ISSN 2158-107X(Print)

Editorial Preface

From the Desk of Managing Editor...

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

Thank you for Sharing Wisdom!

Kohei Arai

Editorial Board

Editor-in-Chief

Dr. Kohei Arai - Saga University

Domains of Research: Technology Trends, Computer Vision, Decision Making, Information Retrieval, Networking, Simulation

Associate Editors

Alaa Sheta

Southern Connecticut State University

Domain of Research: Artificial Neural Networks, Computer Vision, Image Processing, Neural Networks, Neuro-Fuzzy Systems

Domenico Ciuonzo

University of Naples, Federico II, Italy

Domain of Research: Artificial Intelligence, Communication, Security, Big Data, Cloud Computing, Computer Networks, Internet of Things

Doroła Kaminska

Lodz University of Technology

Domain of Research: Artificial Intelligence, Virtual Reality

Elena Scutelnicu

"Dunarea de Jos" University of Galati

Domain of Research: e-Learning, e-Learning Tools, Simulation

In Soo Lee

Kyungpook National University

Domain of Research: Intelligent Systems, Artificial Neural Networks, Computational Intelligence, Neural Networks, Perception and Learning

Krassen Stefanov

Professor at Sofia University St. Kliment Ohridski

Domain of Research: e-Learning, Agents and Multi-agent Systems, Artificial Intelligence, e-Learning Tools, Educational Systems Design

Renato De Leone

Università di Camerino

Domain of Research: Mathematical Programming, Large-Scale Parallel Optimization, Transportation problems, Classification problems, Linear and Integer Programming

Xiao-Zhi Gao

University of Eastern Finland

Domain of Research: Artificial Intelligence, Genetic Algorithms

CONTENTS

Paper 1: Spatio-Temporal Features based Human Action Recognition using Convolutional Long Short-Term Deep Neural Network

Authors: A F M Saifuddin Saif, Ebisa D. Wollega, Sylvester A. Kalevela

PAGE 1 – 15

Paper 2: Usability and Security of Knowledge-based Authentication Systems: A State-of-the-Art Review

Authors: Hassan Wasfi, Richard Stone

PAGE 16 – 25

Paper 3: Super-Resolution of Brain MRI via U-Net Architecture

Authors: Aryan Kalluvila

PAGE 26 – 31

Paper 4: Sentiment Analysis on COVID-19 Vaccine Tweets using Machine Learning and Deep Learning Algorithms

Authors: Tarun Jain, Vivek Kumar Verma, Akhilesh Kumar Sharma, Bhavna Saini, Nishant Purohit, Bhavika, Hairulnizam Mahdin, Masitah Ahmad, Rozanawati Darman, Su-Cheng Haw, Shazlyn Milleana Shharudin, Mohammad Syafwan Arshad

PAGE 32 – 41

Paper 5: An Enhanced SVM Model for Implicit Aspect Identification in Sentiment Analysis

Authors: Halima Benarafa, Mohammed Benkhalifa, Moulay Akhloufi

PAGE 42 – 53

Paper 6: Ethereum Cryptocurrency Entry Point and Trend Prediction using Bitcoin Correlation and Multiple Data Combination

Authors: Abdellah EL ZAAR, Nabil BENAYA, Hicham EL MOUBTAHIJ, Toufik BAKIR, Amine MANSOURI, Abderrahim EL ALLATI

PAGE 54 – 64

Paper 7: Security in the IoT: State-of-the-Art, Issues, Solutions, and Challenges

Authors: Ahmed SRHIR, Tomader MAZRI, Mohammed BENBRAHIM

PAGE 65 – 75

Paper 8: A Mobile App for the Identification of Flowers Using Deep Learning

Authors: Gandhinee Rajkomar, Sameerchand Pudaruth

PAGE 76 – 102

Paper 9: A Study of Prediction of Airline Stock Price through Oil Price with Long Short-Term Memory Model

Authors: Jae Won Choi, Youngkeun Choi

PAGE 103 – 108

Paper 10: Method for Ad-hoc Blockchain of Wireless Mesh Networking with Agent and Initiate Nodes

Authors: Kohei Arai

PAGE 109 – 116

Paper 11: Recommendation System on Travel Destination based on Geotagged Data

Authors: Clarice Wong Sheau Harn, Mafas Raheem

PAGE 117 – 128

Paper 12: Input Value Chain Affect Vietnamese Rice Yield: An Analytical Model Based on a Machine Learning Algorithm

Authors: Thi Thanh Nga Nguyen, NianSong Tu, Thai Thuy Lam Ha

PAGE 129 – 134

Paper 13: Cybersecurity in Healthcare: A Review of Recent Attacks and Mitigation Strategies

Authors: Elham Abdullah Al-Qarni

PAGE 135 – 140

Paper 14: Deep Feature Detection Approach for COVID-19 Classification based on X-ray Images

Authors: Ayman Noor, Priyadarshini Pattanaik, Mohammed Zubair Khan, Waseem Alromema, Talal H. Noor

PAGE 141 – 146

Paper 15: Data Sharing using PDPA-Compliant Blockchain Architecture in Malaysia

Authors: Hasventhran Baskaran, Salman Yussof, Asmidar Abu Bakar, Fiza Abdul Rahim

PAGE 147 – 157

Paper 16: Assessing the Impact and Effectiveness of Cybersecurity Measures in e-Learning on Students and Educators: A Case Study

Authors: Ala'a Saeb Al-Sherideh, Khaled Maabreh, Majdi Maabreh, Mohammad Rasmi Al Mousa, Mahmoud Asassfeh

PAGE 158 – 164

Paper 17: Things of Interest Recommendation with Multidimensional Context Embedding in the Internet of Things

Authors: Shuhua Li, Jingmin An

PAGE 165 – 174

Paper 18: Reinforcement Learning-based Aspect Term Extraction using Dilated Convolutions and Differential Equation Initialization

Authors: Yuyu Xiong, Mariani Md Nor, Ye Li, Hongxiang Guo, Li Dai

PAGE 175 – 185

Paper 19: Research on Library Face Book Return Model Based on Hybrid PCA and Kernel Function

Authors: Jianwen Shi

PAGE 186 – 194

Paper 20: A Height Accuracy Study Based on RTK and PPK Methods Outside the Standard Working Range

Authors: Mohamed Jemai, Mohamed Anis Loghmari, Mohamed Saber Naceur

PAGE 195 – 205

Paper 21: Analyze Transmission Data from a Multi-Node Patient's Respiratory FMCW Radar to the Internet of Things

Authors: Rizky Rahmatullah, Puput Dani Prasetyo Adi, Suisbiyanto Prasetya, Arief Budi Santiko, Yuyu Wahyu, B.Berlian Surya Wicaksana, Stevry Yushady CH Bissa, Riyani Jana Yanti, Aloysius Adya Pramudita

PAGE 206 – 212

Paper 22: Performance Analysis of Prophet Routing Protocol in Delay Tolerant Network by using Machine Learning Models

Authors: Bonu Satish Kumar, Sailaja Vishnubhatla, Chevuru Madhu Babu, S. Pallam Shetty

PAGE 213 – 219

Paper 23: DIP-CBML: A New Classification of Thai Dragon Fruit Species from Images

Authors: Naruwan Yusamran, Nualsawat Hiransakolwong

PAGE 220 – 232

Paper 24: Math-VR: Mathematics Serious Game for Madrasah Students using Combination of Virtual Reality and Ambient Intelligence

Authors: Hani Nurhayati, Yunifa Miftachul Arif

PAGE 233 – 239

Paper 25: An Adaptive Channel Selection and Graph ResNet Based Algorithm for Motor Imagery Classification

Authors: Yongquan Xia, Jianhua Dong, Duan Li, Keyun Li, Jiaofen Nan, Ruyun Xu

PAGE 240 – 248

Paper 26: Security Challenges Facing Blockchain Based-IoV Network: A Systematic Review

Authors: Hamza El Mazouzi, Anass Khanouss, Khalid Amechnoue, Anass Rghioui

PAGE 249 – 256

Paper 27: Using Descriptive Analysis to Find Patterns and Trends: A Case of Car Accidents in Washington D.C.

Authors: Zaid M. Altukhi, Nasser F. Aljohani

PAGE 257 – 264

Paper 28: Towards an Adaptive e-Learning System Based on Deep Learner Profile, Machine Learning Approach, and Reinforcement Learning

Authors: Riad Mustapha, Gouraguine Soukaina, Qbadou Mohammed, Aoula Es-Sâadia

PAGE 265 – 274

Paper 29: Industrial Practitioner Perspective of Mobile Applications Programming Languages and Systems

Authors: Amira T. Mahmoud, Ahmad A. Muhammad, Ahmed H. Yousef, Hala H.Zayed, Walaa Medhat, Sahar Selim

PAGE 275 – 285

Paper 30: Feature Selection using Particle Swarm Optimization for Sentiment Analysis of Drug Reviews

Authors: Afifah Mohd Asri, Siti Rohaidah Ahmad, Nurhafizah Moziyana Mohd Yusop

PAGE 286 – 295

Paper 31: A Comparative Study of Machine Learning Techniques to Predict Types of Breast Cancer Recurrence

Authors: Meryem Chakkouch, Merouane Ertel, Aziz Mengad, Said Amali

PAGE 296 – 302

Paper 32: Automated Decision Making ResNet Feed-Forward Neural Network based Methodology for Diabetic Retinopathy Detection

Authors: A. Aruna Kumari, Avinash Bhagat, Santosh Kumar Henge, Sanjeev Kumar Mandal

PAGE 303 – 314

Paper 33: Proactive Acquisition using Bot on Discord

Authors: Niken Dwi Wahyu Cahyani, Daffa Syifa Pratama, Nurul Hidayah Ab Rahman

PAGE 315 – 325

Paper 34: The Contribution of Numerical EEG Analysis for the Study and Understanding of Addictions with Substances

Authors: Aziz Mengad, Jamal Dirkaoui, Merouane Ertel, Meryem Chakkouch, Fatima Elomari

PAGE 326 – 333

Paper 35: The Usability of Digital Game-based Learning for Low Carbon Awareness: Heuristic Evaluation

Authors: Nur Fadhilah Abdul Jalil, Umi Azmah Hasran, Siti Fadzilah Mat Noor, Muhammad Helmi Norman

PAGE 334 – 340

Paper 36: Optimization Design of Bridge Inspection Vehicle Boom Structure Based on Improved Genetic Algorithm

Authors: Ruihua Xue, Shuo Lv, Tingqi Qiu

PAGE 341 – 349

Paper 37: A Real-Time Automated Visual Inspection System for Printed Circuit Boards Missing Footprints Detection

Authors: Xiaoda Cao

PAGE 350 – 358

Paper 38: PM2.5 Estimation using Machine Learning Models and Satellite Data: A Literature Review

Authors: Mitra Unik, Imas Sukaesih Sitanggang, Lailan Syaufina, I Nengah Surati Jaya

PAGE 359 – 370

Paper 39: Developing A Predictive Model for Selecting Academic Track Via GPA by using Classification Algorithms: Saudi Universities as Case Study

Authors: Thamer Althubiti, Tarig M. Ahmed, Madini O. Alassafi

PAGE 371 – 377

Paper 40: Combining GAN and LSTM Models for 3D Reconstruction of Lung Tumors from CT Scans

Authors: Cong Gu, Hongling Gao

PAGE 378 – 388

Paper 41: Optimized Secure Federated Learning for Event Detection in Big Data using Blockchain Mechanism

Authors: K. Prasanna Lakshmi, K. Swapnika

PAGE 389 – 395

Paper 42: Hate Speech Detection in Social Networks using Machine Learning and Deep Learning Methods

Authors: Aigerim Toktarova, Dariga Syrlybay, Bayan Myrzakhmetova, Gulzat Anuarbekova, Gulbarshin Rakhimbayeva, Balkiya Zhylanbaeva, Nabat Suieuoova, Mukhtar Kerimbekov

PAGE 396 – 406

Paper 43: New Arabic Root Extraction Algorithm

Authors: Nisrean Jaber Thalji, Emran Aljarrah, Roqia Rateb, Amaal Rateb Mohammad Al-Shorman

PAGE 407 – 412

Paper 44: An Evolutive Knowledge Base for “AskBot” Toward Inclusive and Smart Learning-based NLP Techniques

Authors: Khadija El Azhari, Imane Hilal, Najima Daoudi, Rachida Ajhoun, Ikram Belgas

PAGE 413 – 422

Paper 45: Knowledge Management Model for the Generation of Innovative Capacities in Organizations that Provide Services

Authors: Cristhian Ronceros, José Medina, Pedro León, Alfredo Mendieta, José Fernández, Yuselys Martinez

PAGE 423 – 430

Paper 46: Recognition of Lung Nodules in Computerized Tomography Lung Images using a Hybrid Method with Class Imbalance Reduction

Authors: Yingqiang Wang, Honggang Wang, Erqiang Dong

PAGE 431 – 444

Paper 47: A Theoretical Framework for Creating Folk Dance Motion Templates using Motion Capture

Authors: Amir Irfan Mazian, Wan Rizhan, Normala Rahim, Azrul Amri Jamal, Ismahafezi Ismail, Syed Abdullah

Fadzli

PAGE 445 – 451

Paper 48: Development of a New Lightweight Encryption Algorithm

Authors: Ardabek Khompysh, Nursulu Kapalova, Oleg Lizunov, Dilmukhanbet Dyusenbayev, Kairat Sakan

PAGE 452 – 459

Paper 49: An Investigation of Asthma Experiences in Arabic Communities Through Twitter Discourse

Authors: Mohammed Alotaibi, Ahmed Omar

PAGE 460 – 469

Paper 50: Predicting Drug Response on Multi-Omics Data Using a Hybrid of Bayesian Ridge Regression with Deep Forest

Authors: Talal Almutiri, Khalid Alomar, Nofe Alganmi

PAGE 470 – 482

Paper 51: Systematic Analysis on the Effectiveness of Covert Channel Data Transmission

Authors: Abdulrahman Alhelal, Mohammed Al-Khatib

PAGE 483 – 490

Paper 52: Towards Analysis of Biblical Entities and Names using Deep Learning

Authors: Mikolaj Martinjak, Davor Lauc, Ines Skelac

PAGE 491 – 497

Paper 53: Deadline-aware Task Scheduling for Cloud Computing using Firefly Optimization Algorithm

Authors: BAI Ya-meng, WANG Yang, WU Shen-shen

PAGE 498 – 506

Paper 54: A Method for Network Intrusion Detection Based on GAN-CNN-BiLSTM

Authors: Shuangyuan Li, Qichang Li, Mengfan Li

PAGE 507 – 515

Paper 55: A Consumer Product of Wi-Fi Tracker System using RSSI-based Distance for Indoor Crowd Monitoring

Authors: Syifaul Fuada, Trio Adiono, Prasetyo, Harthian Widhanto, Shorful Islam, Tri Chandra Pamungkas

PAGE 516 – 531

Paper 56: A Knowledge Based Framework for Cardiovascular Disease Prediction

Authors: Abha Marathe, Virendra Shete, Dhananjay Upasani

PAGE 532 – 540

Paper 57: Unsupervised Bearing Fault Diagnosis via a Multi-Layer Subdomain Adaptation Network

Authors: Nguyen Duc Thuan, Nguyen Thi Hue, Hoang Si Hong

PAGE 541 – 548

Paper 58: Mask R-CNN Approach to Real-Time Lane Detection for Autonomous Vehicles

Authors: Rustam Abdrakhmanov, Madina Elemesova, Botagoz Zhussipbek, Indira Bainazarova, Tursinbay Turymbetov, Zhalgas Mendibayev

Spatio-Temporal Features based Human Action Recognition using Convolutional Long Short-Term Deep Neural Network

A F M Saifuddin Saif, Ebisa D. Wollega, Sylvester A. Kalevela
School of Engineering, Colorado State University Pueblo, CO 81001, USA

Abstract—Recognition of human intention is crucial and challenging due to subtle motion patterns of a series of action evolutions. Understanding of human actions is the foundation of many applications, i.e., human robot interaction, smart video monitoring and autonomous driving etc. Existing deep learning methods use either spatial or temporal features during training. This research focuses on developing a lightweight method using both spatial and temporal features to predict human intention correctly. This research proposes Convolutional Long Short-Term Deep Network (CLSTDN) consists of Convolutional Neural Network (CNN) and Recurrent Neural Network (RNN). CNN uses Inception-ResNet-v2 to classify object specific class categories by extracting spatial features and RNN uses Long Short-Term Memory (LSTM) for final prediction based on temporal features. Proposed method was validated on four challenging benchmark dataset, i.e., UCF Sports, UCF-11, KTH and UCF-50. Performance of the proposed method was evaluated using seven performance metrics, i.e., accuracy, precision, recall, f-measure, error rate, loss and confusion matrix. Proposed method showed better results comparing with existing research results. Proposed method is expected to encourage researchers to use in future for real time implications to predict human intentions more robustly.

Keywords—Convolutional neural network; recurrent neural network; long short-term memory; human action recognition

I. INTRODUCTION

The recognition and understanding of human activities on video streams have now become crucial in many applications for instance smart video monitoring, automobiles driving, somatic gaming, etc. This task is extremely difficult if both accuracy and robustness are taken into consideration. In the field of human behavior recognition, substantial research is needed. Recognition and prediction of actions are two key tasks in the field of computer vision and action recognition. Understanding the actions of others is the foundation of human social interaction. It is difficult to predict the intent of others from their acts but it's necessary. Recognition of human activities plays a significant role in people's daily lives, for example in applications for medical, protection, and law enforcement fields. Observation of human intentions through motions was introduced to many instances of Human-Robot Interaction. Recognition of actions and prediction of actions can be very different among the different classes of action. Intention prediction, however, infers from the subtle motion patterns of a series of action evolutions of the same action. This makes the prediction of intention a more challenging

task. Recognition of action can essentially be categorized at various abstraction levels depending on the nature of the visual information. It varies from simple actions like activity concepts, interaction with objects and human beings to complex acts as a group activity.

In recent years, one of the popular deep learning models, Convolutional Neural Networks (CNNs), has shown great success in many computer vision's tasks, such as image recognition, image segmentation, object tracking and so on [1] [2]. CNN appears to learn a hierarchy of features from low-level to high-level and researchers find the features that CNN automatically learns are typically better than the handcrafted features. Researchers have put a great effort to develop neural networks capable of capturing spatial-temporal features in recognition of human activities. Most of the researchers have taken advantage of the deep learning approach for the recognition of human activities. Because deep learning techniques allow automated extraction and learning of hierarchical features by human behavior recognition systems, several of these systems have been developed and have shown promising results. Deep Learning (DL) methods have gained significant attention recently due to their remarkable performance in various fields. It is, therefore, not surprising that DL-based methods for identification, prediction and prediction of intention have also increased. Particularly Deep Learning models based on the Recurrent Neural Network have brought much success in the field of behavior analysis in recent years. The most widely used model in RNN is usually the Long Short-Term Memory (LSTM). It is an extension of the RNN structure that essentially allows long-term temporal dependencies by replacing hidden nodes with gated memory cells.

Focusing on that, this research proposes a Deep Learning approach for recognizing human intention. In videos with complex scenarios, proposed method called Convolutional Long Short-Term Deep Network (CLSTDN) can identify human intentions with a good amount of precision. Pre-trained convolutional neural network, Inception-ResNet-v2 is used for extracting spatial features from video sequence and then using LSTM temporal features are extracted from the video sequence. With some more dense layers, training and classification are done to recognize intention from videos. In this task, this research evaluates proposed method on the human action datasets such as UCF Sports dataset, UCF-11 dataset, UCF-50 dataset and KTH dataset where variety of actions of different situations was found. These datasets are

very complex and challenging because of wide variations in camera motion, conditions of lighting, object appearance and posture, size of object, view, cluttered background, etc. Regardless of the point of view, background, inter-class and intra-class similarities are found in image frames, proposed method performed very well with very small data sequences in all the datasets. Experiment results show that the proposed method achieved state-of-the-art performance with low computational resources for action intentions recognition from human behavior. Overall contribution of this research is summarized as below.

1) This research proposes a news method called Convolutional Long Short-Term Deep Network (CLSTDN) consists of a Convolutional Neural Network (CNN) and Recurrent Neural Network (RNN) for efficient human intention prediction. Proposed CLSTDN serves following two purposes:

a) Convolutional Neural Network (CNN) uses Inception-ResNet-v2 to classify scenes to categorize class specific objects by extracting spatial features.

b) Recurrent Neural Network (RNN) uses Long Short-Term Memory (LSTM) for final prediction based on temporal features.

Thus, this research ensures to use spatial and temporal features for improved human intention prediction. Previous research methods used either spatial or temporal features for human intention prediction; however, proposed CLSTDN used spatial-temporal features for human intention prediction.

2) Massive experimental results are demonstrated on four benchmark datasets to validate the proposed method. Four publicly available datasets were used for validation, i.e., UCF Sports, UCF-11, KTH and UCF-50. Seven evaluation metrics were estimated for each dataset, i.e., accuracy, precision, recall, f-measure, error rate, loss and confusion matrix.

3) Proposed CLSTDN performed efficiently based on all the evaluation metrics with limited number of data sequence irrespective of viewpoint, background, inter-class and intra-class similarities present in the image frames in all the datasets which is very promising comparing with previous research methods.

4) Previous research methods provide the evidence that deep learning architectures require huge computational power and GPU clusters which imply the fact that it is wise to consider not only the accuracy but also the cost of a method for implementation. By considering this fact to implicate new research methodology with limited computation resources in lieu of achieving satisfactory computation time, this research proposed Convolutional Long Short-Term Deep Network (CLSTDN) to recognize the human action based on intention. Rest of this research is organized as follows, Section II illustrates existing research methods, Section III reflects proposed research methodology, Section IV reflects comprehensive experimental results for robust validation of the proposed methodology and finally, conclusion section presents concluding remarks.

II. PREVIOUS RESEARCH STUDY

There are essentially two types of human activity recognition approaches, i.e., video-based models and sensor-based models. High-dimensional features are derived from videos or images [3][5][10][13][14][35], whereas sensor-based systems rely on motion information captured by sensing devices [44]. Researchers have focused on analyzing human behavior through radar backscattering echoes with the development of new sensing technology. It is understood that the carrier frequency of the radar signal would be changed when reflected from any moving target which is known as the Doppler Effect. A point network can learn more efficiently about structural features from the micro motion trajectory than it can directly process the raw point cloud and it also shows that the temporal range-Doppler PointNet approach performs better on most behaviors [18]. This uses radar to emit signals, while very high frequency reflected signal analysis captures very fine dynamic behavior. Radar can be used for extreme climates, meaning that it is immune to light and weather conditions, as this system uses radar, human beings can be identified via walls, making radar useful in more situations. For researchers, the hierarchical model is superior to its base counterpart (P-Net). Sensor-based technologies may be a trigger for mental and physical discomfort [43] and wearable technology is not ideal for applications where complex motor activity needs to be monitored and interpreted [15][23][24][25][26][27].

YOLOv3 object detector [8] and SSD [29] can accurately detect a group of people with a high degree of confidence by only taking a few frames from video-based models. There is also a pipeline of Generative Adversarial Networks (GANs), which jointly learns latent information for estimating and group identification of pedestrian trajectories [2]. GAN suggests a learning mechanism for task-specific loss function where a minimum game between the generative and discriminatory models is an objective of training. In the area of computer vision, significant progress has been made concerning recent developments in deep learning methodologies due to the advancement of deeper CNN, parallel computer hardware and wide-ranged annotated datasets. Various approaches have been put on places to address the recognition of action problems. Actions recognition systems can be classified into representations based on shape and appearance, representations based on optical flow and representations based on the point of interest depending on the representations of the feature. The most successful methods of classifying the action involve using CNNs. Deep CNN models achieved state-of-the-art results with tasks of object identification, classification, generation and segmentation. In deep learning, there are two primary strategies used to extract features from the video frames. First, by expanding traditional 2D CNN architectures to 3D, 3D CNN learns convolution kernels in space and time domains [17]. The second strategy is a two-stream CNN [55] that delivers state-of-the-art results in [56][57][58]. A Convolutional Neural Network (CNN) with YOLO is used together for an IoT detection that enables suspicious human behavior with minimal effort [20]. A Deep Neural Network (DNN) is followed by a time-domain classifier method for automatic violent behavior detection designed for video sensor

networks [40]. One distinguishing characteristic of the proposed solution is that it relies entirely on motion characteristics by completely disregarding appearance details. Asymptotically the tests are like optical flow-based approaches and often better than the others. This method is ideally suited for low computing devices and used by researchers for improvement in the future. Researchers achieved state-of-the-art efficiency, using Raspberry-Pi sensor nodes to run on low computational embedded architecture. This approach works perfectly well with low-computing devices and a potential area for enhancement work. Research in [22] compared state-of-the-art machine learning and deep learning approaches suitable for detecting early changes in human behavior, where support vector machine (SVM) and Convolutional neural network (CNN) from the supervised method, One-class support vector machine (OCSVM) and Stacked auto-encoders (SAE) from Semi-Supervised and K-means clustering (KM) and Convolutional auto-encoder (CAE) from Unsupervised is used. Methods based on CNN take many parameters for model learning. This takes hours to months to optimize. In the meantime, using a GPU with parallel architecture significantly reduces the processing time. The more GPUs, the less computational time it takes to train. These factors have given much importance to the transition of transfer learning [11] [12] [32] [38] [41]. Researchers proposed a pre-trained model of a convolutional neural network (CNN) based on Visual Geometry Group network 19 (VGGNet-19) which is used to extract descriptive features [41]. An abnormal event detection system using pre-trained VGGNet-19 and Binary Support Vector Machine (BSVM) videos demonstrates higher detection accuracy than other pre-trained networks: GoogleNet, ResNet50, AlexNet, and VGGNet-16. BSVM needs only a few abnormal detection training patterns and provides reasonable detection accuracy for new patterns with the same features. Several researchers use Deep convolutional neural networks (CNN) to detect violent scenes by transfer learning to classify aggressive human behaviors [28][31][50]. Research in [30] recognized basic human activities using the Deep Belief Network (DBN) method which is a good candidate to the model activity recognition system. DBN is a robust, deep learning method used during training using Restricted Boltzmann Machines (RBMs). At first, they extracted efficient features from the raw data. Then they used kernel principal component analysis (KPCA) and linear discriminant analysis (LDA) to make the data more robust. Research in [16] proposed a Real-time Multi-Person 2D Pose Estimation using Part Affinity Fields (PAFs). The OpenPose program recognizes the key human points better than other methods. The program identifies and generates a student report every three seconds in the classroom. It utilizes a non-parametric representation called PAFs to learn to connect the body components with individuals in the image. Via this approach, the OpenPose system recognizes the human key points better than other approaches. This also operates on the low computational device slowly, leading to a lack of input in real-time and considering only six gestures. Long-term memory networks (LSTM) are another technology which is used in various approaches like in [32] to predict human movements accurately. To send visual signals, they used a deep learning

model that explored combining CNN with LSTM. LSTM is used to derive temporal patterns of human motion outputting the prediction result immediately before movement occurs. LSTM is used by research in [45] for the simulation of spatial-temporal sequences obtained from smart home sensors. They mentioned that approaches based on LSTM yield higher results than the existing DL and ML methods. For pattern recognition, LSTM is also used for anomaly detection with the Recurrent Neural Network (RNN) and Multi-Layer Perceptron (MLP) [21,60]. Different researchers used models to explain human emotion, sentiment, stress, and fatigue using GRU [6][9] and LSTM [19]. GRU is LSTM-like, which has shown that it operates well on smaller datasets. GRU has less operation compared to LSTM and thus it can be trained much faster than LSTMs, while LSTM is more accurate in the long sequence datasets. A method was proposed by research in [43] to identify such behaviors in which humans interact with various objects, considering object-oriented knowledge of the operation, using a hybrid approach to combine deep convolutional neural networks with multi-class support vector machines (multi-class SVM). An Adaptive feature recalibration residual network (AFRRNet) and Quaternion Spatio-Temporal Convolutional Neural Network (QST-CNN) based model is proposed by research in [47] to recognize human behavior. In predicting human action or behavior, the temporal network works much better than other related networks. It also makes use of optical flow representation for the input flow. The pre-processing of the optical flow image corresponds to the spatial flow. Optical flow suppresses horizon details and displays series motion fields. The motion fields highlighted encode motion information between adjacent frames which contribute significantly to the prediction of intention. This essentially improves the ability of the network to derive functionality and accuracy of recognition of behaviors.

Research in [35] proposed a multi-stream model for a better understanding of human activities through 3-channel Depth MHI and Skeleton based ST-GCN. The model defines contextual awareness, global and local intervention recognition motions. These two models have a fusion performance that exceeds each model and is comparable with state-of-the-art results. Researchers proposed an architecture with the multi-stream convolutional neural network (HR-MSCNN) based on a human-related region that encodes the presence, motion and captured tubes of regions with human relations [36]. The improved version of B-RPCA (IB-RPCA) can be defined reliably as the main actor in complex realistic circumstances including vibration, specific luminous conditions and partial occlusions. Human emotions also make a significant contribution to understand human intention. A deep learning approach is focused on the multimodal detection of stress through Convolutional Autoencoders and Recurrent Neural Networks. This also contained a recurrent unit called Gated Recurrent Unit (GRU) [9]. Some researchers use a lightweight CNN model for recognition of facial expression from a given input image [7]. CNN generates a matrix using the input image. After that the pooling process takes place then, the flattening process starts. Finally, the system predicts the facial expression. Using Convolutional Neural Network (CNN) fused with Extreme Learning Machines (ELMs), it can

classify emotions where two layers of the ELM to the fusion make calculation fast. It is found that the fusion based on ELM performed better than the combination of the classifiers [17]. With respect to local feature descriptors, there has been a lot of work to extract and explain useful and robust information. Several feature descriptors have been successfully adapted to enhance the accuracy of human action recognition from the image domain to the video domain. In addition to human-robot interaction, prediction of human intention plays an important role in a wide variety of applications, such as driving assistance systems on cars to predict the lane changes intentions of drivers [4] [34], prediction of pedestrian or cyclist intention [49], as well as monitoring to predict the intentions underlying detected suspicious activities and giving security [20][21].

There were many methods and frameworks with various types of limitations or drawbacks that are needed to overcome to develop a perfect method for human activity recognition. Many of the methods and frameworks were simple to implement and develop but offered considerable computational time. The more GPUs there are, the less computational time it needs for training. However, the solution is costly. It is wise to consider not only the accuracy but also the cost of a method when choosing a method for any implementation, as this can influence the time to build a production-ready method and the operating costs for running it.

III. PROPOSED RESEARCH METHODOLOGY

Previous research provides the evidence that deep learning architectures require huge computational power and GPU clusters to perform in low computational time. By considering this fact to implicate new research methodology with limited computation resources in lieu of achieving satisfactory computation time, this research proposed Convolutional Long Short-Term Deep Network (CLSTDN) to recognize the Human Action based Intention. Proposed method used both spatial and temporal features from a video and predicted intentions robustly. Pre-trained convolutional neural network (CNN), Inception-Resnet-v2 extracts spatial features from a video frame and makes a feature sequence. After that, features are given as input into the LSTM network. LSTM network extracts the temporal features from the sequence and with dense layer and SoftMax activation function, proposed method predicts an intention from the video. Overall proposed method was very resource friendly as this research did not use any external GPUs and only 8 gigabytes of RAM. Later, proposed method was validated with real-world environment videos and performed robustly to identify human intentions.

Proposed CLSTDN by this research consists of a convolutional neural network and a Long-short-term Memory network. Proposed methodology consists of three main parts, i.e., data preprocessing, feature extraction and intention recognition. This research used video-based datasets to train and test the method. In the data processing section, frames are extracted from the video data first and then reshaped those images to 224 x 224. For KTH dataset, this research calibrated images into 120 x 120 as the image dimension of the KTH dataset was smaller than the other datasets used by this

research. Second significant part of the proposed methodology is feature extraction. This research used a pre-trained Inception-ResNet-v2 model to extract an image encoding. In this section, this research stacks the frames to provide a three-channel image to meet the specifications of Inception-ResNet-v2 and after that, this research reshaped images into 299 x 299 and made sequences by extracting features from the image frames for training and testing purpose. The third part of the proposed methodology is training and testing the model from the extracted features using LSTM deep learning method. Here, this research fed the extracted spatial feature into the LSTM model and extracts temporal features and the last layer output using the SoftMax activation function. Overall proposed methodology is shown in Fig. 1 and comprehensively explained in the subsequent sections.

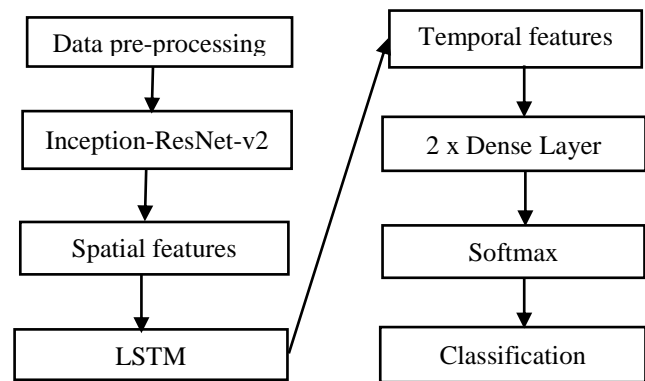

Fig. 1. Components of proposed methodology.

A. Data Processing

This research used UCF Sports, UCF11, UCF50 and KTH dataset to train and test proposed CLSTDN. As these datasets are video-based dataset so this research first extracted image frames from these datasets followed by splitting the data into train and test data and saved each video's number of frames into a CSV file by which extraction of spatial features were done by Inception-ResNet-v2 model. As imbalanced dataset may lead to wrong accuracy and over-fitting problems, this research removed blank image frames from the dataset. After that, this research reshaped images size to decrease computation time. Next, these images are used as input to Inception-Resnet-v2 to extract features.

B. Backbone

To utilize depth features as guidance of 2D convolutions, this research formulates backbone as a two-branch network: the first branch is the feature extraction network using RGB images and the other is the filter generation network to produce convolutional kernels for feature extraction network using the estimated depth as input. These two networks process the two inputs separately and their outputs of each block are merged by the depth guided filtering approach.

The backbone of the feature extraction network is Inception-ResNet-v2[54] without its final FC and pooling layers and is pre-trained on the ImageNet classification dataset [63]. To obtain a larger field-of-view and keep the network stride at 16, this research finds the last convolutional layer (conv5 1, block4) that decreases resolution and set its stride to

1 to avoid signal decimation and replace all subsequent convolutional layers with dilated convolutional layers (the dilation rate is 2). For the filter generation network, we only use the first three blocks of Inception-ResNet-v2 to reduce computational costs. Note the two branches have the same number of channels of each block for the depth guided filtering task. More about Inception-ResNet-v2 is illustrated in the next section.

C. Inception-ResNet-V2

For extracting spatial features from input images, this research used pre-trained Inception-ResNet-v2 model. This architecture is trained on more than a million images from the ImageNet database. The network is 164 layers deep and can classify images into 1000 object categories. Inception-ResNet-v2[54] is from the Inception family convolutional neural network (CNN) architecture which gradually evolved from GoogleNet and was the first Inception neural network through Inception v2 and Inception v3, and finally, Inception v4 [54]. Every one of the architectures brought changes primarily with respect to the Inception module, Inception networks building block. Research in [54] motivated by the results obtained by residual neural networks, experimented with integrating residual connections, key features of residual networks, with the Inception module. The result, Inception-ResNet-v2 is a very deep network, which in a lower number of epochs can achieve high accuracy which motivates proposed method by this research to use Inception-ResNet-v2 model for spatial feature extraction.

Inception-ResNet-v2 architecture contains three separate types of Residual Inception modules, called A, B, and C, and two distinct blocks of reduction. In Residual Inception module, residual connections play significant role for overall manipulation. Residual connection is a simple concept that has been invented as a way of solving the problems of the vanishing gradient and exploding gradient that may appear in a very deep neural network. The theory behind is that residual block only measures the adjustments that will make the input perfect, apply them to the input, and present it as its output, instead of calculating the output from scratch. Residual Inception blends residual learning with the Inception modules by incorporating a residual connection to it. The concept on which the Inception module operates is to expand rather than deeper neural network. The expanded width enables complex patterns to be recorded at different scales. The initial 1x1 convolutions are only used to reduce dimensionality on the axis of the channel to lighten the following convolutions. All convolutions use zero padding for the preservation of height and width. This is important since the outputs are concatenated along the depth dimension after each separate calculation in the module, which would not be possible if the heights and widths differed. The split of a $n \times n$ convolution into two $-1 \times n$ and $n \times 1$ convolution stored one on top of each other is another feature of the Inception module. An important feature of the Residual Inception module is that after the concatenation, there is a 1x1 convolution to allow the addition of identity passed by the residual relation and the actual output by aligning its dimensions [54]. Inception-ResNet-v2 contains reduction modules which are slightly changed Inception modules. Unlike those mentioned earlier, these modules

contain an average pooling on one of the branches followed by a 1x1 convolution. This research extracted spatial features from the Average Pooling layer of Inception-ResNet-v2 architecture (Fig. 1 Top) and fed it as an input to the LSTM model for training the model.

D. Training LSTM Model

After extracting the spatial features, this research uses Long Short-Term Memory (LSTM) network to extract temporal features from a sequence. LSTM is a recurrent neural network (RNN) architecture designed more accurately than conventional RNNs for modeling temporal sequences and long-term dependencies. In the recurring hidden layer, LSTM has special units known as memory blocks. Fig. 2 shows that memory blocks contain a memory cell with self-connections to store the network's temporal state, as well as special multiplication units called information flow gates. An input gate and an output gate were included in each memory block of the initial architecture. Input Gate controls the memory cell flow of the activations. Output gate controls cell activation output flow into the rest of the network. Forget gate was added to the memory block later. The forgotten gate measures the inner cell state before connecting it to the cell through the self-recurring connection of the cell, thereby forgetting or resetting the cell's memory adaptively.

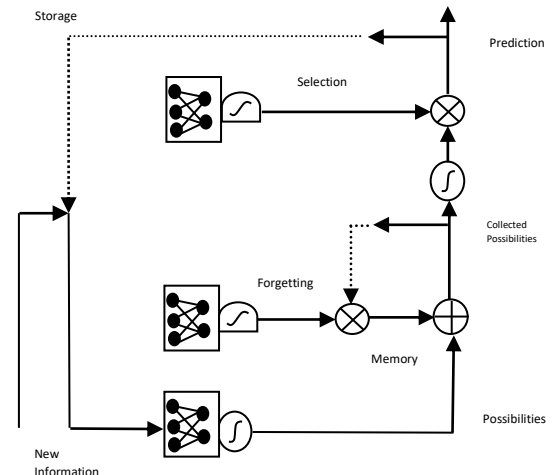

Fig. 2. Long Short-Term Memory (LSTM) network.

For training purpose this research used Long Short-Term Memory Deep Learning approach. During implementation, this research changed learning rate, decay rate, dropout and momentum to find the optimal value of these hyper parameters. A low learning rate helps overall methodology to avoid overfitting problem, where proposed method performs well on both training and test data. In this context, this research tuned parameters into four steps, i.e., tuning LSTM size, tuning batch size, tuning number of epochs and tuning for LSTM and Dense layers for four different datasets.

1) *Tuning for LSTM size:* This research initially fixed number of LSTM and Dense layers to 3, batch size to 32 and number of epochs to 50 and tuned LSTM size over these parameters. This research trained LSTM model with size 512,

1024 and 2048 for every dataset used for experimentation. With size 2048, proposed method generated the highest accuracy for tuning LSTM size. This research also used a fixed dense layer of size 512 and a classification dense layer to classify overall result.

2) *Tuning batch size and no. of epochs:* After tuning LSTM size, this research fixed its size to 2048 and number of LSTM and Dense layers to 3 and tuned batch size and number of epochs. This research performs training with a batch size of 8, 16, 32, 64, 128, 256 and number of epochs of 20, 50, 75 and 100. This research performs training for each set of batch sizes and number of epochs respectively. Here, this research found different batch sizes and number of epochs sets for different datasets which are explained in more details in experimental results section.

3) *Tuning No. of LSTM and dense layers:* For the final step of parameter tuning, proposed method fixed LSTM size to 2048 and different batch sizes and number of epochs for the different datasets and tuned number of LSTM and Dense layers. In this context, this research performs training with one fixed LSTM layers and 2, 3, and 4 Dense layers. This research also tuned the model by changing dense layer size of 256, 512 and 1024. Proposed method generated the best result for 3 layers with different sizes for the different datasets.

In summary, this research proposed a new method called Convolutional Long Short-Term Deep Network (CLSTDN) to recognize human action-based intention. Proposed CLSTDN consists of convolutional neural network and recurrent neural network. For convolutional neural network, this research used pre-trained network which was Inception-ResNet-v2 which is trained on more than a million images from ImageNet database. This network contains 164 layers to classify images into 1000 object categories. For recurrent neural network, this research used Long Short-Term Memory (LSTM) network. Overall proposed methodology consists of three main parts, i.e., data preprocessing, feature extraction, intention recognition. At first, video frames were extracted followed by preprocessing frames according to Inception-ResNet-v2. Then, images are passed to the Inception-ResNet-v2 network to extract the spatial features and create a sequence of the video. After that, the sequences are passed to the LSTM network which extracts temporal features from the sequence. Then dense layers and SoftMax activation function are used in the proposed method to predict the intention from the video. This research performs training with low computational resources by using both spatial-temporal features. Proposed method predicted intentions accurately which was revealed robustly during experimental validation demonstrated in the next section. In addition, implication of the proposed method is resource friendly.

IV. EXPERIMENTAL RESULTS AND ANALYSIS

Evaluation for the proposed Convolutional Long Short-Term Deep Network (CLSTDN) was done by experimenting four publicly available datasets, i.e., UCF Sports, UCF-11, KTH and UCF-50. This research plotted actual and predicted data for each intention into a confusion matrix after

experimentation. From the confusion matrix, this research estimated True Positive (TP), False Positive (FP), True Negative (TN), False Negative (FN) which helped to find out the evaluation metrics. This research estimated accuracy, precision, recall, f-measure and error rate for each dataset. After 62 epochs, this research received best result for UCF Sports dataset which gives an accuracy of 95.74%, precision of 95.83%, recall of 97.49%, F-measure of 96.23%, and an error rate of 4.26%. After 43 epochs, proposed method received best results for UCF 11 dataset which gives an accuracy of 95.44%, precision of 95.3%, recall of 95.33%, F-measure of 95.26%, and error rate of 4.66%. After 45 epochs, proposed method found best result for KTH dataset which gives an accuracy of 90.1%, precision of 90.1%, recall of 90.54%, F-measure of 90.2% and an error rate of 9.9%. After 20 epochs, proposed method received best results for UCF 50 dataset which gives an accuracy of 80.80%, precision of 80.27%, recall of 80.27%, F-measure of 79.68%, and error rate of 19.2%.

A. Hardware and Software Set Up

1) *Hardware set up:* For experimental validation, this research used two different computers with similar configurations. Both computers were running on windows 10x64 platforms with an Intel Core i5-7200U CPU 2.5GHz with turbo boost up to 3.1 GHz and both with 8 Gigabytes of RAM and with no external Graphics Processing Unit (GPU).

2) *Software set up:* This research used python 3.7.1 on Jupyter Notebook 6.0.3 Integrated Development Environment (IDE) on Anaconda Navigator 2, Atom 1.51.0 x64 IDE. This research used different types of python libraries OpenCV 3.4.2, Tensorflow 2.1.0, Keras 2.3.1, Matplotlib 3.2.2 for line graph, Seaborn 0.10.1 for confusion matrix, FFMpeg 4.2.2, NumPy 1.19.1, Pandas 1.0.5, Scikit Learn 0.23.1 for evaluation metrics, Tqdm 4.47.0, CSV, and Glob.

B. Evaluation Parameters

To evaluate the performance of the proposed method, evaluation was done by finding the accuracy, precision, recall, f-measure, and error rate on various datasets. In this context, TP, FP, FN, TN are used to calculate accuracy, precision, recall, f-measure and error rate [67]. True Positive (TP) is the number of correct predictions that an instance is negative. False Positive (FP) is the number of incorrect predictions that an instance is positive. False Negative (FN) is the number of incorrect of predictions that an instance negative. True Negative (TN) is the number of correct predictions that an instance is positive [69].

1) *Accuracy:* Accuracy is the most natural measure of performance which refers a ratio between correctly predicted observation and total observations expressed using following equation [63, 67].

$$\text{Accuracy} = \frac{\text{TP} + \text{TN}}{\text{TP} + \text{FP} + \text{FN} + \text{TN}} \quad (1)$$

2) *Precision:* Precision is the proportion of positive observations accurately predicted to the overall predicted

positive observations which is expressed using following equation [64, 67].

$$\text{Precision} = \frac{TP}{TP+FP} \quad (2)$$

3) *Recall*: Recall is the proportion of positive observations accurately predicted to all observations in actual class which is expressed using following equation [65, 67].

$$\text{Recall} = \frac{TP}{TP+FN} \quad (3)$$

4) *F-Measure*: F-Measure is the weighted average of Recall and Precision which takes both false positives and false negatives into account and is expressed using following equation [67, 68].

$$\text{F Measure} = 2 * \frac{\text{Recall} * \text{Precision}}{\text{Recall} + \text{Precision}} \quad (4)$$

5) *Error rate*: Error rate is simply a ratio of wrongly predicted observation to the total observations which is expressed using following equation [67].

$$\text{Error rate} = \frac{FP+FN}{TP+FP+FN+TN} \quad (5)$$

6) *Loss*: Loss is a number that indicates how poor a prediction of the model was in one particular case [59,60,61,62,66]. Loss is zero if the assumption of the model is right or else the loss is greater. Loss functions are intended to measure how much a method requires to minimize value in training. This research used the categorical_crossentropy as the loss function. The value measured by the loss function is simply called a loss which is usually used when there are two or more than two label classes.

7) *Confusion matrix*: For deep learning classification perspectives, confusion matrix is a performance measurement where two or more classes generate output [59, 60, 61, 62, 66, 69]. Confusion matrix is a table with four different predicted and actual value combinations which is very useful for measuring accuracy, precision, recall, f- measure, and error rate. This research found predicted percentage value comparing to the actual value and inserted the value for that class in the confusion matrix.

C. Datasets

In order to evaluate the performance of the proposed Convolutional Long Short-Term Deep Network (CLSTDN) for Intention recognition, this research evaluated the performance of the network with the publicly accessible datasets like: UCF-Sports [31, 36, 60, 66], UCF-11 [60, 66], KTH [8,31,47,62], and UCF-50 [31,36]. Such challenging datasets are commonly used for benchmarking. Later, this research compared experimental results with state-of-the-art approaches. Details for each of the datasets are illustrated below.

1) *UCF-Sport*: UCF Sport is one of the oldest datasets for action's recognition which consists of a sequence of acts from different sports activities. The dataset consists of 150 videos for 10 human actions with a resolution of 720x480. This

dataset's frame numbers vary from video to video. Frame rate of the UCF Sports dataset was 10 frames per second and on average each video contains 30 to 130 frames in total.

2) *UCF-11*: UCF-11 dataset includes 11 types of action categories. Due to broad variations in camera movement, object appearance and posture, object size, view, cluttering background, lighting conditions, etc. This dataset is very complex and challenging comparing than YouTube video-based dataset.

3) *KTH*: The KTH is the most widely used human behavior public dataset which contains 6 different types of video action with a resolution of 160x120. 25 participants in four different scenarios performed actions multiple times. For each combination of 25 subjects, 6 actions, and 4 scenarios, there are total of 600 video files. All sequences with a static camera with a 25fps frame rate had been taken over homogenous backgrounds.

4) *UCF-50*: UCF50 is a collection of action recognition data with 50 categories of action, consisting of realistic videos taken from YouTube. This dataset is an extension of the YouTube Action dataset (UCF-11). The videos are grouped into 25 groups for all the 50 categories, where each group consisting of more than four action clips with a resolution of 320x240.

This research splits all datasets into 70% for training and 30% for testing. The training and testing data split are shown in Table I.

TABLE I. DESCRIPTION OF TRAIN AND TEST SPLIT OF VIDEOS OF DATASETS

Dataset	Training Data	Testing Data
UCF Sports	103	47
UCF-11	1084	439
KTH	407	192
UCF-50	4636	1839

In the UCF Sports dataset, this research extracted 15 frames from per second of the video. For UCF-11 dataset, this research extracted 10 frames per second of the video as there are more videos. Also, for the UCF-50 dataset, this research extracted 10 frames from per second of the video as the dataset is very big in size and the images are loaded into a resolution of 224x224x3. For the KTH dataset, this research extracted 25 frames per second of the video and images are loaded into a resolution of 120x120x3 as the videos were of low resolution. This research ignored the frames mentioned to be ignored from the official site of the KTH dataset so there is no ambiguous data. This research reshaped images into a resolution of 299x299 because pre-trained Inception-ResNet-v2 network accepts an input of size 299x299 only. Inception-ResNet-v2 is a pre-trained convolutional neural network which was used to extract the spatial features from frames of a video.

To train the model, this research used batch size of 32 for the UCF Sports dataset, 32 for the UCF-11 dataset, 64 for KTH and 128 for the UCF-50 dataset. This research used

LSTM of size 2048 and two more dense layers size of 1024 and 512 with the most common Rectified Linear Unit (ReLU) activation function. This research used dropout probability of 0.1 to reduce any overfitting issues in all layers for UCF sports and UCF-11 dataset. In addition, this research used a dropout of 0.1 on the dense layer size of 512 for KTH and UCF-50 dataset and no dropout on other layers. Finally, this research used SoftMax activation function on the last dense layer of the size of the output class to achieve output. This research used Adam optimizer with a learning rate of 1×10^{-5} , a decay rate of 1×10^{-6} and a momentum of 0.2 for all the datasets. This research sets the model to train for 100 epochs but if the validation loss of the model does not improve for 10 consecutive epochs, this research used early stopper function to stop epochs.

D. Experimental Results

Proposed method received best results for UCF Sports dataset after 62 epochs which needed 2336 seconds with accuracy of 95.74%, precision of 95.83%, recall of 97.49%, F measure of 96.23% and error rate of 4.26% shown in Table II. After 43 epochs that needed 4970 seconds, proposed method received best results for UCF 11 dataset which gives an accuracy of 95.44%, precision of 95.3%, recall of 95.33%, F-measure of 95.26%, and error rate of 4.66%. After 45 epochs that needed 10556 seconds, proposed method achieved best results for the KTH dataset which gives an accuracy of 90.1%, precision of 90.1%, recall of 90.54%, F-measure of 90.2%, and error rate of 9.9%. After 20 epochs which needed 5146 seconds, proposed method received best results for UCF 50 dataset which gives an accuracy of 80.80%, precision of 80.27%, recall of 80.27%, F-measure of 79.68% and an error rate of 19.2%.

TABLE II. EXPERIMENTAL RESULTS FOR THE PROPOSED METHOD IN FOUR DATASETS

Dataset	Accuracy	Precision	Recall	F-Measure	Error rate
UCF Sports	95.74	95.83	97.49	96.23	4.26
UCF-11	95.44	95.3	95.33	95.26	4.66
KTH	90.1	90.1	90.54	90.2	9.9
UCF-50	80.8	80.27	80.27	79.68	19.2

Line graph as Accuracy per epochs of the UCF-Sports dataset is shown in Fig. 3(a) where yellow line indicates testing accuracy and blue line indicates training accuracy. As this research uses deep learning architecture to train and test data, proposed method learns gradually from the train data. From test data proposed method validates performance in each epoch. Fig. 3(a) states that after 62 epochs, training accuracy increased gradually and finally reached 1.0 which is 100%. Test accuracy also increased gradually with each epoch and reached a maximum value of 0.9574 which is 95.74%.

Line graph as Loss per epochs of the UCF Sports dataset is shown in Fig. 3(b) where yellow line is the test loss and blue line is the train loss. Loss is zero if the assumption of the proposed method is right or else the loss is greater. Loss will gradually decrease with each epoch. If test loss value does not decrease for 10 consecutive epochs, then this research stopped

the epoch. Following this, this research receives best result with minimum test loss which is targeted for minimizing overfitting. Fig. 3(b) states that minimum train loss is 0.0042 and the minimum test loss is 0.22254.

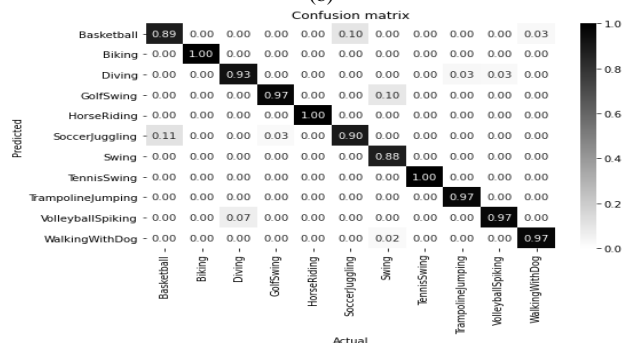

Confusion matrix for UCF Sports dataset is shown in Fig. 3(c) which states that proposed method faced problems in predicting actions like Golf swing and Run side. Running sideways is one time predicted as kicking by the proposed method. On the other hand, Golf-swing is predicted as kicking for one time by the proposed method. For the rest of the activities, proposed method model predicted intentions accurately. After analyzing various actions in videos for which proposed method predicted wrong, this research observed that some frames from the video of golf swing make the intention of kicking due to similarity of patterns. Also, for the running activity, the videos were a bit unclear and made the proposed method predicting it as kicking due to the same reason.

(a)

(b)

(c)

Fig. 3. (a). Line graph as accuracy of UCF sports dataset, (b). Line graph as loss of UCF sports dataset, (c) Confusion matrix of UCF sports dataset.

Line graph as accuracy per epochs of the UCF-11 dataset is shown in Fig. 4(a) where yellow line indicates testing accuracy and blue line indicates training accuracy. Fig. 4(a) states that after 43 epochs, training accuracy increased gradually and finally reached 1.0 which is 100%. Testing accuracy also increased gradually with each epoch and reached a maximum value of 0.9544 which is 95.44%. Line graph as the Loss per epochs of the UCF-11 dataset is shown in Fig. 4(b) where yellow line is the test loss and the blue line is the train loss. Loss is zero if the assumption of the proposed method is right or else loss is greater. Best results were achieved with minimum test loss which is targeted for minimizing overfitting. Fig. 4(b) states that the minimum train loss is 0.0012 and minimum test loss is 0.1557.

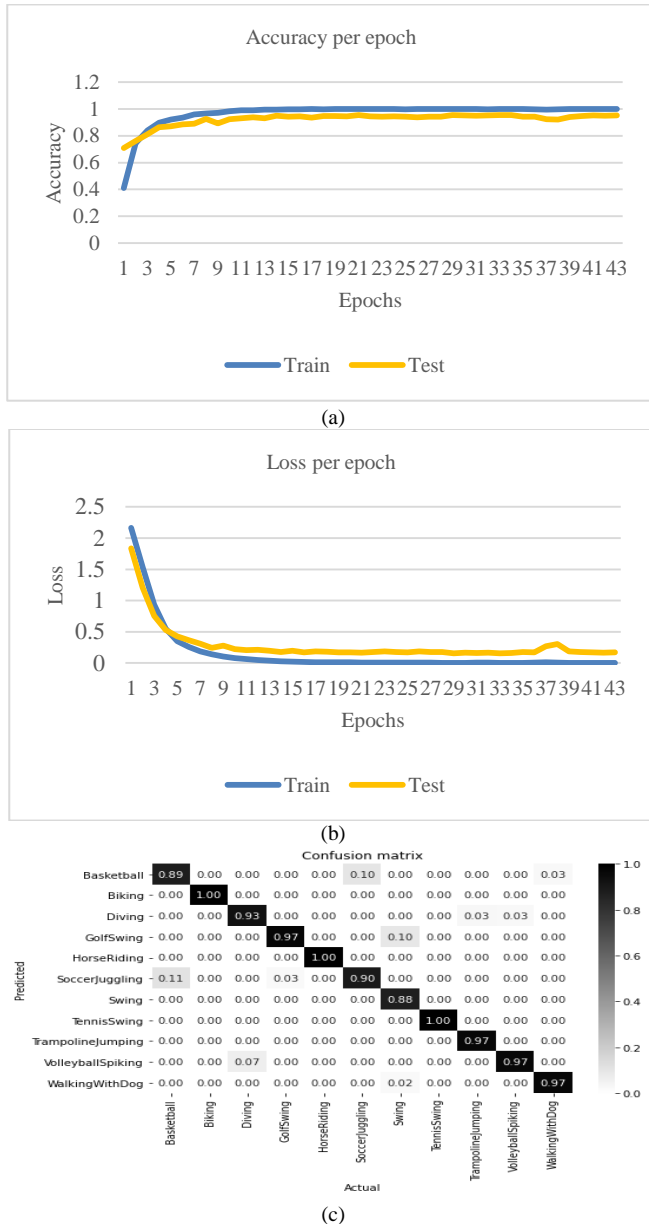

Fig. 4. (a) Line graph as accuracy of UCF-11 dataset, (b) Line graph as loss of UCF-11 dataset, (c) Line graph as confusion matrix of UCF-11 dataset.

Confusion matrix of UCF-11 dataset is shown in Fig. 4(c). From the confusion matrix, this research observed that proposed method almost predicted all the intentions perfectly where for almost all the activities prediction was robust. In some activities like Basketball playing, proposed method predicted some video sequences as soccer as there is a common object which is a ball. In this context, accuracy can be increased if more training is done with these activities. Also, for swing, there were some video angles in which proposed method was not trained which causes wrong prediction for those angles as golf swings.

Line graph as the Accuracy per epochs of the KTH dataset is shown in Fig. 5(a) where yellow line indicates testing accuracy and blue line indicates training accuracy. Fig. 5(a) states that after 45 epochs, training accuracy increased gradually and finally reached 0.9853 which is 98.53%. Test accuracy also increased gradually with each epoch and reached a maximum value of 0.9010 which is 90.10%.

Line graph as the Loss per epochs of the KTH dataset is shown in Fig. 5(b) where yellow line indicates test loss and blue line indicates train loss. Proposed method receives best results with minimum test loss which was targeted for minimizing the overfitting. Fig. 5(b) shows that the minimum train loss is 0.0645 and the minimum test loss is 0.3179. Confusion matrix of the KTH dataset is shown in Fig. 5(c). KTH dataset is robust datasets which contains similar kinds of activities like jogging, running and walking. Confusion matrix states that proposed method by this research predicted the intentions accurately enough. Although, proposed method faced problems for running activity which was predicted as jogging, which is also tough for a normal human being to differentiate between, them due to the similarity of the pattern.

Line graph as the Accuracy per epochs of the UCF-50 dataset is shown in Fig. 6(a) where yellow line indicates testing accuracy and blue line indicates training accuracy. Fig. 6(a) states that after 20 epochs, training accuracy increased gradually and finally reached 1.0 which is 100%. Testing accuracy also increased gradually with each epoch and reached a maximum value of 0.8113 which is 81.13%. Line graph as the Loss per epochs of the UCF-50 dataset is shown in Fig. 6(b) where yellow line indicates test loss and blue line indicates train loss. Proposed method received accuracy was 81.13%, best test loss was achieved with accuracy of 80.8%. Fig. 6(b) states that minimum train loss is 0.0098 and the minimum test loss is 0.7413. Confusion matrix of UCF-50 datasets states that proposed method faced problems in predicting the actions like nunchucks, jumping jack, and javelin throw. In these actions, there are some positions or frames which are like other activities. Nunchucks is often considered as golf swing or swing because it has some position like these two activities. For jumping jacks, it has some frames which make the proposed method predicting other activities like lunges, jumping rope or pullups. In javelin throwing, the actor often jumps to throw the javelin which was predicted as high jump by our proposed method often due to similarity of the pattern.

E. Comparison with Previous Research Results

After experimenting on four different datasets, this research compared proposed method with state-of-the-art methods and found that proposed method performed very well using spatial-temporal features compared to other method with a good amount of accuracy, precision, recall and f-measure.

Proposed CLSTDN received accuracy rate of 95.74% which is higher than previous research methods shown in Fig. 7(a). Research in [59] received accuracy of 93.1% using Convolutional Neural Network and Support Vector Machine. They used three frames of a video instead of the all the frames to understand the human action. Besides, they extracted conceptual features to recognize objects and worked with sports-based dataset only. Whereas proposed CLSTDN used spatial-temporal features caused better performance than research in [59]. Research in [60] received accuracy rate of an accuracy of 93.67% using same method as research in [60]. They used only first and last frames of a video instead of the all the frames to understand human action. Like in research [59], they used conceptual features to recognize objects and used SVM to classify high level and stationary features obtained from CNN; whereas usage of spatial-temporal features by the proposed CLSTDN resulted better performance than research in [60]. Research in [61] received

accuracy rate of 86.67% using action-history and histogram of oriented gradient. They used Motion History Image (MHI), Local Binary Pattern (LBP) and Histogram of Oriented Gradient (HOG) approaches for action recognition. Proposed CLSTDN by this research pre-trained CNN used Inception-ResNet-v2 to extract features from deep inside the image to create sequence. For this reason, proposed CLSTDN achieved better performance comparing with research in [61]. Research in [62] received accuracy rate of 93.7% using fully connected-to-LSTM. They used VGG-16 as pre-trained CNN network and fused the result with LSTM to recognize human actions whereas proposed CLSTDN extract spatial features from average pooling layer and passed the data sequence to LSTM to extract temporal features to recognize human intentions. Also, research in [62] used spatial features only to recognize human actions whereas proposed CLSTDN used both spatial and temporal features to recognize human intention and achieved better accuracy. Research in [66] received accuracy rate of 92.4% using motion history images of frame sequences with spatial information extraction. They used Motion History frame sequence to understand the temporal changes. However, proposed CLSTDN passed spatial feature sequences to LSTM for temporal understanding of the whole video caused higher accuracy than research in [66]. In overall, previous methods used spatial or temporal data for understanding video whereas proposed CLSTDN uses both spatial-temporal understanding of a video which helps for a better understanding of human intention.

Proposed CLSTDN received precision rate of 95.83% which is higher than previous methods shown in Fig. 7(b). Research in [59] received precision rate of 93.27% using Convolutional Neural Network and Support Vector Machine. Precision rate indicates the proportion of positive observations accurately predicted to the overall predicted positive observations. As research in [59] used only three frames of a video instead of the all the frames to understand the human action, their overall positive classifications were less than proposed method by this research. Research in [60] received precision rate of 93.91% using Convolutional Neural Network and Support Vector Machine. As they used first and last frames only of a video instead of the all the frames to understand the human action caused their positive classifications less than proposed CLSTDN by this research. As accurately predicted positive observation by research in [60] is less than proposed CLSTDN, precision is also less than proposed CLSTDN. They used spatial-temporal understanding of an image but they are still unable to learn from an image due to lack of depth features which causes lower accurately predicted positive observations than proposed CLSTDN and precision is also higher than research in [61]. Research in [62] received precision rate of 95% and 89% using fully connected-to-LSTM and Convolutional-to-LSTM respectively. They used VGG-16 as pre-trained CNN network caused number predicted positive observations less than proposed method and finally resulted in better precision rate than in research [62]. Research in [66] received precision rate of 92.46% using frame sequences and spatial features extraction. Like other previous methods, research in [66] used the VGG-16 pre-trained network which caused less accurate predictions than proposed method by this research and

resulted in lower precision rate than by the proposed CLSTDN.

Fig. 7. (a) Detection rate comparison with previous research., (b) Precision rate comparison with previous research.

Proposed CLSTDN received recall rate of 97.5% which is higher than previous methods shown in Fig. 8(a). Research in [59] received recall rate of 93.11% using Convolutional Neural Network and Support Vector Machine which is lower than proposed CLSTDN due to usage of randomly three frames only to understand the overall video. Research in [60] received recall rate of 93.66% using Convolutional Neural Network and Support Vector Machine. However, due to usage of first and last frame to understand overall video without Spatio-temporal features, research in [60] produced lower recall rate comparing with the proposed CLSTDN. Research in [61] received recall rate of 86.67% using Binary patterns of action-history and histogram of oriented gradient. Similarly, research in [62] received recall rate of 93% using

both fully connected-to-LSTM and Convolutional-to-LSTM and research in [66] received recall rate of 92.36% using frame sequences and spatial features extraction. Proposed CLSTDN achieved better recall rate than research in [61], [62] and [66] due to usage of Inception-ResNet-v2 for deep Spatio-temporal features extraction instead of VGG-16.

Proposed CLSTDN received F-Measure value of 96.23% which is higher than previous methods shown in Fig. 8(b). Research in [59] received F-Measure value of 93.18% using Convolutional Neural Network and Support Vector Machine. Similarly, research in [60] received F-Measure value of 93.78% using Convolutional Neural Network and Support Vector Machine. F measure indicates the weighted average of recall and precision which considers both false positives and negative into account. As proposed CLSTDN understands spatial-temporal features of the video sequence and human motion in video, better F-Measure was achieved by this research comparing with research in [59] and [60]. Research in [61] received F-Measure value of 89.44% using Binary patterns of action-history and histogram of oriented gradient. As proposed method used Inception-ResNet-V2 to understand video sequence, better F-Measure rate was achieved than research in [61]. Research in [62] received F-Measure rate of 94% and 91% using fully connected-to-LSTM and Convolutional-to-LSTM respectively. As number of features extraction by VGG-16 is less and not deep as Inception-ResNet-V2 which used by proposed CLSTDN, F measure by research in [62] is not promising like proposed method by this research. Research in [66] received recall rate of F-Measure rate of 92.41% using frame sequences and spatial features extraction. They used VGG-16 pre-trained network to understand temporal changes from Motion History Images. However, proposed CLSTDN used Inception-ResNet-V2 to model spatial features which were passed to LSTM and caused understanding patterns better than research in [66]. For this reason, better F-Measure was achieved by this research comparing with research in [66].

Proposed CLSTDN received error rate of 4.26% which is lower than previous methods shown in Fig. 8(c). Research in [59] and [60] received error rate of 6.9% and 6.33% respectively using Convolutional Neural Network and Support Vector Machine. Error rate by research in [59] and [60] is higher than proposed CLSTDN due to usage of random frames to identify objects in the video scenes. Research in [61] received error rate of 13.33% which is very high comparing with the proposed CLSTDN due to learn features more deeply using Inception-ResNet-V2. Research in [62] received error rate of 6.3% and 10.8% using fully connected-to-LSTM and Convolutional-to-LSTM respectively which made their proposed approach computationally heavy and resulted in higher error rate comparing with the proposed CLSTDN. Research in [66] received error rate of 7.6% using frame sequences and spatial features extraction which is also higher than proposed CLSTDN due to extract more depth features using Inception-ResNet-V2.

Fig. 8. (a) Recall rate in comparison with previous research, (b) F- Measure rate in comparison with previous research., (c) Error rate in comparison with previous research.

In overall, results from experimenting on different datasets showed that proposed Convolutional Long Short-Term Deep Network (CLSTDN) using both spatial and temporal features can lead to a viable solution for significantly improving recognition performance of human intentions of various activities. Proposed method performed well on UCF Sports, KTH, and UCF-11 dataset with low computation power. However, proposed method lacks in performance in the UCF-50 dataset due to the number of frames extracted from the video which was very low.

Proposed CLSTDN was evaluated on four publicly available datasets where accuracy, precision, recall, f-measure, and error rate were estimated for each dataset. To validate the proposed method, satisfactory accurate results were achieved on determining the intention on real time videos. After 62 epochs that needed 2336 seconds, proposed method received best results for UCF Sports dataset which gives an accuracy of 95.74%, precision of 95.83%, recall of 97.49%, f-measure of 96.23%, and an error rate of 4.26%. Previous methods used either spatial or temporal data for understanding the scene [33][37][39][42][46][48][51][52][53], whereas proposed method used both spatial-temporal understanding of a video which helps for a better understanding of an intention. To extract spatial features, proposed method used pre-trained convolutional neural network which was Inception ResNet V2 and passed the sequence to long short-term memory for the temporal understanding of the sequence. Also, this research dealt with limited data sequences whereas other methods used full data which causes the proposed method be faster comparing with previous methods. In addition, another benefit of the proposed method is that it runs on low computational power and resources. As this research illustrated earlier, because of taking both spatial and temporal features, proposed method gives more accurate results.

V. CONCLUSION

This research proposed Convolutional Long Short-Term Deep Network (CLSTDN) to recognize human action-based intention. Proposed CLSTDN consists of Convolutional Neural Network (CNN) and Recurrent Neural Network (RNN). Inception-ResNet-v2 was used as pre-trained network for CNN which contains 164 deep layers deep to classify class specific object categories. Long Short-Term Memory (LSTM) network was used for Recurrent Neural Network. Proposed CLSTDN extracted spatial features by Convolutional Neural Network and temporal features by Recurrent Neural Network to ensure the usage of Spatio-temporal features for efficient human intention prediction. Overall proposed methodology consists of three main phases, i.e., data preprocessing, feature extraction and final classification. Data preprocessing involves reshape, handling of blank image frames and overfitting to prepare the data to feed into Inception-ResNet-v2. Feature extraction phase involves implication of Convolutional Neural Network (CNN) and Recurrent Neural Network (RNN). Finally, dense layers and SoftMax activation function predicts human intention based on spatial-temporal features. Training of the proposed methodology was done on low computation resources and achieved better performance comparing with existing research results. Four publicly available datasets were used for validation, i.e., UCF Sports, UCF-11, KTH and UCF-

50. Validation of the proposed CLSTDN was done based seven evaluation metrics, i.e., accuracy, precision, recall, f-measure, error rate, confusion matrix and loss. Previous research methods used either spatial or temporal features for human intention prediction, however, proposed method used spatial-temporal features for human intention prediction caused more improved performance than previous research methods. In addition, proposed CLSTDN performed efficiently based on all the evaluation metric with a limited number of data sequence irrespective of viewpoint, background, inter-class and intra-class similarities present in the image frames with very small data sequences in almost all the datasets. However, proposed method produced some errors for several activities, i.e., jogging and running in KTH dataset, basketball and soccer game in UCF-11 dataset, nunchucks, jumping jack, and javelin throw in UCF-50 dataset due to similarity of patterns. In future, proposed CLSTDN will be investigated more comprehensively for more similar types of human actions.

ACKNOWLEDGMENT

Authors would like to thank Artificial Intelligence and Data Science Program under Mentoring Access & Platforms in STEM (MAPS) in Colorado State University in Pueblo, USA for financial support for this research. Authors also would like to thank School of Engineering, Colorado State University in Pueblo for various research supports.

Abstract—Knowledge-based passwords are still the most dominant authentication method for securing digital platforms and services, in spite of the emergence of alternative systems such as token-based and biometric systems. This method has remained the most popular one mostly because of its usability, compatibility, affordability of implementation, and user familiarity. However, the main challenge of knowledge-based password schemes lies in creating passwords that provide a balance between memorability and security. This research aimed to compare various knowledge-based schemes in order to establish a strategy that provided high memorability and resilience to most cyberattacks. The overview of this research identifies areas of knowledge-based passwords for further research and enhances the methodology that helps to offer insight into usable, secure, and sustainable authentication approaches. Future work has been recommended to explore the major features and drawbacks of recognition-based textual passwords because this method provides the usability and security benefits of graphical passwords with the familiarity of textual passwords.

Keywords—Knowledge-based authentication; recognition; recall; usability; security; memorability

I. INTRODUCTION

The biggest challenge for several companies is to establish an authentication technique that offers a high level of usability and security. Authentication systems can be classified into three main types: knowledge-based, token-based, and biometric [1], [2]. Large corporations and banks have recently switched to the use of biometrics or token passwords to verify individuals' identities, but these passwords require expensive hardware and high-complexity algorithms [3]–[5]. However, the most usable password is the knowledge-based one, particularly the textual passwords, because it is easy to use and user-friendly and has an extendable security feature [6]. Different researchers have extensively investigated the most common password schemes, as shown in Fig. 1, including usability, security, and deployability benefits. Thus, none of the stated methods converge to the benefits of textual passwords [7], [8]. The text password security requirements have increased dramatically in the last ten years because most people are not aware of the fundamentals of creating a strong password [9]. Users tend to create weak passwords with personal information and predictable patterns, which could be easily guessed by the password owner's close people or attackers [10]. Another scheme called a passphrase has been proposed as an alternative to text-based passwords; it offers better memorability and security [11], [12]. Though, the typing of long passphrases has shown an increase in typographical errors, thus reducing the successful login rate [13]–[15]. Researchers have suggested

algorithms that help avoid small typographical errors but still do not fully mitigate this issue (correct up to 57.7%) [16]. A recent study also found that 8.8% of users' passwords are vulnerable to attacks because of the typo-tolerance software [17]. There is another method considered a competitive strategy to recall passphrases called recognition-based textual passwords. The most usability-centered advantage of this scheme is to reduce the cognitive load and enhance the retrieval performance [18], [19]. Different studies have stated that a recognition passphrase has a better memorability rate than a recall scheme [19], [20]. The main usability and security challenges for recognition-based textual passwords are system design, user login performance, and resistance against guessing, brute-force, and shoulder-surfing attacks [21]. Nowadays, the knowledge-based password scheme needs further research to help to produce a system with large security entropy, low cognitive load, low cost, and resistance to common attacks. The main contribution of this paper is to analyze and evaluate the features and drawbacks of knowledge-based password schemes. We have aimed to present detailed information about the existing knowledge-based methods adopted thus far to critically investigate possible issues and, thus, help to propose ways to establish a new secure and usable knowledge-based authentication approach. This paper argues that the existing authentication systems must thoroughly address users' cognitive limitations or leverage humans', particularly for the recognition of textual passwords. Consequently, despite considerable research, establishing the recognition of textual passwords suggests a low cognition load, high memorability, and resistance to the most common attacks.

II. RELATED WORK

This part will compare the main types of knowledge-based authentication systems, namely textual and graphical passwords.

A. Textual Passwords

1) *Text-Based Passwords*: The traditional text-based password has been the most common authentication method for the past two decades [22]. It has several usability characteristics, such as ease of use and low cost to establish [23]. The password's strength depends on its complexity, length, and unpredictability against a guessing attack [24]. However, people tend to use insecure strategies for password creation, such as the use of common phrases, personal information, or predictable patterns [25]. These behaviors enforce businesses to set strict password policies [26]. Unfortunately, prior research has found

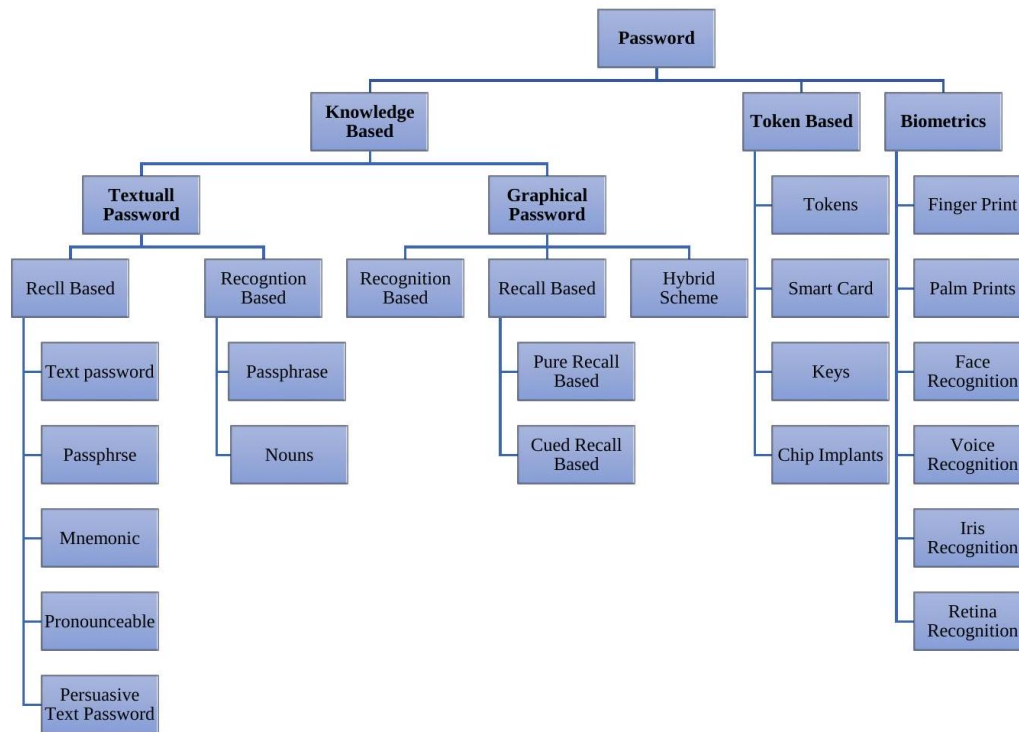

Fig. 1. Taxonomy of authentication systems.

that password policies are not sufficiently effective to form a strong password [10]. Additionally, a majority of people reuse the same passwords for different accounts because of cognitive challenges; thus, this practice might be risky as if one account is compromised, the attacker could use the same password to access the other accounts [27]. A survey result reported that 94% of the participants reused at least one password for more than one account [28].

2) *Passphrases*: A passphrase is a type of password that contains a series of words or text to authenticate an individual identity [29]. Long passphrases provide better security against brute-force attacks and frequently require less cognitive load than traditional passwords [30]. It was found that users spent less time on password activities such as retries and resets when using passphrases than when using traditional passwords [13]. However, a passphrase result in a usability issue related to typographical errors [13], [14], [31]. The typographical errors significantly increased when the passphrase was very lengthy [13], [19], [25] or when the guidelines and policies were followed strictly [8], [32]. In addition, people tend to create passphrases from common words with predictable patterns; this method is vulnerable to guessing attacks [33]. Regarding the previous usability and security issues of the passphrase approach, several studies have suggested the following:

- Tolerate spelling errors by applying a validation algorithm that accepts small typing errors without any influence on security entropy [34]. Still, these algorithms have a significant security degradation, not as previously understood [17].
- Create a long passphrase with specific security policies [12], [14].

- Systemically generate random words to reduce the predictability level [20], [31]. Table I lists the differences between users and system-generated passphrases.

3) *Mnemonic Passwords*: A mnemonic is a concept of sentence abbreviation that assists or is intended to assist memory by utilizing patterns of letters (often, the first letter), numbers, or relevant associations [35]. An analysis of mnemonics and passphrases created based on entire words shows that mnemonics offer a superior memorability rate [36]. Different mnemonic strategies are often utilized, such as sentence substitution “**I**went**H**K4&**h**ya” or special character insertion “**H**e,**l**lo&&**w**orld!” [37], [38]. Moreover, simulating the letters on keyboard buttons with different patterns to produce a mnemonic, such as “**H**” is equal to “**UHBijnhj**” [39]. Consequently, it provides a slight resistance against brute-force attacks as compared to traditional passwords [37].

4) *Pronounceable Passwords*: In 1975, it was established to systemically produce complex and memorable pronounceable passwords [40], [41]. The old version of the pronounceable password algorithm was vulnerable to guessing attacks if an attacker could analyze the pattern of the generated password [40]. Although systemically generated pronounceable passwords are intended to be easier to remember than random sequences of letters, but they still need further strategies. To address this issue, a study[42] suggested a method that partially combines two words while considering the phonotactic and syllabic restrictions of verbal English, which plays a role in determining the memorability rate. A new approach called “ProSemPass” is based on user-chosen pronounceable and semantically meaningful passwords; thus, it has 30% higher memorability than the systemically generated pronounceable

TABLE I. USABILITY AND SECURITY OF RECALL PASSPHRASE

Recall Passphrase			
	Memorability	Security	Comment/Limitation
User Generated	High	Low/Medium	<ul style="list-style-type: none">• Needs guidelines and policies for security enhancement [14], [32]• Is easier to remember than text passwords [13]• Is easy to guess [43], [44]
System Generated	Low	High	<ul style="list-style-type: none">• Is difficult to remember because of the unmeaningful passphrase structure [45].• Is most likely to be written down[46]• Has guaranteed robustness against guessing attacks [30]

methods and is more resilient against guessing attacks [41]. Recently, a new study suggested converting a user-chosen password into phonemes and measuring their pronounceability to enhance the password's usability and security and compared this method with different pronounceable strategies, including the "ProSemPass" scheme; however, on the basis of the findings, the author recommended the use of a passphrase instead of the proposed approach because it promises better usability and security standards [47].

5) *Persuasive Text Passwords (PTP)*: PTP is a user-chosen text password system with a random guideline to create a secure password. It is based on selecting one word, whose security will be enhanced by the system by placing a few randomly selected characters at randomly assigned positions [48]. For instance, users can select the word "security", and the PTP system will generate random changes, such as inserting or replacing the characters as "use>curity". Users can shuffle for repositioning characters until they are persuaded with a memorable password. However, the PTP does not deliver a high security level, particular after insertion, because PTP does not assess the password's strength [49].

6) *Recognition-based Textual Passwords (Human Memory and Words Memorability)*: The human capacity to memorize large amounts of information is limited. Psychological researchers have discussed how the human brain works and how to exploit its features to transfer data from the short- to the long-term memory [50]. In 1956, Miller argued the range of items that individuals can hold for the short-term memory is approximately seven [51]. Different strategies explain how human memory pays attention to information through a human's five senses (sight, hearing, taste, smell, and touch) and is transferred from the sensory register to the short-term memory. Moreover, with rehearsal the information will be transferred to the long-term memory [52]. The capacity of the human brain to store words for a long period differs from person to person, but the stimulus to the human memory has a critical role in how information is effectively stored and retrieved [53]. In general, the major factors in the English language that have a direct impact on the memorability rate are as follows:

- **Word Frequency**: Several research studies have examined the memorability of high-frequency (HF) or common words versus low-frequency (LF) or uncommon words and found that the HF-word versus the LF-word memorability is complex and depends on many aspects, such as recall versus recognition, word familiarity, task nature, mixed lists, pure lists and subsequent memory [54].
- **Concreteness and imageability**: Concrete words are words

that "refer to tangible objects, materials, or persons and can be easily perceived with the senses" and thus, stimulate the mental image [55].

- **Valence**: This belongs to emotional words, which are divided into two main categories: attractiveness/"good"-ness (positive valence) or averseness/"bad"-ness (negative valence) of an object, circumstance, or event [56].
- **Arousal**: Arousal is related to the personal experience of feelings (emotion words), including tension and high energy [57].

Word memorability in education is complex because various physiological factors play a role, such as individual memory capacity, culture, and age [58]. In authentication systems, the English words are established with different strategies as compared to the learning criteria as follows:

- 1) Recall or recognition strategy
- 2) Word-generated methodology: user-generated, system-generated, or both
- 3) Grid design (word presentation)
- 4) Word type
- 5) Word structure (phrase, semantic meaning, etc.)

Previous researchers have attempted to implement a recognition mechanism for different types of passwords to enhance their retrieval performance. A majority of the authentication systems based on recognition methods used graphical passwords to leverage human memory through visual information (images) [59], as discussed in Section 2.2. In contrast, the recognition approach has been used with English words but has still not yet been fully investigated. Word recognition passwords are a relatively challenging area of authentication systems because they are a less common form of authentication. They typically require the users to select specific words as passwords, which can be easier to memorize than complex text-based passwords. In the last decade, several studies have examined the recognition of words with different types of passwords, as shown in Table II.

7) *User-Chosen vs. System-Assigned Passwords*: User-chosen passwords are vulnerable to various attacks because users tend to create easy passwords to remember with predictable patterns [64]. Most websites force their users to create passwords conforming to specific policies; however, these policies are not sufficiently effective to generate secure passwords [65]. Extant research has proven that users have a misconception about creating strong passwords for various reasons, such as using common keyboard patterns, words, phrases, or personal information [66]. To partially

TABLE II. USABILITY AND SECURITY OF RECOGNITION OF TEXTUAL PASSWORDS

Recognition-Based Textual Passwords				
Source	Condition	Memorability	Security	Comments/Limitations
Study [20]	system-generated (a) recall password (b) recall passphrase (c) recognition passphrase	- recognition passphrase > recall passphrase, letter, password - letter recall > passphrase recall	4 words out of 156 (29.14 bits)	<ul style="list-style-type: none"> Some participants commented that their passphrase did not include a verb or semantic meaning (“throat” and “tongue”), which negatively affected the retrieval of the correct password. Recognition method has significantly fewer password resets than word recall. Takes a long time to log in because the GUI contains six groups of words.
Study [18]	system-generated recognition (a) objects (b) image (c) words	- objects > image and words - words = image	5 words out of 48 (27.9 bits)	<ul style="list-style-type: none"> No balance exists between word types presented to users in the registration phase (adjectives less than other types). Word set contains words with the same first letters, which might confuse users in long-term memory such as “Camp” and “Lamp”. Memorizing time for words is less than that for objects and significantly less than that for images.
Study [60]	system-generated (a) recognition nouns (b) text-based password	- text-based password > recognition nouns	3 words out of 104 (20.1 bits)	<ul style="list-style-type: none"> Noun recognition has significantly shorter login times on a mobile and a comparable login time on a desktop computer than text-based passwords.
Study [61]	(a) self-selection of system-generated recognition passphrase (b) system-generated recognition passphrase	- self-selection of generated system passphrase > system-generated recognition passphrase	6 words out of 20 or 100 (25.93 to 39.86 bits)	<ul style="list-style-type: none"> The dictionary used contains a majority of uncommon words; thus, it is not applicable to users with different backgrounds. The experiment was not conducted in a controlled environment such as a lab. Typing the recognized words slightly reduces the successful login rate.
Study [19]	(a) self-selection of system-generated recognition nouns with pure recall nouns (b) self-selection of system-generated recognition passphrase with pure recall passphrase	- recognition nouns and passphrase > recall nouns and passphrase - recognition and recall passphrase > recognition and recall nouns	4 words or more out of 26 words (18.8 bits)	<ul style="list-style-type: none"> The login time for noun recall is less than that for recognition. The login time for a recognition passphrase is almost similar to that for a recall passphrase. Words with the same categorization such as “YouTube” and “Facebook” confuse users to log in successfully. Word set with words with almost the same first letters such as “store” and “story” negatively affects the participants’ retrieval of the correct password. Also, the Unmeaningful structure of passphrases has a negative impact on memorability.
Study [62]	(a) user-selection passphrase (b) conventional password	- passphrase > conventional password	4 words (crossword puzzle with 625 cells)	<ul style="list-style-type: none"> Takes a long time to log in than a conventional password. Is a complex approach and needs more training for users to accomplish the authentication process. Is invulnerable to several attacks such as dictionary attacks, brute-force attacks, and shoulder surfing attacks.
Study [21]	system-assigned recognition (a) nouns (b) nouns with verbal cues (c) nouns with verbal and spatial cues	- nouns with verbal and spatial cues > nouns - nouns with (verbal and spatial) cues > nouns with verbal	words out of 80 (20 bits)	<ul style="list-style-type: none"> The registration time for nouns with verbal and noun (spatial and verbal) cues is significantly higher than that for nouns. The login time for nouns and nouns with (spatial and verbal) cues is significantly less than that for nouns with verbal cues. Nouns with verbal cues have a significantly higher login rate than just nouns. There is no significant difference in the memorability rate between nouns with verbal cues, 94.23 %, and nouns with (spatial and verbal) cues, 96.15 %.
Study [63]	system-assigned passphrases (a) CC-SP is a condition with training features (fixed location of the words, repetition, exposure time, and/or the words with semantic relations) (b) other four conditions	- CC-SP > all conditions	4 words out of 128 (28 bits)	<ul style="list-style-type: none"> This study is based on Implicit learning techniques such as contextual cueing and semantic priming CC-SP method significantly improves the usability of system-assigned passphrases, in terms of recall rates and login time. It includes different training sessions.

cover weak password patterns, several companies have suggested password meters to determine whether the created password is strong, but the results of popular website meters have revealed many weak passwords as very strong [67]. The final goal of password meters has not comprehensively solved the problem of creating a strong password. However, a system-assigned password has been proposed as a solution to the security issue of user-chosen passwords. Different studies have reported that randomly assigned passwords are secure but difficult to remember [68]. Moreover, another study has proven a significantly low memorability rate of system-assigned passphrases than that of user-generated and mnemonic-guided passphrases [43]. A systemic review article of different composition strategies of textual passwords includes text-based, pronounceable, mnemonic, passphrase, system, and user-generated passwords; thus, user-generated passwords are more memorable than system-generated passwords [69]. Additional research attempted to reach a compromise between user-chosen and system-assigned passwords by applying a PTP approach, which requires users to select a password and then the system will perform some modifications to the actual password, as discussed in Section 2.1.5, but the study was not conducted for several sessions that evaluate the memorability rate. Overall, a recent psychological study proved that self-generated passphrases have fewer cognitive load stressors on the working memory than system-generated passphrases [70].

B. Graphical Passwords

Graphical passwords were proposed by Blonder in 1991 and are presented in a certain visual format (as opposed to the text password format). Humans remember pictures better than text, so graphical authentication passwords are possible alternatives to text-based passwords [71]. Graphical passwords have been categorized into four main schemes: drawmetric (pure-recall-based), locimetric (cued-recall-based), cognometric (recognition-based), and hybrid [72]. In general, graphical password systems have various usability and security advantages such as being easy to remember and difficult to guess, higher security level, being human-friendly, and mitigating dictionary attacks; however, they are vulnerable to shoulder-surfing attacks and brute-force attacks (which reduce the common areas in the images) [73].

1) *Drawmetric (Pure-Recall-Based) and Locimetric (Cued-Recall-Based)*: The recall graphical password is divided into pure and cued recall-based methods [74]. The pure recall technique is called drawmetric; users generate their passwords without any clues to remember these passwords. It mainly depends on drawing a secret on a blank canvas or a grid as a simple picture, such as Draw a Secret Algorithm (DAS) Fig. 2(a) and Background Draw a Secret (BDAS) Fig. 2(b) [75]. The users must draw their secrets in an exact manner, which would require help remembering the exact stroke order [76]. These methods have a memorability range of 50%–80% [77]; however, they have less password space and no resistance against shoulder-surfing attacks [78].

The cued-recall-based graphical password, also known as locimetric, is based on displaying an image to the users to choose different points on it [75]. The most common schemes of cued recall are blonder and pass-point. Users are required

Fig. 2. Draw a secret algorithm.

in the login phase to select the same regions in a specific order, as shown in Fig. 3(a) [79]. The blonder method resists brute-force attacks because it contains millions of regions that can be selected as passwords [80]. Nevertheless, the main disadvantage of this method is that users cannot arbitrarily click on the background [78], [81]. Another mechanism called pass-point was proposed to overcome the limitation of the blonder method [82]. It allows users to select any natural image sufficiently rich to have many possible click points, which would be a hint for the users to remember their click points, as shown in Fig. 3(b) [83].

Fig. 3. Blonder and pass-point method.

2) *Cognometric (recognition-based)*: A recognition-based graphical password scheme creates a platform for the user that contains visual passwords, and the user can select some of them as a password [18], [84]. Several image formats have been proposed for this recognition-based scheme: faces, random art pictures, icons, and daily objects [85]. Passfaces is a common method that uses human faces as a verification tool for the authentication procedure [86]. Passface is very memorable for a long period, but it is somehow predictable and vulnerable to a variety of attacks, as a majority of the users tend to select a person's face on the basis of apparent behavioral patterns, as shown in Fig. 4(a) [87]. Another version of Passface was proposed called S-Passface, which is based on replacing some characters by entering random characters corresponding to each face instead of selecting the face by the mouse, as shown in Fig. 4(b). Therefore, S-Passface is 100% resistant to shoulder surfing as compared to the original Passface version, but the security improvement has decreased

some of the usability features [88].

Fig. 4. Passfaces authentication systems.

Furthermore, other common recognition-based methods, Déjà Vu and story, are based on recognizing images with different principles. Déjà Vu is an algorithm that uses the technology of hash visualization of the images, as shown in Fig. 5(a) [89]. This approach showed that 90% of the participants succeeded in the authentication by using this technique, while only 70% succeeded by using text-based passwords [90]. The main disadvantage of this technique is that it takes a long time to log in because storing a large number of pictures causes a delay in transferring over the network, thus delaying the authentication process [79]. The story mechanism is comparable to the Passfaces method; it presents images of places, people, or everyday objects, as shown in Fig. 5(b). Users are instructed to mentally create linked images as a story to quickly and easily remember their passwords. The memorability result revealed that from 236 failed attempts, more than 75% were correct pictures in a wrong order [91]. Moreover, this scheme suffers from guessing and shoulder-surfing attacks [78].

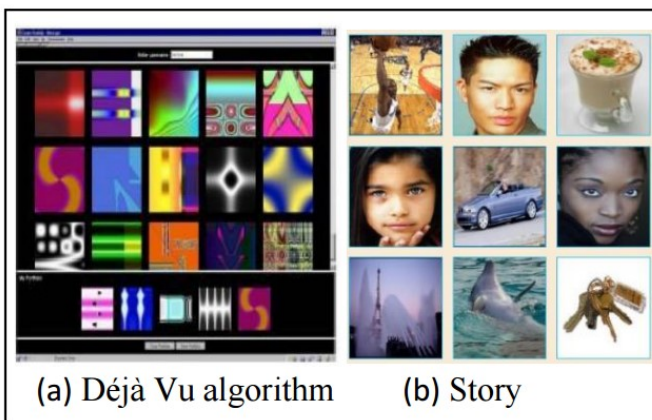

Fig. 5. Déjà Vu and story schemes.

3) *Hybrid Schemes*: A hybrid scheme combines two or more different types of graphical passwords or other authentication techniques for usability and security improvement [92]. According to recent studies, hybrid techniques can be classi-

fied into two categories: hybrid systems with only graphical password methods[72] and a hybrid system with a graphical and textual password [93]. Recent studies have combined recognition-based and cued-recall-based graphical passwords with images and drawn a pattern, as shown in Fig. 6(a) [94].

Moreover, the Passface scheme has been combined with traditional text passwords, as shown in Fig. 6(b) [95]. The hybrid system is utilized to overcome the limitations of graphical password schemes by creating a new system that provides a robust authentication system against spyware and shoulder-surfing attacks [96]. A recent study comprehensively deliberated hybrid graphical passwords' security levels and compared them with other graphical password systems against different attacks; thus, revealing that they had a high level of security against shoulder-surface attacks but were still vulnerable to the others [78]. However, the hybrid graphical password can provide an additional layer of security, but it could also be complex and require users to spend more time creating and entering their passwords [97]. It is critical to consider interaction while creating a hybrid graphical password system to maximize the system's effectiveness [98].

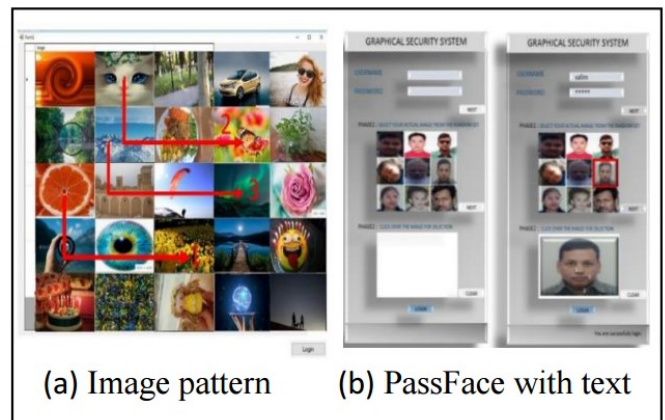

Fig. 6. Hybrid authentication system.

III. COMPARATIVE ANALYSIS OF KNOWLEDGE-BASED PASSWORDS, TOKENS, AND BIOMETRICS

An alternative solution has been discussed to overcome the security issue of a knowledge-based password, which are tokens and biometrics. A token password is a widely used authentication mechanism that enables users to access website resources by verifying their identity by submitting a token produced for one-time use only [99]. However, it primarily depends on third-party providers to produce tokens or one-time passwords, which makes them susceptible to the man-in-the-middle attack [100]. Moreover, researchers have reported that token passwords have a safety issue: time wastage and delays before accessing services [101]. Additionally, losing the token devices and lengthy authentication time are the main issues of this technique [102]. Thus, token passwords have a high computational cost and are expensive to implement [103].

Biometric passwords are based on people's unique behavioral and physiological characteristics and use these features as a password by using different technologies [104]. Recent studies have indicated that biometric passwords provide better

security than most of the other password types [105]. Nevertheless, biometric passwords are expensive to establish because they need high-quality devices and have a high complexity of implementation [106]. There is another concern about biometric methods, which is that no person can regulate the biometric differences caused by injury or aging [107]. The biggest security concern of biometric passwords is deceiving a security system by using copied or fake information [108]. These disadvantages of biometric methods reduce their efficiency as compared to the other types of passwords.

The knowledge-based password still provides extendable usability and security features. It can be comparable to the token and biometrics security levels with respect to mitigating most of the usability issues and security threats [1], [109]. Textual passwords are relatively still the most usable passwords because their ease of use, lack of hardware required, and less required storage [110]. A comparison of textual passwords with graphical passwords revealed a huge difference in the storage space and time consumption to login [98]. Furthermore, the shoulder-surfing attack is the most pressing security concern of graphical passwords because of their visual interface [76]. Regarding the storage problem of graphical passwords, a colored image requires a storage space of around 23.98 MB, which is significantly higher than that required by textual passwords with eight characters (57 bits) [111]. The huge size of images of graphical passwords lead to the maximization of the network latency [112]. Increasing the data transmission over the network costs more because of the complex computation and communication [113]. Furthermore, graphical passwords have an issue with communication speed as compared to textual passwords because of the picture sizes, long configuration size of registration and logging in, as well as the complexity of the encryption process [114]. Overall, graphical passwords are more expensive than textual passwords because they require large storage space to store a large number of images [115].

IV. OPEN CHALLENGE AND FUTURE TRENDS

Authentication systems typically involve different types of credentials, such as tokens, biometrics, textual passwords, or graphical passwords. The main challenges with these systems are related to security, usability, and scalability. Each authentication method has its strengths and weaknesses, and organizations need to consider the benefits and drawbacks of each approach on the basis of their specific needs and security requirements. Biometrics and tokens offer high security, but they are costly and require particular hardware and software. Furthermore, graphical passwords require a large storage space to store large numbers of images, which causes delays in transferring the pictures over the network; therefore, they are not as widely used as textual passwords. Textual passwords are the most common type of passwords used and are regularly required to encounter certain complexity requirements. Recently, companies and government sectors (Microsoft, Canadian Government, FBI, etc.) have encouraged users to create long passphrases with the same complexity as traditional passwords to enhance security and memorability. The biggest challenge of using a long passphrase with policies as the password is the typographical errors, particularly when people need to gain experience with English as a primary language. Therefore, increasing the length of the password

or passphrase helps to increase the security level, but it will make it difficult for users to login successfully. The future trend is establishing user-chosen recognition textual passwords with a high memorability rate and mitigating common attacks. This approach will be the alternated scheme for textual and graphical password schemes. It can solve several issues related to recall textual passwords such as memorization burden, lack of diversity, reuse across multiple accounts, and difficulty of password creation. Moreover, it does not require high storage space, complex implementation, and high load over the network (causing delay to login) as a graphical password scheme.

The main novelty of this paper was that specify the limitations of previous studies of recognition of textual passwords to establish a new strategy that is more competitive with other textual and graphical password, as shown in Table II. The majority of prior research on the recognition of textual passwords is based on system generated approach which results in several drawbacks. Firstly, a recent study stated that system-assigned recognition words have low memorability rates and need spatial cues (pictures) to improve word memorability; thus, they require considerable storage space, which will be costly and delay the login process [21]. Secondly, this approach needs more training to enhance password retrieval performance [63]. Finally, the word selection is limited between 4 and 5 words which cause a low password space as shown in Table II. There are different strategies that can be applied to user-chosen recognition textual passwords to enhance the usability and security level by applying a hybrid system that combines user-chosen recognition textual passwords with recall techniques or using cued recall strategies.

Super-Resolution of Brain MRI via U-Net Architecture

Aryan Kalluvila

Athinoula Martinos Center, Harvard Medical School, Charleston, MA, Hartford Union High School, Hartford, WI

Abstract—This paper proposes a U-Net-based deep learning architecture for the task of super-resolution of lower resolution brain magnetic resonance images (MRI). The proposed system, called MRI-Net, is designed to learn the mapping between low-resolution and high-resolution MRI images. The system is trained using 50-800 2D MRI scans, depending on the architecture, and is evaluated using peak signal-to-noise ratio (PSNR) metrics on 10 randomly selected images. The proposed U-Net architecture outperforms current state-of-the-art networks in terms of PSNR when evaluated with a 3 x 3 resolution downsampling index. The system's ability to super-resolve MRI scans has the potential to enable physicians to detect pathologies better and perform a wider range of applications. The symmetrical downsampling pipeline used in this study allows for generically representing low-resolution MRI scans to highlight proof of concept for the U-Net-based approach. The system is implemented on PyTorch 1.9.0 with NVIDIA GPU processing to speed up training time. U-Net is a promising tool for medical applications in MRI, which can provide accurate and high-quality images for better diagnoses and treatment plans. The proposed approach has the potential to reduce the costs associated with high-resolution MRI scans by providing a solution for enhancing the image quality of low-resolution scans.

Keywords—MRI; U-Net; Super-Resolution; PyTorch; SRCNN; SR-GAN; Deep Learning; GPU

I. INTRODUCTION

Medical imaging has been an essential tool in the diagnosis and treatment of various diseases. Among the different types of medical imaging, magnetic resonance imaging (MRI) has been widely used because it provides detailed images of the internal structures of the body. However, the resolution of MRI images is limited by several factors, such as the hardware used and the acquisition parameters, which can affect diagnostic accuracy and make it challenging to identify subtle anatomical features.

To address this limitation, researchers have been exploring the use of super-resolution techniques to enhance the resolution of MRI images [1]. Super-resolution is a computational method that enhances the resolution of an image beyond the physical limits of the imaging hardware. The primary objective of this approach is to generate high-resolution images that can provide more detailed information about the anatomy and pathology of the imaged area.

Recent advancements in deep learning-based super-resolution techniques for MRI have shown promising results in generating high-resolution MRI images with improved details and contrast [3]. These techniques use advanced machine learning algorithms to learn the mapping between low-

resolution and high-resolution images. High-resolution MRI images are particularly important in the diagnosis and treatment of neurological disorders, where small changes in the brain's anatomy can have significant implications for patient outcomes. For example, in the diagnosis of brain tumors, high-resolution MRI images can help to accurately identify the location, size, and shape of the tumor, which is critical for surgical planning and treatment.

The use of super-resolution techniques in MRI has the potential to revolutionize the field of medical imaging, leading to significant improvements in medical diagnosis and treatment. With the increasing availability of large datasets and the progress of machine learning algorithms, there is enormous potential for further advancements in this field. However, the effectiveness of super-resolution techniques in enhancing MRI images depends on several factors, including the choice of algorithms and evaluation metrics. In this context, several deep learning-based super-resolution algorithms have been developed and tested to improve the resolution of MRI images. The choice of the appropriate algorithm depends on several factors, including the quality of the input data, the complexity of the target structures, and the available computational resources. Additionally, it is crucial to use appropriate evaluation metrics to assess the effectiveness of these algorithms in improving the resolution of MRI images.

In this paper, we aim to evaluate the effectiveness of super-resolution techniques for enhancing MRI images, with a specific focus on the U-Net algorithm. One of the strengths of our approach is the utilization of the Mean Squared Logarithmic Error (MSLE) as the main loss function, which enables accurate reconstruction of high-resolution MRI images. We compare the performance of the U-Net algorithm against four other commonly used networks in terms of generating high-quality images. To assess the quality of the enhanced images, we employ the widely accepted metric, Peak Signal-to-Noise Ratio (PSNR). Notably, our results demonstrate that the U-Net algorithm surpasses the other networks, yielding higher average PSNR values. These findings have significant implications for the diagnosis and treatment of neurological disorders, as enhanced MRI images obtained through the U-Net algorithm can provide improved insights and precision in medical imaging. The advancements showcased in this research have the potential to make a substantial impact on the field of medical imaging as a whole.

II. LITERATURE REVIEW

Super-resolution of MRI is a critical task in the medical field that involves increasing the resolution of magnetic

resonance images to improve their quality and accuracy. Many researchers have proposed various techniques to achieve super-resolution of MRI, including deep learning, image registration, and image fusion. In this literature review, we will summarize some of the recent research works on super-resolution of MRI.

Li et al. [1] proposed a critic-guided framework for super-resolution of low-resolution MRI scans. In clinical practice, vast quantities of MRI scans are routinely acquired but are of sub-optimal quality for precision medicine, computational diagnostics, and neuroimaging research. To address this limitation, the authors utilized feature-importance and self-attention methods in their model to improve interpretability. Their framework was evaluated on paired low- and high-resolution MRI scans from various manufacturers and was shown to produce qualitatively faithful results to ground-truth scans with high accuracy (PSNR = 35.39; MAE = 3.78E-3; NMSE = 4.32E-10; SSIM = 0.9852).

Ottesen et al. [2] proposed a densely connected cascading deep learning reconstruction framework to improve accelerated MRI reconstruction. The authors modified a cascading deep learning reconstruction framework by incorporating three architectural modifications, namely input-level dense connections, an improved deep learning sub-network, and long-range skip-connections. The proposed framework, called the Densely Interconnected Residual Cascading Network (DIRCN), was evaluated on the NYU fastMRI neuro dataset with an end-to-end scheme at four- and eightfold acceleration. The authors performed an ablation study where they trained five model configurations and evaluated them based on the structural similarity index measure (SSIM), normalized mean square error (NMSE), and peak signal to noise ratio (PSNR). The results showed that the proposed DIRCN with all three modifications achieved an SSIM improvement of 8% and 11%, a NMSE improvement of 14% and 23%, and a PSNR improvement of 2% and 3% for four- and eightfold acceleration, respectively.

Similarly, Qiu, Wang, and Guo [3] proposed a novel deep learning-based approach for super-resolution of MRI, which utilizes a generative adversarial network (GAN) to generate high-resolution MRI images from low-resolution images. Due to limitations in hardware, scan time, and throughput, obtaining high-quality MR images can be a challenging task in clinical settings. Therefore, the authors aimed to use a super-resolution approach to enhance the image quality without requiring any hardware upgrades. In that paper, they proposed an ensemble learning and deep learning framework for MR image super-resolution. To create their framework, the authors first enlarged low resolution images using five commonly used super-resolution algorithms, resulting in differentially enlarged image datasets with complementary priors. Then, they trained a generative adversarial network (GAN) with each dataset to generate super-resolution MR images. Finally, they used a convolutional neural network for ensemble learning, which synergized the outputs of the GANs to produce the final MR super-resolution images.

De Leeuw den Bouter et al. [4] highlighted the potential of low-field MRI scanners to make MRI technology more accessible globally due to their significantly lower cost

compared to high-field counterparts. However, images acquired using low-field MRI scanners tend to be of relatively low resolution, which limits their clinical utility. To address this limitation, the authors presented a deep learning-based approach to transform low-resolution low-field MR images into high-resolution ones. They trained a convolutional neural network to carry out single image super-resolution reconstruction using pairs of noisy low-resolution images and their noise-free high-resolution counterparts obtained from the NYU fastMRI database. The trained network was subsequently applied to noisy images acquired using a low-field MRI scanner, producing sharp super-resolution images with most of the high-frequency components recovered. The authors demonstrated the potential of a deep learning-based approach to increase the resolution of low-field MR images.

Wang et al. [5] proposed a CNN-based multi-scale attention network (MAN) to improve the performance of convolutional super-resolution (SR) networks. While convolutional neural networks can compete with transformer-based methods in many high-level computer vision tasks, transformers with self-attention still dominate the low-level vision, including the super-resolution task. The authors exploit large kernel decomposition and attention mechanisms in their design. The proposed MAN consists of multi-scale large kernel attention (MLKA) and a gated spatial attention unit (GSAU). Within the MLKA, the authors rectify LKA with multi-scale and gate schemes to obtain the abundant attention map at various granularity levels. This approach jointly aggregates global and local information and avoids potential blocking artifacts. In GSAU, a gate mechanism and spatial attention are integrated to remove the unnecessary linear layer and aggregate informative spatial context. The authors evaluate MAN with multiple complexities by simply stacking different numbers of MLKA and GSAU. Experimental results illustrate that their MAN can achieve varied trade-offs between state-of-the-art performance and computations.

Bahrami et al. [6] proposed a novel method for predicting high-resolution 7T-like MR images from low-resolution 3T MR images. The predicted 7T-like MR images demonstrate higher spatial resolution compared to 3T MR images, as well as prediction results obtained using other comparison methods. The authors suggest that such high-quality 7T-like MR images could better facilitate disease diagnosis and intervention. This paper demonstrates proof of concept for reconstruction in even high-resolution MRI dynamics.

Koonjoo et al's paper introduces AUTOMAP, a deep learning method for improving image quality in low-field MRI systems [10]. AUTOMAP outperforms traditional Fourier reconstruction and two contemporary denoising algorithms, reducing noise and artifacts in the reconstructed images. It achieves substantial signal-to-noise ratio gains for both human brain and plant root data, demonstrating the potential of deep learning in enhancing image quality in low-field MRI. This approach contributes to advancing resolution and image quality in low-field MRI applications.

The U-Net architecture outperforms other techniques [9] in medical image super-resolution of brain MRI due to its dedicated design for image segmentation tasks and effective

feature extraction. Its skip connections enable the preservation and utilization of both high-level and low-level features, resulting in enhanced resolution. Unlike other architectures, such as the SRCNN, GAN-based approaches, or multi-scale attention networks, the U-Net consistently achieves superior resolution improvement. Its ability to capture fine details and preserve structural information makes it the preferred choice for medical image super-resolution tasks.

III. METHODOLOGY

A. Downsampling Pipeline

In order to accurately simulate the low-resolution scans typically obtained from lower field strength MRI scanners, we employed a symmetrical down sampling pipeline, as depicted in Fig. 1. This pipeline involved reducing each dimension of the scanner by a factor of three, replicating the effects of decreased resolution. By implementing this downsampling technique, we were able to mimic the conditions of low field strength and lower-quality scanners commonly associated with compromised image resolution and reduced overall image quality. To further ensure the authenticity of the simulated low-resolution scans, we applied bilinear interpolation, a widely adopted interpolation method, to generate the corrupted scans. This approach effectively captures the characteristic imperfections and limitations of lower field strength MRI scanners, providing a reliable basis for evaluating the performance and effectiveness of our super-resolution techniques in enhancing the quality and resolution of these low-resolution MRI images.

In order to enhance the computational efficiency of the U-Net architecture, we employed a technique known as residual learning. Instead of directly generating the complete high-resolution scan, our U-Net model was trained to focus on learning the difference between the high-resolution scan and the bilinear interpolated output. By utilizing this residual learning approach, the model became more adept at capturing the fine details and nuances present in the high-resolution image that may be lost during the bilinear interpolation process.

During the inference stage, the U-Net model would generate the residual, which represented the additional information needed to transform the interpolated scan into a super-resolved MRI scan. This residual was then added to the bilinear interpolated scan, resulting in the creation of a high-resolution image with enhanced details and improved quality. This approach not only improved the computational efficiency of the U-Net architecture but also ensured that the generated super-resolved MRI scan closely resembled the original high-resolution scan by effectively compensating for the limitations of the bilinear interpolation.

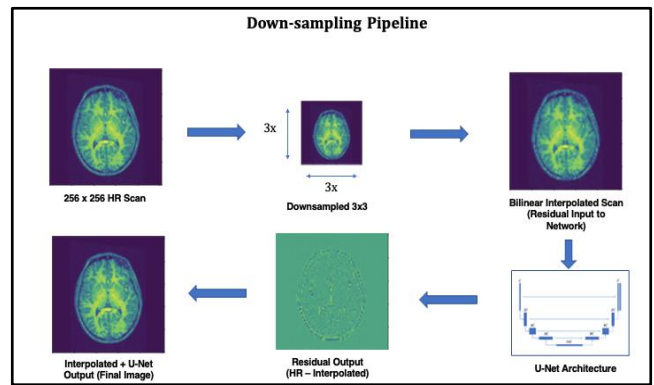

Fig. 1. Downsampling flow chart to create corrupted MRI scans.

B. U-Net Architecture

We used a U-Net architecture as denoted by Fig. 2, as the main super-resolution algorithm to improve the resolution of brain MRI. The U-Net architecture is a type of deep learning neural network that is particularly well-suited for image segmentation tasks, which involve dividing an image into multiple segments to identify specific structures or features within the image.

Fig. 2. U-Net architecture for super-resolution task [7].

The U-Net architecture is specifically designed for biomedical image analysis, making it an effective choice for super-resolution of brain MRI. The architecture consists of an encoder, which gradually reduces the resolution of the input image, and a decoder, which gradually increases the resolution of the image to produce the final high-resolution output. The encoder and decoder are connected by a bottleneck layer that contains information about the original image, allowing for precise reconstruction of the high-resolution output.

Compared to other deep learning architectures, such as fully convolutional networks (FCNs) or residual networks (ResNets), U-Net has several advantages for super-resolution of brain MRI. First, the U-Net architecture allows for the preservation of fine details, which is important for identifying subtle anatomical features in MRI images. Second, U-Net is less prone to overfitting, a common problem in deep learning models, as it contains skip connections that enable the model to learn from features at multiple scales. Finally, U-Net is computationally efficient, allowing for faster training and inference times compared to other architectures.

C. Evaluation Metrics

When evaluating the performance of image super-resolution techniques for MRI, several metrics are commonly used, including Peak Signal-to-Noise Ratio (PSNR) and Structural Similarity Index (SSIM). While both metrics are useful for evaluating image quality, PSNR is generally considered to be more important than SSIM in the context of super-resolution for MRI. PSNR is a widely used metric that measures the quality of an image by calculating the ratio of the peak signal power to the mean squared error of the image. Higher PSNR values indicate better image quality, with a perfect image having a PSNR of infinity. In the context of MRI super-resolution, PSNR is important because it reflects the ability of the super-resolution technique to accurately reconstruct high-frequency details in the image. This is particularly important in MRI, where small details can have significant clinical implications.

SSIM, on the other hand, is a metric that measures the structural similarity between two images. Specifically, SSIM calculates the similarity of the luminance, contrast, and structure of the images being compared. While SSIM is useful for evaluating overall image similarity, it is less sensitive to high-frequency details, which are important in the context of super-resolution for MRI. Therefore, while SSIM can provide useful information about the overall similarity of two images, it may not be as effective at evaluating the ability of a super-resolution technique to accurately reconstruct high-frequency details.

In our paper, we include only PSNR as a metric for evaluating the performance of our super-resolution technique for brain MRI. However, we primarily focused on the PSNR results as this metric provides a more accurate reflection of the ability of the technique to accurately reconstruct high-frequency details. Our results showed that the use of our super-resolution technique significantly improved the PSNR values compared to the baseline low-resolution images, indicating that our technique was effective at accurately reconstructing high-frequency details.

$$PSNR = 10 \log \frac{255^2}{MSE}$$

D. Loss Function Determination

In our paper, we sought to explore the use of different loss functions to optimize the performance of our super-resolution technique for MRI. While Mean Squared Error (MSE) is a commonly used loss function for image super-resolution, we found that it underperformed during the training process for our specific application. As a result, we decided to experiment with different loss functions to identify the most effective option.

After extensive experimentation, we found that Mean Squared Logarithmic Error (MSLE) performed significantly better than MSE in terms of producing higher resolution metrics. MSLE is particularly useful for image super-resolution applications as it is less sensitive to outliers, which can be a common issue in medical imaging data. MSLE also places a higher weight on errors for lower pixel values, which is

important in the context of MRI super-resolution as lower pixel values typically correspond to high-frequency details.

As a result of our experimentation, we established MSLE as the baseline loss function for our super-resolution technique and used it to test all of the networks. This allowed us to accurately compare the performance of different network architectures and identify the most effective approach for our specific application. By using MSLE as our main loss function, we were able to achieve significant improvements in image resolution and quality, ultimately leading to a more effective super-resolution technique for MRI [8].

$$MSLE = \frac{1}{n} \log(\sum Y_i - Y_j)^2$$

E. Technology and Datasets

In order to ensure that our network is well-equipped to handle a wide range of imaging scenarios, we utilized a large dataset of 50-800 3D MRI scans (depending on the architecture). All of these images came from the ABIDE dataset. These scans were carefully selected to include a variety of imaging parameters, such as field strength, contrast, and resolution, in order to ensure that our network is trained to handle the full range of imaging scenarios that it may encounter in clinical practice.

Each of the 3D scans in our dataset contained 256 slices, from which we selected the 128th slice to train our model. This approach was chosen to ensure that we have a sufficient number of training examples while also avoiding any potential bias that might arise from using only a subset of the available slices. By selecting the middle slice of each 3D scan, we can be confident that our training data is representative of the full range of imaging parameters present in each scan.

To evaluate the performance of our network, we tested it on a set of 10 randomly selected images. We used the peak signal-to-noise ratio (PSNR) as our metric for evaluation. These metrics are widely used in the image processing community and are commonly used to assess the quality of reconstructed images.

All of the experimentation for this study was completed on PyTorch 1.9.0 with NVIDIA GPU processing to speed up training time. The use of GPU processing allowed us to train our network more efficiently, enabling us to complete the necessary experimentation in a timely manner. Additionally, the use of PyTorch provided a powerful and flexible framework for implementing and testing our network, allowing us to easily modify and iterate on our approach as needed.

IV. RESULTS

In our study, we utilized Fig. 3 to present the qualitative observations of our super-resolution technique based on the U-Net architecture. The U-Net algorithm is a sophisticated deep learning model that has gained widespread popularity for its high efficacy in image super-resolution tasks, particularly in the medical imaging domain. One of the key strengths of the U-Net algorithm is its ability to reconstruct fine details from low-resolution inputs, particularly in the deeper regions such as the hippocampal areas. These regions are particularly critical in

detecting neurological conditions such as Alzheimer's and Parkinson's disease.

By effectively improving the resolution of MRI images in these regions, the U-Net algorithm can enhance the accuracy and reliability of disease detection, ultimately leading to improved patient outcomes. Furthermore, our study also compared the U-Net algorithm against four other commonly used networks in terms of average Peak Signal-to-Noise Ratio (PSNR) as denoted by Table I. The results of our study demonstrate that the U-Net algorithm outperformed the other networks in terms of average PSNR. This highlights the superiority of the U-Net algorithm in producing high-quality, super-resolved MRI images, which is of paramount importance in medical diagnosis and treatment.

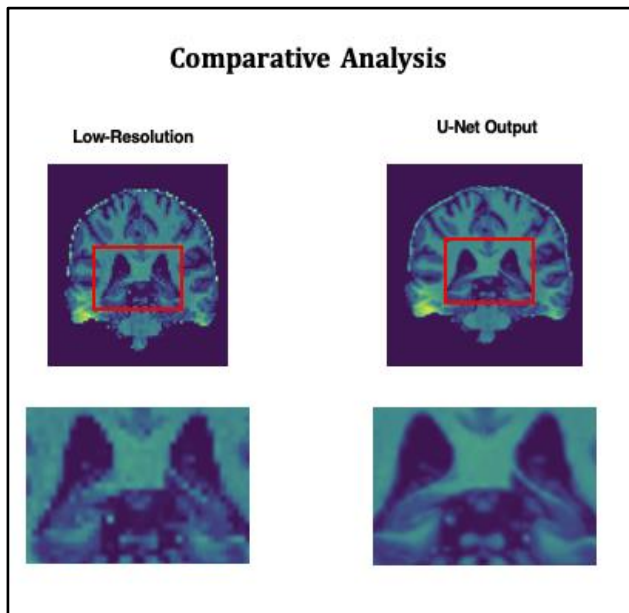

Fig. 3. Qualitative observations from low-resolution (left) to u-net output (right).

TABLE I. PSNR COMPARISON

Dataset I	PSNR
SR DenseNet	29.62458398
VDSR	29.9758636
U-Net	30.40278329
U-Net++	30.18895619
SR CNN	30.13047352

V. DISCUSSION AND CONCLUSION

Our study has delved into the potential of deep learning-based super-resolution techniques to improve the resolution of MRI images in the medical imaging domain. The results of our research are highly promising, demonstrating the effectiveness of the U-Net architecture in reconstructing fine details from low-resolution inputs, specifically in the hippocampal regions that play a crucial role in detecting neurological conditions such as Alzheimer's and Parkinson's disease. Our comparison with four other commonly used networks has highlighted the superiority of the U-Net algorithm in producing high-quality,

super-resolved MRI images. The U-Net performed with an average PSNR of 30.40, outperforming all other algorithms in terms of PSNR.

By improving the accuracy and reliability of medical diagnosis and treatment in the field of neurological disorders, our research could have a significant impact on the lives of patients and their families. However, our study is just the beginning, and there are numerous potential avenues for future research.

For example, we could explore the integration of multiple deep learning models for improved accuracy and efficiency. This could potentially lead to even more precise and comprehensive diagnosis and treatment for neurological disorders.

Another possible direction for future research is to expand the dataset used for training to encompass a broader range of neurological conditions and patient populations. This could help to improve the generalizability of our results and make our super-resolution techniques even more widely applicable in the medical imaging field.

While the U-Net architecture has demonstrated remarkable effectiveness in MRI super-resolution tasks, it is not without limitations. One notable limitation is the potential for overfitting, especially when dealing with limited or imbalanced training datasets. Due to the large number of parameters in the U-Net model, there is a risk of the model memorizing specific features from the training data rather than learning generalizable patterns. This can result in reduced performance when faced with unseen or diverse data during the testing phase. Another limitation is that our U-Net struggled to perform well with regards to the SSIM metric, underperforming current state of the art. Modifying loss function optimized to SSIM could potentially fix this issue.

Additionally, the U-Net architecture may struggle to capture long-range dependencies and complex spatial relationships within the MRI images, which could impact the accurate reconstruction of fine details. Moreover, the U-Net's performance may vary depending on the specific MRI imaging modality or imaging protocols, making it less universally applicable across different types of MRI scans. Addressing these limitations through appropriate regularization techniques, larger and more diverse training datasets, and exploration of alternative architectures could further enhance the performance and generalizability of the U-Net in MRI super-resolution tasks.

Moreover, we could investigate the potential of combining super-resolution techniques with other image processing techniques such as image segmentation and registration. By integrating these techniques, we could potentially achieve even more precise and comprehensive diagnosis and treatment for neurological disorders.

In summary, our study highlights the significant potential of deep learning-based super-resolution techniques for medical imaging, particularly in the detection and treatment of neurological disorders. By enhancing the resolution of MRI images, our research can contribute towards improving patient outcomes and ultimately lead to a better quality of life for

individuals suffering from these conditions. The outcomes of our research could pave the way for further advancements in the field, leading to even more accurate and efficient diagnosis and treatment in the future.

VI. ACKNOWLEDGMENT

I am grateful for the tremendous support and guidance provided by Dr. Matthew Rosen, an associate professor and low-field MRI media director at Harvard Medical School, who introduced me to this fascinating topic and generously shared his computational resources with me. His mentorship and expertise were invaluable to the success of my research. Additionally, I would like to extend my appreciation to Dr. Sean Young, whose support and encouragement were instrumental in my research journey. Their contributions have been instrumental in shaping my research and have inspired me to pursue my academic and professional goals with passion and dedication.

Abstract—One of the main functions of NLP (Natural Language Processing) is to analyze a sentiment or opinion of the text considered. In this research the objective is to analyze the sentiment in the form of tweets towards the Covid-19 vaccination. In this study, the collected tweets are in the form of a dataset from Kaggle that have been categorized into positive and negative depending on the polarity of the sentiment in that tweet, to visualize the overall situation. The reviews are translated into vector representations using various techniques, including Bag-Of-Words and TF-IDF to ensure the best result. Machine learning algorithms like Logistic Regression, Naïve Bayes, Support Vector Machine (SVM) and others, and Deep Learning algorithms like LSTM and Bert were used to train the predictive models. The performance metrics used to test the performance of the models show that Support Vector Machine (SVM) achieved the highest accuracy of 88.7989% among the machine learning models. Compared to the related research papers the highest accuracy obtained using LSTM is 90.59 % and our model has predicted with the highest accuracy of 90.42% using BERT techniques.

Keywords—Covid-19 vaccine; sentiment analysis; machine learning; deep learning; natural language processing

I. INTRODUCTION

In the wake of COVID-19, the healthcare sector has received considerable attention. Safety regulations such as wearing masks, keeping a good hygiene by washing hands regularly, and maintaining a safe distance from people are especially important now. Nevertheless, these measures can only decrease the spread of the virus, not eliminate it. In this case, vaccination proved to be the sole solution that had the greatest effectiveness in eradicating the coronavirus. But from the very beginning, the acceptance and public sentiment surrounding the COVID-19 vaccine have been subject to varying opinions and concerns. People have had mixed feelings

about vaccinations; we have even seen the reluctance of our own family members towards it. Since it is very new to the market, people are not ready to trust the invention and are hesitant about it. This hesitancy and skepticism have highlighted the need to delve deeper into understanding the sentiments of individuals towards the vaccine.

Nowadays, the Internet is the best source for any company to learn about public perceptions of their products and services. For its rich knowledge, the business community is tapping into social media content. It has been utilized to carry out marketing and branding initiatives for organizations in the areas of innovation, product design, and stakeholder relations. It is a useful means of communicating and sharing information with the public for government and non-profit organizations. Every day, people use social media platforms such as Facebook, Twitter, and Instagram to voice their opinions and thoughts. These platforms have emerged as powerful sources for expressing opinions and thoughts, making them ideal for capturing and analyzing public sentiments. People began voicing their concerns on the COVID-19 vaccination process as soon as it began. And since COVID 19 has affected so many lives but the vaccine showed up as a ray of hope amidst these extreme conditions, it has been extremely important to analyze the sentiments of people towards the COVID-19 vaccine [1].

Sentiment analysis is one major task of NLP (Natural Language Processing). It is also called Opinion mining. It is done to capture the author's feelings, emotion towards an entity. Sentiment analysis tries to capture this information by analyzing unstructured text data in the form of reviews and comments [2]. By harnessing the potential of sentiment analysis, the aim is to gain valuable insights into the perceptions and emotions of individuals regarding the COVID-19 vaccine. Sentiment analysis particularly is helpful when it comes to negative reviews. It helps discover the exact

shortcomings of the products. This requires the text to be classified into two sentiment polarities that are positive and negative (or neutral). In this research study, various textual and numerical features from tweets are extracted, evaluated on how they correlate, and used to predict sentiment of people related to the COVID-19 vaccine. The goal is to contribute to the existing knowledge on sentiment analysis and its applicability in the context of COVID-19 vaccines, ultimately aiding in the development of informed strategies and interventions for public health initiatives.

Further, the paper is divided into different sections to bring out all parts of the study properly. Section II shows the works of other people on sentiment analysis related to the COVID vaccine and how people have reciprocated to it. Section III gives information about the background of this study, highlighting a contrast between machine learning and deep learning techniques. Next is Section IV that highlights a major part of the study. It starts with the analysis of the data used in the study. Then it talks the complete process followed to carry out the study- the machine learning and deep learning algorithms used, the pre-processing techniques and feature extraction methods for both the type of algorithms, the performance metrics used to analyze the result of the model and lastly a comparison between the way machine learning and deep learning algorithms work [3][4][5][6]. Section V gives a deep analysis of the results obtained on the data with machine learning and deep learning techniques. It shows the results for all the five machine learning algorithms used with different feature extraction methods and then bar plots comparing their accuracy. Then, it shows the results for the two deep learning models used and their plots for accuracy and loss. Section VI highlights the conclusions and key takeaways from the study, along with the discussion of future plans and scope.

II. LITERATURE REVIEW

Sentiment analysis is being used in a large spectrum of fields right now. And a lot of people are increasingly interested in researching it. In the past year there have been much research on the sentiment of people towards the COVID-19 vaccine that came into existence. One such research employing tweets collected between December 21 and July 2, 2021, had information on the most prevalent vaccines that had just become available around the world. It used a tool called VADER to analyze people's sentiment towards certain vaccines. The tool found that 33.96% responses were positive, 17.55% were negative and the left 48.49% were neutral responses. It applied the basic data preprocessing steps and feature extraction algorithms on the tweets in the dataset. Then it finally used a recurrent neural network (RNN) that included LSTM and Bi-LSTM where LSTM secured an accuracy of 90.59% and Bi-LSTM obtained an accuracy of 90.83%. This study contributes to a better knowledge of public opinion on COVID-19 vaccinations and advances the goal of removing the virus worldwide [7]. Another such study used tweets in general and then only from four countries with the most tweets on the COVID-19 vaccine: India, USA, Canada, and England. It consumed two text mining methods that are LDA and VADER to extract the sentiment from those tweets. The overall analysis showed that there were almost twice people that had a positive feeling towards the COVID vaccine than those having a

negative feeling. However, the country-specific analysis showed that the people's sentiment remained consistent for the vaccines that were approved in their country, while most people had some fear towards other vaccines [8]. Another research performing sentiment analysis had tweets that were taken from the 14th to the 18th of January 2021. Covishield and Bharat Biotech's Covaxin were two vaccines employed in this work. The purpose of this study was to examine the sentiments expressed in tweets about these two vaccines in India. It used the Syuzhet package version 1.0.1 to classify tweets based on sentiments into positive and negative as well as eight other emotions (fear, joy, anticipation, anger, disgust, sadness, surprise, trust). It used the NRC Emotion Lexicon to analyze the tweets. The study showed that while most of the population has positive feelings about these vaccines, there are also negative feelings about them, according to the analysis, associated with the sentiments such as fear and anger [9]. Another study introduces a lexicon-based framework for sentiment classification of tweets, categorizing them as positive, negative, or neutral. The results indicate that the proposed system surpasses existing systems in terms of performance and accuracy [10].

This research makes use of a dataset containing tweets about the opinion of people about vaccines like Pfizer/BioNTech, Sinopharm, etc. in the Kaggle data repository. Tweepy, a Python package, was used to capture the data. It synthesizes the dialogue surrounding worldwide immunization attempts and progress using an API called TextBlob and using word cloud visualizations. TextBlob classified roughly half of the tweets in the dataset as neutral, and the other half comprised of 75% positive tweets and 25% tweets depicting a negative sentiment [11]. This study used web scrapping to extract the data from online news and blogs to work on. TextBlob library was used to analyze the sentiments of the public opinion collected. They gave a result that more than 90% of the articles had positive sentiments towards the vaccination drive [12]. From thirteen Reddit communities, data was collected regarding COVID-19 vaccines. LDA topic modelling was done on this data, and it was found that most of the communities had a positive sentiment towards the drive and found no major change in the opinions of people since December 2020 [13]. A RapidMiner software for data science was used for classifying English and Filipino tweets with the help of Naïve Bayes to conduct opinion mining. The results showed that the research had an accuracy of 81.77%. Their conclusion was that majority of people were enthusiastic and supportive of the vaccination drive [14]. This study takes about 1.2 million tweets to perform NLP and sentiment analysis on them to find out useful insights about the approach of people towards the COVID-19 vaccine and the measures to stay safe from the virus. This research used TextBlob and Vader as sentiment analysis tools and performed time series forecasting at a later stage. The result showed that many people have a positive view of the vaccination drive than negative. But more than that, people were highly conscious about maintaining hygiene and social distancing to combat the spread of the virus [15].

A study that was conducted in Indonesia was focused on analyzing the opinion of Indonesian people towards the newly

introduced vaccine. It collected the data from twitter using Rapid miner tool. The results of this study were slightly different. They showed about 39% of positive sentiment and 56% of negative sentiment and 1% of neutral sentiment. The people did not really trust that the vaccine was safe for them to consume [16]. Following this one, another study was conducted to evaluate the opinion of people of Indonesia about the two most prevalent vaccines, Sinovac and Pfizer in the country and understand people's view on both. The best performing model came out to be Support Vector machine and the study concluded that people were more positive for the Pfizer vaccine as compared to Sinovac. While about 77% of the tweets indicated a positive sentiment towards Sinovac, this number shot up to 81% in the case of Pfizer vaccine [17].

In contrast to a country-specific approach, some studies were conducted to analyze the sentiments of people towards the vaccine on a global level, for different countries. This study collected about 820,000 tweets and analyzed the sentiment of those tweets in two stages. In the first stage, the sentiments of people towards the vaccine around the globe was considered and the findings showed which countries had an overall positive attitude and which countries had a negative one. This stage also included gender-based analysis about the sentiments of people to address those issues in a different way. The second phase included the tweets to be organized into word clouds to analyze the most used words and sentiments by people of different countries [18]. This study made use of 928,402 tweets collected from different countries and the six most popular vaccines' tweets were picked from them to perform the analysis. They conducted an aspect-based analysis considering health, policy etc. and used four Bert models. The total accuracy was found out to be 87% and the F1 score lied between 84% to 88% [19]. This study used two different approaches to understand people's hesitancy towards the vaccine. These were machine learning based and lexicon based. It divided the dataset into two cultures English and Arabic and studied them separately. The study analyzed the performance of both the approaches on the datasets and then used the better performing approach for the spatiotemporal analysis [20]. This research collected the English language tweets posted over a course of 3 months and applied the Vader tool to classify the tweets as positive, negative, and neutral. The results revealed that out of the 2,678,372 tweets in consideration, 42.8% were positive, 26.9% were neutral and 30.3% were negative. The important topics from the positive and negative tweets were drawn out using latent Dirichlet allocation analysis, and these topics were then subjected to a geographical and temporal analysis. The study concluded that the highest positive sentiment tweets came from United Arab Emirates and the lowest positive sentiment tweets came from Brazil. Also, the sentiment score increased a good amount at the start, then slowly decreased and finally remained almost the same till the end of the period of the tweets [21].

