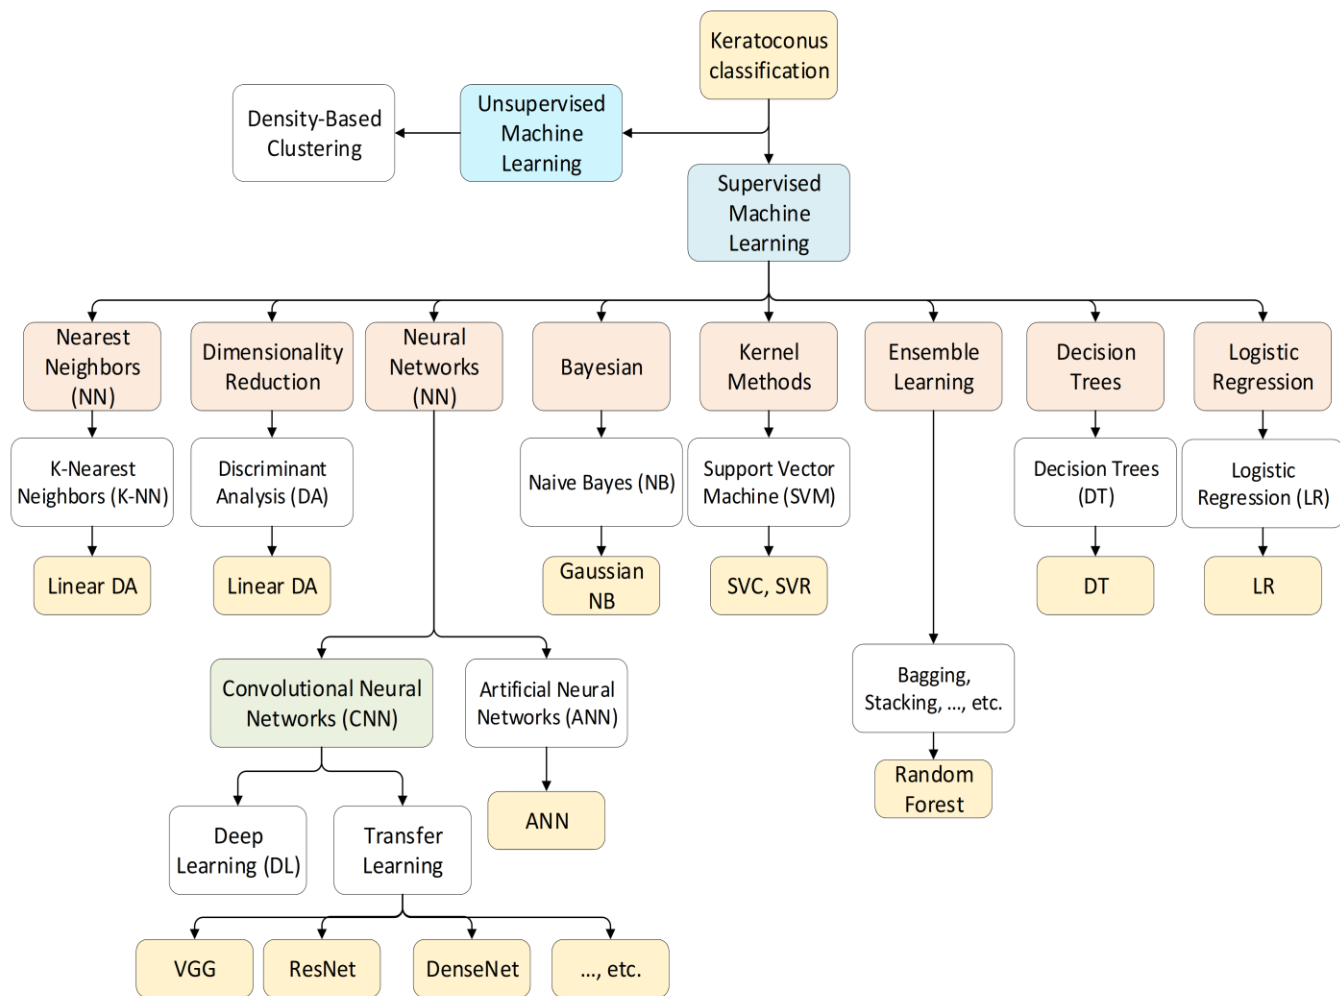

Fig. 4. Explanatory diagram of the commonly used ML techniques in the classification of keratoconus.

Fig. 5 below represents the rates of ML and DL classifiers use in the included papers.

Fig. 5. ML and DL use percentages in selected papers.

C. RQ3. What are the Data Types used by the Different Classifiers for the Classification of Keratoconus?

The diversity of ML algorithms is accompanied by a variety of data types handled by these algorithms. The data types used in the works selected in this study are:

1) *Images*: In most of contributions, using deep learning architectures, authors have used image type data for the classification of keratoconus. Processed images are in different types, such as corneal topography [12], tomography [25], and Placido disc [37].

2) *Corneal parameters*: A set of measurements, obtained using specific devices such as Pentacam, describing the cornea in detail on different aspects (geometric, topographic, ..., etc.). A total of 15 studied documents have handled corneal data and parameters as input data for the classification of keratoconus [16], [28], [21], [17], [18], [22], [23], [24], [30], [32], [34], [38], [40], [41], [42].

3) *Biomechanical data*: Biomechanical parameters refer to the distortion responses of the cornea to an applied force such as corneal hysteresis (CH) and corneal resistance factor (CRF). Biomechanical parameters are generally integrated in the corneal parameters already cited as inputs [14].

4) *Demographic data*: Age and gender are the demographic parameters the most integrated in studied articles as input data [14], [18], [29].

5) *Morphological data*: Morphological data make it possible to describe the morphology of the cornea and to identify any structural anomaly of the latter. Indeed, the thickness of the cornea varies from one individual to another, due to the difference in the radius of curvature of its anterior and posterior faces [29].

6) *Geometric data*: Correspond to information essentially describing the geometry of the anterior and posterior corneal surfaces to diagnose any pathology linked to an alteration in corneal morphology [55]. Among these data the total corneal volume, the anterior corneal surface, the posterior corneal surface, the total corneal surface, the deviation of the anterior apex and the deviation of the posterior apex [26].

Other papers, not included in this review study, introduced other forms of data such as the ethnic properties of patients [56]. Fig. 6 indicates the data types used by the different models of keratoconus classification proposed in the papers treated in this study.

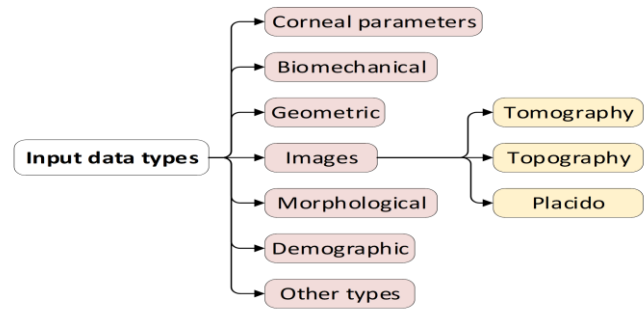

Fig. 6. Types of data adopted as inputs for different ML classifiers used in the studied papers.

D. RQ4. What are the Most used Corneal Features in Keratoconus Classification by the Different ML Models?

Between 38 analyzed documents, 22 papers have reported the list of features used as inputs by the different classifiers implemented for the classification. The 10 most used features in different papers are:

- Radius of the corneal curvature (Radius), used in 10 documents.
- Flat simulated keratometry (Kf), declared in 7 papers.
- Steep keratometry (Ks), appeared in 6 articles.
- Age, reported in 6 different works.
- Astigmatism, reported in 5 different papers.
- Inferior-Superior value (I-S), used in 5 articles.
- Index of height decentration (IHD), used in 5 papers.
- Index of surface variance (ISV), declared in 4 papers.
- Index of vertical asymmetry (IVA), used in 4 works.
- Gender, used in 4 papers.

E. RQ5. What is the Impact of ML use on the Classification Accuracy of Keratoconus Compared to Traditional Techniques?

The detection of keratoconus in its first stage will make it possible to follow its evolution closely and try to slow down, or even stop, it by following adequate measures on a case-by-case basis. The detection of keratoconus in its advanced stages can be ensured by evaluating certain symptoms and clinical signs of the cornea, visibly clear for specialists, given the advanced stage of the disease. For subclinical keratoconus, this operation is not possible, this is due to the similarities in signs with normal eyes. However, the early diagnosis of keratoconus is made using video technologies performing corneal topographies. Thus, the large number of parameters describing the cornea and the difficulties in analyzing corneal topographic images represent the greatest difficulty in the identification of subclinical keratoconus. It is to overcome all these obstacles and to distinguish keratoconus in its early phase in patients, that the ML is used for the analysis of corneal topographies, showing great precision when classifying keratoconus compared to traditional diagnostic methods [14].

F. RQ6. What is the Number of Keratoconus Classes Retained for Each Study Included in this Review?

The number of corneal classes retained in each of the different studies included in the current review varies between 2 and 6 corneal classes. The articles considering 2 and 3 corneal classes for keratoconus classification represent the large part of the papers studied in this systematic review, with a total of 26 papers (15 papers and 11 papers for keratoconus classification considering 2 and 3 corneal classes respectively). Table IV indicates the distribution of studies by the number of corneal classes considered in keratoconus classification.

TABLE IV. DISTRIBUTION OF STUDIED WORKS BY NUMBER OF CORNEAL CLASSES CONSIDERED IN THE CLASSIFICATION

Number of Classes	References	Total of papers
2 classes	[24], [37], [28], [35], [10], [12], [14], [15], [18], [20], [22], [23], [34], [39], [46]	15
3 classes	[11], [13], [23], [25], [26], [29], [32], [33], [34], [42], [44]	11
4 classes	[5], [21], [16], [17], [19], [38], [45]	7
5 classes	[15], [23], [30], [31], [36], [40], [41], [43]	8
6 classes	[24], [27]	2

G. RQ7. What are the Limitations of the Current Literature and the Opportunities for Future Research?

The objective of the current literature review study is to identify scientific studies aimed at the classification of keratoconus using machine learning tools. One of the limitations of this study is the exclusion of certain studies during the execution of the query for selecting papers from Scopus and Web of science databases, the poor choice of titles and keywords of articles by the authors may exclude the article, even if it is a work in the context of this study. Also, the exclusion of certain types of papers, such as conference papers and book chapters for example, may cause the loss of a large number of contributions aimed at the classification of keratoconus. Another limit of this study is that the period from 2005 to 2014 is represented by only four papers, this is perhaps due to the inclusion rules already mentioned and the low number of contributions, using ML techniques to the classification of keratoconus, published in this period. Moreover, this variety of ML techniques and types of data used in different studies makes the comparison of these systems more difficult, if not impossible, in the absence of a referential dataset to test these different systems implemented.

V. DISCUSSION

Based on the current systematic review, concerning the adoption of ML techniques for keratoconus classification systems, reported results show a remarkable increase in scientific productions, according to the selection criteria already cited, these last four years (2019, 2020, 2021 and 2022). This growth is maybe due to the interest of researchers in the use of ML techniques in the objective to take full advantage of the capabilities of these techniques in data analysis, especially in classification problems in several domains. This growth in the use of ML techniques in ophthalmology can be justified by the strong bond of this field

to image processing for the diagnosis of several diseases including keratoconus. As illustrated in Fig. 3, amongst 38 selected documents, 31 papers have been published in the past four years, i.e., 81.56% of all papers.

Regarding the countries of publication of different documents, Fig. 2 shows that the 38 papers were published from 22 different countries. Belgium, China, Spain, Romania, and USA have published 5, 4, 4, 3 and 3 papers respectively, with a total of 19 papers, representing 50% of the studied articles. The 19 other papers were published from 17 other countries.

Table IV indicates that over the 38 retained documents in the current review, 15 papers allowed keratoconus classification considering just 2 classes, 11 papers have considered 3 corneal classes, 7 studies used 4 corneal classes in the classification, 8 articles considered 5 classes of keratoconus in the classification task and 2 papers retained 6 corneal classes. Generally, the adopted classes of cornea are included in the following classes, namely normal, subclinical, mild, moderate, advanced, and severe stages of keratoconus. Among the 38 selected papers, 26 (i.e., 68.42%) opted for a classification of keratoconus by considering only 2 to 3 corneal classes (normal, subclinical and keratoconus). The idea behind is to ensure early detection of keratoconus in its subclinical stage, to treat it early and to stop its progression to advanced stages.

Fig. 4 shows that the authors have used two categories of ML algorithms, unsupervised ML, and supervised ML. Only one study over the studied papers implemented unsupervised ML, using the Density-based Clustering algorithm. In a total of 37 articles, authors proposed classification systems on the basis of supervised ML techniques. Authors of the different papers have proposed various architectures and several techniques to achieve high accuracy during classification. Thus, each of the works uses data, which are generally proprietary and not publicly accessible, which makes the comparison of these proposed methods difficult, if not impossible, in the absence of a public test platform to validate these works on the same dataset and under somewhat similar conditions.

To evaluate the classification performance of the proposed systems in the various works included in this literature review, the most used metrics are as follows:

- Accuracy: Described by “(1)”.

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (1)$$

- Precision: Calculated using “(2)”.

$$Precision = \frac{TP}{TP + FP} \quad (2)$$

- Recall: Estimated using “(3)”.

$$Recall = \frac{TP}{TP + FN} \quad (3)$$

- F1-score: Depicted as “(4)”.

$$F1 - Score = 2 * \frac{Precision * Recall}{Precision + Recall} \quad (4)$$

- Area under ROC curve (AUC): Represents relationship between False Positive rate and True Positive rate of a test for all possible thresholds. The value of ROC lies between 0.5 and 1 and efficient classifier tend to maximize the ROC value towards 1 [21].

Where, True Positives (TP) represents the number of correct samples predicted as ‘yes’, True Negatives (TN) is the number of correct samples predicted as ‘no’, False Positives (FP) is the number of samples that are incorrectly predicted as ‘yes’ when they are actually ‘no’ and False Negatives (FN) represents the number of samples that are incorrectly predicted as ‘no’ when they are actually ‘yes’ [21].

VI. CONCLUSION

This study presents a systematic review of machine learning (ML) tools for detecting and classifying keratoconus. It analyzes various data types including images, text, measurements, etc, and various ML classifiers, achieving good accuracy across different stages of keratoconus. However, the absence of a standardized dataset hinders the comparison of different approaches. Nonetheless, the study demonstrates that ML techniques, when combined with clinical expertise, can yield accurate results. In summary, ML techniques offer promise in enhancing the diagnosis and treatment of eye diseases like keratoconus, but their use should be accompanied by clinical expertise for reliable outcomes. It should be mentioned that the keratoconus classification systems proposed in the studies included in this review are intended to assist practitioners and not to replace them in the diagnosis of this disease. Future research should focus on developing standardized datasets to facilitate comparison and improve accuracy.

Abstract—India is an agriculture-based country, with paddy being the main crop cultivated on nearly half of its agricultural lands. Paddy cultivation faces numerous challenges, particularly diseases that affect crop growth and yield. Adult paddy crops are especially vulnerable to diseases caused by various factors, such as the green rice leafhopper, rice leaf folder, and brown plant leafhopper. These insects inflict damage on the paddy crops, restricting their growth and leading to significant losses. This research paper investigates the impact of environmental factors on disease spread in paddy crops, using the X-Step Algorithm for analysis. The study aims to better understand the role of environmental conditions, including air, water, and soil quality, in the development and progression of diseases in rice crops. This knowledge will help to optimize disease prevention and management strategies for improved crop yields and food security. The X-Step Algorithm, a novel machine learning algorithm, was employed to model and predict disease spread, taking into account various environmental factors. The proposed algorithm analyses images of paddy crops either manually captured or taken by sensors to evaluate disease spread and growth in paddy crops. This data-driven approach allows for more accurate and timely predictions, enabling farmers and agricultural experts to implement appropriate interventions.

Keywords—Paddy crops; cash crop disease; green rice leafhopper; rice leaf folder; brown plant leafhopper; x-step algorithm

I. INTRODUCTION

A. Background and Motivation

Rice is a crucial food crop that nourishes billions worldwide. Ensuring the health and productivity of paddy crops is vital for maintaining global food security [1]. Disease outbreaks can cause considerable yield losses [2], affecting both the quality and quantity of rice. Thus, identifying the factors contributing to disease spread [3], especially the environmental impacts, is crucial for creating effective prevention and management techniques.

Advancements in machine learning and data analysis have opened new avenues to explore the complex interplay between environmental factors and disease propagation in agricultural systems [4]. The X-Step Algorithm is an advanced machine

learning tool with the potential to model and predict disease spread in paddy crops [5].

B. Research Objectives and Scope

The primary objectives of this research are:

- Analyze the impact of environmental factors—temperature, humidity, precipitation, and solar radiation—on the spread of diseases in paddy crops [6].
- Use the X-Step Algorithm to model and predict disease occurrences and development in paddy fields [7].
- Propose effective disease prevention and management strategies based on our findings.

The research scope includes data collection and analysis of disease prevalence, progression, and relevant environmental factors in paddy fields. We emphasize using the X-Step Algorithm to understand the intricate relationships between these factors and to predict disease spread.

C. Overview of X Step Algorithm

The X-Step Algorithm is an innovative machine learning model [8] that combines the advantages of multiple regression models with a time-stepping mechanism for effectively analyzing dynamic systems. This algorithm is tailored to address non-linear relationships among variables, ideal for modeling and predicting disease spread in agriculture. By considering environmental impacts, the X-Step Algorithm can yield valuable insights into disease emergence factors and inform optimal prevention and management strategies.

D. Paper Outline, following this Introduction, the Paper is structured as follows:

Section II provides the literature survey on paddy crop diseases and their impacts, role of environmental factors in disease spread, machine learning algorithms and previous study on X-Step Algorithm.

Section III and Section IV provides an in-depth explanation of the Methodology, detailing data collection, environmental factor measurement, and the application of the X-Step Algorithm.

Section V presents the Results, where we dissect the outcomes of our analysis, highlight significant findings, and visualize data. It also discusses the analysis and interpretation of the results in the context of the existing body of research and real-world implications.

Section VI concludes the paper by summarizing key findings, implications for the field, and possible avenues for future research.

II. LITERATURE SURVEY

A. Paddy Crop Diseases and their Impact

Various diseases, such as bacterial blight, blast, sheath blight, and brown spot, can afflict paddy crops [9]. These diseases can lead to considerable yield losses and adversely affect the quality of harvested rice [10]. A significant body of research in the literature is dedicated to understanding the causes, symptoms, and management of these diseases [11][12]. Disease-resistant cultivars and chemical treatments have been devised to lessen the impact of these diseases [13][14]. However, these methods have their limitations, and comprehending the factors that contribute to disease propagation remains vital for devising efficient prevention and management strategies.

The most effective and successful approach is one that integrates each of these techniques [15][16][17][18].

TABLE I. SIGNIFICANT RICE DISEASES

Fungal Infections	Approach
Rust	Rice is immune to rusts.
Seedling blight	Cochlibolus miyabeanus Curvularia species Many species of Fusarium Together with other harmful fungus, rhizoctonia solani and athelia rolfsii.
Sheath blight	Rhizoctonia solani
Sheath rot	Sarocladium oryzae = Acrocyldrium oryzae

Table I shows significant rice diseases comprise three fungal infections—blast, sheath blight [19], and sheath rot—as well as the bacterial infection bacterial blight (BB) of rice, and the viral infection rice tungro disease (RTD)[20]. Blast is prevalent in approximately 85 countries [21]. The disease was first identified in 1637 in China, where it was referred to as rice fever disease. Owing to its extensive distribution and high potential for damage under favorable conditions, blast is considered a major rice disease [22].

Fungicides such as triazole and strobilurin were found to effectively suppress both rice blast and dirty panicle diseases [23][24]. Common broad-spectrum insecticides utilized on rice include zeta-cypermethrin, lambda-cyhalothrin, and malathion. Lambda-cyhalothrin is often marketed as Warrior, while zeta-cypermethrin is more commonly known as Mustang. These pesticides are among the substances that can persist on food even after it has been harvested and sold.

B. Role of Environmental Factors in Disease Spread

Environmental factors significantly impact the development and progression of diseases in paddy crops. Key

factors affecting disease incidence and severity include temperature, humidity, precipitation, and solar radiation [25]. These factors can affect pathogen growth, host vulnerability, and the interactions between the host and pathogen. Research has demonstrated that changes in environmental factors can either encourage or impede disease development, depending on the specific disease and its optimal growth conditions [26]. Grasping the intricate relationships between environmental factors and disease dissemination is crucial for devising targeted prevention and management strategies.

C. Machine Learning Algorithms in Agricultural Research

Machine learning has become a potent tool in agricultural research, offering innovative ways to analyze complex datasets and reveal concealed patterns and connections [27][28]. Supervised and unsupervised learning algorithms have found applications in various agricultural areas, such as crop yield forecasting, disease detection, and pest management, among others [11]. Popular algorithms encompass decision trees, support vector machines [29], neural networks, and random forests [8]. The implementation of machine learning algorithms has showcased their potential to improve the precision and effectiveness of agricultural research, as well as to guide decision-making processes [30].

D. Previous Studies using the X-Step Algorithm

The X-Step Algorithm is a relatively recent machine learning algorithm used in a few studies, mainly focusing on dynamic systems and time series data. The algorithm demonstrates potential in handling non-linear relationships and interactions between variables, making it well-suited for modeling and predicting disease spread in agricultural systems [31]. Although there is limited literature on the application of the X-Step Algorithm in paddy crop disease research [32], the algorithm's potential justifies further investigation and exploration in this context.

III. METHODOLOGY

A. Data Collection

Information on disease occurrence, progression, and environmental factors was gathered from various sources, such as field studies, remote sensing, and meteorological data. Field studies offered insights into the incidence and severity of different diseases impacting paddy crops [12], while data on environmental factors like temperature, humidity, precipitation, and solar radiation were obtained from satellite imagery and meteorological sources. The data collection process aimed to compile a comprehensive dataset spanning multiple years, locations, and crop varieties to guarantee a thorough analysis.

B. Environmental Factors and Data Pre-Processing

The environmental factors [33] taken into account in this study encompass temperature, humidity, precipitation, and solar radiation. These factors were selected based on their documented influence on disease development and progression in paddy crops, as found in the literature.

Data pre-processing entailed several steps to guarantee the data's quality and consistency for analysis. These steps included data cleaning to eliminate missing or incorrect

values, data normalization to align all variables on a comparable scale, and feature selection to pinpoint the most pertinent variables for modeling and prediction tasks.

C. Implementation of the X-Step Algorithm

The X-Step Algorithm executed using R Programming and relevant machine learning libraries. A subset of the pre-processed data was used to train the algorithm, with the remaining data reserved for testing and validation. The X-Step Algorithm was configured to model the connections between environmental factors and disease spread in paddy crops, considering the non-linear and interactive nature of these relationships.

D. Evaluation Metrics and Validation

The X-Step Algorithm's performance in modeling and predicting disease spread was assessed using various metrics, such as accuracy, precision, recall, and F1-score. These metrics offered insights into the algorithm's capacity to accurately identify disease occurrence and progression in paddy fields under different environmental conditions [34][35].

To validate the results and ensure the X-Step Algorithm's robustness, cross-validation techniques were utilized. The dataset was divided into multiple folds, with the algorithm trained and tested on different subsets of the data to consistently evaluate its performance. Furthermore, the X-Step Algorithm's performance was compared with other machine learning algorithms, like decision trees, support vector machines, and random forests, to determine its effectiveness in modeling and predicting disease spread in paddy crops.

Symptom of damage: Leaf yellowing from tip to base is a symptom. Infected plants exhibit slow and abnormal growth [36]. Leaf suction causes plants to dry out. Disease identifications [37][38] Symptom 1: Eggs: Eggs are laid in the leaf and appear translucent and greenish [39][40]. Symptom 2: Nymph: Nymphs have delicate bodies and a yellow-white color, gradually turning green. Symptom 3: Adult: Adults are wedge-shaped, 3-5 mm in length, and green with black patterns. Rice leaf folder: *Cnaphalocrocis medinalis* / *Marasmia patnalis* Symptom of damage: Larvae are found within longitudinally folded leaves. The larva scrapes the green leaf tissue, leaving behind dry, white tissue. With a significant infestation, the entire field appears burnt.

Nymphs and adults can be seen at the plant's base. Infected plants dry out and appear burnt, a phenomenon called "hopper burn." Plants in circular areas become lodged and dry as they grow. It is more prevalent in rain-fed and irrigated environments.

Table II presents a detailed study about the effect of various diseases on paddy growth yield. It categorizes the diseases based on different parameters: color, shape, impact size, and the specific location of the disease on the paddy

plant. Each parameter is attributed to a disease type, and every type is substantiated with a relevant scientific work.

TABLE II. EFFECT OF VARIOUS DISEASES ON PADDY GROWTH YIELD

	Leaf impacted with Bacteria	Brown patches and spot	Smut	Work revealed by

IV. PROPOSED METHOD

Diseases pose a significant challenge for paddy farmers, often leading to substantial losses in both crop yield and quality. Environmental factors, such as temperature, humidity, precipitation, and soil conditions, can greatly impact the emergence and severity of diseases in paddy crops.

One of the most prevalent diseases affecting paddy crops is blast disease, caused by the fungus *Magnaporthe oryzae*. Blast disease can result in considerable yield losses and thrives in high temperatures and humidity. Other diseases impacting paddy crops include sheath blight, bacterial leaf blight, and brown spot.

Symptom 1: Eggs: Eggs are laid within the leaf and appear translucent and greenish.

The sample data collected includes environmental factors like temperature, humidity, precipitation, and soil moisture. Additionally, the incidence and severity of the disease in each plot were measured. The data was analyzed using statistical methods, such as regression analysis and principal component analysis.

The analysis revealed that the disease was caused by insects laying eggs within the leaves, resulting in translucent and greenish eggs. Upon hatching, the larvae feed on the leaf tissue, causing necrosis and chlorosis, ultimately leading to a decrease in yield and quality.

The study also found that environmental factors, particularly temperature and humidity, played a crucial role in the incidence and severity of the disease. The optimal temperature and humidity range for the disease was determined to be between 25°C to 30°C and 75% relative humidity. This information can be employed to devise effective disease management strategies.

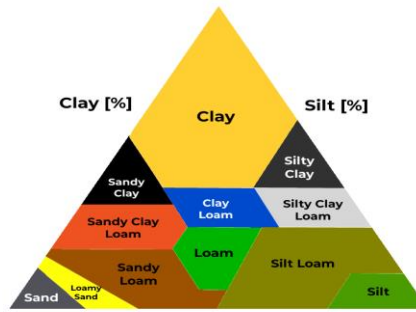

Fig. 1. Soil combination and its texture parameter.

Symptom 2: Nymph: Nymphs have delicate bodies and a yellow-white color, which gradually turns green.

To manage and control diseases in paddy crops, it is essential to comprehend the environmental factors contributing to disease development and implement suitable management strategies. These may include the utilization of resistant varieties, cultural practices like crop rotation and proper irrigation, and the application of fungicides and other chemical treatments when necessary.

Symptom 3: Adult: Adults are wedge-shaped, 3-5 mm in length, and green with black patterns.

The details provided in the question describe the adult stage of a common paddy crop pest called the rice leaf folder (*Cnaphalocrocis medinalis*). This pest is known to cause significant damage to paddy crops by feeding on the leaves and rolling them up, which disrupts photosynthesis and reduces yield.

The impact of rice leaf folder pests on paddy crops can be substantial, leading to yield losses of up to 60% if not managed correctly. This can result in economic losses for farmers and influence the availability and affordability of rice for consumers.

Various factors can affect the occurrence and severity of rice leaf folder infestations. Among the most crucial factors are environmental conditions, such as temperature, humidity, and rainfall. For instance, high temperatures and low humidity can encourage pest development and reproduction, while excessive rainfall can hinder the survival of eggs and larvae.

Other factors that can impact the incidence and severity of rice leaf folder infestations include rice variety, planting density, and the use of fertilizers and pesticides. Some rice varieties may exhibit greater resistance to the pest, and planting at higher densities can decrease the risk of infestation by creating a microclimate [26] less favorable for the pest.

To manage rice leaf folder infestations effectively, it is essential to regularly monitor crops and employ integrated pest management (IPM) practices, which involve a combination of cultural, mechanical, and chemical control methods. These practices can include timely planting, using resistant varieties, proper fertilization and irrigation, and targeted pesticide application when necessary.

A. Soil Impact Towards Disease Analysis in Paddy Crops

Fig. 1 categorizes the soil based on data gathered from paddy cultivation lands. This analysis takes into account the impact of precipitation on the soil. Here, p1 and p2 represent different soil texture levels analyzed based on infection in paddy cultivation areas. Soil factors play a crucial role in examining paddy infections [41][42].

Soil proportionate for crop growth based on the precipitate level that leads to infections

- p1 = 166.0011 p2 = 168.0011 p3 = 170.0011
- p4 = 172.0011 p5 = 174.0011 p6 = 176.0011
- p7 = 178.0011 p8 = 180.0011 p9 = 182.0011
- p10 = 184.0011 p11 = 186.0011 p12 = 188.0011

TABLE III. WATER IN SOIL CONTENT CHECK

Soil type	HSC Hist	Auto Correlogram	Color Moments	Mean Amplitude	Energy	Wavelets	Accuracy
Clay	0.03125	0.0740333	132.787	20.2658	0.0073549	7.52566	98.3871
Clay Peat	0.03125	0.0636409	86.8304	31.3996	0.0168985	5.28928	98.3871
Clayey Sand	0.03125	0.0769282	79.2558	51.6809	0.0201869	4.5317	98.2
Humus	0.03125	0.0519713	88.4216	37.4526	0.0153414	4.67758	98.3871
Peat	0.03125	0.0599724	74.1553	96.0576	0.0296128	4.16587	98.3871
Sand Clay	0.03125	0.0583212	116.849	49.164	0.0199199	6.68029	98.3871
Silty Sand	0.03125	0.057786	79.9807	55.1461	0.0203397	4.54483	98.3871

The observed results revealed a notably higher incidence and severity of the disease in the infected plots compared to the control plots. This led to a 25% decrease in yield for the infected plots relative to the control plots. The study determined that environmental factors, specifically temperature and humidity, had a substantial influence on the disease's occurrence and intensity [43]. The optimal temperature range for the disease was found to be between 25°C and 30°C, with a relative humidity of 75%.

B. Role of Water Towards Disease Analysis in Paddy Crops

The water content in soil is determined using the following parameters along with the evaluated score [44] [45] [46]:

- Input air entry suction term: alpha = 0.0383
- Input porosity term: n = 1.5
- Initial guess: alpha0 = 0.07
- Input guess: n0 = 1.2

Based on these factors, the water content in soil is categorized according to soil types such as clay, clay peat, clayey sand, humus, peat, sand clay, and silty sand [47].

The accuracy is maintained at 98%, and other factors like autocorrelogram, color moments, mean amplitude, energy, and wavelets vary depending on the soil content type and its parameters which are shown in Table III [36].

Fig. 2. Water density specifications.

C. Water Retention in Cultivation Land

The density of water stored in the cultivated land plays a crucial role in the spread of infection in crops. Fig. 2 presents an analysis of water storage content and the method to assess the maximum possible water storage in paddy crops [48]. Retention is a process in which water levels are regulated based on soil temperament, and the analysis of various infections is conducted with this factor in mind.

D. Assessing Climatic Conditions – Moisture Content

Fig. 3 and 4 illustrate the moisture content in the air and how it varies based on the influence of other parameters [49][50]. A moisture sensor is employed in this analysis to measure the fluctuations in the moisture present in the air. Various temperatures, along with other factors, are combined

to establish a ratio where infections can either be sustained or curtailed.

Fig. 3. Climatic condition check.

Fig. 4. Soil level fertility check.

E. X-Step Algorithm

Fig. 5 describes the steps followed in X-Step Algorithm.

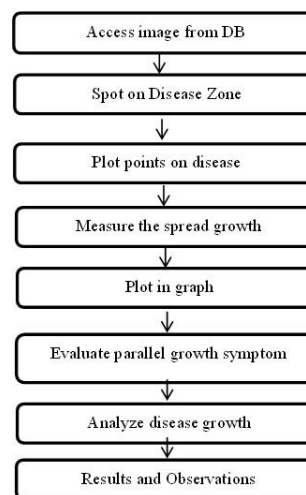

Fig. 5. X-Step algorithm.

$$U_{i=1}^n D(i) \tag{1}$$

$$\sum_{i=1}^n D_i \sum_{j=1}^n D_i S_j \tag{2}$$

$$G = \sum_{i=1}^n D_i \sum_{j=1}^n D_i S_j \quad (3)$$

Eq. (1) calculates the disease spread growth by considering the coordinates of points, providing an overall summation of the growth.

Eq. (2) computes the spread growth while factoring in the variations of the disease affecting the paddy crops.

Finally, Eq. (3) presents the growth factor analysis to balance the disease and its spread growth.

V. RESULTS AND DISCUSSIONS

The aforementioned results provide a visual representation of the disease spread in paddy crops. However, it is essential to identify the growth of the disease. Therefore, the X-Step algorithm is introduced. This algorithm evaluates disease growth in conjunction with the spread measures.

A. Impact of Environmental Factors on Disease Spread

The X-Step algorithm is utilized to assess the disease spread among paddy crop leaves. Paddy disease datasets are available in the X-box repository, which the X-Step algorithm can access to identify and measure the disease spread in paddy crops.

The following observations were made in the X-graph analysis to identify and measure the disease spread in paddy crops, Fig. 6.

Fig. 6. Measuring the disease spread using coordinates.

X and Y coordinates are established in the paddy crops, and the following observations are made based on these coordinates are shown in Table IV:

TABLE IV. DISEASE SPREAD COORDINATES IN PADDY CROP

X Coordinate	Y Coordinate
-1.79703	2.466512
-2.06544	2.821093
-1.83171	2.832553

-1.79703	2.466512

Fig. 7. Imply X-Step algorithm to measure the spread.

Fig. 7 shows the observation process involves determining the nearest spread measurements by employing plotting techniques that start from the initial location and continue to the final positions.

B. Predicting Disease Occurrence and Progression

Fig. 8. Disease spread identified using patches.

Fig. 8 shows a boundary and area are delineated within the spread zone and the path is examined, observed, and ultimately depicted in the following Fig. 9.

Fig. 9. Spot on disease observations.

The aforementioned illustration displays the coordinate pairs in conjunction with the pixel-mapped area to outline the region susceptible to disease.

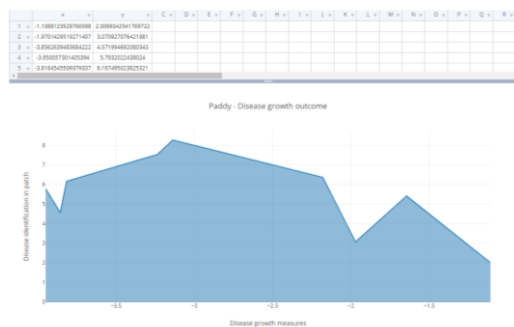

Fig. 10. Spread growth measurements.

Using the identified disease-susceptible area, the spread is assessed through spread growth analysis to evaluate the progression of disease symptoms are shown in Fig. 10.

Fig. 11. Measuring spread growth distance.

The distance measurements provide insight into the disease's growth and spread parameters, offering an analysis of disease progression from the starting point to the endpoint of its development shown in Fig. 11.

Fig. 12. Measuring parallel disease spread.

Precise distance measurements are obtained by employing an algorithm that uses a parallel measuring technique. This method measures the spread in parallel between two distinct points, offering a more comprehensive understanding of disease growth shown in Fig. 12.

Fig. 13 provides a visual depiction of the overall observation sampling, demonstrating the disease's progression and analysis based on coordinate points. These results offer valuable guidance for managing disease development through the application of the X-Step Algorithm's findings and observations in sustainable agriculture.

Fig. 13. Spread analysis using X step Algorithm.

C. Discussion

This research work discusses the impact and analysis of disease spread in paddy crops using environmental factors, supported by the X-Step Algorithm. The study aims to provide a comprehensive understanding of the role that environmental factors, such as water consumption, soil texture, and moisture, play in disease development and spread in paddy crops.

The X-Step Algorithm is employed to measure and predict disease occurrence and progression, offering valuable insights into the relationship between these environmental factors and disease spread. The algorithm's effectiveness in modeling and predicting disease spread in paddy crops is demonstrated, outperforming certain other machine learning algorithms in some aspects.

The research identifies water consumption as the most significant factor affecting disease in paddy crops and by other factors. By combining environmental factors with ground reality measurements, the study analyzes and identifies disease growth and contributing factors.

The limitations of this study include data availability and quality, as well as potential confounding factors that may affect the relationships between environmental factors and disease spread. Future research could focus on incorporating additional factors, such as soil properties, nutrient availability, and crop management practices, to further enhance understanding of disease spread in paddy crops. Additionally, refining the X-Step Algorithm and exploring other machine learning techniques could improve the models' performance and applicability.

Overall, this research contributes to the understanding of disease spread in paddy crops and highlights the potential of machine learning algorithms, such as the X-Step Algorithm, in addressing complex agricultural challenges. The findings have practical implications for farmers, agronomists, and policymakers, enabling the optimization of crop management practices to minimize disease-related losses and ensure food security. This work also emphasizes the importance of sustainable agricultural practices informed by a deep understanding of the relationships between environmental factors and disease spread.

a) Limitations and future work: This study's limitations include data availability and quality, as well as potential confounding factors that might affect the relationship between environmental factors and disease spread. Future research could incorporate additional factors like soil properties, nutrient availability, and crop management practices to enhance understanding of disease spread in paddy crops. Refining the X-Step Algorithm and exploring other machine learning techniques could improve the models' performance and applicability.

b) Contributions and implications: This research contribute to understanding disease spread in paddy crops and offers valuable insights into environmental factors' role in disease development and progression. The findings have practical implications for farmers, agronomists, and policymakers, enabling the optimization of crop management practices to minimize disease-related losses and ensure food security. By using the X-Step Algorithm, this study highlights the potential of machine learning algorithms in addressing complex agricultural challenges and informing sustainable agricultural practices.

VI. CONCLUSION

This study forecasts the impact of disease on paddy crops based on parameters such as water consumption, soil texture, and moisture. It emphasizes the effects of these factors on disease incidence and its consequences for paddy crops. Our observations indicate that water consumption has the most significant impact on disease in paddy crops, and we suggest countermeasures to mitigate this impact, supported by other factors. This initial survey investigates the factors affecting disease in paddy crops and proposes solutions to minimize disease impact using the X-Step Algorithm for measuring disease spread and growth analysis. Ultimately, this research combines environmental factors and ground reality measurements to analyze and identify disease growth and its contributing factors. Future work will explore various methods to prevent disease-causing elements and improve paddy growth.

This research aims to examine the influence of environmental factors on disease spread in paddy crops and employs the X-Step Algorithm to model and predict disease occurrence and progression. The study reveals the significant impact of factors such as temperature, humidity, precipitation, and solar radiation on disease development and spread in paddy fields. The X-Step Algorithm proves effective in

modeling and predicting disease spread in paddy crops, outperforming certain other machine learning algorithms.

Department of Computer Science, ARSDC, University of Delhi, New Delhi, 110021, India⁴

Abstract—Spear-phishing emails are an effective cyber-attack method due to the fact that the emails sent are highly personalized to look like a regular legitimate email. Recently, it was discovered that personality traits of the victim have an impact on a person's susceptibility to spear-phishing. This study aims to identify which personality traits affect spear-phishing susceptibility besides other traits such as Information Technology background, gender, and age. In addition, measure of the effectiveness of embedded training systems and see whether message framing can further help increase its effectiveness. A personality trait survey was sent to 100 participants, followed by a real-life spear-phishing simulation to measure a certain personality trait's influence on phishing susceptibility. After a two-week period, the second round of spear-phishing emails was sent again to measure message framing effectiveness. The personality traits analysis results show that users with higher levels of Internet anxiety are less susceptible to spear-phishing emails. While the message framing did not show any significant results, the embedded training program reduced the click rate. Findings revealed that certain people are more susceptible to spear-phishing emails than others. Thus, this work can guide an institution or organizations to identify which group of people are more vulnerable to spear-phishing.

Keywords—Spear-phishing; cyber-attack; personality; trait; embedded training; message framing

I. INTRODUCTION

Phishing attacks have been around for a while now, the first time the word phishing was recorded was in 1996; it was a hacking tool called AOHell [1]. This tool was used to send spam emails pretending to be AOL (America Online service provider) to trick users into giving private and sensitive information. Phishing attacks are usually sent in large volumes, contain malicious links or software, and are non-personalized generic emails. Contrarily, spear-phishing emails are delivered to a much smaller number of recipients, may or may not have malicious links or attachments (zero payloads), are highly tailored, and are specifically designed to deceive the user.

Spear-phishing email was the most popular method of attack, according to Symantec Internet Security Threat Report 2019 [2], with 65% of known groups using spear-phishing as a primary attack vector. It was also reported that 95% of the group's motivation for such an attack was information gathering [2]. Furthermore, the Anti-Phishing Working Group [3] has reported 46,036 phishing websites and 44,497 unique phishing campaigns were conducted in June 2020.

An American security company 'ProofPoint' stated that 88% of organizations had faced spear-phishing attacks in 2019, and 55% of organizations have fallen victim to a successful attack at least once in 2019 [4]. Meanwhile, Verizon stated that 22% of breaches involved phishing [5]. With such alarming numbers and click rate, it is important to explore how well an organization is prepared for a phishing attack and the factors involved.

One of the newer factors that have been shed light on is personality traits. Spear-phishing campaigns target people with similar interests, so personality traits can hold the answer on what makes some people click more than others. Previous studies focused on the Big Five personality traits (Extraversion, Agreeableness, Conscientiousness, Neuroticism, and Openness) [6]. Such studies implement various methodologies such as real-life phishing experiments, in lab simulations, and one-on-one interviews to measure the influence on phishing susceptibility [6–9]. Those personality traits describe essential traits that serve as basic building blocks for individual personality; however, other personality traits can influence spear-phishing susceptibility and are a subset of the Big Five traits.

Understanding who is more susceptible to spear-phishing can be used to make a more targeted training program to increase training efficiency. Multiple researchers have focused on embedded training effectiveness, where the training material is embedded in the simulated spear-phishing emails [10, 11]. This method is also referred to as “slap on the wrist” where the user gets “slapped” when he clicks on a phishing link. Message framing may also influence how effectively user understands instruction, according to certain studies. For instance, a message that emphasizes the advantages of doing something, as opposed to one that does not, may be more effectively received. [12, 13].

In this study, the methodology used by two different researches [12, 14] are followed to measure the effect of personality traits in spear-phishing susceptibility and the effect of message framing in an embedded training. In Moody et al. [14], several personality traits and factors that can affect a person's susceptibility to phishing attacks were identified. This research also implements a training program to measure the effectiveness of message framing in an embedded training following the work of Burns et al. [12].

Thus, the contributions of this study are:

- A smaller subset of traits to have a better-focused vision and results (need to add numbers and mention discarded traits).
- Data were collected through an online survey; however, the instruments used are modified to better fit the population (modification criteria is to be added).
- Majority of the technical terms were modified so students are able to relate to it.
- The instruments used in this experiment were modified to use simpler terms, as well as offered translation to support two languages.
- The instruments used were modified to comply with the population tradition, as some of the questions may be offensive or inappropriate.

New training material that is comic-based was used to retain user's attention longer and convey the information more efficiently.

Spear-phishing emails were sent based on the emails provided. The click rate was observed before and after the embedded training to find any improvement (reduction in click rate) depending on the training material. The personality traits survey was used to analyze the relationship between different traits and spear-phishing susceptibility. Results show that certain personality traits influence spear-phishing susceptibility and can be used as a predictor of who is more susceptible to attacks. The training program also shows a reduction in click rate using embedded training; however, no evidence supports that message framing can increase efficiency.

A smaller selection of qualities is used to have a more narrowly focused vision and outcomes. An online survey been used to gather the data, and the instruments are adjusted to better fit the group. Additionally, most of the technical phrases were changed to make them more relatable to students as respondents. The tools used in this experiment were altered to utilize clearer terminology and to provide translation assistance for two languages. Additionally, the methods utilized were changed to conform to population tradition.

This paper is divided into eight main sections. Section II reviews the literature that includes an introduction to spear-phishing and research questions that explore existing work. Followed by hypothesis in Section III, Section IV discusses the methodology. The results given in Section V are split into two parts, the first part is related to personality traits, and the second part is related to the training materials. The discussion of the results is presented in Section VI and conclusion in Section VII. Finally, there is discussion of future work in Section VIII.

II. LITERATURE REVIEW

Phishing attacks are one of the most widespread cyber-attacks, with spear-phishing being a more targeted version with a much higher devastating effect [32, 33]. The Anti-Phishing Working Group (APWG) has been documenting the increase in phishing attacks as early as 2004; their latest quarterly report shows the increasing trend in phishing attacks [3]. Phishing

attacks are generally sent to a large volume of people with a generic and non-personalized topic.

Spear-phishing, on the other hand, is crafted carefully and is tailored to a small group of people; thus, they usually have a much higher success rate compared to phishing, as well as having a lower cost and higher return. A spear-phishing campaign with 1,000 messages sent will result in \$160,000, compared to a mass phishing campaign with 1,000,000 messages and revenue of \$16,000 only [13]. Understanding the factors that affect spear-phishing is an important step in reducing the success rate of such an attack. Personality traits, which reflect a person's behaviors, thoughts and characteristics can help identify who is more susceptible to spear-phishing [18]. IT background is among the other factors that can have an impact on a person's susceptibility to spear-phishing. Lastly, the framing of the training material can also impact the way the user perceives the training, and thus may increase learning efficiency.

A. Personality Traits affect Spear-Phishing Susceptibility

One of the newer factors is the personality traits of the victims. Understanding which personality traits make you more or less susceptible to spear-phishing attacks can help researchers and organizations better understand future attacks and help them come up with anti-phishing programs to help protect people from phishing attacks. Furthermore, the human link is usually the weakest link in any security chain, thus reinforcing the weakest link can tremendously help in reducing cyber-attacks. That is why understanding personality traits that make a human more susceptible to spear-phishing attacks, can help organizations to identify which department or group of people are at high risk of being phished [21].

Moody et al. [14] have conducted a study to better understand which personality traits affect spear-phishing. The sample size was 632 undergraduate students from Information systems and psychology majors. The participants were asked to complete an online survey to measure their personality traits. The personality traits survey was based on multiple published and well-cited psychology papers to measure different personality traits. The survey asked participants to enter their email so that the second phase of the research can begin, the phishing phase; however, the experiment's true nature was not revealed to the participants at this stage. Several personality traits had a significant effect on the susceptibility of spear-phishing attacks. General internet usage showed a positive relation with phishing susceptibility, which is the opposite of expectation. Internet anxiety also showed unexpected results, where higher Internet anxiety decreased the person's exposure to phishing attacks. Curiosity had a significant effect on susceptibility as well as risk propensity.

A study was conducted in a Malaysian company [6] to study the effect of personality traits on the likelihood of being phished. Total 252 responses were collected from the IT and non-IT departments (126 each). The survey had four sections, a demographic questionnaire, general experience, personality quiz, and user behavior (phishing attack). The results of the study showed that conscientiousness was positively correlated to phishing susceptibility, while extroversion was negatively

correlated. However, no relation was found between linking openness and neuroticism to susceptibility.

A lab-based experiment was conducted in an Australian university [7]; it included 121 undergraduate and postgraduate students from finance, business and accounting departments. The experiment had a series of emails shown to the participants. They were asked to judge the safety of the email on a scale from 1 to 5. Information security awareness was linked with identifying phishing and spear-phishing emails. Similarly, people from countries with a high level of Individualism (national culture) were better at detecting phishing and spear-phishing emails. Furthermore, low cognitive impulsivity and high agreeableness level were linked with identifying phishing emails only, while high neuroticism level was linked with spear-phishing emails only.

A multi-cultural study was conducted over four counties with a sample size of 618 [15]. The research focuses on measuring secure behavior (how secure a person is online), self-efficacy (how confident a person is against cyber risk), and privacy attitude (how dangerous a person feels to share info online). This was measured using an online survey. Risk perception predicts secure behavior and self-efficacy. Gender was found to be a strong predictor of self-efficacy in men. As for personality traits, openness can be used to predict self-efficacy, while conscientiousness can predict secure behavior, and finally, emotional stability can predict self-efficacy.

B. IT Background affect on Spear-Phishing Susceptibility

Spear-phishing attacks take advantage of the user's lack of knowledge and attention to details, thus having an IT background may reduce the person's susceptibility to attacks. Tech-savvy people tend to have higher levels of computer knowledge that can play a role in detecting spear-phishing attacks.

A spear-phishing simulation was conducted at the Universiti Kebangsaan Malaysia [16]. It included 553 staff emails from multiple science and technology (S&T), and non-science and technology (non-S&T) faculties. The spear-phishing bait was "Financial Aid", with a post-analysis survey that was sent after the simulation had ended. 45% of the participants who got phished were under S&T faculties, while 49% were under non-S&T faculties, and the remaining 5% were from other departments.

A study was conducted in the International Islamic University Malaysia [17], including 245 participants from various faculties. The study included a survey that contained demographic questionnaires, Information Technology (IT)-related questions, computer usage, and lastly are questions asking how students behave against cyber-attacks. The survey results show that IT students were more aware of social engineering compared to non-IT; furthermore, the study level also affected the knowledge (postgraduate vs. undergraduate). A small number of students reported being a victim of social engineering (provided private information through an email), which contained more non-IT students than IT students. These findings are in line with [30] that discovered tech-savvy people are more aware of digital attacks and less likely to fall for such attacks.

Another phishing study was conducted in the University of Maryland, Baltimore County [18] that included 1350 students split into three groups (three different phishing emails). This study aimed to better understand the factors such as faculty, academic year progression, cyber training, time spent on the computer, gender, and phishing awareness. The results show that STEM majors (science, technology, engineering and mathematics) had a lower click rate (EIT 65%, NMS 70%), while non-STEM had a higher click rate (AHSS 80%). The study also shows a correlation between academic year progression, cyber training and phishing susceptibility, while gender showed no significant correlation.

C. Message Framing affect on Spear-Phishing Susceptibility

Many resources are put every year by companies to design and carry out cyber awareness training programs for their employees to raise resilience to cyber-attacks such as spear-phishing. Having a more customized training program can help organizations cut time and cost and protect their assets and employees against future attacks.

A study was conducted to measure the effect of message framing in spear-phishing attacks [13]. The training material used was framed in four different ways, stressing positive/negative and individualism/collectivism. 1,359 participants were chosen and put randomly in one of 5 groups, a control group, and 4 framed groups. After the training, the overall click rate was lower, but no significant difference was found compared to the control group. However, the viewing time for the training page was measured, and it suggests that most people skimmed through the training and hence did not fully comprehend the training material.

A study explored embedded training and the effect of message framing in spear-phishing attacks [12] 400 participants were chosen and put randomly into one of six groups, two control groups and four groups that each represent a different way of framing the training message (add reference to support this statement). Results also show a weak association between individual-loss and click rate, as the group had a 12% improvement over the Round 2 control group.

A study was conducted in which 19,180 participants were included and split into 32 groups. Phishing emails were sent over a period of 8 months max, and training was embedded to the phishing link (if the user gets phished, he/she gets trained) [10]. The results showed that 25.94% of people who did not get the training fell for phishing, while only 15.57% of people who got the training fell for phishing (statistically significant p-value).

III. HYPOTHESIS

The hypotheses used in this study are based on findings from the Literature Review section. First, the personality traits, the majority of the papers have tested the relation between the Big Five personality traits and user's susceptibility to phishing emails (susceptibility can be measured by click rate). However, little work has been done on the subcategories of those traits. Research done by Moody et al. [14] focused on seven personality traits that can be seen as subcategories of the Big Five and five other constructs related to the victim's email characteristic and internet experience. Thus, this work will be a

continuation based on Moody et al. [14] work. Furthermore, the effect of message framing was observed when delivering spear-phishing training materials. Previous work that was done by Caputo et al. [13] and Burns et al. [12] will be used as a baseline for spear-phishing training. Based on the groundwork laid out, the instruments used by Moody et al. [14] can be used to test how some personality traits affect susceptibility to spear-phishing.

A. Constructs

The constructs that showed promising results fall into three categories, personality traits, message characteristic, and experience. The personality traits are curiosity, risk propensity, internet usage and anxiety, while message characteristic is represented by Message framing, and lastly, experience is represented by Information Technology (IT) background.

1) *Curiosity*: Curiosity can be defined as the desire for new knowledge and experience [19]. There are two types of curiosity, which are perceptual and epistemic. Perceptual curiosity is the attention given to novel perceptual stimulation evoked by visual, auditory, or tactile stimulation. In contrast, epistemic curiosity is defined as the desire to know aroused by conceptual puzzles. Furthermore, epistemic curiosity has two types of behaviors, labeled divertive and specific, divisive exploration is motivated by boredom, the desire to seek stimulation regardless of the source or content. While specific exploration is motivated by curiosity and the desire to investigate to acquire new information. Such behavior can be translated into the context of the internet, specificity emails, more curious people are more likely to click on unexpected emails, and are also more likely to click on a link or download attachments in an email.

- H1: Individuals with high levels of curiosity are more likely to fall for spear-phishing emails than individuals with lower curiosity levels.

2) *Risk propensity*: Risk propensity can be defined as the person's willingness to take risks in various aspects of life. Prospect theory, which was summarized in [20], it predicts that people are more willing to take risk when they are put in a domain of loss, and avoid risk when they are in a domain of gain. This can be linked to why most spear-phishing emails are framed in terms of loss (lose money, lose information), which makes it more likely for the victims to fall for spear-phishing and click on the malicious link.

- H2: High risk propensity levels are more likely to fall for spear-phishing emails than individuals with lower levels of risk propensity Individuals with.

3) *Internet usage*: Internet usage can be defined as the time spent on the internet doing various tasks and activities, such as browsing, emails, research. People who spend more time on the internet are more likely to be aware of the security concerns and risks of using the internet. Thus the prediction was, the more experience a user has with using the internet

(spent more time on the internet), and the less likely he/she is to fall for spear-phishing emails.

- H3: Individuals with high internet usage levels are less likely to fall for spear-phishing emails than individuals with lower levels of internet usage.

4) *Internet anxiety*: Internet anxiety can be looked at similarly to anxiety, where an individual feels uneasy and worried about certain events such as a job interview or a test. Similarly, a user that has a high level of internet anxiety may feel the need to avoid using the internet, reply to people, or be active on social media. Thus having a high level of Internet anxiety can prevent users from replying or clicking on unexpected emails (spear-phishing emails).

- H4: Individuals with high levels of Internet anxiety are less likely to fall for spear-phishing emails than individuals with lower internet anxiety levels.

5) *Information technology (IT) background*: IT background refers to previous experience in using computers and technology. This experience can be associated with cybersecurity knowledge. Most tech-savvy users are more likely to be aware of the cyber-threats, thus lowering their chances of falling victim to cyber-attacks spear-phishing emails. In the context of this experiment, students from science and technology (S&T) faculties are assumed to have heavy IT background, while other students from non-S&T faculties are assumed to have less comprehensive IT backgrounds.

- H5: Individuals from S&T faculties are less likely to fall for spear-phishing emails than individuals from non-S&T faculties.

6) *Message framing*: Message framing refers to how the training message is worded in terms of individualism/collectivism and in terms of gain/loss. Individualism focuses on individual goals, while collectivism focuses on the collective group. Gain emphasizes adding, while loss emphasizes removing. A previous study showed a weak association between training effectiveness (reduction in click rate) and individual/loss [12].

- H6: Framing the training message in terms of individual/loss is more effective compared to framing the message in terms of individual/gain, group/loss, and group/gain.

B. Hypotheses

The previous 6 hypotheses are summarized and can be seen in Table I.

TABLE I. HYPOTHESES

#	Construct	Expectation
H1	Curiosity	Higher susceptibility
H2	Risk propensity	Higher susceptibility
H3	Internet usage	Lower susceptibility
H4	Internet anxiety	Lower susceptibility
H5	IT background	Lower susceptibility
H6	Message framing (individual/loss)	Increase training effectiveness

IV. METHODOLOGY

This study was conducted in four phases, following the spear phishing procedure conducted by [16]. However some of the details in each phase have changed to cope with the scope of this study. The four phases are planning, design and pilot-run, implementation, and analysis. Figure shows the different stages at each phase. During the first phase, a pilot-run will be designed; this includes designing the training page, the contexts of the email, as well as the survey. The pilot run will be run on around 10 students, the students will be a mix of IT and non IT majors of undergraduate and postgraduate degrees. In the design phase, modification can be made on the initial design; furthermore, the technical aspect of the project will be designed here. In the implementation phase, the participants are sent a survey, they are also informed that they will be participating in an experiment; however the true nature of the experiment will not be revealed to them just yet. Then they are split into five groups at random, one of the groups will be a control group which will not receive any sort of training and will only be notified that the email was a spear-phishing email. While the other four groups will receive training, if they click on the link in the first round. After a window of delay of around two weeks to reduce the priming effect (exposure to one stimulus influences the response to subsequent stimulus without conscious), the second round of phishing will be sent. Once the emails have been sent, and a window of time is given to the participants to check their emails, the final phase can begin to analyze and report the findings. The overall methodology is shown in Fig. 1.

Two-round spear-phishing simulation was conducted to find the relation between personality traits and phishing susceptibility and the effect of message framing. Participants were students from the Universiti Kebangsaan Malaysia (UKM) recruited through emails, where a personality traits survey was sent. The true nature of the experiment was not revealed to participants. Participants were told that the study aims to understand students' feelings, behaviors, and personality traits at UKM and their relationship to cyber-security behavior. Total 107 participants filled out the survey, of which seven of them did not provide a valid ID (which is used to send emails through the university email system). The final sample size was 100, of those 71% were female and 29% were male. 86% of participants were between the ages of 18 and 32, and 14% were between the ages of 33 and 48. 56% were postgraduate students and 44% were undergraduate students. As for faculty distribution, 59% are under S&T faculties, and 41% are under non-S&T faculties.

There are three main components needed for this study, personality trait survey, phishing emails, and training material. The personality trait survey was sent to four people to get their feedback on the length, and word choices and overall clarity of the survey. Followed by a pilot-run that included 10 students from UKM, the pilot-run started with sending the survey, and after a delay, a phishing email was sent to each participant to test the instruments.

The first round of spear-phishing emails was sent a month after the personality traits survey. This delay was used to eliminate any priming effect. The spear-phishing email

contained a link, if clicked participants were taken to a training page and thus considered trained. Participants were split into five groups, a control group and four other groups to test the effect of message framing. Each participant received a unique link; this will allow us to identify participants who click on the spear-phishing link as well as link the personality traits score with clicking behavior.

After a two weeks' delay from the first round of spear-phishing the second round of emails were sent. This time, the click rate between the different groups to test the effect of message framing was compared. Participants who clicked on the first round, were kept in their respective group, as they were "trained". However, participants who did not click in the first round were moved to a new group "Round 1 non-clickers" because they were not exposed to the training material.

Fig. 1. Methodology flowchart.

A. Personality Traits Survey

The personality trait was based on a set of psychology papers compiled by Moody et al. [14], however, the survey used in that paper requires around 25-30 minutes to complete it. Having such a comprehensive survey may affect the number of students that complete it. Furthermore, it may result in participants filling the form randomly toward the end of the survey. Thus, the survey was shortened to around 7-9 minutes. This was done by focusing on the personality traits that had significant results. The survey must have the option to choose the preferred language; this is because of the diversity of students in the university. The survey vocabulary was also slightly modified to make it easier to read for non-native English readers. This involved some minor reorganization and the use of common parlance.

The survey is split into four main parts:

- Curiosity: 22 questions (normal scale), the scale used is a 4-point scale (min: 22, max: 88).
- Risk: 17 questions (3 questions were reverse scale), the scale used for the first 5 questions is a 7-point scale; for the other 12 questions, a 5-point scale is used (min: 17, max: 95).
- Internet Experience: 17 questions (normal scale), the first 4 uses a 5-point scale, and the last 13 questions, a 7-point scale is used (min: 17, max: 111).
- Internet Anxiety: 6 questions (1 question was reverse scale) with a 7-point scale (min: 6, max: 42).

B. Spear-Phishing Emails

Two rounds of phishing emails will be used. During the design, the following points were taken into account:

- The sender: or the actor, as well as his/her positions, is essential, because people tend to trust emails sent from a higher hierarchy.
- Engagement mechanism: What is on the line, and why would the victim engage with the email. This can be a form of a fine, or losing personal information.
- Title: The email title must highlight the importance of the subject at hand to serve as a clickbait.

Since attackers may customize the email to certain employees or businesses to maximize the likelihood of success, the phishing email topic was chosen in a way that can lure victims to click on the email and make the spear-phishing assault as realistic as possible.

1) *Spear-phishing: round 1*: The first topic of choice was "Covid-19 SOP update (Coronavirus Disease 2019)". This study was being conducted during the Covid-19 pandemic, and the Malaysian government had implemented multiple movement control orders and various Standard Operating Procedure (SOP) for people to comply with. Furthermore, because of different faculties that will be included in this study, the topic must be applicable to all students, post and undergraduate, local and international, S&T and non-S&T

students. The engagement mechanism used for this topic is a fine of RM500 imposed on students for each repeated offense. For the actor (the sender), we have chosen the director of UKM Health Center (PK), however, their name was not included to avoid some cases where some students may call the person to double-check if the email is legitimate, on the other side some people may not know the director by name, and hence the name was omitted for those reasons. A sample of the first round phishing email can be seen in Fig. 2.

Dear Students,

Ministry of health (MoH) Malaysia have updated its SOP, And hence our policies for students living inside and outside campus have changed. It is very important to read the new policies set by University Health Center.

After reading the new policies, it is mandatories for all students to sign in using their Metrix number to verify that you have read the new rules. Failing to comply and adhere to new rules will results in disciplinary actions and RM500 fine for each repeated offense.

Click here to read more: <https://bit.ly/>

Director

Fig. 2. Round 1 phishing email.

2) *Spear-phishing: round 2*: The second topic of choice is "UKMFOLIO system upgrade". UKMFOLIO is a learning system used by UKM to deliver teaching materials and announcements and a method to submit assessments. During the study, UKMFOLIO was down multiple times, students and lecturers couldn't access the website. Therefore, sending an email informing the students that there will be a system upgrade will be a good bait for the second phishing email. All UKM students use UKMFOLIO, and hence it applies to everyone. As for the engagement mechanism, students were told that they would lose access to their accounts if they fail to update and verify their information. For the actor (the sender), the director of the Information Technology Center (PTM) was chosen.

C. Training Materials and Message Framing

The training materials are divided into two sections; the first sections include materials designed to highlight clues in the spear-phishing emails that the user needs to be on the lookout to detect spear-phishing emails. Those clues include:

- Sense of urgency: The matter at hand is time-sensitive and actions must be taken immediately.
- Fake/mismatch in the sender's email field: Spear-phishing emails impersonate well-known figures or authorities, as such, it is essential to look at the sender's email.
- Malicious link: The link is usually disguised or presented in terms of a hyperlink to hide the actual URL.

Fig. 3. Individual / Gain training message.

Fig. 4. Individual / Loss training message.

The second part is an informative bit on the consequence of spear-phishing, and how to protect yourself from spear-phishing. This part of the message is framed in terms of individual/group gain/loss, where the pronouns (yourself/your co-worker) and the tone (positive/negative) are different in each group. Fig. 3 and Fig. 4 show the second part of the training material for two different groups (Individual/ Gain and Individual/Loss, respectively).

Technical phrases were simplified so that students could relate to the training material, and new training materials that are comic-based were employed to keep users' attention for longer and transmit the knowledge more effectively. Additionally, the materials are constructed in a way that evokes a sense of urgency, hinting that the issue at hand is time-sensitive and requires immediate action.

V. RESULTS

The results and discussion will be split into two main sections; the first section will cover the first round of phishing relating to personality traits, which was used to test hypotheses H1-H5, while the second section will cover the second round of phishing relating to message framing in embedded training, which test hypothesis H6. Because of the nature of the output (dependent variable) being binary, where 1 denotes "got phished" and 0 "did not get phished", multiple logistic regression was used to determine the coefficient value. STATA v. 16.1 SE was used to carry out the regression.

As for message framing, a Binomial test was carried between each group and the control group to test the effect of message framing.

A. Personality Traits Result

First, Cronbach's Alpha was calculated to measure the internal consistency and verify the validity of the test. The Cronbach's Alpha is 0.8425 which is above the acceptable level of 0.70. Looking at the alpha value when the item selected is removed, there is no significant change among all 62 questions, with a minimum value of 0.8362 and a maximum value of 0.8456 (difference less than 0.01). Table II shows the statistics summary of the personality traits test. The multiple logistic regression results can be seen in Table III. Curiosity

and risk had a negative coefficient, while internet experience and internet anxiety had a positive coefficient. Furthermore, S&T (refer to students who are in S&T faculties) also had a positive coefficient. Gender and Age were added in the regression; gender (male) had a negative coefficient, while age (young) had a positive coefficient. S&T, gender, and age were coded as binary values such as 1(S&T) and 0 (non-S&T); gender-1 (male) and 0 (female); and for age, 1 represented young (between 18 and 32) and 0 represented participants older than 32.

The Pseudo R2 value is McFadden's pseudo R-squared, because logistic regression does not have a direct equivalent to the R2 value found in OLS linear regression. The Pseudo R2 value is 0.0661, which is still low. However, a low R2 is to be expected when measuring variables related to human behavior, as humans are harder to predict.

TABLE II. STATISTICS SUMMARY OF THE PERSONALITY TRAITS

Variable	Mean	Std. Dev.	Min	Max
Curiosity	69.98	7.717198	54	87
Risk	31.26	9.691838	17	60
Internet experience	36.27	11.26706	20	69
Anxiety	19.34	5.324273	10	33
S&T	0.59	0.494311	0	1

B. Message Framing Result

Two weeks after the first round of phishing (Round 1), a second email was sent to participants. 100 participants received the second phishing email titled "UKMFolio System Upgrade".

Fig. 5. Click rate comparison.

Comparing the click rate between Round 1 and 2 in Fig. 5, there is a decrease in click rate from 43% to 32%. Similar to Round 1, the majority of clicks happened within the first 24 hours.

First, a Pearson Chi-square test was performed among the five groups from Round 1 to check if there are no unexpected differences between the groups by any chance, and found no significant relation between the groups and the phishing rate, $X^2(4, N=100) = 6.0108, p=0.198$. Similarly, in Round 2, a Pearson Chi-square was performed and no significant relation was found between the 6 groups and the phishing rate ("non-clicker Round 1" was added as shown in Table IV and Table V.

TABLE III. MULTIPLE LOGISTIC REGRESSION RESULTS

<i>Phished</i>	<i>Coef.</i>	<i>Std. Err.</i>	<i>z</i>	<i>P>z</i>	<i>95% Conf.</i>	<i>Interval</i>
Curiosity	-0.050147	0.031410	-1.60	0.110	-0.11171	0.011416
Risk	-0.021760	0.023325	-0.93	0.351	-0.06748	0.023956
Internet experience	+0.020639	0.019619	+1.05	0.293	-0.01781	0.059092
Anxiety	+0.084030	0.042934	+1.96	0.050	-0.00012	0.168178
S&T	+0.727525	0.457443	+1.59	0.112	-0.16905	1.624096
Gender	-0.744610	0.498756	-1.49	0.135	-1.72215	0.232935
Age	+0.107320	0.660629	+0.16	0.871	-1.18749	1.402129
Cons	+1.205229	2.377349	+0.51	0.612	-3.45429	5.864748

LR $\chi^2(7) = 9.04$; Prob $>\chi^2 = 0.2501$; Pseudo R² = 0.0661, the bold value indicates a significant value $P < 0.05$

TABLE IV. ROUND 1 RESULTS BY GROUPS

VI. DISCUSSION

This study's objective was to find which personality traits affect a person's susceptibility to spear-phishing emails. Using a personality traits survey to measure personality score, and a real-life simulation of a spear-phishing email, logistic regression are carried out to find factors affecting spear-phishing susceptibility. Furthermore, training material is provided to participants who got phished to test the effect of message framing in embedded training. The second round of spear-phishing is carried to test the training material's effectiveness by carrying out a Binomial test. The summary of results can be seen in Table VI and Table VII.

A. The Effect of Personality Traits on Spear Phishing

The results of this study show that only anxiety has a significant relation with susceptibility to phishing ($p < 0.05$). However, the nature of the relationship is not as theorized in previous sections.

Other factors such as gender and age were also tested. While both had no significant findings ($p = 0.135$ and 0.871), gender (male) had a negative coefficient, which means women are likely to fall for spear-phishing emails. This supports previous studies' findings [22], where it was reported that females are more susceptible to phishing. Age (young) had a positive correlation which also supports previous studies

suggesting that younger people are more susceptible to spear-phishing emails [23, 24]. This can be caused by the fact that younger people have not fallen for or experienced spear-phishing and have a lower ability to detect spear-phishing emails.

1) Curiosity: First, curiosity did not have a significant finding on phishing susceptibility ($p = 0.110$). Thus not supporting hypothesis H1. Furthermore, curiosity had a negative coefficient (-0.050147) on phishing susceptibility, meaning that a person who has a high level of curiosity is less likely to fall for spear-phishing emails. This is counterintuitive because a person who possesses a high level of curiosity may find unexpected emails with a link appealing to explore, and thus clicking on the link. Previous study [25] reported that curiosity was the most common reason for clicking on phishing emails and Facebook messages in the post-experiment survey. Another study [14] reported significant findings on the positive correlation between phishing susceptibility and curiosity. Looking at a broader view on curiosity, openness (from The Big Five) can be defined as a person who is curious. This personality trait was found to be non-significant in some studies [6,7] where no significant finding was found between phishing susceptibility and openness.

TABLE VI. PHISHING DETECTION IMPROVEMENT AND BINOMIAL TEST

	<i>Grp-Gain</i>	<i>Grp-Loss</i>	<i>Ind-Gain</i>	<i>Ind-Loss</i>
Improvement (compared to control group)	+10.7 (+29.9%)	-14.3 (-40.1%)	+2.4 (+6.7%)	-14.3 (-40.1%)
Binomial test (expected value is control group)	0.411217	0.872551	0.591295	0.896560

TABLE VII. ROUND 2 RESULTS WITH BINOMIAL TEST

#	<i>Construct</i>	<i>Expectation</i>	<i>Results</i>	<i>Coef.</i>
H1	Curiosity	Higher susceptibility	N.S	Negative
H2	Risk propensity	Higher susceptibility	N.S	Negative
H3	Internet usage	Lower susceptibility	N.S	Positive
H4	Internet anxiety	Lower susceptibility	Sig.<0.05	Positive
H5	IT background	Lower susceptibility	N.S	Positive

Looking at the survey's curiosity questionnaire, the questions used from previous studies measure curiosity in various aspects in life. For example, in the epistemic curiosity (Diversive) section, questions such as "I like to learn new things / like to find out more", "I enjoy exploring new ideas", and "It is fascinating to learn new information" was used to measure the desire to acquire knowledge aroused by puzzles and motivated by the feeling of boredom regardless of the source. The questions used are not specific to a certain situation and can be applied to the context of spear-phishing emails. An email suggesting a new idea, or giving a new insight can be intriguing to the user. However, other questions under epistemic curiosity (Specific), included questions such as "I enjoy finding a solution to new kind of arithmetic problem", "If I see a complicated piece of machinery, I will ask someone how it works", and "I try and imagine the solution for incomplete puzzle". Such questions are situation specific; a person that is curious about how machines work may not be interested in an email asking the user to read about a new policy. Moreover, in the perceptual curiosity (Uniquely loading items) section, 12 questions with 4-point scale were used (same tense throughout the experiment description is not followed) to measure it; this means that perceptual curiosity had more weight when measuring the overall level of curiosity. This may not be the correct scale when measuring internet curiosity. While general curiosity questionnaires are still a good measure, a scale favouring the user's curiosity in internet-related topics may be more suitable in this situation. For example, asking the user "how often do you watch new shows that you have never heard of" and "how often do you click on online ads" may be a more accurate measure of online curiosity. This may explain the reason why there is no significant relation between curiosity and phishing susceptibility. Furthermore, the negative correlation between curiosity and spear-phishing susceptibility can also be linked to the topic of spear-phishing. While this study was conducted during the Covid-19 pandemic, and the topic of the spear-phishing email is related to covid-19 policies, Pandemic

Fatigue [26] can also explain the negative relation, where users are experiencing Pandemic Fatigue after nearly a year of dealing with Covid-19 related issues, and thus the demotivation of reading related topics.

2) *Risk propensity*: Hypothesis H2 was not supported as well. Risk also had a non-significant finding ($p=0.351$), it also had a negative coefficient (-0.021760). This finding contradicts the theory that a more risk-taking person will likely click on an unexpected link in an email regardless of its risk. Previous studies [15] found that the risk of being a significant predictor of phishing susceptibility suggests that people with higher risk perception are experienced in cybersecurity and are thus more likely to averse the risks associated with clicking on unknown links. Moody et al. [14] also found risk to be a significant predictor of susceptibility to phishing.

The risk questions included in the survey measure risk beliefs (perceived risk) and risk propensity. Part of the risk beliefs scale was reversed because of the negative relation between risk perception and risk-taking behavior, while risk propensity was scored normally because of the positive relation between risk propensity and risk taking [27]. This means that a high risk score (overall) reflects a high risk taking behavior. In theory and based on previous studies, a more willing to take risk is more likely to click on an unexpected link in an email. However, findings suggest the opposite (even if it is not significant), this might be explained by how people overestimate their ability to identify scam emails. Datar, Cole, and Rogers [28] found that more than half the participants that claimed they can identify a scam email failed to identify them. This means even if a person has a low-risk overall score (person scored high perceived risk (inverted) and a low risk propensity score), he/she may not be able to identify an email as a spear-phishing email and thus not perceive the actual risk of clicking on the link.

3) *Internet usage*: Internet experience did not have a significant finding ($p=0.293$); hence hypothesis H3 was not supported, however, there was a positive relation between internet experience and phishing susceptibility. The result is counter-intuitive; however, a study [14] also found similar results. A person who uses the internet is more likely to click on a phishing link. One of the reasons that might explain these results is Habituation [29]. The person's innate response to a stimulus decreases after repeated presentation of the stimulus. In the context of spear-phishing emails. If the user spends a lot of time on the internet (experienced user), he/she may pay less attention over time to spear-phishing clues and this fall for spear-phishing emails.

4) *Internet anxiety*: The last hypothesis relating to personality trait H4 (internet anxiety) had a significant finding ($p = 0.05$) with a small positive coefficient. This finding matches previous research [14]; even if the initial hypotheses suggested the opposite effect (negative correlation), Halevi et al. [22] found a positive correlation between neuroticism (from The Big Five personality traits) and phishing susceptibility for women only. A few reasons might explain the results, first people with high anxiety levels may feel bothered by unanswered emails, thus the need to reply or click on a phishing email. Another reason might be related to being a "people pleaser" where a person may find it difficult to say no, and thus feel the need to provide information in phishing emails.

5) *IT background*: The last hypothesis H5, that was tested in Round 1 of phishing is the relation between IT background and phishing susceptibility, there was no significant finding ($p=0.112$), however, the correlation coefficient was positive, which means participants from S&T faculties were more likely to get phished. While most studies discussed in chapter 2.1.2 suggest a negative correlation between IT background and phishing susceptibility, habituation may explain the positive correlation found in this experiment. Students under S&T faculties may be constantly reminded about cyber-attacks and hence pay less attention to spear-phishing emails.

B. The Effect of Personality Traits on Spear Phishing

The binomial test shows no significant results, this matches a previous study [13], where no significant relation was found among the four groups, and thus H6 was not supported. However, looking at the improvement rate, group-gain had the highest improvement (although not significant) compared to other groups with a decrease of 10.7 compared to control group click rate in Round 2. Furthermore, gain treatment (both group and individual) saw an improvement in detecting spear-phishing emails, while loss treatment (both group and individual) performed worse than the control group.

Several factors contributed to those findings, first there is no way to make sure that participants have taken part in the training, for example, if the participants immediately closed the training page after clicking without reading any of the content. Furthermore, some people may have skimmed through the training and thus have not fully understood the content. While

the use of comics instead of text may have helped in retaining the participant's retention, there is still a possibility that the comics did not convey the information effectively compared to text because the comic's design has to be short and to the point.

Secondly, the information's credibility might not be clear to the participants, as the training was not hosted on an official university website, and hence recipients did not find the training credible. Thirdly, the training effectiveness may require repetition before a noticeable behavior change is observed where the same training is applied multiple times over an extended period of time. Lastly, the sample size for the experiment is relatively small. Because of the experiment's nature, where only people who clicked have received the training, each group's final sample size is very small. It may have produced inaccurate results that do not represent the population.

C. General Implications

Spear-phishing emails are highly targeted by nature; attackers will use current trending topics and events to lure their victims into clicking on malicious links. Spear-phishing emails continue to be a large threat, and with organizations heavily relying on emails for communication, it is more important than ever to understand better the factors that make spear-phishing emails so successful. One of the most important factors is the human link. With humans being the weakest link, it is evident that the attacker will try to exploit such weakness and try to use it to their advantage. A lot of effort has been put into securing information from direct attacks; however, most recent successful attacks have infiltrated organizations through human error. Having a better understanding of what makes a person fall for spear-phishing emails is vital in fortifying the human firewall.

One of the factors that can affect a person's susceptibility is his/her personality traits. Prior research has focused on a wide variety of personality traits, this research narrows down the scope and focuses on key traits that have been found to be a factor in predicting phishing susceptibility [30, 31]. Out of the four personality traits that have been put to the test, internet anxiety has shown significant results in predicting phishing susceptibility. The reason is, internet anxiety affects phishing susceptibility is that anxious people may feel bothered by unresolved issues suggested by the email, and thus have the compulsive need to reply or check the spear-phishing email. While other personality traits did not show significant results, it is still possible that in a different environment, different personality traits may show a stronger correlation with phishing susceptibility due to the difference in culture and background.

Having a better understanding of who is more susceptible to cyber-attacks, such as spear-phishing attacks, can be an important factor in designing a training module for an organization. Knowing which type of people are more susceptible can save many resources in terms of training time and cost when trying to raise security awareness in an organization. While this study does suggest that embedded training lowers the success rate of spear-phishing attacks, however there is no justification to believe that message framing can affect training efficiency.

VII. CONCLUSION

Primary Personality traits may hold the key to better understanding what makes some people more susceptible to spear-phishing than others. This research shows that certain personality traits can contribute to higher susceptibility to spear-phishing emails. A real-life spear-phishing experiment was implemented to measure the correlation between spear-phishing susceptibility and personality traits. The results show that Internet anxiety increases the person susceptibility to spear-phishing. An embedded training was provided to participants through the phishing emails, and through two rounds of emails. The embedded training lowered the overall click rate; however, there is no evidence to support the notion that message framing affects training effectiveness. While the small sample size in this study can provide some limitations, the results show promising results on the effect of personality traits on phishing susceptibility. Future research can aim to test the hypotheses on a larger sample size, and over a longer period of time.

VIII. FUTURE RESEARCH DIRECTIONS

The primary limitation of this study is the sample size. The sample size for this study was 107 participants, which is relatively small to the population of UKM. The main reason for that is the restriction because of the Covid-19 pandemic and time constraints of this study. The distribution of personality traits survey was limited to online forms, and physical distribution was not possible. Other factors that contributed to this small sample size include that participants had to answer a survey for them to take part in the spear-phishing study; while a monetary incentive was formed to encourage participants to fill out the survey, thus unable to determine its effectiveness. Because the invitation emails to do the survey was sent by faculty's staff, lecturers and IT centers, the total number of recipients was not disclosed for privacy reasons. Furthermore, a list of emails for all students contributes to the privacy concerns as well. Furthermore, because this study relies on people getting phished, this results in an even smaller sample size for each group. Previous studies had a click rate of around 40% (similar to study); this means that the final sample size will be even smaller when testing the training module's effectiveness. Another factor that can be improved is the personality traits questionnaire; this study uses existing instruments to measure the various traits. Designing more tailored questions that can relate better to internet behavior can show promising results.

Our study can lead to multiple paths down the road. Future researchers can examine if the findings persist over larger sample size. A sample size that includes all students in the university can lead to more accurate results and can eliminate any anomalies due to small sample size. If the survey had a low response rate, a larger sample size to start with will result in a sufficient number of participants answering the survey. Moreover, using a personality trait instrument that is designed with internet behavior and habits can lead to a better measurement of some traits. Lastly, the effectiveness of embedded training and message framing can be measured better when observed over an extended period of time. This also requires repetition of training, Future research can

implement this study in multiple phases and multiple phishing rounds over an extended period of time, and larger break time between each phishing round to eliminate any priming effect other improvements can be implemented, for example, interactive embedded training that requires user's interaction can be included to make sure that participants have read and understood the training.

ACKNOWLEDGMENT

This study was supported by the Fundamental Research Grant Scheme (FRGS/1/2021/ICT02/UKM/02/1) from Ministry of Higher Education, Malaysia.

Abstract—e-Learning systems have reached their peak with the revolution of smart technologies. In the past few years, the Internet of Things (IoT) has become one of the most advanced and popular technologies, affecting many different areas. Using IoT in an e-learning system is a fantastic technology that improves the e-learning system and makes it more inventive and cutting-edge. The key challenge addressed in this study is the acceptance of IoT usage in e-learning systems as well as how to improve it so that it can be utilized properly. This research concentrates on how IoT can benefit e-learning systems and how it might benefit users of e-learning systems. A comprehensive literature review was conducted to get acquainted with the important research related to IoT technology and e-learning systems through online research databases and reliable scientific journals. The first research finding is that e-learning systems need such modern techniques as IoT to enable interconnection, increase reliability, and enhance the enjoyment of the educational process. The second result is that research related to the development of new technologies like the IoT has a significant impact on enhancing the performance of new systems and bringing about positive change. This study highlights the value of IoT, particularly in e-learning systems. It aids in the development of new strategies that will improve the efficacy of e-learning systems and stimulate researchers to develop advanced technology.

Keywords—e-Learning system; Internet of Things (IoT); software system; education, learning process

I. INTRODUCTION

IoT can deliver unique services in a variety of domains. The IoT connects many devices and things to form a physical network that includes sensing, communication operations, and processing without the need for human involvement. IoT devices have increased dramatically during the previous decade, and by 2025 they may reach 50 billion devices [1]. The IoT is already attracting a slew of academic and business interests. Smarter and smaller devices are introduced in a variety of IoT domains every day, including monitoring management, smart houses, smart vehicles, smart farming, smart tourism, e-health, and e-learning, to mention a few [2-9].

e-Learning refers to using electronics and the Internet in addition to software applications in the learning process and thus making it more effective and dynamic [10-12]. Some of the drawbacks of traditional e-learning systems include

limitations in expanding and distributing computing power, as well as exchanging information among system users [13], which has encouraged the development of new technologies to overcome these obstacles and motivate the learning process [14]. e-Learning is a key part of making education better, and it is the main way for teachers to improve their skills and abilities by adapting to new scientific methods [15]. The use of techniques in e-learning like virtual classrooms improves the knowledge of learners and transforms the educational process into a universal one [16]. The evolution of technologies and communication enhanced the e-learning environment and gave it the nature of expansion through the combination of physical and virtual objects. IoT as one of these technologies has a strong influence and benefits on different fields [17], education is considered one of these fields which plays a key role in its development and quality [18]. e-Learning as part of the education system was also greatly impacted by this modern technology [19]. Students build their knowledge by enabling them to explore the reality around them [20]. IoT converts traditional e-learning into intelligent and interactive e-learning by integrating smart objects. Using smart objects provides learners with good communication and interaction with instructors and other parties from anywhere [21]. IoT motivates students and teachers. It creates an appropriate and comfortable learning environment in addition to increasing performance [22].

For many years, IoT has been used in conjunction with e-Learning. However, under certain circumstances, such as the COVID-19 epidemic, all learning processes have had to totally migrate to e-learning platforms [23, 24]. As a result, the significance of such integration has grown [25]. Still, many educational institutions have had a hard time making the switch to e-learning [26]. This is due to several factors, such as a lack of knowledge, student acceptance, a lack of infrastructure, and a lack of clear guidelines for integrating IoT with e-learning. Also, technical problems with accessibility, design flexibility, interactivity, the system, and the quality of the Internet will affect the stability and continuity of e-learning [12, 27]. There is a continuous change in the methods of the learning process. Therefore, it is necessary to propose and develop new supportive methodologies in order to fulfill the requirements of learners all over the world [28] and achieve satisfactory e-learning outcomes [29]. Accordingly, this article will concentrate on

*Corresponding Author.

the issue of a lack of guidelines to provide a conceptual and clear understanding of the IoT and e-learning processes.

This paper makes a big difference by giving an in-depth look at how the Internet of Things (IoT) is being used to make e-learning better now. This survey includes highlights of the responsibilities of IoT entities when integrated with the e-learning process. This study examines recent research efforts aimed at addressing the deployment of IoT in the e-learning process as well as open research opportunities for future research. This study makes the following contributions: In addition to discussing IoT concepts and e-learning process concepts, it also includes an analysis of the operational deployment of the IoT in the e-learning process as well as IoT e-learning architecture and entities.

The rest of the paper is organized as follows: Section II discusses the research background of IoT technology and e-learning systems. Section III discusses the related work in this field. Section IV explores the methodology applied in this research. Section V discovers the research and analyzes the findings. Section VI, VII and VIII discuss about the tools, architecture and entity model of IoT e-learning. The challenges and future directions of IoT and e-learning integration are discussed in Section IX. Finally, the paper is concluded in Section X.

II. BACKGROUND

A. Internet of Things Overview

The main idea behind IoT is to collect data from their surroundings before analyzing it in order to execute automated operations to assist users. The IoT is gradually gaining ground worldwide. Modern technology has grown in the past few years, in part because sensors and smart devices have become more common [30, 31]. The three stages of IoT activities, including data collection, transmission, and processing, are described below [25, 32-34]. In e-learning, data collection, transmission, and processing are very important parts of how online educational content is delivered and how well it works. This is done by gathering and analyzing data from different sources. It is possible to gain valuable insights into student performance and engagement, which can be used to tailor the e-learning experience [35]. These stages can be summarized as follows:

- **Data collection:** The first phase is data collection, which includes detecting and obtaining data through various communication methods. To identify and gather data, several technologies such as Bluetooth, Near Field Communication (NFC), Global Positioning System (GPS), and Radio Frequency Identification (RFID). When integrating IoT with e-learning, this phase entails receiving information from a variety of sources, including student interactions with the e-learning system, course content, and assessments. A range of techniques, including online applications, polls, monitoring tools, and application logs, can be used to gather data [35].
- **Data transmission:** Transmitting the data is the second phase where the gathered data is transmitted to the

servers or host system for processing via a specific medium (e.g., wireless or wired) and protocol (e.g., IEEE 802.3/802.11 standard). Because falsification tendencies are low, wired transmission channels may send more precise and dependable data. However, wired networks may not be useful for long-distance communication. It is also rather pricey when compared to wireless options. Understanding the optimum transmission route and the geography of the surroundings is critical. When integrating IoT with e-learning the data has been collected about students, it needs to be transmitted to the e-learning systems for storage and analysis using secure networks or cloud-based storage systems [36]. Furthermore, data management systems may be used in combination with data transmission to structure and store the data to be used later [36].

- **Data processing:** This is the final phase, during which the data sent should be properly reviewed and processed in order to make a decision. Data will go through many preparations, cleaning, classifying, and filtering procedures during this phase. Cloud computing allows services to be administered remotely and provides processing resources and virtual storage. In this stage when e-learning is integrated with IoT, the gathered data is analyzed and processed to get the knowledge that can be applied to enhance the e-learning process. This requires using algorithms and analytics tools to reach conclusions and trends from the data [35]. The processed data can be utilized to create reports on student engagement and performance as well as to identify e-learning platform development opportunities [36].

The IoT is a technical improvement in transporting and exchanging data between connected objects using an Internet service [11, 37, 38]. It has the property of quick evolution [39] and the scope has expanded further to connect people to things [13]. IoT gives good control over objects and transforms them into smart objects [14]. Therefore, it is seen as an essential element in the growth of smart environments [40]. The communication and association between physical and virtual objects provide the IoT with the characteristic of being ubiquitous [10]. IoT has devices that let it sense and collect data from other devices, which it then shares for the good of everyone. The association of RFID tags, sensors, and actuators with each other has made this technology a modern and unique model [21]. IoT technologies are different from other technologies because they are everywhere and encourage people to come up with their own independent and smart solutions [41]. It has become a hot and interesting topic among investors in various fields [15]. IoT is distinguished by non-human intervention, use anywhere, no time limit, reducing cost and time, and a perfect connection because it requires high-speed Internet [42, 43]. Fig. 1 explains the most common features of IoT technology, including sensing, connectivity, intelligence, safety, energy, and expression.

Fig. 1. Internet of Things features.

- **Sensing:** Many IoT devices are equipped with sensing capabilities that can be used to gather data from the surrounding environment and adapt their behavior based on the gathered data [36]. In order to gather data for a specific circumstance, IoT should be able to read analog signals from various sources such as light, RFID, GPS, and gyroscope. Light and pressure, for example, might be utilized in automobile applications. To produce the optimum use case, a good sensing approach should be used. The gathered data can be used by IoT in adapting their actions based on the context in which they are used systems [36]
- **Connectivity:** To ensure effective communication between networked IoT system components like computer processors, sensors, and data centers, connectivity is a crucial element to be considered. To achieve this smooth communication, several protocols and standards must be used. IoT systems may communicate and exchange data with one another and with other systems since they are connected through a network. Bluetooth, Wi-Fi, and cellular networks are just a few examples of wireless technologies that are frequently used to facilitate this connectivity [35].
- **Intelligence:** Data is utilized to create significant business observations and make crucial business choices in practically each IoT use scenario in recent times. On top of this vast data, building computational models to gain significant insights that can enable IoT systems to function independently or with minimal human intervention [35]. The sensor readings are refined and transformed into a format that may be used to train computer models. An appropriate data structure should be considered, depending on business requirements to support decision-making [36].

- **Safety:** Security is one of the most important aspects of the IoT system [35]. Sensitive data is delivered from terminals to the analysis layers via connection components throughout the whole cycle of an IoT system. To protect data from abuse and exploitation against cyber-attacks, IoT systems must adhere to adequate security procedures such as using secure communication protocols, encryption, and firewalls as well as the implementation of privacy policies and technologies to protect the personal data of users [36, 44, 45]. Every element of an IoT system that is compromised might ultimately cause the entire process to collapse.
- **Energy:** The entire IoT system requires a lot of energy, from end components to the communication and analysis layer. It is essential to consider design techniques while creating an IoT system so that energy usage is kept to a minimum (IEEE 802.15.4, 2003). For instance, IoT devices can consume less energy by adopting low-power communication protocols and effective power management techniques [11].
- **Expressing:** To improve the user experience, IoT incorporates multiple cross-domain models. It also guarantees that the structural and operating expenditures are properly balanced. IoT devices must be built in a way that allows them to be readily scalable up or down on request to allow for the integration of a large number of devices and sensors [36]. Providers must address future demands for handling such a large quantity of data when creating IoT processes to satisfy additional business demands to enable the creation of large-scale IoT deployments, such as smart cities or agriculture.
- **Interoperability:** Regardless of their manufacturer or operating system, IoT systems can work seamlessly with other systems and devices [36]. As a result, a variety of devices and systems can be integrated into IoT systems.
- **Distributed Real-time architecture:** IoT systems often have a distributed architecture, with devices and sensors located at the edge of the network, rather than centrally located [35]. This decentralized architecture allows for the Real-time collection and processing of data from many devices and sensors.

B. e-Learning Overview

e-Learning technology is a critical component of delivering education through an electronic medium, specifically the internet [46]. Numerous products are available on the market that implement e-learning technologies, which makes it critical for practitioners to be aware of the details of those technologies [47]. The knowledge along with the skills to use e-learning technologies will improve the chances of providing an effective and efficient learning experience for both students and teachers [48]. Because physical connection is banned, e-learning platforms can be used as a substitute for traditional learning and teaching methods. The social dimension is one of the main difficulties for students when

using the e-learning system, which can be reduced by adapting social IoT that can add interest to the virtual educational environment [17]. In order to stop this worldwide epidemic, the world needs more young people who grew up with technology and can quickly adapt to the online world without much trouble. Teleconferencing tools like Skype, Zoom, and WebEx sessions, as well as other similar technologies, can be used by students in online classrooms. Simulcasts, workshops, academic board meetings, and conferences may all be held electronically without having to meet in person. Using this kind of technology to keep people at a social distance is one way to stop the spread of viruses, like the COVID-19 virus, among academics [49]. Online assessment can be done using e-learning platforms, which guarantee the participants' health in such a pandemic. With these kinds of technologies, evaluating students can be done safely because there is less need for physical contact [50]. In the workplace, an internet platform can be used to do things like surveys, staff evaluations, and interviews. This helps keep employees safe.

e-Learning technologies can be categorized into two levels, infrastructure and software. The infrastructure category is further categorized into on-premise and on-cloud [51]. On-premise technology is the infrastructure that uses the local hardware of the educational institution, while on-cloud computing uses cloud computing resources over the Internet [52]. For instance, e-learning infrastructure includes the underlying hardware such as servers, end-user devices such as mobiles and desktops, networking devices, input devices, output devices, and storage devices [53]. Those can be on-premise, which means that the hardware used in e-learning is located on the campus of the educational institution [54]. On-premise infrastructure needs help and skills all the time, but it also gives you more freedom [55]. Using cloud computing also has numerous advantages as it reduces cost and increases flexibility and real-time scalability, but at the same time, it may introduce some issues regarding dependency, security, and confidentiality [56-60].

Likewise, the software category is classified into synchronous and asynchronous technologies. Synchronous technologies support real-time communication, whereas asynchronous technologies support communication at different times and locations but do not support real-time communication [17]. In terms of software, e-learning uses both synchronous and asynchronous tools. Synchronous tools are trying to mimic traditional classrooms and, to some extent, improve the experience of learning by augmenting technological tools that may improve the education process [17]. Synchronous technologies include video and audio conferencing, live chat, whiteboarding, and application sharing [61]. While asynchronous can be combined and formed in learning management systems that support learning resources management, forums, messaging, assessments, and announcements [62].

III. RELATED WORK

Previous literature on improving IoT and e-learning may be divided into numerous areas, such as content management and sharing, creating solutions, e-learning content distribution, tracking the e-learning process, e-learning tool

interoperability, and standards interoperability [63]. The value of the IoT was demonstrated by [64] by developing and enhancing education, as well as the scope of their significance in higher education institutions via smart coursework utilizing the latest methods in the classroom setting, smart labs to run tests more efficiently and enable tests, including the use of gadgets to enhance student communication with their classmates and teachers, and also scientific content. Mohammed and Isa [25] emphasized the significance of IoT in enhancing human-machine connection, which contributes to people's social isolation. The use of IoT to prevent the spread of infections (such as COVID-19) may face unique challenges, especially in developing countries with limited telecommunications infrastructure. In the same way, IT expertise is required when dealing with IoT apps or devices. Individuals prefer to interact personally with another person rather than with a machine. Others may believe that revealing medical details to the machine will compromise their privacy. Such factors represent considerable obstacles to the use of IoT applications to control the virus's spread [25].

Dodero, et al. [65] look at what needs to be done to make the e-learning future a reality. Issues related to IoT and e-learning integration, including CPU and storage limitations, throughput, and bandwidth constraints, should be addressed for successful integration. Accordingly, the trade-off between data-collection efficiency and interoperability may be considered to enhance this integration [65]. In their work, Chituc [66] looked at standards interoperability and pointed out the problems with interoperability that need to be fixed for the IoT and e-learning visions of the future to come true. Perales, et al. [67] demonstrated an online system utilized by the International University of La Rioja. The online service is a remote online lab that delivers experiential learning using engineering experimental tools. The teacher might move from one online workspace to another to help students with their lab instructions. Even though this method is used to offer online labs, it doesn't consider how and why the students interact with each other. In the work of [68], the authors recommended using a context-aware system to capture a vast amount of data about the learner's surroundings. The system automatically adjusts to the customer's wishes based on these facts. Context-awareness incorporation into an e-learning system would be an effective strategy for improving learning.

Zaguia, et al. [24] showed learners a new way to use synchronous e-learning for intelligent e-learning. The paradigm is a new way of thinking about distance learning in which the teacher has more control over the students. Tools for artificial intelligence, IoT, and virtual reality are put together to make a more powerful system that helps the teacher keep an eye on the students during lessons and tests. Most of the changes we will make to our systems in the future will involve adding more computer-aided services to help teachers see and respond to how students are acting. In the work of [69, 70], the authors proposed that artificial intelligence approaches such as data mining and fuzzy logic be used to smarten up e-learning tactics and augment students' learning. Most of these systems are limited by the time to finish the assessment exam, the learner's evaluation criteria, history, and so on [24]. Similarly, Leahy, et al. [71]

investigated the role of emergent technology, such as smart materials, artificial intelligence, and augmented reality, in the future of e-learning. In Zhang and Zhou [72], the importance of locality, interaction, intelligence, openness, and cloud computing were analyzed from the standpoint of e-learning's future vision.

The use of smartphones in e-learning was emphasized by [73]. These gadgets must be integrated into distance learning systems. These gadgets became more widely available and easier to operate as time went on. The authors suggest a platform that has an intelligent agent on a student's smartphone. The necessary information about the students' obsessions, participation in the course, and other factors is collected and sent to the artificial intelligence system for evaluation. The artificial intelligence algorithms look at student data, comments, and ratings of course materials to figure out what course content is suitable. The authors suggested analyzing student behavior with smartphones to make sure that the course content was customized correctly. Tobarra, et al. [74] put the app of the virtual laboratory to the test to see how well it worked. The learners' acceptance was evaluated using the Unified Theory of Acceptance and Use of Technology (UTAUT) model, as well as time allocation, learner's behavior in relation to evaluation items, and material sources. The main result of this research is that the suggested lab has a high level of student acceptability, as measured by several factors (ease of use, perceived usefulness, attitude, intention to use, social influence, and estimated effort).

IV. RESEARCH METHODOLOGY

This study aims to find out the use and importance of integrating IoT with e-learning systems. The strategies and rules presented by [75-79] were adopted in the review process of this paper. Fig. 2 explains the review activities. The study begins with a review of the literature and a survey of the research object's e-learning implementation, followed by a summary of the significant results from the associated literature. Following that, identified a research need from which derived review questions and objectives. Finally, the paper's importance and scope were determined. There were a lot of publications that were looked at, but this review only includes the most important and recent (since 2015) studies. This is because the actual IoT and e-learning integration revolution began after 2014.

This study aims to answer the following research questions: How is IoT used in e-learning systems? To answer the research question, five sub-questions should be addressed to figure out the goals, scope, significance, and future of deploying IoT in the e-learning process, and the future of this emerging technology:

- RQ1: What is IoT in e-learning systems?
- RQ2: Where is IoT implemented in e-learning systems?
- RQ3: How is IoT implemented in e-learning systems?
- RQ4: What is the impact of using IoT in e-learning systems?
- RQ5: What are Challenges and Future Directions sets of

IoT in e-learning systems?

The literature review was conducted by searching scholarly databases; Google Scholar, IEEE Explore, ACM, Springer, MDPI, Wiley, Emerald, and Elsevier. The investigation starts with selecting the topic, analyzing, interpreting, and coming out with the research problem. A range of search phrases and their variations were used to conduct thorough searches including: "e-learning" OR "e-learning" OR "smart learning" OR "smart class" OR "smart teaching" OR "virtual learning" OR "virtual study" OR "virtual class" OR "online learning" OR "online class" OR "online study" OR "online teaching" OR "online tutoring" AND IoT OR internet of things. The focus of this study is on the present state of e-learning and IoT integration. As a result, the following inclusion criteria were used: IoT must be incorporated into the construction, architecture, design, or modeling of e-learning. There should also be proof of deployment (for example, a description or presentation of the actual implementation, or proof of model assessment). Based on the criteria for inclusion, the searches turned up 40 items. Of those, 28 were journal articles and 12 were conference articles. The papers included in this work are depicted in Table I.

Fig. 2. Research methodology.

V. FINDINGS

This section provides a comprehensible overview of applying IoT in e-learning systems. The paper discusses some questions related to IoT and e-Learning systems and how they have been explained and answered in several previous studies. Table I summarized the related work and simplified and clarified the research questions. The answer to each question can be yes or no, which was designated ‘✓’ inclusion in the study and ‘----’ for not implicitly included.

A. RQ1: Internet of Things (IoT) in e-Learning Systems

The integration of new technology such as the IoT in e-learning systems is a practical example of providing different smart services [37] for enhancing the learning process, achieving better outcomes, and decreasing cost and time [22, 41]. IoT is the main supporter of the smart learning (e-classroom) environment via connecting physical and virtual objects, which makes it more scalable and efficient [10]. IoT has changed conventional e-learning and taken it to an advanced level. Individual skills and knowledge are the results of this advancement [11].

e-Learning equipped with IoT may support and facilitate collecting and sharing notes between learners from the learning classroom through applications, smart devices, and network connections [16, 18, 19]. The use of the IoT with e-learning systems simplifies the learning process [39]. IoT in e-learning systems using IoT may result in fast accessibility, hyper-connectivity, good sharing, personality services, and a sustainable learning environment [13]. IoT e-learning does not only mean enhancing the learning process, it also changes the academic infrastructure and adds new subjects and essential concepts to computer science [89]. The e-learning system developed by the IoT has a global characteristic. The advanced system stores enormous amounts of information and performs a great number of equivalent operations [15]. In terms of awareness, the learner is regarded as the most important factor. For learning arrangement and connectivity, his/her relief, contentment, and encouragement are significant [17].

B. RQ2: Applying Internet of Things (IoT) in e-Learning

Online learners and teachers are connected to the internal learning system and global objects through IoT technology, which enables learners to access enormous pedagogical resources [65, 71]. IoT has some good qualities, such as high-quality association between objects, high-quality access, network communications integrations [10], and the ability to add and remove objects from the connection structure [83]. The IoT has the capability of connecting people to people, people to things, and things to things [14]. IoT devices are used in e-learning to deliver and receive information and directions. The benefits of adopting IoT in e-learning include helping to motivate superior lesson ideas, construct safe facilities, monitor important resources, improve data access, and many others [51]. The IoT can be viewed as a novel approach to managing the educational process through the use of developed technologies. The IoT is used in many e-learning tools, such as interactive learning, smart digital boards,

teaching apps for smartphones, laptops, and tablets, systems that track attendance, digital materials, and many other learning tools like Google Apps.

The implementation of IoT and e-learning has been applied in many fields, such as schools, universities, online training, online certificates, and so on. This is especially critical during circumstances where the disease infection is a threat as the substitution of a face-to-face approach is necessary. For instance, Encarnacion, et al. [48] argued that instructors of physical training may utilize smartphones, smartwatches, and the programs they have on them as effective teaching tools. Sportspeople can enhance their athletic performance using these phones and applications, and students can monitor their movements and gain knowledge about physical education [90]. In higher education, Abd-Ali, et al. [64] reported that IoT implementation in e-learning has enhanced the e-learning process and outcomes through smart coursework utilizing the latest methods in the classroom setting, smart labs to run tests more efficiently and enable tests, including the use of gadgets to enhance student communication with the classmates and teachers, and also scientific content. The same has been reported by Perales, et al. [67] that an online lab that delivers experiential learning through the use of engineering experimental tools has assisted students with their lab instructions and enabled shifting from one online working space to another, easily. Moreover, Sabagh and Al-Yasiri [68] recommended using a context-aware system to capture a vast amount of data about the learner's surroundings, which would be an effective strategy for improving learning. In general, the effective implementation of IoT with e-learning has to consider several factors [14, 48]:

- Learner-oriented approach: The first stage in creating a successful e-learning system is to undertake a comprehensive analysis of learners' needs and the conditions in which they live.
- Productive learning processes: In the modern world, learning materials are increasingly individualized and focused, blurring the lines between learners' personal and professional lives.
- Organizational culture: Because every institution has a unique culture, various working techniques must be taken into account.
- IT capabilities: The foundation of the environment conducive to e-learning is smart IT. It requires certain technology (e.g., smartphones, smart TVs, smart pens, etc), software and applications (e.g., Zoom, Microsoft Teams, etc), and interface components, which form the basis of cognitive data interchange.

C. RQ3: Internet of Things (IoT) Implementation in e-Learning Framework

The IoT network is embedded with electronics, sensors, software applications, and other devices linked to the Internet [22]. These integrated devices are applied in the learning process for improvement [37]. IoT technology uses sensors and smart devices for data collection [19]. The data produced by IoT sensors is transmitted through a network, and the combined data is analyzed via big data analytics [16]. A sensor is something that a learner owns and that is linked to the system. These sensors may be utilized for a variety of educational purposes, including medical training, and genuine learning, using devices like wearable watches, headphones, and smart glasses. How to gauge learners' levels of interest and engagement during e-learning is a challenge when employing IoT e-learning systems. Even though linked learners can use these devices as ways to prove who they are, they can't show proof of engagement until, say, a webcam is running [91]. So, even if in theory these devices might accommodate all learners' needs, their inability to replace face-to-face learning is due to students' lack of engagement. The classroom is equipped with smart devices to create a smart environment that speeds up data fetching and collection [13, 88]. Connecting the information sensing tools and information transformation applications can support the learning process with different students' feedback [14]. In other words, e-learning processes can be improved by constantly monitoring and evaluating what students say about how to make e-learning or the use of IoT devices better. For IoT devices to work together, different types of protocols must be used on the sensor platform [17]. The network infrastructure, communications quality, and improvement of intelligent applications are the three important IoT requirements for achieving smart services [41].

VI. INTERNET OF THINGS E-LEARNING TOOLS

Unlimited communication through the IoT enables learners, teachers, and researchers to work globally [21]. IoT can be used in e-learning systems for various activities to support the learning process [18]. Many of the researchers, such as [16, 17, 19, 37, 88] unanimously agreed that the smart classroom, smart lab, and smart notes are some of the most important and efficient educational aspects to which IoT technology has been applied. Other authors reported other smart activities such as electronic books and attendance tracking [14, 41]. AjazMoharkan, et al. [11] reported other smart tools used in e-learning systems coupled with IoT technology, such as smart digital boards, digital highlighters, Scanmarkers, RFID, and QR. The market continuously provides the e-learning system with IoT smart products that can be combined to achieve new and useful services, as explained in Fig. 3. The following are examples of these tools [11, 80, 85]:

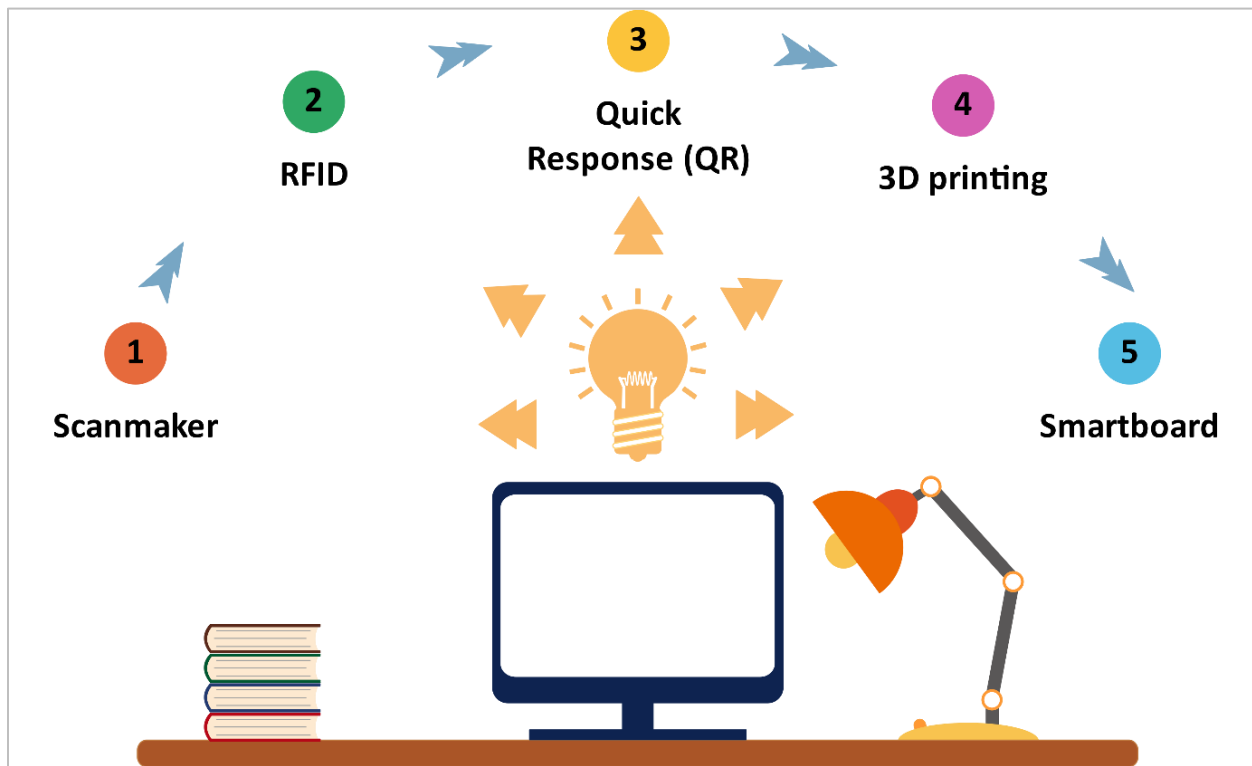

Fig. 3. Internet of Things e-learning tools.

- **Scanmarker:** The Scanmarker is integrated with a computer or smartphone to convert the printed text to these devices, which makes the process of note-taking easy and fast. Users of Scanmarker are able to scan editable text from books, and other documents into their phone, tablet, or computer in seconds. This text can then be translated into over 40 different languages.
- **Learners Attendance using RFID:** The presence of students in the classroom is automatically detected by a Smart Classroom-IOT-based device. RFID chips are embedded in the ID cards of students. Every classroom can have an RFID reader that can read all of the students' ID cards at the same time.
- **Quick Response (QR):** QR code is embedded in books offline work and then linked to online applications. It has the capabilities of quick readability and greater storage capacity.
- **3D printing:** Additive manufacturing, also known as 3D printing, is the process of creating three-dimensional solid objects from a digital file. The 3D printer can be linked to a smartphone, tablet, or computer. Through new technology such as 3D printing, developers hope to create more networked products that can sense, collect, analyze, and communicate data.
- **Smartboard:** enables the teacher and students to work on the same "document" in real-time and share it with the entire class.

VII. INTERNET OF THINGS E-LEARNING ARCHITECTURE

IoT acts as an intermediary between open learning and the classroom [13] and can be used at all levels of learning [39]. Fig. 4 represents the architecture of the IoT technology e-learning system. There are three main layers in this architecture, which are discussed as follows: applications, networking, and sensors [14, 24, 92].

Fig. 4. Internet of Things e-learning architecture.

- **Application layer (Cloud):** The top layer of the architecture is the application layer, which includes business applications like e-learning systems. These programs can be used to manage and streamline business operations as well as to provide new services. Different types of digital devices communicate with other IoT system components directly. This layer will include all of the services that can be provided to learners and teachers. More information is available in the services area.
- **Gateway layer and networking:** Data generated by IoT devices is disseminated through this layer. It includes data storage and identification services for related devices, as well as a device management application with access control, administrative, and business capabilities. The IoT gateway is made up of two major components: edge and Fog nodes. Fog nodes, which are equipped with applications, storage, and more processing power than IoT devices, support local processing. As a result, Fog nodes can assist in managing and controlling IoT devices without requiring IoT devices to communicate directly with the Cloud, resulting in reduced time latency. Data from IoT devices are used to support it, and it functions in accordance with that data. The network component's main focus is communication. Based on the data collected by the sensors, the IoT gateway will make the appropriate decision and send the instructions to the actuators.
- **Sensor's layer:** This layer contains messaging, virtualization, and other components. This primarily consists of detected and managed physical objects relevant to IoT applications as well as learners and teachers. This layer consists of sensors and actuators. Teachers and students interact with the e-learning system using technology such as smartphones, tablets, computers, or more specialized devices. These devices will have a unique user interface that will enable e-learning and effectively guide or support the user.

VIII. INTERNET OF THINGS E-LEARNING ENTITY MODEL

Both learners and teachers communicate via a network using IoT devices that utilize sensors and actuators to interact with the real environment. Sensors detect a physical entity's features and transform them into digital data that can be interpreted by humans. For instance, an IoT audio sensor can measure how loud the noise is, and the system will respond based on this information. Actuators use digital instructions to operate on or affect the attributes of physical things. As shown in Fig. 5, the components of IoT object e-learning are as follows [24]:

1) *Learner unit:* A learner is a real-world object that IoT devices manage and perceive.

- **Learner portfolio:** This component will store the learner's preferences, history, as well as the student's strong and weak aspects, so that it may be considered in order to enhance the learner's level.

- **Awareness module:** The goal of this unit is to give appropriate services to the learner in light of the circumstances. It is a key notion in distributed network computing. Data may be collected in context-aware systems utilizing small resource-constrained devices like smartphones, PDAs, wireless sensors, and other linked objects. This gives better awareness of the context of service and user demands, allowing for more efficient user assistance.

2) *Teacher unit:* The second real-world object is the teacher. This unit refers to a variety of things that may be added to both learner and teacher terminals to help in tracking and identification.

- **Identification:** The purpose of this unit is to determine the identity of the user, availability, and status. For example, this module will identify if a learner spends too much time on one slide throughout revision. In this scenario, he is having difficulty comprehending this slide, thus an alert will be issued to the student to see whether he requires further activities or assistance.
- **Assessment:** This unit sends out messages to learners informing them of upcoming tests and evaluations.

3) *The operation unit:* Operation (i.e., operation and application systems) includes different functions such as monitoring and administering units that enable operators to manage the IoT systems' overall functionality and optimize the overall performance of the systems.

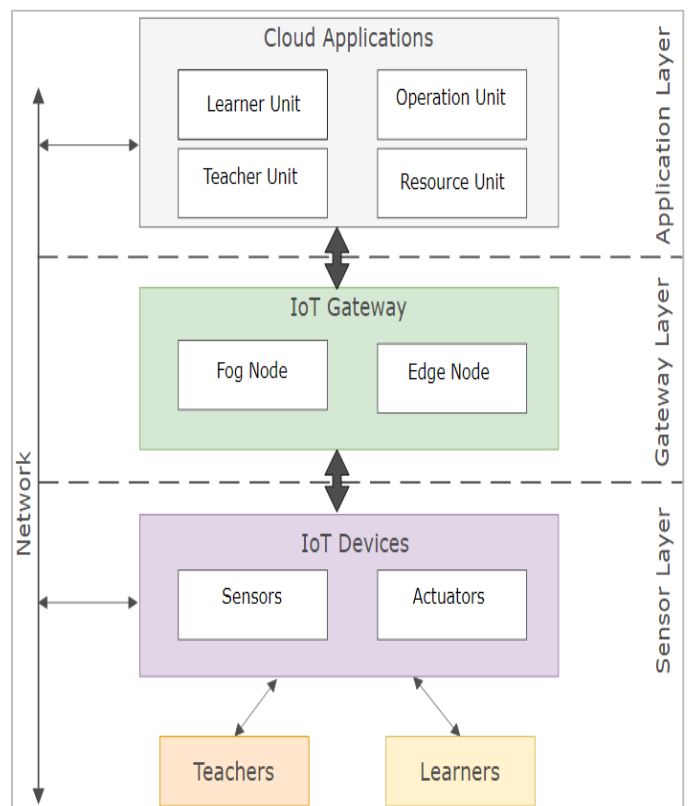

Fig. 5. Internet of Things e-learning system entity model.

4) *Resource unit*: It includes the regulated endpoints that provide services to IoT system participants who interact with each other and the peer system via their devices. It allows them to have access to the capabilities of the IoT system.

- **Material**: The course materials will be contained in this unit. The teacher will keep it up to date. It will give pupils sufficient materials.
- **Support**: The goal of this unit is to give support to learners whenever they require it.

A. *RQ4: The Impact of Implementing Internet of Things (IoT) in e-Learning Systems*

One of the most significant effects of utilizing IoT in e-learning is the expansion that results from linking learning environments with each other. The interconnection is between the learning parties and also between the different learning environments [37]. IoT in e-learning changes the learning process and enhances performance [82]. Accessibility and collaboration are the most important benefits that learners gain from integrating this technology with e-learning systems [21, 22]. Accessibility improves data sharing speed, note delivery costs, and self-skills [19, 88]. Achieving revolutionary technological development lowers the failure rate of e-learning recipients and professionals [16]. IoT e-learning applications can offer modern inventions and ways to upgrade learning activities. It provides effective participation and helps e-learners integrate into the learning community. The smart classroom is an essential part of IoT e-learning because it generates smart features that, in turn, create high-quality education [10]. Virtual classrooms let teachers know what their students need to learn and how they want to learn it [39]. This is good for both the students and the teachers. Applying IoT in the learning environment increases the speed of receiving and retrieving information by learners in addition to the quality of teacher performance, helps to suggest an intelligent lesson schedule, and continuously monitors important resources and other activities [14].

Linking IoT to e-learning systems reduces instructors' administrative work and invests time in promoting students' skills and talents [65]. IoT aids in collecting and analyzing a massive amount of data and statistics related to students [18]. Gathering the data from IoT smart objects, with which the learner interacts, produces special files that contain personal information in the e-learning system for each learner [13]. Smart learning helps to acquire knowledge quickly and easily, generate new perspectives and solutions, and inspire a comfortable environment, which may be the pinnacle of creativity and enjoyment for all learners and instructors [41]. The use of IoT e-learning helps to connect anyone with everything at any time and from any location [17]. IoT smart tools have the capabilities of observing, communicating, and converting research into intelligence [21].

IX. DISCUSSION

This paper aims to answer the main research question of how IoT is used in the e-learning process and, accordingly,

answer the sub-questions that identify the object, design, and future of IoT in e-learning. The following sub-section discusses the implications of the findings of this paper on both the industry and the research community. Also, the future of IoT in the e-learning process (i.e., RQ5) is discussed.

A. *Research Implication*

The interest in keeping track of the emergence of new technology is one of the most substantial issues that must be given priority in the field of research because it is the basis for developments in all areas. e-Learning systems are a topic of interest and concern among research societies. This study shows that using IoT technology in an e-learning environment is important and necessary. There may be obstacles to the acquisition of IoT smart devices. Some learners and instructors are accustomed to the old system and their adherence to the traditional method, which is considered one of those complications, however, the urgent need requires more diligence to achieve the objectives. The compass is now heading towards smart learning, and the learner represents the need; thus, it must be directed in the correct direction.

Due to the major impact of implementing IoT technology in e-learning systems, system sustainability must be maintained through the configuration of environment-appropriate equipment. The quality of the Internet is one of the factors behind the success of this technology, so the network structure must be constantly reviewed and maintained. The novelty of technology requires extensive training and comprehensive awareness for all learning parties. Technology has no alternative but better technology, so the pursuit of development is a basic requirement. Meanwhile, a balance must be struck between many connected devices to improve quality and monitoring them and ensuring their safety to achieve the desired results. This study can argue that the learning process has an enormous social role. There are many electronic devices, but they are not currently listed among the IoT devices, and the number of intelligent devices will increase to several billion.

B. *RQ5: Challenges and Future Directions of IoT in e-Learning Systems?*

Without a strong direction for how diverse "things" and e-learning systems should interact, the area of e-learning continues to grow. As a result, achieving interoperability in future educational experiences powered by the IoT is critical. A lot of challenges, such as access controls, technological and conceptual interoperability difficulties, privacy and security issues, and QoS tracking, must be acknowledged in order to promote smooth interaction and resource sharing among diverse and globally dispersed IoT devices, e-learning systems, IoT devices, software solutions, and users [66]. The identification of the issues of e-learning integration with IoT gives fresh views for academics and organizations, as well as introducing communities from many industries to the present challenges and future potential in this field. This article's review of related work identified five future challenges of e-learning and IoT integration, which are illustrated in Fig. 6, and discussed as follows:

- **Privacy and security:** Even though IoT technologies are evolving, and a growing number of devices are becoming widespread, security remains a major concern. Devices may be attacked, and present security flaws put people in danger. To safeguard students' and instructors' privacy and security while allowing secure information exchange and handling, more research and design efforts are needed [93]. To create effective and acceptable solutions to address IoT security concerns, a collaborative approach to security will be necessary. Moreover, the IoT's true capacity is contingent on privacy-conscious practices. To generate value, new strategies must be developed that take into account the user's privacy preferences and expectations while also encouraging technological innovation and applications [94]. Quantum computing may enable the development of safe processors soon, paving the way for secure products. Regulations and standards must be developed and executed to guarantee secure data transfer and storage under laws and regulations.

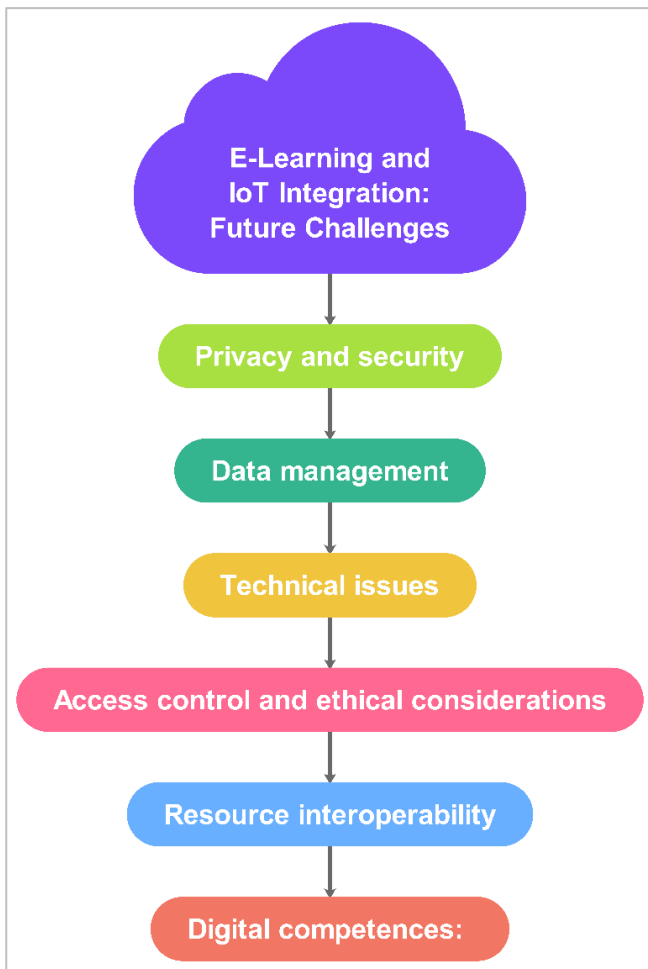

Fig. 6. e-Learning and IoT integration future challenges.

- **Data management:** The massive volumes of data created by IoT devices have significant prospects for advancing e-learning and citizen life. To improve the learning process, this data can be merged with big

datasets and examined instantaneously using new analytics techniques [95]. Nevertheless, there are various issues regarding data ownership accessibility, including the absence of coherent and transparent data ownership legislation. Such issues need further research to be addressed and clear policies to be implemented. Moreover, the massive volumes of data contain a lot of distortion, which makes data analysis difficult. Current methodologies lack the level of resilience necessary, necessitating the implementation of novel data analytics techniques and software tools [78, 95-100]. On the other hand, appropriate visual techniques must be developed in order to acquire meaningful insights into the data collected. Existing methodologies are ineffective when dealing with large amounts of data generated by IoT devices. Information loss, visual distortion, rapidly changing images, huge observation, and high-performance needs are all challenges that need to be handled further.

- **Technical issues:** Although the IoT provides new options for delivering digital courses, it also poses issues in terms of maintaining instructional quality and evaluating students' work. In order to increase the e-learning quality, new IoT applications and tools are required [101]. Future e-learning systems must offer flexibility and context awareness. Educators and educational organizations can deliver an adaptable learning opportunity by assessing the learners' contextual material. Contextual ontologies, on the other hand, remain a significant difficulty [34]. In future e-learning systems, the software systems, integrated e-learning infrastructures, and "things", therefore enabling e-learning systems to use as few resources as possible [101]. This is extremely difficult given the large number of resources that will be required to create future e-learning systems. This problem might be solved by utilizing and creating techniques for scheduling, optimization, reuse software components and strategic planning as well as the utilization of alternative energy sources [45]. Moreover, several e-learning platforms use hybrid Cloud as their business architecture to host IoT applications. Therefore, communication with the Cloud should be easy and have low latency with such a huge amount of data created from ubiquitous resources.
- **Access control and ethical considerations:** It is critical to develop suitable ways to control individuals and their privileged access in forthcoming e-learning systems. Providing a person complete control over activities affecting his or her identification, distributed online identity, and multisensory identity are all concepts that should be thoroughly investigated [93]. In addition, the social value of interoperability in future e-learning systems, as well as the possible risks, must be thoroughly investigated. academic institutions, students, instructors, policymakers, and citizens might all benefit from a paradigm that analyzes the technological and ethical limitations of maintaining interoperability in future e-learning systems [101].

- Resource interoperability: In the e-learning context, usually, the emphasis on interoperability is on technological concerns such as data format and communication protocols [101]. However, addressing the factors of organizational and managerial interoperability such as regulations as well as information/knowledge interoperability such as semantics is crucial. The New European Interoperability Framework, which aims to provide the best service and information flow, might be useful for addressing managerial and information interoperability, in future e-learning systems [66]. Moreover, due to the rapid development of technology, researchers and the e-learning industry must continuously pursue and search constantly to find out what is new and useful. The future of IoT will be favorable as long as there is a continuous evolution and thus will affect the future of e-learning and related technology [66].
- Digital competences: The terms "digital competencies" refer to the creation of digital material, data and information knowledge, collaboration and communication, analysis, and problem-solving. To successfully engage in e-learning, learners must possess certain competencies. Several of these competences may be lacking in learners, which can cause a variety of problems, including difficulties with digital creation (such as system design), problems finding and applying digital materials, a lack of analytic capabilities, struggle while exchanging information via modern technology, and are unable to judge the accuracy and worth of information [94].

In the future, learners should have good skills and capabilities to be more competitive. All e-learning parties will gain great benefits through the advancement of their activities, such as the safety of the learning environment, while management, the institutional structure, and the governments may achieve considerable financial benefits and thus importantly contribute to the stability of the educational sector [14]. Future research may extend this study and introduce new technologies to improve the educational sector and resolve related issues.

X. CONCLUSION

The way services are delivered has changed because of changes in communication technology and the invention and widespread use of IoT devices. Innovations in technology in the field of education make it easier to learn new things and get better at what you already know. e-Learning is one of the most significant systems because it has a great impact on learners, teachers, and the success of the educational process. Adding new technology makes it more effective and attractive. The lack of specific studies in this area encouraged the researchers to concentrate on investigating the previous studies related to integrating IoT in e-learning systems. This paper provides a comprehensive review that includes definition of the IoT e-learning system, the effective impact of utilizing IoT on this system, the advantages of the IoT, the operative tools used to transform learning into smart education and how to use them, and the future challenges and research

directions in the context of IoT e-learning integration. This research encourages innovating with modern technologies and applying them in the e-learning process. In the future, researchers and practitioners will be able to focus more on deep research in this field to add new technologies that help improve the e-learning process and open up new opportunities.

Abstract—This paper proposes a novel approach for scanned document categorization using a deep neural network architecture. The proposed approach leverages the strengths of both convolutional neural networks (CNNs) and recurrent neural networks (RNNs) to extract features from the scanned documents and model the dependencies between words in the documents. The pre-processed documents are first fed into a CNN, which learns and extracts features from the images. The extracted features are then passed through an RNN, which models the sequential nature of the text. The RNN produces a probability distribution over the predefined categories, and the document is classified into the category with the highest probability. The proposed approach is evaluated on a dataset of scanned documents, where each document is categorized into one of four predefined categories. The experimental results demonstrate that the proposed approach achieves high accuracy and outperforms existing methods. The proposed approach achieves an overall accuracy of 97.3%, which is significantly higher than the existing methods' accuracy. Additionally, the proposed approach's performance was robust to variations in the quality of the scanned documents and the OCR accuracy. The contributions of this paper are twofold. Firstly, it proposes a novel approach for scanned document categorization using deep neural networks that leverages the strengths of CNNs and RNNs. Secondly; it demonstrates the effectiveness of the proposed approach on a dataset of scanned documents, highlighting its potential applications in various domains, such as information retrieval, data mining, and document management. The proposed approach can help organizations manage and analyze large volumes of data efficiently.

Keywords—Deep learning; CNN; RNN; classification; image analysis

I. INTRODUCTION

In today's digital era, the amount of information and data that businesses and organizations accumulate has increased significantly [1]. This has made it challenging to manage, analyze, and classify large volumes of data, particularly in the form of documents. Document categorization is a crucial task that aims to classify documents into predefined categories to facilitate their management and analysis. Traditional approaches to document categorization or document classification problem have relied on manual classification or

rule-based systems, which are time-consuming, labor-intensive, and prone to errors [2]. In contrast, deep learning techniques have shown great promise in automating document categorization problems, offering a more efficient, accurate, and scalable solution of the given problem [3].

Scanned documents are a particular type of document that poses unique challenges for document categorization. Unlike digital documents, scanned documents are typically in image format and require optical character recognition (OCR) before being processed by the model [4]. Optical character recognition software aims to recognize the text in the image and convert it into machine-readable format [5]. However, optical character recognition software may introduce errors or inaccuracies that can negatively impact the performance of the document categorization model. As a result, the use of deep learning techniques can help mitigate these challenges and improve the accuracy of scanned document categorization.

In recent years, deep learning techniques have revolutionized the field of document categorization. Convolutional neural networks (CNN) are particularly well-suited for image-based tasks, such as scanned document categorization, as they can automatically learn and extract features from the image [6]. Recurrent neural networks (RNN), on the other hand, are useful for modeling sequential data, such as text, and can learn the context and dependencies between words in a document [7].

The proposed approach in this paper aims to leverage the strengths of CNNs and RNNs to categorize scanned documents accurately. Specifically, the approach involves pre-processing the scanned documents using optical character recognition and converting them into a machine-readable format. The pre-processed documents are then fed into a convolutional neural network, which automatically learns and extracts features from the images. The extracted features are then passed through a recurrent neural network, which learns the dependencies and context between words in the document. Finally, the recurrent neural network produces a probability distribution over the predefined categories, and the document is classified into the category with the highest probability.

The proposed approach is evaluated on a dataset of scanned documents, where each document is categorized into one of four predefined categories. The experimental results demonstrate that the proposed approach achieves high accuracy and outperforms existing methods. The proposed approach achieved an overall accuracy of 97.3%, which is significantly higher than the existing methods' accuracy. Additionally, the proposed approach's performance was robust to variations in the quality of the scanned documents and the OCR accuracy.

The contributions of this paper are twofold. Firstly, it proposes a novel approach for scanned document categorization using deep learning techniques that leverage the strengths of CNNs and RNNs. Secondly, it demonstrates the effectiveness of the proposed approach on a dataset of scanned documents, highlighting its potential applications in various domains, such as information retrieval, data mining, and document management.

Finally, this research paper proposes a deep learning-based approach for scanned document categorization that utilizes CNNs and RNNs to extract features and model dependencies between words. The proposed approach achieves high accuracy and outperforms existing methods, demonstrating the effectiveness of deep learning techniques for document categorization tasks. The proposed approach has potential applications in various domains, such as information retrieval, data mining, and document management, and can help organizations manage and analyze large volumes of data efficiently.

II. RELATED WORKS

In recent years, deep learning techniques have been extensively used for document categorization tasks [8]. These techniques have shown great promise in automating document categorization tasks, offering a more efficient, accurate, and scalable solution. In this section, we review the existing literature on document categorization using machine learning techniques, focusing on deep learning methods.

Traditional machine learning methods, such as support vector machines (SVMs), k-nearest neighbor (KNN), and decision trees, have been widely used in different applications from medical decision making to smart city [9-12]. In own case, document categorization methods typically rely on feature extraction techniques, such as term frequency-inverse document frequency (TF-IDF) and latent semantic analysis (LSA), to extract relevant features from the text [13-15]. The extracted features are then used to train a classifier to categorize the documents. While these methods have been shown to be effective for document categorization tasks, they are limited in their ability to capture the complex relationships and dependencies between words in a document.

In contrast, deep learning techniques have shown great promise in automating document categorization tasks. Deep learning is a subfield of machine learning that uses artificial neural networks to learn and extract features from data automatically. Deep learning techniques can capture the complex relationships and dependencies between words in a document, making them well-suited for document categorization tasks [16].

Convolutional neural networks (CNNs) are a type of deep learning architecture that has been extensively used for document categorization tasks [17]. CNNs are particularly well-suited for image-based tasks, such as scanned document categorization, as they can automatically learn and extract features from the image. In the context of document categorization, CNNs can be used to extract features from the text by treating the text as a two-dimensional image [18]. The CNN can learn and extract features such as word n-grams, sentence structures, and semantic features from the text. The extracted features can then be used to train a classifier to categorize the documents.

Recurrent neural networks (RNNs) are another type of deep learning architecture that has been used for document categorization tasks [19]. RNNs are useful for modeling sequential data, such as text, and can learn the context and dependencies between words in a document. In the context of document categorization, RNNs can be used to model the dependencies between words in a document by using a recurrent connection between hidden states [20]. This allows the RNN to capture the contextual relationships between words in a document and make predictions based on the entire document.

Several studies have used deep learning techniques, such as CNNs and RNNs, for document categorization tasks. For instance, in the study by Zhang et al. (2016), a CNN-based approach was proposed for document categorization [21]. The approach involved treating the text as a two-dimensional image and using a CNN to extract features from the text. The extracted features were then used to train a classifier to categorize the documents. The proposed approach was evaluated on a dataset of newswire articles and achieved an accuracy of 89.4%, outperforming traditional machine learning methods.

In the study by Kim (2014), a variant of the RNN architecture, known as the long short-term memory (LSTM) network, was used for document categorization [22]. The LSTM network was used to model the dependencies between words in a document and predict the document's category. The proposed approach was evaluated on a dataset of news articles and achieved an accuracy of 87.2%, outperforming traditional machine learning methods.

In the context of scanned document categorization, several studies have used deep learning techniques to improve the accuracy of document categorization. For instance, in the study by Gordo et al. (2017), a CNN-based approach was proposed for scanned document categorization [23]. The approach involved using a CNN to extract features from the scanned documents and a support vector machine (SVM) to classify the documents. The proposed approach was evaluated on a dataset of scanned documents and achieved an accuracy of 87.5%, outperforming traditional machine learning methods.

Similarly, in the study by Lu et al. (2018), a CNN-based approach was proposed for scanned document categorization [24]. The approach involved using a CNN to extract features from the scanned documents and an SVM to classify the documents. The proposed approach was evaluated on a dataset

of scanned receipts and achieved an accuracy of 94.6%, outperforming traditional machine learning methods.

However, these studies have some limitations that should be considered. Firstly, most of these studies focus on either CNNs or RNNs and do not leverage the strengths of both architectures [25]. Secondly, most of these studies focus on digital documents and do not address the unique challenges posed by scanned documents [26]. Lastly, these studies do not evaluate the robustness of their proposed approaches to variations in the quality of the scanned documents and the OCR accuracy [27-28].

In contrast, the proposed approach in this paper leverages the strengths of both CNNs and RNNs to extract features from the scanned documents and model the dependencies between words in the documents. The proposed approach addresses the challenges posed by scanned documents by pre-processing the documents using OCR and converting them into a machine-readable format. The proposed approach is evaluated on a dataset of scanned documents, where each document is categorized into one of four predefined categories. The experimental results demonstrate that the proposed approach achieves high accuracy and outperforms existing methods. Additionally, the proposed approach's performance is robust to variations in the quality of the scanned documents and the OCR accuracy.

Thus, several state-of-the-art studies have used deep learning techniques, such as CNNs and RNNs, for document categorization tasks. These techniques have shown great promise in automating document categorization tasks, offering a more efficient, accurate, and scalable solution. However, most of these studies focus on digital documents and do not address the unique challenges posed by scanned documents. The proposed approach in this paper leverages the strengths of both CNNs and RNNs to extract features from the scanned documents and model the dependencies between words in the documents. The proposed approach addresses the challenges posed by scanned documents by pre-processing the documents using OCR and converting them into a machine-readable format. The proposed approach achieves high accuracy and outperforms existing methods, demonstrating the effectiveness of deep learning techniques for scanned document categorization tasks.

III. PROPOSED METHOD

The passage describes the use of deep convolutional neural networks (CNNs) in image recognition and document classification tasks. Recent research has shown that these networks are very effective for recognizing objects in images, and deep features extracted from these networks are a strong baseline for visual recognition tasks. Fig. 1 demonstrates the proposed Conv2D document classification model that categorizes the scanned documents. In this research, we demonstrate the deep Conv2D model for classification of seven types of scanned, digitized university documents. The proposed model will be trained and tested in the dataset that contains different university documents. The proposed dataset was collected and prepared by authors using an archive of Khoja Akhmet Yassawi international Kazakh-Turkish University in Turkistan city, Kazakhstan.

Fig. 1. The proposed system architecture.

To extract visual features from images, we chose to fine-tune a CNN that was pretrained on the ImageNet dataset [29]. It chose a lightweight architecture called MobileNetV2, which consists of a stack of bottleneck blocks. Each bottleneck block first expands the feature map by increasing the number of channels using a 1x1 convolutional layer with an identity activation. Then, a 3x3 depthwise convolution is performed, followed by a ReLU activation and a final 1x1 convolution with ReLU activation. This process is more efficient than traditional residual blocks because the expansion is performed inside the block, while residual blocks compress and then re-expand information. The final MobileNetV2 model contains 19 residual bottleneck layers and is faster than other state-of-the-art CNNs while maintaining similar accuracy levels.

Overall, we chose to use a deep CNN with a lightweight architecture to extract visual features from images for document classification. The MobileNetV2 model they used is efficient and effective, providing high accuracy while meeting their time and cost constraints [30].

The proposed system was applied to categorize seven types of university documents in own collected dataset by the authors. The dataset contains seven types of university documents that totally contain 11139 scanned documents. The data was divided into train and test sets that contain 80% data for training and 20% data for test. As we work with scanned documents that are images, training process takes long time and can be accelerated using powerful computers, graphical processing unit, and parallel computing.

In our case, we use a computer with 12 Intel 4.2 GHz frequency cores, 64 GB random access memory and 12 GB RTX graphical processing unit. Training process is continued to 28 hours.

IV. EXPERIMENT RESULTS

A. Evaluation Parameters

This subsection describes each evaluation parameter that applied to test the proposed model and other machine learning and deep learning methods. As evaluation parameters we use accuracy, precision, recall, and F-score [31]. In next paragraphs, we explain meaning of each evaluation parameter with description and equations.

Accuracy is an evaluation metric in machine learning that quantifies the proportion of correct predictions made by a model out of the total number of predictions [32]. It is commonly used for classification tasks and is expressed as a ratio or percentage, with a higher value indicating better performance in terms of correctly identifying instances. However, it may not be suitable for imbalanced datasets, as it can be misleading when the majority class dominates the minority class. Eq. (1) demonstrates formula of accuracy evaluation parameter, considering true positives (TP), true negatives (TN), false positives (FP), and false negatives (FN) as argument values in the equation.

$$accuracy = \frac{TP + TN}{TP + FN + TN + FP}, \quad (1)$$

Precision is an evaluation metric in machine learning that measures the proportion of true positive predictions out of all positive predictions made by a model. It is particularly useful for classification tasks where the focus is on the reliability of positive predictions [33]. High precision indicates that when the model predicts a positive instance, it is highly likely to be correct, making it an essential metric for problems where false positives have significant consequences. Eq. (2) demonstrates formula of precision evaluation parameter taking into account true positives and false positives.

$$precision = \frac{TP}{TP + FP}, \quad (2)$$

Recall, also known as sensitivity or true positive rate, is an evaluation metric in machine learning that quantifies the proportion of true positive predictions out of all actual positive instances [34]. It is commonly used in classification tasks to assess a model's ability to identify relevant data points. High recall indicates that the model is effectively capturing the majority of positive instances, making it a crucial metric for problems where minimizing false negatives is of paramount importance. Eq. (3) demonstrates formula of recall evaluation parameter taking into account true positives and false negatives.

$$recall = \frac{TP}{TP + FN}, \quad (3)$$

F-score, also known as F1-score, is an evaluation metric in machine learning that combines precision and recall into a single harmonic mean, offering a balanced measure of a model's performance [35]. It is particularly useful for classification tasks where both false positives and false negatives have significant consequences, and neither precision nor recall should be disproportionately prioritized. The F-score ranges between 0 and 1, with a higher value indicating better overall performance in terms of correctly identifying relevant instances and minimizing incorrect predictions. Eq. (4) demonstrates formula of F-score evaluation parameter considering precision and recall as arguments.

$$F1 = \frac{2 \cdot precision \cdot recall}{precision + recall}, \quad (4)$$

B. Results

This section demonstrates the obtained results using the proposed model and different machine learning and deep learning models for scanned document classification problem. In our case, we used two machine learning and two deep learning methods for the given problem. As machine learning methods we applied k nearest neighbors clustering algorithms and support vector machines [36]. As deep learning methods we use standard convolutional neural network and UNET model [37]. Fig. 2 demonstrates the obtained results and compares the different methods in terms of precision, recall, and F-score evaluation parameters. Horizontal axis demonstrates the model accuracy, vertical axis demonstrates the obtained models. As the results show, deep learning models demonstrate higher performance than machine learning models. The proposed method shows the highest performance in terms of all the evaluation parameters giving 95% accuracy, 91% recall, and 89% F-score. The results show, that the proposed model can be applied in real application to multiclass classification of scanned documents.

Fig. 2. Comparison of the obtained results.

Fig. 3 and Fig. 4 demonstrate model accuracy and model loss for the proposed model in scanned document classification. Fig. 3 shows the model accuracy for the train and test set. Horizontal axis shows learning epochs and vertical axis illustrates accuracy of the proposed model. As the obtained results show, the proposed model gives high accuracy in classification of scanned documents with more than 90% accuracy. 90% accuracy for multiclass classification is high result. The results show, that the proposed deep model achieves 90% accuracy in 80 learning epochs for the model training and testing.

Fig. 3. Model accuracy.

Fig. 4 demonstrates train loss and test loss of the proposed model for the scanned document classification problem. Model loss is applied to compare with the model accuracy. Comparison of Fig. 3 and Fig. 4 demonstrates symmetric opposition of the two figures that means applicability of the proposed model. Training continued to 80 epochs. As we can see from the figure, train and test losses coincides with each other. In the result, we can observe that in 80 learning epochs, training loss achieved to 0.25 and test loss achieved to 0.5 that means high accuracy in document clustering.

Fig. 4. Model loss.

Model accuracy and model loss take a hyperbolic shape. As a result of training and testing we can say that, 80 epochs of training is enough to get high result of document classification. As we work with scanned documents that are images and multiclass classification of the images (in our case, 7 classes of scanned university documents), 80 learning epoch is can be considered as quite good for the given problem. Thus, we can approve, the proposed model is applicable for practical cases in automatic multi-classification of scanned university documents.

Fig. 5. Confusion matrix.

Fig. 5 demonstrates confusion matrix for the proposed model. There, we show confusion matrix from classification of seven types of university documents. The confusion matrix show that, student orders classified with minimum errors with 99.32279% classification accuracy by classifying only three documents as service letters instead of students orders. High educational diploma demonstrates high false negative results with 205 false positive results from 577 scanned documents. Thus, the classification result varies from 75% to 99.32% depending on the document type.

V. DISCUSSION

The use of deep learning techniques has revolutionized the field of artificial intelligence (AI), enabling machines to learn and perform complex tasks with high accuracy [38]. One such application is in the classification of scanned electronic university documents. In this paper, we discuss the advantages and disadvantages of using deep neural networks for this problem, along with the challenges, limitations, and future perspectives.

A. Advantages of Deep Learning in Scanned Document Classification

Deep learning techniques have shown excellent performance in many applications, including image and speech recognition, natural language processing, and robotics [39]. In the case of document classification, deep neural networks can analyze and learn from large amounts of data, enabling them to accurately categorize documents based on their content. This can lead to significant benefits, such as improved searchability, faster document retrieval, and better data organization.

Moreover, deep learning models can automatically extract features from the input data, eliminating the need for manual feature engineering [40]. This can significantly reduce the time

and effort required to develop a classification system, making it more scalable and adaptable to different document types.

Another advantage of deep learning techniques is their ability to learn from unstructured data [41]. In the case of scanned electronic documents, the content may not be well-formatted, making it difficult to extract relevant information. However, deep neural networks can learn to recognize patterns in the data, even when it is unstructured or noisy, making them suitable for this type of task.

B. Disadvantages of Deep Learning in Scanned Document Classification

Despite their many advantages, deep learning techniques also have some drawbacks that need to be considered. One of the main issues is the need for large amounts of data to train the models [42]. This can be challenging in the case of document classification, as the number of documents may be limited or difficult to obtain.

Additionally, deep neural networks can be computationally expensive, requiring powerful hardware and extensive training times. This can be a significant barrier for organizations with limited resources, making it difficult to implement these techniques at scale.

Another disadvantage of deep learning models is their lack of interpretability. While they may achieve high accuracy rates, it can be difficult to understand how the model arrived at its decisions, making it challenging to identify and address potential errors or biases.

C. Challenges in Scanned Document Classification Problem

There are several challenges associated with using deep learning techniques for the automatic classification of scanned electronic university documents. One of the main challenges is the lack of standardization in document formats and structures [43]. Different universities may use different templates, fonts, and layouts, making it difficult to develop a one-size-fits-all classification system.

Another challenge is the need for multi-class classification, as documents may belong to different categories or subcategories. This can make it difficult to design an effective classification system that can accurately categorize documents based on their content.

Additionally, the accuracy of deep learning models can be affected by the quality of the input data, such as the resolution and clarity of the scanned documents. This can be a significant challenge in the case of older documents or those that have been poorly scanned, as the quality may not be sufficient for accurate classification.

D. Limitations in Scanned Document Classification

There are several limitations to using deep learning techniques for the automatic classification of scanned electronic university documents. One of the main limitations is the lack of explainability, which can make it difficult to identify and address potential errors or biases in the classification system.

Another limitation is the potential for overfitting, where the model becomes too specialized to the training data and does

not generalize well to new data [44]. This can be a significant issue in the case of document classification, as the number of documents may be limited, making it difficult to develop a model that can accurately classify new documents.

E. Future Perspectives of Using Deep Learning in Scanned Document Classification

Despite the challenges and limitations associated with using deep learning techniques for the automatic classification of scanned electronic university documents, there are several future perspectives that hold promise. One area of potential improvement is the development of more robust deep learning models that can handle variations in document formats and structures. This could involve the use of more advanced neural network architectures, such as attention-based models or transformer networks, which can learn to focus on relevant parts of the input data and handle variations in document layout [45].

Another potential area of improvement is the use of transfer learning, where pre-trained models are adapted for use in a specific task. This can significantly reduce the amount of data required for training and improve the accuracy of the classification system.

Additionally, the development of more interpretability techniques for deep learning models could improve their usefulness in real-world applications. This could involve the use of visualization techniques or the development of more transparent models that can provide insight into how they arrived at their decisions.

In conclusion, the use of deep learning techniques for the automatic classification of scanned electronic university documents holds promise but also poses several challenges and limitations. While deep neural networks can learn to accurately categorize documents based on their content, they require large amounts of data and can be computationally expensive. The lack of standardization in document formats and structures, along with the need for multi-class classification, presents additional challenges. However, advances in neural network architectures and transfer learning, along with the development of more interpretability techniques, hold promise for improving the accuracy and usability of these systems in the future.

VI. CONCLUSION

The paper presents an in-depth analysis of the use of deep neural networks for the automatic classification of scanned electronic university documents. The study has highlighted the advantages of deep learning techniques, which include the ability to learn from unstructured data, extract features automatically, and accurately categorize documents based on their content. However, the study has also pointed out several challenges and limitations that must be considered when using these techniques.

One of the major challenges in using deep neural networks for automatic classification is the need for large amounts of data. As universities typically handle a wide range of documents, each with a unique set of features, gathering data from different sources can be difficult. Additionally, the accuracy of the classification model is dependent on the quality

of the data. Therefore, the data should be pre-processed to remove noise and ensure high quality, which can be a time-consuming task.

Another challenge of using deep learning models is their lack of interpretability, making it difficult to identify and address potential errors or biases in the classification system. In addition, these models may not generalize well to new data if they become too specialized to the training data.

Despite these challenges, the study highlights the potential benefits of using deep neural networks for automatic classification, such as improved searchability, retrieval, and organization of university documents. Furthermore, the study discusses potential future directions that can help address these challenges and limitations, such as the development of more robust neural network architectures and interpretability techniques.

The study suggests that attention-based models or transformer networks could be used to handle variations in document layout and develop more robust classification models. Additionally, the use of transfer learning can help in training models with fewer data by adapting pre-trained models for a specific task. Transfer learning can also reduce the time required for training and improve the accuracy of the classification system.

Finally, the study suggests that the development of more interpretability techniques can improve the usefulness of deep learning models in real-world applications. Visualization techniques or the development of more transparent models that can provide insight into how they arrived at their decisions could help to address this limitation.

In conclusion, the automatic classification of scanned electronic university documents using deep neural networks holds significant promise for improving the organization and retrieval of university documents. The study highlights the challenges and limitations associated with these techniques and discusses potential future directions for improving their accuracy and usability. Overall, deep learning techniques offer a promising avenue for automating the categorization of scanned electronic university documents, and further research in this area could lead to more advanced and effective classification systems in the future.

Combinatorial Optimization Design of Search Tree Model Based on Hash Storage

Yun Liu, Jiajun Li*, Jingjing Chen

Basic School of Computer and Artificial Intelligence, Chaohu University, Chaohu, 238024, China

Abstract—The game search tree model usually does not consider the state information of similar nodes, which results in searching a huge state space, and there are problems such as the size of the game tree and the long solution time. In view of this, the article proposes a scheme using the idea of combinatorial optimization algorithm, which has an important application in solving the decision problem in the tree graph model. First, the special graph-theoretic structure of the point-grid game is analyzed, and the storage and search of states are optimized by designing hash functions; then, the branch delimitation algorithm is used to search the state space, and the evaluation value of repeated nodes is calculated by dynamic programming; finally, the state space is greatly reduced by combining the two-way detection search strategy. The results show that the algorithm improves decision-making efficiency and has achieved 37% and 42% final winning rate, respectively. The design provides new ideas for computational complexity problems in the field of game search and also proposes new solutions for the field of combinatorial optimization.