The works discussed above indicate that previous studies have focused on sentiment analysis using various techniques and datasets. Furthermore, these studies highlight the use of various machine learning and deep learning models for sentiment classification but do not delve deep into comparative studies that evaluate the performance of different models,

feature extraction techniques, and sentiment analysis tools to identify the most effective approaches for sentiment analysis in the context of COVID-19 vaccination. This study employs a comprehensive range of techniques and models, including both machine learning algorithms (Logistic Regression, Naïve Bayes, Support Vector Machine) and deep learning algorithms (LSTM and BERT). It compares the performance of different feature extraction techniques, namely Bag of Words and TF-IDF, to showcase their impact on sentiment analysis accuracy. By utilizing these diverse approaches, it provides a better understanding of the most effective feature extraction methods and evaluation of the performance of different models, highlighting the strengths and weaknesses of each in the context of COVID-19 vaccination sentiment analysis.

III. BACKGROUND

Machine learning and Deep learning both fall under the umbrella of Artificial Intelligence, but they are more efficient in serving different purposes. Deep learning involves the use of something called a neural network which replicates how a human brain works to solve complex problems. But it requires a large amount of data to function with great accuracy, unlike machine learning which can work on lesser amounts of data. Machine learning learns from the data that is provided and makes intelligent predictions on the new data that is fed to it, with some human intervention. Both machine learning and deep learning models have been used on this dataset, but Deep learning has been preferred since the results it gave had better accuracy. Both machine learning and deep learning have a slight difference in how it classifies the data into sentiments.

For machine learning algorithms, firstly input data is fed into the system and pre-processing is performed on it to make it easier for the classification algorithm to classify it. Pre-processing includes converting the whole text into upper or lowercase, removal of extra words such as special characters or words that add no sentiment to the sentence. Then feature extraction is performed onto this data that extracts the important features from the tweet and converts it into vectors for the algorithm to be able to process it. This makes it easier for classification and improves the accuracy of the model in consideration. The next step is the model training which is when the model is trained onto the given data to classify the sentiment of the tweets and then it is tested using the test dataset to give the output or the sentiment of the tweets fed to the model. Here, the sentiment of the tweets can be positive or negative [22].

For deep learning algorithms, the process is slightly different. The input data goes through pre-processing to remove the extra words from the tweets and then it is fed to the deep learning algorithm which takes care of both the feature extraction and model training phase for classifying the sentiment of the data provided. Further the model is tested to check its performance on a test dataset, like how the machine learning algorithms do it [23].

Deep learning solves the problem end-to end whereas machine learning first fragments the problem into smaller statements and then solves it incrementally. In machine learning the data is undergone through feature extraction first and then classification is performed but in deep learning,

feature extraction and classification are performed simultaneously [24]. Deep learning works adequately on large amounts of data by giving higher accuracies. High end systems are required to run deep learning algorithms as it mainly focuses on GPU of the system. Whereas a domain expert is required in Machine learning to spot and reduce the complexity of the data for the traditional algorithms to work. When the amount of data which is fed to the model is less, machine learning performs better than the deep learning models. But as the amount of data increases, the rate with which the performance of a machine learning model was increasing rapidly falls and remains almost the same with further increase in the amount of data. However, for a deep learning model the performance steadily increases with the increase in the amount of data fed to the model. For larger amounts of data, deep learning models perform a lot better than machine learning models. There are two deep learning models used in this study: BERT and LSTM. Both are discussed in detail in the following section.

A. BERT

Bidirectional Encoder Representations from Transformers also known as BERT is a deep learning model which was published by researchers at Google in 2018. It works on the encoder-decoder network where self-attention is used on the encoder side and attention is used on the decoder side. Large text corpus is used to train the Bert model, this gives the model the ability to understand better and grasp variability in data patterns on several NLP tasks. Being bidirectional it gives the model the freedom to learn and understand the context of a word from both the left and the right sides while training the model. This nature of the model helps it to understand the language deeply. Also, for the model to work well, some amount of pre-processing is done on the data. This makes the BERT model suitable for a variety of NLP tasks.

B. LSTM

LSTM also known as Long Short-Term Memory network are a part of a unique kind of RNN that has the potential to learn long-term dependencies. LSTM can remember information for long periods of time without any struggle and reduces the impact of short-term memory. Recurrent neural networks have chain type structure where each module is intertwined several times. LSTMs have a similar structure but instead of caring a single neural network there are four that are connected to each other in a unique way. LSTM networks retain the relevant information from the prior data in the sequence that helps in processing the incoming data points. There are three things that are important to determine the output of LSTM: the cell state, the previous hidden layer, and the input data at the current timestamp. The cell state is like the memory of the network. An LSTM cell has three gates: One is the forget gate, which allows it to forget the irrelevant information from the prior timestamp. The equation for the forget gate is:

$$f_t = \sigma(x_t * U_f + H_{t-1} * W_f) \quad (1)$$

Here, x_t is the input to the current timestamp, U_f is the weight, H_{t-1} is the hidden state of previous timestamp and W_f is the weight matrix of the hidden state.

Next is the input gate, which decides which information must be kept from the current timestamp. The equation for the input gate is:

$$i_t = \sigma(x_t * U_i + H_{t-1} * W_i) \quad (2)$$

Here, x_t is the input to the current timestamp, U_i is the weight matrix of input, H_{t-1} is the hidden state of previous timestamp and W_i is the weight matrix of input corresponding with hidden state.

The last one is the output gate, which determines what the hidden state will be for the next timestamp. The equation for the input gate is:

$$o_t = \sigma(x_t * U_o + H_{t-1} * W_o) \quad (3)$$

Here, x_t is the input to the current timestamp, U_o is the weight matrix of output, H_{t-1} is the hidden state of previous timestamp and W_o is the weight matrix of output corresponding with hidden state [25][26].

IV. METHODOLOGY

A. Data Collection and Analysis

In the initial stages of the research, a dataset comprising 10,000 tweets regarding people's opinions on the COVID-19 vaccine was sourced from Kaggle. However, it was observed that a significant portion of the dataset consisted of neutral tweets. Recognizing the potential impact of these neutral tweets on the data consistency and the subsequent model performance, a decision was made to remove them from the dataset. This cleaning process resulted in a refined dataset of approximately 3,700 tweets. Out of the total tweets, approximately 2,000 exhibited a positive sentiment towards the COVID-19 vaccine, while around 1,700 displayed a negative sentiment. This balanced distribution of positive and negative sentiments provides a suitable foundation for training and evaluating machine learning models.

B. Data Cleaning and Preprocessing

To start with, data pre-processing steps were applied to the given dataset to ensure the data's quality and consistency. These pre-processing steps are crucial in preparing the dataset for accurate model training and reliable outcomes. The dataset was thoroughly cleaned by removing any extraneous data or unnecessary elements that could introduce irregularities. This involved eliminating punctuation, symbols like "#," and Twitter handles such as "@user." Further, this involved removing URLs from the tweet texts, converting the text to lowercase to eliminate case sensitivity, and applying tokenization to break down the text into individual words or tokens. Stopwords, which are commonly used words in a language like "the", "and", "is", were removed from the text. These words are often irrelevant for sentiment analysis and can introduce noise into the data. After that an important step was lemmatization. This was applied to reduce words to their base or root form. This helps in standardizing the text data by converting variations of a word. These pre-processing steps were implemented to ensure the dataset's consistency and to avoid poor model training and inaccurate outcome due to inconsistencies in the dataset [27]. After applying data pre-processing techniques to enhance the quality of the dataset, the

next step involved splitting the dataset into two distinct parts: a training dataset and a testing dataset. The dataset was split in a ratio of 80:20, with 80% of the tweets allocated to the training dataset and the remaining 20% reserved for the testing dataset. This ensures that a substantial portion of the data is utilized for training the model while still leaving a sizable portion for evaluation.

C. Feature Extraction and Model Training

When it comes to the machine learning models, the tweets in the training set undergo a process of vector representation using techniques like Bag of Words and TF-IDF. These techniques filter out irrelevant words and convert the tweets into numerical representations. By utilizing these vectorized representations, the classification algorithms are trained and tested on the given dataset. The results obtained from the testing dataset provide insights into the performance of these models in analyzing the sentiments [28]. The next step involves the classification of the data. In this process, several machine learning algorithms are utilized to train classifiers that can accurately predict the sentiment of the tweets. The following algorithms are applied to the training dataset: Support Vector Machine (SVM), Naïve Bayes, Logistic Regression, Decision Tree Classifier, and Random Forest Classifier. Each algorithm learns from the training data, capturing patterns and relationships between the tweet features and their corresponding sentiments. Once the classifiers are trained, they are evaluated using the testing dataset. By comparing the predicted sentiments with the actual sentiments of the tweets in the testing dataset, various performance metrics such as accuracy, precision, recall, and F1-score are calculated. Finally, the ROC AUC score for each model is compared. It is used to assess the degree of separability between the different classes. A higher ROC AUC score indicates that the model performs well in terms of classification [29]. Thus, these metrics provide insights into how well each classifier can perform in classifying the sentiments of the COVID-19 vaccine-related tweets.

On the other hand, the process for deep learning models differs slightly. In this case, the pre-processed data is directly fed into the deep learning algorithm. The deep learning algorithm itself takes care of both the feature extraction and model training phases. This feature extraction process is performed by the hidden layers of the neural network. It automatically learns and extracts relevant features from the data during the training process, eliminating the need for explicit feature extraction. Deep learning models consist of multiple layers of interconnected artificial neurons. Each neuron receives input signals, applies a mathematical operation, and produces an output signal. The outputs from one layer serve as inputs to the next layer, forming a hierarchical representation of the data. Once the model is trained, it can be tested on a separate test dataset, like how the machine learning algorithms are evaluated. The performance of the deep learning model on the test dataset helps analyze its effectiveness in sentiment classification.

V. RESULTS

The results for the machine learning and deep learning models have been separately illustrated. Deep learning models

perform better than the machine learning models with a maximum accuracy of 90.42%.

A. Machine Learning Models

The results of the proposed models: Support Vector Machine (SVM), Logistic Regression (LR), Naive Bayes (NB), Decision Tree and Random Forest are shown in this section. Different assessment criteria, including Accuracy, Precision, Recall, F-score, Confusion matrix, and ROC curve, were utilized to evaluate the models reviewed here. First, the results for each model using Bag of Words feature extraction algorithm are shown and then using TF-IDF feature extraction techniques are shown. Then, using a unique feature extraction technique that works well, the comparison between the results for each classification model is displayed.

B. Support Vector Machine

Support vector machine model is used for classification, and this algorithm works on the concept of finding a hyperplane that provides the best separability between different classes.

Support Vector Machine model with Bag of Words analyzed and registered 274 positive tweets correctly, 74 positive tweets incorrectly, 362 negative tweets correctly and 31 negative tweets incorrectly as per the confusion matrix. Based on this, Table I shows the major classification metrics precision, recall and f1-score for both the classes individually. Here, 1 is for the positive tweets and 0 is for the negative ones. For the positives, the precision score is 0.83, the f1-score is 0.87 and the recall is 0.92. For the negatives, the precision score is 0.90, the f1-score is 0.84 and the recall is 0.79. The total accuracy of the model comes out to be 0.86.

TABLE I. RESULT OF SUPPORT VECTOR MACHINE USING BAG OF WORDS

	precision	recall	f1-score	support
0	0.90	0.79	0.84	348
1	0.83	0.92	0.87	393
accuracy			0.86	741

Support Vector Machine with TFIDF analyzed and registered 307 positive tweets correctly, 41 positive tweets incorrectly, 351 negative tweets correctly and 42 negative tweets incorrectly as per the confusion matrix. Based on this, Table II shows the major classification metrics precision, recall and f1-score for both the classes individually. Here, 1 is for the positive tweets and 0 is for the negative ones. For the positives, the precision score is 0.90, the f1-score is 0.89 and the recall is 0.89. For the negatives, the precision score is 0.88, the f1-score is 0.88 and the recall is 0.88. The total accuracy of the model comes out to be 0.89.

TABLE II. RESULT OF SUPPORT VECTOR MACHINE USING TF-IDF

	precision	recall	f1-score	support
0	0.88	0.88	0.88	348
1	0.90	0.89	0.89	393
accuracy			0.89	741

C. Naïve Bayes

Naïve Bayes classifier is based on probability. It assumes that each variable input to the classifier is independent but gives good accuracy when applied. It uses conditional probability for obtaining the result. Conditional probability is basically calculating the probability of completing a certain task given a certain condition must always be satisfied.

Naïve Bayes Model with Bag of Words analyzed and registered 281 positive tweets correctly, 67 positive tweets incorrectly, 355 negative tweets correctly and 38 negative tweets incorrectly in the confusion matrix. Based on this, Table III shows the major classification metrics precision, recall and f1-score for both the classes individually. Here, 1 is for the positive tweets and 0 is for the negative ones. For the positives, the precision score is 0.84, the f1-score is 0.87 and the recall is 0.90. For the negatives, the precision score is 0.88, the f1-score is 0.84 and the recall is 0.81. The total accuracy of the model comes out to be 0.86.

TABLE III. RESULT OF NAIVE BAYES USING BAG OF WORDS

	precision	recall	f1-score	support
0	0.88	0.81	0.84	348
1	0.84	0.90	0.87	393
accuracy			0.86	741

Naïve bayes with TFIDF analyzed and registered 271 positive tweets correctly, 77 positive tweets incorrectly, 371 negative tweets correctly and 22 negative tweets incorrectly in the confusion matrix. Based on this, Table IV shows the major classification metrics precision, recall and f1-score for both the classes individually. Here, 1 is for the positive tweets and 0 is for the negative ones. For the positives, the precision score is 0.83, the f1-score is 0.85 and the recall is 0.78. For the negatives, the precision score is 0.83, the f1-score is 0.88 and the recall is 0.94. The total accuracy of the model comes out to be 0.87.

TABLE IV. RESULT OF NAIVE BAYES USING TF-IDF

	precision	recall	f1-score	support
0	0.92	0.78	0.85	348
1	0.83	0.94	0.88	393
accuracy			0.87	741

D. Logistic Regression

Decision tree classifier is used for classification and regression. It forms a tree-like structure and learns simple decision rules to predict the target class value.

Logistic Regression with Bag of Words analyzed and registered 287 positive tweets correctly, 61 positive tweets incorrectly, 358 negative tweets correctly and 35 negative tweets incorrectly in the confusion matrix. Based on this, Table V shows the major classification metrics precision, recall and f1-score for both the classes individually. Here, 1 is for the positive tweets and 0 is for the negative ones. For the positives, the precision score is 0.85, the f1-score is 0.88 and the recall is 0.91. For the negatives, the precision score is 0.89, the f1-score

is 0.86 and the recall is 0.82. The total accuracy of the model comes out to be 0.87.

TABLE V. RESULT OF LOGISTIC REGRESSION USING BAG OF WORDS

	precision	recall	f1-score	support
0	0.89	0.82	0.86	348
1	0.85	0.91	0.88	393
accuracy			0.87	741

Logistic Regression with TFIDF analyzed and registered 295 positive tweets correctly, 53 positive tweets incorrectly, 350 negative tweets correctly and 43 negative tweets incorrectly in the confusion matrix. Based on this, Table VI shows the major classification metrics precision, recall and f1-score for both the classes individually. Here, 1 is for the positive tweets and 0 is for the negative ones. For the positives, the precision score is 0.87, the f1-score is 0.88 and the recall is 0.89. For the negatives, the precision score is 0.87, the f1-score is 0.86 and the recall is 0.85. The total accuracy of the model comes out to be 0.87.

TABLE VI. RESULT OF LOGISTIC REGRESSION USING TF-IDF

	precision	recall	f1-score	support
0	0.87	0.85	0.86	348
1	0.87	0.89	0.88	393
accuracy			0.87	741

E. Decision Tree Classifier

Decision tree classifier is used for classification and regression. It forms a tree-like structure and learns simple decision rules to predict the target class value.

Decision Tree Classifier analyzed and registered 257 positive tweets correctly, 91 positive tweets incorrectly, 347 negative tweets correctly and 46 negative tweets incorrectly in the confusion matrix. Based on this, Table VII shows the major classification metrics precision, recall and f1-score for both the classes individually. Here, 1 is for the positive tweets and 0 is for the negative ones. For the positives, the precision score is 0.79, the f1-score is 0.84 and the recall is 0.88. For the negatives, the precision score is 0.85, the f1-score is 0.79 and the recall is 0.74. The total accuracy of the model comes out to be 0.82.

On plotting its confusion matrix, Decision Tree classifier with TFIDF analyzed and registered 259 positive tweets correctly, 69 positive tweets incorrectly, 322 negative tweets correctly and 72 negative tweets incorrectly in the confusion matrix. Based on this, Table VIII shows the major classification metrics precision, recall and f1-score for both the classes individually. Here, 1 is for the positive tweets and 0 is for the negative ones. For the positives, the precision score is 0.78, the f1-score is 0.80 and the recall is 0.82. For the negatives, the precision score is 0.78, the f1-score is 0.76 and the recall is 0.74. The total accuracy of the model comes out to be 0.78.

TABLE VII. RESULT OF DECISION TREE USING BAG OF WORDS

	precision	recall	f1-score	support
0	0.85	0.74	0.79	348
1	0.79	0.88	0.84	393
accuracy			0.82	741

TABLE VIII. RESULT OF DECISION TREE USING TF-IDF

	precision	recall	f1-score	support
0	0.78	0.74	0.76	348
1	0.78	0.82	0.80	393
accuracy			0.78	741

F. Random Forest Classifier

Random Forest classifier uses many decision trees and finds the average of the results from these trees to obtain improved accuracy for prediction.

Table IX shows the major classification metrics precision, recall and f1-score for both the classes individually. Here, 1 is for the positive tweets and 0 is for the negative ones. For the positives, the precision score is 0.81, the f1-score is 0.86 and the recall is 0.92. For the negatives, the precision score is 0.89, the f1-score is 0.81 and the recall is 0.75. The total accuracy of the model comes out to be 0.84. On plotting its confusion matrix, the random forest model analyzed and registered 258 positive tweets correctly, 90 positive tweets incorrectly, 363 negative tweets correctly and 30 negative tweets incorrectly as shown in Table IX.

TABLE IX. RESULT OF RANDOM FOREST USING BAG OF WORDS

	precision	recall	f1-score	support
0	0.89	0.75	0.81	348
1	0.81	0.92	0.86	393
accuracy			0.84	741

Table X shows the major classification metrics precision, recall and f1-score for both the classes individually. Here, 1 is for the positive tweets and 0 is for the negative ones. For the positives, the precision score is 0.80, the f1-score is 0.87 and the recall is 0.94. For the negatives, the precision score is 0.92, the f1-score is 0.82 and the recall is 0.74. The total accuracy of the model comes out to be 0.85. On plotting its confusion matrix, the random forest classifier with TFIDF analyzed and registered 255 positive tweets correctly, 93 positive tweets incorrectly, 364 negative tweets correctly and 29 negative tweets incorrectly as shown in Table X.

TABLE X. RESULT OF RANDOM FOREST USING TF-IDF

	precision	recall	f1-score	support
0	0.92	0.74	0.82	348
1	0.80	0.94	0.87	393
accuracy			0.85	741

G. Comparing Results

The presented data in Table XI provides a comprehensive overview of the performance metrics evaluated across various

models, specifically focusing on accuracy, precision, recall, and F1-score. These metrics were meticulously analyzed using the Bag of Words technique as the chosen method for feature extraction. By examining these performance indicators, valuable insights are gained into the effectiveness and efficiency of each model in the context of the analyzed dataset.

TABLE XI. COMPARING RESULTS OF ALL THE MODELS USING BAG OF WORDS

Model	Accuracy	Precision	Recall	F1-score
SVM	0.8583	0.8733	0.8303	0.9211
Naive Bayes	0.8583	0.8712	0.8412	0.9033
Logistic Regression	0.8704	0.8818	0.8544	0.8906
Decision Tree	0.7841	0.8010	0.7834	0.8193
Random Forest	0.8556	0.8715	0.8250	0.9236

The following graph in Fig. 1 shows a comparison of accuracy score of different models with Bag of Words as the feature extraction method.

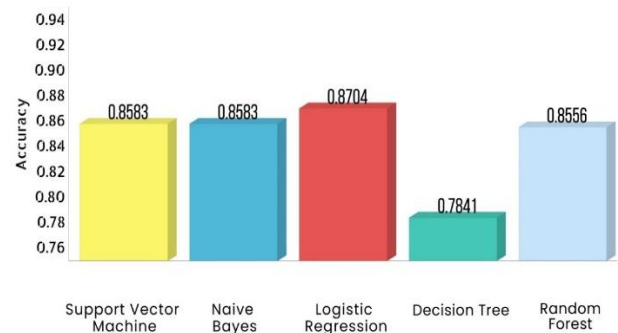

Fig. 1. Accuracy bar plot for machine learning models with bag of words as feature extraction method.

The following graph in Fig. 2 shows a comparison of ROC AUC score of different models with Bag of Words as the feature extraction method.

Fig. 2. ROC curve machine learning models with bag of words as feature extraction method.

Here, ‘RF’ is Random Forest, ‘DT’ is Decision Tree, ‘LR’ is Logistic Regression, ‘NB’ is Naïve Bayes and ‘SVM’ is Support Vector Machine.

From the ROC curve and the accuracy bar plot, it can be observed from these plots that most of the classifiers perform decently, and Logistic Regression classifier with Bag of Words feature extraction method performs the best with AUC score of 0.942 and an accuracy of 87.0445%. Close to it is the Support Vector Machine and Naive Bayes classifier with an accuracy of 85.8300%.

The presented data in Table XII provides a comprehensive overview of the performance metrics evaluated across various models that are accuracy, precision, recall, and F1-score. These metrics have been diligently analyzed for all the models, with a specific focus on the utilization of the TF-IDF technique as the chosen approach for feature extraction.

TABLE XII. COMPARING RESULTS OF ALL THE MODELS USING TF-IDF

Model	Accuracy	Precision	Recall	f1-score
SVM	0.8879	0.8943	0.8954	0.8931
Naive Bayes	0.8664	0.8823	0.8281	0.9440
Logistic Regression	0.8704	0.8794	0.8685	0.8906
Decision Tree	0.7841	0.8010	0.7834	0.8193
Random Forest	0.8367	0.8585	0.7944	0.9338

The following graph in Fig. 3 shows a comparison of accuracy scores of different models with TF-IDF as the feature extraction method.

Fig. 3. Accuracy bar plot for machine learning models with TF-IDF as feature extraction method.

The following graph in Fig. 4 shows a comparison of ROC AUC scores of different models with TF-IDF as the feature extraction method. Here, ‘RF’ is Random Forest, ‘DT’ is Decision Tree, ‘LR’ is Logistic Regression, ‘NB’ is Naïve Bayes and ‘SVM’ is Support Vector Machine.

From the ROC curve and the accuracy bar plot, it can be observed from these plots that all the classifiers perform decently, and Support Vector Machine classifier with TF-IDF feature extraction method performs the best with an AUC score of 0.95 and an accuracy of 88.7989%. Close to it is the Logistic Regression and Naive Bayes classifier with an accuracy of 87.0445% and 86.6397% respectively.

Fig. 4. ROC curve machine learning models with TF-IDF as feature extraction method.

H. Deep Learning Models

1) *BERT*: The deep learning model BERT worked efficiently with the dataset and gave a validation accuracy of 90.42%. The mode ran for three epochs where it gave an accuracy of 89.88% in first epoch, 89.20% in the second epoch and finally 90.42% in the third epoch which was the highest.

The above graph in Fig. 5 shows the relationship between loss and the learning rate. The model experienced the minimum loss when the learning rate was around 10^{-4} .

Fig. 5. A plot between learning rate and loss.

2) *LSTM*: The deep learning model LSTM worked decently with the dataset and gave a validation accuracy of 88.26. The mode ran for 5 epochs where it gave an accuracy of 70.04 in first epoch, 86.50 in the second epoch, 87.58 in the third epoch, 87.72 in the fourth and finally 88.26 in the fifth epoch which was the highest. The following graph in Fig. 6 showcases the plot between the accuracy and the number of epochs with the training and the validation set.

Fig. 6. Accuracy of LSTM model for both training and test set. Here accuracy refers to the training set accuracy and val_accuracy refers to the testing set accuracy.

Here the validation accuracy goes nearly constant after intersecting with accuracy at 0.88 whereas the accuracy plot keeps on increasing and takes over after the intersection.

The following graph in Fig. 7 showcases the plot between the loss and the number of epochs with the training and the validation set.

Fig. 7. Loss of LSTM model for both training and test set. Here loss refers to the training set loss and val_loss refers to the testing set loss.

VI. CONCLUSIONS

The aim of this study is to analyze the sentiments of people about the COVID-19 vaccine that has been introduced recently through the social media platform 'Twitter'. To be able to evaluate the opinion of the public, a dataset with the most recent tweets was taken and applied two word embedding techniques to them. Five machine learning algorithms and two deep learning algorithms have been utilized for classification of tweets into positive and negative. Experimental results suggest that out of the machine learning models used, Support vector machine when used with TF-IDF as word embedding technique gives the highest accuracy. However, deep learning models give a higher accuracy. LSTM model when used with some preprocessing gave the accuracy 88.26% after four epochs. They helped in analyzing that most people have a positive outlook for the COVID-19 vaccine, while some part of the population is still hesitant about it. The possible reasons for the same can be that people fear that the vaccine might have side effects, or they might not be open to accept a new vaccine

introduced to the market, or they are not aware enough about the consequences of not taking the COVID vaccine. Compared to the related research papers the highest accuracy obtained using LSTM is 90.59 % and our model has predicted with the highest accuracy of 90.42% using BERT techniques. This study can be of utmost importance to organizations analyzing the sentiment of a large population towards the COVID-19 vaccine in turn acting as a tool to find out ways to cope with the problem. It can help them find what section of society is hesitant and why, so that they can probably change something or improve the quality of services they provide.

However, it should be noted that this study uses only two feature extraction methods, Bag of Words and TF-IDF. Future work might consider utilizing alternative feature extraction methods such as Word2Vec and GloVe to further improve the effectiveness of the models. Another important aspect to consider can be the geographic and cultural context. While this study analyzed sentiments on a global level, further research could focus on sentiment analysis within specific regions or countries. This would allow for a better understanding of the variations in public opinion and can help identify country-specific challenges, such as vaccine hesitancy, misinformation, or unique socio-political factors that influence sentiment.

Abstract—Opinion Mining or Sentiment Analysis (SA) is a key component of E-commerce applications where a vast number of reviews are generated by customers. SA operates on aspect level where the views are expressed on a specific aspect of a product and have a big influence on the customers' choices and businesses' reputation. Aspect Based Sentiment Analysis (ABSA) is the task of categorizing text by aspect and identifying the sentiment attributed to it. Implicit Aspect Identification (IAI) is a subtask of ABSA. This paper aims to empirically investigate how external knowledge (e.g. WordNet) is integrated into SVM model to address some of its intrinsic issues when dealing with classification. To achieve this research goal, we propose an approach to improve Support Vector Machines (SVM) model to deal with IAI. Using WordNet (WN) semantic relations, we suggest an enhancement for the SVM kernel computation. Experiments are conducted on three benchmark datasets of products, laptops, and restaurant reviews. The effects of our approach are examined and analyzed according to three criteria: (i) kernel function used, (ii) different experimental settings, and (iii) SVM behavior towards Overfitting and Underfitting. The research finding of our work is that the integration of external knowledge (e.g. WordNet) is experimentally proved to be significantly helpful to SVM classification for IAI and especially for addressing Overfitting and Underfitting that are considered as two of the main structural SVM issues. The empirical results demonstrate that our approach helps SVM (i) improve its performance for the three considered kernels and under different experimental settings, and (ii) deal better with Overfitting and Underfitting.

I. INTRODUCTION

Sentiment Analysis (SA), also known as opinion mining, is a research area in the field of Natural Language Processing (NLP) [1] that aims to display emotions and automatically identify the sentiments conveyed in text. SA studies have been conducted at three granularity levels: document level [2], sentence level [3], and aspect level [4]. In Document-level Sentiment Analysis, the entire document is analyzed to determine whether it expresses a positive or negative sentiment. However, in Sentence-level Sentiment Analysis, the opinion of each sentence in the document is analyzed. In Aspect-Based Sentiment Analysis (ABSA), opinions regarding each aspect of the text's existing entities are collected.

The majority of studies are interested in aspect identification task since it is the key task in aspect-level SA. Aspects can be either implicit or explicit. Explicit aspect extraction has attracted a lot of interest, whereas implicit aspects haven't received much attention. Explicit aspects are defined as specific terms that are explicitly stated in the document, they can be expressed using a noun or noun phrase. On the other side, an implicit aspect is not explicitly stated in the text. It takes the form of an adjective, verb, or adverb as shown in [5], [6], and [7]. Implicit aspects are crucial since they can capture the emotions expressed in the text and improve the Opinion Mining Task.

In this study, we propose a method for enriching SVM model by combining its basic kernel function with similarity function inspired from Lesk algorithm [8] when applied to Word Sense Disambiguation (WSD) introduced by Weaver et al. [9]. WSD is the process of automatically assigning a meaning to the ambiguous words in a given context, as defined in [10], [11] and [12]. According to the original Lesk algorithm, a word's appropriate meaning in a particular context is one that has the maximum degree of overlap between its dictionary definition and the given context.

In this paper, we use the fundamental idea of Lesk Algorithm for WSD. However, the originality of our work is established on two different levels: (i) The idea logic: We use WordNet dictionary (WN), developed in [13], to design a similarity function between terms inspired from the Lesk algorithm. We then use this function to create a novel SVM Kernel that assigns higher weights to semantically similar words in terms of the degree of influence they have on classifying new observations. (ii) Model construction: Our similarity function amplifies the similarity score between terms

by first squaring the original score and then adding 1. This new formulation ensures significantly greater similarity scores for terms with similar semantic properties. Nevertheless, it maintains the same basic SVM Kernel value for words with different meanings.

We prepare several experiments in accordance with protocols that are intended to support the goals of our investigation. The key findings of our study are summarized as follows: (i) Our method enhances SVM's performance for the three kernels Gaussian, Anova, and Bessel, for the three considered datasets and under different experimental settings, and (ii) Our approach helps SVM perform better even when dealing with Overfitting and Underfitting which are known to be serious intrinsic issues for SVM classification.

The breakdown of the paper's structure is as follows. Related works on Aspect-based SA are discussed in the second section. Our proposed approach is described in the third section. The experimental setting is provided in section four, which is followed by a section on the results and discussion. The final section concludes this work.

II. RELATED WORKS

There are two major types of techniques used for Aspect Identification. Lexicon based approaches mainly include dictionary-based methods and corpus-based methods, where as machine learning approaches [15] and deep learning-based approaches [14] include supervised, unsupervised, or semi supervised learning methods.

Finding co-occurrence patterns of opinion words with context-specific orientation is the goal of corpus-based approaches. These techniques rely on syntactic patterns and seed opinion words to find additional opinion words and their orientation in domain corpora [16].

Dictionary-based techniques are methods that make use of WordNet or any other dictionary semantic relations. The work in [17], is an earlier dictionary-based method to identify aspects conveyed by adjectives. The authors of [18] perform an implicit aspect identification task for adjectives and verbs using definition and synonym relations extracted from WordNet. In [19], authors propose a new hybrid model for implicit aspect identification that uses semantic relations combined with a frequency-based method and supervised classifiers.

In [20] and [21], two of the most well-known co-occurrence-based approaches are presented. In [20], Schouten et al. predict implicit aspects according to the co-occurrence frequency between explicit aspects and opinion terms. Potential implicit aspects are determined based on a defined threshold value. In [21], the training data are enhanced by the use of WordNet's semantic relations and the co-occurrence score is computed for each extracted implicit aspect and its WordNet synsets. Additional co-occurrence methods are presented in [22] and [23]. The researchers Devi et al. [22] proposed a novel method to detect implicit aspects from opinionated documents using the co-occurrence of aspects with feature indicators and ranking the pair according to how frequently they co-occur. To determine how well a given candidate implicit aspect matches an opinion word, Rana et al. [23] identified implicit aspects using the co-occurrence approach and normalized Google distance.

Traditional machine learning techniques have been frequently used for ABSA. In [24], Sivakumar et al. make use of semantic relatedness between aspect term and opinion sentence to improve some machine learning algorithms for sentiment classification task. Gupta et al. [25], use an ensemble machine learning technique to perform ATE task. They combine the output of different supervised learning algorithms using a majority voting technique. Topic modeling, an unsupervised machine learning technique, has been widely applied to ACD. [26], [27], and [28] all make use of the well-known topic modeling technique Latent Dirichlet Allocation (LDA). García-Pablos et al. [26] suggest an unsupervised system called W2VLDA. To conduct ACD and sentiment classification, the system uses LDA combined with a Maximum Entropy classifier and word embedding. In [27], Poria et al. provide an original LDA technique to group aspect terms into corresponding aspect categories. To enhance the clustering process, semantic similarity between two words is used. Pathik et al. [28] suggest an unsupervised model for ACD using LDA in combination with linguistic rules. To perform ACD, Aspects are first ranked according to their probability distribution values and then clustered into predefined categories using domain knowledge with frequent terms.

Deep learning algorithms have recently begun to be used for ABSA after experiencing great success across a number of application domains. A recent work, [29], provides a hybrid method for detecting implicit aspects that combines a recurrent neural network (RNN) with a similarity function from spaCy and similarity metrics based on WordNet. The authors of [30] suggest a deep learning-based topic-level model for sentiment analysis. They performed ACD and sentiment classification using an LSTM network with a topic-level attention mechanism. Authors in [31] propose a two-step unsupervised model that combines deep learning techniques with language patterns in order to improve the ATE task. First, they extract aspects using a rule-based technique, and then they prune the pertinent aspects using fine-tuned word embedding. The extracted elements from the first phase are used as labeled data in the second phase to train the attention-based deep learning model.

There are numerous challenges and limitations for related works. Some of them conduct evaluations of their proposed models under optimal conditions without considering special situations like Overfitting and Underfitting. Others do not test their models on multiple experimental settings to figure out how they behave in different situations including non-ideal conditions. In addition to the aforementioned general shortcomings, some directly related approaches suffer from particular limitations. It is important to note that every study addresses the same problem, namely "Implicit Aspect Identification". They do, however, operate at various levels. While the techniques proposed in [18] and [19] concentrate on improving training data quality by acting at the data level which is a less challenging level, the approach proposed in [26] and our suggested method operate at the algorithmic level by suggesting modifications or additions. The works in [21], [17], [20] and [28] are hybrid methods that operate at both data level and algorithmic level. The work in [17], treats only aspects implied by adjectives without considering verbs that are very important implicit aspect indicators. In [21], the category is given to a sentence if the greatest conditional probability is greater than the corresponding trained threshold. the main

limitation of this technique is that it needs a sufficient amount of training data to work properly. The amount of training data needed to perform well presents also a limitation for the method proposed in [26] since additional text reviews are needed to compute the topic model and domain-based word embeddings. The technique proposed in [20] suffers from two limitations, the first one is the obvious need for labeled data, and the second one is selecting only one implicit feature for each sentence, since they are working on sentence-level and their datasets contain more than one implicit feature and some implicit aspects can be missed by the algorithm. A common limitation to all these directly related approaches and our technique is that they do not address broad aspects which are often omitted, like the “anecdotes/miscellaneous” aspect on the Restaurant dataset [34]. Unlike [20], [21], and [26], our technique doesn’t require a huge amount of training data to work properly.

Our research concentrates on implicit aspect-level sentiment analysis and its applications, and how to develop more semantic-oriented sentiment analysis. The motivation of our work is to address some of the structural issues of machine learning classification models applied to Implicit Aspect Identification like Overfitting and Underfitting. In this paper, the proposed approach is using semantic relations from WordNet lexical database for enhancing the SVM classification model so that it can better cope with some of its intrinsic issues. To achieve this motivation, we propose our approach which is specifically appropriate thanks to the fact that it captures similarity information between two aspect terms (from WordNet) and uses this similarity to increase the degree of influence on classification between these two aspect terms. Our approach operates at the SVM kernel which controls this degree of influence on classification between two aspect terms and therefore determines how each training term affects the final SVM classification results.

III. PROPOSED APPROACH

In this section, we describe our method, which is illustrated in Fig. 1. Its goal is to integrate relevant external knowledge, namely semantic knowledge obtained from WN lexical database into SVM Kernel calculation. For this purpose, we propose three new semantic kernel functions to SVM.

T_i and T_j are two implicit aspect terms (IAT) in the dataset, and Def_i and Def_j correspond to their respective sets of Wordnet definitions. Def_i and Def_j are defined as follows:

$$Def_i = \{subset_{i1}, \dots, subset_{is}\}, s \in [1, n] \quad (1)$$

$$Def_j = \{subset_{j1}, \dots, subset_{jt}\}, t \in [1, m] \quad (2)$$

Where n and m are respectively the numbers of definitions in Def_i and Def_j , $subset_{is}$ is the set of words representing the s^{th} definition in Def_i , and $subset_{jt}$ is the set of words representing the t^{th} definition in Def_j . The new kernels are computed according to the following formulas:

$$score(Def_i, Def_j) = \max NCW_{ij}(s, t), s \in [1, n], t \in [1, m] \quad (3)$$

$$sim(T_i, T_j) = score^2(Def_i, Def_j) + 1 \quad (4)$$

$$GaussianNew(T_i, T_j) = exp(-\gamma(\|T_i - T_j\|^2 / sim(T_i, T_j))) \quad (5)$$

$$AnovaNew(T_i, T_j) = \sum_{k=1}^n exp(-\sigma((T_{ik} - T_{jk}) / sim(T_i, T_j))^2)^d \quad (6)$$

$$BesselNew(T_i, T_j) = J_0(\sigma\|T_i - T_j\|) * sim(T_i, T_j) \quad (7)$$

Since equivalent word senses are commonly defined by the same terms, the score is determined by comparing word definitions collected from WordNet lexical database [13]. We can make the following assumption: for two terms, the more similar words that their definitions contain the more similar these two terms are. We inspire from Lesk algorithm [8] to create the proposed score. The Lesk algorithm suggests comparing two concepts using the number of common words in their glosses. First, the number of common terms between each subset in Def_i and each subset in Def_j is computed.

Let’s note this number as follows:

$NCW_{ij}(s, t)$ = the number of common terms between $subset_{is} \in Def_i$ and $subset_{jt} \in Def_j$.

As stated in equation (3), the score is then computed as the maximum of all these numbers $NCW_{ij}(s, t)$.

Equation (4) shows how $sim(T_i, T_j)$ is obtained. This latter is calculated by adding 1 to the square of $score(Def_i, Def_j)$.

If T_i and T_j are dissimilar ($score(Def_i, Def_j) = 0$), then the new kernel between them is computed as follows :

- For Gaussian and Anova kernels, the new distance between T_i and T_j is set to the standard distance since $sim(T_i, T_j)$ is equal to 1.
- For Bessel kernel, J_0 (the Bessel function of the first kind) is set to its basic value since $sim(T_i, T_j)$ is equal to 1.

The score is squared to provide higher similarity of terms having a larger number of common words between subsets of their definitions.

In equations (5) and (6), the new SVM kernels ($GaussianNew(T_i, T_j)$ and $AnovaNew(T_i, T_j)$), are calculated by dividing the standard distances used in the original Gaussian and Anova kernel functions by the proposed similarity in equation (4). In each of these new kernels, the division of the distance by the proposed similarity aims to decrease the distance between similar terms and then increase the degree of influence they have on the classification of each others. In other terms, by decreasing the value inside the exponential function, the resulting value of the kernel is amplified for similar terms.

In equation (7), the new Bessel kernel is calculated by multiplying J_0 , which is the Bessel function of the first kind, by

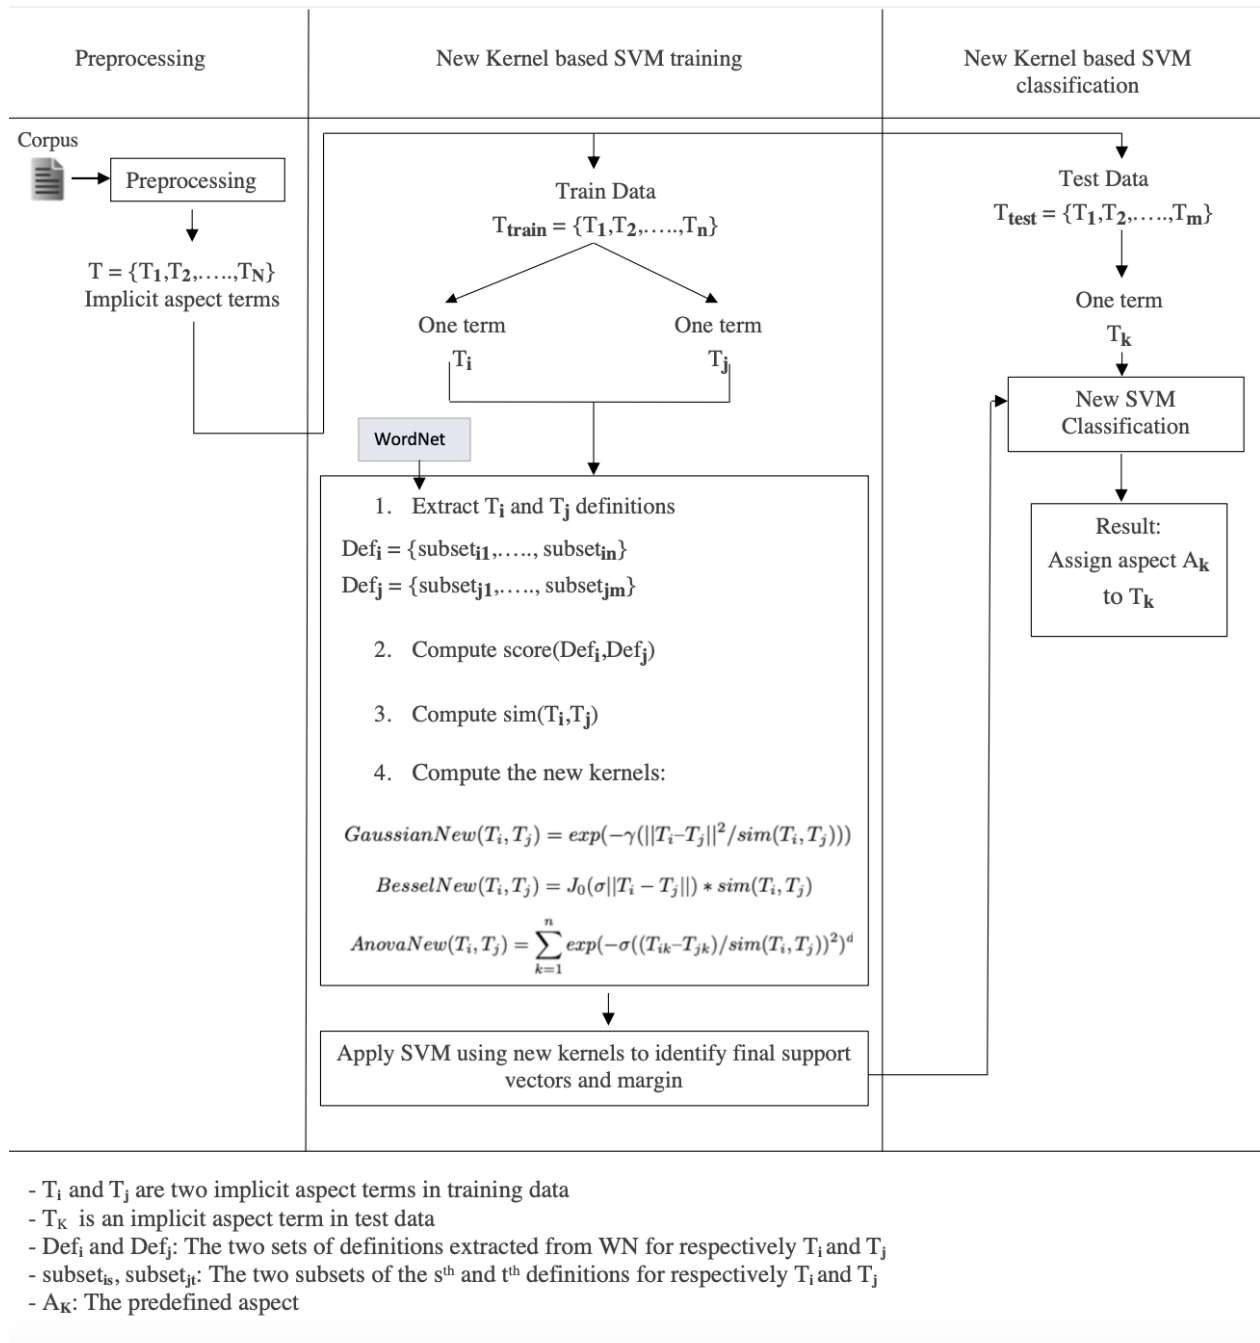

Fig. 1. Summary of our approach.

the proposed similarity in equation (4). The new Bessel kernel value is defined as J_0 multiplied by the proposed similarity function. Consequently, this resulting value is amplified which increases the degree of influence on classification between the nearest terms.

IV. EXPERIMENTS AND RESULTS

This section presents the experiments conducted to assess our proposed method. The pre-processing techniques applied, the classifier used, the utilized datasets, the performance metrics adopted, and the experimental protocols implemented are

all detailed below.

A. Experimental Setup and Protocols

1) *Pre-processing*: Pre-processing begins with corpus parsing to extract a list of adjectives and verbs using Part of Speech Tagger (POS). And then all stop words are removed from the initial list to create the final one.

2) *Classifier used*: Support Vector Machines (SVM) [32] are a group of supervised learning techniques for classification and regression. Putting more emphasis on classification task,

the goal of SVM is to create a hyperplane that divides instances into distinct classes while maximizing the distance (or margin) with the closest data points, known as support vectors.

3) *Datasets*: To evaluate our technique, we used Restaurant, Products and Laptop datasets. Products dataset was created by Cruz-Garcia et al. [33] who manually labeled each IAT. This dataset is based on the customer review corpus described in [36]. It includes five corpora for various electronic products. The primary considered implicit aspects are functionality, performance, appearance, price, quality, weight, and size.

Restaurant dataset is used for SemEval-2014 ABSA task 4 [35]. It contains 3044 English sentences from Ganu et al.'s [34] restaurant reviews with five predetermined implicit aspects: price, food, ambiance, service, and anecdotes/miscellaneous.

Laptop dataset is a modified version of SemEval-2015 ABSA dataset for laptop domain [37]. This corpus is used for SemEval-2016 task 5 for Aspect Based Sentiment Analysis [38]. The primary addressed implicit aspects are operation performance, usability, price, quality, design features, portability, and connectivity.

4) *Evaluation measures*: Accuracy, precision, recall, and F1-score are the most widely utilized evaluation measures for assessing the model's performance. Accuracy is the proportion of correctly predicted samples. Precision, recall, and F1-score are employed instead of accuracy when the dataset is unbalanced since accuracy alone is insufficient. The F1-score is the equally weighted average of precision and recall [39].

$$F1 = \frac{2 \times Precision \times Recall}{Precision + Recall} \quad (8)$$

Where Precision is the percentage of correct predictions over all positive label samples, whereas recall is the percentage of correct predictions across all positive predictions.

5) *Experimental protocols*: Our experimental protocols are prepared in order to evaluate our method according to the following issues:

- SVM behavior depending on kernel functions used,
- SVM behavior under different experimental settings,
- SVM behavior under Overfitting and Underfitting,

To lower the uncertainty of data splitting between testing and training data, 10-fold cross-validation is used in all experiments. The experimental protocols will be detailed in the following four subsections, with an emphasis on each protocol's intended purpose and how each protocol is designed to achieve its goal.

a) *Kernel functions used*: The main function of the kernel is to transform the input data into the required form. There are various types of kernels. In order to evaluate our approach, we used three different kernels.

Gaussian RBF kernel: The Gaussian RBF kernel is one of the most used kernels with SVM. This kernel function is preferred when we do not have any prior knowledge of the data. The equation of Gaussian RBF is presented as follows:

$$K(x, z) = \exp(-\gamma \|x - z\|^2) \quad (9)$$

Where $\|x - z\|$ denotes the Euclidean distance between the two data points x and z , respectively. The parameter γ controls the Gaussian curve's shape and determines how each training sample affects the classification result.

Anova kernel: The ANOVA kernel is a radial basis function that is frequently used in kernel-based techniques, such as SVM. The ANOVA kernel is formulated as:

$$K(x, z) = \sum_{k=1}^n \exp(-\sigma(x_k - z_k)^2)^d \quad (10)$$

Where x and z are two data points, and d denotes the ANOVA kernel's degree. The parameter σ influences both the border of the categorization problem and the shape of the ANOVA kernel.

Bessel kernel: The Bessel kernel is a radial basis function used in kernel-based methods in mathematics, such as SVM. The equation of Bessel kernel is given by:

$$K(x, z) = J_0(\sigma \|x - z\|) \quad (11)$$

Where x and z are two data points, J_0 is the Bessel function of the first kind, and $\|x - z\|$ is the Euclidean distance between them. The parameter σ impacts the boundary of the categorization problem, which also impacts the Bessel kernel's structure.

b) *SVM behavior under different experimental settings*: SVM is a machine learning classification technique whose performance depends not only on kernel function but also on its parameters. The most critical parameters are C , γ , and σ . Parameter C is the error penalty misclassification, It controls the trade-off between maximizing the margin and minimizing the misclassification error. Parameter γ determines the speed of the decrease of the similarity of two points as the distance between them increases. It is in charge of finding the balance between SVM abilities to fitting training data and to generalizing to testing data. Whereas parameter σ decides the boundary uniformity with respect to the quantity of nearby data points considered for Building this boundary. It decides the breath of its corresponding kernel. Thus, both parameters σ and γ determine how far the influence of each training instance reaches.

Protocol 1: Experiments for issues (a) and (b):

For our comparative protocol, we execute BasicSVM and NewSVM using a grid search with respect to combinations $\{C, \gamma\}$ (for Gaussian RBF Kernel) and $\{C, \sigma\}$ (for Anova and Bessel Kernels), where C , γ and σ range within $[2^{-5}, 2^{15}]$ interval, in order to obtain as many as possible significant values for performance ranging from Underfitting values up to Overfitting values.

As the parameter setting changes, the performance of each of NewSVM and BasicSVM models ranges from Minimum to Maximum values that correspond respectively to Underfitting and Overfitting situations. For each model, we identify from its performance range three different pertinent F1 performance values Minimum Value, Median Value, and Maximum Value. The identified Minimum and Maximum performance values

are chosen to be different, if possible, from Underfitting and Overfitting values respectively. This is because Underfitting and Overfitting are treated separately in the next part of this section. Our protocol aims to conduct objective comparisons of F1 performances of both NewSVM and BasicSVM models. In fact, it compares each of the three identified F1 performances of each model to the F1 performance, of the other model, obtained under the same experimental parameter setting leading to the identified performance of the former model.

To deal with issues (a) and (b), we conduct our experiments according to the following protocol:

Protocol 1: kernel functions used and different experimental settings:

For each dataset from {Laptop, Products, Restaurant}:

For each Kernel from {Gaussian RBF, Anova, Bessel}:

If (the best performance is identified for BasicSVM) / (OR the best performance is identified for NewSVM):

Let's denote:

1) BestBasicSVM as the BasicSVM algorithm with the best F1-score performance. (OR BestNewSVM as the NewSVM algorithm with the best F1-score performance.)

2) $NewSVM_{Param-BestBasicSVM}$ as the NewSVM algorithm using the same parameters used by BestBasicSVM. (OR $BasicSVM_{Param-BestNewSVM}$ as the BasicSVM algorithm using the same parameters used by BestNewSVM.)

Compare F1-score average performances of $NewSVM_{Param-BestBasicSVM}$ and BestBasicSVM (OR Compare F1-score average performances of $BasicSVM_{Param-BestNewSVM}$ and BestNewSVM)

If (the median performance is identified for BasicSVM) / (OR the median performance is identified for NewSVM):

Let's denote:

1) MedianBasicSVM as the BasicSVM algorithm with the median F1-score performance. (OR MedianNewSVM as the NewSVM algorithm with the median F1-score performance.)

2) $NewSVM_{Param-MedianBasicSVM}$ as the NewSVM algorithm using the same parameters used by MedianBasicSVM. (OR $BasicSVM_{Param-MedianNewSVM}$ as the BasicSVM algorithm using the same parameters used by MedianNewSVM.)

Compare F1-score average performances of $NewSVM_{Param-MedianBasicSVM}$ and MedianBasicSVM (OR Compare F1-score average performances of $BasicSVM_{Param-MedianNewSVM}$ and MedianNewSVM)

If (the worst performance is identified for BasicSVM) / (OR the worst performance is

identified for NewSVM):

Let's denote:

1) WorstBasicSVM as the BasicSVM algorithm with the worst F1-score performance. (OR WorstNewSVM as the NewSVM algorithm with the worst F1-score performance.)

2) $NewSVM_{Param-WorstBasicSVM}$ as the NewSVM algorithm using the same parameters used by WorstBasicSVM. (OR $BasicSVM_{Param-WorstNewSVM}$ as the BasicSVM algorithm using the same parameters used by WorstNewSVM.)

Compare F1-score average performances of $NewSVM_{Param-WorstBasicSVM}$ and WorstBasicSVM (OR Compare F1-score average performances of $BasicSVM_{Param-WorstNewSVM}$ and WorstNewSVM)

Compute all Improvement Rates (IR) of NewSVM over BasicSVM

Report F1-score averages and IR results

c) SVM behavior under overfitting and underfitting: We design a protocol that is intended to examine and compare the impact of Overfitting and Underfitting on the performance of NewSVM and BasicSVM with three kernels, Gaussian RBF, Anova, and Bessel. To accomplish this aim, our suggested protocol should:

1. Be built under conditions that cause SVM Underfitting and Overfitting. Generally, Overfitting and Underfitting are induced by respectively large values of C , γ and σ , and small values of C , γ and σ . The small and large values of these parameters are experimentally identified using grid search along with cross-validation.

The parameters γ and σ determine the extent of a single training example influence (γ is the hyper-parameter of Gaussian RBF Kernel, and σ is the hyper-parameter of Anova and Bessel kernels). When gamma and sigma are very small the model is too constrained and cannot capture the complexity of the data. Consequently, the region of influence of any selected support vector would include the whole training set. In addition to that, small values of γ and σ consider only nearby points in calculating the separation line. As a result, a low value of γ and σ will loosely fit the training dataset, which causes Underfitting. In contrast to small values, large values of γ and σ consider all the data points in the calculation of the separation line. Consequently, a high value of γ and σ will exactly fit the training dataset, which causes Overfitting.

Parameter C represents the error penalty for misclassification for SVM. The C parameter trades off correct classification of training examples against maximization of the decision function's margin. For larger values of C , a smaller margin will be accepted thus the model will be less tolerant, in other words, the model will be more specific and therefore this leads to Overfitting. A lower C will encourage a larger margin, therefore a simpler decision function at the cost of training accuracy, thus the model will be more tolerant to misclassifications, which causes Underfitting. In other words, C behaves as a regularization parameter in SVM.

2. Provide a measure to analyze the impact of Underfitting and Overfitting on SVM performance, in order to make a comparison between BasicSVM and NewSVM with regard to how they behave under Overfitting and Underfitting situations. In Overfitting, SVM has a good training performance and a bad test performance. In contrast, in Underfitting SVM performs poorly on both testing and training data. For assessing how sensitive both models are to Underfitting and Overfitting, we propose different measures that are presented and described in detail in section B “Results and Discussion”.

Protocol 2: Experiments for issue (c):

We compare the performances of NewSVM and BasicSVM for each of the three kernels (Gaussian RBF, Anova, and Bessel) and for Overfitting and Underfitting conditions. For this comparison, we execute a grid search with respect to $\{C, \gamma\}$ and $\{C, \sigma\}$ combinations, where C, γ and σ range within $[2^{-5}, 2^{15}]$ interval. This range is chosen to be very large (with very small lower bound and very large upper bound) so that grid search results in many combinations of $\{C, \gamma\}$ and $\{C, \sigma\}$ from which we extract relevant values leading to Overfitting and Underfitting that are used to conduct our experimental comparisons of BasicSVM and NewSVM.

In fact, for each situation of Underfitting and Overfitting, grid search identifies several relevant combinations resulting in the same F1-score performance. Thus, for our comparative experiments, we select the combinations of the largest values $\{C_{max}, \gamma_{max}\}$ or $\{C_{max}, \sigma_{max}\}$ and the smallest values $\{C_{min}, \gamma_{min}\}$ or $\{C_{min}, \sigma_{min}\}$ (depending on the kernel used) for respectively Overfitting and Underfitting conditions.

Protocol 2: Overfitting and Underfitting: For each dataset from {Laptop, Products, Restaurant}:

For each Kernel from {Gaussian RBF, Anova, Bessel}:

For each Model from {NewSVM, BasicSVM}:

If Kernel = Gaussian RBF :

If Overfitting :

Select $\{C_{max}, \gamma_{max}\}$ for comparing NewSVM and BasicSVM

Else //Underfitting // :

Select $\{C_{min}, \gamma_{min}\}$ for comparing NewSVM and BasicSVM

If Kernel = Anova or Kernel = Bessel :

If Overfitting :

Select $\{C_{max}, \sigma_{max}\}$ for comparing NewSVM and BasicSVM

Else //Underfitting // :

Select $\{C_{min}, \sigma_{min}\}$ for comparing NewSVM and BasicSVM

Report F1-score average results of Model

- SVM behavior depending on kernel functions used,
- SVM behavior under different experimental settings,
- SVM behavior under Overfitting and Underfitting.

1) SVM behavior depending on kernel functions used and under different experimental settings:: Table I is defined to show the behavior of both BasicSVM and NewSVM models with respect to different experimental settings. It presents, on one hand, the F1-score average performances of BestBasicSVM, MedianBasicSVM, and WorstBasicSVM compared respectively to F1-score average performances of $NewSVM_{Param-BestBasicSVM}$, $NewSVM_{Param-MedianBasicSVM}$ and $NewSVM_{Param-WorstBasicSVM}$, and on the other hand, the F1-score average performance of BestNewSVM, MedianNewSVM, and WorstNewSVM compared respectively to F1-score average performances of $BasicSVM_{Param-BestNewSVM}$, $BasicSVM_{Param-MedianNewSVM}$ and $BasicSVM_{Param-WorstNewSVM}$. It outlines these comparisons for the three considered kernels and the three datasets. Table I reveals that NewSVM outperforms BasicSVM for all kernels and all datasets used (shown by positive IR for all cases). In fact, when we introduce our proposed similarity in SVM kernels this results in tuned kernel values and then enhances the classification performance. These tuned values are obtained by integrating the proposed similarity function in the three considered kernels (Gaussian RBF, Anova, and Bessel), which amplifies kernel values and then increases the level of influence between the nearest terms. As a result, the new kernel functions allow SVM to improve its classification performance.

In addition to global findings marked by positive performance improvement rates of NewSVM over BasicSVM, there are some noteworthy points that clearly show NewSVM's superiority:

- a) We observe that NewSVM outperforms BasicSVM with the lowest, the middle, and the highest average IR over all kernels and datasets respectively for the best, the median, and the worst performances of both models. (IR average values are $\{5, 78\%, 36, 94\%$, $\{34, 48\%, 118, 97\%$, and $\{193, 53\%, 211, 89\%$, for respectively the best, the median, and the worst performances). NewSVM is shown to outperform BasicSVM for all cases but its outperformance rate changes with the level of the performance considered for comparison. Indeed, the best performance, that is chosen for any one of both models, usually corresponds to optimal hyperparameters for both NewSVM and BasicSVM. This fact allows this latter to reach high performances in general, and therefore not to be largely exceeded by NewSVM. Conversely, the worst performance, that is identified for any of both models, leads to the worst hyperparameters mainly for BasicSVM. Hence, this latter achieves its worst performance, which helps NewSVM to highly outperform it.
- b) We notice that NewSVM outperforms BasicSVM with higher average IR over all kernels and datasets when best and median performances

B. Results and Discussion

The results of the experiments are shown and discussed in this part considering the following aspects:

TABLE I. IMPROVEMENT RATES OF NEWSVM OVER BASICSV M UNDER DIFFERENT EXPERIMENTAL SETTINGS FOR THREE DATASETS AND THREE KERNELS

Model	Restaurant			Products			Laptop			Average-IR
	Gaussian	Anova	Bessel	Gaussian	Anova	Bessel	Gaussian	Anova	Bessel	
BestBasicSVM	81.94%	81.94%	81.94%	77.27%	77.02%	77.02%	85.60%	85.60%	85.60%	
NewSVM _{Param-BestBasicSVM}	85.53%	86.56%	87.23%	81.13%	78.76%	80.99%	92.33%	92.47%	92.06%	
IR-BestBasicSVM	4.38%	5.63%	6.45%	5%	1.93%	5.15%	7.86%	8.03%	7.55%	5.78%

are used for NewSVM than when they are used for BasicSVM (Average-IR(IR-BestNewSVM) ζ Average-IR(IR-BestBasicSVM) and Average-IR(IR-MedianNewSVM) ζ Average-IR(IR-MedianBasicSVM)). In fact, the newly included similarity into SVM kernels helps NewSVM to be much less sensitive to the change of setting, the error misclassification, and the influence of training data instances that are controlled by hyperparameters (C, γ , and σ). Whereas, BasicSVM remains very sensitive as usual to these factors. Therefore, the performances of NewSVM do not significantly change even when we change hyperparameters from values leading to its best, median, and worst performances to values corresponding respectively to the best, median, and worst performances of BasicSVM. At the same time, BasicSVM is generally penalized when its own parameters are changed to NewSVM parameters.

- c) We also note that for the worst performances, NewSVM outperforms BasicSVM with higher average IR over all kernels and datasets (Average-IR(IR-WorstNewSVM) ζ Average-IR(IR-WorstBasicSVM)). However, NewSVM is shown to exceed BasicSVM with the same IR for every kernel and dataset except for the Gaussian kernel on Laptop dataset. This is simply explained by the fact that both models share the same hyperparameter values for their worst performances. In others terms, the values of the parameters that correspond to the worst performance of BasicSVM lead to the worst performance of NewSVM and vice versa.

To better show the behavior of both NewSVM and BasicSVM with respect to kernel functions for all datasets, we create Table II that represents an aggregated view of Table I. Indeed, Table II shows for each kernel function and for each dataset: (i) Average-F1-BasicSVM which is the average of F1-score performances of BestBasicSVM, MedianBasicSVM, and WorstBasicSVM, BasicSVM_{Param-BestNewSVM}, BasicSVM_{Param-MedianNewSVM} and BasicSVM_{Param-WorstNewSVM}, (ii) Average-F1-NewSVM which is the average of F1-score performances of BestNewSVM, MedianNewSVM,

and WorstNewSVM, NewSVM_{Param-BestBasicSVM}, NewSVM_{Param-MedianBasicSVM} and NewSVM_{Param-WorstBasicSVM} and (iii) IR which is the improvement rate of Average-F1-NewSVM over Average-F1-BasicSVM. From Table II, it can be observed that the average improvement rates of NewSVM over BasicSVM reach their highest values with Bessel kernel and their lowest values with Anova kernel for all datasets. This observation may be explained by the low BasicSVM performance with Bessel kernel and the high BasicSVM performance with Anova kernel. This shows that BasicSVM performance is one among other impacting factors of the improvement rate of NewSVM over BasicSVM.

2) SVM behavior under overfitting and underfitting:

- a) *Overfitting*: To analyze the behavior of the new and original model in Overfitting conditions, and as stated previously in our protocol, the comparative experiments are conducted using the combination $\{C_{max}, \gamma_{max}\} = \{32768, 32768\}$ for Gaussian kernel, and $\{C_{max}, \sigma_{max}\} = \{32768, 32768\}$ for Anova and Bessel kernels, corresponding to the largest values of parameters.

Table III shows F1-score averages for NewSVM model and BasicSVM model under Overfitting situations (each average is obtained across multiple folds). In Overfitting, the two models perform well on training data but badly on test data.

We provide three indicators in Table III that are utilized to measure how sensitive BasicSVM and NewSVM are to Overfitting.

Delta-test (Delta-test = F1-test(NewSVM) - F1-test(BasicSVM)) values are positive in all experiments in Table III. This demonstrates that NewSVM outperforms BasicSVM for all kernels and for all datasets, even in Overfitting situation. The fact that NewSVM outperforms BasicSVM on test data is the first indicator of NewSVM's less Overfitting sensitivity in comparison to BasicSVM.

The two other indicators of BasicSVM and NewSVM Overfitting sensitivity are respectively Delta-BasicSVM and Delta-NewSVM (Delta-BasicSVM = F1-Train(BasicSVM) - F1-Test(BasicSVM), Delta-NewSVM = F1-Train(NewSVM) - F1-Test(NewSVM)). These two metrics measure the performance losses that are made respectively by BasicSVM

TABLE II. AVERAGE IMPROVEMENT RATES OF NEW SVM OVER BASIC SVM WITH RESPECT TO KERNELS AND DATASETS

Dataset / Kernel	Gaussian	Anova	Bessel
Average-F1-BasicSVM _{Restaurant}	42.67%	69.14%	43.18%
Average-F1-NewSVM _{Restaurant}	74.51%	83.59%	86.87%
IR _{Restaurant}	74.62%	20.90%	101.18%
Average-F1-BasicSVM _{Products}	57.92%	71.07%	49.36%
Average-F1-NewSVM _{Products}	74.35%	76.12%	81%
IR _{Products}	28.37%	7.10%	64.10%
Average-F1-BasicSVM _{Laptop}	44.54%	76.44%	57.87%
Average-F1-NewSVM _{Laptop}	79.99%	89.58%	91.92%
IR _{Laptop}	79.59%	17.19%	58.84%
Average-IR	60.86%	15.06%	74.71%

and NewSVM between testing and training data. A higher Delta-BasicSVM (Delta-NewSVM) results in a poorer performance on testing data than on training data for BasicSVM (NewSVM). This means that BasicSVM (NewSVM) sensitivity to Overfitting increases. The model that is more sensitive to overfitting is indicated by Delta (Delta = Delta-BasicSVM – Delta-NewSVM). The BasicSVM is more sensitive when Delta is positive; otherwise, the NewSVM is more sensitive. Additionally, BasicSVM becomes more sensitive than NewSVM as Delta increases. Table III shows that for all kernels and for all datasets, all Delta values are positive. This means that the differences between F1-score averages in training data and F1-score averages in test data are smaller for the NewSVM model, and this denotes a lower performance loss between testing and training data, and thus, lower sensitivity to Overfitting.

Therefore, our method aids SVM coping with Overfitting more effectively. Thus, the suggested model is less sensitive than the basic one to Overfitting.

b) Underfitting: To analyze the behavior of the original and new models under Underfitting, and as stated previously in our protocol, the comparative experiments are conducted using the combination $\{C_{min}, \gamma_{min}\} = \{0.03125, 0.03125\}$ for Gaussian kernel, and $\{C_{min}, \sigma_{min}\} = \{0.03125, 0.03125\}$ for Anova and Bessel kernels, corresponding to the lowest values of parameters.

Table IV shows the behavior of BasicSVM and NewSVM under Underfitting when both models show poor performance on both testing and training data.

In order to analyze both models sensitivity to Underfitting, we introduce two indicators in Table IV to measure BasicSVM and NewSVM tolerance to Underfitting.

Delta-test (Delta-test = F1-test(NewSVM) – F1-test(BasicSVM)) values are positive in all experiments in Table IV (except for Gaussian kernel on Restaurant dataset). This shows that NewSVM outperforms BasicSVM for all kernels and for all datasets, even in Underfitting situation. The fact that NewSVM outperforms BasicSVM on test data is the first indicator of NewSVM's less Underfitting sensitivity in comparison to BasicSVM.

Delta-train (which is equal to F1-train(NewSVM) – F1-train(BasicSVM)) is the second indicator. Delta-train values are positive in all experiments in Table IV (except for Gaussian kernel on Restaurant dataset). This implies that NewSVM is more performant than BasicSVM on training data. This indicates that NewSVM is more tolerant to Underfitting than

BasicSVM.

V. COMPARISON WITH OTHER WORKS

In order to evaluate the effectiveness of the proposed approach, it is compared against various existing methods from the literature. Table V shows a comparison between the traditional and deep learning methods and our suggested method for Implicit Aspect Identification. It is crucial to note that all the works use the same datasets. However, they operate at distinct levels. While W2VLDA [26], and our proposed method (using 3 kernels) work at the algorithmic level by proposing adjustments or additions, the rest of the techniques focus on enhancing the quality of training data by operating at the data level. Schouten et al.'s supervised method [21] is a hybrid method that operates at both data level and algorithmic level.

From Table V, we observe that:

- In the case of Restaurant dataset, despite the difficulty of adjusting the core model that is more challenging and sensitive, our proposed technique (with the three kernels) shows a highly competitive performance level when compared to all works even the ones operating on data level which is less challenging and even the deep learning methods of [19] that are generally reputed for high classification performance.
- In the case of the Products dataset, our three proposed approaches, which operate at the algorithm level without modifying the training data structure, are mostly surpassed by all methods of [18] and [19] that make use of data-level techniques. These techniques enhance the training data by incorporating semantic relations from WN, which should help mitigate the issue of high-class imbalance present in the Products dataset. However, Our technique (with three kernels) outperforms KNN [40] with its three versions, which is an algorithmic-level technique.
- In the case of Laptop dataset, our proposed approach with all kernels outperforms LSTM+WN+Frequency [19] and Att-LSTM+WN+Frequency [19] which are not only deep learning methods that are generally reputed for high classification performance, but also operating on less sensitive and less challenging data level.

TABLE III. F1-SCORE AVERAGE PERFORMANCES OF NEWSVM AND BASIC SVM UNDER OVERFITTING FOR ALL DATASETS AND USING THREE KERNELS

Kernel	Gaussian { C_{max}, γ_{max} }			Anova { C_{max}, σ_{max} }			Bessel { C_{max}, σ_{max} }

Proposed SVM with Bessel	traditional	89.81%	80.89%	93.42%

VI. CONCLUSION

In this work, we suggest a method to enhance SVM algorithm to address Implicit Aspect Identification. We provide an improvement for SVM kernel computation to support the IAI task through the use of WordNet semantic relations. For empirical evaluation, experiments are conducted on three datasets of laptop reviews, electronic product reviews, and restaurant reviews, and the effects of our approach on SVM performance are examined and analyzed according to three criteria: (i) kernel function used, (ii) different experimental settings, and (iii) SVM behavior under Overfitting and Underfitting.

The key conclusions of our research can be summarized as follows:

- a) Our technique helps SVM improve its performance under different experimental settings and for the three considered kernels and datasets.
- b) Our method helps SVM deal with Overfitting and Underfitting more effectively by minimizing their effects on SVM and thereby enhancing its performance.

Even though our approach helps SVM classifier better deal with some of its main issues, it has some limitations at different levels:

- Machine learning model: it only uses one popular eager machine learning model. It would be more interesting to test other types of machine learning models such as lazy or deep learning techniques.
- WordNet semantic relations: it uses only one semantic relation which is "definition relation". It would be also more interesting to explore other semantic relations offered by WordNet like synonyms, antonyms, and their combinations. These relations seem to have significant linguistic importance that may help improve machine learning models to address their critical issues when applied to IAI.
- Datasets used: it uses three datasets that are medium-sized and noise-free that better suit the SVM classification model. We plan to use other less suitable datasets like noisy and large data which present many challenges to the SVM model.

Future work will investigate the use of our method to improve SVM model with non-distance-based kernels and evaluate it under different aspects like dataset size, curse of dimensionality, and noise tolerance. It will also look into considering our approach to address the above-mentioned limitations of our work.

Abstract—Deep learning methods have achieved significant success in various applications, including trend signal prediction in financial markets. However, most existing approaches only utilize price action data. In this paper, we propose a novel system that incorporates multiple data sources and market correlations to predict the trend signal of Ethereum cryptocurrency. We conduct experiments to investigate the relationship between price action, candlestick patterns, and Ethereum-Bitcoin correlation, aiming to achieve highly accurate trend signal predictions. We evaluate and compare two different training strategies for Convolutional Neural Networks (CNNs), one based on transfer learning and the other on training from scratch. Our proposed 1-Dimensional CNN (1DCNN) model can also identify inflection points in price trends during specific periods through the analysis of statistical indicators. We demonstrate that our model produces more reliable predictions when utilizing multiple data representations. Our experiments show that by combining different types of data, it is possible to accurately identify both inflection points and trend signals with an accuracy of 98%.

I. INTRODUCTION

Trading refers to buying and selling operations carried out on the financial markets. These operations are executed by traders from the trading room of a financial organization or the stock market institution, or from the Internet in the case of independent traders. The operations in financial markets are made in a secure and controlled environment which brings together hundreds of thousands of market participants who wish to buy and sell shares. The buying and selling activities operate electronically on well known platforms for trading. These platforms contain all information and tools that the trader needs to analyse the different markets. Hence, a strong knowledge about the market psychology is essential to trade in the live market. In trading, market movement can be observed and analyzed through various types of trading charts. These charts often contain technical indicators that assist traders in accurately predicting market trends and trading signals. Examples of popular trading charts include bar charts, line charts, point and figure charts, market profile charts, and candlestick charts. In this article, we will specifically focus on candlestick charts, which are widely used in financial markets

for their visual representation of price movements and patterns (see Fig. 1).

Fig. 1. Candlesticks chart : Ethereum vs US Dollar in daily time frame.

Candlestick charts offer unique visual indicators that differentiate them from other types of trading charts. The shapes and patterns of candlesticks on these charts can provide valuable insights into price action. Candlesticks come in various sizes, and understanding the psychology behind the different body sizes is crucial in trading. Each candlestick is formed using the open, high, low, and close prices of the chosen time frame, and analyzing these components can provide valuable information for traders (see Fig. 2). The graph chart contains several types of candles which are decisional and have a strong effect on market trend. The most powerful candlestick patterns are: bearish engulfing bar, bullish engulfing bar, Doji, morning star, evening star, Hammer, shooting star, Harami and the Tweezers tops and bottoms [1], [2], [3].

In this research paper, we have implemented a deep learning algorithm based on Convolutional Neural Networks (CNNs) to predict the trend of Ethereum cryptocurrency. The main objective of this work is to develop an intelligent trading system that can assist traders in automating their trades, predicting market trends, and mitigating high volatility. The proposed system is designed to identify high probability setups and maximize profits. To achieve accurate predictions, we have utilized different data representations. We have found that combining multiple data representations significantly improves the efficiency of the algorithms during the training process, enabling them to learn data dependencies with high accuracy.

Fig. 2. Candlestick price levels.

In addition to incorporating candlestick pattern data and statistical indicators, we have also considered the Ethereum-Bitcoin correlation to precisely identify Ethereum price action.

When using such structured data, a Convolutional Neural Network (CNN) is superior for learning features dependencies in wide datasets. In addition to that, CNN can also provide satisfactory performance with 1-dimensional data [4], [5], [6], [7], [8]. When working with time series data, Long Short-Term Memory (LSTM) algorithm can also learn easily temporal patterns and dependencies using memory cells and gates [9], [10], [11], [12], [13]. To find the most effective architecture, two different 1-Dimensional Convolutional Neural Network training strategies are evaluated and tested : training from scratch strategy and transfer learning strategy.

The current state-of-the-art research in the field of financial time series forecasting using deep learning has primarily overlooked the relationship between predicted market movements and the optimal trading entry point [14], [15], [16]. Financial time series data often contain significant noise, posing challenges for accurate analysis and predictions. Notably, Ethereum cryptocurrency exhibits a price action pattern that closely resembles Bitcoin. However, Ethereum demonstrates comparatively less noise in its price action chart. The presence of fake breakouts and high volatility are considered major hurdles in employing deep learning for financial time series prediction. To address the issue of noise in financial time series data, particularly in the case of cryptocurrency markets like Ethereum, we employed 1D Convolutional Neural Networks (1DCNN) using various strategies. Utilizing 1D Convolutional Neural Networks (1DCNN) is a robust approach for analyzing financial time series data. These networks have demonstrated significant potential in capturing meaningful patterns and dependencies in sequential data. When applied to financial time series, 1DCNNs can effectively learn and extract relevant features such as price fluctuations, trends, and patterns from the input data. The inherent capability of 1DCNNs to capture both local and global dependencies makes them highly suitable for modeling complex relationships in financial time series. By leveraging their multi-layered architecture and convolutional operations, 1DCNNs can uncover valuable insights, enhance prediction accuracy, and assist in decision-making processes related to trading and investment strategies. In order to ensure precise trading entry points, we meticulously collected the data and performed comprehensive feature engineering. We trained and tested three learning strategies based on 1DCNN to compare their performance and determine the most effective strategy. 1DCNN have proven to be highly proficient in identi-

fying short trends and establishing optimal trading entry points. Leveraging their specialized architecture and convolutional operations, 1DCNNs excel at capturing local dependencies and extracting relevant features from sequential financial data. By analyzing price fluctuations and other pertinent information, 1DCNNs can effectively detect and interpret short-term trends, providing valuable insights to traders. These networks possess the capability to uncover subtle patterns that might elude human analysts, leading to enhanced prediction accuracy and informed decision-making for trading strategies. With their robust ability to learn complex relationships within financial time series data, 1DCNNs have emerged as a powerful tool in the field of financial analysis, contributing significantly to successful trading strategies. To the best of our knowledge, this is the first work that uses market correlation combined with price action and moving average data to predict the Ethereum trend signal. Market correlation helps to understand the behaviour of price action and avoid volatility. In our case study, we based on Ethereum and Bitcoin correlation (Fig. 3). These two markets have strong relationship and have almost same price action.

Fig. 3. ETH-BTC correlation.

It can be seen from Fig. 3 that Ethereum and Bitcoin have the same price movement, the thing that facilitates Ethereum trend prediction. This price correlation data combined with the other data representation that we used, can ameliorate the accuracy of our model. A detailed study is presented in Section IV. The rest of the paper is organised as follows: In Section II, we give a brief overview of some significant and recent contributions to market trend prediction using deep learning approaches and Section III describes the proposed approach.

II. RELATED WORK

The majority of works done in the field of market trend prediction using deep learning refer to the data issued from technical analysis of the market. This data is used to train machine learning models. Technical analysis aims to study market behaviour throughout price action data, statistical indicators and news. In the chart of the market, candlestick patterns Fig. 2 are considered as an important visual indicator that can help to analyse the price movement. These patterns are also used to predict the trend of the market. For example, in [17], J.Hao Chen and Y.Cheng Tsai proposed a two-step approach based on a GAF-CNN algorithm to recognize candlestick patterns automatically. They were able to identify eight types of candlestick patterns with 90.7%. In [18], the authors introduced a deep learning-based approach to forecast

trend signals and determine trading entry points. Their method combines LSTM, 1DCNN, and the XGBoost algorithm. The experimental results demonstrate that their approach achieves a high level of accuracy in both predicting market movements and identifying optimal trading entry points. PL Seabe et al. [19], proposed three types of Recurrent Neural Networks (RNNs): Long Short-Term Memory (LSTM), Gated Recurrent Unit (GRU), and Bi-Directional LSTM (Bi-LSTM) for predicting exchange rates of three prominent cryptocurrencies: Bitcoin (BTC), Ethereum (ETH), and Litecoin (LTC), based on their market capitalization. The proposed methodology demonstrates high performance, with Bi-LSTM exhibiting the most accurate predictions compared to GRU and LSTM. The Mean Absolute Percentage Error (MAPE) values for BTC, LTC, and ETH are reported as 0.036, 0.041, and 0.124, respectively, indicating the superior predictive capabilities of Bi-LSTM in this context. RMI.Kusuma et al. [20] used the Convolutional Neural Network to perform candlestick analysis, their method provides a satisfactory result with a recognition score of 92%. A. Andriyanto, A. Wibowo and NZ.Abidin [21] presented a CNN approach to identify the strength of a trend pattern in the movement of the stock market, the proposed approach produces an accuracy of 99% with a remarkable noise during the training process, this problem generally is behind the noisy dataset and a non suitable CNN strategy during the training process. In [22], JH.Chen et al. provide an approach based on the local search adversarial attacks algorithm to predict the patterns of candlesticks. The applied strategy gives good results with an attack ratio of 64.36%. J.Chen et al. [23] propose modeling strategies based on machine learning (ML) techniques. They introduce a vector autoregression (VAR)-based rolling prediction model for forecasting stock prices and a Gaussian feed-forward neural networks (GFNN)-based graphical signal identification method to recognize different types of stock price signals. The experimental results demonstrate improved performance; however, the method encounters challenges when dealing with high volatility signals. These difficulties can significantly impact trading strategies and long-term cumulative profits. In case of Bitcoin trend prediction, S.cavalli and M.Amoretti [24], proposed a methodology for building useful datasets that take into account social media data, the full blockchain transaction history, and a number of financial indicators. The data was trained and tested using CNN model with an accuracy of 74.2%. M Poongodi et al. [25] combined the Latent Dirichlet Allocation (LDA) and Neural Network to predict the Bitcoin trend using data issued from social media and forums. S Alonso-Monsalve et al. [26], implemented and compared various Long Short-Term Memory (LSTM) and Convolutional Neural Network (CNN) architectures for predicting the trend of several cryptocurrencies, including Bitcoin, Dash, Ether, Litecoin, Monero, and Ripple. The proposed approaches demonstrated promising results, particularly for Bitcoin, Ether, and Litecoin cryptocurrencies. In [27], M Poongodi et al. implemented two machine learning techniques to Predict the price of Ethereum blockchain cryptocurrency in an industrial finance system. When using their proposed model, the SVM method has a higher accuracy (96.06%) than the LR method (85.46%). This can be explained by the SVM ability to classify 1-Dimensional data. T. Shintate and L. Pichl [28] provided a trend prediction classification framework named the random sampling method (RSM) for cryptocurrency time series that are

non-stationary. Their proposed approach shows strong results and outperformed those based on LSTM.

III. PROPOSED APPROACH

The proposed approach for Ethereum entry point and signal prediction is illustrated in Fig. 4. The historical data of Ethereum and Bitcoin is extracted from the Exchange broker via the trading platform using python packages. The dataset is then used to train the Convolutional Neural Network (CNN) using two different strategies: 1-dimensional transfer learning and training from scratch strategy. The first block of the system extracts the Bitcoin OHLC dataset and the trend signal, then, it is combined with the price action of Ethereum and the data issued from the moving averages to predict the Ethereum trend. In the following we describe every Block in detail.

A. Dataset and Processing

The Bitcoin and Ethereum cryptocurrencies historical data is extracted from the Exchange via the Broker. The data is characterized by the Open, High, Low and Close of prices during a time interval. OHLC data is used to analyse the price movement and calculate the statistical indicators. The collected dataset contains the OHLC prices of 4 (four) hour timeframe during one year from 11/2021 to 11/2022 as indicated in the Fig. 5. Two important Moving averages are used to determine the entry point and the signal trend: Simple Moving Average (SMA) and Hull Moving Average (HMA).

The Table I shows the used dataset to train our proposed approach. The dataset contains OHLC prices and the calculated Moving averages in addition to the bitcoin trend (1 for uptrend and 0 for downtrend):

B. Ethereum and Bitcoin Correlation

As illustrated in Fig. 3, it can be seen that Bitcoin (BTC) and Ethereum (ETH) have almost the same price action. According to the correlation analysis, Bitcoin (BTC) and Ethereum (ETH) have a strong positive relationship from the period of 2019 to 2022. Notably, data from Coin Metrics (Fig. 6) highlighted that ETH-BTC correlation coefficient was nearing all-time high values, sitting at 0.90. For that reason we used BTC price action data to predict the movement and the signal trend of Ethereum cryptocurrency. The diversity and the quality of the data is very important to determine with high accuracy the trend signal of cryptocurrency markets. Therefore, we combined the price action data and the statistical indicators with the data provided by Bitcoin (BTC) price action to spot with high accuracy the trading entry point and price movement.

C. Ethereum and Moving Averages

Concerning the statistical indicators, we choose to work with both SMA (Simple Moving Average) and HMA (hull moving average). SMA indicator calculates the average of recent prices by the number of periods within this range of prices. SMA can be described by the following formula:

$$SMA = \frac{\sum_1^n P_n}{N} \quad (1)$$

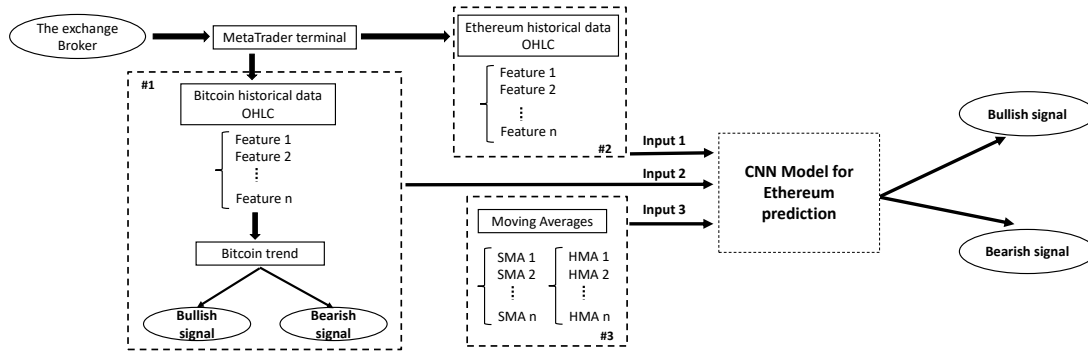

Fig. 4. System overview.

TABLE I. OHLC DATASET COMBINED WITH HMA, SMA INDICATORS AND BITCOIN TREND SIGNAL

	open	high	low	close	close_HMA_361	Close_SMA_19	BTC trend	Ethereum Trend

(a) BTC close prices.

(b) ETH close prices.

Fig. 5. Bitcoin and Ethereum close prices from 11/2021 to 11/2022.

P_n represents the closing price at specific period n , and N is the number of total periods. In this work we chose period (19) which reacts perfectly with the price.

HMA indicator can be calculated using two WMAs (Weighted Moving Average): one with the specified number of periods and one with half the specified number of periods.

$$WMA_1 = WMA(n/2) \tag{2}$$

$$WMA_2 = WMA(n) \tag{3}$$

Then, we calculate the non-smoothed Hull Moving Average:

$$HMA_{nonsth} = (2 \times WMA_1) - WMA_2 \tag{4}$$

The final smooth HMA is calculated with periods of non-smoothed HMA with the following formula:

$$HMA_{sth} = WMA(\sqrt{n}) \tag{5}$$

n represents periods of non smoothed HMA

In addition to their capacity to show the price movement, moving averages are also used to spot trend reversals and the inflection point of the market. It can be seen from the Fig. 7 that SMA(19) is more responsive to the price action and turns quickly than the HMA(361).

Fig. 6. Ehterium and Bitcoin (ETH-BTC) correlation chart based on coin metrics from 2016 to 2022.

The computation for the technical indicators relies on a number of n periods, that was set to 19 candlestick bars (4 hours time frame) for the Simple Moving Average (SMA) indicator, and 361 candlestick bars for Hull Moving Average (HMA) indicator. This parameter was defined at the start and it is optimized. The cross between the two moving averages using the optimised periods provide an excellent trading entry point. In addition to that it provides the start of the price movement.

Fig. 7. Hull moving average(HMA) period 19 and simple moving average(SMA) period 361 crossover.

A crossover occurs when two different moving average lines cross over one another. As indicated in Fig. 7 above, the red entry point marks the beginning of the signal trend and we have a bearish crossover. This takes place when a fast moving average (SMA 19) crosses down through a slow moving average (HMA 361). This implies that the trend is falling or becoming bearish.

At the green entry point, the trend changes again and this produces a bullish crossover. The fast moving average (SMA 19) is the first to react. It crosses up through the slow line (HMA 361). After the crossing, the two lines then follow the same path as the trend continues upwards.

D. CNN Architectures

To determine the entry point and the trend of the Ethereum crypto-currency we implemented the Convolutional Neural Network. CNN algorithm is used to train our collected 1-Dimensional Data. Convolution and pooling layers are configured to learn 1D features using two different strategies: CNN learned from scratch and 1D transfer learning (see Fig. 8).

The two strategies are built using the convolutional neural network architecture indicated in Fig. 9. The output dimensions after every layer is presented in the Table II.

TABLE II. MODEL SUMMARY

Layer (type)	Output Shape	Param #
conv1d_1 (Conv1D)	(None, 7, 64)	192
conv1d_2 (Conv1D)	(None, 6, 64)	8256

The Table I indicates the data fed to convolutional neural network. The data contains seven (7) features: The Open, High, Low and Close (OHLC) features of Ethereum (ETH), the moving averages (SMA 19) and (HMA 361) of Ethereum (ETH) and Bitcoin (BTC) Trend. For the training from scratch strategy, the data is fed from the input to the output of the model, the output. In other side, the proposed 1-Dimensional transfer learning strategy consists on transferring the knowledge from a pretrained model using different dataset to a tar-

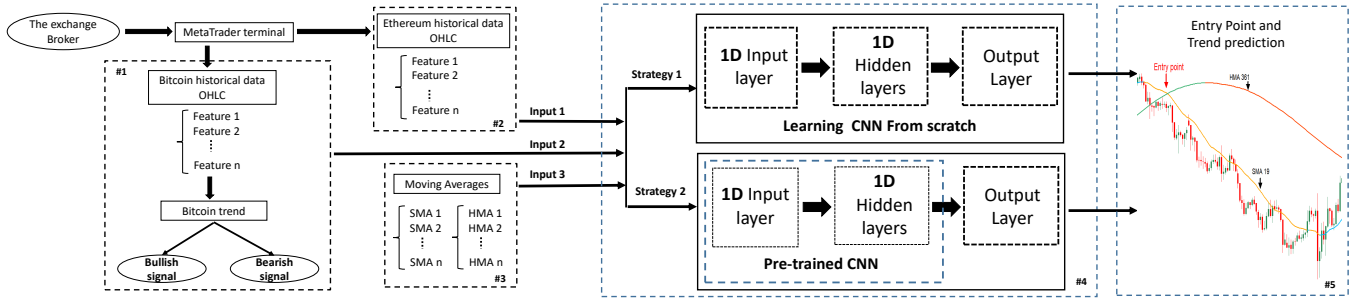

Fig. 8. CNN strategies.

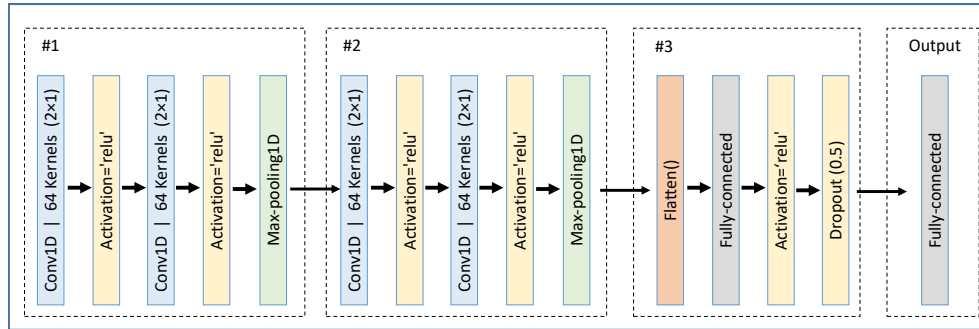

Fig. 9. CNN model architecture.

geted model (see Fig. 8). The pretrained model is trained using BTC OHLC dataset and used to perform the transfer learning strategy. The implementation of pre-trained models offers several benefits in analyzing the Ethereum cryptocurrency market. These models facilitate the extraction of pertinent features and the recognition of common patterns and interdependencies, thereby enhancing the accuracy of forecasts and enabling better decision-making. The potential implications of employing one-dimensional transfer learning in finance are promising, as they have the potential to yield excellent results.

IV. EXPERIMENTS AND RESULTS

A. Experiments and Parameterization

In this section we present the model behaviour and results using the approaches identified in Section III. The two approaches are evaluated in term of Training accuracy, training loss, testing accuracy and testing loss. The experiments were conducted using a system running on a six (06) core processor equipped with 56Go of RAM. The algorithms were implemented using the Python language and processed a multivariate dataset with 10747 samples. The experimental procedure starts with preparing the dataset. After the step of data collection and organisation mentioned in Section III-A, the data were saved in the CSV format for preprocessing convenience. As illustrated in Fig. 7, the entry point occurs when the two moving averages crossover is happening. Therefore, the trader can choose to buy if it is a bullish crossover or sell if it is a bearish crossover. In our case the entry point and also the trend signal are predicted by the proposed algorithms using the collected dataset attributes and parameters (Section III). The training accuracy according to the learning rate, the number of

fully connected layers and Epochs of both learning strategies is indicated in Tables III, IV, VI, VII, V and VIII.

TABLE III. ACCURACY OF CONVOLUTIONAL NEURAL NETWORK TRAINED FROM SRATCH ON TRAINING DATA

B. Results and Discussion

In the study, the multi-layer perceptron was used as baseline. The sensitivity of the multi-layer perceptron was studied using different learning rates and a variety of the number of the fully connected layers (see Tables V and VIII). The accuracy metrics are calculated to compare the effectiveness of the proposed approaches using Training and validation data sets. In general both 1DCNN trained from scratch and 1D transfer learning using CNN provides high accuracy during the training and validation. When analysing the 1DCNN training from scratch accuracy (see Tables III VI), it can be seen that the learning strategy provides high accuracy only for Learning rate (LR) is superior or equal to

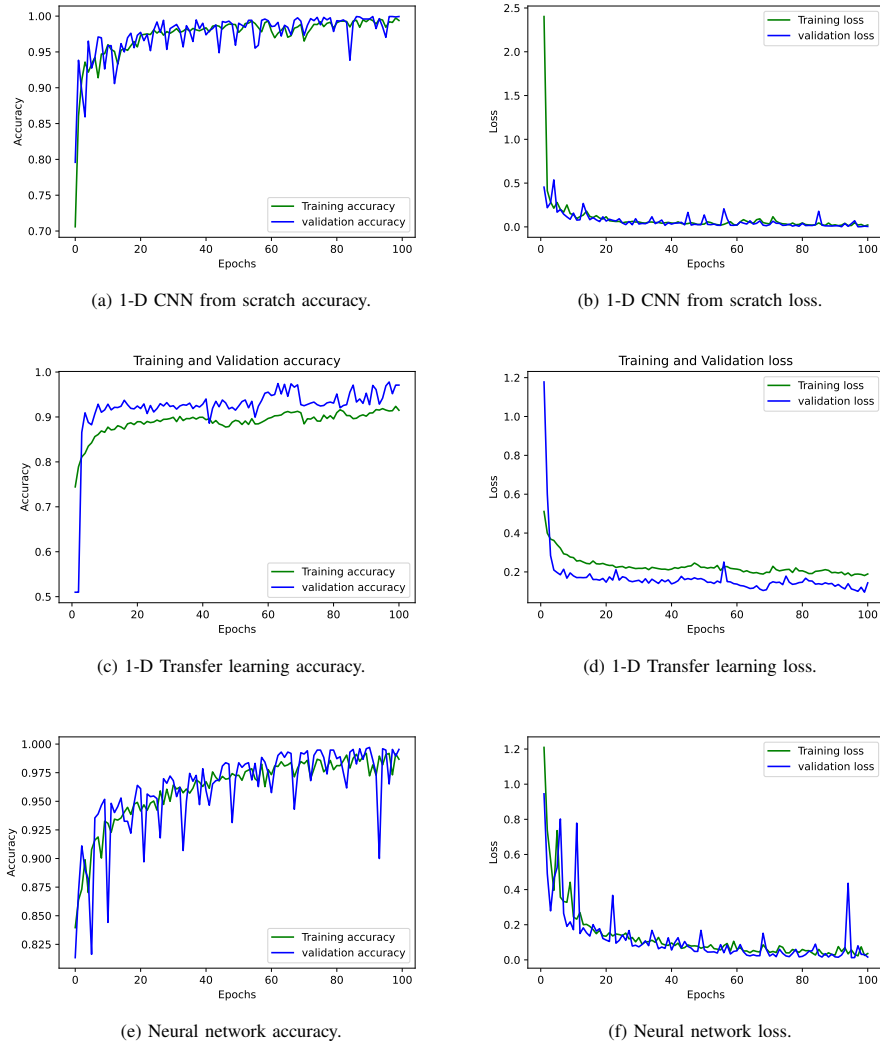

Fig. 10. Proposed approaches behaviour during the training and validation steps.

	0.0001	0.9692	0.9878	0.9913

too small may cause a long training process but effective. Learning rate refers to the step size that the weights are updated during training. It is a configurable hyper-parameter often in the range between 0.01 and 1.0. When analysing the model behaviour during the training process, it can be seen from Fig. 10 that the multilayer perceptron is unstable compared with the 1DCNN using learning from scratch and transfer learning strategies. This can be explained by the ability of CNN to learn perfectly data dependencies using the convolution and pooling functions. It can be analyzed also that the accuracy of 1DCNN attained 98.6% without overfitting and perturbations during the training process. The 1DCNN trained from scratch exhibits superior performance compared to the transfer learning strategy and the Multilayer Perceptron. Although the transfer learning strategy and the Multilayer Perceptron achieve high accuracy, the training process lacks stability. This observation can be attributed to the remarkable ability of the 1DCNN trained from scratch to accurately capture dependencies, particularly when analyzing Ethereum close price data. To evaluate and test our model architectures, we used a test data which was not used for training and validation. Fig. 11a, 11b and 11c show the confusion matrices of the proposed approaches. The x-axis is the prediction and the y-axis is the true label. We observe that the three methods work perfectly on test data

It can be seen from the Tables IX, X, XI and XII that all the used methods perform perfectly with the unseen test data.

TABLE VIII. ACCURACY OF NEURAL NETWORK ON VALIDATION DATA

Model: NN

TABLE XII. PROPOSED MODEL STRATEGIES EVALUATION ON ACCURACY, PRECISION, RECALL AND F1 SCORE. WE USED A TEST DATA WHICH IS NOT USED IN TRAINING AND VALIDATION PROCESSES

	Accuracy	Precision	Recall	F1 Score
Multi-layer perceptron	0.995	0.996	0.993	0.994
1D CNN trained from scratch	0.998	0.996	1.000	0.997
1D CNN and transfer learning	0.977	0.976	0.975	0.975

(a) 1-D CNN from scratch confusion matrix.

(b) Multilayer perceptron confusion matrix.

(c) 1-D Transfer learning confusion matrix.

Fig. 11. Confusion matrices.

Note that the 1 dimensional Convolutional Neural Network trained from scratch obtained the highest accuracy, recall, precision and F1 score. This can be explained by the ability of the CNN to learn perfectly dependencies on providing historical data.

C. Profitability

In this section we will provide profit results based on our 1-DCNN learned from scratch entry point and trend prediction. As mentioned in Section III, our model predicts the entry

point based on Simple Moving Average (SMA), Hull Moving Average (HMA) crossover and Bitcoin-Ethereum correlation. The proposed approach can predict with high accuracy the entry point and avoids the fake breakout.

Fig. 12. Profits based on 1D CNN from scratch entry point prediction.

Fig. 13. Predicted positions using 1D CNN from scratch close.

Fig. 14. Profits based on MLP entry point prediction.

It can be seen from the Fig. 12 That the proposed method based on 1D CNN trained from scratch can reach a profit of 7K dollars in 6 months (from the period of 6 June 2022 to 21 December 2022). Based on predicted entry points (see Fig. 13) which is 14% of the initial Balance (50K Dollars). For the multilayer perceptron (see Fig. 14), the profit is 4.9K dollars with 9.8% of the initial balance based on predicted positions (see Fig. 15). In other side, the predictions based on transfer learning strategy (see Fig. 16) give 7% of the initial balance with a profit of

Fig. 15. Predicted positions using MLP close.

Fig. 16. Predicted positions using transfer learning close.

Fig. 17. Profits based on 1D CNN transfer learning entry point prediction.

TABLE XIII. PROFITABILITY BASED ON ENTRY POINTS PREDICTED BY THE PROPOSED APPROACHES FOR AN ACCOUNT OF 50K DOLLARS

Proposed approach	Profits (USD)	Ppercentage (%)
1D CNN transfer learning	3500	7%
Multilayer Perceptron	4900	9.8%
1D CNN trained from scratch	7000	14%

3.5K Dollars (see Fig. 17). The Table XIII summarizes the profitability percentage using each of the proposed algorithms.

V. CONCLUSION

Market movement and entry point prediction using Deep learning algorithms can help traders to automate their trades and make more profits. The most important thing in trading is controlling the emotions. Indeed, fear, doubt and impulsiveness are the most common causes of capital loss. However, the solution is to employ Deep learning algorithms and a strong strategy. In our case we combined the BTC-ETH correlation with two key moving averages periods HMA(361) and SMA(19). The proposed methods yielded highly accurate results. Therefore, the trained models can be deployed and implemented in real time. Compared with the transfer learning strategy, and the MLP algorithm, the training from scratch provides a higher accuracy (99.8%). The 1D transfer learning strategy can provide better results when working with very large datasets. The difference in accuracy between the transfer learning strategy and learning from scratch is about 2%. In term of profitability using unseen data, the entry points and positions predicted by the 1DCNN from scratch can reach a profit of 14% of the initial balance compared with 7% for the transfer learning strategy and 9.8% for the multilayer perceptron. As a perspective, the proposed approach can be developed to find the relationship between several cryptocurrencies to predict the most profitable position during specific time interval. Moreover, the proposed algorithms will help to avoid fake breakouts during trading and identify the real trends.

VI. DECLARATION OF COMPETING INTEREST

I declare that I have no Conflict of Interest.

Security in the IoT: State-of-the-Art, Issues, Solutions, and Challenges

Ahmed SRHIR¹, Tomader MAZRI², Mohammed, BENBRAHIM³

Department of Electrical Engineering-Networks and Telecommunication Systems-National School of Applied Sciences,
Ibn Tofail University, Kenitra, Morocco

Abstract—Now-a-days, the Internet of Things (IoT) has enormous potential and growth impact due to the technological revolution and the spread and appearance of events. It has received considerable attention from researchers and is considered the future of the Internet; however, according to Cisco Inc. reports, the IoT will be crucial in transforming our standards of living, as well as our corporate and commercial models. By 2023, the number of devices connected to IP networks will reach more than three times the population of the entire world. In addition, there will be 5.3 billion Internet users worldwide, representing 66% of the world's population, up from 3.9 billion in 2018. IoT enables billions of devices and services to connect to each other and exchange information; however, most of these IoT devices can be easily compromised and are subject to various security attacks. In this article, we present and discuss the main IoT security issues, categorizing them according to the IoT layer architecture and the protocols used for networking. In the following, we describe the security requirements as well as the current attacks and methods with adequate solutions and architecture for avoiding these issues and security breaches.

Keywords—Internet of things (IoT); IoT security; IoT protocols; security issues in IoT; network security; data security

I. INTRODUCTION

Due to the continuous fast development of smart environments and broadband networks, the Internet of Things is now widely accepted and popular, earning its designation as the main standard for low-loss networks (LLN) with limited resources. It refers to a network where "objects" or devices that are integrated with sensors are interlinked through a network that may either be private or public [1, 2]. The sharing of information between the different devices is done through the network using standard communication protocols. The intelligent connected devices, or "objects," range from basic accessories to larger devices that each includes chips and detection sensors. For example, smart shoes contain chips that track and analyze fitness data [3]. Likewise, electric devices that may be operated remotely through the IoT, as well as any security cameras that are installed for surveillance of a place can be controlled remotely from anywhere. In addition to personal use, IoT also meets community needs. Several intelligent devices perform various functions such as surgical operation monitoring in hospitals, detection of weather conditions, automobile tracking, and connectivity. Due to its use in daily life, the IoT's potential size is obvious. It keeps expanding quickly as a result of the development of hardware techniques like bandwidth augmentation using networks based on cognitive radio to solve the underutilization of frequency

spectrum resources [4,5]. Limited resources are one of the major challenges to IoT security, given that small devices or objects with sensors have limited computing and processing power and memory, making it easy for attackers to exploit these devices. On the other hand, the main challenge is ensuring consistency and adaptation between solutions with these limited architectures. For this reason, the global deployment architecture should be secured and reinforced against attacks that could impact the services offered by the IoT. In the last few years, considerable work has been done to solve security in the IoT ecosystem paradigm. While some methodologies focus on addressing security concerns at a particular layer, others strive to offer comprehensive end-to-end security for the entire Internet of Things (IoT) layer.

Security issues are categorized according to application, architecture, communication, and data in research by Alaba et al. [6]. The traditional layered design differs from the suggested topology for IoT security. After that, hardware, network, and application component threats are analyzed. Another study by Granjal et al. [7] examines and addresses security risks with IoT protocol definitions. The security studies detailed in [8–9] analyze and contrast various cryptographic algorithms and key management systems. Similar goals are shared by the authors of [10–11], who want to compare and evaluate intrusion detection technologies. IoT privacy, security, access control, and confidentiality contributions, as well as cross-software security, are examined in a review by Sicari et al. [12]. Additionally, Oleshchuk [13] presents an overview of IoT privacy preservation strategies. The author outlines secure multi-party computations that can be used to maintain user privacy, and attribute-based access control mechanisms are outlined as an efficient solution to ensure privacy in the Internet of Things. Numerous security risks for cloud-based IoT are covered by Zhou et al. [14], along with potential preventative measures. They discuss IoT employing clouds for key management, node compromise, layer removal or addition, identity and location privacy, and node compromise. In their article [15], Zhang et al. highlight the fundamental issues with IoT security including the requirement for lightweight cryptographic processes, privacy, unique object identification, authentication and authorization, malware, and software susceptibility.

Our primary contributions and methods are enumerated below in comparison to survey studies that have been published in the literature:

- A parametric examination of security risks and how well they fit with potential IoT solutions.

- IoT security challenges classification and categorization in relation to the various tiers, as well as the solutions employed.
- Future views providing workable answers to security issues with the Internet of Things.

The remaining sections of the paper are structured as follows: The IoT architecture is explained in Section II, as well as the security challenges encountered at every level of the IoT protocol stack. In Section III, the major security challenges and issues are categorized, while Section IV examines and provides a map of potential solutions, and finally, Section V concludes the paper.

II. IOT ARCHITECTURE AND SECURITY REQUIREMENTS

The integration of the Internet of Things is a fundamental element in the development of an intelligent ecosystem, connecting physical objects to the internet. It lets sensors, controllers, machines, people, and objects work together in a new way so that they can be intelligently identified, located, tracked, and monitored. While the Internet of Things is still in its development, many applications and standards must be adopted, including home automation, traffic control, smart cars, smart grids, etc. [16]. Fig. 1 illustrates how an IoT deployment typically consists of a number of heterogeneous devices with embedded sensors connected to one another through a network. These devices are all individually recognizable and typically have low power consumption, little memory, and limited computational power. In order to remotely transmit data and services to IoT consumers, gateways are used to link IoT devices to the public domain.

Fig. 1. Overview of IoT components.

A. IoT Architecture

Protocols are a group of instructions that allow data to be sent and received between electronic devices while respecting the agreements made in advance regarding the structure of the data. Accordingly, IoT protocols are standards that allow data to be exchanged and transmitted across the internet and between devices. Different IoT architectures are proposed by different authors, such as middleware-based architectures, Service-oriented architecture (SOA), architectures with six layers and three layers [17], In our case, and to address the fundamental communication issue, we will focus on the

fundamental three-layer IoT architecture depicted in Fig. 2, which provides a general list of the most widely used protocols and standards for powering IoT devices, applications, and systems. As stated below, these three levels consist of a "perception layer," a "network layer," and an "application layer":

- The perception layer consists of physical and communication devices composed of captors and controllers that collect, desensitize, and treat information before transmitting it to the network layer. It includes the physical devices like cameras, Radio Frequency Identification (RFID),
- The network and transport layer represents a communication tier that uses gateways, switches, and routers to transmit and route data aggregated at the perception layer and delivered to the application layer.
- The application layer is a communication layer that contains the application in charge of the interaction with the users.

Every IoT layer employs a distinct set of protocols and standards, as shown in Fig. 2, protocols used by physical devices and communication technology include Zigbee Wi-Fi, 4G/5G, NB-IoT, and LoRaWAN. Different protocols are used by the network and the transport, including IPv6, 6LoWPAN, RPL, TCP/UDP TLS, and DTLS. The message and application protocols include XML, HTTP, MQTT, and CoAP. Additionally, many protocols, including OAuth 2.0, OpenID, and PKI, are used for key management and authentication [17, 18]. Fig. 2 also illustrates a structured architecture based on the most prevalent IoT protocols for applications, emailing, authentication, key management, routing and transfer, and those for physical devices. The physical layer and the MAC (Media Access Control) layer are two low-level layers specified by the IEEE 802.15.4 standard. The physical layer specification relates to data rates and frequency bands for wireless channels used for communication. The channel access techniques and synchronization are covered by the MAC layer specification. Routing Protocol for Low Power and Lossy Networks (RPL) [19] is used to provide IPv6 across low-power wireless personal area network (6LoWPAN) environments, enabling connection and exchange between numerous points and a single point; this standard also permits point-to-point traffic. Due to the limited payload, User Datagram Protocol (UDP) [20] is used in the IoT application architecture for communication. The UDP protocol is considered more efficient and simpler than the TCP protocol. Additionally, UDP header compression guarantees that the restricted payload space is used more effectively [21]. CoAP (Constrained Application Protocol) [22] presents a model for low-power loss networks working in confined spaces based on demand response. Additionally, it permits asynchronous message transmission and has the ability to connect to IoT resources using HTTP mapping, LPWAN enables long-range connections of IoT "objects." It provides low-power and low-bit-rate connectivity compared to a wireless WAN that demands more energy to operate at a high bit rate. LPWAN provides connectivity between gateways and end devices to manage changing data rates.

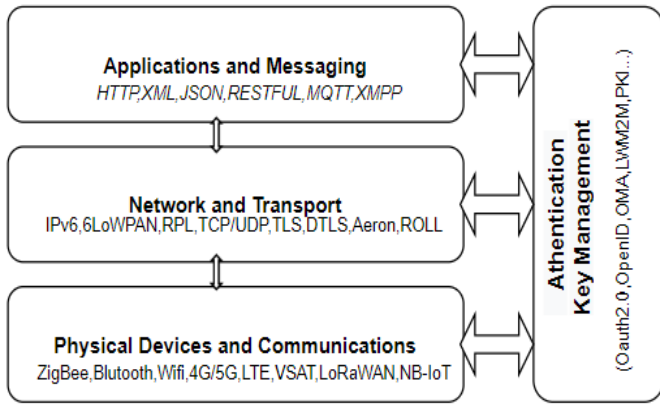

Fig. 2. The protocols and standards of IoT.

B. Security Requirements

Several research initiatives have been proposed in recent years to identify various methods for securing the connection between an end device and its components. The primary objectives of the Internet of Things are the configuration of a smart environment and autonomous devices, such as smart living, smart objects, smart health, and smart cities, among others domains [23]. Ensuring security in smart systems poses a major challenge, due to the diversity and complexity of the end device and its components [24,25]. Fig. 3 illustrates the considerations that must be made to ensure the reliability and security of IoT implementation.

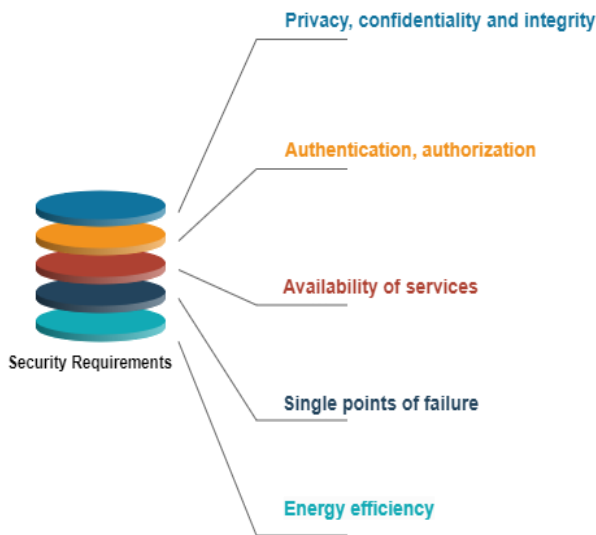

Fig. 3. Security requirements for IoT.

- Privacy, confidentiality, and integrity

Given that IoT data moves over several network hops, an appropriate encryption technique is needed in order to assure

the privacy of the data. And this, because of the diversity of services and microservices integration, means that the vast majority of the information saved and kept on any device is exposed to invasions of privacy, and assaults can allow a malicious user to gain data integrity by changing the saved data for illegal uses.

- Authentication and authorization

In order to ensure secured IoT communication between different devices, authentication is paramount between the different parties who are communicating. the multiplicity of IoT device architectures and different underlying ecosystems are primarily responsible for the IoT devices' wide range of authentication procedures. Creating an associated standard protocol for authentication in the IoT will be extremely difficult in these situations. Similar to that, authorization methods make sure that only authorized people are allowed access to systems or information. Additionally, keeping track of how resources are used and making sure they are used correctly through audits and reports is a reliable and effective way to manage network security.

- Availability of services

Traditional denial-of-service attacks against IoT devices could obstruct the delivery of services. Different tactics, such as replay assaults, sinkhole attacks, and jammer advertisements, employ IoT components at various stages to reduce the quality of service (QoS) offered to IoT users.

- Single points of failure

IoT-based infrastructure's continuous reliance on heterogeneous networks has the potential to expose numerous single points of failure, which could harm the IoT's intended services. As a result, it's necessary to create a safe environment in order to accommodate a greater number of Internet of Things devices and to propose other techniques to build a fault-tolerant system.

- Energy management

IoT devices frequently have a small battery life and a weak storage capacity. Attacks on IoT systems can lead to increased power usage by saturating the network and draining device resources with repetitive and false service queries.

III. SECURITY ISSUES CLASSIFICATION

Nowadays, several reports and research findings indicate that the IoT is susceptible to various forms of attack, such as active and passive attacks, which have the potential to disrupt the operation of the device as well as affect its functionality and remove the benefits of its services. A taxonomy of security issues related to the Internet of Things has been developed and presented in Fig. 4 based on the IoT deployment architecture, as mentioned below:

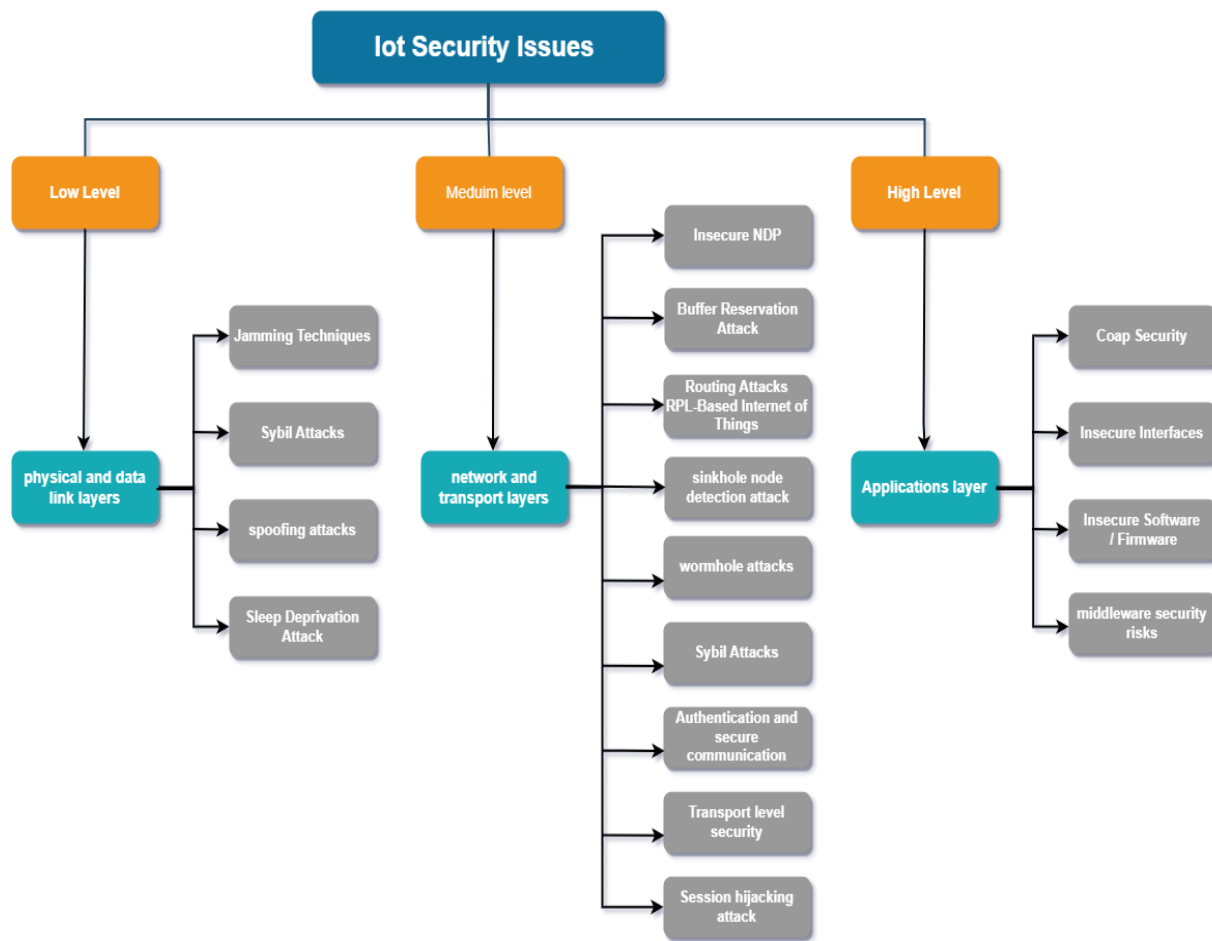

Fig. 4. Classification of security issues.

A. Low Security Issues

It relates to security vulnerabilities at the hardware level as well as the physical and data link levels of communication, as described below:

- Jamming attacks

Jamming is an attack method that disrupts the radio signals utilized by nodes in a network. It's characterized as the intentional use of electromagnetic radiation to disrupt or disable a communication system. These attacks aim to degrade networks by transmitting Radio frequency (RF) signals without having to adhere to a specified protocol [26, 27]. Radio interference has a significant impact on how a network operates because it interferes with authorized nodes' ability to send and receive data, which makes the system unstable or dysfunctional.

- Low-level Sybil attacks:

Malicious Sybil nodes utilize false identities to carry out Sybil attacks on wireless networks and impair IoT capabilities. A Sybil node may employ random, fabricated MAC values on the physical layer to pretend to be another device in order to drain network resources [28]. This could prevent the authorized nodes from getting access to resources.

- Spoofing attacks

Spoofing attacks are simple to launch on an access IoT network. An attacker can pretend to be another approved IoT device by claiming the real user's MAC or IP (internet protocol) address. The attacker can perform attacks on the IoT network after gaining illegal access.

- Sleep deprivation attack

The target of this attack is battery-operated computational hardware, like a sensor node, which is trying to conserve power by entering a low-power sleep state for as long as feasible without disrupting the node's activities [29].

By keeping the sensor nodes awake, "sleep deprivation" attacks can take advantage of energy-constrained IoT devices [30]. The battery is drained when too many tasks are scheduled to run in 6LoWPAN.

B. Medium-Level Security Issues

The security concerns at the intermediate level primarily pertain to the communication, routing, and session management that occur at the network and transport layers of IoT, as outlined below:

- Insecure NDP

Every device must have a unique network identifier in order to comply with the IoT deployment architecture. Secure

communication transmission is required for security purposes. To ensure that all information sent to a device across a continuous connection reaches its intended destination, the phase of neighbor discovery performs a number of operations prior to data transfer, including router detection and resolving addresses [31]. Utilizing neighbor discovery packets without conducting adequate verification could have serious consequences, including distributed denial of service (DDoS) attacks.

- Buffer reservation attack.

An attacker may take advantage of this by delivering incomplete packets to a receiving node must allocate slots for the reassembling of received packets [32]. Due to the attacker's unfinished packets taking up space and causing other fragment packets to be deleted, this attack causes denial-of-service.

- Routing Attacks RPL-Based

The IPv6 Routing Protocol for Low-Power and Lossy Networks (RPL) is susceptible to numerous attacks that are launched by infected network nodes [33]. This attack might cause resource exhaustion and eavesdropping.

- Sinkhole Node detection attacks

The attacker uses falsified routing information to lure nearby nodes, after which it performs selective forwarding or modifies the data traveling through them as illustrated in Fig. 5. The attacking node asserts that it is providing a very alluring link. As a result, this node is skipped by a lot of traffic. The sinkhole attack can be combined with other attacks besides straightforward traffic analysis, such as selective forwarding or denial of service.

Fig. 5. Sinkhole attack in Internet of Things communication.

- wormhole attacks

During a wormhole attack, as illustrated in Fig. 6 the data is delivered across many channels, or the malicious node makes use of the incoming data in various ways. Due to these attacks, which form a tunnel connecting two nodes to ensure that the packets coming from one node immediately reach the other node, 6LoWPAN operations can be further hampered by network attacks [34].

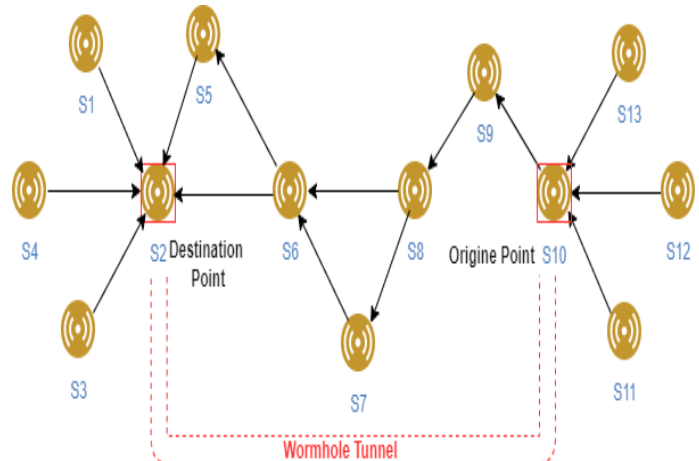

Fig. 6. Wormhole attack in internet of things.

- Sybil Attacks

The deployment of Sybil nodes can affect network performance and breach data privacy. In a network, Sybil nodes communicating under false identities run the risk of sending spam, spreading malicious software, or conducting phishing attacks [35].

In Fig. 7, the lowest layer contains one Sybil node and four regular nodes. However, due to the fact that the Sybil node carries several identities in the overlay network, there are three Sybil nodes in the top layer. In this situation, the Sybil node has the ability to seize network control. For instance, the Sybil node has the ability to transmit malicious software to conduct a DDoS attack or fake computation results to disrupt the nodes that are not malicious.

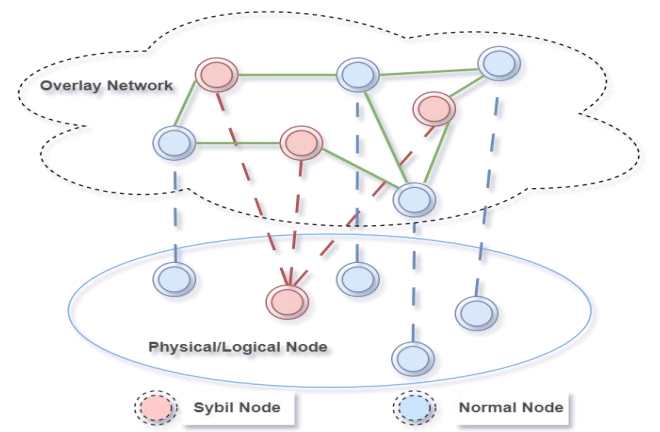

Fig. 7. illustration of Sybil nodes and the Sybil attack.

- Authentication and secure communication

Device identification is done through authentication, and permissions are given through authorization. IoT devices employ these procedures to perform role-based access control and make sure that only the access and permissions necessary for their tasks are granted to devices. The use of applications and other devices requires authorization. Cloud accounts, gateways, and key management systems are required for the IoT to authenticate people and devices. Any security flaw at the network layer or significant cost associated with communication security may expose the network to several vulnerabilities [36–38]. Due to limited resources, for example, Datagram Transport Level Security (DTLS) overhead must be kept to a minimum, and the cryptographic algorithms enabling secure data flow in the Internet of Things require consideration of the lack of other resources and performance [39].

- Transport level security

The goal of end-to-end security at the transport level is to provide secure mechanisms which ensure that the sending node's data is reliably received by the target destination node [37]. It required extensive authentication processes that offer encrypted secure message transfer while maintaining privacy and run with the least amount of overhead possible [40,41].

- Session hijacking attack

Denial-of-service may be caused via the hijacking of a session on the transport layer using falsified messages [42]. An attacker node might prolong the session between the two nodes by acting as though it is the victim node by faking its identity. By changing the sequence numbers, the communicating nodes may even need to resend messages.

C. High Level Security Issues

Most high-level security problems affect IoT apps that run at the application and communications layers, as will be discussed below:

- CoAP security

A CoAP (Constrained Application Protocol) is an IETF standard, and RFC 7252 defines the basic protocol. Additional extensions are defined in several RFCs. It works well for nodes that communicate over LPWAN, such as 6LoWPAN, and are powered by basic microcontrollers with little ROM and RAM. UDP is used as the underlying transport protocol, and it operates at the application layer of the TCP/IP stack. RFC 8323, a new standard that covers CoAP over TCP, TLS, and WebSockets, was published in 2018. Attacks can potentially target the high-level layer, which houses the application layer [43–44]. In order to guarantee end-to-end security, the Limited Application Protocol (CoAP) combines DTLS bindings with a variety of security options. The CoAP messages must be encrypted for safe communication and adhere to a certain format specified in RFC-7252 [22]. Similar to this, suitable key management and authentication techniques are needed for CoAP's multicast capability.

- Insecure Ecosystem interfaces

The user interfaces for IoT services on the web, mobile, and cloud are vulnerable to a number of risks that pose a major risk to data privacy [45].

- Insecure Software / Firmware

Insecure software/firmware is one source of numerous IoT vulnerabilities [45]. Carefully testing the code that uses languages like JSON, XML, SQLi, and XSS is necessary. Similar to this, firmware and software upgrades should be made properly.

- Middleware security

The Internet of Things middleware must be sufficiently secure to enable service delivery among the diverse elements of the Internet of Things paradigm [61,62]. To offer reliable and safe communication, several middleware-based interfaces and environments must be used.

IV. SECURITY SOLUTIONS FOR IOT

IoT security threats take advantage of flaws in a variety of components, including applications and interfaces, network components, and different levels of software, firmware, and physical devices. In the IoT paradigm, users communicate with these components using protocols that might not be secure. We've broken out the security risks for each IoT layer level in this area, along with their relevance and the suggested appropriate solutions for each of the cases listed in Section III.

This section examines the key security solutions that have been put forth. Table I presents a comparative analysis of security threats and potential countermeasures for the lowest level, the middle level, which includes the transit layer, and the highest level, respectively. All of the threat parameters, their effects, and comparative analyses are taken into consideration.

A. Low-Level Security Solutions

Jamming attacks on Wireless Sensor Networks (WSN) involve interference that causes message collisions or channel floods. Young et al. [48] present a method for detecting jamming attacks by determining the signal quality, which will be used to extract noisy signals; attacks can be detected in this manner. Then, for attack detection, these statistics are compared to preset threshold levels. False MAC values could be used by a malicious Sybil node to impersonate another device. It may lead to resource exhaustion and the denial of access to authorized network devices. Demirbas et al. [49] provide a method for identifying Sybil attacks using signal strength measures. In order to determine the sender position during message communication, their method deploys detector nodes. When a different message communication has the same sender location but a different sender identity, a Sybil attack is suspected. MAC address signal strength measurements are used to spot spoofing attempts. The study [30] outlines a methodology for preventing sleep deprivation attacks in WSNs. The suggested architecture uses a cluster-oriented model, in which each cluster is further broken down across various areas. Avoiding long-distance communication lowers energy use. A wireless sensor network architecture with five layers is used by the framework to perform intrusion detection.

TABLE I. COMPARATIVE ANALYSIS OF SECURITY THREATS AT THE IoT LEVEL, IMPLICATIONS, AND POTENTIAL COUNTERMEASURES

IoT levels	Security issue	Implications	layers	Suggested Solution
Low	Jamming Technique	Destabilization and Denial of service (DoS)	Physical	Changing frequencies and locations, encoding packets, and measuring the packet delivery ratio.
	Sybil attacks	Network disruption, DoS	Physical	Measurements of the signal strength and channel estimation
	Spoofing attacks	Network disruption, DDoS	Physical	Measurements of the signal intensity and channel estimation
	Sleep deprivation attack	Energy consumption	Link	Intrusion detection system with multiple layers
Medium	Insecure NDP	IP Spoofing	Network	Using SEND's signature algorithm agility and multiple-key CGA to secure NDP messages Signature authentication using Elliptic Curve Cryptography (ECC)
	wormhole attacks	DoS	Network	Rank verification through hashing chain function Anomaly detection through IDS rank verification via the hash chain function
	Buffer reservation attack	Closing reassembly buffer	6LoWPAN adaptation, Network	Address space layout randomization (ASLR) Split buffer approach
	Authentication and secure communication	Privacy violation	6LoWPAN adaptation, Transport Network	OTP, Digital Signature, and Mutual Authentication Using ECDSA for signing and verification and ECDH for encryption Public Key Cryptography TPM employing RSA, hybrid authentication, compression and software-based AES IACAC using the Elliptic Curve Cryptography
	Routing Attacks RPL-Based	Eavesdropping, man-in-the-middle attacks	Network	Monitoring node behavior and authentication Using hashing and signatures Placement of an IDS or IPS in the IoT Eliminating malicious nodes from RPL by using a whitelist or a blacklist Nodes
	Sinkhole Node detection attacks	DoS	Network	Signal intensity measurement, Graph Traversal Analysis, IDS anomaly detection, cryptographic key management, communication behavior analysis, rank verification via hash chain function
	Sybil Attacks	Privacy violation, spamming	Network	verification of identities observing user behavior and keeping a list of trusted and untrusted users
	Transport level security	Privacy violation eavesdropping	Transport, Network	Using the 6LoWPAN Border Router (6LBR) as a conduit between nodes and the inter-net IKEv2 employing compressed UDP, compressed IPSEC, and DTLS header compression.
Session hijacking attack	DoS	Transport	Encrypting all data transmitted Session Management Session Key	
High	CoAP security	Network bottleneck, DoS	Application, Network	protection by Datagram Transport Layer Security (DTLS) TLS-tunnel Filtering messages using 6LBR
	Insecure interfaces	DoS, invasion of privacy, and network disruption	Application	Use of https and firewalls; prevention of the use of weak passwords by enforcing expiration policies and forcing compliance with password complexity requirements; assessment of the interface against software tool vulnerabilities (SQLi and XSS).
	Insecure Software / Firmware	DoS, invasion of privacy, and network failure	Application, Transport	updating software and firmware securely on a regular basis, using file signatures, and encrypting data with validation
	Middleware security	DoS, invasion of privacy, and network failure	Application, Transport, Network	The safeguarding of communication is achieved through the implementation of authentication protocols, security policies, key management mechanisms between devices, gateways, and M2M components, as well as transparent middleware.

B. Mediate-Level Security Solutions

Riaz et al. [31] suggest a security system that includes modules for secure neighbor finding, authentication, key generation, and data encryption. Elliptic Curve Cryptography (ECC) [50] is utilized for secure neighbor finding. In the neighbor discovery phase, nodes are identified using ECC public key signatures. Depending on the needs of the application, both symmetric and asymmetric key management solutions are recommended for deployment. Then, in order to guarantee node-to-node security, the encrypted data is transmitted.

A node's reassembly buffer could be prevented by a buffer reservation attack. This attack is lessened by the split buffer technique [32], which raises the cost of launching the attack by necessitating the transmission of full fragmented packets in brief bursts. Each node must calculate the completion rate of the packet and monitor the behavior of sending pieces. When under load, the node may reject packets that have low fragment percentages or a high fragment sending pattern fluctuation.

The Directed Acyclic Graph (DAG) is created by the RPL protocol with root at any of the gateways. RPL utilizes ranks to describe the quality of the path to the last sink node. To link to the root for eavesdropping, a node's rank value may be reduced. Version Number and Rank Authentication (VeRA), a proposed security technique, authenticates version numbers and rankings using the hash function (SHA), MAC function (HMAC), and digital signature (RSA) [51,52].

Weekly et al. propose a strategy that involves failover and authentication techniques to counter sinkhole attacks. [53], Pirzada et al. [54] provide another approach to thwart sinkhole attacks by utilizing various trust levels. Their method makes use of a variety of Dynamic Source Routing (DSR) protocol features to identify and prevent wormhole and sinkhole attacks in wireless networks.

Pseudo-identities, also known as Sybil nodes, are used in Sybil attacks on the network layer to impersonate numerous distinct identities. Peer-to-peer (P2P) and distributed systems, such as the Internet of Things, are seriously at risk from these attacks. A trust connection is added to social networks to prevent the establishment of Sybil identities [55]. By moving across the graph randomly or utilizing community detection methods, legitimate nodes can use the countermeasures employing social graphs to identify Sybil nodes. [42,56–57] Similar to this, users' behavior in relation to network activity is examined; users who consistently follow the same pattern are automatically labeled as sybils. [35]. Mahalle et al. have proposed a method that can protect the Internet of Things against attacks involving a man-in-the-middle as well as denial-of-service (DoS) attacks.

In a networked environment, man-in-the-middle attacks resulting from secret keys exposed as a result of eavesdropping may lead to identity theft. Additionally, the credentials or identity information might be replayed by attackers to influence network traffic. The Elliptic Curve Cryptography-based Diffie Hellman algorithm is used to mutually authenticate devices for communication and access via encryption and secret keys. With capability-based access, two

devices' capacity to communicate is first confirmed. Additionally, before performing the actual operation, the device's capacity to carry out the specified functionality is verified. To create secret keys in the proposed method is known as Identity Authentication and Capability-based Access Control (IACAC). Kothmayr et al. [59, 60] detail a strategy for achieving end-to-end security by employing public key cryptography in conjunction with two-way authentication. For the purpose of storing the network's publishers' access privileges, a reliable access control server is built, and the publisher's website must store both the publisher's and the Authority's certificates. Authentication can be done with RSA or DTLS preshared keys by the Trusted Platform Module (TPM) processors [61], whereas TPMs are utilized to transmit RSA certificates in X.509 format.