Keywords—Combination optimization; game search algorithm; state space; transposition table

I. INTRODUCTION

Game search algorithms have gained significant attention in recent years for their applications in decision-making, optimization, and artificial intelligence across diverse domains. However, traditional algorithms such as Minimax and pruning algorithms have some limitations that hinder their effectiveness in solving complex games[1]. The Minimax algorithm, proposed by von Neumann, aims at solving two-player games by constructing a game tree that minimizes the maximum outcome. Despite exploring all possible states, it leads to a vast state space. Pruning algorithms, like alpha-beta pruning by Yang and Feinberg, aim to reduce the search space but struggle with revisiting previously explored states[2].

Alternative approaches have been proposed, such as the PVS search algorithm by Kaufman and the branch-and-bound algorithm by Tucker[3]. However, existing algorithms often overlook superior decisions and yield suboptimal solutions[4]. This paper presents a novel combinatorial optimization algorithm based on branch delimitation to address large state spaces in point-grid chess game graph theory problems. It analyzes the graph structure, optimizes state storage with hash functions[5], employs the branch delimitation algorithm for efficient exploration, calculates evaluation values using dynamic programming, and implements a two-way detection search strategy to reduce the state space[6-8].

Experimental results demonstrate substantial improvements, with a 37% increase in the decision efficiency and a 42% higher final win rate. This paper contributes innovative ideas to address the computational complexity in a game search and provides new solutions for combinatorial optimization. Overall, this study advances understanding and application of game search algorithms, specifically for addressing large state spaces in point-grid chess game graph theory problems[9]. The proposed combinatorial optimization algorithm offers superior performance and has the potential to overcome limitations in traditional approaches[10], making it a valuable contribution to the field.

II. BASICS OF DOTS AND BOXES

A. Introduction to the Game

Dots and boxes are popular intellectual game due to its simplicity, ease of learning, entertainment value, and puzzle-solving nature. Unlike other board games such as Gomoku, dots and boxes has a unique set of rules. In this game, a legal move involves drawing a line between two dots on the board. Players take turns placing their pieces on the board until all four edges of a grid cell have been claimed[11]. Once a player captures a grid cell, they get an extra turn. In a 6x6 dots and boxes game, the mathematical formula for calculating the number of captured grid cells can be expressed as formula (1).

$$C(p) = \{q \in V \mid X_q = 0, (p, q) \in E\} \quad (1)$$

Here, $C(p)$ represents the set of captured cells, V represents the set of points, E represents the set of edges, and (p, q) represents the edge between vertices p and q on the game board. $X_q=0$ means that there is no chess piece on point q . The winner is determined by the number of cells captured by the players when neither side can make any further moves[12].

B. Game Abstraction forms and Theorems

The game of dots and boxes has a special data structure in machine game competitions, where some game states often determine the outcome of the game[13]. This is because the formation of some game states can lead to significant changes in the next game situation, and one player can capture a large number of boxes through these game states, thereby increasing their chances of winning[14].

Theorem 1. Designing checkerboard storage based on move rules.

$$M(p, q) = \begin{cases} \text{short move, } N(p) < 3 \\ \text{long move, } N(p) \geq 3 \text{ and } N(q) \geq 3 \\ \text{invalid move, otherwise} \end{cases} \quad (2)$$

Formula (2) defines the types of moves from point p to point q in dots and boxes games. When the number of empty points around point p is less than 3, the move is called a short step. When the number of empty points around point p is greater than or equal to 3 and the number of empty points around point q is also greater than or equal to 3, the move is called a long step[15]. Other moves are considered invalid moves.

Theorem 2. The long chain theorem predicts sure-win strategies.

$$R(C) = \min_{v \in C} \max_{u \in N(v) \cap C} L(C - v) - L(C - u) \quad (3)$$

Such as formula (3). Let $R(C)$ denote the maximum profit that can be obtained by playing chain C in the game[16], and let $N(v)$ denote the set of points adjacent to the point v. Suppose that there are two players, A and B, in G. Let $S(G)$ be the set of winning strategies for A in G, and let $T(G)$ be the set of winning strategies for B in G. Then the long chain theorem can be stated as following formula (4).

$$C \in S(G) \Leftrightarrow R(C) > 0 \quad (4)$$

If the maximum profit $R(C)$ of a long chain C is greater than 0, then A has a winning strategy, otherwise B has a winning strategy.

Theorem 3. Stumping theorem predicts the likelihood of winning.

$$C(S, p) = 1 - |V(S, p)| / |P(S, p)| \quad (5)$$

Such as formula (5). Let S denote the current state of the board, and let p denote the next player to move (0 represents the first player, and 1 represents the second player). Let $V(S, p)$ be the set of all possible board states in which the next player to move can win[17], and let $P(S, p)$ be the set of all possible board states in which the next player to move can make a move.

Theorem 4. Calculated returns for hybrid strategies in gaming.

Let player A have a mixed strategy $\{x_1^*, x_2^*, \dots, x_m^*\} \in X_A$, and let player B have a mixed strategy $\{y_1^*, y_2^*, \dots, y_n^*\} \in Y_B$, such as formula (6).

$$E(x^*, y^*) = \max E(x, y^*) = \min E(x^*, y) \quad (x \in X, y \in Y) \quad (6)$$

That is formula (7) and (8).

$$\sum_{i=1}^m \sum_{j=1}^n c_{ij} x_i^* y_j^* = \max \sum_{i=1}^m \sum_{j=1}^n c_{ij} x_i y_j^* \quad (7)$$

$$\sum_{i=1}^m \sum_{j=1}^n c_{ij} x_i^* y_j^* = \min \sum_{i=1}^m \sum_{j=1}^n c_{ij} x_i^* y_j \quad (8)$$

In the game, player A and player B each have their own space of mixed strategies, X_A and X_B , respectively. $E(x^*, y^*)$ represents the payoff when using mixed strategy (x^*, y^*) . C is a matrix in which c_{ij} represents the payoff of two players under certain circumstances.

Theorems 5. Hashing for board representation.

Make the board state be represented as a vector $S = [s_1, s_2, \dots, s_n]$ of length n, where s_i represents the state of the i - th position, such as "black piece," "white piece," "empty,"

and so on[18]. Next, define a binary vector $B = [b_1, b_2, \dots, b_n]$ of length n, where the value of b_i is a randomly generated 0 or 1. Then, the new vector $X = [x_1, x_2, \dots, x_n]$ is obtained by performing a bitwise XOR operation between the S vector and the B vector, i.e., $x_i = s_i \text{ XOR } b_i$. Finally, each element of the X vector is treated as an 8-bit unsigned integer, and the hash value is calculated according to the following formula (9).

$$h(S) = \left((x_1 * 2^8 + x_2) * \dots * 2^8 + x_{n-1} \right) * 2^8 + x_n \quad (9)$$

Theorem 6. Generation of moves for the second player.

Given the current board state S, the second player generates a move M_{op} based on the position of the opponent's pieces and the rules, using the formula (10).

$$M_{op} = \text{move}_{op}(S, p) | p \in P_{op} \quad (10)$$

where $\text{move}_{op}(S, p)$ represents all possible moves for the opponent's piece p in the state S, and P_{op} represents the set of opponent's pieces[19].

Theorem 7. Calculation of the Depth of the Game Tree.

Assume that there are n feasible successor states at the current game state, and each successor state has m feasible successor states, and so on, until a game-ending state is reached[20]. Then, the depth of the game tree can be calculated using the following formula (11).

$$\text{Depth} = \log_m n \quad (11)$$

Theorem 8. Updating the branch delimitation benefit interval.

For a given position S, the best move obtained from the search starting from it is M, and the corresponding next position is S^* . According to the definition of branch delimitation algorithm, such as formula (12) (13).

$$\alpha = \max_{1 \leq i \leq n} \{ \alpha, f(S_i) \} \quad (12)$$

$$\beta = \min \{ \beta, f(S^*) \} \quad (13)$$

Theorem 9. Hash function clusters handle hash conflicts.

Select a sufficiently large prime number p so that each possible keyword falls within the range of 0 to p-1. Such as formula (14).

$$Z_p = \{0, 1, 2, \dots, p - 1\}, Z_p^* = \{1, 2, 3, \dots, p - 1\} \quad (14)$$

Now, for $a \in Z_p^*$ and $b \in Z_p$, define the hash function h_{ab} , which performs a linear transformation to reduce modulo m and modulo p, as follows formula (15).

$$h_{ab}(k) = ((ak + b) \text{ mod } p) \text{ mod } m \quad (15)$$

Thus, we obtain a hash function family, such as formula (16):

$$h_{ab}(k) = ((ak + b) \text{ mod } p) \text{ mod } m \quad (16)$$

Z_p and Z_p^* represent the sets of integers from 0 to p-1 and from 1 to p-1, respectively, and represent the range of possible keywords. h_{ab} is a hash function that maps the keyword k to the set of integers from 0 to m-1. H_{pm} is a hash function family[21], where each hash function is composed of the

defined hash function h_{ab} by linear transformation with modulo m and modulo p .

C. Branch Delimitation Algorithm Core Decision

This article focuses on strategic decision-making in the game theory and its relationship to winning odds. The article first proposes Theorem 2, using formulas (3) and (4) to calculate the maximum gain of each chain to analyze the gains of different chains in the game. Secondly[22], Theorem 3 can calculate the winning player through formula (5) and thus predict the final winner in a certain game state. Finally, the unique board of the dot game needs to judge the captured squares, which will cause one party to capture the squares in a row[23]. Theorem 4 is usually applied in the later stage of the game to decide whether to make a concession grid, and the player's payoff is calculated using equations (6), (7) and (8) through a mixed strategy[24]. For the lattice game, the algorithm recursively studies the game tree, quantizes the features into feature vectors, and uses dynamic programming to find the optimal weight until the final state of the game. The evaluation function of the branch and bound algorithm calculates the score for each state of the game[24].

The calculation is done as follows:

For edges of length less than 3 (i.e. short moves), such as formula (17).

$$f(x, y) = \begin{cases} 0, & x = 0 \\ -1, & x = -1 \\ -2, & x = -2 \end{cases} \quad (17)$$

For edges of length equal to 3 or greater (i.e. chain, rings, or long moves), such as formula (18).

$$f(x, y) = \begin{cases} 5 - \text{elength}, & x > 2 \\ -\text{elength} - 1, & x < 2, y = 1 \\ -\text{elength}, & x < 2, y = 0 \end{cases} \quad (18)$$

In formulas (17) and (18), $f(x, y)$ represents the evaluation function, where x represents the number of edges in the current state, and $y=1$ denotes a chain formed by the edges while $y=0$ denotes a loop formed by the edges. The length represents the length of the chain or loop. This evaluation function uses a recursive approach and performs a depth-first search, attempting various possible movements in each state[25].

III. DESIGN OF THE GAME TREE MODEL

A. Algorithmic Chessboard Design

The traditional matrix representation and the bit operation representation for chessboard state in artificial intelligence are analyzed[26]. The time complexity of matrix representation is $O(n^2)$, and the memory usage is high. The bitwise operation representation method requires a large amount of memory space[27], and due to the low efficiency of bitwise operation, it will lead to low searching efficiency. Both methods have disadvantages and limitations.

In this paper, we propose a hash function design based on Theorem 5 to map a chessboard state S to an unsigned 64-bit integer for representing the current game state. The hash function design employs a vector S of length n to represent the chessboard state and defines a binary vector B of length n to

shuffle the arrangement order of the status of each position in S , increasing the randomness and collision resistance of the hash function[28]. Meanwhile, XOR operation is used to enable the hash function to process each chessboard state quickly while maintaining low computational complexity.

We define the data structure of the hash table as $T[h(S)]=PHashNode$, where each $PHashNode$ stores key information about the current state, such as the evaluation value of the game position and the search depth[29]. We utilize the hash function to quickly identify duplicate nodes. When a new node is discovered, its hash value is stored in the hash table, and if it is a duplicate, it is skipped, reducing the number of searches.

Fig. 1. Hash table dots and boxes board position mapping.

As the hash function design process shown in Fig. 1, position is the information of current board position; value indicates the evaluation value of the current board position.

B. Specific Design of the Generation Strategy

The paper explores traditional moving generation methods in dots and boxes, including enumeration, first-player, and second-player methods. The enumeration method generates all possible moves for each point on the board, resulting in a move set of size $O(nm)$. The first-player method moves pieces without considering whether the moves are legal, potentially generating many invalid moves[30]. The second-player method considers only the opponent's piece movements, leading to a move set that does not include invalid moves from one's own piece movements, but may increase program complexity[31].

To ensure that all feasible moves in the game tree can be expanded at the same level, the article uses a breadth-first strategy based on hash storage. This strategy uses a queue to store all successor states of the current game state, enumerates all successor states, adds unvisited states to the queue, and expands them. The depth of the game tree is calculated using formula (11) in Theorem 7, and the breadth-first strategy ensures that all feasible states are traversed, and all possible moves are generated.

A schematic diagram of the landing process generated by players A and B in the same situation is shown in Fig. 2.

Fig. 2. Generated landings diagram.

Using equation (12) and (13) in Theorem 8 to calculate the dynamic gain interval of the branch-and-bound algorithm during the search. When $\beta \leq \alpha$, pruning can be performed. It is necessary to update $\beta \leq \alpha$ as soon as possible. When all moves and states of a board are generated and the available edges are sorted in ascending order, moves with larger evaluation values are searched first, which increases the number of updates to α and reduces the number of updates to β .

IV. ALGORITHM EVALUATION AND OPTIMIZATION OF SEARCH STRATEGIES

A. Transpose Table Storage Optimization

The search algorithm is the core part of decision-making systems, and the evaluation function is the "lighthouse" of the search algorithm. It determines the search direction of the search algorithm on the game tree. The number of nodes for the traditional Minimax search is formula (19).

$$N_d = 1 + b + b^2 + \dots + b^d = b^d \frac{1 - b^{d+1}}{1 - b} = O(b^d) \quad (19)$$

The number of nodes for the branch delimitation search is formula (20).

$$N_d = b^{(d+1)/2} + b^{(d-1)/2} - 1 \quad (20)$$

Where N_d represents the number of nodes in a tree with a branching factor of b and a depth of d . When the number of child nodes at each node is same and the depth is large enough, the number of nodes for the branch delimitation search doubles with the search depth, such as formula (21).

$$N_{2d} = 2b^{(d+\frac{1}{2})} \quad (21)$$

Therefore, when the depth of the branch delimitation algorithm search tree doubles, the increase in the number of nodes is relatively small, indicating that the branch delimitation algorithm is more suitable for searching in cases where the depth is large.

Transposition table is a data structure used to optimize search algorithms by storing the evaluation value and move of previously searched positions for direct use when encountering the same position in the future. First, a hash table is used to optimize the storage of states, and the chess board position is represented as a 32-bit integer using XOR operation, such as formula (22).

$$temp.v32 = position.v32[0] \wedge position.v32[1] \quad (22)$$

The processing result is stored in i and used as an index in the hash table, such as formula (23).

$$i = temp.v16[0] \wedge (temp.v16[1] \ll 4) \quad (23)$$

The paper presents an optimization to reduce the number of computations required to evaluate chess board positions. The proposed algorithm checks for the existence of a Hash Node object in the hash table for each access position, and returns the previously computed evaluation value to avoid redundant calculations. If there is no Hash Node object, a new one is created and stored in the hash table index, which contains information about the current position, alpha and beta values, and the computed evaluation value. This stored information can be reused in the next traversal. Fig. 3 illustrates the process of storing and reusing node information in the transposition table.

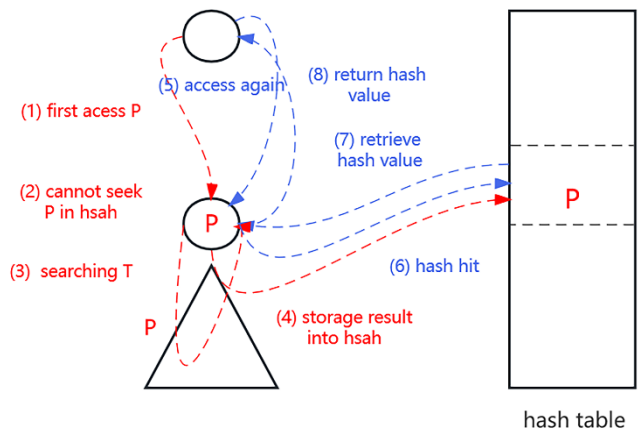

Fig. 3. Hash hit process diagram.

When the node p is visited for the first time and cannot be found in the hash table, a complete search will be performed, and the search result will be stored in column T of the transposition table. Then, the column will be stored in the hash table. When the node p is visited again and its hash value is found in the hash table, the stored result in the hash table can be directly returned. The branch delimitation algorithm incorporating the transpose table hashing can be represented by the algorithmic flow as follows:

Algorithm 1. pruning strategy algorithm

```

Input: board, depth, alpha, beta
Output: optimal evaluate value
1: value=SearchTT(HashKey, alpha, beta, depth);
2: If(value is valid)
3: return value;
4: if(GameOver(board)||depth==0)
5: value=Evaluate(board);
6: if(depth==0)
7: InsertHashTable(value, HashKey, depth, EXACT);
8: return value;
9: best=-∞; ValuesExact = 0;w = CreateSuccessors(board, p);
10: for(i=0; i<w; i++)
11: HashKey=MakeMoveWithTT(board, pi);
12: value=-AlphaBeta_TT(board, depth-1, -beta, -alpha);
13: HashKey=RestoreMoveWithTT(board, pi);
    
```

```

14: if(value>=beta)
15:   InsertHashTable(value, HashKey, depth, LOWERBOUND);
16:   return value;
17: if(value>best)
18:   best=value;
19: if(value>alpha)
20:   alpha = value; ValueIsExact = 1;
21:   InsertHashTable(value, HashKey, depth, EXACT);
22: if(ValueIsExact)
23:   InsertHashTable(value, HashKey, depth, EXACT);
24:   InsertHashTable(value, HashKey, depth, LOWERBOUND);
25: return best;

```

This algorithm utilizes the SearchTT to avoid redundant evaluations of game states in the transposition table prior to AlphaBeta_TT pruning. If the game has ended or the search depth has reached 0, then the current game state is evaluated using the evaluation function and the game state information is inserted into the transposition table through Insert HashTable. Otherwise, all possible moves for the current game state are generated, and AlphaBeta_TT is recursively called for each move to perform pruning. The value returned from each recursive call is used to update the values of alpha, beta, and best. If a move is found that causes beta<=alpha, the function immediately returns and records the move in the transposition table.

B. Optimized Bidirectional Detection Search Method

Search algorithms commonly used in game systems are usually single-directional, searching from the initial state to the target in one direction in the game tree. The paper proposes a bidirectional search algorithm that divides a hash table into two parts: the front and the back. The search algorithm compares the node to be searched with the middle value of the hash table. If the item found during the search is smaller than the middle value, the search continues in the front part of the hash table. If it is larger, the search continues in the back part of the hash table. By using this approach, the algorithm can find the shortest path more quickly. The search process of this algorithm is illustrated in Fig. 4.

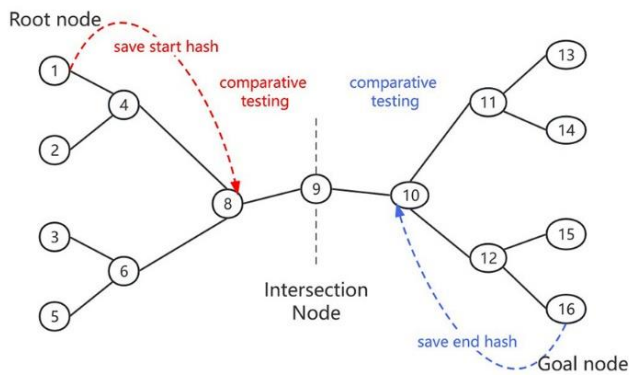

Fig. 4. Schematic diagram of the bidirectional search algorithm.

The paper proposes a two-way detection search algorithm that starts with two queues, one for forward search and the other for reverse search. The algorithm removes the first node from the queue, generates its children, and adds them to the corresponding queue. It continues until a common node is

found in both queues, and then returns the shortest path. With a branching factor of b and a distance of d between the initial and target nodes, each queue will have b^k nodes after k steps. If d is even, the two queues meet at a middle node, and the worst case requires expanding all nodes to the middle node in both queues.

Thus, the total number of nodes expanded by the algorithm can be represented as formula (24).

$$O\left(b^0 + b^1 + \dots + b^{\left(\frac{d}{2}\right)}\right) = O\left(b^{\left(\frac{d}{2}\right)}\right) \quad (24)$$

Therefore, the time complexity of the bidirectional search algorithm is $O(b^{(d/2)})$, which is significantly lower than that of single-directional search algorithms.

The bidirectional hash table formula is used to store the game state, such as formula (25).

$$H(s) = h(s) \% M \quad (25)$$

where $H(s)$ represents the hash value of state s , $h(s)$ represents the integer value obtained by hashing state s , and M represents the size of the hash table. Assuming the depth of the search tree is d and the time complexity of searching each layer is $O(b)$, the time complexity of the bidirectional search algorithm is $O(b^{(d/2)})$. The pseudocode of the bidirectional search algorithm is as follows:

Algorithm 2. bi-directional search algorithm

```

Input: begin, end, gF(begin), turnF, turnB, U, cost(n, c)
Output: U or ∞
1: gF(begin):=gB(end):=0, turnF:={begin}, turnB:={end}, U:=∞
2: while (turnF != null and turnB != null) do
3:   C:=min(prminF, prminB)
4:   if(C=prminF) then
5:     choose n ∈ turnF for which prF(n)=prminF
6:     move n from turnF to ClosedF
7:     for each child c of n do
8:       if c ∈ turnF ∪ ClosedF and gF(c)≤gF(n)+cost(n, c) then
9:         continue
10:    if c ∈ turnF ∪ ClosedF then
11:      remove c from turnF ∪ ClosedF
12:      gF(c):=gF(n)+cost(n, c)
13:      add c to TurnB
14:    if c ∈ turnB then
15:      U :=min(U, gF(c)+gB(c))
16:    else return ∞

```

The proposed algorithm employs two sets, turnF and turnB, to maintain unexplored nodes during the search process. Initially, turnF and turnB are initialized with the initial and target states, respectively. As the algorithm explores, it updates the cost of reaching each node and adds it to the appropriate set. Moreover, the algorithm keeps track of the minimum sum of costs to reach a node from the initial state and the target state, which is stored in variable U. The algorithm terminates when turnF and turnB both become empty or U is less than a certain threshold, ensuring the discovery of the shortest path between the initial and target states.

V. EXPERIMENTS AND RESULTS

A. Search Depth Experiments and Analysis

This experiment compares the performance of Algorithm 1 and Algorithm 2 in optimizing the branch delimitation algorithm for the game of dots and boxes. The study uses a randomly generated 6*6 chess board, with 100 independent experiments conducted. The experiment measures the search depth and number of nodes for each algorithm. All experiments are conducted on the same computer with an Intel i7-9700 processor and 16GB of memory. The experiment sets single-step time limits of 10s, 30s, and 60s, respectively, and the results are shown in Fig. 5(a), 5 (b), and 5(c).

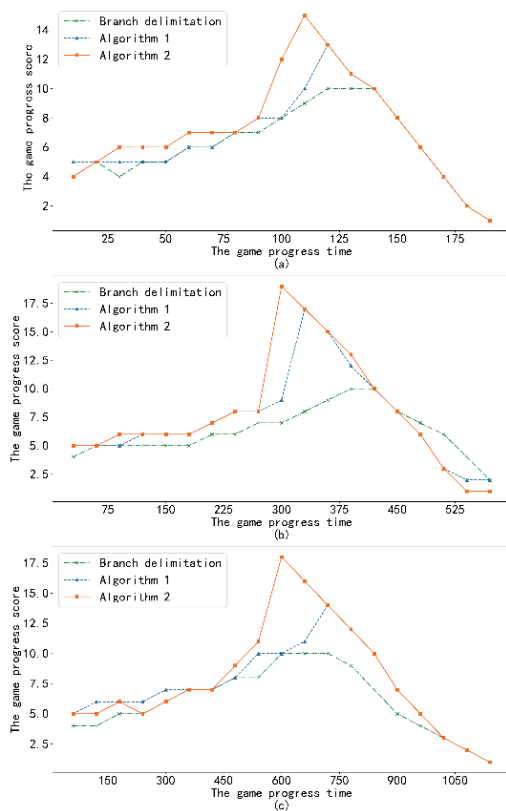

Fig. 5. Comparison of the search depth of the three algorithms.

Algorithms 1 and Algorithms 2 outperform the branch delimitation algorithm in terms of search depth, reaching the maximum depth consistently. All three algorithms show no decrease in the search depth as time limit increases. Heuristic search application in subsequent searches leads to a significant increase in search depth for Algorithms 1 and 2, with Algorithm 2 performing better due to its two-way search strategy. In rounds 9-14, chain and loop states cause an earlier increase in the search depth and hash table node storage for Algorithms 1 and 2, resulting in an overall increase in search depth. At search depth $t=110$ s, Algorithm 2 achieves optimal search efficiency with a search depth of 15, outperforming Algorithms 1 and the branch delimitation algorithm.

B. Node Tree Experiment and Analysis

The environment setup of this experiment is the same as the experiment in A. The comparison experiments with the game

process time as the independent variable and the number of game tree nodes as the dependent variable was conducted with single-step time limits of 10s, 30s, and 60s, respectively, and the experimental results are shown in Fig. 6(a), 6(b), and 6(c), respectively.

Fig. 6. Comparison of the number of nodes of the three algorithms.

The study compared the performance of Algorithm 1 and Algorithm 2 with the branch delimitation algorithm in optimizing the search performance of dots and boxes. The results showed that the branch delimitation algorithm had a higher node search count and searched a large number of invalid nodes. As the time limit increased, the number of nodes searched by all three algorithms increased, but Algorithms 1 and 2 had an advantage due to their fast lookup of node hash tables. Algorithm 2 had a 37% improvement in the search efficiency compared to the branch delimitation algorithm.

C. Game Efficiency Experiments and Analysis

The environment setup of this experiment is the same as the experiment in A. The purpose of this experiment is to compare the scores of branch delimitation algorithm, Algorithm 1 and Algorithm 2 in the game to determine the optimal algorithm for the game. Each game was played for 100 games. The final results were obtained using the average score data. The total score of the game is 25, and a player wins absolutely when the score of one player is greater than 12. The experimental results are shown in Fig. 7, Fig. 8 and Fig. 9 for a single-step game with time limits of 10s, 30s and 60s for the three algorithms played two-by-two.

Fig. 7. T=10s three algorithm game score graph.

Fig. 9. T=60s three algorithm game score graph.

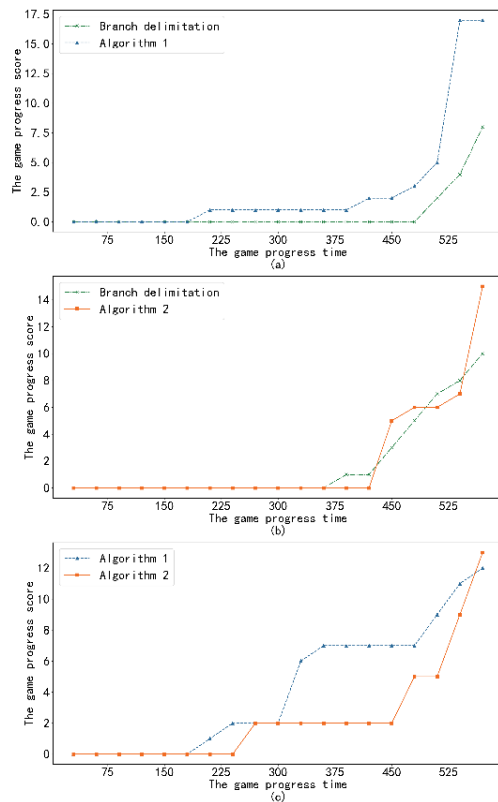

Fig. 8. T=30s three algorithm game score graph.

It is evident from the results shown in Fig. 7, 8 and 9 that Algorithms 1 and Algorithms 2 consistently achieve absolute victory in terms of score within the specified time limits. In subplots (a) and (b) of Fig. 8, both algorithms secure victory one round early with average scores of 14 and 13, respectively. Furthermore, as the time limit increases, both algorithms perform even better in terms of scoring. During rounds 14-19, the game usually witnesses an exponential increase in scores due to the high number of squares with degrees of freedom 2 and 3, along with the emergence of the stumping theorem state. Algorithm 1, as shown in Fig. 7(a), even managed to increase the average score in the 18th round of the game by 12. Algorithm 2 wins 68 times against branch delimitation algorithm and Algorithm 1, which is a 42% improvement compared to the number of times the branch delimitation algorithm wins.

VI. CONCLUSION

In this paper, we have addressed the limitations of conventional branch delimitation algorithms by proposing a novel approach that significantly enhances the search efficiency. Previous algorithms often suffer from searching through numerous invalid nodes, leading to reduced efficiency. While history-inspired pruning and iterative deepening strategies have been employed to improve efficiency, they still face challenges such as unassigned or inaccurately assigned initial nodes and repetitive searches. To overcome these limitations, we have introduced a hash storage search scheme specifically tailored for the evaluation function and game tree search, using dots and boxes as a case study. Our proposed branch delimitation algorithm combines the advantages of

history-inspired and iterative deepening methods, while incorporating a game tree bidirectional search algorithm to further enhance efficiency. Experimental results have demonstrated the effectiveness of our optimized algorithm in reducing the number of nodes in the game tree while maintaining the desired search depth. Moreover, the algorithm has shown remarkable improvements in the chess performance. Particularly, it excels in scenarios characterized by a large number of chains and loops, where the likelihood of position repetition is higher. Overall, our optimized algorithm presents a significant advancement in the field of game search, offering improved efficiency and performance. The introduced hash storage search scheme and the combination of branch delimitation and bidirectional search strategies provide valuable contributions to overcoming computational challenges in game tree exploration. Further research and experimentation can explore the algorithm's applicability in other domains and its potential for solving complex problems with repetitive patterns.

Skin Cancer Image Detection and Classification by CNN based Ensemble Learning

Sarah Ali Alshawi, Ghazwan Fouad Kadhim AI Musawi
Imam Ja'far Al-Sadiq University, Maysan

Abstract—Melanoma is accounted as a rare skin cancer responsible for a huge mortality rate. However, various imaging tests can be used to detect the metastatic spread of disease with a primary diagnosis or on clinical suspicion. Focus on melanoma detection, irrespective of its unusual occurrence, is that it is often misdiagnosed for other skin malignancies leading to medical negligence. Sometimes melanoma is detected only when the metastasis has entered the bloodstream or lymph nodes. So, effective computational strategies for early detection of melanoma are essential. There are four principal types of skin melanoma with two sub types: Superficial spreading, nodular, lentigo, lentigo maligna, Acral lentiginous, and Subungual melanoma. Amelanotic melanoma, one particular type of melanoma, exists in all kinds of skin tones. Classifications of melanoma with its classes are focused on in this research. The ensemble classifier models, namely Adaboost, random forest, voted ensemble, voted CNN, Boosted SVM, and Boosted GMM, have been used in melanoma classification to address misclassification errors, overfitting issues, and improve accuracy. The results of the ensemble classifier achieve high classification accuracy. However, imbalanced classification is found in all six classes of melanoma. Transfer learning and ensembled transfer learning approaches are implemented to reduce the imbalanced classification issues, and performances are analyzed. Four ML/DL models, six ensembled models, four transfer learning models, and five ensembled transfer learning models are used in this investigation. Implementation of all the 19 classifiers is analyzed using standard performance metrics such as Accuracy, Precision, recall, Mathew's correlation coefficient, Jaccard Index, F1 measure, and Cohen's Kappa.

I. INTRODUCTION

Humans are largely perceived through their skin. The dermis, epidermis, and subcutaneous layer make up the skin. The skin has the ability to sense its environment and to protect the body's internal organs and tissues from environmental hazards like bacteria, toxins, and UV radiation. [1]. A variety of internal and external factors can have an impact on the skin. Experimental skin damage, embryogenic infections, chemical exposure, a person's immunological function, and genetic abnormalities are all factors that influence the emergence of skin diseases. Skin problems have a huge impact on a person's life and health. People will eventually try home treatments to address their skin conditions. These procedures may have harmful implications if they are not suitable for that skin disease. As skin problems are easily spread from person to person, they must be treated first. Presumptions about a patient's health are typically based on the doctor's experience and in-

tuition. It could be dangerous to one's health if the decision is made incorrectly or delayed [2].

As a consequence, developing efficient strategies for diagnosing and treating skin problems becomes vital and critical. Technological advancement has enabled the design and implementation of a skin monitoring formative days foundational identification of skin issues. There are numerous advancements accessible for pattern-and image- based identification of several skin conditions.

Deep learning is among the disciplines which can help with the practical and exact identification of a variety of skin problems. Image categorization and deep learning can be used to diagnose diseases [3]. Image classification is a basic problem that requires the creation of multiple objective classifications and the development of a training model to acknowledge each subtype. Deep learning-based technologies could be useful for swiftly recognizing clinical information and providing results. Information treatment is essential due to the complexity of skin diseases, the scarcity and misuse of qualified medical professionals, and the urgency associated with an accurate diagnosis. Improvements in photonics and laser-based health care system technology have allowed for much quicker and more accurate diagnosis of skin problems. Even with advances, the price of diagnostic procedures is still prohibitive. Deep learning systems efficiently classify images and data [4,5]. The reliable recognition of anomalies and classification of diseases utilising magnetic MRI, X-ray, PET, CT, and signalling data including EEG, EMG, and ECG has been requested in health diagnostics. Better health care could be provided to patients if diseases were classified more precisely. By automatically identifying data input features, DL approaches can address critical challenges and are adaptable to shifts in the computational complexity [5]. It is expected that learning techniques would be able to discover and start exploring the features in the discovered data patterns with even basic computer modelling, resulting in substantial efficiency gains. As the categorization of skin diseases relies on an image of the affected region, this prompted the researchers to investigate the possibility of using a DL model for classifications. Invasive illness evaluations would be easier and less expensive for doctors and patients to perform with this tool.

II. RELATED WORK

Chaurasia and Pal [1] demonstrated six distinct order frame- works and a multi-model ensemble strategy for predicting skin disorder.

The findings show that differential expression assessment is essential for reducing the dimensionality of data and selecting effective data, thereby increasing the accuracy of prediction and substantially lowering the computing effort. At such a point, the multi-model ensemble methodology employs the predictions of numerous distinct classification models as input. By using the principal organize predictions as highlights, the classification approach minimizes the generation error and obtains more data than if it were trained in isolation. In addition, by utilising classification methods, the intricate relationships between classifiers are discovered, thereby enabling the order strategy in order to make more accurate predictions.

Loganathan, et al. [2] suggested a new DCNN for classifying malignant melanoma (skin cancer). The recommended method comprises pre-processing, enhanced fuzzy clustering for melanoma detection, and enhanced deep convolutional neural networks (E-DCNN) for categorization of dermoscopy images. Enhanced fuzzy clustering is a technique that incorporates modified region grow image segmentation and fuzzy K-means clustering to produce a more precise classification performance than other methodologies suggested by researchers.

Allugunti [3] developed, built, and tested a Convolutional Neural Network (CNN) framework for melanoma detection using a publicly available dataset. The overall accuracy of 88.83% demonstrates the superiority of the proposed method, which would be a two-stage learning platform. This is not unique to DT, RF, or GBT or any other classification algorithm. The proposed technique is based on CNN and can be seen as a powerful means of multiclass categorization.

Kotian & Deepa [4] identify and categorize various diseases using input images. The MATLAB environment serves as the foundation for this project. The photos come from various online sources like Dermnet and DermWeb. The first step is to preprocess the sample images of the four skin diseases. As a second step, a geometric transformation is applied to the vertically-oriented portion of the image. Relying upon it, three types of skin diseases' features are then extracted, and their correlated variables of feature texture and pixels of lesion regions are accumulated via image segmentation.

Verma, et al. [5] proposed a novel method that employs five distinct data mining methods and then develops an ensemble method that integrates all five methods into a single unit. Using descriptive Dermatology data, the researcher examined various data mining techniques to categorize the skin infection, and then apply an ensemble ML technique.

Rea [7] a survey of people with skin diseases was done in Lambeth, London. A stratified specimen of 2180 adults was sent a mail-in questionnaire asking about skin diseases. A subsample of 614 people was questioned at home and their exposed skin was looked at. There were 92 conditions that were found. These were put into 13 groups based on how severe they were for the patient. 22–5% of people were thought to have skin diseases that needed medical care. With a prevalence of 6–1%, eczema was the most widely accepted essential factor. Certain types of skin diseases had different

rates of occurrence based on age, gender, and social class. Only 21% of people with a skin disease that should have been treated by a doctor said they had gone to their healthcare professional in the previous six months for a skin problem. Medical treatment and self-medication are considered in relation to the existence of skin infection and certain other factors.

Dildar [11] provides a thorough comprehensive study of DL techniques for skin cancer detection. Research papers from reputable journals on the topic of skin cancer diagnosis were reviewed. To aid comprehension, study results are presented in the form of tools, tables, graphs, methodologies, and frameworks.

A. Gap Analysis

Gap analysis for skin cancer classification using deep learning can be conducted by comparing the current state of research in this field with the desired future state. Some potential gaps that could be identified include:

Lack of standardized datasets: There is a need for standardized datasets that are representative of diverse populations and cover different types and stages of skin cancer [1].

Limited generalizability: Many deep learning models developed for skin cancer classification have been evaluated on small datasets or datasets from a single institution. There is a need for models that can be trained on larger and more diverse datasets and can generalize well to different populations [4, 5, 6].

Limited availability of models in clinical practice: Although deep learning models have shown excellent performance in skin cancer classification, they are not yet widely used in clinical practice. There is a need to develop models that are easy to use, reliable, and can be integrated into clinical workflows [7, 8].

Limited attention to ethical considerations: There is a need for greater attention to ethical considerations in the development and deployment of deep learning models for skin cancer classification, including issues related to bias, privacy, and informed consent [9, 10].

III. PROPOSED APPROACH

A. Melanoma Detection using Boosted SVM

Ensembles with an infinite hypothesis are constructed using an infinite ensemble framework. This framework learns all the possible weight combinations for all the possible hypotheses. All the hypotheses are embedded in the kernel of the SVM model. The base classifier is trained by fixing the initial weights, and the error due to misclassification is calculated using the weighted method. Now similar to the boosting algorithm weight of each classifier is adjusted, and the ensemble classifier is computed using the weighted component sum classifier as, where is the weight and is the base classifier. Ensemble majority voting model is shown in Fig. 1.

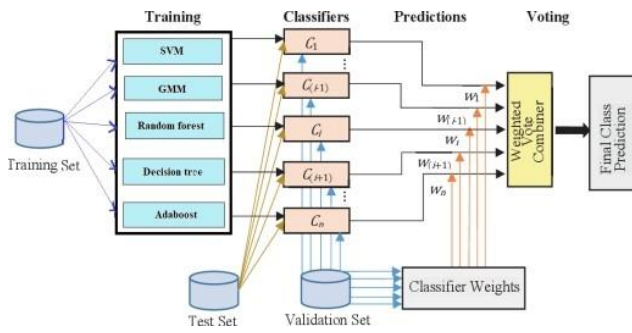

Fig. 1. Ensemble majority voting model.

SVM was developed from the theory of Structural Risk Minimization. In SVM, two essential parameters are to focus on, namely Gaussian width and the regularization parameters [2]. Boosted SVM is applied over the training dataset, and the weights are updated until convergence if the error rate exceeds 0.5. The weighted normal strategy determines the error component (ϵ_m). Only the limited weights of misclassified perceptions are taken as the numerator, separated by the total limited weights [3]. Each SVM is prepared to depend upon the dataset because testing and validation errors decrease as data quantity increases. In both the sections mentioned above, the weight update procedure is addressed by taking into account the distance from each group centroid to each misclassified observation. The modified weights for each misclassified observation are assigned concerning the distance from the centroid of the clusters.

$$G_m = \sum_{j=1}^m \alpha_j * S_j \quad (1)$$

B. Melanoma Detection using Boosted GMM

Using GMM for Ensemble comes under the standard category of clustering ensemble. It is a model-based Ensemble. A model-based Ensemble assumes that the model's clusters will help optimize the relevance between the data and the underlying model. GMM is a probabilistic model [11] frequently used for density estimation, regression, and classification problems. GMM as a classifier is constructed as discussed in Section III. Then the Gaussian mixture components of each object class are compared with the corresponding class object probability. A threshold is fixed to recognize the object with maximum similarity for the specific object class. To generalize different object components and increase the similarity of objects in each class Adaboost algorithm is applied to create a model-based ensemble GMM framework. Here each component in GMM is considered a weak classifier with low accuracy and high redundancy. Adaboost algorithm combines all the weak classifiers into a robust classifier with effective multiclass object recognition.

C. Melanoma Detection using Ensemble CNN

A sequential voting ensemble could be created using convolution neural networks. Theory and implementation of voted ensembles are similar to Section III.C, with one significant difference. Here instead of using different classifier models, we use three models of CNN, and the highest voted prediction is taken as output. Here for each model, three convolution layers, three batch normalization layers are used. Finally, the dense layer with 256 units and softmax layer are

used as the output layer. The Ensemble CNN model is shown in Fig. 2.

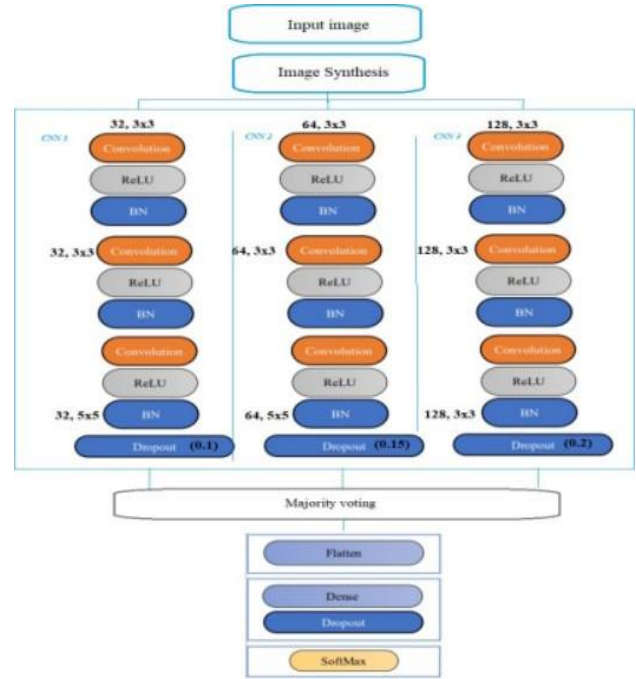

Fig. 2. Proposed CNN model.

Here for the CNN ensemble, three individual models are developed with many ReLU filters. Three models have 32, 64, and 128 filters consecutively. Here the optimizer used is Adam, and the output activation function is softmax. The batch size is 20, and the number of epochs is 30, with 1000 steps for each epoch. An adaptive learning rate is used for each iteration. Dropout for the three models is 0.1, 0.15, and 0.2. Ensemble CNN model is trained using 24000 images, tested using 12000 images, and validated using 12000 images with equally distributed images among each class. During the training of the CNN models, subsamples of the dataset are used. Errors for each subsampled data point are calculated such that if the error is more significant than a threshold, those points are discarded, and training is continued. Also, all three models' features are aligned with highest to lowest priority features. Based on which zero variance features are removed, and features are sent to the next layer.

IV. RESULTS

Improving the accuracy of the classification process and decreasing the misclassification error are two main concerns in ensemble models. This chapter implements six ensemble models for melanoma classification based on the general category aspects. Bagging, boosting, majority voting, infinite ensemble framework, and cluster ensembles are implemented using Random Forest, Adaboost, Majority voting, Boosted SVM, and Boosted GMM classifiers. The Ensemble CNN model is a sequential model developed based on a majority voting ensemble. The ML models used in Section III are SVM, GMM, decision tree, and deepconvnet. These are taken as base models in ensemble models. The basic parameter attributes are tested in Section III, and hyper parameter tuning of the ensemble models is investigated in Section IV. The hyper-

parameters which could be fine-tuned for ensemble models are n estimators, learning rate, and m-features. Since deep learning models are analyzed, m features are not fine-tuned for our investigation. And since n- estimators and learning rates are related, these two parameters are considered for hyperparameter tuning and optimization of the ensemble models. The performance of the classifiers in melanoma prediction is assessed using metrics like accuracy, precision, recall, F1 score, MCC, Jaccard Index, and Kappa. Also, six classes of Melanoma are classified here. In this Stratified 10- fold, cross-validation is used for calculating the performance estimates. Stratification ensures that each class is represented with the same proportions roughly as in the entire data set. Ensemble diversity is used in the datasets to achieve better accuracy and avoid overlapping features in the dataset during clustering. The investigation has carried over 10000 melanoma images generated by GAN. Training of the classifier model has been done with 1000 superficial spreading Melanoma, 1000 Nodular Melanoma, 1000 lentigo melanoma, 1000 acral lentiginous Melanoma, 1000 subungual Melanoma, and 1000 amelanotic Melanoma images. For testing 2000 and validation, 2000 images are used. The entire process has been carried over the python platform. Since CNN models require more datasets to avoid overfitting, it is trained using 24000 images, tested using 12000 images, and validated using 12000 images with images equally distributed among each class.

A. Performance Analysis of Random Forest Classifier

In this investigation, a random forest classifier is implemented for melanoma prediction. Ensemble pruning is done here to reduce the complexity of the network, and the maximum number of features is set to auto. Due to pruning, the random state is fixed to zero. Even though hyperparameter tuning is not necessary for random forest classifiers, the number of estimators varies between 50,100 and 150. The number of estimators (n-estimators) indicates the number of trees or samples required to find the optimum solution. However, it doesn't indicate that the higher the number of trees higher the accuracy. Increasing the number of trees leads to higher computational time. Also, the classifier model's performance will drop for a higher number of estimators. So, choosing the optimum number of estimators is done using the trial-and- error method for our investigation. The minimum sample leaf is restricted to 10, 25, and 50. For each of the six

classes of Melanoma, namely superficial spreading Melanoma, Nodular Melanoma, lentigo melanoma, acral lentiginous Melanoma, subungual Melanoma, and amelanotic Melanoma combinations of n estimators and minimum sample leaves were fixed. The performance of the classifier is tested. The random forest classifier's performance is best for melanoma classification with an accuracy of 90.23 for the n estimator minimum leaf combination of 100:50. It is found that for a smaller number of estimators, Random forests suffer from underfitting problems. Performance analysis of random forest classifier is shown in Table I.

B. Performance Analysis of Adaboost Classifier

Adaboost, one of the popular boosting algorithms, is known to reduce outliers and overfitting issues. It also helps in improving the performance and robustness of the classifier. For Adaboost classification, different n estimators for different learning rate combinations are investigated to improve accuracy. N estimators used are 50,100,150 and learning rates are 0.01, 0.001 and 0.0001.

Adaboost classifier performs well with an accuracy of 96.78 for a learning rate of 0.01 with 50 estimators. Since base estimators affect the performance of the Adaboost classifier, svc is used as the base estimator. Performance metrics for melanoma detection using the Adaboost classifier are shown in Table II.

C. Performance Analysis of Ensemble Voted Classifier

Ensemble voted classifier is implemented using the majority voting method. For ensemble networks, pretrained base learners are necessary. GMM and SVM classifiers are implemented using the same settings discussed Decision tree, AdaBoost, and Random Forest classifier's performance vary over the number of estimators, and the learning efficiency differs for each model. So, ensemble majority voted model has been implemented for different estimator learning rate combinations with a fixed threshold of 0.5. Here the combined majority voting is calculated. For each class prediction, if the vote probability is more significant than 0.5, then the majority vote among the classifier output is chosen. If the probability of none of the classifiers is above 0.5, then the model is again restarted for other weights. Performance analysis of the Ensemble voted classifier in Table III shows that the classifier achieves better accuracy of 96.32 for a learning rate of 0.01.

D. Performance Analysis of Boosted SVM Classifier

From the previous investigation on SVM, it has been proved that the RBF kernel works well on melanoma images for a gamma value of 10. The same parameters are used in the boosted SVM classifier for different n estimators and learning rates. Even though the AdaBoost classifier works well only for 50 n estimators, boosted SVM gives better accuracy of 98.37 with a 0.01 learning rate. MCC is also significantly improved compared to conventional SVM and AdaBoost classifier models. Performance metrics of boosted SVM classifier for melanoma classification are shown in Table IV.

TABLE IV. PERFORMANCE ANALYSIS OF BOOSTED SVM CLASSIFIER

E. Performance Analysis of Boosted GMM Classifier

GMM model works best as a density estimator in clustering, and the EM algorithm is applied for Classification. To maximize the robustness of the GMM classifier AdaBoost algorithm is used here. Boosted GMM classifier is analyzed for different estimators and learning rates, and the best parameter setting for the classifier is fixed. It is found that the boosted GMM classifier works best at 25 estimators for a learning rate of 0.01 to provide an accuracy of 96.17. GMM shows a gradual performance improvement compared to other classifiers. Performance metrics of boosted SVM classifier for melanoma classification are shown in Table V.

TABLE V. PERFORMANCE ANALYSIS OF BOOSTED GMM CLASSIFIER

Estimators	Learning rate	Precision	Recall	Accuracy	F1-score	MCC	Jaccard Index	Kappa

F. Performance Analysis of Ensemble CNN Classifier

Ensemble CNN is a sequential voting approach implemented using three different CNN models for variable learning rates. This model provides a more stable melanoma prediction accuracy than other ensemble approaches. Even though the implementation of this Ensemble is similar to the majority voting ensemble, this model performs better due to its distinctive feature extraction. This model extracts low and high-frequency features irrespective of the CNN type unless fixed features from previous models. Also, three different models have different dropout rates and kernel counts, preserving overfitting issues in the CNN model. Model converges earlier without much misclassification error. Performance metrics of the ensemble CNN model, as shown in Table VI, indicate the accuracy of 98.67 for melanoma classification. The network performs best with a learning rate of 0.0001 for 25 estimators, which is relatively less than other ensemble models.

Performance metrics for the classifiers mentioned above for independent classes of Melanoma are shown in Table VII. Based on the classifier performance, it is clear that all the classifiers perform better in classifying superficial spreading Melanoma, Nodular Melanoma. Due to colossal variation and differences in the structural properties in different stages of other types of other types of melanomas, the accuracy of the classifiers is less compared to superficial spreading and nodular Melanoma. Subungual Melanoma is present in nails and nail beds. Properties of this Melanoma sometimes resemble typical characteristics of vitamin deficiency. So,

classifiers require extreme robustness to achieve better accuracy. Amelanotic Melanoma is one particular type of Melanoma present in all skin variants. Also, amelanotic Melanoma in certain stages resembles superficial spreading Melanoma and nodular Melanoma.

The ensemble classifiers implemented in this work produce better accuracy than the single classifiers. Adaboost and Boosted SVM classifiers perform better for all five types of Melanomas except amelanotic Melanoma. The other three classifiers, namely boosted GMM, Random Forest, and Ensemble voted classifiers, are performing better in superficial spreading, nodular, and lentigo melanoma classification but is moderate in the other two types despite the best hyperparameter settings, as shown in Table VII. Ensemble CNN models can provide consistent performance for all six types of melanoma classification with slight variation for amelanotic Melanoma.

The convergence plot in Fig. 3 shows the robustness of the ensemble models in melanoma classification. The maximum number of epochs used is 30 to check the training and validation accuracy. Out of six ensemble classifier models used, Ensemble CNN, Adaboost, and Boosted SVM classifiers resulted in better convergence. However, the Ensemble CNN model shows overfitting during validation even though accuracy is higher. Further improvements in the network model and data selection need to be made to avoid overfitting issues. Boosted GMM and Random Forest models are showing underfitting of data points. Ensemble voted model shows the best fit from the 28th epoch.

TABLE VI. PERFORMANCE ANALYSIS OF ENSEMBLE CNN CLASSIFIER

V. CONCLUSION

Ensemble learning models as classifiers for melanoma classification. Bagging, boosting, majority voting, infinite ensemble framework, and cluster ensembles are implemented using Random Forest, Adaboost, Majority voting, Boosted SVM, Boosted GMM classifiers, and Ensemble CNN models.

The performance of the classifiers in melanoma prediction is assessed using metrics like accuracy, precision, recall, F1 score, MCC, Jaccard Index, and Kappa. Also, six classes of Melanoma are classified here. In this Stratified 10-fold, cross-validation is used for calculating the performance estimates. Stratification ensures that each class is roughly represented with the same proportions as in the entire data set. Ensemble diversity is used in the datasets to achieve better accuracy and avoid overlapping of features in the dataset during clustering. Ensemble models can perform well for five classes with consistent accuracy out of six classes. The boosted SVM and Adaboost classifiers have higher performance than boosted

GMM, random forest, and Ensemble voted classifiers. Ensemble CNN seems to outperform other ensemble models with an accuracy of 98.67. Though the execution time of ensemble classifiers is high, such a complex network is easier to train, and the network converges ideally. The system's complexity is one point that needs to be considered in the proposed model for further improvement. Also, it was observed that an increase in the number of images in the training dataset increased the size of the feature set, which led to overlapping features.

Abstract—Green cloud computing is a modern approach that provides pay-per-use information and communication technologies with a minimal carbon footprint. Cloud computing enables users to access computing resources without the need for local servers or personal devices to operate applications. It allows businesses and developers to access infrastructure and hardware resources conveniently. Consequently, this results in a growing demand for data centers. It becomes crucial in maintaining economic and environmental sustainability as data centers use disproportionate energy. This points to sustainability and energy consumption as being important topics for research in cloud computing. This paper introduces a two-tiered VM placement algorithm. A queuing model is proposed at the first level to handle many VM requests. Models such as cloud simulation are easily implemented and validated using this model. It also provides an alternate method for allocating tasks to servers. Next, a multi-objective VM placement algorithm is proposed based on the Krill Herd (KH) algorithm. Basically, it maintains a balance between energy consumption and resource utilization.

Keywords—Cloud computing; migration; virtualization; energy consumption

I. INTRODUCTION

Virtualization is a major technology that underpins cloud computing. In order to offer access to mainframe computers in an interactive manner, IBM developed this technology in the 1960s, where multiple users (and applications) could utilize expensive hardware simultaneously [1]. Storage technologies and computing power have made computing resources more abundant, cheaper, and powerful than ever before due to rapid technological advancements [2, 3]. This development has led to the development of cloud computing, where computing resources are provided on an on-demand basis over the Internet [4]. Virtualization technology can be utilized in modern cloud computing environments in order to minimize energy costs and optimize resource utilization [5]. Multiple operating systems can be run on one physical machine using virtualization technology. Operating systems are run on separate Virtual Machines (VMs) controlled by hypervisors [6]. The rapid advancement of emerging technologies such as the Internet of Things (IoT) [7, 8], big data [9, 10], artificial intelligence [11, 12], Blockchain [13], machine learning [14-17], and 5G communication technology [18] has resulted in significant challenges associated with traditional cloud computing data centers, including complex operation and maintenance, inefficient configuration, high construction costs, and an absence of effective unified business monitoring tools.

Live VM migration is one of the key advantages of virtualization, as it facilitates resource management in cloud environments [19]. A VM can seamlessly migrate between physical machines (source hosts) and destination hosts, even as it is running [20]. Load balancing is the primary goal of live VM migration, which migrates VMs from heavy hosts to under-loaded ones [21]. It also provides power management since it consolidates light-load VMs onto fewer servers, resulting in reduced IT operations costs and power consumption [22]. Live VM migration also provides hotspot and cold spot mitigation. In order to meet SLA requirements for VMs, active resource consumption needs to be monitored [23]. Cold spots are physical machines with low threshold values, while hot spots are physical machines with high threshold values. By combining proactive and reactive techniques, hot and cold spots can be detected before they occur and mitigated, thereby maintaining system performance [24]. Server consolidation is another advantage of live VM migration. In this technique, VMs are packed onto a small number of physical machines, and the spare or ideal machine can be powered off or placed in sleep mode, thus reducing both server usage and power consumption [25].

VM migration is the process of moving a VM from one physical host (source node) to another host (target node). VMs are transferred from their source hosts to their destination hosts without interrupting network connections. The original VM continues to run during live migration. Live VM migration is relatively quick, making it ideal for fast migrations. The proposed system aims to migrate VMs from overloaded to underloaded physical machines within a short period of time. The term "live migration of VMs" refers to the process of migrating the VM while it is running in its original state. Live VM migration is beneficial for fast migration since it provides a short amount of migration time [26].

This paper introduces a two-tiered VM placement algorithm. A queuing model is proposed at the first level to handle many VM requests. Models such as cloud simulation are easily implemented and validated using this model. It also provides an alternate method for allocating tasks to servers. Next, a multi-objective VM placement algorithm based on the KH algorithm is proposed. Basically, it maintains a balance between energy consumption and resource utilization. The proposed research aims to achieve the following objectives:

- Generating resource utilization profiles for PMs.
- Using the KH algorithm to identify overloaded and underloaded physical servers.

- Migrating VMs with minimal downtime.
- Reducing the amount of energy required for physical resources.

II. RELATED WORK

Farahnakian, et al. [27] presented an architecture based on the Ant Colony Optimization (ACO) algorithm for dynamic VM consolidation that reduces the energy consumption of cloud data centers while improving quality of service. Kansal and Chana [28] proposed an energy-aware VM migration approach for cloud computing based on the Firefly algorithm. By migrating over-loaded VMs to under-loaded nodes, the energy efficiency of data centers is improved. By comparing the proposed technique with other techniques, the efficacy of this technique is demonstrated. By cutting an average of 73 % of migrations and reducing 35 % of hosts, the data center has achieved an average reduction in energy consumption of 45 %.

Fu, et al. [29] presented a layered VM migration algorithm. Cloud data centers are initially divided into several regions based on bandwidth utilization rates. VM migrations balance network load between regions, resulting in load balancing of cloud resources. Experiments indicate that the proposed algorithm is shown to be able to effectively balance network resource load in cloud computing. Chien, et al. [30] have proposed a novel VM migration algorithm based on the reduction of migrations in cloud computing that can enhance efficiency, meet user requirements, and prevent service level agreements (SLA) violations. The proposed algorithm was found to be more effective than existing algorithms based on experimental results. A threshold algorithm was proposed by Kaur and Sachdeva [31] to allocate tasks to the most capable machine and host and to maintain checkpoints on VMs. Overloaded VMs need to migrate tasks to another VM. This study proposes a weight-based approach for migrating cloudlets between VMs.

Xu and Abnoosian [32] presented a hybrid optimization algorithm based on genetic and particle swarm optimization algorithms for improving VM energy consumption and execution time during VM migration. In the hybrid algorithm, GA is utilized to overcome the limitations of the PSO algorithm, which suffers from slow convergence and limited global optimization. According to the results, the proposed method has improved energy consumption by an average of 23.19% compared to the other three methods. Results also revealed a 29.01% improvement in execution time over the other three methods. Zhou, et al. [33] introduce an energy-efficient algorithm for VM migrations. In this algorithm, host location, VM selection, and trigger time are optimized when memory and CPU factors are taken into account. It migrates some VMs from lightly loaded hosts to heavily loaded hosts using virtualization technology. Energy is conserved by switching idle hosts to the low-power mode or shutting them down. This algorithm reduces SLA violations by 13% and saves 7% of energy over the Double Threshold (DT) algorithm.

VM migration provides an effective and efficient approach to managing cloud resources by providing flexibility in terms

of security guaranteeing [34-36], network traffic optimization [37, 38], reduction of SLA violations [39-41], migration cost minimization [42, 43], and energy minimization [44-46]. However, these approaches do not take into account the performance reduction that occurs when VMs are migrated. Several performance-aware VM migration methods have been proposed [47-49]. However, their performance optimization focused not on maximizing VM performance but on reducing SLA violations or migration downtime. Specifically, the works [39-41] attempted to reduce SLA violations or migration downtime rather than optimize VM performance, and Zhang and Zhou [50] guaranteed that running tasks would meet the VM processing time constraint. Çağlar and Altılar [51] aimed to minimize power consumption while meeting performance requirements rather than maximizing VM performance for their users. Moreover, none of the above VM migration techniques provided a specific performance model to describe how VM performance declines over time.

III. SYSTEM MODEL

A VM request must be arranged for deployment on physical servers. A scheduler determines a server from the available servers to place the specific VM. A queuing model is proposed to schedule the placement of VMs. In Section III A, the queuing structure is explained. Section III B discusses the KH-based VM placement algorithm.

A. Single Queue Single Service Facility

The queuing scheme follows a single queue single service facility - M/M/1 queue. VM requests are processed according to a FIFO discipline before being forwarded to the data center for placement. Assume μ and λ reflect service and arrival metrics in the queue at various intervals. $(N-1)$ VM requests are handled in this way. In the stable situation, P_n represents the likelihood of having n VM requests.

$$\lambda_n = \begin{cases} \lambda, & n = 0, 1, \dots, n-1 \\ 0, & n = N, N+1 \end{cases} \quad (1)$$

$$\mu_n = \mu, \quad n = 0, 1, \dots \quad (2)$$

$$\rho = \frac{\lambda}{\mu} \quad (3)$$

$$P_n = \begin{cases} \rho^n P_0, & n \leq N \\ 0, & n > N \end{cases} \quad (4)$$

Using P_n , the expected number of VM requests in the system (R_s) is determined as follows.

$$R_s = \sum_{n=1}^N n P_n = \frac{\rho[(N+1)\rho^N + N\rho^{N+1}]}{(1-\rho)(1-\rho^{N+1})}; \quad \rho \neq 1 \quad (5)$$

$$R_s = \sum_{n=1}^N n P_n = \frac{N}{2}; \quad \rho = 1 \quad (6)$$

The number of VM requests in the queue (R_q) is determined by $R_q = \lambda T_q$, in which T_q indicates the estimated time required to place the VM. In addition, T_s represents the estimated time for placing the VM in the system. These parameters are determined by Eq. (7) and Eq. (8). Hence, Eq. (9) can be used to calculate the total time required to place a VM request.

$$T_s = \frac{R_s}{\lambda} \quad (7)$$

$$T_q = T_s - 1 \quad (8)$$

$$T = T_q + T_s \quad (9)$$

B. VM Allocation using the KH Algorithm

Appropriate mapping of VMs to hosts is essential for optimizing key performance indicators, including resource wastage and power consumption. The mapping of VMs to proper PMs is known as VM allocation. The VM array $\{vm_1, vm_2, vm_3, \dots, vm_n\}$ comprises n VMs, each requesting resources in the memory and CPU dimensions. A host array $\{H_1, H_2, \dots, H_p\}$ signifies the total number of PMs. A krill matrix is used to model the VM request set. Power consumption and resource waste are optimized simultaneously in the proposed method. The following subsections provide mathematical definitions of the parameters mentioned above in order to optimize them.

1) *Power consumption calculation:* Total power consumption is calculated using Eq. (10), where ut_i stands for host utilization, $power_i^{\min}$ denotes the minimum power consumption at minimum utilization, and $power_i^{\max}$ refers to the maximum average power consumption at maximum utilization. As determined by Eq. (11), efficiency is the percentage of total power consumed to total workload.

$$pow_i = (pow_i^{\max} - pow_i^{\min}) \times ut_i + pow_i^{\min} \quad (10)$$

$$E_{pwr} = \frac{\text{Total workload}}{\text{Power consumed}} = \frac{ut_{cpu}}{(pow^{\max} - pow^{\min}) \times ut_{cpu} + pwr^{\min}} \cdot ((pow^{\max} - pow^{\min}) + pow^{\min}), \quad 0 \leq E_{pow} \leq 1 \quad (11)$$

In this case, efficiency ranges between 0 and 1, with higher efficiency indicating better server utilization. Eq. (12) calculates the aggregate efficiency.

$$E_{tot} = E_{res} + E_{pwr} \quad (12)$$

$$0 \leq E_{tot} \leq 2$$

2) *Resource wastage calculation:* Due to the VM's unpredictable resource usage pattern, server utilization is stochastic in nature. An important criterion for determining the appropriate utilization of a server is the proper use of its resources across all dimensions. Eq. (13) calculates the total amount of resources wasted by a host, where r^{\min} signifies the normalized wastage. Eq. (14) provides a formula for determining the efficiency of a given assignment.

$$waste_i = \sum_{d \neq \min} (r^d - r^{\min}) \quad (13)$$

$$E_{res} = ut_{cpu} \cdot ut_{mem}; \quad 0 \leq E_{res} \leq 1 \quad (14)$$

E_{res} measures the efficiency of resource utilization. The goal is to maximize the utilization of resources in a variety of dimensions. Physical machines are measured in terms of their CPU and memory. A higher efficiency indicates better packing of VMs. This efficiency ranges from 0 to 1. Eq. (15)

can be used to calculate the utilization of the i^{th} host along the d^{th} dimension, where cap_i^d represents the physical host's capacity and $alloc(H_i)$ represents the set of VMs allocated to the i^{th} host.

$$ut_i^d = \frac{\sum_{vm_i \in alloc(H_i)} vm_i^d}{cap_i^d}; \quad d \in \{CPU, mem\} \quad (15)$$

3) *Formulation of the problem:* Numerous engineering problems have been solved using the KH algorithm. VMP can also be viewed as an optimization problem. The inspiration comes from the KH algorithm, where the krills continually move around the environment in search of food sources. Each VM corresponds to a krill, and the optimum food source corresponds to an optimal host for placement. According to Eq. (16), the global solution is a configuration that fulfills the requirements. The KH algorithm is used to obtain a suboptimal solution to the VM placement problem.

$$\min \sum_{i=1}^p waste_i \quad \text{and} \quad \sum_{i=1}^p pow_i \quad (16)$$

Virtual machines are assigned to physical machines based on the following criteria.

- **Placement constraints:** The constraint ensures that a VM will be distributed to only a single host if all required resources are available.
- **Capacity constraints:** This condition ensures that VM resource requirements do not exceed the total resources all the hosts can share in the federation.
- **Assignment constraints:** VMs will be placed on servers that meet all their requirements under this constraint. These constraints can be expressed in mathematical terms as follows:

4) *Krill herd algorithm:* The KH algorithm employs swarm intelligence to solve continuous optimization problems. In comparison to existing algorithmic techniques, it appears to perform better or provide comparable results. Compared to other swarm-intelligence algorithms, this algorithm requires few control parameters and is easy to implement. The KH algorithm models the krill population searching for food within a multidimensional search space with the locations of individual krills serving as decision variables, whereas the distance between the krills and the rich food represents an objective cost. Based on Fig. 1, the KH optimization process comprises three stages, including the movement of other krill individuals, foraging motion, and physical diffusion. These actions can be expressed as a mathematical expression by Eq. (17), where D_i stands for physical diffusion, F_i denotes foraging motion, and N_i signifies other krill movements [52].

$$\frac{dX_i}{dt} = N_i + F_i + D_i \quad (17)$$

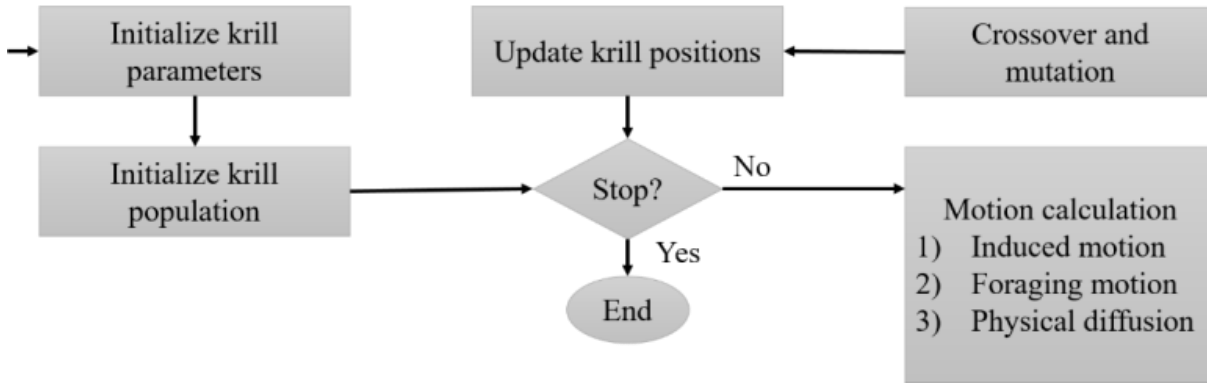

Fig. 1. Flowchart of KH algorithm.

There are three components to the first motion, namely the target effect, the local effect, and the repellent effect. A mathematical representation of the krill i can be derived as follows:

$$N_i^{new} = N^{max} a_i + \omega_n N_i^{old} \quad (18)$$

$$a_i = a_i^{local} + a_i^{target} \quad (19)$$

In the above equations, a_i^{target} indicates the effect of target direction, a_i^{local} represents the local effect, N_i^{old} refers to the last motion induced, ω_n corresponds to the inertia weight ranging from 0 to 1, and N^{max} refers to the maximum speed induced. Food location and previous experience can be described as two aspects of the foraging process. This can be expressed as follows for the i^{th} krill.

$$F_i = V_f \beta_i + \omega_f F_i^{old} \quad (20)$$

$$\beta_i = \beta_i^{food} + \beta_i^{best} \quad (21)$$

In Eq. (20) and Eq. (21), V_f refers to the foraging speed, ω_f represents the inertia weight between 0 and 1, F_i^{old} indicates the last foraging motion, β_i^{food} indicates the food's attractiveness, and β_i^{best} reflects the best fitness of the i^{th} krill. Each krill moves between high- and low-density levels based on Eq. (22), in which d represents a random array of values between 0 and 1 while D^{max} determines the diffusion speed.

$$D_i = D^{max} \left(1 - \frac{I}{I_{max}}\right)^\delta \quad (22)$$

IV. EXPERIMENTAL RESULTS

Cloudsim is the most popular toolkit for simulating cloud environments and conducting simulation-based evaluations. Cloud computing can be continuously exhibited, simulated, and investigated on this completely adaptable platform. In this way, the research community and industry-based designers have the ability to focus on detailed system design. A description of the simulation process is provided in Table I. The simulation was repeated 40 times with up to 200 virtual machines and 200 hosts. This section examines the efficiency

of the proposed algorithm in two scenarios and compares it with previous algorithms. In the first scenario, the proposed algorithm's energy consumption is compared to previous algorithms. The results demonstrate that the proposed algorithm is more efficient than previous methods that require fewer hosts and migrations. Fig. 2 illustrates the energy consumption of First Fit Decreasing (FFD), ACO, and Firefly Optimization (FFO) algorithm. Fig. 3 and 4 depict convergence and stability graphs, respectively. As depicted in Fig. 5, the proposed method produces fewer migrations than the FFO, ACO, and FFD. Fig. 6 illustrates the method's stability for the second scenario.

TABLE I. SIMULATION PARAMETERS

Parameter	Value
Number of physical machines	10-200
Number of virtual machines	10-200
VM size	2 GB
VM RAM	1-4 GB
VM MIPS	1000-2500
PM ram	4 GB
Bandwidth	2 Gbps

Fig. 2. Energy consumption comparison.

Fig. 3. Coverage graph for the first scenario.

Fig. 6. Stability for the second scenario.

Fig. 4. Stability for the first scenario.

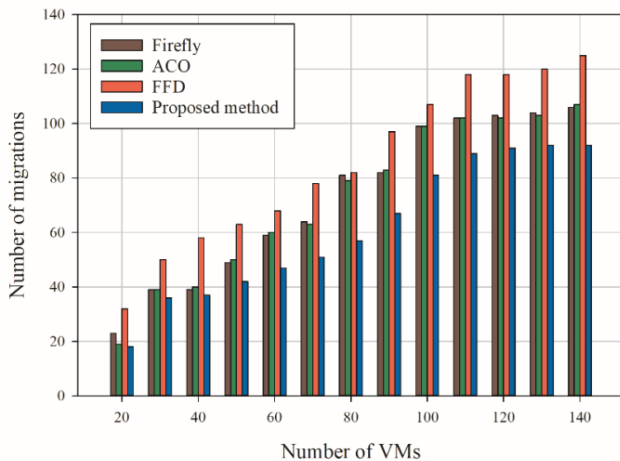

Fig. 5. Number of migrations vs. number of VMs.

V. CONCLUSION

Cloud computing provides unlimited computing resources that can be accessed from anywhere, anytime, on demand. Recent research in cloud computing emphasizes the importance of energy efficiency in data centers. Cloud architecture is characterized by high power consumption and inadequate utilization of physical resources. An idle VM tends to consume 50% to 70% of the total server energy, resulting in an imbalance and insufficient power for the active VMs. This paper proposed a new VM migration method based on the KH algorithm that minimized energy consumption and maximized the utilization of computational resources. The algorithm reduces power consumption by putting idle machines into sleep mode. It also minimizes the number of migrations compared to previous works.

Abstract—With the increasing demand for research on shrimp disease recognition to assist far-off farmers who need the proper assistance for their shrimp farming, shrimp disease prediction research is still in the initial stage. Most current methods utilize vision-based models, which mainly face challenges: symptom detection and image quality. Meanwhile, there are few researches which are language-based to get over the issues. In this study, we will experiment with natural language processing based on recognizing shrimp diseases; based on descriptions of shrimp status. This study provides an efficient solution for classifying multiple diseases in shrimp. We will compare different machine learning models and deep learning models (SVM, Logistic Regression, Multinomial Naive Bayes, (a4) Bernoulli Naive Bayes, Random forest, DNN, LSTM, GRU, BRNN, RCNN) in terms of accuracy and performance. The study also evaluates the TF-IDF technique in feature extraction. Data were collected for 12 types of shrimp diseases with 1,037 descriptions. Firstly, the data is preprocessed with standardised Vietnamese accent typing, tokenized words, converted to lowercase, removed unnecessary characters and stopwords. Then, TF-IDF is utilized to express the text feature weight. Machine learning-based and deep learning-based models are trained. The experimental results show that Random forest (F1-Score micro: 98%) and DNN (Validation accuracy: 84%) are the most efficient models.

Keywords—TF-IDF; machine learning; deep learning; CNN; shrimp disease classification

I. INTRODUCTION

Shrimp is the most commonly consumed worldwide, accounting for 15.5% of total global aquaculture production. Production of shrimp-related goods has increased globally over the past 16 years (from 2000 to 2016) by more than 20%. In which, Vietnam accounted for 9% of total export value (ranked 2nd in the world)[1]. Shrimp farming production has increased significantly to meet a market need, but needs to increase more to keep up with the demand[2]. Research [3] shows that the top five shrimp-farming countries are Ecuador, India, Indonesia, Thailand and Vietnam.

Shrimp farming also faces many challenges due to resource use issues in shrimp farming and shrimp diseases. Diseases in shrimp aquaculture have hindered the sector from growing, directly influencing management and production costs. In 2012, an infectious disease, acute hepatopancreatic necrosis syndrome (AHPNS) or early mortality syndrome (EMS), severely damaged the shrimp farming region, with

one-sixth of the area in Thailand and Vietnam affected[4]. In 2013, in India, the epidemic caused a loss of INR 10,221 million, 48,717 tons and 2.15 million working days were lost[5]. In 2016, white spot disease caused more than \$8 billion in damage and cumulative mortality can reach 90-100% over a period of 3 to 10 days[6].

Most of the current studies have focused on using image processing or machine learning methods to detect shrimp diseases based on the visual features of shrimp. There is research related to disease recognition in shrimp, such as biochemical diagnosis or image-based AI methods. Firstly, diseases can be detected by biochemical techniques performed in the laboratory with measures such as CRISPR to detect white spot virus, acute hepatopancreatic necrosis disease (AHPND)[7], [8], amplification of recombinase polymerase to detect acute hepatopancreas, hemocyte iridescent virus [9], [10], PCR method to detect AHPND[11], etc. There is also an advance in shrimp disease identification methods by applying artificial intelligence algorithms on shrimp disease images, such as: using CNN architecture to create ShrimpNet[12]–[14] to detect yellow head disease in shrimp. This shows that the result of detection of diseases in shrimp is quite impressive, but there are limitations in terms of time and precision. These methods require high-quality images of shrimp and may fail to capture the subtle or complex symptoms that are expressed in natural language. Moreover, these methods may not be easily accessible or affordable for small-scale farmers who lack the necessary equipment or expertise.