Alghamdi et al. [62] recommend using Transport Layer Security pre-shared key ciphersuites (TLS-PSK) to ensure security during the entire transaction, allowing communication to occur between HTTP and CoAP. This necessitates a conversion message on the DTLS layer. Similar to this, a DTLS extension including pre-shared key (PSK) is recommended to provide processing of session keys for multicast message security. The 6LoWPAN Border Router (6LBR) is proposed as a dedicated authentication approach for transport-level security [37]. The 6LBR is able to intercept packets, compute for public key authentication, and then forward them. For the implementation of transport-level security, elliptic curve cryptography (ECC) is used. Also, end-to-end security at the transport level has been proposed using a variety of header compression approaches. Raza et al. [63] offer a method for reducing the size of the maximum transmission unit (MTU) of 6LoWPAN packets by compressing DTLS Record and Handshake headers and other Handshake data. An additional technique for encryption that employs hash functions for devices with limited resources has been suggested. The efficiency of the system is attributed to its minimal computational overhead. A proposed approach for achieving mutual authentication in fog computing environments that involve devices with limited resources is presented in research [58].

Park et al. [42] provide a mutual authentication strategy for safe session management with symmetric key-based encryption techniques. The suggested method first chooses a random number, encrypts it, and creates a session key that is then used to encrypt another random number. The encrypted number serves as an authentication key. Another hash-based encryption technique is also suggested for devices with limited resources that implement hash functions. As a result of the minimal computational overhead, it operates effectively.

C. High-Level Security Solutions

A method using TLS and DTLS is suggested by Brachmann et al. [43] to secure CoAP-based Low-power and Lossy Networks (LLN) connected to the internet. The suggested method is effective in situations where a 6LoWPAN Border Router (6LBR) connects the LLN to the internet so that devices can be accessed remotely. The CoAP and HTTP clients are serviced by the LLN nodes. It is suggested to map TLS and DTLS to provide end-to-end security that shields LLNs against internet-based threats.

Granjal et al. [64] present a different method of protecting messages for applications connecting across the internet utilizing various CoAP security parameters. SecurityOn, SecurityToken, and SecurityEncap are the new security settings for CoAP.

The SecurityOn option is important for the security of CoAP messages at the application level. Through identity and permission, the SecurityToken option at the application level makes it easier to access CoAP resources. The SecurityEncap option performs [65] and proposes a security paradigm that uses 6LBR for message filtration to guarantee end-to-end security for IoT. The TLS-DTLS tunnel can be formed. Similar to this, it is advised that message verification or replay detection be carried out at the CoAP device when two hosts share the same key. Sethi et al. [44] present an energy-efficient security paradigm for IoT-based CoAP based on public key cryptography. The proposed security architecture, which is a model, employs a mirror proxy (MP) and resource directory to service demands throughout the server's sleep process and to supply a catalog of the endpoint's resources.

The OWASP project [45] offers suggestions for IoT security countermeasures to deal with vulnerable high-level interfaces, including setups that prevent the use of weak passwords and evaluate the interface for common software tool weaknesses (SQLi and XSS), and utilize firewalls and secure HTTPS connections. Additionally, through a secure transfer method, the device's software or firmware should be frequently updated. The updated files need to be signed and correctly validated before installation, and they should be downloaded from a secure site.

Conzon et al. [46] have proposed the utilization of VIRTUS middleware to provide authentication and encryption for safeguarding distributed applications that operate within an IoT ecosystem.

IoT middleware solutions are heavily used in contexts with limited resources, such as memory, computational power, and the network. Because of this, middleware system components must cope with lightweight security techniques. However, it is seen as difficult to deploy new security strategies in accordance with the demands of certain Internet of Things applications. Liu et al. [47] propose a middleware server that provides data filtering during communication among heterogeneous IoT environments. The suggested middleware offers effective methods for addressing, naming, and profiling in a variety of settings. A key hierarchy comprising keys for the root, applications, and services is used to achieve the common authentication, authorization, and accounting (AAA) functionalities. A web-based portal is used to register for services, limiting access to those services to approved users. A common architecture with various security layers is suggested for machine-to-machine (M2M) communications in the IoT environment [66].

The resource contents should be encrypted for M2M service layer security, and securing message transmission using TLS or DTLS sessions is recommended. The study [67] suggests a security architecture for IoT middleware that makes use of accepted encryption techniques like AES to ensure data confidentiality. The proposed architecture-based approach has

the ability to secure the communications of IoT entities, such as users, devices, and services.

V. CONCLUSION

Today's Internet of Things devices are unsafe and vulnerable, and they are not able to provide any security to protect themselves. This is due to the resource limitations in IoT devices as well as the lack of developed standards and weakly implemented security measures in hardware and software.

This paper presents an analysis of IoT security issues. The components of IoT technology are defined, and the areas of its application are considered. An analysis of the security of the Internet of Things has been carried out; looking at assets and technologies, and a classification of these issues has been compiled into three groups according to the standard IoT layers: high, medium, and low. We briefly go over the literature-proposed approaches for utilizing IoT security at various tiers; requirement for security, including privacy, authenticity, and integrity, is discussed; in addition, we present a parametric evaluation of IoT possible attacks and countermeasures. We analyze the effects of the attack and connect them to countermeasures that have been presented in the literature. The ultimate goal of addressing IoT security and protection issues is to ensure that all assets are prioritized, maintain the required level of privacy, and achieve and maintain a high level of attack resistance, thereby ensuring comprehensive security.

A Mobile App for the Identification of Flowers Using Deep Learning

Gandhinee Rajkomar, Sameerchand Pudaruth
ICT Department, FoICDT, University of Mauritius, Mauritius

Abstract—Flowers are admired and used by people all around the world for their fragrance, religious significance, and medicinal capabilities. The accurate taxonomy of these flower species is critical for biodiversity conservation and research. Non-experts typically need to spend a lot of time examining botanical guides in order to accurately identify a flower, which can be challenging and time-consuming. In this study, an innovative mobile application named FloralCam has been developed for the identification of flower species that are commonly found in Mauritius. Our dataset, named FlowerNet, was collected using a smartphone in a natural environment setting and consists of 11660 images, with 110 images for each of the 106 flower species. Seventy percent of the data was used for training, twenty percent for validation and the remaining ten percent for testing. Using the approach of transfer learning, pre-trained convolutional neural networks (CNNs) such as the InceptionV3, MobileNetV2 and ResNet50V2 were fine tuned on the custom dataset created. The best performance was achieved with the fine tuned MobileNetV2 model with accuracy 99.74% and prediction time 0.09 seconds. The best model was then converted to TensorFlow Lite format and integrated in a mobile application which was built using Flutter. Furthermore, the models were also tested on the benchmark Oxford 102 dataset and MobileNetV2 obtained the highest classification accuracy of 95.90%. The mobile application, the dataset and the deep learning models developed can be used to support future research in the field of flower recognition.

Keywords—Flowers; deep learning; mobile application; Mauritius

I. INTRODUCTION

Flowers have long been appreciated as a significant phenomenon in the history of mankind [1]. They are adored and used by humans around the globe to embellish their environment as well as for fragrance, religion, and medicine [2]. Flowering plants, commonly known as angiosperms (Merriam-Webster, 2021), have been the most dominant plant biodiversity in our terrestrial ecosystem for over 60 million years [3]. The dominance of these living organisms over more primitive angiosperms, such as pines and palms, was even described as an “abominable mystery” by Charles Darwin [4]. According to [5], there are about 400,000 species of plants on Earth. Over the last few decades, the world’s biomass have undergone a change of more than 10% owing to the various effects of climate change and land use. In addition, the increasing invasion of alien plant species has shown a negative impact on native plants, destroying our natural ecosystem. The accurate identification of invasive non-native plant species can therefore aid in the development of awareness and educational programs contributing to the mitigation of their impacts [5].

According to [6], accurate identification of species is

critical for ecological monitoring. Therefore, proper plant and flower identification can help stakeholders with a variety of activities, such as investigating the biodiversity richness of an area and monitoring the population of endangered species while species misidentification can lead to erroneous conservation strategies [7]. As can be deduced, accurate species classification is essential for biodiversity conservation and research. Furthermore, accurate flower classification is a non-tedious task for skilled taxonomists and for people with expertise in anthology and botany [8]. Non-experts and novices typically find it complex and time-consuming to properly identify a flower. They usually must spend a significant amount of time examining botanical guides [9]. Automatic recognition technologies, such as machine learning (ML) and artificial intelligence (AI), can thus be utilised for the automatic identification of flowers, overcoming this taxonomic gap.

Several studies have been conducted on flower detection and recognition systems by employing different flower images and methods. Flower shape and colour, as well as the stamen region, can be used to identify different flowers [10]. Deep learning techniques such as the convolutional neural networks (CNN) are effective in distinguishing between numerous flower species [11]. Also, a mobile application for the automatic recognition of plants from their leaves was developed by [12]. However, no such application for flower recognition has yet been developed in Mauritius. The purpose of this paper is therefore to create such an application to facilitate the identification of flowers among common people with little or no botany knowledge through pictures taken using a smartphone. Moreover, information on the flower, such as its scientific name, common name, and a brief description will be displayed.

Today, it is still challenging to differentiate flowers in image processing systems. This is because many flower species exhibit similar shapes and colours. In addition, there are several difficulties when images are captured in natural outdoor scenes. For example, lighting is largely dependent on the weather conditions and the time of day. Furthermore, due to illumination considerations, specular highlights can affect the appearance of flowers, for example flowers may appear brighter or whiter than usual. Moreover, differences in occlusions, viewpoints, and scales in flower images, as well as uncertainty across different flower species with similar characteristics such as colour and form, contribute to the difficulties of automatic flower recognition. Another challenge is that the flower in the image must be segmented properly and with as few errors as possible [13].

Thus, a mobile application that can automatically identify and categorise flowers found in Mauritius will be developed.

The system will be created using AI and deep learning approaches and will make use of a new dataset of flowers, which are available in the Republic of Mauritius. This paper proceeds as follows. In section II, we provide an overview of all the related works that have been done on the automatic recognition of flowers. The datasets and the deep learning models used are described in section III. Section III discusses the results for each experiment, together with a comparison with existing works. Section V concludes the paper. A list of all the flowers using in this work are provided in the appendix.

II. RELATED WORKS

Artificial intelligence along with machine learning and deep learning, has been used for the development of software involving image recognition. Numerous models, approaches, and methodologies have been adopted in the classification of flower species. This section includes some pertinent research on various flower recognition studies.

One of the first flower recognition studies was conducted by [14] using an approach that indexes flower images based on their colours and spatial domains. Their research focus was mainly based on developing efficient methods for querying a database by colour for identification of flowers. An iterative segmentation algorithm with the aim of reducing unnecessary processing, was used to extract flower regions from their background using the flower's domain knowledge. This allowed for the indexing of flower images based solely on the colours present in the flower rather than the complete image. The database could then be queried by a specific colour or by supplying a sample flower image. This colour-based algorithm, however, makes it difficult to classify flowers primarily based on their colour, without considering their shape and other features.

An approach with the aim of classifying wildflowers based on more than one attribute (shape and colour) was implemented in [15]. Their method involved the use of a three-layered network along with a back propagation learning algorithm. A dataset consisting of 20 sets of images from 16 flower species was used, with each set containing two images of a plant: a leaf and a flower's frontal image captured using a digital camera. The proposed model was trained using 19 sets of images, with the remaining one was used for testing. They obtained an accuracy of 96% by using four features from the leaf and two from the flower. Their study also demonstrated that having too many features from the input images can have an impact on the recognition performance. Images were taken under controlled environments by positioning a black cloth behind the flower and leaf to enable easier segmentation.

Saitoh et al. enhanced their previous work by conducting further research to automatically recognise blooming flowers [16]. The innovation in their research was a new way of extracting the flowers from their background, as opposed to their earlier work, which used K-means clustering. This new method, called "Intelligent Scissors", was proposed by [17]. In this innovative approach, images were taken such that the flowers appeared in the centre of the photo with a defocused background. A total of 600 pictures, comprising 20 images per flower for 30 different species, were taken for this experiment. Of these, 19 images from each flower species were used for

training and the rest for testing. They achieved a classification accuracy of 90% by using 10 colour and shape features.

Traditional flower recognition studies usually implicate constraints such as variations in flower positions as well as having multiple flowers in an image, resulting in poor recognition performance. Kim et al. therefore proposed using the Difference Image Entropy (DIE) and contour features retrieved from images comprising of multi-flower objects in their mobile system [18]. Their application works by using two images. Firstly, the user draws a contour line around the flower region on the original congregated flower image to retrieve the first image. Next, contour features such as Zero-Crossing Rate (ZCR), minimum distance, and length of the contour line are extracted from the first image. These features are then used to reduce the number of flower candidates in the entire identification process. Following that, pixel subtraction is used to calculate the difference between the second image (the sub image containing the flower from the original image), and the normalized average of the reduced images obtained from the previous step. Their system used a dataset consisting of 20 images per flower species, for a total of 10 species. Ten images per flower for all species were used in training, and the other 10 images were used for testing the model. The recognition accuracy was 95%.

Automatically extracting flower boundaries from flower images is a key part of the recognition process. Given the difficulties of extracting flowers from its background, Aydin and Ugur presented the IPSOAntK-Means algorithm [19]. Their proposed solution combines the K-means algorithm with particle swarm optimisation and an ant colony algorithm to improve the flower boundary extraction process. Their approach was evaluated by using two different datasets, namely the CAVIAR and Oxford 17 datasets. The first dataset contained 1078 flowers from 113 distinct species, while the second one had flowers from 17 different species. Based on images from the CAVIAR dataset, their investigation revealed that the IPSOAntK-means method performed better than the K-means algorithm, with a segmentation accuracy of 96.4%. However, since only colour was used for the extraction process, the proposed method has decreased extraction performance on flowers with similar colours to that of their background.

Flowers come in a variety of colours and contours, and it is difficult to distinguish between them based only on their contours. In their mobile application, Hong and Choi used both colour and contour aspects, as well as K-means clustering and history matching, to increase the recognition accuracy [20]. A dataset consisting of 500 images was built, with 400 images used for training and the remaining 100 images used for testing their model. Their study demonstrated that they could improve contour detection quality by using colour-based contour detection and edge-based contour detection. They also observed that light and camera angle can lead to recognition failures by wrongly detecting the contours of the flowers. Therefore, they applied image recovery and partial recognition to mitigate this issue. With all these measures, their application obtained an accuracy of 94.8%.

Tiay et al. also attempted to recognise flowers based on their colour and edge properties by using the K-nearest neighbour (KNN) algorithm [21]. Their system displayed the top three similar flowers by using seven edge and forty colour

characteristics. Their proposed system consisted of 10 flower species with 50 images per species for testing and 100 images for training. Their study showed that having flowers with overlapping edge and colour properties can impact the classification accuracy. Their method resulted in a classification accuracy of more than 80%.

CNN-based recognition method was used by [22] for apple blossom identification. Dias et al. used a pre-trained CNN model with Support Vector Machines (SVM). Their detection rate was 90%. Another closely related approach was the hybrid method proposed by [23] Their method used CNN models along with feature selection methods. Their dataset had 4242 photos, non-uniformly distributed by species: each flower had a different number of images. Adding to that, their dataset was partitioned into 80% for training and the remaining 20% for testing. For feature extraction, the GoogleNet, AlexNet, ResNet-50, and VGG-16 CNN models were used and trained using the transfer learning method. The features extracted were then combined, and only the efficient ones were finalised using the f-regression and multiple inclusion criterion (MIC) methods yielding two sets of features. The 2-feature sets obtained were then compared and only the intersecting features in both sets (stable features) were extracted and classified using the SVM method. Their research indicated that the stable features obtained by the feature selection methods contributed to their high classification accuracy of 98.91%. However, their study was conducted using only 5 different flower species.

Liao and Zhang also used the feature selection method in their system along with a classification method based on SVM and a DenseNet architecture called DN-F-SVM [24]. DenseNet was utilised to extract several features from the flower images. Furthermore the Fast Correlation-Based Filter (FCBF), was employed to select the most effective features. The proposed model was trained on the Oxford 17 and Oxford 102 datasets. A classification accuracy of 99.12% and 98.90% was obtained, respectively for each dataset.

Researchers have also adopted the CNN ensemble approach to achieve optimum recognition accuracy in real-world applications. Such an approach was proposed by Wang et al. and it consisted of 3 steps [25]. The first phase, known as feature extraction, was achieved by pretraining the MobileNet models on the ILSVRC-2012-CLS image dataset. Following that, the retrieved features were used to train different classifiers. In addition, a re-sampling strategy was used to improve the diversity of the individual models used. Finally, an ensemble model was implemented using the weighted average technique. They tested the effectiveness of their system on two flower datasets consisting of 3670 and 1660 images from 5 flower species. The first dataset consisted of a training set with 3320 images and a test set with 350 images while the second dataset was used entirely for testing. Their findings demonstrated that the ensemble technique outperformed single classifiers. Adding to that, they also noted that the ensemble method can achieve better performance with a larger dataset.

A hybrid approach integrating the Viola-Jones algorithm and multi-template matching for effective and accurate identification of Anthurium flower cultivars was done in [26]. Their system had a computation time of less than 0.5s and a classification accuracy of more than 99%. Their results indicated that the technique had acceptable performance in detecting

the spadix region and very good performance in classifying the flower cultivars. Based on the VGG-16 CNN method, Lv et al. designed a flower classification model using the saliency detection algorithm [27]. They also used the stochastic gradient descent algorithm to adjust network weights. The dropout and the transfer learning methods were also used in optimising the model to reduce overfitting. They utilised the Oxford-102 dataset, which included 102 flower species and around 40-258 images per species for a total of 8189 images. The categorisation accuracy was 91.9%.

III. METHODOLOGY

This section describes the different steps followed to build the flower recognition system. The datasets and the deep learning models are used are described in detail.

A. Datasets

1) *FlowerNet*: The first and most critical step in implementation of the system is data acquisition. As a result of the non-availability of a large image dataset of flowers found in Mauritius at the beginning of the study, a new dataset had to be created to undertake the research. To achieve the primary objective of building a huge dataset, flower images were captured in various locations, including plant nurseries, neighbourhoods, gardens, and parks from the period of November 2021 to April 2022. For this research, the Huawei Y9 2019 smartphone with a resolution of 13 megapixels was utilised to collect data samples for 106 flower species. The dataset was constructed either by capturing close-up flower pictures continuously or extracting frames from recorded flower videos. The images and recorded videos were captured in a natural environment, such as in sunny and rainy weather conditions with variations in viewpoints, illumination and rotation. This new dataset was named as FlowerNet. It consists of 106 classes of flower species with a total of 11660 images. Each class has 110 different flower images. The dataset can be obtained by contacting the authors.

2) *Other datasets*: For a fair consideration, we will compare the performance of our implemented models with the Oxford 102 flower dataset. This dataset contains 40 to 258 images for 102 flower species commonly found in the UK with a total of 8189 images. The dataset contains images that vary in terms of scaling, lighting and poses.

Additionally, three different variations of these two datasets were also created:

- (i) A merged dataset consisting of flower categories from both the Oxford 102 and the FlowerNet but excluding the overlapping flowers from the Oxford 102 dataset,
- (ii) A flower dataset consisting of overlapping flowers from the Oxford 102 dataset only, and
- (iii) A flower dataset consisting of overlapping flowers from the FlowerNet dataset only.

3) *Overlapping flowerNet and oxford 102 datasets*: Table I shows the corresponding overlapping flowers in FlowerNet and Oxford 102 datasets. The flowers in the first column are used to create the overlapping flower dataset for the Oxford 102 dataset while the flowers in the second column are used to create the overlapping flower dataset for the FlowerNet dataset.

Also, flowers of different colours were considered as different flower categories in the FlowerNet dataset. However, for the creation of the overlapping flower dataset for the FlowerNet dataset, the different colours were merged as a single flower category as shown in Table II.

TABLE I. OVERLAPPING FLOWERS IN FLOWERNET AND OXFORD 102 DATASETS

#	Oxford 102 Dataset	FlowerNet Dataset
1	anthurium	Flamingo Lily (Pale Pink) Flamingo Lily (Dark Red)
2	blackberry lily	Leopard Flower
3	bougainvillea	Paper Flower (Fuchsia) Paper Flower (White) Paper Flower (Sundown Orange)
4	barbeton daisy	Gerbera (Dark Pink) Gerbera Daisy (Dark Orange) Gerbera Daisy (Fuchsia) Gerbera Daisy (Pale Orange) Gerbera Daisy (Pale Pink) Gerbera Daisy (Red) Gerbera Daisy (White) Gerbera Daisy (White_Pink) Gerbera Daisy (Yellow)
5	canna lily	Canna Lily
6	desert-rose	Desert Rose (Pink) Desert Rose (Dark Red)
7	frangipani	Frangipani (Yellow) Frangipani (Pink)
8	geranium	Geranium (Pink) Geranium (Red)
9	hibiscus	Hibiscus (Red) Hibiscus (Pale Pink) Hibiscus (Pale Orange)
10	mexican petunia	Mexican Petunia
11	oxeye daisy	Daisy (White)
12	red ginger	Ostrich Plume
13	rose	Rose (Cream) Rose (Pink) Rose (Dark Red)

TABLE II. OVERLAPPING FLOWER DATASET FOR FLOWERNET

#	Flower Category	No of Flowers
1	Canna lily	110
2	Daisy (White)	110
3	Desert Rose	220
4	Flamingo Lily	220
5	Frangipani	220
6	Geranium	220
7	Gerbera	990
8	Hibiscus	330
9	Leopard Flower	110
10	Mexican Petunia	110
11	Ostrich Plume	110
12	Paper Flower	330
13	Rose	330

B. Balancing the Imbalanced Datasets

Table III shows the different datasets: Oxford 102, Merged, Overlapping Oxford 102 and Overlapping FlowerNet. A hybrid sampling strategy combining both data augmentation and under sampling is adopted to balance the imbalanced datasets. Data augmentation is the process of artificially generating new data images using available images by utilising a variety of transformation techniques such as rotation, flipping, zooming, image blurring and adjustment of brightness and contrast. Under sampling, on the other hand refers to a technique whereby samples from the majority classes are randomly removed to balance the dataset.

TABLE III. DATASET SUMMARY

Dataset	# Images per Flower Category
Oxford 102	40 - 258
FlowerNet	110
Merged	40 - 258
Overlapping Oxford 102	42 - 171
Overlapping FlowerNet	110 - 990

C. Classification System

Different CNN models were trained on the FlowerNet dataset using the transfer learning approach. Transfer learning, as the term implies, is the application of knowledge gained from one problem to solve other distinct but related problems. In deep learning, the knowledge of a neural network previously trained to tackle one problem can be leveraged as a starting point to address another classification challenge. AlexNet, GoogleNet, MobileNet, ResNet, and VGG19 are a few examples of CNN models trained on the huge ImageNet dataset which encompasses 1.4 million images with 1000 classes. These pre-trained models can be repurposed for another target domain by using the fixed feature extraction and fine-tuning methods. During this study, several models were implemented, and the optimal model is chosen through a series of experiments and converted into TensorFlow Lite for integration into a mobile application. Fig. 1 illustrates the processes in the flower recognition system.

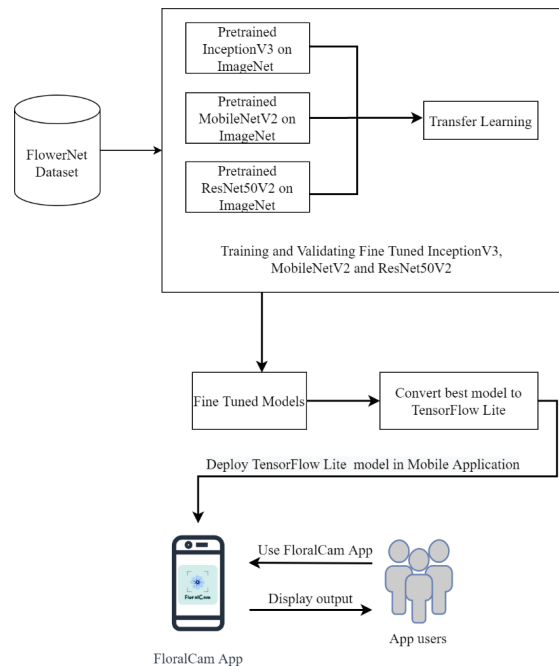

Fig. 1. The flow of processes in the flower recognition system.

D. Fine Tuning Pre-trained CNNs

The InceptionV3, MobileNetV2 and ResNet50V2 models were fine-tuned for the flower classification problem. The fully connected layers of the pretrained networks were removed while the remaining network, consisting of a sequence of convolution and pooling layers, were retained for fixed feature extractor. New classification layers were incorporated to

perform classification on the different flower classes. In our study, a global average pooling layer, dropout layer along with two dense layers with ReLu and a dense layer with SoftMax classifier were added as classification layers as shown in Fig. 2.

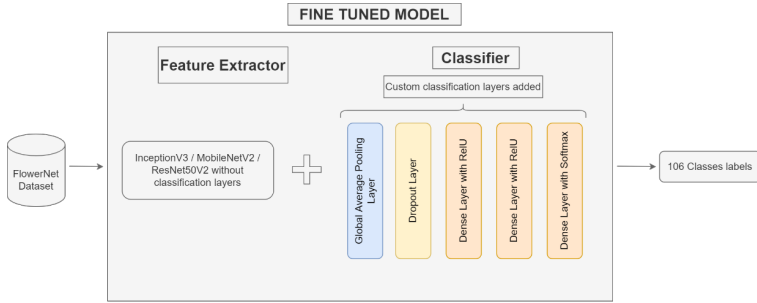

Fig. 2. Proposed architecture of fine-tuned InceptionV3, ResNet50V2 and MobileNetV2.

E. Summary of Models Implemented

Table IV summarises the different models that were implemented in this study.

TABLE IV. SUMMARY OF MODELS

Pre-Trained CNN	Trainable Layer	Classifier
MobileNetV2	True	SoftMax
	False	SoftMax
ResNet50V2	True	SoftMax
	False	SoftMax
InceptionV3	True	SoftMax
	False	SoftMax

F. Summary of Datasets Used

Table V summarises the different datasets that have been used in this study.

TABLE V. SUMMARY OF DATASETS

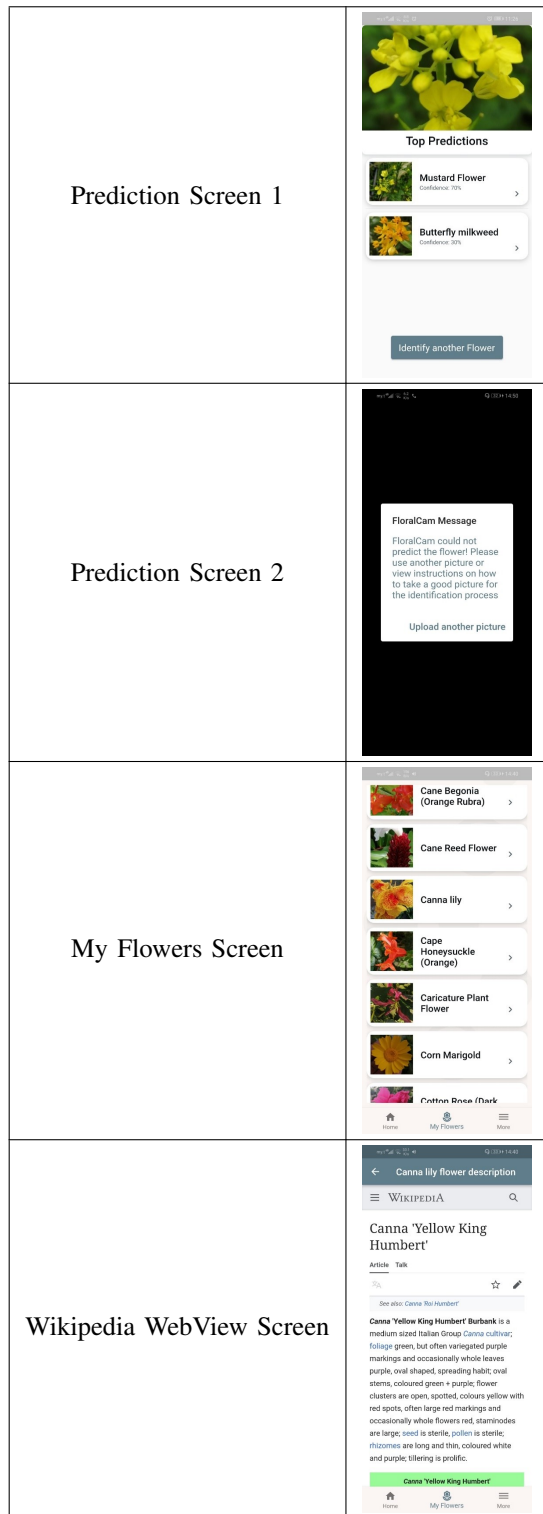

Dataset	Flower Classes	Images per Flower Class	Total Images	Training (70%)	Validation (20%)	Testing (10%)
FlowerNet	106	110	11660	8162	2332	1166
Oxford 102	102	110	11220	7854	2244	1122
Merged	195	110	21450	15015	4290	2145
Overlapping Oxford	13	110	1430	1001	286	143
Overlapping FlowerNet	13	110	1430	1001	286	143

G. Mobile Application

Flutter is chosen as the framework for developing the mobile application since it can be utilised to develop user-friendly interfaces with the help of well-structured documentation. Additionally, Flutter is cross-platform allowing it to run on different mobile operating systems. Table VI shows the different screens developed for the mobile application.

IV. RESULTS AND DISCUSSION

The results obtained by the implemented models on the different datasets are described in this section. The performance of each model is assessed using the classification accuracy and F1 scores. The FlowerNet dataset consists of 11660 images, 106 flowers each having 110 images. The dataset was divided into three sets before training the models: 70% for training, 20% for validation, and remaining 10% for testing.

A. FlowerNet Dataset

Table VII displays the accuracy values achieved after evaluating all the models with the FlowerNet dataset. The MobileNetV2 and InceptionV3 models achieved the highest accuracy scores of 99.74% and 99.31%, respectively. These highest accuracy scores were obtained when the feature extraction layers were set to trainable. When trainable layers are set to true, this implies that all the weights of the neural network are updated during training. When feature extraction layers were not trained, the maximum accuracy score was 98.97%.

TABLE VII. FLOWERNET DATASET RESULTS

Model	#	Trainable Layers	Accuracy	F1 Macro	F1 Weighted
MobileNetV2	1	TRUE	99.74%	0.9974	0.9974
	2	FALSE	98.97%	0.9897	0.9897
ResNet50V2	3	TRUE	98.97%	0.9897	0.9897
	4	FALSE	98.97%	0.9897	0.9897
InceptionV3	5	TRUE	99.31%	0.9931	0.9931
	6	FALSE	98.80%	0.9881	0.9881

B. Oxford 102 Dataset

Table VIII displays the accuracy values achieved after evaluating all the models with the Oxford 102 dataset. The MobileNetV2 and InceptionV3 models achieved the highest accuracy scores of 95.90% and 95.28%, respectively. These highest accuracy scores were obtained when the feature extraction layers were set to trainable. When the layers in the InceptionV3 model are set to non-trainable, the accuracy drops to 91%.

TABLE VIII. OXFORD 102 DATASET RESULTS

Model	#	Trainable Layers	Accuracy	F1 Macro	F1 Weighted
MobileNetV2	1	TRUE	95.90%	0.9594	0.9594
	2	FALSE	92.87%	0.9278	0.9278
ResNet50V2	3	TRUE	92.25%	0.9217	0.9217
	4	FALSE	91.18%	0.9111	0.9111
InceptionV3	5	TRUE	95.28%	0.9530	0.9530
	6	FALSE	91.00%	0.9089	0.9089

When trainable layers are set to true, the feature extraction layers of the pretrained CNNs are re-trained, and their weights are updated according to the FlowerNet dataset. This explains why the best results are obtained when the trainable layers are set to true. However, when trainable layers are set to false, this implies that the feature extraction layers of the CNNs are using the original weights and features of the ImageNet dataset, and this resulted in poor prediction, as compared to re-training all layers in the pretrained CNNs for the FlowerNet and Oxford 102 dataset. The ImageNet dataset, Oxford 102 and the FlowerNet datasets have distinct characteristics. Therefore, training the feature extraction layers from scratch using the FlowerNet/ Oxford 102 dataset resulted in better accuracies.

C. Merged Dataset

Table IX displays the accuracy values achieved after evaluating all the models with the merged dataset. The InceptionV3 and MobileNetV2 models achieved the highest accuracy scores of 97.30% and 97.11%, respectively. These highest accuracy scores were obtained when the feature extraction layers were set to trainable. When the layers in the InceptionV3 model are set to non-trainable, the accuracy drops to 94.22%.

TABLE IX. MERGED DATASET RESULTS

Model	#	Trainable Layers	Accuracy	F1 Macro	F1 Weighted
MobileNetV2	1	TRUE	97.11%	0.9711	0.9711
	2	FALSE	96.13%	0.9603	0.9603
ResNet50V2	3	TRUE	95.15%	0.9513	0.9513
	4	FALSE	94.87%	0.9474	0.9474
InceptionV3	5	TRUE	97.30%	0.9728	0.9728
	6	FALSE	94.22%	0.9414	0.9414

The models which were trained on the merged dataset have obtained a lower accuracy as compared to the original FlowerNet dataset. As the number of classes in a computer vision task increases, the identification process becomes complex. When the number of classes is increased from 106 (FlowerNet) to 195 (Merged), the complexity of the model increases, which makes the model more prone to errors.

D. Overlapping Flowers Datasets

For the FlowerNet dataset, the images were captured as close-up flower pictures. Oxford 102, on the other hand, consists of a variety of images taken in different positions and orientations. In this study, the effect of training a model with close-up pictures is also analysed with flowers found in both the FlowerNet and the Oxford 102 datasets.

Table X displays the accuracy values achieved after evaluating all the models with the overlapping FlowerNet dataset. A general observation is that all models have obtained an accuracy of above 99%. For the MobileNetV2 and ResNet50V2 models, the accuracies and F1 macro and weighted scores are all 100%. For the InceptionV3 model, the accuracy and F1 macro and weighted scores dropped by 0.7% when trainable layers are set to false.

TABLE X. OVERLAPPING FLOWERNET DATASET RESULTS

Model	#	Trainable Layers	Accuracy	F1 Macro	F1 Weighted
MobileNetV2	1	TRUE	100%	1.0000	1.0000
	2	FALSE	100%	1.0000	1.0000
ResNet50V2	3	TRUE	100%	1.0000	1.0000
	4	FALSE	100%	1.0000	1.0000
InceptionV3	5	TRUE	100%	1.0000	1.0000
	6	FALSE	99.30%	0.9930	0.9930

Table XI displays the accuracy values achieved after evaluating all the models with the overlapping Oxford 102 dataset. When trainable layers are set to true, the InceptionV3 model achieved the best accuracy of 99.30% followed by an accuracy of 96.50% by the MobileNetV2 and ResNet50V2 models. When the layers in the InceptionV3 model are set to non-trainable, the accuracy drops to 97.90%.

TABLE XI. OVERLAPPING OXFORD 102 DATASET RESULTS

Model	#	Trainable Layers	Accuracy	F1 Macro	F1 Weighted
MobileNetV2	1	TRUE	99.30%	0.9930	0.9930
	2	FALSE	97.90%	0.9793	0.9793
ResNet50V2	3	TRUE	96.50%	0.9641	0.9641
	4	FALSE	97.20%	0.9719	0.9719
InceptionV3	5	TRUE	96.50%	0.9646	0.9646
	6	FALSE	95.80%	0.9582	0.9582

Models trained on the overlapping FlowerNet flowers have performed relatively better than models trained on the overlapping Oxford 102 dataset. The overlapping FlowerNet dataset

classes consist of mostly close-up images of flowers with minimal background while the overlapping Oxford 102 dataset consists of flower images with a lot of background. This result suggests that the proportion of background in the images has influenced the identification process, hence the difference in accuracy.

E. Model Prediction Time

A good model is not dependent solely on classification accuracy. The prediction time of the model should also be considered. As a result, an experiment is carried out to test the prediction time with models that have trainable layers set to true. To calculate the inference time of the models, the prediction time was recorded for the test images. The experiment was then repeated seven times to obtain an average prediction time for a more realistic inference time. The prediction time per image was then computed and the results are tabulated as shown in Table XII.

From Table XII, it can be deduced that MobileNetV2 has a lower prediction time (0.09 seconds) followed by the ResNet50V2 (0.12 seconds). InceptionV3 has the highest inference time of 0.22 seconds per image. In terms of model size, MobileNetV2 has the smallest size followed by InceptionV3 and ResNet50V2.

MobileNetV2 obtained the least prediction time as compared to ResNet50V2 and InceptionV3. This is because the network size and parameter count affect the inference time and MobileNetV2 (3.1 million) has a lower parameter count as compared to InceptionV3 (23.0 million) and ResNet50V2 (24.8 million). Adding to that, the trained MobileNetV2 model has the lowest size compared to the others. This is another reason influencing the prediction time.

F. Comparison with Existing Works

Wang et al. performed classification on five different flower categories using an initial dataset consisting of a training set to train their model and a test set to evaluate it [25]. Additionally, another dataset set was used to test their models. They used the ensemble method, whereby the predictions of seven MobileNet models were combined. They achieved the best accuracy of 94.63% and 91.14% on their first and second datasets, respectively. Compared to the result in this paper, an accuracy of 99.7% was achieved when the MobileNetV2 model was used. Even with a much more significant number of categories of flowers (106 classes), our models produced better accuracy. The dataset used by [25] was not publicly available to perform additional testing.

Lv et al. used the VGG16 CNN model to perform flower classification [27]. They were able to achieve an accuracy of 91.9% when the model was trained on the Oxford 102 dataset. The Oxford 102 dataset was also used to compare the implemented models with that of [27]. The best accuracy obtained when trained on the Oxford 102 dataset was 95.90% when the MobileNetV2 model was used. Thus, our work outperformed the VGG16 model used in [27].

V. CONCLUSIONS

The classification of flower species is a challenging process. Flower images captured in varying viewpoints, lightings

TABLE XII. MODELS PREDICTION TIME

Model	No of test images	Total Prediction Time for 7 iterations /sec	Average Prediction Time /sec	Prediction time per image /sec	Model Size/ MB
MobileNetV2	1166	730	104	0.09	35.8
ResNet50V2		1010	144	0.12	284.1
InceptionV3		1836	262	0.22	264.4

and occlusion by leaves and other debris make it difficult to classify flower species. Deep learning has recently surfaced as one of the preferred approaches for achieving promising results in such classification problems. A new dataset, named FlowerNet, consisting of 106 flower species was created and deep learning models such as InceptionV3, MobileNetV2, ResNet50V2 were used for the classification. The best performing model, MobileNetV2, achieved an accuracy of 99.74% with the smallest prediction time of 0.09 seconds. Moreover, this model was deployed in a mobile application named FloralCam. In the real environment, FloralCam achieves a good level of accuracy when high-quality close-up flower images are used, but it may result in poor prediction in cases when blurry and low-quality images with a high proportion of background are used. Further experiments may be carried out to fine tune the best model's performance in the real world by utilising a larger and a more diverse dataset.

APPENDIX

TABLE XIII. FLOWER SPECIES IN FLOWERNET DATASET

#	Common Name	Scientific Name	
1	Purple Allamanda	Allamanda Blanchetii	
2	Yellow Allamanda	Allamanda Cathartica	
3	Angel Wing Begonia (Pink)	Begonia coccinea	
4	Angel Wing Begonia (White)	Begonia coccinea	
5	Billygoat weed	Ageratum conyzoides	
6	Butterfly milkweed	Asclepias tuberosa	

7	Cane Begonia (Orange Rubra)	Begonia coccinea 'Orange'	
8	Cane Reed Flower	Cheilocostus speciosus	
9	Canna lily	Canna 'Yellow King Humbert'	
10	Cape Honeysuckle (Orange)	Tecoma capensis	
11	Caricature Plant Flower	Graptophyllum pictum	
12	Corn Marigold	Glebionis segetum	

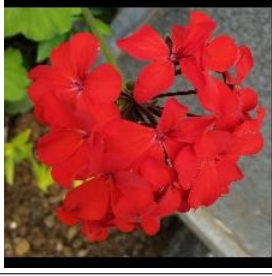

13	Cotton Morning Glory	<i>Ipomoea cordatotriloba</i>	
14	Cotton Rose (Dark Pink)	<i>Hibiscus mutabilis</i>	
15	Cotton Rose (Pale Pink)	<i>Hibiscus mutabilis</i>	
16	Cotton Rose (Red)	<i>Hibiscus mutabilis</i>	
17	Daisy (White)	<i>Bellis perennis</i>	
18	Daylily (Orange)	<i>Hemerocallis fulva</i>	

19	Desert Rose (Pink)	Adenium obesum	
20	Dessert Rose (Dark Red)	Adenium obesum	
21	Double Dahlia (Pale Yellow)	Dahlia	
22	Double Dahlia (White)	Dahlia	
23	Dwarf Marigold (Orange)	Tagetes erecta	
24	Dwarf Marigold (Pale Yellow)	Tagetes erecta	

25	Dwarf Marigold (Yellow)	Tagetes erecta	
26	Easter Lily (Red)	Lilium longiflorum	
27	Easter Lily (White)	Lilium longiflorum	
28	Egyptian Starcluster (Pale Purple)	Pentas lanceolata	
29	Egyptian Starcluster (White)	Pentas lanceolata	
30	Madagascar jewel	Euphorbia Leuconeura	

31	Fairy Lily (Pink)	Zephyranthes candida	
32	Fairy Lily (White)	Zephyranthes candida	
33	False sunflower	Heliopsis helianthoides	
34	Firecracker Flower	Crossandra infundibuliformis	
35	Flamevine	Pyrostegia venusta	
36	Flamingo Lily (Pale Pink)	Anthurium andraeanum	

37	Flamingo Lily (Pink)	Anthurium andraeanum	
38	Frangipani (Pink)	Plumeria rubra	
39	Frangipani (White)	Plumeria pudica	
40	Frangipani (Yellow)	Plumeria rubra	
41	French Marigold	Tagetes patula	
42	Garlic Vine	Mansoa alliacea	

43	Geranium (Pink)	Pelargonium × hortorum	
44	Geranium (Red)	Pelargonium × hortorum	
45	Gerbera (Dark Pink)	Gerbera	
46	Gerbera Daisy (Dark Orange)	Gerbera	
47	Gerbera Daisy (Fuchsia)	Gerbera	
48	Gerbera Daisy (Pale Orange)	Gerbera	

49	Gerbera Daisy (Pale Pink)	Gerbera	
50	Gerbera Daisy (Red)	Gerbera	
51	Gerbera Daisy (White)	Gerbera	
52	Gerbera Daisy (White_Pink)	Gerbera	
53	Gerbera Daisy (Yellow)	Gerbera	
54	Ground Orchid (White)	Spathoglottis plicata	

55	Hibiscus (Light pink)	Hibiscus rosa-sinensis	
56	Hibiscus (Pale Orange)	Hibiscus rosa-sinensis	
57	Hibiscus (Red)	Hibiscus rosa-sinensis	
58	Hummingbird Fuchsia	Fuchsia magellanica	
59	Hydrangea	Hydrangea macrophylla	
60	Pink Orchid Balsam	Impatiens flaccida	

61	Indian chrysanthemum	Chrysanthemum indicum	
62	Ixora (orange)	Ixora coccinea	
63	Japanese Hawkweed	Youngia japonica	
64	Lantana (White)	Lantana camara	
65	Lantana (Yellow)	Lantana camara	
66	Leopard Flower	Iris domestica	

67	Madamfate	Hippobroma	
68	Showy Medinilla	Medinilla magnifica	
69	Mexican Flame Vine	Pseudogynoxys chenopodioides	
70	Mexican Heather	Cuphea hyssopifolia	
71	Mexican Petunia	Ruellia simplex	
72	Moss Flower (Orange_Yellow)	Portulaca grandiflora	

73	Moss Flower (Pale Pink)	Portulaca grandiflora	
74	Mustard Flower	Brassica nigra	
75	Nora Grant (Red)	Ixora coccinea	
76	Ostrich Plume	Alpinia purpurata	
77	Paper Flower (Fuchsia)	Bougainvillea glabra	
78	Paper Flower (Sundown Orange)	Bougainvillea glabra	

79	Paper Flower (White)	Bougainvillea glabra	
80	Parakeet Flower (Red_Orange)	Heliconia psittacorum	
81	Parakeet Flower (Yellow)	Heliconia psittacorum	
82	Peregrina	Jatropha integerrima	
83	Periwinkle (Pink)	Catharanthus roseus	
84	Periwinkle (Red)	Catharanthus roseus	

85	Periwinkle (White with Pink centre)	Catharanthus roseus	
86	Periwinkle (White)	Catharanthus roseus	
87	Princess Flower	Pleroma urvilleanum	
88	Rose (Cream)	Rosa	
89	Rose (Dark Red)	Rosa	
90	Rose (Pink)	Rosa	

91	Rose Balsam (Lavender)	Impatiens balsamina	
92	Rose Balsam (Red)	Impatiens balsamina	
93	Rose Balsam (White_Pink)	Impatiens balsamina	
94	Rose Balsam(Fuchsia)	Impatiens balsamina	
95	Shower Orchid	Congea tomentosa	
96	Silver Cockscomb (Fuchsia)	Celosia argentea	

97	Single Dahlia (Yellow)	Dahlia	
98	Singapore daisy	Sphagneticola trilobata	
99	Spiny sowthistle	Sonchus asper	
100	Stargazer Lily	Lilium Stargazer	
101	Tagar Flower	Tabernaemontana divaricata	
102	Thai Eggplant Flower	Solanum melongena	

103	Thornless Crown of Thorns	Euphorbia geroldii	
104	Turmeric Flower	Curcuma longa	
105	Wax Begonia	Begonia cucullata	
106	Yesterday Today and Tomorrow	Brunfelsia latifolia	

A Study of Prediction of Airline Stock Price through Oil Price with Long Short-Term Memory Model

Jae Won Choi¹, Youngkeun Choi^{2*}

Department of Computer Science, University of Texas at Dallas, Richardson, TX, USA¹
Division of Business Administration, Sangmyung University, Seoul, Korea²

Abstract—This study aims to present a model that predicts the stock price of an airline by setting the economic and technical information of oil as features and taking advantage of the LSTM method. In this study, oil price data for about seven years from January 4, 2016, to April 14, 2023, were collected through FinanceDataReader. The collected data is a total of 1,833 days of AA stock price data. The price data consists of six categories: Date, Open, High, Low, Close, Volume, and Change (price is based on dollars). Data is stored every 24 hours, so it was judged to be most suitable for short-term price prediction (24 hours later) to be conducted in this study. In this paper, normalized closing price data was trained for 50 epochs. As a result of learning, the loss value converged close to 0. The MSE measured by the accuracy of the model shows a result of 0.00049. The significance of this study is as follows. First, it is meaningful in that it can present indicators such as more sophisticated predictions and risk management to airline companies. Oil price as our selected feature can compensate for the poor performance of a simple model and its limitations on overfitting.

Keywords—Stock price prediction; airline; oil; long short-term memory

I. INTRODUCTION

For a considerable period, scholars have been interested in forecasting future stock price movements [1]. While proponents of the efficient market hypothesis argue that accurate stock price prediction is unattainable, empirical evidence suggests that by employing appropriate variables and suitable models, it is feasible to predict future stock prices and detect patterns of stock price movements with a relatively high level of precision. LSTM (Long Short-Term Memory) is a powerful technique for predicting stock prices due for several compelling reasons [2]. Firstly, stock prices exhibit sequential patterns, and LSTMs are designed to capture long-term dependencies in time-series data. They can effectively model the sequential relationships in historical stock price data, enabling them to capture relevant trends, patterns, and seasonality for accurate future price forecasting. Secondly, LSTMs incorporate a memory cell that selectively retains or forgets information over time. This memory cell helps in preserving important historical information while filtering out irrelevant noise, making LSTMs robust in handling noisy and volatile stock price data where multiple factors may affect price movements. Thirdly, stock prices are influenced by a wide range of factors with non-linear relationships, and LSTMs are capable of modeling such non-linearity. With non-linear activation functions and multiple gates, LSTMs can capture complex patterns in the data, allowing them to capture intricate

relationships in stock price data that linear models may miss. Fourthly, LSTMs can automatically learn relevant features from raw data without relying on manual feature engineering. This is particularly advantageous for stock price prediction as relevant features may change over time and may be difficult to identify manually. LSTMs can learn to represent important features from historical data, enhancing the accuracy of predictions. Lastly, LSTMs are adaptable and can be trained on different time scales, such as daily, weekly, or monthly data, depending on the prediction task requirements. They can also be trained on various stock markets or different stocks, making them flexible for different prediction scenarios. Finally, LSTMs can undergo training using extensive historical stock price data, which is often accessible for multiple stocks. This enables them to capture prolonged patterns and trends, rendering them suitable for predicting stock prices over extended timeframes. Consequently, the ability of LSTMs to handle sequential data, capture long-term dependencies, model non-linear relationships, learn relevant features, adapt to different time scales, and scale to large datasets makes them a formidable tool for stock price prediction.

Selecting crucial factors for predicting stock prices using LSTM is imperative to capture relevant information that can impact stock prices [3]. Economic indicators, financial statements, market sentiment, and news are significant factors that can significantly affect stock prices. Incorporating these relevant factors into the LSTM model enables it to capture the complex relationships and patterns in the data, resulting in more accurate stock price predictions. The careful selection of these factors ensures that the LSTM model is trained on meaningful inputs, enhancing its ability to forecast stock prices and potentially assisting in making informed investment decisions.

The stock market is influenced by crude oil prices, which reflect economic conditions. Existing studies present mixed findings, with some reporting positive associations and others indicating negative associations. Park and Ratti [4] discovered a negative influence on composite stock market returns but a positive influence on energy stock market returns. Filis and Chatziantoniou [5] found a negative influence on the stock markets of importing countries but a positive influence on the stock markets of exporting countries. Narayan and Sharma [6] identified that the influence depends on the scale of the enterprise. Bjornland [7] observed a positive influence on crude oil production stock prices and a negative influence on transportation stock prices. Lu and Chen [8] investigated the influence of WTI crude oil prices on stock prices of

*Corresponding Author.

transportation companies across eight countries and found that sea transportation is less affected due to increased crude oil transportation volume. Mohanty et al. [9] revealed a negative impact on US airlines during the financial crisis, while Shaeri et al. [10] identified a stronger impact on airlines. Although there is limited literature on the effect of crude oil prices on aviation stocks, Kristjanpoller and Concha [11] reported a negative relationship between oil prices and aviation stocks. The researchers utilized statistical analysis techniques to examine the impact of oil on stock prices in their academic paper. They employed various datasets and models, such as three-factor and two-factor asset pricing models, GARCH model, the standard market model, the event study methodology, and CAPM with GARCH models. However, no prior research has employed LSTM (Long Short-Term Memory) based on crude oil prices to predict airline stock prices. Predicting airline stock prices using LSTM based on crude oil prices hold significant value due to the influence of oil prices on airline operational costs, industry dynamics, risk management, investor confidence, and operational optimization. Accurate predictions can assist airlines in planning and budgeting for fuel costs, making informed strategic decisions, managing risk exposure, attracting investors, and optimizing operations, potentially impacting profitability and stock prices.

As a result, this study focuses on oil prices while considering the characteristics of airlines. From this perspective, there is a need to identify an accurate method for predicting airline stock prices using machine learning algorithms. Since stock prices do not exhibit seasonality, machine learning models are applicable and beneficial. Therefore, the study has implemented a long short-term memory (LSTM) model, which is one of the popular machine learning algorithms used in previous studies. However, previous studies simply input data into the model without considering data frequency or sample size. Data with different frequencies possess distinct structures, and employing simplistic machine learning algorithms may result in errors such as overfitting due to their complex methods. Thus, in this study, we investigate whether the information concealed in the economic and technological determinants of oil can accurately predict airline stock prices.

II. RELATED WORK

Crude oil is a significant resource, and its price change is closely linked to the stock market, which serves as an indicator of economic development [12][13][14]. While some studies suggest a positive correlation between oil and stocks, other studies also report a negative correlation. Firstly, Park and Ratti [4] emphasize that although the crude oil price hurts the overall stock market returns, it has a positive impact on the energy stock market returns. Filis and Chatziantoniou [5] also conclude that an increase in crude oil prices negatively affects the stock market of crude oil-importing countries, but positively affects the stock market of crude oil-exporting countries. Secondly, Narayan and Sharma [15] analyze the stock market prices of 560 companies across 14 industries listed on the New York Stock Exchange (NYSE), and find that the impact of oil prices on different companies depends on their scale. Bjornland [7] concludes that an increase in crude

oil prices positively affects the stock prices of crude oil production companies, but negatively affects the stock prices of transportation companies.

In particular, Lu and Chen [8] conducted a study on the effects of WTI crude oil prices on the stock prices of 160 transportation companies in eight countries. The findings revealed that sea transportation companies were able to mitigate the negative impact of rising crude oil prices by increasing their crude oil transportation volume, while air transportation companies were more vulnerable to crude oil price volatility. Mohanty et al. [9] examined the impact of WTI crude oil prices on six industries in the US, including airlines, gambling, hotels, recreational services, restaurants & bars, and travel & tourism. They discovered that crude oil prices had a significant negative effect on the stock price returns of airlines, with a stronger impact observed during the 2008-2009 financial crisis. Similarly, Shaeri et al. [10] found that the impact of crude oil price risk on airlines was more pronounced compared to other industries. Despite limited research on the relationship between crude oil prices and aviation stocks, Kristjanpoller and Concha [11] demonstrated a negative association between oil prices and aviation stocks. Specifically, they analyzed the impact of fuel price fluctuations on aviation stocks associated with the International Air Transport Association (IATA) and found a positive influence of oil prices on aviation stocks.

Researchers conducted a statistical analysis methodology to investigate the impact of oil on stock prices. Mohanty and Nandha (2011) utilized a three-factor asset pricing model to analyze monthly data from July 1992 to December 2008. Mohanty et al. [9] employed a two-factor model to analyze industry returns from September 1983 to August 2011. Narayan and Sharma [15] used the GARCH Model to analyze data from January 2000 to December 2008 for 560 US firms listed on the New York Stock Exchange. Nandha and Brooks [16] analyzed the Transport Indices of thirty-eight countries and WTI Crude Oil, as well as all companies in the S&P Transportation industry index from January 1986 to July 2008, using the Standard Market Model and Event Study Methodology. Kristjanpoller and Concha [11] analyzed data from 56 airlines for the period of 2008–1 to 2013–10, employing the CAPM and GARCH Models.

However, utilizing LSTM (Long Short-Term Memory) to predict airline stock prices based on crude oil prices can minimize similarity in academic papers when considering the following points. Firstly, crude oil prices significantly impact airline operational costs, as jet fuel constitutes a significant portion of expenses. Accurate prediction of crude oil prices can enable airlines to plan and budget their fuel costs more effectively, ultimately affecting profitability and stock prices. Secondly, the airline industry is highly competitive and sensitive to external factors, including changes in crude oil prices. Reliable predictions of crude oil prices can provide airlines with valuable insights into industry dynamics, facilitating informed strategic decision-making and operational adjustments, which in turn can impact stock prices as investors closely monitor industry trends. Thirdly, fluctuating crude oil prices introduce risks to airlines' financial performance and stock prices. LSTM-based predictions of crude oil prices can

aid airlines in managing risk exposure by developing risk mitigation strategies such as hedging or adjusting pricing strategies, to minimize the impact of volatile oil prices on stock prices. Fourthly, accurate predictions of airline stock prices based on crude oil prices can enhance investor confidence. Factors such as fuel costs and industry dynamics are often considered by investors when making investment decisions in the airline sector. Reliable predictions of stock prices can attract and retain investors, leading to increased market demand for airline stocks and potentially driving up stock prices. Lastly, timely and accurate predictions of crude oil prices can help airlines optimize their operations for better efficiency. To mitigate the potential impact of rising oil prices, airlines can implement proactive strategies such as optimizing flight routes, adjusting ticket prices, and negotiating fuel contracts. By employing LSTM to predict airline stock prices using crude oil prices, valuable insights can be gained into fuel costs, industry dynamics, risk management, investor confidence, and operational efficiency. These insights can inform decision-making, optimize airline operations, and potentially influence stock prices, making it a valuable tool for financial forecasting in the airline industry.

III. METHODOLOGY

A. Data Collection

This study utilized oil and American Airlines (AA) stock price data from FinanceDataReader. The stock of American Airlines represents the airline industry stock price for the following reasons: Industry leader: American Airlines is one of the prominent airlines in the United States, with a wide network of routes including international air transportation connecting the U.S. and other countries. Moreover, it has a strong competitive position in the U.S. air transportation market, making it a representative indicator of the trend in airline stock prices. Market size: The aviation industry is a significant part of the global economy, closely tied to economic activities in countries around the world. Therefore, airline stock prices can serve as a representative indicator of the market size concerning global economic conditions and expectations for economic growth. Industry trends: The aviation industry is highly sensitive to fluctuations in the economy and various factors such as oil prices, exchange rate fluctuations, government regulations, and international geopolitical situations can impact airline stock prices. The stock of American Airlines reflects these industry trends, representing the movements in airline stock prices. Investor interest: Airline stocks garner significant attention from investors due to the industry's unique characteristics, competitive landscape, technological advancements, and profitability prospects, all of which influence investors' decisions. Therefore, the stock of American Airlines can serve as a representative indicator of the overall trends in the aviation industry and economic conditions, reflecting the factors that represent airline stock prices.

In this study, oil price data for about seven years from January 4, 2016, to April 14, 2023, were collected through FinanceDataReader. The collected data is a total of 1,833 days of AA stock price data. The price data consists of six categories: Date, Open, High, Low, Close, Volume, and

Change (price is based on dollars). Data is stored every 24 hours, so it was judged to be most suitable for short-term price prediction (24 hours later) to be conducted in this study. Fig. 1 shows the change in oil prices over time of the data. Fig. 2 shows the change in the stock price of AA over time of the data.

Fig. 1. Oil price distribution.

Fig. 2. AA stock price distribution.

B. Data Preprocessing

In this study, data pre-processing was performed using Python as follows. Pre-processing is a total of 4 steps, 1) converting raw data into a data frame, 2) data refinement, 3) data normalization, and 4) data division. First, the sequence length of data consisting of daily was set to 30, and it was reconstructed into a data frame matrix in units of 30 days. Second, in the data refinement process, null values or data marked as 0 among the data were replaced with the mean value to handle missing values. Third, all input values were converted into values between 0 and 1 through the data normalization process. Finally, data segmentation was performed. The entire collected Ethereum data was divided in a ratio of 7:3, and 7 parts of data (training data) were used for model learning, and 3 parts of data (test data) were used for testing. However, since the data is composed of time series, considering the order, the test data was selected as the most recent data. In addition, the hyper-parameters were divided into

training and verification parts at a ratio of 8:2 to the 7 parts of the training data split for optimization.

C. Price Prediction with LSTM Model

Recurrent neural network (RNN) can reflect the sequence-related characteristics of financial time-series data, but it has the problem of gradient disappearance or gradient explosion. Also, its mining of historical information for financial time-series data is very limited. LSTM is a special RNN that can well handle the long-term dependencies of time-series data [17]. Therefore, the LSTM model is an improved RNN model, to some extent.

Fig. 3. LSTM network structure.

Fig. 3 shows the network structure of the LSTM. The basic unit of the LSTM model is a memory block, which includes a memory cell and three gate structures that control the state of the memory cell, forget gate, input gate, and output gate. To be specific, the forget gate decides to forget the useless historical information from the memory cell state, the input gate decides the influence of the current input data on the memory cell state, and the output gate decides the output information.

Firstly, the data that must be erased from the cell is identified based on the forget gate (f_t) of the (1) as outlined below:

$$f_t = \sigma(bf + Wf x_t + Uf h_t - 1) \quad (1)$$

The sigmoid activation function σ is used to determine the amount of information retained. The x_t refers to the current input vector, while h_t represents the hidden layer vector. b_f , x_t , and h_t are the bias, input weight, and loop weight of the forget gate, respectively, in the neural network architecture.

Subsequently, the information state is updated within the cell. The external input gate (i_t) is regulated by a sigmoid activation function as described in (2):

$$i_t = \sigma(bi + Wi x_t + Ui h_t - 1) \quad (2)$$

Meanwhile, the update of the cell state (C_t) is carried out by equation (3), which utilizes C_{t-1} as the input.

$$C_t = f_t * C_{t-1} + i_t * \tanh(bc + Wc x_t + Uch_t - 1) \quad (3)$$

The state of the memory cell at time t is represented by C_t .

Lastly, the output gate (O_t) of (4) regulates the information output in the following manner:

$$h_t = (O_t) \tanh(C_t) \quad (4)$$

$$O_t = \sigma(bo + Wo x_t + Uo h_t - 1) \quad (5)$$

The model's accuracy was assessed using Mean Squared Error (MSE), which is a common loss function for regression tasks in neural network models. MSE calculates the average of the squared differences between the predicted values and the actual values. This study chose to use MSE for several reasons. Firstly, MSE is a differentiable function, which makes it suitable for updating the model's weights using the backpropagation algorithm. Secondly, MSE accounts for the magnitude of the error, as larger errors are squared, emphasizing their impact and aiding in reducing prediction errors during model training. Thirdly, MSE is robust to outliers, making it suitable for evaluating model performance even in the presence of data outliers. The calculation of MSE was performed as shown in Equation (6), where y_k represents the predicted value and t_k represents the actual value.

$$MSE = \frac{1}{n} \sum_k (y_k - t_k)^2 \quad (6)$$

where the variable "n" denotes the data size.

D. Train and Test the Model

In this study, after constructing the model, the hyperparameter optimization process of the LSTM model was performed to optimize performance. The primary process explored the number of neurons and the number of times of learning (Epoch). The two layers inside the LSTM model consist of n number of neurons. In this study, we experimented by changing the number of neurons to 16, 32, 64, 128, and 200. In addition, the number of times of learning was experimented by changing to 10, 30, 50, and 100. If the number of training is too small, the model does not train well, and if the number of training is too large, overfitting problems occur. In conclusion, when the number of neurons is 32 and the number of learning is 50, the verification data prediction results are the best.

As a secondary process, the optimal window size and activation function were optimized. The second process was carried out with the number of neurons and the number of learning selected in the first fixed at 32 and 50, respectively. The window size refers to the size of the previous data set used by the model in the process of learning, and the analysis was conducted while reducing it in the order of 10, 7, 5, and 3. An activation function means a function that converts an input value into an output value in the two hidden layers inside the LSTM. Recurrent activation is a commonly used time.

The sigmoid function was used as it is, and the gate function was compared and analyzed with four functions, tanh, relu, linear, and softmax. As a result of the secondary analysis, when the window size was 7 and the gate function was composed of a combination of the tanh function, the verification data prediction result was the best. Additional hyperparameter selection work was carried out through the first and second optimization processes. The dropout ratio means the ratio of randomly disconnecting some of all the lines connected between neurons to prevent overfitting and was designated as 0.25 in this study. Batch size refers to the amount that is passed to the next network after learning by dividing the entire data. The larger the size, the more computer memory is used, so 2 was designated in this study. The sequence length and output dimension were configured in units of 30 days. And

the optimizer used Adam, and the loss function used MSE (Mean Squared Error).

IV. RESULTS

In this paper, normalized closing price data was trained for 50 epochs. As a result of learning, the loss value converged close to 0 as shown in Fig. 4.

Fig. 4. Learning loss value.

Fig. 5. Prediction results.

There was a case where the validation-set loss soared temporarily due to a sudden rise or fall in the stock price, but it generally converged to 0. The results of testing with test data using the trained model are shown in Fig. 5. Inverse normalization was performed on the test results before output. The MSE measured by the accuracy of the model shows a result of 0.0004. As a result of testing with the trained model, it was confirmed that the trend of the actual value was followed with high accuracy, as shown in Fig. 5.

V. CONCLUSION

The selection of influential factors for stock price prediction using LSTM is crucial as it allows for capturing relevant information that can impact stock prices. Economic indicators, financial statements, market sentiment, and news are significant factors that can affect stock prices. Including these relevant factors in the LSTM model enhances its ability to capture complex relationships and patterns in the data, leading to more accurate stock price predictions. Crude oil prices have been found to affect stock markets, but studies show mixed associations with some reporting positive and others negative effects. Previous studies have used statistical analysis methods to study the impact of oil prices on stock prices, but there is a gap in research predicting airline stock prices using LSTM based on crude oil prices. Accurate

predictions can help airlines plan and budget fuel costs, make strategic decisions, manage risk exposure, and optimize operations. Therefore, this study focuses on accurately predicting airline stock prices using machine learning algorithms, particularly LSTM, considering the impact of oil prices on airline operations and industry dynamics. Different frequencies of data have different structures, and simple copy machine learning algorithms may have errors such as overfitting. Hence, this study investigates whether the information hidden in the economic and technological determinants of oil can accurately predict airline stock prices using LSTM. Based on the necessity of this study, this study developed an LSTM model that predicts the price of airline stock prices through oil prices. As a result of learning, the loss value converged close to zero. The MSE value for AA stock closing price predictions resulted in 0.00049.

The significance of this study is as follows. First, it is meaningful in that it can present indicators such as more sophisticated predictions and risk management to airline companies. In addition, many researchers are attempting to develop new algorithms for predicting airline stock prices, and studies have been conducted with various types of statistical models. However, in this study, we developed a model with improved performance by constructing optimal hyperparameters based on LSTM, an existing algorithm. Oil price as our selected feature can compensate for the poor performance of a simple model and its limitations on overfitting. This result is meaningful in that the prediction accuracy of this study is superior to the results of previous studies that attempted to predict airline stock prices based on a simple machine-learning model.

Method for Ad-hoc Blockchain of Wireless Mesh Networking with Agent and Initiate Nodes

Kohei Arai

Information Science Department, Saga University
Saga City, Japan

Abstract—Method for Ad-Hoc blockchain of wireless mesh networking with agent and initiate nodes is proposed. Minimizing the number of hops and maintaining connectivity of mobile terminals are concerns. Through simulation studies, it is found that increasing number of initiator nodes caused nodes to route a large number of messages. Thus, these nodes will die out quickly, causing the energy required to get the remaining messages to increase and more nodes to die. This will create a cascading effect that will shorten system lifetime. Multi-hop routing, however, imply high packet overhead, (more nodes in the network means more hops will be available). The packet overhead of the multi-hop routing is extremely high compared to single path routing since many nodes near the shortest path participate in packet forwarding. This additional overhead caused by moving node can cause congestion in the network.

Keywords—Blockchain; Ad-hoc network; agent and initiate nodes; the number of hops; connectivity; routing protocol; multi-hop routing; packet forwarding

I. INTRODUCTION

Blockchain was born in 2008 when an individual or group of unknown nationality named Satoshi Nakamoto published a paper on Bitcoin. There are two types of blockchains, Public and Private. Public blockchains allow an unspecified number of participants to participate in block generation, but on the other hand, there is a problem that processing speed and safety are impaired due to this. On the other hand, with private blockchains, the authority to generate blocks is given only to a limited number of participants, making it difficult to differentiate from conventional databases and making it impossible to demonstrate the inherent strengths of blockchains.

In this study, ad-hoc blockchain of wireless mesh networking is proposed for private blockchains for mobility services. Connected cars are called as smartphones with mobility services. Mobile devices, mobility service sharing, sometimes, needs ad-hoc blockchain functions such as payment confirmation, etc. In such cases, ad-hoc wireless mesh networking is needed. One of the problems of the ad-hoc wireless networking is continuous connectivity among the moving targets of mobile objects, cars, mobile devices, etc.

Wireless mesh network technology, which connects access points by wireless communication, is being considered as an access network [1], [2], [3], [4]. A wireless mesh network consists of access points with interconnection functions called mesh STAs. In a wireless mesh network, route control is necessary for multi-hop communication between mesh STAs.

Each meshSTA exchanges information used for routing on the network. Since this information exchange is also performed by wireless communication, there is a possibility that the opportunity of data packet delivery may be deprived due to the collision caused by the communication.

On the other hand, in wireless mesh networks, there are studies to improve packet transfer efficiency by adjusting the transfer rate of each path [5], [6]. There is also a method of leaving routes that can achieve high throughput by deleting unnecessary routes from multiple routes [7]. In addition to these, there is a method of constructing detours using signaling messages included in standard specifications [8], and research that utilizes the characteristics of hash functions when searching for moving user terminals in mesh networks [9]. Also, there is a method [10] that exchanges position information with adjacent mesh STAs on the Euclidean plane, constructs a Delaunay overlay network, and builds detour routes with neighboring mesh STAs that are not directly adjacent physically. Furthermore, we proposed a basic method for route design and route control using the estimated adjacency relations between mesh STAs [11], and applied it to IPv6 networks [12]. Moreover, there is Ad-hoc On-Demand Distance Vector (AODV) Routing [13]. There are some related research works to the Ad-Hoc wireless network [14]-[24]. There is such related research work to Ad-Hoc wireless blockchain networking at all.

The method proposed here is based on the ad-hoc networking protocol for a block chain of peer-to-peer (P2P) networks with mobile devices. In particular, nodes of mobile devices move from one coverage area to the other coverage areas. The locations of the mobile devices are known with GPS. Therefore, only thing it has to do is to establish ad-hoc network in the moved network area. An agent node is assumed to be an initiate node for establishment of the network. Thus, a blockchain can be created in Ad Hoc manner. This would be useful for “Web3.0” because “Web 3.0” is a decentralized Internet realized by blockchain technology. The decentralized Internet has the advantage that data and information can be decentralized and managed by individuals without depending on specific companies or administrators. This is the basic idea of the proposed method.

In the following section, research background is described followed by the proposed method. Then, some of simulation studies are described followed by conclusion with some discussions.

II. RESEARCH BACKGROUND

A. Blockchain

A block that stores information = a hash function (which replaces some data with a certain other random string: this replacement makes it impossible to read the original data from the string, acting as a cipher) where a hash function is a function that calculates input data in a fixed procedure and outputs a character string of a fixed length regardless of the length of the data of the input value. This research assumes SHA-3: Secure Hash Algorithm 3 as the hash function. This is because there is no regularity between the input data and the output hash value, and if the input data is even slightly different, a completely different hash value is output. In addition, it is difficult to guess input data that gives a specific hash value (weak collision resistance), and it is not easy to find other input data with the same hash value (strong collision resistance). In addition, it is a method of connecting blocks of data that are equally connected without management in the center of the block and that have been replaced with hash values. The basis of the networking method is the P2P method, which manages data.

When it is wanted to mine to add a new block, encrypt the transaction with a hash function and check the consistency with the previous block before adding. Mining is the issuance of a new block, and this issuance must be confirmed by the computer calculations involved in the blockchain to be consistent. Confirming consistency requires astronomical calculations, and all nodes participating in the blockchain participate in the calculations to confirm consistency.

One of the characteristics of blockchain is that it is resistant to attacks because there is no central administrator. In addition, a huge number of computers are involved in the procedures carried out on the blockchain, and they are also encrypted. If the information is tampered with, the hash value will be replaced, and it will be known that all the nodes in the world have been tampered with. Since the information is distributed and managed, there is no need to centralize it, and the more people who participate, the cheaper the operation becomes.

Governance is also an issue for blockchain. This is the problem of how to design and make decisions that affect the design to securely and stably record and process transactions on the blockchain. There is also the issue of scalability. A public blockchain is a distributed ledger with an unspecified number of participants, so the throughput (processing speed) is slow. In addition, there is the issue of privacy. Since the ledger of information traded on the blockchain is public, anyone who participates in the network can see the transaction information. Therefore, in order for blockchain to be implemented in society and spread widely, it is necessary to ensure the confidentiality of sensitive transaction information.

Tapyrus is one of the publicly available blockchain tools. Anyone can freely participate in this blockchain network and can create and view transactions. On the other hand, since the authority to generate blocks and add functions belongs to the administrator network, the governance problems of conventional public blockchains can be resolved.

Tapyrus clarifies the domain to which the blockchain is applied, and multiple federations (coordinators) can be configured by the stakeholders of the domain. In addition, the consensus algorithm used for block generation can be multi-signed by federation instead of Proof of Work (PoW) adopted by Bitcoin and Ethereum. This ensures consistent and stable approval of transactions. Furthermore, since anyone can participate in node operation and the ledger information is open to the public, the reliability of the public blockchain can be guaranteed. Next, a block verification method will be described. It is necessary to clarify the domain to which blockchain is applied. Select multiple federations (coordinators) from domain stakeholders. Construct a signature network that realizes block generation by "multisignature" by 2/3 of the federation (parameter adjustable). The signing network blocks transactions transferred to the Tapyrus network and broadcasts the created blocks to the Tapyrus network. Network participants will then verify the validity of the blocks created by the transaction and signature network.

Colored Coins were developed as part of the Bitcoin 2.0 project (handling Bitcoin as financial assets such as securities and bonds, assets such as commodities and real estate, and expressing this asset information in colors). Besides the underlying cryptocurrency that maintains the Tapyrus chain, it can support the operation of issuing, canceling, and transferring arbitrary tokens designed with unique value by network participants. This includes support for data provision by Oracle, and Tapyrus will support data provision by a trusted third party (Oracle) to enable the execution of smart contracts conditional on real-world data.

Two important features are introduced here. Atomic Swap and Extension Chain. The former is a technology that enables peer-to-peer exchanges between two cryptocurrency tokens on different blockchain networks, and Tapyrus can support coin/token exchanges between chains with features based on atomic swaps. . In addition, by making the unique functions of various blockchains mutually usable, participants can implement the necessary functions at any time. Also, Extension Chain is a mechanism that adds specific functions to the blockchain without changing the first layer, and only the participants who need the functions bear the additional overhead. This avoids the centralization of the network and the burden of data not directly related to transactions by network participants, which could have been caused by implementing the first layer to handle all needs in the past.

A feature of transactions using blockchain is that all transaction histories are recorded in a block (ledger). When dealing with, huge storage and throughput are required. In addition, with a proprietary protocol that uses an accumulator, a large amount of transaction data is compressed and recorded in each block, thereby solving storage and throughput problems, which was difficult until now without compromising security. Enables massive data transactions.

"Paradium" is a blockchain traceability application. "Paradium" is an application that can manage the movement of large amounts of goods (massive transaction volume) by solving problems of storage and throughput by installing Tracking Protocol using Accumulator developed by

“Chaintope”. It is possible to implement the traceability function of blockchain not only on private chains that are managed independently, but also on public chains that do not have a central administrator. It is possible to safely manage the movement of goods using blockchain technology not only for one company but also between companies or across industries.

Tapyrus version 0.5.0 is now available for download¹. Tapyrus v0.5.0 is supported on three platforms: Linux, MacOS and Windows (WSL). Introduce new opcode `OP_COLOR` (0xbc) to allow issuing/sending/destroying arbitrary tokens in Tapyrus. `OP_COLOR` is based on `OP_GROUP`, which was previously considered for introduction in BCH, with some improvements, and has the following functions.

- Token issuance.
- Issuing reissue able tokens.
- Issuance of non-reissue able tokens.
- Issuing NFTs.
- Sending token.
- Incineration of tokens.

B. Web3.0

Blockchain has affinity with Web3.0 and decentralized applications. Web3.0 (Web3) was proposed by Gavin Wood, co-founder of Ethereum in 2014. It consists of a web system built in a distributed manner instead of the conventional centralized one. It refers to an ecosystem where Blockchain is the underlying technology. Gavin Wood proposed the notation Web3. Initially, Web 3.0 was the Semantic Web advocated by Tim Berners-Lee of W3C, that is, the Web that allows computers to collect information and make decisions autonomously, but this concept has spread to the general public. Web 3.0 and Web3 have come to be equated because they were not.

There is “Infrastructure mode” which is one of the operation modes that can be performed with a wireless LAN. To use the wireless LAN environment, install a router that serves as an access point. Installing an access point enables Internet communication via wireless LAN. Wireless LAN is not limited to Internet communication. In a wireless LAN environment, communication between terminals using the same LAN is possible. The function to communicate between terminals using the same LAN is called infrastructure mode.

On the other hand, “Ad hoc mode” is also one of the operation modes of wireless LAN, but it is a paired function with infrastructure mode. In ad-hoc mode, terminals communicate with each other without using an access point. In ad-hoc mode, communication is encrypted using the WEP method, but because the security standard is older, the risk of being deciphered is higher than in infrastructure mode, where communication is encrypted in a more complicated format. In infrastructure mode, files can be shared faster than in ad-hoc mode. Infrastructure mode is also superior in terms of ease of

setup, so there aren't many benefits to using ad-hoc mode from now on.

When communicating between terminals in ad-hoc mode, the Internet cannot be used while files are being shared. In infrastructure mode, the Internet can be used even while terminals are communicating with each other. Ad-hoc mode allows only one-to-one communication, but infrastructure mode allows one-to-many communication. A single computer can communicate with multiple devices at the same time.

There are no major disadvantages to infrastructure mode, but the following three points should be noted.

- Need to prepare an access point.
- A compatible router is required.
- Peripheral devices must support wireless LAN.

To use infrastructure mode, installation of a wireless LAN router that will act as an access point is needed. Note that one-to-many communication is not possible without a wireless router. In addition, any wireless LAN router is not sufficient, and a model that supports infrastructure mode is required.

In the ad-hoc networking, terminals that can communicate using infrastructure mode are not limited to PCs but can also be used with various peripheral devices.

III. PROPOSED METHOD

The network architecture is based on IEEE 802.11s. Wireless ad-hoc mode is a method for wireless devices to directly communicate with each other. Operating in ad-hoc mode allows all wireless devices within range of each other to discover and communicate in peer-to-peer fashion without involving central access points.

On the other hand, blockchain technology is a type of database that directly connects terminals on an information communication network and processes and records transaction records in a distributed manner using cryptographic technology. Blockchain has a mechanism that can easily detect falsification of data by using encryption technology such as “hash” and “electronic signature”. Blockchain has a mechanism that can easily detect falsification of data by using encryption technology such as “hash” and “electronic signature”. In addition, although an unspecified number of participants conduct transactions in blockchain, many participants (not necessarily all participants) record copies of everyone's transaction history, so some computers may go down. However, the entire system does not go down, as many of the remaining participants continue to keep records. Since the copy of this transaction history cannot be deleted, the transaction record once recorded remains as evidence without disappearing. A system in which data is distributed among many participants is called a distributed system.

Many distributed systems to date have had a central administrator for the system. However, in blockchain, all participants continue to copy transaction history autonomously. This is called an autonomous decentralized system and can be said to be one of the major features of blockchain. The characteristics of this autonomous decentralized system, which

¹ <https://github.com/chaintope/tapyrus-core/releases/tag/v0.5.0>

does not allow fraud or tampering and stably records the history of fair transactions, has been indispensable for transactions that require high credibility, such as cryptocurrencies.

Essentially, networking for the block chain, therefore peer-to-peer based networks. The proposed method is applicable to the block chain networking even for the network nodes are moving devices. Furthermore, the mobile devices can be moved from one to the others. Even so, the network connectivity can be maintained. Therefore, the method works well for block chain networking.

The network situation is illustrated in Fig. 1 where MPP: mesh portals, MP: mesh point, AP: access point, MAP: mesh access point, STA: pure client station.

Fig. 1. Network situation.

The followings are situations,

- 1) Each Node has direction, speed, move with distance.
- 2) Each Node will sense path to others (same area) for send DATA.
- 3) Each node will keep path to Agent for send DATA (to other area).
- 4) Agent is special Node (unlimited Energy).
- 5) Agents become relay to other area.

Research focused on three bottom layers of the OSI model. In the physical layer was air (wireless medium) and the followings are set-up in the Data Link layer (Interface),

- 1) Node addressing.
- 2) Packet transmission / re-transmission,
- 3) Buffer receives / transmit,

The followings are also set-up in the Interface with Link,

- 1) Network layer (Data Handler),
- 2) Route calculation *weight criteria,
- 3) Path determination,
- 4) Packet examination,
- 5) Fragmentation / de-fragmentation,
- 6) Packet re-formation,

When nodes do communicate with others, they will use other node as relay (if destination located far away). The number of relays will determine hops. Relay will receive,

process, and transmit packet. Relay will calculate the best route to next relay / node. Transmission will follow sequential process (from node to node until destination). Source and destination (*also agents) will maintain end-to-end communication (TCP communication type) as shown in Fig. 2.

Fig. 2. Communications among the nodes.

Node to node communication is done in accordance with the following steps,

- 1) Broadcast to get neighbor's knowledge,
- 2) Broadcast to send packet to next node,
- 3) Receive messages (packet, reply/Hello, etc.) from the other node, examine it, and process it,
- 4) During data transmission, each node must follow point to point communication type.

a) In this situation, error transmission through wireless medium is considered. Bit error happen when source sent bit 'b' and receiver doesn't receive 'bit' b. Bit error rate (BER) shows the probability of bit got error. Typical value of BER for electric link was 10⁻⁹, and for optical link was 10⁻¹². Source of error: EM interferences, loss signal, hardware failure and memories error during the path route, etc. In this simulation, BER was set to zero. Also, there is no detection and correction scheme.

Duplex link is assumed as shown in Fig. 3. Packet here imitated IPPacket. On each packet, there were:

- HEADER*.
- Source and destination.
- Flags (to mark packet with certain purpose).
- TTL (time to live).
- Type of protocol used*.
- Detection error CRC*.
- Source hop and destination hop.
- DATA (real transmission goal).

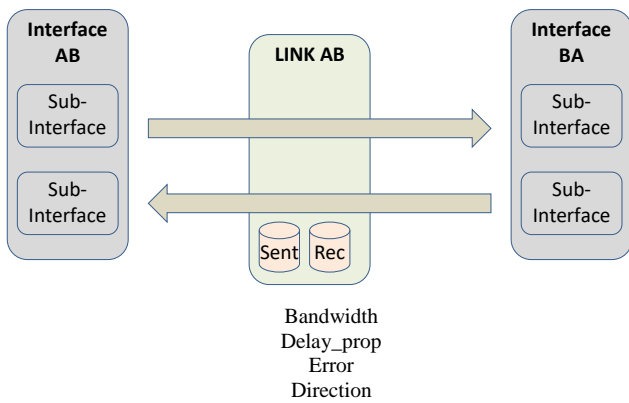

Fig. 3. Assumed duplex link in the simulation model.

There are assumptions made in IPPacket creation. Packets are treated as follows,

- IPPacket formation (executed in Protocol layer).
- IPPacket encapsulation/de-encapsulation.
- IPPacket queue.
- IPPacket transmission (unload/reload source hop and destination hop).
- IPPacket fragmentation / de-fragmentation.
- IPPacket re-formation.

Furthermore, packet formation is as follows,

DATA in BYTES (which intended to be sent).

Header information.

Protocol TCP.

Source and Destination.

Length.

ID.

TTL (time to live).

Source HOP and Destination HOP.

Flags.

Encapsulate DATA within IPPacket.

Packets are transmitted as follows,

Sender Station A:

When IF, send it out; Start Tout timer for this IF,

Wait for Tout (Time-out value) for ACK,

If (ACK) Then clear timer; proceed to next transmission,

Else backoff for a random number of Tout intervals; retransmit; If no ACK after repeated transmissions, give up.

Receiver Station B:

If (CRC(IF) OK && DA(IF) == address(B), send ACK,

If may be damaged by noise or by another station transmitting at the same time (collision).

Any overlap of frames causes collision.

Packet Framing is done as follows,

Responsible for: reliable transmission of frame through Link.

Determine complete packet receiving.

Error detection: CRC check.

Error recovery: retransmission of packets.

Live time of packet exceeded.

Selective ARQ (Automatic Repeat Request).

Boundaries of frame:

Character oriented framing.

Length counts – fix length.

Bit oriented protocols (flags) *used.

Also, Bit Oriented Framing: BOF (Flag) is assumed as follows,

Flag is (actually sequence of bits) that used to indicate the beginning and end of completed packet.

Together with fragment_offset, sequence of fractioned packet can be determined.

Standard protocol used bit sequence of 8 01111110 as ONE flag.

INVENTED ~ 1970 by IBM for SDLC (synchronous data link protocol).

Packet fragmentation means break up the data into smaller pieces. This is necessary when the maximum transmission unit (MTU) is smaller than the packet size. For example, the maximum size of an IP packet is 65,535 bytes while the typical MTU for Ethernet is 1,500 bytes. Since the IP header consumes 20 bytes (without options) of the 1,500 bytes, 1,480 bytes are left for IP data per Ethernet frame (this leads to an MTU for IP of 1,480 bytes). Therefore, a 65,535-byte data payload (including 20 bytes of header information) would require 45 packets $(65535-20)/1480 = 44.27$, rounded up to 45 as shown in Fig. 4. On the other hand, Fig. 5 and 6 show packet transmission in send and receive, respectively.

Meanwhile, as shown in Fig. 7, route / path calculation can be done as follows,

Stated as Table_routing.

Used 3 criteria: buffer on next hop, distance (*RTT), and direction of next hop (getting closer or away).

Buffer and distance made throughput weight on the link.

Route decision is executed in DataHandler layer.

Table_Routing is shown in Table 1. In the table, the followings are detailed assumptions,

Node_address: address of Interface in next hop.

Interface: set Interface must be used to reach next hop.

RTT: round trip time.

Throughput: throughput calculation for link.

Direction: + (getting closer), - (getting away).

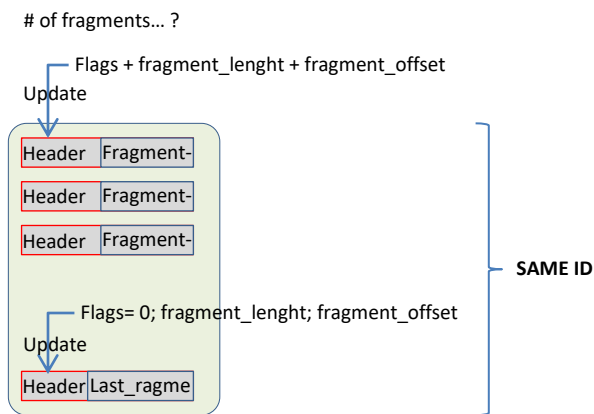

Fig. 4. Packet fragmentation.

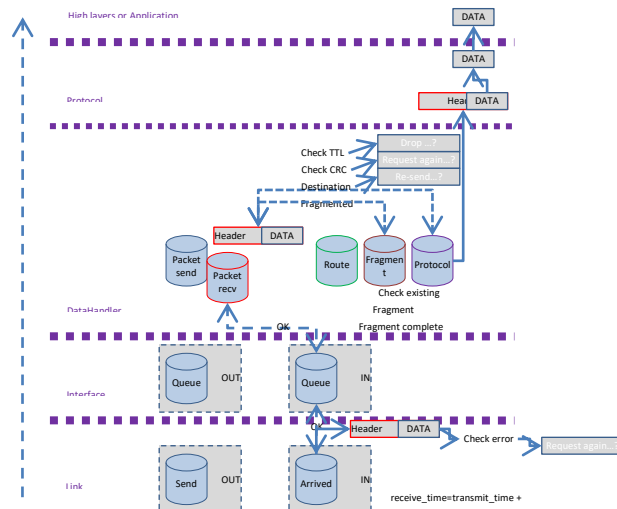

Fig. 6. Packet transmission (receive).

Fig. 7. Route / path calculation.

TABLE I. ROUTING TABLE

Node_address	Interface	RTT	Throughput	Direction
192.168.0.2	ABIface	b ms	1000 Bytes/ms	+
192.168.0.20	ATIface	t ms	8000 Bytes/ms	-
...				

Energy can be calculated as follows,

- 1) Node dissipates $E_{elec} = 50$ nJ/bit to run the transmitter or receiver and $\epsilon_{amp} = 100$ pJ/bit/m² for the transmit amplifier.
- 2) To transmit a k-bit message a distance d, the Node expends:
- 3) To receive the message, the Node expends:
- 4) The communication range of the nodes is a perfect symmetric unit disk. If $dx,y \leq r_x \rightarrow$ then Node-x and Node-y can see each other.

Fig. 5. Packet transmission (send).

IV. SIMULATION STUDIES

Node Deployment is shown in Fig. 8 and is assumed as follows,

Fig. 8. Node deployment.

- 1) Each node examines itself and senses its neighbors.
- 2) Nodes create object Interface (with #Interface equals to #neighbors).
- 3) Ex. Node A has Interface AB, AC, and AD.
- 4) Interface AB is read as Interface at Node A that can reach Node B. Interfaces at a Node have same address.
- 5) Every Interface (in Node) is related with object Link (#Link equals to #neighbors).
- 6) Ex. Node A connected with Link "a", Link "f", and Link "c". Link "a" was used by Interface AB; Link "f" was used by Interface AC; Link "c" was used by Interface AD.
- 7) Nodes calculate buffer, RTT, and throughput through each owned Link.

With these, Node forms a routing table.

- route 1:192.168.0.2; Interface_AB; RTT; throughput; 0.
- route 2:192.168.0.3; Interface_AC; RTT; throughput; 0.
- route 3:192.168.0.4; Interface_AD; RTT; throughput; 0.

In the simulation study, the following 25 nodes and 4 initiators are considered as shown in Fig. 9.

Initiator node is node that initiates transmission of packet. Like other nodes, initiator is always moving with random direction, speed, and distance as shown in Fig. 10.

Fig. 9. Network configuration.

Fig. 10. Packet transmission speed.

V. CONCLUSION

Method for Ad-Hoc blockchain of wireless mesh networking with agent and initiate nodes is proposed. Minimizing the number of hops and maintaining connectivity of mobile terminals are concerns. Through simulation studies, it is found that increasing number of initiator nodes caused nodes to route a large number of messages. Thus, these nodes will die out quickly, causing the energy required to get the remaining messages to increase and more nodes to die.

This will create a cascading effect that will shorten system lifetime. Multi-hop routing, however, imply high packet overhead, (more nodes in the network means more hops will be available). The packet overhead of the multi-hop routing is extremely high compared to single path routing since many nodes near the shortest path participate in packet forwarding. This additional overhead caused by moving node can cause congestion in the network.

The idea of a "decentralized network", which is the greatest feature of Web 3.0, may change the existing corporate form. That is the birth of the decentralized autonomous organization "DAO". A DAO is an organizational form without a centralized administrator. Because it is an organization operated by a program on the blockchain, it has the advantage of being extremely transparent. In addition, since there is no top, it is managed democratically, such as by voting when deciding something, and the direction is decided by the party that wins the majority. The proposal method that can build this block chain ad-hoc can contribute to promote Web3.0.

VI. FUTURE RESEARCH WORKS

Further investigation needs to be conducted on dynamic routing advantages and factors which affect routing mode, e.g., flow type, delay, and etc. The throughput/delay/reliability tradeoff between wireless network areas that deploy agents and without agents is also investigated.

ACKNOWLEDGMENT

The author would like to thank Professor Dr. Lipur Sugiyanta of Jakarta State University (former student of Saga University) for his great effort for creation of Ad Hoc Networking and for his simulation studies. Also, the author would like to thank Prof. Dr. Hiroshi Okumura and Professor Dr. Osamu Fukuda for their valuable discussions.

During from 1985 to 1987, he was with Canada Centre for Remote Sensing as a Post Doctoral Fellow of National Science and Engineering Research Council of Canada. He moved to Saga University as a Professor in Department of Information Science on April 1990. He was a councilor for the Aeronautics and Space related to the Technology Committee of the Ministry of Science and Technology during from 1998 to 2000. He was a councilor of Saga University for 2002 and 2003. He also was an executive councilor for the Remote Sensing Society of Japan for 2003 to 2005. He is a Science Council of Japan Special Member since 2012. He is an Adjunct Professor of University of Arizona, USA since 1998. He also is Vice Chairman of the Science Commission "A" of ICSU/COSPAR since 2008 then he is now award committee member of ICSU/COSPAR. He wrote 77 books and published 670 journal papers as well as 500 conference papers. He received 66 of awards including ICSU/COSPAR Vikram Sarabhai Medal in 2016, and Science award of Ministry of Mister of Education of Japan in 2015. He is now Editor-in-Chief of IJACSA and IJISA. <http://teagis.ip.is.saga-u.ac.jp/index.html>.

Recommendation System on Travel Destination based on Geotagged Data

Clarice Wong Sheau Harn, Mafas Raheem

School of Computing,

Asia Pacific University of Technology and Innovation, Technology Park, Kuala Lumpur, 57000, Malaysia

Abstract—Tourism research has benefitted from the worldwide spread and development of social networking services. People nowadays are more likely to rely on internet resources to plan their vacations. Thus, travel recommendation systems are designed to sift through the mammoth amount of data and identify the ideal travel destinations for the users. Moreover, it is shown that the increasing availability and popularity of geotagged data significantly impacts the destination decision. However, most current research concentrates on reviews and textual information to develop the recommendation model. Therefore, the proposed travel recommendation model examines the collective behaviour and connections between users based on geotagged data to provide personalized suggestions for individuals. The model was developed using the user-based collaborative filtering technique. The matrix factorization model was selected as the collaborative filtering technique to compute user similarities due to its adaptability in dealing with sparse rating matrices. The recommendation model generates prediction values to recommend the most appropriate locations. Finally, the model performance of the proposed model was assessed against the popularity and random models using the test design established using Mean Average Precision (MAP), Root Mean Square Error (RMSE), and Mean Absolute Error (MAE). The findings indicated that the proposed matrix factorization model has an average MAP of 0.83, with RMSE and MAE values being 1.36 and 1.24, respectively. The proposed model got significantly higher MAP values and the lowest RMSE and MAE values compared to the two baseline models. The comparison shows that the proposed model is effective in providing personalized suggestions to users based on their past visits.

Keywords—Geotagged data; travel recommendation system; travel recommender; collaborative filtering; matrix factorization

I. INTRODUCTION

A. Background

The World Travel and Tourism Council reported that the tourism industry contributed around 11% to the global economy in 2019 before the pandemic outbreak [1]. This illustrates that the tourism industry has been one of the most influential and profitable industries and has been a major contributor to the global economy. It is also one of the most promising sectors. The travel industry has evolved dramatically over time, and the introduction of big data analytics has profoundly impacted people's travel. Travelers used to rely on newspapers, magazines, and radio to get to know about places and plan their trips with help of the travel agencies. However, in modern society, travelers have numerous options to plan their trips.

The rise of big data and the evolution of technology have significantly impacted people's travel [2], [3]. Today, many people book their trips online using platforms such as TripAdvisor and Expedia. The increasing amount of data collected and accessible by travel providers has facilitated the creation of sophisticated analytics and forecasting algorithms. The rise of social media has also greatly impacted how people communicate allowing users to exchange content, such as pictures and videos, and has greatly aided in human interaction. The report by Wyman [4] further illustrates that travelers have expanded their social media usage by 44% since the pandemic, and 92% of users find useful information online about places to visit.

The impact of social media on travel destinations was investigated in several studies in the past. Various social media platforms, blogs and online communities are becoming more prevalent in the travel industry as they allow users to connect and share their experiences [5-7]. Social media platforms such as Twitter, Flickr, and Facebook have enabled travelers to share information and express their travel experiences online, which has helped boost the reputation of a city as a desirable travel destination. The study also noted that Generation Z and Millennials are more likely to utilize social media to plan their vacations because they value online experiences more than commercials. The study [8] elaborated that having a strong online presence is very important for a destination to gain a positive reputation, and social media significantly impacts how customers choose travel destinations.

The travel industry is one of the most data-driven industries in the world due to the exponentially increasing amount of data. It is often difficult for individuals to select the ideal holiday destination due to a lack of understanding of the various attractions and the complexity of the planning process. Consequently, several research works were conducted on travel recommendations that consider the different elements to deliver personalized recommendations based on the preferences and behaviours of users [9-11].

A geotagging service is a type of geographic identification service that may be used to identify the location of a media file or social media post. The data typically includes a latitude and longitude coordinate that may be used to locate the captured place on a map, as well as the date and time the picture or post was filmed [12]. According to the study, the growth of location-based social networks has enabled individuals to construct their social networks based on interpersonal contacts. Studies explained that the expansion in publicly available geotagged social media data may be attributed to the adoption

of social media platforms such as Facebook, Instagram, and Flickr [13-15]. In addition, geotagged data is rich in information about the users' interests and may be utilized to discover new regions of interest. The statement is reinforced and demonstrated that the analysis of geotagged data may assist the government in promoting tourist places [16]. Therefore, using geotagged social media data to identify tourist hotspots is advantageous for developing a trip recommendation model.

A major portion of establishing successful travel recommendation systems has focused on examining the reviews from Google Maps and TripAdvisor. Although the models are accurate, oriented towards a few famous landmarks and do not utilize geotagged data to make personalized recommendations depending on the user's preferences.

B. Problem Statement

Numerous studies indicate that the prevalence of social media networks that supply geotagged data is increasing the influence of this data type on users' destination selections [5], [7], [17]. Due to the rising popularity of geotagged social media as a source of travel destinations, the existing travel recommendation system lacks the efficiency to fully leverage the information gathered from geotagged data to construct a travel recommendation model that can study users' preferences.

C. Aim

The research aims to determine the role of geotagged data in shaping the selection of attractions using clustering techniques and develop a travel recommendation model as well as compare it to the models with different approaches.

D. Significance and Scope

Extensive studies have attempted to develop a personalized travel recommendation model to assist people in filtering data to attractions that match their preferences [10], [18], [19-20]. The proposed travel recommendation system allows travelers to discover possible destinations based on their interests. Additionally, the tourist sector may utilize the potential information gathered from the research to establish successful marketing plans in the tourism sector and increase operational efficiency. The dataset for this research was acquired from Kaggle which contains 20,000 geotagged data points in London between 2014 and 2019 [21]. London is recognized for its various attractions, including stunning architecture and historical buildings. Given that the coronavirus pandemic in 2020 may impede travel mobility, the final year of 2019 in the dataset is ideal [22]. Given that the data obtained for this research was collected at random and across time, the recommendation model will focus on location recommendations rather than route suggestions.

II. RELATED WORKS

A brief history of the recommendation system describes various forms of recommendation systems including the current state-of-the-art techniques for the travel recommendation system. Past studies conducted using geotagged data were reviewed and summarized at the end of this section.

A. Recommendation System

During the 1990s, research in the field of recommendation models started focusing on developing systems that can predict product ratings [23-24]. The recommendation model suggests the best suitable goods and services to its consumers through the information gathered [25]. The most notable examples include Amazon's personalized shopping system, YouTube's suggestions for videos relevant to the viewers' interests, and Facebook's system allows users to interact with more people. The rise of information technology made users and organizations more dependent on recommendation systems to sift through the vast amount of data collected in this century.

B. Types of Recommendation Systems

The recommendation systems can be categorized into four different categories such as content-based, collaborative-based, hybrid-based, and knowledge-based [25-30]. The content-based method connects user traits with items most likely to satisfy their demands. The collaborative filtering technique, on the other hand, believes that individuals with similar interests and historical behaviours would act similarly in the future. The disadvantage of implementing a content-based system is that it heavily relies on the knowledge base to provide recommendations while implementing collaborative filtering can be very challenging when the users are relatively new to the platform. A knowledge-based system can be very useful in helping users find the best products and services that are seldom acquired, such as luxury goods and real estate. As the calculation is based on the similarity between the item descriptions and the user's needs, it is essential to outline the knowledge base needed to generate recommendations [31]. However, the process can be very time-consuming and costly. Besides, a hybrid recommendation system uses the best elements from various techniques to overcome these shortcomings. The research [29] proposed the hybrid system integrated the characteristics of content-based and collaborative filtering to have the right predictions.

To date, numerous pieces of literature have studied the recommendation system in a broad range of industries. For instance, [30] proposed a matrix factorization-based recommender system that can recommend books based on the similarities and ratings of users. In contrast, a movie recommendation system was developed by applying the content filtering technique to exploit the movie's genre characteristics and requested the users to answer a few questions while building up their profiles to enrich the users' data [32]. Moreover, [33] used the content-based approach to suggest music to users based on the musical features utilizing the convolutional recurrent neural network (CRNN) method. As online learning sites grew in popularity, a knowledge-based recommendation system was proposed, which serves as an agent to assist users in recommending appropriate courses and materials based on their preferences and requirements [34].

C. Algorithms used in Travel Recommendation System

Multiple studies on recommender systems in the tourism industry were undertaken over the years to assist individuals with their trip decisions. The authors in [35] analyzed the essential information and interests of the users on social media platforms to suggest travel-related activities in Tunisia. The

proposed system created user profiles using the content-based filtering algorithm based on the content they posted on social media sites such as Facebook, TripAdvisor, and Twitter. Furthermore, [11] conducted a study that analyzed the opinions of Korean undergraduates on various destinations. The study used a collaborative method to analyze the similarities and differences between the users. It also considered the various restrictions and demands to provide personalized suggestions. However, since the data for the study was only collected from a single university, the results might be biased.

The study [10] collected users' reviews from TripAdvisor and developed a collaborative system to deliver suggestions to their users. The researchers used a combination of text processing and semantic clustering to analyze the data and extract their preferences for recommendations. However, the research only acquired 100 reviews from the site on specific locations, which may have led to skewed findings and the neglect of other less-visited attractions. Likewise, [20] sought to discover the ideal tour route for international visitors in South Korea by examining TripAdvisor ratings. Text mining and network analysis were used to perform a comprehensive analysis of user preferences. However, the study overlooked the lesser-known attractions since the model only collected reviews from top attractions in the country.

The research [18] proposed a travel recommendation model to analyze the reviews collected from Google Maps and identify the most relevant locations for travellers based on the similarities and differences between the users' reviews. The Jaccard Similarity and Cosine Similarity were used to calculate the similarity scores. The algorithm ranked the most popular locations using a neural network and associated the users' preferences through the similarities of their reviews. On the other hand, [9] used Twitter data and built a system using a collaborative filtering framework with users' profile matrix and their interests. The travel-related tweets were mined for sentiment analysis, and a follow-up step was performed to determine the social media activity of their friends. The algorithm will generate travel recommendations and suggest various destinations based on relevant tweets. Unlike previous systems, the model was time-sensitive, allowing it to collect the users' most recent interests.

Moreover, [36] proposed a deep learning-based recommendation model to analyze the data from blogs, Google Maps and TripAdvisor to recommend travel activities in the country. Latent Dirichlet Allocation (LDA) was employed by the researchers for topic modelling in tourist blogs. These topics were used to extract the sentiments from Google and TripAdvisor reviews. The user history was extracted based on the information and a collaborative filtering technique was used to predict the most likely visited locations based on the users' preferences.

D. Analyzing Geotagged Data

The development of geotagging services and Web technologies have boosted the amount of geotagged data accessible. Through social media platforms like Foursquare, Facebook, and Flickr, individuals can now easily share their locations with others. Consequently, a growing corpus of

research explored the use of geotagged data in personalized travel destination suggestions [37-39].

The authors in [38] presented a travel recommendation system that combines geotagged data with users' textual information. The multiclass SVM classifier was used to identify candidates from the user's travel history. The data was analyzed using a gradient-boosting regression model, which ranked the candidates based on their interests. Moreover, [19] proposed a weighted multi-information criteria matrix factorization model for recommending travel locations based on geotagged photos from Flickr. The model was built to examine the various aspects of a user's visit sequence, as well as the textual and visual information to recommend travel locations. The textual information in the photos was processed using Latent Dirichlet Allocation (LDA) to profile the attractions, and the model was tested on a sample of six Chinese cities.

The researchers in [37] combined the sequential and temporal information from the geotagged photos to build personalized itineraries based on the travel patterns of individual users. The model was developed using a collaborative filtering strategy to analyze the visit sequences and preferences of other users. In addition, [39] established a framework for determining the interests of Hong Kong tourists based on geotagged data. The study combined image processing, text processing, and clustering algorithms to evaluate geotagged data in three geographical locations, enabling the government to comprehend better and promote popular vacation spots.

Numerous studies have identified landmarks and tourist attractions based on geotagged data acquired using clustering algorithms [36-37], [39-40]. The geotagged data was clustered using several techniques, including K-means clustering, mean shift clustering, and density-based clustering to build a location database containing the travel records of users to different destinations.

E. Summary

According to the existing travel recommendation models, the most common technique used in developing travel recommendation models is the collaborative filtering approach, which involves analyzing the users' interactions or similarities. However, most studies have focused on leveraging reviews from travel websites or textual information for topic modelling from geotagged data. This demonstrates a deficiency in using the implicit information from the geotagged data, which does not require extra information. Additionally, clustering techniques are often used to group geotagged data to build a location database. Therefore, the proposed model would employ a clustering algorithm to identify locations from the geotagged data, and the collaborative approach will be utilized to compute user similarities. The model will then deliver personalized recommendations to the users based on their travel histories.

III. MATERIALS AND METHOD

The research process was structured as a sequence of stages designed to achieve the study's goals. The steps include data selection, data pre-processing, data transformation, model

building, and evaluation. A flowchart is also provided to visualize the whole process as shown in Fig. 1.

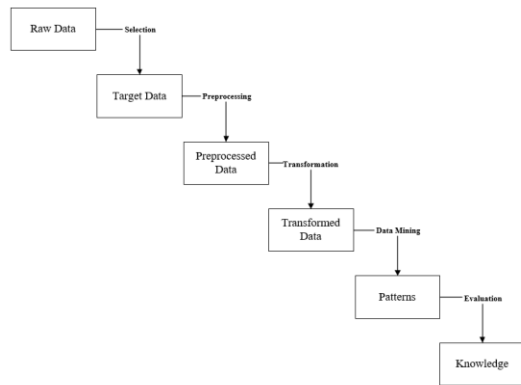

Fig. 1. KDD process.

A wide variety of data mining approaches are available for detecting patterns and interpreting data to develop a model. Knowledge Discovery in Databases (KDD) was chosen as the data mining methodology to develop the travel recommendation model. It is a process of studying data to uncover patterns that can be utilized to identify meaningful information [41]. Fig. 2 illustrates the entire process of developing the travel recommendation model.

Fig. 2. Project workflow.

F. Selection

The literature review and research objectives provided a clear understanding to create the model. The selection procedure defined the target dataset for model building. The variables that could be used to construct the travel recommendation model were chosen at this stage.

1) *Variables selection*: As specified in the research scope, the dataset used for this study was obtained from Kaggle with 20,000 records and 13 attributes [21]. The attributes that contain the geographical information, the owner and the time were used to develop the recommendation model.

2) *Dataset exploration*: Data exploration is the process of examining data to comprehend better the data and reduces the likelihood of incorrect decisions [41]. The data properties were examined, and the geotagged data were visually analyzed. In addition, the missing values were also inspected.

G. Pre-Processing

Data pre-processing is typically performed to prepare the data before data modelling. The geotagged data were clustered, and redundant data was removed to improve the efficiency of the analysis.

1) *Data cleaning*: Data is the foundation of every data mining project. However, as data comes in a variety of formats and sizes, it must be thoroughly analyzed to ensure no discrepancies or outliers. Therefore, data cleaning was performed to identify missing values, outliers, and inconsistencies. The two most important attributes used in developing the travel recommendation model were the geotagged data, which includes latitude and longitude information. As a result, individuals with incomplete information for these two attributes were removed from the dataset, as the imputation of geographic location may disrupt the dataset's balance.

2) *Clustering technique*: The initial step in the development of the travel recommendations model was to identify the locations from the geotagged data. This process was carried out through the clustering technique, which was used to group the collected data into clusters. Three main types of clustering techniques were commonly used in this process: hierarchical clustering, partitional clustering, and density-based clustering [42].

Several studies have been conducted on identifying landmarks and hotspots from the geotagged data. A classical method used in discovering tourist attractions is the Density-based spatial clustering of applications with a noise clustering algorithm (DBSCAN) [37], [40], [43-45]. DBSCAN is effective in clustering geotagged data since it requires less knowledge to detect arbitrary shape clusters with varying densities. This method seems to be more effective when analyzing spatial data concerning latitude-longitude coordinates. The clustering process shall result in a dataset that resembles Table I.

TABLE I. DATASET AFTER DBSCAN

photo_id
user_id
lat
lon
Taken (time stamp)
location_id (cluster label)
cent_lat (cluster lat)
cent_lon (cluster lon)

3) *Location database*: A location database is built by applying the appropriate clustering technique which helped to label the geotagged data. The resulting database was found with the sorted locations visited according to the timestamp included. According to the study by [19], if the user concurrently uploads two geotagged posts during the same visit, the two posts should be regarded as one. This is to reduce the number of repeat visits by the same users and improve the quality of the location database. The duplicate records would be deleted if the time interval between two

successive postings is less than three hours and assumed to have originated from the same visit.

Individuals with less than three geotagged posts were excluded from the dataset since the model was constructed using the collaborative approach. As illustrated in Table II, the final location database containing user travel histories shall have five variables: location id (cluster label), user id, lat, lon, and time taken (timestamp).

TABLE II. LOCATION DATABASE

location_id	user_id	lat	lon	time_taken
-------------	---------	-----	-----	------------

H. Transformation

The data transformation process involves arranging the data into a suitable form for modelling. In this stage, the user-location rating matrix was built using the pre-processed geotagged data.

1) User-location rating matrix: Using their historical travel records, individuals' preferences for a place may be inferred by the frequency of their visits to a travel destination. Inspired by the research of [19], the user-location rating table estimates the frequency of a user's visits to a travel location as ratings. Therefore, the number of times a user has visited a specific location is used to construct a new variable, ratings. As illustrated in Table III, three variables: user id, location id, and ratings depending on the frequency of visits were transformed into a matrix as shown in Table IV. The ratings were standardized using the min-max approach to ensure that the forecast is not skewed towards popular attractions.

TABLE III. USER-LOCATION RATING TABLE

location_id (cluster label)	User_id	Ratings
-----------------------------	---------	---------

TABLE IV. USER-LOCATION RATING MATRIX

User_id	location_id			
	A	B	C	D
1	rating	rating	rating	rating
2	rating	rating	rating	rating
3	rating	rating	rating	rating

I. Data Mining

Data mining is the process of examining data to uncover hidden insights and patterns. This process aims to develop a personalized travel recommendation model that can provide the best possible Matrix Factorization Model.

Multiple techniques are used in the construction of the recommendation model. According to the literature review, there are four main techniques such as content-based, collaborative-based, knowledge-based, and hybrid-based. This study used a collaborative approach based on user similarities since many prior studies relied on collaborative techniques to investigate user interactions and provide recommendations. For instance, [11] investigated destination reviews and user similarities to recommend vacation places, while [37] presented an itinerary planner by assessing different travel

patterns from other users and matching the suggestions to the users' preferences.

TABLE V. USER-USER SIMILARITY MATRIX

User_id	User_id		
	1	2	3
1	similarity	similarity	similarity
2	similarity	similarity	similarity
3	similarity	similarity	similarity

Similarity value is one of the most crucial aspects when building a recommendation system using a collaborative method. The user-location rating matrix was used to generate the user-user similarity matrix (Table V) to construct the recommendation model. The cosine similarity algorithm was selected as the metric to determine the similarities between various users since it is one of the most extensively used and well-known similarity measures [18-19], [40], [46-50].

The recommendation model was built to predict the ratings to generate recommendations based on the user profiles from the user-user similarity matrix with a sparse rating matrix. Despite the popularity of the K-Nearest Neighbor (KNN) model as a collaborative-based technique, the KNN model required users to select the number of nearest neighbours, making the prediction unstable [51]. The study found that the non-negative matrix factorization model outperformed the k-nearest neighbour model in terms of accuracy and error metrics while constructing the movie rating recommendation system. Besides, [52] noted that the matrix factorization model was able to provide more precise pairwise preference scores and ranking predictions. Therefore, using the value generated from the cosine similarity algorithm, the matrix factorization model, which was extensively used in recommender systems in a variety of domains, was used to provide personalized recommendations to the target users [47], [53-55]. The system would be able to identify latent factors in the data and recommend the most appropriate destination according to their preferences without requiring additional features.

The matrix factorization can be equation as:

$$P \times Q^T \approx R \quad (1)$$

The main idea of a matrix factorization technique is to fit the rating matrix with a low-ranking approximation that considers the latent features. For instance, the matrix P in the equation represents the association between the user and its features. The matrix Q represents the association between the item and its features. The prediction of the rating is the dot product of the latent factors. The model is fueled by the ratings provided by the user-location rating matrix. The prediction values will be used to rank the top-n suggestions. This aligns with the project's goal of providing personalized suggestions ranked according to the prediction values.

J. Evaluation

Model evaluation is an integral part of the data mining process for measuring the performance of models using a variety of evaluation metrics. Multiple studies indicate that Mean Average Precision (MAP), Root Mean Square Error (RMSE), and Mean Absolute Error (MAE) are the common

assessment metrics for measuring the performance of a recommendation model [19], [30], [38], [47], [53], [55-57].

1) Mean average precision@n (MAP@n) [38]

The formula:

$$Precision = \frac{True\ Positive}{Total\ Positive\ Results} \quad (2)$$

$$MAP@n = \frac{1}{N} \sum_{i=1}^{N_q} AP_i, AP_i = \frac{1}{r} \quad (3)$$

2) Mean absolute error (MAE)

The formula:

$$MAE = \frac{1}{N} \sum |Predicted\ Ratings - Actual\ Ratings| \quad (4)$$

3) Root mean square error (RMSE)

The formula:

$$RMSE = \sqrt{\frac{\sum (Predicted\ Ratings - Actual\ Ratings)^2}{N}} \quad (5)$$

4) Comparison with two baseline methods: The performance of the proposed travel recommendation model was compared with two baseline models. The random selection technique and the popularity-based strategy were chosen for comparative studies [37], [47], [58]. The popularity-based technique recommends the most popular vacation destination based on an overall popularity score. The random selection strategy, on the other hand, generates travel destinations at random from the location database, ignoring similarities between users.

The data was split into training (80%) and testing (20%). The recommendations were made based on the users' past travel experiences, and the recommended locations were ranked based on the projected values. The top-n recommendations to the target users were compared with the actual ratings.

IV. IMPLEMENTATION

A. Data Pre-Processing

The data pre-processing is crucial to building the model since it allows the dataset to be prepared for modelling purposes.

The data was obtained from Kaggle with over 20,000 records and 13 attributes as described in Table VI.

1) Variables selection: The project's objective was to recommend travel destinations to users based on geotagged information collected. As shown in Table VII, the study employed only five variables for building the model such as picture id, user id, geographical information, including the latitude and longitude of the images, and the time at which the photos were taken.

TABLE VI. DATASET DESCRIPTION BEFORE VARIABLES SELECTION

No	Attributes	Description
1	photo_id	photo id
2	owner	user id related to the owner of the photo
3	gender	owner's gender
4	occupation	occupation of owner
5	title	title of photo
6	description	description of photo
7	tags	photo tag
8	faves	photo's favorite rate
9	lat	photo's latitude
10	lon	photo's longitude
11	u_city	owner's city
12	u_country	owner's country
13	taken	the time of the photo taken

2) Data exploration: The data type of the dataset was inspected after eliminating unnecessary attributes. Suitable type conversions were done to the variables such as date, latitude, and longitude to prevent slower operations during data transformation and model construction. The dataset was examined for missing values and confirmed with no imputation or removal of data required.

3) Clustering algorithm: The initial step in developing the travel recommendation model involved identifying the locations of the geotagged data. The study [59] highlighted that it is often challenging to process spatial data due to the existence of redundant points. By transforming the number of latitude-longitude coordinates into the corresponding values generated by the clustering technique, DBSCAN can reduce the size of a geographical data set to a small collection of representative points. The data were grouped into clusters to serve as a location for recommendations. The latitude and longitude data were extracted as dbscan_data as the first step.

The two main parameters for the DBSCAN algorithm are the epsilon (eps) and the minimum points (MinPts). The epsilon specifies the radius of a neighbourhood around the center point of the clusters, and it is important to determine the optimal number of clusters. If the eps value is too low, a significant amount of the data will be omitted from the cluster. This is because the value is insufficient to produce a dense region. Conversely, if the value is very high, many objects will be merged into a cluster, making the clustering meaningless. Besides, the parameter MinPts specifies the minimum number of points necessary to create a cluster. The estimation of the various parameters used is often a challenge during the development of an algorithm. Therefore, different combinations of eps and MinPts values were examined to discover the optimal values.

Research [59] stated the haversine metric was used as the metric of the DBSCAN algorithm to minimize the noise generated by the random selection process by computing the great-circle distances between the various points in the data set. Given their respective latitudes and longitudes, the haversine formula relates the great-circle distance of a sphere to two locations on a specified plane. The parameter and coordinates were then converted to radians to ensure the algorithm to perform precise calculations.

Fig. 3 shows the number of clusters generated by various parameter combinations. The optimal value for eps and MinPts was determined using the elbow approach, which is a basic procedure used in cluster analysis [60]. As a result, the eps and minimum points selected were 0.15 and 10, respectively.

The geographical coordinates were converted from 20,000 data points to 181 clusters using the given parameters. With cluster_num = 0 as the noises in the data, 180 clusters were found as the representative points of the travel locations for recommendations. The coordinates of the geotagged data that were formed as part of the cluster were labelled by its cluster labels using the points closest to the cluster's centroid. It was accomplished by taking a set of points and returning to the centermost point of the cluster.

Fig. 4 illustrates the original data set which was reduced to a cluster-representative collection of points where different colours correspond to each cluster formed by the DBSCAN algorithm. The grey dots represent the outliers of the geotagged data points, often known as the dataset's noise.

Fig. 3. Selecting DBSCAN parameters.

TABLE VII. DATASET DESCRIPTION AFTER VARIABLES SELECTION

No	Attributes	Description
1	photo_id	photo id
2	owner	user id related to the owner of the photo
3	lat	photo's latitude
4	lon	photo's longitude
5	taken	the time of the photo taken

Fig. 4. DBSCAN result.

4) *Remove outliers*: The outliers were eliminated as found as noise in the dataset and not beneficial for the recommendation process after constructing the cluster labels for each geotagged data set.

5) *Remove duplicate data*: It is important to note that users may take multiple photos of the same location while visiting a venue. Therefore, if the timestamps between two photos taken at the same location are less than three hours, the visit must be treated as a single visit. The most recent timestamps of the images taken at the same place are then used to determine the time. The elimination of duplicate data was done by merging users with visits within three hours. In addition, for consistency, a random number between 100 and 999 was generated in place of the cluster labels 0 to 180.

6) *Remove users with less than three visits*: Users who have visited less than three distinct places were eliminated as the model was developed using a collaborative filtering approach.

B. Data Transformation

The rating matrix to construct the recommendation model was formed by calculating the number of times a user visited a certain location as a rating. The ratings were scaled to a range between 1 and 5 using the min-max scale function to eliminate bias in the training phase and enhance the efficiency of the data mining process. After the data scaling process was completed, the user-location rating matrix was generated using the pivot_table function to develop a travel location recommendation model and provide users with ideal suggestions based on their previous visits.

The final dataset was split into two: training (80%) and testing (20%) to assess the recommendation model.

C. Data Mining

This section discusses the matrix factorization model, a widely used technique in the collaborative filtering approach to construct the travel location recommendation model.

1) *Matrix factorization model*: The rating matrix is sparse by nature. The goal of the modelling process was to forecast the ratings of the areas that have not been visited by the target

user through user similarities. Therefore, the user-user similarity matrix is crucial for determining the possibility that they will visit other travel destinations. According to [61], the sparsity in the rating matrix is a major factor that affects the performance of collaborative filtering systems, and the matrix factorization model is effective in addressing the insufficiency of ratings. Therefore, the modelling process utilized the matrix factorization model to factorize the various similarities between different pairs of users. The main objective of this process was to predict the missing values of the user-user similarity matrix. The cosine similarity was selected as the metric to predict the similarities between the users. The matrix factorization model decomposed the original matrix of user preferences into two smaller matrix elements, known as latent factors. The model discovered the hidden features of the interactions between different users and analysed the various factors that affect the users' behaviour to recommend the most appropriate destination according to their preferences. The approach was inspired by the study by [57], who revealed that the matrix factorization performed well with sparse data using movie ratings.

After determining various similarities between every pair of users, a weighted average of the ratings from the users like the target user was then used to calculate the ratings to a location for the current user. The projected rating of a specific location was the weighted sum of the ratings given to a certain location by the number of users like the target user. The predicted rating was the expected value that the target users will be assigned to the specific location.

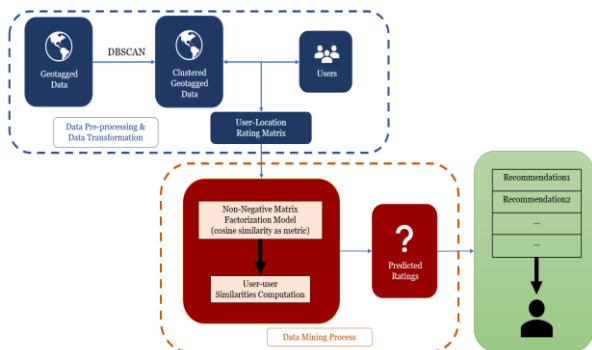

Fig. 5. Data mining process.

Fig. 5 provides a summary of the model implementation. Multiple approaches were used to prepare and transform the data, and the data mining process enables the model to learn and predict ratings for the target user to a certain location.

V. RESULTS AND DISCUSSION

This Section provides a comprehensive analysis of the performance of the developed model. Several evaluation metrics were used to test the model's performance. The results of the study were analyzed through a comparative analysis with two baseline models.

A. Results

The testing datasets were used to construct the test rating matrix for evaluating the proposed model. In the testing dataset, the ratings were also scaled to a range of 1 to 5. Using the proposed model, the predict function was defined to forecast the ratings of locations for a user. Fig. 6 shows the top five suggestions for the representative target user, 41087279@N00. The ratings are displayed side by side with the predictions.

	true	pred
location_id		
137	5.000000	3.261260
511	1.363636	2.655470
115	0.000000	2.650794
152	0.000000	2.650794
155	0.000000	2.650794

Fig. 6. Prediction result.

The proposed model was evaluated against two different baseline approaches selected from past studies, and the assessment was conducted using the same dataset [37], [47], [58]. One of these is the popularity-based method, which used a general popularity score as the basis for its recommendations. It considered the number of unique visits to these locations. On the other hand, the random model generated random travel destinations for the target users regardless of their similarities or popularity scores.

B. Model Comparison

1) *Mean average precision@n (MAP@n)*: The mean average precision (MAP) is a measure that takes into the list of recommendations and compares it with the true set. The n represents the number of recommendations generated to the users. Using n = 5, 10, 15, the MAP for each model was calculated and tabulated for comparison. Based on Fig. 7 and Table VIII, the results show that the proposed matrix factorization model got an average precision value of 0.83, which is higher than the popularity and random models.

Fig. 7. MAP@n.

TABLE VIII. MAP@N

MAP@n	Popularity Model	Random Model	Matrix Factorization Model
5	0.746	0.744	0.829
10	0.749	0.744	0.829
15	0.753	0.745	0.831

2) *Root mean square error (RMSE)*: The Root Mean Square Error (RMSE) is a statistical tool used to assess the accuracy of rating predictions. It measures the square root of the difference between predicted and actual values. As shown in Fig. 8 and Table IX, the matrix factorization model got an RMSE value of 1.36, which is the lowest compared to the two baseline models.

Fig. 8. RMSE.

TABLE IX. RMSE

Models	RMSE
Popularity Model	1.41
Random Model	1.39
Matrix Factorization Model	1.36

3) *Mean absolute error (MAE)*: The Mean Absolute Error (MAE) represents the deviations between the model's predictions and the actual results. Fig. 9 and Table X reveal that the proposed matrix factorization model got the lowest MAE of 1.24 value among the three models. In contrast, the MAE value for the popularity and random models is 1.27 and 1.28, respectively.

The Mean Average Precision@n (MAP@n), Mean Absolute Error (MAE), and Root Mean Square Error (RMSE) of the three models are summarized in Table XI. The results demonstrate that the proposed model has the lowest RMSE and MAE values and the highest MAP@n regardless of the number of recommendations. This proves that the user-based collaborative filtering technique, which computes user-user similarities using a matrix factorization model, effectively identifies the ideal destination for the target users based on their previous visits.

Fig. 9. MAE.

TABLE X. MAE

Models	MAE
Popularity Model	1.27
Random Model	1.28
Matrix Factorization Model	1.24

TABLE XI. MODEL COMPARISON

Models	MAP@n			RMSE	MAE
	5	10	15		
Popularity Model	0.74 6	0.74 9	0.75 3	1.4 1	1.2 7
Random Model	0.74 4	0.74 4	0.74 5	1.3 9	1.2 8
Matrix Factorization Model (Proposed Model)	0.82 9	0.82 9	0.83 1	1.3 6	1.2 4

VI. CONCLUSION

This Section summarizes the findings and the study's contribution to the research field. Limitations and future recommendations are additionally highlighted to improve the algorithm's performance and enhance its usability for the general population.

A. Conclusion

The rapid development and growth of the tourism industry has led to the need for more effective tools and methods to help travellers make informed decisions when planning their trips. Numerous studies have been conducted on the development of effective travel recommendation systems, but most of them have been reliant on reviews and descriptions of the attractions.

The study develops a recommendation system for travellers using geotagged data to provide personalized location recommendations based on user interactions. The evaluation metrics used, such as MAP@n, RMSE and MAE, revealed that the proposed model outperforms the two baseline models chosen by exhibiting recommendations with the highest MAP values and the lowest RMSE and MAE values. As per the findings, the proposed model obtained the highest MAP value using the different number of recommendations generated, with an average value of 0.83. Further, compared to the two baseline models, the proposed model got the lowest RMSE and MAE, with values of 1.36 and 1.24, respectively. This proves that the matrix factorization model effectively generates personalized location recommendations based on users' past visits and interactions with other users.

The study has significant implications for the tourism industry, as the proposed system can help travellers make informed decisions when planning their trips. The use of geotagged data provides a more comprehensive and unbiased view of travel destinations, as it considers both popular and less popular spots. Additionally, the results of this study also contribute to the existing literature on travel recommendation systems by showcasing the efficacy of utilizing geotagged data to generate personalized recommendations.

B. Contributions and Importance of the Study

Overall, the study has accomplished its aim of analyzing the impact of geotagged data in selecting attractions and proposing a travel recommendation model based on geotagged data. The proposed travel recommendation model can analyze the collective behaviour of tourists and identify regions that are ideal for them. It also introduces serendipity by enabling users to discover new interests in different areas depending on the interests indicated by other similar users based on the data collected.

In conclusion, the proposed model has the potential to be a valuable tool for users who have uploaded geotagged social media posts to get travel destination ideas from other places. This can ultimately reduce the time spent browsing through different websites to find the ideal destination to travel to. Additionally, the tourism sector may incorporate this model into their applications to promote tourism in their respective countries to create revenue and contribute to their Gross Domestic Product (GDP). With further implementation in the future, this can provide significant benefits to both users and the tourism industry.

C. Limitations and Future Recommendations

The collaborative filtering technique does not require domain knowledge since embeddings are automatically learnt, and the matrix factorization can solve the sparsity problem. However, the proposed model suffers from the cold-start problem, which occurs for users that are relatively new due to insufficient connection with other users. To address this issue, users with less than three visits were excluded from the recommendation process. It is recommended to incorporate other algorithms such as content-based filtering to build a hybrid recommender to eliminate the cold-start issue. Content-based filtering can be used to construct user profiles by collecting user information based on their social media postings or through a questionnaire.

It is also recommended to build a mobile application or a graphical user interface (GUI) using the developed recommendation model to provide personalized recommendations. The application should have an interactive interface that allows the users to select their previous visits and display the various locations that it recommends. In addition to providing locations as recommendations, the proposed model should also add side features collected from sites like Google Maps to enhance the location profiles. For example, it can provide the type of activities and opening hours in the area to allow users to understand more about the recommended locations.

Abstract—Input value chains greatly affect rice yield, however previous related studies were mainly based on empirical survey and simple statistics, which lacked generality and flexibility. The article presents a new method to predict the influence of input value chain on rice yield in Vietnam based on a machine learning algorithm. Input value chain data is collected through field surveys in rice-growing households. We build a predictive model based on the neural network and swarm intelligence optimization algorithm. The prediction results show that our proposed method has an accuracy of 96%, higher than other traditional methods. This is the basis for management levels to have orientation on the input supply value chain for Vietnamese rice, contributing to the development of the Vietnamese rice brand in the world market.

Keywords—Value chains; Vietnamese rice; machine learning; neural network

I. INTRODUCTION

A value chain is a sequence of activities in which the product passes through all the activities in order and at each activity, the product acquires some value [1]. Value chain development plays a very important role in the development of Vietnam's agriculture. The role of the value chain manifests itself in aspects such as promoting the improvement of productivity and quality of agricultural products, being a basic solution for product distribution and consumption, and increasing the attractiveness of investment in agriculture, etc. With underdeveloped agriculture in Vietnam, the role of the value chain is becoming more and more important. The effectiveness of the value chain depends on the cooperation of the members of the chain. When participating in cooperation in the value chain, members enjoy many benefits, especially the conditions to reduce costs, improve productivity and product quality, reduce sourcing time, be stable in production, etc. If participating in the global value chain, members also enjoy higher benefits, have conditions to increase productivity, improve product quality, have the opportunity to easily penetrate international markets, and increase profits, etc. In Vietnam, developing linkage cooperation along the value chain model is a condition for agricultural development. More than 75% of our agricultural products have to go through intermediaries or foreign brands to approach the international market. Therefore, many people combine to form a value chain, which will attract the participation of suppliers, distributors, and processing companies [2][3][4].

With favorable natural conditions, Vietnam has become a powerhouse in rice exports, just behind India and Thailand. According to UN FAO data, in 2017, Vietnam had more than 80 rice-exporting enterprises, accounting for about 20% of global rice exports [5]. However, because Vietnamese rice brands are not outstanding enough in the international market, although the export volume is high, it is mainly in the low and medium-quality segments. To overcome this problem and create sustainable development for the rice industry, the Vietnamese government is finalizing many drafts of the Regulation on the management of national certification marks for Vietnamese rice. Along with that, the development of stages in the rice value chain is also invested and interested. In the current Vietnamese rice industry, the value chain is mainly vertical. The main interlinked actors are input, production, conversion, distribution, and consumption. The input value chain is the opening stage and determines the output and productivity of Vietnamese rice [6][7]. Therefore, research to assess the impact of factors in the input value chain affecting Vietnamese rice is extremely necessary.

In recent years, along with the development of computers, artificial intelligence, and machine learning algorithms have been born that have solved countless problems of statistical analysis in economics that traditional analytical methods have not been able to achieve. Machine learning makes data processing, calculation, and analysis faster and more accurate, helping economic researchers' approach and evaluate hot issues [8][9][10]. Valendin et al. [11] used recurrent neural networks to analyze customers. They propose a new approach by using the history of individual customer transactions and relevant contextual factors to predict future behavior, and linking the characteristics of the individual and customer. This approach can help managers capture seasonal trends and buying dynamics. Chen et al. [12] designed a manufacturing enterprise environmental cost control system using the decision tree algorithm of machine learning. This method can realize the optimization of the circular economy value chain, and put forward important suggestions for the control of environmental cost schemes. Liu et al. [13] explored the application of artificial intelligence in global value chains. The results confirm that there is a significant positive correlation between artificial intelligence and the industry's global value chain. Liu et al. [14] established an economic risk prediction model using artificial intelligence algorithms based on the analysis of global value chains. This method can realize its trend prediction and

provide an important theoretical reference for global value chain economic risks.

Traditional methods of studying the effects of value chains on products are mainly based on empirical surveys and simple statistics, which lack generality and flexibility, leading to many non-conforming conclusions, even imprecise. Therefore, applying intelligent assessment methods to value chain analysis is essential, it can solve some problems existing in traditional methods. This study proposes a new method of analyzing the input value chain affecting the yield of Vietnamese rice based on a machine learning method. First, we collect data through actual survey sources. Next, based on a new machine learning algorithm to build a predictive model, to improve the accuracy of the model, an optimization algorithm is applied to optimize the parameters. Finally, experiments to evaluate the effectiveness of the proposed model.

II. METHOD

A. Data Collection and Processing

In this study, data were collected from rice-growing households in the Mekong Delta of Vietnam including Kien Giang, Long An, An Giang, Dong Thap, and Soc Trang provinces. Information and data were collected through direct interviews with rice growers, soil quality statistics, and from input suppliers such as agricultural mechanical engineering companies, companies providing seeds and plant protection drugs. Data collection is based on trained collaborators and under the supervision of the research team. We use random sampling in combination with different geographic zoning, this combination will increase the generality for many regions. In addition, we conducted interviews with long-term rice growers and experts to assess, and gain practical experience and the current situation, thereby deepening our understanding of the actual situation in the data collection area. Finally, we selected input data to build predictive models including soil quality, water source, seed supply, fertilizer supply, agricultural medicine supply, science and technology, access to credit, age of homeowners, number of years in occupation, and qualification of homeowners.

Since the collected data is heterogeneous, it is necessary to normalize the data to enhance the training process of the model. In this paper, we use the method of max normalization to normalize the data [15], this method will select the largest number to return to 1, and the remaining numbers will be proportional to the range from 0 to 1.