Because of the above reason, we propose a novel approach to detect shrimp diseases from text, based on the textual symptom descriptions that can be obtained from various sources. There are also a few papers that have performed text-based classification of shrimp diseases, but they only used a few machine learning models and achieved not high results[32]. Therefore, we conduct this research with different machine learning models and deep learning models (SVM, Logistic Regression, Multinomial Naive Bayes, Bernoulli Naive Bayes, Random forest, DNN, LSTM, GRU, BRNN and RCNN), and improve the accuracy. We hope that our research will contribute to the advancement of NLP applications in the field of aquaculture and provide a valuable tool for shrimp farmers and experts to diagnose shrimp diseases in an efficient and reliable way. We perform in-depth exploratory research on:

- Shrimp disease data is collected from texts describing the status of shrimp on the farm. This is something that farmers often describe in daily farm management through observation. The study collected 1,037 symptom descriptions of 12 common diseases in Vietnamese (attached data set). For example, the description is “Shrimp is a weak, limp, soft shell, intestines without food, swimming sluggishly on the water surface, on the shore, slow to grow; hepatopancreas is more yellow than usual; gills, tail swollen.”
- Data preprocessing with standardised Unicode and Vietnamese accent typing, tokenising words, converting to lowercase, removing unnecessary characters and stopwords.
- Then, the study combined TF-IDF technique with machine learning (ML) and deep learning (DL) algorithms.

The remainder of this article is organized as follows: in Section II, we give a brief review of this domain research and re-evaluate the descriptive dataset of related studies. Section III describes the data processing steps, the dataset¹, TF-IDF technique, training process and popular ML/DL algorithms. The experimental method is described in Section IV. The results after implementing the system are covered in Section V. The discussion and conclusion are presented in Section VI and Section VII respectively.

II. LITERATURE REVIEW

A. Traditional Methods

Currently, a variety of techniques are utilized to identify diseases. The issue in this field can be broken down into two different classification techniques: biochemistry and AI-based. Many researchers focus their work on computer vision for categorization using AI; moreover, more attempts have been made with text recognition, particularly regarding shrimp diseases.

The conventional method, which is often used, relies on visual inspection, observation, and testing on shrimp samples to identify the disease's presence[15]. High accuracy is used when using this technique. The drawback of this approach is that it necessitates a laboratory, time, and specialist topic knowledge.

Another option is to utilise test kits, such as bacterial test kits, viral test kits, and antigen test kits to detect infections in shrimp. This method has several advantages, including high accuracy, simplicity, speed, and convenience, but it also has disadvantages, including the difficulty of distinguishing many different diseases.

The following technique, which uses PCR and immunoglobulin analysis, is based on genetic analysis to identify disease resistance. RFLP (Restriction Fragment Length Polymorphism)[16], [17], RAPD (Random Amplification of Polymorphic DNA)[18], and SSR (Simple Sequence

Repeat)[19], [20] are examples of specific approaches. The benefits of this procedure are the same as those of test kits and conventional methods. But it still has high cost, complexity, and inability to detect all diseases.

To sum up, the biochemical approach also has advantages for swiftly detecting diseases in shrimp. However, it has the drawback of requiring time to assess the severity of the sickness and choose the best approach.

B. Method of using Artificial Intelligence

Artificial intelligence is an approach that has been widely used recently, especially in research on shrimp disease classification based on images, genetic data, chemical data, etc. This method can be divided into different categories. The first is an image-based shrimp disease classification method using deep learning models such as Convolutional Neural Network (CNN)[12], [13], [21], YOLO model [22], and machine learning[23], [24]. The effectiveness of this strategy depends mainly on the picture size and quality. The environment is the major obstacle affecting the accuracy of the results and data processing. Next, the study uses machine learning algorithms to accurately detect the disease in shrimp by identifying its early symptoms. This shows that it is possible to identify diseases in shrimp using natural language processing techniques and methods.

Some encouraging findings have been made regarding the classifying diseases using natural language processing. In the medical field, more than 20,000 findings use an NLP-based approach to classify diseases. The majority of trials[25]–[28] produced accurate disease diagnosis outcomes. There are about 9,000 studies agriculture employing NLP to enhance agricultural development and productivity. In studies on crops [29], [30], rice[31] have achieved promised accuracy (over 90%) by disease description and support chatbot system. In addition, research [32] has shown the first steps in approaching using NLP to identify diseases in shrimp with basic machine learning techniques with an accuracy of over 80%. It proved that the use of NLP in diagnosing of shrimp diseases is essential.

NLP techniques have been increasingly developed. Among them, there are processing techniques such as tokenization to divide sentences or paragraphs into smaller ones, stop word removal from removing words that have no critical meaning, stemming used to remove suffixes from meaningless words, lemmatization to return words to their infinitive form (lemma), part-of-speech (POS) tagging to classify each word in a sentence into word type parts, named entity recognition (NER) to recognize and classify named objects, sentiment analysis to analyze emotions in text, topic modelling to find the main themes in a corpus, word embeddings to convert words into vectors[33]. Data processing techniques in NLP are commonly used in text classification, automatic translation, chatbots and many other fields.

In conclusion, research into several sectors demonstrates the effectiveness of NLP in text processing. However, no studies currently combine NLP data processing methods with ML and DL analyses to identify shrimp diseases. As a result, data collecting and diagnostic processing related to shrimp

¹Dataset: <https://github.com/nqanh312/shrimp-diseases-dataset>.

sickness are crucial, which is considered the study’s novelty, which makes an important contribution to the establishment of a system to answer farmers' questions regarding shrimp diseases (Fig. 1).

Fig. 1. Some statuses of shrimp farmers describe to seek treatment on the social network Facebook.

III. MATERIALS AND METHODS

In this paper, we conduct a research on term frequency/inverse document frequency (TF-IDF) approach to extract characteristic words to construct the sentence embedding. Then, we apply the sentence embedding based machine learning and deep learning to categorize the documents into 1 type of diseases. Our proposed method comprises of following steps as shown in Fig. 2.

Fig. 2. System components are proposed in this research.

C. Dataset

We prepared a novel dataset which was collected from the internet, the majority of which came from certain aquaculture pages, as there isn't an available dataset of infected shrimp. We perform statistics on the frequency of occurrence of the words shown in Fig. 3.

The collection of 1,037 documents includes descriptions of diseased shrimps, as seen in Table I. We gathered altogether, which are then utilized to train and test our model.

D. Data Pre-Processing

Preparing sentences for analysis is a step that transforms an input into understandable data. Steps that sentences pass:

- All of the data is processed using the most straightforward and efficient method of text preprocessing—lowercase.
- Stemming is a heuristic technique that correctly transforms words into their root form by chopping off the ends of words.
- Stopword removal: removes poor information terms from the text so that the work can concentrate on the keywords.
- Turning a text into a standard form is known as normalization. This stage removes distracting text elements, including abbreviations, typos, and words that are not commonly used.
- Remove any letters, numbers, or text fragments that can interfere with text analysis by doing noise reduction. The result is shown in Fig. 4.

TABLE I. STATISTICS OF DATA USED IN THIS RESEARCH

No.	Name	Quantity
1	Acute hepatopancreatic necrosis	74
2	Black gill	77
3	Filamentous bacterial	77
4	Infection with vibrio	91
5	Infectious myonecrosis	101
6	Loose shell	139
7	Luminous bacteria disease	81
8	Plaque disease in shrimp	90
9	Taura	72
10	VitaminC deficiency in shrimp	78
11	White feces	79
12	Yellow head	78
Total		1.037

Fig. 3. List of words and its frequency.

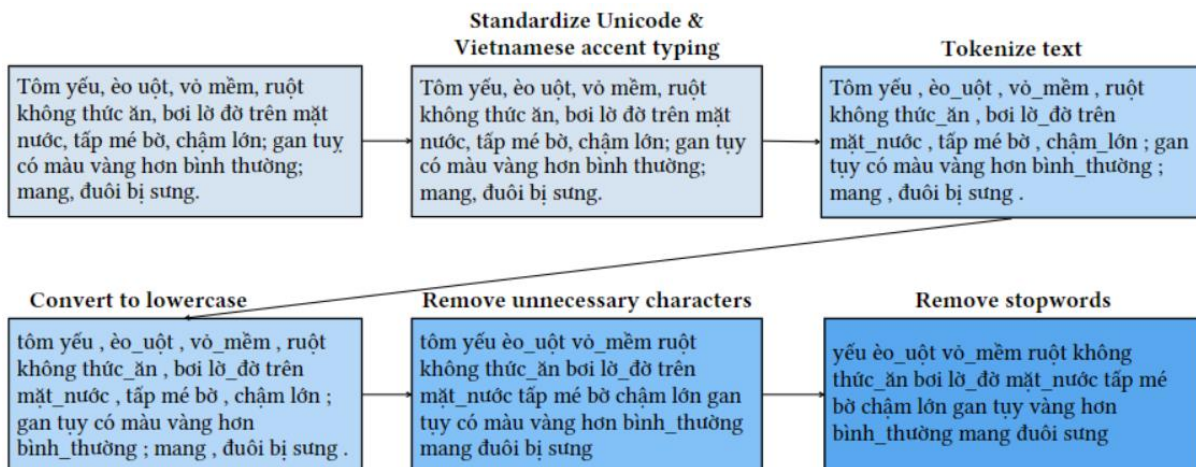

Fig. 4. The result of the preprocessing.

C. Feature Extraction with TF-IDF

By converting text into vector space (VSM) or sparse vectors, the TF-IDF method is frequently used in text data mining to estimate a word's significance [34]. Sentence embedding:

- The number of words in a set of documents is counted by TF-IDF. We typically assign a score to each word to show how much weight it has in the corpus and document. This approach is every now and again utilized in data recovery and text mining.
- Frequency of Term (TF): Using the heuristic that a term's importance is proportional to how frequently it appears in a document, it shows how important a word is to a document.

IDF:

- Outlines the genuine significance of an expression. It is pointless for terms like stopwords, which frequently show up in certain records, to be critical (the, that, of, and so on). Stopwords ought to have stayed away since they dark the unique circumstance. They are ignored by IDF because of the way it operates.
- It penalizes the word used frequently throughout documents.
- The appropriate term receives a more excellent IDF score, while the stopword receives a lower weight.

In this research, the frequency of words related to shrimp diseases tf_{Shp} is the number of words t_{Shp} compared to d_{Shrp} .

$$tf_{Shp}(t_{Shp}, d_{Shrp}) = \frac{f_{Shrp}(t_{Shrp}, d_{Shrp})}{\max\{f_{Shrp}(w_{Shrp}, d_{Shrp}) : w_{Shrp} \in d_{Shrp}\}} \quad (1)$$

In which:

- $tf_{Shp}(t_{Shp}, d_{Shrp})$: term frequency of t_{Shp} in d_{Shrp} .
- $f_{Shp}(t_{Shp}, d_{Shrp})$: number of the t_{Shp} appears in d_{Shrp} .
- $\max\{f_{Shp}(w_{Shrp}, d_{Shrp}) : w_{Shrp} \in d_{Shrp}\}$: the maximum of number of terms related to shrimp diseases in d_{Shrp} .

The IDF of a term indicates the percentage of corpus documents that contain the term. Words that are only found in a small number of documents, such as technical jargon terms, are given more excellent relevance ratings than words that are used in all documents, such as a, the, and. $idf_{Shp}(t_{Shp}, D_{Shp})$ is calculated as the following formula:

$$idf_{Shp}(t_{Shp}, D_{Shp}) = \log \frac{|D_{Shp}|}{|\{d_{Shp} \in D_{Shp} : t_{Shp} \in d_{Shp}\}|} \quad (2)$$

In which:

- $idf_{Shp}(t_{Shp}, D_{Shp})$: inverse document frequency idf_{Shrimp} of term t_{Shp} in D_{Shp} .
- $|D_{Shp}|$: number of document in the corpus $|D_{Shp}|$
- $|\{d_{Shp} \in D_{Shp} : t_{Shp} \in d_{Shp}\}|$: number of documents d_{Shp} in the corpus D_{Shp} contain the term t_{Shp} .

The $tf - idf(t_{Shp}, d_{Shp}, D_{Shp})$ is calculated by multiplying TF and IDF scores:

$$tf - idf(t_{Shp}, d_{Shp}, D_{Shp}) = tf_{Shp}(t_{Shp}, d_{Shp}) \times idf_{Shp}(t_{Shp}, D_{Shp}) \quad (3)$$

D. Training

The classification model will be trained using machine learning (ML) algorithms and deep learning (DL) models using the training dataset. The model will learn from labeled data, which have been digitized into feature vectors through feature extraction. On this processed data set, parameters will be learned and optimized by machine learning and deep learning algorithms. The classification model will receive data (extracted features) after learning to predict results and return the appropriate label as a result (Fig. 5).

In addition to dividing the models/algorithms used into two types of deep learning/machine learning. They can be divided into three other categories based on structured data, i.e. regression algorithms, binary classifiers and multiclass classification algorithms on structured data.

Types of regression algorithms include Linear Regression (LiR), Random Forest (RF). LiR is used to predict the value of a continuous variable based on different input variables[35]. The RF algorithm builds multiple decision trees and combines their predictions to make the final prediction[36].

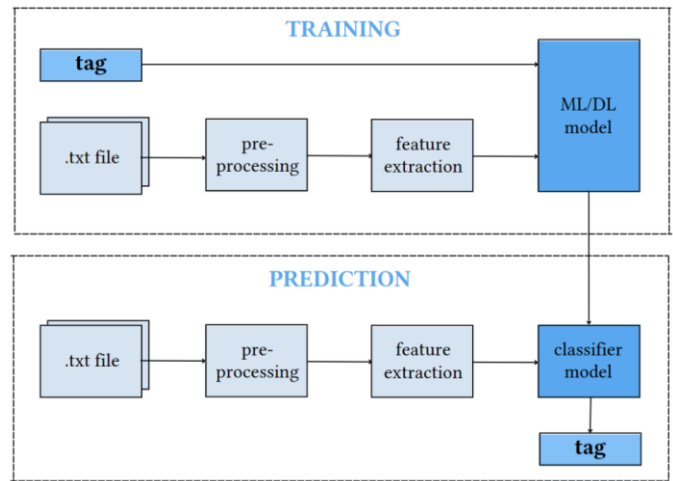

Fig. 5. Illustrate the process of using ML/DL for training and recognition.

Types of binary classification algorithms include Logistic Regression (LoR), and Bernoulli Naive Bayes (BNB). LoR is based on the sigmoid function to predict the probability of a linearly combined data sample of the input feature; the advantage of this algorithm is that it is simple and can explain the results[37]. Similar to LoR, BNB calculates the probability of each input feature, but it will conditionally consider each class based on the probabilities[38].

Types of multi-class classification algorithms on structured data include Support Vector Machine (SVM), Deep Neural Network (DNN), Long Short-Term Memory (LSTM), Gated Recurrent Unit (GRU), Bidirectional Recurrent Neural Network (BRNN), Recurrent Convolutional Neural Network (RCNN), Multinomial Naive Bayes (MNB). In which SVM classifies data by finding the best boundary[39], DNN uses many hidden layers to learn complex features of data [40]. LSTM uses an artificial neural network to record and store previous information to predict outcomes[41]. GRU has similar characteristics to LSTM. Still, it uses fewer parameters[42], BRNN uses two symmetric neural networks to learn data features [43], RCNN combines recurrent neural network and convolutional neural network to process sequence data[44], MNB is also based on the assumptions of BNB but features independent and differentiated input Multinomial distribution on each class[45].

In general, each predictive model has its advantages and limitations, depending on the specific data set and intended use. However, these models are all predictive and can be applied to the dataset after vectorization using the TF-IDF technique.

IV. EVALUATION

To evaluate the performance of the model, we use a confusion matrix which comprises four building blocks, namely True Positive (TP), True Negative (TN), False Positive (FP), and False Negative (FN).

TP and TN allude to situations where the forecasts are exact and negative. Positively false predictions are called FP, while negative false predictions are called FN. We use the confusion matrix to evaluate our model to generate additional

distinct metrics. Accuracy, Precision, Recall, and the F1 score are the precise metrics calculated using the formulas below.

1) *Accuracy*: Accuracy is one of the evaluating metrics and is informally interpreted in Eq. (4). It is the proportion of specifically classified shrimp diseases and the total number of shrimp diseases in the test set. The result shows how good the model works. The higher score of accuracy the more accurate our method is:

$$Accuracy = \frac{TruePositive+TrueNegative}{TotalPredictions} \quad (4)$$

2) *Precision*: The proposition of classified disease (TP) and the ground truth (the sum of TP and FP) defines the precision. It calculates the percentage of accurately classified disease as Eq. (5).

3) *Recall*: The percentage of correctly classified disease among all diseases belonging to that class Eq. (6).

4) *F1-score*: The following Eq. (7) is used to calculate the metric: the symphonic average of precision and recall. F1-score will be in (0,1], as F1 score higher as better model is.

$$Precision = \frac{TruePositive}{TruePositive+Falsepositive} \quad (5)$$

$$Recall = \frac{TruePositive}{TruePositive+Falsenegative} \quad (6)$$

$$F1 - Score = 2 \frac{Precision*Recall}{Precision+Recall} \quad (7)$$

In this study, we used Micro avg: F1-score is calculated by considering all classes' total number of true positives, false negatives and false positives. This method is often used to measure the correct prediction ratio of the model over the entire dataset. This research belongs to the case of a multi-class classification problem with the condition that each sample belongs to only one class; test accuracy will be equal to the F1-score micro.

The confusion matrix shows and summarizes a better view of the performance of a classification algorithm. It evaluates

the results of the classification problem by considering both the accuracy and generality of the prediction for each class. The accurate/false prediction is shown as a percentage of each class.

V. RESULT

This experiment is based on Intel(R) Core(TM) i5-10210U CPU @ 1.60GHz, RAM 8 Gbytes. In this research, we adopted machine learning and deep learning method in natural language processing to classify deceases of shrimps. The model's performance was evaluated using accuracy and F1-score micrometric on the validation and test dataset. The result is shown in Table II.

According to the Table II, it is found that:

- Machine learning method: SVM has the highest accuracy score on the validation data (0.83), while Random forest obtained the highest F1-score micro on the test data (0.96). This shows that SVM works for matching better while Random forest has better generalization
- Deep learning: DNN has the highest accuracy score on both validation and test set. It is proved in Table II that DNN outperforms other models in shrimp classification. Other models, such as LSTM, GRU, BRNN, and RCNN, all have close results, with the micro F1-score ranging from 0.93 to 0.97.

Moreover, we used a confusion matrix for each algorithm and model to evaluate the confusion among shrimp diseases. Based on Fig. 6, the research found that the confusion of the models on acute hepatopancreatic necrosis, Filamentous bacteria, Infection with vibrio, Taura, and Vitamin C deficiency in shrimp, White feces, Yellow heads are quite low, while Plaque disease in shrimp confusion prediction obtained a high rate. The results prove that DNN is the most suitable model for shrimp disease classification.

TABLE II. ACCURACY AND F1-SCORE RESULTS OF ML ALGORITHMS AND DL MODELS ON SHRIMP DISEASE DATASET

Methods	SVM	LoR	MNB	BNB	RF	DNN	LSTM	GRU	BRNN	RCNN
Validation accuracy (without TF-IDF)	0.725	0.727	0.724	0.646	0.779	0.738	0.542	0.479	0.665	0.671
Validation accuracy (using TF-IDF)	0.825	0.800	0.725	0.763	0.788	0.838	0.575	0.575	0.788	0.750
F1-score micro (without TF-IDF)	0.896	0.858	0.808	0.704	0.917	0.971	0.779	0.742	0.854	0.842
F1-score micro (using TF-IDF)	0.963	0.908	0.821	0.767	0.975	0.971	0.929	0.950	0.967	0.971

VI. DISCUSSION

In this section, we will discuss the results obtained and the remaining limitations of the study. Based on the accuracy and validation accuracy results, the research finds that the test data set has a different distribution from the validation dataset and is more suitable for the model, leading to a difference in the error in the test data model. However, when comparing ML algorithms and DL models, the performance of DL is higher in this problem. This can be explained by the ability of DL models to learn complex and semantic features of expressions. DL models also have the advantage of dealing with unbalanced data so that minority classes can be correctly classified.

In machine learning algorithms, the algorithm with the highest results on the test set is RF. The algorithm can minimise overfitting and increase the diversity of decision trees. The SVM, LoR and NB algorithms are all based on

linear classifier architecture. Although these algorithms are easy to implement, they are not suitable due to the nonlinearity of shrimp disease data.

Deep Neural Network gives the best results among deep learning models because of their ability to represent non-linear features of the data. However, this model is challenging to train and adjust parameters and does not use sequence information of disease expression description in shrimp. Thus may need to understand the significance of this model regarding contextual meaning. The models based on Recurrent Neural Network architecture (LSTM, GRU, BRNN and RCNN), although capable of using information about the sequence of expression, have problems of vanishing gradient or exploding gradient when training because of long-term dependence between time steps in the data series (if the link weights between steps are too small or too large, the gradient will disappear or explode when propagating back through the long sequence).

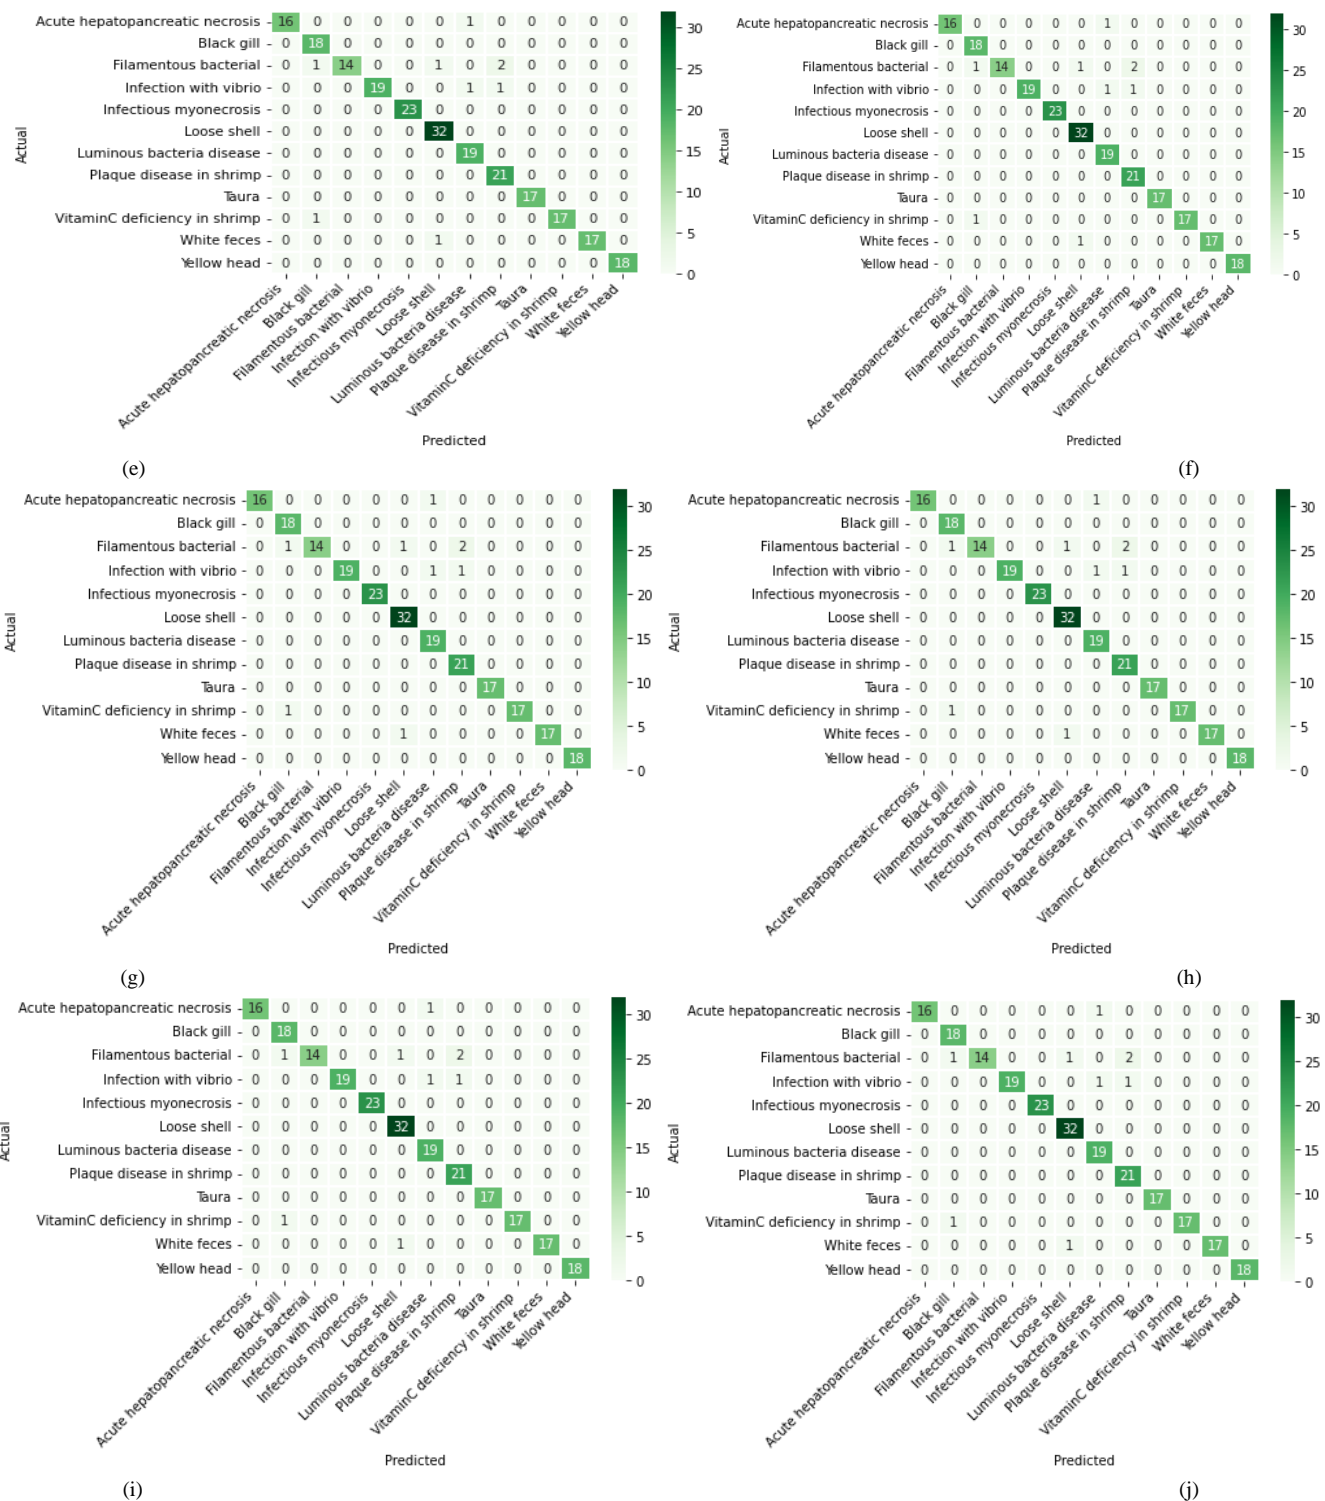

Fig. 6. Confusion matrix of algorithms: (a)SVM, (b)LoR, (c)MNB, (d)BNB, (e)RF, (f)DNN, (g)LSTM, (h)GRU, (i)BRNN, (j)RCNN.

VII. CONCLUSION

This research classified shrimp diseases based on deep learning and machine learning methods. We preprocessed 1.037 samples of 12 prevalent shrimp diseases and divided them into three groups: training data, test sets, and validation sets. After training, the model is put through its paces on the

validation and test sets. Compared to other models, the outcome demonstrates that DNN achieves the highest performance on this data.

This study applies the theoretical results of natural language processing (NLP) to analyze shrimp description and classify shrimp disease to enhance the productivity and

sustainability of aquaculture by providing timely and accurate diagnosis of shrimp diseases. Another motivation is to reduce the economic losses caused by shrimp diseases and increase the competitiveness of the shrimp industry. Furthermore, NLP can facilitate the prevention and treatment of shrimp diseases by offering instant services recommendation and early interventions. Additionally, NLP can advance the scientific knowledge and innovation in the field of NLP and its applications for aquaculture. However, this study still has some limitations that need to be overcome. First, the data size is relatively small and uneven across disease classes. This can affect the generalization ability of algorithms and models. Second, we only use TF-IDF as a feature extraction method for machine learning algorithms. TF-IDF is a simple and effective method, but it cannot represent the semantic meaning of the expression. Therefore, in the future, we will continue to collect more data to assess the methods on different datasets, and use other feature extraction methods, such as word2vec or BERT, to compare with TF-IDF.

Abstract—In this article, we provide a MoveNET-based technique that we think may be used to detect violent actions. This strategy does not need high-computational technology, and it is able to put into action in a very short amount of time. Our method is comprised of two stages: first, the capture of features from photo sequences in order to evaluate body position; next, the application of an artificial neural network to activities classification in order to determine whether or not the picture frames include violent or hostile circumstances. A video aggression database consisting of 400 minutes of one individual's actions and 20 hours of videodata encompassing physical abuse, as well as 13 categories for distinguishing between the behaviors of the attacker and the victim, was created. In the end, the suggested approach was refined and validated by employing the collected dataset during the process. According to the findings, an accuracy rate of 98% was attained while attempting to detect aggressive behavior in video sequences. In addition, the findings indicate that the suggested technique is able to identify aggressive behavior and violent acts in a very short amount of time and is suitable for use in apps that take place in the real world.

Keywords—MoveNET; neural networks; skeleton; bullying; machine learning

I. INTRODUCTION

The purpose of this project is to scrutinize the problem of aggressive behavior and bullying in schools in order to propose the best possible solution. According to Olweus [1], school bullying is an unwanted aggressive behavior on the part of one or more other students that exposes a victim to negative actions repeatedly and over time. Negative actions can be carried out by physical contact, by words or in other ways, for instance, making faces and obscene gestures, or often ostracizing the victim from the common social community. Generally speaking, bullying may be identified by the three characteristics that are listed below: (1) It is violence-related behavior or purposeful "harm-doing," (2) it is activity that is carried out "repeatedly over time," and (3) it is behavior that occurs in an interpersonal relationship defined by a real or expected imbalance of power [2]. Scientific evidence suggests that bullying affects future mental health functioning of both victims of bullying and those who cause harm/bullying. Apart

from physical aggression, bullying also includes psychological pressure, intimidation, rumor spreading, extortion, and mockery.

Aggression may take both direct and indirect forms when it comes to bullying. Direct types of bullying, consisting of an overt demonstration of physical power, can take the form of physical or verbal violence. The term "physical bullying" refers to any kind of physical attack, including in particular striking, shoving, kicking, choking, and any harmful action towards the victim. Bullying victims may be subjected to verbal harassment or intimidation when they are called names, threatened, taunted, teased maliciously, or psychologically intimidated by offensive language. Children may be bullied in a variety of ways, including stealing, vandalizing, making offensive looks or gestures, and making faces [3].

The National report "Factors influencing health and well-being of children and adolescents in Kazakhstan" published by the National Center for Public Health of the Ministry of Health of the Republic of Kazakhstan [4] provides results about health, social conditions and well-being of teenagers aged 11 to 15 years. The study is based on HBSC methodology, a WHO collaborative cross-national survey. The report contains information on social and health indicators that are related to the health and well-being of both children and adolescents. And bullying was defined as one of the risk factors affecting the health and well-being of children in this report.

According to the data published in the National report, 17% of teenagers aged 11 to 15 years were bullied at school one or more times per month. 20% of teenagers from the same age group were involved in bullying others at least once. This rate is higher among 11 and 13 year old boys compared to girls.

The goal of this research is to develop Artificial Intelligence (AI) Solutions in order to utilize them as a basis for designing a prototype of a software-hardware complex that can automatically detect cases of aggressive behavior and potential physical bullying in educational institutions.

The remainder of this paper is structured as follows: The next part discusses cutting-edge physical aggression detection, after which a problem statement is presented and described.

The goals and aims of the research are thoroughly explained in the third part. The human skeleton-based physical aggression detection approach is discussed in the fourth part of this article. The procedure of data collecting and the investigation's outcome are laid out in the fifth part of the report. In the sixth part, findings are discussed, and ongoing issues in the field of violence identification in videos are described. The report is brought to a close with the last part, which discusses the plans for and issues associated with physical bullying detection in video. The creation of an automatic and rapid physical aggression detection system in video security cameras based on human skeleton is the key objective of the work. The developed technique makes it possible to recognize violent events in the video without the need for highly processed hardware.

II. RELATED WORKS

The National Center for Educational Statistics (2019) showed that one in five students (20.2%) reported being bullied at school in numerous places, such as a hallway or stairway (43%), in the cafeteria (27%), outside on school grounds (22%), online / text (15%), in the bathroom or locker room (12%), on the school bus (8%) [5].

One of the first systematic studies to collect data on the nature and extent of violence in schools in Kazakhstan was conducted by the United Nations Children's Fund (UNICEF) in 2013, which revealed that 66.2% of schoolchildren were exposed to school violence and discrimination, 63.3% were witnesses, 44.7% were victims, and 24.2% were perpetrators of violence and discrimination against other children in school. [6]

Video analysis is an area of AI and machine learning that has shown good results in recent years and is widely used. Bullying in its various forms poses a serious problem that a vast amount of schoolchildren faces. For various reasons, there are not many scientific investigations in the world which attempt to fix the negative consequences of bullying by means of video analysis. Among the few, slow development in this vector can be mentioned. There are some studies related to cyberbullying and depression detection on online user contents [7-9]. However, there is no evidence about such researches in the Republic of Kazakhstan. This substantiates the novelty of the proposed project.

The current level of development of AI methods for video analysis allows using them to process video footage from school cameras. However, there are not many researchers who study the effectiveness of using AI methods to reduce cases of bullying and its negative effects at school. According to this project, video analysis using AI methods will enable early detection of aggressive behavior. Consequently, the early detection of such cases will facilitate the work of school psychologists in terms of early warning of bullying.

A distinctive feature of this project is its interdisciplinarity: new proposed solutions of AI will push the boundaries of bullying studies to a social phenomenon. The collected data will be used to conduct a psychological study on the effect of bullying on the psychological and emotional health of schoolchildren. The combined use of AI methods and

psychology will provide the results that may find application in those areas of life where video analysis is needed.

Using neural network technologies will allow for the intelligent video footage processing in order to assess human behavior and determine aggressive actions.

In the proposed study, software models of artificial intelligence will be trained on the basis of LGD-3D architecture, a two-stream I3D structure. A recent study examined the problem of recognizing aggressive actions based on RGB video data, the I3D architecture showed better results compared to C3D and R3D in all respects.

For video classification, a method based on a neural network with deep convolutional graphs (DCGN) will be used. According to the results of research, this method is superior to alternative ones, such as LTSM and GRU.

The categorization of activities, in addition to the categorization of facial expressions, is an active topic of study that is, nonetheless, fairly difficult. Large variations in action performance brought on by differences in individual's anatomy, as well as temporal and spatial variations (including differences in the pace at which people do actions), are some of the issues that are linked with the categorization of actions [10]. It might be difficult to tell the difference between activities that are just part of the game (such as wrestling or hurling things at each other), and those that constitute bullying. Either adjusting the system to disregard activities that are related to typical children's games or integrating numerous algorithms might be the answer to this issue (for example, a combination of the classification of emotions and actions).

In recent years, researchers have raised concerns about physical bullying detection [11-13]. Previous researches [11] used the transfer learning approach on the identification of violent conduct. The authors developed a violence detector that was based on transfer learning and tested it using three different datasets. They had an accuracy rate of 80.90 percent on average when it came to identifying violent content (from a video that was obtained from YouTube). Next study [12] investigated the use of information about irregular mobility to identify violent behavior in surveillance cameras. By using of the Motion Co-occurrence Feature, the authors were able to conduct an analysis on the properties of the motion vectors that were produced in the vicinity of the item (MCF). They utilised the CAVIAR database, but, however, the research did not provide any numerical results about the accuracy on average.

The National Autonomous University of Mexico conducted a study using a systematic observation strategy called SDIS-GSEQ [14-15] to describe the behavioral patterns in children who were identified by the program as "victims" and their changes. The purpose of the study was to investigate the effects of the program on these children.

III. PROBLEM STATEMENT

The purpose of this research is to provide a method for rapid identification of violent incidents captured by video security cameras. The scientific contribution made by this study is the invention of a system for the rapid identification of violent behavior. The objective was accomplished by training a

neural network using a tracking by detection method like MoveNet retrieved points from human skeletons. The following goals need to be completed in order to succeed in this endeavor: a) Development of a Video Dataset with aggressive behaviour scenes; b) Extract human skeleton points using MoveNet; c) Train the neural network applying the extracted points d) Evaluate the trained neural network.

IV. DATA

The problem of identifying violent and aggressive conduct may be broken down into a variety of more specific subtasks. Fig. 1 presents the research process as a flowchart for a reference. The flowchart for the study project is divided into its primary components, which are feature extraction, data collection, and classification problem. The section on data characteristics is where the pattern parameters of the perpetrator are defined. The portion responsible for data collection assures the availability of relevant video data, marks up videos according to classifications, stores them in .json format, and trims the marked video sequences that include violent situations in order to produce a dataset. In this section, we present all kinds of data operations from collection to the preparation for neural network training.

A. Data Collection

The first step is to determine the various categories of information that need to be compiled. We came up with different distinct categories of traits to differentiate a victim from an aggressor. These traits may be categorized as either passive or active. In the beginning, we determined their characteristics based on the predetermined classifiers. These characteristics are the ones that should be assessed during the process of data collection. Afterwards, the characteristics of the victim and the aggressive behavior were broken down into 13 different groups.

When searching for video materials that are available for free access on the internet, we applied a variety of search phrases, including "aggression," "physical aggression," "violence," "bullying," "fight," "group fight," and others. After gathering them, the next step was to assign appropriate classes to the spatiotemporal segments included within the videos, and the information about their labeling was saved in the *.json file format. To accomplish this task, we used VGG Image Annotator. Following the completion of the tagging, each of the movies was clipped, and then they were arranged into classes.

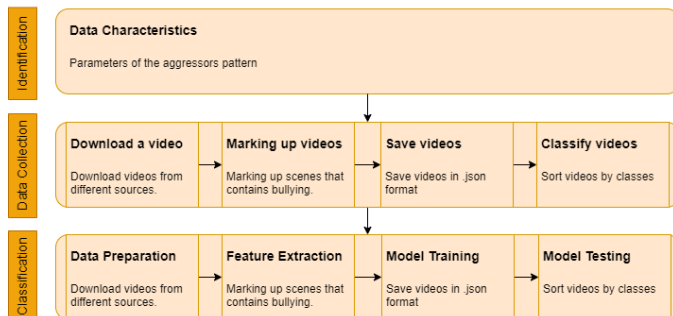

Fig. 1. Flowchart of the research.

B. Dataset

The initial step of our investigation consisted of collecting footage of acts of violence committed by a single individual. There are thirteen categories of violent acts that have been categorized. As a result, there were a total of 80 classifications that were found to belong to either an offender or a victim over the course of the inquiry. In order to put the training model into practice, we needed to determine the activities of a single individual. For such purpose, we broke the project down into 13 courses that each only needs one person to complete. Table I provides an illustration of the thirteen courses that were used in the training of the model. In the course of our research, we developed our very own dataset, which is made up of the thirteen categories that were previously established. The dataset was used for both training and testing of the model that we have suggested. After that, it was put to the test by making use of free datasets of footage of violent acts.

The information shown in Fig. 2 pertains to the videos that were gathered. Videos are gathered in three different formats. Statistical information on the various kinds of video data files that were collected may be seen in Fig. 2(a). The dissemination of video sequences is shown in Fig. 2(b). It was determined that a total of 2,093 short videos illustrating incidents of physical bullying and aggressive behavior should be collected. Approximately 20 hours were spent gathering all of the video data. The following is a list of the file formats that were used to gather the data on the videos:

- video in .mp4 format: 2 017 files;
- video in .mov format: 44 files;
- video in .wmv format: 32 files.

TABLE I. COMPARISON OF THE OBTAINED RESULTS

Class id	Class type
0	Large range of hand movements
1	The head is directed towards the victim
2	The body turned to face the victim
3	The shoulders back and the arms back
4	Hands on hips
5	Takes off the outer clothes
6	Kicking
7	Punching
8	Covering the face
9	Legs pointing in different directions
10	A series of bouncing blows
11	Bend over
12	Finger pointing

Throughout the collected data, we also recorded videos of a single person committing physical aggression actions. Additional films are necessary for the first stages of the neural network training. The whole of the brand new video content clocks in at close to four hundred minutes. There are two distinct categories of violent videos, each of which is defined by its intended purpose. The first category of videos depicts acts of violence in crowded places. The second category deals with secluded violence, which can take place between just two people in uncrowded scene and typically involves one

participant acting as a bullier and the other participant acting as a victim.

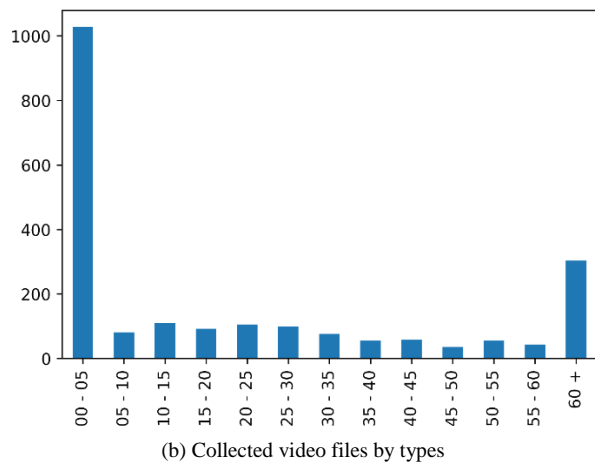

Fig. 2. Collected dataset of videos.

V. MATERIALS AND METHODS

A. The Proposed Approach

In the next paragraphs, we will discuss our methodology, which is known as the tracking by detection. The suggested system's general design is shown in Fig. 3, which may be seen below. The system may be broken down into three different subproblems. In the first step of this process, we approximate the human stance on each image sequence by applying the MoveNet model to the input image sequence. In the second step, we take each frame and retrieve important points as vectors. MoveNet provides a total of 17 important locations for each frame. As a direct result of this, we are able to generate vectors that include 34 individual components. In the subsequent phase, we combine all of the k vectors into a single vector before passing it on to the step that deals with features extraction and activity identification. In the last step, known as stage three, we train a neural network to solve tasks related to action recognition. There are two different kinds of algorithms for determining the location of a human skeleton based on RGB images: top-down and bottom-up. The first ones will trigger a human detector and examine body joints in boundary boxes that have already been determined. Top-down methods include the ones described in MoveNet [22], HourglassNet

[23], and Hornet [24]. There are a few other bottom-up algorithms, such as Open space [25] and PifPaf [26].

Fig. 3. Flowchart of the study.

We carried out our training using a strategy known as the skeleton approach. The described approach has the potential to reduce the costs associated with processing. A MoveNet based neural network is employed in order to create an accurate appraisal of the figure of either the perpetrator or the victim. Using a MoveNet that has already been pre-trained, a function extraction has the ability to transfer the data obtained in the input space to the target domain. The output of MoveNet represents the human skeleton with 17 primary body points together with their positions and the confidences associated with those sites. There are 17 vital points on the body, including the nose, eyes, ears, shoulders, elbows, wrists, thighs, knees, and ankles. Fig. 4 depicts an instance of 17 key points that MoveNet might obtain and use to train the neural network. These points are applied to the network. The x and y coordinates of the important points are what are used to represent them in the two-dimensional coordinate space.

The following formula illustrates one possible approach to depict the human body:

$$r_b(x_i; \theta), \tag{1}$$

Where θ is neural network parameters, and x_i is training samples. The representation of the human body $rb(x_i; \theta)$ is classified using a layer of fully linked neural networks that have been installed.

It is possible to train the extra neural network by lowering the category cross-entropy loss. This must be done before the network is normalized by the "Softmax" layer. Fig. 5 presents an overview of the architecture of the MoveNet based ANN. In the first step, human activity frames are sent into MoveNet so that crucial points may be extracted. Afterwards, the coordinates of skeleton points are shown and used to represent

them in the feature space. In the final step, the human skeleton's essential points are used to train the network.

Fig. 4. Extracted points by MoveNet.

Fig. 5. ANN for MoveNet based physical bullying detection.

As a result, in the first phase of the research, we gather the required data, organized and split it into classes, and afterwards we built a dataset that will be fed into the neural network. The use of MoveNet for the purpose of extracting human skeleton points constitutes the second stage of the study. In order for a neural network to be able to distinguish human activities, we used human skeleton points in the training process. The development of a neural network for the detection of violent actions is the final process of the proposed framework. After that, training and testing the results of the neural network are carried out in order to determine whether or not the proposed approach is suitable for use in the real world.

B. Evaluation

Displaying the outcomes of a prediction model with the help of a confusion matrix is possible. Actual variables are defined by the columns of the confusion matrix, whereas anticipated classes are represented by the rows of the matrix. The matrix displays the number of true positives (TP), false positives (FP), false negatives (FN), and true negatives (TN) for each class. A number of other efficiency measures, including as accuracy, precision, recall, and F1-score, may be computed with the use of the matrix. Formulae like as precision, recall, F-measure, and accuracy are used in order to assess the outcomes of the suggested methodology, and Eq. (2)-(5) provide an illustration of these respective Eq. [27-29].

$$precision = \frac{TP}{TP + FP}, \quad (2)$$

$$recall = \frac{TP}{TP + FN}, \quad (3)$$

$$F1 = \frac{2 \cdot precision \cdot recall}{precision + recall}, \quad (4)$$

$$accuracy = \frac{TP + TN}{TP + FN + TN + FP}, \quad (5)$$

We employed a technique called weight-averaging to combine the metrics that were generated for each class into a single variable. This variable weights the values based on the proportion of the class that they represent. In order to validate the prediction models, we resorted to the tried-and-true train/test split. The data set was separated into eighty and twenty percent halves.

VI. EXPERIMENTAL RESULTS

In this part, we provide the research results into the categories of data collecting, feature extraction, and the identification of violent behavior. First subsection depicts human skeleton points' extraction findings; second portion exhibits violent activities detection results. At the conclusion of the second subsection, we compare the achieved findings with the study results that are now considered cutting edge. The research outcome is discussed with the use of evaluation metrics such as confusion matrices, model accuracy, precision, recall, and F1-score.

A. MoveNet-based Keypoints Detection

In this part of the article, we retrieved points of the human skeleton from the video sequence. The PoseNET model was used to determine the 17 most important locations. Fig. 6 is a demonstration of human skeletal points that have been retrieved from a live video frame. The extraction of human essential points was performed in a time span of every using a frame as a shot. Due to the rapid nature of the changes that occur in a video feed, the relative positions of the combatants may be immediately adjusted in the event of a conflict. As a direct consequence, there may be many sequenced classes for each participant in the fight. Therefore, the ability to make fast decisions is essential for the identification of violence in videos.

Fig. 6. Testing the proposed framework.

B. Detection of Violent Actions

Throughout the entire period of our experiment, we worked on developing and testing a neural network for violence detection. In order to train the neural network, the MoveNet architecture was applied. Out of the tagged video data, we used it to choose 13 classes for which we then captured further video data. When it came to recognizing aggressive behavior, the constructed action recognition model based on the gathered data performed very well.

(a) Validation and test accuracy

(b) Validation and test loss

Fig. 7. Model testing.

The results of the evaluation of the suggested model are shown in Fig. 7. Fig. 7(a) depicts the validation and testing accuracy of the system for the identification of physical bullying throughout the course of eight training epochs. According to the data, the accuracy reaches 98 percent after 8 training epochs have been completed. The values of the neural network loss function are shown in Fig. 7(b) during the course of eight training epochs. According to the data, the amount of validation that is lost is very little even during the beginning stages of the training process.

Fig. 8 depicts the evaluation of the outcomes of classification for a total of 13 different classes. As it can be seen from the graph, every one of the criteria for the evaluation is of an exceptionally high standard. For instance, the accuracy can range anywhere from 0.92 to 0.98, the recall can go anywhere from 0.89 to 1.0, and the F-measure may go anywhere from 0.92 to 0.99. The confusion matrix for the 13 various categories of aggressive behavior are shown in Fig. 9. According to the confusion matrix, the rate of categorization is

quite high, and there is a slight misunderstanding between the classifications.

Fig. 8. Confusion matrix of different classes' percentage.

Fig. 9. Confusion matrix for classes.

Fig. 10 illustrates how the proposed framework may be used in a scenario including group fight. In the end, we identify each person's behavior, categorize them, and decide in real time whether they are an aggressor or a victim based on their location, kind of action, and whether they are the bully or the victim. This kind of display of the findings may be helpful for video operators, as it enables them to identify fighting and other forms of physical bullying in real time and to swiftly recognize the attacker and the sufferer in both busy and uncrowded scenes of violence.

Fig. 10. Model testing.

Table II draws a comparison between the acquired results and the most recent study findings. We analyzed the numerous studies on the detection of physical aggression in the context of three primary assessment criteria: precision, recall, and f-measure. However, the recall and F-score assessment criteria are not used in the majority of the investigations. In situations like this, the Accuracy metric is the most important assessment measure to use when comparing the overall performance of the many recommended methods. In addition, the majority of studies do not include the amount of time spent processing their methods since doing so would be difficult due to disparities in the datasets used and the capabilities of the computer equipment.

TABLE II. COMPARISON OF THE ACHIEVED RESULTS WITH THE OTHER STUDIES

Study	Approach	Precision	Recall	F-score
The proposed approach	MoveNet based physical bullying detection	0.94	0.93	0.93
Fenil et. al., 2019, [11]	Bidirectional LSTM	0.94	-	-
Senst et. al., 2017, [12]	Scale-Sensitive Video-Level Representation	0.91-0.94	-	-
Zhang et.al., 2016, [13]	Linear SVM	0.82-0.89	-	-
Sharma & Baghel, 2020 [19]	ResNet-50 and ConvLSTM	0.924	-	-
Cheng et. al., 2020 [30]	Flow Gated Network	0.8725	-	-
Carneiro et. al., 2019 [31]	Multi-Stream CNN	0.8910	-	-
AlDahoul et. al., 2021 [32]	CNN-LSTM based model	0.7335	0.7690	0.7401
Deepak et. al., 2020 [33]	Gradients based violence detection	0.91	0.88	0.88

The findings demonstrate that the suggested method is capable of being used in real-world implementations for the identification of violent behavior by means of security camera footage. The suggested method is more rapid than the model that relies just on pictures due to the use of skeleton points during the training and testing of the neural network. In addition, the developed system will be useful in a variety of settings, including educational institutions and other locations that have video security cameras installed.

VII. CONCLUSION

This study established a physical violence detection based on MoveNet model, which can be employed in real-time and does not need highly processing hardware. The following is the primary benefit offered by the system that has been suggested. To begin with, it is not necessary to provide the system on a regular basis with huge amounts of video footage and photos. Our proposed technology is able to complete tasks more quickly than other systems on the market since it is based on

the MoveNet key points of the human skeleton. In this particular instance, this characteristic enables the suggested system to be used for applications that take place in real time and in the actual environment.

The proposed study aims to develop methods for the rapid and accurate identification of violent acts in real time by using video security cameras. In order to accomplish this objective, we would like to provide the following three proposals: Determine the different sorts of violent acts that are shown in a video stream that include both of these categories of violent acts. The first section of the data set consists of the aggressive behavior of a single individual that extends over the course of more than 400 hours. The violent acts committed by a single individual were separated into 13 categories, and the films that were included in the dataset were recorded from a variety of perspectives and acquired using a variety of tools. The second section of the dataset consists of violent acts committed in crowded scenes. The neural network is trained using violent behaviors performed by a single individual, while the suggested system is tested using violent actions performed by a group of bullies.

In order to save time, we employed the MoveNet model to extract skeleton points in order to retrieve an artificial neural network using skeleton key points rather than high-volume video. Using a time interval of one second, skeleton points were retrieved from each frame of the movie. Since human key points are being used, there is no need to load an extremely large number of video frames or photos. The findings of the experiment demonstrate an accuracy of between 95 and 99 percent in the identification of violence based on video; consequently, it is safe to assume that the suggested method is suitable for usage in real-world settings.

Abstract—In order to meet the business requirements of different applications in heterogeneous, random, and time-varying mobile network environments, the design of a reliable transmission mechanism is the core problem of the mobile Internet of vehicles. The current research is mainly based on the computing power support of roadside units, and large delays and high costs are significant defects that are difficult to overcome. In order to overcome this deficiency, this paper integrates edge computing to design task unloading and routing protocol for the reliable transmission mechanism of mobile Internet of vehicles. Firstly, combined with edge computing technology, a mobile-aware edge task unloading mechanism in a vehicle environment is designed to improve resource utilization efficiency and strengthen network edge computing capacity so as to provide computing support for upper service applications; Secondly, with the support of computing power of edge task unloading mechanism, connectivity aware and delay oriented edge node routing protocol in-vehicle environment is constructed to realize reliable communication between vehicles. The main characteristics of this research are as follows: firstly, edge computing technology is introduced to provide distributed computing power, and reliable transmission routing is designed based on vehicle-to-vehicle network topology, which has prominent cost advantages and application value. Secondly, the reliability of transmission is improved through a variety of innovative technical designs, including taking the two hop range nodes as the service set search to reduce the amount of system calculation, fully considering the link connectivity state, and comprehensively using real-time and historical link data to establish the backbone link. This paper constructs measurement indicators based on delay and mobility as key elements of the computing offloading mechanism. The offloading decision is made through weighted calculation of delay estimation and computing cost, and a reasonable computing model is designed. The experimental simulation shows that the average task execution time under this model is 65.4% shorter than that of local computing, 18.4% shorter than that of cloud computing, and the routing coverage is about 6% higher than that of local computing when there are less than 60 nodes. These research and experimental results fully demonstrate that the mobile Internet of vehicles based on edge computing has good reliable transmission characteristics.

Keywords—Mobile network; internet of vehicles; reliable transmission; edge computing

I. INTRODUCTION

Vehicular ad hoc networks (VANETs) are the basic networking mode of mobile Internet of vehicles. It mainly

relies on a vehicle-to-vehicle (V2V) and vehicle-to-roadside unit (V2R) to provide a variety of data transmission and information interaction services [1]. The concept of Internet of Vehicles is extended from the Internet of Things. With the rapid development of Internet of Things technology and applications, especially the significant progress of sensing technology in the perception layer of the Internet of Things, it provides real-time perception and feedback of operating vehicle and road condition information, providing an essential big data foundation for the research and application of the Internet of Vehicles.

Unlike traditional networks, the mobile Internet of vehicles has unique internal characteristics regarding the network environment, node mobility, channel characteristics, computing power, cache space, and energy constraints. In particular, the dynamic change of topology leads to frequent network segmentation, which is difficult to ensure the end-to-end connected link; In addition, the massive data of diversified new applications have great pressure on the response delay and network load, which poses a severe challenge to the computing power of car coupling network [2]. Therefore, studying the characteristics of mobile vehicle networks and building a reliable transmission mechanism is the core problem to be solved urgently.

Currently, the research and application of reliable transmission mechanisms of mobile vehicle networks far lag behind the industrial technology demand, which does not match the current development of mobile vehicle networking. On the other hand, the research of introducing edge computing into a reliable transmission of mobile Internet of vehicles has been widely concerned and applied. The overall research status in this field is briefly described below.

As early as 2009, the United States released the intelligent transportation strategic research plan. In 2016, China released the development plan for the innovation of the mobile Internet of vehicles, focusing on the deployment and promotion of common key technologies, standards, infrastructure construction, platform experimental verification, application, and promotion, and successively launched a series of standards and specifications for the mobile Internet of vehicles industry, including Tencent, Alibaba, and Baidu has also established corresponding cooperation with various car enterprises. International academic circles, such as IEEE, have founded IEEE Transactions on vehicular technology and other top journals, bringing together important innovative research

achievements in the world. Although the research on the reliable transmission of the mobile Internet of vehicles has made great progress, considering the scale of the mobile vehicle network, the rapid movement of vehicles, and the complex channel environment, ensuring the reliable transmission of information is still a very challenging problem [3][4].

Firstly, the location-based routing mechanism is a widely used key technology to solve data transmission. However, the existing related work still has corresponding limitations in node mobility characterization, routing index modeling, and relay node selection. It is mainly reflected in the following:

1) The vehicle network's scale, complexity, and dynamics are not fully considered. The existing routing mechanism is often applicable to local or single network form, resulting in the algorithm falling into optimal local solution and difficulty in adapting to the dynamic changes of mobile vehicle network effectively;

2) Rely on historical traffic information to quickly find routes in sparse scenarios and alleviate the occurrence of local optima while ignoring the positive role of real-time link information in assisting data transmission and avoiding collisions in congested flow scenarios.

Secondly, the effective calculation of data plays a great role in strengthening the performance of vehicle communication, and the calculation of massive data brings great pressure on the network bandwidth. By sinking the cloud computing function to the user side, edge computing will greatly reduce the network load and network delay; the current research work has the following deficiencies:

1) Most of the existing computing unloading mechanisms rely on the assistance of roadside unit RSU and fail to fully explore a large number of idle intelligent vehicle resources to improve the edge performance of the network;

2) Although some edge computing designs consider the impact of intermittent connection caused by vehicle movement on computing unloading, they do not make full use of the service opportunities created by vehicle movement, ignoring that service vehicles far away (vehicles providing computing services) still have the opportunity to enter the communication range of task vehicles (vehicles requiring data computing) and participate in task computing.

To sum up, it is an important research and application direction of the current mobile vehicle networking to effectively combine data communication with calculation to provide computational support for the routing and distribution of mobile vehicle network data with the formulation of calculation unloading decisions [5] and to achieve the reliable transmission of mobile vehicle network data.

The rest of this paper will be organized as follows: Section II gives research contribution of this paper, Section III presents design of edge task unloading mechanism, Section IV elucidates edge routing design, Section V concludes the paper.

II. RESEARCH CONTRIBUTION OF THIS PAPER

It is estimated that the scale of the Internet of vehicles industry will reach 200 billion yuan in 2025. Benefiting from the development of new generation communication technology, the mobile Internet of vehicles has strong ubiquitous interconnection ability, intelligent processing ability, and big data processing ability. It organically connects the traffic elements of the on-board network, including people, vehicles, roads, and clouds, breaks through the limitations of single-vehicle information perception and processing, and achieves the purpose of strengthening safety, improving efficiency, improving the environment and saving energy, It has become the core field of scientific and technological innovation and industrial development in the world, and has spawned a series of new technologies, new products, and new services.

Firstly, in terms of the outstanding feature of the dynamic topology of the mobile Internet of vehicles, different from the traditional wireless mobile network, the rapid movement of vehicle nodes is easy to cause the interruption of transmission links and affects the successful reception of information. Urban buildings, obstacles, and random channel environments exacerbate signal transmission instability, making the traditional network transmission mechanism difficult to work in the environment of the Internet of vehicles. Because the traditional network data transmission protocol is difficult to adapt to the frequent changes of topology and high-speed movement of nodes in the vehicle environment and is limited by the communication range of vehicles and the scale of vehicle network, in the design of multi-hop information transmission mechanism widely used in the industry, path selection and relay node selection are two key problems. This paper constructs a delay model based on the distribution and motion characteristics of road nodes, and weights the calculation of delay and computational cost for the next hop forwarding node's routing selection. The experiment shows that the coverage can be improved by 6% in sparse scenarios.

Secondly, in terms of the outstanding characteristics of the massive data of the mobile Internet of vehicles, the endless on-board applications pose a severe challenge to the computing power of the mobile Internet of vehicles, especially the new services promoted by communication technology and equipment manufacturing, such as augmented reality (AR) and automatic driving. A single vehicle with limited resources cannot meet the computing requirements of the above services. The on-board network based on cloud computing can improve service performance by integrating communication and computing resources, but it will lead to unpredictable delays. Therefore, this paper introduces vehicular edge computing (VEC). By taking delay and mobility as the key elements of the measurement indicators to build the measurement indicators of an effective calculation unloading mechanism, a weighted calculation model based on weight is designed, and experimental data validation is carried out to make up for the shortcomings of local computing and cloud computing.

In short, the mobile Internet of vehicles is the key technical means to realize the smart city and intelligent transportation. In view of the prominent characteristics and application challenges of its lack of dynamic topology and computing power, this paper designs a reliable transmission mechanism for the mobile Internet of vehicles driven by edge computing, which provides a certain reference value for scientific research and application.

III. DESIGN OF EDGE TASK UNLOADING MECHANISM

Most current research relies on roadside service units with rich computing and storage resources or integrates multiple edge servers to calculate vehicle unloading tasks. However, deploying edge servers in all sections will bring huge economic costs. The ideal way is to unload the computing tasks of task vehicles to multiple service vehicles. The service vehicle executes each subtask and feeds back the results to the task vehicle [6]. After receiving all the calculation results, the task vehicle starts to run the application. Therefore, from the perspective of vehicle unloading mechanism research, this paper integrates the parked idle vehicle resources to provide edge computing power and overcomes the defect that the influence of vehicle mobility on the unloading decision is not fully considered in the existing unloading mechanism. In the design of the unloading mechanism, the core measurement indicators introduced include response delay (including local processing time, data upload time, processing time, and feedback time), incentive mechanism (encouraging vehicles participating in task computing to overcome the selfishness of nodes), mobility (establishing a mobile model to predict and evaluate the effective link time of vehicles).

A. Search and Optimization of Service Vehicles

By adding its computing resource information to the beacon, the service vehicle indicates its availability to the surrounding vehicle nodes and brings the one-hop and two-hop vehicles relative to the task vehicle into the search range (Fig. 1). It is necessary to study and design the construction method of the service vehicle group according to distance, moving direction, speed, and angle, and optimize and model the service vehicle group by using the result measurement index of throughput according to time delay [7].

Vehicles exchange speed and position information with each other through periodic broadcast beacons. Service vehicles can indicate their availability to surrounding vehicles by adding their computing resource information to the transmitted beacon information[8]. When a task vehicle needs to process a task, it can find the service vehicle that can be used to participate in the calculation and unloading by listening to the beacon information from the surrounding nodes.

Fig. 1. Example of a two-hop search range.

1) *One-hop service vehicles*: For a task vehicle, the vehicles within its one-hop range are called one-hop vehicles, which are candidate service vehicles. This is because the task vehicle can directly communicate with vehicles within one hop, which provides favorable conditions for task unloading in the workshop. When both vehicle 2 and vehicle 3 are within the communication range of vehicle 1, vehicle 1 can unload tasks to vehicle 2 and vehicle 3 directly through workshop communication to seek assistance.

2) *Two-hop service vehicles*: Vehicles within the two-hop range of mission vehicles are potential service vehicles, such as vehicle 4 and vehicle 5, which are called two-hop service vehicles. Due to the limitation of communication range, although the two-hop vehicle cannot directly communicate with the task vehicle, with the help of vehicle mobility, the two-hop vehicle has the opportunity to travel within the communication range of the task vehicle so that it can serve the task vehicle. In the initial stage, although the task vehicle. Such as, vehicle 1 cannot directly communicate with its two-hop vehicle, but it can indirectly obtain the speed, location, computing resources, and other information of the two-hop vehicle through the relay of one-hop vehicles, such as vehicle 2 and vehicle 3. Based on the obtained information, the task vehicle can judge whether the two-hop vehicle meets the conditions of task unloading. If a two-hop vehicle is selected as a service vehicle to assist the task vehicle in processing the task, it first needs to obtain the task of unloading the task vehicle through the relay of the one-hop vehicle [9]. After the selected two-hop vehicle completes the assigned task, once it enters the communication range of the task vehicle, it will feed back the result to the task vehicle.

3) *Service collection optimization*: We introduce the concept of expected throughput (ET), the expected value of throughput between vehicle user nodes and sink nodes during road movement. ET comprehensively considers the average level of throughput within the physical coverage of sink nodes, which can be used to measure the effectiveness of service integration scheme optimization [10].

The expected throughput parameter can help design performance test scenarios. Based on the estimated throughput data, it can correspond to the frequency and number of transactions in the test scenario. After the test is completed, it can measure whether the algorithm achieves the expected goal according to the actual throughput.

If P_i is set as the actual link throughput when $T(x)$ is equal to T_i , the corresponding probability can be seen from the concept of ET:

$$ET = \sum_{i=1}^N P_i T_i \quad (1)$$

To get the value of ET, we need to solve each P_i first. Let L be the distance between the sink node and the vehicle user node, and $T(x)$ represents the throughput of the actual link. According to the knowledge of probability theory, the corresponding probability when $T(x)$ is equal to T_i is:

$$P_i = P(l_i < L < l_{i+1}), i=1,2,\dots,N-1; \quad (2)$$

$$P_i = P(0 < L < l_i), i=N \quad (3)$$

According to the research results of reference [11], the specific form of the Formula (2) and (3) can be expressed as (4) and (5):

$$P_i(i \neq N) = \frac{(1+2\ln a)(a_i^2 - a_{i+1}^2)}{a^2} - \frac{2a_i^2 \ln a_i - 2a_{i+1}^2 \ln a_{i+1}}{a^2} + \frac{(1+2\ln a)(a_{2N-i}^2 - a_{2N-i+1}^2)}{a^2} - \frac{2a_{2N-i}^2 \ln a_{2N-i} - 2a_{2N-i+1}^2 \ln a_{2N-i+1}}{a^2} \quad (4)$$

$$P_i(i = N) = \frac{(1+2\ln a)(a_N^2 - a_{N+1}^2)}{a^2} - \frac{2a_N^2 \ln a_N - 2a_{N+1}^2 \ln a_{N+1}}{a^2} \quad (5)$$

Where $a_i, a_{i+1}, a_{2N-i}, a_{2N-i+1}$ are the change points when t_i is the link throughput.

B. Modeling and Analysis of Link Connectivity

The connectivity time between vehicle nodes is used to describe the connectivity of links, which represents the duration of effective links when the workshop distance is less than the vehicle communication range. It is necessary to study and design the network connectivity model under the relative position of one hop or two hops, opposite or reverse driving, to provide a basis for selecting service vehicles for task unloading [12].

For vehicles A and B, if the workshop distance between them is less than the communication range of the vehicle, there is an effective link between the two vehicles. Therefore, we can use the connectivity time of the workshop to describe the connectivity of the link.

Suppose (x_A, y_A) and (x_B, y_B) are their respective coordinates, and V_A and V_B are their respective velocities. At the same time, D_{AB} is defined as the initial distance between two vehicles:

$$D_{AB} = (x_B - x_A) \quad (6)$$

According to the respective states of the two vehicles, we calculate the connection time between the two vehicles through the following two cases.

1) *Driving in the same direction:* If $V_A > V_B$, the direct connection time between the two vehicles can be expressed as:

$$T_{liffe} = \frac{R + D_{AB}}{|V_B - V_A|} \quad (7)$$

Where R is the communication radius of the two vehicles.

Otherwise, the connection time of the two vehicles can be expressed as follows:

$$T_{liffe} = \frac{R - D_{AB}}{|V_B - V_A|} \quad (8)$$

2) *Driving in different directions:* When two vehicles are driving in opposite directions, the connection time of the two vehicles can be expressed as:

$$T_{liffe} = \frac{D_{AB} + \sqrt{R^2 - (y_A - y_B)^2}}{V_B + V_A} \quad (9)$$

Otherwise, the connection time of the two vehicles can be expressed as follows:

$$T_{liffe} = \frac{D_{AB} - \sqrt{R^2 - (y_A - y_B)^2}}{V_B + V_A} \quad (10)$$

C. Edge Unloading Algorithm

It is defined here that edge service vehicles have different computing power, and the computing power of edge service vehicles is expressed by C_e . The vehicle generates a calculation task T_A at A:

$$T_A = \{D_{in}, D_{out}, C_{comp}, T_{max}\} \quad (11)$$

where D_{in} represents the data amount of the task, D_{out} represents the output amount of the result, C_{comp} represents the calculation amount of the task, and T_{max} represents the maximum completion time that the task can tolerate.

1) *Upload phase:* We use t to represent the period when the number of hops does not change, which is determined by the vehicle's movement. In a period t , the equivalent bandwidth BW does not change, so in a period t_x , the amount of uploaded data $D_{upx} = t_x \times BW_x$. We assume that at a time t_i , the number of hops changes n times. When the first $(n-1)$ change is completed, it is t_j .

$$\sum_{x=0}^{n-1} D_{upx} + (i - j) BW_n = D_{in} \quad (12)$$

When the above formula is satisfied, the task upload is completed, and the whole-time span T_U is recorded as the upload time of the task.

2) *Calculation stage:* Take the calculation unloading of the task once, that is, switching from task vehicle A to service vehicle B as an example. Here, E_A represents the computing power of vehicle A and E_B represents the computing power of vehicle B.

Then the task calculation time T_C is:

$$T_C = C / E_A \quad (13)$$

The download time of the calculation result is:

$$T_D = D_{out} / BW_A \quad (14)$$

Where BW_A represents the equivalent bandwidth of the result downloaded from task vehicle A to service vehicle B.

Then the task completion time is:

$$T_{comp} = T_C + T_D \quad (15)$$

3) *Download phase:* The principle is the same as that of the upload stage, so in a certain period t_x , the amount of downloaded data $D_{Dx} = t_x \times BW_x$. We assume a time t_1 , when the number of hops changes n times, and the time when the $(n - 1)$ st change is completed is t_2 .

$$\sum_{x=0}^{n-1} D_{Dx} + (t_1 - t_2) BW_n = D_{out} \quad (16)$$

When the above formula is satisfied, the task upload is completed, and the whole-time span T_D is recorded as the download time of the task.

To optimize the completion time of tasks in unloading, the problem optimization model is as follows:

$$\text{Min } [T_U + T_C + T_D] \quad (17)$$

D. Edge Unloading Simulation

The statistical data of this experiment is obtained from five groups of simulation experiments based on six vehicle nodes. Under the constraints of the same amount of task calculation, compare the simulation results of the average task execution time and average task completion time of the 2-hop experimental scenario, and keep two decimal places for all parameters.

It can be seen from the Fig. 2 that in terms of average task execution time, the execution time of tasks under the edge unloading calculation mode is the shortest, which is 62.38 seconds, and compared with the average task execution time calculated by itself of 179.4 seconds, it is shortened by 65.4%; The execution time in the cloud is 76.46 seconds, which is 57% shorter than the vehicle's own calculation. This is because once the task is generated, the calculation amount is a fixed value, sorted according to the calculation power: edge > cloud > itself.

Fig. 2. Task unloading algorithm performance results.

The experimental results show that when only the task execution time is considered, the task will not be calculated locally and should be unloaded to the edge node with strong computing power. It can be seen that the execution time and communication time of the generated tasks need to be considered. When the tasks in the cloud are executed and coordinated, although the cloud has rich computing resources, if a large number of tasks are uploaded to the cloud for execution, it is bound to increase the burden on the cloud in the core network.

IV. EDGE ROUTING DESIGN

It is designed to build a delay model based on road section nodes' distribution and movement characteristics. Combined with the connectivity model established in the previous discussion, it is necessary to introduce the road section (as shown in Fig. 3) evaluation mechanism for the evaluation of road weight and then establish a backbone link composed of a series of intersection edge nodes and in road edge nodes for all roads. The intersection edge node is responsible for calculating and distributing the road weight, while the inner edge node is

used for transmitting information [13]. The optimal path selection algorithm is designed according to the road weight. According to the complexity, the node can calculate the route itself or through task unloading to avoid local optimization and data congestion.

Fig. 3. Example of road section composition.

A. Algorithm Framework

V2V communication mostly adopts two specific data packet formats, including cooperative sensing messages. It is mainly used to periodically broadcast vehicle information and distributed environment notification message [14][15]. It is based on event triggers and is mostly used for vehicle safety alarms and emergency notifications. The cooperative sensing message can periodically broadcast application requests and network transport layer requirements (network heartbeat) according to the specified broadcast frequency. Its broadcast frequency is determined by the communication management entity based on the application scenario and network status. By analyzing the received data packet, the vehicle node can obtain other vehicle information within its driving range so as to obtain the network topology information and vehicle node information in this area, including vehicle position, direction, speed, stability, i.e., acceleration and destination, etc.

The broadcast of security alarm messages and other burst service information is mostly sent through data packets. It has the highest access priority and simple Dayton format design and can flexibly transmit various business applications [16]. The data format of the emergency message mainly consists of starting characters, identification code, data unit, and check code, with a total length of 25 bytes.

This routing mechanism design applies the advantages of real-time traffic estimation in vehicle and road condition information prediction to the broadcast routing protocol, fully considers the relevant factors affecting vehicle communication, is committed to maintaining the improvement of the overall performance of the network, and designs a comprehensive weighted multi-hop broadcast routing algorithm based on real-time traffic estimation.

The design idea of the algorithm can be summarized as follows: firstly, the real-time traffic estimation algorithm with excellent performance is used to accurately predict the target road condition and vehicle behavior, including the vehicle density, vehicle speed, vehicle geographical location and destination of the road section; Secondly, the target vehicle uses the relevant information obtained from real-time traffic estimation to design a comprehensive weighting algorithm, which maps the network topology and node information into weight factors, and uses the comprehensive weighting algorithm to obtain the weighted value of each node in the target road section relative to the information source node; Thirdly, the ranking of the reliability of forwarding nodes is

realized according to the size of the comprehensive weighted value, and the two nodes with the highest reliability (optimal and suboptimal nodes) are encapsulated into the broadcast packet as the destination forwarding nodes, so as to suppress the number of forwarding nodes; Finally, the forwarding node parses the broadcast packet. Suppose it can parse its own relevant information. In that case, it uses the weight mapping algorithm to map the corresponding weighted value into the forwarding waiting time. The optimal forwarding node has the shortest waiting time to effectively reduce the forwarding delay and ensure the real-time effectiveness of the broadcast information [16]. In addition, to maximize the network's reliability, the algorithm also introduces a timeout retransmission mechanism.

B. Flow Design Algorithm

In this algorithm, in order to effectively overcome the network dynamics caused by the high-speed mobility of vehicles, effectively estimate the network topology and estimate the real-time traffic; In order to reduce the number of forwarding nodes and avoid the broadcast storm, a comprehensive weighting algorithm is introduced to select trusted relay nodes; And to ensure the real-time performance of secure broadcast messages, an adaptive waiting slot mechanism based on comprehensive weighted value mapping is needed[17][18]; For ensuring the reliability of security alarm message propagation, the packet timeout retransmission mechanism is introduced[19][20]. The main implementation process of the algorithm is shown in the figure below. The algorithm mainly includes the related processing between nodes and candidate forwarding nodes. The detailed implementation process can be summarized as follows:

Step1- Broadcast: The vehicle node broadcasts relevant messages regularly to make the node become an information source node;

Step2- Determine impact factors: The information source node performs real-time traffic estimation on its on-board nodes' relevant information, outputs the nodes' pre-judgment information, and determines the relevant impact factors.

Step3-Comprehensive weighting: The information source node maps the relevant influence factors of each node into weight factors and uses the comprehensive weighting algorithm to calculate the comprehensive weighting value of each node, which is used as the basis for the selection of the next hop forwarding node.

Step4-Select the optimal forwarding node: The information source node selects the optimal and secondary forwarding nodes according to the weight value, encapsulates the relevant nodes' identification (and corresponding weight) into the secure broadcast packet, and the information source node sets a timeout retransmission timer.