B. Extreme Learning Machine

The training set has N samples $(\mathbf{x}_i, \mathbf{t}_i)$, $\mathbf{x}_i = [x_{i1}, x_{i2}, \dots, x_{in}]^T \in \mathbf{R}^n$, $\mathbf{t}_i = [t_{i1}, t_{i2}, \dots, t_{im}]^T \in \mathbf{R}^m$, the mathematical expression of extreme learning machine (ELM) [16][17][18] is shown in Equation (1).

$$f_{ELM-L}(\mathbf{x}) = \sum_{j=1}^L \beta_j g(\mathbf{w}_j \cdot \mathbf{x}_i + b_j) = \mathbf{t}_i; b_j, \beta_j \in \mathbf{R} \quad (1)$$

here, $\mathbf{w}_j = [w_{j1}, w_{j2}, \dots, w_{jn}]^T \in \mathbf{R}^n$ is the input weight, L is the hidden layer nodes, b_j is the bias, β_j is the output weight,

and $g(\bullet)$ is the activation function. Equation (1) and Equation (2) are the same.

$$\mathbf{H}_1 \beta_1 = \mathbf{T} \quad (2)$$

here,

$$\mathbf{H}_1(\mathbf{w}_1, \dots, \mathbf{w}_L, b_1, \dots, b_L, \mathbf{x}_1, \dots, \mathbf{x}_N) = \begin{bmatrix} g(\mathbf{w}_1 \cdot \mathbf{x}_1 + b_1) & \dots & g(\mathbf{w}_L \cdot \mathbf{x}_1 + b_L) \\ \vdots & & \vdots \\ g(\mathbf{w}_1 \cdot \mathbf{x}_N + b_1) & \dots & g(\mathbf{w}_L \cdot \mathbf{x}_N + b_L) \end{bmatrix}_{N \times L} \quad (3)$$

$$\beta_1 = \begin{bmatrix} \beta_1^T \\ \vdots \\ \beta_L^T \end{bmatrix}_{L \times m} \quad \mathbf{T} = \begin{bmatrix} \mathbf{t}_1^T \\ \vdots \\ \mathbf{t}_j^T \end{bmatrix}_{N \times m} \quad (4)$$

\mathbf{T} is the actual value matrix.

The β_1 is calculated by the Equation (5).

$$\beta_1 = \mathbf{H}_1^+ \mathbf{T} \quad (5)$$

here, \mathbf{H}_1^+ is the Moore Penrose matrix of \mathbf{H}_1 .

C. Differential Squirrel Search

The differential squirrel search (DSS) method was presented in 2021 [19]. This approach combines the differential evolution and the squirrel search algorithm. Originally, the squirrel's position is determined at random. Its fitness is measured by the fitness function and is similar to the quality of the food supply found by the squirrel at that place. Then, the best position \mathbf{PS}_{nt} is in the fitness values. We record the three best position values $\mathbf{PS}_{\text{at}}(1:3)$, the remaining locations $\mathbf{PS}_{\text{nt}}(1:\text{NP}-4)$ are believed to have yet to find any food sources. In the presence of a predator, squirrels shifted courses at random while foraging. Equation (6) depicts the revised locations of the squirrels on the acorn trees.

$$\mathbf{PS}_{\text{at}}^{\text{new}} = \begin{cases} \mathbf{PS}_{\text{at}}^{\text{old}} + d_g \cdot G_c (\mathbf{PS}_{\text{ht}}^{\text{old}} - \mathbf{PS}_{\text{at}}^{\text{old}} - P_{\text{avg}}), & r_1 \geq P_{\text{dp}} \\ \text{random position}, & \text{otherwise} \end{cases} \quad (6)$$

where d_g is the random gliding distance, P_{avg} is the average of all squirrels position, P_{dp} is the predator presence probability, G_c is the gliding constant.

The authors use the crossover method to increase the diversity of squirrels and avoid entering local minima, and Eq. (7) depicts its mathematical model.

$$\mathbf{PS}_{\text{at},j}^{\text{cr}} = \begin{cases} \mathbf{PS}_{\text{at},j}^{\text{new}}, & \text{if } (\text{rand}_j \leq \text{Cr}) \text{ or } j = j_{\text{rand}} \quad j = 1, 2, 3, \dots, D \\ \mathbf{PS}_{\text{at},j}^{\text{old}}, & \text{if } (\text{rand}_j > \text{Cr}) \text{ or } j \neq j_{\text{rand}} \quad i = 1, 2, 3, \dots, \text{NP} \end{cases} \quad (7)$$

where $\mathbf{PS}_{\text{at},j}^{\text{new}}$ and $\mathbf{PS}_{\text{at},j}^{\text{old}}$ are new and old positions, NP is the population size, $\mathbf{PS}_{\text{at},j}^{\text{cr}}$ is the positions of the squirrels after

crossover operation, D is the dimension of the problem, $j_{rand} \in [1, D]$ is a random value, $rand_j \in [0, 1]$, and $Cr=0.5$.

The position of the squirrels in the normal trees is updated as shown in Eq. (8).

$$PS_{nt}^{new} = \begin{cases} PS_{nt}^{old} + d_g \cdot G_c (PS_{at}^{old} - PS_{nt}^{old}), & r_2 \geq P_{dp} \\ \text{random position,} & \text{otherwise} \end{cases} \quad (8)$$

where $r_2 \in [0, 1]$ is a random number.

The new positions of the remaining squirrels are shown in Eq. (9).

$$PS_{nt}^{new} = \begin{cases} PS_{nt}^{old} + d_g \cdot G_c (PS_{ht}^{old} - PS_{nt}^{old}), & r_3 \geq P_{dp} \\ \text{random position} & \text{otherwise} \end{cases} \quad (9)$$

The Eq. (10) is the crossover algorithm.

$$PS_{nt,i,j}^{cr} = \begin{cases} PS_{nt,i,j}^{new}, & \text{if } (rand_j \leq Cr) \text{ or } j = j_{rand} & j = 1, 2, 3, \dots, D \\ PS_{nt,i,j}^{old}, & \text{if } (rand_j > Cr) \text{ or } j \neq j_{rand} & i = 1, 2, 3, \dots, NP \end{cases} \quad (10)$$

The new positions of the squirrels in the hickory trees are updated by Eq. (11).

$$PS_{ht}^{new} = PS_{ht}^{old} + d_g \cdot G_c (PS_{ht}^{old} - PS_{at}^{avg}) \quad (11)$$

D. Propose an Algorithm based on ELM and DSS

ELM uses a random method to initialize the parameters of the input layer and the hidden layer, and calculates the output weight through the Moore Penrose matrix. Since it does not need to iteratively update parameters, the running time of the model is greatly reduced, and it is an efficient neural network algorithm. However, due to the way of random input parameters, it will bring algorithm uncertainty, and the model cannot be guaranteed to be in the optimal state. Therefore, the input parameters need to be optimized to improve the accuracy and stability of the model. DSS has been proved to be an efficient optimization algorithm. Therefore, this study uses DSS algorithm to optimize the input parameters of ELM, and proposes an algorithm called DSS-ELM. The optimization process of the algorithm is shown in Fig. 1.

III. RESULT

Survey data includes 378 rice farmers, rice farms, and rice farming cooperatives. For rice farmers, the labor force is

mainly family members. With rice farms, hired labor is the main source. Farmers still produce rice based on experience, and following habits, but most have had the support of local agricultural extension organizations in technical advice. However, focusing on convenience is still deeply rooted in households' awareness, and economic efficiency and productivity are not high. From there, it shows that individual rice-producing households still face many difficulties to increase rice productivity. With large-scale farms or cooperatives, the organization of production is quite modern with the application of many mechanized machines and basic technical staff.

Fig. 1. DSS-ELM algorithm flowchart.

The data is divided into two classes. One class is the households that have achieved the desired yield after harvesting the rice and the other class is the households that have not achieved the desired yield. We randomly split it into a training set of 60% and a test set of 40%. Through the proposed algorithm, we build a training model to predict rice yield based on the input value chain. Fig. 2 shows the optimization process of the rice yield prediction model based on DSS-ELM. Here, we choose the number of iterations to be 100. We see that by the 15th iteration, the model has reached the maximum optimal level, the model converges quickly, and the error from 10% to 4%. Experimental results show that the DSS algorithm can optimize the model quickly, the model converges quickly and improves the classification ability. This result proves that DSS is an optimal algorithm with fast convergence speed, a good choice for parameter optimization

problems. Using DSS to optimize the parameters of the ELM algorithm helps to improve the prediction accuracy of ELM. From there, it gives reliable results and serves as a reference for researchers or experts, and managers in the rice industry.

Fig. 2. Optimization process of DSS-ELM.

TABLE I. PREDICTION ACCURACY OF EACH CLASS

Class	Accuracy (%)
1	95.5
2	96.8
Overall	96.0

The two classes are labeled as 1 and 2. Table I is the accuracy of each class, the results show that the accuracy is high, with the accuracy of class 1 being 95.5%, and the accuracy of class 2 being 96.8% and the overall accuracy was 96%. Fig. 3 shows the difference between the samples of the two classes. We can see, the difference between the predicted number and the actual number is very small, only 6 out of 151 samples are wrong. From there, it shows that the model has good predictive results, and can predict well about rice yield based on input value chain data. This can be considered one of the important methods to support rice-growing households in choosing suitable inputs and orienting a particular rice-growing area. At the same time, it is also the basis for local authorities and managers to have specific orientations and directions to develop wet rice farming in Vietnam.

Fig. 3. Deviation between samples.

IV. DISCUSSION

A. Key Characteristics of Input Value Chains affecting Rice Yield

In this study, we take into account the characteristics affecting Vietnamese rice yield including soil quality, water source, seed supply, fertilizer supply, agricultural medicine supply, science and technology, access to credit, age of homeowners, number of years in occupation, and qualification of homeowners. The value chain of fertilizer supply, agricultural medicine supply, seed supply, and science and technology have a great influence on rice yield. They are also mentioned in studies around the world such as those of Amjath et al. [20], Darakeh et al. [21], and Katsu et al. [22].

For fertilizer supply, Vietnam is a country that actively produces fertilizers for agriculture, and becomes the main source of fertilizer for the rice industry. The main source of urea fertilizer supply is from enterprises such as Phu My fertilizer, Ca Mau protein, Ha Bac fertilizer, etc. The main source of phosphate fertilizer is the Lam Thao factory, and Long Thanh factory. In addition, there are a few enterprises producing and supplying organic and micro-organic fertilizers. However, the supply of fertilizer in Vietnam has not yet met the actual demand. According to recent statistics in three years, Vietnam imported 4.5 million tons of fertilizers of all kinds.

As for the supply of agro-pharmaceuticals, the market value of pesticides in Vietnam is about \$900 million, and the growth

rate is 6.8 %/year. There are more than 300 companies manufacturing and processing agro-pharmaceuticals in the whole country, but this number only meets 25% of the demand. The main supply comes from imports, and the supply from China accounts for 40% of the market share. Agro-pharmaceuticals are distributed through sales channels of enterprises and agents. The choice of agro-pharmaceuticals is usually based on self-drawing experiences and the introduction of neighboring households along with advertising information of agents. The capital for buying agricultural drugs is also limited, so it also greatly affects the yield of rice.

The supply of rice seeds is mainly through three main sources: farmers who self-seed, farmers who buy seeds from high-yielding fields, and farmers who buy seeds from seed centers. Farmers leave seeds for themselves, accounting for 10% of the number of seeds used, most of them are small production households, and do not accept large costs. Moreover, the seed dealers are quite difficult to reach. Seeds from high-yielding fields account for about 65%. The rest are people who buy seeds from seed centers across the country.

For technical-technological information sources, farmers associated with enterprises, enterprises are an important transfer channel in science and technology to rice growers through the regular organization of training sessions on the application of scientific and technical advances to production. For the remaining households, the source of access to science and technology mainly relies on pesticide companies, agricultural extension centers, and mass media.

B. Compare with other Models

Traditional methods commonly used to build models in economics include logistic regression (LR)[23], and support vector machine (SVM) [24][25]. In this study, we compare our proposed method with ELM, LR, and SVM methods. The comparison results are shown in Table II and Fig. 4. It can be seen that DSS-ELM has higher accuracy than other methods. Specifically, DSS-ELM is 6% higher than the ELM method, 4% higher than the SVM method, and 8.6% higher than the LR method. The LR and SVM algorithms use the Sigmoid function as a non-linear factor, thereby performing the classification problem. The ELM algorithm uses a neural network that simulates the human nervous system, through random weights and bias values, and then relies on the Moore-Penrose matrix to calculate the output weights. In this study, we use the swarm intelligence optimization method combined with the random parameters of ELM to conduct parameter optimization, thereby increasing the predictive ability of the algorithm. The results of the experiment proved that our proposal is accurate, and suitable for the problem of predicting rice yield in Vietnam based on the input value chain.

TABLE II. ACCURACY OF THE MODELS

Models	Overall accuracy (%)
LR	87.4
SVM	92.1
ELM	90.0
DSS-ELM (This study)	96.0

Fig. 4. Results of comparing the accuracy of the methods.

V. CONCLUSION

This study proposes a method to predict the effect of rice yield based on the input value chain and machine learning algorithm. The data surveyed by the research team from rice-growing households. The results show that the model has good predictive ability about the influence of the input value chain on rice yield. Our proposed method is also more accurate than methods such as ELM, SVM, and LR. This is the basis for management levels to have orientation on the input supply value chain for Vietnamese rice.

Cybersecurity in Healthcare: A Review of Recent Attacks and Mitigation Strategies

Elham Abdullah Al-Qarni

Department of Computing and Information Technology
University of Bisha
Bisha-Saudi Arabia

Abstract—Cyberattacks on several businesses, including those in the healthcare, finance, and industrial sectors, have significantly increased in recent years. Due to inadequate security measures, antiquated practices, and sensitive data, including usernames, passwords, and medical records, the healthcare sector has emerged as a top target for cybercriminals. Cybersecurity has not gotten enough attention in the healthcare sector, despite being crucial for patient safety and a hospital's reputation. In order to prevent data breaches that could jeopardize the privacy of patients' information, hospitals must deploy the proper IT security measures. This research article reviews many scholarly publications that look at ransomware attacks and other cyberattacks on hospitals between 2014 and 2020. The report summarizes the most recent defensive measures put forth in scholarly works that can be used in the healthcare industry. Additionally, the report provides a general review of the effects of cyberattacks and the steps hospitals have taken to manage and recover from these disasters. The study shows that cyberattacks on hospitals have serious repercussions and emphasizes the significance of giving cybersecurity a priority in the healthcare sector. To combat cyberattacks, hospitals must have clear policies and backup plans, constantly upgrade their systems, and instruct employees on how to spot and handle online threats. The article comes to the conclusion that putting in place suitable cybersecurity safeguards can reduce the harm brought on by system failures, reputational damage, and other associated problems.

Keywords—Cybersecurity; healthcare industry; malware; ransomware; DoS; DDoS

I. INTRODUCTION

The healthcare sector is very concerned about security, especially on the internet, where cyberattacks are becoming more common and sophisticated. Access control violations, assaults that inject and execute malware, and denial of service (DoS) attacks are some of the most frequent threats to healthcare security. In contrast to Distributed Denial of Service (DDoS) assaults, which employ numerous hosts to attack a system, DoS attacks include a single source that floods the target system with requests. This makes it difficult to pinpoint the attack's origin. Patients may suffer as a result

of these attacks, and healthcare organizations may suffer reputational damage [1].

Another major threat to the healthcare sector is malware, which virtually always comes in new varieties. Ransomware is one malware family that healthcare institutions are becoming worried about. Ransomware was listed second on a list of cybersecurity dangers to healthcare companies in a poll by the Healthcare Information and Management Systems Society (HIMSS), with 17% of respondents reporting having been the victim of a ransomware attack [2].

Healthcare businesses have been the subject of several high-profile cyberattacks in recent years. For instance, a ransomware assault that affected the Irish Health Service Executive (HSE) in 2021 severely disrupted healthcare services [3]. Similar to this, over 150 nations were impacted by the WannaCry ransomware assault in 2017, which forced the UK's National Health Service (NHS) to reschedule procedures and cancel appointments [4].

Healthcare institutions must put robust cybersecurity safeguards in place to stop cyberattacks and safeguard sensitive patient data. Many healthcare institutions, however, continue to lack adequate security protocols, leaving them open to intrusions. Only 44% of healthcare businesses, according to a study by the Ponemon Institute, have a thorough security policy in place [5].

Based on responses from 167 healthcare cybersecurity specialists, Fig. 1 shows the survey's ranking of cyberattacks in 2021. The author's method involved doing a content assessment of scientific papers from 2014 to 2020 that discussed malware, DoS, and social engineering attacks on hospitals.

There are five sections in the paper. Hospitals that experienced cyberattacks from 2014 to 2020 are covered in Section II. Hospitals can apply the measures discussed in Section III to lessen or prevent a cyberattack. Results and discussion are presented in Section IV, and the paper is wrapped up in Section V.

Fig. 1. A list of the most significant cyberattacks for 2021 [2].

II. CYBERSECURITY IN HEALTHCARE SYSTEMS

In this section, we'll talk about a number of hospitals that experienced cyberattacks, the steps we took to deal with the situation, and the effects of the attacks.

Table I gives a summary of cyberattacks on hospitals, including ransomware and distributed denial of service (DDoS), as well as the results. For instance, on March 20, 2014, a DDoS attack targeted Boston Hospital, causing a network outage that lasted two weeks and adversely disrupting hospital operations. In 2016, ransomware that used social engineering techniques struck Lukas Hospital and Hollywood Presbyterian Medical, disrupting the systems and making patient data unusable. In 2020, ransomware attacks affected three hospitals, one each in the Czech Republic, the United States, and London. Boston Children's Hospital had the longest attack duration, lasting 14 days, while Champaign-Urbana Public Health District had the shortest, lasting only four days.

The table shows that the effects are harsh regardless of the attack strategies and tactics used by cybercriminals. Therefore, if cybersecurity was given top priority in the healthcare sector, system failures, reputational damage, and other related problems might be lessened.

Table II lists the methods that hackers use to attack the healthcare sector as well as the defenses used by hospitals to fend against and recover from attacks. All of these institutions, which were targets of various cyberattacks, including those at Boston Hospital, Lukas Hospital, Brno Hospital, and Hancock Hospital, followed the same course of action: they shut down their systems to limit the harm. The table demonstrates that hospitals did not have defined strategies or backup plans to deal with intrusions, demonstrating a disregard for cybersecurity. For instance, Brno Hospital continued to run Windows XP into 2020. This emphasizes how important it is for healthcare businesses to address cybersecurity and implement preventative steps to lessen and eliminate online dangers.

Information on the ransom payments made by hospitals to hackers to recover access to their systems is shown in Table

III. In comparison to attempting to restore compromised information technology systems without the decryption key needed to remove the infection, paying the ransom may be less detrimental to operations and profit margins. Boston Hospital spent the most to restore its systems, close to \$600,000, and Champaign-Urbana Public Health District spent the second-most, \$350,000. The least amount was paid by Hollywood Presbyterian Medical, at \$17,000. Although paying a ransom may incur financial costs, it is preferable to endangering lives, tarnishing one's image, or disclosing private information. Hospitals should put patients' safety first, even if doing so would inspire hackers to undertake additional cyberattacks. It is crucial that hospitals.

Fig. 2 illustrates how cyberattacks are divided into three distinct attack categories.

1) *Injection attack*: A web application may be "injected" with malicious data by an attacker, affecting the way it operates by directing it to execute certain commands. Injection is one of the early varieties of web-based attacks. Malware is an illustration of an injection attack. According to [6], malware is any computer code written with the purpose of gaining unauthorized access to digital devices and IT infrastructures. This is done by breaching the security measures protecting them and taking advantage of security flaws. Three distinct malware subtypes were discernible:

a) *SamSam*: Initially appearing in late 2015, a ransomware malware, primarily targets the healthcare sector. SamSam specializes in using RDP, FTP, and Java-based web server vulnerabilities to access the victims' machines [7].

b) *Locky*: It is a ransomware family that uses a hybrid cryptosystem and was launched in 2016. Its mechanism of operation involves scanning the victim's drives, such as network drives, for particular file types to encrypt them using RSA and AES [8].

c) *Netwalker*: Also known as Mailto, is a type of attack where the attacker uses the victim's network to encrypt all Windows-based devices. The attacker can use either phishing emails or executable files that travel throughout networks to carry out his attack [9].

TABLE I. EXAMPLE OF HOSPITALS EXPOSED TO CYBER-ATTACKS

Targeted system/ Region, Year	Cyber Attack Category	Result	Source
Boston Children's Hospital/ Boston, 2014	DDoS	For a period of two weeks, the hospital's network was inactive, seriously disrupting everyday operations and leading to the closure of the fundraising website.	[21]
Lukas Hospital/ Germany, 2016	Social engineering & Malware	High-risk surgeries were postponed by the hospital while they evaluated and sanitized their infected servers and computer systems.	[19] & [21]
Hancock regional hospital/ United States, 2018	Malware (SamSam)	The backup files are permanently destroyed.	[19]
Hollywood Presbyterian Medical Center/ Los Angeles, 2016	Malware (Locky) & phishing	Staff employees were unable to access patient information, X-rays, and other devices during the attack and were unable to use backup systems to restore the data.	[22]
Champaign-Urbana Public Health District/ United States, 2020	Malware (NetWalker)	In order to provide updates on COVID-19, the organization blocked its website and used its Facebook page instead.	[27]
Brno University Hospital/ Czech Republic, 2020	Ransomware	The hospital's IT network was completely shut down as a result of a significant service disruption, preventing personnel from accessing patient records, X-rays, and other devices. Handwritten notes and transfer procedures had to be used by the hospital, which may have compromised patient safety and slowed down operations. Two further hospital departments had to be shut down as a result, including the motherhood department and the children's hospital.	[17]
Hammersmith Medicines Study/ London, 2020	Ransomware	Birth dates, insurance numbers, and passport information were among the many private details stolen from patient records.	[17]

TABLE II. METHODS OF CYBER-ATTACK ON HOSPITALS AND RESPONSES TO CYBERATTACKS

Hospital	Attack method	Response	Source
Boston Children's Hospital	The hospital network was targeted by hackers who attempted to breach it by focusing on "exposed ports and services," as well as launching a phishing email campaign that specifically targeted hospital employees.	The hospital took the measure of stopping all web-facing programs, including email services, to effectively close all firewall entry points and prevent staff members from accidentally clicking on a malicious link.	[18]
Lukas Hospital	Technique for social engineering	All systems have been turned off. Backups were used to restore systems.	[19] & [20]
Hancock regional hospital	The hackers utilized the Microsoft Remote Desktop Protocol to infiltrate the administrative account of a hardware vendor.	Turn off all desktop and network systems.	[19]
Hollywood Presbyterian Medical	NAN	Pay a ransom	[20]
Champaign-Urbana Public Health District	NAN	Employees exchanged information using their systems and networks.	[23]
Brno University Hospital	Exploiting vulnerability in the WindowsXP operating system.	Shut down the entire information technology network	[17]
Hammersmith Medicines Study	Use of the ransomware-as-a-service model.	NAN	[17]

TABLE III. AMOUNTS PAID BY HOSPITALS TO RESTORE THEIR SYSTEMS

Hospital	Financial Cost	Source
Boston Children's Hospital	\$300,000 - \$600,000	[18] & [24]
Hancock regional Hospital	\$50,000	[25]
Hollywood Presbyterian Medical	\$17,000	[20]
Champaign-Urbana Public Health District	\$350,000	[26]
Hammersmith Medicines Study	No ransom was paid	[17] & [27]

Fig. 2. Cybersecurity attacks classification.

2) Social engineering: It is a method where an attacker uses interpersonal interactions to prey on psychological flaws in the victim to persuade them to divulge critical information to the attacker [10]. Phishing is a type of social engineering that hackers employ to trick their victims into divulging sensitive information like usernames, passwords, bank account details, etc. This is accomplished by tricking the user into clicking on a link to a false website or downloading a malicious program.

3) Denial of service attack: It is a type of cyberattack that mostly focuses on consuming resources, including memory or computing power. Both wireless and cable connections can be used to carry out this assault [11]. A particular kind of DoS assault that targets websites is known as a distributed denial-of-service attack. To assault a single victim, an attacker uses malicious script that has been placed on several other computers. The website is intended to become inoperable [12].

III. MITIGATION STRATEGIES

As indicated in Fig. 3, we will cover risk classifications and the most recent techniques hospitals can use to lessen the effects of cyberattacks in this section.

According to [13], risk is the potential for loss or harm if an attacker exploits a security hole. An operational risk associated with online activities that threatens information assets, resources for information and communication technology, and technological assets and may cause material damage to an organization's tangible and intangible assets, business interruption, or reputational harm is another comprehensive definition of cybersecurity risk [14]. Risk reduction and risk avoidance are two alternatives provided by risk mitigation strategies. Preventative measures are used in mitigation strategies to lessen the possibility or impact of a cyberattack. These tactics are focused on locating and addressing any weak spots and security risks in the organization's rules and information. Risk-mitigation measures can include putting in place infiltration detection systems and protection barriers, as well as updating software and hardware often and training staff on best practices for cyber security.

A. A Proactive Incident Response (IR)

Planning and preparation, detection, analysis, and evaluation, containment and eradication, recovery, and post-incident activities are the six steps that make up this procedure. The firm must first establish its security policy and incident response capability. This involves putting together a team to manage incidents and acquiring the necessary tools and supplies. In the second stage, an event is automatically detected using tools like network- or host-based intrusion detection systems or manually using manual requirements like alerting users to problems. In the third stage following the incident, the incident response team analyzes and verifies the incident. Implementation of containment strategies, such as sandboxing, occurs in the fourth stage. In stage five, the administrator will check that the systems are operating normally and correct any issues to prevent future occurrences. After an incident, a meeting should be held as the final step. The purpose of this meeting is to advance technology and gain knowledge [15].

B. Secure Architecture based on Blockchain Technology and Artificial Intelligence

Five layers make up the suggested architecture for a safe system based on artificial intelligence and blockchain technology. The first layer, referred to as the "data layer, gathers information from patient sensors, including temperature and heartbeat. Additionally, malware samples are gathered in this layer and sent to the malware analysis layer. Tools like Pestudio and Process Explorer are used in the second layer, known as malware analysis, to examine the malware. The second layer's harmless samples are included in the third layer's intelligence, which checks them for security flaws using artificial intelligence techniques like support vector machines (SVM) and random forests (RF). Data transferred from Layer 3 is safely stored in Layer 4, the Blockchain layer. Hospitals, pharmacies, laboratories, and ambulances are examples of healthcare data recipients at the applications layer (layer three) [16].

Fig. 3. Proposed strategies to mitigate cyber-attacks.

C. Design of a Multi-Agent Framework

The framework is created in two steps. First, five system agents need to be made. Patient, nurse, doctor, ambient, and database agents. The next step is to provide a tiered architecture that classifies agents according to their data storage and power capabilities. The wireless sensor network platform was utilized in this framework [16].

D. Scheme Relies on Stacked Autoencoder for Intrusion Detection

Scheme's framework for intrusion detection uses stacked autoencoders. Data pre-processing, feature extraction, and intrusion behavior determination make up the method's three steps. Infiltration behavior is defined at the Data Pre-Processing phase. A stacked autoencoder is used in the feature extraction stage to get parameter weights for various features. The XGBoost algorithm is used in the Intrusion Behavior Determination stage to determine if a behavior is normal or intrusive.

IV. RESULTS AND DISCUSSION

As healthcare companies become more popular targets for hackers, cyberattacks against hospitals are on the rise, according to the evaluation of scholarly articles done for this research paper. Because of its outmoded practices, weak security measures, and sensitive data, the healthcare sector is a prime target for hackers. These attacks can have serious effects, including harm to patients, harm to the reputation of healthcare organizations, and monetary losses.

The study also outlines a number of research papers' protection against cyberattacks and solutions that healthcare institutions might use. These tactics comprise staff training, routine system updates, and the application of cutting-edge security tools like intrusion detection systems and firewalls. According to the study, hospitals should prioritize cybersecurity and have detailed strategies and backup plans to deal with intrusions.

Hospitals are vulnerable to attacks because of insufficient security standards, according to the assessment of scholarly studies. The majority of healthcare firms do not have a thorough security strategy, which shows a disregard for cybersecurity. The study recommends that healthcare institutions take proactive steps to safeguard sensitive patient data and lessen the effects of system errors, reputational damage, and other related problems.

V. CONCLUSIONS AND FUTURE WORKS

This study concludes by emphasizing the urgent necessity for healthcare institutions to address cybersecurity in order to prevent data breaches that could jeopardize patient information. Hospital cyberattacks can have serious repercussions, so healthcare companies need to create clear policies and backup plans to cope with these situations. The report provides a summary of hospital cyberattacks from 2014 through 2020, including ransomware assaults, and offers many tactics hospitals might employ to lessen or prevent a hack.

Future studies can concentrate on creating innovative techniques and tools to defend healthcare companies against

cyberattacks. For instance, research may look into how to employ machine learning and artificial intelligence to detect and stop cyberattacks on hospitals. Additionally, studies might look into how cyberattacks affect patient security and consider the moral ramifications of data breaches in the healthcare sector.

Overall, the importance of cybersecurity in the healthcare sector is highlighted in this research study, and healthcare companies must take proactive steps to safeguard sensitive patient data. Healthcare institutions must emphasize cybersecurity given the increase in cyberattacks on hospitals in order to limit losses from system failures, reputational damage, and other associated problems.

ACKNOWLEDGMENT

The author wishes to express her deep appreciation and respect to Salahaldin M.A. Abuabdou for inspiring and motivating her to write this paper.

Abstract—The novel human Corona disease (COVID-19) is a pulmonary sickness brought on by an extraordinarily outrageous respiratory condition crown 2. (SARS -CoV-2). Chest radiography imaging has a significant role in the screening, early diagnosis, and follow-up of the suspected individuals due to the effects of COVID-19 on pneumonic-sensitive tissue. It also has a severe impact on the economy as a whole. If positive patients are identified early, the spread of the pandemic illness can be slowed. To determine whether people are at risk for illnesses, a COVID-19 infection prediction is critical. This paper categorizes chest CT samples of COVID-19 affected patients. The two-stage proposed deep learning technique produces spatial function from images, so it is a very expeditious manner for image category hassle. Extensive experiments are drawn by considering the benchmark chest-Computed Tomography (chest-CT) image datasets. Comparative evaluation reveals that our proposed method outperforms amongst other 20 different existing pre-trained models. The test outcomes constitute that our proposed model achieved the best rating of 97.6%, 0.964, 0.964, and 0.982 concerning the accuracy, precision, recall, specificity, and F1-score, respectively.

Keywords—COVID-19; coronavirus; deep learning; classification; chest X-ray images; DenseNet-121; XG-Boost classifier; EfficientNet-B0

I. INTRODUCTION

COVID-19 has become a global health emergency of concern since it was first identified in December 2019. It is generating unheard-of societal and economic devastation. According to the WHO report, by March 29, 2021, there were 126,890,643 afflicted people worldwide, 2,778,619 of whom passed away. There is a severe scarcity of medical resources as a result of the global COVID-19 pandemic, which has put tremendous strain on healthcare institutions. Coronavirus pneumonia has been known as COVID-19 since its discovery, and it is both exceedingly contagious and harmful [1][2]. Pneumonia could arise if the signs get worse. Major health problems and the failure of numerous organs may ensue from this. Additionally, the patient is at risk of getting severe pneumonia. Medical practitioners, governments, organizations, and nations from all over the world face significant difficulty in trying to diagnose people with COVID-19 as soon as possible. Even though immunological testing is generally accessible, COVID-19 is frequently identified via RT-PCR, or Real-Time Polymerase Chain reaction (rt Chain Reaction). Images of patients' lungs can be used to detect the harmful effects of

COVID-19 and ensure prompt treatment rather than depending on RT-PCR, which has a low susceptibility (60-70%) and is also a time-consuming procedure. When providing care for patients who have COVID-19, it is imperative to closely observe how a patient's status evolves. When used in conjunction with additional diagnostic testing, medical imaging techniques like Computed Tomography (CT) and chest X-rays can be used to monitor the patient's progress and confirm the diagnosis of COVID-19 pneumonia. These images demonstrate the rapid onset of ground-glass opacities following the onset of COVID-19 symptoms.

Artificial Intelligence (AI) is broad term for several methods intended to simulate human thought and behavior (AI). The development of methods that enable powerful computers to recognize complex patterns and connections in empirical data is the focus of a branch of artificial intelligence known as "Machine Learning" (ML) [4]. To acquire greater power and flexibility, Deep Learning (DL) draws inspiration from biological neural networks. In contrast to typical ML approaches [8], which are restricted in their ability to handle complicated problems like the classification of medical images, DL is inspired by biological neural networks to achieve better power and flexibility.

A significant collection of images that have been tagged is necessary for a DL-based detection or classification system to function well. Deep Feature Detection (DFD) and Transfer Learning (TL) are the best alternatives to using a limited sample size of images when a large sample size is not practical TL. Teaching a language involves using strategies that have already been learned to get around unexpected barriers (TL). TL is a method that can be used to build a new machine learning model, not a particular category of algorithms. The model will be able to apply the knowledge and skills it has acquired from prior training to novel circumstances [3][4][5]. The data must be organized by file type, just like in the previous step. Another application for TL is the extraction of deep feature data. Instead of manually changing the CNN's activation layers, feature vectors can be extracted using pre-trained CNN models. Installations of lower-level layers activate deeper layers that contain higher-level components crucial for detecting visuals [6].

The article addresses the above gaps including limited training data, class imbalance, interpretability challenges, robustness to variations, and transferability issues across

populations. To address these gaps, there is a need for more large datasets, improved model interpretability, better handling of class imbalance, enhanced robustness to image variations, and increased transferability to different populations. Addressing these gaps is vital for enhancing the accuracy and reliability of deep learning models in COVID-19 classification using X-ray images.

To distinguish between patients with COVID-19 infection and healthy people, this work presents a DFD-based method that makes use of XG-Boost [6][7]. The whole article is briefly reviewed in Section II, and the database and different methodologies are explained in Section III. In Section IV, the proposed work is introduced and the whole experimental work with results is explained in Section V. Section VI discusses the findings and Section VII concludes the research work with future outlook.

II. REVIEW WORK

Recently, researchers observed imaging patterns on chest CT to detect COVID-19. Lunagariya et al. [24] used TL to train Squeeze Net, DenseNet-121, and ResNet18 to distinguish between Covid-19-infected and non-infected individuals using CXR photos and were successful in identifying COVID-19. Gravitational search optimization-DenseNet121-COVID-19 was proposed by Khan et al. [19] suggested CoroNet, a deep CNN built on the Xception paradigm, as a way to distinguish Covid-19 from CXRs. The COVID-19 and Multiclass Xception models are used to categorize pneumonia in this study. H. Panwar et al. [20] introduce a novel method that combines deep learning techniques with gradient-weighted Class Activation Mapping (grad-CAM) for the swift identification of COVID-19 cases using chest X-ray and CT-scan images. The authors propose a color visualization technique to enhance the interpretability of the deep learning model's findings. The article showcases the experimental results, highlighting the potential of their approach in quickly and accurately detecting COVID-19 cases based on medical imaging data. Luz et al. [21], the authors discuss their efforts to develop a deep-learning model that can accurately and efficiently detect COVID-19 patterns in X-ray images. The authors detail their approach, and techniques employed, and present the outcomes of their experiments conducted to train and assess the model's performance. The article emphasizes the potential of deep learning methods in aiding the detection and diagnosis of COVID-19 through X-ray imaging technology. J. Zhang et al. [22] used 100 CXRs from COVID-19 cases and pre-trained weights from the ImageNet database to build their ResNet-based model. With an f-score of 0.72, their top model could distinguish between CAP and COVID-19 infection. Eduardo Luz et al. [23] demonstrated a DFE-based hierarchical categorization technique using EfficientNet models [11][12]. Classifiers are located between the tree's nodes, whereas target categories are located at the tree's leaves. At the root node, one classifier was used to separate the Normal and Pneumonia patients, while another classifier was used at a higher level to separate the Pneumonia patients only.

III. DATABASE AND METHOD ANALYSIS

The COVID-19, Pneumonia, and Healthy Chest X-ray PA Dataset [9][10] is being used in this study, and it was available

in April 2021. This data set contains 4575 images divided into three groups of 1525 images each. The images were obtained from a variety of web resources by the dataset's creator. The dataset contains chest X-ray Poster Anterior (PA) images and is divided into three categories (covid, pneumonia, and normal). GitHub, Radiopaedia, The Cancer Imaging Archive (TCIA), and the Italian Society of Radiology were used to collect 613 X-ray images of COVID-19 cases (SIRM). Rather than having the data independently enhanced, a dataset with 912 already-augmented images was obtained from Mendeley. 1525 images were obtained from the Kaggle repository and the NIH dataset. To validate a proposed technique, the experimental dataset is divided into two parts: training and testing. The remaining 30% of the images are used to test the effectiveness of the proposed technique, while the training set consists of 70% randomly selected images (i.e., 3202). (i.e., 1373). The assessment measure for each pre-trained model is created by combining ten cycles of a training-testing assessment in which different sets of randomly selected images are used for both the supplied model's training and testing.

The training set comprised 70% of the total dataset, while the test set comprised 30%. The dataset was further divided into three sections: learning, validation, and testing. To employ the transfer learning strategy, following are used:

EfficientNet-B0: Unlike custom, the EfficientNet-B0 [4][5][6] scaling method uses a set of predetermined scaling coefficients to gradually increase the network's resolution, depth, and width. EfficientNet-B0[4][5] scales the network's resolution, depth, and width using a compound coefficient. Compound scaling [6][9][11] was developed based on the idea that a larger input image requires more levels and channels in the networks to expand the available field and capture fine details on the larger image.

DenseNet-121: As a CNN's layers increase, the "vanishing gradient" problem becomes more common. As an alternative to using it, DenseNets-121[6][7] modifies the traditional CNN architecture and reduces the connections between the various layers. The name "Densely Connected Convolutional Network" is appropriate because each layer in the network is densely connected.

Tune the XG-Boost Classifier [7]: To accurately predict the outcome, the XG-Boost Classifier's parameters must be tweaked. The procedure for tuning is fully described in XG-Boost Classifier Tuning Algorithm 2, the maximum depth (MD), number of estimators (classification trees), and learning rate (LR) of each classification tree are XG-Boost classifier tuning parameters.

IV. PROPOSED TECHNIQUE

Fig. 1 shows the proposed architecture. A two-step process is used to retrieve the X-ray image characteristics. In the first stage, a pre-trained model is used to extract features from a collection of all X-ray images [13]-[18]. After the features have been collected, they are ranked using the Recursive Feature Elimination method. Finally, it is decided to keep only the top-ranked characteristics. The following describes the two-stage feature extraction process using Algorithm 1 (Deep Feature Detection).

Fig. 1. Proposed two-stage deep feature detection technique.

The algorithm "Deep Feature Detection" is designed to extract deep features from a set of images using a pre-trained model. It takes as input a pre-trained model (M), a set of N images (I1, I2, ..., IN), and the desired size for the resized images (K*K). The procedure involves removing non-convolutional layers from the pre-trained model to create a modified model (MR). An empty array called DF is initialized to store the extracted deep features. For each image in the set, the algorithm resizes it to the desired size and passes it through the modified model to obtain the features. These features are then flattened and added to the DF array. The algorithm also includes a step for ranking the features based on an unspecified criterion. Finally, the algorithm selects the features with a rank value of 1 and stores them in the selected features array. The output of the algorithm is a 2D array representing the selected deep features (DF).

Algorithm 1: Deep Feature Detection

Input: Pretrained Model (i.e. M), Set of 'N' Images I1 .. IN, Required Image Size (i.e., K*K) Output: A 2D array of chosen deep features is produced (i.e., DF)

```

Procedure:
MR ← Remove_Non_Conv_Layers (M)
DF = []
for i=1 to N do
  Resize image Ii to size (K*K) features ← MR (Ii)
  features ← Flatten (features) DF.append (features)
feature_rank ← FeatureRanking (DF) selected_features = DF[feature_rank==1]
    
```

Algorithm 2: Tune XG-Boost Classifier

Input: 2D array of class labels and selected features, Output: Best Parameters for Tuning the XGBoost Model

```

Procedure:
Acc_array = []
for max_depth = 3 to 5 do
  for learning_rate = 0.1 to 0.5 (step size 0.2) do
    for n_estimator = 300 to 800 (step size 50) do:
      accuracy ← K_Fold_XGBoostModelEvaluation (Folds=10, max_depth, learning_rate, n_estimators)
    acc_array [max_depth, learning_rate, n_estimators] ← Accuracy
  Select combinations of Parameters from acc_array which gives the highest accuracy.
    
```

V. EXPERIMENTAL RESULTS

The dataset [9], which was released in April 2021, is used for testing. This data set includes 4575 photos divided into

three groups of 1525 images each. These images as shown in Fig. 2 were obtained by the dataset's creator from a variety of web resources.

Fig. 2. Healthy and infected input dataset.

Using 10-fold cross-validation, the prediction accuracy of suggested experiments is investigated. The prediction accuracy of the XG-Boost Classifier, when trained using deep features detected using the DenseNet-121 model, is shown in Fig. 3, Table I, Table II, and Table III for various configurations of the Depth of the Tree, Learning Rate, and Number of Estimators variables. The model's classification accuracy is highest when trained with the values 0.3, 350, and 5 for the LR, MD, and classification trees, respectively. While, the prediction accuracy of the XG-Boost Classifier, when trained using deep features detected using the EfficientNetB0 model, is shown in Fig. 4 for various configurations of the Depth of the Tree, Learning Rate, and Number of Estimators variables. The model's classification accuracy is highest when trained with the values 0.3, 350, and 5 for the LR, MD, and classification trees, respectively.

VI. DISCUSSION

The whole experimental procedure rebels that by considering different techniques, such as DenseNet-121 with XG-Boost Classifier, and EfficientNetB0 technique with different depth range 3- 5, the estimator range from 100 to 800, we achieved different results, as shown in Table I to VI. Table I shows that the technique named DenseNet-121 with XG-Boost Classifier with depth 3 outreaches an accuracy of 0.94468524 in 450 Estimator. Similarly, by changing the depth to 4 with the same DenseNet-121 with XG-Boost Classifier, the accuracy reaches 0.94489594 in the 750 range of estimator. By using EfficientNetB0 with XG-Boost Classifier, we can have a comparison with the other techniques and find the differentiation of accuracies in different estimators' range with diverse depth values. The learning rate for all the techniques with different depths and estimators are numbered with values of 0.1, 0.3, 0.5, and 0.7. Fig. 5 depicts the accuracy of several pre-trained models as well as customized XG-Boost models that incorporate characteristics collected by method 1. The proposed technique is compared with various existing state of art techniques i.e. VGG16, VGG19, InceptionResNet-V2, InceptionV3, MobileNetV2, ResNet101V2, ResNet50V2, Xception, and hence the proposed technique was found to have the highest accuracy in finding the COVID infection. The modified XG-Boost model was trained using Algorithm 1 and EfficientNetB0 features, which explains its accuracy of 0.976, or 97.6% which explains its accuracy of 0.976, or 97.6%. This is the best result as compared to previously proposed algorithms given in [22] [23].

Fig. 5. Accuracy of tuned XGBoost models trained using deep features detection technique and various pre-trained models.

VII. CONCLUSION

A Deep Feature Detection based method for identifying pneumonia and the COVID-19 virus in patients is

demonstrated using chest X-rays. After lung area segmentation, this article describes a two-stage method for extracting deep features from X-Ray images. These characteristics are then used to train the XG-Boost classifiers to distinguish between pneumonia patients, healthy people, and people infected with COVID-19. When the results of 20 different pre-trained models are compared, it is clear that using EfficientNetB0 for deep feature detection results in the best detection accuracy, precision, recall, specificity, and F1-score. The following values correspond to these criteria: 97.6%, 0.964, 0.964, and 0.982. These findings support the proposed strategy's efficacy. The tables show that the proposed diagnostic testing model was better than the competitive models. The proposed testing model is a technological alternative to COVID-19 testing tools. A CNN method for COVID-19 can be used to test image classification with a large dataset and complete with symptoms.

Abstract—Data privacy is undoubtedly the biggest concern for the modern society. Data privacy is also becoming a key policy in data protection regulations. Organizations assemble massive amount of personal data of the users for monetary and political purposes. These data can be sold for commercial purpose without the prior knowledge or permission from the respective data owners. This can be mitigated by having blockchain to provide a much-needed transparency. However, blockchain's own transparency becomes its own disadvantage when data owners want to be completely anonymous. Blockchain's transparent nature will be conflicting with non-linkability. Since the data in blockchain is publicly viewable, any personal data or private transactions being processed through blockchain will be exposed to every node in the network. Hence, blockchain implementations also must comply with privacy acts such as Personal Data Protection Act (PDPA) to have privacy by design and by default. Hence, this paper proposes a PDPA-compliant blockchain architecture for data trading that provides complete control of data and anonymity to the users. A prototype is created using various tools to implement the proposed architecture. This study presents anonymous data sharing for users, data access, data delete features to verify the correctness of the proposed architecture.

Keywords—Blockchain; smart contract; legitimacy; access protocol; retention protocol; data processor; data subject; data user; blockchain regulations

I. INTRODUCTION

Sharing data is one of the most basic operations being performed on the Internet. Data can be shared to one or many depending on the need for the operation [1]. Nowadays, data is being considered as a valuable asset due to the growth of Internet of Things (IoT), cloud computing and big data [2]. There are many benefits of data sharing that underlines its importance. For example, data sharing can benefit enterprises, research and also our society [3]. Enterprises can reduce their inefficiencies, increase collaborations and open up new ventures between businesses. Researchers can build more connections and collaboration with other researchers. This will allow them to work on novel research topics rather than repeating existing works. The society can benefit through information shared to increase economic benefits, improved innovations and higher rates of advancement in technology and medical research.

However, there are some issues with data sharing that concerns the parties involved in it. Data integrity and user anonymity are very serious aspects of data sharing that

regularly concern the data owners. Data owners might have less trust on data management solutions due to the fear of their personal data being exposed and exploited without their permissions. It is also possible for data sharing to result in the violation of the users' privacy and losing control over the data produced by the users themselves [4].

We chose blockchain as the solution to tackle the issues that rise with data sharing. The users' concerns with data sharing mentioned previously can be handled by blockchain. Blockchain is a distributed ledger technology that was popularized by cryptocurrency applications. It is a ledger that consists of a record of transactions. From information technology perspective, blockchain can be seen as a database. This technology is designed to facilitate distributed transactions without depending on a central point of authority. Multiple users can make changes to the ledger simultaneously. The ledger will be stored in multiple nodes that participates in the blockchain network.

Blockchain technology rose to popularity with the rise of Bitcoin and many cryptocurrencies followed the suit. Cryptocurrencies are a virtual coin that holds a certain value that can be monetized. Users can buy, sell, and trade these cryptocurrencies with blockchain. Blockchain is immutable in nature so it will preserve data integrity. This enables data integrity to be preserved and prevent any false transactions.

Since blockchain is decentralized and transparent, any transactions happening in the network will be publicly available to all users. Blockchain eliminates the need for a trusted third party and ensure the data ownership of the users by enforcing smart contracts. Users do not have to worry about their data being exploited because the usage and the users of data can be defined by the data owners using smart contract. These features give the users an increased control and trust over their data. The core concept can also be used to enable users to trade their data in return for money in Malaysian context. Instead of sending cryptocurrencies through blockchain, users can also trade different types of data through blockchain.

However, some additional components need to be added to a generic blockchain architecture to protect user's data privacy due to blockchain's transparent nature. Users' personal data could be publicly viewable if it is shared on blockchain. Users also should be able to control how much and to whom their data can be exposed to. Blockchain addresses' linkability; also needs to be handled to not expose the identities of the users.

Personal Data Protection Act 2010 (PDPA) in Malaysia is an act that enforces the regulation of the processing of personal data concerning commercial transactions. A bill relating to the PDPA of Act 709 was passed by the Malaysian Parliament on 16th May 2011. Following this, the Personal Data Protection Department was established under the Ministry of Communications and Multimedia Commission (MCMC). PDPA is applicable to any person who processes and collects data for commercial purposes. Hence, this research discusses the current blockchain ecosystem in Malaysia and proposes the first PDPA-compliant blockchain architecture for data trading purposes in Malaysia.

Hence, this paper discusses the current blockchain ecosystem in Malaysia and proposes the first PDPA-compliant blockchain architecture for data trading purpose in Malaysia. This paper contains six sections. Section I is the introduction and explains the need for implementing a user centric data privacy protection for data trading on blockchain platform. Section II provides the relevant works done in relation to data privacy and blockchain. Section III introduces our proposed PDPA-compliant blockchain architecture. Section IV discusses implementation and testing of the proposed blockchain architecture using tools such as Multichain, Solidity, Truffle and PYPSV (Python library). Section V provides the conclusion for this paper.

II. RELATED WORKS

This section discusses the definition of data privacy and the types of profitable data associated with it. It also discusses briefly about blockchain technology and its components, data management solutions with blockchain, and the relevance of PDPA to blockchain.

A. Data Privacy

The concern for data privacy is ever increasing among us today, considering the amount of big data generated by our daily life activities. Data privacy is also becoming a key policy in data protection regulations.

We are witnessing massive developments in statistics and computer science that enable computers to analyse and interpret data automatically. These processed data are being used by computers for decision making and knowledge discovery. Nowadays, we can see computers are used for decision making in various sectors. The shift from decision making by humans to automated decision making will raise multiple issues and leave a huge impact.

When thousands or millions of individual data are combined together, they can form digital profiles of people using the particular service. This data can be used for monetary purpose or to shift tides in politics. Some types of data that can be used for these purposes are as follows [5, 8]:

- Age
- Gender
- Address
- Job Title
- Ethnicity

- Religion
- Salary
- Personality traits

While the concept of privacy is very subjective due to the difference in individuals and their cultures, it shares a common theme of having the “right to be alone” [6]. Smith et al. defines privacy as the concern of an individual regarding the access to his/her identifiable personal information [7]. The ISO_IEC_15408-2_2008 standard is referred to identify the data privacy properties. The standard is stating anonymity, pseudonymity, unlinkability and unobservability as the required properties.

Anonymity is when the data user or subject who own the data might act without releasing their user identity to others such as users, subjects, or objects. If a subject is anonymously performing an action, another subject will not be able to determine either the identity or even a reference to the identity of the user employing the subject.

Pseudonymity is when a subject can be referred back directly by being related to a reference (alias) held by the Data Controller, or by providing an alias that will be used for processing purposes. The alias could be in the forms such as an account number or smart contract ID if it's a blockchain implementation. Both pseudonymity and anonymity protect the identity of the user, but in pseudonymity a reference to the user's identity is maintained for accountability or other purposes.

Unlinkability is intended to protect the user identity against the linking of the operations done by the user. Unlinkability requires that different operations cannot be related. For example, the user associated with the operation, or the terminal which initiated the action, or the time the action was executed.

A number of techniques can be applied to implement unobservability. The information might be allocated to a single randomly chosen part of the system/architecture/nodes such that an attacker does not know which part of the system/architecture/nodes should be attacked. An alternative system might distribute the information such that no single part of the system/architecture/nodes has sufficient information that, if circumvented, the privacy of the user would be compromised. It can be achieved by methods such as cryptography and encryption

B. Blockchain Technology

Blockchain is a type of distributed ledger technology that contains the transactions shared by participating parties in the network. Blockchain maintains an immutable record of this transactions with a P2P network where the copy of the ledger is duplicated to all the participating nodes [9]. Every node gets to keep a copy of the ledger. Transactions in blockchain are validated and authorized by these nodes using a consensus algorithm.

Blockchain can be separated into four types, public, private, hybrid and consortium based on usability [10]. There are different trade-offs for each type. There are various consensus algorithms such as Proof of Work, Proof of Stake, and Proof of

Byzantine Fault Tolerance that can be used by blockchain to verify the transactions made [11].

Blockchain also eliminates the need for a trusted third party by providing digital trust through its smart contract [12]. Users are not required to share any personal information to make transactions through blockchain. Transactions are verified by comparing the provided keys as no authority figure is needed. These features enable blockchain to be a good platform to introduce user-centric data management solutions.

C. Data Management Solutions using Blockchain

Since data market places are becoming a common phenomenon, there is a great need for data management solutions that satisfies users. Data management solutions in blockchain are already witnessing increased adoption. Blockchain is a suitable platform for data sharing because of its decentralization architecture and the ability to have a system that eliminates the need for a trusted third-party.

Bajoudah et al. proposed a decentralized marketplace that facilitates IoT data brokering among selected nodes. This will require minimal trust since the smart contract is enforced to carry out the instructions sent by the user and the transaction details are recorded on a public network [13]. They are using Ethereum's public network and smart contract to mediate the interaction among data producers and consumers. This method ensures complete transparency and non-repudiability.

The authors in [14] proposed a data trading framework based on smart contract using machine learning and blockchain. The authors enforce data trading centers to not be able to retain the shared data during the data trading process with their solution. Hence, the framework is designed to eliminate the need for a trusted third party and give complete control to the data producers. An off-chain download mechanism and challenge response mechanism to download the purchased data and to authenticate data owner are incorporated into the framework.

A consortium blockchain-based data trading framework for the Internet of Vehicles (IoV) was proposed by Chen et al. in [15]. They applied an iterative double auction mechanism that induces users to submit bids and decide the amount of data to trade and its price. The proposed framework's algorithm also extracts the hidden information of participants gradually to ensure their privacy is protected.

The authors mentioned above provided great data management solutions with blockchain. However, the PDPA has a set of regulations that has to be complied by those who makes data-centric solutions. Both regulations definitely affect the way previous researchers dealt with data, especially personal information. Hence, these solutions do not comply fully with key principles of PDPA such as the right to be forgotten and the need for a data controller.

Onik et al. has proposed a solution to have a privacy-aware blockchain for personal data sharing and tracking that complies with European Union's General Data Protection Regulation (GDPR) [16]. Any businesses or organizations that deal with EU subjects has to comply with GDPR even if they are outside the EU. GDPR ensures the protection of its citizens' personal

data regardless of the territories [19,20]. The proposed system in [16] stores personal data on off-chain storage and successfully tracks the data movement between the parties involved in the data sharing transaction. However, due to the tracking feature, it does not satisfy one of the properties of data privacy which is unlinkability. Hence, the proposed architecture in this paper takes non-linkability as a fundamental feature and build upon it. The architecture aims to provide complete anonymity and control to the data producers/owners.

D. PDPA, Blockchain and Data Trading

Malaysia's PDPA is an Act that regulates the processing of personal data in regards to commercial transactions. It was gazetted in June 2010. The penalty for not complying to PDPA is between RM100,000 to 500,000 and/or between 1 to 3 years imprisonment. The importance of PDPA as provided by the Department of Personal Data Protection [17] is as follows:

- To enhance public confidence and trust with ongoing enforcement
- To avoid and minimize the incidents of data breach
- To increase the efficiency and governance of personal data
- To ensure prudence and integrity in personal data handling

Data Subjects are the owners of the data being uploaded to the blockchain architecture. Data Processors are the third parties that are interested to buy data produced by Data Subjects. Data controller is the authority figure that can verify transactions and help make data trading for data user and Data Subject [18]. There should be at least one Data Controller to enforce the rights of the Data Subjects.

Data controllers must obtain explicit consent from users before making any transfer of the data to the Data Processors [18]. The controllers are also required to have a list of consents given by the Data Subjects. This rule can be applied by getting smart contracts from the data and storing the transaction details in the blockchain.

PDPA also encourages PDPA's Retention and Access Principles mandate that data can be modified or erased to comply with legal requirements as mentioned in Section 34, 35, 36 and 37 of PDPA [18]. This conflicts with blockchain's immutable nature that emphasizes on data integrity. Data cannot be modified or erased from blockchain.

However, it can be solved by storing the data on off-chain storage instead on the blockchain. The PDPA sections mentioned earlier also can be enforced by having functions in the smart contract that can access or delete data required by the Data Subjects. PDPA is also applicable only when the data breach happens in Malaysia. This can be enforced by having an off-chain storage in Malaysia.

III. PROPOSED BLOCKCHAIN ARCHITECTURE

A PDPA compliant blockchain architecture is proposed based on the discussion in our previous paper [21] where we studied the gaps between PDPA and blockchain and also the

PDPA-compliant features, and PDPA [18] as shown in Table I.

TABLE I. PDPA COMPLIANT FEATURES

Feature	PDPA	Description
Smart Contracts	Right to erasure and modification, consent to collect data	Both regulations emphasizes on enabling the users to erase or modify the data shared by them. Both regulations requires for the consent to be collected from the users before collecting their data.
Stealth Address [22]	Not Associated	By using stealth address, only the sender and receiver can determine where a data was sent. They allow and require the sender to create random one-time addresses for every transaction on behalf of the recipient. This provides complete anonymity.
Off-chain storage [23-25]	Right to erasure, Territorial limitation	Data on blockchain cannot be erased. However, this can be solved by using off-chain storage. The PDPA can only be enforced if the data storage or breach happens in Malaysia. A off-chain storage in Malaysia will ensure immediate enforcement of PDPA.
Data Controllers	Having data controller is recommended	Data Controllers are needed to enforce or process the data on behalf of the Data Subjects. A minimum of 2 Data Controllers are needed for a Data Subject.

Table I provides the explanation for the PDPA features implemented in our proposed architecture. This section provides the detailed description of the blockchain based PDPA-compliant Data Sharing architecture. This study uses a permissioned blockchain where three stakeholders, Data Subject, Data Controllers and Data Processors form the blockchain network.

The key terms such as Data Subject, Data Controllers and Data Processor are used here and explained below:

- Data Subjects are the data producers.
- Data Controllers are the legal entities that determines the purpose of the data processing and enforces the smart contracts on behalf of the Data Subjects.
- Data Processors are the third-party companies that process data on behalf of the Data Controller.

These terms are from the PDPA as the blockchain architecture is designed to be PDPA compliant. The architecture is designed to have the implementation of key principles of PDPA as the core features. Our definition of data in this proposed architecture is subjective. It can be any type of data that the users want to share. The data type can vary from personal information, bank transactions, energy consumption data, health information and etc.

The architecture enables Data Subjects to share data produced by them to a Data Controller in return for a monetary or point-based reward. The reward received by the Data Subjects can be stored in their preferred digital or

cryptocurrency wallet depending on the type of reward given to them. Data Processors can purchase these datasets from the Data Controller for data processing purpose.

Fig. 1 shows the proposed blockchain architecture. This architecture implements stealth address, an access protocol and a retention protocol. It comprises of three layers, user layer, system management layer and storage layer. The green dotted lines indicate the interactions of the nodes with blockchain. The solid lines indicates the interaction between the stakeholders. Stealth Address (SA), Access Protocol (AP) and Retention Protocol (RP) are used for the interaction between nodes. AP and RP are explained in sub-section 2 of this section and the implementation is shown in sub-section B under System Implementation and Testing. Components used in the proposed blockchain architecture are described below:

- Node: Data Subjects, Data Controllers and Data Processors.
- Block: A new block is generated and added to the existing blockchain each time data sharing happens successfully among the nodes.
- Block header: A block header stores hash of the previous block, transaction time, transaction ID and data encoding style.
- Transaction data: Storing of smart contract ID and hash of the shared data.
- Consensus algorithm: Round-robin mechanism provided by Multichain.

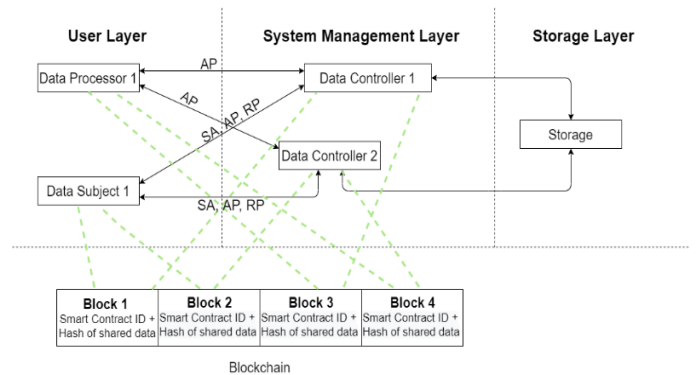

Fig. 1. Proposed blockchain architecture.

1) *User layer*: Each time Data Subjects want to share some data, they can choose the amount and the types of data to be shared. The system then creates a smart contract with their preferred data types. Then a one-time stealth address is created for users to send their smart contract to the blockchain and Data Processor. Users’ smart contract ID and transaction details will be stored in blockchain. The data shared by them will be stored in an off-chain storage. Data Processors exist in this layer to purchase Data Subject’s data from the Data Controllers.

2) *System management layer*: In this layer, data controller enables Data Subjects to claim reward for the data they shared

by providing the smart contract ID related to the dataset. Access protocol (AP) facilitates the data exchange between Data Subject, Data Processor and data user. Users send their smart contract ID linked to the dataset they want access to and data controller retrieves the dataset based on it. Retention protocol (RP) is very crucial in exercising Data Subject's rights to erase their data by providing the smart contract ID linked to the particular dataset. Retention protocol is only available for Data Subjects. Both AP and RP are enforced by data controller in this layer.

3) *Storage layer*: An off-chain storage is used to store the data as it enables PDPA to be enforced should any data breach happens. Once, the user has shared the data to the Data Processor, the data will be sent to the off-chain storage and the transaction details are stored in the blockchain. Since the data is stored in off-chain storage, it is easier to apply AP and RP to access or delete the user's data. Off-chain data is erasable and the remainder of the hash of the shared data will be useless and unidentifiable. This can be ensured by cross-checking the hashes generated after the modification and deletion. This makes the storage layer to comply with PDPA's principle to enable users to modify and erase their data.

4) *Creation of blocks*: Any transaction in the blockchain will only be added to a block after the creation of the genesis block. The architecture shown in Fig. 1 assumes the genesis block is already created during the instantiation of the blockchain. Then, it shows the block creations and the transactions related to them. The contents and the interaction between the nodes during the block creation are explained below.

- Block1: Data Subject1 shares data to Data Controller1. Block is created after consensus is achieved from the Data Subject1 and Data Controller1. The smart contract ID and the hash of the shared data is stored in the block.
- Block2: Data Subject1 shares data to Data Controller2. Block is created after consensus is achieved from the Data Subject1 and Data Controller2. The smart contract ID and the hash of the shared data is stored in the block.
- Block3: Data Processor1 retrieves data from Data Controller1. Block is created after consensus is achieved from the Data Processor1 and Data Controller1. The smart contract ID and the hash of the shared data is stored in the block.
- Block4: Data Processor1 retrieves data from Data Controller2. Block is created after consensus is achieved from the Data Processor1 and Data Controller2. The smart contract ID and the hash of the shared data is stored in the block.

Stealth Address (SA), Access Protocol (AP) and Retention Protocol (RP) are used for the interaction between nodes. The execution of AP and RP are explained below.

Access Protocol can be used in three different methods. The first two different ways can be used by Data Subject only, where the Data Subject can trigger the AP to create a new dataset or access already shared data. The last method is for Data User to buy dataset from Data Controller. Table II describes the components needed to complete the Access and Retention protocol.

TABLE II. PROTOCOL COMPONENTS FOR AP AND RP

DSi	Data Subject is the Data Producer / Owner
DCi	Data Controller determines the purpose of the data processing and enforces the smart contracts on behalf of the Data Subjects.
DPI	Data Processors are the third-party companies that buys data from Data Controller
BC	Blockchain
OCS	Off-chain storage
MSG	Data sent by Data Subjects (e.g: duration and the types of data to be shared)
MSGhash	Hash of the data sent by the Data Subject
DDC	Data sent by Data Controller
SCiID	Smart Contract ID
PSCiID	Previous Smart Contract ID
TiID	Transaction ID
RD	Request for data
PR	Points based reward
DR	Data Price Rate
P	Payment
E	Notice of data erasure

a) *Access protocol for sending new dataset*:

- DSi creates a smart contract to send a new dataset, MSG. The smart contract is being sent to DCi with SCiID, TiID, and MSG. The SCiID is stored by DSi for future reference.
- DCi stores the SCiID, TiID, and MSGhash in BC for auditing purpose.
- MSG and the associated SCiID is stored in OCS for future processing, access or deletion.
- DCi pays PR for the MSG shared by the DSi.

Fig. 2 shows the first method of AP to be used by Data Subject to send a new dataset to the Data Controller.

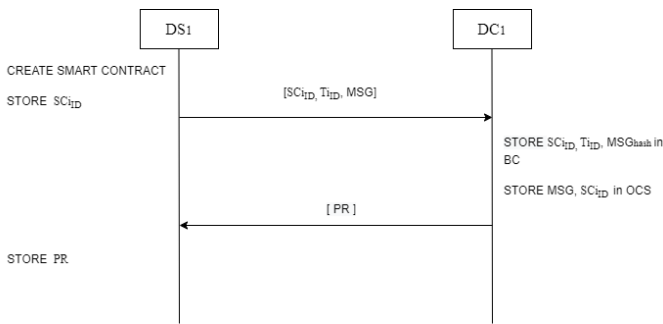

Fig. 2. Data subject sending data using AP.

b) Access Protocol for requesting previously shared data:

- DSi creates a smart contract to request for previously shared dataset, MSG. The smart contract is being sent to DCi with SCiD, TiD, and MSG that contains PSCiD. The SCiD is stored by DSi for future reference.
- DCi checks the match for PSCiD in OCS to look if matches with any data.
- If there is any match with PSCiD, the MSG associated to it is retrieved.
- The SCiD and TiD is stored in for the current transaction is stored in BC for auditing purpose.
- DCi sends DDC that contains the previously shared MSG to the DSi.

Fig. 3 shows the first method of AP to be used by Data Subject to send a new dataset to the Data Controller.

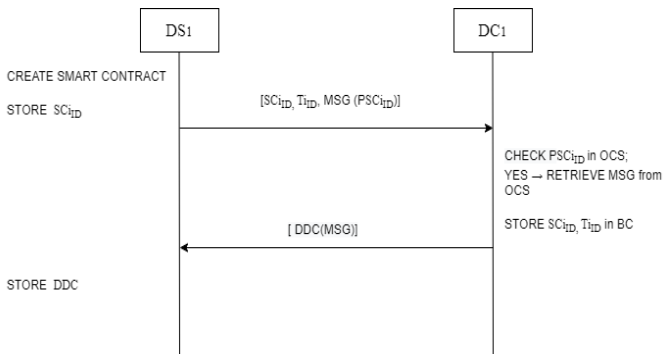

Fig. 3. Data subject using AP to access shared data.

AP is limited in terms of functionality for Data Processor, as shown in Fig. 4.

c) Access Protocol for data purchase:

- DPi creates a smart contract to request for some data. The smart contract is sent to DCi with SCiD, TiD, and DR. The SCiD is stored by DPi for future reference.
- The SCiD and TiD is stored in for the current transaction in BC for auditing purpose.
- The DCi issues the payment of DR for the data requested by the DPi.
- The DPi then pays the DR to the DPi.

- The DPi DDC from the OCS and sends it to DPi.

Fig. 4 shows the method of AP used by Data Processor to buy a dataset from the Data Controller.

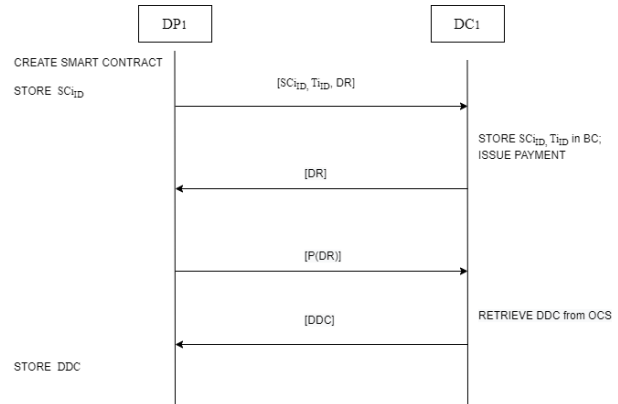

Fig. 4. Data processor requesting data using AP.

d) Retention Protocol:

- DSi creates a smart contract to request of deletion for previously shared dataset, MSG. The smart contract is being sent to DCi with SCiD, TiD, and MSG that contains PSCiD. The SCiD is stored by DSi for future reference.
- DCi checks the match for PSCiD in OCS to look if matches with any data.
- If there is any match with PSCiD, the MSG associated to it is erased.
- The SCiD and TiD is stored in for the current transaction is stored in BC for auditing purpose.
- DCi sends E to DSi to complete the transaction.

Fig. 5 shows how RP is used by Data Subject to erase previously shared dataset to the Data Controller.

Fig. 5. Data subject requesting the data to be deleted using RP.

IV. IMPLEMENTATION AND TESTING

This section explains the implementation and testing of the proposed architecture. In the first sub-section, case study for the architecture is discussed. In the following subsection, system implementation and testing of the proposed architecture is explained.

A. Case Study: Data Management Scenario

This case study test is done by referring to a similar case study implemented by the authors in [16]. A use case scenario is described with three different situations to further explain the

PDPA-compliant blockchain architecture. The three situations explained here are: Data Subject-controller data sharing scenario, Data Processor-controller data sharing scenario and data deletion scenario.

a) *Data subject-controller data sharing scenario:* Every time the Data Subjects send a set of data to the Data Processor, the transaction details and smart contract ID will be stored in the blockchain and in their local storage. For any set of data, it will be linked with the smart contract's ID. The data controller separates the data into data shared by user, hash value generated for the shared data, transaction ID and smart contract ID. A combination of smart contract ID and data shared by user is stored in the off-chain storage. The combination of generated hash value and smart contract ID are stored in a new block and added to the current blockchain.

An appropriate amount of reward for the shared data will be sent to the Data Subject's temporary address created by stealth address mechanism. Then, the Data Subject can transfer the reward to their digital or cryptocurrency wallet. The transfer of the reward to the user's personal wallet will not be recorded on the blockchain as it happens internally on the end device.

When a Data Subject sends a request with AP to data controller to get a copy of a specific set of data, the data controller will verify and grant the request by the Data Subject. Data controller proceeds to check for the data by using the smart contract ID and its matching data in the off-chain storage. If a match is found, the data controller will send a copy of the requested data by retrieving it from the off-chain storage. Transaction details will be stored in the blockchain for auditing purpose.

2) *Data processor-controller data sharing scenario:* A Data Processor sends a request with AP to Data Controller to get a copy of a specific set of data from the off-chain storage. Data controller will verify and grant the request. Then, the data controller will send a copy of the requested data by retrieving it from the off-chain storage. Transaction details will be stored in the blockchain for auditing purpose. When Data Processor executes the access protocol, they need to pay the Data Controller corresponding to the amount of data they need access to. The payment could be in fiat currency.

3) *Data deletion scenario:* Data Subject sends a request to data controller with relevant Smart Contract ID to erase their data. Data controller will verify and grant the request. After the verification, the data controller searches for any data associated with the Smart Contract ID provided by the user in the off-chain storage. Any data found with matching Smart Contract ID will be erased and the transaction details are stored in blockchain.

B. System Implementation and Testing

This sub-section presents a pilot implementation scenario of the PDPA-compliant blockchain architecture with various tools. The tools used here are Multichain (for network setup with off-chain storage), Remix IDE and Solidity (for writing smart contract), Truffle suite (to test the smart contract) and

pyspv library from python (to build stealth address functionality).

1) *Node and network setup:* A private network with one Data Subject, two controllers and one Data Processor is set up on the blockchain platform with Multichain 2.1.2 [26] as shown in Fig. 6. We have implemented the prototype of the architecture on four computers. The details are as follows:

- Data Controller 1: Windows 10 64-bit, i5-9400F @ 2.90GHZ, Acer Predator Orion 3000.
- Data Controller 2: Windows 10 64-bit, i5-8300H @ 2.30GHZ, Acer Nitro 5.
- Data Subject: Windows 10 64-bit, i7-4600U @ 2.10GHZ, HP Elitebook 840.
- Data Processor: Windows 10 64-bit, A12-9720P @2.70GHZ, HP Laptop 15-bw0xx.

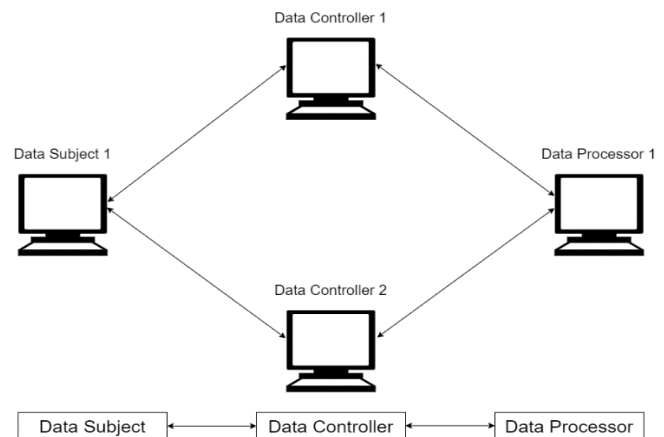

Fig. 6. Experimental network setup.

Multichain is mainly selected due to its off-chain storing mechanism. The built-in off-chain feature enables easy management of data among the nodes. Multichain also helps to add the hash of the off-chain data to the existing block.

Since this is a private network, the consensus only requires minimum difficulties to be achieved. No nonce is used and the consensus is achieved with a round robin mechanism since the node identities are known in a private blockchain. Masking of the node identity will be explained in subsection 3. Multichain is used here for its off-chain storage and easy blockchain deployment capability.

An example of data stored in the off-chain storage is shown in Fig. 7. This is retrieved by the Data Processor1 node after getting the permission from the Data Controller1 to subscribe to the data stream that contains this dataset. The status of off-chain section is shown as true to indicate that the data is being stored in the off-chain storage.

```
"offchain" : true,  
"available" : true,  
"data" : {  
  "text" : "Name: Hasventhran, Age:26, Gender: Male, Address: Selangor, Malaysia"  
},  
"confirmations" : 1,  
"blocktime" : 1626973259,  
"txid" : "d0057749f30abd82fd714aea34e03641099f2b3c13229f13c4a3a88ffff8573"
```

Fig. 7. Data stored in off-chain storage.

2) Smart contract:

The smart contract has four functions that helps AP and RP to be applied in the blockchain architecture. This contract was written in Solidity language with Remix IDE. The contract was tested with Truffle Suite on Geth's Ropsten test network. A few researchers have already used Truffle to test their smart contracts [27 - 31].

Algorithm I: Pseudocode for Data Sharing Smart Contract

```
contract DataSharing{
/*Defining variables and their types*/
int ContractId
string memory name
int age
string memory gender
string memory address
int expiry_date

User[] internal users;
uint public currentID equal to 1010;
RETURN currentID

FUNCTION create_data(string name, int age, string gender,string user_address,
int expiry_date){
Set name = name in name
Set age = age in age
Set gender = gender in gender
Set user_address = user_address in user_address
Set expiry_date = expiry_date in expiry_date
Increment currentID by one when this function is called
RETURN currentID
}

FUNCTION search_data(int ContractId) return (name, age, string
gender,user_address, int expiry_date){
Call find_data and pass ContractId to ContractId
Set i = ContractId
RETURN name = name in users[i]
RETURN age = age in users[i]
RETURN gender = gender in users[i]
RETURN user_address = user_address in users[i]
RETURN expiry_date = expiry_date in users[i]
}

FUNCTION delete_data(uint id) {
Call find_data and pass ContractId to id
Set i = id
delete users[i]
}

FUNCTION find_data(uint ContractId) {
Get the value of ContractId
FOR i = 1 to user's length step 1 DO
IF users[i] in ContractId equal to ContractId
RETURN i
ELSE
PRINT "Smart Contract ID does not exist!"
ENDIF
ENDFOR
}
```

The pseudocode above reflects the smart contract written to facilitate the data sharing in the proposed architecture. We referred to the template written by authors in [32] to write the pseudocode for our proposed smart contract. The four functions written in the contract are *create_data*, *search_data*, *delete_data* and *find_data*. There are seven variables named *ContractId*, *name*, *age*, *gender*, *address*, *expiry_date* and *currentID*. An array named *users* is created to contain the instances of the structure, *User*.

In the function *create*, users can fill in the data they want to share. For testing purpose, four personal information such as

name, age, gender and address are chosen to be shared by the user. The expiry date of the data is also set by the users (in the format of DDMMYY) to prevent the data from being kept longer than necessary. If users only wish to share their name, they can fill in the remaining fields with "NIL" or "0". Once the user creates their data, the variable *currentID* is incremented by 1.

In the function *search_data*, index of the structure *User* that we need is retrieved. *User* enters their index/smart contract ID and passes it to the function *find_data*. A for-loop statement is then used to find if the smart contract ID entered by the user exists in record. If there is no relevant entry, an error message is displayed and cancels the current execution. This function is called as the Access Protocol in the architecture.

In the function *delete_data*, users enter their smart contract ID. The function takes a single argument and calls the function *find_data* to get the index of the structure in the users array. If the relevant index/smart contract ID is found, the data associated to the index is deleted.

Algorithm II: Truffle test case for smart contract

```
const DataSharing = artifacts.require('DataSharing.sol');

contract('DataSharing',() => {
let datasharing = null;
before(async() => {
datasharing = await DataSharing.deployed();
});

it('Creating new dataset', async () => {
await datasharing.create('Hasventhran', 26, 'Male',
'Malaysia', 110721);
const user_data = await
datasharing.search_data(1010);
assert(user_data[0].toNumber() === 1010);
assert(user_data[1] === 'Hasventhran');
assert(user_data[2].toNumber() === 26);
assert(user_data[3] === 'Male');
assert(user_data[4] === 'Malaysia'
assert(user_data[5] === '110721');
});

it('Deleting a dataset', async () => {
await datasharing.delete_data(1010);
try {
await datasharing.search_data(1010);
} catch(e) {
assert(e.message.includes('Smart
Contract ID does not exist!'));
return;
}
assert(false);
});

it('Should NOT delete a dataset with non-existing details', async
() => {
try{
await datasharing.delete_data(1010);
} catch(e){
assert(e.message.includes('Smart
Contract ID does not exist!'));
return;
}
assert(false);
});
});
```

A test case was written in Javascript to test the smart contract's correctness in the architecture. Three public functions of the smart contract, *create_data*, *search_data* and *delete_data* were included in the test case as shown above. The

function *find_data* is not included as it is an internal/private function of the smart contract to access the smart contract ID assigned to the user. *search_data* is a function that depends on the value passed by *find_data*. Successful test of *search_data* ensures the passing of *find_data*.

In the first *it* function in the test case, *create* is tested by adding smart contract ID and five different values according to the data types defined in the smart contract. The *search_data* function is also defined in this function as it can be tested along with the *create_data* and *delete_data* functions. Successful test of these two functions ensures the passing of *search_data*.

The *delete_data* function is separated into two *it* functions. The first function tests whether the dataset is correctly deleted after obtaining the smart contractID from the *search_data* function. If the smart contract ID does not exist, it should be able to display an error message. The second *it* function checks for the smart contract's correctness in not deleting data with non-existing details.

The contract is tested on Ropsten network of Geth with the truffle command, *truffle test*. As shown in Fig. 8, all three *it* functions of the test has successfully passed the test. Hence, the correctness of the smart contract is ensured. Hence, it can be deployed in the architecture to enforce AP and RP.

```
C:\Users\ASUS>cd Desktop\TestContract
C:\Users\ASUS\Desktop\TestContract>truffle test
Using network 'test'.

Compiling your contracts...

```

Fig. 8. Successful test of smart contract.

3) *Stealth address*: A python script is written to test stealth address. This python script uses the *pyspv* library to run the stealth address functions. This script is tested on a simulated blockchain and it is explained below. Data Controller is mentioned as Data User in the code sections.

```
def main () :
    Data_User_key=pyspv.keys.PrivateKey.create_new()

    Data_User_public_key=Data_User_key.get_public_key(
        True)
    print("Data_User's public key=",Data_User_public_key.as_hex())
```

Code Snippet 1 Creating Data Controller's public key

Python's *pyspv* library is used to test stealth address functions. Data Controller's public and private key is created through the code shown in the code snippet 1.

```
Data_Subject_key = pyspv.keys.PrivateKey.create_new()
Data_Subject_public_key=Data_Subject_key.get_public_key(True)
Data_Subject_shared_secret_point=Data_User_public_key.multiply(
    Data_Subject_key.as_int())
print("Ephemeral key (Data_User needs this to redeem) = ",
    Data_Subject_public_key.as_hex())
```

Code Snippet 2 Data Subject creating new key for Data Controller

The same method applies for the Data Subject in the section of code below. The Data Subject's public and private key is also created and shown in code snippet 2. The Data Subject wants to pay/send data to the Data Controller. So, the Data Controller gives the Data Subject his/her public key. Then, the Data Subject creates a new key and multiplies the Data Controller's public key with his/her private key and sends her public key to the Data Controller as shown in the code in code snippet 2.

```
import hashlib
hasher = hashlib.sha256()
hasher.update(Data_Subject_shared_secret_point.pubkey)
shared_secret = hasher.digest()
print("Shared secret =", pyspv.bytes_to_hexstring(shared_secret,
    reverse=False))
```

Code Snippet 3 Hashing the shared secret

The next task is to hash the shared secret. Python's *hashlib* library is used to hash the shared secret with SHA256 algorithm. This is done by the code in code snippet 3.

```
new_Data_User_public_key=Data_User_public_key.add_constant(int.from_bytes(shared_secret, 'big'))
print("New_Data_User Public Key = ",
    new_Data_User_public_key.as_hex())
print("New_Data_User=",new_Data_User_public_key.as_address(pyspv.Bitcoin))
```

Code Snippet 4 Adding shared secret to Data Controller's public key

After hashing the shared secret, it is added to the Data Controller's public key. This will be used later to compute the Data Controller's private key. This is done by the code in code snippet 4.

```
Data_User_shared_secret_point=Data_Subject_public_key.multiply(Data_User_key.as_int())
```

Code Snippet 5 Computing the private key to Data Controller

```
hasher = hashlib.sha256()
hasher.update(Data_User_shared_secret_point.pubkey)
shared_secret_by_Data_User = hasher.digest()
print("Data User figured out the shared secret =",
    shared_secret_by_Data_User == shared_secret)
```

Code Snippet 6 Producing the shared secret by hashing private key

In order to compute the private key to the new Data Controller public key, the Data Controller has work to do as

shown in code snippet 5. First, the Data Controller multiplies the ephemeral key produced by the Data Subject by his private key. Then, the shared key is produced by the Data Controller by hashing the private key as shown in code snippet 6.

```
new_Data_User_key=Data_User_key.add_constant(int.from_bytes(shared_secret_by_Data_User, 'big'))
new_Data_User_computed_public_key=new_Data_User_key.get_public_key(True)
print("Data_User figured out the correct private key =",new_Data_User_computed_public_key.pubkey==new_Data_User_public_key.pubkey)
```

Code Snippet 7 Adding the Shared Secret to the Private Key

Finally, Data Controller adds the shared secret to his private key as shown in code snippet 7. This works because, given $Q = dG$, then $(d+n)G = dG + nG = Q + nG$ and the Data Subject computed $Q + nG$ above and sent data to the Data Controller, but now the private key $d+n$ is known.

V. CONCLUSION

This research aimed to produce a PDPA-compliant user-centric privacy preserving features for blockchain based data sharing architecture. Blockchain was chosen to be the platform to develop the data sharing architecture, due to its inherent privacy properties and also flexibility of implementing other features on top of it. Based on the gaps identified by literature review, features such as private blockchain, use of data controllers, stealth address, smart contracts (with access and retention protocols), and off-chain storage are identified to produce the proposed architecture with user control being given importance. The results indicate that the implemented features fulfil the required PDPA regulations.

The proposed blockchain architecture is developed mainly to comply with PDPA in Malaysia. The architecture is appropriate to be followed for Malaysian context. It is acceptable to use the proposed architecture to develop any data management solutions using blockchain in Malaysia. However, the proposed architecture may not be suitable to be used in a general manner globally due to different data protection regulations all around the world.

The proposed blockchain architecture is developed by combining existing privacy preserving and user-centric components. Moreover, the proposed architecture can be used by blockchain developers to develop data management solutions without worrying about the potential breach of privacy. This is because the proposed architecture adheres to the "privacy by design" principle.

This research proposed a user-centric privacy preserving blockchain architecture for data sharing according to existing data protection regulations. Hence, to better understand the effectiveness of the architecture, future studies can implement the architecture for various type of data sharing solutions across multiple fields. These new solutions derived from the proposed architecture can also be modified according to compliance with each country's data privacy protection regulations.

ACKNOWLEDGMENT

Abstract—As e-learning has become increasingly prevalent, cyber security has become a major concern. e-Learning platforms collect and store large amounts of sensitive information, such as personal data and financial information, making them attractive targets for cybercriminals. To address these challenges and concerns, e-learning platforms must implement a comprehensive cyber security strategy that includes strong access controls, data encryption, regular software updates, and student training to help them identify and prevent insider threats. This research aims at investigating and determine how satisfied students are with e-learning security and privacy, as well as whether these concerns affect the overall standard of education. A sample study is presented to assess both the impact of the security framework on students' academic achievements and the student's satisfaction with the security countermeasures in an e-learning system. Statistical analysis showed that the use of security and cyber security countermeasures had a significant effect on the frequent use and participation of students in the contents of the system. Furthermore, encouraging feedback and communication from students about their e-learning experience to share their concerns, questions, and suggestions can help in addressing any security issues or concerns, as well as increasing students' participation in the e-learning content.

Keywords—e-learning; security; cyber security; privacy; countermeasure; Moodle; education

I. INTRODUCTION

Technological advancements have significantly impacted the field of education, particularly with the rise of online learning (e-learning). e-Learning refers to the use of digital technology to deliver educational content over the internet [1]. With e-learning, students can access learning materials and participate in classes and discussions from virtually anywhere, using their computers or mobile devices. Technological advancements include high-speed internet connections, learning management systems, video conferencing software, and mobile applications. These tools have made it possible for educators to create engaging and interactive online courses that can be accessed by students all around the world. Furthermore, students can learn at their own pace, review materials as often as they need to, and access course materials anytime, anywhere. Additionally, online learning can be less expensive than traditional classroom-based learning since it eliminates the

need for travel and other associated expenses. In the age of technological advancement and transformation in the field of education, and for the considerations mentioned above, the significance of improving the security environments for e-learning systems is growing daily.

Now-a-days, many universities have turned to electronic learning as an efficient solution for providing on-demand learning to their instructors and students. Therefore, and because e-learning primarily depends on Internet technology to achieve its function, information security and cybersecurity become hot topics in the e-learning environment to avoid vulnerabilities and security weaknesses regarding user privacy and content protection [1]. As a result, cybersecurity becomes a key concern when dealing with user privacy, authentication, and confidentiality [7][24][25]. Thus, there is an increasing and significant need for the adoption of strong security countermeasures to protect users' information against any malicious attack. The rest of this study is organized as follows: the next section introduces a background about the e-learning platforms and their impact on security. Section III discusses the related works, the study objectives, and hypothesis is presented in Section IV, Section V states the results and finally, the conclusion is drawn in Section VI.

II. BACKGROUND

Security in e-learning refers to the protection of the system and data from unauthorized access, alteration, or destruction. Cybersecurity, on the other hand, refers to the protection of digital systems, networks, and data from cyber threats such as hacking, malware, phishing, and ransomware attacks. In the context of e-learning, cybersecurity involves protecting e-learning platforms from such attacks, ensuring the integrity of the data, and minimizing the risk of data breaches.

A. e-Learning Platform Architecture

The architecture of an e-learning platform is designed to provide a seamless user experience while ensuring that all data is stored securely and managed efficiently. It typically includes several key components that are integrated to deliver content and services to users. The main components of an e-learning architecture are [2][3]:

1) **User Interface:** Front-end component that users interact with to navigate the platform, access courses, and manage their profiles.

2) **Application Server:** The middleware layer that connects the user interface with the e-learning platform's back-end. It receives requests from the user interface, processes them, and sends back responses.

3) **Database:** The back-end component provides a centralized storage location that stores all data related to courses, users, progress tracking, and other information.

4) **Content Management System:** The component that manages course content, including the creation, editing, and delivery of course materials.

5) **Learning Management System:** The component that manages the delivery of courses and tracks user progress. It provides features such as course enrollment, tracking, and reporting.

6) **Authentication and Authorization:** Manages user authentication and authorization to ensure that only allowed users can access the e-learning system.

7) **Security:** Responsible for ensuring the e-learning is secure from external threats, including attacks on user data and platform infrastructure.

B. Moodle e-Learning System

Moodle is a popular open-source e-learning platform used by many educational institutions and organizations around the world. Irbid National University (INU) as a case study in this research uses the Moodle e-learning system. The Moodle database schema includes a set of tables and relationships that define how data is stored and organized within the system. Some of the key tables in the Moodle database schema include, for example, the Users table, which stores information about each user in the system, including their first and last name, username, password, email address, and role. The courses table stores information about each course in the system, including its name, description, start and end dates, and visibility settings. Grades: This table stores information about the grades earned by each user in each course. It includes fields for the user ID, course ID, module ID, and grade value. Tables in the database schema are linked together through a series of relationships that define how data is accessed and manipulated within the system. Moodle supports the use of a distributed database architecture, where the database layer is designed to be abstracted from the rest of the system, which means that it can be replaced with different database solutions depending on the needs of the installation. With the distributed database, the data is distributed across multiple nodes, providing greater scalability and fault tolerance than a single database instance [4]. Moreover, it can improve security by replicating data across multiple servers or nodes, making it more difficult for hackers to access or manipulate the data.

C. Security Challenges on e-Learning Arising from the COVID-19 Pandemic

Since the educational process is based primarily or fully on online platforms, the risks presented by e-learning cybersecurity attacks significantly increased during the

coronavirus epidemic. Electronic educational tools' reliability and accessibility are now essential, as teaching is impossible without them [5]. Recently, important steps have been taken to create an appropriate legislative framework to ensure an acceptable level of cybersecurity is obtained in Jordan. Jordan is globally ranked 73 on the Global Security Index. They established a National Center for Cybersecurity to strengthen the policies and procedures [6]. The education infrastructure comprises universities, colleges, schools, libraries, teachers, and students. Education infrastructure is more critical when compared to other systems because, for example, universities are designed as open spaces for research and information, making them vulnerable to cyber-attacks even by using simple methods like email attachments [3][13]. So, new cybersecurity measures for educational institutions are necessary. An approach to managing educational resources must take into account the current global environment by adopting new strategies that give digital educational resources far greater consideration [5].

D. Security Issues in e-Learning

e-Learning faces several security issues that organizations and individuals need to be aware of. Some of these issues are:

1) **Data privacy:** One of the biggest concerns in e-learning is data privacy [7][8][24][25]. e-Learning platforms store a vast amount of sensitive information, including personal information such as names, addresses, and email addresses, as well as sensitive information such as course progress and assessment results [9].

2) **Cybersecurity:** e-Learning platforms are susceptible to cybersecurity threats, such as hacking, phishing, and malware attacks [10][26][27]. Hackers may target e-learning platforms to gain access to sensitive data or disrupt the system.

3) **Identity theft:** Identity theft is a severe security issue in e-learning. Hackers may steal personal information to impersonate a user and gain access to e-learning platforms [11].

4) **Intellectual property:** e-Learning platforms contain valuable intellectual property, including course materials, videos, and assessments [12].

Therefore, e-learning platforms must implement robust security measures to protect sensitive data and intellectual property from cybersecurity threats. Organizations and individuals must also be aware of these security issues and take appropriate precautions to safeguard their information [14]. This research aims to evaluate the degree to which students are satisfied with e-learning security and privacy as well as to examine whether these issues have an impact on the overall quality of education. Measuring the effect of e-learning security on the academic environment is a complex task because other factors can affect it, such as the technology used, how students trust learning as online than others, and the student's background on security challenges and cyberspace.

In conclusion, this research focuses on responding to the following study questions:

- What are the students' attitudes toward e-learning security?

- Does e-learning security affect the quality of education?
- Does the security of the e-learning system influence the students' achievements?
- Do the students trust e-learning content?

III. RELATED WORKS

In recent years, there has been an increasing amount of research regarding online learning education. Several studies have begun to examine e-learning regarding design and efficiency. Other earlier studies have concentrated on how the e-learning environment affects student achievement [15][16], while others have discussed and analyzed the performance of those systems. The need for secure online learning environments has given rise to many studies that aim to address the growing significance of the security and sensitivity of an e-learning system's contents. Habib et al. [1] discuss cybersecurity issues related to the e-learning management system, the significance of e-learning, and the database management system also presented, along with the methods that lessen them. Their paper has provided some remedies for obtaining data integrity and recommends that government agencies provide more financial funding to improve the quality of the e-learning system. A survey of the current protections of e-learning systems based on the source of vulnerabilities is presented by Satria et al. [17] They categorize the open-source learning systems as vulnerable points because these systems have suffered many attacks due to security problems. Emad and Mustafa [18] discuss DB integrity and data confidentiality using access control policies and data encryption as two of the main pillars in building information systems.

As e-learning systems are increasingly used by universities due to the low costs associated with education, Ioan et al. [19] presented the security issues related to these platforms. Such issues can be used by cybercriminals for phishing and spamming activities. They suggest law authority enforcement cooperate with academia and private sectors fight to these threats. Anghel and Pereteanu [20] illustrated different approaches that manage the cyber security issues related to e-learning systems. They also showed some practice examples concerning cyber security management techniques and suggested implementing security policies and procedures accepted by individuals to overcome those security threats. The effectiveness of e-learning as well as the potential security issues are discussed by Nguyen et al. [21]. Suggested countermeasures to deal with the security attacks are also outlined. The main recommended countermeasure to make the users feel secure was cryptography.

By reviewing previous studies related to the subject of this research, the researchers focus on the security issues that threaten e-learning systems and suggest effective solutions to mitigate the security attack on the contents of those systems [22]. This research will investigate the security of a database server, which contains the user information and the cyberspace through which this information travels.

IV. STUDY OBJECTIVES AND HYPOTHESIS

The study of security in e-learning should equip students with the necessary knowledge and skills to protect themselves and their data, while also promoting the responsible and ethical use of e-learning systems. Important aspects of security and cybersecurity in e-learning systems include:

- Understanding the potential security threats, where students should be able to identify the various types of security threats that can affect e-learning systems, such as hacking, phishing, and malware attacks.
- Knowledge of security measures: Students should learn about the various security measures that can be implemented to protect e-learning systems, such as encryption, firewalls, and multi-factor authentication.
- Learning how to protect personal information: e-Learning students should be taught how to safeguard their personal information, such as usernames, passwords, and credit card details, from theft or misuse.
- Familiarity with data protection regulations: Students should be familiar with data protection laws and regulations that govern e-learning systems, such as the General Data Protection Regulation (GDPR).
- Awareness of ethical considerations: e-Learning students should be taught about ethical considerations regarding the use of e-learning systems, such as respecting the privacy of other students, not plagiarizing content, and using technology responsibly.
- Preparation for emergencies: Students should be taught how to respond to emergencies, such as a cyber-attack or a system failure, and how to protect themselves and their data in such situations.

To evaluate the current situation of the e-learning system as a case study, find the strengths and weaknesses points in the security structure of those systems, and propose suitable recommendations that would improve the services provided, this study aims to suggest and investigate the security measures that are needed to evaluate the satisfaction and acceptance of students towards e-learning services. The measurement process will be analyzed through the following hypothesis: The use of e-learning systems that prioritize security and privacy are more likely to be perceived positively by students and may result in higher levels of engagement, satisfaction, and academic achievement.

A. Methods and Procedures

Methods and procedures are standardized and systematic approaches used to solve problems or answer questions in a study field. They involve a step-by-step process that helps to ensure that the solution is accurate, reliable, and repeatable. The process typically involves the next steps and methods observed:

- Collecting the necessary information on the e-learning security measures and students' perceptions of them.

- Designing a questionnaire that addresses the study's objectives.
- Selecting the right sample of respondents.
- Analyzing the information gathered and concluding the findings.

B. The Population of the Study

As the population of a study refers to the group of individuals that the research is focused on, it must determine the generalizability and validity of the research findings. Since studying the whole population is costly and impractical, a sample is selected to observe and measure the study hypotheses. The population of this study consisted of undergraduate students enrolled in four faculties at the Irbid National University, Jordan. The students are chosen from the second year or higher because they are expected to have some experience using the e-learning system. Their age range is 19 to 23 years old. In this study, the margin of accepted error is assumed to be five, the confidence level needed is 95% and the response distribution is expected to be 80%. Based on the study's objectives, time availability, research budget, and degree of precision, the sample size is 200 students out of 1000 in the four colleges.

C. Sample of the Study

A small-scale survey was created based on the study objectives to measure how students trust the Moodle e-learning system's security and privacy. Two hundred (200) students were chosen at random to receive the questionnaire. One hundred eighty four (184) respondents correctly completed it. The demographic distribution of the students by field of study is shown in Table I.

TABLE I. TOTAL RESPONDENTS BY COLLEGE

Collage	Male	Female	Total Number	Percentage
Faculty of science and information technology	50	28	78	42.40
Faculty of Business Administration and Finance	27	24	51	27.71
Faculty of Nursing	9	19	28	15.22
Faculty of Law	16	11	27	14.67
Total	102	82	184	100

By monitoring the response rate which exceeds 90%, we hope that the sample accurately reflects the population interested in the study.

D. Questionnaire Items

An online survey was used to investigate students' opinions about the security and privacy of the e-learning system operated by Irbid National University. The online survey has been circulated via Facebook and WhatsApp groups. The survey includes 25 questions, distributed as follows: Questions 1–5 were used to collect general information (e.g., gender, year of study, familiarity with using internet resources). Questions 6–15 were used to collect information about students' attitudes toward the level of satisfaction with the current security measures used in the e-learning system. Finally, questions 16–25 were used to measure students' attitudes regarding the influence of the e-learning system with the current security and

privacy procedures on their achievements. To facilitate the measurement of the study's hypotheses, questions 6–25 are grouped into eleven categories, as shown in Table II.

E. Study Hypotheses

Ho: e-Learning platforms that are hosted on secure servers do not affect the levels of user trust and confidence.

Ha: e-Learning platforms that are hosted on secure servers will lead to higher levels of user trust and confidence.

V. RESULTS AND DISCUSSION

This study uses a 5-point Likert scale because it balances variation in responses and nuanced opinions while remaining simple and easy to use [23]. Meanwhile, respondents are less likely to become confused or overwhelmed when faced with a complex or lengthy survey. It also lessens the central tendency bias and makes the measurement process easier. Table II shows the percentage of the student responses for each group (strongly agree, agree, strongly disagree, disagree, and do not know). The "do not know" response is used for missing answers or a student's actual answer to some study questions.

As shown in Table II, 56% of students are satisfied with the current security level, which is considered a low indication regarding security and cybersecurity. This may be due to several reasons, including a lack of awareness, which can lead to confusion and frustration and may result in lower levels of satisfaction with the security level, or students may feel that their data is not being adequately protected. Another possible reason may regard some technical issues, such as slow load times or frequent errors, which may lead to dissatisfaction among students. To address these issues, educators and institutions need to prioritize student security and take steps to ensure that students are fully informed and aware of the security measures in place. This can include providing clear and concise instructions on how to use security features, regularly updating security measures, and being transparent about how student data is collected and used. Additionally, educators and institutions should regularly gather feedback from students and take steps to address any issues or concerns that arise.

Data in Table II indicates that there is a reluctance among students to use the system in the event of security attacks (88%), while their confidence increases when the system adopts strict countermeasures (69%). Furthermore, if students perceive the e-learning system as insecure, they may be more likely to seek out alternative ways of accessing course content and resources, such as through unsecured channels or external websites. This could increase the risk of data breaches and compromise the security of student data. Therefore, it is important for educators and institutions to take student concerns about e-learning system security seriously and to take steps to address them. This can include implementing additional security measures, such as two-factor authentication or data encryption, and providing clear and transparent information about how student data is collected, stored, and used. Educators and institutions can help to build trust and confidence among students in the security of e-learning systems. This, in turn, can lead to increased engagement and academic achievement, as students feel more comfortable and

secure in using the system to access course materials and interact with their peers and instructors. By adopting these measures, educators and institutions can demonstrate their commitment to student data privacy and security, fostering trust and confidence among students in the e-learning environment. As long as more than 90% of students expressed their desire to take intensive courses relating to cybersecurity and its latest developments. More than 86% of students, as shown in Table II, concur that improving the security of the Moodle e-learning platform will increase student achievement and engagement, which may either directly or indirectly improve their academic performance.

The use of personal devices in e-learning systems has become increasingly popular in recent years. With the proliferation of smartphones, tablets, and laptops, students now have access to a wide range of digital devices that can be used to support their learning. However, there are also some potential drawbacks to using these devices. One concern, as expressed by 64% of respondents, is that it can increase the risk of data breaches and cyber-attacks due to the potential for unsecured devices and networks. So, it is important for educators and institutions to carefully consider how to effectively integrate these devices into their teaching and learning strategies and to ensure that all students have equal access to learning resources and opportunities. Cloud-based storage allows data to be stored securely on remote servers

rather than on individual devices. This means that if a student's device is lost or stolen, their data remains safe and can be accessed from another device. Additionally, cloud-based storage can provide automatic backups of data, reducing the risk of data loss. 67% of students indicated this positively. Enhancing the security countermeasures in the e-learning system can potentially enhance student engagement and achievement. When students feel that their data is secure, they may be more likely to actively engage with the e-learning system and its resources, leading to increased achievement. By implementing the necessary security measures, students may feel more confident in using the Moodle e-learning system and its resources. This, in turn, can lead to increased engagement and achievement, as 86% of students state.

Social engineering is indeed an important aspect of e-learning security that should not be overlooked. 92% of students, report having encountered social engineering-related problems and affirm that intensive training boosts their confidence in the e-learning system and helps them protect their data. Protecting students from such issues requires a combination of technical and educational measures, including educating them about the tactics used by cybercriminals, such as phishing and pre-texting baiting. Providing two or more forms of authentication, including a strong password and a one-time code, makes it more difficult for cybercriminals to gain access to accounts.

TABLE II. RESULTS OF THE STUDY SURVEY

Response Option	Strongly Agree	Agree	Strongly Disagree	Disagree	Do not know
The current Moodle e-learning system is considered a secure and effective learning tool.	0.29	0.27	0.2	0.22	0.02
Students who report concerns about e-learning systems security may be less likely to use the system frequently which could lead to reduced engagement and academic achievement.	0.43	0.45	0.07	0.03	0.02
Students who perceive e-learning systems as secure may be more likely to use the system frequently and engage with it more effectively.	0.41	0.44	0.08	0.06	0.01
Students who are required to use strong security measures such as strong passwords or two-factor authentication may perceive the system as more secure and trustworthy.	0.33	0.36	0.11	0.14	0.06
Students who receive training on e-learning system security best practices may be more likely to engage with the system and use it effectively and may also report higher levels of trust and confidence.	0.47	0.44	0.02	0.04	0.03
Students who receive regular updates and communication about the e-learning system's security can help them feel more informed about the security measures, leading to more positive attitudes and trust.	0.41	0.43	0.03	0.07	0.06
Students who receive training on cyber security practices and awareness may be more likely to protect their personal data and privacy.	0.51	0.41	0.01	0.03	0.04
The use of personal devices in e-learning systems can increase the risk of data breaches and cyber-attacks due to the potential for unsecured devices and networks.	0.31	0.33	0.16	0.19	0.01
e-Learning systems that use cloud-based storage and security measures can help protect student data and privacy when using personal devices and networks.	0.34	0.33	0.15	0.1	0.08
Enhancing the security countermeasures in the Moodle e-learning system will enhance the student's engagement and achievement.	0.42	0.44	0.03	0.05	0.06
Providing training to students on how to recognize and avoid phishing or fraudulent emails and other forms of cybercrime is an important step in promoting digital safety and security. It can help to develop better digital literacy skills and create a safer online environment for all users.	0.49	0.45	0.01	0.03	0.02

A. Statistical Analysis

The data collected is analyzed using descriptive statistics to summarize their frequency and distribution. The study sample and variables were described using frequencies and standard deviations. To ascertain whether there were any statistically significant differences between the study group means, the one-way analysis of variance (ANOVA) was also utilized to prove the study hypothesis. All statistical analyses were performed using SPSS version 25.0. It specifically evaluates the null hypothesis, thus if there are at least two group means that are statistically significantly different from one another, the alternative hypothesis (Ha) will be accepted.

According to the statistical analysis shown in Table III, the "Strongly Agree" group has the highest mean (0.40), followed by the "Agree" group (0.39). Strongly disagree, disagree, and do not know with respective mean values of 0.07, 0.08, and 0.03. The research reveals that the 'Strongly Agree group' has the highest standard deviation (0.074), which is relatively small and indicates less dispersion than the means of the other groups. Because of this, there is a large statistical difference between the groups. A low standard error indicates that the data points in a sample are tightly clustered around the sample mean, suggesting that the sample accurately represents the population being studied and that the estimated value is closer to the true population parameter. An ANOVA test for the study variables at a 0.95 confidence interval is figured in Table IV. The value of P (9.03518E-23) is less than 0.05, which indicates that the probability of obtaining the observed test statistic under the null hypothesis is very low, and hence, the null hypothesis is unlikely to be true. Consequently, there is evidence to imply that there is a statistically significant difference between the means of the variables for at least one of the groups being compared. As a result, the alternative hypothesis (Ha) has been accepted and the null hypothesis (Ho) has been rejected. So, e-learning platforms that are hosted on secure servers will lead to higher levels of user trust and confidence.

TABLE III. DESCRIPTIVE STATISTICS OF THE STUDY VARIABLES

Groups	Count	Sum	Average	Variance	Std. Dev.	Std. Error
Strongly agree	11	4.41	0.400909	0.005529	0.0743	0.02241

VI. CONCLUSION AND FUTURE WORK

With the increasing popularity of e-learning, there has been a corresponding rise in security and cybersecurity concerns. This is because e-learning platforms and tools store and transmit sensitive information, such as personal identification details, financial information, and intellectual property. Therefore, e-learning platforms are also vulnerable to cyber threats due to the large amounts of data they handle, the use of multiple devices and networks, and the diversity of users.

This research aims at exploring whether e-learning security and privacy concerns have an effect on the overall standard of education and can provide valuable insights into the relationship between cybersecurity and educational outcomes. The effectiveness of the security framework on students' academic achievement and their satisfaction with the security countermeasures in an e-learning system are both evaluated using a sample study that is presented. Statistical analysis finding suggests that implementing security and cybersecurity countermeasures can positively impact students' engagement with a system. Encouraging feedback and communication from students about their e-learning experience can be an effective way to address any security issues or concerns and improve their engagement with the e-learning content. By actively seeking and listening to feedback, instructors, and administrators can identify potential areas of vulnerability in the system and take steps to improve security measures.

Abstract—The emerging Internet of Things (IoT) makes users and things closely related together, and the interactions between users and things generate massive context data, where the preference information in time, space, and textual content is embedded. Traditional recommendation methods (e.g., movie, music, and location recommendations) are based on static intrinsic context information, which lacks consideration regarding real-time content and spatiotemporal features, failing to adapt to the personalized recommendation in IoT. Therefore, to meet users' interests and needs in IoT, a novel effective and efficient recommendation method is urgently needed. The paper focuses on mining users' things of interest in IoT via leveraging multidimensional context embedding. Specifically, to address the challenge from massive context data embedding different user preference information, the paper employs Convolutional Neural Networks (CNN) to mine the intrinsic content information of things and learn their represent. To solve the real-time recommendation problem, the paper proposes a real-time multimodal model embedded into location, time, and some instant content information to track the features of users and things. Furthermore, the paper proposes a matrix factorization-based framework using the regularization method to fuse real-time context embedding and intrinsic information embedding. The experimental results demonstrate the proposed method tailored to IoT is adaptable and flexible, and able to capture user personalized preference effectively.

I. INTRODUCTION

The emerging Internet of Things (IoT) is promoting the growth of connected things (e.g., sensors, actuators, and mobile devices), which makes a large amount of data available from interactions between users and things. The data includes time, locations, textual contents, and interaction records. In addition, in IoT, some context data is changing over time to time, such as users' locations, and things' function availability (things in use or not in use), and in term of that one, the data could be divided into intrinsic context and instant context. Therefore, the data is characterized by massive, multidimensional, and variant. To accelerate proactively searching and promote convenient life from the massive and overloaded data, an intelligent and automated method capable of deeper understanding and mining the information is needed for personalized recommendations in IoT. The things

recommendations tailored to IoT should put more emphasis on users' and things' states under different scenarios and time besides historical interactive preferences. Hence, the things recommendation is more complex than the conventional recommender systems like movie recommendations [1-4], music recommendations [5-7], and other location recommendations [8-10].

In IoT, each user has its own unique behavior pattern, and the things of interest and interactive behaviors usually vary with time in a day, and these behaviors are regular and cyclical. To clearly observe users' real behaviors, the paper conducts an example for the spatiotemporal feature analysis on the real datasets from CASAS¹, which is a database collected from a smart home environment. Due to the space limitation, only three users' behavior records are shown on the locations and time. In Fig. 1, the three users interact with similar things except for their own locations, such as latitudes and longitudes. And Fig. 2 depicts the three users' action frequencies in the different time period are unique: user 1 usually interacts with things in the morning and afternoon, user 2 at noon, and user 3 in the early morning and evening. Consequently, the recommendation in IoT is personalized independence, context-dependence, real-time, and complexity. The following are the main challenges of achievement for things recommendations in IoT.

- *Mining and indicating things intrinsic content information.* When users decide to use a thing, they always make a primary assessment that the function of the thing meets interest or not. The descriptions of functional features are derived from the textual contents of things. Failure to mine and indicate the intrinsic content of things may result in some inaccurate recommendation results.
- *Highly dynamic.* In IoT, the locations and interests of users and the availability of things are dynamic, calling for the model capable of adapting to the changes in real-time and presenting the most timely recommendation results.
- *Data sparsity.* Compared with massive things in IoT, the things generating interactions with each user are limited, namely, the density of user-thing rating matrix

¹<http://ailab.wsu.edu/casas/datasets/>

is quite low. Therefore, under this circumstance, it is difficult to sharply explore what users may be interested in.

In light of the challenges above, the paper proposes a matrix factorization framework fusing multidimensional context embedding (McEMF), including time, intrinsic textual content, and instant location and status information to address the recommendations in IoT. Specifically, to represent and learn users' periodic behavior regularly, the paper develops a temporal-user-thing rating matrix to record interactions between users and things. Then the rating matrix is used to implement the users' preference model. To mine and indicate the things intrinsic content, the paper employs CNN to learn intrinsic content embedding, which could be used to measure the semantic relationships on the functions of things. And leveraging the semantic relationships, users' preferences could be further explored with CF. To embed instant information, the paper adopts a particle filtering-based tracking method to capture the latest states of users and things. The benefit of instant information embedding is that it could help the recommender system enhance the efficiency of real-time state awareness and solve the cold-start problem. Indeed, data sparsity is a critical problem for historical data based recommender systems, and the textual content, location information, and time information are fused into the model to effectively alleviate the problem of data sparsity.

To sum up, the main contributions of the proposed McEMF are as follows:

- McEMF is a personalized things recommendation method tailored to IoT. By taking multidimensional contexts into account, McEMF captures both intrinsic content and instant information, addressing time awareness.
- Intrinsic contents and instant information are fused with improved matrix factorization technique (MF). In particular, the paper develops a CNN-based method to concatenate textual content and real-time states of things, and the real-time locations of users can constantly updated in the model to estimate the geographical relationships between things and users.
- The paper implements experiments to validate and evaluate the performance of the proposed McEMF on a real-world IoT database. The experimental results demonstrate that McEMF outperforms state-of-the-art baseline methods in effectiveness and efficiency, and it achieves the capability of IoT recommendation in real-time.

The rest of the paper is organized as follows. The paper reviews the related researches on things recommendation and IoT-oriented things recommendation in Section II. The paper presents the proposed McEMF model and describes the technical details of each procedure in Section III. The paper gives the experimental settings and reports the evaluated results of performance in Section IV. The paper is concluded in Section V.

II. RELATED WORKS

A. Things Recommendation

At present, things recommendation is a hot academic issue, and it not only benefits the person but also the third-party business. The recommender could proactively recommend users some things that they may be interested in or need, and the third-party business could also obtain more potential preferences of users. Traditional recommendation systems employ two kinds of techniques in general. One is collaborative filtering (CF) technique, and the achievement of many popular recommendation methods is based on CF to learn user preference on things from user daily records. The CF techniques are divided into the memory-based CF and the model-CF. The works [11, 12] adopt the memory-based CF, namely, they use the data collected from user behavior records to compute the similarity of users or things, to recommend things of interest for users, called as user-based CF and item-based CF respectively. Besides, the studies [3, 4, 13-15] leverage the model-based CF (e.g., Matrix Factorization) in the recommendation system. They treat each thing as an item and conduct a user-item matrix to learn the user preference on things, and each user and thing in the matrix are indicated with a k -dimensional latent vector respectively. MF has become one of the most popular techniques in the personalized recommendation, due to its effectiveness and efficiency for large sparse user-item rating matrix. Focusing on solving the problem of data sparsity, [16, 17] employ singular value decomposition (SVD) for matrices, and [18-20] propose a non-negative MF to handle high-dimensional and sparse data collected from industrial applications. Meanwhile, probabilistic MF (PMF) [21] is proposed and shown good achievements. Different from previous works with the explicit

rating as feedback, [22,23] propose a second-order decomposing method to treat feedback records as implicit information. Another technique is content-based filtering, which works with the profiles of users or things in historical behavior records and recommends things in terms of the similarity from profiles. Study [10] presents a CF fusing the contents of users and things, and it recommends preference things according to the satisfaction of similar users for different things. [24, 25] expand the contents of things, associating some geographical information and social information with the contents, for recommendations. These methods alleviate the data sparsity problem to some extent. Recently, a few works integrate more context information, and they achieve better performance. Among them, some works [26-30] combine contexts with CF. e.g., [30] proposes a social spatio-temporal PMF framework, which exploits things similarity and user similarity via modeling the social space, geographical space and things category space, to achieve recommendations. The others [31-33] employ neural networks to fuse contexts, such as, [33] proposes a multisource fusion recommendation model, which jointly considers user preference, geographical information, and social information modeled by performing network representation. However, the methods above only consider some intrinsic information or historical records and ignore the important real-time or instant information that could play an important role for recommendations in IoT. For example, a chef cooks in a restaurant during the day and in the kitchen at home at night, and in this situation, people have different spatiotemporal characteristics that change over time to time, and obviously, traditional recommendation systems fail to it.

B. Things Recommendation in IoT

Time is a critical factor in modeling recommenders, as data is changing from time to time, and some works [27,29,32,34,35] have shown the importance of temporal features for the improvement of the efficiency of the recommenders. In IoT, the growth of data is exponential, and they have obvious temporal features. Therefore, when modeling user preference, temporal information is essential. Recently, there are few works on things recommendation systems in IoT. Research [36] proposes a Trinity method, and the method constructs three categories of graphs related things

from things usage records, namely, user-thing graph, time-thing graph, and location-thing graph, to mine possible user preference. The author in [37] presents a STUnion model, whose core work is two created graphs. One is the spatiotemporal graph that represents the relationships between users, things, time, and locations. Another is the social graph that indicates the social relationships of users. And the two graph relationships are used to model the user preferences on things with a linear combination. Recently, [38] proposes a time-aware smart thing recommendation model, which integrates user preferences and different social relationships between objects learned via graph embedding. And then, to capture more potential relationships between users and things, [39] models the influences of geographical, social, manufacturer, and economic factors on interactions and integrates them in the recommender system by deriving transition probabilities. These methods above take advantage of spatial information and temporal information in the recommenders. However, they are insufficient for real-time information. Compared with traditional web data, physical things and users are more dynamic in IoT, thus the recommendation model tailored to IoT should be able to adapt up-to-date information. Consequently, the paper focuses on achieving a real-time recommendation system in the paper, and proposes a things-recommendation method with multidimensional context embedding, which captures intrinsic information and instant information, to make more accurate recommendations.

III. MULTIDIMENSIONAL CONTEXT EMBEDDING FOR THINGS RECOMMENDATIONS

In this section, the paper develops a multidimensional context embedding framework fusing intrinsic information and instant information as Fig. 3 and gives the procedures in detail. The proposed framework employs the historical interactive records (data) between users and things to model user preference. Meanwhile, it captures the instant information on locations of users and states (availability) of things for fitting the historical user preference to make the most up-to-date recommendations. Specifically, the framework consists of four procedures: (1) problem definition and notations in the framework; (2) intrinsic information embedding model; (3) real-time information embedding model; (4) fused model.

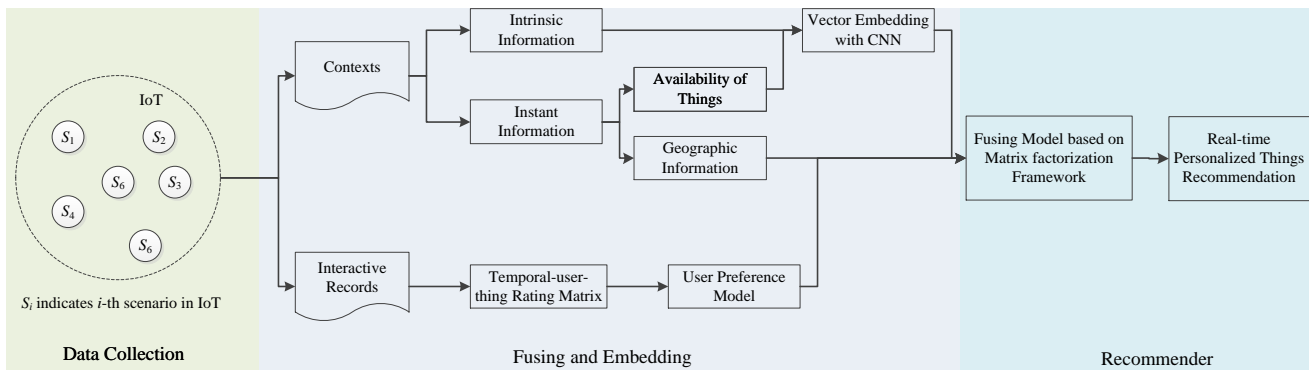

Fig. 3. Overview of the system framework.

A. Problem Definition and Notations

Formally, a thing’s interactive record is created when a person interacts with a particular thing. Let U be a set of users, $u_i \in U$, and T a set of things, $t_j \in T$, and the record is represented as a pairwise $r_{ij}=(u_i, t_j)$, which forms a matrix $r_{ij} \in R|U||T|$. Besides, for each record, some context information is considered, such as, temporal information that indicates when the interaction happens, and spatial information that indicates where the interaction happens, and the profiles of things that indicate the functions of things. Each record is a quadruple of User, Thing with a certain function, Timestamp, Location as the following definitions.

Definition 1 (Things Interactive Record) Let $U=\{u_1, u_2, \dots, u_m\}$, $T=\{t_1, t_2, \dots, t_n\}$, $L=\{l_1, l_2, \dots, l_p\}$, and $I=\{r_1, r_2, \dots, r_q\}$ represent the set of users, things, locations, and timestamps, respectively, where each t_j has a bag of keywords C_d indicating its function review. An interactive record of a thing t is denoted by $h \in H=\{h_1, h_2, \dots, h_j\}=\{<u, t, l, r> | u \in U \wedge t \in T \wedge l \in L \wedge r \in I\}$, indicating that user u uses thing t in the location l at timestamp r .

Definition 2 (Three-Level Time Granularity) According to our life experiences, users behave periodically in daily life. Specifically, people (users) may regularly stay at the workplace on weekdays and at the entertainment places or home on the weekends, namely, each user may have a different periodic behavior pattern on weekdays and weekends respectively. Let the temporal states $\Gamma =\{weekday, weekend\}$. Furthermore, one day is divided into 24 hours, thus $2*24=48$ temporal units I can be obtained, and $r \in I \in \Gamma$. The paper exploits the three types of time to learn the temporal features of interactions.

Definition 3 (Temporal-User-Thing Rating Matrix) In a record h , the timestamp r is cyclical, therefore, matrix $R|U||T|$ is extended to $R|U||T, I, l, ru, t, r \in R|U||T, I, l$. Note that due to location l with random and real-time, it is not suitable for merging into the matrix $R|U||T, I$ indicating the historical interaction records. Location l is a piece of instant information.

$R|U||T, I$ is a sparse matrix, and user historical preference is approximately expressed as $R_{|U||T, I} \approx p_u^T q_{t, r}$, where p_u and $q_{t, r}$ are the user latent k -dimensional vector and the thing latent k -dimensional vector at timestamp r , respectively. The

proposed framework is to predict the missing entities, and it will recommend the things with the bigger predicted ratings to given users. The major notations in the framework are summarized in Table I.

B. Intrinsic Information Embedding Model

When a user uses a specific thing, he/she mainly considers whether the functions of the thing can meet his/her needs or not. Therefore, the paper proposes an intrinsic information embedding model to represent the functional features of things as the low-dimensional vectors so that the model could learn the semantic relationships between things. The descriptions on things’ functions are captured from the textual content, and CNN is employed for intrinsic information embedding. More specifically, as Fig. 4 illustrates. Given a text with C_d , each word c_z in C_d will be represented by an n -dimensional vector leveraging a non-static word embedding function. Supposing that there are N words in C_d , an $N \times n$ embedding matrix of C_d could be constructed, represented as:

$$\prod(C_d) = \Phi(c_1) \oplus \Phi(c_2) \oplus \dots \oplus \Phi(c_N), \quad (1)$$

where $\prod(C_d)$ indicates the $N \times n$ embedding matrix of C_d , and $\Phi(c_z)$ is a word embedding function to map the c_z into an n -dimensional vector, and \oplus is the concatenation operator. The model inputs the word embedding into CNN, and uses convolution layers with filter windows of unigram, bigram and trigram, where the model applies a convolution operation to the inputs. Each convolution filter applies a filter f_j to a window of s words to generate a new feature z_j^k :

$$z_j^k = F(\prod(C_d) * f_j + b_j), \quad (2)$$

TABLE I. NOTATIONS IN THE FRAMEWORK

Notation	Description
U, T, L, I	user set, things set, location set, and timestamp set.
r, I, Γ	the timestamp, the temporal unit, and the temporal state, $r \in I \in \Gamma$.
$R_{ U T, I}$	temporal-user-thing rating matrix, $r_{u, t, r} \in R_{ U T, I}$.
$p_u, q_{t, r}$	user latent vector, thing latent vector at r .
k	the dimension of the latent vector.
$q_{t, r}^*$	the real-time thing latent vector.
$[y_{u, t, r}]$	the user preference matrix.
$[g(u, t, r)]$	the user-thing geographical relationship matrix.

Fig. 4. The representation learning model of the intrinsic information.

where F is the activation function, and inspiring by [40], in Eq. (2), Rectified Linear Units (ReLU) is used as the activation function. $*$ is the convolution operation, and b_j is a bias term. Furthermore, the model sorts the biggest value from each feature map in the max-pooling layer:

$$\mathcal{L}_h = \{\ell_1, \ell_2, \dots, \ell_{n_f}\}, h \in \{1,2,3\}, (3)$$

where ℓ_j denotes the feature corresponding to filter f_j , and there are n_f filters. For each ℓ_j :

$$\ell_j = \max\{z_j^1, z_j^2, \dots, z_j^{N-s+1}\}. (4)$$

Afterward, the max-pooling layer \mathcal{L}_1 , \mathcal{L}_2 , and \mathcal{L}_3 are concatenated:

$$\mathcal{L} = \mathcal{L}_1 \oplus \mathcal{L}_2 \oplus \mathcal{L}_3. (5)$$

The model feeds \mathcal{L} obtained by max-pooling into the fully connected layer to integrate the intrinsic information embedding vector of the functional features of the thing t $q_t^{intrinsic}$:

$$q_t^{intrinsic} = F(W_{intrinsic} \times \mathcal{L} + B_{intrinsic}), (6)$$

where $W_{intrinsic}$ is the weight corresponding to \mathcal{L} , and $B_{intrinsic}$ denotes a bias term. $W_{intrinsic}$, $B_{intrinsic}$, and other parameters in the model are trained together with McEMF via backpropagation. $q_t^{intrinsic}$ is a high-level feature vector combining non-linearly $n_{intrinsic}$ feature vectors of the thing's functions.

C. Real-time Information Embedding Model

$p_u^T q_{t,r}$ could capture user preference things only based on the past interactive records and could not make use of some instant information to meet user real-time needs. To tackle the issue, the paper proposes an instant information embedding model for recommender in IoT. There are two main kinds of instant information in IoT, namely, two subproblems that need to be solved. One is the thing's availability, which indicates a thing in use or not in use at timestamp r , and that is because a thing could not be used by multiple users at the same time in general (e.g., Automatic Teller Machine, ATM). To address the subproblem, the paper firstly employs a particle filtering [41] to track the latest things' availability and continuously refine the functions of things, obtaining the instant information embedding vector of the thing t $q_t^{instant}$ with $n_{instant}$ -dimensional features. Then $q_t^{intrinsic}$ and $q_t^{instant}$ are fused into a new $(n_{intrinsic} + n_{instant})$ -dimensional vector $V_{t,r}$:

$$V_{t,r} = q_t^{intrinsic} \oplus q_t^{instant}. (7)$$

$V_{t,r}$ is input into the fully connected layer to synthesize a high-level feature vector $q_{t,r}^*$:

$$q_{t,r}^* = F(W \times V_{t,r} + B), (8)$$

where W is the weight corresponding to $V_{t,r}$ inside layer, and B denotes a bias term and $q_{t,r}^*$ is a high-level vector including the intrinsic functional features and instant functional features, indicating the real-time features of thing t at timestamp r .

Another one is the users' locations, which are used to measure the geographical relationships between users and things, and according to Tobler's First Law of Geography [42]: "near things are more related than distant things". Thus, users intuitively tend to use nearby things. To address this subproblem, the users' locations l_p at timestamp r is tracked and the geographical relationships between users and things geo-tagged l'_j are computed as follows:

$$D_r(u, t, r) = \begin{cases} 1 & , l_p \text{ and } l'_j \text{ in same region at } r \\ 1 + \frac{d(l_p, l'_j) + d(c(u), c(t))}{2 \times \min} & , \text{otherwise} \end{cases} (9)$$

where the paper partitions the regions based on the things' coordinates (longitudes and latitudes). Each region has a region center, and when both user u and thing t are in the same region, they have the same region center, assuming the geographical relationship as 1. Otherwise, the paper computes the geographical relationship by leveraging two types of distances. $d(l_p, l'_j)$ is the distance between user u and thing t , and $d(c(u), c(t))$ corresponds to the distance between the region centers of user u and thing t , and \min indicates the minimum distance between different region centers. Furthermore, the geographical influences $g(u, t, r)$ is as $g(u, t, r) \propto \frac{1}{D_r(u, t, r)}$. Therefore, the user real-time interactive preference $y_{u,t,r}$ is given as:

$$y_{u,t,r} = p_u^T q_{t,r} \cdot g(u, t, r). (10)$$

D. Fused Model

In this section, the paper proposes a comprehensive framework based on MF with regularization (McEMF). The user real-time interactive preference $y_{u,t,r}$ is used to be close to the historical interaction rating $r_{u,t,r}$ for the user preference model. Moreover, the paper employs the Frobenius norm to fuse $q_{t,r}^*$ into the framework for the influence of the functional features of things, and adopts the regularizations to avoid over-fitting. Specifically, the objective function is as follows:

$$\mathcal{G} = \frac{1}{2} \sum_{u \in U, t \in T, r \in I} (r_{u,t,r} - y_{u,t,r})^2 + \frac{\lambda_q}{2} \sum_{t \in T} \sum_{r \in I} \sum_{l \in I} \|q_{t,r} - q_{t,r}^*\|^2 + \frac{\lambda_p}{2} \sum_{u \in U} \|p_u\|^2 + \frac{\lambda_v}{2} \sum_{t \in T} \sum_{r \in I} \sum_{l \in I} \|q_{t,r}\|^2, (11)$$

where λ_q is a trade-off parameter, which balances the importance between the user preference model and the real-time functional features of things. When λ_q is equal to zero, the objective function ignores the influence of the functional features, and a bigger λ_q means that $q_{t,r}^*$ is closer to $q_{t,r}$. λ_p and λ_v are the regularization coefficients. When λ_p and λ_v are limited to zero, the objective function tends to over-fit the training dataset, and when λ_p and λ_v approach to infinite, it tends to under-fitting. For the framework optimization, the paper uses gradient descent in u and t to find a minimum of

the objective function as follows:

$$u \leftarrow u - \delta \cdot \frac{\partial G}{\partial u} \quad (12)$$

and

$$t \leftarrow t - \delta \cdot \frac{\partial G}{\partial t}, \quad (13)$$

where δ is the learning rate. After optimizing the framework, the user personalized preferences on things in real-time could be found by computing the rating given the interactive records, intrinsic information embedding, and instant information embedding. Then a recommendation list is constructed via sorting the rating for each user at a specific time period.

Time complexity analysis: The time complexity analysis of the framework is divided into three parts. The first one is the time for updating the user and thing latent vectors, which takes $O(k2|R|+k3(|U|+|T|))$. The second one is the time for updating a CNN embedding things' information, and the complexity is $O(nf \times N \times n \times |T|)$. The third one is the time complexity for updating a fully connected layer, which takes $O(|W| \times |T|)$. Therefore, the total time complexity is $O(k2|R|+k3(|U|+|T|)+nf \times N \times n \times |T|+|W| \times |T|)$ for per given data.

IV. EXPERIMENTS

A. Experimental Setup

1) *Dataset:* The paper leverages CASAS datasets, which are augmented with the dataset as in [36, 37] collected from a smart home environment for a period of four months. The environment contains six diverse categories: entertainment, office, cooking, transportation, medical, and house appliances. And the users with less than 10-time records and things that are used less than five times are eliminated to reduce abnormal data. To the end, these datasets contain 1020 users, 855 things, and 108650 interactive records, illustrated in Table II. The paper separates the data into 8:2 ratio as training data and testing data, respectively. Then, some abnormal data filtered out is selected to validate the proposed model on the cold-start problem.

TABLE II. STATISTICS OF THE DATASET

Dataset	Users	Things	Categories	Records	Density
CASAS	228635	10256	6	1586507	6.8×10^{-4}

2) *Evaluation metrics:* As the proposed model generates a recommendation list for each user in real-time, the users will receive different recommendation results at different time period. The recommendation list is denoted as $\mathcal{Y}_i = \{\psi_i^1, \psi_i^2, \dots, \psi_i^K\}$, where ψ_i^j is the j -th recommended thing in terms of the rating and $i = (u, r)$. Therefore, the paper evaluates the proposed model via leveraging two ranking-based metrics: Recall@K and mean reciprocal rank (MRR).

Recall@K means the proportion of the things related to the ground-truth things in the top-K recommendation results. The Recall@K is defined as:

$$\text{Recall@K} = \frac{1}{|S_{test}|} \sum_{i=1}^{|S_{test}|} \frac{|\mathcal{R}_i \cap \mathcal{Y}_i|}{|\mathcal{R}_i|}, \quad (14)$$

where \mathcal{R}_i is the ground-truth things, and S_{test} represents the testing dataset, $\mathcal{R}_i \in S_{test}$.

MRR is a metric for ranking position. It refers to that in the recommendation list, the more things related to the ground-truth things are ranked in the front, the better the recommendation results are. MRR is defined as:

$$\text{MRR} = \frac{1}{|S_{test}|} \sum_{i=1}^{|S_{test}|} \frac{1}{\text{rank } i}, \quad (15)$$

where $\text{rank } i$ means the ranking position of the relevant thing in \mathcal{Y}_i found together from \mathcal{R}_i and \mathcal{Y}_i for the first time.

3) *Baseline methods:* To evaluate the performance of the proposed model, the paper selects the following classical and state-of-the-art methods as the baseline methods:

MF: A classical and popular collaborative filtering method for things of interest recommendation.

STUnion [37]: The method uses the context information to create a spatiotemporal graph and a social graph, which are linearly combined to model the user preference things.

KGE[39]: The method proposes to fuse various things social relationships via graph embedding for enhancing user preference predictions.

SORec[40]: The method proposes to represent richer relationships between users and things by contexts and integrate them in the recommender system.

McEMF: The proposed method.

4) *Parameter settings:* In McEMF, there are four set parameters, including $\lambda_q, \lambda_p, \lambda_v$, and δ . The paper uses the grid search method to adjust the parameters and finally sets $\lambda_q = 1$, regularization coefficients $\lambda_p = \lambda_v = 0.1$, and $\delta = 0.01$. In other compared baseline methods, the paper tries the best to ensure that their parameters are consistent with the original papers.

B. Discussion of Baselines

To further elaborate on the contributions and innovations of McEMF, the paper shows the difference between baselines as Table III illustrated. MF is a classical and popular collaborative filtering method without fusing any contexts, and it could only depend on the historical interactions to learn user preferences, which fails to overcome the data sparsity and meet users' real-time demand. The others, such as STUnion, KGE, and SORec, consider intrinsic context factors like spatiotemporal and social information etc, however, they ignore the instant information that can indicate users' real-time demands and fail to achieve the best things recommendation under different scenarios and time. The specific performance evaluation is given in the next section.

C. Experimental Results

Firstly, the paper evaluates the performance of all methods with top-5 recommendation things in different dimensions, $k=\{5, 10, 20, 40\}$. The results are shown in Table IV. McEMF

outperforms all other baselines on both Recall@5 and MRR. Specifically, the popular STUnion, KGE, SORec, and the proposed McEMF are superior to the classical MF. Besides, McEMF achieves 51.12% improvement over MF. When k is smaller, the performance of STUnion, KGE, SORec, and McEMF is closer, however, when k is bigger and $k=20$, the other baselines are inferior to McEMF, obviously. The reason is that McEMF naturally integrates more real-time information into the recommender system, such as the real-time geographical relationships and the real-time availability of things, which play an important role in things of interest recommendation in IoT. There is little difference between KGE and SORec, because both of them fuse multiple intrinsic context information. It can observe that McEMF achieves the best performance when $k=20$, hence let $k=20$ in the next experiments.

Then, the paper evaluates the performance of all methods with top- K recommendation things in the dimension $k=20$. The results are illustrated in Table V. From the results, it can observe that the longer recommendation lists recommenders give, the higher recall recommenders can achieve. McEMF achieves better performance compared with the other baselines on MRR and Recall with different K . Moreover, when $K=1$, McEMF achieves 29.20% improvements over SORec respectively, which implies McEMF could give the best recommendation result in real-time. With the increase of K , the changing rates of Recall and MRR are slowing down. The reason may be that there is little difference in user preferences for things at the end of the lists when the recommended lists reach a certain length.

Furthermore, the paper evaluates the performance of the proposed McEMF for the cold-start problem. The paper adopts the eliminated data, where the number of the interactive records of a user is $n=\{1, 3, 5\}$. The results are shown in following Table VI. Obviously, for the cold-start problem, McEMF has outstanding advantages compared with other baselines, which benefits from real-time information embedding. In particular, when $n=1$, McEMF achieves 32.79% improvement over SORec, respectively. MF that ignores the context information is the worst among all methods.

TABLE III. THE DIFFERENCE BETWEEN BASELINES

Methods	Intrinsic context			Instant context	
	Social	Spatiotemporal	Content	Users' states	Things' states
MF					
STUnion	√	√			
KGE	√	√			
SORec	√	√	√

Next, the paper examines the sensitivity of McEMF to parameters λ_q , λ_p , and λ_v . The paper conducts three sets of experiments. Fig. 5 shows that the performance is changing with λ_q when fixing $\lambda_p = \lambda_v = 0.1$. It can observe that the performance is sensitive to λ_q . At first, Recall@5 and MRR are increasing with λ_q and then decreasing after $\lambda_q = 1$. Therefore, it is believed that $\lambda_q = 1$ is the optimal setting. When λ_q is smaller, McEMF will degenerate into the classical MF as expected. Fig. 6 shows that the performance is changing with λ_p when fixing $\lambda_q = 1$ and $\lambda_v = 0.1$. It can observe that both Recall@5 and MRR achieve the best performance somewhere near $\lambda_p = 0.1$. Fig. 7 illustrates that the performance is changing with λ_v when fixing $\lambda_q = 1$ and $\lambda_p = 0.1$. It can observe that both Recall@5 and MRR achieve the best performance somewhere near $\lambda_v = 0.1$.

To evaluate the impact of the instant contextual embedding and the intrinsic information embedding to the proposed McEMF, the paper excludes the intrinsic information embedding from the model, denoted as McEMF/intrinsic, the instant contextual embedding from the model, denoted as McEMF/instant, and both the instant contextual embedding and the intrinsic information embedding from the model, denoted as McEMF/instant_intrinsic, respectively. The comparison results are shown in Fig. 8. McEMF outperforms McEMF/intrinsic, McEMF/instant, and McEMF/instant_intrinsic, which indicates both the instant contextual embedding and the intrinsic information embedding effectively promote the recommendation effects. Furthermore, McEMF/intrinsic is superior to McEMF/instant, which implies that the real-time information play a more important role than the intrinsic information in IoT scenarios.

Fig. 6. Recall@5 and MRR for different λ_p .

Fig. 7. Recall@5 and MRR for different λ_v .

Fig. 8. The comparison of the impacts of the instant contextual embedding and the intrinsic information embedding to McEMF.

The paper uses the traditional Control Variate Technique to adjust the hyper-parameters of CNN in McEMF, as shown in Table VII. As it can see, the optimal combination of the parameters is Cross features + Hidden layers (512-256-128-64-1, ReLUs, Normal initializer, Dropout). From the results, the following conclusions can be inferred. (1) The number of neural units and hidden layers are not the most crucial factors for recommendation performance, and less hidden layers could avoid over-fitting. (2) Both activation function and initializer play an important role, because a proper activation or initializer can adjust the data distribution fed in each layer well. (3) Dropout and L2 regular are widely used to avoid over-fitting, and in the experiments, Dropout has more advantages.

TABLE VII. THE HYPER-PARAMETERS ADJUSTMENT OF CNN IN MCEMF

V. CONCLUSION

The user-thing interactions in real IoT scenarios are dynamic and sparse, which is a challenge for things of interest recommendations. To solve the challenge, the paper proposes a recommendation model with multi-dimensional context embedding, which learns the user preferences in real-time by fusing the instant information and the intrinsic information into the matrix factorization framework. In the proposed model, the paper employs CNN to model the functional

features of things. As conventional rating matrices fail to represent the temporal features, the paper proposes a temporal-user-thing rating matrix, which is used to model user preference via integrating the instant geographical information. The paper evaluates the performance of the proposed model through experiments on real-world IoT datasets. The paper compares the model with other state-of-the-art methods on three sets of experiments, as Table III, Table IV, and Table V. The results demonstrate that the effectiveness and efficiency of the proposed model.

Though the proposed model achieves an improvement for things recommendations in IoT, its performance is still limited by the interaction data sparsity. Therefore, the future work will focus on investigating a novel method against data sparsity.

Abstract—Aspect term extraction is a crucial subtask in aspect-based sentiment analysis that aims to discover the aspect terms presented in a text. In this paper, a method for ATE is proposed that employs dilated convolution layers to extract feature vectors in parallel, which are then concatenated for classification downstream. Reinforcement learning is used to save the ATE model from imbalance classification, in which the training procedure is posed as a sequential decision-making process. The samples are the states; the network, and the agent; and the agent gets a more significant reward/penalty for correct/incorrect classification of the minority class compared with the majority class. The training phase, which typically employs gradient-based approaches, including back-propagation for the learning process, is tackled. Thus, it suffers from some drawbacks, including sensitivity to initialization. A novel differential equation (DE) approach that uses a clustering-based mutation operator to initiate the BP process is presented. Here, a winning cluster is identified for the current DE population, and a new updating strategy is used to generate candidate solutions. The BERT model is employed as word embedding, which can be included in a downstream task and fine-tuned as a model, while BERT can capture various linguistic properties. The proposed method is evaluated on two English datasets (Restaurant and Laptop) and has achieved outstanding results, surpassing other deep models (Restaurant: Precision 85.44%, F1-score 87.35%; Laptop: Precision 80.88%, F1-score 80.78%).

Keywords—Aspect term extraction; sentiment analysis; differential evolution; reinforcement learning; BERT

I. INTRODUCTION

Sentiment analysis (SA) [1] is a challenging task in NLP that aims to extract overall sentiment from a single sentence or document. However, sentence-level SA doesn't reflect specific features or attributes that a user likes or dislikes. Aspect-based sentiment analysis (ABSA) provides a solution by specifying sentiment at a fine-granular level, giving sentiment to each phrase property. Aspect term extraction (ATE) is a component of ABSA that identifies every particular characteristic or aspect of the good or service being addressed. AT is a textual entity, a sequence of tokens within a sentence that must be referred to explicitly within the text. Such data is vital and frequently mandates an educated decision-making procedure [2].

From the literature, the ATE approaches can be categorized as lexicon-based methods [3], machine learning methods [4], and deep learning approaches [5]. Traditional ATE approaches mainly use feature engineering methods, including part-of-speech [6] and bag-of-words [7], to train machine learning classifiers, including SVM and Naïve Bayesian. Generally, traditional approaches have two shortcomings. First, they mainly do not utilize semantic information in keywords, rules, or features, forcing them not to regard relationships between sentences. Second, handmade rules and feature extraction are not flexible, resulting in inferior generalization ability [8]. DNNs have earned significant success in numerous industries since the introduction of neural networks in recent years [9-12]. ATE works have moved from feature engineering approaches to DNN approaches. Deep learning-based approaches for ATE typically hire RNN [13, 14], CNN [15-17], RecNN [18], and Memory Networks [19]. Besides the direct uses of various DNNs, the attention mechanism coupled with DNNs is increasingly popular. Other kinds of ATE approaches include embedding techniques and transfer learning. The BERT model [20, 21] is the language model, superior to other language models, which captured the benefit of the statement proposed in transformers [22], which is being applied extensively and utilized in NLP studies [23, 24]. Deep learning-based ATE approaches have shown promising results in identifying and extracting aspect terms from textual data. However, the performance of these models is greatly affected by the imbalance of the datasets. Imbalanced datasets are common in the ATE task, as the number of aspect terms in a sentence is typically small compared to the number of non-aspect terms. This can lead to biased models that are unable to capture the underlying distribution of the data. Another challenge faced by deep learning-based ATE approaches is the sensitivity to initialization during the training phase. The quality of the initial weights of a neural network greatly affects its ability to learn meaningful representations from the input data. Poor initialization can lead to suboptimal performance, and in some cases, the model may fail to converge.

Data imbalance is a significant challenge in ATE, as it can lead to a drop in performance. There are two methods to tackle class imbalance: algorithm-level and data-level [25]. The data-level approach involves under-sampling or over-sampling methods, or both, to counteract the negative impact of class

imbalance. SMOTE [26] and NearMiss [27] are examples of under-sampling and over-sampling methods, respectively. Algorithm-level approaches raise the weight of the minority class through decision threshold adjustment [28], ensemble learning [29], and cost-sensitive learning [30]. Deep-learning approaches have also been proposed to address imbalanced classification. Research has focused on understanding the discriminative characteristics of imbalanced data while maintaining inter-class and inter-cluster margins, and developing a method based on the bootstrapping algorithm that balances data in convolutional networks per mini-batch [31]. Deep reinforcement learning (DRL) has been used in various domains to improve classification performance by eliminating noisy data and discovering better features. However, there have been few studies that apply DRL to classify imbalanced data, despite its suitability for this task. DRL's learning approach, which employs a reward function that discriminates between classes by imposing penalties on minority classes or rewarding them with greater rewards, makes it particularly well-suited for imbalanced data classification.

In the field of neural network methods, gradient-based algorithms like back-propagation have traditionally been used to find the optimal weights [32]. However, these methods can be limited by issues like initialization of parameters and getting stuck in local optima [33, 34]. A potential solution to these problems is to use meta-heuristic algorithms like DE [9], which have been successfully adapted to various optimization problems. DE operates through three main steps: mutation, crossover, and selection, with the mutation operator being particularly significant. By utilizing DE to optimize the learning process, it may be possible to overcome the limitations of gradient-based algorithms and achieve better model performance.

This paper suggests a framework for ATE founded on BERT word embedding, a clustering-based DE algorithm, and a reinforcement learning-based training algorithm. The suggested ATE model contains three dilated convolution layers, aiming to extract rich features in parallel, then concatenated for final classification. The ATE model should classify every word in three classes $\{B, I, O\}$, where B, I show the beginning and non-beginning words of an aspect term, and O means non-aspect terms. Since the number of members in class O is more significant than those in the remaining classes (B and I), the classifier assigns the majority of members to class O , resulting in an unbalanced classification that dramatically reduces system efficiency. Reinforcement learning is used to solve this issue, and design ATE as a guessing game with sequential decision-making steps. At each stage, the agent uses a training instance to represent the environmental state and then, guided by a policy, performs a three-class classification operation. The classifier will accept a positive reward if the operation is completed; otherwise, it will get a negative reward. The minority class receives higher compensation than the majority class. During the sequential decision-making process, the agent's objective is to classify the samples as precisely as possible in order to collect the maximum number of cumulative rewards. An enhanced DE technique is presented based on clustering for weight initialization in order to identify a favorable region in the

search space from which to launch the BP algorithm in all networks. Here, the best candidate solution in the best cluster is chosen as the starting solution in the mutation operator, and a new updating technique is used to generate candidate solutions. The proposed technique is assessed using two English benchmark datasets (Restaurant + Laptop), the experimental findings of which show that the suggested model outperforms its competitors.

Following is a summary of the model's contributions:

- An ensemble of dilated convolutions is provided for the ATE model, enabling the model to extract valuable features from text to make a better decision for classification.
- The proposed model uses BERT word embedding to automatically learn and extract complicated and meaningful text representation from the input data.
- A reinforcement learning architecture is provided for the ATE problem in order to address imbalanced classification.
- As an alternative to random weight systems for model weights, an encoding method is created, and a starting value is computed using an enhanced DE algorithm.

The article's body has the following structure: In Section II, a review of the literature on ATE works is presented. In Section III, further depth into the suggested approach is delved. Section IV provides the experimental results and necessary analyses. Section V represents the conclusion of this article.

II. RELATED WORKS

To date, numerous domains have seen the proposal of a wide range of approaches for SA [35-37]. The majority of current tasks focus on detecting sentiments within single sentences or documents. Due to the limited availability of labeled datasets, supervised learning methods are commonly used, with few exceptions such as the unsupervised clustering method [38, 39]. Turney [40] suggested the utilization of an unsupervised learning method. To do this, the phrases containing adverbs or adjectives are initially evaluated for their semantic direction. Then, by examining the correlation between the average semantic orientation scores, the review can be classified as "recommended" or "not recommended." Pang and Lee [40] introduced a supervised machine learning technique to categorize the sentiment of movie reviews. They employed various linguistic features, such as part-of-speech tags, the presence of adjectives, unigrams, bigrams, etc., and trained them on machine learning classifiers such as Maximum Entropy and Naive Bayes. Pang et al. [35] proposed using a star rating system for movie reviews and argued that the labels derived from it were not independent. They suggested that the system should assign equal ratings to comparable reviews, and submitted a meta-algorithm that uses the connection among labels to improve the multi-class categorization outcome. Meanwhile, Kim and Hovy [41] used a probabilistic technique to identify a paragraph's comment and comment owner and employed the WordNet resource to determine word-level sentiments for sentiment categorization in a sentence. Lastly, Ganu et al. [42] conducted aspect category sentiment

categorization in restaurant reviews by identifying six primary restaurant categories and classifying the reviews into one of four sentiment categories. Moreover, they showed that the review's textual content is a superior signal to the other meta-information. Go et al. [43] adopted a sentiment classifier by comparing PoS tags and N-grams with emoticon data. However, their suggested model does not use the data provided by emoticons. They remove emoticons from the tweet, so if the testing data has an emoticon, it does not impact the classifier because there was no emoticon in the training data.

According to the literature, ABSA has recently garnered the interest of scholars worldwide. [44, 45]. In 2014, the first dataset, SemEval-2014 [46], was shared, addressed ABSA's challenges, and provided a particular benchmark configuration. For additional improvement of the issues, two more datasets, SemEval-2015 [47] and SemEval2016 [47], on ABSA were. These datasets introduced the ABSA problem in multiple fields, including laptops, restaurants, hotels, cameras, and languages such as Arabic, English, Chinese, and Dutch.

The task of ATE which is a crucial part of ABSA has captured the attention of many researchers. Liu et al. [48] presented a solution to the ATE problem through the application of RNNs in their research. They discovered that the LSTM-RNN technique was more effective than the Conditional Random Field with many features (CRF) method, which relied on a multitude of features. Majumder et al. [49] integrated positional-based account data from other ATs in their research to classify aspect terms. The aim was to enable the method to recognize the position of other parts-of-speech words and their associated sentiment-carrying phrases, thus avoiding being sidetracked by them. Their modifications led to better performance and introduced a new approach for the laptop and restaurant domains. Yin et al. [50] employed word embeddings in the dependency path to acquire word representations. Xu et al. [51] proposed the DE-CNN model, which incorporates a dual embedding mechanism consisting of domain-specific and general-purpose embeddings. Xu et al. [52] fine-tuned BERT [53] on a specialized dataset to obtain advanced word embeddings. Yin et al. [54] created a word

embedding approach that exploits positional dependence to take into account both positional setting and reliance correlations. They utilized assorted neural network architectures to capture diverse factors of the mission, such as illustrating the association between a unit and its appropriate sentiment term in a sequence identification system [55], and transfiguring the task into a Seq2Seq problem to grab the all-purpose objective of the entire sentence for identifying the part with more crucial contextual data [56]. Since annotating every component of an expression can be a time-intensive task, unsupervised ATE models have been widely advocated by analysts [57]. He et al. [58] put forward an autoencoder design for neural network-powered methods that diminishes insignificant terms to amplify the consistency of extracted features. By employing this approach, Luo et al. [59] coerced sememes to enhance lexical semantics during the creation of phrase representations. Tulkens and Cranenburgh [60] offered a solution named CAT, which uses a POS tagger and in-domain word representations to find component terms. The POS tagger discovers nouns as candidate features before using a contrastive attention technique to choose features. Shi et al. [61] formulated the ATE problem as a self-supervised contrastive learning task to discover feature representations that are more precise.

III. METHOD

A. Word Embedding

BERT [20] is a word embedding model often fine-tuned from a layer for various classification tasks and trained on huge datasets, like Wikipedia, to produce contextual word representations. Fine-tuning enables the use of the problem-specific meaning with a trained generic meaning and trains it for classification tasks. The general BERT architecture is shown in Fig. 1. In BERT, representations are jointly conditional on the left and proper context in all layers thanks to a bi-directional transformer. In contrast to Word2Vec and GloVe models, which create an embedding in one direction to disregard contextual differences, BERT produces an embedding in both directions.

Fig. 1. Structure of the BERT model.

B. Prediction

Fig. 2 depicts the structure of the suggested ATE model. The model receives a sentence $s = [w_1, w_2, \dots, w_n]$ as input, where w_i are the words, and n is the maximum number of words in a sentence and passes it to the BERT model. The output of the DistilBERT model is the embedding matrix $M = [e_1; e_2; \dots; e_n]$, where e_i is the embedding of the word w_i . Three dilated convolution layers are employed on the matrix M working in parallel. Each of the three branches independently extracts a feature vector from the sentence. After obtaining text features by convolution, the rich features are extracted by max pooling to simplify the network's computational complexity. Finally, the connection obtained from the Maxpooling layers enters the MLP network for classification. The output of MLP is a vector whose length is $3 \times n$, as every word w_i should be classified into three classes $\{B, I, O\}$, where B, I show the beginning and non-beginning words of an aspect phrase, and O shows non-aspect words.

As most words from a sentence are in class O than two other classes, the classifier faces the problem of imbalanced classification, which drastically decreases system performance. A sequential decision issue is created using the imbalanced classification Markov decision process (ICMDP) to solve this.

The neural network weights are initialized in Step 0 through pre-training with the enhanced DE algorithm. In Step 1, a sample (s_t) is randomly selected from the dataset, which is part of the RL environment. The network processes the sample in Step 2. In Step 3, the network's prediction (action a_t) is

returned to the environment to obtain the next sample (s_{t+1}) and its corresponding reward r_t in Step 4. The transition $\{s_t, a_t, r_t, s_{t+1}\}$ is then stored in the replay memory in Step 5. Multiple transitions are stored in the replay memory until a minibatch of transitions can be randomly drawn for updating the network weights in Step 7, after being drawn in Step 6. This process is repeated until the network is capable of correctly classifying the input sample. The algorithm stops when the number of episodes has been reached.

C. Pre-Training

At this stage, the weights of the proposed model are initialized. For this, an enhanced differential evolution method boosted by a clustering scheme and a novel fitness function is introduced.

a) *Clustering-based Differential Evolution*: The enhanced DE algorithm employs a clustering-based mutation and updating technique to improve the optimization performance.

The proposed mutation operator, which draws inspiration from [62], pinpoints a potential area in the search space. The k-means algorithm is used to partition the current population P into k clusters, each of which covers a distinct area of the search space. The number of clusters is chosen at random from the range $[2, \sqrt{N}]$. After clustering, the best cluster is identified as the lowest mean fitness of its samples. An illustration of this procedure for a toy problem with 19 potential solutions separated into three clusters is shown in Fig. 3.

Fig. 2. Overview of the proposed ATE model.

Fig. 3. Population clustering in search space to find the optimal region.

The proposed clustering-based mutation is defined as

$$\vec{v}_i^{clu} = \vec{win}_g + F(\vec{x}_{r_1} - \vec{x}_{r_2}) \quad (1)$$

where \vec{x}_{r_1} and \vec{x}_{r_2} are two randomly chosen candidate solutions from the current population, and \vec{win}_g is the best solution in the promising region. Note that \vec{win}_g is not necessarily the best solution for the population.

After generating M new solutions by clustering-based mutation, the current population is updated based on GPBA [63]; proceedings are as follows:

- 1) *Selection*: Create k individuals randomly to serve as the algorithm's initial seeds.
- 2) *Generation*: generate M solutions with clustering-based mutation as set v^{clu} .
- 3) *Replacement*: Select M solutions randomly from the existing population to comprise set B . Update: Select the top M solutions from $v^{clu} \cup B$ as set B' . The new population is found by $(P - B) \cup B'$.

b) *Encoding Strategy*: The primary structure of the proposed model includes three convolutional layers and a feed-forward network. As illustrated in Fig. 4, all weights and

bias terms are arranged into a vector to form a candidate solution in the proposed DE algorithm.

c) *Fitness Function*: To calculate the quality of a candidate solution, the fitness function is defined as

$$F = \frac{1}{\sum_{i=1}^N (y_i - y'_i)^2} \quad (2)$$

where N shows the number of training examples, y_i and y'_i are the i -th target and output predicted by the model, respectively.

D. Deep Q-Network Training

This article employs RL to tackle ATE. Each sentence in the training set represents a state of the environment, and the network serves as the agent that executes a series of classifications on all sentences. When the agent predicts the class label of a sentence, it takes action, where the sentence observed at the t^{th} time-step is the state s_t , and the classification performed is a_t . In return, the environment offers a reward, r_t , to guide the agent. The rewards are assigned such that classifying a sample from the majority class yields a lower absolute value than the minority class. The reward function can be expressed as:

Fig. 4. Encoding strategy in the proposed algorithm.

$$r_t(s_t, a_t, y_t) = \frac{1}{n} \times \sum_{i=1}^n r_{w_i} \quad (3)$$

where r_{w_i} is the reward received for classifying the word w_i , which is described as:

$$r_{w_i} = \begin{cases} +1, \hat{y}_{w_i} = y_{w_i} \text{ and } y_{w_i} \in \{D_B \cup D_I\} \\ -1, \hat{y}_{w_i} \neq y_{w_i} \text{ and } y_{w_i} \in \{D_B \cup D_I\} \\ \lambda, \hat{y}_{w_i} = y_{w_i} \text{ and } y_{w_i} \in D_O \\ -\lambda, \hat{y}_{w_i} \neq y_{w_i} \text{ and } y_{w_i} \in D_O \end{cases} \quad (4)$$

where D_B and D_I represent the larger class and D_O denotes the smaller class. Properly/improperly classifying a sample from the larger class results in a reward of $+1/-1$, where $0 < \lambda < 1$. In the deep Q-learning approach, the agent's aim is to choose actions that maximize the predicted future rewards. The future rewards are discounted by a factor of γ at each subsequent time step, where

$$R_t \sum_{t'=t}^T \gamma^{t'-t} r_{t'} \quad (5)$$

where T shows the last time-step of the episode. An episode ends when all the samples have been classified or the agent misclassifies a sample from the minority class. Q values, measures of state-action quality, are defined as the expected return of the following strategy π , after seeing state s and taking action a :

$$Q^\pi(s, a) = E[R_t | s_t = s, a_t = a, \pi] \quad (6)$$

The optimal action-value function equals the maximum expected reward overall strategies after seeing state s and taking action a :

$$Q^*(s, a) = \max_{\pi} E[R_t | s_t = s, a_t = a, \pi] \quad (7)$$

This function satisfies the Bellman equation, which asserts that the optimal expected return for a given action is equal to the sum of the rewards from the current action and the maximum expected return from future actions at the following time:

$$Q^*(s, a) = E[r + \gamma \max_{a'} Q^*(s', a') | s_t = s, a_t = a] \quad (8)$$

The Bellman equation is used as an iterative update to estimate the optimal action-value function:

$$Q_{i+1}(s, a) = E[r + \gamma \max_{a'} Q_i(s', a') | s_t = s, a_t = a] \quad (9)$$

During training, after a state s is shown to the network, the network outputs an action a for that state while the environment returns a reward r , and the next state becomes s' . These parameters are embodied in a tuple (s, a, r, s') that is saved into the replay memory, M . Minibatches B of these tuples are selected from the replay memory to perform gradient descent. The loss function is denoted as:

$$L_i(\theta_i) = \sum_{(s,a,r,s') \in B} (y - Q(s, a; \theta_i))^2 \quad (10)$$

where θ represents the model weights, and y , is the estimated target for the Q function. The latter is equal to the reward for the state-action combination plus the discounted maximum future Q value:

$$y r + \gamma \max_{a'} Q(s', a'; \theta_{k-1}) \quad (11)$$

Of note, the Q value for the terminal state equals zero. The gradient of the loss function at step i is calculated as:

$$\nabla_{\theta_i} L(\theta_i) = -2 \sum_{(s,a,r,s') \in B} (y - Q(s, a; \theta_i)) \nabla_{\theta_i} Q(s, a; \theta_i) \quad (12)$$

By performing a gradient descent step on the loss function, the model weights will be updated so as to minimize the error:

$$\theta_{i+1} = \theta_i + \alpha \nabla_{\theta_i} Q(s, a; \theta_i) \quad (13)$$

where α represents the learning rate of the network.

IV. EMPIRICAL EVALUATION

The SemEval-2014 English dataset is employed to analyze the proposed method [46]. The SemEval-2014 dataset is a collection of text data designed for the task of sentiment analysis and opinion mining. This dataset was part of the 8th International Workshop on Semantic Evaluation (SemEval-2014), a shared task initiative that aimed to promote research and development in natural language processing and computational linguistics. The SemEval-2014 dataset contains various subtasks, including aspect-based sentiment analysis, sentiment classification, and sentiment polarity detection. The dataset is composed of two parts, the first of which is the Laptop dataset. This dataset contains a total of 2,186 laptop reviews, each labeled with the corresponding aspect terms, aspect categories, and sentiment polarity. The aspect terms are the specific aspects of the laptop that the reviewer is commenting on, such as keyboard, battery life, or screen. The aspect categories are the broader categories that these aspects fall under, such as design features, performance, or usability. The sentiment polarity is the overall sentiment expressed by the reviewer towards the aspect, which can be positive, negative, or neutral. The second part of the SemEval-2014 dataset is the Restaurant dataset. This dataset contains a total of 3,851 restaurant reviews, each labeled with the corresponding aspect terms, aspect categories, and sentiment polarity. Similar to the Laptop dataset, the aspect terms represent specific aspects of the restaurant that the reviewer is commenting on, such as service, food quality, or atmosphere. The aspect categories are the broader categories that these aspects fall under, such as food, service, or ambience. The sentiment polarity is the overall sentiment expressed by the reviewer towards the aspect, which can be positive, negative, or neutral.

In the first experiment, ten deep learning-based approaches are compared to the algorithm, namely Baseline, System [64], DLIREC [65], IHS_RD [66], PSO-EN [67], MTNA [68], RNCRF [55], CMLA [69], E2E [2].

Table I displays the quantitative outcomes of the proposed model for two datasets. In addition to comparing the suggested method with cutting-edge algorithms, the ATE without RL method is used to assess the efficacy of the RL component on the model ATE. For the Restaurant dataset, the suggested model outperformed competing models, including E2E, resulting in an error reduction of more than 40% and 24% in the F1-score and accuracy criterion, respectively. The suggested model reduces the error rate by roughly 51% compared to ATE without RL, demonstrating the significance of the RL technique. For the Laptop dataset, the approach outperformed E2E and PSO-EN algorithms in terms of F1-

score and accuracy, so for the F1-score and accuracy criteria, the error improving rates are roughly 30.13% and 21.00%, respectively.

A. Comparison with other Metaheuristics

The improved DE algorithm is compared with a number of metaheuristic optimization algorithms. Different metaheuristics are used to obtain the initial model parameters while keeping the other model components. Seven different algorithms are used, namely standard DE [70], BA [71], COA [72], ABC [73], GWO [74], WOA [75], and SSA [76]. Table II contains the obtained results for the Restaurant and Laptop datasets. For the Restaurant dataset, the proposed model reduces error by about 31% compared to the standard DE. It clearly shows that the model has a substantial ability compared to the standard one. Also, DE offers more acceptable results than other algorithms, including ABC, GWO, and BAT. There is a minor improvement for the laptop dataset, so the error rate is reduced by around 17.17%.

B. Word Embeddings

Word embedding is a critical component of deep learning models, as incorrect embeddings can mislead the model. In this study, BERT, one of the latest embedding models, was utilized

as the word embedding. Five other word embeddings, including One-Hot encoding [77], CBOW, Skip-gram [78], GloVe [79], and FastText [80], were employed to compare various word embeddings with the model. One-Hot encoding is a vital step in converting the collected data variables into binary features, which improves the accuracy of predictions and classifications. A binary feature is generated for each class, and each sample's feature is assigned a value of 1 corresponding to its original class. The Skip-gram and CBOW algorithms use neural networks to convert a word to its word embedding vector. GloVe is a technique for aggregating global word-word co-occurrence data from a corpus. The FastText word embedding technique expands on the Skip-gram paradigm by encoding each word as an n-gram of letters instead of learning word vectors. The results of this study are presented in Table III. As anticipated, One-Hot encoding is the least effective among the others. Therefore, the proposed model's improvement rate is around 53.72% and 61.95% for the Restaurant and Laptop datasets, respectively. Due to their similar design, Skip-gram and CBOW perform almost equally across all datasets, and both outperform the GloVe word embedding. Compared to the FastText model, BERT reduces errors by 14% and 10% for the Restaurant and Laptop datasets, respectively.

Fig. 6. Examples of ATE output with and without reinforcement learning.

C. Impact of the Reward Function

In the suggested ATE design, appropriate rewards of +1/-1 and $+\lambda/-\lambda$ are assigned for the accurate/inaccurate identification of the dominant and subordinate classes, respectively. The value of λ is reliant on the relative proportions of the majority to minority samples, and it should decrease as the ratio increases. To evaluate the effect of λ , the ATE model's performance was assessed by initiating λ with incremental values from the set $\{0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1\}$, while holding the majority class bonus constant (Fig. 5). At $\lambda = 0$, the influence of the majority class is eliminated, and at $\lambda = 1$, both majority and minority classes have equivalent impacts. Across all metrics, model performance peaks at a λ value of 0.4 (increasing from 0 to 0.4; decreasing from 0.4 to 1). As a result, while λ needs to be adjusted to weaken the

impact of the majority class, a too-low value can impair the overall model performance.

D. Case Study

To evaluate the effectiveness of RL in the proposed ATE model, five samples were randomly selected from the SemEval-2014 dataset. The results are illustrated in Fig. 6, where the first column shows the model's output without RL, the second column represents the model's output with RL, and the third column displays the actual aspect term. The results reveal that the model without RL tends to assign a higher score to class O. On the other hand, the model with RL generates the maximum number of scores for correctly classifying classes B and I.

E. Discussion

The use of artificial intelligence in natural language processing has seen significant progress in recent years. The paper presents an approach for ATE that employs dilated convolution layers and reinforcement learning to address the problem of imbalance classification. A novel DE approach is proposed to initiate the BP process and use the BERT model as word embedding. The experimental results on two English datasets show that the suggested ATE model outperforms other systems.

However, there are some limitations that need to be addressed in future works. Firstly, the proposed method was only evaluated on two English datasets. The method's performance on other languages or domains needs to be explored to demonstrate its generalizability. Secondly, the BERT model is used, which is computationally expensive due to its large number of parameters. Although they suggest using other BERT extensions, such as the DistilBERT language model, for reducing the computing costs, it would be interesting to investigate other lightweight and efficient models for word embedding. Finally, no analysis of the extracted aspect terms, such as their relevance or coherence with the context was provided, which could have been a valuable addition to the evaluation metrics.

In addition to the aforementioned limitations, another area that could be explored in future works is the effectiveness of the proposed method on long texts. The ATE task becomes more challenging when dealing with longer texts, as there may be multiple aspects mentioned in the same text, and identifying the relevant aspects requires a more sophisticated approach. Therefore, it would be beneficial to investigate how the proposed method performs on longer texts and whether any modifications or adaptations are necessary to improve its performance. Another potential avenue for future work is to explore the interpretability of the ATE model. While the proposed approach achieved high accuracy in extracting aspect terms, it is not clear how the model makes its predictions. Understanding the reasoning behind the model's decision-making process could help to identify any biases or errors in the model and improve its performance. Furthermore, it would be interesting to investigate the impact of different hyperparameters on the performance of the proposed method. A specific set of hyperparameters was used for the experiments, and it is not clear whether these hyperparameters are optimal for all scenarios. A more thorough analysis of the impact of different hyperparameters on the model's performance could help to identify the most effective settings for different use cases.

V. CONCLUSION

In this article, the problem of ATE was handled, which was constructed from three dilated convolution layers deployed to extract feature vectors in parallel, concatenated for downstream classification. An improved DE algorithm is used for pre-training the model networks. The improved DE algorithm clusters the current population to find a suitable region in the search space and implements a new updating technique. Moreover, Reinforcement learning, which presents the training process as a sequential decision-making process, was applied

to shield the ATE model from imbalanced classification. At each stage, the agent receives samples and classifies them. The environment rewards the agent for each categorization act in which the minority class gets a greater reward than the majority class. Finally, with the help of a particular reward function and a conducive learning environment, the agent reveals the optimal strategy. The proposed models are evaluated using the Restaurant and Laptop datasets. The experimental results showed that the suggested ATE model outperformed other systems.

The BERT model typically comprises millions of parameters, increasing the computing costs associated with these models' environmental scaling. This problem can be solved using other BERT extensions, like the DistilBERT language model. The other language models with fewer parameters will be used for the following work.

Research on Library Face Book Return Model based on Hybrid PCA and Kernel Function

Jianwen Shi

Fujian Chuangzheng Communications College, Library, 350007, China

Abstract—With the improvement in the quality of university education in China, the behavior of college students and school teachers to borrow and return books in the library is becoming more and more frequent. In peak periods of returning books, managers cannot even assist in returning books in time. Therefore, this research uses kernel function, multi-dimensional principal component analysis method, and multi-dimensional linear discriminant analysis method to construct a new face recognition algorithm for the automatic return of books in the university library. The test results show that the XT_2D_PL algorithm designed in this study has a face recognition rate of 96.8%. When the number of face samples of each type in the test sample set is 11, and when the number of feature dimensions is 14, the recognition rate of 96.3% reaches the highest level. However, if the sample to be processed is 500 pictures, the calculation speed is 1.072ms/per photo, higher than most comparison algorithms. The proposed face recognition algorithm has high recognition accuracy on the library face data; the calculation speed meets the needs of practical applications, and has certain practical promotion potential.

Keywords—Kernel function; multidimensional principal component analysis; face recognition; intelligent book return

I. INTRODUCTION

The traditional way of returning books in university libraries is that the returner puts his valid borrowing certificate in the designated sensing area to identify his identity, returns the book, and takes it away [1-2]. The whole process of returning books in the library is cumbersome, and book returners often forget to carry valid borrowing certificates, which lead to the failure of book return and wastes the time and energy of book returners [3]. Therefore, some university administrators and technical experts propose applying advanced face recognition technology to the library return process and building a university library intelligent return model, so that book returners do not need to carry additional documents and only use their social biometric information and the book return process can be completed [4]. However, the recognition accuracy of algorithms used in the same type of products in the current market still needs to be improved. Directly using the face recognition algorithms of these products to build an intelligent book return system may lead to face-matching errors, face recognition failures, and other problems. This is also the main gap between previous research results and market applications. Therefore, it is necessary to design an algorithm with higher facial recognition accuracy for the intelligent face book return model of college students in order to solve such problems. Therefore, it is necessary to design an algorithm with higher recognition accuracy for the

intelligent face book return model of college students. This research attempts to use multidimensional principal component analysis and multidimensional linear discriminant analysis to reduce the dimension of face data, reduce the redundant information in the image, highlight the key image features, and combine the kernel function to map the reduced data to the high-dimensional feature space, stoned a more suitable classification and recognition space, which is also the innovation of this research. The significance of this study is to improve the efficiency of library borrowing and returning books, reduce the losses caused by work errors of library management personnel, and provide useful references for improving the borrowing experience of borrowing personnel. The significance of this study is to improve the efficiency of library borrowing and returning books, reduce the losses caused by work errors of library management personnel, and provide useful references for improving the borrowing experience of borrowing personnel. The content of this article can be divided into four major sections. The second section is used to elaborate and compare relevant research at home and abroad, and to introduce the purpose of conducting this research. The third module is to design an improved model for face recognition. The main content of the fourth module is to design and carry out experiments to verify the performance of the designed library face recognition model. The main content of the fifth module is to summarize the experimental results of this study and point out the direction for future research.

II. RELATED WORKS

To apply face recognition technology to more real-life scenarios and improve identification quality, scientists and scholars have carried out a lot of related research. Timur I et al. found that hierarchical temporal memory, a new type of machine learning algorithm, performed better in some supervised learning tasks, so they proposed a hierarchical temporal memory algorithm with a learning mechanism. The important features of all images create templates, thereby greatly reducing the computer memory requirements of the algorithm and increasing the calculation speed of the algorithm. The face recognition results show that the recognition accuracy of this algorithm is significantly improved compared with the unimproved hierarchical time memory algorithm when recognizing a large amount of face data [5]. Scholar Clwa found that the face recognition algorithm can be applied to the recognition of other primates such as chimpanzees, but it cannot be applied to the recognition of rhesus monkeys, but rhesus monkeys are widely used in biomedical research and can be effectively recognized; conducive to the development of auxiliary medical research.

Therefore, researchers combine the face recognition method with face detection technology to design a new rhesus monkey face recognition algorithm. The test results show that the method has high classification accuracy [6]. Hansen et al. used the common VGG model in face recognition, the Fisherfaces algorithm, and their algorithm to recognize the face of artificially raised pigs, and found that the algorithm they designed had the highest recognition accuracy on 1553 pig face pictures [7]. Lu et al. found that the resolution of face images captured by surveillance cameras is low, which will adversely affect the performance of gallery image matching. Therefore, they proposed an improved ResNet algorithm incorporating the idea of deep coupling, using a variety of face recognition algorithms in training. The commonly used data sets are tested, and the results show that the proposed algorithm has better consistency and judgment accuracy compared with the existing algorithms [8]. Bours et al. found that autism spectrum disorder is related to the difficulty of emotional recognition of patients through face recognition technology [9]. Ahmed et al. used the Gabor wavelet transform to construct a face recognition algorithm for recognizing symmetrical face images. The test results show that the recognition accuracy of the algorithm on various face recognition task datasets is higher than that of common neural network algorithm [10]. Wu found that the recognition accuracy of many face recognition systems declined during the COVID-19 epidemic. This is because many face recognition systems were trained based on face image data with no or little occlusion. The face image recognition ability is poor. Therefore, in this study, to improve the recognition accuracy of large-area-covered face images, a face recognition algorithm integrated with the attention mechanism was designed. The test results show that the algorithm has significantly higher recognition accuracy on face image data with large area coverage than the traditional face recognition algorithm [11]. Martins et al. studied the expression performance of the parallax energy model in an expression-invariant facial recognition system and found that the model significantly improved the measurement performance compared with the accurate laser ranging map calculation results [12]. Jain et al. found that deep neural networks outperformed traditional machine learning algorithms in processing face image recognition tasks containing facial expressions, so they proposed a hybrid convolutional recurrent neural network algorithm, which consists of convolutional layers and recursive neural networks; neural network composition. The test results show that, compared with the existing algorithms with better processing performance for face recognition tasks with expressions, the algorithm can obtain higher recognition accuracy and the calculation speed can also meet most application scenarios [13].

In summary, the current artificial intelligence experts have carried out a lot of research to improve the accuracy and speed

of face recognition in different application scenarios, and have proposed some algorithms or improvement ideas that can practically solve the problem. However, due to the characteristics of face images that need to be processed in the university library's face return book model, there are fewer expressions, more environmentally redundant information, and higher image similarity, so the previous research results cannot be directly used. Therefore, this research attempts to design a targeted face recognition algorithm according to the data characteristics in the library face book return scene.

III. BUILDING A LIBRARY FACE BOOK RETURN MODEL COMBINING KERNEL FUNCTION, PCA AND LDA

A. Design of Bidirectional Linear Feature Extraction Algorithm based on 2D PCA and 2D LDA

In the face recognition problem, due to the high feature dimension in the face image data, appropriate dimensionality reduction processing will help to improve the face recognition effect [14-15]. Principal Component Analysis (PCA) is an effective and commonly used linear data dimensionality reduction algorithm, and its dimensionality reduction principle is shown in Fig. 1.

As shown in Fig. 1, this method treats the face image as a high-dimensional vector and maps the data to a lower-dimensional feature subspace according to the criterion of maximizing the variance of the principal component data after dimension reduction [16]. The Linear Discriminant Analysis (LDA) method is a classic pattern recognition method. Due to its extremely low computational complexity and simple computational logic, it can also be used to process face data [17]. The calculation principle of the LDA method is shown in Fig. 2.

Fig. 1. Schematic diagram of PCA algorithm dimensionality reduction.

Fig. 2. Calculation schematic diagram of the LDA method.

To be processed to an optimal classification direction in a way that makes the heterogeneous samples mapped in a certain direction has the largest distance in space or the most dispersed distribution, to achieve data classification. However, PCA has the disadvantage of not using the original sample type, and LDA also has limitations when dealing with small samples [18-19]. Therefore, to improve the processing speed and processing accuracy of face data, and consider the multi-directional correlation of data, a bidirectional linear feature extraction algorithm based on two-dimensional PCA and two-dimensional LDA (hereinafter referred to as T_2D_PL algorithm) is proposed. In the T_2D_PL algorithm, the rows in the horizontal direction and the columns in the vertical direction are processed at the same time to obtain the optimal projection axis [20]. When the algorithm is applied to face image dimensionality reduction, it is equivalent to projecting the face image to the column direction, that is, two-dimensional LDA and row direction, that is, the optimal projection of 2DPCA, and according to the feature matrix variance maximization and Fisher criterion The optimization is carried out in a maximizing way so that the number of output feature vectors is greatly reduced, and the data dimensionality reduction is completed. In the T_2D_PL algorithm, if the original image is A_i , and the average image is μ , then the two can be expressed by formula (1).

$$\begin{cases} A_i = [(a_i^{(1)})^T, (a_i^{(2)})^T, \dots, (a_i^{(m)})^T]^T \\ \mu = [(v^{(1)})^T, (v^{(2)})^T, \dots, (v^{(m)})^T]^T \end{cases} \quad (1)$$

Among them $a_i^{(j)}$, $v^{(j)}$ represent the row vector of the i th sample A_i and μ the j th row respectively, then the covariance matrix G can be expressed by formula (2).

$$G = \frac{1}{N} \sum_{i=1}^N \sum_{j=1}^M (a_i^{(j)} - v^{(j)})^T (a_i^{(j)} - v^{(j)}) \quad (2)$$

Where N and M represent the total number of samples and the row vector size of the average image, respectively. It can be seen from Eq. (2) that the operation object of the image covariance matrix is the row vector of the matrix. G After the eigenvalues are decomposed, the former d eigenvectors are formed into a projected multidimensional vector space X_{opt} . In the column direction, the algorithm uses the two-dimensional LDA method to find the best projection vector Z to maximize the Fisher function, as shown in Eq. (3).

$$J(\tau) = \frac{Z^T S_{FB} Z}{Z^T S_{FW} Z} \quad (3)$$

In formula (3), S_{FB} and S_{FW} represent the inter-class scatter matrix and the intra-class scatter matrix, respectively, which are represented by formulas (4) and (5), respectively.

$$S_{FB} = N^{-1} \sum_{i=1}^C N_i (\bar{A}_i - \bar{A})(\bar{A}_i - \bar{A})^T \quad (4)$$

Eq. (4) \bar{A}_i represents the mean of the i th image sample, which is the mean \bar{A} of the total samples of all images.

$$S_{FW} = N^{-1} \sum_{i=1}^C \sum_{j \in C_i} (A_j - \bar{A}_i)(A_j - \bar{A}_i)^T \quad (5)$$

Obtaining S_{FB} and S_{FW} calculating, $S_{FW}^{-1} S_{FB}$ the optimal projection matrix can be obtained, which consists of the previous d largest eigenvalue of the calculation result. To sum up, the calculation flow of the T_2D_PL algorithm can be shown in Fig. 3.

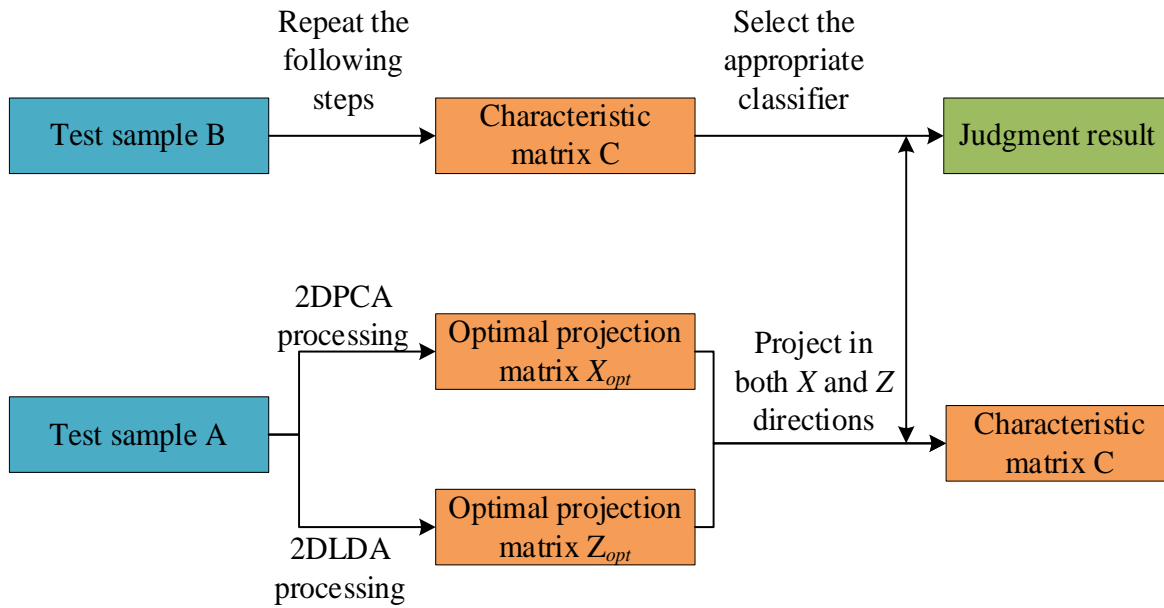

Fig. 3. T_2D_PL algorithm calculation flow chart.

As shown in Fig. 3, $m \times n$ a face image sample of size 1 is A subjected to two-dimensional PCA transformation in the row direction and two-dimensional LDDA transformation in the column direction, thereby outputting the optimal projections in the two directions X_{opt} , Z_{opt} , and then according to the two optimal projections matrix to form a feature matrix C . Projection dimension reduction B will be performed according to the optimal projection to obtain a reduced dimension matrix A . After repeating the above operations, the face image data with an appropriate dimension reduction can be output. Note that the calculation method of the feature matrix C is shown in formula (6).

$$C = Z_{opt}^T A X_{opt} \quad (6)$$

Finally, the nearest neighbor classifier is used to calculate the Euclidean distance between the two C and the k sub-processed feature matrix C_k to complete the classification of the input data. The calculation method of the Euclidean distance between the two is shown in formula (7).

$$D(C, C_k) = \sum_{i=1}^q \sum_{j=1}^d \sqrt{(C^{(i,j)} - C_k^{(i,j)})^2} \quad (7)$$

Where q and d are the number of eigenvectors selected in multiple directions, respectively. So far, the data dimensionality reduction algorithm applied to the library face recognition book return model has been constructed.

B. Design of Improved Nonlinear Feature Extraction Algorithm based on Fusion Kernel Function

At the same time, performing two-dimensional PCA processing on the horizontal direction of the pixel matrix of the image data and two-dimensional LDA processing on the vertical direction of the pixel matrix can effectively reduce the dimension and compress the image on the premise of retaining the core information of the original image as much as possible. However, the above methods are often used to process linear structural data, and the processing effect of nonlinear image data is not good. Therefore, in this study, referring to the idea of kernel function, a feature extraction method of face image data combining T_2D_PL algorithm and combined kernel function is proposed and the recognition algorithm (hereinafter referred to as improved T_2D_PL algorithm). In the improved T_2D_PL algorithm, a kernel function is introduced to deal with the non-linear data brought by facial expression, facial posture, lighting environment and other conditions, which have a negative impact on face recognition. The data processing principle of the kernel function is shown in Fig. 4.

It can be seen that for nonlinear data, it may not be possible to find an identification plane that can clearly distinguish it in the plane, because it has the property of linear inseparability, so it needs to be mapped to three or more dimensions to find a suitable dividing plane. In the algorithm, the T_2D_PL method is still used to reduce the dimensionality of the face data, which is used to delete redundant information and improve the accuracy and speed of subsequent face recognition; column-wise feature extraction and face recognition. Since the data is mapped into a more dimensional feature space by the combined kernel function, the overall time complexity of the algorithm is significantly increased, so the algorithm needs to reserve more storage space and time for data calculation when running. The following is a detailed design of the combined kernel function in the improved T_2D_PL algorithm and the calculation flow of the algorithm.

Fig. 4. The schematic diagram of the kernel function mapping processing data.

Different types of combined kernel functions will lead to different applicable objects and different sensitivity to different data processing. Specifically, the local kernel function can process local information accurately and efficiently. The global kernel function is more suitable for extracting global data information and has stronger generalization ability. For example, the Gaussian kernel function is a commonly used local kernel function. When the parameter increases, its extrapolation ability will gradually weaken, and the global data processing ability of the polynomial kernel function is better, which belongs to the global kernel function. Since the selection of the kernel function will directly affect the final recognition performance of the model, this study adopts the idea of combining kernel functions to construct the calculation kernel function in the algorithm. Specifically, it refers to a reasonable linear combination of various types of kernel functions by judging different processing requirements, so as to achieve the premise of retaining the overall information of the data, highlight the local features from different face image categories, and output more excellent judgment results. In this study, the optimal parameter combination of various single kernel functions was first tested experimentally, and then the search center was used to determine the optimal combination of kernel function parameters by grid search method, so that various weight coefficients could be tried in the future., to obtain the best recognition effect. The specific calculation steps of the improved T_2D_PL algorithm have four steps. The first is to map the dimensionality-reduced dataset to the multi-dimensional feature space using the combined kernel function. Assume that the processed input face dataset is $X = [X_1, X_2, \dots, X_M]$

and $X_i = \left[(X_i^1)^T, (X_i^2)^T, \dots, (X_i^m)^T \right]^T$ the kernel matrix K of size, $(i \times k, j \times l)$ can be calculated using Equation (8).

$$K = \Psi(X_i^k) \cdot \Psi(X_j^l) = \Psi(X_i^k) \cdot \Psi(X_j^l)^T \quad (8)$$

Eq. (8) $\Psi()$ represents the combined kernel function, which represents X_i^k the j row vector of the k image sample, X_i and l is the shape parameter of the kernel matrix. The second step is to use Eq. (9) to calculate the eigenvalues and eigenvectors of the kernel matrix.

$$Kb = b\hat{\lambda} \quad (9)$$

In Eq. (9), $\hat{\lambda}$ is the largest eigenvalue obtained by decomposing the kernel matrix, from which the previous P largest eigenvalue in descending order is selected as the eigenvector of the kernel matrix b . Then, the kernel matrix that has been mapped to the high-dimensional feature space is centered, and the feature vector $V^{(i)}$ can be calculated using Eq. (10).

$$V^{(i)} \cdot V^{(i)} = 1 \quad (10)$$

In formula (10) $i \in 1, 2, \dots, P$. Finally, extract the principal components of the row vector of the sample, and obtain the matrix after the row vector is projected by the eigenvectors in the high-dimensional kernel space. $Y_t^{(i)}$ The calculation method is shown in formula (11),

$$Y_t^{(i)} = \sum_{j=1}^M \sum_{k=1}^n \frac{\alpha_{(j-1)n+k}^{(i)}}{\sqrt{\hat{\lambda}^{(i)}}} K(X_i^l, X_j^k) \quad (11)$$

Where the first $\hat{\lambda}^{(i)}$ feature α is in the largest feature set, and i is the known mapping parameter. From this, a matrix of Y_t size can be obtained $m \times P$, and its calculation method is shown in formula (12).

$$Y_t = [Y_t^{(1)}, Y_t^{(2)}, \dots, Y_t^{(P)}] \quad (12)$$

Fig. 5. Data dimensionality reduction process of T_2D_PL method.

After using the improved T_2D_PL algorithm to compress the row and column bidirectional information of the sample, the feature matrix can be obtained Y , and then the matrix is subjected to two-dimensional linear discriminant analysis (2DLDA), that is, through the classification, information of the data itself is subjected to secondary dimensionality reduction and compression, and its specific dimensionality reduction process is shown in Fig. 5.

The process shown in Fig. 5 will be explained in detail below. It is assumed that the total number of images to be processed is M the number of $M_i Y_k$ samples in the training sample of the first category. There are C two i categories $Y_j^{(i)}$ in the j image data Y_k . k A sample matrix, $\bar{Y}^{(i)}$ \bar{Y} respectively represent i the mean image information of the first-class sample and the mean matrix of all sample images, and there is the relationship of formula (13).

$$\bar{Y} = \frac{\sum_{i=1}^M Y_i}{M} \quad (13)$$

Assuming that Y is the size $m \times p$ of the image data to be tested, after mapping it to the W direction, it will form a matrix Z , and its size is $d \times p$ ($d \ll m$), then the average inter-class distance of the image data after the projection can be calculated according to formula (14).

$$H_b = \left[\sum_{i=1}^c M_i (\bar{Y}^{(i)} - \bar{Y})(\bar{Y}^{(i)} - \bar{Y})^T \right] / M \quad (14)$$

The average intra-class distance after projection can be obtained by formula (15).

$$H_w = \sum_{i=1}^c \sum_{j=1}^M (\bar{Y}_j^{(i)} - \bar{Y}^{(i)})(\bar{Y}_j^{(i)} - \bar{Y}^{(i)})^T / M \quad (15)$$

Therefore, the Fisher criterion function after projection can be expressed by Eq. (16).

$$J(Z) = \frac{W^T H_b W}{W^T H_w W} \quad (16)$$

Finally, the matrix is calculated $H_w^{-1} H_b$, and the previous largest eigenvalue in descending order d and the corresponding orthogonal eigenvector are selected to w_1, w_2, \dots, w_d form the optimal projection space of the image, which is expressed by formula (17).

$$W = [w_1, w_2, \dots, w_d] \quad (17)$$

That is to say, after the improved T_2D_PL algorithm dimensionality reduction processing, a dimensionality $d \times p$ reduction matrix of size can be obtained to represent the judgment result of the algorithm on the input data, and the calculation formula is shown in formula (18).

$$Z = W^T Y \quad (18)$$

IV. LIBRARY FACE BOOK RETURN MODEL PERFORMANCE TEST

Before putting it into a practical environment, it is necessary to test the practical performance of the model. The test core of the face-returning-book model is the face recognition ability of the algorithm that composes the model. Therefore, the improved T_2D_PL algorithm is designed in this study (hereinafter referred to as the XT_2D_PL algorithm). For the test, the data selected for the test came from 200 people from many domestic colleges and universities. Each person was photographed with 12 face images with different postures and expressions, and the image type was 112×92 a grayscale image. In the test experiment, the recognition rate and calculation time are selected as the evaluation indicators for the quality of face recognition results. To compare the relative performance of the designed algorithms, two-dimensional LDA, two-dimensional PCA, T_2D_PL algorithm, and VGG neural network algorithm are selected as comparison methods. The parameters of the two-dimensional LDA model include the number of topics, the number of iterations, and the overfitting coefficient; The two-dimensional PCA model has parameters such as target dimensionality reduction quantity and whether to perform whitening treatment; T_2D_ the parameters of PL and its derived algorithms are all the parameters of the two-dimensional LDA model and the two-dimensional PCA model; The parameters of VGG neural network mainly include the number of neurons in each layer, the type of activation function and objective function, and the parameter initialization mode. These parameters are determined by combining industry

experience and usage practices, and conducting experiments by repeatedly debugging and selecting the model with the best testing results. First, analyze the face recognition rate of 2D LDA and 2D PCA under the condition of different number of features, as shown in Fig. 6.

Fig. 6. Statistics of face recognition rate of 2D LDA and 2D PCA under different number of features.

In Fig. 6, “2DPCA” and “2DLDA” represent two-dimensional principal component analysis and two-dimensional linear discriminant analysis, respectively. The gray dotted line in the figure is the fitting trend line of the characteristic curve, that is, Fig. 6[(a), (b)] represents the

statistical graphs of the face recognition rate curves under different numbers of features obtained by using the 2DPCA and 2DLDA methods for face recognition processing. Observing Fig. 6, it can be seen that as the number of features of the image to be processed increases, the face recognition rate of the 2DPCA algorithm first increases and then tends to converge, and the 2DLDA first increases rapidly and then slowly decreases. When the number of feature dimensions of the 2DPCA and 2DLDA methods reaches 8 and 7, respectively, the recognition rate reaches the maximum value of 93.1% and 92.8%. The following analyzes the algorithm recognition rate when the T_2D_PL algorithm is used alone, and the number of PCA and LDA feature dimensions in the algorithm takes different combination schemes. The statistical results are shown in Table I.

Observing Table I, it can be seen that when the dimension of the linear discriminant is fixed and the dimension of the PCA feature is increased, or when the dimension of the PCA feature is fixed and the linear discriminant feature is increased, the change rule of the recognition rate is roughly the same as that in Fig. 6, both of which show a rapid growth first and then are steady and slightly down. When the PCA feature dimension and the linear discriminant feature dimension of the T_2D_PL algorithm are both 12, the recognition rate reaches the maximum value of 94.4%. Next, we will analyze the recognition rate of each algorithm when the number of samples under each type of face samples is different. The statistical results are shown in Fig. 7.

Fig. 7. The face recognition rate statistics of the algorithm under different sample numbers of each type.

TABLE I. RECOGNITION RATE STATISTICS OF T_2D_PL ALGORITHM UNDER DIFFERENT FEATURE DIMENSION NUMBER SCHEMES (UNIT: %)

PCA feature dimension	Linear discriminant feature dimension						
	3	6	9	12	15	18	21
3	64.3	77.8	81.2	80.3	81.9	81.2	80.7
6	85.2	90.9	91.0	89.5	90.2	88.3	90.5
9	88.0	90.7	91.9	90.2	90.8	89.5	90.2
12	89.2	91.8	92.8	94.4	89.7	91.4	91.3
15	89.7	91.9	92.8	93.9	91.7	91.6	90.6
18	90.1	92.4	93.2	93.7	91.2	90.9	90.2
21	89.7	92.0	92.1	93.4	90.8	90.3	90.0

The horizontal axis in Fig. 7 is used to describe the number of samples for each type of facial image in the sample to be processed, the vertical axis represents recognition rate, and different line colors represent different recognition algorithms. Observing Fig. 7, it can be seen that the trend of the recognition rate change curve of each face recognition method is generally consistent with the increase of the number of face samples in each class. When the number of face samples in each class is less than 5, the recognition rate of each recognition model increases rapidly as the number of face samples in each class increases. However, when the number of face samples in each class is 5, the recognition rate growth curve of each model basically reaches a turning point. Subsequently, the number of facial samples in each category continued to increase, and the growth rate of facial recognition rates in each model gradually slowed down, reaching its maximum value when the number reached 11. Specifically, when the number of samples for each type of face is 11, the face recognition rates of the 2DLDA, 2DPCA, T_2D_PL, VGG, XT_2D_PL algorithms are 88.2%, 88.4%, 93.3%, 94.7%, and 96.8%, respectively. When the number of face samples is small, the face recognition rate of each algorithm has a small gap, and the recognition rate of the VGG algorithm is the lowest. This is because VGG belongs to a neural network algorithm and requires a high amount of training data and diversity. Therefore, In this case, a good application effect cannot be obtained. When the number of face samples of each type is large, the recognition performance of the VGG algorithm is significantly improved, and the recognition rate is only lower than the XT_2D_PL algorithm designed in this study. Therefore, the VGG algorithm and the XT_2D_PL algorithm are grouped into a group below, and they remain in the same group with the algorithm, and the changes of their recognition rate with the feature dimension are grouped and counted. The statistical results are shown in Fig. 8.

Assuming that the number of feature dimensions in Fig. 8 is a variable x , the feature dimension parameters of the T_2D_PL algorithm are taken in the row and column directions (x, x) , and the feature dimension parameters of the XT_2D_PL algorithm have the best recognition effect after multiple debugging $(x, x-3)$. Observing Fig. 8, it can be seen that VGG and XT_2D_PL. The change pattern of facial recognition rate curve of PL algorithm is significantly different from other algorithms in different feature dimensions. VGG and XT_2D_PL. There is a significant overall positive correlation between the recognition rate of the PL algorithm and the number of feature dimensions, but in other algorithms, only when the number of feature dimensions is less than 8, there is a certain positive correlation between the recognition rate and the number of feature dimensions. After the number of feature dimensions is greater than 8, there is no significant increase in the recognition rate of each algorithm's face. With the increase in the number of feature dimensions, T performs dimensionality reduction in both column and column directions_2D. The face recognition rate of PL algorithm is significantly higher than that of using only 2DLDA algorithm or 2DPCA algorithm, because the former has more dimensionality reduction directions and can retain more original image information. Observing in Fig. 8(b), it is found

that when the number of feature dimensions is less than 4, the recognition rates of the VGG algorithm and the XT_2D_PL algorithm are both low, but increase rapidly. When the number of feature dimensions exceeds 14, the face recognition of both exceeds that of the other three algorithms, and the highest face recognition rates of the two are 95.4% and 96.3%, respectively. Finally, the computational efficiency of each algorithm is compared, and the computational time-consuming evaluation under different computational sample sizes is used. The statistical results are shown in Fig. 9.

Fig. 8. Statistics of face recognition rate of each algorithm under different feature dimensions.

Fig. 9. The calculation of time-consuming statistics of each algorithm under different calculation samples.

The horizontal axis in Fig. 9 is used to describe the number of samples to be detected in each experiment, and the vertical axis is the calculation time of each algorithm, and the unit is ms. Analysis of Fig. 9 shows that, as a whole, with the increase of the data to be detected, the calculation time of each algorithm increases linearly, and the calculation time of the 2DLDA algorithm or the 2DPCA algorithm under various experimental schemes is significantly lower than that of other algorithms. The algorithm, mainly because it has the smallest algorithm complexity requires the fewest computational steps. The calculation time of the XT_2D_PL algorithm and the T_2D_PL algorithm is higher than the first two algorithms, and the calculation time of the XT_2D_PL algorithm is better. The calculation time of the VGG algorithm is the highest among all the experimental schemes. A large number of processing steps are required before outputting the recognition results. When the number of samples to be processed is 500 images, the computation time of 2DLDA, 2DPCA, T_2D_PL, XT_2D_PL, and VGG algorithms are 391ms, 395ms, 481ms, 536ms, and 754ms, respectively, and the calculation speed is 0.782ms/per photo, 0.79ms/per photo, 0.962ms/per photo, 1.072ms/per photo, 1.508ms/per photo. Although the face recognition speed of the library face return mode based on the XT_2D_PL algorithm is not the fastest, the calculation speed is enough to satisfy the library staff Facebook's needs.

V. CONCLUSION

The daily book return behavior of the university library occurs frequently, and a reasonably designed intelligent book return system can help improve the efficiency of the university library and save time for the majority of teachers and students on campus. In this study, the XT_2D_PL algorithm was constructed by using the kernel function and multi-dimensional principal component analysis method, and it was applied to the face recognition work in the library intelligent return system. The experimental results of the algorithm performance test show that the changing trend of the recognition rate change curve of each face recognition algorithm with the increase of the number of face samples of each type is roughly the same, and the growth rate is accelerated first, then the growth rate is greatly reduced and finally stabilized within a certain range of values. When the number of samples for each type of face is 11, the face recognition rates of the 2DLDA, 2DPCA, T_2D_PL, VGG, and XT_2D_PL algorithms are 88.2%, 88.4%, 93.3%, 94.7%, and 96.8%, respectively. When the number of feature dimensions is less than 4, the recognition rates of the VGG algorithm and the XT_2D_PL algorithm are both low, but grow rapidly. When the number of feature dimensions exceeds 14, the face recognition rates of the two algorithms exceed those of the other three algorithms, and the face recognition rates are 95.4% and 96.3%, respectively. When the sample to be processed is 500 pictures, the calculation speed of 2DLDA, 2DPCA, T_2D_PL, XT_2D_PL, VGG algorithm is 0.782ms/per photo, 0.79ms/per photo, 0.962ms/per photo, 1.072ms/per photo, 1.508ms /per photo. The experimental data proves that the library face-to-book model based on the XT_2D_PL algorithm designed in this

research has high face recognition accuracy, and the recognition speed meets the application requirements.

Abstract—The aim of this paper is to study and analyze the Jack Up Vessel (JUV) foundation height accuracy, with the objective of the precise installation of an Offshore Wind Farm (OWF), based on Real Time Kinematic (RTK) and Post-Processing Kinematic (PPK) modes applied on short and long baselines length. The offshore wind farm project is located far from the coastline, not always in the standard working range of RTK. The standard allowed vertical installation tolerance for foundations is less than 10 cm. Taking into account all error sources, deformation of the vessel, motion, lever arms that impact the height measurement of the foundation, it is required that RTK and PPK perform within an accuracy less than 5 cm. In this work, all measures will be evaluated according to the tolerance specification of ± 2.5 cm. The survey GNSS tests executed during the project on board of a JUV should be able to provide answers to the following questions: Despite the critical environment, does RTK method allow reaching the theoretical specifications? Does PPK improve accuracy compared to the RTK solution? What is the influence of the baseline length? How much of the time the results fall within the range tolerance? What is the ideal logging period in which accurate and reliable results can be obtained? What is the influence of the hardware and software variants used in testing process on the results accuracy? Based on the test results and analysis a clear description of the influence of different parameters in the OWF precise height measurement in challenging environment will be exposed.

Keywords—Real time kinematic; post-processing kinematic; high-precision positioning

I. INTRODUCTION

In this paper, we deal with Differential Global Navigation Satellite System (DGNSS) solutions that have been used to reach accurate measurement at the centimeter level [1] on board a Jack Up Vessel (JUV) with the objective of the precise installation of an Offshore Wind Farm (OWF) located far from the coastline, not always in the standard working range. Indeed, many sources of errors relating to the satellite position, the orbits anomaly, the spatial environment, the satellite clock bias, the receiver clock offset, motion of JUV, will decrease the position accuracy [2-7]. To reduce the effect of these errors a differential positioning is needed, there are two emerging and developing methods for doing this [8], the first with real-time and the second with post-processing namely respectively Real Time Kinematic (RTK) and Post-Processing Kinematic (PPK) (Fig. 1).

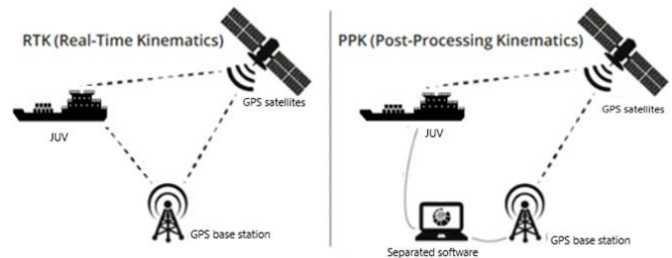

Fig. 1. RTK and PPK principle.

These two methods enhance the traditional method of deploying Ground Control Points (GCP) and become primary methods when we seek high-precision for any mapping, positioning or surveying task. It has been proven that RTK or PPK method extends the Precise Point Positioning (PPP), which needs a longer convergence time compared to differential methods, by incorporating a nearby local base station that perform and accelerate the integer ambiguity resolution, to reach a centimeter and sub-centimeter precision level [9, 10]. Therefore, the uses of GNSS have extended to many areas as Intelligent Transport System (ITS) including structural monitoring, geo-referencing of moving platforms and support for robotics and machine guidance, to name a few [11, 12]. Among the most relevant and recent works, we can cite the comparative study aimed to compare Unmanned Aerial Vehicle (UAV) based on RTK and PPK methods in mapping different surface types via five approaches: RTK Continuously Operating Reference Station (CORS) method, short-baseline PPK method obtaining corrections from a GNSS base station and three long-baseline PPK methods that obtained corrections from three Turkish RTK- (CORS) [13]. It is also promising to apply RTK-PPK to emerging industries like intelligent vehicle navigation and Low Earth Orbit (LEO) constellation augmented positioning [14].

RTK requires two receivers, a rover and a local base station, and a data radio connection between them. In this case, a local base station is placed at a known position. It can calculate the absolute distance of the satellites, based on its own position and the satellite navigation signals. It transmits the differences in distances to the rover as a differential correction. Then, the rover corrects its own distance, based on the correction data received from the base station. It is important to mention that it is not necessary to have a second receiver as a local base all the time. Alternatively, local services sharing base corrections over the Networked

Transport of RTCM via Internet Protocol (NTRIP) technology can be a good option. In case of PPK, there is no radio connection between the two receiver stations. The function of the base station, in the PPK case, is to continuously calculate the differential correction as a function of time and to store the data. The rover station stores the coordinates and data of the satellites used for its calculations as it moves. After the measurement, the data from the two stations can be compared according to the measurement times. After that, the correction can be calculated by separate software.

The present study evaluates the accuracy of the RTK and PPK methods to measure the foundation height of an Offshore Wind Farm (OWF). In standard GNSS positioning applications, it is a well-known fact that it is not possible to get the same precision for the vertical component as for the horizontal components. Indeed, since satellite sky distribution can never be homogenous on the vertical component, as there are no visible satellites under the horizon, errors on the pseudorange and phase observations propagate more adversely on the vertical component than on the horizontal components [15], which explain the strong correlation between the vertical component and some of the main systematic biases (receiver clock error and tropospheric bias). In addition, during the last decades there is a growing interest in being able to continuously monitor movements and deformations in man-made structures that have to withstand strong external forces like those in terrains that are subject to movements such as landslides, ground subsidence. Therefore, analyzing the Jack Up Vessel (JUV) foundation height accuracy in an OWF located far from the coastline, constitutes a real challenge for this work. During the project on board of a Jack Up Vessel (JUV), for the installation of OWF foundations vertical installation, tolerances of ± 10 cm are imposed. Taking into account all error sources, deformation of the vessel, motion, lever arms ... that impact the height measurement of the foundation, the vertical accuracies for GNSS must be lower than 5cm. Based on the theoretical specifications from the hardware used in this project which are Septentrio AsteRx-U & AsteRx-SB and Trimble SPS852 & SPS 855, the expected accuracy at 50 km would be 6 cm for Septentrio and 6.5 cm for Trimble. We will see later that the obtained measurements will be more precise than the indicated theoretical specifications.

According to previous works [16], the position information should be determined, in RTK mode, with accuracy in the range of centimeters in real time as the vessel sails. If the system also provides raw data in Receiver Independent Exchange (RINEX) format, it is also possible to determine the position using PPK method, with centimeter or sub-centimeter precision. In PPK mode, all calculations required for position correction are made post sailing by separate software.

During the project on board the JUV, we should be able to provide answers to the following questions: Despite the critical environment, does RTK method allow reaching the theoretical specifications? Does PPK improve accuracy compared to the RTK solution? What is the influence of the baseline length? How much of the time the results fall within the range tolerance? What is the ideal logging period in which accurate and reliable results can be obtained? What is the

influence of the hardware and software variants used in testing process on the results accuracy?

Based on the test results and analysis a clear description of the influence of different parameters in the OWF precise height measurement outside RTK working range and in challenging environment will be exposed.

II. TEST AND EXPERIMENTATION

This section describes the test and experimentation process, as well as hardware and software variants that will be used in testing process. The development of offshore energies requires ever larger cranes. For this, magic of evolution, boats have grown legs. One of these giants is the jack-up platform that has been developed for oil drilling and offshore wind. For the latter case, the location of the wind turbines must be precise and the height measurement must be accurate. The quality of the bottom having been previously studied, the foundations must rest in the intended place. For this, two factors are essential: controlling the position of the vessel and ensuring that it is stable so that the lifting is clean. To meet the first constraint a geolocation system and motion sensors are provided. Then come the feet that lift the ship and thus ensure that the crane will operate without being disturbed by the movement of the waves.

A. Test Location

Wind turbines require wind. They are therefore often installed in areas prone to strong storms. Although favorable weather windows are preferred, it is necessary to be able to withstand severe conditions. The test location is situated in the Baltic Sea in the most eastern part of Danish territorial waters and Danish Exclusive Economic Zone, directly next to the maritime border to Germany and Sweden. The closest distance to the Danish coastline (Island of Møn) ranges between 13 km and 39 km. The OWF project is located far from the coastline, not always in the standard working range of RTK.

B. Hardware GNSS Setup

The standard allowed vertical installation tolerance for foundations is less than 10 cm. Taken into account accumulative errors of other hardware in the setup required to determine the height of the foundation, it is required that the RTK performs within an accuracy of 5 cm. Based on the test results and analysis a clear definition and installation procedure (logging time, processing service, processing software and error budget) must be defined to determine the height measurement of an offshore base station outside the RTK working range. Two GNSS GA830 antennas were installed on board of the helideck of the JUV (Fig. 2), guaranteeing a clear view of the sky. The two GNSS antennas are installed close to each other and thus experience the same influence of any minor vessel movement.

Fig. 2. GA830 antenna.

For the purposes of this study, we use two Global Navigation Satellite System (GNSS) units namely Trimble and Septentrio units, five receiver brands referenced as DGPS4 (SPS852), SPS855, DGPS5 (AsteRx-U), Sept2 (AsteRx-U), Sept SB (AsteRx-SB).

We should note that the used GNSS constellation is composed from Global Positioning System (GPS), GLObal NAVigation Satellite System (GLO), Galileo (GAL) satellite system, and BeiDou (BEI) satellite system. We should note, again, that SPS852 was receiving GPS+GLO+BEI+GAL, DGPS 5 (AsteRx-U) was receiving GPS+GLO+BEI+GAL, Sept 2 (AsteRx-U) was receiving GPS+GLO+GAL and SPS855 was receiving RTX+(GPS+GLO+GAL). The AsteRx-SB remained working on RTK+(GPS+GLO+GAL)+(OSS KF B – baseline of 8 – 10 km), so it could be used as a reference.

In RTK or PPK modes, the receiver needs to know the type of antenna used at the base station in order to properly compensate for the phase center variation at the base. This information is typically included in the correction stream received from the base station. In this project, heights will be referred to the Antenna Reference Point (ARP) of DGPS5. One antenna is installed 0.080 m lower than the other antenna. Further, AsteRx units refer to ARP heights while Trimble units refer to Antenna Phase Center (APC) heights. Therefore, it is necessary to take into account the difference of 0.0885 m between ARP and APC of a GA830 antenna when comparing a Trimble receiver to an AsteRx receiver. An overview of the internal loggings and the time window is given in Table I.

TABLE I. OVERVIEW DATASETS AND TIMESLOTS USED FOR ANALYSIS

	TEST PURPOSE	TIME WINDOW OF DATASET (IN UTC TIME)
DATASET 1	Comparison RTK on different hardware units with a short baseline (± 8 km)	11/02/2021 19:00 – 12/02/2021 19:00
		13/02/2021 01:00 – 13/02/2021 21:00
		14/02/2021 01:30 – 14/02/2021 19:00
		15/02/2021 02:20 – 15/02/2021 12:00
DATASET 2	Comparison RTK (± 8 km) and RTK <i>GPSnet.dk</i> (29km from closest station)	10/02/2021 00:00 – 10/02/2021 23:59
DATASET 3	Comparison RTK (± 8 km) and PPP-RTK RTX	15/02/2021 16:00 – 16/02/2021 12:00
DATASET 4	Comparison RTK <i>GPSnet.dk</i> and PPP-RTK RTX	17/02/2021 00:00 – 17/02/2021 23:59
DATASET 5	Comparison RTK (± 8 km), PPP-RTK RTX and PPP	18/02/2021 18:00 – 19/02/2021 18:00
		20/02/2021 01:00 – 21/02/2021 01:00

C. Real Time RTK Performances

1) *Analysis of vessel settlement*: All tests are done on board of JUV in jacked up position. However, depending of the soil conditions it is possible that the legs can settle which can

have an influence on the height of the GNSS antennas since they are considered as static during the test processing. Before performing analysis on the RTK loggings, it was checked whether significant height changes could be determined during one jacked up position. Per location, the vessel was jacked up, the data was plotted for each GNSS receiver. A linear trend line is obtained and plotted on the graph (Fig. 3).

Fig. 3. Linear trendline of DGPS 5 height in function of time of Jack up 2.

The slope coefficient of this trend line was then recalculated and the average settlement per 24 h measured (Table II). To give an indication of the influence on our specific loggings during these tests, the average settlement for each logging is measured. The loggings were respectively 24 h, 20 h, 17.5 h and 9.5 h long.

TABLE II. JUV SETTLEMENT CALCULATION PER GNSS UNIT PER LOCATION

	JACK UP1 12/02-24H	JACK UP2 13/02-20H	JACK UP3 14/02-17.5H	JACK UP4 15/02-9.5H
AVERAGE SETTLEMENT PER 24 HOUR (m)				
DGP S4	-0.013	-0.039	-0.001	-0.063
DGP S5	0.006	-0.028	-0.011	-0.019
SEP T 2	0.002	-0.028	-0.011	-0.019
SEP T SB	0.006	-0.030	-0.011	-0.026
SPS8 55	0.004	-0.028	-0.006	-0.019
AVERAGE SETTLEMENT FOR EACH LOGGING (m)				
DGP S4	-0.013	-0.032	-0.001	-0.025
DGP S5	0.006	-0.023	-0.008	-0.008
SEP T 2	0.002	-0.023	-0.008	-0.008
SEP T SB	0.006	-0.025	-0.008	-0.010
SPS8 55	0.004	-0.024	-0.004	-0.008

First of all, one can observe a significantly higher value of height change for DGPS4 in two out of four locations. For the second location (Jack up 2), the settlement is high for all the devices. So, the problem arises mainly for Jack up 4. One might think this could be caused by the vessel movement and the load change due to unloading wind turbine parts. However, as mentioned before the two GNSS antennas are installed close to each other, and thus experience the same vessel movement. However, the other units do not show this same trend. If, we compare the average settlement per 24 h and the average settlement for 9.5 h logging for DGPS4-height, we note a significant difference between them, so we can think that the shorter time logging period may be the cause of this significant deviation.

For the first, third and fourth logging, it can be concluded that there is no significant settlement which has to be taken into account. All values (except for DGPS4) are 0.010 m or lower. Only on the second location, the subsidence coefficient is higher than 0.022 m for all GNSS receivers. This can be considered as a settlement. The surface might be softer at this location. However, it will not be applied to the data, since we cannot say with certainty that this is the cause of the height difference.

2) *Analysis of RTK height and standard deviation:* In the following tests, a more in-depth analysis was done to evaluate whether real time RTK performs as within ± 2.5 cm accuracy on a short baseline (<10 km), as specified in the hardware manufacturer specifications. Note that this analysis is based on in total 71 hours of data on four different locations.

As per manufacturer specifications Septentrio baseline length should be less than 40 km and Trimble baseline length should be less than 30 km (Table III). Based on these specifications, we can expect a Root Mean Square (RMS) error of respectively 18 mm (Septentrio) and 23 mm (Trimble) with a baseline of 8 km. In the below paragraphs, the results are compared to the results of the Septentrio AsteRx-SB, which is chosen as vertical reference, since it is connected to the base station (OSS KF B – baseline of 8 – 10 km) + RTK during all the performed tests.

TABLE III. MANUFACTURERS RTK SPECIFICATIONS

ASTERX-U & ASTERX-SB	Vertical accuracy 1cm + 1 ppm RMS	Open sky conditions RMS levels Baseline < 40km RTK fixed ambiguities
SPS852 & SPS 855	Vertical accuracy 15mm + 1ppm RMS	Baseline < 30km

3) *Statistics full loggings:* The average height of each logging at 8 km baseline and the difference between the units and the AsteRx-SB are listed in Table IV.

TABLE IV. RTK AVERAGE HEIGHT AND DIFFERENCE

	DGPS4 SPS852	DGPS 5 ASTERX- U	ASTERX- U SEPT 2	ASTE RX-SB	SPS855
HEIGHT (m)					
JACK UP 1	89.177	89.166	89.166	89.166	89.182
JACK UP 2	89.253	89.241	89.241	89.240	89.256
JACK UP 3	89.206	89.200	89.200	89.199	89.216
JACK UP 4	89.199	89.189	89.189	89.189	89.206
DIFFERENCE (m)					
JACK UP 1	0.011	0.000	0.000	-	0.016
JACK UP 2	0.012	0.001	0.000	-	0.015
JACK UP 3	0.007	0.001	0.001	-	0.017
JACK UP 4	0.010	0.000	0.000	-	0.018
TOTAL AVG. DIFF.	0.010	0.000	0.000	-	0.016

Note that the vessel aims to always jack up at the same keel height. For this reason, the height for each jack up is

similar. Table IV shows that the average results of all receivers lay close to each other. However, the results of Septentrio units are almost similar; we note a maximum of 0.001 m difference. The Trimble units show slightly higher differences, but the differences stay within 0.020 m, which is still within specifications. This does not mean that the Trimble results are less good than Septentrio units but indicates that the results may also differ depending on the receiver brand.

The difference of results between different GNSS brands could be caused by several factors; processing of results, usage of different antenna models. Depending on the brand and unit, Trimble relative, National Geodetic Survey (NGS) absolute or NGS relative antenna model are used. This can induce differences between ARP and APC. For the GA830 antenna, the difference between NGS relative and absolute is 0.017 mm. For Trimble SPS855 unit, Trimble relative is used, which explain the difference observed in Table IV for this unit.

The average Standard Deviation (SD) of a long logging is already at the limit of the specifications (Table V).

TABLE V. STANDARD DEVIATION OF THE UNITS ON RTK FOR EACH JACK UP

	DGPS4 SPS852 (m)	DGPS 5 ASTERX-U (m)	ASTERX-U SEPT 2 (m)	ASTER X-SB (m)	SPS8 55 (m)
JACK UP 1	0.017	0.021	0.021	0.020	0.020
JACK UP 2	0.020	0.022	0.022	0.020	0.020
JACK UP 3	0.016	0.021	0.021	0.019	0.019
JACK UP 4	0.019	0.021	0.021	0.019	0.020
Total	0.018	0.021	0.021	0.019	0.020

Table V shows that the average standard deviation of the data of the full logging is similar for all units and for a long logging it is already at the limit of manufactures specifications. The values are between 0.160 m and 0.220 m. This shows that on long term loggings, the stability of different brands is similar and within specifications.

Table VI shows how many data per second per logging are not within the ± 2.5 cm tolerance. We not that 12% up to 24% of the logged data is not within specifications, thus 76% up to 88% of the measurements during these 71 loggings at 8 km baseline are within tolerance.

TABLE VI. PERCENTAGE OF POSITIONS PER SECOND NOT WITHIN ± 2.5 CM OF THE 24 HOUR AVERAGE OF THE LOGGING, PER JACK UP

	DGPS4 SPS852	DGPS 5 ASTERX-U	ASTERX-U SEPT 2	ASTER X-SB	SPS 855
JACK UP 1	16%	22%	22%	19%	19%
JACK UP 2	18%	23%	24%	20%	23%
JACK UP 3	12%	21%	21%	17%	18%
JACK UP 4	16%	24%	24%	18%	20%

One of the scopes of the next tests was to try to define the ideal logging period in which accurate and reliable results can be obtained with a minimum of critical operational time. Below, the averages will be evaluated for 1h and 15 min periods.

4) *Statistics logging per hour*: For the statistical analysis of the data per hour, average heights and standard deviations per hour are evaluated. In total, 71 hourly average values are calculated. The minimum, maximum and average values are calculated and we estimated how much of these values are not within the predetermined tolerance of ± 2.5 cm. This is done in order to evaluate the performance of RTK when logging a specific period. The results per hour are summarized in Table VII and Table VIII. Table VII exposes the height difference between one hour average and total logging average and Table VIII exposes the standard deviation of RTK per hour.

TABLE VII. HEIGHT DIFFERENCE BETWEEN 1 HOUR AVERAGE AND TOTAL LOGGING AVERAGE

	DGPS4 SPS852 (m)	DGPS 5 ASTERX-U (m)	ASTERX -U SEPT 2 (m)	ASTE RX-SB (m)	SPS8 55 (m)
MIN	-0.024	-0.016	-0.016	-0.016	-0.018
MAX	0.016	0.018	0.024	0.017	0.020
AVERAGE	0.000	0.000	0.000	0.000	0.000
% OUTSIDE TOLERANCE (± 2.5 CM)	0.0%	0.0%	0.0%	0.0%	0.0%

TABLE VIII. STANDARD DEVIATION OF RTK RESULTS PER HOUR

	DGPS4 SPS852 (m)	DGPS 5 ASTERX-U (m)	ASTERX-U SEPT 2 (m)	ASTE RX-SB (m)	SPS855 (m)
MIN	0.000	0.000	0.000	0.000	0.000
MAX	0.025	0.032	0.032	0.029	0.025
AVERAGE	0.015	0.019	0.019	0.017	0.017
% OUTSIDE TOLERANCE (± 2.5 CM)	0.0%	1.3%	2.7%	1.3%	2.7%

Logging with RTK during 1 hour gives 100% of the time values within 0.025 m difference from the average over 24 h, with a maximum difference observed of 0.024 m over the 71 hours of data, which is in accordance but so close to the tolerance limit. The SD minimum over 1 hour is no longer that 0.000, but has maximum values of 0.032 m. We note that 97.3 to 100% of the time, the SD is less than 0.025 m, which is considered a very good percentage. There are no significant differences between the units and brands, although the Trimble SPS852 shows the best results. We can conclude that 1 hour of logging is a good period to achieve fairly accurate results.

5) *Statistics logging per 15 min*: The same exercise was done with the same data, per 15 min. For in total 285 loggings

of 15 min, the average height difference between 15 min average and 24 h average as well as the standard deviation have been calculated and analyzed. The results are summarized in Table IX.

TABLE IX. HEIGHT DIFFERENCE BETWEEN 15' AVERAGE AND 24 HOUR AVERAGE

	DGPS4 SPS852 (m)	DGPS 5 ASTERX-U (m)	AsteRx-U SEPT 2 (m)	AsteRx-SB (m)	SPS8 55 (m)
MIN	-0.053	-0.036	-0.036	-0.035	-0.032
MAX	0.029	0.029	0.031	0.023	0.027
AVERAGE	0.000	0.000	0.000	0.000	0.000
% OUTSIDE TOLERANCE (± 2.5 CM)	2%	4%	5%	2%	3%

The 15 min loggings in RTK are between 95 – 98% of the time within ± 0.025 m tolerance to total logging average. There are no significant differences between the brands and devices. The maximum average difference observed over all 15 min loggings is -0.053 m. All minimum and maximum values now exceed the ± 2.5 cm limit. This was not yet the case when analyzing the data per hour.

The minimum SD according to 15 min is no longer 0.000, but has maximum values of 0.033 m. The average SD is less than the tolerance 95.1% to 99.3% of the time (Table X). There are no significant differences between the units and brands. Overall, the height is also stable over periods of 15 min, but the period of 1 h shows higher performances.

TABLE X. STANDARD DEVIATION OF RTK RESULTS PER 15'

	DGPS4 SPS852 (m)	DGPS 5 ASTERX-U (m)	AsteRx-U SEPT 2 (m)	AsteRx-SB (m)	SPS8 55 (m)
MIN	0.000	0.000	0.000	0.000	0.000
MAX	0.031	0.030	0.033	0.030	0.033
AVERAGE	0.014	0.017	0.017	0.016	0.016
% OUTSIDE TOLERANCE (± 2.5 CM)	0.7%	3.9%	4.9%	1.8%	3.9%

6) *Trend analysis of height plot*: In the analysis below, the overall performances were analyzed by looking into detail the time series GNSS height graphs. For each logging, a graph is made per hour. The trend of the data was analyzed visually, the vertical axis shows a gridline per 5 cm and each device is visualized in its specific colour.

In Fig. 4, two graphs from two days are shown. When visually looking to the graphs, it was observed that the data sometimes show a different behavior – trend between the different brands.

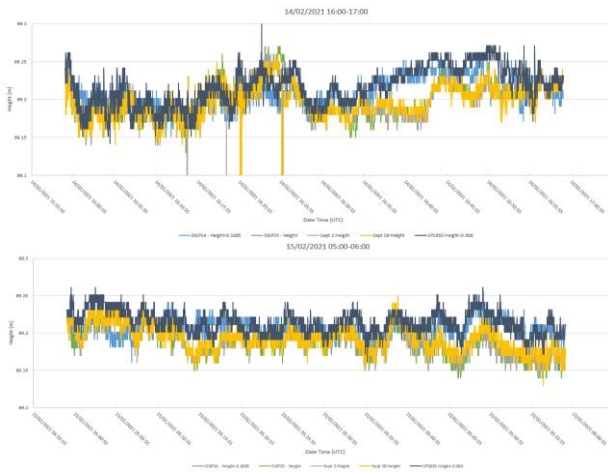

Fig. 4. Height results of five units in RTK short baseline.

Indeed, the three Septentrio units mostly match very well, despite the fact that these are two different models, which can be noted on the Sept AsteRx-SB (yellow graph) compared to the DGPS5 AsteRx-U (green graph) and Sept2 AsteRx-U (grey graph). In general the results of both Trimble resemble more to each other than to the height results of the Septentrio units, but the two Trimble units are different models as well SPS852 (light blue graph) and SPS855 (dark blue graph), which explains the small differences between the two Trimble graphs.

It can also be seen that the Trimble units in Fig. 4 are always slightly higher than the Septentrio units. Therefore, it can be said that the receivers from the same brand tend to follow the same behavior. This can be confirmed on these periods 14/02 16:41 – 16:45 and 16:48 – 16:50 as well as 15/02 05:45 – 05:50, where the difference between the Trimble and the Septentrio units achieved 0.040 m for several minutes. Knowing that the Trimble SPS855 is connected to the same GNSS antenna as the Septentrio units, this clearly proves the differences in results caused by the RTK engine and justify the use of different brands.

D. Post-Processing PPK Performances

In this section, we evaluate the PPK performance on different baseline lengths. Indeed, data is post-processing using different base stations on different distances (base line lengths). As a check, post-processing was also performed with base station OSS KF B. Base stations on land are obtained from two external correction services: GPSNET.DK and SWEPOS (Table XI).

TABLE XI. OVERVIEW BASE STATIONS FOR SINGLE BASE POST-PROCESSING

Denmark - GPSNET.DK	STEG	±30km
	FAXE	±50km
	ORHO	±60km
	GDS1	±70km
Sweden - SWEPOS	SKAN	±40km
	SMYG	±50km

Furthermore, data of 3 out of 5 receivers was post-processed: DGPS5 (AsteRx-U), Sept2 (AsteRx-U) and DGPS4 (SPS852). Data is post-processed for one jack up cycle of 24 h from 19 h on 11/02 until 19 h on 12/02. This was done in a static and kinematic way. Static post-processed data is compared to results from online post-processing services (AUSPOS and CSRS-PPP) and kinematic post-processed is compared to real time data. For post-processing, two software programs are used: Trimble Business Center (TBC) V5.10 and Qinertia V2.2.5847. Static post-processing will be done in TBC, kinematic post-processing will be done in TBC and Qinertia.

7) *Static mode:* As mentioned below, static post-processing is done in TBC with seven base stations (OSS KF B, STEG, SKAN, SMYG, FAXE, ORHO and GDS1) and one rover (DGPS 5). The static results were compared to AUSPOS and CSRS-PPP online services and were summarized on Table XII. The height of DGPS5 is sent to online services.

DGPS5 and Sept 2 are expected to have the same results since it concerns the same receiver type and the same antenna. Differences between the online services are ranging between 1 mm for the AsteRx-U to 7 mm for the SPS852. OSS KF B and all other base stations seem to match slightly better with the AUSPOS data than with CSRS-PPP data as shown on Table XIII.

Despite the superiority of AUSPOS online service, we always remain within specifications for the two online services for all baseline lengths. This shows that post-processing results match well with online services even with longer baselines (Table XIII).

TABLE XII. HEIGHT DGPS5 SENT TO ONLINE SERVICES AND POST-PROCESSED WITH DIFFERENT BASE STATIONS

	SPS852 (m)	DGPS 5 ASTERX-U (m)	SEPT 2 ASTERX-U (m)
AUSPOS	89.207	89.213	89.213
CSRS-PPP	89.200	89.211	89.212

AUSPOS	0.003	0.002	0.004
CSRS-PPP	0.010	0.004	0.005

8) Kinematic mode

a) Trimble Business Center: Kinematic post processing was done in TBC with five base stations (OSS KF B, STEG, FAXE, ORHO and GDS1) and one rover (DGPS 5). Data will be compared to the real time DGPS 5 data.

From Table XIV, we note that all data are almost continuously in RTK Fix and does not decrease with distance. Let us also note that Post-Processed (PP) data are a bit more in RTK Fix mode than the real time solution.

TABLE XIV. PERCENTAGE OF EPOCHS IN RTK FIXED, PER BASE STATION

Real Time OSS KF B	PP OSS KF- B (m) (8.4KM)	PP STEG (m) (29.2KM)	PP FAXE (m) (51.9KM)	PP ORHO (m) (62.5KM)	PP GDS1 (m) (74.1KM)
99.92%	99.98%	99.98%	99.98%	99.98%	99.98%

Overall, data seem to follow the same trend as the real time DGPS5 data (Fig. 5). However, in the graph of Fig. 5 is visible that the datasets tend to spread up to ± 0.100 m mainly for the OSS KF B case.

Fig. 5. Kinematic post processed height data from TBC vs real time DGPS 5 data (20-21h).

Table XV gives an overview of the statistics of the kinematic post-processing of the full logging of 24 h.

TABLE XV. AVERAGES AND SD OVER 24 HOUR KINEMATIC PROCESSING

REAL TIME OSS KF B	PP OSS KF B (m) (8.4KM)	PP STEG (m) (29.2 KM)	PP FAXE (m) (51.9KM)	PP ORHO (m) (62.5KM)	PP GDS1 (m) (74.1KM)
AVERAGE HEIGHT FOR 24H					
89.166	89.153	89.191	89.189	89.193	89.191
STANDARD DEVIATION FOR 24H					
0.021	0.019	0.026	0.033	0.041	0.036
HEIGHT DIFF. WITH REAL TIME DGPS5 FOR 24H					
-	-0.013	0.025	0.023	0.027	0.025

The average of 24 h data processed at +25 km baseline show results that are 2.5 cm or more higher compared to the real time height (Table XV). Average over 24 h of the check base OSS KF B, is 1.3 cm lower. We can still deduce that the standard deviation and the differences between the real time and post-processing height increase with the baseline length. Note that the differences are higher than the static logging for the same period.

In the Table XVI, we present the difference between 1 h average and 24 h average.

When taking averages per hour, 4.2% of the time the values for STEG were outside this 2.5 cm upper/lower tolerance from the 24 h average, with a maximum absolute difference of 4.5 cm. While, this is $\pm 8.3\%$, for baseline distance of 50-75 km (FAXE, ORHO and GDS1). The maximum absolute difference for all base stations is 9.4 cm.

TABLE XVI. REAL TIME AND POST PROCESSING (TBC) STATISTICS FOR 1 HOUR LOGGINGS OVER A 24 HOUR PERIOD

	DIFFERENCE BETWEEN 1H AVERAGE AND 24H AVERAGE					
	Real time OSS KF B (m)	PP OSS KF B (m) 8.4km	PP STEG (m) 29.2km	PP FAXE (m) 51.9km	PP ORH O (m) 62.5k m	PP GDS1 (m) 74.1km
MIN	-0.012	-0.011	-0.020	-0.028	-0.018	-0.027
MAX	0.013	0.015	0.045	0.094	0.089	0.086
AVERAGE	0.000	0.000	0.000	0.000	0.000	0.000
% OUTSIDE TOLERAN CE (± 2.5 CM)	0.0%	0.0%	4.2%	8.3%	8.3%	8.3%
SD PER HOUR						
MIN	0.014	0.011	0.009	0.010	0.010	0.010
MAX	0.032	0.026	0.052	0.075	0.128	0.080
AVERAGE	0.020	0.017	0.019	0.020	0.025	0.024
% OUTSIDE TOLERAN CE (± 2.5 CM)	4.2%	4.2%	4.2%	12.5%	20.8%	20.8%

These results can mean that RTK logging during one hour with a base station at a distance of 30 km in 95.8% can be considered long enough to define the coordinate within tolerance. And for 50-75 km (FAXE, ORHO and GDS1) this percentage decreases to 91.7% and in 8.3% of the time there is a risk of reaching values that exceed the tolerance threshold.

The differences between 1 h and 24 h confirm that there is no significant difference in real time and post-processed results from shorter baseline, since real time and PP OSS KF B show similar results and are both 100% of the time within tolerance.

When looking to the SD values, an increase of percentage outside of tolerance can be noted with the baseline length. For 62 km and 74 km baseline, only $\pm 79.2\%$ of the loggings per one hour are within tolerance, which is a fairly low percentage. Note that these last distances exceed the manufacturer requirement of 40 km.

However, STEG base station is less than 40 km from the rover, which is according to the manufacturer requirements. Despite that, 4.2% of the time the value per hour is outside of the ± 2.5 cm tolerance. For this reason, it was looked more in detail what happens there. It was noted that 13-15% of all the values outside of tolerance are falling in a timepan of less than 1 hour (02:59-03:40, 04:27-04:40, 18:05-18:44). This first timepan with a lot of high values is seen in Fig. 6. This clearly shows that data is not matching despite the RTK fixed solution.

No specific reason can be given to these decreased results. It could be related with ionosphere and troposphere and thus baseline. These effects tend to increase the vertical error with baseline length. STEG with the shortest baseline (29.2 km) shows slightly less disturbance than GDS1, ORHO and FAXE.

The same exercise as done per hour, was done per 15 min. The real time and post processing statistics are summarized in Table XVII.

With a baseline of more than 25 km, averages over a period of 15 minutes, values are outside the 2.5 cm upper/lower tolerance for 13% up to 19% of the time. Heights post-processed with the base station OSS KF B are more within tolerance than the real time result (1% versus 6%). The minimum and maximum values increase significantly with the baseline length. The range of the average height values per 15' is already ± 0.200 m for base stations at 50 km or further.

Fig. 6. Kinematic post processed data from TBC vs. real time DGPS 5 data (3-4h).

TABLE XVII. REAL TIME AND POST PROCESSING (TBC) STATISTICS FOR 15' LOGGINGS OVER A 24 HOUR PERIOD

	DIFFERENCE BETWEEN 15' AVERAGE AND 24H AVERAGE					
	Real time OSS KF B (m)	PP OSS KF B (m) 8.4km	PP STEG (m) 29.2km	PP FAXE (m) 51.9km	PP OR HO (m) 62.5 km	PP GDS1 (m) 74.1km
MIN	-0.036	-0.027	-0.045	-0.039	-0.038	-0.043
MAX	0.029	0.024	0.095	0.172	0.145	0.154
AVERAGE	0.000	0.000	0.000	0.000	0.000	0.000
% OUTSIDE TOLERANCE (± 2.5 CM)	6%	1%	18%	13%	14%	19%
SD PER 15'						
MIN	0.000	0.005	0.001	0.002	0.002	0.002
MAX	0.031	0.034	0.060	0.084	0.219	0.127
AVERAGE	0.017	0.014	0.014	0.015	0.018	0.018
% OUTSIDE TOLERANCE (± 2.5 CM)	4%	3%	4%	8%	11%	13%

The SD shows the same trend, the values increase by baseline length. However, it is quite particular that the percentages of values outside of tolerance are smaller than those per hour. This is due to the fact that over short periods the SD varies little.

b) *Qinertia*: The second software that can be used for kinematic post-processing is Qinertia. Processing has been done as well with this software, to get a better view on the consistency between Post-Processing (PP) software. This also gives a better view on the reliability of the PP results. The same data were processed: DGPS 5 was processed with four base stations (STEG, FAXE, ORHO and GDS1). Data are compared to the real time DGPS 5 data.

First of all, Table XVIII shows the percentage of the time that RTK fixed solution is achieved.

TABLE XVIII. PERCENTAGE SOLUTION MODE IN RTK FIXED

Real Time OSS KF B	PP STEG (m) (29.2KM)	PP FAXE (m) (51.9KM)	PP ORHO (m) (62.5KM)	PP GDS1 (m) (74.1KM)
99.92%	85.16%	76.09%	72.68%	57.28%

RTK fixed solution decreases significantly with distance. This is a big contrast with TBC, where all base stations could achieve RTK fixed for 99.98% of the epochs. We can deduce that Qinertia has more difficulties to recover RTK fixed solution even for shorter baseline.

Fig. 7. Kinematic post processed data from qinertia vs real time DGPS 5 data (20-21h).

Overall, data seem to match the real time DGPS 5 data (Fig. 7). It can be observed that the real time data seems choppy, this is due to a difference in rounding between QINSy loggings and Qinertia: QINSy data has two decimals while Qinertia has three decimals.

On an average of 24 h STEG, FAXE, ORHO and GDS1 data are very close to the real time height within 1 cm. These differences are much smaller than those of TBC processed heights. The SD has much higher values, but in the same line as the TBC results. Longer is the baseline, higher is the standard deviation (Table XIX).

TABLE XIX. AVERAGES AND SD OVER 24 HOUR

REAL TIME OSS KF B	PP STEG (m) (29.2KM)	PP FAXE (m) (51.9KM)	PP ORHO (m) (62.5KM)	PP GDS1 (m) (74.1KM)
AVERAGE HEIGHT FOR 24H				
89.166	89.161	89.159	89.167	89.176
STANDARD DEVIATION FOR 24H				
0.021	0.017	0.036	0.031	0.059
HEIGHT DIFF. WITH REAL TIME DGPS5 FOR 24H				
-	-0.005	-0.007	0.001	0.010

It looks like Qinertia loses RTK fixed location even at a shorter distance. But if Qinertia achieves RTK fixed, the results are very precise. This is not the case with data processed by TBC. This can be seen by comparing Fig. 6 with Fig. 7.

From Table XX, the difference per hour with the 24 h average is still quite low for a 30 km baseline, but with longer baselines this increases. Also the difference between minimum and maximum values follows this same trend, showing a 0.137 m difference at GDS1.

ORHO shows better results than FAXE, but it must be mentioned that the data in this graph are partially distorted since the data was often not in RTK fixed. Only RTK fixed results are included in the summary in Table XX, which implies that the averages are not always based on 24 h values and 1 h of data does not always actually includes 3600 values, in case RTK Fix is lost in the meantime.

TABLE XX. REAL TIME AND POST PROCESSING (QINERTIA) STATISTICS FOR 1 HOUR LOGGINGS OVER A 24 HOUR PERIOD

	REAL TIME OSS KF B (m)	PP STEG (m) (29.2KM)	PP FAXE (m) (51.9KM)	PP ORH O (m) (62.5K M)	PP GDS1 (m) (74.1K M)
% RTK FIXED	99.92%	85.16%	76.09%	72.68%	57.28%
DIFFERENCE BETWEEN 1H AVERAGE AND 24H AVERAGE					
MIN	-0.012	-0.016	-0.039	-0.029	-0.059
MAX	0.013	0.025	0.044	0.057	0.078
AVERAGE	0.000	0.000	0.001	-0.003	-0.005
% OUTSIDE TOLERANCE (±2.5CM)	0.0%	0.0%	22.2%	12.5%	58.8%
SD PER HOUR					
MIN	0.014	0.004	0.005	0.007	0.003
MAX	0.032	0.037	0.102	0.020	0.041
AVERAGE	0.020	0.012	0.018	0.013	0.016
% OUTSIDE TOLERANCE (±2.5CM)	4.2%	4.8%	16.7%	0.0%	5.9%
HEIGHT DIFFERENCE COMPARED TO REAL TIME AVERAGE					
MIN	-	-0.030	-0.049	-0.028	-0.046
MAX	-	0.013	0.024	0.056	0.086
AVERAGE	-	-0.005	-0.006	-0.002	0.005
% OUTSIDE TOLERANCE (±2.5CM)	-	4.8%	11.1%	12.5%	35.3%

As it was suggested earlier that the RTK fixed solution from Qinertia is generally speaking better at longer distances than TBC, this is no longer valid after analyzing the data more in detail. This is also confirmed when looking at the time series graphs of Fig. 8. Indeed, a reduced availability of data can be observed, only the closest station (STEG) seems to give useful data. Further, it can be observed that data after losing RTK fixed solution can be less accurate. It should also be noted that the heights jumps can only be caused by the Qinertia engine, which is not handling data well at larger distances.

The same exercise is done at a 15 min interval (Table XXI). Here, the same remark must be made about the distortion on the data. Since the results are for quite some time not in RTK fixed, the averages are not based on 24 x 4 quarters.

The difference in height compared to the 24 h average shows the same trend as the data per hour. While real time data was 100% within tolerance, this is now only 93.7% of the time. The percentage of values outside tolerance increases. At a distance of 74 km, only 43.4% of the values are within tolerance, this rate is low even for 1 h average logging. This proves the superiority of 1 h average logging versus 15 min average logging.

Fig. 8. Kinematic post processed data from TBC vs real time DGPS 5 data (8-9h).

TABLE XXI. REAL TIME AND POST PROCESSING (QINERTIA) STATISTICS FOR 15' LOGGINGS OVER A 24H PERIOD

	REAL TIME OSS KF B (m)	PP STEG (m) (29.2K M)	PP FAXE (m) (51.9K M)	PP OR HO (m) (62.5 KM)	PP GDS1 (m) (74.1K M)
% RTK FIXED	99.92%	85.16%	76.09 %	72.6 8%	57.28%
DIFFERENCE BETWEEN 15' AVERAGE AND 24H AVERAGE					
MIN	-0.036	-0.026	-0.100	0.03 9	-0.068
MAX	0.029	0.057	0.067	0.09 4	0.092
AVERAGE	0.000	0.000	0.000	0.00 0	0.001
% OUTSIDE TOLERANCE (±2.5CM)	6.3%	3.6%	23.3%	23.2 %	56.6%
SD PER 15'					
MIN	0.000	0.000	0.000	0.00 2	0.003
MAX	0.031	0.039	0.168	0.12 9	0.192
AVERAGE	0.017	0.008	0.013	0.01 1	0.017
% OUTSIDE TOLERANCE (±2.5CM)	4.2%	3.6%	8.0%	4.2%	13.2%
HEIGHT DIFFERENCE 15' COMPARED TO REAL TIME AVERAGE 15'					
MIN	-	-0.043	-0.115	- 0.04 3	-0.054
MAX	-	0.047	0.051	0.09 5	0.110
AVERAGE	-	-0.005	-0.007	0.00 2	0.011
% OUTSIDE TOLERANCE (±2.5CM)	-	15.7%	31.5%	33.3 %	45.3%

The SD values are increasing with distance. For the longest baseline, 86.8% of the SD are smaller than 0.025 m, which is quite good. This shows that Qinertia results are in general stable over time and there is not much difference between 1 h average logging and 15 min average logging.

Height difference 15 min logging compared to real time average 15 min logging out of tolerance is 10-20% higher per 15 min than per 1h. However, the averages match well with the real time data. The extreme values show min-max ranges of respectively 0.090 m, 0.166 m, 0.138 m and 0.164m. While at 1 h averages, only GDS1 min-max range was above 0.100 m. However, we always observe an increase of the outside tolerance rate of the height difference between post-processing and real time for both 1 h and 15 min logging.

III. CONCLUSION

The tests in this work were performed to find all the elements that go into the precise measurement of the height of OWF outside the standard RTK working range. For the installation of OWF foundations vertical installation tolerances of ±10 cm are imposed. Taking into account all error sources, deformation of the vessel, motion, lever arms that impact the height measurement of the foundation, the vertical accuracies for GNSS must be lower than 5 cm. In these tests, we considered the specifications of ±2.5 cm tolerance.

Based on test results, following conclusions are made:

- GNSS units:

The statistical analysis does not show a real difference between the different units, but a finer analysis of the time series graphs shows that overall all the receivers follow the same trend. But in some periods, units from the same brand follow the same trend and show significant variations from the other brands. Sometimes these variations are bigger than the tolerance, even if the same antenna is used. This confirms that using different receivers from different brands is necessary for reliable measure.

- Baseline length:

Data of DGPS5 were post-processed with base stations on different lengths. For shorter baseline the results are similar for both RTK mode and PPK mode. This is no longer the case for longer baseline. If, we are outside the manufacturer specification range +30 km for DGPS5, the results show a clear decrease in quality, but remains mostly within the recommended standards.

- RTK vs PPK:

During the tests, it was proved that for shorter baseline; according to manufacturer specification length PPK performances exceed RTK performances, despite the fact that for longer baseline PPK results show a decrease in quality. For static post-processing, the results of the different base stations match well with online services. For kinematic post-processing, the choice of the software program is important. The percentage of epochs in RTK fixed, per base with TBC software is very interesting and it looks like Qinertia has more difficulties to recover RTK fixed solution even for shorter

baseline. But, if Qinertia achieves RTK fixed, the results are very interesting, even for a short period logging. Although, if we want to reach at least a 95% certainty of having a logging within tolerance, the logging must be longer one hour or more and the base station should be within the manufacturer specifications range.

In conclusion, this paper shows that for precise installation of an Offshore Wind Farm (OWF) located far from the coastline, and to reach better measurement quality and centimeter accuracy outside the standard working range, it is important to take into account several parameters, like statistical parameters, settlements of the device brand, baseline length, time logging interval, and the choice of the software program. This work is of utmost importance in the GNSS application process and should open new possibilities in high accuracy positioning. In future work, we will test a high precision correction services from a Virtual Reference Station (VRS) method. This VRS service can provide RTK and PPK correction based on a network of base stations which can give stable results even in larger areas (longer baselines). This should improve the performances and maximize the centimeter level availability in challenging conditions.

Abstract—This is the development of a system that has been made, FMCW radar for human or patient breathing which will then determine the type of disease or disorder in the patient just by looking at the type of breathing. This research uses data from FMCW Radar for human or patient breathing, which is then converted to data that can be read in real-time by the public, doctors, or medical teams through a web server; the web server used is iotmedis.brin.go.id. The novelty of this study is that various types of respiratory data are taken from various points so that it will cause new analysis, namely the process of transmitting data on server traffic or uplink and downlink processes. Specific data and research novelty is how Multi patient respiratory data from OmnipreSense or FMCW Radar can be processed by a microprocessor using MQTT, and multi-patient data can be displayed on the server in real-time.

Keywords—FMCW Radar data; realtime monitoring; internet of things; transmission data; multi node

I. INTRODUCTION

Biomedical technology is overgrowing with various modes or types of research using the latest devices, such as Internet of Things (IoT) modules [12]. Some IoT modules, such as WiFi module server ESP32 [8,9] or ESP 8266 used for server communication, continue to be developed to get the best performance from previous research using FMCW radar. FMCW radar [10,11] is an active type of radar sensor that transmits continuous transmission power such as continuous wave (CW Radar); the FMCW type Radar is measured based on the difference in phase or frequency between the signal emitted and the signal received. In this study, the focus is on the patient's respiratory condition, which is monitored from the FMCW Radar [13-15], as shown in Fig. 1. The principle of this Radar can be seen in Fig. 4. and the Block Diagram of FMCW radar sensor shown in Fig. 2 and Fig. 3. This research will focus on displaying radar data and analysis on the iotmedis.brin.go.id server, multipoint. One of the analyses performed is RF Propagation Radar between patients and Radar with different distances [5,6,7].

II. THEORY

A. FMCW Radar Module and Block Diagram

Radar Frequency Modulated Continuous Wave (FMCW) [16-20] is a specific type of Radar that continuously varies the

frequency of a transmitted signal at a known rate over a set period, using a periodic linear function such as a sawtooth signal to modulate a sinusoidal radar signal [1]. An FMCW radar's unique ability to differentiate between ranges is accomplished by frequency modulating an ongoing transmission. It can even calculate range, velocity, or phase simultaneously for multiple targets using a process known as IQ demodulation and multiple chirps [2].

Furthermore, Fig. 3 shows the concept of FMCW radar for non-contact detection [3]. The splitter splits the signal generated by the FMCW signal generator. A power amplifier amplifies the signal before the transmitting antenna transmits it. Electromagnetic waves sent out from the transmitting antenna are received by the receiving antenna. Low-noise amplifiers amplify low-power signals without significantly degrading the signal-to-noise ratio (SNR).

Fig. 1. OPS243-C FMCW and Doppler Radar Sensor used in this research (personal research data).

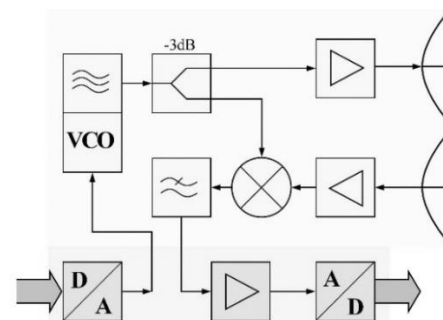

Fig. 2. Block Diagram of FMCW radar sensor (personal research data).

*Corresponding Author.

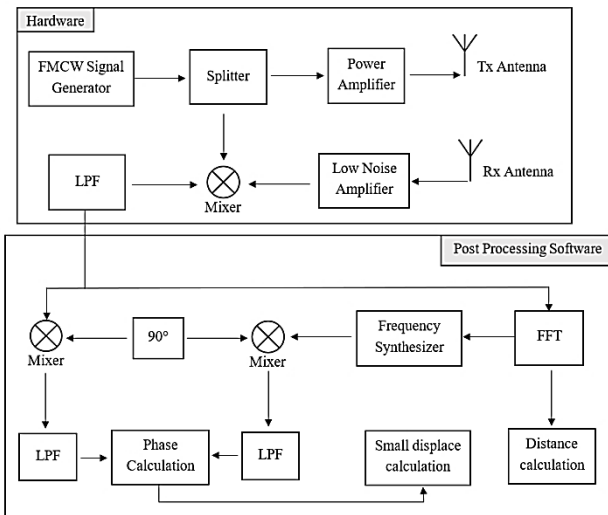

Fig. 3. The concept of FMCW Radar for non-contact detection (personal research data).

Moreover, the signal split by the splitter and FMCW signal generator is combined with the output of the low noise amplifier at the mixer. A lowpass filter (LPF) is used to filter the signal frequencies. The LPF principle is a filter that passes signals with frequencies below the cutoff frequency. After passing through the LPF, the output signal can be computed with a Fast Fourier Transform (FFT) to determine the target range. The output signal contains phase shift information. The LPF output is affected by the phase difference between reflected and transmitted waves. The formula used in this calculation is the phase difference caused by propagation delay due to target range shift.

The phase computation of the LPF output can be used to calculate a small shift. Phase processing from the LPF output is accomplished by IQ demodulation of the RF circuit. Two double-balanced mixers are combined. By changing the In-phase (I) and quadrature (Q) inputs in the branches of the IQ demodulator (1), the LPF output is combined with a reference signal [4]. Reference signals are written as (2) [4]. The phase data can then be obtained using the arctangent computation. A sinusoidal signal phase shifted by 90 from the FFT output is used as the basis for the LPF output approximation. It can determine the frequency of the output signal from the LPF by applying the FFT and performing Fourier transform computations. The phase-shifted output of an FMCW radar system is formulated as (3).

$$S_{LPF} = S_{LPFO} \cos(2\pi f_c \tau + 2\pi \frac{\Delta f \tau^2}{t_r}) \quad (1)$$

$$S_{syt} = S_{sy} \cos(2\pi \frac{\Delta f \tau^2}{t_r}) \quad (2)$$

$$\tau = 2\pi f_o^{-1} \tan^{-1} \left(\frac{E_q(t)}{E_i(t)} \right) \quad (3)$$

$$\varphi(t) = \tan^{-1} \left[\frac{Im\{Q(t)\}}{Re\{I(t)\}} \right] \quad (4)$$

B. Doppler Effect and FMCW Equation

The Doppler effect principle of this formula is used for systems on Radar, including FMCW; for that, it is necessary to

understand the formula for the Doppler effect, which is affected by the Speed of light (c). The Doppler frequency (f_r), which is determined by the Speed of light in air with the formula $c' = c/1.0003$, is slightly slower than in a vacuum, and v is the target speed, which can be written as Eq. 5. And the Doppler frequency is generally written with the formula by looking if $v < c'$ or $c' - v = c'$, and $f_d = 2v \frac{f_t}{c'}$ as the equation 6.

$$f_r = f_t \left(\frac{1 + \frac{v}{c'}}{1 - \frac{v}{c'}} \right) \quad (5)$$

$$f_d = f_r - f_t = 2v \left(\frac{f_t}{c' - v} \right) \quad (6)$$

Furthermore, in FMCW Radar, the signal is transmitted by periodically increasing and decreasing the frequency; when the echo signal is received, there will be a change in frequency or a time delay denoted by Δt . In FMCW radar, the phase and frequency differences between the transmitted and received signals are both measured. The signal from the radar position R radiates to a certain plane or object shown in Eq. (7).

Fig. 4. Ranging with an FMCW system (personal research data).

$$R = \frac{c_0 |\Delta t|}{2} = \frac{c_0 |\Delta f|}{2 \left(\frac{df}{dt} \right)} \quad (7)$$

c_0 = Speed of light ($3 \cdot 10^8$ m/s)

Δt = delay time (s)

Δf = measured frequency difference (Hz)

R = distance between the antenna and reflecting object (ground) (m)

$\frac{df}{dt}$ = frequency shift per unit of time

Furthermore, for the Range Resolution of FMCW radar, the bandwidth BW of the transmitted signal is decisive, as in chirp radar. However, the technical possibilities of the Fast Fourier Transform are limited by time, i.e., by the duration of the sawtooth T as Eq. (8). The resolution of an FMCW radar is determined by the frequency changes that occur within this time limit.

Fig. 5. Triangular modulation pattern (personal research data).

$$\Delta f_{FFT} = \frac{1}{T} = \frac{d(f)}{d(t) \cdot (f_{up} - f_{down})} \quad (8)$$

Δf_{FFT} = slightest measurable frequency difference

$\frac{d(f)}{d(t)}$ = Steepness of the frequency deviation

f_{up} = Upper frequency (end of the sawtooth)

f_{down} = Lower frequency (start of the sawtooth)

In the sinusoidal frequency modulation theory in Fig. 5, the time domain formula is obtained $y(t)$ value.

$$y(t) = \cos\{2\pi[f_c + B \cos(2\pi f_m t)]t\}, \text{ where } B = \frac{f_d}{f_m} \quad (9)$$

Moreover, Eq. (9) is applied to the condition of the radar transmission to the reflector or object, as in Eq. (10) and (11). Where δt is the time delay. Then, the transmitted signal is eliminated; this is due to the time delay and modulation index value in the data transmission process from the Radar to the object or reflector.

$$y(t) = \cos\{2\pi[f_c + B \cos(2\pi f_m(t + \delta t))](t + \delta t)\} \cos\{2\pi[f_c + B \cos(2\pi f_m t)]t\} \quad (10)$$

$$y(t) \approx \cos\{-4t\pi B \sin(2\pi f_m(2t + \delta t)) \sin(\pi f_m \delta t) + 2\delta t\pi B \cos(2\pi f_m(t + \delta t))\} \quad (11)$$

And the modulation spectrum spread (MSS) formula is as in Eq. (12) with an equal range of $0.5C/\delta t$.

$$MSS \approx 2(B+1)2(B+1)f_m \sin(\delta t) \quad (12)$$

The relationship between the adjusted Doppler frequency of the distance determination and the Doppler frequency of the moving target is shown in Eq. (13) and (14).

$$f(R) = \frac{\Delta(f_1) + \Delta(f_2)}{2} \quad (13)$$

$$f(D) = \frac{|\Delta(f_1) + \Delta(f_2)|}{2} \quad (14)$$

$f(R)$ = frequency as a measure of distance determination

$f(D)$ = Doppler frequency as a measure of the speed measurement

$\Delta(f_1)$ = frequency difference at the rising edge

$\Delta(f_1)$ = frequency difference at the falling edge

III. METHOD

The method in this research is shown in Fig. 7 by looking at a more specific step-by-step process in the flowchart, Fig. 6. while the real-time respiratory Radar is documented in Fig. 8. In the case of these radar-based respiratory patients, it is essential to understand the algorithm shown in Algorithm 1.

Algorithm 1: Radar-based respiratory system readout

```

Start
Initialize of Radar
While Radar Capture loop
  For (Patient's position ready), do
    --Capture and read respiratory patient data from Radar
    --Perform Filtering
    --Remove Noise
    --Perform respiratory motion detection
    --Calculate the respiratory frequency
    --Display the reading result
    --Pause for a few seconds to allow the next breath to be detected
  if (Respiratory patient's data is not readable)
    -- Restart the Radar Functionality and restart the detection of the respiratory patient.
  else
    -- Radar Error
  Finish
End
    
```

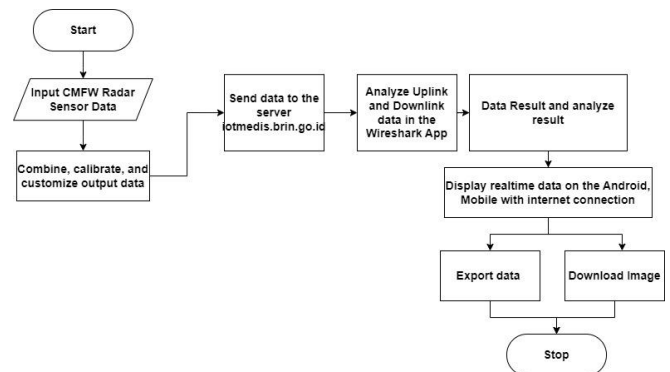

Fig. 6. Flowchart system (personal research data).

Fig. 7. Positioning of FMCW Radar during respiratory measurement (personal research data).

IV. RESULT AND ANALYSIS

The analysis results show the respirometer and magnitude of the Radar and patient with different distances, namely 30 cm, 60 cm, 100 cm, 300 cm, 450 cm, and 1000 cm or 10 meters. The respirometer and magnitude are different from each distance difference, and this is due to the Doppler frequency of the distance determination.

Fig. 9 shows the position of the FMCW Radar that has not been given a mounting case, this is for initial testing and to obtain signal accuracy.

Specifically, Data Radar for respiratory patients is shown in Fig. 10 (30 cm), Fig. 11 (60 cm), Fig. 12 (100 cm), Fig. 13 (300 cm), Fig. 14 (450 cm), Fig. 15 (1000 cm), and precisely or detail respiratory patient in Fig. 16 the difference is in the distance, which is the closest distance of 30 cm to 10 meters.

Fig. 9. Positioning of FMCW Radar on this research prototype (personal research data).

Fig. 8. Breathing GUI display of FMCW radar results (personal research data).

Fig. 10. Radar output for a respiratory patient at a distance of 30 cm.

Fig. 11. Radar output for a respiratory patient at a distance of 60 cm.

Fig. 13. Radar output for a respiratory patient at a distance of 300 cm.

Fig. 12. Radar output for a respiratory patient at a distance of 100 cm.

Fig. 14. Radar output for a respiratory patient at a distance of 450 cm.

Fig. 15. Radar output for a respiratory patient at a distance of 1000 cm.

Fig. 16. Radar output for a respiratory patient detail.

Furthermore, by sending MQTT-based data, with Raspberry Pi 4 as a processor, Radar data can be displayed on the Application Server iotmedis.brin.go.id in realtime from several patients or multi-nodes, as shown in Fig. 17. In Fig. 17, sample data is taken from four different patient conditions, namely with varying conditions of breathing, in taking samples, there is a conditioning of patient breathing, namely fast breathing, slow breathing, holding the breath, and normal breathing, this is done to get different results to get the most accurate radar reading system. As for the download process, it can be done quickly. Real-time patient respiratory data can be downloaded in SVG, PNG, and CSV formats, as shown in Fig. 18.

Fig. 17. Multi-data respiratory patient from server real-time and smartphone.

Fig. 18. Download realtime data.

V. CONCLUSION

FMCW radar can accurately detect breathing from each experiment, for example, when the patient is sitting, standing, or running results, or from differences in male and female gender who have different lung volumes. The experiments conducted produce respiratory data that is in accordance or synchronized with the FMCW radar measurement data. Next is to send breathing data to the iotmedis.brin.go.id server. While the server functions very well by displaying the respire meter and magnitude display of human or patient breathing results, this data can be viewed in real-time with Multi data Respiratory Patients' real-time use of Android and a smartphone with an internet connection. Finally, downloading real-time graphs of respiratory data can be done easily on a smartphone device. Specific data and research novelty is how Multi patient respiratory data from OmnipreSense or FMCW Radar can be processed by a microprocessor using MQTT, and multi-patient data can be displayed on the server in real-time; this process was a success and was successfully tested.

ACKNOWLEDGMENT

Thank you to the National Research and Innovation Agency (BRIN) of the Republic of Indonesia, especially colleagues at the BRIN Telecommunications Research Center, who have struggled to find data for the current research, and thanks to the team from Telkom University who helped complete this research. Hopefully, this research can continue to be developed by other researchers for the perfection of the study and can be a good reference for similar research, especially in the medical.

Abstract—Delay-Tolerant Networking (DTN) or Disruptive-Tolerant Networking comes under the category of networks that works without infrastructure wireless networks. DTN is one type of computer network that provides solutions for several applications. Delay tolerant network communications are networks that are accomplished by storing packets briefly in intermediate nodes till a certain time an end-to-end route is been re-setup or regenerated. This leads to thought as Delay Tolerant Networks. The paper presents the developed models using Artificial Neural Networks (ANN) and Convolutional Neural Networks (CNN) for predicting the best alpha, beta, and gamma parameters of Probabilistic Routing Protocol for Intermittently Connected Networks (PROPHET) protocol for delay tolerant networks. The first data set is generated using ONE simulator, and the generated data is analyzed using python panda's module. From the above dataset, 80% was used for training and the remaining 20% each has been used for testing and validation. The models were developed and tested using the r2 score for both models to predict alpha, beta, and gamma parameters. Based on the predicted parameters extensive experiments were done and it was found that the ANN model is better than the CNN model. The ANN model can predict optimum alpha, beta, and gamma whereas CNN Model failed to produce accurate prediction.

Keywords—DTN; ONE; Prophet; CNN; ANN

I. INTRODUCTION

Wireless Networks are dynamic. Nowadays Wireless Networks have become a part of life to communicate with others. Delay Tolerant Network (DTN) is a type of wireless communication to communicate data. DTN is a wireless network designed to operate efficaciously in severe conditions and over very massive distances, including space area communications [1]. DTN networks are proven the most beneficial network in deep space communications. Space communications are lengthily distances of millions and hundreds of miles. So routing the data between massive distances leads to delays in transferring data, records losses, and errors. Present communication technology is not enough to handle such problems. That is wherein delay tolerant networks are introduced [2, 3].

To increase the quality of data-transferring services in large communications machine learning models are developed to predict the parameters for given inputs. The main reason for choosing DTNs is it decreases the delay and increases the

throughput of the network [4]. As routing is a tedious task in communication hence DTN networks are chosen. Machine Learning (ML) belongs to a Sub-Category of Artificial Intelligence (AI) which doesn't need to program explicitly and it takes the input as the data samples and creates its insights from the data [5]. Here, the author created models of Deep Learning (DL) which take input as throughput and delay and output alpha, beta, and gamma values without simulation. Deep Learning is a part of Machine Learning where Neural Networks (NN) are used to solve machine learning problems [6]. Neural Networks require high computational power to train the model.

Two neural network models Convolution Neural Networks (CNN) and Artificial Neural Networks (ANN) are defined for prediction. CNN is an architecture that is used for deep learning algorithms, specifically in the processing of pixel data in image processing concepts and pattern recognition in computer-related vision. The CNN also is the feed-forward network that is widely used for routing and multiple communication network tasks [7, 8]. An ANN is formed from a group of linked units or artificial neuron nodes, which are the simple model of the biological brain. ANN is the capability of paralleled processing, working with incomplete data, and memory distribution [9, 10].

In the present work, the author created machine learning models which can predict the required values just by inputting the data without simulation. The proposed paper is arranged as follows: The introduction part introduces the delay tolerant networks of the prophet routing protocol by using two machine learning models such as artificial neural networks and convolutional neural networks. The literature survey part presents the existing system. The next section methodology and simulation deals with the methods used to implement the performance of the prophet routing protocol in DTNs and shows the output using ONE simulator. The results and simulation part presents the prediction values that came from the CNN and ANN models. Comparing the above two models one is more accurate for all models and selected the best one is ANN. After doing extensive experiments, it was found that the ANN model is better than the CNN model with an accuracy of 99%. The final section deals with the conclusion of the present work and proposed a future scope of this study.

II. LITERATURE REVIEW

Delivery ratio and packet drop influence quality of service in the delay tolerant networks are found and explained [11]. They proposed a solution to maintain the quality of service in DTN. They said that providing quality service in wireless networks is a challenging task. They investigated that no researcher now talked about fairness in the delay-tolerant network to maintain the Quality of service.

Research [12] worked in DTN routing as an ML classification problem. The authors discussed a machine learning-based style to directing the route for delay tolerant networks (DTNs). They explained various machine learning classification techniques to forecast a set of adjacent nodes which have the maximum possible to distribute communication to an anticipated location based on the message of the past delivery info. Their results showed that ML classification is a workable technique to expect network traffic, reducing overhead in epidemic-based routing approaches. Their model is not concentrated on new data arriving; this is the drawback of their work.

The thought and design of a machine learning-based routing for delay-tolerant planetary systems were discussed [13, 14]. They stated that the methods of Bayesian learning and reinforcement learning are used to enhance the routing decisions. Cognitive communications prototypes are studying popular ML algorithms which may be used further to enhance the functionality of existing routing algorithms. This approach proved the adaptive aids established in opportunistic transmitting strategies. In delay-tolerant network algorithms, strategies, and applications they incorporated Machine-Learning methods that can be fixed to overwhelm such struggles [15]. ML enhances the network lifespan in delay tolerant network. ML works on DTN routing by adjusting to the network changes diminishing congestion, and cutting overhead. The authors did not work to enhance the quality of service parameters like throughput and delay.

Study [16] used the Support Vector Machines (SVM) concept in machine learning used to solve non-linear classification and regression. The network traffic predictive method proposed here with some results, they prepared a dataset by using it for testing and training. They found that their approach to finding correctness is better than detecting the attacked traffic. The inclusion of neural networks of machine learning in wireless sensor networks is a useful tool to increase network performances was suggested in [17]. Work was done on ML techniques for the prediction of routing parameters and protocol to obtain optimal performance [18]. Their results show that improvement in the quality of service has been achieved.

Extensible Provisioning Protocol (EPP) is proposed to consider specific physical attributes of collaborating mobile nodes, at the side of their positional attributes with a current message time-to-live value, and determine routing hops [19]. Their primary aim is to increase message delivery rate while keeping an optimal balance between hop count, routing overhead, and cooperation among nodes. Extensive provisioning protocol works on delivery rate, this predictability value is manipulated using a weighted function of parameters

like bandwidth, power, nodes buffer, deliverable probability, and popularity. Extensive provisioning protocol maintains high probability delivery while structured overhead ratio average hop count and balancing average latency.

Cognitive Radio Mobile Ad-hoc Networks (CR-MANETs) are proposed as an efficient quality of service protocol, where a quality of service route is formed by exploiting Deep Reinforcement Learning (DRL) [20]. The higher Packet Delivery Ratio (PDR) and lower energy consumption provides by the proposed quality of service routing protocol than the Cognitive Radio Ad-hoc On-demand Distance Vector (CR-AODV). Moreover, the cognitive radio Ad-hoc on-demand distance vector protocol spends too much energy for the Route Request Packet (RREQ) flooding, while the quality of service routing protocol just unicast an RREQ packet to the best neighbor relying on the Deep Reinforcement Learning (DRL) model, thus consuming the small energy.

A systematic and comprehensive study of investigation on various modern approaches for intensifying security in Mobile Ad-hoc Networks (MANETs) is represented in [21]. A review on routing protocol and security attacks in mobile ad-hoc networks studied different security attacks in MANET. The author also examined how different layers under the protocol stack become vulnerable to different types of attacks [22]. A different routing protocol was designed for infrastructure-less networks and described the operation of each protocol and then compared their characteristics. They classified the routing method based on the operation [23]. An Ad hoc routing protocol of table-driven and on-demand category are selected for their study [24]. This paper studied table-driven routing protocols and listed their pros and cons in various situations. Results getting from the Taguchi approach, it is conferred that one ideal setting for one response metric is not similar to another metric. Hence multiple-response metric study may yield better results as it gives one optimum setting to enhance all metrics [25]. The data transfer between air-linked devices to the ground station using Micro Aerial Vehicle (MAVlink) protocol is explained [26]. The work describes the transfer between micro aerial vehicles or unmanned aerial vehicles to ground control stations in different circumstances.

They categorized various machine learning algorithms based on security approaches in mobile ad-hoc networks. The security approaches are divided into three dimensions (3D) ML Based Intrusion Detection System (IDS), trust-based models, and attack detection models. In the existing system people who worked on DTNs simulated the model to improve the network throughput and to decrease the delay. The above models are worked to increase the throughput of the delay tolerant networks using the simulation.

III. METHODOLOGY AND SIMULATION

A. Artificial Neural Network

Artificial Neural Networks (ANNs) are simply called Neural Networks (NN), these are the computing systems that are inspired by human and animal brain process information [27]. ANNs accumulate their expertise utilizing detecting the patterns and trained similarities within the data through experience, not from programming. The architecture of ANN is

shown in Fig. 1. An ANN is formed from a group of linked units or artificial neuron nodes, which are the simple model of the biological brain.