Step5-Broadcast data analysis: After receiving the broadcast data packet, other nodes within the communication range parse it. Suppose they parse the identifier that matches themselves (they are determined as candidate nodes).

Step6-Weight mapping: The candidate node maps the corresponding weight to the forwarding waiting time. The larger the weight, the smaller the forwarding waiting time;

Step7-Waiting for timeout processing: If the same packet is received within the waiting time, the waiting time will be stopped, and the packet will be discarded directly. If the same packet is still not received after the waiting timeout, the candidate node will forward the packet.

Step8-Timeout Retransmission: If the information source node receives the same broadcast packet, the timeout retransmission timer will stop. Otherwise, if the retransmission timer times out, it will broadcast the packet again.

Step9-Update forwarding node set: The candidate node forwards the packet and resets the forwarding hops of the packet. At this time, the forwarding node becomes a new information source node and repeats the process. After the final packet exceeds the forwarding times, stop forwarding and discard it.

C. Relay Selection Strategy

The one-hop communication distance R of the information source node is evenly divided into N segments according to the distance from near to far. If the relative distance between the target node and the information source node is D_R , the given time slice of the vehicle in each section can be expressed as:

$$T_d = S_{ij} * \vartheta \quad (18)$$

Where, ϑ is the estimated one-hop relay delay, including the access delay and propagation delay of the channel, and S_{ij} is the number of time slices corresponding to the location of a given target node, i.e.:

$$S_{ij} = N \left[1.8 - \frac{\text{MIN}(D_R, R)}{R} \right] \quad (19)$$

$$N = R / 2r \quad (20)$$

here r is the relay selection radius.

The definition of the number of time slices S_{ij} is mainly based on the fact that the selection mechanism of the default waiting time T_d is a delay redundancy process. When the waiting time T_d is too large, the packet transmission delay will increase, but it is easier to avoid redundant data forwarding at the same time; When the waiting time T_d is too small, it will lead to frequent packet forwarding and increase redundant data, but it can also reduce the packet transmission delay and ensure the timeliness of the information. Therefore, considering the actual scenario and optimization mechanism, the confirmation of N can be realized through the above formula 20. Select the default waiting time t to be at least greater than $N/2$ time slices to weigh the real-time performance and efficiency.

For the optimal forwarding node, because it corresponds to the maximum weighted value and the range of weighted value σ_i is between (0,1), we can design an adaptive forwarding waiting time determination mechanism:

$$T_r = T_d * (1 - \sigma_i) \quad (21)$$

This waiting time confirmation mechanism ensures that the optimal forwarding node forwards packets at the fastest speed. When the weight of the optimal forwarding node tends to the maximum value of 1, the T_r value tends to 0, indicating that this node fully meets the forwarding conditions. Therefore, the node hardly needs to wait and can directly forward packets. The waiting time of the suboptimal forwarding node will also be shorter than that of the slot persistence algorithm, that only depends on the confirmation of geographical location information, so it can effectively ensure the real-time performance of the forwarded packet. The dual guarantee of the optimal and suboptimal nodes can effectively improve the reliability of packet forwarding. Moreover, the optimal and suboptimal gradient waiting time settings can effectively avoid the collision of forwarded packets in competing channels.

D. Experimental Simulation of Routing Effect

In the simulation, the target road section with 80 vehicle nodes is set, and the contracting rate is 2 packet / s. Count the number of nodes receiving data packets at a specific time within the two-hop range, and calculate the corresponding coverage. It can be seen from the simulation results that the algorithm can achieve high area coverage in a very short time. With the increase in forwarding nodes, the network load index will increase and finally form a broadcast storm, resulting in serious network congestion. Therefore, it takes a long time to cover the road far enough effectively. The algorithm effectively suppresses the number of forwarding nodes, avoids the occurrence of a broadcast storm, and effectively improves the real-time performance of packet broadcasting.

The following Fig. 4 shows the comparison of experimental data:

Fig. 4. Relationship between vehicle density and broadcast coverage.

As can be seen from the experimental data in Fig. 4, the real-time packet forwarding performance of the MBR routing algorithm based on edge computing is higher than that of the routing algorithm supported by local computing.

V. CONCLUSION

This paper constructs the measurement index of effective computing unloading mechanism, takes the delay and mobility as the key elements of the measurement index, discusses the reasonable allocation of weights, takes into account one-hop and two-hop vehicle nodes, and analyzes the impact of mobility in relative operation direction on link connectivity. In

the aspect of task unloading decision-making, this paper analyzes how the task vehicle selects the task unloading object from the service vehicle set and how to allocate the task. This paper expounds on the weighted calculation design of time delay and calculation cost, how to localize or unload the adaptive decision task to one-hop / two-hop vehicles, and carries out the corresponding experimental verification. Finally, it explains how the mobile vehicle network constructs the backbone link composed of intersection edge nodes and inner edge nodes, as well as the calculation method and simulation experiment of the weight of each section.

The experimental simulation shows that the average task execution time under this model is 65.4% shorter than that of local computing, 18.4% shorter than that of cloud computing, and the routing coverage is about 6% higher than that of local computing when there are less than 60 nodes. These research and experimental results fully demonstrate that the mobile Internet of vehicles based on edge computing has good reliable transmission characteristics. However, there are still shortcomings in the study of dense vehicle nodes in complex scenarios. Further in-depth analysis of unloading and routing mechanisms in various types of road scenarios is needed, and the idle computing power of stationary vehicle nodes has not been included in the task calculation application.

In addition, with the vigorous development of various applications, some studies consider using the advantages of the global perspective of software-defined network (SDN) to provide rich traffic conditions and network information for vehicles to reduce the control cost of the workshop; There are also attempts to introduce UAVs into the mobile vehicle network, rely on the mobile and high-altitude characteristics of UAVs to improve link connectivity and provide relay services.

With the increase in the number of intelligent networked vehicles and the popularization of application services, it will also be necessary to consider the scenario of multi-level tasks, meet the development trend of differentiated services in terms of delay, energy, and economic cost, and provide differentiated resource allocation for different service levels.

Design of Intrusion Detection System using Ensemble Learning Technique in Cloud Computing Environment

Rajesh Bingu*, S. Jothilakshmi

Research Scholar, Department of Information Technology, Annamalai University, Chidambaram, Tamil Nadu 608002-India

Abstract—The key advantage of the cloud is that it fluidly propagates to fulfil changeable requirements and provides an environment that is repeatable and can be scaled down instantly when needed. Therefore, it is necessary to protect this cloud environment from malicious attacks such as spamming, keylogging, Denial of Service (DoS), and Distributed Denial of Service (DDoS). Among these kinds of attacks, DDoS has the capability to establish a high flood of malicious attacks on the cloud environment or Software Defined Networking (SDN) based cloud environment. Hence in this work, an ensemble based deep learning technique is proposed to detect attacks in cloud and SDN based cloud environments. Here, the ensemble model is formed by combining K-means with deep learning classifiers such as Long Short term Memory (LSTM) network, Convolutional Neural Network (CNN), Recurrent Neural Network (RNN), Gated Recurrent Unit (GRU) and Deep Neural Network (DNN). Initially, preprocessing with data cleaning and standardization is applied to the input data. Meanwhile, a random forest is implemented for extracting the minimum significant features. After that, the proposed ensemble based approach is utilized for detecting the intrusion. This approach is used to enhance the performance of the deep learning classifiers without much computational complexity. This model is trained and evaluated using two datasets as CICIDS 2018 and SDN based DDOS attack datasets. The proposed approach provides better intrusion detection performance in terms of F1 measure, precision, accuracy, and recall. By using the proposed approach, the accuracy and precision value attained is 99.685 and 0.992, respectively.

Keywords—Cloud; distributed denial of service; intrusion detection; ensemble; recurrent neural network; convolutional neural network; random forest; gated recurrent unit; K-means clustering; long short term memory

I. INTRODUCTION

Cloud Computing (CC) is a different kind of Internet-based infrastructure for providing Information Technology and various resources such as storage services, hardware equipment, operating system, network infrastructure, and entire software applications to users at low cost [1]. It has the advantage of scalability, higher cost efficiency, faster development, and minimal management effort [2]. The introduction of the cloud is a watershed moment in technological advancement for quick information processing. When a new computing system is introduced, scholars and researchers are concerned about its protection. Securing information processing across any information system has

become critical to a knowledge acquisition system's success. Always CC or grid computing enables rapid and location-independent information processing. Because of the location-independent processing, the trust is a major issue among Cloud users when using their resources is a major issue [3], [4].

The complex architecture of CC is vulnerable to several kinds of attacks. Compared to a single Intrusion Detection System (IDS), the detection accuracy is improved with a cooperative IDS system. It is due to limited knowledge of attack patterns or implications [5]. The only solution to this type of threat is the development of effective IDS [6]. The approaches of attack detection by the IDS are of two types, they are signature based and behavior based. Out of these two approaches, the most traditional way of discriminating the normal traffic the malicious traffic is signature based. This approach is capable of achieving higher accuracy, but it is prone to a new type of attack [7], [8].

But the behavior-based IDS achieves better results for a new type of malicious attacks. Hence, the behavior-based IDS performs well when compared to signature-based IDS in terms of detection rate and seems to be the most preferable for deployment [9]. Moreover, the classification of the IDS can also be made based on the location of its deployment, and it is two types they are host based and network based [10]. The host based IDS (HIDS) is installed in the space which is nearer to the host in order to capture the intruders, whereas the network-based IDS (NIDS) tends to capture the intruders at the network level [11]. Nowadays, most cloud space is associated with software defined technology to empower its accessibility and reliability for all application services. In this regard, this hybrid environment creates more chances of launching a high flood of malicious attacks [12].

The anomaly based IDS detects the deviation by analyzing the current system with a predefined normal profile. But it is affected by the issue of false alarms in real world implementation [13]. The hybrid IDS provides protection by combining both anomalies based and signature based detection. It is resolved with the issue of intelligent false alarm technique by involving adaptive algorithms [14]. The performance enhancement of IDS is challenged by considering the features such as access independence, elasticity, sufficient computing power, and scalability. In a distributed system, several applications require shorter response times, and it might require large quantity for heavy

load networks [15]. Due to the delay, these applications are not sufficient to support the applications of CC. In recent years, machine learning (ML) has been used in various fields to resolve issues related to high false alarms and low detection rates [16].

An extreme learning machine (ELM) is a new ML that falls into local minima, and the training is extremely fast. Better scalability and generalization in the learning process are obtained with Support Vector Machine [17]. It is used in several areas for resolving classification and regression problems. To get an optimal representation of the input data, deep learning based approaches such as RNN, Artificial Neural Networks (ANN), Deep Belief network (DBN), Deep Boltzmann Machines (DBM), and Autoencoder are commonly used [18]. The performances of this algorithm are further enhanced with the hybrid combination of AlexNet, FractalNet, GoogLeNet, Visual Geometry Group (VGG), and Dense CNN [19], [20]. Based on the position and orientation of the input data, the classification process is hard, and the performance is varied for each network based on the input data. In order to select the optimal deep learning classifier, the ensemble based architecture is proposed. It contains several DNN classifiers in which the better result is taken into consideration. Hence it's right to design an intrusion detection framework for SDN based cloud platforms. To accomplish this task, in this research work, the proposed DL model has been trained and evaluated using two kinds of dataset, i.e., the first dataset is cloud based attack, and the second Dataset is SDN based cloud DDoS attack.

1) *Research gap:* Most of the prior researches particularly focused on machine or deep learning based approaches and the architecture based on its application. Most of them are based on systematic mapping for providing meaningful and comprehensive research. To the best of our knowledge, there are no researches based on the feasibility of utilizing ensemble learning. In addition to that, no researches include the comparison of the classifiers used in ensemble based technique through systematic mapping. None of the researches consider intrusion detection based on attack type, evaluation metric, and dataset characteristics, and strength and weakness of deep learning approaches. The proposed approach is developed with the consideration of above mentioned research gaps.

The overall contribution of the work can be described as listed below.

- Removing inconsistent or missing values to make the data easier to process. For the traffic instance of the dataset, data pre-processing techniques such as standardization and data cleaning have been applied.
- Extracting the minimal set of discriminative features from the pre-processed data using a random forest algorithm. The complexity and storage space are reduced with a minimal set of discriminative features.
- Clustering the dataset with the K-means algorithm eliminate incorrect detection.

- Classifying the traffic clusters as benign and malicious using the proposed ensemble based deep learning approach. Also, performing multi label classification with these clusters for efficient feature identification. The accuracy is improved with optimal selection of deep learning approach.
- Comparative analysis of the five deep learning classifiers has been done using various performance metrics such as accuracy, precision, recall and F1-measure.

The paper organization is given as follows. Section II describes the related work, and Section III describes the proposed methodology. The experimental results of the proposed intrusion detection are given in Section IV. Section V describes the significant aspects of the proposed methodology and conclusion.

II. RELATED WORK

The work related to the proposed intrusion detection system is described as follows.

Loheswaran Karuppusamy et al. [21] had proposed a Chronological Salp Swarm Algorithm-based Deep Belief Network (CSSA-DBN) for detecting intrusion into a cloud environment. The optimal solution was obtained with the fitness, which accepts a minimum error value for providing better performance. The accuracy, sensitivity, and specificity obtained with the CSSA-DBN approaches are 0.9618%, 0.9702%, and 0.9307%, respectively.

Idhammad et al. [22] proposed an ensemble classifier-based intrusion detection model is ideally suited for the cloud environment. The model used in this work was trained and assessed using the CICIDS-001 dataset, and it is currently running on the Google Cloud platform. Here, Naive Bayes and the random forest method are used to build the ensemble classifier. This system took 0.23 seconds to run and had an average accuracy of 97% and a false positive rate of 0.2%. Jaber et al. [23] developed with ensemble classifiers that are made up of fuzzy c-means clustering and SVM classifiers. The hybrid algorithm FCM-SVM was evaluated with NSL-KDD Dataset for detecting anomalies with higher accuracy.

S. Krishnaveni et al. [24] recommended a univariate ensemble feature selection method to find an appropriate reduced feature set from an incursion dataset. To create robust classifiers using a voting mechanism, single classifiers were fused. With performance indicators like FAR and ROC, this technique performed admirably enough. Nguyen et al. [25] proposed a security framework for SDN enabled cloud environment by combining the intrusion detection model based on three different nodes such as edge, fog and cloud. By developing policies, a collaborative and network intelligent architecture is created for anomaly detection. Better anomaly detection performance in SDN-based cloud IoT networks helped to reduce the bottleneck issue.

Using the Ant Lion optimization strategy, T. Thilagam et al. [26] proposed an improved Recurrent Convolutional Neural Network (RCNN) for intrusion detection. With a classification accuracy and a small error rate are 94% and

0.0012, network layer threats are well categorized. Smitha Rajagopal et al. [27] had developed a Meta classification technique with binary and multi-label classification. Robustness has been improved with an optimal set of hyperparameters and discriminative features of Azure machine learning. The efficiency of the approaches was validated, and an accuracy of 99.8% was achieved for the UNSW NB-15 dataset.

Abusitta et al. [28] proposed a cooperative intrusion detection framework for the cloud environment, and it was designed using a stacked autoencoder and multilayer perceptron. The decision making was enabled with an aggregation algorithm, in which the detection accuracy was achieved by up to 95%. Ammar Aldallal et al. [29] developed SVM with GA and fitness for evaluating accuracy. SVM was deployed with varying hyperparameters such as kernel, degree, and gamma. In cloud computing, a high level of symmetry was reached between attack detection, information security, and the discovery of bad things.

Mayuranathan et al. [30] proposed an effective intrusion detection model based on RHM-RBM. Here the author utilized Random Harmony Search (RHS) optimization model for feature selection and Restricted Boltzmann Machines (RBM) for classification purposes to yield better results. The security issues related to the network layer have been resolved with enhanced detection accuracy and low computational complexity.

At the end of the survey analysis, it can conclude that most of the existing solution does not rely on the ensemble-based approach using a deep learning algorithm to enhance its efficiency without much computational complexity. Hence in this work, an ensemble based deep learning technique has been deployed. To achieve this, clustering followed by a classification task has been carried out. By doing so, the unsupervised technique (clustering) collaborates with the supervised technique (classification). A convolutional neural network and the K-means clustering procedure are used to carry out this strategy. Convolutional neural networks (CNN) and the other four deep learning algorithms (DNN, RNN, GRU, and LSTM) are evaluated in terms of performance.

III. PROPOSED METHODOLOGY

In Fig. 1, the components involved in the proposed model have been elucidated, and its data flow can also be visualized. The modules involved in the proposed model are the data pre-processing layer, feature extraction layer, clustering process and classification. Each module has been explained in the following subsection

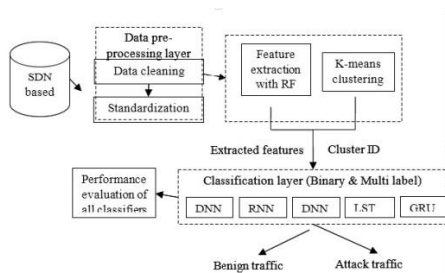

Fig. 1. Overall architecture of the proposed intrusion detection system.

A. Data Pre-Processing

In the data pre-processing layer, the instances of the two datasets are manipulated accordingly to ease the classification process. These instances have undergone two pre-processing techniques, such as data cleaning and standardization.

1) *Data cleaning*: In the CICIDS-2018 Dataset, some columns with infinity values were stripped away, including ‘Dst Port’, ‘Timestamp’, ‘Bwd PSH Flags’, ‘Fwd PSH Flags’, ‘FlowByts/s’, ‘Bwd URG Flags’, ‘Fwd URG Flags’ and ‘Flow Pkts/s’. Two protocol columns have been used instead of feature protocol for binary classification. They are named Protocol 17 and Protocol 6 by implying the feature in a categorical type. The ‘protocol’ column has been used without alteration for the multiclass classification. Likewise, for the SDN DDoS dataset, the null values are removed for all the features.

2) *Standardization*: To get a normal distribution with a mean of zero and a standard deviation of one, standardized measures are applied to each input variable independently by subtracting the mean and dividing by the standard deviation. In standardization, the values are scaled in column wise manner using the standard scalar format. This process facilitates the classification process, which is easily performed using deep learning.

B. Feature Reduction

The random forest algorithm has been utilized for feature extraction in this work. Random forest is an effective unsupervised machine learning technique that falls within the area of embedded methods. For the predictor variable, the subset is chosen for dividing the internal node based on predetermined constraints, considered an optimization issue. The classification is based on entropy, which specifies the lower bound of the random variable. The entropy is computed as follows for each internal node of the decision tree.

$$F = -\sum_{j=1}^d q_j \times \log(q_j) \quad (1)$$

Where, d represents the amount of unique classes and the prior probability for the class is represented as q_j . This value is increased to obtain more information in each decision tree split.

The embedded method combines both the quality of the filter and wrapper method. Furthermore, it can be used for classification and feature extraction. So Random Forest inherently has a built-in feature selection approach. Since it is well suited for feature selection, a Random forest has been used for the feature selection task. The reduced features of the SDN based dataset can be listed as dt, bytecount, packetins, pktperflow, byteperflow, pktrate and Protocol. In CICIDS 2018 dataset, the features are reduced, and it can be elucidated as ‘Fwd Seg Size Min’, ‘SubflowBwd Pkts’, ‘Tot Bwd Pkts’, ‘Fwd Pkt Len Std’, ‘Flow IAT Mean’, ‘Init Fwd Win Byts’, ‘Bwd Pkt Len Max’, ‘URG Flag Cnt’, ‘FIN Flag Cnt’, ‘Bwd Pkt Len Std’, ‘Pkt Size Avg’ and ‘RST Flag Cnt’. Fig. 2 and Fig. 3 show the robust feature set of the SDN based dataset

and cloud dataset correspondingly. Here, random forest is evaluated with 5-fold cross validation to extract some meaningful features from the two datasets separately.

Fig. 2. Significant feature in SDN dataset by random forest.

Fig. 3. Significant feature in CICIDS 2018 dataset by random forest.

C. Clustering Layer

The process of clustering is to group the instances given in the dataset into many clusters. This process assigns each instance a unique cluster ID. This was done based on a pattern extracted by the K-means clustering algorithm. Therefore, along with the reduced features yielded by the random forest, the Cluster id was also given to the Deep learning classifiers to improve its performance. The working principle of the K-means clustering process is given below:

1) *K-means clustering algorithm*: K-means clustering always work in an unsupervised manner by grouping the instances in the dataset without a label for the training and testing process. Based on the predefined value, the number of clusters is generated by this clustering algorithm. This algorithm forms the clusters based on their centroid value. The main goal of the clustering algorithm is to shorten the distance between the data instances and the groups to which they belong. This step is repeated continuously until the algorithm finds the better clusters. At the end of the process, ‘K’ number of clusters has been obtained, whereas k is a predetermined value. The procedure of the K-means algorithm is given as follows.

Algorithm 1: K-means clustering

Step 1: Specify the number of clusters k .

Step 2: Assign k centroids randomly.

Step 3: repeat, until the position is not varied.

Step 3.1: Closet centroid is assigned with each point.

Step 3.2: For each cluster, a new centroid is computed with mean value.

D. Classification Layer

At this level, the reduced features, as well as the cluster ID were given as input for the classification process. To classify the normal traffic instances from the malicious traffic instances, five deep learning techniques were implemented separately for this task. These five deep learning were analyzed comparatively for both binary and multiclass classification. To perform binary classification, SDN Dataset was used for training and testing purposes, while CICIDS 2018 was used for the same purpose for multiclass classification. A detailed explanation for these five DL classifiers is given in the following sub-sections.

1) *Convolutional Neural Network (CNN)*: Convolutional Neural Network is also known as Convnets and is mainly used for image processing and object detection purposes. This CNN has several layers the process goes through to get the desired output. The architecture of CNN consists of many layers, namely Convolution Layer, Rectified Linear Unit, Pooling Layer, and Fully Connected Layer. The input goes through all of these layers, each of which contains a variety of operators and filters to get the right output.

The convolution layers are interpreted with the sub-sampling layers to minimize the computation time. In the convolution layer, the feature map from the previous layer is mixed with kernels that can be provided, and the resulting feature map is sent to the activation function. The convolution is combined with multiple feature maps in each output map. In general, it is represented as,

$$y_k^u = g \left(\sum_{j \in N_k} y_k^{m-1} * l_{j,k}^m + c_k^m \right) \quad (2)$$

Where, N_k is the input map selection which includes the pair of all triplets. For each output map additive bias of C is added. The input is convolved with various kernels for each output map. If the output map k and l are integrated with the output map j . Then the kernel is applied to various output maps k and l .

2) *Deep Neural Network (DNN)*: An artificial neural network (ANN) with numerous hidden layers between the input and output layers is called a deep neural network (DNN). DNNs may simulate complex non-linear interactions just like shallow ANNs. This particular kind of neural network consists of an input, an output, and a deep network of sequential data flow. In order to solve practical problems like

categorization, neural networks take in data, run it through complex calculations, and then output the results.

DNN has several fully connected layers in which nodes of each layer are connected with each node of the previous layer. The DNN is a linear combination of independent variables with corresponding weights and bias terms. The DNN output computation is represented as,

$$A = c + x_1 y_1 + x_2 y_2 \dots + x_p y_p \quad (3)$$

Where, x represents the weights or beta coefficients and y represents the input or independent variable. The loss or error term is computed to find the deviation from actual and predicted values. It has the objective of minimizing the loss function in order to achieve an optimal error term. Based on the previous layer computation, the output is estimated as follows:

$$A = x_{i_0}^T * i_2 + c_{i_0} \quad (4)$$

Where, x_{i_0} is the weight matrix between two layers, C is the bias, and T represents the transpose. After estimating the output, it passes through the activation function for computing the node value. The output error is estimated, and the error is minimized with the optimal weight value.

3) *Recurrent Neural Network (RNN)*: Recurrent neural networks (RNNs) are artificial neural networks where nodes' connections can cycle, allowing output from one node to control how input to that node is processed. The term "recurrent neural network" refers to a group of networks that have an infinite impulse response. Common uses of RNNs include natural language processing, time series analysis, handwriting recognition, machine translation, and photo captioning. RNNs are capable of handling inputs of any length. In contrast to infinite impulse recurrent networks, finite impulse recurrent networks can be unrolled and substituted with tight feedforward neural networks.

In a RNN, the output of a certain layer is fed into the input of the layer before it to predict the output layer. A single RNN layer is created by combining the nodes of several NN layers. The input layer is represented with y , the output layer is represented with Z , and i represents the hidden layer. The output of the model is increased with the network parameters. For the given duration u , the input is estimated with the integration of $y(u)$ and $y(u-1)$. The output of each state is represented as,

$$i(u) = g_d(i(u-1), y(u)) \quad (5)$$

Where, $i(u)$ represents the new state, $i(u-1)$ represents the old state, g_d represents the function with parameter d , and $y(u)$ is the input vector with time u .

4) *Long Short-Term Memory (LSTM)*: It is a kind of RNN that can recall and learn long-term dependencies. Due to their ability to remember past inputs, they are also utilized in time series prediction. They communicate in an original fashion thanks to their chain-like arrangements with four interacting levels. These are employed for purposes other than only time series prediction. Additionally, they are employed in medicinal research, music composition, and voice recognition. It is connected in such a way that directed cycles are formed, and it permits the LSTM output to be used as the input of the current layer. It can also recall previous inputs due to its internal memory.

LSTM is modelled to avoid long term dependencies, and it has three parts. The first eliminates irrelevant information, the second updates or adds new information, and the third pass the updated information. In LSTM, it initially decides to keep the information obtained from the previous step or not. The forget gate equation is represented as follows.

$$f_u = \sigma(y_u * v_g + i_{u-1} * x_g) \quad (6)$$

Where, y_i represent the current timestamp of the input, i_{u-1} represent the hidden state of the previous timestamp, v_g denotes the weight of the input, and x_g is the weight matrix of the hidden state. The sigmoid function is applied to make the forget gate between 0 and 1. Then it is multiplied by the timestamp of the previous layer.

$$d_{u-1} * g_u = 0 \text{ if } f_u = 0 \quad (7)$$

$$d_{u-1} * g_u = d_{u-1} \text{ if } g_u = 1 \quad (8)$$

The significance of new information is quantified with the input gate, and the equation is denoted as,

$$i_u = \sigma(y_u * v_u + i_{u-1} * x_j) \quad (9)$$

Where, y_i represents the input of the current timestamp, v_u represents the weight, and x_j represents the hidden state. The output of the current timestamp is estimated using the activation function of softmax.

$$z = \text{softmax}(i_u) \quad (10)$$

Where, i_u represents the hidden state.

5) *Gated Recurrent Unit (GRU)*: In order to overcome the vanishing exploding gradient problem faced by the Recurrent neural network, many variants of RNN have started to occur. Out of those findings, the GRU(gated recurrent unit), a variant of RNN architecture, has seemed to perform well. The architecture of GRU comprised three gates without any internal cell state. Instead of an internal cell state present in the LSTM architecture has been replaced by a hidden cell state

in the architecture of GRU. The gates used in this architecture can be listed as Update Gate, Reset Gate and Current Memory Gate.

The input of GRU is represented as y_t , a previous timestamp $u - 1$, and the hidden state is represented as i_{u-1} . The new hidden state is the output of the next timestamp; and it contains two gates, namely the reset gate and the update gate. The reset gate is considered a hidden state i_u . The equation for the reset gate is represented as follows.

$$s = \sigma(y * v + i * x) \quad (11)$$

Where, v , x represents the weight, y represents the input. By using the sigmoid function, the values of s is converted within the range between 0 and 1. The update gate is similar to the reset gate, only the weight matrix is varied. To estimate the hidden state i_u , the two state processes are used. Initially, the candidate's hidden state is estimated with the following equations.

$$\hat{i}_u = \tanh(y_u * v_h + (s_u * i_{u-1}) * x_h) \quad (12)$$

The input is taken from the hidden and previous timestamp and multiplied by the output of the reset gate. The overall information is passed through the activation function tanh; the resultant value is the candidate's hidden state. The GRU network is accurate in a longer sequence dataset. The information in GRU is transferred through the cell state and hidden state.

IV. EXPERIMENTAL RESULTS AND DISCUSSION

The Python 3.6 software environment was utilized to create the deep learning model and the intrusion detection system based on clustering method for this experiment. Python was installed over the Windows 10 operating system, which is on the laptop and has 2GB ram and 1TB hard disk memory with a 2GHz i3 processor. Initially, the input data is pre-processed with data cleaning and standardization. In data cleaning, the corrupted, incorrectly formatted, incomplete, incorrect, or duplicate data are eliminated within the dataset. Then the data is converted into a simplified format to simplify the intrusion detection process. The features are extracted with 5-fold cross validation of the random forest algorithm. On the other hand, data is grouped into clusters, and each instance is assigned a unique cluster ID. The extracted features and the cluster ID is given to the input of the ensemble classifier. In the proposed algorithms, the parameters are included based on the existing results. In the existing papers, these parameters provide better performance than assigning other parameter. Hence, the parameters are selected for enhancing the intrusion detection performance. By using this parameter optimal level of intrusion detection was attained with the proposed ensemble based approach. Table I provides a description of the implementation parameters used in the suggested technique.

TABLE I. PARAMETERS OF DEEP LEARNING TECHNIQUES

Parameters	Value
Number of clusters	4
Batch Size	Binary:2500, Multilabel:5000
Loss Function	Binary: Binary_crossentropy Multi-label: Categorical_crossentropy
Activation	ReLU
Epoch	150
Verbose	0
Metric	Accuracy
Optimizer	Adam
Epoch	Binary:15 Multilabel:10

A. Dataset Description

1) *SDN based dataset*: This dataset was designed to generate a DDoS attack by the mininet simulator in order to replicate the Software defined networking environment [15]. Here the network traffic was collected at the switch setup in the environment. The instances given in the dataset were broadly classified into two categories: benign and malicious. Hence the benign instances were labelled as 0, whereas the malicious instances were labelled as 1. SDN based datasets are used to train and evaluate the proposed model for binary classification.

2) *CIC IDS 2018*: This is one of the datasets used to train and evaluate the proposed model, which is extracted from the official website [16], and it is simulated in the real time cloud environment to capture cloud based attacks. This dataset is utilized here to perform a multiclass classification of cloud attacks using an ensemble based approach. It has 2830540 instances and 83 attributes. Among these 83 attributes, 80 attributes are utilized for feature extraction procedure.

The benign instances in the dataset were labelled as 0, and bot attack instances were labelled as 1. Likewise, the instances of DoS attacks-SlowHTTPTest, and DoS attacks-Hulk were labelled as 2 and 3, respectively. Table II elucidates the sample distribution of benign and attack instances used for training and testing purposes.

TABLE II. SAMPLES DISTRIBUTION FOR DL MODELS

Type	SDN based DDoS attack dataset (Binary classification)		CIC IDS 2018 dataset (Multi-label classification)	
	Training	Testing	Training	Testing
Benign	25496	10902	646603	161601
Attack	20404	8735	86811	21709
DoS attacks-SlowHTTPTest			34	7
DoS attacks-Hulk.			87117	21811

B. Performance Metrics

In this sub-section, the performance of both binary as well as multi-label classification done by the five classifiers was evaluated and discussed using the below given metrics:

Accuracy: It estimates the classifier performance in overall, which is computed as follows.

$$A_c = \frac{TN + TP}{TN + FN + TP + FP} \quad (13)$$

Where, *TP* represents the true positive, *FP* represents the false positive, *TN* represents the true negative, and *FN* represents the false negative.

3) *Precision:* It represents the capacity of the classification models to classify the significant models of the data set. It is calculated using the ratio of expected positives from all samples. Precision is denoted as follows.

$$P_r = \frac{TP}{FP + TP} \quad (14)$$

4) *Recall:* It represents the capacity of the classification technique for categorizing essential data points in the dataset. It is measured as the ratio of positives from the whole set of positive samples. Recall R_c can be computed as

$$R_c = \frac{TP}{FN + TP} \quad (15)$$

5) *F-measure:* It uses the mean value to combine the result of precision and recall. F-measure F_m is measured as,

$$F_m = \frac{2}{1/P_r + 1/R_c} \quad (16)$$

6) *Receiver operator characteristic curve:* ROC curves are a useful visual tool for comparing different classifiers. It describes the trade-offs that could be made between a false positive rate (FPR) and a true positive rate (TPR). The model's ROC curve accuracy is evaluated using the Area Under the Curve (AUC).

Where the performance monitors used in the above-mentioned equations can be defined as

- **TP (True Positive):** It is defined as the count of the attack instances successfully predicted as an attack by the classifier.
- **TN (True Negative):** It is defined as the count of the benign instances successfully predicted as benign by the classifier.
- **FP (False Positive):** It is defined as the count of the benign instances wrongly predicted as an attack by the classifier.
- **FN (False negative):** It is defined as the count of the attack instances wrongly predicted as benign by the classifier.

In Table III, the values of the performance metrics for the binary classification have been enumerated. In this table, each classifier is implemented with and without clustering separately. The clustering process is carried out using the K-means algorithm. By observing the values for the five classifiers, it shows that the accuracy value without K-means ranges from ~72% to ~77%. But with K-means implementation for the five classifiers achieves better results for accuracy; it ranges from ~93% to ~99%. Hence it is clearly shown that the binary classification, the implementation of the ensemble approach, performs better than the standalone DL architecture. Out of those five DL classifiers, CNN performs well than the others. In the same way, Table III explores the performance analysis of multi-label classification. Unlike binary classification, the results of the standalone DL algorithm and the ensemble approach show only a minimal gap. Both models yield good results for multi-label classification. In this classification, DNN performs better than all four DL classifiers.

TABLE III. PERFORMANCE ANALYSIS OF BINARY AND MULTI-LABEL CLASSIFICATION

Algorithm Used	Binary classification				Multi-label classification			
	Accuracy	Precision	Recall	F1-measure	Accuracy	Precision	Recall	F1-measure
K-Means+CNN	99.685	0.992	0.999	0.995	99.685	0.996	0.996	0.996
CNN	77.911	0.799	0.574	0.668	97.906	0.979	0.979	0.978
K-Means+DNN	99.178	0.980	0.998	0.989	99.735	0.997	0.997	0.997
DNN	77.821	0.780	0.596	0.676	97.244	0.972	0.972	0.971
K-Means+RNN	93.262	0.894	0.936	0.915	99.649	0.996	0.996	0.996
RNN	72.162	0.606	0.802	0.691	94.111	0.790	0.996	0.856
K-Means+LSTM	96.128	0.943	0.958	0.950	99.671	0.996	0.996	0.996
LSTM	75.853	0.890	0.430	0.580	90.076	0.895	0.900	0.895
K-Means+GRU	95.602	0.908	0.986	0.945	99.712	0.997	0.997	0.997
GRU	73.767	0.636	0.756	0.691	97.135	0.973	0.971	0.972

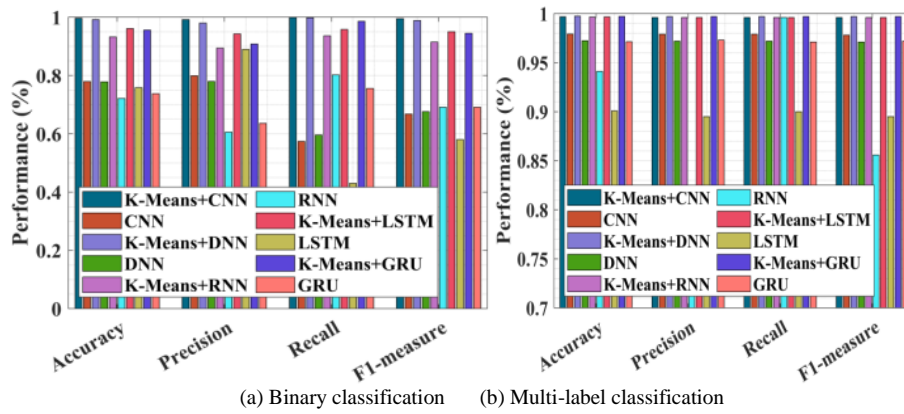

Fig. 4. Comparison of accuracy, precision, recall, and F1-measure with different voting techniques.

The suggested ensemble-based strategy for binary and multi-label classification is compared in Fig. 4 for both cases. It is evaluated in terms of accuracy, F-measure, recall, and precision. For binary classification, better performance is obtained using the K-means+CNN approach. The accuracy, precision, recall, and F1-measure obtained with K-means+CNN approach are 99.685, 0.992, 0.999, and 0.995, respectively. Compared to other deep learning-based approaches, K-means+DNN performs better on multilabel-based classification. K-means with deep learning approaches provide better performance than only deep learning based approaches. If the clustering is not performed for the proposed approach, the performance is lower than 0.8.

Fig. 5 compares the accuracy and loss for the CNN and K-means+CNN techniques. The accuracy improves and the loss decreases as the number of epochs rises. The accuracy of validation is greater than that of training. The optimal value of accuracy is reached with the epoch between 10 and 15. The lower loss value is reached with a higher epoch that is nearer

to 15. The accuracy and loss comparison with DNN and K-means+DNN for binary classification is shown in Fig. 6. Increased accuracy and decreased loss result from more approaches. The optimal accuracy is obtained with the number of epochs 14. When the number of epochs reaches 3, the accuracy rate crosses the value of 0.9. The accuracy below 0.75 is reached, and the loss value is higher up to the number of epochs is 3. When it goes beyond 3, there is a gradual decrease in loss, and the smooth curve is obtained up to 14 epochs.

The accuracy and loss comparison for GRU and K-means+GRU is shown in Fig. 7. There is a gradual increase in accuracy value from 1 to 5 epochs. After 5, the accuracy deviation is low, and it isn't very important. For the GRU approach, this deviation is higher up to 14 epochs. The training accuracy is lower than the validation accuracy in all aspects. When the numbers of epochs are 3, the loss is higher than 0.5 and 0.15 for the validation set and training set of the K-means+GRU approach.

Fig. 5. Accuracy and loss comparison for training and validation set of CNN, and K-means+CNN (Binary Classification).

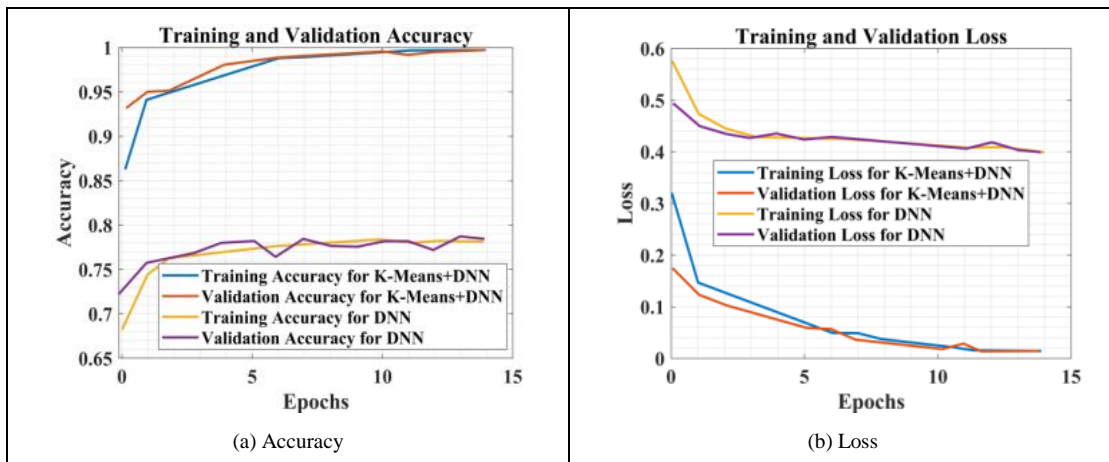

Fig. 6. Accuracy and loss comparison for training and validation set of DNN and K-means+DNN (binary classification).

Fig. 7. Accuracy and loss comparison for training and validation set of GRU and K-means+GRU (binary classification)

The accuracy and loss comparison for K-means+LSTM and LSTM approaches are shown in Fig. 8. There is a fluctuation in the accuracy value as the number of epochs is increased in the LSTM approach. The accuracy is above 0.9

for most epochs in the training and validation set of K-means+LSTM approaches. The accuracy loss is higher than 0.5 for LSTM and K-means+LSTM with fewer epochs. The lower loss is reached with the number of epochs 14.

Fig. 8. Accuracy and loss comparison for training and validation set of LSTM, and K-means+LSTM (binary classification).

The performance evaluation of RNN and K-means+RNN for binary classification is shown in Fig. 9. The K-means+RNN and the validation set provide better performance than only RNN and the training set. When the number of the epoch is 3, k-means+ RNN and RNN approaches interfere with each other. When the number of epochs is decreased, the variation in loss for the training and validation sets is also decreased. When the number of epochs is decreased, the loss deviation for training and validation is also decreased. The training and validation loss is less than 0.5 for the K-means+RNN approach. For only the RNN approach, the training and validation loss is less than 0.3.

The accuracy and loss comparison for the multi-label classification of K-means+CNN is shown in Fig. 10. For all epochs, the validation accuracy is higher and nearer to 1. But, for the training set, the accuracy is lower with a reduced number of epochs. The accuracy value is between 0.85 and 0.9 for the CNN approach of the training and validation set. It is

increased to the level between 0.95 and 0.99 for the numbers of epochs are 8. The loss value is lower for the validation set of the K-means+CNN approach. For the training set, it is higher with lower epochs. For lower epochs, the loss value is between 0.5 and 0.6. The loss is reduced to 0.1 for the number of epochs between 8 and 10.

The accuracy and loss comparison for the DNN and K-means+DNN approaches is shown in Fig. 11. The accuracy value is higher with the validation set of K-means+DNN approaches. The training accuracy is lower than the validation set. The higher value is reached with the number of the epoch is 4, and the value remains the same up to 10 epochs. K-means+DNN has a lower training and validation loss than the DNN-based method. The loss is decreased when the number of epochs is increased. The loss value of GRU and K-means+GRU is compared for the training and validation set. The loss is decreased with an increasing number of epochs.

Fig. 9. Accuracy and loss comparison for training and validation set of RNN and K-means+RNN (binary classification).

Fig. 10. Accuracy and loss comparison for training and validation set of CNN, and K-means+CNN (multi-label classification).

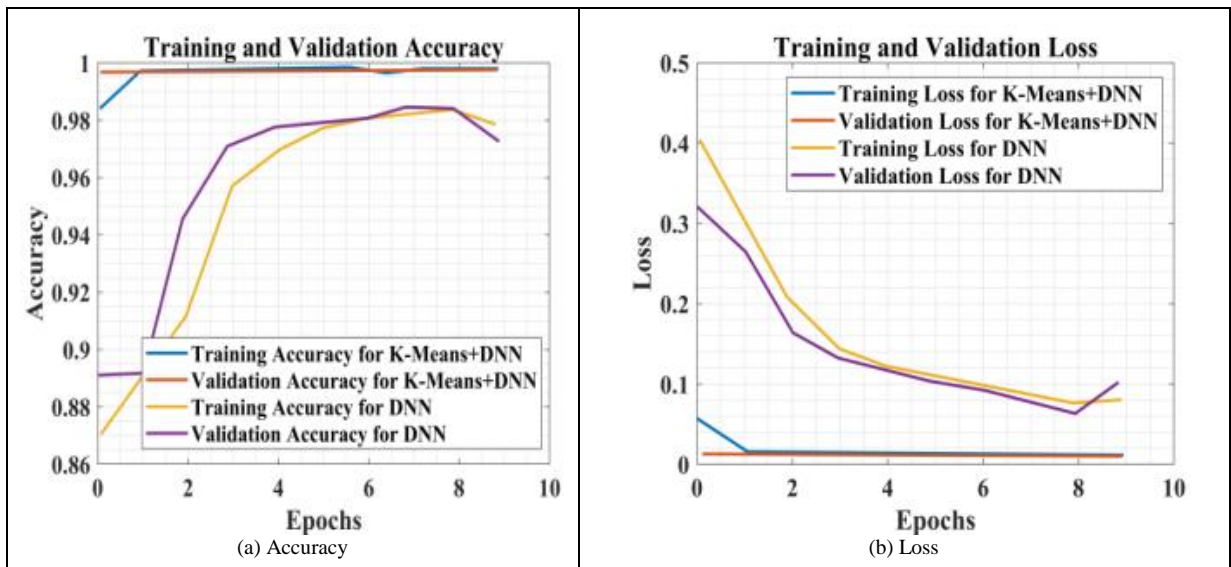

Fig. 11. Accuracy and loss comparison for training and validation set of DNN and K-means+DNN (multi-label classification).

The multi-label classification of the training and validation set for K-means+GRU and GRU based approaches are given in Fig. 12. The accuracy is higher with the K-means+GRU approach, and it is lower with GRU based approach. If the number of the epoch is 1, the training accuracy of K-means+GRU is lower than the validation accuracy.

The accuracy comparisons with multi-label classification for K-means+LSTM and LSTM approaches are shown in Fig.

13. When the number of epochs is 7, the validation accuracy of LSTM highly deviates from the training accuracy of LSTM. The validation accuracy of K-means+LSTM achieves a constant value nearer to 1. With a lower amount of epochs, the accuracy value is lower than 0.9. The value of the training and validation set is lower for K-means+LSTM and higher for LSTM.

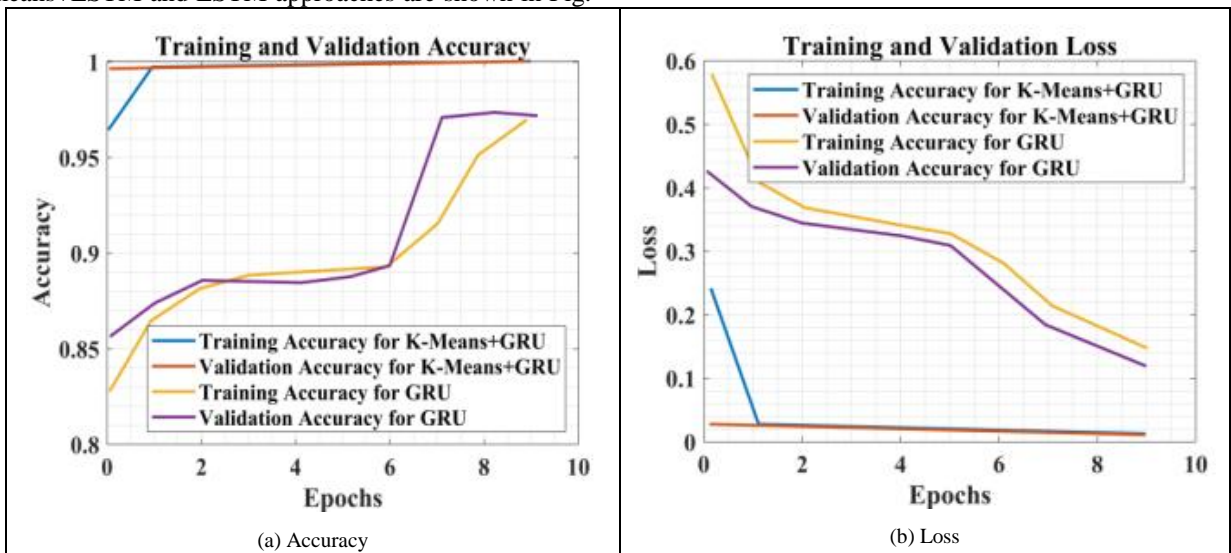

Fig. 12. Accuracy and loss comparison for training and validation set of GRU and K-means+GRU (multi-label classification).

Fig. 13. Accuracy and loss comparison for training and validation set of LSTM and K-means+LSTM (multi-label classification).

The accuracy comparisons of multi-label classification for K-means+RNN and RNN approaches are shown in Fig. 14. The accuracy is higher for the K-means +RNN approach than the RNN approach. The training accuracy is lower than the validation accuracy. By increasing the number of epochs, the accuracy is increased for K-means+RNN and RNN approaches. The loss value is lower for the K-means+RNN approach, whereas it is higher for the RNN approach. When the number of the epoch is 9, the training and validation accuracy for K-means+RNN and RNN is the same.

The confusion matrix for the proposed ensemble-based approach is shown in Fig. 15. For binary classification, the

CNN-based approach provides better detection performance; for multi-label classification, DNN provides better intrusion detection results. The precision recall curve for the ensemble approach is shown in Fig. 16. If the recall value is closer to 1, then the precision also gets closer to 1. The best results from the multi-label categorization are displayed in Fig. 16. Fig. 17 depicts the receiver operating characteristic curve for the ensemble method. It's a graph made up of true positive and false positive numbers. The DNN method of multi-label classification has achieved a macro-average ROC of 1. The ROC curve value reached for class 0 is 1.00, class 1 is 0.99, class 2 is 1.00, and class 3 is 1.00.

Fig. 16. Precision-Recall Curve for ensemble approach.

Fig. 17. ROC curve for an ensemble approach.

V. CONCLUSION

In this work, an intrusion detection framework has been designed using the ensemble based deep learning algorithm for the SDN based Cloud environment. This proposed model performs both binary as well as multi-label classification. The feature extraction with a decision tree provides accurate

feature extraction. It reduces overfitting and is a flexible approach to feature reduction. The clustering process makes the interpretation easier than other approaches. By implementing the clustering process, the computational complexity of the DL algorithm got reduced by neglecting the hybrid DL algorithm. With the proposed ensemble approach, higher prediction accuracy is obtained by handling different

models. By using the deep learning approaches, the identical features are correlated and combined for an efficient learning process. The features are automatically learned from the data, and thus, the processing efficiency is increased. The performance of the ensemble based method achieves a higher detection rate of around 99.8% approximately. By deploying the clustering process, the training process also can be reduced to some extent. In future work, the performance is enhanced with the Quality-of-Service requirement.

A Novel Method for Anomaly Detection in the Internet of Things using Whale Optimization Algorithm

Zhihui Zhu^{*1}, Meifang Zhu²

Guangzhou Maritime University, Guangzhou 510725, Guangdong, China^{*1}
Guangdong Lingnan Institute of Technology, Guangzhou 511510, Guangdong, China²

Abstract—The Internet of Things (IoT) is integral to human life due to its pervasive applications in home appliances, surveillance, and environment monitoring. Resource-constrained IoT devices are easily accessible to attackers due to their direct connection to the unsafe Internet. Public access to the Internet makes IoT objects more susceptible to intrusion. As the name implies, anomaly detection systems are designed to identify anomalous traffic patterns that conventional firewalls fail to detect. Effective Intrusion Detection Systems (IDSs) design faces three major problems, including handling high dimensionality, selecting a learning algorithm, and comparing entered observations and traffic patterns using a distance or similarity measure. Considering the dynamic nature of the entities involved and the limited computing resources available, more than traditional anomaly detection approaches is required. This paper proposes a novel method based on Whale Optimization Algorithm (WOA) to detect anomalies in IoT-based networks that conventional firewall systems cannot detect. Experiments are conducted on the KDD dataset. The accuracy of the proposed method is compared for classifiers such as kNN, SVM, and DT approaches. The detection accuracy rate of the proposed method is significantly higher than that of other methods for DoS, probing, normal attacks, R2L attacks, and U2R attacks compared to other methods. This method shows an impressive increase in accuracy when detecting a wide range of malicious activities, from DoS, probing, and privilege escalation attacks, to remote-to-local and user-to-root attacks.

Keywords—Internet of things; anomaly detection; intrusion detection; firewall; whale optimization algorithm; accuracy

I. INTRODUCTION

Scientific and technological advancements in the fields of optical networks [1, 2], Internet of Things (IoT) [3], cloud computing, Complementary Metal-Oxide Semiconductor (CMOS) [4, 5], machine learning [6], 5G connectivity [7, 8], Blockchain [9], artificial intelligence [10, 11], and smart grids [12] have greatly benefited society. In recent years, the internet has grown tremendously and is now used to connect objects. The Internet of Things (IoT) influences almost every aspect of human and industrial life [13, 14]. By linking physical things together, the IoT is expected to bridge various technologies [15]. Wireless technology advancements such as radio frequency identification (RFID), Bluetooth, and WiFi enable better communication among objects and with the internet [16, 17]. A unique identifier can also be assigned to each item [18]. A lack of security mechanisms and the Internet connectivity of

IoT devices makes them vulnerable to attacks [19]. By gaining control over smart devices, an attacker can hack IoT devices and use them maliciously to hack other IoT devices [20]. As part of anomaly detection, intrusion detection examines incoming traffic for abnormality or abnormality [21]. In order to recognize abnormal traffic within a network efficiently, intrusion detection systems need to automate their detection procedures [22]. The majority of network intrusion detection systems analyze incoming traffic using data mining and clustering techniques. A fundamental function of an intrusion detection system is to identify normal or abnormal traffic patterns based on the current traffic pattern [23].

An Intrusion Detection System (IDS) tracks network activity in real-time and alerts or takes proactive action when suspicious transmissions are detected [24]. The main difference between IDS and other network security tools is that IDS can detect ongoing invasions as well as recent intrusions. An intrusion detection system generally distinguishes between normal and anomalous network traffic behavior and determines the type of attack based on a binary classification problem [25]. It is primarily motivated by improving classification accuracy by detecting intrusive behavior. Network information security has gradually gained attention over the past 30 years [26]. IDS systems are currently categorized as anomaly-based detection systems and signature-based detection systems. The signature-based detection system compares the signatures extracted from the subsequent detection systems with those extracted from known attack methods to detect upcoming attacks and notify users. While anomaly-based detection systems are accurate, they are limited in their ability to detect unidentified attacks, such as 0-DAY vulnerabilities and advanced persistent threats.

A classifier based on ensembles is proposed as a method for improving the accuracy of IDS. Twelve experts are trained and tested to form an ensemble. WOA weighs each expert's opinion. As a meta-optimizer, the LUS method finds high-quality parameters based on the behavioral parameters inserted by the user. The weights of each expert are then adjusted using WOA. Seven stages are involved in the system framework: data preprocessing, SVM classification, k-NN classification, decision tree classification, weighting with WOA, and comparison of results. The remainder of the paper is organized as follows. The Section II reviews related work. A detailed description of the proposed method appears in Section III. Section IV reports the results of the experiments. The paper is concluded in Section V.

II. RELATED WORKS

This section will review the existing anomaly and intrusion detection methods and determine their main features and weaknesses.

Alamiyedi, et al. [28] have proposed an IDS scheme based on the Grey Wolf Optimization (GWO) algorithm. The GWO algorithm is employed for feature selection in order to identify the optimum dataset features for accurate classification. Besides, the support vector machine has been utilized in evaluating the accuracy of selected features in attack prediction. Experiments confirm that the offered method has obtained classification accuracy of 94%, 92%, 58%, and 54% for DoS, probing, R2L, and U2L attacks, respectively.

An IDS approach based on a genetic algorithm and Deep Belief Network (DBN) has been presented by Zhang, et al. [29]. When faced with multiple iterations of the genetic algorithm and varying attacks, generating several neurons in each layer and an optimal number of hidden layers, the proposed mechanism uses DBN to achieve a high detection rate while maintaining a compact structure. The performance of the method has been assessed based on the NSL-KDD dataset. The results indicate that the combined IDS and DBN model effectively reduced neural network complexity and improved intrusion detection rates.

Moreover, a random neural network-based IDS for IoT has been developed by Qureshi, et al. [30], in which, with the NSL-KDD dataset, neurons are trained and then tested at different rates of learning. The accuracy of RNN-IDS was increased from 86% to 96% by using two methods to evaluate the proposed approach. Simulation outcomes indicate that the proposed IDS can distinguish anomalous traffic more accurately from normal traffic.

An EFSAGOA method, which combines an Ensemble of Feature Selection (EFS) and Adaptive Grasshopper Optimization algorithm (AGOA), has been introduced by Dwivedi, et al. [31]. At first, in order to determine the highest-ranked attributes, the EFS method was applied to rank attributes. Using the AGOA method, key attributes derived from the reduced datasets were identified for network traffic prediction. To optimize the classification process, AGOA applies Support Vector Machines (SVM) as a fitness function. Additionally, the method was used to optimize the tube size, kernel parameter, and penalty factor of SVM classifiers. Utilizing ISCX 2012 dataset, the performance of EFSAGOA has been evaluated. In comparison to existing methods in ISCX 2012 data, the proposed method produced better accuracy, false alarm rates, and detection rates.

A novel host-based automated framework for IDS in the IoT has been presented by Gassais, et al. [32], in which user and kernel space information are combined with machine learning approaches to identify intrusions of different types. Tracing methods have been utilized to detect the behavior of devices automatically, transform data into numeric arrays, and train machine learning algorithms. Several machine learning algorithms have been implemented to improve detection capability with minimal overhead on monitored devices.

Furthermore, a novel IDS combining deep learning and a dendritic cell algorithm has been proposed by Aldhaferi, et al. [33]. Classifying IoT intrusions and preventing false alarms are the main aims of the approach. By selecting the appropriate set of features from the IoT-Bot dataset, the proposed IDS categorizes signals and then performs classification using the dendritic cell algorithm. The proposed approach demonstrated a better ability to detect IoT attacks, achieving an accuracy rate of 97% and a low false positive rate.

Brown and Anwar [34] have developed a deep neural network-based validation model integrated into an artificial immune system based on human intelligence. The solution provides implementation strategies and a pilot implementation of the core component to address the challenges associated with IoT networks. The suggested approach is suitable for discovering real-time attacks and is adaptable to changing network environments. This mechanism may serve as a baseline for the development of holistic IoT IDS in which each node plays a role in network security.

Finally, Ge, et al. [24] have offered a novel IDS for IoT utilizing a customized deep-learning technique. They have utilized an innovative IoT dataset of real-world attacks, such as data theft and denial of service attacks. They have developed a feed-forward neural network model embedded with multi-class classification layers. Besides, a binary classifier based on a second feed-forward neural network model was built using transfer learning to encode categorical features of high dimensions. For both binary and multi-class classifiers, the proposed method achieves higher classification accuracy.

III. PROPOSED METHOD

In this section, at first, the problem statement is described as well as the adopted network model is explained. Then, the suggested strategy is clarified step by step.

A. Problem Definition

With the rise of IoT applications and smart objects, IoT networks generate more data and traffic, resulting in a rise in IoT vulnerabilities and, consequently, RPL threats. Although RPL offers mechanisms for achieving confidentiality, integrity, and replay protection through encryption of control messages, local and global repairs, and loop detection, it is still susceptible to internal attacks. The RPL network has vulnerabilities beyond its encryption and authentication defenses. The second line of defense for networks is IDSs, which monitor network activity and node behavior for disruption attempts.

B. Network Model

First-line defenses against computer system cyberattacks are security frameworks that enforce industry standards such as authentication, authorization, and confidentiality. Vulnerabilities in system software, operational errors, and other issues may make attacks more likely. IDSs are critical in identifying and alerting system administrators to such attacks. Depending on the configuration, an IDS can be installed on individual hosts, at a central location, or distributed throughout the network. Fig. 1 illustrates how IDS operates in several areas across the network system. The IDS is a kind of IDS

intended to detect attacks on a computer network rather than a single system. It is designed to detect malicious activities such as unauthorized access, data manipulation, and denial of service attacks. It monitors the network for suspicious activities and flags any potential threats, allowing for quick response and mitigation of possible damage. These systems monitor network operations using network telemetry, which may comprise network traffic, network flow metadata, and host event logs to identify attack events. By analyzing this telemetry, the system can detect and classify malicious activity, alerting administrators to potential malicious activity and allowing for remediation of any potential threats [35].

Fig. 1. Intrusion detection system and different places of the network [35].

An IDS funnels all network traffic via its sensors to identify intrusions and anomalies. As network traffic increases, using a single IDS on a network poses congestion issues if the network throughput is too high. Deep Packet Inspection may include significant pattern matching against complicated attack rule signatures. *Pattern matching* is a time-consuming procedure that requires substantially more computer resources than a firewall, which might cause an IDS to become overloaded. When an IDS becomes overburdened and begins dropping or ignoring packet content, it might compromise the network's security. Eventually, some intrusions may go unnoticed since some packets associated with the same attack may evade the IDS's inspection, leading to incomplete packet matching [6]. There are several strategies for handling high levels of network traffic for IDS, including:

C. Proposed Algorithm Description

As stated earlier, this paper aims to improve the accuracy of IDS by developing ensemble-based classifiers. An ensemble of twelve experts is formed after training and testing twelve experts. Each expert's opinion is weighed according to WOA. User-inputted behavioral parameters are a vital indicator of the effectiveness of WOA. Each expert's weights are then adjusted

based on the improved WOA. A seven-stage system framework is designed to simplify the process: preprocessing data, classifying data with five distinct SVM experts, classifying data with five distinct KNN experts, classifying data with five distinct decision tree classifiers, setting weights with WOA, and comparing the results.

1) *Adopted dataset*: Experiments are conducted using the Knowledge Discovery and Data Mining 1999 (KDD99) dataset. Thousands of records describe connections in the dataset. Each TCP/IP connection contains 41 qualitative and quantitative features. Observations are classified as normal or intrusive based on their features. The performance of each classifier must be evaluated on two datasets: training and testing. The data is taken from [36]. The KDD99 dataset contains four types of attacks.

- User to Root (U2R): connects an attacker to the root account after gaining access.
- Remote to Local (R2L): An entry attempt into a computer or network illegally.
- Probe (Probing): Examining the target machine for potential weaknesses.
- Denial of Service (DoS): The attempt to deny authorized users access to a targeted computer's services.

2) *Data preprocessing*: Each observation must have a set of numerical values in order to be classified using the proposed methods. Additionally, each class must be given a numerical value. The proposed classification algorithms are incompatible with three symbolic features of KDD99 data:

- Flag: The connection status flag is represented by this feature.
- Service: It represents a destination service (for example, telnet, FTP, etc.).
- Protocol type: This feature signifies the connection protocol.

Data preprocessing involves two steps: data mapping and state identification.

- State identification: The KDD99 defines states for different features, such as regular connections or attacks. The data has five major classes: R2L, U2R, Probe, DoS, and Normal. Numerical values are assigned to each state.
- Data mapping: Every observation is mapped to a numerical value in the training, validation, and testing datasets. The three features are each given a numerical value between 1 and n, where n represents the symbol count.

3) *SVM classifier*: Support vector machines (SVM) can effectively solve classification and regression problems. This technique has a low generalization error and does not overfit training data. When a model performs poorly outside the

training set, it is referred to as over-fitting or having a high generalization error. SVM is most effective when separating data sets linearly, which means instances in one class are all positioned along the same hyperplane H. SVM chooses the hyperplane H with the shortest distance between every pair of instances in each class. Up to this point, only linearly separable data have been considered. Such a hyperplane may only be possible for some real-life data sets. Such separation can be achieved using SVM based on data mapping to another feature space. In most cases, this transformation involves mapping into high-dimensional spaces. Kernel functions perform these modifications.

A multi-class SVM is extended by training five binary classifiers, one for each class. Suppose $i = (1, \dots, 5)$ belongs to the quintuple $F = (R2L, U2R, DoS, Probe, \text{and Normal})$, and B_i denotes the binary classifier for target class i within F . Binary classifiers are trained on the entire training set for their respective target classes. Training the classifier B_i involves labeling observations belonging to class i as 1 and all other observations as 0. Classifying observations into one of the five classes is referred to as the One-versus-All approach. The 5-classifier set is used to distinguish between binary classifiers. According to Fig. 2, binary classifiers and experts have different relationships illustrated in their output formats. Binary classifiers take input data and output one of two possible classes, while experts take input data and output a continuous value. This difference in output formats reflects the different ways in which the two types of models process data.

In SVM, the RBF kernel function yields the best results [37]. Various RBF functions are employed in experiments to determine the performance of SVM classifiers with RBF kernel functions. In order to maximize the efficiency of the SVM algorithm, six different SVM experts are trained with different RBF parameters. In addition, this approach ensures that ensemble classifiers have a greater variety of experts. The RBF vector defines the selected values for RBF parameters as follows: $RBF = [5, 2, 1, 0.5, 0.2, 0.1]$. RBF vector values determine the accuracy of binary classifiers in each expert system. Six SVM experts are developed based on the RBF vector:

- SVM 1: RBF = 5
- SVM 2: RBF = 2
- SVM 3: RBF = 1
- SVM 4: RBF = 0.5
- SVM 5: RBF = 0.2
- SVM 6: RBF = 0.1

4) *kNN classifier*: An effective and simple tool for object classification is the k-nearest neighbor (kNN) algorithm [38]. Consider observations and targets $(o_1, t_1), \dots, (o_n, t_n)$, where observations $o_i \in R^d$ and targets $t_i \in \{0, 1\}$. For a given i in the training sample, kNN predicts the test vector class based on the class labels of the nearest neighbors. A kNN classifies new points by identifying the points with the most votes based on

the K closest points. The Euclidean distance is a distance metric commonly used in kNN to compare two vectors (points):

$$d^2(x_i, x_j) = \|x_i - x_j\|^2 = \sum_{k=1}^d (x_{ik} - x_{jk})^2 \quad (1)$$

In contrast to SVM, kNN classifiers can solve multi-class problems. However, five binary classifiers are needed to make kNN and SVM experts compatible. Accordingly, kNN expert systems are structured similarly to the SVM expert systems, as shown in Fig. 2. The compatibility of SVM and kNN expertise allows them to be combined into an ensemble expert system. kNN classifiers use the k parameter to determine how many neighbors close to a given observation are in a training set. The accuracy of binary classifiers inside an expert will vary as this parameter is changed. The kNN classifier can be optimized by creating six experts with different values of the k parameter as defined by the k vector: $K = [1, 3, 5, 7, 9, 11]$. The six k-NN experts are created as follows by selecting different k parameters:

- k-NN 1: k=1;
- k-NN 2: k=3;
- k-NN 3: k=5;
- k-NN 4: k=7;
- k-NN 5: k=9;
- k-NN 6: k=11;

5) *Whale optimization algorithm for IDS*: The WOA algorithm is a swarm-based intelligent algorithm for continuous optimization problems. Compared to recent meta-heuristics methods, it exhibits superior performance. It is more straightforward and robust than other swarm intelligence algorithms, making it comparable to other nature-inspired algorithms. A single parameter (time interval) is required to achieve the desired result in practice. WOA involves humpback whales searching for food in a multidimensional space. Humpback whale locations are considered decision variables, while distances between them and food are represented as objective costs. Three operational processes determine a whale's time-dependent location: search for prey, bubble-net attacking method, and shrinking encircling prey [39]. The primary presentation of the WOA is shown in Fig. 3. These operational processes are described and mathematically expressed in the following. A spiral mathematical formulation can describe the bubble-net behavior of humpback whales as follows.

$$\vec{X}(t+1) = \vec{D}' \cdot e^{bl} \cdot \cos(2\pi l) + \vec{X}^*(t) \quad (2)$$

$$\vec{X}(t+1) = \begin{cases} \vec{X}^*(t) - \vec{A} \cdot \vec{D} & \text{if } p < 0 \\ \vec{D}' \cdot e^{bl} \cdot \cos(2\pi l) + \vec{X}^*(t) & \text{if } p \geq 0 \end{cases} \quad (3)$$

In Eq. (3), p is a constant used to explain the logarithmic spiral's shape, and k is a uniformly distributed number. As a global optimizer, if $A > 1$ or $A < -1$, a randomly chosen search agent replaces the best search agent as follows:

$$\vec{D} = |\vec{C} \cdot \vec{X}_{rand} - \vec{X}| \quad (4)$$

$$\vec{X}(t + 1) = \vec{X}_{rand} - \vec{X} \cdot \vec{D} \quad (5)$$

The current iteration nominates x_{rand} arbitrarily from whales. Whales with a minimum fitness function represent the ideal solution. A whale with the best fitness represents the optimal set of weight coefficients $w = (w_1, w_2, \dots, w_n)$, where n denotes the number of experts. This means that each whale has its own set of weight coefficients. Using Eq. (2), every observation x in the sample is classified according to the voting algorithm y . Every observation in the training set is provided with the correct class (target). As a training sample of size m is classified correctly, c is the number of instances where an output is predicted to have the same value as a target T , or $y = T$. Based on the validation sample, $ACC(w) = \frac{c}{m}$ is the fraction of correctly classified observations, $ACC(w) = \frac{c}{m}$, where m is the

number of observations. The accuracy of ensemble classifiers should be maximized, or the error minimized for each whale in order to achieve improved performance.

Weights are generated separately for each class. According to Fig. 2, the ensemble classifier created by WOA weights will have the same structure as an expert. Consequently, five weights need to be generated with WOA, one for each binary classifier in the base expert. Weights are generated based on the validation data. An accurate evaluation of the accuracy of classifiers based on training data is required. It is not acceptable to evaluate model performance using the same data for training since this would lead to strongly biased weights and could easily result in an overfitted model. The fitness value of an expert system cannot also be determined by testing data since it is necessary to use only testing targets to evaluate the performance of each expert system, whether it is a basic classifier or an ensemble. The validation dataset was created by taking a subset from the corrected.gz file used for testing and removing it from all testing datasets. This ensures the independence of the validation process.

IV. EXPERIMENTAL RESULTS

This study was conducted using Matlab-2018 32bit on Windows 7 Professional 32bit, with an Intel Core i5 processor and 8GB of RAM. As mentioned earlier, the KDD-99 dataset is used in the proposed IDS strategy. KDD-99 consists of a large number of records that fall into five different categories. In fact, KDD-99 records fall into one of these five classes. The number of randomly selected records from the KDD-99 dataset is listed in Table I.

It should be noted that the selected dataset is divided into two groups of training and testing datasets. The training dataset is used to train the classifier, while the testing dataset is used to evaluate it. These datasets are shown in Table II and Table III.

A. Detection Accuracy Evaluation

The classification accuracy criterion is one of the main and most significant evaluation criteria for each IDS mechanism. Considering that the dataset considered in this article includes five different classes. As a result, each of the fifteen presented classifiers includes five binary classifiers. According to Eq. (6), it is possible to calculate the classification accuracy of each binary classifier. In this regard, A indicates the classification accuracy of the binary classifier, S indicates the total number of test samples of the desired class, and C indicates the number of correctly identified samples of the same class. The fifteen classifiers will be examined in the following according to their accuracy of identification.

$$A = \frac{C}{S} \quad (6)$$

- Classifiers based on support vector machine: Five different classifiers can be formed based on the SVM. These classifiers include a multi-class SVM based on the RBF kernel function with γ values set to 0.1, 0.2,

0.5, 1, and 2. Table IV shows the accuracy of different SVM-based classifiers.

- Classifiers based on k-nearest neighbor: There are five types of kNN-based classifiers. Classifiers include multi-class kNNs with k values of 1, 3, 5, 7, and 9. The accuracy of these classifiers is shown in Table V.
- Classifiers based on decision tree: There are five types of classifiers based on the C4.5 classification algorithm. These classifiers contain 19, 21, 23, 25, and 27 features. Previous research has determined the number of selected features. In fact, the difference between these five classifiers is the number of selected features. Table VI shows the accuracy of these classifiers.
- Proposed algorithm: The proposed IDS strategy in this paper comprises fifteen different classifiers. By combining these classifiers, the proposed IDS system is designed and built. Each classifier is also given a suitable weight based on the WOA. The proposed system based on the WOA was trained with 70% of the data and tested with 30% of the data. Table VII shows the number of training data, the test results, and the recognition accuracy. This proposed method outperforms fifteen different classifiers regarding average detection accuracy, as shown in Fig. 4.

B. Performance Analysis on the UNSW-NB15 Dataset

This scenario tests the efficiency of the ensemble-based WOA model in terms of accuracy, F-measure, precision, recall, and AUC. The UNSW-NB15 dataset contains 175,341 records for training and 82,332 records for testing. Similarly, to the NSL-KDD dataset, the ensemble classifier with WOA demonstrated superior performance for intrusion detection with an AUC of 99.6%, F-measure of 99%, recall of 99.1%, precision of 99.2%, and accuracy of 99.3%. Fig. 5 compares the ensemble-based WOA model with other approaches.

V. CONCLUSION

The IoT enables physical objects in different domains to become Internet hosts, raising high expectations. Nevertheless, attackers may also use the IoT to threaten the privacy and security of users. Hence, the IoT requires security solutions. IDSs play a critical role in keeping IoT networks accessible and secure. This paper proposed a new strategy to improve the accuracy of IDS by developing ensemble-based classifiers. Twelve experts are trained and tested to form an ensemble. With LUS, user-supplied behavioral parameters are used as meta-optimizers to estimate high-quality parameters. WOA is then used to adjust the weights of each expert. The detection accuracy rates of the proposed method were significantly higher than those of other approaches for attacks, such as DoS, probing, normal, R2L, and U2R. We will investigate the efficiency of the ensemble-based WOA model using other intrusion datasets in the future, and apply this approach to other optimization problems as well.

Autonomous Path Planning for Industrial Omnidirectional AGV Based on Mechatronic Engineering Intelligent Optical Sensors

Yuanyuan pan*

Jiangxi Technical College of Manufacturing, Nanchang 330095, Jiangxi, China

Abstract—With the rapid development of modern industry, the application of automated mechanical and electronic technology is gradually increasing, and the research on automatic path planning is also receiving increasing attention. In this environment of rapid technological progress, rapid growth of the knowledge economy, and fierce competition, industrial intelligence has become an indispensable part of social development. Industrial Automated Guided Vehicle (AGV) has put forward higher requirements for the application of automatic control technology in the planning and research of autonomous path planning. Autonomous path planning with AGV as the service object is currently the most widely used direction in industrial production processes, with the best development prospects and the highest market demand. Optimizing autonomous path planning for AGV is of great significance in promoting the process of industrial modernization and improving industrial production efficiency. In order to solve the problems of low path planning efficiency, excessive reliance on the rich experience and subjective judgment of relevant personnel, and excessive consumption of path planning costs in traditional AGV omnidirectional autonomous path planning, this article attempted to introduce sensor technology to conduct in-depth research on AGV omnidirectional automatic path planning. Based on intelligent optical sensors and combined with ant colony algorithm, the autonomous path planning model for AGV was optimized, and an innovative AGV omnidirectional autonomous path planning model application experiment was conducted in two industrial production enterprises in a certain region. Comparative analysis of experimental data showed that the innovative AGV omnidirectional autonomous path planning model studied in this article had an average improvement of about 17.8% in four evaluation indicators compared to traditional AGV omnidirectional autonomous path planning models.

Keywords—Smart machinery; optical sensors; industrial development; autonomous path planning

I. INTRODUCTION

The development of science and technology is a very complex, lengthy, challenging, and competitive process. In order to adapt to the increasingly competitive modern industrial market, the research on autonomous path planning for systematic omnidirectional AGVs has become the primary task at present. The path planning research that combines the motion transformation of an object or device with the surrounding environment is a flexible design aimed at adapting to external conditions and constraining internal targets. This design idea can achieve response to external environmental

stimuli, allowing the target subject to perform autonomous control to complete specified tasks. In the research of automatic path planning, this article has conducted in-depth research, promoting the industrialization process of cities.

Some scholars have conducted experimental analysis on the autonomous path planning of mechanical equipment and summarized some issues that arise in conventional research. They hope to optimize the research direction of autonomous path planning. Gul Faiza conducted in-depth discussions on the purpose of autonomous path planning research and discussed how to find the optimal and shortest path in the autonomous path planning process [1]. Karamuk Mustafa proposed a high-performance autonomous path traction system by studying the optimization direction of AGV autonomous path planning during the interaction between upper software and lower mechanical components [2]. Pantic Michael proposed a novel autonomous path planning scheme to enable machines and equipment to perform motion planning tasks interacting with the environment in complex industrial production activities [3]. Marosan Iosif Adrian optimized the omnidirectional autonomous path planning system for AGVs by studying the use of autonomous mobile platforms in modern industry and combining various sensor systems [4]. In order to improve the path tracking accuracy and stability of AGV vehicles in complex environments, Liu Yaqiu proposed an improved autonomous path control tracking method, which greatly improves the trajectory deviation phenomenon [5]. The above research summarizes the theoretical framework of autonomous path planning.

The optimization of autonomous path planning models is aimed at adapting to more complex industrial production environments and exploring for this purpose. Seder Marija has developed a new omnidirectional AGV autonomous path planning solution based on an open logistics innovation platform for local manufacturing logistics automation systems. It is suitable for complex and difficult transportation tasks, which can improve the control level of local mobile robots and prove its effectiveness [6]. Zhang Jie analyzed and studied the dynamic control of AGV in local industrial production activities. He combined autonomous guidance of mechanical equipment in the Internet of Things with decentralized decision-making methods for path planning and proposed an AGV design scheme using McNumb wheels for autonomous omnidirectional path planning [7]. Quan Yanming explored the balance and motion trajectory of AGV in industrial production activities, and evaluated the safety and reliability of

autonomous trajectory planning during AGV cargo transportation by combining different production line scenarios, loading situations, and motion states [8]. Shentu Shuzhan focused on optimizing the autonomous positioning of mobile robots in indoor industrial problems. He integrated hybrid navigation systems and optimized them on the basis of traditional mobile robot autonomous positioning systems [9]. The above research summarizes and analyzes the autonomous planning problem of mechanical equipment in industrial production processes.

In addition, some researchers have considered how to improve the stability and reliability of AGV autonomous path planning in complex industrial production environments. Fragapane Giuseppe analyzed the scheduling application of AGV in local internal logistics business and proposed a central control unit design model that dynamically responds to system state and environmental changes [10]. Moshayedi Ata Jahangir explored the autonomous path planning and design process of AGV robots and the obstacles to their application in modern industry. He conducted a comparative analysis of AGV autonomous path planning systems for different construction schemes [11]. Lin Rui studied the application effects of guided logistics robots for pallet transportation in local areas. Through performance evaluation and analysis of the stability of automated guidance and the reliability of path planning, he determined that the research on machine automation is the future trend of industrial production [12]. The above studies have all analyzed autonomous path planning for automatic transportation machines, but no specific research plan has been proposed.

In order to solve the unstable performance of AGV autonomous path planning applied in traditional industrial production activities, it is difficult to plan the optimal path to complete the task. In the automated transportation process of AGV, there are still many issues such as manual manipulation. This article comprehensively analyzed the traditional AGV autonomous path planning system and summarized its advantages and disadvantages. Combining an intelligent optical sensor system based on mechatronics and intelligent algorithms, an autonomous path planning model for omnidirectional AGV was studied. This model not only fundamentally solves the problems encountered in some traditional AGV autonomous path planning models, but also has good autonomous path planning capabilities in complex industrial production environments and difficult industrial transportation tasks. It also has strong risk response capabilities in the face of unexpected transportation problems in industrial production activities, making contributions to the modernization process of industrial production.

II. TECHNICAL APPLICATION OF INTELLIGENT OPTICAL SENSORS IN ROBOT AUTONOMOUS PATH PLANNING MODEL

In recent years, the highly integrated technology of sensors continues to make breakthroughs and innovations. Optical sensors are widely used in more and more fields, such as intelligent control, path planning, mode transformation, and so on. In the application of autonomous path planning, how to improve the accuracy of robot intelligent identification applications in the path is the main research direction at

present. Autonomous path planning requires robots to complete tasks with the most efficient motion trajectory in a complex and dynamic production environment. The best collision free path can be found in known or unknown production environments and relatively efficient path planning can be carried out. It can not only reduce the wear and tear of mechanical equipment during movement, but also improve production and work efficiency in industrial activities, which has extremely high practical significance in the process of industrial modernization [13-14].

In order to conduct better road condition analysis and path planning for complex environments in industrial production activities, intelligent research on autonomous path planning of machinery and equipment is the future trend of industrial development. Industrial production activities often require a large number of industrial raw materials and manufactured products to be transported and transmitted cyclically on the industrial assembly line. Artificial methods are mainly used to analyze road conditions and identify paths in complex industrial production environments, which require subjective judgment and visual identification by professional scholars or experienced staff. It is not possible to enable autonomous learning of transportation equipment, greatly reducing transportation efficiency. It is also difficult to ensure the safety and reliability of the planned transportation path.

With the rapid development of science and technology, complex, diverse, and rapidly changing information abounds in daily life and production work. In order to effectively collect this information and promote the progress of industrial automation and control, intelligent optical sensors have emerged, and are applied on working paths with obstacles, thereby improving the dynamic capture performance of obstacles on the path [15-16]. Based on practical needs, this paper tentatively introduces intelligent optical sensor technology to optimize the design of industrial intelligent production and equipment transportation processes. In industrial transportation operations, optical sensors are used to collect real-time road condition information, and the collected road condition information is fed back to the control center using wireless communication technology. Finally, through learning algorithms, road conditions are analyzed and identified in real time. The autonomous path planning system for robots based on intelligent optical sensors has a higher speed of updating road information and adaptability to complex production environments.

Optical sensors generate varying degrees of electrical signals from different photoelectric effects by collecting information on the intensity of light emitted by the light source on the sensor [17]. This principle enables the conversion of light intensity into quantitative digital data. An autonomous path planning model for intelligent optical sensors is introduced to collect photoelectric signal data in industrial production environments. The collected photoelectric signals are subjected to data analysis and feature extraction before being further optimized for processing. Finally, combined with fuzzy rules, road conditions are intelligently identified. As a result, the process utilizes optical sensors to meet real-time monitoring of road conditions and can plan the optimal path to complete the task, improving the intelligence and accuracy of

road condition analysis and path planning on the basis of traditional path planning models.

III. DEVELOPMENT OF AUTONOMOUS PATH PLANNING RESEARCH FOR INDUSTRIAL OMNIDIRECTIONAL AUTOMATED GUIDED VEHICLE

With the extensive practical application of information collection and intelligent control technology in modern science, autonomous robot movement has developed rapidly. Autonomous path planning technology for robots refers to the optimal path planning for robots in complex work environments that does not encounter any collisions from the starting point to the end of the task and meets constraints while following some movement constraints, such as the shortest straight path, the shortest actual time, and the lowest energy consumption. In the construction of modern industry, optimization research on AGV omnidirectional autonomous path planning technology with AGV as the service object is conducive to improving the production efficiency and development process of modern industry.

AGV is mainly used for automatic transportation of raw materials and finished products in industrial production processes. Due to its simple integration, simple programming, and high efficiency, AGV is widely used in industrial manufacturing systems. The working environment of AGVs is mostly under harsh terrain conditions. AGVs need to choose efficient and collision free planning paths as much as possible while completing specified tasks. During transportation, they need higher travel speeds to improve the efficiency of automatic placement and movement of various objects in complex industrial production environments. The optimization of AGV omnidirectional autonomous path planning is an important development direction for modern industries such as discrete manufacturing.

The traditional AGV autonomous path planning method has a low degree of freedom, requiring relevant staff to visually collect road condition information for transportation tasks in complex industrial production environments. Extensive work experience is used to plan paths and set more rigid paths for AGV through programming and other means. The path planned under the traditional AGV autonomous path planning method is difficult to cope with the complex industrial production environment. In the face of sudden and complex road conditions and path obstacles, it is impossible to continue the task set by the program, resulting in a life-and-death lock phenomenon, requiring a large amount of labor costs to detect and correct errors. This does not achieve the original purpose of freeing manpower, reducing costs, and improving production efficiency.

Traditional AGV path planning requires a large amount of manpower and material resources to collect road information in complex industrial production environments. It relies on the professional knowledge of relevant staff with rich work experience and experts to manually plan the AGV transportation path, as well as embedding the program into the AGV core through programming and other methods. The AGV transportation path set in this way is quite rigid. Whenever encountering overly complex road conditions, structures, or sudden obstacles, AGV deadlock occurs, which is not conducive to the conduct of industrial production activities, causing serious consequences such as delayed delivery of production materials at critical moments, leading to the disconnection of the production chain. The optimization of the AGV omnidirectional autonomous path planning model is conducive to promoting the improvement of industrial production efficiency and the advancement of the modernization process. It is necessary to establish evaluation indicators for the AGV omnidirectional autonomous path planning model. Table I shows some evaluation indicators and their behavioral rules.

TABLE I. EVALUATION CRITERIA AND THEIR EVALUATION RULES

Evaluation indicators	Rules of conduct
Road condition monitoring	Speed of road condition information collection Number of road condition information collected Road condition monitoring response time
Road conditions prediction	Speed of road information prediction Number of road condition information forecasts Predicted response time for road condition information

In the optimized AGV omnidirectional autonomous path planning model, highly integrated intelligent optical sensor components are combined, greatly enhancing the ability to collect road information in complex industrial production environments. Then, the obtained road condition information is subjected to data calculation and model learning using a deepening learning algorithm to achieve road condition prediction in complex industrial production environments, and has a higher risk response ability in the face of sudden path obstacle problems. The optimal path that meets the constraints is determined on the premise of completing the set tasks, which greatly improves the level of intelligence and automation in modern industrial production activities, and also has a high task completion rate during the progress of AGV transportation tasks. The AGV path planning research structure is shown in Fig. 1.

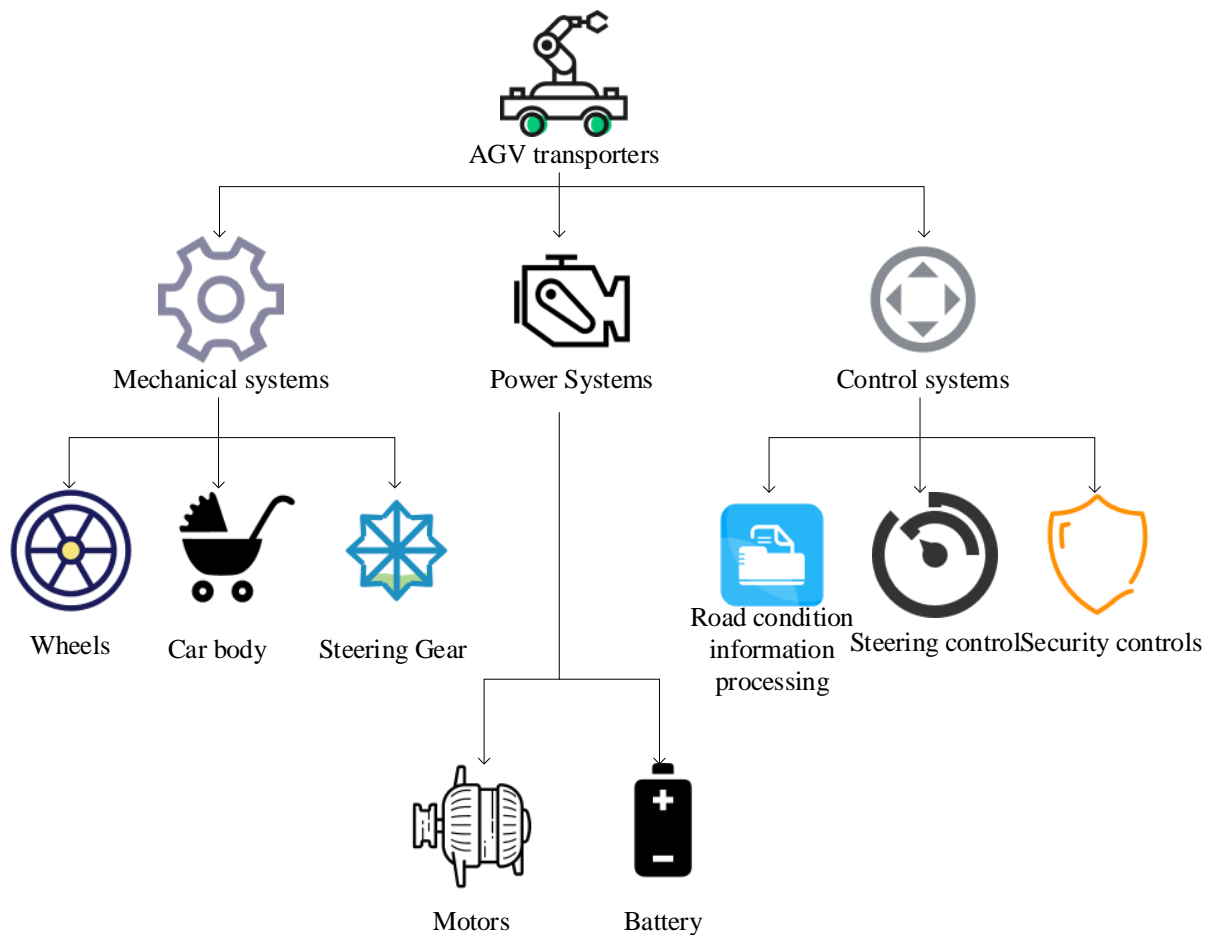

Fig. 1. Structure of the automated guided vehicle path planning study.

IV. APPLICATION OF ANT COLONY ALGORITHM IN AUTOMATED GUIDED VEHICLE OMNIDIRECTIONAL AUTONOMOUS PATH PLANNING

Path planning is one of the important foundations for realizing automatic transportation of AGV, which calculates and classifies the collected data. Then, based on fuzzy rules of data fusion, the optimal path planning is carried out in a complex industrial production environment [18]. In order to overcome the problems of excessive computational cost, difficulty in obtaining optimal solutions, and difficulty in implementing planned paths in complex construction environments, it is possible to solve the path planning problem of a large number of irregular obstacles that hinder AGV from completing industrial transportation tasks in complex industrial production environments. In this paper, an evolutionary ant colony algorithm is used to solve the problem by simulating the process of ants searching for food in nature.

During movement, ant colonies leave a special pheromone secreted on their path. Later, ant colony members make decisions about their direction of travel based on the concentration of pheromones left on the path. The longer the path, the lower the concentration of pheromones. When the ant colony team arrives at the intersection later, they choose a path with a high pheromone concentration to travel, and ultimately find the optimal foraging path through continuous exchange of

information throughout the self-organized travel of the entire ant colony. The ant colony algorithm designed based on this principle can play an important role in the AGV omnidirectional autonomous path planning model [19].

Data collection is the premise and foundation of algorithm calculation. A highly integrated intelligent optical sensor emits light beams from a transmitter on a complex industrial production environment path, and a receiver receives the returned light beams. Different photoelectric signals are generated by varying the intensity of the returned light beams, which are used to reflect the specific road condition information of the complex path in the industrial production environment. The collected road condition information is exchanged with the control center through wireless communication technology, and a large number of collected data samples are used as training samples for learning and calculation by ant colony algorithm. The number of samples is Q . $c_{a,b}(a = 1, 2, \dots, n_1; b = 1, 2, \dots, n_2)$ is the distance between location points a and b in a planar environment, and n_1 and n_2 are two-dimensional vectors corresponding to the planar environment. $J_a(t)$ is the number of environmental samples at position a at time t . $v_{a,b}(t)$

represents the residual pheromone concentration at time t in path (a, b) . The total concentration of pheromones can be calculated by Formula (1).

$$\tilde{v} = \sum_{a=1}^n j_a(t) \quad (1)$$

At the initial moment of the ant colony algorithm calculation, the pheromone concentration content on all paths is quantitatively preset by Formula (2).

$$v_{a,b}(0) = \zeta \quad (2)$$

Among them, ζ is a constant. During the calculation process, sample $q (q=1, 2, \dots, Q)$ determines the next moving direction based on the pheromone concentration on each path. The probability of movement can be calculated by Formula (3).

$$P_{a,b}^q(t) = \begin{cases} (v_{a,b}^\alpha(t) \lambda_{a,b}^\beta(t)) / (\sum_{e \in M_a^q} (v_{a,e}^\alpha(t) \lambda_{a,e}^\beta(t))), & b \in M_a^q \\ 0 & , \text{ other} \end{cases} \quad (3)$$

Among them, $P_{a,b}^q(t)$ represents the probability of a transition from position a to b at time t . $\lambda_{a,b}(t)$ is a local heuristic function for visibility. The parameters α and β represent the influence weights of $v_{a,b}(t)$ and $\lambda_{a,b}(t)$ on the overall sample transfer probability, respectively. M_a^q represents the feasible area of sample q at position a . As time goes on, the pheromone content on the algorithm's decision path gradually decreases. Formula (4) calculates the pheromone content of the path path when the sample movement completes a cycle of movement after u moments.

$$v_{a,b}(t+u) = \theta v_{a,b}(t) + \sum_{q=1}^Q \Delta v_{a,b}^q \quad (4)$$

Among them, θ represents the residual degree after the pheromone gradually decreases on a certain path. $\Delta v_{a,b}^q$ represents the amount of pheromone tracks that the sample remains on path (a, b) during this cycle. Finally, through the tradeoff and comparison of pheromone content and concentration, the optimal path planning decision to complete the task is obtained. The above is the calculation process of ant colony algorithm used in the AGV autonomous path planning model in this article. The application of ant colony algorithm makes the AGV omnidirectional autonomous path planning model more efficient. The computational structure of the ant colony algorithm is shown in Fig. 2.

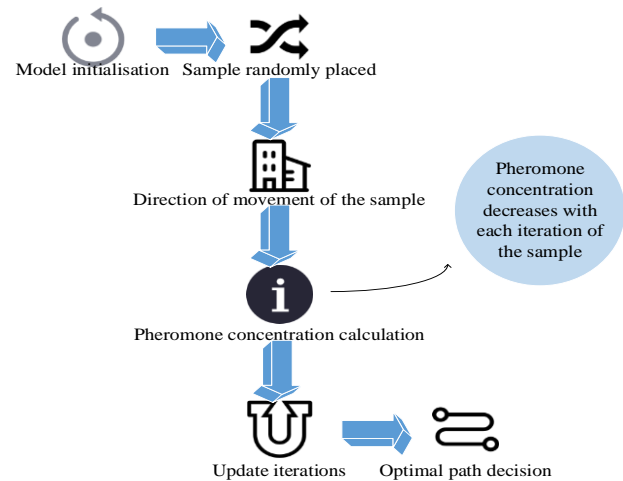

Fig. 2. The computational structure of the ant colony algorithm.

V. APPLICATION EXPERIMENT OF AUTOMATED GUIDED VEHICLE OMNIDIRECTIONAL AUTONOMOUS PATH PLANNING MODEL BASED ON INTELLIGENT OPTICAL SENSORS

With the continuous advancement of industrial modernization, the degree of automation is also gradually improving, and the optimization and upgrading of automatic control systems is the current development trend. The invention of intelligent materials and the development of highly integrated sensor technology pose new challenges to industrial automation. However, in the process of industrial production and transportation, there are still many transportation risks and room for improvement. As an important component of modern industrial development, AGV autonomous path planning and multi-directional parallel control methods are being studied in the direction of high accuracy and reliability.

This article conducts an in-depth analysis of the original AGV omnidirectional autonomous path planning model and identifies the advantages and disadvantages of the traditional AGV omnidirectional automatic path planning model. It proposes solutions to some risks and hidden dangers in the traditional AGV omnidirectional automatic path planning mode. In this paper, based on highly integrated intelligent optical sensors and neural network technology, combined with ant colony algorithm, an omnidirectional autonomous path planning model for AGV was constructed. Laser light was emitted through a transmitter into the industrial production environment, and then the returned refracted light was collected by highly integrated optical sensors. Different light intensities irradiate the photosensitive element to generate different photoelectric signals, and the collected photoelectric signals are exchanged and transmitted by wireless communication technology and the control center. The obtained electrical signal data was injected into the AGV omnidirectional autonomous path planning model as an original sample, and the data was calculated and classified by an ant colony algorithm. Combined with fuzzy rule planning, the optimized path for transportation tasks can be better completed. In this process, real-time monitoring of road information in the industrial production environment was

carried out, and risk issues arising on the planned path were promptly investigated and resolved.

With this model structure and data algorithm, an omnidirectional autonomous path planning model for AGV based on intelligent optical sensors was formed. On the basis of inheriting the advantages of traditional AGV path planning models, optimization was conducted to address the shortcomings of traditional AGV path planning that are not intelligent and reliable, improving the monitoring effect of traditional AGV path planning models on complex industrial production environments and their ability to respond to obstacles and risks in planning paths. This AGV omnidirectional autonomous path planning model improves the objectivity and scientificity of traditional AGV path planning models in path planning tasks. It saves a lot of manpower and material costs, and effectively allocates computing resources, which can open up a new direction for the research of AGV omnidirectional automatic path planning. However, it still requires some experiments to conduct in-depth verification.

First, two local industrial production enterprises, A and B, were tested for AGV omnidirectional autonomous path planning applications. During the experiment, the laser probe of the AGV transportation equipment emits laser light on the path in the industrial production environment, and the probe on the AGV transportation equipment collects the light reflected from the path. Intelligent optical sensors collect different photoelectric signals generated by the returned light shining on photosensitive devices, and generate corresponding digital data through analog-to-digital conversion. The obtained large amount of signal data is transmitted to the control center through wireless communication technology, and the large amount of data is calculated and analyzed by the ant colony algorithm as the original sample to build a learning model. Combining fuzzy rules for optimal path planning, an AGV autonomous planning path that can complete transportation

tasks with the highest efficiency is obtained. While monitoring the industrial production environment in real time, it can conduct sensitive monitoring of light fluctuations for sudden obstacles appearing on the path, thereby effectively and timely avoiding the risk of sudden obstacles.

The managers and relevant staff of the AGV omnidirectional autonomous path planning model of Enterprise A were surveyed with an application satisfaction questionnaire, and the upper limit of the evaluation index for each satisfaction index was 10. Based on the exponential feedback from the model application satisfaction questionnaire, the application satisfaction evaluations of traditional and innovative AGV omnidirectional autonomous path planning models were analyzed using an exponential comparison, as shown in Fig. 3.

Fig. 3(a) shows the four satisfaction evaluation indicators of Enterprise A under the traditional AGV omnidirectional autonomous path planning model. The four evaluation indicators are road condition monitoring, road condition prediction, transportation time, and risk response. The evaluation index sizes of the four satisfaction evaluation indicators were 6, 5, 4, and 5, respectively. Fig. 3(b) shows the four satisfaction evaluation indicators of Enterprise A under the innovative AGV omnidirectional autonomous path planning model. The evaluation index sizes of the four satisfaction evaluation indicators were 6, 6, 5, and 6, respectively. The innovative AGV omnidirectional autonomous path planning model outperformed the traditional model in terms of the evaluation index of all indicators except the satisfaction evaluation index of road condition monitoring. This indicates that intelligent sensor technology is not omnipotent, and tradition does not mean backwardness. In the process of optimizing the AGV omnidirectional autonomous path planning model, it is necessary to proceed from reality, based on the advantages and disadvantages of tradition, to improve the shortcomings and shortcomings.

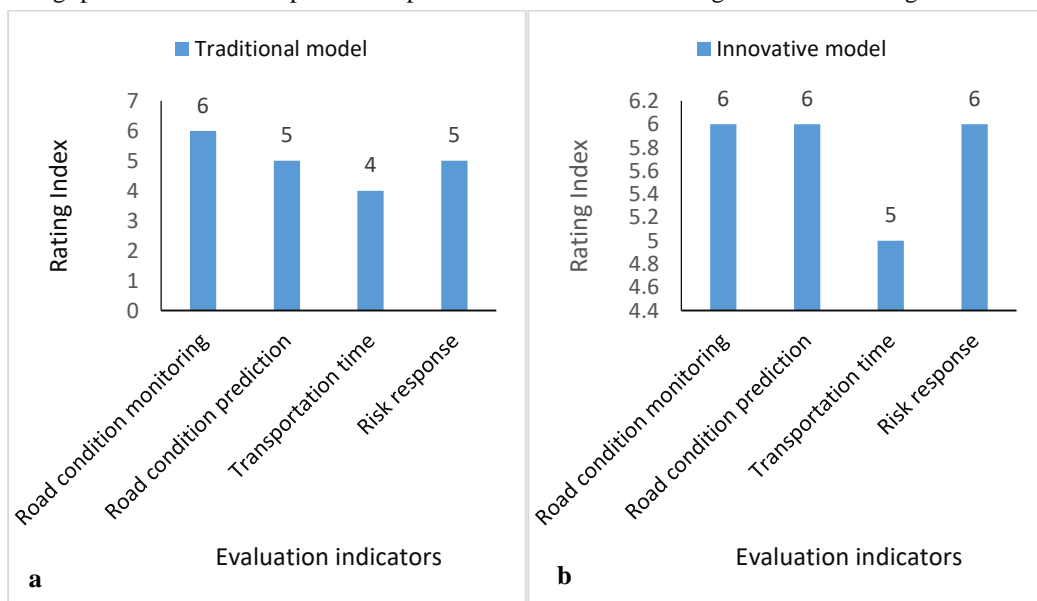

Fig. 3. Satisfactory comparative analysis of the application of traditional and innovative models in Enterprise A, (a). Evaluation of satisfaction with the application of the traditional model in Enterprise A, (b). Evaluation of satisfaction with the application of the innovative model in Enterprise A.

Then, the managers and relevant staff of the AGV omnidirectional autonomous path planning model of Enterprise B were surveyed with an application satisfaction questionnaire. Based on the index feedback from the model application satisfaction questionnaire, an index comparison analysis was conducted on the satisfaction evaluation of the application effect of traditional and innovative AGV omnidirectional autonomous path planning models in Enterprise B. The upper limit of each evaluation index was 10, as shown in Fig. 4.

Fig. 4(a) shows the four satisfaction evaluation indicators for Enterprise B under the traditional AGV omnidirectional autonomous path planning model. The evaluation index sizes for the four satisfaction evaluation indicators, namely, road condition monitoring, road condition prediction, transportation time, and risk response, were respectively 5, 5, 6, and 4. Fig. 4(b) shows the evaluation index sizes of these four satisfaction evaluation indicators for Enterprise B under the innovative AGV omnidirectional autonomous path planning model, which were respectively 6, 6, 7, and 5. As shown in the comparison between Fig. 4(a) and Fig. 4(b), the innovative AGV omnidirectional autonomous path planning model was superior to the traditional AGV omnidirectional autonomous path planning model in terms of four satisfaction evaluation indicators. This indicates that the omnidirectional autonomous path planning model for AGV based on intelligent optical sensors is more efficient than the traditional omnidirectional autonomous path planning model for AGV in terms of overall performance. Electronic information automation technology provides an intelligent and automated development direction for AGV transportation projects in industrial production activities. It improves transportation efficiency in industrial production activities, and contributes to the process of combining industrial automation and information technology.

Finally, this paper analyzed the performance differences between the AGV omnidirectional autonomous path planning model based on intelligent optical sensors and the traditional AGV omnidirectional autonomous path planning model, as shown in Fig. 5.

By summarizing the application performance of traditional and optimized models in Enterprises A and B, the performance differences between traditional and optimized models in four aspects of road condition monitoring, road condition prediction, transportation time, and risk response were analyzed. Fig. 5(a) shows the performance of traditional models in practical applications. In the application process, traditional models have poor performance in coping with risks of sudden problems, and their performance in road condition prediction and transportation time consumption is relatively ordinary. Therefore, there is potential for further optimization in road condition monitoring.

Fig. 5(b) shows the performance of the innovative model in practical applications. From the data shown in the figure, it can be seen that the optimized model has more advantages in performance compared to traditional models. Due to the use of advanced technology and algorithmic processing, innovative models have a more efficient information processing speed, with varying degrees of performance optimization in road condition monitoring, road condition prediction, transportation time, and risk response.

After a comprehensive comparative analysis of the two data, it can be concluded that the innovative AGV omnidirectional autonomous path planning model proposed in this article had an average improvement of about 17.8% in four satisfaction evaluation indicators compared to the traditional AGV omnidirectional autonomous path planning model.

Fig. 4. Satisfactory comparative analysis of the application of traditional and innovative models in Enterprise B; (a). Evaluation of satisfaction with the application of the traditional model in Enterprise B. (b). Evaluation of satisfaction with the application of the innovative model in Enterprise B.

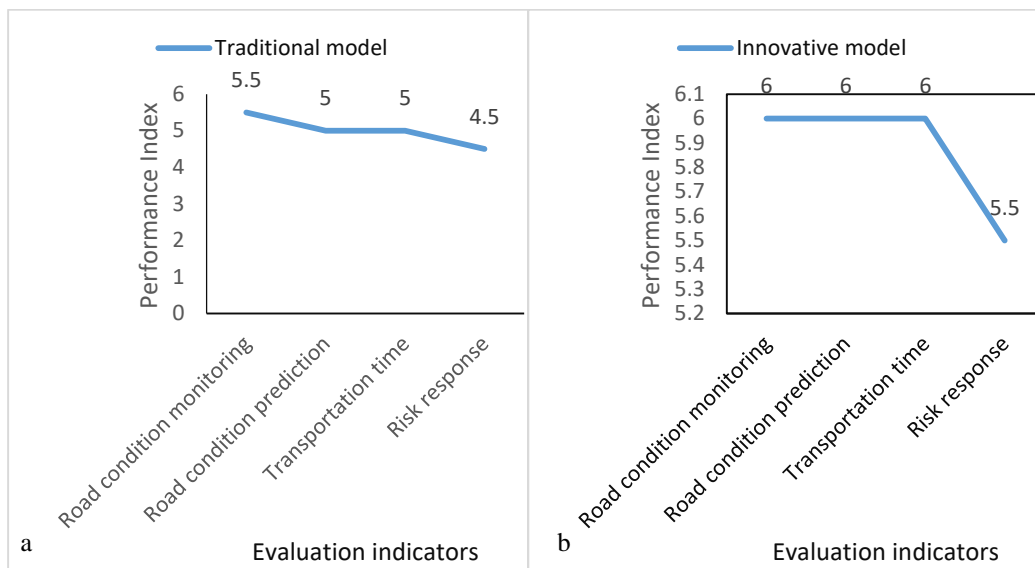

Fig. 5. Comparative analysis of the performance differences between traditional and innovative models, (a). Performance evaluation of traditional model application, (b). Performance evaluation of innovative model application.

VI. CONCLUSION

With the development of modern industry, AGV autonomous path planning technology has become an important field that has attracted much attention. It can not only be used as a new transportation tool for industrial production activities, but also become the most widely used technology carrier for information transmission and processing in future industrial production activities. Although the application of AGV in the field of industrial automated transportation is approaching maturity, there are still many problems, such as complex mechanisms, high costs, and low operating efficiency. With the development and innovation of highly integrated sensor technology, new challenges have been posed to AGV omnidirectional autonomous path planning. In order to solve the problems of high cost in collecting road condition information during the route planning process of traditional AGV autonomous path planning models, rigid route planning for AGV transportation tasks, and untimely response of AGV to unexpected problems arising from planned routes during transportation tasks, based on highly integrated intelligent optical sensors, this paper combines intelligent ant colony algorithm to optimize the AGV omnidirectional autonomous path planning model. In the application process of this model, corresponding countermeasures have been proposed to address the shortcomings and shortcomings of the traditional AGV omnidirectional autonomous path planning model. In the actual industrial production activities, the transportation efficiency of industrial production activities has been improved, and a large amount of manpower and material costs have been saved. At the same time, the complex industrial production environment has been monitored in real time, and sudden obstacles on the AGV transportation path have been risk predicted and timely responded to. Planning a more efficient route on the basis of ensuring the completion of industrial production and transportation tasks has promoted the process of industrial production modernization. This article has

conducted model application experiments using this innovative model in two industrial production enterprises in a certain region, and conducted a satisfaction evaluation questionnaire survey on the application effect of intelligent optical sensors in the AGV omnidirectional autonomous path planning model. Based on the analysis of the satisfaction evaluation index of the experimental results, it can be concluded that this AGV omnidirectional autonomous path planning model using intelligent optical sensors has greatly improved the efficiency of transportation tasks in industrial production activities. It is worth affirming that the optimized AGV omnidirectional autonomous path planning model has a higher level of intelligence compared to traditional AGV omnidirectional autonomous path planning models. Traditional models consume a lot of costs to plan paths that are too fixed, making it difficult to specify safer avoidance plans based on road conditions when facing sudden obstacles and emergency risks. The optimization model in this article can save a lot of time and labor costs while ensuring the progress of transportation operations in the face of complex industrial production environments, and its emergency avoidance ability is also more outstanding. However, research on energy consumption and resource integration is not yet complete, and further exploration is needed. On the basis of inheriting the advantages of traditional path planning, this article has optimized some shortcomings and made contributions to the application of advanced technology in modern industrial development. However, further in-depth research is needed to explore the integration of model computing resources and energy consumption, in order to design an efficient model with faster path planning speed and lower energy consumption.

A Study on the Evaluation Model of In-depth Learning for Oral English Learning in Online Education

Yanli Ge

Office of Foreign Language, Basic Teaching Department,
Changchun University of Architecture and Civil Engineering, Changchun, 130607, China

Abstract—The trend of globalization in the world is becoming increasingly frequent, and people from different regions are communicating more closely. Therefore, the demand for a second language is constantly expanding, accelerating the development of the field of English oral evaluation and also accelerating the development of online education. The study proposes a text priori based oral evaluation model, which is based on the Transformer model and uses target phonemes as input to the Decoder. The model successfully predicts the relationship between actual pronunciation and error labels. At the same time, a self-supervised oral evaluation model with accent is constructed, which simulates the training process of misreading data by calculating semantic distance. The experimental results show that when the training set ratio reaches its maximum in the Speed Ocean dataset and the L2 Arctic dataset, the F1 values of the proposed method are 0.612 and 0.596, respectively; the length of the target phoneme has a smaller impact on this model compared to other models. Experiments have shown that the proposed deep learning method can alleviate deployment difficulties, directly optimize the effectiveness of oral evaluation, provide more accurate feedback, and also provide users with a better learning experience. This has practical significance for the development of the field of oral evaluation.

Keywords—Spoken English; online education; transformer model; deep learning; evaluation model

I. INTRODUCTION

Deep learning technology has largely enhanced the efficiency of speech recognition. Deep speech recognition technology can recognize the phonemes of students' speech and compare them with the text they read. Compared with traditional evaluation methods, this method only needs to train a single recognition model, without complex modeling or providing additional comparative corpus. This speech recognition technology has become the main solution in spoken language testing [1-2]. However, the current spoken language testing methods based on deep learning mostly focus on speech recognition, mainly from improving the accuracy of speech recognition. These methods tend to use better acoustic models in speech testing to improve the effect of oral testing, thus ignoring the shortcomings of speech recognition in oral testing. The spoken language test algorithm based on speech recognition mainly aims at the phoneme and target phoneme in speech recognition to misread. Its optimization aims at improving the accuracy of speech recognition, rather than directly optimizing the effect of oral test. The misreading result

generated by the algorithm is binary. It misreads the identified phoneme and target phoneme by aligning them, and judges whether to align the target phoneme or not, so it is unable to adjust the severity of the evaluation. At present, most of the mainstream recognition patterns need autoregressive recognition and decoding. This process is not real-time, which is a big defect for students who require fast feedback [3-4]. Therefore, to solve the above problems, a text priori oral evaluation model is proposed. This model uses the Transformer mode as the basis of the oral test, and appends a target text entered by the Decoder. By converting the non-differential calibration to the data preparation stage, the misreading of each target is improved, thus realizing the error recognition of each target. Furthermore, the study further discusses the role of phonemes in speech recognition models, demonstrating the key role of phonemes in English oral teaching. The innovation of this method lies in optimizing the speech recognition model from the perspective of oral phonemes, enabling learners from different regions and accents to learn from online oral teaching. The method proposed in the study can effectively recognize the phonemic features of spoken language, making oral learning more widely applicable and playing an important role in promoting online oral teaching.

II. RELATED WORK

The gradual development of deep learning has become the research object of many international scholars and has achieved certain results. Wang et al. implemented a new fault location by using multiple feature groups for depth and breadth learning. They analyzed suspicious features based on spectrum and mutation by combining the combination features of invariants based on suspiciousness, static measurement, collapse stack tracking and invariants change features. Through testing a real software defect standard, Defects4J, higher early diagnosis performance than traditional methods were confirmed [5]. KotaV et al. adopted neural networks for emotion analysis. Methods CNN, double LSTM, attention mechanism and other methods were used for emotional analysis. CNN can reduce complexity, while dual LSTM can help handle long input text. This method uses the attention mechanism to determine the importance of each hidden state and weight it [6]. Seebeck and other scholars developed a DL method, which can automatically obtain comprehensive retinal sensitivity from OCT volume. The relative error of PWS and multiple sclerosis is 2.34 dB, and the minimum relative error is 5.70 and 3.07. Pearson correlation coefficient is 0.66 and 0.84,

Spearman correlation coefficient is 0.68 and 0.83. Their research showed that predicting the retinal function of each measurement site based on OCT scanning can be used as a new visual function prediction method [7]. Kong and his team developed a second-order one-dimensional phase expansion method. The first step is to encode the phase of one dimension using quasi-Grani matrix. The second step is to use the deep convolution neural network to unwrap the phase. Both simulation and measurement results showed that the phase unwrapping quality of this algorithm is significantly improved when the SNR is less than 4 dB, and it can still maintain good performance under negative SNR [8].

There are many types of oral teaching models in the current research field. Chen S introduced an online oral English teaching platform based on the Internet of Things. This platform adopts the technology of Internet of Things to realize the design of the system structure of online oral English teaching platform and establish a virtual teaching environment. The platform corrects the user's mouth shape and pronunciation through the voice teaching system, and establishes a vocabulary tagging model based on long-term memory. He also introduced the attention mechanism into the long-term memory network. The test results showed that the network delay of the system is between 0.26 seconds and 0.37 seconds, which reduces the development time by 50% and increases the human-computer interface by 13.20% [9]. Liu used speech recognition technology to analyze and deal with differences in phoneme expression in spoken English, and made statistics on some errors and areas to be improved in English. The development and promotion of speech recognition technology can effectively reduce the cost of college oral English teaching and promote the improvement of college students' oral English ability [10]. Xu first proposed the concept of five dimensions of AR situational telepresence, i.e. the sense of scene, immersion, reality, interaction, and social telepresence. Then, combined with the actual situation of English teaching, he put forward a theoretical framework to strengthen the teaching of spoken English. Finally, he made a systematic analysis and discussion on the relationship between the proposed

dimensions. He explored the application of augmented reality technology in classroom and online teaching from three levels of perception, acceptance and application [11].

To sum up, deep learning has been widely used in many fields and has shown strong performance. However, the field of oral evaluation is still in the development stage, so the research applies the deep learning technology to the oral evaluation model for the first time. The purpose of the study is to improve the oral evaluation model and further promote the development of oral evaluation.

III. ORAL ENGLISH LEARNING EVALUATION MODEL FOR ONLINE EDUCATION BASED ON IMPROVED DEEP LEARNING ALGORITHM

A. The Construction of Transformer Oral Evaluation Model based on Text Priors

With the continuous development of computer deep learning technology, the task of speech recognition has been greatly improved. The evaluation model based on in-depth learning of spoken English has been applied in online oral English education [12-14]. The research first proposes a text priori-based oral evaluation model, whose structure is shown in Fig. 1.

The model built in Fig. 1 obtains the error status label of the phoneme by comparing the actual phoneme with the target phoneme. The obtained wrong label can avoid the model from introducing an improbable alignment operation during training, and at the same time, the alignment operation will be transferred to the data preparation stage. This model is significantly different from the spoken language evaluation model using speech recognition. The model used in the research does not use the actual pronunciation phoneme as the input of Decoder, but uses the target phoneme. The prediction expression of actual pronunciation and error label is shown in formula (1).

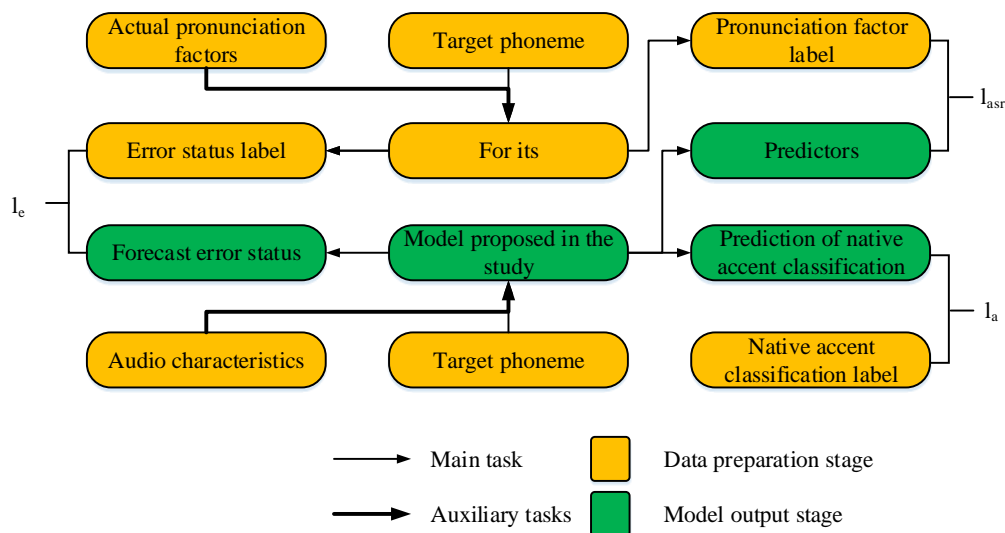

Fig. 1. Work flow of oral evaluation based on text priori.

$$\hat{P}, \hat{E} = Decoder(H, P^{tgt}) \quad (1)$$

In formula (1), \hat{P} represents the actual pronunciation. \hat{E} indicates an error label. P^{tgt} is the target phoneme. H represents the characteristics of audio. When outputting the model, the output length should be paid attention. In the oral language evaluation model of speech recognition, when to output <EOS> determines the output length of speech sequence. Moreover, when the length of speech sequence is aligned with the target text, the model will output an error status sequence, which is the same length as the target text. The model used in the study has used phoneme tagging to align the speech sequence with the target text in the training process, which can also make the length of the error state equal to the target text. The research takes “hi” as an example, and aligns the labeled actual phoneme “HH EY” with the target text phoneme “HH AY” in the data preparation stage, and then obtains the phoneme error status target. For audio features and target phonemes, the output of the model reflects the matching between the two. A two-layer convolutional network is superimposed on the back end of Decoder, and the convolution core size of the network is $3 * 3$. ReLU function is used as the activation function, and the output value is mapped to $[0,1]$ interval through linear layer and sigmoid function. The oral language evaluation model based on text priori is shown in Fig. 2.

Since the evaluation can be differentiated in the output of the evaluation error state, the loss function between the predicted state and the real label can be directly calculated and optimizes the whole model using back-propagation. The research uses Binary Cross-Entropy (BCE) to train the predicted value and label, and its expression is shown in formula (2) [15-17].

$$l_e^{BCE} = BCE(\hat{E}, E) \quad (2)$$

In formula (2), E represents the real label. In the evaluation task, BCE loss does not represent a loss function.

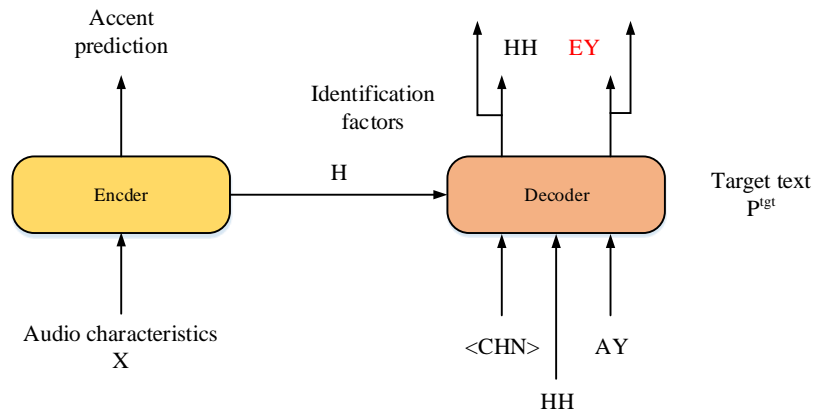

Fig. 2. Structure of spoken language evaluation model based on text priori.

B. Self-Supervised Acoustic Model Construction

In the practice of second language learning, learners are extremely vulnerable to the objective influence of their mother

When the model extracts the relevant acoustic features of the speaker's mother tongue as an auxiliary task, the research adds a module about mother tongue prediction to the output of Encoder. This module predicts the speaker's mother tongue through the input audio features. The input sequence audio features need to be converted into a single classification output, so the research uses the Statistics pooling layer based on mean variance statistics to achieve the above purpose. Its expression is shown in formula (3).

$$\hat{a} = StatisticsPooling(H) \quad (3)$$

In formula (3), \hat{a} represents the single classification output of the sequence audio feature transformation. Cross Entropy (CE) is also used for the training of \hat{a} and a . Its expression is shown in formula (4).

$$l_a = CrossEntropy(\hat{a}, a) \quad (4)$$

The criterion for classifying the error state is the misreading of the target phoneme. The model needs more samples for training, otherwise the model cannot combine the output target with the corresponding audio and target phonemes, and then over-fitting occurs. At present, there are few data sets that can be used in oral evaluation, so the research needs to obtain an acoustic model first. The model can be trained by standard speech recognition dataset. After completing the pre-training task, the research will still require the model to complete the auxiliary task of speech recognition, so as to mine more relations between audio features and phonemes. Finally, the loss function is integrated to obtain the formula (5).

$$\begin{cases} l = l_e + \alpha l_a + \beta l_{asr} \\ l_{asr} = CrossEntropy(\hat{P}, P^{out}) \end{cases} \quad (5)$$

In formula (5), α represents the weight of the auxiliary task of native language recognition. β represents the weight of loss function of speech recognition auxiliary task.

tongue pronunciation, which leads to the deviation of their second language pronunciation from the standard pronunciation. There is unavoidable misreading in oral English

assessment. There is a large error between the text annotation of the Second Language (L2) phonetic feature and the actual pronunciation. Therefore, in the absence of actual pronunciation marking, it is difficult to accurately model L2 speech features based on the text priori oral evaluation model. Self-supervised learning (SSL) is a common machine learning method. It can use auxiliary tasks to accurately mine the supervision information related to itself from the massive unsupervised data without external tag data, and then realize effective network training [18-20]. In recent years, the research on SSL in the voice field has attracted more and more attention. The most classic structure in SSL is the Noise Reduction Auto Encoder (DAE). Its main structure is divided into three parts, namely encoder, bottleneck layer and decoder, as shown in Fig. 3.

According to Fig. 3, the DAE will first learn a compressed feature vector from the original features. Then the decoder will process the feature vector to recover the corresponding original data. The feature vectors in the original feature will be compressed once in the encoder and bottleneck layer respectively. Therefore, the original data recovered by the decoder is no longer accompanied by noise and other influence elements, and will be more representative and typical. From Fig. 1, the DAE will modify the original features before importing them. According to the different types of input features, there are also some differences in the modification methods of features, mainly including transformation, masking, and comparative learning. Transformation refers to converting the original voice input information into spectrum information, and then requiring the network model to recover the original waveform from it. Masking refers to treating the input speech feature as 0 randomly, and the most widely used is the

Bidirectional Encoder Representations from Transformer (BERT) model. Comparative learning can ensure that the model can screen out more typical and distinctive speech features under specified conditions. This modification method no longer only destroys and modifies the original input information, but helps the network model learn valuable representative features by adding interference items. The most typical model is Wav2Vec model. The BERT model and Wav2Vec model are organically combined, and a discrete process is added after the encoder completes the encoding of the original features. This realizes the effective integration of discretization process and comparative learning, and obtains the Wav2Vec2 network model, whose structure is shown in Fig. 4.

Fig. 3. Network structure diagram of DAE.

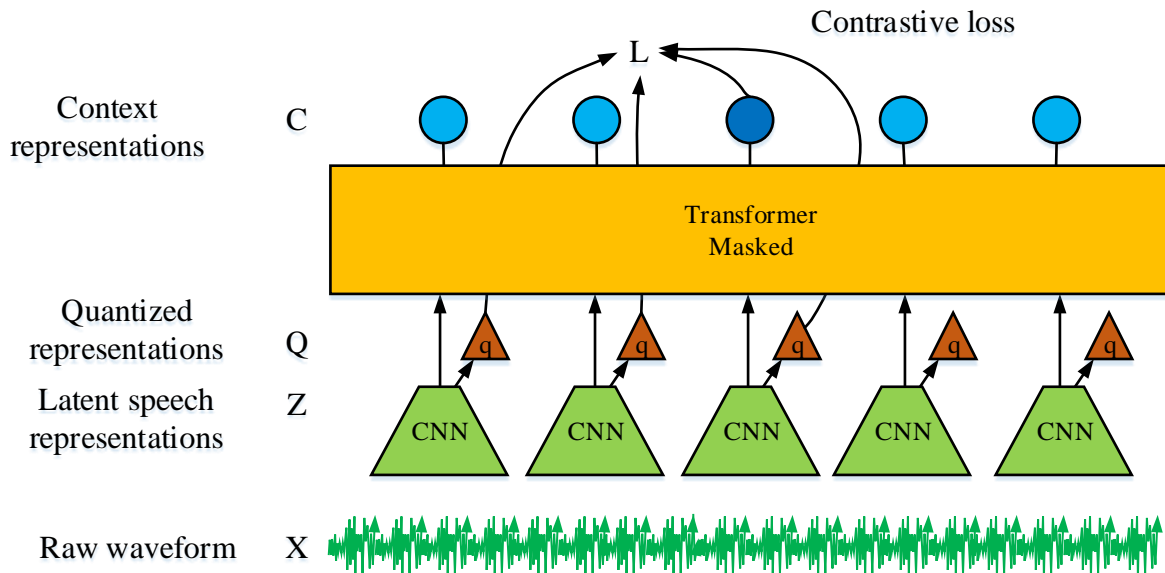

Fig. 4. Structure and training diagram of Wav2Vec2 network model.

Looking at Fig. 4, the original speech feature X can be encoded as Z under the action of the encoder, and Z has a higher degree of abstraction. Then the Wav2Vec2 network

model will enter the discretization process, from which Z can be converted into speech feature Q . Finally, Transformer

can integrate it into a new context feature C . The Wav2Vec2 network model also includes the contrast loss function training model, which can generate a richer discrete code table. On this basis, the discrete acoustic units can be obtained by clustering them with k-Means algorithm, as shown in Fig. 5.

Fig. 5 shows the complete acoustic unit construction process. The circle represents the cluster, the red label and the blue label represent the original acoustic unit and the replaced acoustic unit respectively. Black dots represent each voice data in the training process of the clustering model network. The semantic vector is extracted from the target speech standard and L2 speech feature, and then Class- K speech information is obtained under the clustering effect of k-Means algorithm. Finally, it is converted into discrete acoustic unit sequence- U , as shown in Eq. (6).

$$U = \{u_1, u_2, \dots, u_T\} \quad (6)$$

In formula (6), T is the corresponding length of the discrete acoustic unit sequence, which can replace the original voice features as the input of the network model. For any U , ranking the other $K-1$ acoustic units according to their distance from U , and their corresponding distance is obtained as shown in Formula (7).

$$S^d = \{s_1^d, s_2^d, \dots, s_{K-1}^d\} \quad (7)$$

In formula (7), d is the single semantic distance, that is, the difference between the vector distance of the acoustic unit before and after the replacement in the semantic subspace. It

Fig. 5. Self-supervised clustering of original speech features and its replacement.

can accurately reflect the matching degree between the replaced acoustic unit sequence and the original speech features. The research selects the unit closest to k from the dataset as a substitute, and uses normal distribution to select it, as shown in formula (8).

$$k = \min(K-1, \text{int}(\frac{r(K-1)}{3})) \quad (8)$$

The above method can obtain the vector distance difference of the acoustic model in the semantic subspace before and after the replacement. Euclidean distance is selected as the calculation method of distance difference, and the expression is shown in formula (9).

$$d(u, u^r) = \text{MSE}(v, v^r) \quad (9)$$

In formula (9), d refers to the distance difference of the vector. The mute part of the original audio will have a huge distance from other acoustic units after clustering. These outliers will interfere with the model, so the replacement method used in the study should be used under the condition of $d(u, u^r) < H$. If the condition is not met, it will not be replaced. The pre-training process based on acoustic unit replacement is shown in Fig. 6.

In Fig. 6, the original audio is converted into a discrete audio sequence U . Then the new sequence U^r is obtained by replacing the acoustic unit. The distance difference between the two in the quantum space is shown in formula (10).

$$D = \{d_1, \dots, d_T\} \quad (10)$$

Fig. 6. Pre-training process based on acoustic unit replacement.

To obtain the corresponding distance between phonemes, the initial position of phonemes is searched through the forced alignment tool. Therefore, the corresponding distance of phonemes is shown in formula (11).

$$D^p = \{d_1^p, \dots, d_L^p\} \quad (11)$$

In formula (11), L represents the sequence length of the target phoneme. Finally, the research attempts to predict the distance model of each phoneme with the model, and then make the model learn the degree of deviation from the target text. The loss of the model is expressed by the mean square error function, as shown in formula (12).

$$l_{ed} = MSE(\hat{D}^p, D^p) \quad (12)$$

Formula (13) is the loss function when using the substitution method based on acoustic units for migration prediction.

$$l = l_{ed} + \beta l_{asr} \quad (13)$$

The clustering model is trained in L1 and L2 speech, and the characteristics of standard and non-standard pronunciation

of the target speech are obtained. These features can obtain more fine-grained audio replacement by changing the number of clusters, which greatly increases the authenticity of misread samples.

IV. PERFORMANCE VERIFICATION OF ORAL ENGLISH LEARNING EVALUATION MODEL FOR ONLINE EDUCATION

A. Performance Analysis of Oral Language Evaluation Model based on Text Priori

Before the experimental analysis, the weight of the auxiliary task of mother tongue recognition was set to 0.1. If no native language information is added, the weight is set to 0. The weight of loss function of speech recognition auxiliary task is set to 0.1. The ASR pre-training uses the Librispeech data set. The ratio of training set, verification set and test set is approximately 10:1:1 in this data set. The L2-Arctic data set is used in the oral evaluation task. The data set is divided into training set, verification set and test set according to the ratio of 10:1:4. The test of model performance is mainly evaluated by seven indicators: Phoneme Error Rate (PER), Precision, Accuracy, Recall, F1, False Rejection Rate (FRR) and False Acceptance Rate (FAR). The effect comparison of different models in oral evaluation is Table I.

TABLE I. ORAL EVALUATION OF DIFFERENT METHODS

Model		PER	PRE	ACC	REC
Primitive phoneme	ASR	0.224	0.426	0.787	0.524
	TC-ASR	0.120	0.452	0.833	0.396
	TC-Direct	0.129	0.506	0.824	0.474
Extended phoneme	ASR	0.286	0.403	0.789	0.401
	TC-ASR	0.155	0.569	0.842	0.502
	TC-Direct	0.173	0.500	0.823	0.521
Extended phoneme+	ASR	0.293	0.398	0.786	0.413
	TC-ASR	0.172	0.552	0.838	0.519
	TC-Direct	0.181	0.488	0.818	0.629

Table I shows the performance comparison of different models under different conditions. In Table I, there is a certain gap between the PER, RRE, ACC and REC indicators of ASR model and the other two models. The ACC index of TC-ASR model is higher than TC-Direct, while the remaining three indexes are lower than TC-Direct model. The PER value of TC-Direct model in “extended phoneme+” is 0.181. The ACC value in “extended phoneme” is 0.823. The REC value in “extended phoneme+” is 0.629. The experimental results show that the TC-Direct model has better performance in oral evaluation.

Fig. 7 shows the F1 value result of the translation model. Fig. 7 (a) shows the F1 value of the model in the original

phoneme. The F1 of ASR is 0.464. TC-ASR model is a text priori phoneme level speech recognition model, its F1 value in the original phoneme score is 0.462. The TC-Direct model is a text priori model proposed by the study, and its F1 score in the original phoneme is 0.538. Fig. 7 (b) shows the F1 value of the model in the extended phoneme. The F1 score of ASR model is 0.402. The F1 score of TC-ASR model is 0.533. The F1 of TC-Direct is 0.554. Fig. 7 (c) shows the F1 value of the model in “extended phoneme+”. The F1 score of ASR model is 0.405. The F1 score of TC-ASR model is 0.535. The F1 score of TC-Direct model is 0.549. The experimental results show that the F1 value of TC-Direct model is the highest in the three environments, and the validity of extended phoneme is also shown.

Fig. 7. F1 values of machine translation models in different models.

Fig. 8. F1 scores of the model before and after adding mother tongue accent information.

Fig. 8 shows F1 scores of each model after adding native language feature information. Fig. 8(a) shows the F1 score of the model adding native language feature information to the original phoneme. The F1 value of ASR is 0.464 without adding native language accent label; The F1 score of the ASR model is 0.473 when the mother tongue accent label is added. Similarly, the F1 scores of TC-ASR model before and after adding mother tongue information were 0.462 and 0.469 respectively; The F1 scores of TC-Direct model before and after adding mother tongue information were 0.538 and 0.550 respectively. Fig. 8(b) shows the F1 score of the model in which the mother tongue accent information is added to the expanded phoneme. The F1 scores of ASR model were 0.402 and 0.404 before and after the addition of mother tongue accent information. The F1 scores of TC-ASR model before and after adding mother tongue information were 0.533 and 0.551 respectively. The F1 of TC-Direct before and after adding mother tongue information were 0.554 and 0.562 respectively. Fig. 8(c) shows the F1 score of the model in which the mother tongue accent information is added to "extended phoneme+". The F1 scores of ASR model were 0.405 and 0.408 respectively before and after adding native accent information. The F1 scores of TC-ASR model before and after adding mother tongue information were 0.535 and 0.552 respectively. The F1 scores of TC-Direct model before and after adding mother tongue information were 0.549 and 0.555 respectively. From the comparative analysis of model results, TC-Direct model has a higher F1 score compared with other models, indicating that the model has better performance. From the analysis of the results before and after adding the mother tongue accent information, adding the mother tongue accent information can improve the F1 score of the model, indicating that the mother tongue accent information can help the model obtain better recognition performance.

B. Analysis of Influence of Parameters on Model Performance

Adjusting the weight θ between FAR and FRR can make the oral evaluation model different in difficulty, as shown in Fig. 9. Fig. 9(a) shows the change of the Recall-Recision curve of the loss function when adjusting θ . The larger the value of

θ , the effective adjustment range of Focal function is between 0.05 and 0.95. The effective adjustment range of BCE function is about 0.38 to 0.78. The effective adjustment range of F1 function is 0.59 to 0.62. Fig. 9(b) shows the change of the FAR-FRR curve of the loss function when adjusting θ . The effective adjustment range of Focal function is also between 0.05 and 0.95. The effective adjustment range of BCE function is about 0.22 to 0.42. The effective adjustment range of F1 function is 0.37 to 0.39. The experimental results show that Focal loss function has a wider adjustment range, which is a better choice for practical application.

Fig. 10 shows the effect of target phonemes of different lengths on the reasoning duration. Fig. 10(a) shows the reasoning time results of ASR model for different length phonemes. The longer the length of the target phoneme is, the longer the reasoning time of ASR model is, which is in positive proportion. Fig. 10(b) shows the reasoning time results of TC-Direct model for different length target phonemes. The reasoning time of the model is also positively correlated with the phoneme length, but the influence is low. The model has the best performance when the target phoneme length is 25-40.

Fig. 11 shows the effect of the scale of the training set on the performance of the model. Fig. 11(a) shows the F1 value of the model in the L2-Arctic dataset. The F1 of ASR is 0.372 without training; The F1 value is 0.473 when the training set proportion reaches the highest. The F1 value of TC-Direct is 0.596 when the training set proportion is the highest. Fig. 11(b) shows the F1 value of the model in the Speed Ocean dataset. The F1 of ASR is 0.356 without training, and the ratio of training set is 0.446 when it reaches the maximum. The F1 of TC-Direct is 0.612 when the training set proportion is the highest. The F1 value is higher than that of ASR model in both data sets regardless of the proportion of the training set. Comparing the two data sets, the F1 value of ASR in the Speed Ocean data set is slightly lower than that in the L2-Arctic data set. The F1 value of the TC-Direct model in the Speed Ocean dataset is higher than that in the L2-Arctic dataset. Thus, the TC-Direct has wider applicability.

Fig. 9. Influence of the weight between FAR and FRR on the loss function.

Fig. 10. Reasoning duration results of target phonemes with different lengths.

Fig. 11. F1 value of model in different training set proportions.

V. DISCUSSION

The proposed model was experimentally validated through comparative experiments. Analyzing the performance of the model from three datasets, among which the TC-ASR and TC-Direct models have better performance. In the original phonemes, the PER and ACC indicators of TC-ASR are slightly better than those of TC-Direct, but both exceed 0.1; The PER and REC indicators of the TC-Direct model are significantly higher than those of the TC-ASR model. In the "extended phoneme" and "extended phoneme+" models, the TC-ASR model showed lower REC indicators than the TC-Direct model, while the PER, PRE, and ACC indicators were higher than the TC-Direct model. Through the above four indicators, it is difficult to distinguish the performance gap between models. The study continued to use the F1 value to measure the superiority of the model's performance. After introducing the F1 value, the TC-Direct model showed the highest F1 value in all three phoneme conditions, indicating that the model had good performance. Not only that, the study also added native accent information, which can enhance the F1 value of the model, indicating that native accent information

helps the model to perform more accurate recognition. To verify the rigor of the experiment, several parameters were validated. Adjust the weight of parameters, adjust the length of phonemes, and adjust the size of the training set. In the experiment, the weight of FAR-FRR has a direct impact on the performance of the model. If its weight ratio is about, the worse the model performance; The length of phonemes does not directly affect the performance of the model, indicating that the model has a wide range of applications; The performance of the model also depends on the size of the training set, and with sufficient training sets, the model can perform better.

VI. CONCLUSION

For the low performance of the conventional speech recognition oral evaluation model, a text priori-based oral evaluation model is proposed. By using the self-supervised learning method to build the acoustic model, the speech recognition and misreading detection are combined to achieve the purpose of error state prediction. The research verifies the performance of the proposed model through Librispeech dataset, L2-Arctic dataset and Speed Ocean dataset. The

experimental results show that the F1 value of the model in the "original phoneme" is 0.538, the F1 value in the "extended phoneme" is 0.554, and the F1 value in the "extended phoneme+" is 0.549; After adding native accent features, the F1 value of the model is 0.550 in the "original phoneme", 0.562 in the "extended phoneme", and 0.555 in the "extended phoneme+". The proposed model has good F1 values in different phoneme datasets, indicating that the model has good performance in phoneme recognition and can improve the recognition performance of English spoken language. In the experiment, the study also verified the impact of the length of the target phoneme on the model performance, and the results showed that the change in model performance was less affected by the change in the length of the target phoneme. The experiment has verified that the performance of the model has a direct impact on the size of the training set. If the model is trained in sufficient training sets, it cannot continuously increase the F1 value, further improving the model's performance, and indicating that the model has a wider adaptability. However, there are still deficiencies in the study. The research did not explore the speech style when it was used for oral evaluation, so the follow-up research needs to preserve the speech style without accent.

Attribute-based Access Control Model in Healthcare Systems with Blockchain Technology

Prince Arora, Avinash Bhagat, Mukesh Kumar
Computer Applications, Lovely Professional University, Jalandhar, India

Abstract—Blockchain and the healthcare sector have a serious concern with context to scalability, which has a challenge of converting arbitrary values to fixed values. The transfer of arbitrary data coming from diverse resources has another point of concern in the blockchain. In this paper, the author proposed a model that will receive data from diverse sources and will convert it to a fixed type of value. The paper also proposes an access control scheme with various permission and consensus level protocols which will allow a reduction in block size with respect to scalability. The consensus level will allow access to the individual or a group of users and the permission level with respect to each block via considering the access granted to nodes of the blockchain. The addition of various permission and consensus levels will allow only a restricted type of data to pass the model. Once the data is verified and approved by various levels, then the data is all set to be part of the blockchain. The paper introduces a model where the time taken to create a new hash is 0.15625 microseconds. A total number of 64 transactions taken from the data set where the throughput is calculated for individual access are considered. After applying the formula, the calculated throughput is 32.5 microseconds. By the lighter block size data can be made available to the patients. The research is for the patients so they can keep track of their medical history and the deaths due to overdose of the medicines can be reduced.

Keywords—Blockchain; healthcare; permission level; consensus level; scalability

I. INTRODUCTION

Blockchains are incredibly popular nowadays. As the name indicates, a blockchain is a collection of blocks associated with a timestamp. It ensures the irreversibility and immutability of the data block. A blockchain technology is a distributed ledger which allows the data to be stored across the network along with the next hash and previous hash. There are some applications of the blockchain like bitcoin and etherium that ensure the correct transmission of the data over the network. Security and privacy challenges arise in the medical field due to rapid growth in data collection and subsequent analysis by a variety of organizations. The devices that relate to the internet or Internet of Things (IoT) data come from various sources. Scalability is a huge challenge that comes with it. Personal Health Records (PHR) are usually owned by the patients; however, they can also be shared with third-parties based on the patient's approval. Medical professionals can use Electronic Medical Records (EHR) to retain and share patient data, but paper-based medical records cannot be transferred across institutions or locations. Healthcare data collection is expected to reach 4.5 billion dollars by 2030. It is expected to expand at a percentage of 26.9 from 2022 to

2030 [1]. It becomes vital to design an online model which helps the patient and the doctors keep track of all the medicines and treatments given by the doctor to the patient. Consequently, third parties must be limited in their access to this data. Controlling who can and cannot access a system's resources is the major aspect of access control.

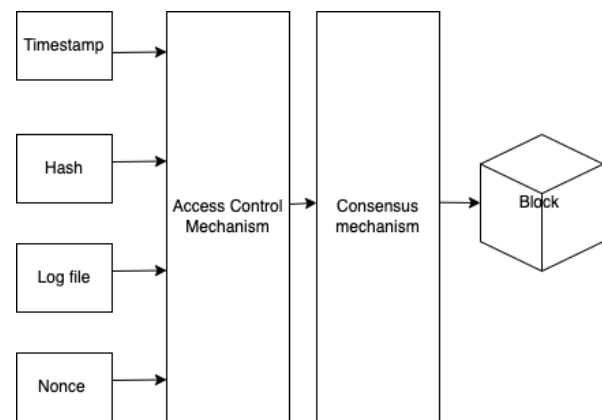

Fig. 1. A log file based access control model.

Personal or medical health data [2] kept by many parties, and which may be required for third-party access to third-party aims (such as medical or insurance companies), is a difficult task to manage. The data collected from heterogeneous sources is difficult to manage for any insurance or medical organization. This is due to the complexity of the data and the need to make it usable for the organization. Obtaining and normalizing the data from diverse sources requires considerable efforts, making it a challenging task for organizations. Interoperability is the major issue that comes up in this matter. The availability of the data cannot be achieved without the attribute-based scheme.

A timestamp embeds the time of the transaction. Fig. 1 explains the basics of the access control model. A hash value is used to ensure the uniqueness of the transaction. A Nonce is a randomly generated 32-bit number that is used by miners to adjust the hashing of a block and make it valid for use. Once the perfect nuance is found, it is connected to the hashed block. The log file is a part of the proposed model that stores the calculation of the address. By using this calculation, the next address can be allocated to the chain of the blockchain model. An access control mechanism is used to collaborate on the attributes of the block. Thus, the blockchain can have a unique value that easily differentiates the block with other blocks.

To resolve the issues related to address control in a huge system like e-Health, a technique is proposed in this study as shown in Fig. 1, which allows data to be accessed with various levels of authorization and granularity. Adding, updating, or removing rights to their data should be easy for the data keepers to do. Permissions should be able to be defined at the user and source level with sufficient precision in such a system.

An overview of access control in e-Health systems, focused on blockchain technologies for access control, is provided in the first section of this paper. In the following section, a breakdown is found for the intended solution architecture. As a next step, few essential components for building a working model are discussed. There are also a few concluding comments that summarize the contributions and hint at future advancements. The issue related to the healthcare field is the huge amount of data coming from diverse resources. Data management is a huge task, and, if any patient wants to fetch their medical history from the offline database, it would be even more difficult to find the data in a quick time. Another issue is the maintenance of centralized storage, which has various overhead issues and a high reliance on servers. To ensure that the data is available on time and at every end, the blockchain technology is used for the work.

Purpose and need of the study: The study is important because once the patient has undergone some treatment from the doctor, it is important that the medical health history being maintained by the patient and the doctor as well. If the patient is not satisfied by the treatment of the doctor, patient changes the doctor and it becomes vital for the patient to know what medicines or injections are already given to the patient, it can be maintained through Electronic Health Records (EHR). With the help of EHR data can be stored, in a blockchain based system which allows the availability of the data at patient end. When the patient changes the doctor, patient should be having the updated medical history available all the time so that it will be easy for the new doctor to understand the patient history. Every doctor who has done any treatment of the patient has to fill the attributes. The system works remotely and ensures the availability of the data. By using this, data can be made available to each end and access can be granted based on access control mechanism used in the proposed model. The model can be embedded with a variety of technologies like: Internet of Things (IoT) and Artificial Intelligence (AI). By associating these technologies with blockchain the medical record collection can be more automated; where if a patient has gone through X-Ray, the record can be automatically recorded in the EHR. A block in the blockchain typically consists of approximately 2000 transactions. To make the node lighter, reducing the size of the transaction can be beneficial. Gas amount is used to operate the blockchain, and a limited amount of gas can be passed. Heavy nodes with duplicate values allow only a few nodes to be connected to the blockchain; on the other hand, light nodes have less total weight, requiring less gas to operate the blockchain, allowing for more nodes to be added to the network [3].

Limitations of blockchain scalability: The scalability of current blockchain technology is limited by its transaction throughput, cost, network latency, data storage, and energy consumption. As the number of transactions grows, the cost of running a blockchain increases and the data stored on it becomes more difficult to manage. Furthermore, the time it takes for a transaction to be validated and added to the blockchain is too long, and the consensus algorithms used by blockchain networks are often very energy intensive. All these factors demote scalability.

The paper is arranged as follows: After the introduction section, the advancement of blockchain for healthcare, in Section II, Literature Review is discussed on blockchain and healthcare. Section III focuses on data sets where various attributes are taken to show the results and it discusses the proposed methodology to achieve the goal. Section IV talks about the evaluation parameter. Section V focuses on how the model can be developed. Section VI focuses on implementation of the proposed model. Section VII presents the results and discussions and Section VIII summarizes the paper.

II. RELATED WORK

To find and analyse the results of the various existing models and compare them with the proposed model, various models are studied. The literature review is discussed in the related work section, where several existing models are there, and the results are compared in the final section. Ayache, M. et al. [2], proposed a Decentralized Accessible Scalable and Secure (DASSCare 2.0) model that works on real-time health monitoring that route all the data from various resources and makes it available to various end users, which allows the collaborative health monitoring and maintains the bills paid by the patient. The model gives an extra edge to other frameworks. Using a distributed database is a consensus of shared and synchronised digital data spread along a set of nodes. Contrary to popular belief, however, not all decentralized ledgers are in fact distributed ledger technology (DLT). The duplicity is high when the data is shared across various blocks.

Karaki, A. et al. [3], proposed a Decentralised Accessible Scalable and Secure (DASSCare) model which is a decentralised framework, which is scalable and accessible. It allows real-time access of data that comes from diverse resources. To maintain this, the generated clinical data is signed. The sign ensures that the type of data coming from diverse resources is of the same type, and then it is considered. This framework solves the problem of real-time access of medical records in healthcare, which is a primary part of the work and ensures that privacy is not compromised.

The healthcare data stored on various resources is a difficult task to be followed. Mira, S. et al. [4] proposed a CrowdMed model that works on managing the data and, to ensure the data is in the correct format, a review team is assigned. The data reviewer resolves two issues: one is to resolve the issues coming from diverse resources and the other is to make data more homogeneous to ensure the scalability of the chain across the network. In this

framework, the patient has full access to the data, so if the patient has taken any medical treatment of his own, the data can be updated by the patient itself.

The CrowdMed model allows the data reviewer to review the data and the data is reviewed at different ends simultaneously. Tampering of data is a prime concern that is associated with the CrowdMed model. To overcome this, Hu, C. et al. [5], developed a scheme CrowdMedII where the smart contract allows only insertion in the model. The healthcare workers are not allowed to update the data. By this, the data quality can be improved and the chances of tampering of data from diverse resources can be made more specific. The disadvantage is also associated with the model, which requires a lot of space.

Developed by Nakamoto, S. [6], the blockchain is a distributed record that serves as the foundation for the Bitcoin digital currency. Digital signatures and digital fingerprints (hashing) are two methods that can be used to ensure the integrity of data and prevent tampering with data. The ledger must be secure from malicious attempts to undermine it as well as from peers submitting incorrect data, computer/network failures that are only partially or fully finished, or even by peers providing incorrect data out of ignorance. The blocks that make up a blockchain contain data on transactions. A digital signature is attached to each one of these transactions. Using this method, a state transaction system (state machine) is implemented, in which every node adds a snapshot to the existing model to various existing models. The peer-to-peer network relies on a proof-of-work concept to move to consensus on a block's validity. There are various alternatives to proving work. The block that is to be pushed inside with various existing timestamps allows the transaction to be a unique transaction.

Blockchain, according to Buterin, V. et al. [7], is divided into three parts: public, private, and consortium. Unlike private blockchains, public blockchains (e.g., Bitcoin) are accessible to anybody who wants to read them, send transactions, and expect them to be added if they are genuine. "Fully-private blockchains" where the participants (e.g., a supply chain) are called "fully-private blockchains" since the write permissions are centralized within a single organization (even if they are spread across multiple facilities). An open blockchain may or may not restrict who has access to perform blockchain queries. To ensure that the access control mechanism is working well, identity is confirmed from where the data is fetched.

Salman, A. et al. [8] granted a controller which indicates that the identity is genuine or not. The address of the sender can be used as a certificate and attached with the complete model to ensure that the transaction is authentic or not. This scheme is an identity-based scheme where the identity of the sender acts as a certificate and allows only the verified transactions to be approved from the end. Nakamoto, S. [5] introduces the concept of "blockchain," a distributed ledger technology that allows data to be transferred from one node to another while retaining a copy in the user's node rather than storing all data in a single shared database. Maesa, D. et al. [9], present a paper which is based on bitcoin. The

access control mechanism is based on the resources that are being used for the transactions of the blockchain. The XACML (Extensible Access Control Markup Language) is used to develop the code of the resources that allows the end resources to access and transform similar types of data.

Castiglione, A. et al. [10], proposed a model that is a device-based model. Various types of data are made available at various points. Different duties are allocated to various devices that play different roles in the transaction. Each device has its own restrictive access control mechanisms that allow only quality data to be inserted into it. To handle IoT devices, Novo, O. [11] proposes a distributed blockchain-based permission method. The work included a unique concept to prevent integrating blockchain with IoT devices, which is the major part of the model. This approach correlates the use of blockchain with IoT, particularly for devices with limited resources. Fair Access is a blockchain-based authorization mechanism described by Ouaddah A et al. [12]. Smart contracts were utilized to exchange access tokens for the fulfilment of access control protocols. The authors incorporated various IoT devices into the blockchain and investigated the issues of real-time permission and the efficiency of the scheme.

Using a smart contract, Xu, R. et al. [13] suggested a decentralized, federated capability-based access control method. The technique was used for multi-hop delegation and was also reliable and scalable. Based on objectives, models, architecture, and mechanisms, Ouaddah. A et al. [14] gave a complete review of various access control methods. The report also focuses on the various taxonomy-based author reviews and the advantages and disadvantages of each are discussed in the model. Novo, O. [15] proposed scalable decentralised access management for IoT devices based on blockchain technology. To avoid network overheads, the architecture removed IoT devices from the blockchain-enabled network. In terms of IoT access control, the system has various advantages, including accessibility, parallelism, lightweight, immutability, scalability, and transparency. This framework has managers that allow IoT devices to be registered and verified. Although this method achieves scalability by distributing query rights through management hubs, it faces various security risks.