In the ANN, each neuron is connected with weights (Coefficients) to each one to transmit signals from each other and organized in layers [28]. The coefficients decrease and increase with the strength of the signal in some thresholds. Based on the threshold the signal passes through the neurons within the unit. The output of the signal (neurons) is calculated by the non-linear equation of the sum of its input.

Fig. 1. Architecture of ANN.

B. Convolutional Neural Networks

The problem with regular NNs is the lack of adaptability. At the same time complexity and size of the data to be increased, and the calculation power of the model should be increased this leads to more expensive neural networks. The parameter sharing is well known that the associated weight (Coefficient) in the CNN layers is remaining fixed. The parameter sharing in the CNN layer system will be less computationally intensive than the artificial neural networks. The architecture of ANN is shown in Fig. 2.

CNN is an architecture that is used for deep learning algorithms, specifically in the processing of pixel data in image processing concepts and pattern recognition in computer-related vision [29]. CNN also shows connectivity pattern similar to a human brain just like ANN and it consists of a group of linked neurons to connect. The CNN delivers better performance with image inputs, and also with speech or audio signal inputs.

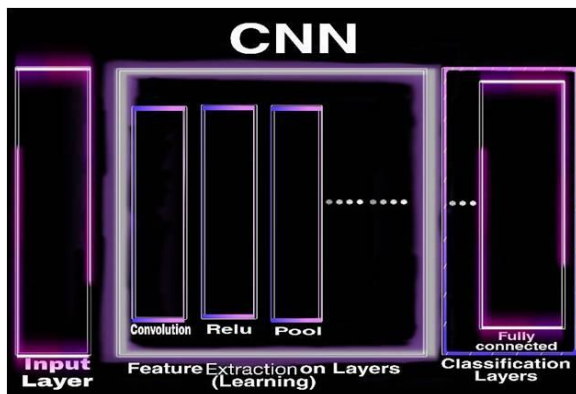

Fig. 2. Architecture of CNN.

C. Simulation

A simulation is a duplicate model that mimics the operation of a current or proposed work, imparting proof for decision-making by having the ability to test distinct situations or different scenarios or method modifications, or process changes. A network system is a set of network elements, including switches, routers users, links, and packages operating collectively to acquire some assignments. The scope of a simulation examination, can also most effectively be a system inside another system as in the case of sub-networks.

The state of a network system is the set of suitable parameters and variables that narrate the system at a precised time that incorporates the scope of the study. As an example, if the interest is in the usage of a link, then recognize the quantity of bits transmitted through the link in a second and the full capacity of the link, instead of the variety of buffers to be available for the ports in the switches connected via link.

1) *Types of simulators:* Different network simulators offer different features.

- Network Simulator2.
- Network Simulator3.
- OPNET.
- OMNeT++.
- NetSim.
- ONE.
- REAL.
- QualNet.
- J-Sim.

2) *ONE Simulator:* DTN is a communication networking pattern that enables communication in environments wherein there may be no end-to-end paths, communication opportunities come and cross and their programming languages can be very lengthy and now not even identified beforehand. Routing messages in this type of surroundings may be unique and different from traditional standard networks. This gap has created a need to find different types of new routing protocols that take efficaciously into consideration the distinct nature of these networks.

Distinct procedures may be tested and evaluated by way of simulation. So in this work, the author considers and thinks about Opportunistic Network Environment (ONE) Simulator shown in Fig. 3. Not like other delay tolerant networks simulators, which typically pay attention to routing simulation, the ONE combines delay tolerant network routing, mobility modeling, and visualization in one package deal that is effortlessly extensible and offers a rich set of reporting and studying modules. The ONE simulator is a simulation tool that is used widely by researchers operating on studies related to opportunistic and DTN networks. The default_settings.txt notepad file is essential for running or compiling the stipulated simulation.

Standardize the simulation's configuration parameters along with alpha, beta, and gamma parameters from the Internet Engineering Task Force (IETF) draft of the Prophet routing protocol wherein static values are not suitable for delay tolerant networks; that are dynamic values shown in Table I. The working environment and parameters for the simulation setup are shown in Table II.

TABLE I. IETF DRAFT PARAMETERS FOR PROPHET ROUTING PROTOCOLS

Parameter	Default Value	Description
Alpha	0.75	Predictability initialization constant
Beta	0.25	Delivery predictability transitivity scaling constant
Gamma	0.98	Predictability aging constant

TABLE II. VARIABLES FOR SIMULATION SETUP

Name of Parameter	Value
Time of Simulation	0.5hr-12hr
Node Density	40,80,120
Update interval	0.1
Interface Type	Simple Broadcast
Interface	Bluetooth
Interface Transmit Speed	2 Mbps
Transmit Range	100m
Routing Protocols	PRoPHET
Message TTL	300 minutes(5hours)
Message Generation Rate	25sec-35sec
Buffer Size	2 MB
Message Size	500 KB-1 MB
Movement Model	Shortest Path Map Based
Simulation Area Size	4500m×3400m
Load time	1Mb,2Mb,3Mb,4Mb,5Mb

D. Graphical User Interface Mode

The Graphical User Interface (GUI) additionally maintains track of noted events or activities and disposes them inside the panel of the event log. By clicking a message or a node name within the panel of the event log, more statistics may be proven approximately that message or node. The panel of event log dominance panel may be used to alter which events or activities are shown within the event log and the simulation also can be made mechanically paused in the case of some sort of activities or events.

E. Methodology

The overall algorithm for this work is as follows and the flow chart of the algorithm is shown in Fig. 4.

- Step1. Read the data from the data set.
- Step2. Processing the data.
- Step3. Apply artificial neural network.
- Step4. Apply convolution neural network.
- Step5. Evaluate and Compare the results.

A Java simulator is used to create the data, and Anaconda software is used to perform machine learning algorithms. Many people used Fuzzy Models to enhance the performance of DTN but here we used Machine Learning Models.

The following steps are discriminating the proposed methodology:

1) Reading the data:

a) By using the Pandas module imported the training Data set and testing data which was stored in Comma Separated Values (CSV) format.

b) Here, two lists are created that contain labels and targets.

2) Modifying data:

a) Using the time step of 30 apply time-series.

b) Here 30 denotes the input size to the model which is used to predict the targets.

c) Perform the Min Max Operation on the data.

d) Split the data for training and testing purposes with an 80:20 ratios.

3) Modeling: Modeling presents the detailed procedure for this study using two models such as convolutional neural networks as model-1 and artificial neural networks as model-2. The procedure of the above two models is discussed in the results and discussions.

Fig. 3. ONE simulator GUI.

Fig. 4. Flow chart for the proposed system.

IV. RESULTS AND DISCUSSIONS

A. Convolutional Neural Networks(Model-1)

1) Model-1 (CNN):

- a) Import Sequential and Dense from Keras. models and keras.layers respectively.
- b) Initialize the Sequential Model.
- c) Add 4 dense layers with normal kernel initializer and Rectified Linear Unit (ReLU) activation function with 20, 25, 10, and 1 neurons in each respectively.
- d) Compile the model with Adaptive Moment Estimation (ADAM) optimizer and Mean_Squared_Error Loss.
- e) Fit the model with a validation split of 20% and run it for 70 epochs.
- f) Make the Predictions and compare them with actual values shown in Table III.
- g) Compute the r2 Score.
- h) Finally, this model too failed to predict the output.
- i) Now retrain the Conv1D Model with modified data for 100 epochs and a 20% validation split.
- j) Compare the predicted values with the actual values and compute the r2_score.
- k) The model worked successfully with 98% accuracy.

For this experiment, a total of five samples were used, and the samples are numbered 0, 1, 2, 3, and 4. Where the actual and predicted values obtained from the above CNN model are more similar to each other and their accuracy is approximately 98%.

TABLE III. PREDICTED AND ACTUAL VALUES OF THE CNN MODEL

Value	Actual	Predicted
0	0.835	0.820380
1	0.840	0.826132
2	0.850	0.832045
3	0.855	0.837852
4	0.860	0.843962

Added four dense layers with the return sequence of each one with 70 neurons and Epoch of 1/100, 2/100, and 3/100 for each 1 neuron add the dense layer to get the predicted output shown in Table IV. The training dataset of the CNN model is shown in Fig. 5.

```
Epoch 1/100
4/4 [=====] - 0s 57ms/step - loss: 0.1997 - val_loss: 0.5681
Epoch 2/100
4/4 [=====] - 0s 18ms/step - loss: 0.2074 - val_loss: 0.5570
Epoch 3/100
4/4 [=====] - 0s 16ms/step - loss: 0.1916 - val_loss: 0.5449
```

Fig. 5. The training data set of the CNN Model.

TABLE IV. DENSE LAYERS STEP EPOCH OF CNN MODEL

Epoch	Step	Loss	Val_Loss
1/100 (4/4)	0s 57ms	0.1997	0.5681
2/100 (4/4)	0s 18ms	0.2074	0.5570
3/100 (4/4)	0s 16ms	0.1916	0.5449

```
Accuracy score of the predictions: 0.9872868277769965
```

Fig. 6. Accuracy output of the CNN model.

Fig. 7. Actual and predicted values of the CNN model.

Then retrain the Conv1D model with modified data for 100 epochs (1/100, 2/100, 3/100) and a 20% validation split. Compare the predicted values with the actual values and compute the r2_score. The CNN model worked successfully with an accuracy of 98% shown in Fig. 6. The graph shown in Fig. 7 represents the accuracy CNN model with actual and predicted values. The yellow line shows the predictions and the blue one shows those actual values.

B. Artificial Neural Networks(Model-2)

1) Model-2 (ANN):

- a) Import sequential and utils from TensorFlow.keras and import Flatten, Dense, Conv1D, MaxPool1D, and Dropout from TensorFlow. Keras. layers.
- b) Initialize the Sequential Model.
- c) Add 3 Conv1D Layers with kernel size (3) and ReLU activation function with 32, 64, and 128 neurons each.
- d) Add a Flattening Layer.
- e) Add three Dense Layers with ReLU activation function with 50, 20, and 1 neurons.
- f) Compile the model with mean_squared_error and Adam optimizer.
- g) Fit the model with a 20% validation split for 100 epochs.
- h) Predict the values using the model and compare with actual values and compute the r2_score shown in Table V.
- i) This model too failed to predict the outputs and gave less accuracy.
- j) Now retrain the Conv1D Model with modified data for 100 epochs and a 20% validation split.
- k) Compare the predicted values with the actual values and compute the r2_score.
- l) The model worked successfully with 99% accuracy.

TABLE V. PREDICTED AND ACTUAL VALUES OF THE ANN MODEL

Value	Actual	Predicted
0	0.835	0.830679
1	0.840	0.836426
2	0.845	0.842122
3	0.850	0.847810
4	0.855	0.853515

For this experiment, a total of five samples were used, and the samples are numbered 0, 1, 2, 3, and 4. Where the actual and predicted values obtained from the above ANN model are more similar to each other and their accuracy is approximately 99%.

The test data has been sent to the model to predict the output and the predictions have been stored in a variable as a data frame. The actual value and the predicted value have been compared to evaluate the model.

Add 3 Conv1D Layers with kernel size (3) and ReLU activation function with 32, 64, and 128 neurons each and Epoch of 1/100, 2/100, and 3/100 for each increasing neuron add the dense layer to get the predicated output shown in Table VI. The training dataset of the ANN models is shown in Fig. 8.

```
Epoch 1/100
4/4 [=====] - 1s 72ms/step - loss: 0.2069 - val_loss: 0.2005
Epoch 2/100
4/4 [=====] - 0s 20ms/step - loss: 0.0488 - val_loss: 0.1579
Epoch 3/100
4/4 [=====] - 0s 20ms/step - loss: 0.0362 - val_loss: 0.0081
```

Fig. 8. Training data set in ANN Model.

TABLE VI. DENSE LAYERS STEP EPOCH OF ANN MODEL

Epoch	Step	Loss	Val_Loss
1/100 (4/4)	1s 72ms	0.2069	0.2005
2/100 (4/4)	0s 20ms	0.0488	0.1579
3/100 (4/4)	0s 20ms	0.0362	0.0001

Now retrain the Conv1D Model with modified data for 100 epochs and a 20% validation split. Compare the predicted values with the actual values and compute the r2_score. The model worked successfully with 99% accuracy shown in Fig. 9.

```
Accuracy score of the predictions: 0.9897303879778176
```

Fig. 9. Accuracy output of the ANN model.

The actual values of the data and the predicted values of the data have been plotted into a graph to check the variance between values shown in Fig. 10.

After the predicate of the actual and predicted values using ANN and CNN models the final output should be shown in Table VII. The actual values of the data and the predicted values of the data have been differentiated with equal intervals of 0.10, 0.01, 0.01, 0.009, and 0.009.

Fig. 10. Actual and predicted values of the ANN model.

TABLE VII. PREDICTED VALUES OF THE CNN AND ANN MODELS

Value	CNN Predicted	ANN Predicted
0	0.820380	0.830679
1	0.826132	0.836426
2	0.832045	0.842122
3	0.837852	0.847810
4	0.843962	0.853515

V. CONCLUSION AND FUTURE SCOPE

Prophet routing protocol is one of the extensively studied delay-tolerant network protocols. In probabilistic routing protocol for intermittently linked networks, a message is forwarded to a touch node if the touch node has a better delivery quality of being expected to the destination of the message. A delay tolerant network is a Prophet routing protocol that gives confident delivery of facts using automatic store and forward mechanisms. Delay tolerant network comes under the category of networks that works without infrastructure wireless networks. Each data packet of transmission is received and immediately forwarded if possible, but these are stored for further transmission if forwarding is not possible currently however is predicted to be possible in future transmission.

In this research work, ANN and CNN models are used to predicate the best alpha, beta, and gamma parameters of prophet routing protocol for delay tolerant networks using a dataset simulated by ONE simulator. While considering models like CNN, ANN performed well on the test dataset. Of the dataset, 80% was used for training and the remaining 20% each has been used for testing and validation. While comparing the two models (CNN and ANN) the impact of CNN is mainly on the dynamic values of all datasets with an accuracy of 98% and ANN is mainly on the dynamic values of all datasets with an accuracy of 99%. Comparing the above two models one is more accurate for all models and selected the best one is ANN with 99%. After doing extensive experiments, it was found that the ANN model is better than the CNN model with an accuracy of 99%. At the same time, the ANN model can predict

optimum alpha, beta, and gamma whereas the CNN model failed to produce accurate prediction.

The future scope should be trying to simulate a large number of datasets and trying to use predefined models like VGG-16, ResNet, and Efficient Net. Also considering the other parameters of DTN Routing Protocols to predicate the accurate results.

DIP-CBML: A New Classification of Thai Dragon Fruit Species from Images

Naruwan Yusamran, Nualsawat Hiransakolwong

Department of Computer Science-School of Science, King Mongkut's Institute of Technology, Ladkrabang Bangkok, Thailand.

Abstract—The attractiveness of dragon fruit is that it has a strange exterior, beautiful colors, and high nutritional value. In Thailand, there is both import and export of dragon fruit. Each package for export must contain only one species of dragon fruit. From the survey, there are seven species of dragon fruit cultivated in Thailand and only some farmers can identify them on his/her farm. Therefore, this research focuses on the classification of Thai dragon fruit from laboratory images and outdoor images; which is different from the previous works which studied only laboratory images. This method was named DIP-CBML that stands for digital image processing with content-based and machine learning. The method consists of image type identification, pre-processing, red and yellow classification, image background removal, and six classes of red species classification. From the results, DIP-CBML can work with both datasets. It gave 100%, 100% and 95.53% accuracy for the image type identification, red and yellow classification, and the classification of six red species respectively. Hopefully, this research will lead to the innovation for the pre-harvest classification of Thai dragon fruit cultivars, applied to industrial applications, and robot harvesting. In the future, may add value to the yield of Thai dragon fruit cultivation.

Keywords—Dragon fruit; classification model; outdoor dataset; image pre-processing; segmentation

I. INTRODUCTION

Dragon Fruit is a fruit in the cactus family (Cactaceae) with genus *Hylocereus* Spp. and *Selenicereus* Sp. It has been planted in Thailand since 1997. With its unusual exterior and beautiful colors, it has received much attention. The advantage of dragon fruit is that it is a fruit that has high nutritional value. It can be used in the food, pharmaceutical, and cosmetic industries [1-4]. Since dragon fruit is a juicy fruit, it will be bruising and perishable in a short time after harvesting. It must be eaten or processed quickly, or storing at low temperatures for slowing down spoilage [5].

Currently, there is import and export of dragon fruit. Therefore, the agricultural standard for dragon fruit has been established by the National Bureau of Agricultural Commodity and Food Standards (ACFS), the Ministry of Agriculture, and Cooperatives of Thailand. Dragon fruit is divided into three groups by the peel color and the pulp color, namely Group 1, red peel with white pulp (*Hylocereus undatus*), Group 2, red peel with red pulp (*Hylocereus polyrhizus*) or pink pulp (*Hylocereus* spp.) and Group 3, yellow or gold peel with white pulp (*Hylocereus* sp. and *Selenicereus* sp.). The package must contain the same dragon fruit species per package [6].

From a survey on the cultivation of dragon fruit in Thailand. Loei Province located at the top of the Northeast of Thailand is the area that can harvest the most products in the country [7]. It was found that there are seven species of Thai dragon fruits planted. If divided like ACFS, the First group has two species, which are Jumbo White and Vietnamese White. The second group has four species, which are Pink, Siam Red, Taiwan Red, and Ruby Red. The third group has only one species called Israel Yellow. Each species has different care and maintenance which affects cultivation costs and selling prices.

The main problem is that only some farmers can identify the cultivars which are grown. Like the middleman, most farmers only know the color of the peel and of the pulp. As a result, the price of each species of dragon fruit is determined according to the standard in only three groups. If farmers or middlemen can classify dragon fruit species, they know how to manage production of dragon fruit, take care the produce before and after harvesting, and manage the transportation according to the specific morphology of each species. This will affect the cost and selling price, and also promote the conservation of fruit species.

However, species identification based on morphology requires a great deal of knowledge and expertise. For the general public new farmers and middlemen can identify dragon fruit species accurately and easily, the researcher has researched only the laboratory dataset [8,9] which gave a high accuracy of 98%.

Therefore, this research will present the classification of Thai dragon fruit species from images in both indoor (laboratory) and outdoor datasets. The research conducted experiments with image processing techniques, content-based techniques, machine learning, and deep learning. In the future, hopefully, this will lead to the development of innovations for the classification of Thai dragon fruit species pre or post harvesting that can be easy to use, convenient, and suitable for people. This can be applied to industrial applications and robot harvesting. It may add value to the yield of Thai dragon fruit cultivation. This paper has presented Theories and Literature Reviews in Section II, The DIP-CBML Method in Section III, Experiment Results in Section IV, Discussion in Section V, Conclusions in Section VI and Suggestion in Section VII.

II. THEORIES AND LITERATURE REVIEWS

A. Color Model

Color Model is a color system that controls the display of digital images on a digital device. Each type of color model has its own way of generating colors that have different structures. Therefore, different types of color models are used for different purposes [10]. The most popular color models in image processing are the RGB, HSV, and Lab model.

The RGB is a color system formed by the combination of primary colors. There are Red, Green, and Blue which are channels of color digital images. Each channel has 0-255 color levels [11].

The HSV is a color model which is close to the color perception of human vision. It consists of Hue (H), Saturation (S), and Value (V). Hue is the color tone defined by the angle of the color wheel. In image processing by OpenCV, the H value ranged from 0° to 180°. The S is the saturation of the color tone. If S is 0, the white color is always displayed. The V is the brightness of the tone. If the brightness value is 0, the result will be black. In OpenCV processing, S and V values ranged from 0 to 255. If both values are set to 255, it will display a pure color tone [12, 13].

The Lab color model consists of three channels. There are the L channel, a channel, and b channel. L channel is the lightness value, an a channel is a green gradation to red, b channel is a blue gradation to yellow. In OpenCV, Lab values are scaled in the range from 0 to 255 for all three channels [11, 13].

B. Digital Image Processing

Digital image processing is a process that uses a digital image as input for a specified processing purpose, such as image resizing, converting a color image to grayscale, data augmentation, etc. A digital image can be represented by $F(x,y)$ where x and y are spatial coordinates. Each coordinate is called a pixel. There are three types of images: color images, grayscale images, and binary images [14].

C. Image Pre-processes

Image pre-processing is an important step in digital image processing because the raw data from the acquisition, which is interpolated with multifactorial noise, cannot be processed immediately. Therefore, images must be done with image pre-processes to reduce those noise. For example, image segmentation is a technique that helps extract and segment desired or unwanted image data. It helps to get more specific information and it is easier to analyze information. However, processed data must be ensured that the remaining information is correct. There is no excess or missing [15]. Techniques used in image segmentation are the segmentation by thresholding-based, edge-based, area-based, and energy-based [16-18]. There are also other techniques to prepare data such as intensity estimation, geometric estimation, elementary processing, holistic processing, etc. [15].

D. Feature Extraction

Feature extraction is the process of extracting important characteristics of an image to describe all information in the

image. The feature descriptor may be all or part of the image data that can represent the whole image. In general, attributes about color, shape, size, and texture are used in image analysis or image classification. Of course, image data may not have only one attribute that can identify specific characteristics. For Image classification by machine learning, the image features will be represented by a feature vector that is a 1-dimensional array [14, 15]. In contrast for deep learning, the feature extraction process is performed automatically. The researchers are responsible for specifying the desired feature map size, making it very convenient for researchers.

E. Image Classification Model

The Image Classification Model is a classifier that was created to identify or classify groups of image data. The classifiers use rule-based classifiers which are processed under a "condition" that is defined in the IF condition THEN conclusion form. Image classification model with a content-based feature in which researchers must extract features for suit methods such as support vector machine (SVM), k-nearest neighbor (KNN) and decision trees (DT), etc. [19-24].

The deep learning model is the popular automated method. The model gives high predictive performance [25] by mimicking the operation of human neurons by building a neural network with multiple nonlinear processing layers [14, 26]. Each layer takes the result of the previous layer as input. The strength of deep learning is that it supports the extraction of ambiguous features. The model extracts feature automatically. The researcher is responsible for preparing the data that will be used for learning only. It is very convenient for researchers.

F. Literature Reviews

This research focuses on reviewing literature related to fruit classification to study methods that can be used to classify Thai dragon fruit from images. Literature reviews are found that most researchers carried out research in four major steps: data acquisition, data pre-processes, feature extraction, and classification [15, 27]. Image datasets used include both image datasets created in the laboratory [22, 24, 28-31] and image datasets created at the outdoor environment [20, 23, 32-37]. Of course, image datasets from outdoor environments are more complex than those created in laboratories. Therefore, the steps to process this type are also more complicated.

Most researchers focused on image pre-processing like image segmentation techniques to prepare image data differently. Either the graph cut method [20], the conversion of a color image to a binary image by calculating the threshold value [8, 29], or using machine learning to segment the fruit from the background. This can be applied to the detection of fruit on the tree [23, 33, 34, 36, 37]. It reduces the complexity of the image and improves efficiency in feature extraction and classification. Muresan and Oltean [28] has proposed the use of threshold values in image segmentation with the HSV color model to separate the dragon fruit from the background of the plant. The objective is to detect and count the amount of dragon fruit on the tree by the image dataset of *Hylocereus Undatus* dragon fruit species in the outdoor environment. The accuracy is more than 80%.

Jana. et al. [20] has presented the recognition of fruits from the natural image in eight types. The image data was prepared by the graph cut method, which can separate the background from the fruit very well. After the image data preparation step, color and texture features were used for fruit recognition with the support vector machine (SVM) algorithm, giving an accuracy of 83.33%.

Muhammad [22] presented the use of color, texture, shape, and size attributes in classifying four date palm species by histogram of the local binary pattern (LBP) and Weber local descriptor (WLD) data. The Fisher discrimination ratio (FDR) was used to select the top 10 most important features that gave the greatest FDR. For shape and size features, the image data were analyzed from four features, namely Major axis length, Minor axis length, Ellipse eccentricity, and Area. In total, there are 14 features with a support vector machine (SVM) which gives an accuracy of up to 99%.

Fu. et al. [23] has presented the detection of bananas on the tree with machine learning. There is an image data pre-processing to reduce the complexity of the image by using Otsu's algorithm to find threshold values for converting HSV images to binary images. In the detection process, a histogram of oriented gradients (HOG) and local binary patterns (LBP) were used to extract the shape and texture features of the banana. The experiments found that the algorithm which combines HOG, LBP, and SVM gives maximum efficiency. It has an accuracy of 100% for the training set and 89.63% for the test set.

The DIPDEEP method [8] was the classification of Thai dragon fruit from a laboratory images dataset. DIPDEEP used image processing techniques to prepare images based on a threshold value to separate the background from the dragon fruit. Then, the images were used to classify the seven cultivars using rule-based classification techniques to classify dragon fruit groups by skin color and deep learning model based on a 13-layers of convolutional neural network that starts with an RGB image size of 100x100 pixels as an input layer and ends with six output nodes. Optimizer based on Adam algorithm and set Learning rate equal to 0.001, batch size and epoch equal to 100. The accuracy of red and yellow classification was 100%, the accuracy of DIPDEEP was 98.80%. For outdoor images, the results were not satisfactory.

The CBML model [9] was the classification of Thai red dragon fruit from a laboratory images dataset. CBML method used a content-based model that uses a total of 34 attributes, consisting of two attributes of texture features from dissimilarity (D) and asm properties only directions: 0° of GLCM algorithm with RGB image and 32 attributes of color features with RGB, HSV, and AB of Lab color model, for each channel in any color model using four statistical features: mean, standard deviation, skewness, and kurtosis. Each attribute used minmaxscaler to normalize into the 0 to 1 range and uses machine learning for giving optimization results with the support vector machine (SVM), setting kernel for polynomial in 8 degrees. It has an accuracy of 100% for the training set and 98.47% for the test set. The outdoor image was not processed.

Therefore, this paper focused on modeling the classification of Thai dragon fruit species from images that support two types of image datasets; laboratory and outdoor. The required model will support pre- and post-harvest processing. Hopefully, this research will be applied to industrial applications and agriculture technology.

III. THE DIP-CBML METHOD

This paper presents algorithms to classify species of Thai dragon fruits automatically that support two types of image datasets called DIP-CBML which stands for digital image processing with content-based and machine learning. The DIP-CBML will be able to process both types of images when DIP-CBML is able to classify the image types. It makes subsequent processing work correctly according to the characteristics of the two image types which are different processes. If the DIP-CBML can classify the group of dragon fruit from the peel color which is red or yellow, the processing time was reduced because the yellow group takes shorter time to process than the red group. Therefore, the DIP-CBML structure consists of image type identification, pre-processing, red and yellow classification, image background removal, and six classes of red classification as Fig. 1.

A. Datasets

The image datasets consisted of 9,754 laboratory images and 9,067 outdoor images from [8], each image containing one dragon fruit of one species. Both datasets were taken with a mobile phone camera. The 1:1 aspect ratio was set for laboratory recording. Unlike the outdoor images, the aspect ratio is set independently, i.e., 3:4 and 9:16, resulting in different image sizes with any lighting conditions.

In addition, the characteristics of the images are different, because the images in the laboratory are an image of the post-harvest dragon fruit placed in a photographic box and used black velvet fabric in the background as Fig. 2(a), but the outdoor images are the dragon fruit growing on the tree until it is ready to be harvested as Fig. 2(b). Obviously, the outdoor images have more complex backgrounds such as sky, ground, grass, and branches, while the laboratory images have a black background.

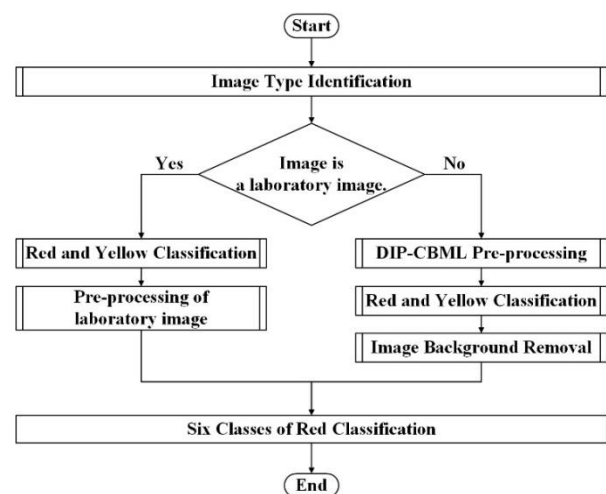

Fig. 1. The Steps of DIP-CBML method.

Fig. 2. Examples of two datasets as (a) laboratory images and (b) outdoor images.

B. Image Type Identification

This step is used to identify the type of images from either laboratory image or outdoor image because the image data pre-processing of the two types are different. The procedure is shown in algorithm 1.

Algorithm 1: Image Type Identification

```

Input: Original image with RGB color model.
Output: Type of image; laboratory or outdoor.
Resized Image = Resize the input image to not over 300 on each side.
R = R channel of Resized Image.
Gray = Gray scale of Resized Image.
Mean Threshold = (Sum of R value)/(image size)
MKR = The conversion result of R image to binary by Mean Threshold.
BG Pixel = The gray pixel at the same coordinate as a black pixel in
            the MKR.
If (BG Pixel != 0) then
    MP = Mean value of BG Pixel
    STD = Standard Deviation value of BG Pixel
    KS = Kurtosis value of BG pixel
    If (MP < 31.77) then
        | Output is a laboratory image type.
    else if (MP > 48.62) then
        | Output is an outdoor image type.
    else
        | If (STD < 15.27) then
        | | Output is a laboratory image type.
        | else if (STD > 20.52) then
        | | Output is an outdoor image type.
        | else
        | | If (KS >= 8.32 && KS <= 54.37) then
        | | | Output is a laboratory image type.
        | | else
        | | | Output is an outdoor image type.
        | | End
        | End
    End
End
else
    | Output is an outdoor image type.
End
    
```

From the characteristics of the laboratory images with a flat background, it is not as complex as the outdoor images. Therefore, the three statistical properties of the background pixels are used to identify the type of images. There are the mean, standard deviation, and kurtosis as shown in Fig. 3.

Fig. 3. The statistical properties of each type of image.

From the random 700 samples of each type of image, it was found that the laboratory images had an average of background pixels in a gray level ranging from 2.39-48.62 and outdoor images in ranging 31.77-196.22, because there is an overlap range. When considering the other statistics of the overlapping range, it was found that other statistics such as mode, median, standard deviation and skewness still overlap. Therefore, the statistics value that has the least overlap is the standard deviation. From the overlapping average range, it was found that the laboratory images had a standard deviation of background pixels in a gray level ranging from 6.88-20.52 and outdoor images from 15.27-44.78. Successively, at the overlapping standard deviation range, it was found that a kurtosis of background pixels in a gray level range is not overlapping. The laboratory images had a kurtosis of background pixels in a gray level ranging from -0.15-5.71 and outdoor images from 8.32-54.37.

Therefore, this step begins with the original image being reduced to a size of no more than 300x300 in proportion. Set the R image to represent the R channel of the RGB image and Gray to represent the grayscale image. The R image was used to create a segmentation mask, which is a binary image, using the mean threshold as the threshold value for the binary conversion as equation (1).

$$\text{Mean Threshold} = (\text{Sum of R value})/(\text{image size}) \quad (1)$$

If any pixel of the R image is greater than the mean threshold, this pixel will be set to white as the object, otherwise, this pixel will be set to a black background. The morphology function opening is used to decrease noises of the object, the Fill Hole from OpenCV is used to fill in any hole in the object, and the morphology function erosion is used to slightly decrease the edges of the image, respectively. The result is the MKR mask, a binary image with black pixels as the background (BG) as shown in Fig. 4 on the 2rd row.

Fig. 4. Characteristics of Laboratory and Outdoor images after converting to binary mask by using the mean threshold.

For an image where background pixels are not found, it can be concluded that it is an outdoor image. On the other hand, calculate the mean, standard deviation and kurtosis of BG pixels which is a gray pixel at the same coordinate as a black pixel in the MKR and replace mean with MP, replace standard deviation with STD and replace kurtosis with KS.

As mentioned above, the mean of the background pixels of both images overlaps. Therefore, the type of image can be clearly identified. An image with an average less than 31.77 is a laboratory image. An image with an average greater than 48.62 is an outdoor image. If any image is within the overlapping average range of the background pixels which is from 31.77-48.62, consider a standard deviation of the background pixels instead. If a standard deviation of the background pixels less than 15.27, an image is a laboratory image. If a standard deviation of the background pixels greater than 20.52, an image is an outdoor image. As the same, any image is within the overlapping standard deviation range of the background pixels which is from 15.27-20.52, consider a kurtosis of the background pixels instead. If a kurtosis of the background pixels between 8.32 and 54.37, an image is a laboratory image. On the other hand, that image was an outdoor image.

C. DIP-CBML Pre-processing

As mentioned above, the image data pre-processing of the two types are different. The laboratory image can use the process of creating MKR mask as image pre-processing but not for an outdoor image. Therefore, the pre-processing of DIP-CBML was used to support an outdoor image especially. This process still aims to separate the background from the dragon fruit by creating a mask that can be used to divide into two parts. The steps as shown in algorithm 2 and Fig. 5, DIP-CBML uses the graph cut algorithm to create the segmentation mask. It is generally known that graph cut requires a position of interest object covered in a rectangle. Therefore, it needs to locate the dragon fruit before the graph cut algorithm was used to create the segmentation mask.

To locate the dragon fruit, the HSV color model was used to create a binary image that helps locate the fruit in the image by HSV ranging same as [8] which consists of the H range, S range, and V range in the OpenCV system. There are H ranging from 0-23 and 151-179 for a red and 23-37 for a yellow. For S and V ranging from 100-255. The result is a binary image that is created by any pixel in the HSV image within this range will be scaled as a white pixel represent for a fruit pixel. On the contrary, a black pixel is an out of range; represent for a background pixel. Then, bring the binary image

to the detect location of dragon fruit subprogram as shown in Fig. 5.

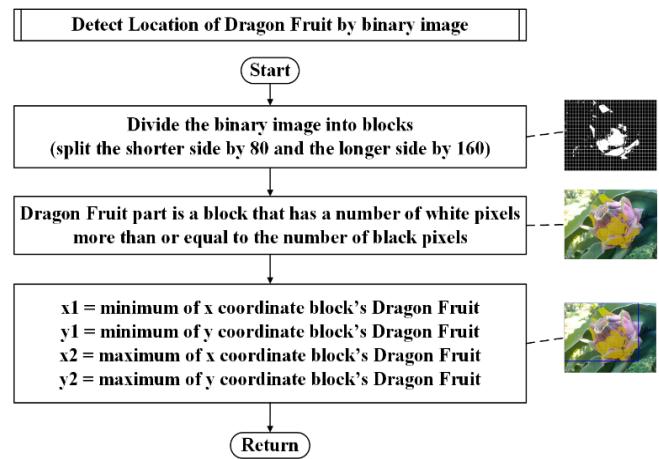

Fig. 5. Flowchart of detecting dragon fruit location.

In Fig. 5, the binary image is divided into grid blocks by that have no more than 160x80 blocks. The size of each block was calculated by dividing the shorter side by 80 and the longer side by 160. For example, the image size is 4,608x2,240 pixels, the longer side was divided, as $4,608/160 = 28.8$ approximated 29, and the shorter side was divided, as $2,240/80 = 28$. Therefore, each block size is equal to 29x28 pixels. Then, the binary image is segmented into many blocks with 29x28 pixels as the grid block size. From this block size, the number of blocks is equal to 158x80 blocks. The number of blocks is not over 160x80 blocks. Any block with the number of white pixels greater than or equal to the number of black pixels is defined as part of the dragon fruit. The position of all the blocks that are part of the dragon fruit is the location of the fruit. If all blocks are merged into one rectangle then let x1 equal the minimum value of the x-coordinate, y1 equal the minimum value of the y-coordinate, x2 equal the maximum value of the x-coordinate, and y2 equal the maximum value of the y-coordinate. The coordinate (x1,y1) is the northwest corner of the rectangle, and the coordinate (x2,y2) is the southeast corner of the rectangle. The coordinates (x1,y1,x2,y2) will be the boundary used to segment the image with the graph cut, which must not be equal to the border of the image. If the coordinates (x1,y1,x2,y2) is equal to the border of the image, the binary image was modified by the morphology function erosion with kernel size 5x5 and returned to the detect location of dragon fruit processes until the coordinates are not equal to the border of the image. Then, the coordinates (x1,y1,x2,y2) were set as the rectangle that will be used to create the mask by the graph cut algorithm that can separate the background from the dragon fruit.

To create the mask, DIP-CBML uses a graph cut algorithm with the coordinates which were modified to four directions, namely (x1,y1,x2,y2), (0,y1,x2,y2), (x1,0,x2,y2), and (0,0,x2,y2) because the background around the fruit was removed as shown in Fig. 6. The four results are RGB color images, converted them to a mask that is a binary image by setting the part of the dragon fruit to be a white pixel and the

background part to be black. Then we bring all four masks to the white pixels together with an intersection mask represented by the HSV1-Mask.

The HSV1-Mask can be used to separate the background from the dragon fruit where black pixels refer to the background and white pixels refer to dragon fruit. Any coordinate in RGB image that has the same coordinates as a background pixel are changed to 0. The result is RGB image with some or all of its background black, represented by the Image-HSV1. The illustration of DIP-CBML pre-processing as shown in Fig. 6 and the result of this step is shown in Fig. 7(b).

Algorithm 2: DIP-CBML pre-processing

```

Input: Original image with RGB color model.
Output: Image-HSV1, HSV1-Mask, and Coordinates (x1,y1,x2,y2).
hsv_img = Result of converting input image RGB to HSV color model.
binary_img = Result of converting hsv_image to binary by HSV ranges from [8]
(x1,y1,x2,y2) = Return values of Detecting Dragon Fruit Location by binary_img

D. Red and Yellow Classification

Red and yellow classification is the procedure to classify the dragon fruit group into two groups using the characteristics of its peel color, consisting of dragon fruit red peel, and yellow peel. This process has already been discussed in [8]. The laboratory images can use the original image for processing. The results of the laboratory images are highly satisfactory, but the results of outdoor images are not. Therefore, in this research, the Image-HSV1 was used as an input image to classify the dragon fruit groups based on peel color instead of the original image.

The process uses HSV color images to calculate the red ratio and yellow ratio by using the HSV range of red and yellow as the threshold value for counting the number of red pixels and the number of yellow pixels. There is an H value from 23-37 for yellow. The red is divided into two ranges: 0-23 and 151-179. The Saturation (S) and Value (V) values are set from 100-255. Then divide each value by the image size and multiply by 100 to calculate the percentage as Eq. (2) and (3). If any image has a yellow ratio greater than a red ratio, it is an image of yellow peel. The method can immediately be classifying the species of dragon fruit in the image because there is only one species of yellow peel in the dragon fruit.

$$Yellow\ ratio = YP / (image\ size) * 100 \quad (2)$$

$$Red\ ratio = RP / (image\ size) * 100 \quad (3)$$

where YP is the number of yellow pixels and RP is the number of red pixels.

This work has performed greatly for the results of outdoor images. For laboratory images, the results are still satisfactory. This step reduces the volume of the dataset because the remaining data are red peel groups and affects processing time. It is an advantage of adding this step into research operations.

E. Image Background Removal

Image background removal is a process in which only the background is removed from the image. From Fig. 7(b), the pre-process can remove the background of some images completely, especially the laboratory images. While some outdoor images still have backgrounds left. Therefore, DIP-CBML added this process to remove the remaining background, especially the outdoor image by following the steps in algorithm 3. The illustration of image background removal process is shown in Fig. 8.

Fig. 8. Illustration of image background removal.

Algorithm 3: Image Background Removal

Input: Original image with RGB color model.

Output: Fit scaled image.

HSV2-Mask = Result of remaining background removal by HSV color model.

A-Mask = Result of background removal by Lab color model.

HSVA-Mask = Result of Intersection A-Mask and HSV2-Mask

Erosion Mask = Result of Erosion HSVA-Mask with kernel 5x5

Filled Hole Mask = Result of Fill Hole HSVA-Mask by OpenCV Library

Removed Background Image = Result of Removing Background in the input image by Filled Hole Mask

Fit Scaled image = Result of cropping proportion of fruit and fit scale its size not over 100 on each side

This process is designed with two background removals, first using an output of pre-process procedure as shown in algorithm 2; input to a subprogram of the remaining background removal by the HSV color model and the second using the original image input to subprogram of the background removal by lab color model. Both subprograms yield two masks named HSV2-Mask as Fig. 10(b) and named A-Mask as Fig. 10(c) respectively. After that take the two masks to the intersection represented by the HSVA-Mask as Fig. 10(d). Use the morphology function erosion to remove extraneous pixels in the HSVA-Mask with kernel size 5x5 and fill the hole with the OpenCV library. Then use the modified HSVA-Mask to remove the background from the image where black pixels refer to background pixels and white pixels refer to dragon fruit pixels. Any coordinate in the original RGB image with the same coordinate as the background pixel will be changed to 255. The result will be a dragon fruit image with a white background, as Fig. 10(e), and the final step is to fit scale the image of the dragon fruit proportion to 100x100 pixels, the result is Fig. 10(f).

1) *Subprogram of remaining background removal by HSV color model:* This subprogram is the remaining background removal process. The input data is the result of pre-processing as shown in algorithm 2 and Fig. 6. consisting of Image-HSV1, HSV1-Mask, and Coordinates (x1,y1,x2,y2). This data will be used as initial processing steps in the algorithm 4 which is processed similarly to pre-processing as mentioned in Section 3(C). The output of the pre-processing procedure was reprocessed again to remove any pixel that expected part of the background out of the image. The final output of this subprogram is a binary image named HSV2-Mask that can be used to split the background off.

As algorithm 4, starting from the processing of the check mask and image subprogram as shown in algorithm 5, the Image-HSV1 is recalculated for the yellow ratio and the HSV1-Mask is detected for the new coordinates, represented by coordinates (a1,b1,a2,b2) by the detect location of dragon fruit subprogram as Fig. 5 and take the coordinates (a1,b1,a2,b2) to remove the background from the image by 4 graph cut. The result is a binary image represented by the RM-Mask.

If the background has been completely removed, the yellow ratio of Image-HSV1 will be equal to 0 that means not a yellow pixel in the image already or the new coordinates (a1,b1,a2,b2) must be equal to the old coordinates (x1,y1,x2,y2) that means if continue to remove background again, the result is still the same, but if these conditions are not met, the RM-Mask will be used as a mask to remove the background from the original image again; where black pixels refer to background pixels and white pixels refer to dragon fruit pixels. Any coordinate in RGB image that has the same coordinates as a background pixel is changed to 0. The result is RGB image represented by Image-HSV2. The yellow ratio of Image-HSV2 is recomputed and increases the value of the NR variable by 1 to count the number of background removal attempts. This will not remove the background more than 3 times.

After that, if the yellow ratio of Image-HSV2 is equal to 0 or the coordinates (a1,b1,a2,b2) are equal to the original coordinates. (x1,y1,x2,y2) sets the HSV2-Mask value to be the same as the RM-Mask and terminates the subprogram immediately because the background is considered eliminated, but if the conditions are not met, it will continue to remove the background by using the RM-Mask as the initial data to remove the next background.

The process is restarted using the RM-Mask as the starting point, creating a new set of inputs: specifying new (x1,y1,x2,y2) coordinates with the detect location of dragon fruit subprogram, creating a new HSV1-Mask by 4 Graph Cut that used new (x1,y1,x2,y2) coordinates and reconstructing new Image-HSV1 with a new HSV1-Mask. After that, the new HSV1-Mask and new Image-HSV1 were processed with the check mask and image subprogram again to compute the yellow ratio, specify the coordinates (a1,b1,a2,b2), and finally create a new RM-Mask. This new RM-Mask will be used to reconstruct the Image- HSV2 and calculate the yellow ratio of the new Image-HSV2, with the NR variable increased by 1 as before. The image with the background removed will have a yellow ratio of 0 or coordinates (a1,b1,a2,b2) equal to coordinates (x1,y1,x2,y2). If this condition is met, the background removal will be stopped. Set the mask HSV2-Mask as same as RM-Mask. On the other hand, we will remove the background repeatedly, but not more than three times, because it may remove the background too much and cause the dragon fruit part to be removed as well. The results obtained from this step are shown in Fig. 10(b).

Algorithm 4: Remaining Background Removal by HSV Color Model

```

Input: Image-HSV1 , HSV1-Mask and (x1,y1,x2,y2).
Output: HSV2-Mask.
Yellow_Ratio, (a1,b1a2,b2) and RM-Mask = Return values of Check
Mask and Image by Image-HSV1 and HSV1-Mask.

NR = 0 /*stand for number of removing*/
If (Yellow_Ratio == 0) then
    | RM-Mask = HSV1-Mask
else
    | If ((a1,b1a2,b2)==(x1,y1,x2,y2)) then

RM-Mask = GrabCut 4Directions by (a1,b1,a2,b2)
    
```

2) *Subprogram of background removal by lab color model:* The subprogram of background removal by lab color model is a process that uses Lab color model's properties to remove background pixels as shown in the algorithm 6. The illustration of background removal by lab color model process

as shown in Fig. 9. First, the original image, which is RGB color model, is converted to a Lab color model. After that, a channel is split and converted to a binary image by Otsu' Threshold. Take the binary image into the process of the detect location of dragon fruit subprogram as shown in Fig. 5, which gives the coordinates (x1,y1,x2,y2) as the location of the dragon fruit.

As before, take the coordinates (x1,y1,x2,y2) as the rectangle that will be used to remove the background from the image by graph cut with four directions. If (x1,y1,x2,y2) is the same coordinate as the border of the image, Use the morphology function erosion with kernel size 5x5 to modify the binary image before reading the new position again until the coordinates (x1,y1,x2,y2) are not equal to the border of the image.

Take the results from graph cut with four directions and convert them to a mask. Make the dragon fruit part into white pixels. The background part is black. Bring all four masks to find the white pixels together by using the intersection area. The result is a binary image, represented by A-mask which can be used to remove the background from the image. The results obtained from this step are shown in Fig. 10(c).

Algorithm 6: Background Removal by Lab Color Model

```

Input: Original image with RGB color model.
Output: A-Mask.
lab_img = Result of converting input image RGB to Lab color model.
binary_img = Result of converting A channel of lab_img to binary
image by Otsu's Threshold
(x1,y1,x2,y2) = Return values of Detecting Dragon Fruit Location by
binary_img
While ((x1,y1,x2,y2) == Border of image) do

(e) Output from remove background by HSVA-Mask process. and (f) Output from fit scale fruit to 100x100 process.

F. Six Classes of Red Classification

From the procedure in Fig. 1, this method classifies the dragon fruit into two groups from the peel color. Because there is only one species of yellow-skinned in the dataset. For red-skinned dragon fruit, the background in the image will be removed. Then, the dataset will leave only the image of six species of red peel. Therefore, at this stage, only the red-skinned dragon fruit species will be classified by using the content-based technique and deep learning.

Classification using the content-based technique in this research is divided into two parts: feature extraction and classification model. The feature extraction section consists of 24 color attributes, 3 texture attributes, and 2 attributes from edge and line feature. A total of 29 attributes are used as shown in Table I. In The classification model section used a machine learning method by support vector machine algorithm (SVM) with polynomial kernel (degree = 11).

The deep learning models such as DIPDEEP[8], VGG16[38], ResNet50[39], and MobileNetV2[40] were used to classify six species of red peel dragon fruit. All models start with an RGB image size of 100x100 pixels as an input layer and end with six output nodes. There is an optimizer using the Adam algorithm. The learning rate was set at 0.001. For the training process, the batch size and epochs were set at 100. The remaining parameters are not specified using all Keras default values.

For an experiment, DIP-CBML was compared with CBML[9] which is the model that uses content-based

techniques, and DIPDEEP[8], VGG16[38], ResNet50[39], and MobileNetV2[40] are the models that use deep learning techniques.

TABLE I. FEATURE EXTRACTION OF DIP-CBML METHOD

Extracted Features	Description	Feature Dimension
Colors	Statistical features (mean, standard deviation, skewness, kurtosis) extracted from color channel R,G,B of RGB color model H of HSV color model and a, b of Lab color model.	24
Texture	Properties features (dissimilarity, contrast and asm) extracted from GLCM of RGB only 0° direction.	3
Edge and Line	The ratio of edge pixels from Canny Edge algorithm and the number of lines from Hough Transform Standard algorithm	2

G. Feature Extraction of DIP-CBML

1) *Color feature*: Color features used in this research include statistical properties of the RGB, HSV, and Lab color models. All three models were split from three channels to one channel to get six image data: Red (R), Green (G), Blue (B), Hue (H), Red/Green Value (a), and Blue/Yellow Value (b). The pixel data of each image were calculated for the mean, standard deviation, skewness, and kurtosis as Eq. (4) to (7) [41]. The total of color features is 24 attributes.

$$Mean = \frac{1}{N} \sum_{k=0}^{N-1} P_k \quad (4)$$

$$Standard\ Deviation = \sqrt{\frac{1}{N} \sum_{k=0}^{N-1} (P_k - Mean)^2} \quad (5)$$

$$Skewness = \frac{\frac{1}{N} \sum_{k=0}^{N-1} (P_k - Mean)^3}{\left[\frac{1}{N} \sum_{k=0}^{N-1} (P_k - Mean)^2 \right]^{\frac{3}{2}}} \quad (6)$$

$$Kurtosis = \frac{\frac{1}{N} \sum_{k=0}^{N-1} (P_k - Mean)^4}{\left[\frac{1}{N} \sum_{k=0}^{N-1} (P_k - Mean)^2 \right]^2} - 3 \quad (7)$$

where P_k is the pixel value in order k of image pixel and N is the number of image pixels.

2) *Texture feature*: Texture features used in this research are the features from the gray-level co-occurrence matrix (GLCM) algorithm of RGB images. For feature extraction, importing RGB images into the GLCM algorithm with the skimage.feature library. Three features of GLCM have been extracted: dissimilarity (D), angular second moment (ASM), and contrast (Ct). Each feature uses horizontal direction information (0°). For a total of three features as Eq. (8) to (10) [42,43].

$$Dissimilarity = \sum_{i=0}^{n-1} \sum_{j=0}^{n-1} g(i,j) \cdot |i-j| \quad (8)$$

$$Angular\ Second\ Moment = \sum_{i=0}^{n-1} \sum_{j=0}^{n-1} (g(i,j))^2 \quad (9)$$

$$Contrast = \sum_{i=0}^{n-1} \sum_{j=0}^{n-1} (i-j)^2 \cdot g^2(i,j) \quad (10)$$

where n is the number of gray levels, $g(i,j)$ is the value of GLCM normalized where i and j are column and row numbers of GLCM normalized as a square matrix $n \times n$ in size. The values of i and j are between 0 and $n-1$.

3) *Edge and line features*: Edge and line features are representative of the density of the bracts surrounding the dragon fruit. If there are many bracts, the number of edges and lines will also be large. Each specie of dragon fruit has different a number of bracts. The edge of a fruit part and the direction of a line seem to be characteristics of dragon fruit. The edge and line may be a suitable feature for modeling the dragon fruit classification. Edge and line features are used in this research include the edge pixel ratio by processing with the canny edge algorithm[44,45] and the number of straight lines by processing the hough transform algorithm[46,47].

The canny edge algorithm [44,45] is a popular edge detection algorithm with multi-steps used to detect any pixel expected that is the edge of the object in the image. It consists of the noise removal with a 5x5 Gaussian filter, finding the intensity gradient of the image and direction, removing any unwanted pixels by a local maximum in its neighborhood in the direction of gradient and the last step is selecting whether the pixel expected is the edge or not by two threshold values, $minVal$ and $maxVal$. Any pixels with an intensity gradient more than $maxVal$ are sure to be edges and less than $minVal$ are sure to be non-edges. Any pixels with an intensity gradient between two thresholds are identified as edges or not by their connectivity. If they are connected to the sure-edge pixels, they are decided to be part of the edges. Otherwise, they will be rejected. It is very important to define two thresholds to get the correct result.

Therefore, to get an edge pixel ratio, this method uses the output image of the image background removal process which is the image that was scaled of the dragon fruit proportion to 100x100 pixels as shown in Fig. 10(f) and converted to a grayscale image. Then bring the grayscale image to frequency distribution by histogram. Set the data layer equal to 10. Use the lower boundary of the first layer and the last layer as lower threshold as $minVal$ and upper threshold as $maxVal$ respectively. The thresholds are processed to determine edge pixels using the canny edge algorithm through the $cv.Canny$ function of the OpenCV library[45]. The resulting image is a binary image with white pixels representing the edge pixels. So, the edge pixel ratio is equal to the number of white pixels divided by the image size and times 100, as shown in Eq. (11).

$$Ratio\ of\ Edge = (Edge\ pixels/image\ size)*100 \quad (11)$$

For the line features, the Hough transform algorithm[46,47] was used. Typically, it is a detection of the shape in the picture; that shape can be represented in a mathematical form such as lines, circles, ellipses, etc. It can detect the shape even if it is broken. This paper focuses on the straight line detection. The line equation in parametric form as shown in Eq. (12).

$$\gamma = x \cos\theta + y \sin\theta \quad (12)$$

where x,y is a pixel coordinate, γ (ρ) is the perpendicular distance from the origin to the line, and θ (θ) is the angle by

this perpendicular line and horizontal axis measured counter clockwise.

That means any pixels that are on the same line, have the same ρ and θ value. The first step of the algorithm is creating a 2D array as the accumulator, to collect the calculated values of each pair of ρ and θ for each pixel. The array initial with a zero value. Let rows equal to the ρ and columns equal to the θ . Any pixel was expected to be an edge of the object in the image, the ρ was computed by the pixel coordinate (x,y) and every possible θ . Then increment the values by 1 in the accumulator at the column and row that correspond to the ρ and θ value that is a result of computing. The number in each cell of the accumulator means the number of pixels that can be on the same line. In the last, this algorithm required minimum voting as a threshold to decide the group of pixels that can be the line. It may be the minimum length of the line that should be detected.

Therefore, to get the number of straight lines, this method takes the results of the canny edge algorithm to be processed, using the function $cv.HoughLines$ of the OpenCV library[47], setting ρ which is the distance resolution of the accumulator in pixels to 1, and θ which is the angle resolution of the accumulator in radians to $\pi/180$. An accumulator value was distributed to the histogram frequency, set the data layer equal to 11, take the data from layers two to six which are normal curve area, calculate the mean that rounded up to make an integer, and set it as the threshold as a minimum length of the line that should be detected. Finally, get the number of straight lines from the result of the $cv.HoughLines$ function. From the hypothesis, any dragon fruit with more bracts around the fruit will also have more straight lines.

4) *MinMaxScaler*: Because the result of the feature extraction mentioned above gives results in numbers with different scales. Therefore, this method adjusts the scale to the same scaling by $MinMaxScaler$ which will have a scale between 0 to 1 by using the formula as in Eq. (13).

$$MinMaxScaler\ Transform = (x - min) / (max - min) \quad (13)$$

where x is the data, min is the lowest value in the column, and max is the maximum value of the data in the column.

IV. EXPERIMENTAL RESULTS

The image dataset consists of 9,754 laboratory images and 9,067 outdoor images. Each dataset includes seven species of Thai Dragon Fruit. The laboratory images were divided into Jumbo White 1,172 images, Vietnamese White 1,190 images, Pink 1,309 images, Siam Red 1,869 images, Taiwan Red 1,184 images, Ruby Red 1,110 images, and Israel Yellow 1,920 images. The outdoor images were divided into Jumbo White 1,241 images, Vietnamese White 2,478 images, Pink 1,013 images, Siam Red 950 images, Taiwan Red 1,021 images, Ruby Red 871 images, and Israel Yellow 1,493 images.

The experiment was divided into three experiments. The first experiment is the image type identification. The second experiment is the red and yellow classification. The final experiment is the classification of six classes from the red peel group.

A. Experiment 1

The first experiment is the image type identification which is laboratory image or outdoor image. Before doing the experiment, images of two types were randomly selected 700 images per type (100 images per species) to study an average of background pixels in a gray level range. Test the range with all data. The experiment results are shown in Table II.

TABLE II. RESULTS OF IMAGE TYPE IDENTIFICATION

Types	Number of Samples	Accuracy (%)	Number of Samples	Accuracy(%)
Laboratory Image	700	100.00	9,754	100.00
Outdoor Image	700	100.00	9,067	100.00
Laboratory Image and Outdoor Image	1,400	100.00	18,821	100.00

B. Experiment 2

The Second experiment is the classification of the dragon fruit group from the peel color which is red or yellow. All images were divided into three methods. There are non-pre-processing, graph cut with [23] localization and pre-processing of DIP-CBML. The experiment results are shown in Table III.

TABLE III. CLASSIFICATION RESULTS BETWEEN RED AND YELLOW WITH THREE DIFFERENT METHODS

Types	Number of Samples	Accuracy(%)		
		Non-pre-processing	[23]+Graph Cut	Pre-processing of DIP-CBML
Laboratory Image	9,754	100.00	100.00	100.00
Outdoor Image	9,067	97.06	99.96	100.00
Laboratory Image and Outdoor Image	18,821	98.53	99.98	100.00

C. Experiment 3

The Third experiment is the classification of six classes from the red peel group by content-based and deep-learning models. The datasets used for this experiment are the results of the image background removal procedure, which is a dragon fruit image with a white background as Fig. 10(f). Before doing the experiment, the images were randomly selected at 1,000 per class. Any class with less number than 1,000 will be added to the image data by the augmentation technique. Here, this method uses only the horizontal flip image method because the required amount is only small. After that, create the dataset into four forms. The first form is only the 6,000 laboratory images in the dataset which were pre-processed by the creating MKR mask method, namely the Laboratory dataset. The second form is only the 6,000 outdoor images in the dataset which were pre-processed by the DIP-CBML method, namely the Outdoor dataset. The third form combined 12,000 images between the first form and the second form, namely the Mixdata1 dataset. The last form is combined images both the 6,000 laboratory images and the 6,000 outdoor images which are pre-processed by the DIP-CBML method, namely the Mixdata2 dataset. Each dataset was divided into 80%, 10%, and 10% for the training set, the validate set, and the test set, respectively. Using the 10-folds validation technique the DIP-

CBML was compared with CBML[9], DIPDEEP[8], VGG16[38], ResNet50[39], and MobileNetV2[40]. The experiment results are shown in Table IV.

V. DISCUSSION

This research presents the classification of Thai dragon fruit species from images that support two types of image datasets; laboratory and outdoor called DIP-CBML. The first experiment results showed that DIP-CBML can identify image types correctly with accuracy 100.00%. Therefore, the proposed method can support two types of images.

After identifying image types, the next process is the classification of the dragon fruit groups; red peel color and yellow peel color. The experiment results showed that the pre-processing of DIP-CBML was able to increase efficiency in classifying dragon fruit groups from peel color by 100% when compared to classifying by the original image. For graph cut with [23] localization, it was found that the dragon fruit group could be classified by the color of the peel with an accuracy of 99.98%. Therefore, the pre-processing of the DIP-CBML gives better results. The volume of the dataset was reduced because the process can stop when a yellow peel specie was founded, the remaining data are red peel groups which affect processing time.

Finally, dragon fruit images were changed the background to white and fit proportion of fruit size not over 100 on each side which were used to perform datasets for the classification of six classes from the red peel group. The experiment results showed that the DIP-CBML can get 100% accuracy for training set, but the other models do not. The DIP-CBML can classify six species of red peel group with 97.85%, 94.00%, 95.53% and 95.05% accuracy for Laboratory dataset, Outdoor dataset, Mixdata1 dataset and Mixdata2 dataset respectively. The confusion matrix of best accuracy which is Mixdata1 dataset can be shown in Fig. 11. and an example of the misclassified images is shown in Fig. 12.

Fig. 11. Confusion matrix of DIP-CBML classification method with Mixdata1 dataset.

Fig. 12. Examples of the misclassified images.

TABLE IV. COMPARISON FOR ACCURACY OF DIFFERENT CLASSIFICATION METHODS AND DIFFERENT DATASETS FOR 6 SPECIES OF RED PEEL RESULTS BY 10-FOLD VALIDATION

Method	Mean (SD.)											
	Laboratory			Outdoor			Mixdata1			Mixdata2

VI. CONCLUSION

For this paper, the characteristics of laboratory and outdoor images were used to create the classification of Thai dragon fruit species from images that support two image datasets. The DIP-CBML method is used in the completed work. The channel R of RGB color model and gray image were used to identify the type of images between laboratory and outdoor images. The DIP-CBML can identify image type correctly with an accuracy of 100.00% with all datasets. The HSV color model and graph cut algorithm were used to pre-process the images which are able to increase efficiency in classification of dragon fruit groups by peel color with 100% accuracy for outdoor images. As a significant result, the method can classify image group of the laboratory type correctly with 100% accuracy same as other methods. Especially, non-pre-processed gives the same result. Therefore, if the laboratory type was detected, the method can use the original image of laboratory image to classify image groups. The HSV color model, channel of Lab color model and graph cut algorithm were used to remove the background of image which changed the background into white and fit scale on dragon fruit part to 100x100 pixels. The DIP-CBML used these images to classify the six species of Thai red dragon fruit by 29 features from color, texture, edge and line feature. The method gives 95.53% accuracy for both image types with a different pre-processed method. Finally, the entire research process was completed with all components. The precision of each step influences the others. The DIP-CBML may be developed again to increase the accuracy of the last step. The DIP-CBML was designed for the classification, especially Thai dragon fruit species. For other fruits, the DIP-CBML may work or not. This is a challenge for future research. Hopefully, the proposed model will be a guideline for developers to develop tools that can classify species of Thai dragon fruit from images that support pre- and post- harvesting image datasets. This research will add value to the yield of Thai dragon fruit cultivation and can be applied to industrial applications harvesting with robots.

VII. SUGGESTION

After a laboratory image was detected, the DIPDEEP[8] method may be used in the final step because it gives an accuracy of 98.80%. After an outdoor image was detected, the purpose method was used with an accuracy of 95.53%. The

combination of several methods in one application is a good approach that works.

Math-VR: Mathematics Serious Game for Madrasah Students using Combination of Virtual Reality and Ambient Intelligence

Hani Nurhayati, Yunifa Miftachul Arif

Department of Informatics Engineering, Universitas Islam Negeri Maulana Malik Ibrahim, Malang, Indonesia

Abstract—The challenge to increasing understanding of mathematics lessons for students in madrasah schools makes the learning process require the support of adaptive alternative learning media. In this study, we propose a serious game-based learning media supported by virtual reality and ambient intelligence technology to equip students with adaptive responses to subject matter scenarios. Ambient intelligence works based on recommendations generated by the Multi-Criteria Recommender System (MCRS). In calculating a similarity between users and reference data, MCRS uses cosine-based similarity calculations, and average similarity is used for ranking. We developed this learning media experiment called Math-VR using the Unity game engine. The experimental test results show that MCRS-based ambient intelligence technology can provide an adaptive response to the choice of geometry subject matter recommendations for students according to their pre-test results. The analysis results show that the recommendation system as part of ambient intelligence has the highest accuracy rate of 0.92 when using 80 reference data.

Keywords—Mathematics; serious game; virtual reality; ambient intelligence; MCRS

I. INTRODUCTION

In Indonesian national education, madrasah is one of the education providers with Islamic overtones. Madrasah play an essential role in educating the nation's children through educational institutions with a combination of general subject matter and Islamic education [1]. Based on its level, madrasah consist of Madrasah Ibtidaiyah, which is equivalent to Elementary Schools; Madrasah Tsanawiyah, which is equivalent to Junior High Schools; and Madrasah Aliyah, which is equivalent to Senior High Schools. Of all these levels, the madrasah has its challenges and obstacles in the learning process for students, especially in mathematics. One indicator of problems in the learning process in madrasah is low student achievement. The leading indicator can be seen from the average National Examination scores for mathematics in madrasah students, which are lower than students from public schools [2] [3]. This problem could be born because more facilities, media, and learning methods still need to be used where it indirectly affects students' understanding of each learning material.

The madrasah curriculum combines general science and Islamic religious knowledge [4] [5]. The breadth of knowledge you want to transfer to students is a different obstacle for students to understand every material the teacher

presents. In addition, the level of intelligence and different backgrounds of students makes the level of understanding of students vary. Therefore, to increase madrasah students' understanding of mathematics subject matter, it is necessary to develop learning media that can provide knowledge through interactive visualization and simulation to students. The aim is to make it easier for students to understand compared to when using other conventional learning media such as books or student worksheets. Besides that, it is also necessary to develop learning media that can choose subject matter according to student's level of understanding. Learning media adaptively can provide material according to student's needs as a solution to variations in students' understanding that are different even in the same class.

To answer some of the problems regarding the need for instructional media for madrasah students, in this study, we propose using ambient intelligence-based serious games as an alternative to new interactive, adaptive, fun, and easy-to-understand learning media. Games with interesting interactive and visualization capabilities are needed in learning activities [6]. Serious games are currently being developed as alternative learning media that can provide knowledge to players through the educational, visualization, simulation, exploration, and training functions contained therein [7][8]. Using serious games in education allows players to understand knowledge content in more detail with interactive visualization images via mobile (smartphone) [9]. Furthermore, the addition of ambient intelligence technology in serious games is expected to increase the ability of the system to predict and provide recommendations for learning material choices effectively. That still needs to be better understood by students as game players based on their obtained scores, where scores are an essential part of computer games [10]. Subject matter wrapped in fun interactive games is expected to increase students' interest in and understanding of the subject matter [11].

Ambient intelligence is a technology that makes the virtual environment in the system sensitive, flexible, and adaptive to the presence of users [12]. In this study, we used a Virtual Reality (VR) framework to handle interactive visualizations for students. VR is a type of learning media that is gaining popularity in various fields of science, such as biology [13], tourism [14], digital engineering [15], english [16], and engineering controller [17]. VR-based learning media provides an exciting visualization through the virtual environment provided for players. Furthermore, we also

introduce the use of recommender system-based ambient intelligence to predict the level of student understanding so that the system can adaptively choose visualization of mathematics subject matter suitable for madrasah students. The combination of VR technology and ambient intelligence is our effort to increase learning enjoyment, understanding of mathematical content, and students' engagement with the proposed serious game, which we call Math-VR.

II. RELATED WORK

The implementation of serious games as learning media is an exciting field of research and presents a challenge. One of them is that conducted by Hamari et al., who shows that involvement in serious games has an apparent positive effect on the game's challenge and has a positive effect on learning both directly and through increased involvement. Becoming skilled at games does not directly affect learning but increases engagement in games. In the design of educational games, researchers suggest that game challenges must be able to keep up with the development of student's abilities and learning to support continuous learning in a game-based learning environment [18]. In another study, Mohammad Iqbal stated that there were seven steps in designing serious games as learning media. This method begins with analyzing the specification of the pedagogical goals to be achieved and then selecting the type of game model to be used. The third is the adjustment of pedagogical scenarios with fun game scenarios, and the next is the search for software components that can be used. The next step is the detailed description of scenarios and pedagogical quality control, and the final is determining subcontractors' specifications and game design tools [19]. Some of these studies are the primary references of this research proposal. To design serious games as interactive and adaptive learning media, we use the implementation of ambient intelligence supported by Virtual reality technology and a recommender system.

Furthermore, several studies have introduced games as learning media, especially in mathematics for example, M. Hartono et al. Authors use games developed in 2-dimensional visualization so that they are for students studying in elementary school. The experimental results show that students prefer learning mathematics through game media rather than conventional media. In addition, another advantage is that mathematics subject matter becomes more accessible for students to understand [20]. In another study, Sun et al. propose the use of game-based learning media also for mathematics lessons. In the experiment, the authors involving many students and teachers in collecting data through observation and interviews. This study's results indicate that using games as a medium for learning mathematics positively influences learning activities and understanding of mathematics [21]. Based on research by Sun et al. it is necessary to increase adaptive intelligence to the surrounding environment, according to Yunifa et al, one of the adaptive intelligence technologies is ambient intelligence which can be applied to serious games to arrange response scenarios for selecting tourist destinations [22]. In this study using ambient intelligence to set scenarios for selecting responses to games for selecting mathematics learning materials. Some studies that have been carried out use simple game media that still

have prospects for improving their abilities, for example, by utilizing game genres with better visualization and simulation capabilities. One of the game genres that can answer the ability challenges from several previous studies is the serious game. Therefore, this study proposes the implementation of serious games as a mathematics learning technology for students in madrasah schools.

Several studies have discussed the idea and design of game-based learning media for madrasah students. One of them is done by Melati et al. in 2022. In their research, authors use educational games as a medium for learning English for madrasah students. They take advantage of educational games that can be accessed online by students. The results of the study show that online game media can help the process of learning English for madrasah students [23]. In contrast to previous research, in this study, we propose using games as a medium for mathematics for madrasah students.

III. SYSTEM DESIGN

This study discusses the proposed serious game system as an interactive and adaptive mathematics learning media for madrasah students. Games are built with story scenarios that describe what is adapted to the subject matter that becomes game content. Therefore, for students who play to get an apparent experience of simulation and visualization of subject matter, we build and design virtual environments and objects that support the process of learning mathematics. Next, we use Unity 3D as the game engine that will be used to build scenarios, objects, characters, and 3-dimensional virtual environments in this serious game.

Fig. 1 shows the proposed mathematics learning system using a serious game. Where to produce interactive and adaptive mathematics learning media, we offer the implementation of ambient intelligence technology in serious games supported by virtual reality visualization and recommender systems. The virtual reality (VR) platform provides visualization and simulation of subject matter content so that it is easy for students to understand, which can be assisted with several types of markers for their interactions. Furthermore, we use the Multi-Criteria Recommender System (MCRS) to provide recommendations for selecting suitable material levels for students based on the scores they obtained through the pre-test.

Fig. 1. Architecture of the proposed Math-VR system as mathematics learning media.

In this study, we chose one of the subject matters of mathematics as serious game content, which is about geometric shapes. A VR-based spatial learning game is a game that simulates the activities of students at school. The system starts the game scenario activity by displaying the main menu page, which consists of three options: starting the game, about the game, and exiting the game. After the player selects the start game option, the player will enter the school scene where several classes have different content, and there are material content and tests. When a player completes a test session and gets a score, the system will calculate the Score, so players can get recommendations for subjects that players still must study. Besides recommendations, players can also choose their desired class goals by pressing the destination button. The system will help with the direction of the goal with arrow direction indicators. Fig. 2 shows the rule of a serious game for mathematics educational media based on VR introduced in this study.

Fig. 2. The rule of proposed Math-VR.

A. Object, Character, and Environment Design

Developing game elements begins with creating assets consisting of the environment, user interface (UI), and characters. We design each asset using Blender software. The characters designed in this game function as non-playable characters (NPC), representing a teacher teaching in class. The process of making a character has a higher level of difficulty compared to making an environment. Character creation requires rigging and animation processes so that the character can move according to the running scenario. The following process is creating 2-dimensional assets in the form of illustrations and UI. Making these assets aims to help users

interact with the game. One example is the creation of button images that function as game navigation. As shown in Fig. 3, 4, and 5, we designed the environment and character using Blender software.

Fig. 3. Designing a school environment.

Fig. 4. Designing a class environment.

Fig. 5. Designing game character.

B. MCRS-Based Ambient Intelligence

This study utilized a multi-criteria-based recommender system to provide ambient intelligence capabilities in serious games. MCRS generates recommendations based on player pretest value data at an early stage when playing a spatial learning game. The value data includes the value of the answer score (R1) and the length of processing time (R2). The MCRS system performs calculations using a heuristic approach based on the multi-criteria recommender system (MCRS). Eq. (1) shows the calculation to get the value of R1 after the player completes the pretest session. Twenty questions will be randomized from the 64 questions available

in the game database. In the pretest session, besides being required to answer correctly, players must also answer questions as quickly as possible. The faster the player answers the questions, the bigger the Score they get.

$$R1 = \frac{(JS-SS) \times MS}{SF} \quad (1)$$

The calculation that occurs to get the value of R1 is shown through (1). First, the number of questions (JS) is reduced by the number of wrong questions (SS), then the multiplier is multiplied by the correct answers (MS). The purpose of multiplying by the multiplier is to get a score of 100/100 where this value will be displayed on the game interface. In this research, the multiplier value used is 5. Furthermore, the value is divided by the simplified value (SF) or simplified value. The reason is that R1 only has a value range of 0-10. The simplified value in this study is 10. After that, the value of R1 or the first criterion will be obtained.

$$R2 = \frac{\sum_{CT=n}^{JS} CT_n - TS}{JS} \quad (2)$$

In (2), the calculation of the long processing time criterion (R2) begins with the process of obtaining the current time (CT) and start time (TS) values. The following process calculates the time required by the value (CT) minus the value (TS). The process will repeat until all questions (JS) has been answered. In this study, there were five items in each type of question. For example, the cube problem has five questions, five blocks, five prisms, and five pyramids for 20 questions. After all the questions have been answered, all the reduction values will be added and divided by the number of available questions (JS).

R1 and R2 values are rating values used in MCRS calculations. In this study, we used the MCRS algorithm based on a heuristic approach with several steps to calculate the similarity of u' and u ratings. The first step is to calculate the similarity rating of the new player u' , and all the ratings of previous players u using the cosine-based similarity formula. At (3), $I(u, u')$ is an item rated by players u and u' . While $R(u, i)$ is the rating value, new players give to items [24] [25].

$$sim(\mu, \mu') = \frac{\sum_{i \in I(\mu, \mu')} R(u, i) R(\mu', i)}{\sqrt{\sum_{i \in I(\mu, \mu')} R(u, i)^2} \sqrt{\sum_{i \in I(\mu, \mu')} R(\mu', i)^2}} \quad (3)$$

After the results of the calculation of similarity between players are known, the second step is to calculate the individual similarity values using the average similarity formula $sim_{avg}(\mu, \mu')$ as in (4). This calculation aims to find out the player who has the highest overall Score with the highest level of similarity among all players. The value n indicates the number of criteria rated by the player, while $sim_c(\mu, \mu')$ is the similarity for each criterion between user u and the previous user u' [26] [27].

$$sim_{avg}(\mu, \mu') = \frac{1}{n+1} \sum_{c=0}^n sim_c(\mu, \mu') \quad (4)$$

IV. RESULT AND DISCUSSION

A. The User Interface and Environment Result of Math-VR

In this research, we developed game elements for Math-VR using the Unity 3D game engine. When players start the game for the first time, they will find three options on the main menu, namely "Mulai" to enter the game's gameplay, "Tentang" to find out information about the application, and "Keluar" to navigate out of the application as in Fig. 6. After starting the game, the player will immediately enter the school environment as in Fig. 7. Where at this stage, the system will show the first-person view of players who use VR devices and are synchronized with movements in the virtual game environment. Furthermore, players will be directed using arrows to go to class. Fig. 8 shows an example of visualizing a virtual classroom environment used in learning activities using Math-VR.

Fig. 6. Math-VR menu.

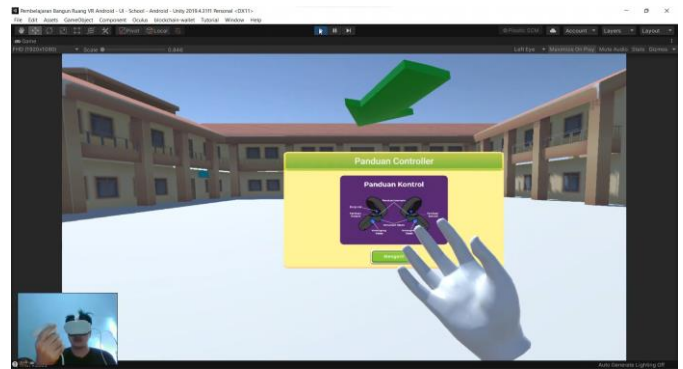

Fig. 7. School environment in the player view.

Fig. 8. Classroom environment in the player view.

When entering the classroom environment, the system provides pre-test questions to the player as the first step to obtaining the rating data needed by the recommendation system. In the pretest class, the Math-VR system guides players to pay attention to the questions on the blackboard and answer them by taking the alphabet according to the selected answer. After the player has answered all the questions, then the game displays the pretest results panel in the form of the Score obtained by the player, the number of questions answered correctly and incorrectly, as shown in Fig. 9. Players can press the "Lanjutkan" button to find out the results of the system evaluation regarding the recommended subjects to study. Fig. 10 shows the display of recommendations generated by the system using the MCRS method to implement ambient intelligence technology in Math-VR. In this session, players can choose one of three subjects that they want to study first. Fig. 11 shows example of the results of the visual display of the condition of the virtual environment when the player has entered one of the learning scenarios about geometric shapes.

B. MCRS-Based Ambient Intelligence Results

In this study, we tried implementing ambient intelligence technology into a serious game proposal using the multi-criteria-based recommender system method. The system uses the results of the recommendations as a reference in responding to players regarding the choice of lesson scenarios that are appropriate to their level of understanding. In the process of generating recommendations, MCRS requires initial data as a reference to predict the similarity of the new user ratings.

Fig. 11. Example of virtual environment visualization for geometry learning.

In this study, we obtained reference data through a direct test that 125 students attended. There are two assessment factors in the test: the correct or incorrect answer and how long it takes the participant to answer the question. The longer the time it takes, the smaller the Score the participant will get. We also carry out a selection process for each data based on variations in the criteria value. We do not use exact respondent rating data.

Meanwhile, we only use rating data very far from the average participant score. After the data selection process, we got 110 valid test data values divided into two, namely 100 reference data and 10 test data. This study uses five scenarios of experimental testing, namely with 40, 50, 60, 70, and 80 reference data. The aim is to see the relationship between accuracy and the amount of reference data used. At the same time, some of the variables resulting from the testing experiment are precision, recall, accuracy, and F1 Score. Table I shows the test results based on 40, 50, 60, 70, and 80 reference data. We also carry out tests for the results of the Top N recommendations 1, 2, and 3.

TABLE I. RECOMMENDATION SYSTEM TEST RESULTS FOR PRECISION, RECALL, ACCURACY, AND F1 SCORE

Top N	Result	Reference Data					
		40	50	60	70	80	Average
1	Precision	0,50	0,60	0,70	0,73	0,82	0,67
	Recall	0,56	0,55	0,64	0,73	0,90	0,67
	Accuracy	0,78	0,78	0,83	0,85	0,92	0,83
	F1 Score	0,53	0,57	0,67	0,73	0,86	0,67
2	Precision	0,61	0,67	0,68	0,75	0,85	0,71
	Recall	0,58	0,60	0,68	0,75	0,85	0,69
	Accuracy	0,63	0,65	0,70	0,75	0,85	0,72
	F1 Score	0,59	0,63	0,68	0,75	0,85	0,70
3	Precision	0,52	0,60	0,64	0,74	0,76	0,65
	Recall	0,60	0,68	0,70	0,77	0,90	0,73
	Accuracy	0,40	0,58	0,60	0,72	0,80	0,62
	F1 Score	0,56	0,64	0,67	0,76	0,83	0,69

Fig. 12, 13, and 14 show the test results in graphical form on the variables precision, recall, accuracy, and F1 Score for 40, 50, 60, 70, and 80 reference data. These results also show

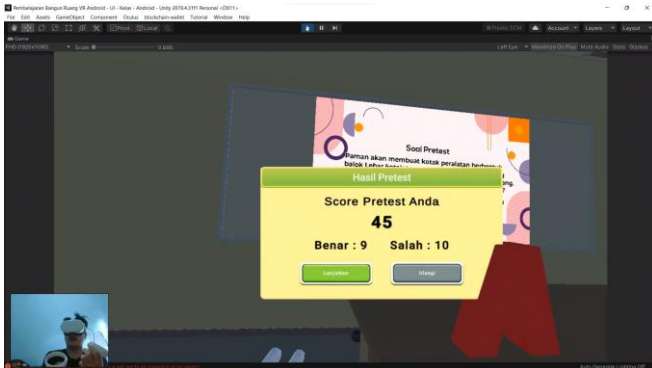

Fig. 9. Pre-test score result.

Fig. 10. Visualization of geometry learning material recommendation.

that the more test data used, the better the accuracy of the recommendations. The highest accuracy value is 0.92 when using 80 test data for Top 1 recommendation results. While the highest average accuracy value is 0.83 for Top 1 recommendation results, the highest average precision is 0.71 for Top 2 recommendation results, average -the highest average recall is 0.73 for Top 3 recommendation results, and the highest average F1 Score is 0.70 for Top 2 recommendation results.

V. CONCLUSION

In this study, we propose a serious game-based mathematics learning media supported by virtual reality technology and ambient intelligence called Math-VR. This study utilizes a multi-criteria-based recommendation system to generate ambient intelligence system responses. The recommendations generated by MCRS respond to the choice of geometry learning scenarios following the results of the

pre-test player. In the MCRS system, the formula algorithm used to calculate similarity is cosine-based similarity, while calculating ranking uses average similarity. In this research, we developed Math-VR using the Unity game engine. Furthermore, the test results show that Math-VR can respond to the recommendation of subject matter scenarios that are adaptive to the results of the pre-test player. The highest accuracy value is 0.92 when using 80 test data for Top 1 recommendation results. While the highest average accuracy value is 0.83, precision is 0.71, recall is 0.73, and F1 Score is 0.70.

Several parts of this research have prospects for further development in future research plans. One of them is the recommendation system-based ambient intelligence section. We can also use machine learning methods to get better results. Besides that, in the following research, Serious games can be used in content other than learning mathematics. To make it more interesting, the VR-based serious game, the subject of this study, can be developed into a metaverse-based learning technology.

An Adaptive Channel Selection and Graph ResNet Based Algorithm for Motor Imagery Classification

Yongquan Xia, Jianhua Dong, Duan Li*, Keyun Li, Jiaofen Nan, Ruyun Xu
School of Computer and Communication Engineering, Zhengzhou University of Light Industry,
Zhengzhou, Henan, China

Abstract—In Brain-Computer interface (BCI) applications, achieving accurate control relies heavily on the classification accuracy and efficiency of motor imagery electroencephalogram (EEG) signals. However, factors such as mutual interference between multi-channel signals, inter-individual variability, and noise interference in the channels pose challenges to motor imagery EEG signal classification. To address these problems, this paper proposes an Adaptive Channel Selection algorithm aimed at optimizing classification accuracy and Information Translate Rate (ITR). First, C3, C4, and Cz are selected as key channels based on neurophysiological evidence and extensive experimental studies. Next, the channel selection is fine-tuned using spatial location and absolute Pearson correlation coefficients. By analyzing the relationship between EEG channels and key channels, the most relevant channel combination is determined for each subject, reducing confounding information and improving classification accuracy. To validate the method, the SHU Dataset and the PhysioNet Dataset are used in experiments. The Graph ResNet classification model is employed to extract features from the selected channel combinations using deep learning techniques. Experimental results show that the average classification accuracy is improved by 5.36% and 9.19%, and the Information Translate Rate is improved by 29.24% and 26.75%, respectively, compared to a single channel combination.

Keywords—Brain-Computer Interface; motor imagery; channel selection; deep learning; graph convolutional neural network

I. INTRODUCTION

Brain-Computer Interface (BCI) systems allow for direct communication with the outside world without relying on the brain's typical output pathways [1,2]. Within the field of BCI, motor imagery is one of the most commonly utilized paradigms. Motor imagery (MI) involves mentally simulating the movement of a limb without actually moving it [3]. BCI systems can capture EEG signals from the brain during these imagined movements through electrodes, and thereby enable control over external devices [4]. With their potential applications in fields such as rehabilitation and medical care, communication security, and environmental protection, BCI systems have a wide range of possible uses [5].

Deep learning [6] is a widely used approach in the field of BCI. Compared to shallow learning models like traditional machine learning, deep learning uses neural network architecture with multiple complex network layers that perform varying functions. This leads to a significant improvement in the quantity and quality of feature extraction and recognition. Many studies have applied deep learning methods such as convolutional neural networks (CNN), long short-term

memory (LSTM), and deep Boltzmann machine (DBM) for motor imagery classification, achieving good recognition results. However, these methods overlook the rich topological relationships between electrodes by treating EEG data as simple two-dimensional data. In contrast, the utilization of graph convolutional neural networks for EEG signal classification addresses this issue.

Different regions of the human brain have distinct functions. For instance, the motor cortex is responsible for motor functions, while the parietal lobe processes various sensory information like touch, smell, and taste. However, most current studies have used EEG data from all channels to extract features, which inevitably introduces redundancy. Additionally, the brain's electrical activity may vary among individuals. Therefore, selecting task-specific signal recording sites can reduce preparation time and improve user comfort in nonclinical BCI applications [7]. By choosing the optimal channel, the impact of noise interference can be minimized, and the computational costs of processing high-dimensional data can be reduced.

The objective of this study is to address the issue of individual variability and to decrease the computational complexity involved in processing high-dimensional EEG data. The main contributions of the paper are as follows:

- An Adaptive Channel Selection algorithm is proposed. For different individuals, the method selects all or partial channels as input to the BCI system by itself, and the partial channels are selected based on the correlation between channels and spatial location.
- A residual-based graph neural network is used to decode the MI signal.
- This method achieves good results on the SHU dataset and the PhysioNet dataset.

The main part of this paper consists of five sections. The first section is the introduction, which provides the background, significance, and methodology of the motor imagery study, as well as the reasons for conducting channel selection. The second section is the related work, where research related to feature extraction and classification algorithms of EEG signals is discussed. Section III presents the core part of the paper, introducing the channel selection algorithm and the Graph ResNet model. Section IV presents the experimental testing of the algorithms proposed in Section III, along with the corresponding results and analysis. Finally,

Section V concludes the research approach and provides future outlook.

II. RELATED WORKS

A. Feature Extraction

The method of feature extraction method has a significant impact on the performance of BCI systems. Popular methods include CNN and RNN [8-13]. In [11], a combination of convolutional and recurrent neural networks achieved an accuracy of 98.3% on the PhysioNet dataset. However, these methods only considered regular data in Euclidean space and did not take into account the topological relationships between electrodes. To address the issue of non-Euclidean space data being unable to be convolved, the first graph convolutional neural network (GCN) was proposed in [14] and applied to non-Euclidean space structured data. In [15] and [16], GCN was applied to MI decoding, achieving the highest accuracy of 93.056% and 98.08% on the PhysioNet dataset, respectively, demonstrating the superiority of GCN in processing EEG signals. However, in order to fully utilize the topological relationship between electrode channels, all channel data are typically used as network inputs, resulting in a large amount of redundant data [17].

B. Channel Selection

EEG signals are acquired using multi-channel electrodes, but using all channels as network input can consume more computational resources and degrade system performance due to noise in some channels. Therefore, channel selection is necessary [17]. One simple method is to select data from the three channels (C3, C4, and Cz) where potential changes during motor imagery are mainly concentrated [18]. Additionally, the StEEGCS algorithm, proposed in [19], utilizes EEG shapelet-transformed for EEG channel selection. It selects the top-k EEG channels by solving a logistic loss-embedded minimization problem while simultaneously learning EEG shapelets, hyperplanes, and channel weights. and in [20], a Spatiotemporal-Filtering-Based channel selection (STECS) method was introduced to extract discriminative information from EEG signals. The STECS method was able to achieve the same classification performance as the full channel by using only half of the number of channels. However, these methods lack a neurophysiological basis. In [21], it was assumed that the channels associated with MI should contain public information, and channels were selected based on inter-channel correlation. An iterative multi-objective optimization channel selection (IMOCS) algorithm was proposed in [7] that selects optimal channels using anatomical and functional correlations of EEG channels, but it does not consider the spatial distribution of electrodes.

Subject-independence can reduce the time of data preprocessing in BCI systems. However, the investigation results showed [22] that subject-specific classification accuracy is higher than that of subject-independent BCI systems. This suggests that the optimal channel varies across subjects.

In summary, the paper addresses the problems of data redundancy and individual variability faced by using deep neural networks for EEG signal classification. An adaptive Channel Selection is proposed, which considers both the

neurophysiological basis and the correlation between channels to select the optimal channel for each subject individually.

III. MATERIALS AND METHODS

A. Overview

The framework of this paper is shown in Fig. 1.

- 1) Computing the channel correlation and obtaining the graph Laplacian.
- 2) Selecting electrodes using an Adaptive Channel Selection algorithm.
- 3) Generating a graph representation of the channel correlation from the graph Laplacian.
- 4) Applying the residual graph neural network to decode EEG signals.
- 5) Determining the optimal channel selection scheme based on the test results.

The Adaptive Channel Selection algorithm automatically selects the combination of channels with a higher Information Transfer Rate (ITR) based on the ITR obtained after training data from both schemes. Fig. 2 illustrates the algorithm framework, which includes one scheme that uses all channels in the original data and another that uses proposed channel selection algorithm. Channel selection is based on the following two criteria.

B. Adaptive Channel Selection Algorithm

To minimize computational effort during graph pooling, the number of selected channels is chosen as integer powers of two since the number of channels is reduced by half each time.

1) *Neurophysiological basics and spatial location*: Motor imagery EEG refers to the spontaneous electrical activity of brain tissue that reflects the functional state of the brain. Different bands of EEG activity typically appear in different functional areas of the brain, and changes in their activity can reflect various brain states. Previous studies [23] have shown that during motor imagery, the phenomena of ERD and ERS in the mu (8-13 Hz) and beta (13-30 Hz) bands are concentrated in the C3 and C4 electrodes of the cerebral motor cortex. in addition to Cz, which also receives the influence of hand movements. Therefore, first selected the C3, C4, and Cz channels that are most relevant to motor imagery EEG activity. Next, selected another set of channels that are spatially closest to the selected channels, with the already selected channels being referred to as "Fixed Channels".

2) *Absolute pearson coefficient*: For the remaining channels, they needed to be closely related to EEG activity in the motor cortex of the brain, and considering the variability among individuals, this work selected a unique set of channels for each subject based on the absolute Pearson correlation coefficient. These channels were referred to as "Free Channels", and the three sets of channels were combined to form the input to the model. The composition of each part of the channel is shown in Fig. 3.

Fig. 1. Illustration of the proposed framework.

Fig. 2. Adaptive channel selection algorithm flowchart.

Fig. 3. Diagram of channel composition.

The absolute Pearson coefficient is a commonly used method for feature selection and extraction, as it measures the degree of correlation between two variables. In channel selection, this work aims to identify channels that are highly correlated with changes in motor cortex EEG signals. To achieve this, this work uses the absolute Pearson coefficient to evaluate the degree of correlation between each channel and

the motor functional areas of the brain, and select the channels with high correlation [21].

The Pearson correlation coefficient between two variables is calculated as the quotient of the covariance and the standard deviation between the two variables.

$$\rho_{X,Y} = \frac{\text{cov}(X,Y)}{\sigma_X \sigma_Y} \quad (1)$$

where $\rho_{X,Y}$ denotes the overall Pearson correlation coefficient of variables X and Y , $\text{cov}(X,Y)$ represents the covariance between variables X and Y , and $\sigma_X \sigma_Y$ represents the product of the standard deviations of variables X and Y . The estimation is based on the sample with respect to the variance and covariance.

$$\sigma_X^2 = \frac{1}{n-1} \sum_{i=1}^n (X_i - \bar{X})^2 \quad (2)$$

$$\text{cov}(X,Y) = \frac{1}{n-1} \sum_{i=1}^n (X_i - \bar{X})(Y_i - \bar{Y}) \quad (3)$$

Bring (2) and (3) into (1). The absolute Pearson coefficients of the samples are obtained as follows.

$$r = \left| \frac{\sum_{i=1}^n (X_i - \bar{X})(Y_i - \bar{Y})}{\sqrt{\sum_{i=1}^n (X_i - \bar{X})^2} \sqrt{\sum_{i=1}^n (Y_i - \bar{Y})^2}} \right| \quad (4)$$

With the EEG channels considered as variables and their corresponding data as observations, the Pearson correlation coefficients were calculated for all channels and the three channels most closely associated with motor imagery, C3, C4, and Cz. To ensure that negative correlations between channels and changes in EEG signals in the motor cortex of the brain were not overlooked, the absolute values of the Pearson correlation coefficients were taken. The correlation degree between all channels and the three motor imagery-related channels was calculated, and the channels with the highest correlation were selected as “Free Channels” for model input. The number of “Fixed Channels” and “Free Channels” selected for different datasets are shown in Table I.

C. Graph ResNet

The graph convolution network can be divided into two categories: spectral graph convolution network and spatial graph convolution network [24]. The spectral method defines graph convolution in the spectral using the convolution theorem, while the spatial method aggregates the central node and its neighboring nodes by defining an aggregation function in the node domain. In this paper, the spectral graph convolution method is employed.

1) *Graph represents*: For an undirected graph, it can be represented as $G = \{V, E, A\}$, where $|V| = n$ denotes the number of nodes, E denotes the set of edges, and A denotes the adjacency matrix that defines the connectivity between nodes. The Laplacian matrix of the graph is denoted by $L = D - A$, where D is a diagonal matrix. The normalized Laplacian matrix [24] is defined as

$$L = I_n - D^{-\frac{1}{2}} A D^{-\frac{1}{2}} \quad (5)$$

and since L is a real symmetric matrix, an eigen-decomposition of L yields $L = U \Lambda U^T$, where U denotes the identity matrix of L , Λ is the diagonal array of eigenvalues. The correlation matrix, Pearson matrix, absolute Pearson coefficient matrix, adjacency matrix, degree matrix, and Laplace matrix of subject 1 in SHU-Dataset are given in in Fig. 4.

2) *Graph convolution*: In the spectral, the graph convolution of signals x_1, x_2 is defined as

$$x_1 *_g x_2 = U((U^T x_1) \odot (U^T x_2)) \quad (6)$$

where $*_g$ represents the graph convolution operator and \odot represents the Hadamard product. For an input signal x , the graph convolution operation through a convolution kernel filter $g \in \mathbb{R}^n$ is defined as

$$x *_g g = U(U^T x \odot U^T g) \quad (7)$$

Define g as $g_\theta = \text{diag}(U^T g)$, then the graph convolution operation for x can be simplified to

$$x *_g g_\theta = U g_\theta U^T x \quad (8)$$

To parameterize the convolution kernel g_θ , Chebyshev network (ChebyNet) [25] is used instead of the convolution kernel in the spectral. g_θ is defined as $g_\theta = \sum_{i=0}^K \theta_i T_i(\tilde{\Lambda})$, where $\tilde{\Lambda}$ can be represented as

$$\tilde{\Lambda} = \frac{2\Lambda}{\lambda_{max}} - I_n \quad (9)$$

TABLE I. DISTRIBUTION OF DIFFERENT CHANNEL TYPES

Dataset	Number of Channels	Fixed Channels	Free Channels
SHU Dataset	32		
	16	13	3
Physionet MI Dataset	64		
	32	21	11
	16	3	13

Fig. 4. The correlation matrix, Pearson matrix, absolute Pearson coefficient matrix, adjacency matrix, degree matrix, and Laplace matrix of subject 1 in SHU-dataset.

and the Chebyshev polynomial is defined as $T_i(x) = 2xT_{i-1}(x) - T_{i-2}(x)$, where $T_0(x) = 1$ and $T_1(x) = x$. Therefore, the ChebyNet graph convolution operation is

$$x *_G g_\theta = U(\sum_{i=0}^K \theta_i T_i(\tilde{\Lambda})) U^T x \quad (10)$$

Let $\tilde{L} = \frac{2L}{\lambda_{max}} - I_n$, then $T_i(\tilde{L}) = UT_i(\tilde{\Lambda})U^T$, and the ChebyNet graph convolution operation can be simplified as

$$x *_G g_\theta = \sum_{i=0}^K \theta_i T_i(\tilde{L}) x \quad (11)$$

ChebyNet convolution does not require feature decomposition of the Laplacian matrix, and the convolution kernel has only $K + 1$ trainable parameters [25]. Therefore, the parameter complexity is significantly reduced.

3) *Graph pooling*: ChebyNet implements pooling operation using a complete binary tree. In the coarsening phase based on the Graclus multi-level clustering algorithm [26], the input feature tensor is divided into blocks of equal

Fig. 5. ChebyNet implements pooling operators using complete binary trees[25].

IV. RESULTS AND DISCUSSION

A. Dataset Description

1) *SHU dataset*: This work utilized the SHU Dataset, a publicly available motor imagery dataset from Shanghai University in 2022[28]. The dataset includes 25 subjects who underwent a total of 5 sessions every 2-3 days. Each session included 100 trials, which were automatically labeled by using EEGLAB with amplitudes greater than $100 \mu V$. Experts then reviewed and eliminated any bad segments, resulting in a small number of missing trials in some sessions. The motor imagery tasks consisted of left-hand (L) and right-hand (R). EEG data were recorded using 32 electrodes based on the International 10-10 system with a 250 Hz sampling rate and a 4-second time window. Each subject had a total of 500 trials (5 sessions * 100 trials), and each trial included 1000 sampling points. The EEG data acquisition paradigm is shown in Fig. 6.

Fig. 6. Timing paradigm of SHU dataset.

2) *PhysioNet dataset*: The PhysioNet dataset included 109 subjects who performed motor imagery tasks using their left

hand (L), right hand (R), both fists (B), and both feet (F). EEG data was recorded from 64 electrodes based on the International 10-10 system, with a sampling rate of 160 Hz and a time window of 4 seconds. Each subject completed 84 trials (3 runs * 7 trials * 4 tasks), with each trial consisting of 640 sampling points.

4) *Residual learning*: Deep neural networks are known for their improved ability to fit nonlinear functions as the number of layers and neurons increases. However, simply stacking layers can lead to problems such as vanishing gradients, exploding gradients, and network degradation. To address these issues, Residual Learning proposed in [27]. This framework assumes that $H(X) = X$ represents the optimal solution mapping, and the general convolutional neural network is directly fitted with $H(X) = X$. In contrast, the residual network aims to fit the residual mapping, $F(X) = H(X) - X$. The optimal solution mapping is then given by $H(X) = F(X) + X$.

hand (L), right hand (R), both fists (B), and both feet (F). EEG data was recorded from 64 electrodes based on the International 10-10 system, with a sampling rate of 160 Hz and a time window of 4 seconds. Each subject completed 84 trials (3 runs * 7 trials * 4 tasks), with each trial consisting of 640 sampling points.

B. Channel Selection Results

1) *SHU dataset*: The original SHU-Dataset had 32 channels. Firstly, three channels C3, C4, and Cz -were selected, and then 10 additional channels were selected based on their spatial location: FC1, FC2, FC5, FC6, T3, T4, CP1, CP2, CP5, and CP6. In total, 13 channels were selected and has been marked in Fig. 7(a). Finally, three Free Channels are selected based on the absolute Pearson coefficients, and a total of 16 channels were used as input for the model.

Taking the first three subjects in the dataset as an example, computing the sum of the absolute Pearson coefficients for all channels and C3, C4, and Cz channels. The computation results are presented in Fig. 7(b), and the channels that were selected based on this result are listed in Table II.

2) *PhysioNet dataset*: The original dataset consists of 64 channels, which are reduced to 32 and 16 channels respectively. In both cases, three channels (C3, C4, Cz) were first selected from the source channels, and the remaining channels were selected using the following method:

- For the 32 EEG channels, 18 channels were initially selected based on their spatial location, resulting in a total of 21 Fixed Channel as shown in Fig. 8. Then, 11 Free Channels were selected based on the absolute Pearson coefficients.
- For the 16-channel subset, due to the densely arranged 64 channels based on the international 10-10 system and the need for fewer channels, the remaining 13 Free Channels were all selected based on the absolute Pearson coefficients.

Fig. 7. (a) Shows schematic diagram of SHU Dataset Fixed Channels, (b) Shows the sum of the absolute Pearson coefficients between all channels and the C3, C4, and Cz channels for the first three subjects in the SHU-Dataset was calculated.

TABLE II. FREE CHANNELS SELECTED OF THE THREE SUBJECTS

Subject	Added channels label	Added channels

Fig. 8. Schematic diagram of physionet dataset fixed channels.

C. Evaluation Metrics

To evaluate this algorithm, this work introduces the Information Translate Rate (ITR) [29] as an additional evaluation metric, in addition to the traditional precision metric. ITR is a standard method for measuring communication systems, expressing the amount of information transmitted per unit time. The bit rate depends on both speed and accuracy. The formula for calculating ITR is as follows

$$ITR = 60 \cdot \frac{\log_2 M + P \log_2 P + (1-P) \log_2 \frac{1-P}{M-1}}{T_0} \quad (12)$$

Here, T_0 represents the prediction time of each sample in the model, M represents the number of categories, and P represents the classification accuracy. The unit of ITR is bits/min.

D. Equipments

This work utilized a remote server that runs on the Ubuntu 18.04 operating system to conduct experiments. The experiments were conducted in a Python 3.6 environment using the TensorFlow 1.15 deep learning framework. The models were trained and evaluated using 1 NVIDIA Tesla V100-PCIE-32GB GPU and 1 Intel Xeon Processor (Skylake) 2.4GHZ CPU. The system was equipped with 147GB RAM for system memory and had 6TB hard disk capacity.

E. Model Parameters

The network architecture consists of 12 convolutional layers, each connected to a pooling layer every two layers. The dataset is split into 90% training data and 10% test data. A training cycle of 100 batches is utilized and the performance of the trained model is evaluated on the test set after each cycle. Evaluation metrics including ITR and accuracy are calculated, and finally the average value of the successive ITR is taken to reduce randomness. The model hyperparameters are shown in Table III.

TABLE III. MODEL HYPERPARAMETERS

Hyperparameter	Value
Chebyshev Order	3
Activation Function	Leaky ReLu
Batch size	1024
Epoch	50
Optimization Algorithm	Adam
Learning Rate	0.001
Dropout	0.5

F. Experimental Results

1) *SHU dataset*: For this dataset, choosing to train the EEG dataset of the first 15 subjects separately, and the outcomes are presented in Fig. 9.

Table IV presents the results of motion imagery classification accuracy using all 32 channels, with an impressive accuracy of 83.98% reported in [16]. This outperforms the various benchmark classification methods used in [28], which achieved a maximum accuracy of 78.9%

on the cross-session task. After applying proposed method to halve the channels, the classification accuracy improved by 1.86%, the ITR improved by 14.4%, and the sample prediction time decreased by 22.7%. This result indicates that reducing the number of channels effectively reduces interference information, reduces data redundancy, and improves information transmission rate. In particular, some subjects who previously had poor classification accuracy and ITR, such as subjects 4, 5, 8, and 10, showed significant improvement after channel reduction. Using only half of the channel data, higher average classification accuracy and ITR were achieved compared to using all 32 channels. Furthermore, after applying the Adaptive Channel Selection algorithm, significant improvements were observed in classification accuracy and ITR compared to using all channels and only 16 channels. The classification accuracy improved by 5.36% and 3.5%, ITR improved by 29.24% and 12.97%, and single-sample prediction time was reduced by 12.56% and 13.13%, respectively.

2) *Physionet dataset*: For this dataset, training the EEG data of the first 20 subjects separately, and the experimental results were obtained by taking the mean values of the different subjects. These results are presented in Fig. 10.

Table V shows that with the input of all 64 channels data [16], the classification accuracy is improved by 1.26% and 8.21% compared to 32 and 16 channels, respectively, due to the availability of more extracted features. However, this leads to more data redundancy and the longest single-sample prediction time, resulting in a lower ITR compared to 32 channels. Although the ITR of 16 channels has only a 3.85% difference compared to 64 channels, the classification accuracy loss is higher due to less information available and less training

time. By using the proposed Adaptive Channel Selection algorithm, the classification accuracy is improved by 0.98%, 2.24%, and 9.19% compared to 64, 32, and 16 channels, respectively, and the ITR is improved by 26.75%, 7.66%, and 22.05%, respectively.

Fig. 9. (a) Shows the classification accuracy of the model under different channel strategies. (b) Shows the ITR of the BCI system under different channel strategies.

TABLE V. PHYSIONET DATASET EXPERIMENTAL RESULTS

Channels Strategies	Acc (%)	ITR (bits/min)	T_0 (μ s)
64	91.53	1123454	33.8
32	90.27	1322665	30.1
16	83.32	1166775	27.25
Ada	92.51	1424018	29.75

TABLE VI. PERFORMANCE OF DIFFERENT METHODS ON PHYSIONET DATASET

Work	Channels Strategies	Average Acc(%)
This work	Ada	92.51
Jia et al. [16]	All Channels	91.53
Hou et al. [31]	All Channels	92.5
Ma et al. [32]	All Channels	68.2

In short, the proposed method utilizes less channel data while achieving comparable accuracy to some studies using full channel data, and higher ITR as shown in Table VI. Specifically, the method achieves an average classification accuracy of 92.51%, while in [16], using the same feature extraction method with full channel data, achieves 91.53% accuracy. The method is slightly better than the 92.5% average classification accuracy obtained in [30] using scout EEG source imaging (ESI) with a convolutional neural network (CNN) algorithm. Furthermore, it is much higher than the average classification accuracy of 68.20% obtained in [31] using Spatial and Temporal Recurrent Neural Networks for classification.

V. CONCLUSION

This work proposes an Adaptive Channel Selection algorithm that automatically selects the optimal combination of EEG channels for each subject to maximize the information transmission rate of the BCI system. The channel combinations include all channels and some selected channels based on the spatial location of each channel in the dataset and the absolute Pearson coefficients of each channel with the key channels C3, C4, and Cz, which are commonly used in motor imagery experiments.

To extract features, this work uses a deep graph convolutional neural network with residual blocks added to

prevent overfitting. Applying this method to the SHU dataset improved the classification accuracy by up to 5.36% and the information transfer rate (ITR) by up to 29.24% compared to using a single channel combination. On the Physionet dataset, the classification accuracy is improved by up to 9.19% and the ITR is improved by up to 26.75%. The proposed algorithm effectively addresses the problems of data redundancy and individual differences faced by deep neural networks in extracting features, and significantly improves the classification accuracy and ITR.

In summary, the study demonstrates the effectiveness of the proposed adaptive channel selection algorithm for decoding EEG-based motor imagery. The algorithm outperforms the single-channel combination scheme and has the potential to improve the generalization capability of deep neural networks for BCI applications. Future work will focus on exploring the generalization capability of this channel selection algorithm across different datasets and experimental conditions.

Abstract—The Internet of Vehicles (IoV) is an innovative concept aimed at addressing the critical problem of traffic congestion. IoV applications are part of a connected network that collects relevant data from various smart sensors installed in connected vehicles. This information is freely and easily exchanged between vehicles, which leads to improved traffic management and a reduction in traffic accidents. As the IoV technology continues to grow, the amount of data collected will increase, presenting new challenges for data privacy and security. The use of blockchain technology has been proposed as a solution, as its decentralized and distributed architecture has been proven reliable with cryptocurrencies such as Bitcoin. However, studies have shown that blockchain alone may not be sufficient to address privacy and security concerns, and there are currently no tools available to evaluate its performance in an IoV simulation environment. This research aims to provide a comprehensive review of the challenges associated with the implementation of blockchain technology in the IoV context.

Keywords—Internet of vehicles (IoV); traffic congestion; smart sensors; connected vehicles; data privacy; data security; blockchain technology

I. INTRODUCTION

With the rapid development of the automobile industry, the Internet of Vehicles (IoV) technology is expected to grow as the most promising solution to ensure road safety and efficiency. However, this growth has brought numerous challenges regarding data storage, processing power, and data privacy and security. Traditionally, IoV data is all stored in a central node, where all network communication passes through, putting the security of the IoV network at serious risk because an attack on the central node would compromise all nodes in the network. Additionally, a centralized approach cannot handle real-time responses efficiently due to dynamic and large IoV scenarios.

Blockchain technology, originally developed for the cryptocurrency Bitcoin, ensures secure, trustworthy, and reliable transaction sharing among users based on peer-to-peer networks. As a decentralized approach, blockchain offers a transparent and secure exchange of information in the IoV network. Its decentralized and distributed architecture has demonstrated great ability in storing and processing big data while preserving the privacy and security of information. By combining the IoV with blockchain technology, security and privacy issues can be addressed. However, a blockchain-based IoV network still faces many obstacles, such as resource deficiency and large and dynamic IoV scenarios.

This paper proposes a contribution based on a systematic review methodology to address the challenges facing the blockchain-based IoV network. The methodology section explains the method used to search and select articles, the challenges associated with the blockchain-based IoV section focuses on analyzing the selected articles, and the results and important discoveries section presents a classification of the preceding challenges and highlights important observations. Finally, the conclusions and future directions section provides insights on the potential of blockchain in securing information exchange in IoV networks.

II. BACKGROUND

A. Blockchain Architecture

A blockchain is a sort of distributed ledger technology (DLT) that comprises of a sequence of data containers called blocks. Where each block is containing a complete list of transaction information. Furthermore, each block is linked to the previous block by containing its hash value, and since each block is linked to the previous one, they then create a sequence of blocks called blockchain. Fig. 1 illustrates an example of a blockchain.

Fig. 1. Example of a blockchain.

1) **Block**: As predefined, blocks are data containers that consist of a block header and a block body. The header of the block contains valuable information required for its identification within the network. Each block header contains the following information:

- Block Version.
- Hash value of the previous block.
- The hash value associated with of all transactions recorded in this block, known as Merkle root hash.
- nBits, which represents the difficulty with which the current block was created.

- Timestamp.
- A random number which increases every hashing calculation known as Nonce.

As for the block body, it contains all transactional information which occurred in this block.

2) *Transactions*: Transactions are the most important part of blockchain, the whole blockchain ledger is designed to ensure a successful creation of transactions, and then move to spreading these transactions through the network to be validated by the other nodes. A transaction combines three key values, recipient address, sender information, and transaction record. That after being validated, gets added to the global blockchain as a new block.

3) *Consensus*: Once a new block is created, it must be validated by all nodes in the blockchain distributed ledger. This process is referred to as "consensus making." Depending on the blockchain and its use, there are several types of consensus algorithms that vary in terms of energy consumption, security, and scalability, but serve the same purpose of verifying that transactions are accurate and authentic. Some of the most commonly used consensus algorithms are proof of work (PoW), which is used with Bitcoin, and proof of stake (PoS), which is more energy-efficient.

"Mining" (proof of work) is a well-known process responsible for adding a new block to the blockchain ledger, distributed among all blockchain users. Participants in this process are called "miners." Mining involves solving a highly complex mathematical problem, which requires a large amount of time and energy, in order to find the correct hash. Miners try to solve this problem using powerful computers, and the first computer to find the correct hash receives the new block.

Proof of stake (PoS) techniques require "validators" to store and hold tokens in exchange for the right to collect transaction fees. PoS reduces the computational effort required to validate blocks and transactions. Proof of work ensures the security of the blockchain, while proof of stake changes the way blocks are confirmed by leveraging the computing resources of currency owners, requiring less computational effort. Owners stake their currency for the opportunity to validate blocks and become validators.

1) *IoV architecture*: Internet of vehicles (IoV) is a network connecting cars, pedestrians, and road infrastructure, through a process of information exchange. The network is equipped with a variety of sensors, which are responsible for collecting data from surrounding environments, to be shared with other parts of the network through the internet. IoV aims to enhance traffic conditions and reduce accidents and traffic congestion through interconnectivity. Fig. 2 illustrates IoV network structure. IoV architecture is composed of three main layers:

2) *Perception layer*, which englobes all vehicular sensors and devices required to collect environmental data. It also

contains every hardware device required for the network functioning.

3) *Network layer*. This layer is responsible for data transmission among IoV devices through network connectivity. The most known networks for supporting these transmissions are Wi-Fi, 4G/5G, and Wlan.

4) *Application layer*, is the layer responsible for data storage, data analysis, and decision-making regarding safety measures, in case of urgent traffic conditions. And in the case of autonomous driving cars, this layer controls the brakes, accelerator, and the engine, based on traffic conditions information received from different sensors in the network.

Fig. 2. IoV Structure.

III. SYSTEMATIC REVIEW METHODOLOGY

This research aims to answer the following question: what are the security limitations of the application of blockchain technology in IoV? This research question was the main subject of the analysis methodology of different research articles on the application of blockchain technology in IoV. It was used to select, filter, evaluate these studies, and exploit their results.

1) *Search method*: A systematic review regarding the application of blockchain technology in IoV was conducted using Scopus, Web of Science, and IEEE Xplore. To find relevant information on the subject, this combination of keywords was used ("data privacy and security", "blockchain", and "IoV"). Relevant scholarly articles were identified and selected to move forward in this review of the literature.

2) *Criteria*: Only the articles that fulfill the predefined criteria were considered, there are four key criteria that a study needs to achieve in order to be eligible, as shown in Table I.

TABLE I. INCLUSION CRITERIA

No	Criteria
1	The study focused on blockchain-based IoV.
2	The paper discussed a security issue with the application of blockchain technology in IoV.
3	The proposed solution aimed to ensure data privacy and security in a blockchain-based IoV network.
4	Papers should be published recently.

3) *Data collection*: All information regarding the challenges, solutions, and results was extracted. The collected data from each paper was mainly about the security and privacy of exchanged information in a blockchain-based IoV network. However, some papers discussed other issues such as computing power, and handling dynamic and large IoV scenarios, which can cause a problem in achieving a secure and private exchange of information between vehicles, to this end we've decided to include these researches in our review in order to have a more exhaustive vision of the results Fig. 3.

Fig. 3. Review process.

IV. THE CHALLENGES ASSOCIATED WITH BLOCKCHAIN-BASED IOV

Our systematic review concerns a total of forty articles. The reviewed studies have shown a variety of limitations regarding the application of blockchain technology in IoV. These limitations should be examined in future studies on adopting blockchain technology as a solution to solve the security and privacy issues. As shown in Table II, more than half of the reviewed articles focused on solving the problem of security and privacy. However, other studies in this review that concentrate on other challenges, such as the security of smart sensors and resource limitations, were selected as well due to their impact on achieving a private and secure blockchain-

based IoV network. The challenges associated with technological aspects are clearly dominating the article outcomes. The primary technology problems are identified as security, privacy, scalability, data collection, and security of smart sensors. It is worth noting that security, the driving force behind blockchain technology, is still a major concern for many academics. More information on these challenges, however, may be found in the challenges and results sections.

A. Security and Privacy

The growth of the Internet of Vehicles (IoV) has brought to light various challenges in regards to data storage, processing, and information privacy and security. In order to address these issues, Jiang, Fang, and Wang in [7] utilized blockchain technology in their implementation of IoV. The authors simulated the network's communication performance using MATLAB and found that under traffic congestion, the number of retransmissions increases, potentially leading to switching to a cellular network. However, the study does not take into account the impact of car traffic or the reliability of cellular networks. Vehicles in the IoV network communicate through third parties, which increases the risk of rogue cars transmitting false data. As a result, authentication of vehicles and service providers is crucial to prevent this issue. However, the authentication process involves exposing the vehicle's identification, and compromising privacy. Sharma and Chakraborty in [19] proposed a blockchain-based architecture (BLOCKAPP protocol) to address this challenge, which reduces the number of verifications and increases transaction rate by issuing pseudo-IDs to each vehicle. Wang, Zeng, Patterson, Jiang, and Doss in [23] studied the use of a blockchain-based authentication technique for IoV networks. The simulation results showed that this approach can handle information exchange, authentication, and encryption while being secure against malicious attackers. However, significant packet loss was observed during car registration and key distribution processes. Securing the IoV network becomes more challenging as the network becomes larger and more dynamic. To address this issue, a secure architecture based on blockchain technology was proposed in [15]. The framework allows for knowledge exchange among vehicles while maintaining privacy and security. The study used distributed smartphone applications and OBD-II to gather data and save it in the blockchain. The results showed that the framework can handle a high amount of concurrent traffic, but there were still some observed packet losses due to connection challenges. Narbayeva, Bakibayev, Abeshev, Makarova, Shubenkova, and Pashkevich in [14] focused on improving IoV cybersecurity through the use of blockchain technology. The authors utilized blockchain to create a secure system that provides parameters about a car through signals from nearby vehicles, and to track the movement of cars using the Exonum platform. However, this technique still relies on users being careful with their private keys.

TABLE II. CATEGORIES OF RELEVANT STUDIES

Aspects	Challenges	Description	Reference
Technological	Security and Privacy	Maintaining a secure and private exchange of information among vehicles	[1-2-3-4-5-6-7-8-9-10-11-12-13-14-15-16-17-27-28-29-30-31-32-33-34-35-36-37-38-39-40]
	Scalability	Blockchain's lack of scalability in case of huge amount of data	[18-19]
	Data collection	Enhancing the process of data collection	[20,14]
	Smart Sensors	Securing smart sensors against malicious attacks	[21,22]
Energetical	Resource limitations in the light of a high network performance	Analysis to enhance network performance, while respecting limited resource allocation	[23-24-25-26]

Due to the variety of security standards, the exchange of shared information between vehicles faces several security challenges. The use of blockchain technology can enhance the security of information exchange, however, it is still vulnerable to malicious attacks at higher layers and applications. Researchers Gunasekaran Raja et al. in [16] attempted to address the security flaws of blockchain by applying an AI-powered blockchain to Internet of Vehicles (IoV). The suggested system was evaluated by comparing it to traditional blockchain smart contracts, and the results showed that the smart contract vulnerabilities resulted in a significant cost for the system. Additionally, advancements in technology may pose a threat to the entire network. On the other hand, AI-powered intelligent contracts have a self-learning capability, allowing the system to improve its security. The study found that AI-powered intelligent contracts performed better in terms of preserving blockchain characteristics compared to blockchain smart contracts. Pranav Kumar Singh et al. in [21] addressed the same issue by combining AI and blockchain. However, the security of the system may be compromised by malicious or rogue nodes in the network. AI, with its predictive capability based on machine learning algorithms, is an effective solution for dealing with rogue nodes. It can quickly detect malicious peers, but there have been no real-world tests to evaluate the performance of the proposed framework. Jiawen Kang et al. in [8] proposed a soft security enhancement solution, which involves miner selection based on a reputation voting scheme, and block verification by standby miners using contract theory. The results of the simulation showed that the proposed approach outperforms traditional reputation schemes in detecting malicious miner candidates and increases shared information security. On the other hand, other researchers used a Byzantine consensus algorithm based on time sequence and gossip protocol (BCA-TG), on top of blockchain technology, to enhance the security of communication, consensus, and authentication of nodes in an IoV network [6]. The simulation results showed that consensus can be reached when the number of Byzantine nodes is less than half of the total number of nodes in the network. However, further testing needs to be done in real-world systems with a larger number of nodes and dynamic IoV scenarios.

One of the significant limitations in the Internet of Vehicles (IoV) network is the spectrum sensing process and ensuring a secure flow of information without interference. In case of a vehicle attack, the Cognitive Radio Network (CRN) can enhance decision-making in the IoV network. However, even though CRN has its benefits, network performance can be affected if malicious attackers modify data. To enhance

network performance, a study by Geetanjali Rathee et al. suggested implementing a blockchain approach in CRN-based IoV to allow vehicles to keep track of all network operations and detect untrusted devices using the Technique for Order Preference by Similarity to Ideal Solution (TOPSIS) mechanism. According to simulation data, this method improves attack detection by 70%. However, the study did not address the authentication concerns in the TOPSIS method, and only a limited number of factors were evaluated in improving the spectrum sensing process and information transmission between vehicles. Another study by Yonggang Xiao et al. aimed to address the issue of safe information transmission between cars by building a rapid false news detection framework that uses edge computing and blockchain to identify fake news and prevent the exchange of any questionable information. The simulation results suggest that the proposed framework can provide accurate information about ongoing traffic events one minute after it starts and 4 minutes after the incident. However, the study did not address the issue of load balancing, and the framework has not been tested in a real-world setting. A study by Song-Kyoo Kim aimed to prevent network breakdown due to malicious attacks by designing a secure connected car network using a Blockchain Governance Game (BGC). BGC has been mathematically proven to be a robust model for defending systems from malicious attacks. However, there was no mention of simulation experiments in this study. Leo Mendiboure et al. focused on addressing security challenges in IoV using Software-Defined Networking (SDN) and regulating application identity and behavior using blockchain technology. This study did not contain any information on the simulation environment or findings, and various issues with the theoretical solution were raised. Another study by Saltanat Narbayeva et al. focused on safeguarding data transmission between vehicles using a hierarchical blockchain framework. According to simulation findings, blockchain was able to protect the network from rogue cars. However, the overhead and transactional throughput of the proposed framework were not studied, and there was no simulation in a real-world setting. The centralized approach no longer meets the requirements of knowledge exchange among intelligent cars due to the fast growth of information technology. With the advent of IoV technology, a more advanced intelligent transportation system may be realized. However, IoV still faces challenges such as handling diverse situations and failure tolerance. On the other hand, the centralized approach is considered weak due to its lack of flexibility and vulnerability to a single point of failure. Blockchain technology can address this issue, but it is difficult to determine the appropriate blockchain settings due to the

unpredictable vehicle density. To solve this issue, Liming Gao et al. proposed a multichannel blockchain scheme that can select the best parameters based on the vehicle density.

A major challenge in a blockchain-based Internet of Vehicles (IoV) network is balancing privacy protection with information availability. Vehicles gather and share traffic data, and there is a risk of conflicts between this shared information. To mitigate this, a semi-centralized approach based on blockchain was suggested by Lichen Cheng et al. in [2]. This approach regulates traffic lights to guarantee efficient traffic flow while protecting shared information and the users' identities. However, this mode requires reducing interaction and encryption computation costs. The rapid increase in automobiles has led to the overuse of spectrum resources. To address this, a multiuser k-anonymous location protection method was proposed by Hongning Li et al. in [11]. The system preserves users' location privacy by creating anonymous zones and encouraging primary users to share spectrum. In [27], Zhang et al. proposed a blockchain-based solution for secure and privacy-preserving data sharing in the IoV. They analyze the challenges of privacy and security in the IoV and introduce a framework that includes privacy-preserving and secure data sharing. The framework was evaluated and shown to be effective in securing and preserving data privacy in the IoV environment. Hu and Li in [28] reviewed the security challenges in the IoV and discussed how blockchain technology can be used to address these challenges. They presented an overview of the IoV architecture and highlighted the security problems that exist in the data collection, storage, and transmission phases of IoV. They also described the characteristics of blockchain technology that make it suitable for use in the IoV and discussed existing blockchain-based solutions for securing IoV data. Tang, Wang, and Su in [29] proposed a secure and efficient communication scheme for the IoV based on blockchain technology. The proposed scheme uses a blockchain-based consensus algorithm to ensure data communication security in the IoV and a multi-layer encryption mechanism to protect data privacy. Simulation experiments showed that the proposed scheme was secure, efficient, and capable of meeting the communication requirements of the IoV. Iqbal, Liu, Guo, and Zhang in [30] proposed a blockchain-based trust management framework for the IoV. The framework uses blockchain technology to establish a trust mechanism that enhances the security and privacy of data transmission in the IoV. The performance of the framework was evaluated through simulation experiments, which showed that it effectively enhanced the security and privacy of data transmission in the IoV. Finally, Yang, Yang, and Huang in [31] presented an overview of the challenges and opportunities of using blockchain technology in the IoV. They analyzed the security and privacy problems in the IoV and discussed how blockchain technology can be used to address these challenges. They also described the architecture of a blockchain-based IoV system and highlighted the potential benefits of using blockchain in the IoV, such as increased data security and privacy.

Chen, X., and Li, Y. in [32] proposed a blockchain-based secure and privacy-preserving data sharing framework for the Internet of Vehicles (IoV). The authors aimed to address the

security and privacy challenges associated with data sharing in the IoV by utilizing blockchain technology. The proposed framework comprised a data sharing process that utilized a smart contract to ensure data authenticity and integrity, as well as a privacy-preserving mechanism that used homomorphic encryption to protect the privacy of the data. The authors evaluated the proposed framework through a simulation experiment, which showed that it could effectively improve the security and privacy of data sharing in the IoV. Wang, X., Huang, Y., and Lu, R. in [33] proposed a blockchain-based secure data sharing framework for the Internet of Vehicles (IoV). The authors aimed to address the security and privacy challenges of data sharing in the IoV by utilizing blockchain technology. The proposed framework included a consensus mechanism and a smart contract to guarantee the authenticity and integrity of the data, as well as a privacy-preserving mechanism that used homomorphic encryption to protect the privacy of the data. The authors evaluated the proposed framework through a simulation experiment, which showed that it could effectively enhance the security and privacy of data sharing in the IoV. Zhang, Y., Yang, X., Yang, Y., and Huang, X. in [34] proposed a secure and privacy-preserving data sharing framework for the Internet of Vehicles (IoV) based on blockchain technology. The authors aimed to tackle the security and privacy challenges of data sharing in the IoV by using blockchain technology. The proposed framework consisted of a consensus mechanism and a smart contract to ensure the authenticity and integrity of the data, as well as a privacy-preserving mechanism that used homomorphic encryption to protect the privacy of the data. The authors evaluated the proposed framework through a simulation experiment, which showed that it could effectively improve the security and privacy of data sharing in the IoV. Zhang, Y., and Li, J. in [35] focused on applying blockchain technology to secure and privacy-preserving data sharing for the Internet of Vehicles (IoV). The authors proposed a blockchain-based framework for secure and privacy-preserving data sharing in the IoV, which could effectively secure and protect the privacy of the data shared by vehicles. The framework provided a secure and privacy-preserving platform for IoV applications and services, enabling trustworthy and secure data sharing among different parties in the IoV. The authors also analyzed the security and privacy of the proposed framework through experiments and simulations, demonstrating the effectiveness and feasibility of the framework in the IoV. Fang, S., Liu, X., and Wang, S. in [36] conducted a study that focused on the application of blockchain technology to secure data sharing in the Internet of Vehicles (IoV). The authors proposed a secure data sharing mechanism that utilized blockchain to guarantee data privacy and security in the IoV. They presented a prototype system to demonstrate the feasibility of their proposed solution. The results showed that their proposed system was effective in terms of data security and privacy protection in the IoV. Li, H., Li, H., and Lu, R. in [37] focused on using blockchain to secure data sharing in the Internet of Vehicles. The authors presented a blockchain-based secure data sharing framework for the IoV, which aimed to protect the privacy and security of data in the IoV. The framework consisted of several components, including a data storage layer, a consensus layer, and a privacy protection layer. The

authors evaluated the performance of their proposed framework, and the results showed that it was efficient and effective in terms of security and privacy

B. Scalability

With Bitcoin's dominance in the cryptocurrency market, scalability issues related to blockchain technology have come to the forefront. Articles have analyzed various critical criteria to assess Bitcoin's scalability, including maximum throughput and latency, which significantly impact the user experience. However, the transaction throughput receives the most attention, with reports indicating that Bitcoin has a maximum transaction throughput of only 7 transactions per second, which is low compared to other technologies. As a result, blockchain may not be able to support large-scale transactions. Blockchain is a novel technology that enables secure transactions between parties in a decentralized and transparent network. However, besides scalability and latency, it also faces the challenge of high energy consumption [10]. In the Internet of Vehicles (IoV) network, a large amount of data is collected to improve traffic safety, and blockchain's scalability limitations become a significant issue when dealing with big data [10]. To address this issue, some articles have proposed a Deep Reinforcement Learning (DRL) based performance optimization framework for blockchain-based IoV, which aims to optimize transactional throughput while preserving network latency and privacy [12].

C. Data Collection

Data collection in the Internet of Vehicles (IoV) is crucial for achieving its goals. However, this process is hindered by a major issue: the reluctance of vehicles to participate in sensing operations. Additionally, some sensing tasks may arise unexpectedly, placing a strain on the resources of a single vehicle. As a result, it is necessary to have a large number of vehicles participate. To address this challenge, a novel paradigm of two vehicles collaborating was proposed in [26]. This strategy is based on a bidding process that incentivizes vehicles to collaborate and share resources. In case of an emergency task, a time-window-based mechanism for task management among vehicles is used to increase vehicle involvement. Moreover, a blockchain architecture is utilized to secure data sharing through smart contracts. According to simulation studies, the processing time decreases as the number of vehicles increases.

Haoye Chai, Supeng Leng, Yijin Chen, and Ke Zhang in [1] aimed to improve the data collection process by incorporating Artificial Intelligence (AI) to help vehicles learn from their surroundings using a federated learning algorithm based on machine learning. The simulation results showed that the proposed algorithm is 10% more accurate than conventional federated learning algorithms. However, the overhead and transactional throughput of the proposed framework were not studied, and there was no simulation conducted in a real-world setting.

D. Security of Smart Sensors

The Internet of Vehicles (IoV) employs various smart sensors that are vulnerable to malicious attacks, which could compromise network security. To address this issue, Anastasia Theodouli, Konstantinos Moschou, Konstantinos Votis,

Dimitrios Tzouvaras, Jan Lauinger, and Sebastian Steinhorst in [22] focused on securing software updates for smart sensors, as an incorrect update could lead to incorrect data being generated on the network.

This study proposed a blockchain-based system for managing identity and trust across the entire IoV network with the aim of securing the update process. On the other hand, Geetanjali Rathee, Ashutosh Sharma, Razi Iqbal, Moayad Aloqaily, Naveen Jaglan, and Rajiv Kumar in [18] provided a blockchain infrastructure to protect smart sensors from malicious intrusions.

E. Resource Limitations in the Light of a High Network Performance

In a blockchain-based Internet of Vehicles (IoV), reaching consensus requires a high level of computational power, which some IoV nodes may not be able to support. To address this issue, Liya Xu, Mingzhu Ge, and Weili Wu in [25] proposed integrating edge computing into the blockchain-based IoV by installing roadside units as edge servers. They used an algorithm to simulate the IoV environment and found that additional factors, such as transmission distance, can impact the edge servers. Meanwhile, Liming Gao, Celimuge Wu, Zhaoyang Du, and others in [3] focused on resource management by using a hierarchical resource scheduling approach for the blockchain-enabled IoV. Their proposed scheme was tested using the Hyperledger Fabric platform, and the results indicate its promise. However, as blockchain is a relatively new technology, there is no suitable instrument for testing its performance in an IoV simulator, so only changes in network workload can be tracked. Artificial Intelligence (AI) has been utilized to handle IoV problems and manage its infrastructure, but this requires computing resources and accurate data. Without these, deploying AI could put the entire infrastructure at risk. Moreover, installing both blockchain and AI would consume a significant amount of IoV resources. To address this challenge, Ahmad Hammoud and his colleagues in [5] presented a Vehicular Edge Computing-based architecture that aims to deploy both AI and blockchain technologies while mitigating resource constraints. Despite its benefits, the architecture faces several challenges, such as increased demand on processing and storage resources during traffic congestion and imbalanced network congestion causing uneven data loads on different fog servers. Additionally, updating AI models across multiple servers may cause inconsistencies, and updating blockchain ledgers may be difficult due to the large number of transactions required. To solve this energy problem, Vishal Sharma in [20] proposed an efficient approach that regulates the number of transactions via distributed clustering, which was found to be 40% more energy-efficient than standard blockchain and 82% more efficient in terms of transactions. However, this proposed model has not yet been tested in a real-world setting.

V. RESULTS AND IMPORTANT DISCOVERIES

The purpose of this study was to review published articles that investigate the use of blockchain technology in the Internet of Vehicles (IoV). This review evaluated the existing deficiencies in the proposed solutions for ensuring privacy and security in the IoV network using blockchain technology, and

provided practical suggestions for improving privacy and security while considering computational power and resource consumption. The following patterns were identified:

- The use of a DRL-based performance optimization framework to tackle the scalability issues in blockchain technology.
- The application of edge computing and distributed clustering to manage network resources.
- The integration of AI technology to strengthen the security of blockchain-based IoV network through the use of Byzantine consensus algorithms (BCA-TG) and blockchain governance game (BGC).
- The use of AI technology in the sensing process to improve vehicle data collection through federated learning algorithms.

Security and privacy are the primary challenges in the IoV network, as connected vehicles face difficulties in securely exchanging information and preserving user privacy. The review showed that the proposed solutions tend to converge towards using blockchain technology in IoV networks, but its limitations such as scalability, security issues, and high energy consumption require the use of other technologies along with blockchain to improve privacy and security.

AI technology was proposed to be used with blockchain to enhance network security, but still struggles with resource limitations. Distributed clustering and edge computing were proposed as solutions to the resource limitations, but emerging and unbalanced IoV scenarios such as congestion and accidents can increase data flow and consume more resources. A hierarchical resource scheduling scheme was also proposed to manage computing resources efficiently.

Moreover, the study addressed the growing consumption of spectrum resources in the automotive industry through a k-anonymous location protection scheme for multiuser. The review also emphasized the importance of securing smart sensors against attacks and highlighted the use of blockchain-based frameworks and quick fake news detection frameworks based on edge computing and blockchain to secure information exchange between vehicles. However, these solutions were not tested against emerging IoV scenarios and large load balancing.

VI. CONCLUSIONS AND FUTURE DIRECTIONS

The significance of blockchain in ensuring the security of IoV networks has increased over the recent years. This research aims to provide a comprehensive overview of the challenges faced while adopting blockchain technology to secure IoV networks. A systematic review was carried out to assess the research topic "What are the difficulties in adopting blockchain for securing IoV networks?" as reported in the existing literature.

The difficulties encountered in adopting blockchain for IoV networks were categorized into three categories: security of smart sensors, security and privacy concerns, computing power and resource limitations. The findings of this research suggest that the use of blockchain technology alone is not sufficient to

address privacy and security issues. However, integrating blockchain with AI technology has shown promise in enhancing the security of the network. Nevertheless, the integration still faces challenges such as resource limitations and infrastructure malfunctions. Therefore, future research should concentrate on combining AI technology with blockchain to improve privacy and security in IoV networks.

To tackle the issue of resource limitations, edge computing and distributed clustering appear to be effective in managing resources and reducing consumption. The scalability of the network, especially with the growing number of connected vehicles and dynamic IoV scenarios, should also be taken into consideration in future studies.

Using Descriptive Analysis to Find Patterns and Trends: A Case of Car Accidents in Washington D.C.