Dorri, A. et al. [16] advocated leveraging private blockchain technology to provide a lightweight architecture for protecting the IoT. The proposed method ensures security with an access control permission list and their design, including various models. All the devices based on the model are mined by miners. This approach has control of the policies in the header part of the policy. It does not use a Proof of Work (PoW) concept to ensure its uniqueness. They claimed that the solution's overheads are modest in comparison to the security benefits. By concentrating on user preferences, which can find access and denying methods, Touati, L. et al. [17] suggested an activity control method (a broader version of context-aware access control). For dynamic access policy adaption, ciphertext-policy and a finite state automaton are used to keep track of all the updates in the network. By analysing the logical approach to trust computation from language-

based information received from IoT devices, Mahalle, P. et al. [18] proposed an energy efficient architecture which is both energy efficient and dynamic in nature. An individual or a group with the authority to provide access to privileges and resources can be easily accessed. The Table I compares the different models studied in literature review.

Zhang, R. et al. [19] suggested a sensor network-specific distributed privacy-preserving access control method. It requires users to have a token from the owner and then request sensor data, which is supplied after the token is verified. To prevent the reuse of tokens, which would allow unwanted access, they deploy a distribution token reuse detection system. Their focus was on preserving privacy and they did not consider access control settings for end devices. Access Control In current operating systems, Access Control Lists (ACLs) are a typical method of controlling access. An ACL lists people who have access to an object, as well as the amount of access (or privileges) they have. Alternatively, other systems employ an Access Control Matrix, which consists of rows and columns, where a column denotes an object and a class denotes a subject. Health care is a good example of the use of Oole-Enabled Access Control and privileges linked with those roles are used to determine a user’s access rights in RBAC. The consortium’s XACML can be used to express Attribute Based Access control Model (ABAC) policies Access control systems can be designed and implemented using the XACML standard’s reference architecture that defines the system components and usage flow. More expressive access control policies can be defined using Entity-Based Access Control (EBAC) [27], another commonly used technique. Both attribute value comparisons and relationship traversals along arbitrary entities are supported, so this is possible. There is also an authorisation system that provides realistic policy language and an assessment engine for the system. Application of Blockchain to Access Control One solution to the issue related to access control in e-health is based on blockchain technology. According to Maesa. D et al. [9], the XACML standard architecture can be used to construct Attribute Based Access Control on top of blockchain technology for access control. Using Bitcoin as a base, this strategy can be proven to work.

TABLE I. RESEARCH PAPERS CONSIDERED FOR THE LITERATURE REVIEW PURPOSE

Name of Authors	Model Name	Access Control	Blockchain Enabled	Permission Control
Ayache, M. et al. [2]	DASSCare 2.0	Yes	Yes	No
Wang, T. et al. [23]	Audit Model	Yes	No	Yes
Karaki, A. et al. [3]	DASSCare	Yes	Yes	No
Salman et al. [8]	Access control list	Yes	Yes	No
Novo, O. et al. [11]	Blockchain based	Yes	Yes	No

	permission control method			
Novo, O. et al. [15]	IoT Access Control	Yes	Yes	Yes
Maesa, D. D. F. et al. [9]	Extensible Access Control Markup Language	Yes	Yes	No
Dorri, A. et al. [16]	Permission Control	Yes	Yes	No
Ouaddah, A. et al. [12]	Fair Access	Yes	Yes	No
Bogaerts, J. et al. []	Entity Based Access Control Model	Yes	No	No
Castiglione, A. et al. [10]	Attribute Based Access Control Model	Yes	Yes	No
Zhang, R. et al. [19]	Network Specific Access Control	Yes	Yes	No

However, in the e-Health context, this method does not consider the possibility of having several authorities and/or companies as the resource owners.

A Healthcare Data Gateway (HGD) blockchain model can be used for e-Health by Chen, Y. et al. [20] has the capability to store patient records where patients can keep track of their medical history. The patient’s history is recorded on blockchain as part of this solution. I. Baldine et al. [21], has a solution to the issues raised in the previous paper, despite the uniqueness of this strategy, it is likely to need a significant amount of time and effort to implement, which may put the current utility of this method into question. If the patient is unable to enable the access, or if some governmental regulations require that the data be accessed without the patient’s permission, then this solution has no capacity to do so (e.g., some family members allow the data access). Keeping e-health data on the blockchain will cause its size to explode, far beyond the capacity of currently available hard drives, necessitating the purchase of specialized hardware for full nodes and possibly even leading to the centralization of the blockchain.[28,29]

III. MATERIALS AND METHODS

The dataset which is used for the implementation is taken from Kaggle, which consists of a huge variety of databases related to EHRs. Data is gathered and, as per the model, the data is converted into a decision-based format where the data can be made available for the blockchain construction. The description gives an overview of the dataset and focuses on various attributes used for them [22]. The data set consists of various attributes to maintain the patient records. The data set is based on the chronic kidney disease of the patients, which requires the medical history of the patients to be stored so that if the patient is undergoing some surgery or treatment, the data can be accessed from

the EHR that maintains the history of the patient. The detailed description of the dataset taken into consideration for this study is given in Table II.

TABLE II. DETAILED DESCRIPTION OF THE DATASET USED FOR THIS STUDY

Attribute Name	Domain Values	Attribute Name	Domain Values
Gender	{0=M, 1=F}	HTNmeds	Range = {0, 1}

This is a dataset of electronic medical records of 491 patients collected at Tawam Hospital in Al-Ain city (Abu Dhabi, United Arab Emirates). The patients included 241 women and 250 men, with an average age of 53.2 years. Each patient has a chart of 22 clinical variables, that expresse her/his values of laboratory tests and exams or data about her/his medical history. The attribute starts with patient name and is based on various attributes like doctor and medicine. The patient record is based on the updating done by various doctors and patients. The dataset contains the information of attributes related to the patients and the results are calculated based on that data. The record of the patient can be updated by the doctor and if any medicine is given to him that must be added to the chain. To achieve scalability, the block of the blockchain is compressed by using various hashing techniques. The attributes are defined in the model so to ensure the fixation of the inputs prescribed by the doctor.

IV. EVALUATION PARAMETER

Wang, T. et al. [23], proposed a model. The paper also includes various factors by which the model can be evaluated and compared with the other models that are based on various factors like execution time, latency, and throughput. Xu, Z. et al. [24], evaluates the performance of the model based on the time that it takes to generate the hash, the amount of delay that is required to keep the transaction and the time required to complete the transaction. Description of each evaluation parameter is discussed in Table III.

TABLE III. DIFFERENT EVALUATION PARAMETERS OF PROPOSED MODEL

S. N	Evaluation Parameter	Description of the parameters
1	Execution Time	It is the time taken as the difference between once the transaction is confirmed and the execution of the blockchain.
2	Latency	It is the time taken by the system that waits for the other system to complete the action.
3	Throughput	It is the amount of data that can be shifted from one block to other block of the blockchain in a unit of time.
4	Performance Assessment	It is the measurement done on the models by providing the described hardware and can be calculated based on time frame.

To understand how the proposed model performs, various users can apply operations on the blockchain-based model.

All standard paper components have been specified for three reasons: (1) ease of use when formatting individual papers, (2) automatic compliance to electronic requirements that facilitate the concurrent or later production of electronic products, and (3) conformity of style throughout conference proceedings.

V. PROPOSED ATTRIBUTE-BASED ACCESS CONTROL MODEL

After Access control Data management is used to ensure that the data coming from various sources must have an arbitrary value that is difficult to handle. The model will ensure that the data coming from various resources is converted into fixed values. The model access controller establishes a relationship with various subjects and objects, which ensures the data can be easily stored and passed through the blockchain model and creates a block. The methodology works on various entities like permission levels, data keepers, policies, and records [25, 26]. The proposed attribute-based access control is given in Fig. 2. Classes and entities of the proposed attribute-based access control are discussed below:

Entity (UID): The entity contains the records of the various transactions, read, write or any other. Whether the

entity should be given read, write or read/write access, is maintained in the record file.

Data Keeper: The data keeper keeps track of all the access granted so that it can be compared with the upcoming transactions. It records the various levels of the permissions that can be granted to the various entities of the model. The type of the access granted to the entity is also decided by the data keepers.

Policies are rules and regulations that govern which types of access are granted. Policies are based on permission levels and consensus levels, which are useful for filtering the data. The consensus level policy, which is based on permission level, requires Unique Identity (UID), record and permission level to fetch the data. Once the UID is compared and verified, the permission is granted based on levels and the consensus level policy works on UID, record and the type of permission granted. Various policies can be created to improve the quality of the blockchain model. The policies correlate various data keepers with their permission level. Some exceptional cases, like if a patient wishes to have a medicine without the permission of the doctor, can also be considered in the patient's record history file. The permission level defines various types of permissions that can be read, written, or both read and written. The access, once granted, is compared with the access required by the transaction to be verified and completed.

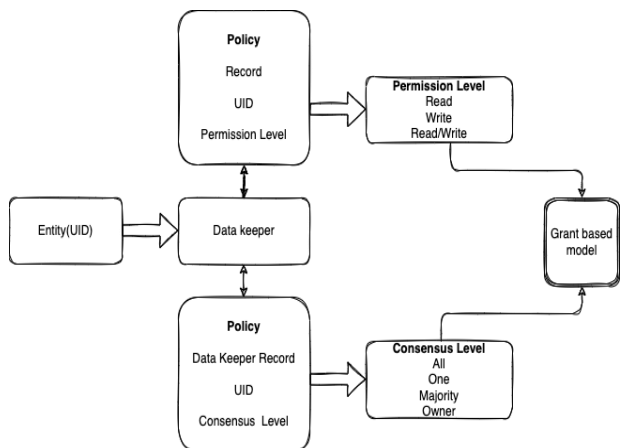

Fig. 2. Proposed attribute based access control model.

Grant based Model Structure: Model of Access Control
 There are many entities and relationships that must be defined before a model can be created. Fig. 3 shows such a model, and it may be used to classify objects into five different types. There are three types of access that can be granted to the model, like Read, Write, and Read/Write. The data keeper keeps a record of all the data and ensures that only authentic people can access it. The data keeper tracks the UID, consensus, and pointer to maintain the integrity of the record as well. This also prepares a policy to provide more validation to the access by checking the record and entity and allocating a certain permission level. The permission level can be read, write, or read and write as well. By ensuring this, the quality of the access mechanism can be enhanced and not every type of transaction can access all types of data in it. Each policy with various

permission levels generates a particular consensus level which allows the model to get restricted input from various channels. The state machine can also be a useful part of the model. This machine gives an inside view of how the permissions are granted by the data keeper. Fig. 3 indicates that once the transaction is inserted into the model, it must pass through various blocks like request, verify, and require.

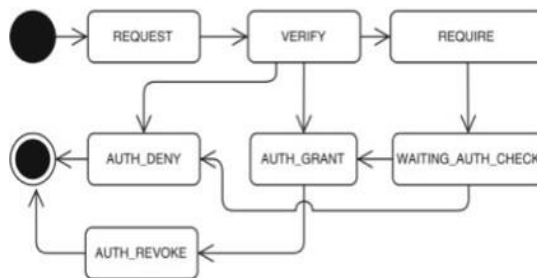

Fig. 3. Grant based access model.

The request block allows the block to be requested and verified by using the properties of the blockchain like: irreversibility and immutability. The verification also checks the hash value of the block. The hash value is compared with the previous block hash value then it is a valid transaction. Once the verification is successful, the access is granted and the transaction is performed. The verify block in the model also has the power to deny the access when the requested block does not match the hash value in further. If the access granted is only a write operation access that usually is given to the doctors of the hospitals then the medical history of patient can be written. Once the updating in the record is done by the doctor then the revoke operation can be performed on the transaction. After the verification of the hash values time stamps are compared with the previous block, if there is a scenario where any other specific requirement is there. The hash value matches but the issues are there in the timestamp, in that case the transaction is sent to the waiting state that will wait for the grant condition to be performed on it. Various parts of the block model for blockchain structure are mentioned in Table IV.

TABLE IV. NUMBER OF CASES AND THE REDUCTION IN EXECUTION TIME

S. N	Components	Description of the components
1	Index	Represents the present index of the block
2	Timestamp	Represents the time when block is generated
3	Previous Hash	The hash of the previous block
4	Digital Sign	Cryptographic hash of the most recent data block
5	Data	This block's content. Access control policies, records information, and individual authorizations are all described in this set of transactional data

6	Nonce	For a block's hash to include leading zeroes, it must have this value set. Iteratively, the value is implemented until it is completed and discovered to meet the requirements. The correct nonce value is proof of effort because it takes time and resources to get it right
7	Hash	<p>Hash of the block data in SHA256 form. The effort of the proof-of-work is defined by the leading sequence of this hash, which must be predetermined. Additionally, the data field must be comprehensive because it serves as a repository for transaction information. There are three sub-fields that make up this data category:</p> <p>a) A record is a piece of data pertaining to a certain state machine transaction, such as the creation, modification, or deletion of an e-Health record.</p> <p>b) Information on the creation and revocation of access policies related to transactions in the state machine shown in Fig. 2. Transactions relating to individual authorization by each of the Record Data Keepers in connection to each Policy.</p> <p>c) There is no need for a central authority because any change in data would result in a new hash, which would invalidate the next blocks on a chain of transactions that is immutable without a central authority. Accountability and auditability are additional possible outcomes. Assuring the authenticity of each block on the blockchain is done by assigning an individual key pair to each entity with access to it</p>

the access that is being demanded by the transaction. The role of patient is just to have a view of the data so the access read is required all the time. Consider a situation where the patient wants to write the medical record but not mentioned in the peers. In that situation, low level access is given. The reason why these protocols are being added to the model is that once the data is being transferred to the block chain the data should be of fixed type that is being approved by various peers.

When the high-level access is being granted, in that case the transaction has passed the peers and it can move to the blockchain as shown in Fig 4. The blockchain easily accepts the type of attribute based fixed transaction. The algorithm also defines some roles which includes insertion, updating and deletion of the data. While working with various operations, the add functions inserts a value along with the parameter passed to the function.

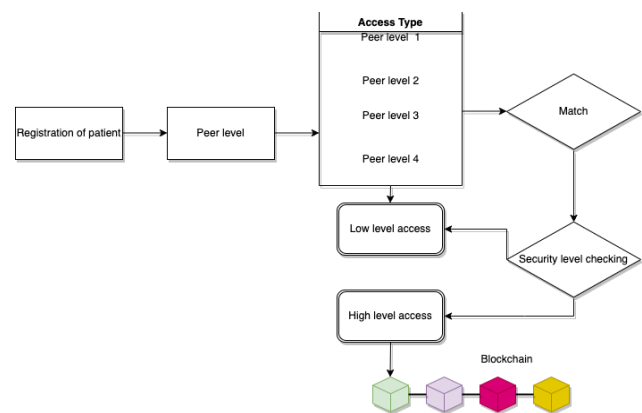

Fig. 4. Methodology of designing attribute-based access control model in healthcare system.

VI. IMPLEMENTATION OF PROPOSED ATTRIBUTE-BASED ACCESS CONTROL MODEL

The model starts with registration of the patient in the system; various peers are the sources from where the data is originated. To ensure that the access control mechanism works well, the levels which are discussed in Fig. 2 ensure the type of the data that will only be allowed to be inserted in the node. In Fig. 4, the security level object ensures the type of the access provided by the system to the framework. The security level checker matches the access type from which the access is being granted and the type of data which comes from various resources with various access rights. If the data matches the access granted and the access demanded by the transaction coming from the source, the access is considered as high-level access. The peer level stores the access related data, when the data requirement comes from any patient or the doctor, it is compared with

The limit for the passing of the arguments can be at most the total number of the patient attributes. Except the doctor one is not allowed to insert the data into the blockchain environment. Once the data is verified, the registration number is updated with 1. Suppose, if the patient has taken medicine after doctor prescription 76 times the new entry where the data is added can be considered as 77, also if the patient has taken medicine by his own consent, the database is required to be updated. The OR gate allows that both the doctor and patient is capable for the necessary modification in the record. The updating can be done with the update function record but more validation check is being added to it. If the sender of the data is the concerned doctor or the patient, then the other condition is checked and verified. The patient ID is compared with the existing ID available of the patient that allows or denies the updating of the data. Once the criteria meet both the conditions, the data can be updated otherwise the data needs to be on hold for the upcoming transaction.

Algorithm 1: Algorithm used for attribute-based access control Model

```
Add Data:
method Add Patient Record (var1, var 2.....n)
if (record.input = = doctor || patient || healthworker)
  Regist_ID = Regist_ID+1
end if
end method
Data added successfully
```

```
Update Data:
method Update Patient Record (var1, var2.....n)
if (record.input = = doctor || patient ||healthworker)
  and if (id = = patient id)
  then Update patient_record
end method
Data updated successfully
```

```
Delete Data:
method Delete Patient Record (patient id)
if (record.input = = doctor)
  and if (id = = patient id)
  then delete patient record & Abort
Set Record =Record-1;
end method
Record deleted successfully
```

The deletion of the data depends on the id verification, the patient ID is compared with the existing ID, once the ID is verified then the deletion of the data can be processed. Inside the method, if the data is sent by the doctor and the patient ID is verified to be true, the account of the patient which is also considered as a block is verified as true as shown in algorithm 1. The record set is decreased by 1. One block in the blockchain contains the record file which consists of the total values used in the block. The value of the record is decremented by 1.

VII. RESULTS AND DISCUSSION

The focus of result is on data calculation and on that basis the performance of the blockchain is calculated. The section explains the metrics based on those metrics the results generated by the models can be compared and evaluated with the other models. The results prove that the performance of the model can be enhanced based on some inputs. The performance can be improved as when the hash value is generated with high participants, the chance of getting the maximum digits of the model can be same. The model allows the performance to be enhanced based on increase in number of users.

Execution Time is the time taken for the process to be completed. It starts with the initialization of the transaction with the completion of the transaction. The hash value is generated by SHA-256 algorithm in the blockchain. The average time taken to generate the hash value is 3ms and if the transactions are 100 transactions, 300 ms would be taken to complete the transactions.

Case 1: Let us take a hash key that is of 64 bits and the generation of 100 hash values will take 300 ms. By applying the proposed model various improvements can be done in the existing blockchain model. This case covers the cases and assumes that if the value of hash next evaluated hash has a single bit change.

Hash Key =
8F434346648F6B96DF89DDA901C5176B10A6D83961D
D3C1AC88B59B2DC327AA4

- Total number of digits used by Hash = 64
- Generation of 100 Hash values will take 300 ms
- Total number of digits for 100 Hash values =6400
- Time consumed for one bit Hash Key generation= 300/6400=0.046875
- Block size generation after applying attribute-based log file model

Case 2: Let us take a Hash Key that is of 64 bits and the generation of 100 hash values will take 300 ms. By applying the proposed model various improvements can be done in the existing blockchain model. This case covers the cases and assumes that if the value of hash next evaluated hash has all the bits changed as written in Table V.

Hash Key =
8F434346648F6B96DF89DDA901C5176B10A6D83961D
D3C1AC88B59B2DC327AA8

- Number of digits modified in the block=1 Ratio of digits =1/64
- Total number of digits used by Hash=64
- Generation of 100 Hash values will take 300 ms
- Total number of digits for 100 Hash values =300
- Time consumed for one bit Hash Key generation= 300/300=1

One out of 100 cases exists in the model the results can be improved by transferring the data from 1/100 which makes 99.015625 to 1. Increase in number of cases will improve the quality of the algorithm as compared to another non-attribute-based model.

Average Execution Time=Total Execution Time/Total number of Transactions.

TABLE V. NUMBER OF CASES AND THE REDUCTION IN EXECUTION TIME

Numbers of Cases	Execution Time	Growth Rate
1	99.015625	0.0984375
2	98.03125	1.96875
3	97.046875	2.953125
4	96.0625	3.9375
5	95.078125	4.921875

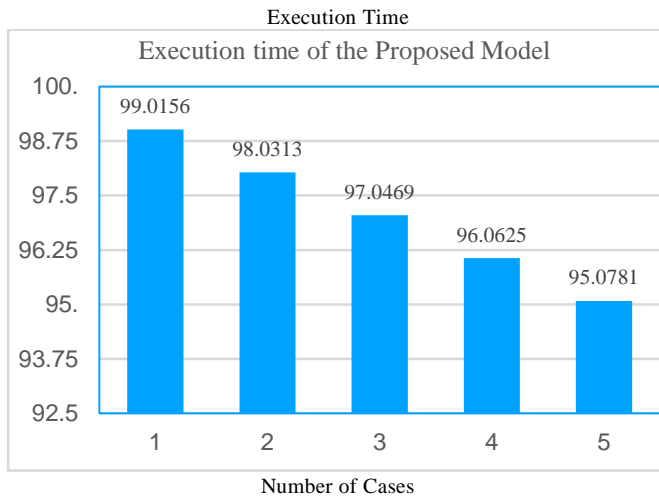

Fig. 5. Execution time of the proposed model.

Average Latency: It can be calculated by the difference between the request sent and the response generated by the model. However, the latency of the model is calculated by JMeter. In Fig 5, it is clearly visible that execution time is reduced after each bit change. The average latency can be measured in the context of milliseconds. The average latency can be measured:

Average Latency = Time taken to update Hash/Number of Hash bits

The performance of the model is also evaluated by accessing the size and cost of the generated Hash value. The transaction payload can also be accessed by the transaction size.

TABLE VI. NUMBER OF CASES AND IMPROVED LATENCY

Hash size	Change in hash bits	Time taken by existing model in ms	Same bits in hash value	Proposed model
64	4	64	60	0.0625
64	3	64	61	0.046875
64	2	64	62	0.03125
64	1	64	63	0.015625
64	0	64	64	0

One Hash code is of 64 bits, the time taken to 1 bit Hash = 1 sec,

Time taken to update 64-bit Hash =64 seconds

Latency of log-based model =1/64=0.015625.

Time taken to generate the 2nd Hash Value=0.015625 + 2nd Hash value

Throughput is the amount of the data to be passed from one location to the other location. The throughput can be referred based on time and data. Only a single hash bit is required to be changed and the throughput time can be reduced by the possible number of favorable cases.

Throughput = Time taken to get result/Number of units.

A total number of 64 transactions taken from the data set where the throughput is calculated for individual access is considered. After applying the formula, the calculated throughput is 32.5 ms. The value of throughput can be considered as 32.5 ms. The average throughput can be considered as 32.5/64 which is 0.5078125ms where 32.5 is the sum of the throughput of the total 64 cases and the number of total cases is 64. The average latency of the 64 units can be calculated as 32.5/64 which is equivalent to 0.5078125ms. The proposed framework works better when the complete data set with 64 different values are applied to it. With the existing model the throughput is considered as 1 ms but the proposed model improves the average throughput by approximately 49 percent. The Table VI demonstrates the reduction in the time taken to construct the hash.

Different parameters are discussed that are based on which comparisons can be made without compromising the security and privacy of the model. After incorporating these parameters, the model can be further optimized as demonstrated in Table VII.

A. Scalability

Scalability is considered as the ability of the system never degrades once the data is increased or decreased. Scalability requires a permanent solution of the problem. The proposed system reduces the block size which makes the chain light in size. The logic behind the model is that the data stored in blockchain is comparatively lighter than the actual data. The log file associated with it keeps the load light and enhances the scalability of the network. This is also ensured that the security is not compromised while enhancing scalability.

B. Access Control

By adding the access control mechanism it is ensured that the restricted amount of data is required to be passed from the model. The definition of the roles is defined and data is passed from the chain. This not only promotes the security but also when the data is verified and passed the mechanism converts it into fix set of values. The fix data is forwarded to the blockchain model easily. This promotes scalability as well as security.

C. Security

The security is one of the prime attributes of the blockchain. The model allows the arbitrary values to be cross verified by the attribute-based model. This proposed model uses various permission and consensus levels to ensure the security of the model. Only authentic data is required to be transmitted from one node to other. Moreover, the data becomes even secure using blockchain technology because of its temper-proof and immutable nature.

TABLE VII. COMPARISON OF PROPOSED MODEL WITH RELATED WORK

Parameter	DASSCAR E 2.0 [2]	Permission Control Model [11]	DASSCare [3]	CrowdMed [4]	Proposed Model
Scalability	High	High	Low	Low	High
Access Control	High	Moderate	Low	Moderate	High
Security	High	Low	Moderate	High	High
Data Integrity	Moderate	High	High	High	High
Access Control	Moderate	High	High	High	High

D. Integrity

Integrity is the trustfulness of the system which can be easily achieved by the blockchain technology. The stored information can never be changed by unauthentic channel. Integrity allows the information to be available to end users like doctors and patients. The developed smart contract does not allow any entry to change the values of the model. The access control model is responsible for managing and making the data available at each end.

E. Data Confidentiality

Data Confidentiality: The patient's medical records are stored and are confidential from any third-party disturbance. All these types of data are made available to the doctors and the patients. The patient data include various reports like blood group, records of X-Rays and Magnetic Resonance Imaging (MRI) scans. Smart contracts make this confidential as it consists of some strict rules placed inside it. The privacy can be ensured by using blockchain as well as the access control mechanism.

VIII. CONCLUSION

A solution to the challenge of managing access control in an e-health ecosystem has been described in this paper. This paper describes a solution to the problem of managing access control in an e-health ecosystem. Access control in e-health is particularly difficult because resources and data are dispersed across various places and institutions. The problem is exacerbated by the fact that not all e-health resources are owned by a single organization or individual. To establish the correctness of the scheme idea, a proof-of-concept had to be built and implemented. Success was largely due to proof-of-concept. Even if they are preliminary, some functional and application tests and validations verify that the technique is sound. Overall, we believe the technique is feasible, with numerous advantages over existing systems when compared. The benefits of this system include, but are not limited to, the fact that access control policies are communicated and synchronised across the consortium's institutions and organizations, assuring

their integrity, transparency, and authenticity. The paper introduces a model where the time taken to create a new hash is 0.15625 microseconds. A total number of 64 transactions taken from the data set where the throughput is calculated for individual access are considered. After applying the formula, the calculated throughput is 32.5 microseconds. By the lighter block size, data can be made available to the patients. The research is for the patients so they can keep track of their medical history; and the deaths due to overdose of the medicines can be reduced. The future work of the proposed model includes finding more computational forces to make the blockchain size lighter and more scalable. Additionally, access control mechanisms should be implemented to ensure the integrity of the data coming from various sources.

Abstract—This paper presents a new design of optical NOR and XNOR logic gates using a two-dimensional-hexagonal photonic crystal (2D-HPhC) that allows for both Transverse Electric (TE) and Transverse Magnetic (TM) polarization modes. The structure is very small in size and has a low delay time. The design includes three inputs (A, B, C) and one output (Q) waveguide, with the NOR gate having a delay period of 0.75 ps and the XNOR gate having a delay period of 0.9 ps. The contrast ratio between the input and output for both gates is 7-8 dB. The XNOR gate has an optimum transmission signal rate of $T = 96\%$. The purpose of the structure is to use a reference input to create the fundamental logic gates NOR and XNOR by adjusting the signal phase angle.

Keywords—Photonic crystal; hexagonal lattice; NOR; XNOR; transverse electric; transverse magnetic

I. INTRODUCTION

Future electronic circuits will have speed constraints due to the growth of telecommunication systems to enhance the speed and bandwidth acceptable for data transfer (frequency). In optical networks and signal processing systems, high-frequency, all-optical logic gates are essential. All-optical logic switches and gates are among the basic components for designing future information processing systems and optical networks. Using optical networks, speed and capacity limits in communication networks are solved [1]. Optical crystals are considered a suitable structure in optically integrated circuits due to their compressibility. For the implementation of all-optical logic gates, several architectures have been suggested thus far. Logic gates through linear and nonlinear photonic crystals have gotten special attention in order to ease the integration of the suggested architectures [2]. A logic gate in a digital system executes a logical operation on one or more rationale inputs before producing a rationale yield. All digital circuits often employ Boolean logic, which is the foundation of this logic. Logic gates use binary logic, mostly made of transistors and diodes in electrical devices.

Photonic crystals are alternating structures on the nanoscale and affect the motion of photons due to changes in the refractive index of the components and the proportional wavelength. This is what semiconductor crystals do with electrons. Similar to how the Schrodinger equation involves electrical potential, the refractive index plays a part in the Helm-Holtz equation. The periodicity in the refractive index, more or less within the crystal, serves as the foundation for photonic crystals. The wavelength of the photons affects how they are emitted inside these structures. Modes are the light

wavelengths that are permitted to move. A group of diffuse fashions forms the bandgap. Unauthorized bands of photonic crystals are called bandgaps. If we have materials of the dielectric material, which have a forbidden band for photons, at a certain frequency range no light can move inside the crystal structure of matter. The most important difference between photons and electrons is their velocity. Electrons belong to the group of fermions due to their incorrect spin, and the Pauli Exclusion Principle governs them. In contrast, photons have the correct spin and are considered bosons, so there is no limit to the number and energy of photons in the crystal. The effect of photons on each other is much less than the interaction of electrons, which reduces losses in dielectrics. Because the shrinkage of optical circuits faced problems such as energy loss, photonic crystals have been proposed to solve this problem. Defects in photon crystal structures can be created and based on the defects in the photon crystal lattice, these structures are divided into three categories: one-dimensional, two-dimensional, and three-dimensional [3].

Due to the use of photonic crystals to make all-optical logic gates and their use in all-optical systems, structures with low losses and high efficiency are required for all-optical logic gates. The proposed structure for all-optical logic gates based on photon crystals should have small dimensions (for integration), low losses, and a suitable distance between to be logic surfaces. In addition to the above, the working wavelengths of the proposed structure should be in telecommunication windows so that these logic gates can be used in filters, switches, sequential circuits, and all-optical composite circuits. Given the importance of processing speed, bandwidth, and dimensions in today's all-optical integrated circuits, it is necessary to provide a structure with such specifications. In this research, we will try to design and simulate a structure with the mentioned capabilities, and the proposed structure will be flexible and will change the type of logic gates with a small change in the arrangement of dielectrics. The initial structure proposed is the NOR logic gate, based on a photonic crystal, the subsequent gates being designed by trial and error and the experience of previous articles in the field.

Today, the demand for high bandwidth to reduce the speed limit of electronic devices is increasing rapidly. Optical signal processing requires complex logic gates. To build all-optical systems, it is necessary for all the components used to be able to work in the optical network. Gates are key components for building all-optical systems. In order to convert digital gates into all-light gates, changes in the original design are needed.

To design all-optical gates, it is necessary to apply an alternating layer of dielectrics, which modulates the signal to produce the desired results. Nonlinear effects can be achieved using various methods such as nonlinear ring mirrors, linear fiber, photon crystals, changing the refractive index of materials, filters, waveguides, or optical semiconductor amplifiers [4]. Optical elements that reduce the size of optical integrated circuits are good candidates for future optical networks and optical computations due to the transmitted wavelength. All-optical communication is one of the solutions to the problem of the speed and size of electronic circuits. Logic gates are one of the most important components in all-optical circuits. In recent years, researchers have developed all-optical logic gates for use in nonlinear effects in optical fibers, but one of the limitations has been a large size, low speed, and size of integrated circuits [5].

Many researchers have been interested in all-optical signal processing techniques recently, but all-optical devices must be fully utilized to use optical transmission capabilities. These devices include optical filters [6, 7], optical multiplexers [8, 9], optical analogue-to-digital converters [10, 11], optical switches [12], optical logic gates [13, 14], optical accelerometers [15], optical half-adders [16], and other similar optical devices. A device known as an "all-optical logic gate" produces logic outputs by performing logic operations on light with light. When one or more lights with light inputs are subjected to logic operations, the device is known as a logic gate. High-speed all-optical logic gates are necessary in the processing of signal as well as optical networks. The complication, speediness, reliability, steadfastness, and straightforwardness of integration of the numerous designs created hence distant to degree the execution of all-optical rationale gates shift. Rationale entryways based on through straight and nonlinear photon precious stones have gotten extraordinary consideration and have been significantly broadened to help in joining the recommended structures [17, 18]. All-optical rationale gates based on photon precious stones may be made, recreated, and fabricated utilizing nanocavity, nonlinear fabric characteristics, ring resonators, and the Mach Zehnder interferometer. On the premise of XOR, XNOR, NAND, and NOT rationale entryways, Nozhat et al. effectively outlined high-contrast nonlinear two-dimensional gem photonics in 2015. The tall differentiate proportion of around 20 dB between "1" and "0" [19] may be a recognizing quality of this rationale entryway in comparison to other rationale gates already formulated. A two-input, two-dimensional photon crystal-based NAND gate with a ring resonator was recommended by Siraj M. The proposition incorporates an add up to zone of 249.75µm², and the delay time is, at best, 3.6 ps [16, 20]. Most newly suggested rationale entryway designs can as it were work within the TM or TE polarization modes. Both the delay time and the auxiliary estimate are significant.

Employing a hexagonal cross section in silicon photon gems on a cover and autonomous of polarization, a strategy for building all-optical rationale entryways is given in this inquire about. An assortment of entryways utilized in this way can join optical rationale gates through the obstructions wonders, utilizing direct blemishes and obstructions between light bars.

II. NUMERICAL METHODS

The finite difference time domain (FDTD) approach may demonstrate light diffusing in a photonic crystal. The center thought behind the limited contrast time space approach is to inexact spatial and worldly subsidiaries utilizing the limited contrast in Maxwell conditions. The microstructure under examination is split into a small number of constant lattice points in the FDTD technique, where the field values are computed. For the expression of spatial and temporal derivatives, magnetic and electric fields use backslash and anterior differences, respectively. For the electric and magnetic regions of Maxwell's Eq. (1) and (2), the derivatives listed below can be used in their place.

$$\frac{\partial E(r,t)}{\partial r_i} \rightarrow \frac{\Delta_i + \hat{E}}{\Delta r_i} = \frac{\hat{E}(r + q_i u_i, t) - \hat{E}(r, t)}{q_i} \quad (1)$$

$$\frac{\partial E(r,t)}{\partial t} \rightarrow \frac{\Delta_i + \hat{E}}{\Delta t} = \frac{\hat{E}(r, t + \delta t) - \hat{E}(r, t)}{\delta t} \quad (2)$$

$$\frac{\partial H(r,t)}{\partial r_i} \rightarrow \frac{\Delta_i - \hat{H}}{\Delta r_i} = \frac{\hat{H}(r, t) - \hat{H}(r - q_i u_i, t)}{q_i} \quad (3)$$

$$\frac{\partial H(r,t)}{\partial t} \rightarrow \frac{\Delta_i - \hat{H}}{\Delta t} = \frac{\hat{H}(r, t) - \hat{H}(r, t - \delta t)}{\delta t} \quad (4)$$

In these equations, q_i denote distance among the grid's lattice points and u_i the unit vectors that constitute the computational grid, are used to measure the geometric space. Reclaimed by fields:

$$\hat{E} = q_i E \rightarrow \text{and} \rightarrow \hat{H} = q_i H \quad (5)$$

The x and z axes of the FDTD simulator's coordinate system are specified to lie in $\Gamma - M$ and $\Gamma - k$ planes, correspondingly. The direction of y is vertical/perpendicular to crystal's surface for fitting the hexagonal configurations' geometry. The rectangular coordinate is regarded for the lattice coordination where the distance of lattice is considered $qx = \sqrt{3} \cdot qz$. The FDTD software accordingly ensures stability.

$$\delta t = 0.99 \sqrt{\frac{3}{7}} \left(\frac{q_x}{c} \right) \quad (6)$$

Where q_x denotes the x-directional lattice distance, the relationship between the spatial grid and worldly steps is illustrated by the statement mentioned above, which states that for a more precise spatial lattice, numerous more worldly steps are vital. The output contrast ratio is yet another factor of significance in the development of logic gates [21]. The ratio of the control for "1" rationale to the control for "0" rationale from the condition is utilized to compute the differentiate proportion for both TE and TM polarizations.

$$\text{ContrasrRatio(CR)} = 10 \log (P_1/P_0)(\text{dB}) \quad (7)$$

Where P_0 stands for the control of the consistent "0," whereas P_1 speaks to the coherent control of "1." In this work, we decide the differentiate proportion for this rationale gate at 1.550 µm wavelength.

III. PHOTONIC BAND STRUCTURE

The behavior of light as it passes through a periodic structure, which generates a number of potential barriers and wells for photons, is referred to as the photonic band structure. Similar to the energy bands for electrons in a solid, the structure produces photonic bands and energy gaps known as photonic band gaps. In order to ascertain the band structure and operating wavelength of photonic structures, it is essential to comprehend the microstructure of photonic bandgap graphs. The band structure of the in-demand unit cell depends on the microstructure of the photonic bandgap graph. In order to create photonic crystals with distinctive optical characteristics, the photonic band structure and the microstructure of photonic bandgap graphs are crucial.

Here, the microstructure of the photonic bandgap graph has been selected to begin with some time recently continuing to the specifics of the plan and displaying. Getting the recurrence crevice is one of the key thoughts within the microstructure of

vitality groups. The working wavelength is the wavelength that can be exchanged from the source to the yield without being scattered, losing vitality, or entering the structure. According to Blah's theory, this requires knowledge of the microstructure's unit cell. The hexagonal photonic crystal's unit cell is seen in Fig. 1.

In arrange to decide the in-demand unit cell's band structure, we must to begin with decide the structure's unit cell. The bandgap structure is seen in Fig. 2. The recommended microstructure within the wavelength run of $\lambda = 1.4874\mu\text{m} \sim 1.621\mu\text{m}$ as appeared, and encompasses a full photonic bandgap within the normalized recurrence run of a $\lambda = 0.3516 \sim 0.3832$.

Remember that the structure has a complete bandgap since the specified gates are polarization-independent. The bandgaps for the TM and TE modes cross across, as seen in the above picture.

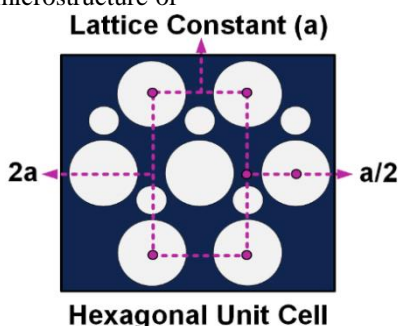

Fig. 1. The hexagonal cell of the planned rationale entryways.

Fig. 2. Photonic band structure.

IV. OPTICAL LOGIC GATE

In expansion to the two essential inputs, another input is included within the plan of rationale entryways to alter the application and increment the applications, such as NOR and XNOR. This extra input permits fluffy control of the optical signals. So, when there are three input waveguides and one yield waveguide, the suggested structure is as takes after. (Fig. 3) The performance of the constructive and destructive interference in the controller waveguide results in the logic gates. On the SOI substrate, the recommended plan comprises

of an $X \times Z$ hexagonal cross section with a number of 17×15 gaps separated into two bunches. The sweep was selected to produce two diverse photonic bandgaps. The two air holes have a radius of $r_b = 0.36a$ for the larger air hole and $r_s = 0.16a$ for the smaller air hole, where (a) is the cross-section steady, which is equivalent to $a=550$ nm. The greater air holes are completely in the middle of the smaller ones. The two-dimensional photonic crystal's holes are partially removed to produce the waveguides. Using the effective refractive index approach, two-dimensional analysis is carried out since three-dimensional computations take more time and memory.

$n(TM) = 2.150$ and $n(TE) = 2.890$ and, respectively are determined as the successful chunk refractive records for the TE and TM modes at the wavelengths= $1.550\mu\text{m}$. The suggested design has been determined to be capable of acting as all-optical logic gates after the microstructure has been tuned for both polarization modes at wavelength.

The suggested structure has four waveguides that serve as input and output ports for designing and simulating all-optical rationale gates with three inputs. The two major input ports are the Q output and a C reference or Controller input. Depending on the staging point, the port's reference signal or control indicator generates a stage contrast between the input indicators, coming about in either helpful or dangerous obstructions between the input indicators. Since the symmetry of the reflect picture around the waveguides, most light is caught in this construction's waveguide locale. Also, the input and yield waveguide borders are changed by the incorporation of more discuss gaps with lower radii. An enormous discuss gap and two littler discuss gaps maximize the optical control

transmission. This method has impressive focal points for optical control transmission to the yield and avoiding optical control misfortune within the structure. Within the following step of the plan, four waveguides with a gap within the center are proposed. Again, this gap is tuned for both TM and TE modes with a polarization-dependent central gap sweep of 0.23. When combined with the reference flag, both input signals provide the highest possible value for TM and TE polarizations, making this sweep ideal for the input flag. The most effective regulation happens once one of the two input signals is propagated on two input waveguides at once, leading to light-generating impedances at the junction of four waveguides when all of the signals are onstage. Since dangerous impedances happens when the signals are out of stage, the portrayed strategy may be utilized to execute the NOR and XNOR optical rationale gates. Less control will be shown within the yield waveguide as a result.

Fig. 3. The proposed of 2D-HPHC structure.

V. RESULT AND DISCUSSION

There are three different kinds of general logic operations that will be executed in this suggested architecture. If a light signal with $\varphi = 0^\circ$ is applied to either the A or B input port and a control signal with $\varphi = 0^\circ$ is applied to the reference port, then a logical "1" is produced. When a light signal with a $\varphi = 0^\circ$ is excited at either the A or B input port and the reference port is stimulated with a control signal with a $\varphi = \pi^\circ$, a logical "0" is produced. And, the highest output power is achieved when the reference port is activated only by the controller signal at either $\varphi = 0^\circ$ or $\varphi = \pi^\circ$ out of phase.

A. NOR Optical Logic Gate

The NOR logic gate, primarily employed in most digital devices' design, follows the reverse OR gate. Four separate states are used to characterize the NOR logic gate's operation [19, 21]. Table I displays this logic gate's potential states and the transmission rate.

Within the 'to begin with' situation, no flag is connected to any of the input ports, and the control flag is connected to the reference harbour with a stage point of $\varphi = \pi^\circ$. When utilizing

TE or TM polarization, the yield harbour, in this occasion, gets "1" rationale at a transmission rate of 67% or 58%, separately. The reference harbour is concurrently energized with the light flag with a stage point of $\varphi = \pi^\circ$ and the control flag by a stage point of 180 degrees ($\varphi = \pi^\circ$) within the moment and third occurrences, separately, and A and B input ports are energized concurrently by the light flag within the moment and third cases. Fig. 4 portrays the introductory state. As watched, the TE-polarization mode has the most reduced delay time or the fastest working speed with a NOR Entryway within the moment state, 0.75ps.

Segments (a) and (b) of Fig. 5 show the field conveyance designs for the TE and TM polarization modes, individually. The consequences illustrate that the planned strategy capacities as a NOR optical rationale gate.

This gate has a signal in each of its reference ports at an angle of 180 degrees ($\varphi = \pi^\circ$), as observed. Also, 7dB is used for the contrast parameter.

B. Optical Logic Gate of XNOR

Within the ‘to begin with’ state, no flag is connected to any input ports, whereas the control flag is connected to the reference harbour with a stage point of $\varphi = 0^\circ$ [18]. Within the moment and third stages, a light flag with a stage point of $\varphi = 0$ is used to individually excite the A as the input port and, subsequently, the second input port B. In contrast, a control signal by a phase angle of $\varphi = \pi^\circ$ is utilized to exclusively energize the primary input harbour A and, hence, the moment input harbour B. In differentiate, a control flag with a stage point of $\varphi = 0^\circ$ fortifies A and B i.e., input ports and reference harbour C within the fourth state. In this occurrence, constructor obstructions is fulfilled since all three light signals are at co-phase in yield harbour 1. Table II lists the findings for every possible combination of TM and TE polarizations. At 1550 nm wavelengths, the difference percentage for this reasonable entrance is 8dB.

The three fundamental states within the TE and TM polarization modes are appeared within the field dissemination in Fig. 6(a) a persistent Gauss a wavelength of 1550 nm. Section (a), which can be seen in the image, simulates the three principal states while applying an optical signal source in TE mode to the microstructure. The inputs in the section receive an optical signal source operating in TM mode (b).

The reenactment discoveries appear that the stage alter point of the reference harbour C is utilized to construct all of the elemental optical rationale entryways utilized in optical coordinates circuits. Another significant benefit of the suggested microstructure is its ability to receive polarization and supply the correct output. The TE-polarization modes and the TM-polarization mode’s respective minimum delay times are one period (ps) and nine periods (ps), respectively.

VI. CONCLUSION

This paper plans and mimics all base rationale gates (TE/TM) free of polarization modes utilizing a hexagonal photonic gem with silicon dielectric on a separator. Embracing the recommended microstructure will empower the headway of all prior thinks about to a brand-new era of polarization-independent gates. In this paper, a novel optical NOR and XNOR logic gate design is introduced utilizing a two-dimensional-hexagonal photonic crystal (2D-HPHC) that facilitates Transverse Electric (TE) and Transverse Magnetic (TM) polarization modes. The size of the structure is relatively small, and it possesses a low delay time. The design incorporates a waveguide with three inputs (A, B, C) and one output (Q). The NOR gate demonstrates a delay period of 0.75 ps, while the XNOR gate showcases a delay period of 0.9 ps. The contrast ratio between input and output for both gates is 7-8 dB. Furthermore, the XNOR gate displays an optimal transmission signal rate of T = 96%. The work of hexagonal photonic gems, silicon dielectric fabric on cover with a satisfactory thickness, and the span of the gaps within the structure causes the mutual bandgap in equally TM and TE polarization types. The current study is only considered the specific design and parameters of the gates and does not explore other possible configurations or applications of the 2D-

HPHC. Future study could explore the potential of integrating the 2D-HPHC design with other technologies for advanced functionality and performance.

Abstract—Early detection of armed threats is crucial in reducing accidents and deaths resulting from armed conflicts and terrorist attacks. The most significant application of weapon detection systems would be found in public areas such as airports, stadiums, central squares, and on the battlefield in urban or rural conditions. Modern surveillance and control systems of closed-circuit television cameras apply deep learning and machine learning algorithms for weapons detection on the base of cloud architecture. However, cloud computing is inefficient for network bandwidth, data privacy and slow decision-making. To address these issues, edge computing can be applied, using Raspberry Pi as an edge device with the EfficientDet model for developing the weapons detection system. The image processing results are transmitted as a text report to the cloud platform for further analysis by the operator. Soldiers can equip themselves with the suggested edge node and headphones for armed threat notifications, plugged into augmented reality glasses for visual data output. As a result, the application of edge computing makes it possible to ensure data safety, increase the network bandwidth and provide the device operation without the internet. Thus, an independent weapon detection system was developed that identifies weapons in 1.48 seconds without the Internet.

Keywords—Internet of Things; gun recognition; edge device; Raspberry pi; military systems control; network analytic

I. INTRODUCTION

Recent world events show that the number of terrorist attacks per year and armed conflicts continues to grow. According to the report of Global Terrorism Index 2022 [1], even developed countries such as the United States of America ranked 30th in the overall terrorism index score, while France and Germany were in 34th and 35th places and the United Kingdom was in 42nd place among 195 countries. More than 20 countries are involved in armed conflicts and civil wars in 2023 [2]. Most of these acts of violence involve armed people whose goal is to seize territories and destroy stability in a region or state. Often enemy strikes and terrorist attacks occur at strategic targets and in public areas. Defence forces and intelligence agencies should monitor the situation to prevent and minimize the consequences of those violent acts. One of

that approaches is early weapons detection.

The conventional surveillance and control system of Closed-Circuit Television (CCTV) cameras involve human as operator and requires manual control of a large number of cameras [3]. Thus, it is requiring a significantly large number of personnel to monitor cameras in vast areas. Modern Weapons Detection Systems (WDS) mainly apply an Artificial Intelligence (AI). The initial task of the first AI recognition and detection systems was to recognize a person and a face [4]. Since the process of face recognition is one of the most important task in the field of Computer Vision (CV) with various promising applications from academic research to intelligence services [5]. Moreover, a human pose [6] can give some information about the probability that a person is going to use a weapon.

This paper describes the process of creating a weapons detection system for military and civil purposes. To avoid the disadvantages of cloud architecture, such as low network bandwidth, threats to data safety and lack of computing resources of a data center, the edge computing architecture has been applied in the development of the weapons detection system. A single-board computer, Raspberry Pi, has been selected as an edge computing device, or it is briefly called an edge device [7, 8]. Our previous studies have shown the excellent results in the application of computer vision and edge computing to number plate recognition system on the Raspberry Pi [9], as well as in the development of an intelligent task offload system [10]. Thus, the Raspberry Pi would be able to complete the task of weapon recognition based on the EfficientDet model and significantly reduce the cost of the technical solution. In order to minimize the possibility of bias or overfitting with subsequent performance degradation [11], some method optimization parameters can be applied.

This study aimed to develop a weapons detection system based on Raspberry Pi with a camera module using the EfficientDet model and edge computing algorithms, as well as notification about armed threats through headphones and the capability of visualization output on the interface of soldiers' augmented reality (AR) glasses and send results to the Internet

This research is sponsored by the Science Committee of the Ministry of Science and Higher Education of the Republic of Kazakhstan (Program No. BR1090140221).

of Things (IoT) cloud platform for further report analyses by an operator.

As a hypothesis, it is assumed that the application of edge computing significantly decreased the volume of transcended data to the cloud, offloading the computing resources of the data center and affording the edge device functioning without an Internet connection.

The paper is organised as follows: Section II reviews the related works in the area of weapon detection and Internet of Things application. Section III presents the EfficientDet and edge computing architectures, the process of building a model for weapons detection and its algorithms. Section IV provides a detailed description of the results for each various experimental case of weapons detection. Section V compares the obtained experimental results with the existing related works. Finally, Section VI summarises all text and indicates a direction for future work.

II. RELATED WORKS

During the last years, object detectors have been greatly improved technologically and allow security forces to identify weapons with fast speed and high accuracy. Nevertheless, there is an issue in practice when it comes to recognising small objects or the reflective surface of the knife [12, 13]. One study has focused on training a model for tilling approach using Single Shot Detector MobileNet V2 and Armed CCTV Footage dataset to detect small weapons [14]. The mean average precision (mAP) of that research was about 0.758 for pistol and knife evaluation. Also, a rather significant problem is the detection of a weapon in the attacker's hand [15] or whether it is hidden from an observer in the other part of the body.

As previously noted, there are many related works describing Deep and Machine Learning methods that are currently used to detect weapons. One of the most widely used classic real-time weapons detection approaches is the Convolutional Neural Networks (CNN). The accuracy and speed of weapon detection by the CNN approach through the transfer learning method using the Visual Geometry Group and fine tuning [16] show a moderate result. This is true that CNN had quite impressive image classification performance, but without enormous data and multiview cameras, it has a problem with overfitting [17]-[19]. Since the architecture of CNN can be transformed in Faster Region CNN due to a feature extractor Inception-ResNetV2 [20], that model type can demonstrate a high per cent of mAP. However, You Only Look Once V2 (YOLO) is faster in testing and training time compared to Faster Region CNN. The other study showed that Region CNN (R-CNN) and Region Fully Convolutional Networks (R-FCN) approaches have increased the speed of weapon detection, according to the experiment conducted by Arif [3]. However, in their experimental part of the study, there were false positive results for the detection of weapons. The next paper has considered CNN approach with applying Transfer Learning and two techniques such as AlexNet and GoogLeNet [21]. Nonetheless, they have the same issue connected with false positive results as previously considered work. To overcome false positive results, Debnath and Bhowmik [12] have developed an Iterative Model Generation

Framework (IMGF), which detects only moving persons with a gun and decreases the consumption of computing resources. Goenka and Sitara [23] have applied Gaussian deblur technique for Mask RCNN to detect guns better in case of a blurred image. Comparing Deep Learning (DL) and Machine Learning (ML) approaches for weapons detection [24] in terms of speed and accuracy, the former is better.

The newest and most accurate model for object detection is YOLO, and it has a lot of versions. The paper described difference between YOLOv3 and YOLOv4 in terms of sensitivity and processing time [25]. The experimental part of following studies confirms the superiority of YOLOv4 over previous YOLOv3 [26]-[28]. Also, this model can be implemented for custom object detection on Jetson Nano GPU from Nvidia with a TensorRT network optimizer [29]. The newer YOLOv5 allows to significantly increase the accuracy of weapons detection [30, 31]. The processing time per frame is 0.010 seconds compared to the 0.17 seconds of the Faster R-CNN [32]. There is also an implementation of the YOLOv5 model on high-cost device Nvidia's Jetson AGX Xavier with an impressive accuracy of 98.56 percent [33]. The applying complex hardware and DL algorithms allow for achieving effective results, but they are expensive and difficult to deploy [34]. Besides YOLO, there is a promising method based on the use of semantic embeddings and a pre-trained Contrastive Language-Image Pre-Training (CLIP) model. The highest accuracy rate of this method was 99.8 percent [35], which is quite competitive with FireNet and YOLO algorithms.

The majority of modern WDS solutions are based on the IoT. The IoT applications automate routine processes and work without human interactions [36]. The IoT technology has a wide range of applications [37], ensuring people's safety in smart homes, industry, transportation and cities [38, 39]. Most IoT solutions use cloud services as a data treatment center, for instance, data collected from sensors of smart farm are sent to the server [40], as well as the video stream data are transmitted to the cloud for further processing [41, 42]. However, some studies point to insufficient network bandwidth [43], massive generated data [44], high power consumption [45, 46], weak network security [47] and data privacy issues [48] because of using the cloud paradigm in the IoT. Those issues of IoT applications are strongly critical for military purposes. Mainly the latest researches are focused on the security of the IoT [49] since the consequences of disabling the network are not measurable. The application of military IoT could be found in the field of battlefield perception, improving the early warning, weapons and equipment management, intelligence sharing ability and support efficiency of the military, logistics support, military training and so on [50, 51]. To be more specific, military IoT studies also consider WDS, such as rope roaming robots for 360 degrees of monitoring a specific area [52], a semi-autonomous robot with WDS and stair climbing functions [53], drones or Unmanned Aerial Vehicles (UAV) for WDS [54] and explosive weapons detector [55]. To partially solve the issue associated with high power consumption, it was advised [56] to use Field Programmable Gate Array (FPGA). However, in order to finally resolve all the above list of issues, it is highly recommended to replace the cloud paradigm with edge computing [57]. FPGA provides high energy-efficient,

accelerating and high performance for complex AI tasks [58]-[60]. Thus, the edge device implements pre-processing data and sends the result to the data server [61] with much lower network bandwidth.

III. MATERIALS AND METHODS

As previously mentioned in the first section, it was decided to apply Raspberry Pi 4 Model B (4 GB) with a camera, which are shown below as edge device in Fig. 1.

Fig. 1. Raspberry Pi with a camera as an edge node.

Headphones and a power bank have been used for audio notifications about armed threats and for the power supply of the Raspberry Pi. Raspberry Pi OS (Raspbian) has been picked as the operating system. 'Thingspeak' has been chosen as the IoT cloud platform for report and analytics formation due to visual infographic capabilities. However, the Message Queue Telemetry Transport (MQTT) without graphical support could be applied for more private message exchanges between publisher and subscribers.

A. Edge Node

The high-level programming language Python has been selected for supporting a computer vision by progressive libraries and frameworks: TensorFlow Lite, Numpy, OpenCV, Python Imaging Library (PIL) and Picamera. Since Raspberry Pi (RPi) have limited CPU and GPU resources to train a model, it was decided to use the computing server of Google Colaboratory, the framework TensorFlow Lite and 1588 images from the Kaggle dataset of various types of weapons [62, 63]. Some samples of weapons for the model training and the flow scheme are illustrated in Fig. 2.

Fig. 2. The scheme of model training using Google Colab and TensorFlow Lite.

The EfficientDet has been selected as the model for weapons detection because it creates a smaller output model file, consumes less computing resources, and implements algorithms faster [64]. Moreover, EfficientDet offers a list of mobile-size lite models, which are suitable for IoT and edge devices. The EfficientDet architecture is illustrated below in Fig. 3.

Fig. 3. The EfficientDet architecture.

EfficientDet can be considered as the one-stage detector paradigm that applies EfficientNet as the backbone network. Bi-directional feature pyramid network (BiFPN) acts as the feature network and utilizes level 3-7 features {P3, P4, P5, P6, P7} from the backbone network. It repeatedly applies bidirectional feature fusion, both top-down and bottom-up, resulting in fused features that are then fed to the class and box network for object class and bounding box predictions.

There are a few EfficientDet-Lite variants, and their checkpoints and results are shown in Table I.

TABLE I. EFFICIENTDET-LITE CHECKPOINTS AND RESULTS

Model	Mean average precision (float)	Quantized mean average precision (int8)	Parameters, millions	Mobile latency, milliseconds
EfficientDet-lite0	26.41	26.10	3.2	36
EfficientDet-lite1	31.50	31.12	4.2	49
EfficientDet-lite2	35.06	34.69	5.3	69
EfficientDet-lite3	38.77	38.42	8.4	116
EfficientDet-lite4	43.18	42.83	15.1	260

Since it is necessary to prioritize safety and provide the highest speed of object detection, the EfficientDet-Lite0 has been chosen.

The general equation for compound scaling of the EfficientDet model would be the following:

$$f = \alpha + \beta^\phi + \gamma^\phi \quad (1)$$

Where α is a depth scaling factor, β is a width scaling factor, γ is a resolution scaling factor, ϕ is a number of network variation, and f is a network scaling factor.

The BiFPN network width and depth would use scaling equations:

$$W_{bifpn} = 64 \times (1.35^\phi) \quad (2)$$

$$D_{bifpm} = 3 + \varphi \quad (3)$$

Box/class prediction network would be scaled with the following equation:

$$D_{box} = D_{class} = 3 + \lfloor \varphi / 3 \rfloor \quad (4)$$

Input image resolution uses the next scaling equation:

$$R_{input} = 512 + \varphi \times 128 \quad (5)$$

Thus, the EfficientDet allows us to decrease the size of the model file by 4x–9x and use 13x–42x fewer Floating-point operations per seconds (FLOPs) than most previously reviewed detectors.

The flowchart of weapons detection is presented below in Fig. 4.

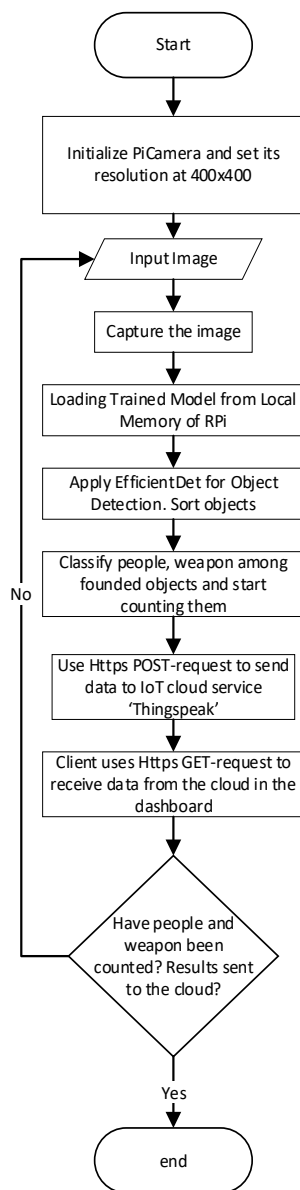

Fig. 4. The flowchart of weapons detection process.

Firstly the Pi's camera has been initialized, and its resolution has been configured at 400x400. Then algorithm started capturing an image and loading a trained model by Google Colab and TensorFlow Lite. An applying that model and EfficientDet architecture allowed to detect objects from captured image. The sorted objects were counted and classified by a model as person, rifle, pistol (handgun) and knife. Finally, the results were transcended to IoT cloud platform 'Thingspeak' through HTTP-request. After that a subscriber can send Http GET-request to collect results. If an armed threat was detected, the user of the system would receive a voice notification via headphones.

The common scheme processing of captured image is demonstrated in Fig. 5.

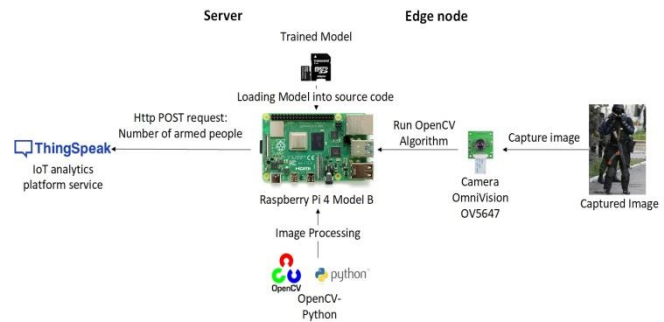

Fig. 5. The scheme of image processing.

B. Server Side

The IoT cloud platform 'Thingspeak' has been used to monitor the results of weapons detection on the server side, as mentioned before. 'Thingspeak' supports Representational State Transfer of the Application Programming Interface (RESTful API) and due to this users can easily exchange messages between edge device, client and server. The client-server model is illustrated in Fig. 6.

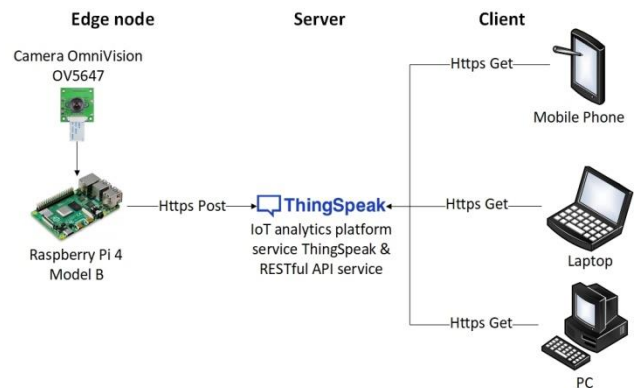

Fig. 6. The client-server model for the weapons detections system.

To observe the processed data securely from any type of device, an admin has logged in to the 'Thingspeak' account and created a private channel. Then he has gotten an API and started the configuration process of private channel. The configuration of channel and widgets are shown in Fig. 7.

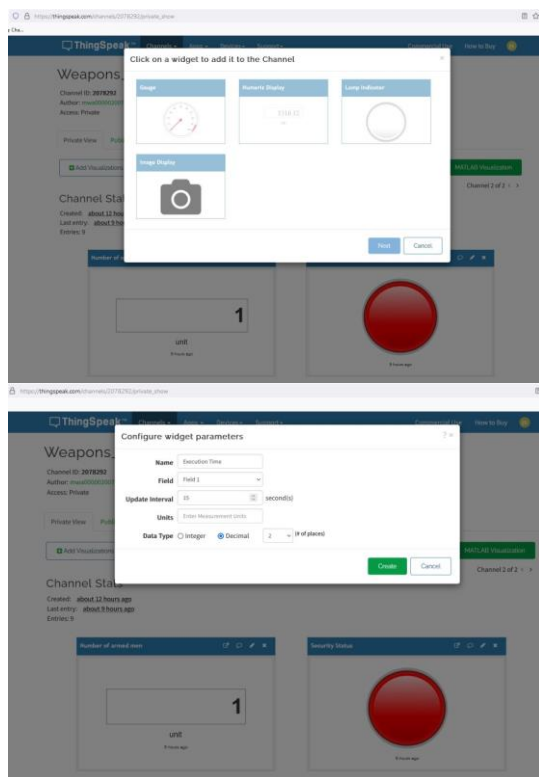

Fig. 7. The procedure of configuration the channel and adding widgets in Thingspeak.

C. Client Side

An operator browsing a private channel from any accessible type of device (table, smartphone, personal computer) and collect all data for report and analysis. The processes data are presented in the widgets of the web application 'Thingspeak', which could be found in Fig. 8.

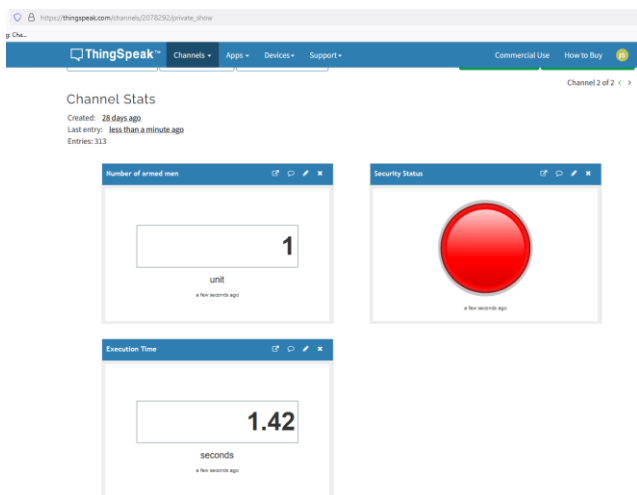

Fig. 8. Results in the web application 'Thingspeak' for the case with rifle detection.

The operator has a capability to apply the MQTT protocol as an option to keep data privacy and output received results in a terminal window, which is shown in Fig. 9.

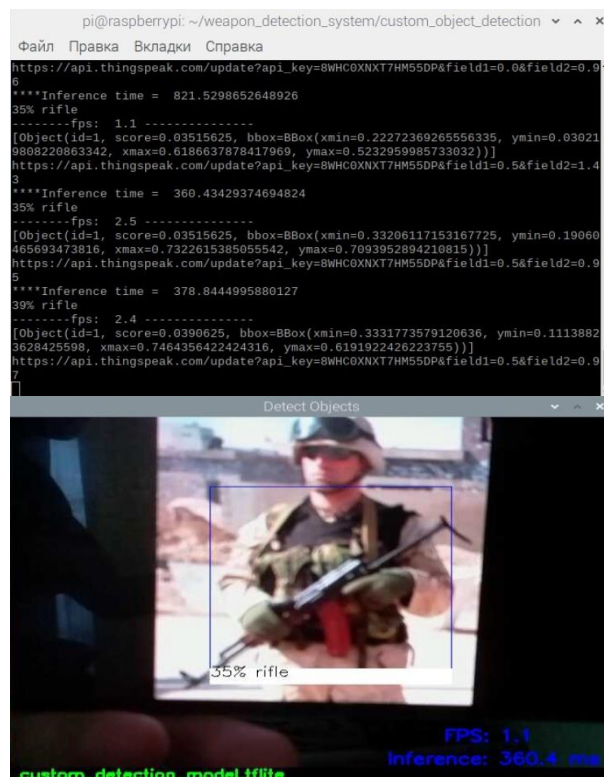

Fig. 9. Results in a terminal window.

D. The Application of Weapons Detection System for Augmentation Reality Glasses

To improve the user experience of armed threats detection in addition to voice notification, it has been proposed to plug in Raspberry Pi to AR glasses for better visualization. The result of marking an armed threat will be displayed on the interface of the soldier's glasses, providing him with the necessary information to make a quick decision. The scheme of AR glasses interaction with Raspberry Pi is shown in Fig. 10.

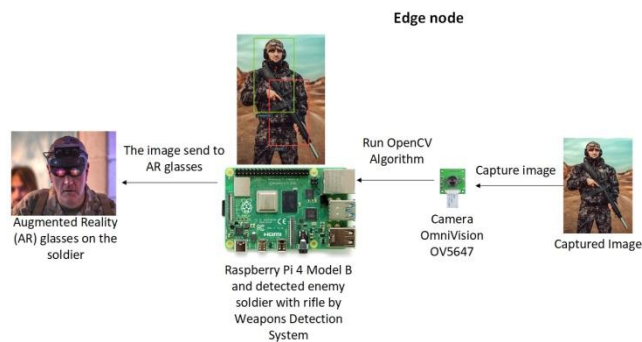

Fig. 10. The scheme of AR glasses interaction with Raspberry Pi.

IV. EXPERIMENTAL RESULTS

Three cases of weapons detection have been considered such as rifle, pistol (handgun) and knife. The first case with the rifle detection from smartphone display has been presented in the previous section in Fig. 9. The terminal window describes the following information: weapon type with accuracy recognition in per cent, inference time in milliseconds, and

frame per second. For this case, an operator can find such information in the web application: number of armed persons and time for algorithm execution, which are presented in Fig. 8.

The results of the next case with handgun are shown in Fig. 11.

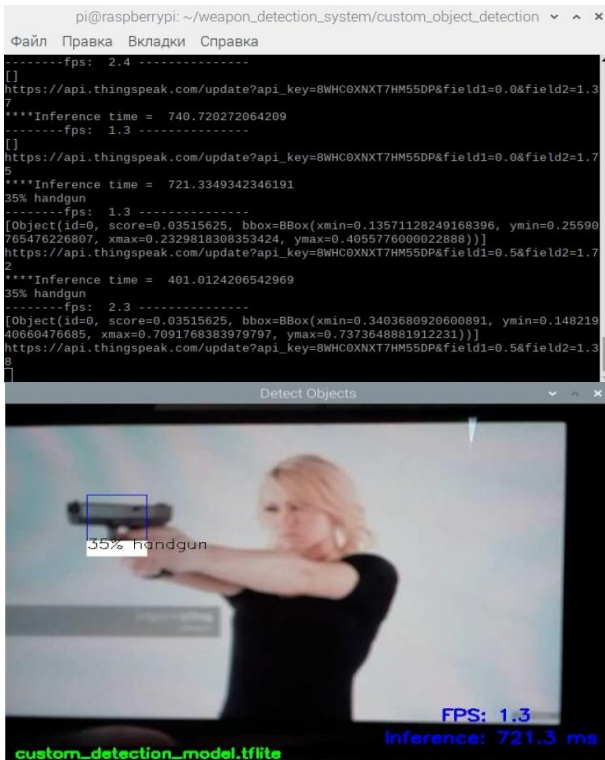

Fig. 11. The case with pistol (handgun) detection.

The handgun has been marked by rectangle and labeled. The terminal window also outputs the type of detected weapon, inference time and Http POST-request. The results of that case in web application are shown in Fig. 12.

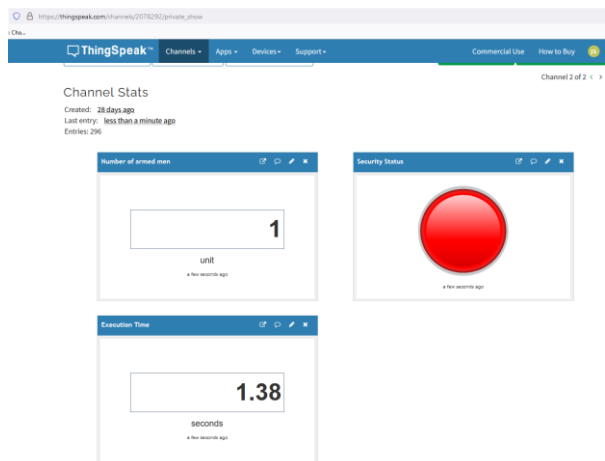

Fig. 12. The view of the web application for the case with pistol (handgun) detection.

The first widget from the left presents the number of armed persons. The lamp of the next widget has become active and red since the armed threat has been detected. The last widget shows the execution time of the algorithm.

Finally, the last case of cold steel weapon (knife) detection from the real scenario is shown in Fig. 13.

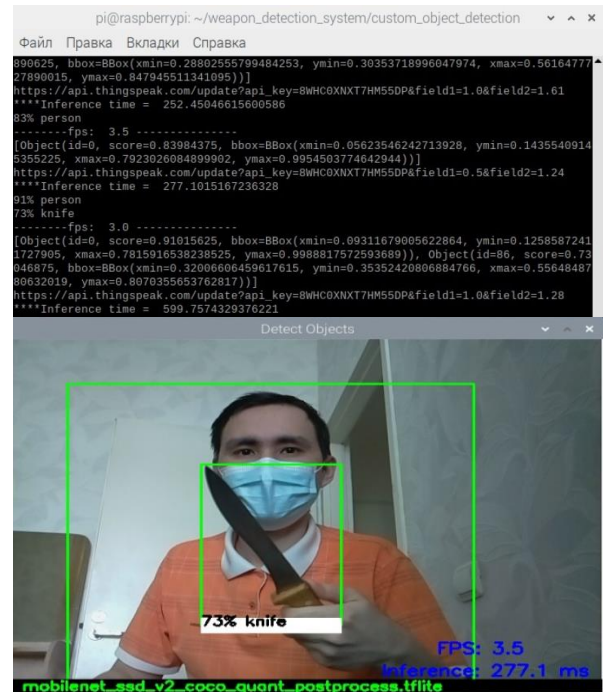

Fig. 13. The case with knife detection.

The common view of the knife detection case for the web application is shown in Fig. 14.

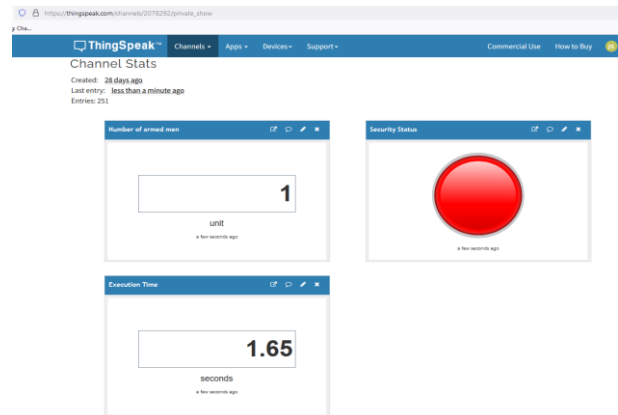

Fig. 14. The view of the web application for the case with knife detection.

To collect information about network traffic and bandwidth, the web application 'Monitorix' was deployed on the Raspberry Pi for the local host. Fig. 15 demonstrates that the maximum transmitted data to the IoT cloud platform have reached about 53 kilobytes per second or 40 packets per second without any network error during transcending data

Fig. 15. The web application 'Monitorix' for monitoring network traffic.

V. DISCUSSION OF RESULTS

To compare with the transmission of the video stream with an average required throughput of over 1.8 megabytes per second [43], the proposed approach requests less network bandwidth and significantly reduces the amount of transmitted data. As a consequence, it also reduced the load on the network and server resources. The average time for algorithm execution is approximately 1.48 seconds. It is quite a medium time of algorithm execution compared to 1.76 seconds for the Inception-ResNetV2 model and 1.1 seconds for the ResNet50 CNN model [20]. That is true that YOLO and MobileNetV2 [15, 20] are almost twice as fast in terms of object recognition and detection as EfficientDet-Lite0, but it should be noted that the productivity of the proposed algorithm execution time can be improved with Coral USB Accelerator. However, YOLO and ResNet require over 10 million parameters for object classification [41, 64]. Consequently, those models consume more disk space and computing resources. The highest accuracy of the knife detection case for EfficientDet-Lite0 model is an average result compared to 71.44 per cent for Faster R-CNN [17] and 77.78 per cent for YOLOv4 [26].

VI. CONCLUSION

In this paper, the weapons detection system has been developed based on the Raspberry Pi using computer vision and edge computing. The suggested approach has successfully overcome the resource limitation of Raspberry Pi to train a model through Google Colaboratory and TensorFlow Lite. Also, the hypothesis has been confirmed and obtained results indicating a significant decrease in the amount of data transmitted over the Internet, and as a result, it allows optimizing the server resources to accomplish other tasks. The presented data in the web application allows the operator to create a report. Moreover, it has been considered the capability to plug in Raspberry Pi with a camera module to AR glasses of soldiers for visually marking humans with weapons in real-time. The application of edge computing made it possible for the device to work without the Internet connection and thus ensure data safety. In addition to that, edge computing has reduced the cost of the technical solution and provides an

option to operate the device on a local area network using MQTT protocol for message exchange. As a result, an autonomous weapon recognition system has been proposed that can operate without an Internet connection and detect weapons within 1.48 seconds.

In the future, it is considered expanding our research to detect explosive devices, heavy tanks and unmanned aerial vehicles. Though there may be some issues related to the detection of fast-moving objects, poor lighting conditions and quality of images, which should be solved with an FPGA and high megapixels infrared camera.

ACKNOWLEDGMENT

The authors thank the editor and anonymous reviewers for their comments that helped to improve the quality of this work.