Zaid M. Altukhi, Nasser F. Aljohani

Faculty of Computer and Information Systems, Islamic University of Madinah, Madinah, Saudi Arabia

Abstract—The descriptive analysis could be used to find the trends and patterns in historical data. In this article, descriptive analysis has been used to describe the car accidents in Washington, D.C., between 2009 and 2020. The dataset was downloaded from the District Department of Transportation (DDOT), the department responsible for car accidents in Washington, D.C. Multiple analytics and statistical models have been applied to find the relationships between different variables and the patterns and trends among the data, such as correlation analysis, confidence interval, One-Way-ANOVA, decision tree, and visualizations. The article aims to find the common reasons for accidents and help DDOT find ways to reduce and eliminate accidents in the area. The statistical and analytical tools examine multiple features to find the patterns and trends among the datasets. Four main findings were found after analyzing the data. First, the main reason for most crashes is drunken people, either drivers or pedestrians. The second finding is that the top reason which causes deadly accidents is speed. Also, we have found that most of the accidents are not dangerous. In addition, we found the top ten streets that contain the highest accident number, and we found that they are located on the north side of the town.

Keywords—Descriptive analysis; trends; patterns; analytics; statistics; car accidents

I. INTRODUCTION

What are the reasons that car accidents are one of the most dangerous events on roads? The World Health Organization says that around 1.3 million persons die because of car accidents which cost around 3% of most nations' gross domestic [1]. According to the National Highway Traffic Safety Administration of the United States Department of Transportation, this is the highest six-month rise ever recorded in the Fatality Analysis Reporting System's history [2]. In the first half of 2021, a projected 20,160 individuals died in car accidents, rising 18.4 per cent over the same period in 2020, and since 2006, this has been the highest number of expected fatalities in that period [2]. There are two main reasons that can cause crashes on roads. First, external effects are the effects that the driver cannot avoid or are hard to avoid, such as weather conditions and road situations. Second, internal effects are related to the car's driver, such as the driver's health condition, distractions, or car tier issues. According to [3], driver distraction is the leading cause of automobile accidents. Intoxicated drivers, speeding, hostile conduct, rain, failure to obey traffic signs, night driving, vehicle troubles, tailgating, [4] improper turns and driving lean are all factors to consider.

According to data acquired from the District Department of Transportation, about 258,000 accidents occurred in Washington, D.C., between 2009 and 2020 [4]. Because it is

the capital of the United States, Washington D.C. is one of the most important locations in the country. It includes all government offices, tourist attractions, and educational institutions. Furthermore, according to demographic data, the population in 2020 will be 689,545 people living in 68.34 square miles [5].

This article explores and performs a descriptive-analytical analysis of the car accidents that happened in Washington, D.C., between 2009 and 2020 to find insights and patterns in those accidents and understand the reasons and the relationships between different variables that lead to those crashes.

II. OBJECTIVE

This article has analyzed the car accidents in the Washington, D.C. area from 2009 to 2020. The researchers have examined the common factors between accidents, the locations of the accidents, and the car crashes factors that may cause deaths or injuries compared to the number of accidents; also, the factors that significantly correlate with the number of injuries and accident elements. The accident elements are vehicles involved in an accident. In addition, we rank the accidents into groups.

Finding patterns in many incidents gives a clear view of the likely causes that lead to an accident. It will also reveal whether any issues need to be addressed to limit the number of incidents. Because automobile accidents result in numerous injuries, the causes of such injuries will be investigated. On the other hand, many accidents result in merely automobile damage and no human injuries. In addition, assessing the automobile collision location will offer helpful information about areas where authorities should focus their efforts. It can also determine which areas have a high number of injuries or accidents that result in fatalities.

III. DATASET

A. Original Dataset

District Department of Transportation (DDOT) provides a high-quality dataset containing the accidents in Washington, D.C. The data were collected by DDOT and Metropolitan Police Department (MPD) [4]. The data that was downloaded contains 258,122 records and 60 features. However, 19 features have been dropped because they have no relation to the kind of analysis performed on the data. Also, all car accidents that happened before 2009 were dropped. After dropping the unrelated column and data before 2009, those accidents have no vital data. There are seven columns added to the datasets.

Because the dataset is very detailed, those columns were added to aggregate some columns to calculate the number of injuries per accident.

B. Preprocessing and Exploring the Dataset

The shape of the final dataset that will be analyzed contains 237,193 and 55 columns. After exploring the dataset and determining the needs, many processes were performed to clean and prepare the data. The researchers have used some offered software to perform the data analysis, statistical models, and visualizations. First, import the packages used to clean and prepare the data. There are eight libraries that were added as follows:

- Anaconda [6].
- Pandas [7].
- Numpy [8].
- Sklearn [9].
- SciPy [10].
- Altair [11].
- Matplotlib [12].
- Seaborn [13].

C. Feature Engineering

Once the original dataset had been imported, there 18 columns were dropped because either they had too many null values or have not relevant to our analysis. Then there, nine columns were added, as shown in Table I below. They all aggregate multiple numeric columns except the rate column, which classifies the crashes into categories.

Then, there were some columns need to edit their data types from numerical to other type of data as shown in Table II.

After converting the data type for the columns that need to be edited, we found that the data contains old accident information, but it is few, and they contain many null values, so they were removed. The data will remain on the accidents that happened between 2009 and 2020. The original dataset contains accident information up to August 2021. However, it decided to remove the accidents that happened in 2021 because it may affect the analysis results since they were just for eight months.

D. Null Values

After performing feature engineering, we found five columns containing missing values: FROMDATE, ADDRESS, LATITUDE, LONGITUDE, and EVENTID. All these values were removed because it is hard to fill them.

However, some accidents had zero accident elements and zero injuries. Those accidents were also removed.

E. Classify Accidents

To analyze the accidents, it must be categorized. In this article, the authors have decided to divide the accidents into five categories lowest, low, medium, high, and extreme. The categories are done by using the cut-point function provided in

Panda's library [7]. The cut points range is shown in the Table III. However, these numbers were picked based on the observations and data distribution. The result of this rank is as follows:

F. Explore the Data

To properly understand the data and distribution, it is necessary to present statistical information and visualize the data [14]. First, using the describe function on the data frame that contains the data we provide vital information about the data. The Table IV shows the count, mean, standard deviation, min, max, 25%, 50%, and 75% for the added columns.

The data distribution is displayed in the Table IV. A richness of details assists in deciphering the data that can be acquired from simply reading the number. For example, it can be noticed that the maximum number of fatal is two, which is a good indicator that although the number of accidents is high, the fatal cases are too few. Also, visualization is considered one of the best ways to explore and understand data. To better comprehend the data range and distribution, various graphics have been generated.

TABLE I. NEW COLUMNS

Column Name	Description
TOTAL FATAL	Sum of all attributes that contain fatalities data, which are: driver, bicyclist, pedestrian, and passengers.
TOTAL MAJOR INJURIES	Sum of all attributes that contain major injuries data, which are: driver, bicyclist, pedestrian, and passengers.
TOTAL MINOR INJURIES	Sum of all attributes that contain minor injuries data, which are: driver, bicyclist, pedestrian, and passengers.
TOTAL UNKNOWN INJURIES	The sum of all attributes that contain unknown injury data, which are: driver, bicyclist, pedestrian, and passengers.
RATE	Divided the accidents to six levels based on the total injuries and accident elements.
FATAL	Indicates if the accident has any fatal case or not

TABLE II. EDITED DATA TYPES

Column name	Old data type	New data type
REPORTDATE	String	Date/time
FROMDATE	String	Data/time
OBJECTID	Integer	String
CRIMEID	Integer	String
ROUTEID	Integer	String
MARID	Integer	String

TABLE III. ACCIDENT RATES WITH THE TOTAL NUMBER OF ACCIDENTS IN EACH CATEGORY

Rank	Range	Number of accidents
Lowest	0-2	115,755
Low	3-10	121,254
Medium	11-13	129
High	14-30	49
Extreme	>30	6

TABLE IV. NEW COLUMNS DESCRIPTION

	TOTAL FATAL	TOTAL MAJOR INJURIES	TOTAL UNKNOWN INJURIES	TOTAL ACCIDENT ELEMENTS	TOTALINJURIES
count	237193	237193	237193	237193	237193
Sum	476	25,980	18,161	532,660	114,316
mean	0.002007	0.109531	0.076566	2.245682	0.48195
std	0.045961	0.459874	0.311264	0.66367	0.83825
min	0	0	0	0	0
25%	0	0	0	2	0
50%	0	0	0	2	0
75%	0	0	0	3	1
max	2	51	16	17	51

The chart in Fig. 1 shows the total number of elements and injuries based on the sector. It can be noticed that there are some outliers and the car crash distribution based on these regions.

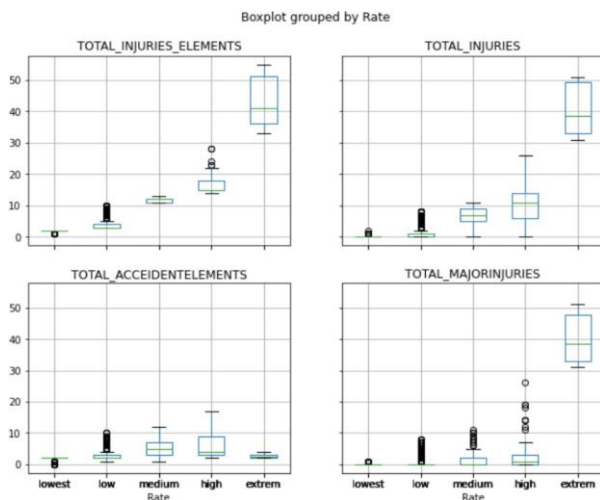

Fig. 1. Distribution of the total number of accidents and injuries based on the accident rate.

These box plots show the relationships and distribution between the total number of injuries and elements, total injuries, total accident elements, and total major injuries based on the accident category rank.

IV. THE SYSTEM

This article has examined many statistical and analytical models to find the patterns and trends in data. The first model that has been used is the correlations between features. This model can provide a good idea of how columns interact with each other. If there are high correlations this indicated, we can analyze these columns and find if there is an actual relationship or not. As known, correlation does not mean causation, but this phrase has been wrong in some cases.

Also, a decision tree analysis is performed to find the factors that lead to fatal accidents; to understand in which cases accidents could be fatal to people. In addition, visualizations are a great way to explore the data and find the outliers and data distribution. Understanding the data makes the analyzing process done in the right way. If data were understood well and in context, this would help to understand the result better. In

addition, some statistical models could be performed to test if there is a significant relation between features, such as Spearman correlation and ANOVA analysis.

The statistical and analytical tests that will be performed can answer many questions. For example, is there a relationship between the location and the number of accidents or injuries? Is there a relationship between week days or weekend days and the number of accidents or injuries? What are the common factors between accidents that cause deaths, major or minor cases? These are some questions this search will answer using data analytics tools. In addition, answering those questions contributes positively to identifying the car accident problem and finding solutions to reduce the number of accidents.

On the other hand, using visualizations will make understanding the data much more straightforward by visualizing the data. It makes the data complexity present in such a way that many people can understand. Also, charts and maps can visually answer several questions. Because we have geospatial data, we can present the accident on maps, quickly understanding the locations that hold a high or a low number of accidents. Also, we can find the locations of the significant injuries or where precisely the taxis had accidents. Besides, a timeline chart, which is an excellent way to find the number of incidents within a time range, can provide many answers to understand the issue.

A. System Architecture

In the analyzing phase, many steps are performed to get the analyzed results and find the patterns and the relationships between different variables. First, to prepare the data for some analysis, a new column has been added to show whether the accident resulted in death. This can help to perform the decision tree analysis. Second, convert string and categorical data into numbers which makes applying statistical model applicable. All statistical models cannot work with non-numerical data. Five columns were converted from string to number: ADDRESS, NEARESTINTSTREETNAME, NEARESTINTROUTEID, INTAPPROACHDIRECTION, and Rate. Finally, we need to group the data to apply the statistical models. In this project, the data were grouped by accident rates.

B. Software and Hardware Development Platforms

We need to use some offered software to perform the data analysis, statistical models, and visualizations. This project

mainly uses the Python programming language. To use Python, the researcher will work on Microsoft Visual Studio, and MS VS is software that can run many programming languages [15]. The hardware used to clean, prepare, and process the data has 16 GB RAM and a 2.3 GHz Quad-Core Intel Core i5 process.

C. Data Analytics Algorithms

The data visualizations done in this project show the relationships and trends among the datasets. Most charts were generated by Tableau software [16], and the charts were implemented after the data was cleaned and prepared for analysis. Also, some data analytics algorithms are used to prepare the dataset for the statistical and analytical models. The first algorithm used is the cut function for binning [17]. This function allows us to classify the accidents using the total accident elements and injuries, making the analytics operations more resealable. In our case, we apply the statistical models to five groups. The second algorithm was used to label the categorical variables. Because the statistical models cannot understand the string data types, we need a way to convert the string values into numerical values.

D. Data Analytics and Statistical Models

Several statistical and analytical methods were applied to the data to understand the relationships between the different variables and answer the questions we asked in the introduction part. Some of these tools are descriptive, inferential, and advanced tools [18] [19] [20].

1) *Descriptive models:* The first model used is confidence intervals. Confidence intervals give the estimated value of a variable to have happened with 90% and 95% probability [18]. This model examined multiple variables to understand that the most number might appear in most cases. For example, what are the total injuries and accident elements that could happen in 90% of the accidents accrued in Washington D.C, and what are the total injuries in 95% of the car crashes?

Then, a correlation analysis was conducted to determine the relationship between the various features. There are 15 features used in this analysis: total vehicles, total pedestrians, pedestrians impaired, drivers impaired, total taxis, total government, speeding involved, fatal passenger, total fatal, total major injuries, total minor injuries, total unknown injuries, total accident elements, total injuries, and total injuries and elements.

2) *Inferential models:* The third statistical model used is ANOVA to examine an independent variable with two dependent variables. The fourth, MANOVA, allows us to examine an independent variable with more than two dependent variables [19].

3) *Advanced models:* The fifth one is the decision tree. We used decision tree analysis to find the reasons that lead to fatal accidents.

4) *Visualizations:* Finally, to see the model results, it needs to visualize them into charts, making it easy to understand the patterns and identify any relationships. Data visualizations could present patterns and trends in the dataset that are hard to find by looking at the values shown in the

data, especially if the dataset is relatively large. Many types of visualizations could be used to illustrate the data. For example, the bar chart shows the frequency of the categorical variables. The map shows the geospatial points on a map, which helps find helpful information that could be used to find the car crash patterns.

V. EXPERIMENTAL RESULTS AND ANALYSIS

A. Confidence Interval

First, we perform the confidence intervals on multiple features: total injuries and elements, total injuries, total accident elements, total fatal, total major injuries, and total minor injuries. This can give us the chance of total injuries and vehicles in 90%-95% of accidents. The results are presented in Table V and Table VI.

TABLE V. CONFIDENCE INTERVAL BASED ON ACCIDENT RATES

Rate	count	TOTAL INJURIES		TOTAL ACCIDENT ELEMENTS		TOTAL_FATAL	
		ci95 High	ci95 Low	ci95 High	ci95 Low	ci95 High	ci95 Low
extreme	6	47.96	33.03	3.32	2.01	0	0
high	49	12.46	9.20	7.34	4.89	0.14	-0.02
medium	129	7.08	6.15	5.55	4.63	0.07	0.005
low	1212 54	0.90	0.89	2.58	2.58	0.001	0.001
lowest	1157 55	0.03	0.03	1.88	1.88	0.002	0.001

TABLE VI. CONFIDENCE INTERVAL BASED ON VARIABLES

Variable	90%		95%	
	Low	High	Low	High
Total injuries and elements	2.723932	2.731337	2.723223	2.732046
Total injuries	0.479122	0.484784	0.478580	0.485326
Total accident elements	2.243440	2.247923	2.243010	2.248352
Total fatal	0.001851	0.002162	0.001821	0.002191
Total major injuries	0.107977	0.111084	0.107680	0.111381

B. Correlation Analysis

The second model that was performed was correlation analysis. The correlation analysis helps find the relationships between different variables to understand how the data relate to each other and what factors have come together. There are two kinds of correlations: the positive correlation between 0.5 and 1.0 and the negative correlation between -0.5 and -1.0. The more significant number indicates high correlations, while the smaller number indicates weak correlations [19].

The 20 highest correlations between the variables are displayed in Table VII. The correlation between 0.5 and 1.0 indicates a high positive correlation. On the contrary, the correlation between -0.5 to -1.0 indicates a high negative correlation. The table gives vital information about how the features relate to each other. However, if we ignore similar

features, such as the total vehicles and total taxis, because all of them are cars, it is normal to see a high correlation between these columns. The exciting result could be seen from the columns that have no relationships. For example, the total injuries and taxis have 0.88, indicating a highly positive correlation. We can say that the number of taxis accident accrue affects the number of injuries positively. In other words, taxi accidents cause more injuries than other vehicles involved in an accident. Nonetheless, we can conclude from this table that there are highly significant relationships between the different variables as follow.

TABLE VII. THE TOP 20 HIGHEST CORRELATIONS

Variable 1	Variable 2	Correlation
Total Fatal	Total Minor Injuries	0.996284
Total Injuries Elements	Total Injuries	0.993960
Total Accident Elements	Total Vehicles	0.992893
Total Pedestrians	Total Minor Injuries	0.991245
Total Minor Injuries	Total Accident Elements	0.990081
Total Pedestrians	Total Fatal	0.988103
Total Injuries	Total Major Injuries	0.983547
Total Accident Elements	Total Fatal	0.978477
Total Vehicles	Total Minor Injuries	0.977746
Speeding Involved	Total Injuries Elements	0.974481
Total Vehicles	Total Unknown Injuries	0.974045
Total Fatal	Total Vehicles	0.971432
Total Pedestrians	Total Accident Elements	0.966891
Total Major Injuries	Total Injuries Elements	0.957828
Total Unknown Injuries	Total Accident Elements	0.954655
Speeding Involved	Total Injuries	0.945711
Total Pedestrians	Total Vehicles	0.941978
Total Unknown Injuries	Total Minor Injuries	0.938114
Total Fatal	Total Unknown Injuries	0.936562
Total Government	Total Pedestrians	0.931648

There are many significant relations between different variables; here are the most notable ones:

- The total number of injuries and accident elements with taxis.
- The total number of injuries and speed and taxis.
- the speed and
 - total accident and injuries total injuries
 - total major injuries
 - total taxes
- major injuries with taxis
- Total number of accident elements with
 - fatal passenger
 - minor injuries
 - total fatal
 - pedestrians
 - government
 - driver impaired

- Total number of vehicles involved in the accidents with:
 - Fatal passenger
 - minor injuries
 - total fatal

C. One-Way-ANOVA

The third statistical model that was applied is the One-Way-ANOVA algorithm tests the differences between one independent variable and two dependent variables. This can help find if the data are random or if there is a significant relationship between the independent and dependent variables. Here are the results that we found:

TABLE VIII. ONE-WAY-ANOVA RESULTS

Independent Variable	Dependent variable 1	Dependent variable 2	p-value
Total Injuries Elements	Drivers impaired	Speeding Involved	0.03978
Total Injuries Elements	Total Fatal	Speeding Involved	0.03974
Total Accident elements	Drivers Impaired	Pedestrians Impaired	0.000154
Total Fatal	Total Taxis	Drivers Impaired	0.01528
Total Fatal	Total Government	Drivers Impaired	0.05858
Total Fatal	Total Taxis	Speeding Involved	0.04698
Total Fatal	Total Government	Speeding Involved	0.11406
Fatal passenger	Total Taxis	Speeding Involved	0.03778
Total Major injuries	Pedestrians Impaired	Speeding Involved	0.28874

The Table VIII shows significant relationships between the independent and dependent variables where the p-value is less than 0.05 [21]. It can be seen that the total injuries and elements have a significant relationship between impaired drivers and speed. Also, total injuries have a significant relationship with total fatalities and speed. However, the total accident elements variable has a significant relationship with drivers impaired and pedestrians impaired. In addition, it can be noticed that the total fatal has significant relationships between multiple dependent variables: total taxis & drivers impaired, total taxis & speed. Nevertheless, there is no significant relationship between total government and drivers impaired and total government and speed.

D. MANOVA

The MANOVA model is similar to the ANOVA. Nevertheless, the difference is examining more than one dependent variable to fit MANOVA, which is in our project's RATE column because it contains five groups [19]. We examine four statistical tests that use in MANOVA, which are Wilk's lambda, Pillai's trace, Hotelling-Lawley trace, and Roy's greatest root. The number of degrees of freedom (DF) is five, and the denominator degrees of freedom (Den DF) is 237183. Where the probability of obtaining an F-ratio is zero in all tests. The Table IX shows the results for the different variables examined.

TABLE IX. FIRST MANOVA ANALYSIS RESULTS FOR WILK'S LAMBDA, PILLAI'S TRACE

Variable	Wilks' lambda		Pillai's trace	
	Value	F Value	Value	F Value
Total Injuries Elements	0.8365	9270.002	0.1635	9270.002
Total Accident Elements	0.9948	247.9693	0.0052	247.9693
Total Injuries Elements	0.8365	9270.002	0.1635	9270.002
Total Minor Injuries	0.9884	554.5788	0.0116	554.5788
Total Fatal	0.9992	37.7784	0.0008	37.7784

TABLE X. FIRST MANOVA ANALYSIS RESULTS FOR HOTELLING-LAWLEY TRACE, AND ROY'S GREATEST ROOT

Variable	Hotelling-Lawley trace		Roy's greatest root	
	Value	F Value	Value	F Value
Total Injuries Elements	0.1954	9270.002	0.1954	9270.002
Total Accident Elements	0.0052	247.9693	0.0052	247.9693
Total Injuries Elements	0.1954	9270.002	0.1954	9270.002
Total Minor Injuries	0.0117	554.5788	0.0117	554.5788
Total Fatal	0.0008	37.7784	0.0008	37.7784

- The above Table X shows Rate column with:
 - TOTAL_INJURIES_ELEMENTS
 - TOTAL_ACCIDENTELEMENTS
 - TOTAL_MAJORINJURIES
 - TOTAL_MINORINJURIES
 - TOTAL_FATAL

TABLE XI. SECOND MANOVA ANALYSIS RESULTS FOR WILK'S LAMBDA, PILLAI'S TRACE

Variable	Wilks' lambda		Pillai's trace	
	Value	F Value	Value	F Value
Drivers impaired	0.9999	7.3326	0.0001	7.3326
Speeding Involved	0.9989	64.4123	0.0011	64.4123
Total Fatal	0.9993	40.5339	0.0007	40.5339
Total Taxis	0.9993	5833.992	0.0896	5838.244
Total Government	0.9058	6163.467	0.0942	6166.538

TABLE XII. SECOND MANOVA ANALYSIS RESULTS FOR HOTELLING-LAWLEY TRACE, AND ROY'S GREATEST ROOT

Variable	Hotelling-Lawley trace		Roy's greatest root	
	Value	F Value	Value	F Value
Drivers impaired	0.0001	7.3326	0.0001	7.3326
Speeding Involved	0.0011	64.4123	0.0011	64.4123
Total Fatal	0.0007	40.5339	0.0007	40.5233
Total Taxis	0.0983	5830.1229	0.0977	5790.4932
Total Government	0.1039	6160.6854	0.1034	6133.7925

- The second Table XI and Table XII show the results of MANOVA of the Rate column with:
 - DRIVERS IMPAIRED
 - SPEEDING INVOLVED
 - TOTAL FATAL
 - TOTAL TAXIS
 - TOTAL GOVERNMENT

E. Decision Tree

The sixth model used is a kind of machine learning model, a decision tree algorithm. The decision tree can help find the factors that lead to a specific event [14]. In this project, we use a decision tree to find the factors that lead to fatal accidents, which could help us understand the causes that might lead to deadly accidents.

The decision tree in Fig. 2 shows that speed is a significant cause of deadly accidents. This chart shows four-level depth, which gives a scenario if the accident has a speeding case, the total injuries and accident elements are less than 6.5, and there are government cars involved. The chance of an accident having a fatal case is high. The model accuracy is 99.8% which is high accuracy.

Fig. 2. Decision tree.

F. Data Visualization

Data visualization is a critical tool for evaluating and learning from enormous datasets. They are especially helpful in spotting patterns, trends, and linkages that may not be visible from raw data. In the context of data analysis, visualizations can provide a more natural and accessible approach for stakeholders to communicate complicated information.

The visualizations in this scenario were created with Tableau software [16]. This section's four charts give a detailed overview of the data distribution, allowing the viewer to discover trends and other significant insights immediately.

Fig. 3 depicts the pattern of automobile accidents over time, giving a clear picture of how the frequency of accidents has evolved over time. Fig. 4 shows crashes across time but removes the lowest and lowest, allowing the viewer to focus on the most relevant trends. Fig. 5 is a bar chart displaying the top 20 streets with the most accidents, offering a more thorough look at the data and aiding in the identification of places that may require more attention. Finally, Fig. 6 depicts a map of the District of Columbia with the top ten streets and all accidents depicted as dots, allowing for a visual depiction of the geographical distribution of accidents.

Fig. 3. Total number of accidents over time (2009-2020).

This chart shows the accident number from 2009 to 2020. It can be seen that the number of accidents rose from 2009 to 2016 from 11,982 to 26,470, respectively. After that, the numbers changed slightly from 2016 until 2019. However, the accident number hit its peak in 2019 with 26,711 accidents. In contrast, car crashes dropped significantly in 2020, with 18,230 accidents. The reason for that drop is the Covid-19 lockdown.

Fig. 5. Top 20 streets with the number of accidents.

The map (Fig. 5) below depicts the top ten streets in the District of Columbia where accidents happened between 2009 and 2020. By mapping the geographic distribution of incidents, this visualization can assist in identifying patterns and trends that may not be immediately obvious from raw data alone. Closer examination reveals that most incidents happened in the city center and on routes going out of town from the northeast. This shows that certain issues, such as heavy traffic, bad road conditions, or insufficient signs, may contribute to the high incidence of accidents in these regions.

Fig. 4. Number of extreme, high, and medium accidents.

The above chart shows the number of extreme, high, and medium accidents from 2009 to 2020 divided by quarters of each year. The number shown in the bars represents the total number of injuries and the number of vehicles involved in those accidents. It can be seen that the extreme accidents stopped in 2013. The number of accidents reached its highest point in 2012, with approximately 163 accidents resulting in 144 injuries and damage to vehicles in the second quarter. Furthermore, the first quarter of 2009 saw the highest number of severe accidents, with a total of 90. This chart provides insight into the distribution of accidents over time and helps to understand the correlation between the type of accident and the year it occurred.

This bar graph represents the top 20 streets with the number of accidents in those streets sorted ascending. It can be noticed that most accidents happen in the northwest regions. From this chart, we can conclude that the streets located in the northwest have the highest chance of having accidents more than the other regions in Washington, D.C.

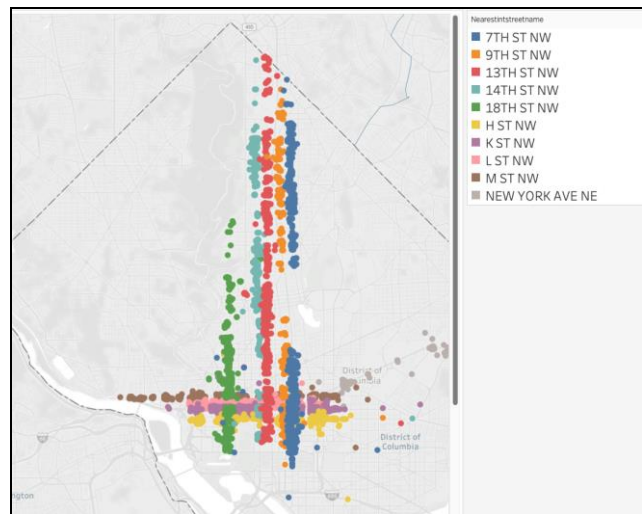

Fig. 6. Map of the top 10 streets that contained accidents.

It is also worth mentioning that while there were some incidents on the city's northeast and southwest sides, the number of accidents on the northwest side was substantially lower. This might imply that characteristics peculiar to the northwest side contribute to the high incidence of accidents in that area. Overall, this visualization might be useful for

identifying the streets with the most accidents and researching the causes to design remedies. Policymakers and city planners may strive to improve road conditions, change traffic patterns, and take other steps to minimize the frequency of accidents and enhance overall safety for cars, cyclists, and pedestrians alike by identifying high-accident zones.

VI. CONCLUSION

In conclusion, this paper studies the dataset related to car accidents in Washington, D.C., between 2009 and 2020. The data has multiple processes to be ready for analytical models. First, we cleaned the data by dropping the unrelated columns and null values that the known ways could not fill. Then the data were explored to understand the data distribution and find the columns that may benefit this analysis. After that, the data was prepared to be ready for the analytical and statistical models. The preparation processes include classifying the accidents into five groups (lowest, low, medium, high, and extreme) and creating a separate dataset that contains the categorical data mapped the string values into numbers. Then we applied correlation analysis, ANOVA, confidence interval, decision tree model, and visualizations. These models were used to find the trend and patterns among the data and find any significant relationships between different variables. This project aims to help the authorities to understand car accidents within the area so they can find the proper solutions to reduce the number of accidents and fix any issues that can be fixed. We have found that most crashes in the area are caused by impaired persons, while deadly accidents happen if one of the accident cars is driving fast or a government car is involved in the accidents. Also, we have found a significant relationship between the number of fatal and the number of taxis involved in the accidents. In addition, most roads that hold accidents are located in the northern area of the district.

On the other hand, we believe that this project could be enhanced by analyzing the crash address and zip codes. There are some issues in the address feature that need to be handled. For instance, some addresses are not complete, and others contain missing numbers or street names to name a few. Also, we found that there was no information about impaired people before 2015. This issue needs to be found the proper way to solve. If these problems are fixed, we think the results could be better.

Towards an Adaptive e-Learning System Based on Deep Learner Profile, Machine Learning Approach, and Reinforcement Learning

Riad Mustapha, Gouraguine Soukaina, Qbadou Mohammed, Aoula Es-Sâadia
Mathematics and Computer Science Department, ENSET of Mohammedia, Mohammedia, MOROCCO

Abstract—Now-a-days, the great challenge of adaptive e-learning systems is to recommend an individualized learning scenario according to the specific needs of learners. Therefore, the perfect adaptive e-learning system is the one that is based on a deep learner profile to recommend the most appropriate learning objects for that learner. Yet, the majority of existing adaptive e-learning systems do not give high importance to the adequacy of the real learner profile and its update with the one taken into account in the learning path recommendation. In this paper, we proposed an intelligent adaptive e-learning system, based on machine learning and reinforcement learning. The objectives of this system are the creation of a deep profile of a given learner, via the implementation of K-means and linear regression, and the recommendation of adaptive learning paths according to this deep profile, by implementing the Q-learning algorithm. The proposed system is decomposed into three principal modules, data preprocessing module, learner deep profile creation module, and learning path recommendation module. These three modules interact with each other to provide a personalized adaptation according to the learner's deep profile. The results obtained indicate that taking into account the learner's deep profile improves the quality of learning for learners.

Keywords—Adaptive e-learning system; deep learner profile; reinforcement learning; Q-learning; k-means; linear regression; learning path recommendation; learning object

I. INTRODUCTION

In traditional learning systems ("all to all" system), the learning content was determined without taking into consideration the specific needs and characteristics of the learners. As a result, all learners were learning the same learning content, which did not ensure the effectiveness of the learning activity. In the last decade, due to technological developments, various approaches to teaching and learning have come onto the scene, accelerated by e-learning in particular during the covid19 pandemic. However, finding the appropriate learning path and content for a given learner is a very interesting question for achieving learning goals, especially in today's education and teaching systems. It is in this context that intelligent tutoring systems are developed to enable learners to locate educational resources that meet their needs and concerns [1].

Adaptive learning presents a new approach to teaching and learning compared to traditional learning. This new approach allows learners to learn at any time and any place, taking into

account the needs and characteristics of learners who are usually heterogeneous to achieve a specific skill within a certain time [2], [3]. In fact, learners have different learning profiles in terms of learning speed, knowledge, preferences, intellectual abilities, learning styles, etc., therefore, have different learning paths [4], [5], [6]. In this perspective, many studies have been realized during the last decade on the personalization of learning with the help of e-learning systems. However, most of these systems do not have methods to perfectly represent the learner's profile (deep profile), on which the system can propose and intelligently adapt the learning path that corresponds to this learner at the time of the execution of a learning activity.

In this paper, on the one hand, we focus on the creation of the deep learner profile from raw datasets on this learner, by combining two machine-learning algorithms: K-means classification and linear regression after executing the data preprocessing technique. On the other hand, the researchers focused on the adaptation and recommendation of learning paths to the learner according to their created deep profile. Next step is the implementation of the developed algorithm Q-learning of the reinforcement learning approach at the time of the execution of a learning activity, Fig. 6, and this via an intelligent and automatic choice of the most appropriate learning objects.

The plan followed in this paper includes, in the second section, a literature review is conducted on adaptive e-learning systems. Then, in the third section, the researchers described the architecture of the proposed approach, while defining the main concepts of the algorithms used to create the deep profile of the learner and to generate the learning path most adapted to this type of profile. The fourth section presents an example of the implementation and results of the application of the algorithms. Finally, the fifth section concludes the present paper and proposes suggestions and perspectives for future work.

II. RELATED WORK

In this section, we have briefly reviewed work related to adaptive systems in e-learning environments and the machine-learning approaches that are used to identify and adapt learning objects to learners.

Recently, adaptive e-learning systems have been frequently developed and used to identify the most appropriate learning objects for learners' profiles. [7-9]. The vast volume of these

learning objects presents different opportunities, though, presents constraints for learners to locate the most adequate learning objects for their profiles [2]. The majority of these systems use techniques just based on the learner's learning style and knowledge level to generate a personalized learning context [10]. These techniques are generally underpinned by the Felder-Silverman model [11] to determine this learning style and knowledge level. A few of these systems are discussed in the next paragraph.

Nafea et al. [12] proposed a novel and effective recommender algorithm that recommends personalized learning objects, this algorithm based on the student learning styles. In this system, various similarity metrics are considered in an experimental study to investigate the best similarity metrics to use in a recommender system for learning objects. Vedavathi et al. [13] created a hybrid system that generally uses the learning styles, and knowledge level of the learners to select the relevant learning objects. This system uses a two-step process to generate adaptation via the recommendation of the most appropriate learning objects. First, it categorizes learners based on their learning style, and knowledge level. Then, it looks for learning objects that match his request and that are of interest to similar learners. In the same context, P. Dwivedi et al. [14] and Alshammari et al. [15] have built a similar hybrid adaptation system that clusters learners based on their similarities and proposed the most appropriate learning objects to them. This system is based on learners' history activity, learning styles, and knowledge levels to create learner profiles. Then, it groups learners by using the Nearest Neighbor algorithm (KNN). Consequently, it provides adaptations according to the profile of the group of learners obtained, rather than to individuals.

M. Boussakssou et al. [16] presented an adaptation model based on reinforcement learning. This system takes merely the learning style to adapt and suggest the learning path to the learners' needs. Similarly, H. El Fazazi et al. [17] proposed an adaptive e-learning system design based on the multi-agent system approach and reinforcement learning to recommend an adaptive learning path for a learner with the following profile: intermediate knowledge level, verbal learning style, and hearing impairment. This system tries to recommend a list of learning objects appropriate for this learner profile.

Moreover, W. Intayoad et al. [18] proposed a method based on reinforcement learning, more precisely the State-Action-Reward-State-Action algorithm (SARSA). This method is able to explore the environment to obtain information and exploit it to recommend appropriate learning objects to learners in an e-learning system.

Based on previous studies, it was observed that the proposed learning systems do not have powerful techniques in terms of the quality of learner classification (deep profile creation), which allow to significantly represent the learner and provide the learning system with pertinent information to adapt the learning to the learner's profile. Generally, these systems just consider the learning style and knowledge level of the learner to generate the adaptation.

Therefore, the researchers proposed this system to create a personalized learning experience. That is, it can analyze the

learner's learning style, preferences, and abilities, etc. to establish a customized learning path for them. As a result, it can adjust the difficulty level of the content, provide feedback, and offer additional resources based on the learner's performance.

In this study, this system takes into account not only learning style and knowledge level but also other types of profiles (preference profile, knowledge profile, feature profile, etc.), as well as the learner's learning objectives, via the application of machine learning algorithms. This deep profile created will be used to adapt the learning to the specific needs and characteristics of the learner in question, using reinforcement-learning approach. This system will be able to search and select the most appropriate learning objects for this depth profile, thus providing each learner with a learning path that is the most advantageous and adequate.

III. METHODOLOGY

The approach proposed in this paper takes into account the deep learner's profile by using two approaches; namely machine learning and reinforcement learning to intelligently adapt the content of the learning activity to the individual needs of the learners. This latter is done by the recommendation of the most appropriate list of learning objects according to the learner's deep profile. At first, after the preprocessing phase, we used the K-means algorithm and linear regression on the resulting datasets to identify the deep profile of a given learner were used. Then the Q-learning algorithm was applied to generate the learning path of each learner according to his or her deep profile. Our system is composed of three principal modules; data pre-processing module, learner deep profile creation module, and learning path recommendation module. These three modules interact with each other to provide a personalized adaptation according to the learner's deep profile.

A. Overall Process

In this section, the general process of the study was presented in Fig. 1. The important step at the beginning of the pipeline is to initiate the data preprocessing process.

Fig. 1. The overall process for learning path recommendation.

- Data collection: A collection of learner information and characteristics to build a raw dataset containing a volume of pertinent learner information of learners.
- Data preprocessing: This technique consists of removing all redundant, non-pertinent, or less important attributes, extracting the information, and transforming the raw datasets into a useful and efficient format, which allows us to proceed to the next step. The extracted information is relevant and truly represents the learner's deep profile in terms of personal data,

learning style, and prerequisites, etc., and help in their classification. Feature extraction is a difficult and usually time-consuming process.

- K-means classification: Once the datasets are well defined, K-means is used for the classification and generation of homogeneous (similar) learner clusters.
- Linear regression: Once the clusters are generated by K-means, the linear regression algorithm is used to distinguish the different data that generate the same cluster i.e. help K-means to represent the data correctly in each cluster.
- Q-learning algorithm: Once the classification of the learners is completed by using K-means and linear regression, the Q-learning algorithm is used to search and determine the optimal learning path taken by the learner according to his or her deepened profile.
- Learning path recommendation: This step consists of recommending the most appropriate learning objects in real time to the learner based on their deepened profile.
- Result evaluation: The proposed system provides excellent results in terms of precision and quality obtained.

B. Description of the Learning Path Recommendation Process

In examining previous studies on the topic of adaptive e-learning systems development, it has been observed that they are generally based on the Felder-Silverman model (FSLSM) technique [19], to identify the learning style and knowledge level, as the learner profile. However, these types of profiles do not always represent the real learner in terms of specific learner needs and characteristics. To address this need, an intelligent mechanism based on artificial intelligence (AI) was proposed in this study to create the deep profile of a given learner from raw datasets on this learner, by applying in cascade the two machine learning algorithms: K-means and linear regression. Finally, recommending the most appropriate learning objects in real-time to this learner as the most beneficial adaptive learning path to this deep profile via the application of the Q-learning algorithm. The figure below Fig. 2, describes the developed system:

The figure describes the proposed system that integrates Artificial Intelligence (AI) for the creation of the deep profile of the learner connected to the system and for the adaptation of learning paths to the needs and characteristics of learners. In fact, the creation of the deep profile is a very interesting step in the context of recommending adequate learning objects to the learner, because if the created profile does not represent correctly the learner, then the proposed learning path will not be well adapted to him.

In this system, the key modules used are: **1)** the data preprocessing module, which consists of reducing the dimension of the datasets vectors, using techniques associated with dimension reduction, **2)** the module for creating the learner's deep profile from a volume of raw data on the learner in question, and **3)** the learning path recommendation module.

These three modules interact with each other to provide personalized adaptation based on the deep profile created in the Module 2 phase. This system will try to find the appropriate learning objects for this deepened profile.

Fig. 2. The process of constructing the adaptive learning path developed.

A. Data Preprocessing

In a datasets, not all attributes are necessarily important. Some may be redundant, others may be not pertinent, etc. Ignoring or removing these non-pertinent or less important attributes reduces the load on the machine learning algorithms and improves the quality of the results obtained. In this context, the technique of dimension reduction plays a very interesting role, in reducing the dimension of high-dimensional datasets vectors [20]. Among these techniques, the best known according to the literature is Linear Discriminant Analysis (LDA), as a supervised algorithm. The aim is to project the features of a higher-dimensional space into a lower-dimensional space. This technique is based on two criteria to create another axis on which to project:

- 1) Maximize the distance between the means of the two classes;
- 2) Minimize the variation within each class;

Assuming two classes and d-dimensional elements such as x_1, x_2, \dots, x_n , where: n_1 is an individual from class C_1 and n_2 from class C_2 . If x_i is the data point, then its projection on the line represented by the unit vector v can be written as $v^T x_i$:

$$\tilde{u}_1 = \frac{1}{n_1} \sum_{x_i \in C_1} v^T x_i = v^T u_1 \quad (1)$$

The same goes for \tilde{u}_2 ,

$$\check{u}_2 = v^T u_2 \quad (2)$$

Then the dispersion for the elements of C1 is:

$$\check{s}_1^2 = \sum_{y_i \in C_1} (y_i - u_1)^2 \quad (3)$$

The same goes for \check{s}_2^2 ,

$$\check{s}_2^2 = \sum_{y_i \in C_2} (y_i - u_2)^2 \quad (4)$$

B. Creating the Deep Learner Profile

The adaptive e-learning system has been developed to provide a personalized learning path in the experience of executing a pedagogical activity. However, this adaptation must be based on the learner's deep profile that is created when the learner as soon as it is connected to the system, and that will be updated over time by the learner's feedback with the system. The use of deep profiles in Computer Environments for Human Learning (CEHL), and especially in distance learning platforms, is one of the most important ways to adapt learning to the specificities of learners. It plays a very interesting role in the individualization of learning paths. In fact, it focuses on learners' preferences, such as a learner's preference for video over text, or his or her preference for teaching to begin with an example and not a theoretical introduction. But also the features of the learners which contain important information allowing to describe the learner not only from the point of view of his demographic features such as age or gender but also from the point of view of his possible disabilities (e.g. hearing 85%; sight 30%, etc.), preferred time for learning, preferred language, culture, country, hobbies, preferred type of media, prerequisites, the learner's learning objectives, etc. which can be described finely.

The module in charge of creating the learner's deep profile within the system is decomposed into two sub-modules:

- The K-means classification algorithm;
- The Linear regression algorithm.

1) *K-means classification algorithm*: In the literature, there are many classification algorithms including K-means, KNN, SVM, etc. In this paper, the K-means Algorithm, which is one of the most popular algorithms due to its simplicity and intuitive interpretation [21] was adopted. It can be defined as the process of organizing objects in a dataset into clusters, such that objects in the same cluster have a high degree of similarity, while those belonging to different groups have a high degree of dissimilarity.

The key step for any unsupervised algorithm is to identify the optimal number of clusters (optimal K) into which the data can be grouped. The Elbow method [22], is one of the most popular methods for identifying this optimal value of K. i.e. the optimal k is the point after which the distortion/inertia starts to decrease linearly, where distortion is computed as the average of the squared distances of the cluster centers of the sample and inertia is the sum of the squared distances of the elements to their nearest center of gravity. It consists in calculating the variance of the different cluster volumes considered, and then placing the variances obtained on a graph:

intra – Cluster Variance

$$= \sum \sum Distance(x, centroid)^2 \quad (5)$$

After calculating the optimal value of k, by the formula (5), we proceed to the running of the K-means algorithm, explained by the mathematical formula below:

$$\arg \min_c \sum_{i=1}^k \sum_{x \in C_i} ||x - \mu_i||^2 = \arg \min_c \sum_{i=1}^k |C_i| \text{Var } C_i$$

Where μ_i is the average of the points in C_i . For its implementation, in the system, the following steps are respected:

- Step 0: Select optimal K calculated by the formula (5);
- Step 1: Select K random points in datasets as initial group centers;
- Step 2: Create K Clusters by associating each data point with its nearest center, according to the Euclidean distance defined by the formula:

$$d(x, y) = \sum_{i=1}^n (x_i - y_i)^2 \quad (7)$$

- Step 3: Recalculate the center of gravity of each cluster, as the average of all data points in that cluster;
- Step 4: Repeat steps 2 and 3 until the centers of gravity no longer change;

By examining the results of previous studies on the subject of data classification, the researchers find that after the execution of the K-means algorithm on the datasets, there is a problem in the distributions of the vectors of each cluster, i.e. different data can be represented by similar clusters, which results in a false classification of the data. In this paper and to overcome this problem, the researchers suggest to add another criterion to distinguish the different data that give the same cluster, by using in cascade the linear regression algorithm on each cluster obtained by K-means, to approximate the data and characteristics that make up the learner's deep profile, to improve the quality of classification, precision and error reduction.

2) *Linear regression algorithm*: In the literature, linear regression is classified among the multivariate analysis methods that deal with quantitative data, with the objective to find a linear relationship between a quantitative variable Y and one or more also quantitative variables X, i.e. to find the line that passes "as close as possible" to all the points of the cloud. This relationship can be expressed mathematically by the formula below:

$$y_i = \beta_0 + \beta_1 x_{i1} + \dots + \beta_p x_{ip} + \epsilon_i \\ = X_i^T \beta + \epsilon_i \quad (8)$$

Where T denotes the transposition, so that $X_i^T \beta$ is the internal product between the vectors X_i and β .

C. Learning Path Recommendation

1) *Domain model of the proposed approach:* In the adaptive e-learning system, the pedagogical content is divided into many pedagogical activities, each of which is composed of several chapters. A concept tree represents each chapter. The concept tree contains a list of learning objects (LOs) that represent external representations, such as images, videos, examples, exercises, etc. This learning content is generally stocked in a database as a tree of 4 levels called the domain model. The figure below Fig. 3, describes the overall domain model structure of our system:

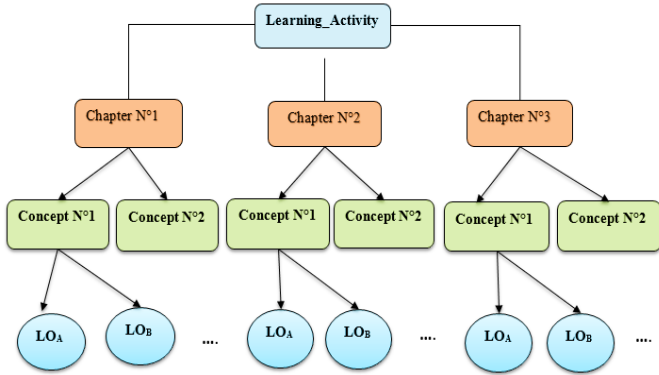

Fig. 3. Learning activity organization of the proposed approach.

The learning activity organization of the proposed approach is mapped into four hierarchical levels:

- Level 1: represents the root of the domain model structure, which presents the learning activity to be taught.
- Level 2: represents learning activity chapters, which particularly address a learning activity element to be taught.
- Level 3: represents the concepts of each chapter of the learning activity taught and is generally identified by a level: advanced, intermediate, or beginner.
- Level 4: represents the different types of learning objects (LOs) that represent external representations, such as images, videos, examples, exercises, etc. Each LO is characterized by several properties such as autonomy; adaptation; indexing; accessibility; durability, and reusability as the most important property. Each LO must be provided with a description, usually called a metadata file, allowing it to be easily found. This file uses emerging technologies associated with the development of learning objects, such as the semantic web and ontologies.

The figure below Fig. 4, describes the metadata file of each domain model level of the proposed system, based on the ontology technology:

In a traditional learning system, learners use a linear path of learning objects $\{LO_A, LO_B, LO_C, \dots, LO_z\}$ regardless of their preferences, knowledge level, etc. The figure below Fig. 5,

shows an example of the sequence of learning objects as a learning path for five learners $\{L_1, L_2, L_3, L_4, L_5\}$ when executing a learning activity in this system.

However, in a personalized adaptive e-learning system, learners use a non-linear learning path to build the optimal sequence of learning objects according to their needs and characteristics. The figure below Fig. 6, shows the adaptive learning path for the same learners $\{L_1, L_2, L_3, L_4, L_5\}$ when running the same pelagic activity.

In this learning path, the system can ignore some learning objects like $LO_E, LO_F, LO_G,$ and $LO_H,$ since they do not correspond to any profile of the five learners in question.

2) *Adaptation and recommendation of learning paths:* Many algorithms are available for Reinforcement Learning (RL), which uses Q-function as a learning strategy like Opponent Modeling, Q-learning, and Ascending Gradient. In this paper, the Q-learning algorithm was adopted to recommend the most appropriate learning path for a given learner. It is more efficient than other algorithms in terms of precision and quality of results. Thus, it converges towards an optimal strategy, i.e. it leads to maximizing the total reward of the successive steps. The figure below Fig. 7, presents the overall process of reinforcement learning.

Fig. 4. Metadata file of the domain model levels.

Fig. 5. Learning path in a traditional system.

Fig. 6. Learning paths in an adaptive e-learning system.

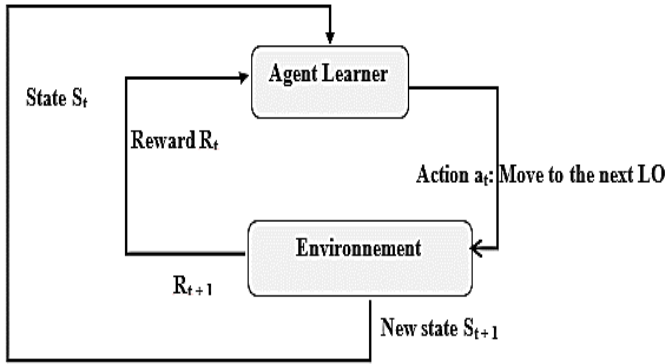

Fig. 7. The overall process of reinforcement learning.

In the proposed system, the high number of users will allow us to consider each learner as an agent. The agent can move from one state S (LO_A) to another S_{t+1} (LO_B) by choosing an action A . This transition gives the agent a reward/sanction on which we calculate the total gain to define its optimal adaptive learning path. This gain is estimated and calculated by a Q-Value () which evaluates the quality of the combination of each state-action pair $Q(s, a)$ over the long term and updates its table. Mathematically the Q-Value() function is expressed as follows.

$$V(S) = [R_{t+1} + \gamma R_{t+2} + \gamma^2 R_{t+3} + \dots] \left[\sum_{k=0}^{\infty} \gamma^k R_{t+k+1} | S_t = s \right]$$

Where the parameter γ is the discount rate between 0 and 1, k is the number of states, and R is the rewards. The agent learns from experience due to exploration, often called an episode [23]. The figure below Fig. 8, presents the overall process of learning by the Q-learning algorithm developed:

Fig. 8. Overall process of learning by the Q-learning algorithm.

The general algorithmic structure of this algorithm is detailed in Fig. 9.

Where α is the learning rate between 0 and 1. It determines how well the new calculated information will overcome the old, If $\alpha = 0$, the agent (learner) learns nothing, but if $\alpha = 1$, the agent still ignores everything it has learned so far and will only take into account the last information. In a deterministic environment, the learning speed $\alpha_t(s,a) = 1$ is optimal; γ is the discount factor between 0 and 1. It determines the importance of future rewards. A factor $\gamma = 0$ would make the agent (learner) myopic by considering only current rewards, but a factor γ near 1 would also include more distant rewards and the value of Q can diverge; s' is the new state; s is the previous state; a is the chosen action and R is the reward received by the agent (learner), and $Q [v_1, v_2, \dots, v_p]$ is Q-table.

Algorithm 1: Heading

```

Input
    α ;
    γ ;
Output
    Q [v1, v2, ..., vp];
Initialize
    Q [s, a] for any non-terminal state s, any action a arbitrarily;
    Q [terminal state, a] = 0;
Repeat
    // start of an episode
    s := terminal state
    Repeat
    // for each episode
    Choose an action a from s using the policy specified by Q;
    Execute the action a;
    Observe the reward r and the new state s';
    Update the values of Q
    | Q(s,a) = α * (r + γ * maxQ(s') - Q(s,a))
    | Define the next state as the current
    Until s is the terminal state
    End
End
    
```

IV. RESULTS AND DISCUSSION

A. Implementation Example

In this part, the researchers start with a data preprocessing module to prepare datasets which will be used to create a deep profile of the learner connected to the system. By doing this, the deep profile is processed by using the developed Q-learning algorithm to find the ideal learning path for this learner. The experiments are conducted on a Dell computer with a CORE i5 processor using the Collaboratory platform and Python for result generation.

1) *Data preprocessing:* The datasets used in the experiments contain different raw information about 100 learners $\{L_0, L_1, \dots, L_{99}\}$, with 23 characteristics {Age, Gender, Handicap, Country, Language, Learning style; Knowledge level; etc.} numbered from 0 to 22. The specifications of the datasets are summarized in the figure below, Fig. 10.

In the first experiment, the researchers start to reduce the dimension of the vectors of the datasets, by ignoring the less important or unimportant attributes to improve the quality of the results obtained, by applying the LDA technique, while focusing on the criteria of "Minimizing the variation" within each cluster. Firstly, the variance of all the attributes of the datasets is calculated using the following formula:

$$V = \frac{1}{n} \sum_i^n (x - \bar{x})^2 \tag{9}$$

	Age	Gender	Handicap	Culture	...	Obj2N	Obj3	Obj3F	Obj3N
0	18	1	1	2	...	2	8	5	3
1	19	1	1	3	...	17	8	5	2
2	22	2	0	1	...	5	8	3	9
3	20	1	1	2	...	14	7	2	14
4	22	2	1	1	...	7	7	3	17
5	19	1	1	1	...	0	9	1	11
6	22	1	0	2	...	2	8	3	11

...
70	21	1	0	1	...	10	7	5	12
71	17	2	0	2	...	10	9	3	6
72	22	2	1	3	...	15	7	4	10
73	19	2	0	3	...	2	7	4	11
--	--	--	--	--	--	--	--	--	--

Fig. 10. Raw Datasets of learners.

Then, the researchers try to find the attribute whose variance is the smallest compared to the others (the less significant attribute). The figure below, Fig. 11, shows the result of calculating the variance of all the attributes of the datasets:

```
[ 3.83545455 0.24434343 0.25242424 1.3069697 11.92515152 0.67232323
 4.91909091 0.25090909 0.25 0.25090909 0.25090909 0.64
 2.19555556 2.01373737 0.79707071 1.87585859 31.29292929 0.64
 1.92515152 33.90494949 0.64434343 2.22222222 43.73848485]
```

Fig. 11. Result of variance calculation.

By examining the figure above, the researchers notice that the minimum variance is 0.24434343. This variance corresponds to the 2nd attribute of the datasets whose index is 1 (gender). In fact, it was imperative to delete this attribute because it is not significant in terms of importance. To evaluate the performance of the approach, the datasets must be divided into two sections: the training set (80%) and the test set (20%)

B. Creating a Learner Deep Profile

1) *Application of K-means Algorithm:* In the second experiment, and once the data preprocessing step is over, the researchers try to classify all learners into homogeneous (similar) groups. Initially, a sample of 100 learners {L₀, L₁,..., L₉₉} was used. In this case, the system categorized the learners into three clusters (0, 1, and 2). The figure below, Fig. 12, shows the list of learners in each Cluster.

```
Console 15/A
Learners liste of cluster 0 :
[1, 3, 6, 7, 11, 12, 16, 19, 21, 22, 23, 29, 30, 31, 32, 36, 37, 50, 53, 56, 57, 60, 65, 74, 78, 84, 89, 95, 96]
Learners liste of cluster 1 :
[2, 8, 9, 10, 13, 14, 17, 24, 27, 33, 34, 35, 39, 40, 41, 42, 44, 48, 54, 59, 61, 63, 66, 67, 69, 72, 76, 77, 87, 88, 90, 93, 94]
Learners liste of cluster 2 :
[4, 5, 15, 18, 20, 25, 26, 28, 38, 43, 45, 46, 47, 49, 51, 52, 55, 58, 62, 64, 68, 70, 71, 73, 75, 79, 80, 81, 82, 83, 85, 86, 91, 92, 97, 98, 99, 100]
```

Fig. 12. Lists of learners in each group.

The results in the form of a 2D histogram graph are presented in the figure below, Fig. 13 as follows: we have 33 learners in Cluster 0 and 38 learners in Cluster 1, and 29 learners in Cluster 2:

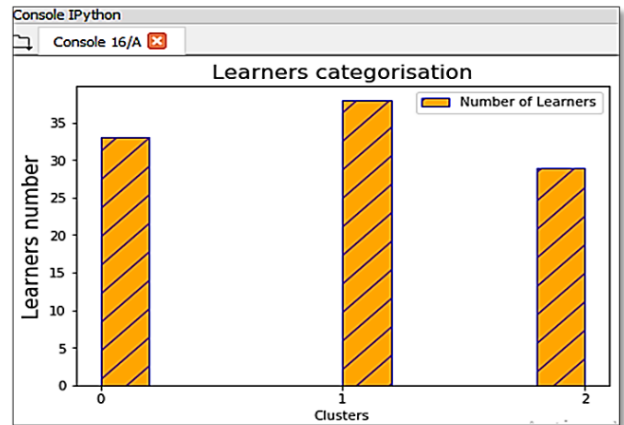

Fig. 13. Classification of learners into cluster.

The results in the form of a 3D sector graph are presented in the figure below, Fig. 14 and as follows: we have 33% learners in Cluster 0 and 38% learners in Cluster 1 and, 29% learners in Cluster 2.

Fig. 14. Classification of learners into clusters.

In the third experiment, the results of classifying learners concerning the two attributes age and motivation for each cluster are presented in the figure below, Fig. 15:

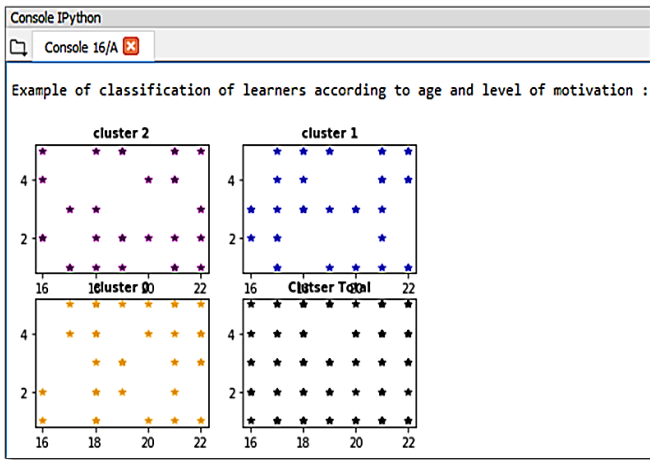

Fig. 15. Classification of learners according to age and motivation level.

The results above show the distribution of learners in the three clusters (Cluster 0, Cluster 1, and Cluster 2) according to age and the degree of motivation among learners. While in the cluster, whose name is “All_Cluster” presents the union of the three clusters. To identify the learners in each cluster to reduce the error, the researchers propose to run the linear regression algorithm in cascade on the clusters generated by the K-mean classification algorithm.

2) *Application of the linear regression algorithm:* By examining the results obtained previously on the classification of the learners according to their age and their degree of motivation, via the application of the K-means algorithm, and to improve the quality of classification, the performance of calculations, the precision, and the reduction of the error, the researchers propose to apply in cascade the linear regression algorithm on each cluster to identify it well to distinguish it compared to the other clusters. First, the researchers start to calculate the slope and the intercept of each cluster. The results are presented in the figure below, Fig. 16.

These values allow us to draw linear regression lines for each cluster. This method allows us to identify the learners of each cluster and to build homogeneous clusters in terms of the classification quality of the learners according to their deep profiles. The figure below, Fig. 17, graphically presents a comparison of the linear regression of the three clusters:

The results in the Fig. 17 show that there is a relationship between the “age” and the “degree of motivation” of learners during the execution of an educational activity. Where the researchers notice that the degree of motivation of the learners is remarkable when the age ≥ 15 the level of motivation of the learners equals 2.5 for cluster 0 and cluster 2, on the other hand, the level of motivation of the learners equals 3 for cluster 1. Moreover, when the age = 25, the motivation among the learners reaches the peak: 4 for Cluster 1 and 3.8 for Group 0, and 2.8 for Cluster 2.

C. Learning Path Recommendation

In this example, the researchers show in the form of a graph Fig. 18 how to define an adaptive e-learning activity for a

given learner, using "Bloom's taxonomy" [16], [24], [25] the researchers give a list of states (LOs) that describe the learning activity: Introduction; Chapter N° 1; Examples, Exercises, and Exam. Bloom's taxonomy" helps us to give each transition a reward (at the basis of a scale from 0 to 10) according to its difficulty level, where each level depends on the previous one:

Stay = + 00; Next_level = + 0,5; High_level = + 0,5; Exercising = + 0,4; Look_Examples = + 0,2; Previous = + 0,1 and Passing_Quiz = + 0,3.

Fig. 16. Slope calculation and cluster interception.

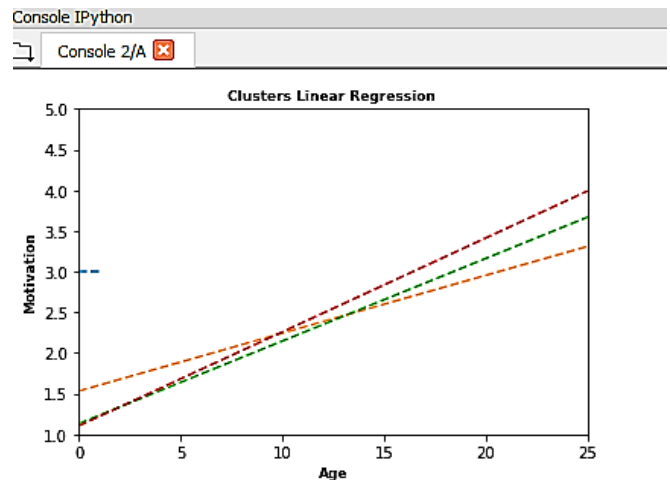

Fig. 17. Cluster linear regression.

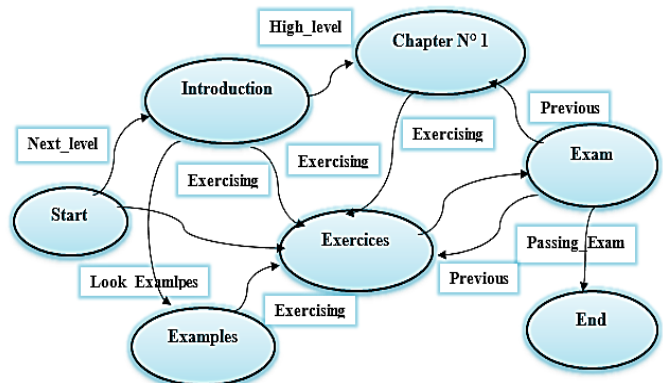

Fig. 18. Example of a state-action combination graph for the execution of an educational activity.

Applying "Bloom's taxonomy" to our example above, the researchers deduce the reward matrix of state-action pairs on the set of related (directly connected) states:

$$M_{ij} \begin{pmatrix} +00 & +0,5 & +00 & +00 & +0,4 & +00 \\ +00 & +00 & +0,5 & +0,2 & +0,4 & +00 \\ +00 & +00 & +00 & +00 & +0,4 & +00 \\ +00 & +00 & +00 & +00 & +0,4 & +00 \\ +00 & +00 & +00 & +00 & +00 & +0,3 \\ +00 & +00 & +0,1 & +00 & +0,1 & +00 \end{pmatrix}$$

Reward matrix of state-action pairs

Where, the rows i of the matrix M_{ij} represent the states, while the columns j of the matrix M_{ij} represent the actions. To determine the optimal adaptive learning path to be taken by the learner for this learning activity cited in Fig. 17, based on their deep profile, the researchers must first generate the Q-value of the Q-learning algorithm as follows:

1	[0 ; 1,157229998544553 ; 0 ; 0 ; 0,0999999999991 ; 0]
2	[0 ; 0,0,98899999588963 ; 0,6699999971061 ; 0,6999999955544 ; 0,2999999997890]
3	[0 ; 0 ; 0 ; 0,626999999999999 ; 0 ; 0,299999999999999]
4	[0 ; 0 ; 0 ; 0 ; 0,699999999999999 ; 0]
5	[0 ; 0 ; 0 ; 0 ; 0 ; 0,299999999999999]
6	[0 ; 0 ; 0 ; 0 ; 0 ; 0]

Fig. 19. Q-table matrix of the Q-value function for the action-state.

The matrix above presents the results obtained by running the Q-learning algorithm on our system, where rows i of the Q-table represent states, while columns j represent actions. They show how the Q-learning algorithm proposes the most optimal learning path for a given learner. The learner can choose to start with any learning object at the time of the learning activity, after which the system will recommend the best learning path, by choosing and organizing the sequence of learning objects appropriate in real time to their deeper profile.

If the agent (the learner) were to use the policy described in the Q-table above to find the most appropriate learning path for her deep profile, then:

- From state zero (Start), the action with the maximum value is Next_level, so that's what he will do, achieving state one (learning object Introduction).
- From state one (Introduction), the action with the maximum value is High_level, This leads the learner to state two (learning object Chapter N°1).
- From state two (Chapter N°1), the action with the maximum value is High_level, This leads the learner to state four (learning object Exercises).
- From state four (Exercises), the action with the maximum value is Passing_Exam, This leads the learner to state five (learning object Exam).

Based on these transitions, we can deduce the adaptive learning path for this learner:

Start → Introduction → Chapter N° 1 → Exercises → Exam → End.

V. CONCLUSION

Deep learner profiles are very interesting objects that can contribute to the success of adaptive e-learning systems. These deep profiles must be able to contain different types of information and characteristics about the learner, to take into account the different facets of their learning. Therefore, generic models are needed to properly represent learners. To address this need, the researchers have presented in this paper a new intelligent approach based on K-means, linear regression, and algorithms Q-learning. The system is designed to create the most detailed and best structured in-depth profile for a given learner, and then recommend the most appropriate learning path for that learner. The proposed system ensures that it can be used by various learning management systems (LMS) in these various contexts.

As a perspective, on the one hand, the researchers plan to propose a technique for the choice of optimal k in the learner classification phase and on the other hand to experiment with the approach while adding as many states and actions as possible for each state (learning object) to allow the discovery of the optimal action for each learner. This can of course lead to complexity and convergence constraints, especially if the system is to be put online. For this, the use of deep reinforcement learning (Deep Q-learning) will be a good idea for issues of complexity and optimization of the system.

This study has potential limitations, since Reinforcement learning has various drawbacks while appearing to be a very potent and useful technique, it needs to store values for each state; it frequently uses too much RAM. That is, it might become a memory-intensive process. Moreover, due to the small sample size, the results may not be representative of the entire population. Therefore, it may limit the validity and generalizability of the findings. A larger sample size would be needed to increase the statistical power and improve the representativeness of the sample since there would be the chance of having different deep profiles

Abstract—The growth of mobile application development industry made it crucial for researchers to study the industry practices of choosing mobile applications programming languages, systems, and tools. With the increased attention of cross-platform mobile applications development from both researchers and industry, this paper aims at answering the question of whether most of the industries are using cross-platform development or native development. The paper collects feedback about industry's most used mobile development systems. In addition, it provides a map of the different technologies used by mobile applications development companies according to some of the demographics like company size and location. An online questionnaire is carried out to collect the data. The survey targeted both amateur and professional mobile developers. A total of 85 participants participated in answering the survey. Qualitative analysis using descriptive statistics is done on the results of the survey. Although the results show that there is an industrial trend towards using the cross-platform languages, native development is still used by the well-established companies. More than 50% of the participants are found to be aware of the performance issues of the cross-platform development languages and frameworks. Comparison with findings of related work is discussed which raises more research questions and draws out future research in this field.

Keywords—Android; cross-platform; development; iOS; mobile applications, questionnaire

I. INTRODUCTION

Mobile applications are becoming essential in human lives. During the corona pandemic, many countries had totally shut down to protect their people from the crisis. Mobile applications played a very important role in providing people the ability to do all their daily tasks through their mobiles. Health organizations and governments have developed numerous mobile applications for managing the pandemic [1]. Hundreds of applications emerged to aid people in their work, education, shopping, entertainment, and more. In fact, the second quarter of 2020 became the largest for mobile app usage, with new downloads reaching billions. Mobile applications are found in two main stores: Apple store for iOS platform and Google play store for Android platform. Recently, Huawei released a new platform called Harmony OS for Huawei mobile phones and devices. This release was a response for the Huawei ban which happened in May 2019 [2].

Development of mobile applications for the different platforms is done in one of two ways: either the applications are developed natively for each platform, or the application is developed once on a cross-platform framework. Native development means to develop the application in java or Kotlin for Android and in swift or objective C for iOS. However, for the past few years, swift is being used more than objective C and is considered the official language for iOS platform. Regarding Android in 2018, Google announced that they support Kotlin for Android [3]. Native development might take much time, money, and effort from mobile application vendors. However, native development provides the flexibility for developers to handle platform-specific functionalities [4] like push notifications, camera access, and GPS.

On the other hand, Cross-platform development is a way adopted by several frameworks that depend on variant methodologies to save the time and effort of developing the application specifically for each platform. Cross-platform frameworks have their own challenges and limitations. One of the most important challenges is the dependency of these frameworks on languages that are different from the native languages. This implies developers to learn these new languages and frameworks. Many researchers evaluated these frameworks and compared them to each other and to the native development [5]–[10]. Most of this research figured out that cross-platform development has limitations regarding the performance of the product applications. These limitations include memory, speed, user experience, and security. However, the inventors of these frameworks are enhancing and improving their tools every day. Many libraries are emerging to aid developers and increase the flexibility of developing the applications.

Researchers are continuing to introduce new cross-platform techniques. They depend on the research findings that the existing cross-platform frameworks are not closing the gap between developers and end-users' needs regarding applications' development and performance. Therefore, it is essential to make studies that aim at investigating the industry and practitioners' feedback on using cross-platform frameworks. In addition, researchers also need to know how industry practitioners use Kotlin, compared to Java, after six years of 2017 announcement of Google. On the other hand, there is a need to investigate whether there are developers for the new platform released by Huawei company, or the platform

is not being used yet. This feedback will lead researchers to industrial needs regarding the cross-platform and native development techniques and their practical usage.

The aim of this empirical study is to answer three research questions that are believed will aid researchers in this field. The questions are presented in section three. These questions are answered by conducting an online questionnaire among junior and professional mobile applications practitioners. Analysis of the survey results will be used to draw a conclusion on the practitioners' perspective regarding mobile application development techniques, which is the most used, and what are the most performance issues they face. It will also guard practitioners and researchers to decrease the gap between them and use the implications presented in this article in their future work.

The rest of this paper is organized as follows: Section two will present the literature of mobile applications development. Section three will present the research questions and our methodology for creating the questionnaire to answer these questions. In addition, the methodology of analyzing the data is explained. In the fourth Section, the results of the conducted questionnaire are presented in the form of descriptive statistics and graphs. Section five includes discussion of the results and implications for practitioners and researchers. Section six then compares our findings to the related work findings. Finally, a conclusion that summarizes the results and analysis is presented in Section seven.

II. RELATED WORK

The related work and literature of this topic are summarized in two main subsections. Subsection one will highlight the existing tools and approaches. Subsection two will present the survey papers that are done on this topic while subsection three will summarize the practitioner studies done. These studies are the most related to our work.

A. Approaches and Tools

Originally, mobile application development was done using the native development language for each platform. The mobile application was developed once for each platform. Languages used for the native development are java or Kotlin for Android and Objective C or swift for iOS. Some years ago, new approaches appeared to develop the application once for multiple platforms. These approaches are called cross-platform development approaches. These approaches are categorized into: 1. Web-based, 2. Hybrid, 3. Interpreted, 4. Compiled approach, 5. Model driven [11][12].

The web-based approach simply relies on the web languages that are already supported by all platforms. The Hybrid approach hybrids web and native code to reach the native UI of mobile applications. Continuous communication between the web view and native components represents the overhead of this approach. The interpreted approach depends on having a layer that interprets the JavaScript code and bridges the JavaScript engine with the native engine to be able to render the native components. This bridging also represents an overhead for the applications developed by this approach. Compiled approach depends on compiling the source code of an application to another code. Flutter which is considered the

most used cross-platform framework nowadays uses the compiler-based approach. One subcategory lies under the compilation approach is called trans-compilation. Trans-compilation involves compiling source code from one high-level language to another high-level language [13]. Tools introduced in [14]–[19] used this approach to translate source code of mobile applications from java for Android to swift for iOS and vice versa. The limitation of these tools lies in their dependence on having corresponding code for each functionality used in the mobile application. This mapping concept might be successful for small applications, but it is not tested yet on conversion of real or complicated applications. The model driven Development (MDD) approach depend on generation of user interface code and business logic from models and templates of the application [20]. This approach is limited by the features and abilities provided by the models used and the experience of developers in using the models. MD2 is one of the tools which depend on the concept of model driven development [21].

Each of the mentioned approaches has its own advantages and its limitations and drawbacks. It is now totally dependent on the applications features and requirements to select the suitable development approach. However, it is not common to see a developer or even a team of developers work with a different approach for every project depending on its requirements. This raised our research questions about the most used tools and techniques, whether more than one approach is used by the same vendor, and whether developers are aware of the performance issues of the used frameworks.

B. Literature Studies

This section summarizes literature studies related to our work, identifying similarities and differences between our work and each study. A systematic study was conducted to create a classification scheme for existing research in cross-platform mobile app development. The study aimed to identify research gaps and challenges in the field by mapping 30 studies. The primary research question focused on identifying the contributions of each of the 30 included studies [22]. Most of our literature is included in that study.

Bjorn-Hansen et al. [23], conducted an empirical study using an online questionnaire to survey 101 industry practitioners. Their study aimed to identify the most used cross-platform frameworks by developers and the issues they face. Their findings revealed that PhoneGap, Ionic, and React Native were the most used frameworks, but cross-platform solutions still faced performance and user experience issues compared to native solutions. While some of our survey questions overlapped with theirs, the main difference is that our study targets both developers and management and provides more detailed respondent demographics through in-depth questions on job position and experience. Our study thus extends some of the limitations of their work.

Ahmed [24] conducted a qualitative study by using two-phased research approach. The first phase is using systematic literature review to identify nine challenges that are found in literature. Then in the second phase, they interviewed 34 participants from industry to validate the literature by identifying 13 challenges and issues of web, native and hybrid

mobile development with nine of them already extracted from the Systematic Literature Review (SLR). The main difference with our study is that this study used an interview to gather qualitative data regarding issues facing mobile application development while our research, an online survey is used to gather quantitative data on both cross-platform and native mobile development.

Francese et al. used a qualitative study [25] in 2017 to gather qualitative data related to mobile application development and management. They invited four mobile application managers to discuss differences between mobile applications and web applications. The interview outcome was used to plan and create the survey questionnaire. The online survey was sent to 510 developers using their LinkedIn profile, but only 82% responded. The results showed that junior developers are the ones that mainly develop applications and there is a huge issue regarding testing mobile applications.

Puvvala [26], conducted a survey to investigate mobile development, and used a Delphi study with 11 senior developers to identify the top four factors influencing platform choice: development costs, ease of coding, support, and expected return. They then used these factors to create a survey on their impact on developers' platform choices, finding that availability of SDKs was the most significant factor. However, their study differs from ours in that it focused specifically on the factors influencing platform choice for application development.

Biørn-Hansen et al. investigated the approaches of Android mobile applications development through exploring applications on Google Play Store. A dataset called Androzo[27] that has 661,705 apps was used to detect the framework used for developing each of these applications. The investigation aimed to answer three research questions about the distribution, usage of cross-platform development frameworks on the Google Play Store and how the usage of deployed apps changed within the last decade. The findings showed that only 15% of the total dataset were cross platform applications and Cordova was the most used cross-platform framework.

Previous studies have not kept up with the fast-paced advancements in the mobile application development industry, as they only focused on either cross-platform frameworks or native development and did not consider both. Additionally, they lacked information on respondent demographics and did not provide in-depth questions for developers. This paper aims to address these gaps by exploring the relationship between respondent demographics and their responses. Our survey methodology, including the questions, target audience, and response validation process, will be detailed in the following section. The results of our study can also be compared to previous surveys in this field.

III. METHODOLOGY

This study used the empirical research specific steps that were stated in [28] as a reference to formulate the literature review, research questions, survey questions and analysis method. Both the survey guidelines in the review done by JS Molleri et al. [29] and the check list provided in [30] are used

to help us in evaluating our survey questions and methodology. The research questions are formulated after reviewing previous work and figuring the limitations of previous empirical studies on mobile applications development in order to ensure that answering these research questions will decrease the gap between researchers and practitioners. An online questionnaire using Pollfish website [31] is used for gathering the data. The questionnaire is shared with LinkedIn users who are working in the field of mobile application development. The next subsections will present our research questions, the survey questions, and how the survey questions are answering the research questions. Afterwards, the methodology of publishing our survey and how we selected the participants is discussed. Finally, the statistical methodologies that we used to analyze the results are explained.

A. Research Questions

RQ1: Which mobile applications development techniques do practitioners use and which platform they are developing for?

Researchers need to know the percentage of cross-platform users among mobile applications vendors and developers. Are the majority using cross-platform development? or the majority are using native development? And why? It is also important to know whether most companies are developing applications for more than one platform, or the majority is developing for only one platform. Does Huawei new platform have companies and/or developers?

RQ1.1: Which native languages are used the most?

For years, java for Android has been the most used language for developing Android applications. A few years ago, Kotlin language started to be used for Android development. Google announced in 2017 that Kotlin will be the official language for Android. We need to know the impact on practitioners and how much did they switch to Kotlin language after this announcement. A similar story happened between Objective-C language and swift for iOS development. We need to know if swift has taken over objective-C or if there are still some developers using Objective-C language.

RQ1.2: Which Cross-platform framework is used the most?

Former surveys and research were done to answer the question of the most popular and most used cross-platform framework. However, this information is changing rapidly due to the continuous evolution of existing frameworks. In addition, new frameworks are appearing, and researchers may not even be aware of their existence. Therefore, it is very important to investigate which frameworks are being used by developers and which are the most used.

RQ2: Are practitioners realizing that cross-platform development is not closing the gap with native development in terms of performance?

In the research field of mobile applications development, it is well known for researchers that cross-platform tools available do not provide the same performance and user experience as natively developed applications. Research comparing the cross-platform frameworks is done on certain applications and case studies. However, we need the

practitioners' point of view regarding this matter. This question is to investigate the performance and the issues of the cross-platform frameworks that face the practitioners and whether native development is the best way to get a high-performing application.

RQ3: Do developers know about trans-compiler-based solutions? Are developers interested in having a trans-compiler-based conversion tool?

Trans-compiler-based solutions for cross-platform development have been recently introduced by researchers [14]–[19]. These solutions are using compilers to translate the source code of mobile applications from one language to another to be available for more than one platform at a time. Researchers need to know practitioners' feedback about these solutions and whether they are a point of interest or not.

B. Questionnaire Design

In this study, questionnaires are considered because they are the fastest and easiest way to gather information for our research purpose. With wide use of professional social media like Linked in, it is easy to spread an online questionnaire among developers across the globe to obtain very useful qualitative data and analyze this data. However, this research is limited by the questionnaire drawbacks that does not allow us of know why or on what basis each participant chose a certain answer. This work can be extended later by making Interviews to focus on that point.

The questionnaire is created by Pollfish website [32] which was chosen over survey monkey and google forms to overcome the limitations regarding the number of participants and the limitations of forcing users to have a google account which may prevent some participants from taking the survey. While formulating our survey questions, we have considered making the questions clear and unbiased. We have also focused on designing questions that would answer the research questions stated previously.

The survey starts by five demographic questions that ask about age, gender, job status, job position and nationality. All these questions are predefined by Pollfish website except the job position (SQ1) and nationality (Q1) questions; we had to add them manually. The job position question was defined as a screening question since it is used to form the logic of the rest of the survey questions.

Then the following four questions (Q2,Q3,Q6,Q7) or (Q4,Q5,Q6,Q7) are profession questions that would help us draw a more rigid conclusion and deeper analysis of the results and exclude any non-valid responses. It will also help us identify correlations or dependencies between variables. Depending on the role of the participant defined in SQ1, the questions flow will differ as shown in Fig. 1. For managers and developers, we ask about the company they are working for and its location (Q2,Q3). For students, we ask about the university/college they are from and its location (Q4,Q5) while freelancers are directly navigated to Q6. The years of experience are also identified in the profession part for all participants and the number of mobile applications developed by the participant (Q6,Q7).

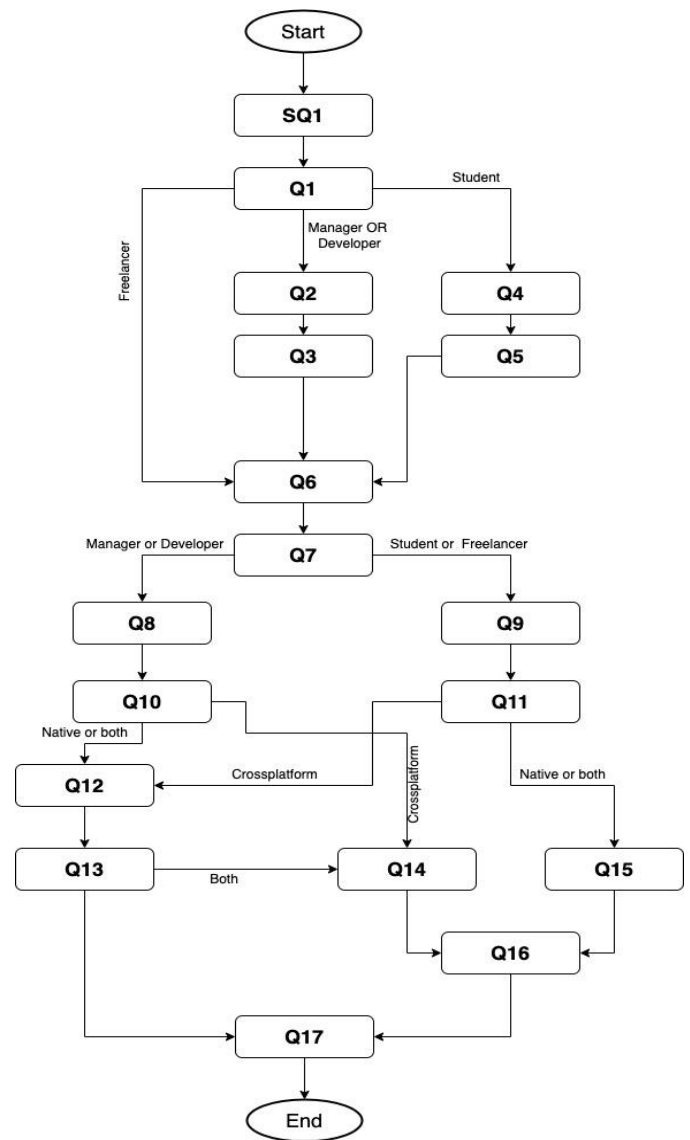

Fig. 1. Survey questions logical flow.

The personal information part is followed by technical questions. The technical questions also have two paths according to the role of the participant. In case the respondent is a student or freelancer, then the question is asked in a personal way “do you use”. If the participant is a manager or developer, then the question is asked targeting the company he/she is working for, like “does your company use”. First technical question (Q8 or Q9) is asking about the target platform whether it is Android, iOS, both platforms, or other platform. The participant can write an alternative. Then a direct question targets the approach used whether it native or cross-platform development (Q10 or Q11). For the native development, another question is asked targeting the language used in developing (Q12,Q13). Choices will be Kotlin or java for Android and swift or objective C for iOS. Then (Q14 and Q15) are targeting the most used cross-platform framework between developers and within companies. The choices of frameworks are added according to monitoring and collecting the most popular frameworks from related work and Statista

website [33]. Some frameworks have been well known for years, and others emerged recently. These two questions use Likert scale from 1 to 5, 1 corresponds for always using the framework and 5 corresponds to never. The question about the framework is followed by a question about the performance issue experienced while using the cross-platform framework (Q16). Finally, a question (Q17) about the familiarity with the Trans-compiler-based approaches is asked with a Likert scale answer between extremely familiar to not familiar at all.

C. Publishing the Questionnaire

Before publishing the questionnaire, we conducted a pilot test to check the availability of the website, the time taken and how clear the questions are. The pilot test was made among five participants of different experiences. The questionnaire took two minutes on average. The questions were clear and understandable. However, some questions needed proper branching. For example, the cross-platform frameworks question should appear only to the participants who chose cross-platform development and should not appear to the participants who chose native development. Similarly, the questions about the native language should not appear to those who chose cross-platform only. The pilot test helped us modify the logic of the questions and branching them correctly. Fig. 1 shows the flow of the questions and the different paths according to the selected answers.

We have created two different links for the survey, one for the Facebook community and the other one for LinkedIn. After publishing on Facebook communities and mobile applications development pages, we got only six participants. On the other hand, the link shared on LinkedIn showed 85 participants. Therefore, we decided to depend on LinkedIn participants. It proved to be a more professional social media through which we can communicate with real practitioners and get accurate answers to our questionnaire. The six responses we got from Facebook were excluded as we couldn't guarantee the level of professionalism the respondents had.

We used the search engine LinkedIn to search for people working in mobile applications development. We used the keywords "mobile application" with applying no filters first. Then, we applied different filters with it. For example, we used "manager" and "senior" keywords in the job title filter. We also used the location filter to reach developers in different countries like USA, Canada, England, India, Pakistan, Germany, Saudi Arabia, Emirates, and many other countries. We applied the filter of each country separately so we can send the survey to multiple people in each country. We have sent the survey link to more than 350 people through LinkedIn.

D. Analysis Methodology

The first step before conducting the analysis is filtering the responses and excluding any responses that were not valid. Two of the responses had answers that showed the participants were not answering the survey correctly. For example, one of the respondents chose all cross-platform frameworks as always used and in the native language question chose other and wrote the name of a cross-platform framework. This showed that either the participant was not reading the survey questions or had very little experience. Therefore, we excluded such

responses to guarantee that the answers and analysis are correct.

Since most of our questions were close ended, we have used descriptive statistics for qualitative analysis to report the survey results. Any provided open-ended text by the participants was used to draw more intuitions and verify the implications of the study. This will be mentioned in discussion sections.

We used a filter to categorize the participants into two main categories according to their role in the mobile applications development industry: Managers or developers and freelancers or students. For some questions, we used this filter to know the results of each category separately.

A filter by the company name was used to identify which method each company uses in developing mobile applications. Companies' names are not revealed in the results to keep the confidentiality and privacy of the respondents' answers. Companies' names were only used to retrieve the company size information from LinkedIn and validate the location information too which is already provided by the participant. Thus, we could categorize for different company sizes and locations whether they are using cross-platform or native development or both, which cross-platform is used by each company category, and which native language is used. There is a difference between the number of managers and developers and number of companies for two main reasons: 1) Not all employed participants provided their company name 2) Some participants were unemployed at the time they answered the survey; therefore, they didn't provide a company name.

Another important filter we used was the cross-platform framework filter. We filtered the answers to frameworks issues question for every framework separately. Thus, for each framework, we could know the most reported issues from its users. All the used filters and the resulting statistics according to each filter used are analyzed and presented by graphs and charts in the results section.

IV. RESULTS

From the results of the survey, we can infer much different information. Before presenting the results and the different filters applied, a general analysis is done on the demographics of the participants like their age, nationality, gender, and years of experience. The general analysis is followed by subsections presenting the results of each question with applying different filters on the results. The technical analysis is presented in three subsections. Each section represents the answer of one of the research questions.

A. Demographics Analysis

A total of 85 participants answered the survey. Most of the participants' nationality is Egyptian with some Indians, Pakistanis, and Belgians. However, they are working in different countries: Egypt, USA, Saudi Arabia, India, Netherlands, Romania, and Germany. The number of participants employed for companies is 71. We had nine participants who didn't provide their company name. However, some of them provided the company location without the

name. Therefore, the companies' location statistics are done for 62 companies as shown in Fig. 2.

Among the 62 companies, 10 of them have unknown names, thus their size is categorized as unknown. The size of the companies was retrieved from Linked in website. Therefore, the size categories are like the categorization in Linked in as shown in Fig. 3. The company size is represented by the number of employees. Most of the companies' sizes are small to moderate sized companies, 27 companies are of size 50 and below. The rest of the 52 companies are almost normally distributed among the rest of the size categories. We have nine companies from 51 to 200 employees. Another nine are from 201 to 1000 employees, and ten companies are of size 1000+.

Among the participants 91% are males the remaining are females. 32% of the participants' age ranges are between 18 to 24, 62% ranges between 25 to 34 and around 5% are above 35. These percentages were also reflected in the years of experience question. Most participants have 2-5 years of experience in the field. Regarding the employment status of the participants, 62% are employed for wages, while the rest are self-employed or out of work currently or students or working in military.

Fig. 2. Participants' companies' locations.

Fig. 3. Companies' size vs number of participants from each category.

We categorized the participants according to their job position into two main categories: Managers or developers who are considered and freelancers or students. This categorization differentiates between participants whose answers represent the companies they are working for and participants who are self-employed. Around 85% of the participants work as managers and developers in the field of mobile applications. 15% are freelancers and students. In the following subsection, we will present statistics answering our research questions. In the statistics of most of the questions, we will use the filter of job position to differentiate between both categories

B. Technical Questions Analysis

The technical questions' part is represented by six questions in the survey for each participant. The analysis of the answers to these questions will answer our previously mentioned research questions. Results of analyzing the participants' answers are presented as follows:

RQ1: Which mobile applications development techniques do practitioners use and which platform they are developing for?

One of the main research questions that we were eager to answer was whether the industry now is going towards cross-platform development or returning to the native development. In the questionnaire, we provided three options for this question: cross-platform, Native or both. The results revealed that most of the participants chose the "both" option. Cross-platform development came in the next level then the native development. Fig. 4 shows the statistics of the approach used by both participants' categories. The statistics showed that most of the freelancers and students are using both approaches together. However, if we observe the companies' representative participants alone, we could notice that companies are either depending on cross-platform frameworks alone or on both cross-platform and native together. Few companies are using the native approach alone. This made us use the company size filter to analyze which companies are using which approach. Table I shows the company size vs. the used approach. From examining the data in the table, we can infer that 38.7% are using cross-platform development alone, 38.7% are using both native and cross-platform development, while 22.58% are using native development alone. Since Egyptian companies have a big share among the companies, we applied the same analysis but with excluding the Egyptian companies. We got nearly the same statistics for the non-Egyptian companies.

The second part of the first RQ asks about the platform which the respondent develops applications for. "Android", "iOS", "both platforms", or "other" are the four options for the platform question in the survey. The results in showed that 73% of participants are developing for both platforms Android and iOS. However, if we examined the freelancer's percentage separately, we could notice that the majority develop applications for Android platform. No participants chose the "other" option which shows that windows phone is obsolete now and that new platforms, like Harmony OS by Huawei, are still not very popular.

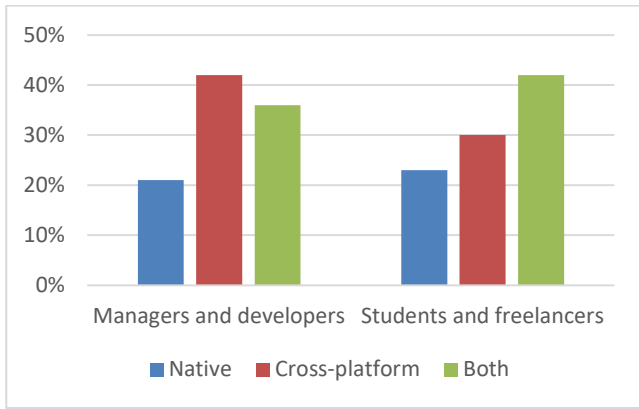

Fig. 4. Percentage of participants using native, Cross-platform or both approaches according to their category.

TABLE I. COMPANY SIZE VS DEVELOPMENT APPROACH

Company size vs used approach	Both	Cross-platform	Native
10,000+	5		
1000-5000	1		1
501-1000	1	1	1
201-500		2	4
51-200	4	5	
11-50	5	6	6

RQ1.1: Which native languages are used the most?

For native development, Java and Kotlin are the languages used to develop Android applications. Swift and Objective C are used for iOS applications. Our aim is to know if there is any language that is preferred among developers over the other. The results showed that 47% of participants chose Kotlin for Android while 39% chose java and the rest use both. On the other hand, 92% chose swift for iOS. When we applied the companies filter, Java and Kotlin for Android are considered evenly used among practitioners. However, swift is used much more than Objective C. only one company is using Objective-C. This company is a very large sized and old governmental company. When we removed Egyptian companies from the analysis, we got the same statistics for both Android and iOS languages. Fig. 5 shows the company size vs. the used native language for 37 companies. These 37 companies are either using native development alone or native development with cross-platform development. The small-sized companies are using Kotlin and java evenly. The medium-sized companies are using Kotlin more than java, while the big companies are using java more than Kotlin.

RQ1.2: Which Cross-platform framework is used the most?

For the cross-platform development selectors, they were asked about the framework they are using. The options of this question included ten different frameworks. The most used framework according to the results is flutter, followed by React

Native, then comes Xamarin, Ionic, JQuery mobile, NativeScript, and Swiftic frameworks. The previous studies showed that React Native was on top [23], [34]. However, now flutter took the first place, and it seems to be very popular among both freelancing developers and companies. Fig. 6 shows the pie chart for seven frameworks. By applying analysis on the companies using cross-platform frameworks, we got similar ranking for the frameworks. When we tried to filter and exclude the small-sized companies then the large-sized companies alone, we got the same result. In addition, excluding Egyptian companies also resulted in the same statistics.

Fig. 5. Company size vs. number of companies using different native languages for android development.

Fig. 6. Statistics of the most used cross-platform frameworks.

RQ2: Are practitioners realizing that cross-platform development is not closing the gap with native development in terms of performance?

To investigate the issues facing the developers using cross-platform frameworks, we asked the developers who are using cross-platform frameworks about the issues they face. This question allowed the participants to choose more than one answer among six different issues: Memory, speed, development effort, security, user experience and testability. An “other” option is also provided to let participants provide any other issues they see. In general, the most reported issue is Memory then comes the Speed and development effort then user experience and security, the least reported issue is testability. By filtering the results on each cross-platform

framework separately, we could see the issues related to each framework. For example, for flutter, the same order of issues is noticed, and this is normal since flutter is the most used framework. For React Native users, security then speed, and development effort were the most reported issues. However, for jQuery and Xamarin, memory, speed and security were the most reported in addition to user experience for Xamarin framework. Fig. 7 shows the statistics of the issues for the four most used frameworks according to the survey results. On the other hand, 12.5% of the participants chose the “other” option only without providing any extra issue. Few of them wrote and they cannot see any issues while using the cross-platform frameworks.

Fig. 7. Reported performance issues by each cross-platform framework.

RQ3: Do developers know about trans-compiler-based solutions? Are developers interested in having a trans-compiler-based conversion tool?

The final question of the survey asked how familiar participants are with the trans-compiler-based cross-platform solutions. 58% of the participants are not familiar with these solutions and 14% are moderately familiar, while 18% are extremely familiar. This shows that the trans-compiler-based solutions are never really tested by practitioners, and they are still under the research umbrella only.

V. DISCUSSION

The most important findings from our survey are discussed as follows: Most companies and practitioners are developing for both Android and iOS platforms. Very few participants chose only one platform. This shows that although developing the applications for more than one platform is a tedious task, and although iOS users are much less than Android users, mobile application vendors are developing applications for both platforms either natively or using cross-platform frameworks. No participant wrote other platform which shows that windows phones are now obsolete and new Operating systems like Harmony OS by Huawei are not very popular.

Only 25% chose native development solely. This means that the industry now is using a mix of cross-platform development and native development together. Almost 75% of

the survey participants are equally split between the “both” option and cross-platform when they were asked about the technology used in development. These statistics are almost similar regardless of the role of participants and regardless of the company size or location for professional participants. This shows that cross-platform frameworks proved to be a good solution but sometimes they are not enough for implementation of sophisticated functionalities on the different platforms. One of the survey participants who was using flutter framework wrote a comment stating that some functionalities must be written using native code then connected to flutter. In addition, cross-platform frameworks have performance issues regarding memory, speed, security, and user experience.

Our study also shows that Flutter is the most used right now. The numbers show that Flutter is becoming very popular among both freelancers and developers working in companies. However, the participants are aware that flutter has its own issues. The most reported issues by Flutter users were memory and speed.

Kotlin language is competing now with java for Android development. More than half of the Android developers who participated in the survey chose Kotlin as the native language they use for development. This was predicted as an impact to the announcement made by Google stating that they will use Kotlin as the official language for Android [35]. We encourage future researchers to investigate more the capabilities of Kotlin language and to support Kotlin language in their proposed development tools for mobile applications. On the other hand, swift language proved to be the most dominant for iOS development, only one participant chose objective C language. The participant who chose objective C is working for a very big and old company which means that objective C might still be used in old companies that do not want to change their structure of operation.

Regarding the familiarity of practitioners with the trans-compiler-based solutions, the results showed that practitioners are almost unaware of these solutions. They are dealing with the current cross-platform frameworks now as their current solution. However, the shift that has occurred from React Native, Phone gap, Ionic and Xamarin to flutter over the recent few years shows that whenever a better solution appears for developers and practitioners, they will easily move to it. These findings also encourage researchers to test their solutions by real practitioners and spread them to industry. This will help them introduce new solutions and tools that might close the gap between current solutions and performance issues.

VI. COMPARISON WITH RELATED WORK

To compare our work with the related works mentioned in the introduction, we focused on five main points based on our findings compared to their findings. These five main points are: What mobile platform do practitioners like to develop applications using? What development approach do practitioners prefer to use, native or cross-platform? Which cross-platform framework is the most used in the industry? What native language do practitioners use the most? What are the performance issues that are facing cross-platform mobile frameworks?

Puvalla et al. [36] discussed the factors that affect developers in choosing a development platform. They concluded that although Android has more apps than iOS, developers are switching from Android apps to iOS due to the monetization potential of the iOS apps. Therefore, iOS developers are paid more than Android developers. The findings of the survey show that the factor that affects the developer's choice of the platform the most is the availability of SDKs to support the platform. But our results show that most practitioners and companies prefer to build applications for both platforms rather than one specific platform. Our results are synonymous with the prediction made by Francesca et al.[37] in 2017, which asked a futuristic question, "In the next 5 years, on which native platform will your company actively develop?". They stated that regardless of what platform the respondents were using at that time, the target platform in the next five years would be both Android and iOS.

Regarding the question of whether practitioners prefer native or cross-platform development approaches. In 2017, Ahmed et al. findings show that most of their participants prefer using native development over cross-platform development. This is different to our findings as our result shows that only 25% are using native development alone while 37.5% are cross-platform and the remaining 37.5% chose both technologies. These differences are related to technological enhancements to the cross-platforms over the years. Besides the technical improvement, cross-platform frameworks are easier to use by developers since development community are getting bigger and giving more support to developers [23].

Bjorn-Hansen et al. [23] conducted an empirical study by targeting 101 industry practitioners. The reason is to find out which cross-platform frameworks are used the most by developers as a hobby and professionally, and what issues are facing cross-platform frameworks. Their findings show that PhoneGap, React-native, and Ionic are the most used apps both as a hobby and professionally. The findings of their research are similar to the findings of Francesca [38], which shows that PhoneGap is the most used. But the result differs from ours because in our study we found that flutter is the most used cross-platform development framework both in companies and by practitioners. This is due to the time that their survey was conducted in 2018 [23], so new technology now dominates the market. The same research group in 2022 [39] investigated approaches to Android mobile application development through applications on the Google Play store. The findings also show that Cordova is the most popular cross-platform framework. Their findings also contradict our findings. However, only 15% of their total dataset are cross-platform applications and the rest of the 85% are native applications, and the applications that are mentioned in the dataset are not recent, which is why they are not developed using flutter, one of the most recent frameworks.

In terms of the native language that the developers are using, Bjorn-Hansen et al. [23] predicted that Kotlin is the most used android development nowadays, not Java. This prediction is proven in our survey, as seen in the results section, that Kotlin is the most used android language by practitioners and companies. On the other hand, Swift is the dominating iOS programming language.

Lastly, regarding the issues that are facing cross-platform mobile frameworks, Bjorn-Hansen et al. [23] state that cross-platform solutions are still facing performance and user experience issues when compared to native solutions. Our findings suggest that memory and speed are the issues that affect Cross-platform frame works, most specifically flutter, which is the most dominant cross-platform framework in our survey.

VII. CONCLUSION AND FUTURE WORK

This paper investigates the most used development technique in the industry and to gather feedback on mobile application development. It seeks to answer the question of whether most industries use cross-platform mobile development or native mobile development. Furthermore, it investigates whether developers and industry have a perspective that is consistent with academic research by collecting data through an online questionnaire. The survey was aimed at both novice and experienced mobile developers. A total of 85 people responded to the survey, which enables us to get perspectives from the industry.

The implications that can be drawn from our findings are stated as follows: (1) Most companies and practitioners develop for both Android and iOS platform with only few choosing one platform. (2) Developers are moving towards cross-platform development. However, they are still using native development besides the cross-platform frameworks. This is due to the flaws and issues that still exist in these frameworks despite the noticeable technological enhancements. (3) Flutter is now the most used framework in the industry and the most reported issues by Flutter users were memory and speed. (4) In terms of which native language is used in the industry the most, Kotlin language currently leads the android development. However, Swift is still the main iOS programming language. (5) Most of the people in the industry are unaware of trans-compiler-based solution.

The findings presented and discussed in this article may all be significant and extensive topics for future research, both individually and collectively. This future work encourages researchers to: (1) Focus on expanding and generalizing the survey so that it will reach a large scale of people by covering more locations and adding interviews. (2) Investigate more the capabilities of Kotlin language and to support Kotlin language in their future work (3) to test their solutions by real practitioners and spread them to industry especially the Trans-compiler-based solutions. (4) To introduce a new way to decrease the issues and flaws facing cross-platform solutions.

Feature Selection using Particle Swarm Optimization for Sentiment Analysis of Drug Reviews

Afifah Mohd Asri¹, Siti Rohaidah Ahmad², Nurhafizah Moziyana Mohd Yusop³

Department of Computer Science-Faculty of Defence, Science and Technology,
Universiti Pertahanan Nasional Malaysia, Sungai Besi, Kuala Lumpur, Malaysia

Abstract—Feature selection (FS) is an essential classification pre-processing task that eliminates irrelevant, redundant, and noisy features. The primary benefits of performing this task include enhanced model performance, reduced computational expense, and modified “curse of dimensionality”. The goal of performing FS is to find the best feature group that can be used to build an effective pattern recognition model. Drug reviews play a significant role in delivering valuable medical care information, such as the efficacy, side effects, and symptoms of drug use, facilities, drug pricing, and personal drug usage experience to healthcare providers and patients. FS can be used to obtain relevant and valuable information that can produce an optimal subset of features to help obtain accurate results in the classification of drug reviews. The FS approach reduces the number of input variables by eliminating redundant or irrelevant features and narrowing the collection of features to those most significant to the machine learning model. However, the high dimensionality of the feature vector is a major issue that reduces the accuracy of sentiment classification, making it challenging to find the best feature subset. Thus, this article presents a perceptive method to perform FS by gathering information from the potential solutions generated by a particle swarm optimization (PSO) algorithm. This research aimed to apply this algorithm to identify the optimal feature subset of drug reviews to improve the classification accuracy of sentiment analysis. The experimental results showed that PSO provided a better classification performance than a genetic algorithm (GA) and ant colony optimization (ACO) in most datasets. The results showed that PSO demonstrated the highest levels of performance, with an average of 49.3% for precision, 73.6% for recall, 59% for F-score, and 57.2% for accuracy.

Keywords—Sentiment analysis; feature selection; particle swarm optimization; drug reviews

I. INTRODUCTION

As the world becomes increasingly digitised, there is a growing need for the automation of various processes. One area that has experienced significant expansion is sentiment analysis, which is a crucial component of natural language processing. Sentiment analysis involves identifying the emotional responses elicited by a given text. One area where sentiment analysis has proven useful is in the analysis of drug reviews [1]. Sentiment analysis can identify the overall sentiment of a drug review, which can help healthcare providers understand the effectiveness and side effects of a given drug. However, a significant challenge in sentiment analysis is figuring out which features, or aspects of a text are essential in determining the sentiment. Feature selection (FS) involves identifying a relevant subset of features from a larger

set of potential features [2], [3]. By decreasing the number of features, FS can enhance the accuracy and efficiency of a sentiment analysis model [4], [5].

Particle Swarm Optimization (PSO) is a well-known optimization algorithm commonly used in FS due to its ability to simulate the behaviour of a swarm of particles. Each particle represents a possible solution to an optimization problem, and they interact with each other as they move through a solution space in search of the optimal solution [6], [7]. PSO is a suitable method for feature selection in sentiment analysis, as it can determine the optimal feature subset to maximise the model’s accuracy [8]. The features to be selected must be encoded as binary values, with 1 indicating their inclusion in the subset and 0 indicating their exclusion.

The PSO algorithm commences the optimization process by randomly assigning a set of particles to represent feasible feature subsets to form a swarm. The fitness value of each particle is then calculated by evaluating the accuracy of the sentiment analysis model with its corresponding feature set. Subsequently, the particles navigate through the solution space, influenced by their individual best position (pbest) and the best position of the swarm (gbest). This iterative process persists until a pre-defined termination criterion is reached, such as reaching a maximum number of iterations, or a specific level of accuracy [6], [9]. Once the PSO algorithm has identified the optimal subset of features, the sentiment analysis model can be trained using only these features, which would result in a more efficient and accurate model. Thus, utilising PSO for FS in a sentiment analysis of drug reviews can enhance the accuracy and efficiency of the model, ultimately leading to a more comprehensive understanding of the effectiveness and side effects of reviewed drugs.

This study aimed to utilise PSO as part of a feature selection method to identify an optimal set of features in drug review datasets that can enhance the classification accuracy. The use of PSO for FS has been demonstrated to be effective in identifying relevant and non-redundant subsets of features that can enhance the performance of machine learning algorithms [10], [11]. The results of these studies showed that PSO outperformed two algorithms by demonstrating the highest level of performance. The application of PSO in drug review datasets can uncover feature subsets that can enhance the accuracy of sentiment analysis models. This achievement can ultimately lead to a deeper comprehension of the efficacy and adverse reactions of various drugs. The experimental results indicated that PSO possessed the capability to produce high-

quality feature subsets, which increased the classification accuracy of the sentiment analysis model.

This article begins with an introduction to the background of this study, leading to a clear overview of the conducted experiments. The main body of this article is divided into several sections, with each section focusing on a specific topic, such as literature reviews, related works, brief explanation on PSO, research methodology, experimental setup, and analysis of results. Within each section, subtopics are introduced to offer explanations, support evidence, examples, and analysis. The conclusion section summarises the main points, restates the experiments, and ends with a concluding statement or call to action. The reference section is included to list the sources used in this article.

II. LITERATURE WORK

A. Sentiment Analysis

Sentiments can be defined as an individual’s attitude or belief that are often influenced by emotions rather than logical reasoning. Therefore, the process of analysing opinions is also commonly known as sentiment analysis, which aims to extract subjective information from various sources, such as speech, text, tweets, and databases [12]. Sentiment analysis involves using Natural Language Processing (NLP) techniques to automatically detect emotions, perspectives, opinions, and attitudes that are expressed in texts and to categorise them either as neutral, positive, or negative [13]. According to [14], sentiment analysis can be applied to social media and medical records to acquire information on the effectiveness of medical treatments or medications. By analysing public archives and social media posts, specific adverse effects of drugs can be identified more efficiently, leading to potential benefits for the pharmaceutical industry in terms of pharmacovigilance [15]. Thus, sentiment analysis can be used to extract information that can assist in making accurate judgments regarding public health and substance safety. Machine Learning and Lexicon-based approaches are commonly used in sentiment analysis.

Lexicon-based methods primarily depend on a sentiment vocabulary, or a set of well-known and precompiled emotional

words, sentences, and idioms, which is created for conventional communication categories [16]. The Machine Learning (ML) approach relies on the quantity of labelled data marked by specialists to train a classification [2]. ML can be divided into two categories, namely, supervised and unsupervised methods. An appropriate collection of features must be selected and retrieved to identify sentiments in order to improve the performance of these approaches [17]. The analysis of sentiments using machine learning was the focus of this study.

B. Drug Reviews

In recent years, there has been a significant surge in the number of social networks dedicated to discussing health-related matters. This has led to a substantial increase in the availability of healthcare information in the form of drug reviews on the Internet [18]. According to [15], Drugs.com is the biggest and most viewed medicinal information website that serves customers among the public and healthcare experts. According to [18], a substantial number of drug reviews has been created and published through various healthcare and drug-related online platforms, including AskaPatient and Drugratingz, where users express their first-hand experiences and reactions to various medications.

Drug reviews are written evaluations of numerous drugs by users based on their personal experiences and preferences [19]. Drug reviews can also be described as an individual’s impressions regarding several drug-related fields, such as efficacy, adverse effects, convenience, and value [14]. These reviews offer abundant data that can be utilised to make informed decisions concerning public health and medication safety [20].

III. RELATED WORKS

This section presents related studies on sentiment analysis of drug reviews. Table I shows an extended summary of related studies based on the techniques used in the sentiment analysis of drug reviews [20].

TABLE I. RELATED STUDIES ON TECHNIQUES USED IN SENTIMENT ANALYSIS OF DRUG REVIEWS

Not stated in paper.	Rule-based Linguistic	Precision, Accuracy, Recall and F1_Score
Fuzzy-Rough Quick Reduction (FRQR).	Random forest, Ripper, Decision tree and Naive Bayes	Accuracy, Performance of running independent hold-out test, time required to develop the model.
Pethe nguin Search Optimization (PESOA)	Naive Bayes (NB), K-Nearest Neighbour (KNN), support vector machine (SVM)	Precision, Accuracy, Recall and F1_Measure
Related Words (RW) Vector	Bidirectional Encoder Representation from Transformer (BERT)	Recall, Precision, and F-Measure
Not stated in paper	Bidirectional Encoder Representation from Transformer (BERT) with Long Short-Term Memory (LSTM)	Accuracy and F1_Score

IV. PARTICLE SWARM OPTIMIZATION

The study [21] first proposed Particle Swarm Optimization (PSO) in 1995. It is a stochastic optimization method for a population that takes its cue from the cooperative nature of flocking birds [22]. As stated by [6], PSO is an algorithm for population-based optimization that simulates the social interaction and communication among groups of animals, such as flocks of birds or schools of fish [39].

In PSO, each particle represents a candidate solution to the optimization problem. This set of particles will move through a search space in search of the optimal solution. Each particle has a position and a velocity, and the goal is to find the optimal position in the search space that minimises or maximises an objective function [23].

At each iteration of the algorithm, the particles will adjust their position and velocity based on their own best-known position (i.e., the best solution they have found so far) and the best-known position of the entire swarm (i.e., the best solution found by any particle in the swarm). This is done using a set of mathematical equations that determine each particle's new position and velocity. This process will continue until a stopping criterion is met, such as the maximum number of iterations or a satisfactory level of convergence. The final position of the particles represents the optimal solution to the optimization problem [23].

The PSO version employed in this study is represented by the equation in Fig. 1. Learning rates c_1 and c_2 are positive constants, r_1 and r_2 are random numbers in the range of 0 to 1, and P_i , X_i , and V_i represent the swarm's best previous location, the particle's current position, and the rate of change of position (velocity), respectively, for a D-dimensional

problem space at iteration t . Additionally, w indicates the inertia weight, g represents the best particle among all particles in the population, and V_{max} is the maximum velocity for the particles in each dimension. V_{max} is applied, if the total number of elements on the right side of the equation exceeds a predetermined fixed value.

$$V_i(t+1) = w_i V_j(t) + c_1 \cdot r_1(t) \cdot |P_i(t) - X_i(t)| + c_2 \cdot r_2(t) \cdot |g - X_i(t)|$$

$$X_i(t+1) = X_i(t) + V_i(t+1)$$

Fig. 1. Particle swarm optimization equation.

V. METHODOLOGY

This section presents a summary of the methodology used to conduct sentiment analysis of drug reviews using PSO for feature selection, as illustrated in Fig. 2.

A. Data Cleaning and Pre-processing

Prior to analysing the collected text data, data cleaning and text pre-processing steps were implemented to obtain satisfactory results. Data pre-processing involved the removal of words that did not help convey the meaning of the text, or were deemed unnecessary, thereby, enhancing the efficacy of

the search for valuable words in each sentence [4]. To create a standardised dataset, several pre-processing techniques were applied, including correcting misspelled words, tokenisation, removing stop words, segmentation, and part-of-speech tagging.

Datasets to be analysed need to undergo pre-processing because reviews are typically written by non-experts in the field of language and could contain various errors, such as spelling mistakes, incorrect use of capital letters, punctuation errors, and grammatical errors. These errors can negatively impact the accuracy and effectiveness of sentiment analysis models, which rely on clean and standardised datasets. By applying pre-processing techniques, the datasets can be cleaned and standardised to make them more suitable for sentiment analysis [4], [24].

In this study, drug review datasets were cleaned and pre-processed by excluding all blank reviews, HTML tags, and spacing. Capitalisation of words and punctuations were verified, words were checked for errors, such as grammar and spelling, and paragraphs were segmented into sentences. This process was performed using Microsoft Word and Microsoft Excel software. Fig. 3 shows an example of the reviews before and after undergoing the cleaning and pre-processing process.

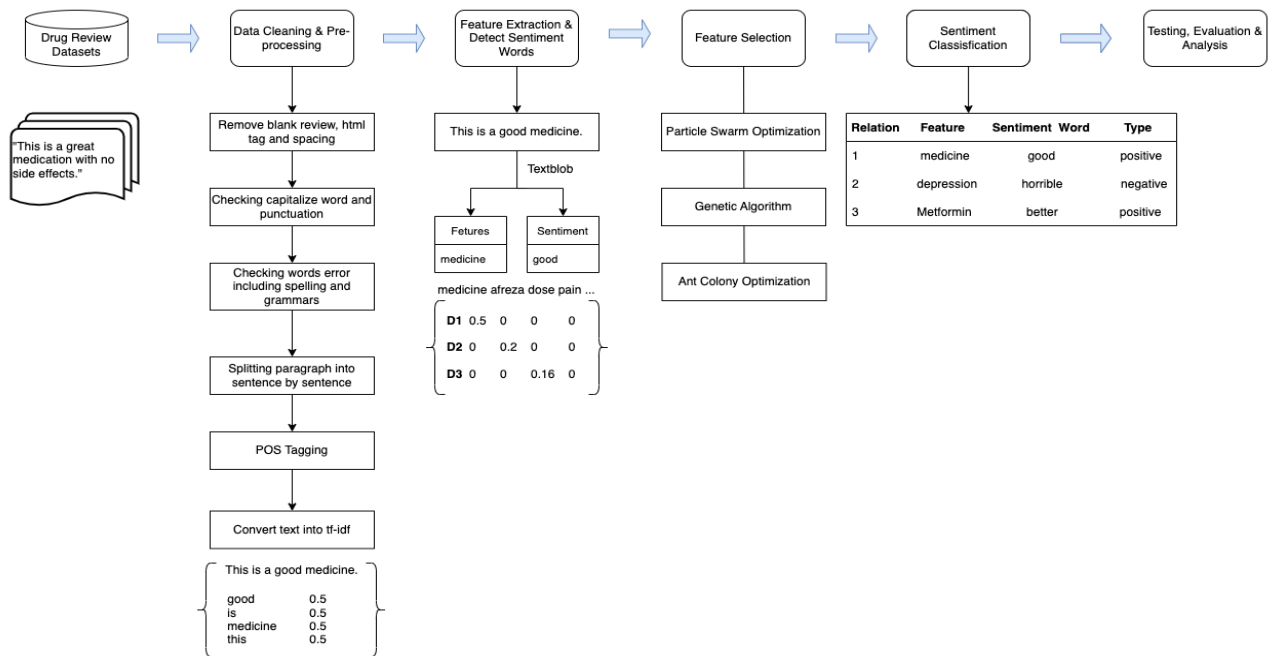

Fig. 2. The methodology of the study.

Sentence before preprocessing:
 “I’ve experienced NO Side Effects.”
Sentence after preprocessing:
 “I have experienced no side effect.”

Fig. 3. An example of a cleaned and pre-processed review.

The figure shows a sentence that contains HTML code syntax “',” which represents the apostrophe symbol. This syntax was removed and replaced with the full-form word. There were also capitalisation errors, such as “NO” and “Side Effect,” as well as a spelling error in the word “Effect,” with an extra “f”. After completing the cleaning process, part-of-speech tagging was conducted on each sentence to identify the features and sentiment words in the text.

B. Feature Extraction and Sentiment Word Identification

The identification of pertinent information from textual data through feature extraction is of utmost importance in sentiment classification, as it can inevitably affect the model’s performance [25]. The extraction of important terms from a dataset is known as feature extraction [24]. This approach seeks to select significant data that encompass the most important features of the text [25]. This study employed the TextBlob library, which is a Python-based tool that utilises the Natural Language Toolkit (NLTK) to conduct Natural Language Processing (NLP) tasks and to evaluate sentiment polarity. The library’s noun phrase extraction capabilities and sentiment analyser were used to extract all feature and sentiment words from the datasets.

C. Feature Selection

The first step in constructing a classification model is to detect relevant features within the dataset [2], [21]–[23]. The extracted features would then undergo data transformation from text data into feature vectors. Sentiment analysis is utilised for its emphasis on text documents, since a classifier cannot understand or interpret a text directly.

Consequently, it is necessary to transform textual documents into a format recognisable by a computer, with the Vector Space Model being the preferred technique to accomplish this. Term frequency-inverse document frequency (TF-IDF) was used in this study, as it is one of the most basic methods of conveying features through term count [26]. This model employed a vector space representation of the documents in the dataset, wherein the dimensions of the vector corresponded to the features selected from the dataset [27]. The data objects can be expressed as feature vectors in the feature space. Feature selection will then identify and remove non-essential features from a set of features to improve the classification accuracy, while reducing the feature space dimensionality [28]. In this study, PSO was chosen as a feature selection method to obtain the optimum subset of features.

D. Sentiment Classification

Sentiment classification is a crucial subfield of sentiment analysis, which entails the identification and categorisation of emotions conveyed in a textual data, including reviews and tweets. The primary objective of sentiment classification is to classify texts into various categories based on their subjective information, which typically include positive and negative sentiments [29]. In this study, feature and sentiment words were obtained feature extraction and sentiment word identification section. They underwent manual reviews in conjunction with the datasets to ascertain their conformity with the contextual information presented in the data collection.

E. Testing and Evaluation

The testing and evaluation procedure involved measuring how well the feature and sentiment words were related to one another. This procedure was performed to evaluate the ability of the proposed algorithm to detect and acquire dependable features along with correct sentiments. The efficacy of the proposed method is evaluated based on the following four metrics: precision, recall, F1-score, and accuracy using the measures shown in Table II:

- True Positive (TP) denotes correctly identified positive reviews.
- True Negative (TN) denotes correctly identified negative reviews.
- False Positive (FP) denotes positive reviews incorrectly identified as negative.
- False Negative (FN) denotes negative reviews incorrectly identified as positive.

TABLE II. CONFUSION MATRIX

	Predicted Positive	Predicted Negative
Actual Positive	TP	FN
Actual Negative	FP	TN

$$\text{Precision} = \text{TP} \div (\text{TP} + \text{FP}) \quad (1)$$

$$\text{Recall} = \text{TP} \div (\text{TP} + \text{FN}) \quad (2)$$

$$\text{F1} = (2 \times \text{Precision} \times \text{Recall}) \div (\text{Precision} + \text{Recall}) \quad (3)$$

$$\text{Accuracy} = (\text{TP} + \text{TN}) \div (\text{TP} + \text{TN} + \text{FP} + \text{FN}) \quad (4)$$

VI. EXPERIMENTS

This section summarises the drug review datasets obtained from the University of California Irvine (UCI) machine learning repository, along with the methodology employed for feature selection. Specifically, this study has introduced PSO as the primary feature selection technique, with Ant Colony Optimization (ACO) and Genetic Algorithm (GA) as the benchmarks.

A. Datasets

In this study, 1,229 drug reviews from druglib.com were analysed for several conditions, such as diabetes, high blood pressure, heart attack, etc. The datasets contained patient feedback on medications, information on associated conditions, and a patient rating of 10 stars, which reflected the overall patient happiness. Data were gathered by crawling the pharmaceutical review website, Drugs.com. The datasets utilised in this study were stratified into two distinct polarity levels based on review ratings, namely, positive (class 1, rating ≥ 5) and negative (class -1, rating ≤ 5), as previously defined in [30]. These datasets comprised a total of 719 positive reviews and 509 negative reviews, representing a valuable resource for training and evaluating sentiment classification models. These datasets were then divided into 10 sets. The first set includes 10% of the overall features, while the second set contains 20% and so on, as shown in Table III. Using a stratified random

sampling method, 70% and 30% of the datasets were put aside for training and testing.

The distribution of the two classes is illustrated in Fig. 4, with approximately 41% of the reviews having a negative polarity (class -1) and 59% having a positive polarity (class 1).

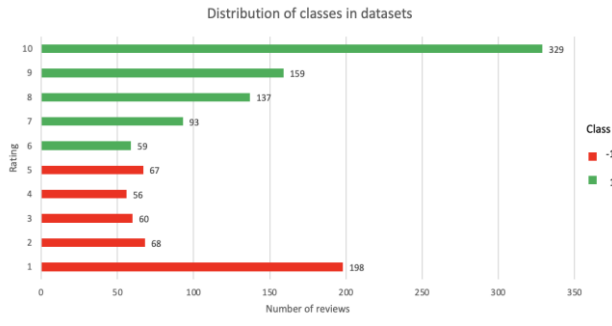

Fig. 4. Class distribution of drug review datasets.

B. Baseline Algorithms

Due to their proven effectiveness in improving the performance of sentiment analysis [31]–[33], the ACO and GA were chosen as the baseline algorithms for the PSO algorithm in this study. The aim was to compare the performance of PSO against these algorithms in identifying an optimal feature subset for the sentiment analysis of drug reviews.

TABLE III. SUMMARY OF TOTAL FEATURES AND REVIEWED SENTENCES IN EACH DRUG REVIEW DATASET

Dataset	Total Features	Total of Reviewed Sentences
Set 1	83	398
Set 2	167	583
Set 3	250	762
Set 4	334	923
Set 5	417	1030
Set 6	501	1135
Set 7	584	1231
Set 8	668	1329
Set 9	751	1417
Set 10	835	1506

C. Experimental Setups

The aim of the present study was to evaluate the efficacy of the proposed algorithm through a series of experiments designed to compare its performance with existing algorithms in the field. The experiments were conducted on a computer system equipped with an Apple M2 processor and 16 GB of RAM, which provided sufficient computational power and memory capacity to perform the required tasks. The high processing power and ample memory capacity of this machine facilitated the efficient execution of experiments and reliable collection of data. The proposed PSO algorithm was implemented using Python and was run on the Jupyter Notebook, while the ACO and GA algorithms were executed using an established algorithm in WEKA on the same machine.

TABLE IV. PSO PARAMETER SETTING

Parameter	Value
Acceleration Coefficients, c_1 & c_2	2
Inertial weight, w	1
Population Size	20
Iteration	20
Fitness	1

Table IV lists the PSO parameters that have been employed to identify the optimal parameter configuration that would yield a sentiment analysis model with superior performance based on the test set. The testing was performed to evaluate the ability of the PSO algorithm to produce a feature subset that was both significant and non-redundant, aiming to determine the most optimal feature set. The effectiveness of the proposed algorithm was measured using several performance metrics, namely, precision, recall, accuracy, and F-score, as elaborated in testing and evaluation section.

VII. ANALYSIS OF RESULTS

This section presents the outcomes of utilising the PSO algorithm for feature selection of a drug review dataset. Its performance was compared with the performance of the ACO and GA. The purpose of this research was to evaluate the effectiveness of PSO in identifying a relevant and non-redundant feature subset that could improve the performance of the sentiment analysis model. To achieve this objective, accuracy, precision, recall, and F-score were used as performance metrics to assess the quality of the outputs generated by each algorithm.

Table V presents the experimental outcomes of the proposed PSO algorithm, along with the compared algorithms (ACO and GA) based on the performance metrics (precision, recall, F-score, and accuracy). These results indicated that PSO outperformed ACO and GA in most of the datasets, with an average of 49.3% for precision, 73.6% for recall, 59% for F-score, and 57.2% for accuracy.

Fig. 5 to Fig. 9 show the performance evaluation of PSO compared to ACO and GA for feature selection in sentiment analysis based on precision, recall, F-score, and accuracy. The results showed that PSO outperformed both ACO and GA in terms of the average precision, recall, F-score, and accuracy. The average precision of PSO was 49.3%, which was higher than ACO with 46.4% and GA with 46.2%. Similarly, the average recall of PSO was 73.6%, which was higher than ACO with 71.5% and GA with 70.5%.

The experimental results listed in Table VI show that PSO has selected a higher number of features on average (197) compared to ACO (111) and GA (112). The table also shows that PSO was more efficient in selecting relevant features, as evidenced by its superior performance in terms of precision, recall, F-score, and accuracy. Therefore, the higher number of selected features by PSO can be attributed to its ability to identify and retain more relevant features, which ultimately improved its classification performance.

TABLE V. THE RESULTS OF ACO, GA, AND PSO BASED ON PERFORMANCE METRICS (PRECISION, RECALL, F-SCORE, AND ACCURACY) ON DRUG REVIEW DATASETS

Dataset	Precision			Recall			F-Score			Accuracy

Fig. 8. Accuracy results for ACO, GA, and PSO on drug review datasets.

Fig. 9. Average performance and selected features of ACO, GA, and PSO on drug review datasets.

This study has shown that PSO was a highly effective algorithm for feature selection in sentiment analysis. The results showed that PSO outperformed the other two algorithms, demonstrating the highest level of performance. In these experiments, the parameters were set up appropriately to ensure the validity of the results. However, these experiments were not intended to determine the optimality of the selected

parameter values for PSO in the feature selection process of sentiment analysis. Consequently, further research is needed to investigate the optimal parameter values for PSO in this specific application domain. Additional experiments are also required to obtain accurate parameter settings for PSO in feature selection for sentiment analysis to enhance its performance and accuracy in this context.

The experimental results indicated that PSO possessed the capability to produce high-quality feature subsets, which increased the classification accuracy of the sentiment analysis model. This algorithm explored the vast search space of possible feature subsets to identify the most relevant and discriminative features, while discarding redundant or irrelevant ones. The global optimization capabilities of PSO ensured that the algorithm was able to converge the optimal solution, which further enhanced the quality of the selected feature subset. Therefore, the empirical evidence has shown that PSO was a highly effective method for feature selection, since it was capable of producing feature subsets that could improve the classification accuracy of a variety of applications.

VIII. CONCLUSION

This paper presents a novel approach that utilised the PSO algorithm for feature selection in drug reviews, with the objective of improving the performance of the sentiment analysis model. To verify the efficacy of the proposed approach, three feature selection methods were employed to compare the results obtained from drug review datasets. The results showed that PSO provided a better classification performance than GA and ACO in most datasets. PSO was both simple to use and well-known for accelerating convergence, since all particles learned from the global best, which was the current best value achieved by any particle in its neighbourhood. The results have also indicated that these techniques could yield favourable outcomes in acquiring the optimal feature subset. However, in a complex optimization, PSO could suffer from premature convergence. There is a scope for further research into the use of PSO for sentiment analysis in other domains, such as social media and customer reviews. Additionally, the combination of PSO with other optimization techniques, such as genetic algorithms or k-nearest neighbour algorithms could further improve the accuracy of sentiment analysis algorithms.

Abstract—The prediction of breast cancer recurrence is a crucial problem in cancer research that requires accurate and efficient prediction models. This study aims to compare the performance of different machine learning techniques in predicting types of breast cancer recurrence. In this study, the performance of logistic regression, decision tree, K-Nearest Neighbors, and artificial neural network algorithms was compared on a breast cancer recurrence dataset. The results show that the artificial neural network algorithm outperformed the other algorithms with 91% accuracy, followed by the decision tree (DT) algorithm and K-Nearest Neighbors (kNN) also performed well with accuracies of 90.10% and 88.20%, respectively, while the logistic regression algorithm had the lowest accuracy of 84.60%. The results of this study provide insight into the effectiveness of different machine learning techniques in predicting types of breast cancer recurrence and could guide the development of more accurate prediction models.

Keywords—Breast cancer; machine learning; recurrence prediction; classification multi-classes; logistic regression; decision tree; K-Nearest Neighbors; artificial neural network

I. INTRODUCTION

Breast cancer is one of the most common types of cancer in women worldwide, with approximately 2.3 million new cases diagnosed in 2020 alone [1]. Although treatment options for breast cancer have advanced significantly in recent years, thanks to improved surgical techniques, chemotherapy and radiation therapy, the risk of recurrence remains a significant concern for patients and their clinicians.

Recurrence of breast cancer can occur in a variety of forms, including local, regional and distant recurrence. Local recurrence is when the cancer recurs in the same area where it was initially treated, while regional recurrence is when the cancer recurs in the lymph nodes of the axillary or supraclavicular region [2]. Distant metastases are when the cancer spreads to distant organs such as the lungs, liver, or bone. Each type of recurrence has its own clinical characteristics and treatment considerations, which makes customization of treatment particularly important for each patient.

In recent years, there has been increasing interest in developing predictive models that can accurately identify the likelihood of different types of breast cancer recurrence, allowing for more personalized treatment plans and better patient outcomes [3]–[9]. Predictive models are based on a variety of factors, such as the characteristics of the initial cancer, the patient's age, the stage of the cancer and the type of treatment received. Tools such as the Online Recurrence Score (Oncotype DX) [10], Metastatic DNA Prognosis Score (MammaPrint) [11], and Molecular Profiling Signature Score (EndoPredict) are available to help clinicians assess the risk of recurrence in patients with breast cancer [12]. These predictive models can help clinicians decide whether a patient requires adjuvant chemotherapy, radiation therapy, or hormone therapy, or whether she should simply be monitored closely. This can help avoid unnecessary treatment and reduce potentially harmful side effects of treatment.

In this paper, a multi-classification model is proposed, with the aim of producing predictions about the types of recurrence in breast cancer patients. This model is based on several important parameters, such as initial TNM status of the tumor, estrogen and progesterone receptors (ER, PR), HER2 expression levels, and previous treatments received by the patients. Additionally, new variables such as physical activity, diet type, and post-treatment psychology are incorporated to improve risk assessment and patient management. Indeed, previous research has demonstrated the importance of considering psychological and behavioral aspects of patients to better predict the risk of recurrence.

In the second section of this article, the predictive variables included in the model will be presented. A description of various data coding techniques such as data collection, preprocessing, cleaning, and transformation of the pathological, biological, and clinical dataset will be provided in the third section. The fourth section will explain the proposed multi-classification technique, including Logistic Regression (LR), K-Nearest Neighbors (kNN), Decision Tree (DT), and Neural Network (NN). Finally, the performance of the proposed model in predicting recurrence types for breast cancer patients will be evaluated.

II. MATERIALS AND METHODS

A. Data Collection

Clinical and pathological data were collected from electronic medical records of patients treated for breast cancer between 2015 and 2022 at a single center in the Meknes, Morocco. The dataset included 1189 patients who underwent surgery, radiation therapy, and/or chemotherapy - the follow-up of at least 60 months.

The dataset included 19 features, including tumor size, age, hormone receptor status, histological grade, lymph node status, human epidermal growth factor receptor 2 (HER2) status, progesterone receptor (PR) status, estrogen receptor (ER) status, chemotherapy, Targeted therapies, radiation therapy, hormone therapy, healthy eating, physical activity, type of psychosocial stress and type of recurrence. The important factors of our study are outlined in Table I.

B. Data Preprocessing

In this study, the data set was preprocessed to handle missing values, categorical variables, and feature selection. The Python programming language and the Pandas library were used to preprocess the data, as well as to analyze the medical records of cancer patients to identify factors associated with cancer recurrence. Several preprocessing techniques were used to prepare the data for machine learning, as shown in Fig. 1. First, missing or invalid values were verified and replaced where appropriate. Second, the categorical variables were recoded such as 'POSTMENOPAUSAL' and 'CHEMOTHERAPY (ANTHRACYCLINES / TAXANE)', 'TYPE OF PSYCHOSOCIAL STRESS' into numeric variables for easy analysis. The 'LYMPH_NODES' variable was also transformed into an ordinal variable, assigning values from 0 to 3 to represent the different levels of lymph node involvement. Additionally, variables such as AGE_DIAGNOSIS, TUMOR_SIZE, and KI67 were scaled into a common range to avoid bias in the analysis. Then, one-hot encoding was employed to convert categorical variables such as 'HER2,' 'ER,' 'PR,' 'SURGERY_TYPE,' 'TARGETED THERAPIES,' 'RADIOTHERAPY,' 'HEALTHY EATING,' and 'PHYSICAL ACTIVITY' into binary variables to enhance model accuracy. Fourth, a new target ordinal variable representing types of breast cancer recurrence (No, local, regional, or distant) was created, as shown in Table I.

Finally, feature screening was performed to identify the most important variables in predicting types of breast cancer recurrence. This reduced the dimensionality of the data improved the efficiency of the analysis.