Distributed Cooperative Control for Multi-UAV Flying Formation

Belkacem Kada, Abdullah Y. Tameem, Ahmed A. Alzubairi, Uzair Ansari
Aerospace Engineering Department, King Abdulaziz University Jeddah, KSA

Abstract—The problem of collaborative pattern tracking in multi-agent systems (MAS) like unmanned aerial vehicles (UAV) is investigated in this article. First, a new method for distributed consensus is constructed inside the framework of the leader-following approach for second-order nonlinear MAS. The technique canceled the chattering effect observed in the conventional sliding mode-based control protocols by transmitting smooth input signals to agents' control channels. Second, a novel formation framework is proposed to accomplish three-dimensional formation tracking by including consensus procedures in the formation dynamics model. This will allow for formation tracking in all three dimensions. The Lyapunov theory provides evidence demonstrating the proposed protocols' stability and convergence. Numerical simulations have been carried out to prove the proposed algorithms' effectiveness.

Keywords—Formation control; distributed consensus; multi-agent systems; multiple-UAV

I. INTRODUCTION

The increased complexity of the missions of engineering systems has led to the development of distributed and cooperative control for networked systems under the paradigm of multi-agent systems (MAS). The benefits of using MAS include increased efficiency, precision, flexibility, robustness, and affordability. Real-life applications of MAS include ground systems [1], [2], unmanned aerial vehicles (UAV) [3]–[12], transport aircraft [13], [14], helicopters [15], spacecraft [16]–[19], satellites [20], [21], and missiles [22], [23].

One of the most fascinating and challenging applications of networked aerial systems is the cooperative control of multi-UAV systems. Research on multi-UAV cooperative control has recently increased, employing various methods and theories. Using the net contract protocol, Liu & Zhang [3] developed a model for assigning tasks to manned and unmanned aerial vehicles in real environments. The formation control problem of multi-UAV systems was treated as a differential game problem in [4], with the open-loop Nash strategy for each agent being to construct fully distributed formation control. The creation of autonomous quadrotor aircraft was addressed in [5] by developing a non-smooth distributed cohesive motion control using the virtual structure approach. The non-smooth backstepping design technique was used to create a distributed formation flying control algorithms [6]. Using a differential evolution method, Zhang et al. [7] designed an adaptive formation control to find the optimum formation for a swarm of UAVs. An algorithm based on the Riccati equation was used in [8] to solve the problem of formation-containment control for a fleet of multirotor UAVs. Ziyang et al. [9] proposed a

decentralized, self-organized mission planning algorithm. According to [10], a distributed formation control free of collisions can be created using a Voronoi diagram or partition. Path planning for a formation control approach with constraints and without collisions was examined in [11] utilizing rapid particle swarm optimization, considering chaos-based initialization, parameter optimization, and topology updating. For linear MAS, Almalki & Kada [24] offered a sliding-PID control that can be applied directly for multi-UAV consensus tracking.

Although the methodologies and approaches discussed above have been shown to be effective, there are still several critical obstacles to be solved in the cooperative control of MAS, particularly in multi-UAV systems. Formation keeping, communication failures inside MAS, altering communication topologies, and the smoothness of control inputs are some practical issues that must be addressed. Within the framework of a smoothly distributed consensus and formation control paradigm, we address these challenges and provide potential solutions in the study that we have presented here. As a result, the first thing we have contributed is the invention of distributed consensus procedures that are smooth for multi-agent systems with nonlinear dynamics integrated into them. In place of the signum-based control used in classic MAS control, which results in controller chattering, a continuous PI-like (proportional-integral) control is used to design the control inputs to the agent closed-loop dynamics. This allows for more precise and accurate control over the system. The second significant contribution made by this study is a model for maintaining airborne formation. We create the formation model by combining distributed protocols into a six-degree-of-freedom dynamical framework. This allows us to simulate the formation of complex structures. For a fair comparison, one can see, for example, the work presented in [25] and [26].

II. PRELIMINARIES

Graph theory can be used to model the topology of information exchange in a networked system with n agents.

The interaction among an agent set $\mathcal{M} = \{1, 2, \dots, n\}$ is represented by a weighted graph $\mathcal{G} = (\mathcal{V}, \mathcal{E}, \mathcal{A})$ where $\mathcal{V} = (\nu_1, \nu_2, \dots, \nu_n)$ denotes the vertex set, $\mathcal{E} \subseteq \mathcal{V} \times \mathcal{V}$ denotes an edge set, and $\mathcal{A} = (a_{ij} \geq 0) \in \mathbb{R}^{n \times n}$ describe a nonnegative adjacency matrix. The elements a_{ij} are defined such that $a_{ij} > 0$ if $(\nu_i, \nu_j) \in \mathcal{E}$, $a_{ij} = 0$ if $(\nu_i, \nu_j) \notin \mathcal{E}$, and $a_{ij} = 0$ (no self-loop).

Definition 1: Each agent i in the set \mathcal{M} has a set of neighbors denoted by its connectivity set, $\mathcal{N}_i = \{ \nu_j | (\nu_j, \nu_i) \in \mathcal{E} \}$.

Definition 2 Laplacian matrix $\mathbf{L}(l_{ij}) \in \mathbb{R}^{n \times n}$ is associated with the graph \mathcal{G} , where $l_{ij} = -a_{ij}$ for $i \neq j$ and $l_{ij} = \sum_{j=1, j \neq i}^n a_{ij}$

Assumption 1: As the graph \mathcal{G} is not fully connected, the topology is directed communication that allows only the leader to communicate with the followers.

Unlike undirected communication, where a symmetric matrix comes from the exchange of information in both directions, directed communication involves a one-way flow of data (due to the symmetry of the coupling weights).

Assumption 2: When defining the Laplacian matrix, the eigenvalues $\lambda_i(\mathbf{L})$ are specified as $0 \leq \lambda_1(\mathbf{L}) < \lambda_2(\mathbf{L}) < \dots < \lambda_n(\mathbf{L})$.

III. SYSTEM MODEL

A. Distributed Consensus Problem for Nonlinear Second-Order MAS

MAS can be considered a team consisting of a single virtual leader 0 and a diverse set n of identically-behaving, second-order dynamics followers.

$$\begin{cases} \dot{\mathbf{x}}_i = \mathbf{v}_i \\ \dot{\mathbf{v}}_i = \mathbf{f}_i(t, \mathbf{x}_i, \mathbf{v}_i) + \mathbf{u}_i \end{cases} \quad (1)$$

where the agent's position, velocity, and control input vectors are represent respectively by $\mathbf{x}_i, \mathbf{v}_i, \mathbf{u}_i \in \mathbb{R}^m$, It is detailed how the dynamics of the virtual leader work by

$$\begin{cases} \dot{\mathbf{x}}_0 = \mathbf{v}_0 \\ \dot{\mathbf{v}}_0 = \mathbf{f}_0(t, \mathbf{x}_0) \end{cases} \quad (2)$$

where $\mathbf{x}_0, \mathbf{v}_0 \in \mathbb{R}^m$ are the position and velocity of the leader. The dynamics of the leader and the followers are modeled by the functions $\mathbf{f}_0, \mathbf{f}_i \in \mathbb{R}^m$, respectively.

Assumption 3: System (1) is stabilizable if and only if the functions \mathbf{f}_i are uniformly bounded with respect to t and locally uniformly bounded with respect to \mathbf{x}_i and \mathbf{v}_i . As a consequence of that,

$$\|\mathbf{f}_i(t, \mathbf{x}_i, \mathbf{v}_i)\|_2 \leq \delta_{f_i} \quad (3)$$

Where $\delta_{f_i} \in \mathbb{R}^+$

B. Distributed Consensus Control Algorithm

Here, we examine the issue of smooth distributed consensus control for a second-order nonlinear MAS under the assumption of time-varying velocities. The aim of controlling is to design distributed individual protocols \mathbf{u}_i that will lead to the following sort of consensus agreement:

$$\begin{cases} \lim_{t \rightarrow \infty} \|\mathbf{x}_i(t) - \mathbf{x}_0(t)\|_2 = 0 \\ \lim_{t \rightarrow \infty} \|\mathbf{v}_i(t) - \mathbf{v}_0(t)\|_2 = 0 \end{cases} \quad \forall i \in \mathcal{M} \quad (4)$$

In order to find a solution to this consensus problem, we have come up with certain smooth distributed control protocols, which are as follows:

$$\mathbf{u}_i = -\alpha \mathbf{e}_i - \beta |\mathbf{e}_i|^\gamma \quad (5)$$

$$\mathbf{e}_i = \sum_{j=0}^n a_{ij}(\mathbf{x}_i - \mathbf{x}_j) + c \sum_{j=0}^n a_{ij}(\mathbf{v}_i - \mathbf{v}_j) \quad (6)$$

while α and β represent control gains and $c \in \mathbb{R}^+$ is constant, and the exponent γ is a positive constant chosen by the designer.

Assumption 4 There exists a constant $\delta_L \in \mathbb{R}^+$ for which

$$\|\mathbf{L} \otimes \mathbf{I}_p\|_\infty \leq \delta_L \lambda_{\max}(\mathbf{L}) \quad (7)$$

Where \mathbf{I}_p denotes the p -identity matrix, $p = n \times m$

Theorem 1 Let's suppose that assumptions 1-4 are valid, and that the communication graph \mathcal{G} is connected. It is possible that the parameters of the distributed protocols (5)-(7) can be satisfied if:

$$\begin{cases} \alpha < \frac{\beta \delta_{f_i}}{(1+c)\lambda_{\max}(\mathbf{L} \otimes \mathbf{I}_p)} \\ \beta > \binom{\gamma}{0}^{-1} \frac{1}{\lambda_2^{\gamma+1}(\mathbf{L})} \left(\frac{2V_x(0)}{\lambda_{\max}(\mathbf{L})} \right)^{1-\gamma} \\ \delta > 0 \end{cases} \quad (8)$$

Therefore, the consensus argument (4) is reached by a nonlinear leader-follower MAS (1)-(2). A Lyapunov function associated with the positions of the agents is indicated by $V_x(0) = V_x(t=0)$, where λ is an eigenvalue.

Proof: The time dependence is left out of the notation for simplicity. Each piece of evidence is described in detail below.

First, let's define the vectors $\tilde{\mathbf{x}}_i = \mathbf{x}_i - \mathbf{x}_0 \in \mathbb{R}^m$, $\tilde{\mathbf{v}}_i = \mathbf{v}_i - \mathbf{v}_0 \in \mathbb{R}^m$, $\tilde{\boldsymbol{\xi}}_x = [\tilde{\mathbf{x}}_1^T, \dots, \tilde{\mathbf{x}}_n^T]^T \in \mathbb{R}^p$, $\tilde{\boldsymbol{\xi}}_v = [\tilde{\mathbf{v}}_1^T, \dots, \tilde{\mathbf{v}}_n^T]^T \in \mathbb{R}^p$, $\mathbf{u} = [\mathbf{u}_1^T, \dots, \mathbf{u}_n^T]^T \in \mathbb{R}^p$, where $p = n \times m$, the system of (3-1)-(3-2) is modified by applying those notation to be

$$\begin{cases} \dot{\tilde{\boldsymbol{\xi}}}_x = \tilde{\boldsymbol{\xi}}_v \\ \dot{\tilde{\boldsymbol{\xi}}}_v = \mathbf{f}(\tilde{\boldsymbol{\xi}}_v) + \mathbf{u} \end{cases} \quad (9)$$

Second, employing (5) and (6) to (9), it gives

$$\begin{cases} \dot{\tilde{\boldsymbol{\xi}}}_x = \tilde{\boldsymbol{\xi}}_v \\ \dot{\tilde{\boldsymbol{\xi}}}_v = \mathbf{f}(\tilde{\boldsymbol{\xi}}_v) - \alpha(\mathbf{L} \otimes \mathbf{I}_p)\tilde{\boldsymbol{\xi}} - \beta|(\mathbf{L} \otimes \mathbf{I}_p)\tilde{\boldsymbol{\xi}}|^\gamma \end{cases} \quad (10)$$

Third, determine the following Lyapunov function for the system (3-10):

$$V = V_x + V_v + \tilde{\boldsymbol{\xi}}_x^T \mathbf{I}_p \tilde{\boldsymbol{\xi}}_v^T = \frac{1}{2} \tilde{\boldsymbol{\xi}}^T \begin{bmatrix} \sigma(\mathbf{L} \otimes \mathbf{I}_p) & \mathbf{I}_p \\ \mathbf{I}_p & \mathbf{I}_p \end{bmatrix} \tilde{\boldsymbol{\xi}} \quad (11)$$

$$\begin{cases} V_x = \frac{1}{2} \sigma(\mathbf{L} \otimes \mathbf{I}_p) \tilde{\boldsymbol{\xi}}_x^T \tilde{\boldsymbol{\xi}}_x \\ V_v = \frac{1}{2} \mathbf{I}_p \tilde{\boldsymbol{\xi}}_v^T \tilde{\boldsymbol{\xi}}_v \\ \tilde{\boldsymbol{\xi}} = [\tilde{\boldsymbol{\xi}}_x^T \quad \tilde{\boldsymbol{\xi}}_v^T]^T \in \mathbb{R}^{2p} \end{cases} \quad (12)$$

As a result, the following condition must be true for $\sigma \in \mathbb{R}^+$

$$V \geq \frac{1}{2} \tilde{\boldsymbol{\xi}}^T \begin{bmatrix} \sigma \lambda_2(\mathbf{L}) & 1 \\ 1 & 1 \end{bmatrix} \otimes \mathbf{I}_{n \times p} \tilde{\boldsymbol{\xi}} \quad (13)$$

Substituting the following form for (13):

$$V \geq \frac{1}{2} \xi^T \begin{bmatrix} A & B \\ B^T & C \end{bmatrix} \otimes I_{n \times p} \xi \quad (14)$$

Furthermore, V is positive using Schur's complement, if σ is chosen such that $\sigma > \frac{1}{\lambda_2}(\mathbf{L})$:

$$A - \mathbf{B}\mathbf{C}^{-1}\mathbf{B}^T = \sigma \lambda_2(\mathbf{L}) - 1 > 0 \quad (15)$$

Forth, utilize trajectories (10) to get the time derivative of the function V :

$$\begin{aligned} \dot{V} &= \xi^T \begin{bmatrix} \sigma(\mathbf{L} \otimes \mathbf{I}_p) & \mathbf{I}_p \\ \mathbf{I}_p & \mathbf{I}_p \end{bmatrix} \xi \\ &= \sigma \xi_x^T (\mathbf{L} \otimes \mathbf{I}_p) \xi_v + \xi_v^T \mathbf{I}_p \xi_v + \xi_x^T \mathbf{I}_p \xi_v + \xi_v^T \mathbf{I}_p \xi_v \\ &= \sigma \xi_x^T (\mathbf{L} \otimes \mathbf{I}_p) \xi_v + \xi_v^T \mathbf{I}_p \xi_v + (\xi_x^T + \xi_v^T) \xi_v \quad (16) \end{aligned}$$

This is the consequence of applying system dynamics (3-10) to the situation.

$$\begin{aligned} \dot{V} &= \sigma \xi_x^T (\mathbf{L} \otimes \mathbf{I}_p) \xi_v + \xi_v^T \mathbf{I}_p \xi_v + (\xi_x^T + \xi_v^T) \mathbf{f} \\ &\quad - \alpha (\xi_x^T + \xi_v^T) (\mathbf{L} \otimes \mathbf{I}_p) \xi_x + c (\mathbf{L} \otimes \mathbf{I}_p) \xi_v \\ &\quad - \beta (\xi_x^T + \xi_v^T) |(\mathbf{L} \otimes \mathbf{I}_p) \xi_x + c (\mathbf{L} \otimes \mathbf{I}_p) \xi_v|^\gamma \quad (17) \end{aligned}$$

By adopting Newton's generalized binomial theorem to the setting of the fixed-time graph topology, we demonstrate that

$$\begin{aligned} \dot{V} &= \sigma \xi_x^T (\mathbf{L} \otimes \mathbf{I}_p) \xi_v + \xi_v^T \mathbf{I}_p \xi_v + (\xi_x^T + \xi_v^T) \mathbf{f} \\ &\quad - \alpha (\xi_x^T + \xi_v^T) (\mathbf{L} \otimes \mathbf{I}_p) \xi_x + c (\mathbf{L} \otimes \mathbf{I}_p) \xi_v \\ &\quad - \beta (\xi_x^T + \xi_v^T) \sum_{k=0}^p \binom{\gamma}{k} [(\mathbf{L} \otimes \mathbf{I}_p) \xi_x]^{Y-k} [c (\mathbf{L} \otimes \mathbf{I}_p) \xi_v]^{-k} \quad (18) \end{aligned}$$

Therefore, if we want to show that $\dot{V} < 0$ holds when $\forall t > t_0$. As a starting point, let's consider about the term:

$$\begin{aligned} \sigma \xi_x^T (\mathbf{L} \otimes \mathbf{I}_p) \xi_v - \beta (\xi_x^T \\ + \xi_v^T) \sum_{k=0}^p \left\{ \binom{\gamma}{k} [(\mathbf{L} \otimes \mathbf{I}_p) \xi_x]^{Y-k} [c (\mathbf{L} \otimes \mathbf{I}_p) \xi_v]^{-k} \right\} \end{aligned}$$

We put a limit on this term by rewriting it as follows:

$$\begin{aligned} &\sigma \xi_x^T (\mathbf{L} \otimes \mathbf{I}_p) \xi_v - \beta (\xi_x^T \\ &+ \xi_v^T) \sum_{k=0}^p \left\{ \binom{\gamma}{k} [(\mathbf{L} \otimes \mathbf{I}_p) \xi_x]^{Y-k} [c (\mathbf{L} \otimes \mathbf{I}_p) \xi_v]^{-k} \right\} = \\ &\sigma \xi_x^T (\mathbf{L} \otimes \mathbf{I}_p) \xi_v - \beta \binom{\gamma}{0} (\xi_x^T)^T (\mathbf{L} \otimes \mathbf{I}_p)^Y \xi_v \\ &\quad - \beta \sum_{k=1}^p \left\{ c^k \binom{\gamma}{k} (\xi_x^{Y-k}) (\mathbf{L} \otimes \mathbf{I}_p)^Y \xi_v^k \right\} = \\ &\xi_x^T (\mathbf{L} \otimes \mathbf{I}_p) \xi_v \left[\sigma - \beta \binom{\gamma}{0} (\xi_x^{Y-1})^T (\mathbf{L} \otimes \mathbf{I}_p)^{Y-1} \right] \\ &\quad - \beta \sum_{k=1}^p \left\{ c^k \binom{\gamma}{k} (\xi_x^{Y-k}) (\mathbf{L} \otimes \mathbf{I}_p)^Y \xi_v^k \right\} \quad (19) \end{aligned}$$

According to the characteristics of the matrix \mathbf{L} , (19) is limited as follows:

$$\begin{aligned} &\sigma \xi_x^T (\mathbf{L} \otimes \mathbf{I}_p) \xi_v - \beta (\xi_x^T \\ &+ \xi_v^T) \sum_{k=0}^p \left\{ \binom{\gamma}{k} [(\mathbf{L} \otimes \mathbf{I}_p) \xi_x]^{Y-k} [c (\mathbf{L} \otimes \mathbf{I}_p) \xi_v]^{-k} \right\} \leq \end{aligned}$$

$$\begin{aligned} &\xi_x^T (\mathbf{L} \otimes \mathbf{I}_p) \xi_v \left[\sigma - \beta \binom{\gamma}{0} \lambda_2^{Y-1}(\mathbf{L}) \|\xi_x^{Y-1}\|_2 \right] \\ &\quad - \beta \sum_{k=1}^p \left\{ c^k \binom{\gamma}{k} (\xi_x^{Y-k}) (\mathbf{L} \otimes \mathbf{I}_p)^Y \xi_v^k \right\} \quad (20) \end{aligned}$$

We get that since V_x , is a quadratic function of $\|\xi_x\|$

$$\begin{aligned} &\xi_x^T (\mathbf{L} \otimes \mathbf{I}_p) \xi_v \left[\sigma - \beta \binom{\gamma}{0} \lambda_2^{Y-1}(\mathbf{L}) \|\xi_x^{Y-1}\|_2 \right] \\ &\quad - \beta \sum_{k=1}^p \left\{ c^k \binom{\gamma}{k} (\xi_x^{Y-k}) (\mathbf{L} \otimes \mathbf{I}_p)^Y \xi_v^k \right\} \leq \\ &\xi_x^T (\mathbf{L} \otimes \mathbf{I}_p) \xi_v \left[\sigma - \beta \binom{\gamma}{0} \lambda_2^{Y-1}(\mathbf{L}) \left(\frac{2V_x(0)}{\lambda_{\max}(\mathbf{L})} \right)^{Y-1} \right] \\ &\quad - \beta \sum_{k=1}^p \left\{ c^k \binom{\gamma}{k} (\xi_x^{Y-k}) (\mathbf{L} \otimes \mathbf{I}_p)^Y \xi_v^k \right\} \quad (21) \end{aligned}$$

By selecting on σ , you will be taken to a

$$\sigma = \beta \binom{\gamma}{0} \lambda_2^Y(\mathbf{L}) \left(\frac{2V_x(0)}{\lambda_{\max}(\mathbf{L})} \right)^{Y-1} > \frac{1}{\lambda_2(\mathbf{L})} \quad (22)$$

The gain of control β can be adjusted as

$$\beta > \binom{\gamma}{0}^{-1} \frac{1}{\lambda_2^{Y+1}(\mathbf{L})} \left(\frac{2V_x(0)}{\lambda_{\max}(\mathbf{L})} \right)^{1-Y} \quad (23)$$

When applying (23) to (21), we get

$$\begin{aligned} &\sigma \xi_x^T (\mathbf{L} \otimes \mathbf{I}_p) \xi_v \\ &- \beta \sum_{k=0}^p \left\{ \binom{\gamma}{k} [(\mathbf{L} \otimes \mathbf{I}_p) \xi_x]^{Y-k} [c (\mathbf{L} \otimes \mathbf{I}_p) \xi_v]^{-k} \right\} \leq \\ &\quad - \beta \sum_{k=1}^p \left\{ c^k \binom{\gamma}{k} (\xi_x^{Y-k}) (\mathbf{L} \otimes \mathbf{I}_p)^Y \xi_v^k \right\} \quad (24) \end{aligned}$$

Lemma 2: [27] For a vector $\mathbf{v} \in \mathbb{R}^n$ with $1_n^T \mathbf{v} = 0$ with $1_n = [1, \dots, 1]^T_n$, inequalities involving the following hold $\lambda_{\min}(\mathbf{M}) > 0$.

$$\begin{cases} \mathbf{v}^T \mathbf{M} \mathbf{v} \geq \lambda_{\min}(\mathbf{M}) \mathbf{v}^T \mathbf{v} \\ (\mathbf{S} \otimes \mathbf{I}_N) \mathbf{v} \leq \lambda_{\max}(\mathbf{S}) \|\mathbf{v}\|_2 \end{cases} \quad (25)$$

It follows from (23) and (24) that

$$\begin{aligned} \dot{V} &\leq \xi_v^T \mathbf{I}_p \xi_v - \alpha \lambda_{\max}(\mathbf{L} \otimes \mathbf{I}_p) (\|\xi_x^T\|_2 \|\xi_x\|_2 + \|\xi_v^T\|_2 \|\xi_x\|_2) \\ &\quad + c \lambda_{\max}(\mathbf{L}) \|\xi_v\|_2 \\ &\quad - \beta \sum_{k=1}^p \left\{ c^k \binom{\gamma}{k} (\xi_x^{Y-k}) (\mathbf{L} \otimes \mathbf{I}_p)^Y \xi_v^k \right\} \quad (26) \end{aligned}$$

Next, we rewrite (3-17) so that the term $\xi_v^T \mathbf{I}_p \xi_v - \alpha (\xi_x^T + \xi_v^T) (\mathbf{L} \otimes \mathbf{I}_p) \xi_x + c (\mathbf{L} \otimes \mathbf{I}_p) \xi_v$

$$\begin{aligned} \dot{V} &\leq \xi_v^T \mathbf{I}_p \xi_v - \alpha \lambda_{\max}(\mathbf{L} \otimes \mathbf{I}_p) (\|\xi_x^T\|_2 \|\xi_x\|_2 + \|\xi_v^T\|_2 \|\xi_x\|_2) \\ &\quad + c \lambda_{\max}(\mathbf{L}) \|\xi_v\|_2 \\ &\quad - \beta \sum_{k=1}^p \left\{ c^k \binom{\gamma}{k} (\xi_x^{Y-k}) (\mathbf{L} \otimes \mathbf{I}_p)^Y \xi_v^k \right\} \quad (27) \end{aligned}$$

Condition $\dot{V} < 0$ holds when $\forall t > t_0$, (27) is found by rearranging as follows:

$$\dot{V} \leq \xi^T \mathbf{Y} \xi - \beta \sum_{k=1}^p \{c^k (\gamma_k) (\xi_x^{\gamma-k}) (\mathbf{L} \otimes \mathbf{I}_p)^Y \xi_v^k\} \quad (28)$$

where

$$\begin{cases} Y_{11} = \beta \delta_{f_i} + 1 \\ Y_{12} = Y_{21} = \frac{1}{2} \alpha (1 + c) \lambda_{\max}(\mathbf{L} \otimes \mathbf{I}_p) \\ Y_{22} = \frac{1}{2} \alpha (1 + c) \lambda_{\max}(\mathbf{L} \otimes \mathbf{I}_p) \end{cases} \quad (29)$$

It follows from (28) that \dot{V} is negatively definite if and only if

$$\alpha (1 + c) \lambda_{\max}(\mathbf{L} \otimes \mathbf{I}_p) - \beta \delta_{f_i} < 0 \quad (30)$$

Which results in

$$\alpha < \frac{\beta \delta_{f_i}}{(1+c) \lambda_{\max}(\mathbf{L} \otimes \mathbf{I}_p)} \quad (31)$$

IV. DISTRIBUTED COOPERATIVE CONTROL FOR UAV MAS

A. UAV MAS Dynamics

Consider a network of n UAVs are operating autonomously, and that the three-dimensional trajectory of each vehicle $i \in N$ is defined by a vector \mathbf{q}_i where

$$\mathbf{q}_i [\mathbf{x}_i, \boldsymbol{\vartheta}_i]^T = [(x_i, y_i, z_i)^T, (\gamma_i, \theta_i, \psi_i)^T]^T \in \mathbf{R}^6 \quad (32)$$

Where the position vector is denoted by \mathbf{x}_i , whereas the angular rotation vector is denoted by $\boldsymbol{\vartheta}_i$, which includes roll, pitch, and yaw. Within the boundaries of the body airframe, the angular velocity vector $\boldsymbol{\omega}_i$ is defined as

$$\boldsymbol{\omega}_i = \begin{bmatrix} 1 & 0 & -\sin\theta \\ 0 & \cos\gamma & \cos\theta \sin\gamma \\ 0 & \sin\gamma & \cos\theta \cos\gamma \end{bmatrix} \boldsymbol{\vartheta}_i \quad (33)$$

All of the following agent and leader dynamic models are considered as following

Agents:

$$\begin{cases} \dot{\mathbf{x}}_i = \mathbf{v}_i, \dot{\mathbf{v}}_i = \mathbf{f}_{it} + \mathbf{u}_{it} \\ \dot{\boldsymbol{\vartheta}}_i = \boldsymbol{\omega}_i, \dot{\boldsymbol{\omega}}_i = \mathbf{f}_{ir} + \mathbf{u}_{ir} \end{cases} \quad (34)$$

Leader:

$$\begin{cases} \dot{\mathbf{x}}_0 = \mathbf{v}_0, \dot{\mathbf{v}}_0 = \mathbf{f}_{t0} \\ \dot{\boldsymbol{\vartheta}}_0 = \mathbf{T}^{-1} \boldsymbol{\omega}_0, \dot{\boldsymbol{\omega}}_0 = \mathbf{f}_{r0} \end{cases} \quad (35)$$

where t and r denote translational and rotational motions, respectively; $\mathbf{f}_{it} = \mathbf{T}^{-1} \mathbf{f}_{t0}$, $\mathbf{f}_{ir} = \mathbf{f}_{r0}$; \mathbf{T} is the matrix that connects the body frame to the inertial frame; it is obtained, from Euler rotations, as

$$\mathbf{T} = \begin{bmatrix} T_{11} & T_{12} & T_{13} \\ T_{21} & T_{22} & T_{23} \\ T_{31} & T_{32} & T_{33} \end{bmatrix} \quad (36)$$

where

$$\begin{cases} T_{11} = \cos\psi \cos\psi - \cos\theta \sin\gamma \sin\psi \\ T_{12} = -\cos\psi \sin\gamma - \cos\gamma \cos\theta \sin\psi \\ T_{13} = \sin\theta \sin\psi \\ T_{21} = \cos\theta \cos\psi \sin\gamma - \cos\gamma \sin\psi \\ T_{22} = \cos\gamma \cos\theta \cos\psi - \sin\gamma \sin\psi \\ T_{23} = -\cos\psi \sin\theta \\ T_{31} = \sin\gamma \sin\theta \\ T_{32} = \cos\gamma \sin\theta \\ T_{33} = \cos\theta \end{cases}$$

B. UAV MAS Consensus Control

Lemma 3: Theorem 1 is used to construct the \mathbf{u}_{it} and \mathbf{u}_{ir} control inputs for translation and rotation, respectively.

$$\begin{cases} \mathbf{u}_{it}(t) = -\alpha_t \mathbf{e}_{it} - \beta_t |\mathbf{e}_{it}|^Y \\ \mathbf{u}_{ir}(t) = -\alpha_r \mathbf{e}_{ir} - \beta_r |\mathbf{e}_{ir}|^Y \end{cases} \quad (37)$$

where α_t , β_t , α_r , and β_r are computed by using (23) and (30), and

$$\begin{cases} A_{it}(t) = \sum_{j=0}^n a_{ij} (\mathbf{x}_i(t) - \mathbf{x}_j(t)) \\ \quad + c \sum_{j=0}^n a_{ij} (\mathbf{v}_i(t) - \mathbf{v}_j(t)) \\ A_{ir}(t) = \sum_{j=0}^n a_{ij} (\boldsymbol{\vartheta}_i(t) - \boldsymbol{\vartheta}_j(t)) \\ \quad + c \sum_{j=0}^n a_{ij} (\boldsymbol{\omega}_i(t) - \boldsymbol{\omega}_j(t)) \end{cases} \quad (38)$$

C. UAV MAS Formation Control

The goal of formation control is to develop translational and rotational controls that allow multi-UAVs to precisely track a predetermined geometric pattern $\mathcal{P}(x, y, z)$ in three-dimensional space with

$$\sum_{i=1}^n p_{ix} = p_{0x}, \sum_{i=1}^n p_{iy} = p_{0y}, \sum_{i=1}^n p_{iz} = p_{0z} \quad (39)$$

Where (p_{0x}, p_{0y}, p_{0z}) is the center of the geometric pattern $\mathcal{P}(x, y, z)$.

In this scenario, we assume that the formation states are denoted by that η_{1i} , η_{2i} and, η_{3i} , and that the formation control protocols are denoted by u_{1i} and, u_{2i} , and that the formation evolves according to the following dynamics system [28]:

$$\begin{cases} \dot{\eta}_{1i} = u_{1i} \\ \dot{\eta}_{2i} = u_{2i} \\ \dot{\eta}_{3i} = u_{1i} \eta_{2i} - k_0 |u_{1i}| \eta_{3i} \end{cases} \quad (40)$$

where $k_0 \in \mathbb{R}^+$. The following illustrates how the trajectories of the agents relate to the pattern's trajectory:

$$\begin{cases} x_i = \cos(\eta_{1i}) [\eta_{2i} - k_0 \text{sign}(u_{1i}) \eta_{3i}] + \sin(\eta_{1i}) \eta_{3i} + p_{xi} \\ y_i = \sin(\eta_{1i}) [\eta_{2i} - k_0 \text{sign}(u_{1i}) \eta_{3i}] + \cos(\eta_{1i}) \eta_{3i} + p_{yi} \\ z_i = p_{zi} \end{cases} \quad (41)$$

If $\lim_{t \rightarrow \infty} (\eta_{ki} - \eta_{k0}) = 0$ and $\lim_{t \rightarrow \infty} (u_{li} - u_{l0}) = 0$ for $k = 1, 2, 3; l = 1, 2; 1 \leq i \leq n$, then for $1 \leq i \neq j \leq n$ the MAS of n -UAV achieves

$$\begin{aligned} \lim_{t \rightarrow \infty} \begin{bmatrix} x_i - x_j \\ y_i - y_j \\ z_i - z_j \end{bmatrix} &= \begin{bmatrix} p_{xi} - p_{xj} \\ p_{yi} - p_{yj} \\ p_{zi} - p_{zj} \end{bmatrix}, \lim_{t \rightarrow \infty} \left(\sum_{i=1}^n \frac{x_i}{n} - x_0 \right) = 0, \\ \lim_{t \rightarrow \infty} \left(\sum_{i=1}^n \frac{y_i}{n} - y_0 \right) &= 0, \lim_{t \rightarrow \infty} \left(\sum_{i=1}^n \frac{z_i}{n} - z_0 \right) = 0 \end{aligned} \quad (42)$$

where the leader coordinates are denoted by x_0, y_0, z_0 respectively (the formation pattern centroid). The definition of the vector $\tilde{\eta}_i = [(\eta_{1i} - \eta_{10}), (\eta_{2i} - \eta_{20}), (\eta_{3i} - \eta_{30})]^T$ as the tracking error vector for each UAV $_i$ and applying control law (5) to both u_{1i} and u_{2i} , we are able to establish that

$$\begin{cases} u_{ki} = -\alpha_k A_{ki} - \beta_k |A_{ki}|^\gamma \\ A_{ki}(t) = \sum_{j=0}^n a_{ij} (\eta_{ki}(t) - \eta_{kj}(t)), k = 1, 2. \end{cases} \quad (43)$$

Following is the reduced dynamic system that is generated as a result of substituting protocols (42) into the first two dynamic equations of the system (39):

$$\begin{cases} \dot{\eta}_{1i} = -\alpha_1 \sum_{j=0}^n a_{ij} (\eta_{1i}(t) - \eta_{1j}(t)) \\ -\beta_1 \left| \sum_{j=0}^n a_{ij} (\eta_{1i}(t) - \eta_{1j}(t)) \right|_i^\gamma + \dot{\eta}_{10} \\ \dot{\eta}_{2i} = -\alpha_2 \sum_{j=0}^n a_{ij} (\eta_{2i}(t) - \eta_{2j}(t)) \\ -\beta_2 \left| \sum_{j=0}^n a_{ij} (\eta_{2i}(t) - \eta_{2j}(t)) \right|_i^\gamma + \dot{\eta}_{20} \end{cases} \quad (44)$$

In the form of a vector, equation (44) is identical to the auxiliary closed-loop system that is presented in the following:

$$\dot{\tilde{\eta}} = -\alpha(\mathbf{L} \otimes \mathbf{I}_2)\tilde{\eta} - \beta|\mathbf{L} \otimes \mathbf{I}_2\tilde{\eta}|^\gamma - \dot{\eta}_0 \quad (45)$$

where

$$\begin{aligned} \tilde{\eta} &= [\tilde{\eta}_1^T, \tilde{\eta}_2^T]^T = [\tilde{\eta}_{11}, \dots, \tilde{\eta}_{1n}, \tilde{\eta}_{21}, \dots, \tilde{\eta}_{2n}]^T \\ \dot{\eta}_0 &= [\mathbf{1}_n^T \dot{\eta}_{10}, \mathbf{1}_n^T \dot{\eta}_{20}]^T \\ \alpha &= \begin{bmatrix} \alpha_1 \mathbf{I}_n & \mathbf{0}_{nn} \\ \mathbf{0}_{nn} & \alpha_2 \mathbf{I}_n \end{bmatrix}, \beta = \begin{bmatrix} \beta_1 \mathbf{I}_n & \mathbf{0}_{nn} \\ \mathbf{0}_{nn} & \beta_2 \mathbf{I}_n \end{bmatrix} \end{aligned}$$

Theorem 2: Considering Assumptions 1-3 hold true, the communication graph \mathcal{G} is connected and the control inputs to the closed-loop system (46) are selected according to (43), the agents' states η_{1i} and η_{2i} will converge to the formation states η_{10} and η_{20} , respectively, if the tracking error converges to zero $\lim_{t \rightarrow \infty} (\tilde{\eta}_i) = 0$.

Proof: The following quadratic function can be considered of as a potential Lyapunov function

$$V = \frac{1}{2} \tilde{\eta}^T (\mathbf{L} \otimes \mathbf{I}_2) \tilde{\eta} \quad (46)$$

If we assume that V is continuously differentiable with regard to ζ , we may formulate its time derivative \dot{V} as

$$\dot{V} = \tilde{\eta}^T (\mathbf{L} \otimes \mathbf{I}_2) \dot{\tilde{\eta}} \quad (47)$$

If the auxiliary closed-loop system (45) is used, we obtain

$$\dot{V} = -\alpha \tilde{\eta}^T (\mathbf{L} \otimes \mathbf{I}_2) \tilde{\eta} - \beta \tilde{\eta}^T (\mathbf{L} \otimes \mathbf{I}_2) |\mathbf{L} \otimes \mathbf{I}_2 \tilde{\eta}|^\gamma - \dot{\eta}_0 \quad (48)$$

Since $\gamma > 0$ and the gain matrices α and β are both diagonal, we have

$$\begin{aligned} \dot{V} &\leq -\det(\alpha) \tilde{\eta}^T (\mathbf{L} \otimes \mathbf{I}_2) \tilde{\eta} \\ &\quad - \det(\beta) \tilde{\eta}^T (\mathbf{L} \otimes \mathbf{I}_2) |\mathbf{L} \otimes \mathbf{I}_2 \tilde{\eta}|^\gamma \end{aligned} \quad (49)$$

Furthermore, the inequation (49) satisfies

$$\dot{V} \leq -\det(\alpha) \lambda_{\min}^2(\mathbf{L} \otimes \mathbf{I}_2) \|\tilde{\eta}\|_2^2 \quad (50)$$

Since $V = \frac{1}{2} \tilde{\eta}^T (\mathbf{L} \otimes \mathbf{I}_2) \tilde{\eta} \leq \frac{1}{2} \lambda_{\max}(\mathbf{L} \otimes \mathbf{I}_2) \|\tilde{\eta}\|_2^2$ and $\lambda_i(\mathbf{L} \otimes \mathbf{I}_2) = \lambda_i(\mathbf{L})$, it follows that

$$\dot{V} \leq -\det(\alpha) \frac{\sqrt{2} \lambda_{\min}^2(\mathbf{L})}{\sqrt{\lambda_{\max}(\mathbf{L})}} \sqrt{V} \quad (51)$$

It is concluded from (51) that

$$\sqrt{V} \leq \sqrt{V_0} - \frac{\det(\alpha)}{\sqrt{2}} \frac{\lambda_{\min}^2(\mathbf{L})}{\sqrt{\lambda_{\max}(\mathbf{L})}} t \quad (52)$$

Formation tracking is guaranteed to converge if and only if $\sqrt{V} = 0$

$$\begin{aligned} t &\geq \sqrt{V_0} \frac{\sqrt{2}}{\det(\alpha)} \frac{\sqrt{\lambda_{\max}(\mathbf{L})}}{\lambda_{\min}^2(\mathbf{L})} \\ &= \frac{\sqrt{\zeta^T(0)(\mathbf{L} \otimes \mathbf{I}_2)\zeta(0)} \sqrt{\lambda_{\max}(\mathbf{L})}}{\det(\alpha) \lambda_{\min}^2(\mathbf{L})} \end{aligned} \quad (53)$$

V. SIMULATION

A. Consensus of Formation Pattern

Here, a team of $n = 4$ UAVs performs out a path-following mission within a simulated environment. As illustrated in Fig. 1, the path under consideration follows a half-parabolic shape. A swarm of UAVs forms in a specified formation is shown in Fig. 2 (a), following the common trajectory. Using the topology depicted in Fig. 2 (b), they track together a predetermined 3D trajectory through space.

Fig. 1. Desired formation and trajectory.

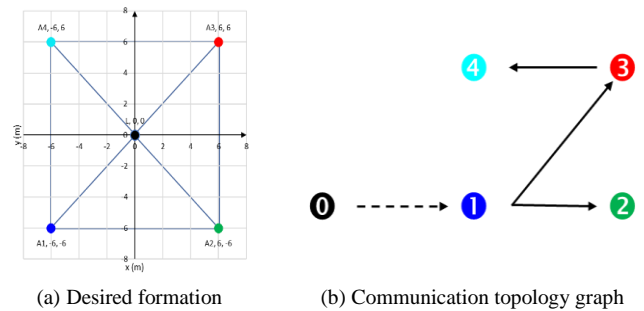

Fig. 2. Desired formation and fixed-time directed communication topology graph.

Fig. 3 illustrates the consensus in three dimensions among the four agents, as well as the timeline of how the agents' orientations gradually approach those of the virtual leader. Meanwhile, Fig. 4 illustrates the path taken for the leader and the followers by the centroid formation as it moves along the motion axes.

(a) Consensus of the team of four agents.

(b) Agents' orientations.

Fig. 3. Formation tracking with the control law.

Fig. 4. Geometric pattern centroid tracking.

B. Tracking of Formation Pattern

Within the context of the simulated scenario, a team of four UAVs performs out a routing path following mission. Parametric trajectories take into account the considered path as defined by:

$$\begin{cases} x = \frac{x_0 + \cos^{-1} t - b r \sin t}{\sqrt{a^2 + b^2}} \\ y = \frac{y_0 + \cos^{-1} t - b r \sin t}{\sqrt{a^2 + b^2}} \\ z = z_0 + r \cos t \sqrt{a^2 + b^2} \end{cases} \quad (54)$$

With $a = 10$, $b = 10$, and $r = 50$

The formation mission can be accomplished with a switching communication topology like that illustrated in Fig. 5 and a dwell duration of 15 s.

Fig. 5. Switching undirected topology interaction graph.

Fig. 6 illustrates how the proposed control law was applied to the formation tracking.

Fig. 6. Formation tracking with the proposed control law.

Fig. 3 to 6 show that the four UAVs achieved the formation requirements with the proposed distributed protocol despite the complex communication limitations and dynamic constraints. the tracking error of the formation is 0, as shown in Fig. 3. This demonstrates that the distributed formation control protocol is successful for UAV formation even under communication loss and topology switching conditions. If the formation of the UAVs needs to be adjusted while they are in flight, the control protocol can be used even when the UAVs' configuration changes dynamically. The results of the simulation demonstrate the effectiveness of the proposed control scheme.

VI. CONCLUSION

Based on leader-following consensus in MAS, a smooth distributed cooperative control for multi-air vehicles such as UAVs was designed. First, we developed smooth distributed consensus protocols, as opposed to the traditional sliding-mode based algorithms, by substituting the discontinuous signum function with a continuous integral function. Then, a model for flying formation control was developed to track and maintain three-dimensional geometric patterns. A Lyapunov function-based approach was used to set the necessary and sufficient requirements for the convergence of both consensus and formation algorithms. The primary focus of the presented study in the near future will be on event-based formation control for multi-UAV systems, formation tracking in harsh environments, obstacle avoidance and disturbance rejections among aerial moving agents.

Abstract—Economic indicator prediction in big data requires treating all random variables as an independent set of selective values and used as a discriminative method for classification tasks. A Bayesian network is a popular graphical representation approach for modeling probabilistic dependencies and causality among a set of random variables to incorporate a huge amount of human expert knowledge about the problem of interest involving diagnostic reasoning of big data. In our study, we set out to construct the Bayesian networks using the standard error for a least-squares linear regression (STE) and the domain knowledge from the literature in the field for predicting the big data economy prediction. The experimental results show that the proposed STE baseline provided us with an accuracy of 20% to 58% in seven out of eight regions, including the aggregate for “World”. In comparison, the Bayesian Networks generated by our first Domain Knowledge Model improved accuracy from 54% to 75% in the same regions.

Keywords—STE; Bayesian networks; domain knowledge; discriminative methods; economic forecasting

I. INTRODUCTION

Although methods exist to construct Bayesian networks using expert knowledge [1][2], genetic algorithms [3][4], and topological ordering [4][5] few methods exist to construct a Bayesian network using purely mathematical relations between the variables [5]. We believe such a method to be an important contribution to the field, for which reason we set out to develop it.

We based our method on the standard error for a least-squares linear regression, or STE [6]. This metric is consistent with commonly used statistics such as the correlation coefficient ([7], [8]) and has the additional advantage of allowing us to test causation. This, combined with minimal domain knowledge, allows us to define an unambiguous, valid Bayesian network.

To test our method, we set out to apply it to the problem of predicting economic growth. This problem not only has a large number of variables on which to build on, but it has also become particularly important in the past eight years given the considerable slowdown that has occurred in the global economy. More informed prediction mechanisms would prove invaluable to policy makers and help them make better decisions. However, it seems unlikely (and in fact is strongly

discouraged [9]) that a single model can encompass all the countries in the world accurately. It is necessary, then, to subdivide the countries into regions and build a prediction model for each. This makes it an ideal fit to test our Bayesian Network construction methodology: our problem is not only to create a good prediction model, but how can we build prediction models for each country or region.

Our Bayesian Networks aim to show such how significant these factors are to economic growth in each region. We select a series of variables that measure Economy, Production, Education, and Innovation. We will relate them using STE to create a network, establishing a link where a strong relation is found, and discarding the links that contradict domain knowledge. We will then train and test the networks against the data from the variables.

The next section explains in greater detail the problem of economic growth. Section III describes previous work, both in computing factors of economic growth, and in developing Bayesian Network construction methodologies. Section IV gives the formal problem formulation. Section V explains the complexity of the dataset. Section VI goes into our Bayesian Network construction methodology. Section VII will show how we applied it to the economic prediction problem, followed by a discussion of our results, both as far as computed networks and our evaluation of them. We conclude by evaluating our successes and remaining challenges.

II. BACKGROUND THEORY

The global economy is in trouble. Global GDP has been generally falling for nearly a decade (see Fig. 1). Governments worldwide and investors have been forced to cut back on spending [10], reducing the strength of the actors that have traditionally been expected to spur economies [11]. A return to the year-to-year growth observed prior to the Great Recession is desirable (the Great Recession can be observed between the years 2007–2009 in Fig. 1). This would indicate a return to a global economy capable of withstanding events such as the Asian Financial Crisis (1997–1999 in Fig. 1) and the dot-com crash (2001–2003 in Fig. 1) without affecting the overall global trend. However, such a strengthening does not seem likely under current conditions. It is only natural for the global question to be how to achieve this.

Fig. 1. Percentage of growth in worldwide Gross Domestic Product per capita based on Purchasing Power Parity [12]. The percentage $(y_i - y_{i-1}) / y_{i-1}$ is shown with a solid line. The trend (as given by an ordinary linear regression on the years covered) is shown with a dotted line.

Decisions in recent years have seen education funding cut, with widespread opposition. Worldwide, UNESCO has largely led the fight on preventing education funding from being cut.

The 2020 report [10] had the explicit aim to develop policy and public awareness on the “social and economic” importance of preparing engineers. The question of what to cut ultimately boils down to how important each of these factors is.

Recent research has shown that investment in education and technology would be extremely favorable to economic growth. As Irina Bokova said in a 2020 UNESCO report, the current economic crisis presents challenges and opportunities for engineering. There are encouraging signs that world leaders recognize the importance of continuing to fund engineering, science and technology [This investment] may provide a path to economic recovery and sustainable development [13].

A country’s economic growth has been proven to depend strongly on the number of experts that country has in several areas. ([14], [15]) Specifically, economic growth depends on the knowledge gained by these persons that can be used to manufacture goods, perform services, and improve the productivity of existing processes. This knowledge is known as “productive knowledge” ([16], [10]) and is usually a subset of the knowledge gained by these persons in their higher education studies, or new knowledge generated by them. Therefore, we can measure productive knowledge, and thereby the effect of higher education on the economy, by comparing the number of graduates in different areas, and the research they perform. However, the exact weight of productive knowledge in comparison to more traditional factors such as government spending [11] has never been quantitatively assessed. Detriments of favoring any one factor exclusively, are well known [17], but the strength of the influence is observed through trial and error if it is assessed at all.

In this paper, we posit that the Bayesian interpretation of conditional probability is a good measure of this influence. To this end, we will construct a Bayesian network to predict two economic indicators from: two production indicators, one education indicators, and two innovation indicators.

III. PREVIOUS WORK

Much has been published linking different economic and education variables to economic growth. In recent years, research has shown that economic development depends strongly on the number of engineers ([10], [15]), scientists ([10], [16], [14]), researchers ([10], [14]), and experts in technology ([12], [15]) While the existence of a strong relation cannot be denied, none of these studies have measured the strength of this link compared to other possible factors mostly because they lack a practical application. A Bayesian Network provides such a practical application.

Procedures for constructing Bayesian networks, however, are scant [5]. The most basic method ([1], [18]) consists of the arrangement of variables in cause and effect ordering and the exploitation of conditional independence assumption such that Chain rule can be applied to form the conditional probability table. However, this method is strongly dependent on the ordering of the variables which, in the absence of any true natural order, ends up being pure guesswork.

Methodologies have been developed to construct Bayesian networks for specific purposes, mainly using genetic algorithms ([19], [3], [5]). These algorithms are strongly dependent on their initial population which because they are generated at random, is also pure guesswork. Comparing variables using purely their statistical properties has been done previously using mutual information as a measure of dependence in [7]; however, this work also points out that this approach does not seek to optimize any statistical and makes no use of the existing domain knowledge. The authors attempt to introduce an external optimization metric but notes that it is computationally intensive. In our approach, the variables are compared with a measure of dependence based on an optimized square error.

The authors of [7] also indicate that the number of parents for each node must be restricted in some way, but provide no guidelines on how to do so, leaving the possibility of all other variables to be considered, creating a factorial-order problem. In our approach, we use a domain knowledge graph, thus restricting the number of operations to a polynomial-order problem.

IV. BIG DATA PROBLEM FORMULATION

To allow future research to perform similar tasks and compare more easily, we present a mathematical formulation presented first as an agent-environment problem and then as a “black box” problem. An agent charged with the task of predicting development indicators would live in an environment where all the data from all the countries and regions in the world exist. A state in this environment would be defined by the intersection of a year and a region/country; for instance, the state given by ⟨Sub-Saharan Africa, 1999⟩. Such an agent would, taking a selection of these variables, output a prediction for any other variable (For instance, GDP growth). Its goal is to make the correct prediction. We define success of this goal if the prediction is exact, and failure if it is not. Because we will take the dependences of these variables (x_1, x_2, \dots, x_n) , each defined in the discretized domain $\{High,$

Medium, and Low}, an exact prediction only needs to be exact if it matches the corresponding discrete variable.

Our task is the generation of said agents is to better understand the problem, we offer a black box formulation: Our economic prediction agents are black boxes that take education, innovation, and production indicators and output economic indicators. However, at a higher level we have the problem of how to generate such a black box. Given that every region is different [9], we should create an agent for each. We therefore define a black box prime as a black box that outputs agent black boxes from variables and domain knowledge.

V. DATASET

To properly estimate the economy, we need to measure the variables related to productive knowledge ([16], [10]). We used as our data source the World Bank open data bank [12] and hand-picked six variables from their list of world development indicators.

- GDP per capita, PPP (constant 2011 international \$).
- GDP growth (annual %).
- Industry, value added (% of GDP).
- Agriculture, value added (% of GDP).
- Labor force with tertiary education (% of total).
- Scientific and technical journal articles.
- General government final consumption expenditure (% of GDP).

Each indicator has data from 1960 to 2013, with some values missing. We categorized the indicators into Economic (GDP per capita and GDP growth), Innovation (Journal articles and Government expenditure), Production (Industry and Agriculture), and Education (Tertiary education). We choose

PPP as a suitable measure of the economy independent of inflation; Industry as a measure of mining, manufacturing, and construction [20]; Journal articles as a measure of the amount of research being performed in the region; and Government Expenditure as a measure of how much money the local governments are pumping into their economies, whether it be as incentives or investments.

Labor Force with Tertiary Education refers to the number of working-age adults that have completed College or its local equivalent [21]. We chose this over other education measures based on conclusions in [15] pointing it out as more significant.

A. Regional Subdivision

Because there are 217 countries and territories in the World Bank, it seems prudent to aggregate them somehow and make use of their combined data. However, this creates the problem of how to perform this aggregation, and how to assign weights to each country. Fortunately, the World Bank also defines 32 aggregations, with the values of each country correctly weighted and added together. We will use the World Bank’s seven regions of the world, which will allow us to cover the world completely [22]. In the cases where a region is divided into “developing only” and “all income levels”, we use the latter. Finally, we consider the aggregate for “world” as an eighth region be able to evaluate our accuracy in predicting the global economy.

B. Dataset Size

In our dataset, we have 4752 data points, 2135 of which are missing, representing 45% missing and 55% not missing. The World Bank handles data at country-level granularity. When it performs an aggregate, it leaves the value for that year blank if the data from one-third of the countries in that region are missing [23]. However, most regions have very completed data for at least half of the variables. For exact proportions of missing data and dataset dimensions, see Table I.

TABLE I. PROPORTION OF MISSING VALUES AND DATASET DIMENTION SIZE

A. Preprocessing Stage

In the preprocessing stage, there are some initial steps are implemented such as big data scaling, and missing value treating.

1) *Big data scaling step*: Most variables in our dataset are percentages. However, the variables for journal articles are numerical quantities. It is good practice to train Bayesian networks with normalized values, all within the same range, for which reason we perform a simple scaling.

Simply we take the value for each of these variables according to its region and divide it by the population of this region times 100. This is formally stated in (1) where R refers to each region in the dataset.

$$Scaled_{variableR} = \frac{old_variableR}{PopulationR} \times 100 \quad (1)$$

2) *Big data missing value treatment*: The missing values were simply ignored. Since each variable has a deep complex economic implication defined solely by The World Bank [23], and they highly depend on many other evidences, we decided that the prediction of those missing values by filling in the best values or with distribution using EM algorithm would be a crude estimation if not biased towards the low amount of data in our study. We select which rows to ignore in each operation using matlab's *isnan* function.

VI. METHODOLOGY

Our main contribution to the field lies in our methodology, which can be summarized in the following steps:

- Selection of Parameters.
- Calculation of dependency.
- Determination of causality.
- Construction of the Bayesian Network.
- Evaluation of the Bayesian Network.

This methodology is fully automatable and can be adapted to any domain. We start off by selecting and categorizing the variables. A simple linking of the categories using the domain knowledge creates a graph which we term our Domain Knowledge Model, which allows the procedure to readily be applied to other domains by simply changing the variables involved. We then calculate the degree of dependence between all the variables in every pair of linked categories, after some minimal preprocessing. By using just, the links between categories, as opposed to comparing all against all, this reduces our computations from $(n+m)!$ (similar to the approaches used by [7], [1], and [18]) to $n \times m$; where n and m are the number of variables in each category. The resulting Bayesian network can then be trained and evaluated normally.

B. Bayesian Network Construction Stage

In the proposed work, we used the standard error for a least-squares linear regression or STE ([6], [15]) to calculate dependence. In particular, we used the implementation by Sansom [22]. We note that the methodology is not tied to this statistical (Friedman et al. [7] suggests correlation or mutual information for this purpose; however, STE is known to be consistent with both of these statistical). We use STE because it gives an indication of which variable is the dependent variable and which one is the independent variable. Specifically, a small STE (Y, X) implies a strong causative relation where Y depends on X [24].

The formula for STE is shown in Equation (2) with Y and X being vectors of values that have a length n , and with \bar{Y} and \bar{X} being their respective sample means.

$$STE(Y, X) = \sqrt{\frac{1}{n-2} \left(\sum_{y \in Y} (y - \bar{Y})^2 - \frac{\sum_{x \in X, y \in Y} (x - \bar{X})(y - \bar{Y})^2}{\sum_{y \in Y} (x - \bar{X})^2} \right)} \quad (2)$$

To make the result easier to interpret, we use Equation (3) from [15] so that higher values are better. This equation also normalizes the measure into the [0,1] range for better readability. We call this the degree of dependency. Note that vertical bars denote absolute value.

$$Dependency(Y, X) = \frac{1 - |STE(x, y)|}{\bar{y}} \quad (3)$$

If $dependency(Y, X) > dependency(X, Y)$, we conclude there may be a causal relationship between X and Y , with X being the cause and y being the effect, and thus add an arc from X to Y in our Bayesian network. However, if $dependency(Y, X) < dependency(X, Y)$ rather than concluding Y is the cause and X is the effect, we discard it entirely. This is because the comparison is made following the links in the Domain Knowledge Model, and adding such an arc would contradict the domain knowledge. Because data may be prone to errors, outliers, or may simply not be complete enough, we define the case when $dependency(Y, X)$ is slightly less than $dependency(X, Y)$. This is the case when $dependency(Y, X) \leq dependency(X, Y)$, but are close enough to consider that, given slightly better data, we could have $dependency(Y, X) > dependency(X, Y)$. We define a threshold of three percent as the limit of this closeness; however, this threshold is user-defined as any number between zero and one and only depends on the desired number of arcs. Note that we can similarly use simple STE (2) instead of dependency, but in this case the threshold would have to be defined between $-\bar{Y}$ and \bar{Y} . In other words, the normalization of STE in (3) means that, when the threshold values are interpreted as maximum error, they are expressed in means of Y .

Finally, it has been define the case when $dependency(Y, X)$ is simply too small to imply a causal relationship. Since we do not want to add an arc in these cases even if $dependency(Y, X) > dependency(X, Y)$, we discard the results entirely. We define a minimum of 60% as the measure of this smallness. Again, this minimum is user-defined between zero and one and only depends on the desired number of arcs, and again, one can use simple STE, but the range becomes a function of \bar{Y} . The result is a Bayesian network graph. Any graph representation can be used. In our work, we

used a simplified adjacency matrix T where only node that could have children, as given by the domain knowledge, were columns and only nodes that could have parents, as given by the domain knowledge, were rows. That is, if the Domain Knowledge Model is seen as a graph K , we omit the source nodes of K from the rows of T and the sink nodes of K from the columns of T . The network construction algorithm is summarized in Fig. 2.

Function Dependency_Graph (<i>Child_Layer, Parent_Layer, Threshold, Minimum</i>)	
Inputs	
<i>child_layer</i>	set of vectors, values of each of the believed dependent variables
<i>parent_layer</i>	set of vectors, values of each of the variables the members of <i>child_layer</i> are believed to
<i>threshold</i>	Difference below which the possibility of dependence is accepted
<i>minimum</i>	Value at which the possibility of dependence is discarded
Return digraph T	
Outputs:	
for $i \in parent_layer, j \in child_layer$	
if $DEPENDENCY(i, j) \geq minimum$	
if $DEPENDENCY(i, j) > DEPENDENCY(j, i)$	
T.add_arc (i to j)	
else if $DEPENDENCY(j, i) - DEPENDENCY(i, j)$	
$< threshold$	
T.add_arc (i to j)	
end	
end	
end	
return T	

Fig. 2. Pseudocode for the bayesian network construction algorithm.

1) *Complexity analysis step:* The runtime of the construction algorithm depends strongly on the Domain Knowledge Model and how many variables it receives. In the best case, each category will have exactly one variable, which would imply the Bayesian network structure is already known, and merely needs to be simplified. In this case, the algorithm performs $2m$ operations ($dependency(Y, X)$ and $dependency(X, Y)$), where m is the number of arcs in the Domain Knowledge Model. Since a Bayesian network must be a directed acyclic graph, this case may have m being anywhere between $n - 1$ (Markov chain) and $n(n - 1)/2$ (transitive closure of a fully reachable graph), where n is the number of variables. Therefore, the algorithm is $\Omega(n)$ and $O(n^2)$ in the best case. This is comparable to the best case in [7] where each node has one or two candidate parents.

In the worst case, each category has the same number of variables: n/c where c is the number of categories and n is a multiple of c such that $n \geq 2c$. To evaluate each arc, the members of each category in the arc's source have to be compared with the member of each category in the arc's sink, each comparison of which requires two operations, or $2(n/c)^2$ per arc between categories for a total of $2m(n/c)^2$. Since,

again, there may be anywhere between $n - 1$ and $n(n - 1)/2$ arcs between categories, the algorithm is $\Omega(n^2)$ and $O(n^4)$ in the worst case. This is much better than the worst case in [7] where all other nodes are candidate parents, leading to $(n!)$.

It should be noted that, given the nature of Bayesian networks as inference engines, the worst case is highly unlikely to be encountered in practice. It is more likely that there will be a category with much less variables than the others, since there is always a small group of target variables (usually one). For this reason, we can assume an average order of n^2 .

C. Bayesian Network Evaluation Stage

The Bayesian network designed is manually built to handle discrete values and thus learn the Conditional Probability Tables for the network. Inference is then performed using elimination or enumeration on the learned probabilities. For comparison purposes, we define a Baseline Structure, consisting of the joint probability of all variables – in effect, a Domain Knowledge Model with just two categories: One containing the target variable(s), and one containing all others..

1) *Discretization step*: To perform the conversion, values are discretized into High, Medium, or Low using Equation (4), where x is the specific value being converted; X is the multiset of all the values the variable takes on in the dataset; H, M, L represent High, Medium, or Low respectively; $m(x)$ is the Maximum Likelihood estimator for the mean, given by $(\sum_{x \in X} x)/|X|$; and $d(X)$; is the Maximum Likelihood Estimator for the standard deviation, given by Equation (5). Note that here, the vertical bars denote the cardinality of the set.

$$Discretized(x \in X) = \begin{cases} H & \text{if } x > m(x) + d(x) \\ L & \text{if } x < m(x) - d(x) \\ M & \text{otherwise} \end{cases} \quad (4)$$

$$\sqrt{\frac{1}{x} \sum_{x \in X} (x - m(x))^2} \quad (5)$$

2) *Baseline structure step*: In the Baseline structure, the joint probability of everything is computed (all the variables). In this model, all variables directly affect the target (the economic indicators in our work).

3) *Learning step*: In the learning part, the Bayesian network parameters have been learned by computing the conditional probabilities through Maximum Likelihood. By using the formula in Equation (6).

$$P(x_1, \dots, x_n) = \prod_{i=1}^n p(x_i | parent(X_i)) = p(x_1)p(x_2)p(x_3|x_1)p(x_4|x_1)p(x_5|x_2, x_3, x_4) \quad (6)$$

The algorithm steps for parameter learning is illustrated in Fig.3, (a), (b), and (c) respectively.

Function LEARNING (<i>Dataset, bn, k</i>) returns CPT of all variables in the Bayesian network	
Inputs	
<i>Dataset</i>	the dataset (already discretized)
<i>bn</i>	the Bayesian network
<i>k</i>	Laplacian smoothing coefficient
<i>minimum</i>	Value at which the possibility of dependence is discarded

Outputs:
$X \leftarrow bn.Vars$ /* All variables in the Bayes net */
$Q(X) \leftarrow$ a distribution over X /* initially empty*/
for each x_i of X do
if parent (x_i) is empty
then $Q(X) \leftarrow PR(x_i Dataset)$
else
$Q(X) \leftarrow CPT(x_i, parent(x_i) Dataset)$
end
end
return $Q(X)$

(a)

Function PR (X, d) returns probability of X given the domains is d
Inputs
X , the data of a random variable d , the domains of X
Outputs:
$k \leftarrow GET_LAPLACE_K()$;
$Q(X) \leftarrow$ a distribution over X , initially empty
for each <i>value</i> of d do
$Q(X) \leftarrow (COUNT(X == value) + k) / (COUNT(X) + k * LENGTH(d))$
end
end
return $Q(X)$

(b)

Function CPT (X, e) returns probability of X given the evidence e
Inputs
X , the data of a random variable e , the evidence variables
Outputs:
<i>domain</i> $\leftarrow GET_DOMAINS()$;
$Q(X) \leftarrow$ a distribution over X , initially empty
for each <i>value</i> of <i>domain</i> do
$Q(X) \leftarrow PR(X, value)$
then $Q(X) \leftarrow PR(x_i Dataset)$
else
$Q(X) \leftarrow CPT(x_i, parent(x_i) Dataset)$
end
end
return $Q(X)$

(c)

Fig. 3. Pseudocode for parameter learning algorithm, (a) Bayesian network learning function, (b) Patren Recognition (PR) function, (c) CPT function.

4) *Inference step*: The proposed model is experimented with the prediction of the economic indicators using two exact inference algorithms, which may be used interchangeably. In Fig. 4 (a), we give the elimination inference algorithm which accepts a set of evidence, and the joint factors of all variables then checks if an evidence variable is hidden to sum out all its possible values otherwise just lookup the probability from the probability distribution. In Fig. 4 (b), we give the enumeration algorithm. These algorithms are run iteratively over all the data samples.

Function PREDICT_BY_ELIMINATION ($e, factors$) returns prediction of PPP variable
Inputs

```

e, the evidence factors, the joint factors
Outputs:
probability ← factors
for each variable ∈ e do
  if variable is missing then
    probability ← add all values in probability for
    this variable
  else
    probability ← Lookup all values in probability where
    this variable = variable ∈ e
     $Q(X) \leftarrow \text{CPT}(x_i, \text{parent}(x_i)|\text{Dataset})$ 
  end
end
prediction ← MAX_INDEX (probability)
return  $Q(X)$ 

```

(a)

```

Function PREDICT_BY_ENUMERATION (t, P, e) returns
prediction of PPP variable
Inputs
t, the target variable
e, the known evidence
P, conditional probabilities
Outputs:
for each parent of t
  if parent ∈ e not missing then
    joint[parent] ←  $P(\text{parent} = \text{parent} \in e)$ 
  else
    joint[parent] ← PREDICT_BY_ENUMERATION
    (parent, P, parents(parent) ∈ e)
     $Q(X) \leftarrow \text{CPT}(x_i, \text{parent}(x_i)|\text{Dataset})$ 
  end
end
for each possible value ∈ t
  probability [possible value] ←  $\sum P(\text{possible value})$ 
  ×  $\prod \text{joint}$ 
return MAX (probability)
return  $Q(X)$ 

```

(b)

Fig. 4. Pseudocode for inference algorithm (a) by elimination and (b) by enumeration.

5) *Accuracy calculation step*: To define our accuracy, which is success if the prediction is exact, and failure if it is not, we will take the dependences of these variables (x_1, x_2, \dots, x_n), each defined in the discretized domain {High, Medium, and Low}. We recall that an exact prediction only needs to be exact if it matches the corresponding discrete variable or not. Mathematically, we define it as the number of predicted values that match the actual values divided by the total number of known values. This is summarized in equation (7). Note that here vertical bars denote cardinality.

$$\text{accuracy} = \frac{|\{i: x_i \in \text{predicted} \wedge y_i \in \text{actual}: x_i = y_i\}|}{|\{y: \text{actual}: y \text{ is not missing}\}|} \quad (6)$$

D. Development Indicators Domain Knowledge Model

To build the Domain Knowledge Model, consider the categories from section V. Previous work has shown that relationships between these broad categories is known: Education affects Innovation and Production ([10], [14], [15]);

Innovation and Production affect the Economy ([11], [8]). Education is known to not have a direct effect on the economy due to the necessity of applying productive knowledge to Innovation and Production for its effects to become visible ([10], [16]). This gives us a three-layer structure (Fig. 4).

Modelling the domain knowledge also allows us to delimit the number of dependency values we would have to calculate. Suppose we have six variables. If we were to compare all variables against all others (worst case in [7]), we would need to perform 6! comparisons, or calculate 1440 dependency values. The three-layer domain knowledge model for the development indicator problem is summarized in Fig. 5.

Following the three-layers structure, with four variables in the middle layer and two in each of the others, we only need to compute 16 dependency values. We note that, although this is in the order of 6^2 , it is much less than 6^2 .

Fig. 5. Three-layer domain knowledge model for the development indicators problem.

VII. EXPERIMENTAL RESULTS

A. Generated Bayesian Network

Five different networks are constructed for our first belief system: a baseline as described in section VI.C.2), and a network with the dependency analysis results for each of the eight regions. The resulting networks are shown in Fig. 6. Only considered six of the selected variables to construct these networks: Tertiary education, Agriculture, Industry, Government spending, Journal articles, and GDP by PPP. Then, just keep the previously established categories for these variables.

In most regions where Tertiary education is considered, it is found to be linked to industry and innovation, but not to agriculture. This makes intuitive sense. Latin America is the exception, but it is known to traditionally have placed higher emphasis on using its tertiary institutions to improve agriculture than to perform research. The service sector was left out of all networks which again make sense because service-based economies are a very recent development [25][26][27][28] and our data spans 54 years. We are similarly unable to find any variables that affected GDP growth, for which reason it is absent from all networks. We believe this is because GDP growth is the only variable that measures change from year to year.

B. Evaluation Results

This paper presents the proposed model results first for the Baseline Belief Network, which was run for the data from each of the regions. Next, present the proposed model results for the network specially computed for each of the regions, run on that

regions' data. The designed Baseline Belief network is running for "Middle East and North Africa" using the Elimination algorithm. We run all other networks using the Enumeration algorithm [29] [30].

1) *Baseline structure*: As described above, the baseline structure is the joint probability for all variables affecting PPP. The highest inference accuracy is for "Europe and Central Asia" with 92% accuracy and the lowest one is the World with 20% accuracy.

2) *Belief network no.1 structure for world regions*: As with the Baseline structure, the highest inference accuracy is for the "Europe and Central Asia region"; however, the accuracy for the computed network is of 79% accuracy which is lower than the baseline by 13%. The lowest inference value is in the North America with 54%. This is better than the baseline, where the accuracy was 46%. We also improve on the accuracy of the world, which was the lowest for the baseline as is shown in Fig. 6.

Fig. 6. Performance comparison between Baseline Belief Networks and the computed Belief Network 1

A comparison of the baseline and the networks computed for each region is shown in Fig. 7.

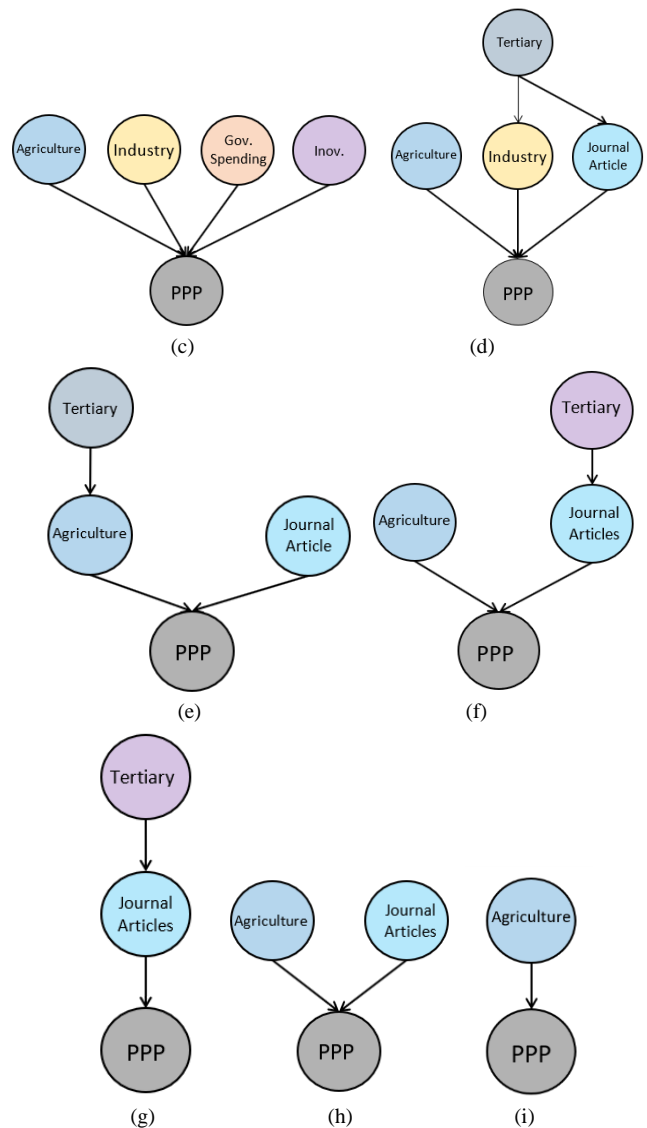

Fig. 7. Belief Network 1 structures for (a) the baseline (used for comparison purposes), (b) Sub-Saharan Africa region, (c) Middle East and North Africa region, (d) Europe and Central Asia region, (e) Latin America region, (f) North America region, (g) South Asia region, (h) East Asia and Pacific region, (i) World; where "Agr" represents Agriculture, "Innov. Art" and "Jour" represent Scientific and Journal Articles, "Inds" represents Industry, "Gov" represents Government final consumption expenditure, "Tertiary" represents Labor force with tertiary education, and "PPP" represents GDP per capita by Purchasing Power Parity.

VIII. CONCLUSION

In this paper, logical models for all selected regions are designed and created based on the proposed methodology. The resulting models are consistent with the knowledge known about the regions during the years covered by the data. The proposed networks in general provide accuracy improvements over the baseline. Designed baseline provided us an accuracy of 20% to 58% in seven out of eight regions, including the aggregate for “World”, while the Bayesian networks generated by our first Domain Knowledge Model improved that accuracy from 54% to 75% in the same regions. For Europe, we were not able to improve on the accuracy of the baseline (92 percent). We suspect this may be due to insufficient data (the aggregation caused the existence of too many missing values) or because Europe is inherently exceptional. We were similarly unable to construct networks to determine GDP growth for all regions, or GDP per Capita by PPP in South Asia. Better data, as well as variables that measure year-to-year changes, are needed to fully determine whether this methodology is adequate for these cases.

IX. FUTURE WORK

In future analysis, we would like to reduce our proportion of missing values to better evaluate our Bayesian networks. One of the main reasons our proportion of missing values was so high was because of how the World Bank aggregates regions and the way its regions are defined. One way to reduce this proportion is to aggregate regions differently, or change how missing data is handled during aggregation [21].

Bayesian networks are also capable of handling multiple queries other than just the target variable. We would like to evaluate the accuracy of questions like:

- What does a strong economy and a weak education system imply for the production sectors?
- How high must education be in each region for a high GDP?
- What is the probability the GDP will drastically change given how we know current events affect other indicators?

We also have, so far, manually implemented each of the Bayesian networks. We are aware that this process is automatable, especially given that our methodology generates a graph adjacency matrix. We would like to experiment with different Domain Knowledge models and see their effect on the accuracy. Similarly, we would like to use more variables from the World Bank to see their effect on the accuracy.

In addition, we do not yet have a mathematically proven estimate on the effects of tuning the “minimum” and “threshold” parameters to have on the accuracy we would like.

The Application of Virtual Technology Based on Posture Recognition in Art Design Teaching

Qinyan Gao

College of Communication and Art Design
University of Shanghai for Science and Technology, Shanghai 200093, China

Abstract—With the development of virtual technology, posture recognition technology has been integrated into virtual technology. This new technology allows users to further understand and observe the activities carried out in life scenes based on their original observation of the external world. And it enables them to make intelligent decisions. Existing posture recognition cannot meet the requirements of precise positioning in virtual environments. Therefore, a two-stage three-dimensional pose recognition model is proposed. The experiment illustrates that the three-dimensional gesture recognition performance is excellent. In addition, under the ablation experiment, the error accuracy of the research model decreased by more than 5 mm, and the overall error accuracy decreased by 10%. In the P-R curve, the accuracy rate of the model reaches 0.741, and the recall rate reaches 0.65. When conducting empirical analysis, the virtual posture disassembly action is complete; the disassembly error is less than 5%, and the disassembly error accuracy is good. The fit degree of the leg bending amplitude reaches over 96%, and the fit degree of the arm bending amplitude reaches over 95%. When the model is applied to actual teaching, the overall satisfaction score of teachers and students reaches 94.6 points. This has effectively improved the teaching effect of art design and is of great significance to the development of education in China.