TABLE I. CODE AND VALUE OF THE VARIABLES USED IN THIS STUDY

Variable_Name	Code or Value
AGE_DIAGNOSIS	≤ 25; 25 to 35; 36-45; 46 ≥ years old
POSTMENOPAUSAL	0 < 49 ; 1 ≥ 50)
TUMOR_SIZE	≤2 ; 3-4 ; ≥5
LYMPH_NODES	0 = "No" ; 1 = "1-3" ; 2 = "4-9" ; 3 = "0>9"
TUMOUR_GRADE	1 ; 2 or 3
HER2	0 ; 1
ER	0 ; 1

PR	0 ; 1
KI67	≤ 20; 21 to 40; 41-60; 61 ≥
SURGERY_TYPE	0= "lumpectomy"; 1= "mastectomy"
CHIMIOThERAPY	ANTHRACYCLINES 0="No" ; 1="EC 50"; 2="FEC 100";3= "AC60"
	TAXANE 0="No" ; 1=" PACLITAXEL "; 2=" DOCETAXEL "
TARGETED THERAPIES	0= "No"; 1= " TRASTUZUMAB "
RADIOTHERAPY	0= "No"; 1= " RADIOTHERAPY "
HORMONOTHERAPY	0= "No"; 1= " Tamoxifen "; 2="Aromatase inhibitors"; 3="Tamoxifene + Aromatase Inhibitors" ;4="Aromatase Inhibitors + Tamoxifene".
HEALTHY EATING	0= "No"; 1= " Yes "
PHYSICAL ACTIVITY	0= "No"; 1= " Yes "
TYPE OF PSYCHOSOCIAL STRESS	0="No"; 1= "Cognitive stress"; 2="Familial stress"; 3="Work-related stress"; 4="Environmental stress"; 5="Event-related stress".
TYPE OF RECURRENCE	No="0000" ; Local="0100"; Regional="0010" or Distant="0001")

Fig. 1. The typical data mining procedure used in this study.

C. Machine Learning Models

The forms of recurrence in breast cancer patients were categorized into classes in this study using classification models based on demographic, biopsychological, and clinical traits. Fig. 2 depicts the complete experimentation procedure.

Fig. 2. Model machine learning use.

In this paper, the performance of four machine learning techniques was compared: logistic regression, decision tree, K-Nearest Neighbors, and artificial neural network. The Python programming language and the Scikit-learn library were used to implement the models. The models were trained and tested using a 10-fold cross-validation method [13].

1) *Artificial neural networks*: Artificial neural networks are a machine learning technique based on the architecture of interconnected neurons inspired by the functioning of the human brain [14]. They are very useful in multi-class classification, where several categories are to be predicted. In the case of recurrence in breast cancer patients, neural networks can be used to predict whether a patient is likely to experience a recurrence of the disease.

Once the data is prepared, the neural network model is constructed. It can consist of several layers of neurons, each with a specific number of neurons. The input layer is the one that receives the input data, while the output layer is the one that gives the classification results [15]. The intermediate layers are called hidden layers and are responsible for learning the relationships between the input features and the output classes.

The learning process is done using a gradient back-propagation algorithm, which calculates the gradients of the loss function with respect to the model weights and adjusts the weights to minimize the loss function [16]. The loss function can be a cross-entropy, which measures the distance between the model predictions and the actual classes.

2) *Logistic regression*: Logistic regression is a statistical technique commonly used in modeling binary data, where the dependent variable can take only two possible values[17]. However, it is possible to apply logistic regression to multi-class classification problems, such as the classification of recurrence types in breast cancer patients.

To use logistic regression in this context, there are several approaches. One is to apply multinomial logistic regression, which models the probability of each class of recurrence. In this case, the model will produce several equations for each class that describe the relationships between the input variables and the probabilities of each class.

Another approach was used, binary logistic regression for each recidivism class, treating each class as a separate binary variable. In this case, several logistic regression models must be fitted for each recurrence class, and the final class for each patient is determined based on the probabilities predicted by each model.

3) *K-Nearest Neighbors (K-NN)*: K-Nearest Neighbors (K-NN) is a classification algorithm used to predict the category of a new sample based on the training data samples closest to that sample[18]. In the case of multi-class classification of recurrence types in breast cancer patients, the K-NN algorithm can be used to predict whether a given patient is likely to experience local recurrence, distant recurrence, simultaneous local and distant recurrence, or no recurrence. The above steps can be applied after preprocessing the data as follows:

Distance definition: the distance can be calculated using Euclidean distance or other distance measures appropriate for the types of variables used.

Determining the K number: the K value can be chosen by cross-validation using different values for K and choosing the one that gives the best performance.

Category prediction: once the closest data samples have been identified, the majority of their categories can be used to predict the most likely recurrence category for the patient.

4) *Decision tree*: A decision tree can be an effective tool for multiclass classification of recurrence types in breast cancer patients[19]. The decision tree is a machine learning model that progressively divides a dataset into smaller subsets based on specific criteria, until each subset can no longer be divided. Each division of the dataset is based on a specific variable, which can be a continuous or categorical variable. At the end of the process, the decision tree provides a set of decision rules that can be used to predict the target classes.

D. Performance Indicators

In this study, the performance of each model was evaluated using the confusion matrix to calculate the following metrics: precision, sensitivity, specificity, and AUC-ROC.

1) *Confusion matrix*: A multiclass confusion matrix is used to evaluate the performance of a classification model that predicts classes belonging to more than two categories. In this case, assuming that the four classes are: "No recurrence," "Local recurrence," "Loco-regional recurrence," and "Remote recurrence," the confusion matrix will look like this, as shown in Table II.

TABLE II. CONFUSION MATRIX FOR MULTI-CLASS CLASSIFICATION OF RECURRENCE TYPE

Actual class / Predicted class	No recurrence	Local recurrence	Locoregional recurrence	Distant recurrence
No recurrence	True Positives	False Negatives	False Negatives	False Negatives
Local recurrence	False Positives	True Positives	False Negatives	False Negatives
Locoregional recurrence	False Positives	False Positives	True Positives	False Negatives
Distant recurrence	False Positives	False Positives	False Positives	True Positives

In this confusion matrix, TP stands for True Positives, TN stands for True Negatives, FP stands for False Positives and FN stands for False Negatives [20].

- True Positives (TP): The model correctly predicted the recurrence class for breast cancer patients who actually had a recurrence of that type.
- True Negatives (TN): The model correctly predicted the "No Recurrence" class for breast cancer patients who did not experience a recurrence.
- False Positives (FP): The model incorrectly predicted that a patient had a recurrence, when in fact there was no recurrence.
- False Negatives (FN): The model incorrectly predicted that there was no recurrence for a patient who actually had a recurrence.

The Sum of each row and column gives us useful statistics to evaluate the performance of the model, including:

Accuracy (1) is the proportion of the total number of correct predictions made by the model divided by the total number of predictions made by the model. It is typically represented as a percentage and is one of the most commonly used performance metrics for classification models [21]. The formula for accuracy is:

$$Overall\ Accuracy = \frac{\sum_{i=1}^N c_{i,i}}{\sum_{i=1}^N \sum_{j=1}^N c_{i,j}} \quad (1)$$

Sensitivity (or recall) (2) for each class, which measures the proportion of true positives among all true positive cases of this class.

$$Recall_{class} = \frac{TP_{class}}{TP_{class} + FN_{class}} \quad (2)$$

Specificity (3) for each class, which measures the proportion of true negatives among all the true negative cases in that class is given as,

$$Specificity_{class} = \frac{TN_{class}}{FP_{class} + TN_{class}} \quad (3)$$

Precision(4) for each class, which measures the proportion of true positives among all predicted positive cases in that class is given as,

$$Precision_{class} = \frac{TP_{class}}{TP_{class} + FP_{class}} \quad (4)$$

F1-Score (5) for each class, which is a measure of the combined accuracy and sensitivity is measured as,

$$F1 - Score = \frac{2 * TP_{class}}{2 * TP_{class} + FN_{class} + FP_{class}} \quad (5)$$

2) *The Roc and AUC curve:* Receiver Operating Characteristic (ROC) and Area Under the Curve (AUC) curves are commonly used evaluation tools in binary classification to assess the performance of classification models [22].

In the case of four-class classification of recurrence types in breast cancer patients, these curves can be used to evaluate the ability of a classification model to distinguish between different types of recurrence.

The ROC curve plots the true-positive rate (sensitivity) against the false-positive rate (1 - specificity) for different classification cut-off values. The AUC represents the area under the ROC curve and measures the overall ability of the model to discriminate between classes. The closer the AUC is to 1, the better the performance of the classification model.

In the case of four-class classification, several ROC curves can be plotted for each class. The overall performance of the model can be evaluated by calculating a weighted average of the AUC for each class.

Using these curves, physicians and researchers can evaluate the performance of classification models and select the best model for predicting recurrence types in breast cancer patients.

III. RESULTS

A. Analysis of Result

The study evaluated the performance of four classification algorithms - Neural Network, Decision Tree, kNN, and Logistic Regression - in predicting the type of recurrence in breast cancer. The evaluation metrics used to assess the performance of these algorithms were AUC, CA (Classification Accuracy), F1 score, Precision, Recall, and Specificity. The variables used to predict the type of recurrence were age at diagnosis of breast cancer, primary tumor size (TS), postmenopausal status, number of involved axillary lymph nodes, histological grade of the tumor, type of surgery, cellular marker of proliferation (Ki67), PR status, ER status, HER2 status, healthy eating, physical activity, type of psychosocial stress. Including these variables improved the performance of the classification algorithms. The study used 10-fold cross-validation to ensure that the results were representative and not overfit to the data, see Table III.

Table III provides the results of four different classification algorithms (A, B, C and D) for four classes (0000, 0100, 0010 and 0001). The columns represent the predictions of the algorithms and the rows represent the actual classes. The values in the cells indicate the number of times each class was predicted for each actual class.

For Algorithm A (neural network), it correctly predicted class 0000 for 904 times, class 0100 for 105 times, class 0010 for 24 times and class 0001 for 49 times. There are 107 incorrect predictions in total for algorithm A.

For Algorithm B (decision tree), it correctly predicted class 0000 for 904 times, class 0100 for 99 times, class 0010 for 27 times and class 0001 for 41 times. There are 118 incorrect predictions in total for algorithm B.

For Algorithm C (kNN), it correctly predicted class 0000 for 900 times, class 0100 for 110 times, class 0010 for 17 times and class 0001 for 22 times. There are 140 incorrect predictions in total for algorithm C.

For Algorithm D (logistic regression), it correctly predicted class 0000 for 903 times, class 0100 for 63 times, class 0010 for 8 times and class 0001 for 32 times. There are 183 incorrect predictions in total for algorithm D.

Looking at the overall results, it is evident that Algorithm A gave the best result with the least number of incorrect predictions, while Algorithm D gave the worst result with the highest number of incorrect predictions. The other algorithms (B and C) gave intermediate results. However, further analysis of the data, including measures of precision, recall, and F1-score for each class, would be required to provide a more complete and accurate assessment of the performance of the algorithms.

TABLE III. MULTI-CLASS CONFUSION MATRIX OF THE APPLICABLE CLASSIFICATION MODELS

A : Neural Network - Classifier						
		Predicted				
		0000	0100	0010	0001	Σ

B. Performance Evaluation

The four algorithms' performances were compared using classification metrics; see Table IV for details.

TABLE IV. PERFORMANCE METRICS OF MACHINE LEARNING MODELS

Model	AUC	CA	F1	Precision	Recall	Specificity
Neural Network	0.976	0.910	0.907	0.905	0.910	0.887
Decision Tree	0.899	0.901	0.898	0.897	0.901	0.863
kNN	0.934	0.882	0.868	0.873	0.882	0.778
Logistic Regression	0.941	0.846	0.826	0.822	0.846	0.652

Based on the table, we can see that the neural network model has the highest AUC (0.976) and the highest classification accuracy (0.910). It also has high precision (0.905), high recall (0.910), and high specificity (0.887), indicating that it performs well in both detecting positive instances and avoiding false positives and false negatives.

The decision tree model has a lower AUC (0.899) and classification accuracy (0.901) than the neural network, but still performs relatively well. It has a similar F1 score (0.898) and precision (0.897) to the neural network, but slightly lower recall (0.901) and specificity (0.863).

The kNN model has a lower AUC (0.934) and classification accuracy (0.882) than both the neural network and decision tree models. It has a lower F1 score (0.868) and precision (0.873) than the other two models, but a similar recall (0.882) and lower specificity (0.778).

The logistic regression model has the lowest AUC (0.941) and classification accuracy (0.846) of all the models. It also has the lowest F1 score (0.826), precision (0.822), recall (0.846), and specificity (0.652). This suggests that the logistic regression model may not be as effective at distinguishing between the positive and negative classes and may have a higher rate of false positives and false negatives than the other models.

C. ROC and AUC Curve

Knowing the associated Receiver Operating Characteristic (ROC) curve, True Positive Rate (TPR), and False Positive Rate (FPR) is important when evaluating the performance of classification models. In this study, it can be concluded that all machine learning classifiers predict with >89% accuracy on the type of recurrence in Boobs cancer patients, this shows that these classification algorithms work well to classify different types of recurrence. Using the following iteration type codes (0000 - 0100 - 0010 - 0001), the neural network obtained the maximum AUC (area under the curve) of the ROC (see Figure 3).

In the curve cube graph (Fig. 3), there are four ROC curves, each representing the performance of a different classifier for a different class. The classifiers include a neural network, a decision tree, logistic regression, and K-Nearest Neighbors (KNN).

For class code "0000," which represents non-recurrence, the ROC curve shows that the neural network and logistic regression have the highest sensitivity (TP rate) of 0.8, while the decision tree and KNN have a sensitivity of 0.6. The false positive rate (FP rate) is relatively low across all classifiers, indicating that they have good specificity.

For class code "0100," which represents local recurrence, the ROC curve shows that the neural network has the highest sensitivity of 0.6, followed by the decision tree and logistic regression with a sensitivity of 0.4, and KNN with a sensitivity of 0.2. The false positive rate is relatively high for all classifiers, indicating that they have poor specificity.

For class code "0010," which represents loco-regional recurrence; the ROC curve shows that the neural network and logistic regression have the highest sensitivity of 0.8, followed by the decision tree with a sensitivity of 0.6, and KNN with a sensitivity of 0.4. The false positive rate is relatively low for all classifiers, indicating that they have good specificity.

For class code "0001," which represents distant recurrence, the ROC curve shows that the neural network has the highest sensitivity of 1, followed by logistic regression with a sensitivity of 0.6, the decision tree with a sensitivity of 0.4, and KNN with a sensitivity of 0.2. The false positive rate is relatively high for all classifiers, indicating that they have poor specificity.

Overall, the ROC curves in the curve cube graph demonstrate that the neural network and logistic regression classifiers perform better than the decision tree and KNN classifiers, particularly for classes that are more difficult to classify, such as local recurrence and distant recurrence. The curve cube graph is a useful visualization tool for comparing the performance of multiple classifiers for different classes in a multi-class classification problem.

IV. DISCUSSION

This paper presents four different types of classifiers (neural network, decision tree, kNN, and logistic regression) for predicting recurrence type in breast cancer patients. The classifiers were evaluated for their ability to correctly predict recurrence type (0000, 0100, 0010, or 0001) for a data set of 1189 patients. The results show that the neural network classifier performed the best, correctly predicting recurrence type with an overall accuracy of 91%. The decision tree classifier was the second best performer with an accuracy of 90.1%, followed by kNN with 88.2% and logistic regression with 84.6%.

Indeed, the article also points out that incorporating biopsychological variables into recidivism prediction studies is important for improving understanding of recidivism risk in individual patients. This may lead to more personalized treatment decisions and better monitoring after initial treatment. In addition, regular psychological and social assessments can help identify patients who need additional support to improve their quality of life and overall well-being.

These findings underscore the importance of considering not only medical factors, but also psychological and social factors in the management of breast cancer. By incorporating these factors into clinical decision making, physicians can improve the quality of care for breast cancer patients.

Overall, the results of this study indicate that these classifiers can be used to accurately predict the type of recurrence in breast cancer patients. However, further studies are needed to confirm the effectiveness of these models and determine their utility in clinical practice. Nevertheless, this study is an important contribution to the field of medical research, as it shows the potential of machine learning techniques to improve outcomes for cancer patients.

A. Limitations

Validation of our results using other datasets would be necessary to generalize our findings to other populations. Additionally, our study focused only on predicting the type of breast cancer recurrence and did not consider other factors such as disease-free survival or overall survival. Further studies may investigate the potential use of machine learning techniques to predict these outcomes.

V. CONCLUSION

The study used a dataset of 1189 patients with breast cancer and applied various machine learning techniques, including logistic regression, decision tree, K-Nearest Neighbors and artificial neural network, to predict the type of recurrence. The results showed that the artificial neural network outperformed the other models in terms of accuracy, precision, recall, and F1-score.

The high performance of the artificial neural network can be attributed to its ability to capture complex non-linear relationships between the features and the target variable. The logistic regression model, which is a linear model, achieved a lower performance than the other models, indicating that non-linear relationships exist between the features and the target variable.

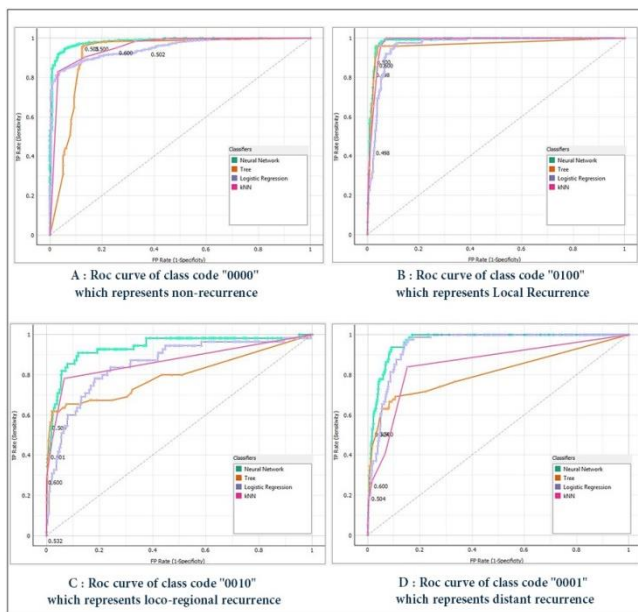

Fig. 3. AUC - ROC curve of classifiers used in the prediction of types of recurrence in patients with breast cancer.

The findings of this study have significant implications for breast cancer patients and clinicians. Accurate prediction of the type of recurrence can help to guide treatment decisions and improve patient outcomes. Machine learning techniques can provide a valuable tool in predicting breast cancer recurrence and may lead to more personalized treatment plans.

However, it is essential to note that machine learning techniques are not without limitations. One potential limitation is the need for large datasets to train the models effectively. Additionally, machine learning models may not always be transparent, and it may be challenging to understand how the models arrive at their predictions. Further investigation is needed to address these limitations and improve the clinical application of machine learning techniques in predicting breast cancer recurrence.

Abstract—The detection of diabetic retinopathy eye disease is a time-consuming and labor-intensive process, that necessitates an ophthalmologist to investigate, assess digital color fundus photographic images of the retina, and discover DR by the existence of lesions linked with the vascular anomalies triggered by the disease. The integration of a single type of sequential image has fewer variations among them, which does not provide more feasibility and sufficient mapping scenarios. This research proposes an automated decision-making ResNet feed-forward neural network methodology approach. The mapping techniques integrated to analyze and map missing connections of retinal arterioles, microaneurysms, venules and dot points of the fovea, cottonwool spots, the macula, the outer line of optic disc computations, and hard exudates and hemorrhages among color and back white images. Missing computations are included in the sequence of vectors, which helps identify DR stages. A total of 5672 sequential and 7231 non-sequential color fundus and black-and-white retinal images were included in the test cases. The 80 and 20 percentage rations of best and poor-quality images were integrated in testing and training and implicated the 10-fold cross-validation technique. The accuracy, sensitivity, and specificity for testing and analysing good-quality images were 98.9%, 98.7%, and 98.3%, and poor-quality images were 94.9%, 93.6%, and 93.2%, respectively.

Keywords—Retinal lesion (RL); Fundus Images (FunImg); Microaneurysms (MAs); Principal Component Analysis (PCA); Standard Scaler (StdSca); Feed-Forward Neural Network (FFNN); cross pooling (CxPool)

I. INTRODUCTION

Diabetic Retinopathy (DR) eye disease (ED) is correlated with chronic type diabetes, which is the primary trigger of sightlessness in children, workforce employees, and elderly people across the globe, and it is impacting more than 96 million people [1]. DR is a type of diabetes that causes damage to the retinal blood vessels (BV). Primarily, it is symptomless and changes vision-based issues. As it becomes more severe, it disturbs both eyes and ultimately causes partial to complete vision loss. It principally arises when blood sugar levels are uncontrollable. The premature detection of DR can prevent the possibility of permanent blindness. Consequently, it needs an effective screening scheme [2]. Detection of the initial stages of DR-ED is one of the challenging tasks in the DR diagnosis process, it helps in the advancement to vision loss, which can

be decelerated, but it can be complicated as DR-ED regularly indicates rare symptoms until it is extremely late to deliver efficient medication [4] [5]. Consequently, uncovering DR at an early stage is crucial in preventing the complications of this illness, as shown in Fig. 1 [2]. CNN in DL manages to deliver helpful results while it comes up to the job of classification of medical images [5].

Fig. 1. Hard exudates, hemorrhages, abnormal growth of blood vessels, aneurysm and cotton wool spots of DR affected retina.

Recognition of the initial clinical signs of DR initiation is a crucial constraint for interference-free and efficient medication. Ophthalmologists qualified to detect DR focus on analyzing minor fluctuations in patient microaneurysms (MAs) of the eyes, retinal bleeds, macular edema, and fluctuations in retinal blood vessels. Segmentation of MAs is another crucial constraint for primary identification of DR, which has attracted the major attention of the research community across the early years [27]. According to the International Clinical DR Disease Severity Scale, DR seriousness is marked into five degrees, such as non-DR, mild-NPDR, moderate-NPDR, PDR, or severe-NPDR [7] [8]. Mild-NPDR is specified as the occurrence of microaneurysms. Moderate NPDR is specified as being further than exactly micro-aneurysms, although less severe NPDR produces CWS, retinal hemorrhages, and hard exudates. DME was analyzed if difficult exudates were identified in the interior of 500 μ m of the macular centre corresponding to the specification of the initial medication for DR research [9]. Ascribable-DR is specified as DME, moderate NPDR, or both. Based on the recommendations for image procurement and clarification of DR assessment in China [10], the image quality was rated conferring to requirements specified in terms of three characteristic factors such as field definition (FD), clarity, and artifacts (AF). The overall result was equivalent to a grade for transparency plus a

grade for FD and minus the score for AF; the overall count was less than 12, which counted as ungradable [8]. Recognizing the first clinical signs of DR is a significant barrier to effective intervention and treatment. Ophthalmologists who are trained to identify DR focus on analyzing minute changes in patient microaneurysms (MAs), retinal bleeding, macular edema, and changes in retinal blood vessels. Another important barrier to the initial identification of DR is the segmentation of MAs, which has received significant attention from the academic community in recent years.

The article is planned in a section wise manner: Section I included an introduction and research objectives; Section II comprised the associated works along with the background of the research; and Section III included the proposed methodology of the Automated Decision Making ResNet Feed-Forward Neural Network (RNFFNN) Methodology for Recognition of DR Stages and its executional scenarios. Section IV described the experimental setup and analysis through Image Normalization Principal Component Analysis (PCA) and Multi-level ConvNets based Pooling and Feature Integrations, along with the results and discussion; Section V contains the results and discussions. Finally, Section VI addresses the conclusion and future direction.

II. RELATED WORK

DR is one of the significant interests that have captured the healthy world. Accepting the interest from numerous scientists to discover the ideal solutions for initial recognition of DR disease, subsequently prominent to avoidance of early oscillations in eyesight. Several investigations were performed and continued in this field with the intention of improving the lives of patients. This section articulates an analysis of DR-related research [2].

The author, Anumol Sajjan et al., proposed the detection of DR stages using deep learning (DL). It proposed an automatic classification system, in which it analyzes fundus images (FunImg) with fluctuating illumination and fields of assessment and produces a severity grade for DR using ML replicas such as VGG-16, Convolutional Neural Network (CNN), and VGG-19 through five groups of classified images ranging from 0 to 4, where 0 is no DR and 4 is proliferative DR. It accomplishes 82%, 80%, and 82% accuracy, sensitivity, and specificity, respectively [1]. Author Mushtaq et al. proposed detection of DR using DL-based densely connected CNN (DenseNet-169) for identification of early recognition of DR, which categories the FunImgs based on their levels of severity: Proliferative-DR, Severe, Moderate, Mild, and No-DR with integration of DR-Recognition-2015 and Aptos-2019-Blindness-Recognition from Kaggle in the inclusion of data-gathering, pre-processing, augmentation, and modeling levels and achieved 90% accuracy (ACU) [2]. The fifth most common cause of blindness in the world is now diabetes. One of the main causes of vision loss and blindness among diabetes individuals worldwide is diabetic retinopathy. According to the WHO, diabetic retinopathy is a serious eye condition that needs to be addressed right once by government agencies and medical specialists. [3]. Image artifact, clarity, and field definition are the three main criteria used to evaluate the quality of fundus images. Unfortunately, the majority of

quality assessment techniques now in use only consider overall image quality without providing comprehensible quality feedback for real-time correction. Furthermore, these models frequently lack generalizability under various imaging settings and are susceptible to the particular imaging devices [11].

The author, J. De Calleja et al. [31], integrated a 2-stage scheme for DR recognition. FE was processed through local binary patterns, and the classification stage was processed through ML-based Support Vector machines (SVM) and Random Forest (RF) and attained a 97.46% ACU rate with a test case of 71 images. M. Gandhi et al. [32] proposed automatic DR recognition through SVM by sensing exudates from FunImgs with manual FE with DL for J. Orlando et al. [24] integrated CNN with manual and enhanced features for FE for sensing RED-lesion in the retina eye. U. Acharya et al. [33] integrated 331 FunImgs through MAs, BV, haemorrhages, exudates-based features using SVM and attained 85% of ACU. K. Anant et al. [26] integrated texture and wavelet features for DR recognition in basic level analysis with involvement of DM and IP on the DIARETDB1 database and accomplished 97.95% of ACU. In a different study, 331 fundus images were analyzed and morphological image processing and support vector machine (SVM) techniques were utilized for the automatic detection of eye health [34]. S. Preetha et al. [14] described DM and ML methods in their analysis for the prediction of various diabetic-related diseases such as DR, skin cancer, and heart disease. S. Sadda et al. [13] used a quantitative based method to recognize new parameters for sensing proliferative DR based on hypotheses of lesions location, surface area, number, and distance from the ONH center, which progressed the prediction procedure of DR with the involvement of imaging data and quantitative lesion parameters. The authors, J.Amin et al. [27], deliver an assessment of numerous practices for DR by sensing hemorrhages, MAs, exudates, and BV and analyzing numerous outcomes obtained from these practices experimentally. Y. Kumaran et al. [18] emphasize the dissimilar types of pre-processing and segmentation methods typically used for the detection of DR in the human eye, which contain several classification models. I. Sadek et al. [25] proposed automatic DR detection through DL with the integration of four CNNs to categorize DR into three classes: normal, exudates, and drusen and achieved 91%–92% ACU. G. Zago et al. [6] proposed a lesion localization model using a deep NN through CNN with integration of regions in the place of segmentation localization processes and 2-CNNs implicated for training through the Standard DR Database and DIARETDB1 and achieved 95% sensitivity. P. Kaur et al. [17] proposed the NN method for the categorization of several RIs using the MATLAB environment. A comparison study was done among the proposed methods using SVM. SVM helped generate an accurate result.

M. Voets et al. [12] proposed a study that integrated the Kaggle dataset EyePACS for finding DR from retinal FunImgs test cases and experimented on existing work on several data sets that provided 95% of ACU [2]. It aimed to improve the performance of detecting certain retinal lesions (RL) with their grading levels through a cost-effective ResNet implicated RL-aware sub-network (RLASN) for reducing vanishing gradient complexity, which was improved with more sensitive FE for

small lesions compared to VGG and Inception's existing net designs [15]. The RLASN included a feature pyramid structure that was intended to describe features of multi-scale and dig out lesion types and position relationships [16] [23]. Identifying several types of RIs can help with making decisions in the clinical process, like fenofibrate for patients with hard exudate [19] and antiplatelet drugs used thoroughly in patients with bleeding retina [20]. Progression is another major problem in DR screening, as advancement of RIs is symptomatic of improving sight-threatening DR [21–23]. It stated that, as a substitute for direct end-to-end training from FunImgs to DR grades, a cost-effective RLASN was established to improve the capability of acquiring features of lesion [26]. For the purpose of ultimately detecting nonproliferative diabetic retinopathy, the author outlined different ways for detecting microaneurysms, hemorrhages, and exudates. Techniques for detecting blood vessels are also covered for proliferative diabetic retinopathy [28]. Author Veena Mayya et al. [30] proposed an analytical study through automated MAs recognition and segmentation for DR early diagnosis, which was achieved using color fundus photography, optical coherence tomography angiography, or fluorescein angiography images. This study was categorized into classical IP, conventional ML, and DL based practices and achieved significant analytical progress.

This section articulates the DR study based on the accessibility of FunImgs data. A fundus camera is utilized to acquire two-dimensional digital RIs. The highly accessible early-stage DR recognition works make use of databases, including images obtained by dilating the pupil. While many RI datasets such as Kaggle DR [38] [39], MESSIDOR [35] [36], STARE [30], DeepDR [41], HRF [37], ODIR [40], UoA-DR [42], DRIVE [31], and so on are openly accessible for the persistence of DR research studies, MAs are generally the initial visible sign of DR; their recognition can decrease beyond difficulties and loss of vision. The present manual assessment is hard to scale and a time-consuming process for a large patient population. Efficient automated detection and segmentation (ADS) of MA will be able to decrease the liability of ophthalmologists to a certain level by computerizing the assessment activity and assisting in the early stages of DR diagnosis. The research society for ADS in MA has developed numerous methodologies for early DR diagnosis [29]. In order to evaluate deep learning models and further investigate the clinical applications, particularly for lesion recognition, the author T. Li et al. [43] developed a new dataset called DDR. Using the ideas of mathematical morphology, the authors B. Lay et al. [44] devised a computerized method for the detection of microaneurysms (MA) in fluorescein angiograms.

The authors, Wejdan L. et al. [45], proposed an analysis of the detection of DR using DL practices. It has reviewed various detection and classification techniques using DL techniques, which analyze DR stages based on color fundus retina images. Author S. Mishra et al. [46] proposed DR recognition using DL. It integrated artificial intelligence (AI) techniques and used DenseNet to train the model on a massive dataset consisting of 3662 images to instinctively distinguish the DR stage, which has been categorized as having superior FunImgs resolution. It integrated APTOS data derived from Kaggle with

DR's five stages, categorized into 1 to 4 numbers. By using patients' fundus eye images as input, DenseNet's FE process produced results through activation function, achieved 0.9611 ACU, and described the distinction between the VGG16 and DenseNet121 designs. The authors, Ayala et al. [47], proposed DR-improved detection using DL. It integrated CNN to perform a fundus oculi image to identify the structure of the eyeball and establish the occurrence of DR. The factors improved using the TL approach for mapping an image with the subsequent labeling structure. Training, testing are accomplished with a medical fundus oculi image dataset, and a pathology seriousness scale appears in the eyeball as labels and attains 97.78% of ACU.

Author M. Mohsin Butt et al. [48] proposed a multi-channel CNN-based approach for the detection of DR from eye fundus images. It integrated 35,126 images from EyePACS and achieved 97.08% ACU. The authors, Fatima, Muhammad Imran, et al. [49], proposed a unified method for entropy improvement-based DR recognition using a hybrid NN. It devised manipulating the discrete wavelet transforms to enhance the visibility of medical imaging by making the delicate features more prominent, and it classified images for further stages. It integrated three datasets, such as those from the Asia Pacific Tele Ophthalmology Society (APTOS), Ultra-Wide Field (UWF), and MESSIDOR-2. The authors, Yuhao Niu, Lin Gu, et al. [50], intended explicable DR recognition through RIs. It has proven a direct relationship between the lesions and isolated neuron activation for pathological justification. Initially, it described new pathological signifiers using triggered neurons of the DR detector to determine both lesions appearance and spatial data, then visualized the DR indication encoded in the descriptor through Patho-GAN, which was used to produce medically possible RIs. The author, Abdel Maksoud E. et al. [51], proposed the E-DenseNet computer-aided diagnosis system for detecting various diabetic retinopathy grades based on a hybrid DL technique. E-DenseNet integrated DenseNet and EyeNet versions based on TL. It modified conventional EyeNet by incorporating blocks of dense and improving the resultant hyperparameters of blended E-DensNet versions. The author, Sikder, N. et al. [52], proposed classification of DR severity with integration of collaborative learning algorithmic sequences through examining RIs. It included various additional IP practices and steps of FE and feature selection and attained 94.20% classification accuracy with 0.32% boundary error and a 93.51% F-measure with 0.5% boundary error.

The authors, Nikos Tsiknakis, Dimitris, et al. [53], proposed DL integrated recognition and classification for DR based on FunImgs. It included a description of all DR recognition stages, such as DR grading, complexity levels. The author, M. T. Al-Antary et al. [54], integrated features to enhance the interpretation, and after that, a pyramid of multi-scale features was incorporated to define the retinal structure in a distinct region. It has trained a model in the traditional sense using cross-entropy loss to categorize severity levels of DR through healthy and non-healthy RTs, and it has integrated EyePACS and APTOS datasets. The author, Veena Mayya et al. [55], proposed a study on automated MAs recognition for early diagnosis of DR with a description of various DR

diagnosis techniques with their advantages and limitations. The author, Shah P. et al. [56], proposed validation of deep CNN-based algorithmic sequences for recognition of DR-AI against the screening clinician process. The authors, Chetoui M. et al. [57], proposed reasonable end-to-end DL for DR recognition across multiple datasets. It included 90,000 images from nine open datasets, which were employed to evaluate the effectiveness of the planned procedure. The planned DL process tunes a pre-trained deep CNN for DR recognition. The author, Sebt, R. et al. [58], proposed a DL-based methodology for the recognition of DR. It presented an automated classification scenario from a certain set of RI to identify the DR. An automatic retinal image analysis (ARIA) method has been created by authors Shi, C. et al. [59] that combines transfer net ResNet50 deep network with the automatic features generation approach to automatically assess image quality and differentiate between eye abnormalities and artefacts that are associated with poor quality on color fundus retinal images. According to individual risk variables, authors Alfian, G. et al. [60] suggest using a deep neural network (DNN) in conjunction with recursive feature elimination (RFE) to offer an early diagnosis of diabetic retinopathy (DR). Color fundus photography, fluorescein angiography, B-scan ultrasonography, and optical coherence tomography are a few of the crucial imaging modalities that are utilized to diagnose diabetic retinopathy [61].

A multi-classification prototype has been generated through CNN algorithmic sequences with numerous parameters on a dataset of DR with several structures. The authors R K. Jha et al. [64] stated an analysis to assess various categorization algorithmic sequences for estimation of HD where several conventional processes like SVM, KNN, DT-DNN, NB, and RF [65–66] were utilized to be valid selection of features over the Rapid Minor (RM) instrument to train-learn employing the Cleveland dataset from the UCI repository environment [67–72]. The Diabetic Retinopathy Debrecen Data Set from the UCI machine learning repository was taken into account by the author Nagaraja Gundluru et al. [73] who then designed a deep learning model with principal component analysis (PCA) for dimensionality reduction and Harris hawks optimization algorithm to extract the most crucial features. To distinguish the stages of DR, the author Asia, A.-O et al. [74] use fundus photography and a deep learning tool called a convolutional neural network (CNN). The Xiangya No. 2 Hospital Ophthalmology (XHO), Changsha, China, provided the study's pictures dataset, which is very vast, sparse, and labeled in an uneven manner. A hybrid method for the detection and classification of diabetic retinopathy in fundus pictures of the eye is proposed by author Butt, M.M. [75]. On pre-trained Convolutional Neural Network (CNN) models, transfer learning (TL) is applied to extract features that are then combined to produce a hybrid feature vector. The literature on AI approaches to DR, such as ML and DL in classification and segmentation, that has been published in the open literature within six years (2016-2021), is covered by author Lakshminarayanan, V [76]. A thorough list of the accessible DR datasets is also presented. The PICO (Patient, I-Intervention, C-Control, O-Outcome) and Preferred Reporting Items for Systematic Review and Meta-analysis (PRISMA) 2009 search methodologies were both used to create this list.

Many researchers have achieved significant progress in early DR diagnosis and detection, but various complexities and disparities still occur, emphasizing a significant possibility for the advancement of completely automated early DR diagnosis [29].

III. METHODOLOGY

The Deep Convolutional Neural Network (D-CNN) designs are extensively used in multi-labeling mapping and classification, which improves the analysis of the various DR grades such as normal, mild, moderate, severe, proliferative DR, and non-proliferative DR. DR degrees are articulated by seeming multiple DR lesions concurrently on the color retinal FunImgs. The various lesion types have numerous features that are difficult to segment and recognize by employing conventional methods. Consequently, the practical solution is to utilize an effective CNN model with a dual image ResNet mapping approach. Retinal diagnosis promotes early detection of DR stages, which helps with timely treatment.

To accelerate the screening process, this research uses the Automated Decision Making ResNet Feed-Forward Neural Network (RNFFNN) Methodology to detect early-to-late stages of DR. The majority of the uses for CNN's high-level features are in the detection and classification of retinal lesions. This research is mainly focused on developing the best RI interpretation, which further helps to enhance the implementation of DR detection simulations. To obtain the best possible interpretation, features obtained from various pre-trained ConvNet simulations were intermingled using the intended multi-modal blended module.

The final stage of descriptions is employed to train a D-CNN used for DR recognition and severity level prediction. Each ConvNet obtains unique features, blending them using 1D and cross pooling, which leads to improved interpretation compared to using features extracted from a single ConvNet. This research will adopt deep learning-based convolutional neural networks to achieve varying objectives. First, an exploratory research study is to be carried out to gain an in-depth understanding of AD. The second objective is the core objective of my research, in which we are going to propose a new framework and apply this framework to the public dataset. The proposed methodology module for training the image with labeled deep understanding could satisfy unlabeled data because deep learning could satisfy supervised and unsupervised segmentation. Finally, to check the feasibility of the proposed framework, an empirical evaluation will be carried out. The classification and detection of DR stages are integrated using the dual image approach of integration and aggregation of color fundus images and black-and-white images. Both photos are analyzed separately and combined with the missing points of each image sequence of the color fundus and black-and-white images. This research has integrated more than ten thousand images from different age groups, such as 10 to 25 years, 26 to 35 years, 36 to 45 years, and above 56 years. Initially, all color fundus images are collected from the various age-group patients; we consider these to be the primary input images. In data collection, all gathered color fundus images are classified into two groups: sequential and non-sequential images.

Fig. 2. Dual-image multi-layer mapping methodology for identification of DR early stages.

The sequential images are the images that have been picked from the same patient and age group. The various sequential images hold a slight variation in the color fundus and help the research generate the best outcomes and high predictions for the five stages of DR. The automated system feels complex when it tries to tune non-sequential images. The proposed methodology for training proficiency completely depends on balanced error-free data, so it's required to tune the data for training and testing purposes to process it further in the proposed deep learning-based CNN implicated dual-image

multi-layer mapping approach. The color fundus and black-and-white image-based data uniformly divide according to every DR stage, such as Non-DR, MiDR, MoDR, SeDR, and PrDR, which helps the model minimize any inequality during the training and progression of the proposed approach. All input color fundus and black-and-white images are equally sized, then processed in a systematic series way that is elected the combination images for analyzing the grading for further predictions as shown in Fig. 2. The classification task is mainly performed based on the deep learning Inception-Resnet model.

Furthermore, the classification task has initiated the cross-entropy loss function based on two variations: binary-class and multi-class classification.

IV. EXPERIMENTAL SETUP

The integration of dual-type sequential and non-sequential cluster images is required for auto-detection of DR stages. This research proposes an auto-fine-tuning system for the recognition of DR stages using a dual-image ResNet mapping approach. The sequential and non-sequential images were processed parallelly in the pre-processing and classification stages. The mapping techniques integrated to analyze and map missing connections of retinal arterioles, microaneurysms, venules and dot points of the fovea, cottonwool spots, the macula, the outer line of optic disc computations, and hard exudates and hemorrhages among color and back white images. Missing computations are included in the sequence of vectors, which helps identify DR stages. A total of 5672 sequential and 7231 non-sequential color fundus and black-and-white retinal images were included in the test cases. The 80 and 20 percentage ratios of best and poor-quality images were integrated in testing and training and implicated the 10-fold cross-validation technique.

The proposed methodology's training ability is variable on reasonable error-free data, which is essential to tune the data for training-testing purposes and manage it for the advanced process in the anticipated deep learning-based CNN (DL-CNN) implicated dual-image multi-layer mapping approach. The color fundus and black-and-white image-based data uniformly divide according to every DR stage, such as Non-DR, MiDR, MoDR, SeDR, and PrDR, which helps the model eliminate any inequality during the progression of training and testing the proposed approach. All input color fundus and black-and-white images are equally sized, then processed and tuned in a systematic series way, which are elected as the combination images for analyzing the grading for further predictions. The Fig .3 representing the dual-image Structural design of custom-built DL-CNN based network stem segment with extracted features

A. Image Normalization Principal Component Analysis (PCA)

The Eq. (1) has integrated for normalizing the dataset features, X signifies the features of dataset, μ signifies mean value for separately feature $x(i)$ of dataset, and σ signifies subsequent standard deviation. This normalization method was executed using the scikit-learn based Standard Scaler (StdSca) [62] and employed Principal Component Analysis (PCA) for dimensionality decrease if in case of MNIST and Fashion-MNIST which has selected for representing features of image data. Which is achieved using the scikit-learn based PCA.

$$z = \frac{X - \mu}{\sigma} \quad (1)$$

It has implicated a feed-forward neural network (FFNN) and CNN, mutually come up with two different classification functions such as ReLU and SoftMax. DL solutions to classification difficulties typically utilize the SoftMax function

to perform classification task, which indicates a discrete probability distribution (DPD) for K classes, expressed as

$$\sum_{k=1}^K P_k \quad (2)$$

If it takes x as the activation at the penultimate layer of a neural network, and θ as its weight parameters at the SoftMax layer, it has 'o' as the input to the SoftMax layer,

$$o = \sum_i^{n-1} \theta_i x_i \quad (3)$$

Subsequently, y^{\wedge} is expected class.

$$P_k = \frac{\exp(O_k)}{\sum_{k=0}^{n-1} \exp(O_k)} \quad (4)$$

$$y^{\wedge} = \max \arg \max_{i \in \{1, \dots, N\}} p_i \quad (5)$$

ReLU is an activation function presented by, which has strong biological and mathematical Underpinning [63].

$$y^{\wedge} = \operatorname{argmax}_i; i \in \{1, \dots, N\}; \max(0, o) \quad (6)$$

$$l(\theta) = - \sum y \cdot \log(\max(0, \theta x + b)) \quad (7)$$

Let the input x be replaced the penultimate activation output h ,

$$\frac{\partial l(\theta)}{\partial h} = \frac{\theta \cdot y}{\max(0, \theta h + b) \cdot \ln 10} \quad (8)$$

The backpropagation algorithm as shown in the eq. 8. is the same as the conventional SoftMax-based deep neural network.

$$\frac{\partial l(\theta)}{\partial \theta} = \sum_i \left[\frac{\partial l(\theta)}{\partial p_i} \left(\sum_k \frac{\partial p_i}{\partial O_k} \frac{\partial O_k}{\partial \theta} \right) \right] \quad (9)$$

B. Multi-level ConvNets based Pooling and Feature Integrations

This research has integrated two distinct pooling-based methods such as cross pooling (CxPool) and 1D pooling (1DPool) to merge multi-level feature extraction from VGG32 through fc1 and fc2 with integration of Xception net environment. The CxPool has implicated with two distinct feature vectors (FV) of A and B are adopted as input and a further FV C is produced, where A, B, C $\in \mathbb{R}^d$. Every feature element c_i , of the output vector C, is processed employing through the Eq. (10) to Eq. (13).

$$c_i = \max(a_i, b_i) \forall i \in \{1, 2, \dots, d\} \quad (10)$$

$$c_i = \min(a_i, b_i) \forall i \in \{1, 2, \dots, d\} \quad (11)$$

$$c_i = \text{mean}(a_i, b_{i+1}) \forall i \in \{1, 2, \dots, d\} \quad (12)$$

$$c_i = a_i + b_{i+1} \forall i \in \{1, 2, \dots, d\} \quad (13)$$

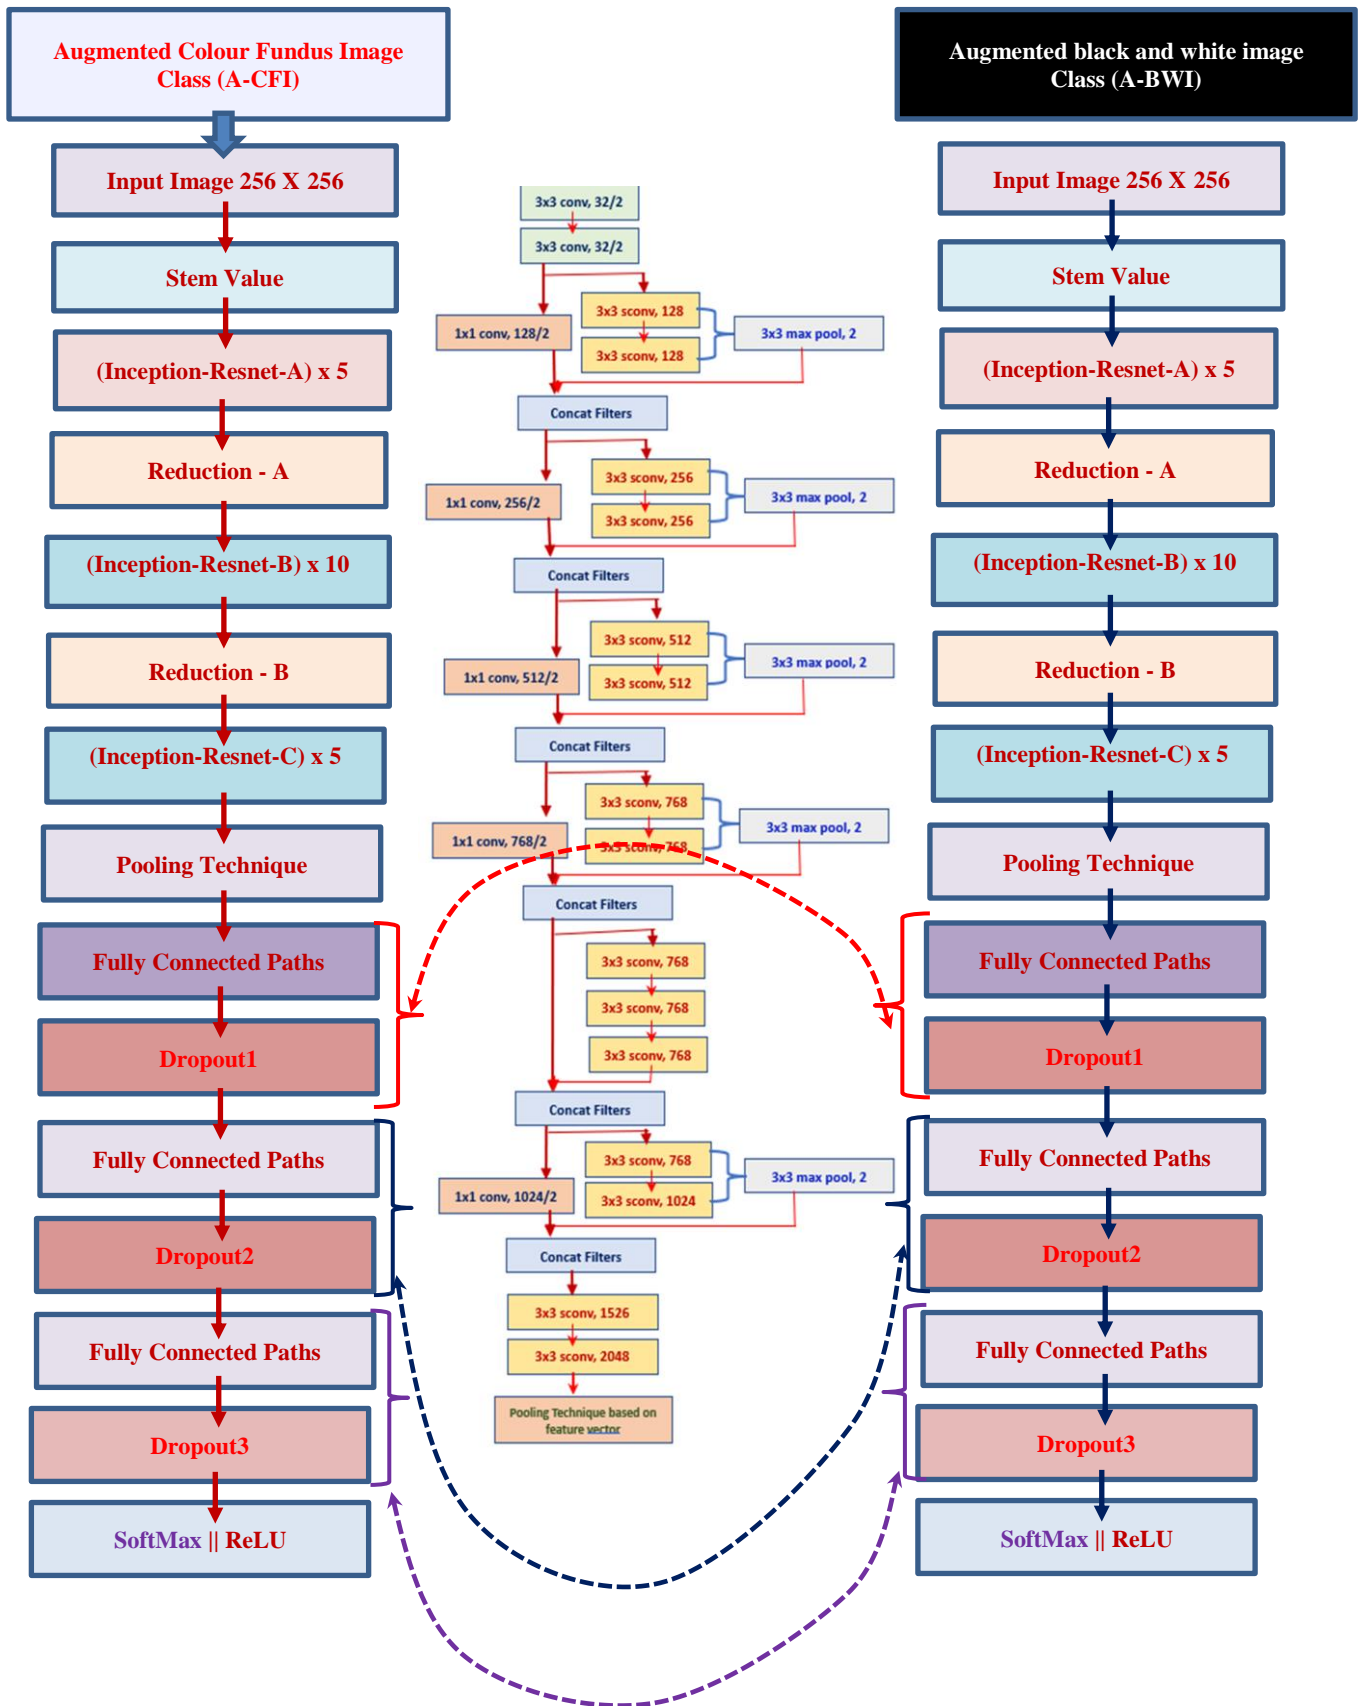

Fig. 3. The Structural design of custom-built DL-CNN based network stem segment with extracted features.

The 1D Pool is employed to choose leading regional features from every VGG32 region, where the Cr-Pool permits accumulating the leading features achieved by 1D Pool with global interpretation of Xception net environment. The 1D Pool based synthesis brings one FV 'K' as an input and which generates a further FV of K^{\wedge} , where K belongs to $Rd1$, K^{\wedge} belongs to $Rd2$ with the executional condition of $d2 \leq d1$. K^{\wedge} is a decreased interpretation of K, where $K = \{k1, k2, \dots, kd1\}$ and $K^{\wedge} = \{k^{\wedge}1, k^{\wedge}2, \dots, k^{\wedge}d1\}$. In this environment, every feature element $k^{\wedge}i$, of the output vector K^{\wedge} , is calculated employing through the Eq. (14) to Eq. (17).

$$k^{\wedge}i = \max(ki*2, ki*2+1) \forall i \in \{1, 2, \dots, d2\} \quad (14)$$

$$k^{\wedge}i = \min(ki*2, ki*2+1) \forall i \in \{1, 2, \dots, d2\} \quad (15)$$

$$k^{\wedge}i = \text{mean}(ki*2, ki*2+1) \forall i \in \{1, 2, \dots, d2\} \quad (16)$$

$$k^{\wedge}i = ki*2 + ki*2+1 \quad \forall i \in \{1, 2, \dots, d2\} \quad (17)$$

The 1D Pool has been employed individually on extracted features of VGG32 based fc1 and fc2 layers. After that, the CxPool method has been employed on the subsequent pooled features, which FV has unified with the extracted features from the Xception, which are generated from the two individual sets of input image classes, such as the Augmented Color Fundus Image Class and the Augmented Black and White Image Class sets, using CrPool, as shown in Fig. 3 and 4. As the final FV is a unified form of the global and local interpretations of the RIs, it offers robust hyper features.

V. RESULTS AND DISCUSSION

The multi-decision Inception-ResNet blended hybrid model has integrated with multi-layers of dual image-based parameters that process sequential and non-sequential images. The proposed model has been trained with a multi-layered transfer learning mechanism that has been tuned with 172 weighted multi-layers, of which 86 weighted layers are connected with color fundus images and 86 more weighted layers are connected with black-and-white images. The images are graded manually on a scale of 0 to 4 (0, normal DR; 1, mild; 2, moderate; 3, severe; and 4, proliferative DR) to indicate different severity levels, and the grading process has been extended to binary bit form, such as:

Dual Labeling Mechanism (P, Q) \leftrightarrow (~P, ~Q).

where $Q1 = \{q1 / q1 \in \{000, 001, 010, 011, 100\}\}$ and $Q2 = \{q2 / q2 \in \{00, 01, 10, 11\}\}$.

Q1 representing primary case of labeling and Q2 representing secondary case of labeling based on positive (1), true-positive (11), true-negative (10), false-positive (01), false-negative (00).

Grade-0: Normal \leftarrow 000.00.

Grade-1: Mild DR \leftarrow 001 Various levels \rightarrow {001.01, 001.10, 001.11}.

Grade-2: Moderate DR \leftarrow 010 Various levels \rightarrow {010.01, 001.10, 001.11}.

Grade-3: Severe DR \leftarrow 011 Various levels \rightarrow {011.01, 001.10, 001.11}.

Grade-4: Proliferate DR \leftarrow 100 Various levels \rightarrow {100.01, 001.10, 001.11}.

The DL-CNN based Layered Integration with training and testing scenario with grading process has shown in the Fig. 4 which are integrated for detection of DR stages. The data has collected for training and testing purpose which are clustered according to the DR stage and according to the DR symptoms through binary bit formation which is shown in the Table I.

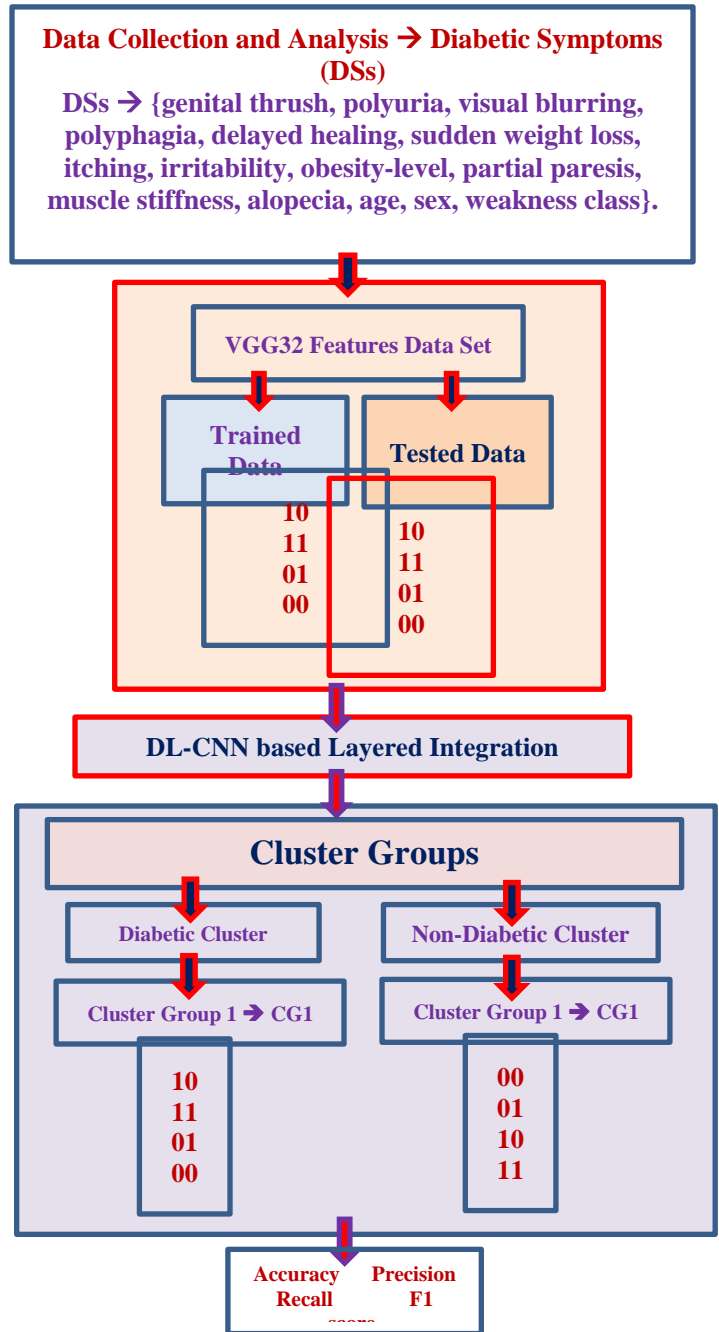

Fig. 4. DL-CNN based Layered Integration with training and testing scenario for detection of DR stages.

TABLE I. INTEGRATED SET OF IMAGES AND DR GRADING CLASS

DR Stages / Grade	Impact	Base binary class	Supporting sub-class	Sampling	Sequential and Non-sequential Images	Single / Dual Image Processing
Grade-0	Normal	000	000.00	2150	Sequential	Dual Image
Grade-1	Mild DR	001	{001.01, 001.10, 001.11}	526	both	Dual Image
Grade-2	Moderate DR	010	{010.01, 001.10, 001.11}	1325	both	Dual Image
Grade-3	Severe DR	011	{011.01, 001.10, 001.11}	372	both	Dual Image
Grade-4	Proliferate DR	100	{100.01, 001.10, 001.11}	158	both	Dual Image

TABLE II. PARAMETERS TURNING AND INTEGRATION FOR CLASSIFICATION-BASED DECISION MAKING, AND TEST-CASE CONDITIONS BASED ON STOCHASTIC GRADIENT DESCENT OPTIMIZATION (SGD) ← PARAMETERS TURNING AND INTEGRATION

Test conditions	Epochs Value	Image Learning Rate (imlr)	Momentum1
Test condition 1 (TC1)	epochs>70 then	0.0001	0.4
Test condition 2 (TC2)	epochs>140 then	0.0002	0.5
Test condition 3 (TC3)	epochs>210 then	0.0003	0.6
Test condition 4 TC4	epochs>280 then	0.0004	0.7
Test condition 5 (TC5)	epochs>350 then	0.0005	0.8

The Table II is representing the dual-image-based multi-layer mapping approach based on classification and regression → used at the end to classify the five stages of DR based on the features extracted from a series of networks. Each stage consists of the following data. The Table III representing the A dual-image-based multi-layer mapping approach based on classification and regression which used at the end to classify the five stages of DR based on the features extracted from a series of networks for further decision making (dm).

Every dual image based multi-layer mapping approach.

$imlr1 = 0.001$, $momentum1 = 0.4$.

$imlr2 = 0.005$, $momentum2 = 0.8$.

$cim1$ ← first moment of color image based exponential decomposition rate in AOpt.

$cim2$ ← second moment of color image based exponential decomposition rate in AOpt.

$bwim1$ ← first moment of black-white image-based exponential decomposition rate in AOpt.

$bwim2$ ← second moment of black-white image-based exponential decomposition rate in AOpt.

$cim1 = 0.7$, $cim2 = 0.890$.

$bwim1 = 0.7$, $bwim2 = 0.890$.

The experimental scenarios are framed based on the Kaggle APTOS dataset, which has shown that the proposed trained modelized approach represents a greater contribution to the active methodologies through blended features. The proposed methodology has been compared with the existing approaches based on integrated DR symptoms, their affecting factors, data metrics, and dual image processing techniques. This research has experimented with dual images, which has helped to analyze the images in depth for detection of DR stages and has helped to identify and map the missing patches with color fundus images and black-and-white images.

TABLE III. A DUAL-IMAGE-BASED MULTI-LAYER MAPPING APPROACH BASED ON CLASSIFICATION AND REGRESSION WHICH IS USED AT THE END TO CLASSIFY THE FIVE STAGES OF DR BASED ON THE FEATURES EXTRACTED FROM A SERIES OF NETWORKS FOR FURTHER DECISION MAKING (DM)

Test Condition stage1	Test Condition stage2	Each epoch range	tiny cluster	cim1	cim2	bwim1	bwim2
initialized Adaptive Moment Estimation → bhm	Adaptive Moment Estimation (Adam) ← Parameters turning and integration.	1 to 70	for each tiny-cluster1 → $(P_{mini}, Q_{mini}) \in (P, Q)$	0.7	0.890	0.4	0.5
initialized Adaptive Moment Estimation → bhm then.	Adaptive Moment Estimation (Adam) ← Parameters turning and integration.	71 to 90	for each tiny-cluster2 $(P_{mini}, Q_{mini}) \in (P, Q)$	0.7	0.890	0.5	0.6
Adaptive Moment Estimation →	Update the multitasking parameters	above 90	If validation error is not improving for four epochs, then $imlr1 = avg((imlr1 * 0.01) + ((imlr2 * 0.01)))$ $imlr2 = avg((imlr1 * 0.01) + ((imlr2 * 0.01)))$	0.7	0.890	0.7	0.8

VI. CONCLUSION

A trained clinician or ophthalmologist must analyze and estimate digital color fundus photographs of the retina to identify DR based on the presence of lesions associated with the vascular malformations brought on by the disease. This labour-intensive and manual process takes time. This study suggested ResNet feed-forward neural network technology for automated decision-making. In the pre-processing and classification steps, the sequential and non-sequential pictures were analyzed concurrently. The mapping approaches combined to evaluate and map the hard exudates and hemorrhages, microaneurysms, venules and dot points of the fovea, cottonwool spots, the macula, the outside line of computations of the optic disc, and retinal arterioles between color and black-white pictures. Missing computations are incorporated into the vector sequence, which makes it easier to recognize DR phases. The test cases comprised a total of 5672 sequential and 7231 non-sequential color fundus and black and white retinal pictures. The 10-fold cross-validation technique was used in testing and training using the 80 and 20% ratios of high- and low-quality photos. For testing and analyzing high-quality photographs, the ACU, sensitivity, and specificity were 98.9%, 98.7%, and 98.3%, respectively; for low-quality images, they were 94.9%, 93.6%, and 93.2%.

Abstract—Data deletion increases challenges in cybercrime investigation. To address the problem, proactive forensics for evidentiary collection is acknowledged to help investigators to acquire the potentially needed digital evidence. This study proposes a bot machine to record data from the Discord server in advance, hashing and saving it in proper storage for further forensic analysis. The recording process can be managed to collect activities and their related data (intact, modified, deleted), including text, pictures, videos, and audio. The Discord bot is designed by utilizing the main features of the Discord Social Networks Application Programming Interface (API). This paper examines how this approach is applicable by embedding the bot in a Discord server. Observation showed that the bot records the real-time data as it is always alive on the server, including the deleted or modified messages and their timestamps. All the recorded data is saved locally on the server's storage in easy-to-read formats, CSV and JSON. The results showed that the bot could conduct the data acquisition for 37 concurrent users with a 2.3% error rate and 97.7% accuracy.

Keywords—Discord; bot; cybercrime; social networks API; digital evidence

I. INTRODUCTION

One of the challenges digital forensics investigators face is the inability of forensic tools to acquire deleted data [1]. The challenge makes investigative activities require more time and effort to find data remnants from other sources that can provide more evidence. In addition, from an information security perspective, there is a need to guarantee data deletion [2].

Proactive forensics supports investigators in collecting data before an incident occurs [3]. This approach will collect live data, thus enabling all data and changes that occur to the data to be collected [4]. For example, keystroke logging methods have been proposed to logically acquire keystrokes in cloud applications for forensic readiness [5]. The method shows how forensic activities can be assisted through data collection techniques initially considered malicious acts.

It is understood that many bots are known for their harmful impact. Even several guides for conducting bot crime investigations are available [6]–[8], and IoT-Botnet datasets have also been developed for network forensic analytics [9]. However, no known study in this area examines the benefits of bots for acquiring potential evidence data. This gap is identified by a previous study that stated some important future works in instant messaging forensic investigation, including users editing/deleting messages and Discord bots [10]. Therefore, this current research examines proactive forensics using bots by taking the example of the Discord application.

The Discord data is collected in advance to reduce the time and complexity of investigations to obtain more complete data. The proposed bot is tested for positive reasons and measured how far this acquisition method could help. Understanding its advantages and identifying its issues are essential to guide investigators' practice and academics in developing the proper bot system.

Discord enables users to indirectly publish substantial amounts of information, including voice calls, video calls, text messages, media, and file sharing. From cybercriminals' perspective, these features can be exploited to conduct cybercrimes. However, the offender could modify evidence of interest by deleting, editing, and clearing messages on the cache. The action is anti-forensics - data concealment by implementing data hiding and trail obfuscation techniques to remain anonymous or undetected [11], [12]. In addition to anti-forensic issues, it could lead to incomplete attributes of collected artifacts and affect the integrity of digital evidence [13].

Therefore, it is necessary to have an acquisition method that can acquire the attributes of digital evidence completely and does not affect its integrity. An example of the potential method is by using the Social Networks API. The API is used in the acquisition process by focusing on features that the Discord application API has fully provided, and it can be modified and adjusted according to acquisition needs [14]. These characteristics of the APIs can complement the lack of attributes from collecting digital evidence. In this study, a Discord Bot is developed based on the features of the Social Networks API's Discord to facilitate digital evidence acquisition. A test scenario of the Social Networks API based on Discord Bots was set up to simulate digital evidence collection from the Social Networks API method. Another key point is to improve the performance of the acquisition process and extract complete digital evidence.

The rest of this paper is organized as follows: Section II outlines the related work of proactive forensics, and Discord acquisition. Section III explains the bot design. Section IV presents the results and discussion. Section V contains the conclusion and suggestions for future work.

II. RELATED WORKS

Proactive forensics involves collecting data before or during the incident by promoting the automation of live investigation [3], [15]. Applying proactive forensics in incident response teams would equip the team to respond appropriately to an incident. At the same time, for investigators, advanced data collection would help speed up the investigation process

because the data is already available. This proactive approach is essential in digital investigation, especially in environments like social networks where editing and deleting messages are common for users to remove their unwanted traces; also, in critical systems such as Industrial Control Systems where real-time analysis may enable rapid triaging and response to attack [16], [17]. Meanwhile, the live data collection approach can be conducted by recording data from the running activities. For example, previous authors proposed a method of keystroke logging to acquire keystrokes in cloud applications for forensic readiness [5] and installing software on the target system to preserve deleted files that might interest forensic examiners [3].

Motivated by the best communication feature for gamers, Anderson ran a qualitative ethnography study to understand if Discord helps enforce the values and behaviors of the Harbormen gaming community [18]. This study revealed that the ease of use and the convenience of interacting with different communities on various servers are experienced by its users. With this positive experience, the gamer's community and other fields, such as education, utilize Discord. It was used as a platform for physical education learning during the COVID-19 pandemic in a high school [19]. Some higher education institutions have innovatively used Discord to deliver teaching listening as an e-learning tool in the sciences and humanities [20].

Instant messenger provides communication via text, voice, videos, and photos. However, there is an increasing trend of cyber criminals who use instant messaging applications to do malicious acts. The ease of their registration and usage attracts many users, including criminals. The vast amount of user data inside the apps becomes potential evidence in digital forensic investigations. As different apps manage their data differently, it is essential to conduct application-specific forensics.

A previous study analyzed the Google Chrome cache structure inherited from Discord [21]. The study showed it could successfully get Discord-related metadata through the cache on Discord apps for the PC version. Nevertheless, further work still needs to be conducted to cover evidence from Discord Web Applications and Discord Mobile Applications. Another study examined Discord desktop applications on Windows 10 from a forensic value and cybersecurity perspective [22]. Similarly, the study demonstrated that Discord metadata could be successfully acquired through the cache on Discord Applications. A recent study on Discord forensics based on data from the Google Chrome browser also recovered various artifacts [23]. However, while much important information can be acquired through cached data, an issue of its deletion may prevent the acquisition.

Research on Linux OS computers found Discord-specific data, including messages, usernames, and passwords [10]. Examination of the broader platform by including the Discord mobile app identified locations of artifacts, such as received/sent messages, shared files, chat rooms, and user account information [24]. Conducting forensic analysis on client-based devices can successfully acquire interesting data remnant, but the analysis should be done individually for each device.

As Discord provides services on instant messaging and VOIP, there has been a significant interest in examining the forensic analysis of other similar tools. A study conducted a forensic survey and analysis of Tango VoIP for iOS and Android platforms [25]. A research environment was set up for different mobile devices by installing WhatsApp, Skype, Viber, and Tango, and a list of target artifacts was defined. In addition to the forensic analysis, this study investigated how cloning IM sessions and intercepting communications can facilitate data acquisition. It was observed that encrypted data presents challenges to the acquisition process.

Research on WhatsApp discussed forensic approaches to creating real-time insights into WhatsApp communications [26]. This approach uses eavesdropping, decrypting WhatsApp databases, open-source information, and analyzing WhatsApp web communications. The research evaluated the method in various WhatsApp forensic scenarios to prove its feasibility and efficiency. It was found that various data, including profile pictures, user activities, location data, remote access to suspicious WhatsApp accounts, voice messages, shared contacts, documents, images, and videos, are accessible.

Tools are needed for application-specific forensics analysis to acquire and analyze the data. A study has presented a brief overview and a comparative analysis of various commercial and open-source mobile forensic tools [27]. The review used a cross-device and test-driven approach to predefined software parameters. Test scenarios addressed digital threats and assessed whether the tool has the expected functionality. The parameters used to compare are cost, MD5 hash mechanism, ease of use, and platform support.

To the extent of our review, existing studies on tools to support Discord forensic analysis depend on the data remnant of the apps, both on the client and server sides. There is no study on proactive evidence acquisition by recording all user activities at once using a bot. In this study, the usage of a bot installed on the Discord server is proposed to obtain all the exchanged messages, including text and multimedia data, for the intact and the deleted data.

A. Discord

Discord is a social networking app used by people (over 13) to discuss many topics, including games. It hosts communities of all sizes but is primarily used by small, active groups that interact regularly. It hosts communities of all sizes but is primarily used by small, active groups that interact regularly. Therefore, Discord comprises artifacts that contain vital information such as text, attachment files, and member lists in one event. Unlike other popular social network apps, no algorithm is involved in deciding what to watch, infinite scrolling, and no news feeds on Discord. Table I presents the commonly used Discord features by users.

B. Social Network API

Application Programming Interface (API or WEB API) is a module that enables interaction with application service resources. Examples of resources owned by application services are documents, images, and text messages [28]. Therefore, there is a potential to utilize Social Networks API to collect evidence artifacts from social network apps. Utilization

is possible because the generated resources comprise metadata that describes the corresponding data. Furthermore, Social Networks API allows us to adjust the code according to the acquisition needs.

TABLE I. DISCORD FEATURES

Function	Description
Text channels	Feature for users to send messages to each other
Voice channels	Feature for users to communicate with each other
Share screen	Feature for users to share videos live with other users
Sharing images	Feature for user sharing images
Text channels	Feature for users to send messages to each other
Upload files	Feature for users to share documents

The Discord API provides another user account dedicated to automation called a bot account. Anyone can create a bot account from the app page and authenticate with a token (i.e., without a username and password). Unlike the regular Open Authorization (OAuth2) API, a bot account has full access to all API routes and can connect to a real-time gateway without an authentication token.

III. RESEARCH METHOD

Discord provides various functions via API. The bot uses the official Web API Discord to acquire the data stored on the Discord cloud server.

A. API Usage

The flowchart in Fig. 1 presents the two steps of using Discord API. Firstly, Discord API records every message and returns the log or cache in the bot. Before the log or cache returns, Discord Bot will check any edited or deleted message/data. Secondly, Discord API is used to request features and give responses. After these two main usages of the API, the bot performs read or write disk operations to save the messages in CSV or JSON format.

B. Discord Bot Design

Discord bot is an application created by the user with the admin group role. For example, user A as the admin, creates a discord server, and user B join the discord server created by user A. After that, user B sent message on the text channel. The message from user B will record by the discord bot and reproduce the cache. Discord bot is designed to hook websites as a function to get message channel history which can list

return message attributes, including the deleted and edited messages. The Discord bot will save all record messages on private channel that can be seen by user A as the group admin. The use case of the designed Discord bot is presented in Fig. 2.

Before starting the Discord bot, the admin must create a guild and text chat channel. Next, the admin can create a bot, enter it into the created guild or channel, and share the guild. Users could then join the guild and interact with other users by sending messages, pictures, documents, videos, and audio. Subsequently, these activities are recorded, and their data will be acquired and saved in the Discord bot. This flow is presented in Fig. 3.

C. System Requirement

The bot is built using Python and utilizes the currently available Discord API. The details of our bot specification are presented in Table II.

To acquire Discord data from the server, the required functions are implemented on the bot to get the messages, data attachment, timestamp, and message id, calculate data hash value, and prepare the data saving on local storage. Table III lists these functions embedded in the Discord Bot.

D. Testing Scenarios

During the testing, 37 users accessed the Bot server simultaneously. The users simulated the common activities as follows:

- Sending:
 - text messages.
 - document files.
 - audio files.
 - video files.
 - picture files.
- Deleting the first sent text, document, audio, video, and picture files.

Comparison between the actual sent and deleted data and the successfully acquired data are examined to measure the bot's performance.

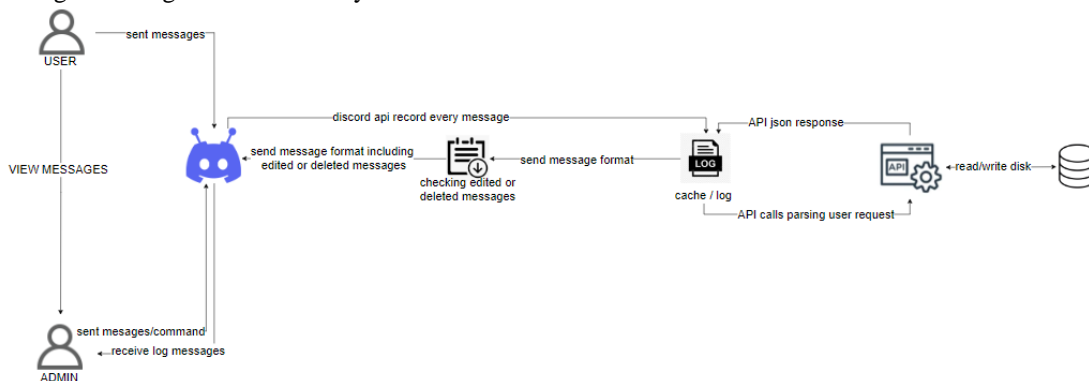

Fig. 1. The flow of API usage.

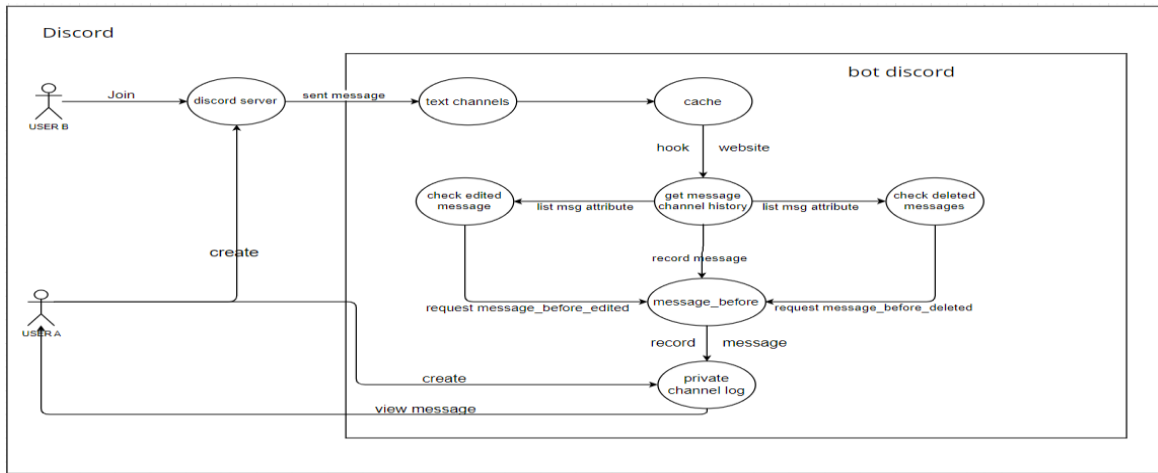

Fig. 2. The use case of the discord bot.

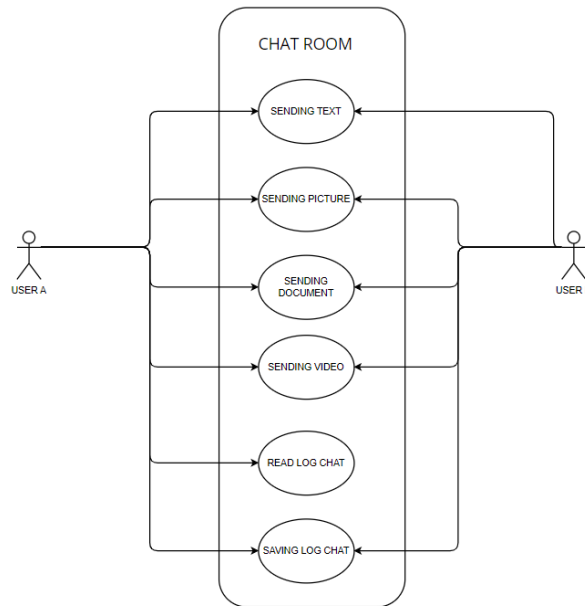

Fig. 3. User interaction in the bot.

TABLE II. THE BOT SPECIFICATION

Discord Bot Application		
No	Specification	Detail
1	Name	DEVICO BOT
2	Version Name	1.0
3	Application ID	936165836010426369
4	API Version	9.0
5	Token	OTM2MTY1ODM2MDEwNDI2MzY5.GMbjAH.SwcAiKb_s_1-kWLt53TQnz9KCUqxxxxxxxxxxxx
Discord Account		
No	Specification	Detail
1	Name	Simpleman (as admin) Simpleman1 (as normal user)
2	Authorization	OTI5NjM4ODIxNzkwOTA0MzMx.YjHTaQ.TKBgkamryyoHa5G2EGMWnpyxxxx (authorization admin) OTI5NjQxODk4NjczNTkwMzIy.YjHTrg.TIEmtB-sBtm-dzSg3OpvV5Rxxxx (authorization normal user)
Python		
No	Specification	Detail
1	Name	Python
2	Version	3.10.2

TABLE III. THE BOT FUNCTION DETAILS

No	Function	Detail
1	get_messages	get chat messages sent
2	get_images	get the picture sent
3	get_attachment	get documents sent
4	get_message author	get the author who sent the message
5	get_timestamp	get time sending message
6	get_editedtimestamp	get the time when the message was edited
7	get_guildname	get the name of the guild or group
8	get_channelname	get channel name in group
9	get_editedmessage	get edited message
10	get md5 and sha256	get md5 and sha256 hashing
11	get_deletedmessage	get deleted messages
12	get_url_attachment	get all URL where attachments are stored on the Discord database
13	save json.dumps	save all deleted or edited messages and regular messages
14	save embed_message	save all deleted or edited messages and regular messages in one private channel
15	save CSV	Save all messages CSV format

IV. RESULTS AND DISCUSSION

This section presents acquisition results as part of internal testing to test the functionality and external testing to measure the bot's performance. It is followed by a discussion that explores how the bot supports available research to acquire Discord's data.

A. Experimental Configuration

The tests in this paper were carried out using a custom-built experimental apparatus. The following information describes the system setup used for the investigations:

1) *System configuration:* The studies were carried out on an ASUS TUF Gaming FX504 laptop, which served as the study's principal hardware platform. This laptop model, noted for its durability and dependability, provided a suitable computing environment for experimental activities. The laptop, which included a 2.2 GHz Intel Core i7-8750H CPU with six cores, gave the processing capability to tackle difficult computations. With 16 GB of DDR4 RAM, it provided sufficient memory capacity to accommodate huge datasets and ensure the smooth execution of the experimental methods. The laptop also has a 512 GB NVMe SSD for quick and efficient data storage and retrieval. An NVIDIA GeForce GTX 1050 Ti graphics card with 4 GB provided the graphical capabilities.

2) *Software environment:* The Windows 10 operating system (version 10.0) was used as the platform for the studies in the experimental setup. For the study, Windows 10 offered a user-friendly and generally compatible environment. Python (version 3.9.6) was used as the primary programming language for carrying out the experiments and analyzing the results. Python's adaptability and vast library ecosystem made it an excellent choice for scientific computing jobs. The Discord API interfaced with the Discord platform to gather and analyze data. The most recent version of the Discord API was used, assuring compatibility with the most recent Discord

features and functions. The Pandas package (version 1.3.4) was used for data processing and analysis in the studies. Pandas provide efficient data structures and handling tools.

B. Acquisition Results

Internal testing ensures all features are working as intended and ready to be used by external users.

1) *Text acquisition:* The bot automatically saves all text messages in the Discord server, whether intact, deleted, or edited. The messages are captured on the admin's private channel text created previously and stored in the embedded_message format. The output of text acquisition is shown in Fig. 4.

The detailed content of the acquired text data is presented in Table IV. There is a title as the type of message, a Message ID as a unique id denoted by the message, and the hash value of the data is computed to support data integrity checking.

2) *Document acquisition:* The bot is set to be able to acquire various document formats such as pdf, docx, xlsx and others. Like text acquisition, the document acquisition results are stored directly in the private channel text. Fig. 5 presents two scenario results: the acquisition of the intact document and the deleted document. The hash value of the acquired documents was calculated for both scenarios. The detailed attributes of the documents are presented in Table V.

3) *Audio acquisition:* The bot collected its attributes for audio data, namely name, extension, resolution, and size. The acquired data is stored directly on the private channel text. The screen capture of the example result can be seen in Fig. 6, while the complete type of the acquired data from the audio is presented in Table VI.

4) *Image and video acquisitions:* Users can upload various images and video formats. Fig. 7 presents the details acquisition results of the files. The data are stored directly on the private channel text. The detailed data is shown in Table VII.

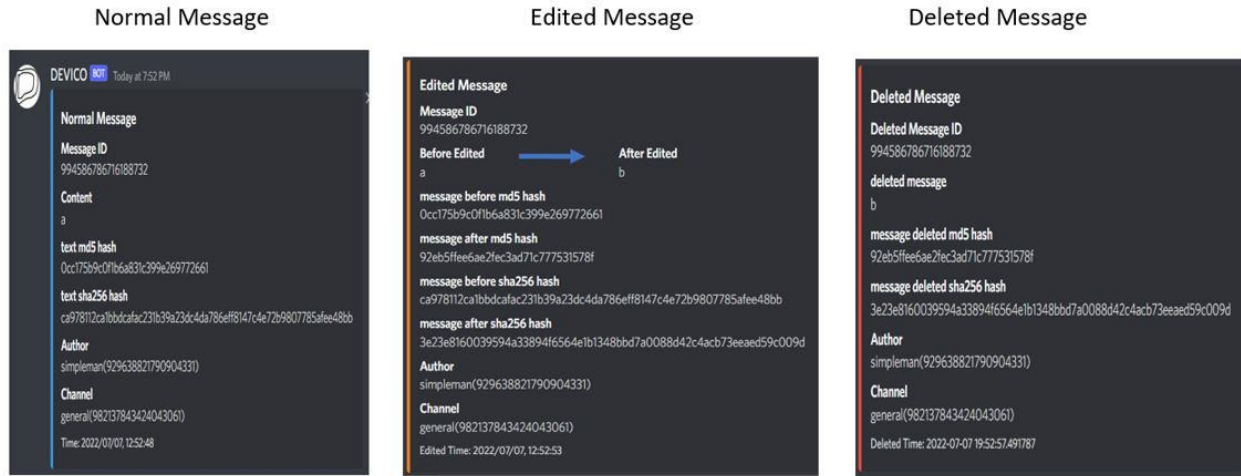

Fig. 4. Sample output of the text acquisition.

C. Error Rate and Accuracy

The testing was conducted with 37 users running the bot simultaneously for about one hour. Our record showed that the total sent text messages, files, and deleted data during the testing phase were 74, 296, and 185, respectively. Meanwhile, the acquired data are 74, 289, and 177. Details of the acquired data are presented in Table VIII. It can be observed that the bot

cannot identify seven intact and eight deleted files; therefore, these files cannot be acquired.

The error rate (ERR) and Accuracy (ACC) metrics are measured based on the dataset and the acquired data by using Eq. (1) and (2). ERR is calculated as the number of all incorrect predictions divided by the total number of data sets.

Accuracy (ACC) is calculated as the number of all correct predictions divided by the total number of data sets.

$$\text{Error Rate (ERR)} = \frac{FP+FN}{TP+TN+FN+FP} \quad (1)$$

$$\text{Accuracy (ACC)} = \frac{TP+TN}{TP+TN+FN+FP} \quad (2)$$

where,

FP = the application falsely predicts the true dataset

FN = the application falsely indicating the false dataset

TP = the application accurately predicts the dataset

TN = the application accurately predicts the incorrect dataset

Based on the ERR and ACC formulas above, Table IX presents the confusion matrix based on the performance test results.

TABLE IX. CONFUSION MATRIX FOR A BINARY CLASSIFIER PREDICTING ACCURACY AND ERROR RATE STATUS

	Predicted Positive	Predicted Negative
Actual Positive	289 (TP)	0 (FN)
Actual Negative	7 (FP)	0 (TN)

In Table IX, there are 289 true positives (TP), meaning the classifier correctly identified 289 messages sent by the user. However, there are seven false positives (FP), meaning the classifier predicts seven users have already sent the message, but the fact is not sent yet.

Looking at the values in the confusion matrix in Table IX, the number of error rates generated by the Bot Discord application is 2.3%, and its accuracy is 97.7%.

D. Discussion

The observed results show that the bot successfully recorded messages sent through the Discord app, including the edited and deleted data. However, it is noticed that some data could not be recorded and acquired from the performance results. A potential explanation is that this testing was conducted for the 37 concurrent users, and some data arrived simultaneously. Managing the buffer for storing the consecutive arriving data shall become our concern for future work. It is also necessary to consider storing the acquired data on special storage, including the cloud, because it is possible to get a vast amount of data.

The proposed bot is designed by utilizing the Discord API. The acquired data is presented in Table X. The implementation of the bot by using the Discord API approach gives flexibility because it can be modified according to the acquisition needs, for example, to acquire a guild that contains text messages, images, documents, videos, and audio. This approach opens the possibility of gathering more data as a digital forensic investigation is needed, as much as the app's API can access them.

The other benefit of the bot approach to conduct the acquisition is it can be used to proactively collect the data from all users at once, as it is conducted on the server side. Nevertheless, implement it without compromising user privacy [29] needs to be considered; this could be achieved by providing a notice to the users.

TABLE X. ARTIFACTS ACQUIRED FROM THE PROPOSED DISCORD BOT

Type	Discord Data	API-based Bot Discord
Guild	Name, name_channel, created_at, Id, Category name	✓
Messages	Id, Type, Content (intact, edited, deleted), Attachment (id, filename, size, url, for intact and deleted attachment), Chanel id, Author (id, username, avatar, discriminator, public flag), Embeds, Mentions (roles, everyone), Pinned, Tts, Timestamps (intact, edited, deleted), Flags, Hash (md5 and sha256)	✓

V. CONCLUSION

This study proposed a novel way to collect Discord data using a bot in proactive forensics. The Discord API-based bot saves the data as the embedded message card, stored in a private channel created by the admin. The real-time data can be recorded as the bot is always alive on the server. Therefore, intact, edited, and deleted data are available in advance to be analyzed as needed. All the recorded data is saved locally on the server's storage in easy-to-read formats (i.e., CSV and JSON). The bot is equipped with calculating hash values (i.e., md5 and sha256) for the individual data. Future works may focus on improving the bot's performance to handle massive users, adding remote/cloud storage access, and handling data acquisition for VoIP and encrypted messages.

Abstract—Computerised electroencephalography (EEG) is one of a wide variety of brain imaging techniques used in addiction medicine. It is a sensitive measure of the effects of addiction on the brain and has been shown to show changes in brain electrical activity during addiction. But, the clinical value of computerised EEG recording in addictions is not yet clearly established. However, several studies argue that this non-invasive technique has an undeniable contribution to the understanding, prediction, diagnosis and monitoring of addictions. The aim of this article is to assess, through a systematic review, the contribution and interest of computerised EEG in the study and understanding of substance abuse by describing the different electrical activities that underlie it across the main frequency ranges: delta, theta, alpha, beta and gamma. We have been conducting a systematic review according to the recommendations of Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) and the Cochrane Group. We included 25 studies with a total of 1897 cases of addiction and 1504 controls. The studies dealt with addictions related to 05 licit and illicit psychoactive substances (alcohol, nicotine, cannabis, heroin and cocaine). The group of addicted patients showed significantly different brain electrical characteristics from the group of controls in the different EEG rhythms, whether during acute substance intoxication, abuse, withdrawal, abstinence, relapse, progression or response to treatment. The majority of studies have used EEG for diagnostic, predictive, monitoring purposes and also to discover electro-physiological markers of certain addictions.

Keywords—*Electroencephalography (EEG); quantitative electroencephalography; drug addiction; spectral analysis; coherence analysis*

I. INTRODUCTION

Over the past twenty years, we have witnessed some important advances in the study of the human brain. Possibly the most challenging has been the development of structural and functional brain imaging techniques, which have revolutionised cognitive and behavioural neuroscience by offering us a view into the brain activity underlying complex human behaviour. These technological progresses have also allowed to the rapid conversion of basic neuroscience discoveries into more specific therapies for clinical application.

There is a rich diversity of brain imaging techniques, which can be categorised into three main types: (1) nuclear medicine

imaging techniques; (2) magnetic resonance imaging techniques and (3) electro-physiological imaging techniques, which comprise electroencephalography (EEG). Each one of these techniques reveal a distinct facet of brain structure and/or function, providing a wide range of findings on the biochemical, electro-physiological and functional processes of the brain.

Electroencephalography (EEG) has been used to investigate brain function since the publication of Berger's paper in 1929. It registers the synchronised activity of excitatory (EPSP) and inhibitory (IPSP) postsynaptic potentials in the cerebral cortex and exhibits the activity as a tension change in amplitude with time [1]. Over the past forty years, the EEG has been used extensively in drug addiction research. It is known to be a sensibly measurement of the effects of substances on the brain and, in particularly, of the effects of drugs on the size and time course of postsynaptic potentials [2]. The enhancing effects of many substances modulated by the mesolimbic dopamine (MD) channel have been shown to alter EEG recordings [3]. Five frequency ranges are generally recognised and studied: delta (0-4 Hz), theta (4-8 Hz), alpha (8-13 Hz), beta (15-30 Hz) and gamma (<30 Hz).

EEG analysis methods included quantitative EEG, spectral analysis, coherence analysis and visual analysis. Substance use has been found to be associated with broad alterations in intrinsic neural activity, typically expressed as neuronal hyperactivation and decreased neuronal communication between brain regions. Some studies have shown that the use of alcohol, tobacco, cocaine, cannabis and heroin was positively correlated with these changes. These alterations may partially recover after abstinence, which differs between drugs and may reflect their degree of neurotoxicity. In summary, EEG can be used for diagnostic, predictive and monitoring purposes and also to discover electrophysiological biomarkers of certain addictions.

Therefore, this article presents a systematic review of EEG studies in substance addiction, to guide further work in the field. The main objective is to review the empirical research of the last decades, providing crucial information on EEG findings in addiction to the most commonly used substances. It therefore aims to investigate the interest and contribution of EEG in these addictions.

II. METHOD

A. Inclusion and Exclusion Criteria

The selected studies included people with addiction, without restrictive geographical, age, gender, ethnicity or nationality criteria. To be included in this review, studies had to be based on samples of subjects with substance addiction investigated by electroencephalography as the main investigative tool.

In order to limit the abundance of data from different databases, the studies included in this review were those that could provide us with data dealing with the role or use of EEG in addictology in English or French only. All were concerned with the study of brain activity in addicts. They were essentially quantitative studies carried out on addicted subjects without any other concomitant pathology. Priority was given to studies that used quantitative EEG with coherence analysis or spectral analysis.

We excluded any papers that did not directly address the brain activity of addicts as measured by EEG. For example, we eliminated all studies that only dealt with the use of other means of brain investigation such as scans, MRIs, PET scans, etc., without a direct link to the EEG.

B. Research Strategy

MEDLINE, PSYCHINFO, PUBMED, SCIENCE DIRECT and GOOGLE SCHOLAR databases were searched in January, February and March 2022 with publication date limitation since 1990 when computerised automated EEG analyses began using the following search terms: "Electroencephalography, EEG, substance addiction, drug abuse". Both authors (M.A. and D.J.) independently examined the title, abstract and keywords of each identified reference and then selected the studies according to the inclusion criteria. The same method was then used to review the full text of each selected study. In order to identify additional relevant articles that this search strategy would have missed, we also managed and examined the bibliographic references of each article included in the review using ZOTERO software. In case of incongruence

between the data extracted by authors M.A. and D.J., the review and opinion of author E.F. was sought.

The initial database search identified 165 references. Following an initial review of titles, abstracts and keywords, 61 studies were not included because they did not correspond to the inclusion criteria. Following a full text review, 25 studies were included in the systematic review. The search strategy is detailed in a flow chart (Fig. 1).

C. Extracted Data

The authors (M.A. and D.J.) independently extracted data from the articles included in the review. A list of analysis criteria was compiled in the form of a reading grid (Table I) to extract data from the articles: author and year of publication, country, characteristics and size of the sample, substance studied, method of electroencephalographic analysis and the main rhythms studied.

The different types of EEG analysis that will be discussed in this paper are: 1) Quantitative analysis (QEEG) which is a modern type of EEG analysis that involves recording digital EEG signals that are processed, transformed and analysed using complex mathematical algorithms; 2) Spectral analysis, which is a frequency analysis technique that breaks down a complex cyclic signal into several sub-functions. This analysis technique is used in particular to finely dissect the electroencephalographic (EEG) signal. It provides information on fluctuations in the quantity and strength of cortical activities that are not visually perceived during the inspection of the trace; 3) EEG coherence, defined as the frequency-normalized cross-power spectrum of two signals recorded simultaneously at different scalp locations, is a sensitive method for assessing the integrity of the structural connection between brain areas, describing the temporal, spatial and frequency relationships of brain activities and 4) Visual analysis of the EEG: It relied heavily on waveform recognition, the EEG trace during wakefulness is much less synchronous than during sleep, but more homogeneous. The amplitude of the awake EEG trace in adults varies on average between 10 and 50 microvolt and the frequency of the wave's ranges from 0.3 to 70 Hz.

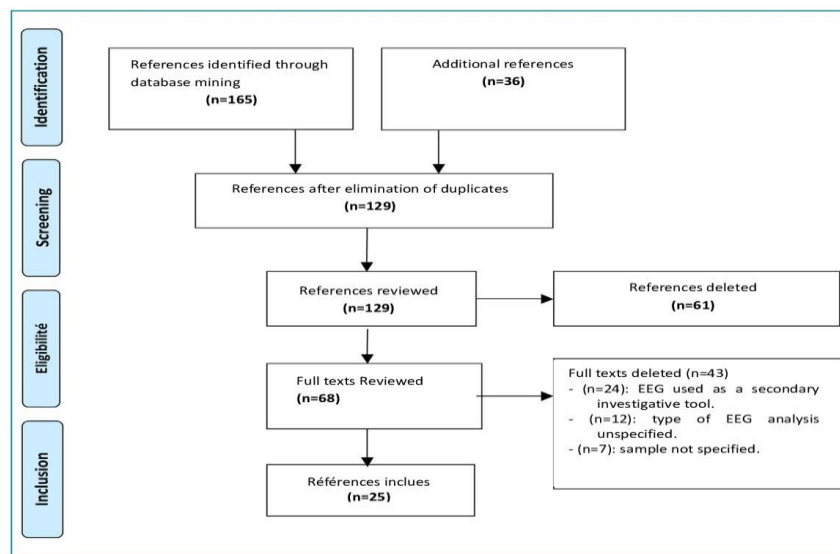

Fig. 1. Flow chart of the search strategy.

III. RESULTS

A. EEG and Substance Addiction

1) *Alcohol*: Several studies have found a more accentuated theta rhythm in alcoholics when compared to corresponding controls, theta power appears higher in the central and parietal regions in male alcoholics, and in the parietal region in female alcoholics[20]. The offspring of alcoholics do not show an increase in resting theta, which suggests that this measurement may signify a state of alcohol dependence [29].

Previous EEG mapping studies have found increased beta power and decreased alpha and delta/theta power in de-addictive alcoholic patients, compared to normal controls. Since slow activity is considered inhibitory, fast beta activity excitatory and alpha activity an expression of normal brain function, the desynchronised low-voltage fast patterns can be translated as CNS hyperexcitation [30], [31].

Opinions as to the cause of these EEG changes in alcoholics show that incoherencies in brain function, particularly in frontal parts of the brain, may be participating in the development of alcoholism [5], [30], [31]. This is documented by a variety of studies: beta activity has been linked to the combination of the two pre-morbid factors of childhood behaviour disorders and paternal alcoholism. [5]. As well as subjects with a positive family history of alcoholism have EEGs characterized by an increase in relative beta power and a reduction in absolute and relative alpha power in both the occipital and frontal regions. Also Hazardous alcohol consumption (HAC) is a pattern of alcohol use that may result in harm for the user and/or for those around them. Prior research has suggested that HAC and alcohol dependence share some neurophysiological features but differ in others, the HAC group presented with higher beta absolute power and relative power, as well as a lower beta mean frequency than the control group, while the group with risk of alcohol dependence presented lower delta absolute power than controls [13]. Therefore, the majority of this research has found that alcoholics are distinct from controls in that their beta power is increased [5], [22].

Furthermore, beta power is faster in relapsing alcoholics than in abstainers[5], which suggests that desynchronised beta activity may be a precious indicator of relapse in abstinent alcoholics. Given that, the augmentation of beta power in abstinent alcoholics is not correlated with the period of abstinence[22] and is also found in children of alcoholics at risk of alcohol addiction[21], the increased beta power is thought to be a marker of vulnerability rather than a trait or state variable (that's to say it may predate the development of alcoholism).

Beta activity has also been used as a predictor of relapse in alcohol addicts. It was found[5] that high-frequency beta activity can significantly distinguish between relapse-prone and abstinence-prone patients. Also, prediction [28] of relapse in chronic alcoholics using quantitative EEG (Q-EEG) was able to successfully classify 83-85% of patients, outperforming most previous efforts to predict relapse rates based on clinical assessments.

The results of some studies [5], and those reported by others, indicate that the value of rapid EEG power in predicting relapse can be generalised to all patients with a history of addiction to alcohol, cocaine, cocaine and alcohol or opioids. In summary, the EEGs of alcoholic patients clearly differ from those of both normal controls and patients with other psychiatric disorders, and the EEG can therefore be used for diagnostic reasons[32]. Therefore, EEG mapping can be used also as an objective method to predict relapse in chronic alcoholism[5].

2) *Nicotine*: A seminal work on smoking [33] reviewed previous research on the effects of smoking on the EEG. The immediate effect of smoking generates an "arousal" or "activation" EEG profile as smoking produces an increase in the beta band (14-30 Hz), an increase or decrease in the alpha band (8-13 Hz), a decrease in the delta (1-4 Hz) and theta (4-8 Hz) bands, and a passage to a higher dominant alpha frequency. EEG topographic representations show important regional spatial distributions and smoking induced changes in brain waves.

The administration of acute nicotine has been related to strong increases in brain activity from low frequencies (delta, theta, lower alpha) to high frequencies (alpha, higher beta), which reflects an excited state [10], [27]. Research has also revealed an increase in craving, a decrease in excitation and a deterioration in mood with a decrease in alpha frequencies during smoking abstinence [27].

Daily smokers had reduced resting delta and alpha EEG power and higher impulsiveness (Barratt Impulsiveness Scale) compared to nondaily smokers and non-smokers. Both daily and nondaily smokers discounted delayed rewards more steeply, reported lower conscientiousness (NEO-FFI), and reported greater disinhibition and experience seeking (Sensation Seeking Scale) than non-smokers. Nondaily smokers reported greater sensory hedonia than nonsmokers. [7].

It is very important to separate the different components of smoking, including psychological and pharmacological, by studying the EEG effects of fake and real smoking of a cigarette of the subject's preferred brand Nicotine-free cigarettes contain other components, such as tar and a very little quantity of nicotine. The inhalation of the fictitious cigarette concerns only the ambient air. EEG theta power was decreased when subjects smoked their cigarette in a telic (excitation avoiding) state. Beta 2 power was elevated when subjects smoked their cigarettes in a paratelic (excitation searching) state.

3) *Cannabis*: Cannabis is the most commonly consumed illicit recreational substance in the world, with an estimated annual prevalence of 3.8 per cent of the adult population having used cannabis in 2021 [34]. At present, cannabis use has been legally established in many countries, both as a recreational and medical drug [35].

Resting-state activity in cannabis users has been characterised as the inverted of typical frequency dynamics, because it reduced delta and augmented theta, beta and gamma

[25]. This neural oscillation tendency is generally observed in task-related EEG signals, indicating that cannabis users presented increased cortical activation, also during the resting state. Similar resting state patterns have been found in heroin users [14], alcohol users [5], [22], and cocaine dependent users [9].

Smoking marijuana cigarettes [6] modify the strength and coherence of the alpha, theta and beta EEG bands. However, very few studies have analysed the influence of cannabis on the high frequency EEG bands, like gamma and high frequency oscillations (HFO) [8]. These oscillations have been related to a wide range of higher cerebral functions such as consciousness, working memory and perception [36].

The association between cannabis use and resting EEG is still ambiguous. Researchers discovered [6] that the theta resting state, with eyes closed, had a correlation with performance on a working memory task after acute cannabis intoxication, reflecting that the resting EEG can be related to cognitive performance. They also found effects in the dose-induced theta and beta bands, suggesting that these particular frequencies could be more sensitive to cannabis-related changes in cortical activity [6].

The relationship between resting EEG with eyes closed in cannabis and alcohol users [11] reported a positive correlation between delta power and cannabis dependence. Other researchers [26] have consistently found an increase in alpha and theta power and a decrease in delta and beta power at rest with eyes closed in long-term cannabis users and that cumulative exposure to marijuana over a very long period of time may be associated with slower cognitive processing; however, other studies have found a decrease in alpha and beta frequencies in posterior regions in abstinent cannabis users [16].

In addition, delta-9-tetrahydrocannabinol (THC) in the acute phase can disturb gamma oscillations via inhibitory interneurons [37]–[39], which suggests that cannabis users may have impaired gamma oscillations. Furthermore, a link between disruption of neuronal γ -band oscillations and cannabinoid-induced psychosis has been reported [8]. These results add to a large literature which proposes some overlapping of the acute effects of cannabinoids with the behavioural and psycho-physiological abnormalities identified in the psychotic diseases.

4) *Cocaine*: Cocaine's effects on human EEG [17] have been described as increasing beta-band activity. This has been repeated in more recent researches with larger sample sizes [4], [9], [19]. Excessive alpha activity and decreased delta activity [4], [7], [19] were observed, however others have found increased beta power [17] in cocaine addicts during resting conditions with eyes closed. Alterations in the EEG, predominantly in the anterior cortical regions, have been found to be associated with the quantity of cocaine previously consumed [19]. The EEG has been widely applied to characterise the effects of withdrawal in cocaine addicts. Many researches have shown that during prolonged cocaine abstinence, EEG effects are characterised by sustained

increases in the alpha and beta bands and decreased activity in the delta and theta bands. [4], [19].

Recently, qEEG profiles [23] have been studied in cocaine addicts in reaction to acute self-administered smoked cocaine (50 mg) versus placebo. Theta, alpha and beta absolute potentials were elevated in prefrontal cortical areas for up to 25 minutes after cocaine use. Increased theta power was related to a positive subjective effect of the drug (high), and elevated alpha was correlated with nervousness. Cocaine also induced a Delta Coherence increase over the prefrontal cortex, which was related to nervousness. The placebo produced only a small alpha power elevation over the prefrontal cortex. These qEEG data reveal the implication of the prefrontal cortex in acute cocaine and suggest that the slow waves of qEEG activity, delta and theta, are implicated in the processes associated with experiencing the gratifying properties of cocaine [23].

The notion of linking baseline EEG activity to cocaine dependence in subjects in treatment programmes shows that cocaine addicts have a durable change in brain function as measured by qEEG, present at baseline assessment 5 to 14 days after the latest report of cocaine use, and persisting at one-month and six-month follow-up assessments [4], [19], [40]. A number of recent QEEG studies have shown an increased beta activity in the EEG to be related to relapse to cocaine abuse [5]. A reduction in the delta and theta bands of the EEG can be interpreted as a strong indicator of brain disturbances.

5) *Heroin*: A limited number of investigations have examined QEEG changes in heroin addicts. In more than 70% of heroin users, changes were seen at the beginning of the abstinence period (acute withdrawal), and they included low-voltage activity in the background with decreased alpha activity, increased beta rhythm, and a large quantity of delta and theta waves of low amplitude in the central regions [18]. Abstinent heroin addicts [14] have increased rapid beta power when compared to normal controls, and this result is consistent with several other EEG findings in cocaine and alcohol users [4], [17], [21]. Most studies have shown considerable, if not complete, normalisation of EEG spectral power in formerly dependent heroin users who have been abstinent for at least three months [9], [18].

Another study on heroin [18] found that heroin users who had been using heroin for at least 18 months showed frequency changes in the fast alpha band at frontal and central sites and a slowdown in the average frequency of slow alpha at central, temporal and posterior recording sites. Acute heroin withdrawal is typically characterised by marked desynchronisation, but as noted above, studies [9], [18] show that EEG spectral power tends to return to near-normal after several weeks of abstinence. The most consistent changes in the EEG of heroin users were observed in the alpha and beta frequencies. In early heroin withdrawal, there was a lack of alpha activity and overactivity in fast beta. This latter abnormality, which can be considered an acute withdrawal effect, appears to be significantly reversed when heroin use is discontinued for several months.

The increased power of beta, alpha and theta rhythms in people with a history of opiate use suggests potential deficits in cognitive function, according to a quantitative study of resting EEG changes after methadone treatment in opiate users [15] suggests that the increased power of beta, alpha and theta rhythms in people with a history of opiate use signals potential deficits in cognitive function. In fact, studies have shown that chronic opioid users are impaired in visual memory, perception, motor function and inhibitory control [41], [42]. However, it seems that these deficiencies are not so severe in patients undergoing methadone maintenance treatment, as their EEG measures are less impaired than those of healthy controls.

IV. DISCUSSION

Electroencephalography (EEG) has revealed for the first time how addiction affects the brain and how it is diagnosed. For example, acute exposure to nicotine is associated with a large increase in scalp activity from lower (Delta, Theta, Low Alpha) to higher (Alpha, High Beta) frequencies, which is indicative of excitement. [10], [27]. Theta power was reduced when the participants in the telic state were smoking, whereas beta 2 power was increased when the participants in the paratelic state were smoking; this finding was only true for men. On the other hand, changes in the beta and theta frequency bands have been shown in EEG studies to be caused by doses of alcohol. In alcohol-dependent subjects, an increase in absolute power was detected at all scalp locations in Beta 1 (12.5-16 Hz) and Beta 2 (16.5-20 Hz), the increase was most pronounced in the central region. Beta 3 (20.5-28 Hz) power increased frontally in alcoholics. Male alcohol dependent subjects had clearly higher beta power in all three bands but Female alcoholics did not show a statistically significant increase. [22].

In the same sense, the augmentation of absolute theta power was also observed in all locations of the scalp in alcohol addict subjects; this increase in theta power was significantly greater in the central and parietal cortex in male alcoholics and in the parietal cortex in female alcoholics. Increased theta power in the EEG may represent an impairment of the central nervous system's information processing capacity in alcoholics [20]. Therefore the EEG of alcoholics differs significantly from those of normal controls, so the EEG can be used for diagnostic purposes. Therefore, the EEG of alcoholics is considerably different from that of normal controls, and the EEG can be used for diagnostic purposes. Furthermore, EEG may also have predictive utility because relapsers differ from abstainers in that they present with significantly more pronounced CNS hyperexcitability [24].

Cannabis users showed increased resting-state cortical activation, reflecting changes in the timing of neural oscillations that may be associated with cognitive impairment in cannabis use [25], with increased alpha and theta power and decreased delta and beta power in long-term cannabis users [26]. Therefore, the impact of THC on theta power and memory performance was correlated. [6].

In the same way, heroin induces: (a) a marked reorganisation of cerebral waves, with an augmentation in the proportion of fast beta and mainly in alpha frequency

segments, (b) Prolonged temporal stabilisation for alpha and beta brainwaves and brief temporal stabilisation for polyrhythmic theta activity, and (c) dominance of the right hemisphere (greater presence of certain spectral characteristics in the EEG channels) than in the left hemisphere [12]. Similarly, there is some evidence that heroin addicts have an increase in relative beta 2 power and an increase in gamma coherence on intra-hemispheric and left hemisphere. In addition, coherence measures have shown significant correlations with clinical variables [14].

Increased absolute and relative alpha power have been seen with quantitative EEG correlates of crack cocaine addiction [4]. Cocaine also markedly increased beta at the front and centre, and increased alpha at the front and temporal parts of the brain. Cocaine produced a similar cortical distribution of increases in EEG beta power to that induced by benzodiazepines and barbiturates. [17]. Cocaine's acute effects [23] produce rapid increases in absolute, alpha and beta-theta power over prefrontal cortical areas (FP1 and FP2) that persist for up to 25 minutes after exposure. Increased theta power was associated with feeling good effect and increased alpha power was associated with nervousness. There is a similar increase of delta coherence measured in the prefrontal lobe, which were a positive correlation with plasma cortisol and a negative correlation with nervousness. These findings provide evidence for the prefrontal cortex being implicated in the qEEG response to the acute administration of cocaine.

EEG measurements may also have a predictive and biomarker role. For example, in the prediction of alcohol and drug abuse relapse, is related to an increase in high frequency beta activity (19.5 to 39.8 Hz) with the coexistence of two pre-morbid factors, paternal alcoholism and the childhood conduct disorder. [5]. This prediction of alcohol relapse was found [28] and it was noted that, compared to abstainers, relapsers had more desynchronised EEGs in frontal regions, which was explained as a prefrontal cortex dysfunction. The elevation in EEG beta power can therefore be seen as a probable risk marker for the development of alcohol addiction and can be considered as an endo-phenotype predictor [21]. This suggests that subjects with a family history of alcohol abuse show alpha decreases and beta over-activity and have reduced relative and absolute alpha power in the posterior (O1; O2) and frontal (F3; F4; Fz) and elevated relative beta in both areas when compared to controls who do not have a family history of alcohol dependence. [13]. EEG recordings are also useful for monitoring the evolution of the addictive state and in case of withdrawal or abstinence.

Grace Y. Wang (2015) [15] examined the electrophysiological activity related with methadone maintenance treatment (MMT) in opiate addicts and found that patients taking MMT or active opiate consumers showed a considerable increase in beta and theta band power compared to controls and that the abnormal electrical activity of the nervous system, which is present in people who are still illegal opiate users, can be reduced after MMT. This increase in beta power was considerably higher in the inpatient groups addicted to alcohol and cocaine and in the 1-6 months abstinent group [9].

A pronounced hyperactivity of alpha relative power and deficits in absolute and relative delta and theta power demonstrate the presence of anomalies in brain function in withdrawal cocaine dependent subjects (not dependent on any other substance), These changes tended to be higher in the anterior than in the posterior cortex, and inter-hemispheric relations were also disrupted [19]. The cumulative evolution of the effect of heroin on brain function shows that a significant desynchronisation is characteristic of acute heroin withdrawal, and there is an almost complete return to normal over several weeks of abstinence, with the mean alpha 1 frequency decreasing, most markedly in the central, temporal and occipital lobe, and frequency changes in the alpha 2 frequency, most pronounced in the frontal and central lobe [18]. This slowing of alpha frequency is similar in smoking cessation [27]

V. CONCLUSION

Although the literature on EEG in addictions is highly heterogeneous, some authors agree that it is a relevant technique for discerning the phenomenology of addictions. EEG is sensitive to how addiction affects the brain and has shown changes in brain electrical activity during addiction. However, the clinical value of EEG recording in addictions is not yet clearly established. However, several studies argue that this non-invasive technique has an undeniable contribution to the understanding, prediction, diagnosis and monitoring of addictions. But future EEG studies are needed to identify other robust brain-electrophysiological specificities in addiction. The collection of more comparative data between EEG findings and clinical changes in addicts could also be useful and be improved by methodological insights.

Abstract—Digital Game-based Learning (DGBL) that attracts many practitioners to engage students in promoting low carbon awareness has been understudied. The evaluation phase plays a crucial part in determining the usability of the learning material. This study aims to identify the usability of DGBL which consists of four components: game usability (GU), mobility (MO), playability (P), and learning contents (LC) from the perspective of targeted end-user using heuristic evaluation. This study will also provide recommendations to help improve the quality of any related DGBL for novice designers or practitioners. A prototype of DGBL was developed which aims to promote low carbon awareness by learning about fuel cell. The study was designed in two phases, which are (1) developing the heuristic evaluation instrument validated by experts and (2) playtesting to identify the issues of usability in DGBL via heuristic evaluation by targeted end-users, which are forty-six selected students aged fourteen years old. Hence, it shows that the DGBL prototype developed for fuel cell learning has succeeded in achieving learning objectives while promoting low carbon awareness.

Keywords—Heuristic evaluation; digital game-based learning; usability; low carbon awareness

I. INTRODUCTION

Digital game-based learning (DGBL) refers to the combination of digital games and educational content because it can create an interesting yet challenging learning environment [1]. The problem with DGBL is that it is complex and often involves multiple components, such as game mechanics, instructional design, and user interfaces. As a result, identifying and addressing usability issues can be challenging [2,3]. Furthermore, DGBL may be used by learners with varying levels of technical proficiency and familiarity with gaming conventions, which can further complicate the usability evaluation process. For example, a game mechanic that is intuitive to one learner may be confusing to another.

Usability can be done in a variety of ways, including thinking aloud, cognitive walkthroughs, laboratory usability testing, questionnaires, and guideline reviews [4]. Heuristics evaluation is one usability evaluation that identifies usability problems based on usability principles or heuristics [5]. However, existing heuristics proved to be very generic and some were not validated [6]. Therefore, the issue for the usability of DGBL using heuristic evaluation is how to effectively apply heuristic evaluation methods to identify and address usability issues in DGBL systems, taking into account the complexity of the system and the diversity of user profiles.

This will enable designers to create more effective and engaging DGBL systems that support learning outcomes.

Digital game-based learning (DGBL) has become a popular choice for younger learners as it can enhance motivation and active learning [7, 8]. DGBL's flexibility and accessibility make it an effective tool for enhancing motivation and learning, which has prompted researchers to investigate its advantages [9]. The use of attractive features such as audio, graphics, and animations in DGBL has proven to be effective in motivating students, especially for complex subjects like science or chemistry [10].

DGBL can also be a powerful strategy for achieving the goals of environmental awareness education, which aims to change the younger generation's mindset toward preserving nature [11,12]. Environmental issues, such as carbon emissions, have caused a significant increase in climate change and have impacted human health due to high levels of industrialization and urbanization [13]. A case study on the impact of a DGBL called "2020 Energy" was carried out that focuses on Spanish and American teenagers aged 12 years old and above aimed to explore issues of climate change [14]. The findings show that the game has a positive influence on the student's intention towards low-carbon activities which is related to the attitudes toward environmental awareness.

Low-carbon technologies such as solar, wind, and fuel cell have increasingly become a priority study in promoting environmental sustainability. Fuel cell technology, particularly which uses hydrogen as fuel, has the potential for zero-carbon emission. This study used a DGBL prototype that has been developed to increase the awareness of secondary students towards low carbon emissions by focusing on fuel cell technology. This study aims to (1) develop a heuristic evaluation using a set of questionnaires validated by experts and (2) identify the issues of usability in DGBL via heuristic evaluation through playtesting by targeted end-users.

In conclusion, DGBL presents challenges in evaluating its usability due to its complexity and diverse user profiles. Heuristic evaluation is a potential method for addressing usability issues in DGBL systems. DGBL is an effective tool for enhancing motivation and learning for younger learners, and it can play a crucial role in environmental awareness education. This study aims to address usability issues in a DGBL prototype focused on fuel cell technology by developing questionnaires validated by experts and applying

heuristic evaluation through playtesting by targeted end-users. By addressing usability issues, designers can create more effective and engaging DGBL systems that support learning outcomes and contribute to environmental sustainability.

II. LITERATURE REVIEW

In this section, related work on the usability of DGBL and Heuristic evaluation will be discussed as the key themes of this study.

A. Usability of DGBL

A good DGBL is capable of encouraging players to learn and enjoy learning content while keeping the players motivated throughout the gameplay [15]. However, to understand the whole gameplay experience, the usability of the DGBL cannot be disregarded. Usability proposes basic requirements for the functionality of an object in use [16] and, in this context, refers to the capability of a DGBL to be understood, learned, operated, and attractive to users when used to achieve the determined goals. Moreover, it can be evaluated through the interface review and user experience using heuristic evaluation [17].

Measuring usability is crucial for any DGBL application, especially in the early stages of development [4, 18]. Several studies on the design of heuristic questionnaires have evaluated usability issues in DGBL areas. One study suggested that the intended end-users may contribute by involving them as co-designers either in the development or evaluation stage [19] as this helps ensure the effectiveness of DGBL. All essential stakeholders in [20], including language experts and targeted students, were involved in the study of the usability of DGBL for language through heuristics and think-aloud approaches. A study that involved end-users in their heuristic evaluation also shows that it has improved the quality of their electronic health record (EHR) [21]. By involving end-users in the usability phase, designers and developers can create a DGBL that is designed with the user in mind. This will help develop a user-centered design that meets the needs and preferences of the target audience.

B. Heuristic Evaluation

Heuristic evaluation was introduced by Nielsen and Molich [22] and consists of usability components to be evaluated in any product such as application software, digital games, or mobile applications but not specifically for DGBL. However, it has become widely researched and has been applied across varieties of disciplines including educational technology. Defining specific domains of heuristics for evaluating the usability of DGBL by upgrading an existing domain of specific heuristics is cost-effective [4]. A set of systematic procedures that include usability evaluation methods that can easily detect usability problems within a limited time frame should also be established [17].

While heuristic evaluation is a useful tool for evaluating the usability of DGBL, it still has some limitations. The number of heuristics used may not cover all aspects of usability in the context of DGBL and more comprehensive heuristics that are specifically tailored to evaluate the usability of DGBL need to be developed. Furthermore, heuristic evaluation is typically

conducted in a controlled laboratory setting, which may not accurately reflect the real-world context in which the DGBL will be used [16]. These limitations can restrain the generalizability of evaluation results and may not fully capture the complexities of user interactions with the DGBL in real-world settings.

Heuristic evaluation involving targeted end users is a usability evaluation approach that involves the direct participation of end users in the evaluation process. This approach is based on the premise that end users are the best judges of usability and can provide more meaningful feedback to improve DGBL [6] in terms of the DGBL interface, navigation, game mechanics, and overall usability [23]. The advantage of involving targeted end users in heuristic evaluation is that they can provide valuable insights into the usability of DGBL from the perspective of the intended audience. By incorporating end user's feedback in the evaluation process, the DGBL can be designed to meet their specific needs and preferences leading to a more effective and engaging learning experience.

III. METHODOLOGY

In this approach, end users were given a set of heuristics or usability principles and identified any usability issues based on these heuristics using the DGBL prototype. All the items proposed for this usability testing use Bahasa Malaysia (the Malay language), which is the national language of the targeted end-users, as the mediated language to make it easier for them to evaluate the usability of the DGBL.

A. Heuristic Evaluation Components

A review of pertinent literature served as the first step toward identifying the required data. In this context, the heuristic evaluation consists of four components that cover all the usability aspects in DGBL, which are Game Usability (GU), Mobility (MO), Playability (PL), and Learning Content (LC) adapted from [24].

The GU component focuses on the interaction between the game design interface and the player's responses through the gameplay. The MO component represents how the player can easily enter the game world without any technical difficulties. The PL component describes the gameplay of the DGBL and includes the player's experience throughout the gameplay session that involves interactions between the players with the game mechanics and rules. The LC component concentrates on the learning content incorporated in the DGBL as the players should understand and acknowledge the specific learning contents when playing the DGBL prototype.

The study was designed in two phases that consist of (1) developing heuristic evaluation using a set of questionnaires validated by experts and (2) playtesting to identify the issues of usability in DGBL via heuristic evaluation by targeted end-user which are forty-six selected students aged fourteen years old. All research processes and procedures for both parts of this study were adapted from [17] as shown in Fig. 1 because it recommends specific and clear instruction from developing heuristic, validation processes by experts until usability testing using the developed heuristic.

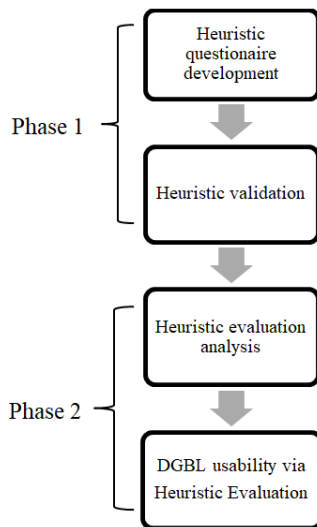

Fig. 1. Heuristic evaluation development process.

B. Phase 1

The first phase consists of developing and validating the heuristic evaluation. A questionnaire was developed that comprises 32 items based on the four components that specifically measure the Game Usability, Mobility, Playability, and Learning content. The questionnaire was rated using a five-point Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree) as recommended by [25] to allow respondents to indicate their level of agreement or disagreement with the items stated.

Next, all the items underwent a series of checking and review from a panel of experts to ensure the validity from the perspective of experts [26]. The expert panel review started with the sending of invitations via e-mail to the identified experts: three authorities from DGBL experts, a game developer, and a schoolteacher specializing in science secondary subject as shown in Table I. These experts, who did not take part in the design or the development of the DGBL, were given a set of heuristic evaluation questionnaires and a set of content validity instruments containing items adapted from [27]. Then, the findings from the panel expert review were calculated to determine the content validity level by dividing the total expert score (x) by the total maximum score (y) and then multiplying by 100%. These items for validation include the checking of the content for correctness in each item in the heuristic evaluation and verifying that the language is well chosen for the intended population.

TABLE I. EXPERTS PROFILE FOR HEURISTIC VALIDATION

Expert	Position	Academic qualification	Affiliation	Years of experiences
A	Associate Professor	PhD	School of Creative Industry Management & Performing Arts, Universiti Utara Malaysia (UUM)	21
B	Game Developer	Bachelor Degree	Nusantara	10
C	Practitioner	Bachelor Degree	SMK Seri Indah	15

C. Phase 2

The second phase involved conducting usability testing on forty-six students aged fourteen years old from selected schools in one state in Malaysia (Selangor) via the final heuristic evaluation. They are selected using purposive sampling with characteristics similar to the target end users. The characteristics of the students include the following: (1) already learned the topic of “air” in science subject taught in secondary school, (2) exhibit extremely high interest in playing mobile games, and (3) with prior experience in playing a game-based learning application at least once.

The Standard Curriculum for Secondary School (KSSM) is a curriculum designed by the Ministry of Education Malaysia for secondary students' comprehensive and integrated science education. Topics on “air” covers the various types of environmental pollution, including air, water, and soil pollution, and the impacts of pollution on human health and the environment [28]. All the students that have been selected participated in a playtesting session using the DGBL prototype to gather feedback on their experience to improve the gameplay, identify any usability issues, and evaluate the overall user experience.

There is no specific playtesting period as they can freely take their time to test and explore the DGBL, then answer the heuristic evaluation through a set of questionnaires given after the playtesting session. This is to ensure that the playtesting session happens in a natural setting without having any formal circumstances [24]. Therefore, evaluating aspects such as game usability, mobility, playability and learning content of the DGBL can be determined by the player’s feedback based on their experience.

IV. RESULTS

A. Heuristic Validation Result

The heuristic evaluation applied in the evaluation process by targeted end users is shown in Table II. The GU component was extended from having 10 items [24] to 14 items based on Expert A’s suggestion to specify the component in more detail.

The LC component was also extended from 4 items to 5 items [24], where LC5 focuses on language as one of the components and aims to evaluate the language used to ascertain whether it is understandable or not by the targeted end-user. This is a very important aspect of usability testing that can show the educational content’s relevance in the DGBL. The content validity scores from the expert panel for all the items in the questionnaire obtained an average of 96.7%, as shown in Table III. The content validity level is considered high when the value is more than 70% which indicates that the items are acceptable [27, 29].

B. Heuristic Evaluation Analysis

Table IV provides the results of the heuristic evaluation. The first component of the evaluation is GU. As seen in Fig. 2, mean = 4.079 (SD = 0.951) indicates all items, except for items 10, 11, and 13 have high mean scores between 4.0 to 4.3. The high value of GU shows that usability in a digital application gives a big impact on the interaction between the interface and the interaction of players throughout the gameplay. Overall, the

respondents are satisfied with the game’s visual graphics, game layout, and suitable audio used in this DGBL. However, respondents reported that there was an issue with using the game controls.

TABLE II. HEURISTIC COMPONENTS

Tag	Game Usability Component
GU1	Interesting game visual graphic
GU2	Suitable audio with the game
GU3	The Screen layout is visually pleasing
GU4	The interface is used for their purposes
GU5	The Navigation menu is easy to use
GU6	Control keys are consistent
GU7	Control keys follow standard conventions
GU8	The Interactive features provided are sufficient
GU9	Game controls are flexible
GU10	Game controls are convenient
GU11	The game gives feedback on the player’s actions
GU12	The player cannot make irreversible errors
GU13	The player does not have to memorize things unnecessarily
GU14	The game contains help
Tag	Mobility Component
MO1	The game and play sessions can be started quickly
MO2	The game accommodates with surroundings
MO3	Interruptions are handled reasonably
Tag	Playability Component
PL1	The game provides clear goals
PL2	The player sees the score progress in the game
PL3	The players are rewarded in the game
PL4	The player is in control of the game
PL5	Challenges in the game are in balance
PL6	The game is fun to be repeated
PL7	The game story is meaningful
PL8	There are no boring tasks
PL9	The game does not stagnate
PL10	The gameplay is consistent
Tag	Learning Content Component
LC1	The content can be learned easily
LC2	The game provides learning content
LC3	The learning objective from the game is achieved
LC4	The content is understandable
LC5	The language used is understandable

TABLE III. CONTENT VALIDITY SCORES

Expert	Total score	Content validity
A	10	100%
B	9	90%
C	10	100%
	Mean	96.7%

TABLE IV. MEAN AND STANDARD DEVIATION OF HEURISTIC COMPONENTS

Statistic	Heuristic Components			
	GU	MO	PL	LC
Mean	4.079	4.036	4.107	4.304
SD	0.951	1.017	0.925	0.782

Fig. 2. Average score of game usability.

Respondents agreed that the MO of this DGBL prototype is high with an overall mean = 4.036 (SD = 1.017) as shown in Fig. 3. This indicates that the player can easily enter the game world without any technical difficulty.

Fig. 3. Average score of mobility.

For the PL component, the relatively high mean = 4.107 (SD = 0.925) in Fig. 4 indicates that the respondents have a good experience throughout the gameplay session that involved interactions between the players with the game mechanics and the game rules. However, some respondents found that the task in bonus round is tedious due to repetition (item PL8 with mean = 3.956).

Fig. 4. Average score of playability.

For the LC components, the result in Fig. 5 shows the highest mean = 4.304 (SD = 0.782) compared to the other heuristic components. The majority of the respondents agreed that they can easily understand and acknowledge the specific fuel cell learning content when playing the DGBL prototype.

Fig. 5. Average score of learning content.

V. DISCUSSION

The expert panel's review findings verified that the language used was appropriate for the intended audience and validated the content's accuracy in each item's heuristic evaluation. The experts also agreed that all the items given are appropriate and can be used to test the usability of DGBL based on the four components stated.

According to the GU component results, the user interface, gaming controls, and user experience all have an impact on how the game plays out. Due to bugs found in the game controls, there are instances where gameplay is not running smoothly. These bugs need to be fixed to avoid the player feeling burdened and dissatisfied throughout the gameplay [23]. Game control is important in DGBL because it helps to create a structured learning experience that is effective in achieving the desired learning outcomes. Game control can also help to increase learner engagement and motivation. By carefully controlling the game mechanics, DGBL designers can create a sense of flow, where the player is completely absorbed in the game and loses track of time [30].

Finding form MO components emphasizes the importance of mobility in enhancing the overall user experience of the game. If the game is difficult to access or requires technical expertise, it can discourage players from engaging with it [24]. On the other hand, if the game is easy to access and play, players are more likely to enjoy the game and be motivated to

continue playing. This highlights the need for designers to prioritize accessibility and ease of use in game development to ensure a positive user experience.

The playability results showed that the respondents enjoyed their gaming session. However, several responders thought the bonus round work was boring because of the repetition. In the bonus stage, as shown in Fig. 6, the players need to drag Platinum, Hydrogen, and Oxygen molecules into the fuel cell. The task focuses on the correct locations of Platinum, Hydrogen, and Oxygen molecules in the fuel cell parts such as electrodes, Anode, or Cathode. The task was designed to be repeated three times in each phase of the bonus stage, where which will help the player to understand and remember the basic concept of the fuel cell. This was also supported by studies where repetitive tasks can help in memorizing as well as increasing understanding of basic knowledge [31, 32]. In order to keep player interest throughout the games, this task needs to be improved, for as by raising the level of difficulty in each bonus stage.

Fig. 6. Screenshot of the bonus stage.

Most of the participants in the survey acknowledged that, after using the DGBL prototype, they could quickly comprehend and acknowledge the particular fuel cell learning content. This is because the learning content itself has gone through a validation process from experts and a focus group test in the design phase of the DGBL. The learning content is also aligned with the players' existing knowledge as supported in Constructivism theory, e.g., the shape of Hydrogen molecules was designed by referring to their KSSM science textbooks used in standard schools (Fig. 7). This concern is supported by other studies where it is important to understand the basic knowledge to help in promoting environmental awareness [12, 33].

Fig. 7. (a) Shape of Hydrogen molecules in the DGBL prototype, (b) Shape of Hydrogen molecules in KSSM science textbooks.

The findings of this study can help improve the design and usability of DGBLs that can better promote low carbon awareness. By developing a set of questionnaires validated by experts and involving targeted end-users in playtesting, DGBL developers can obtain more meaningful feedback on the usability of their products. This can help identify and address usability issues early in the development process, leading to more effective and engaging DGBLs. While each study may focus on different aspects of usability, such as navigation, interaction design, or visual design, the use of heuristic evaluation allows researchers to identify potential issues and make recommendations for improvements. Additionally, the development of specific heuristics for evaluating the usability of DGBLs can provide a cost-effective and efficient way to detect usability problems within a limited time frame.

VI. CONCLUSION AND FUTURE WORK

Heuristic evaluation is an effective method for evaluating the usability of DGBL as this approach involves directly targeting the end user by applying a set of heuristics or guidelines to identify potential usability issues in the DGBL. This ensures that the game is more user-friendly, intuitive, and engaging for the targeted user group. By involving end users in the evaluation process, designers can better understand their needs and preferences, leading to more meaningful improvements to the game.

The heuristic evaluation in this work was adapted and extended for some items to specify the components accordingly. The findings may benefit any novice designer or practitioner in evaluating DGBL usability as this study provides a systematic guideline that can easily be followed. However, researchers and designers need to continue exploring new methods and approach for evaluating DGBL usability, particularly in the context of emerging technologies and changing user needs, to further improve the design and implementation of DGBL systems.

Abstract—Excessive self-weight of bridge inspection vehicles increases the safety risk of the inspected bridge structures. In this study, a bridge inspection vehicle arm structure self-weight optimization design model is proposed to improve the efficiency and safety of bridge structure inspection. The model uses a finite element model of the arm structure to generate force data to validate and train a back propagation (BP) neural network-based self-weight prediction model of the arm structure, and uses an improved genetic algorithm to assist the prediction model in searching for the optimal solution. The experimental results show that the maximum stress and maximum deformation of the optimal solution from the optimization model designed in this study are lower than the allowable values of the material, and the total weight of the structure from the optimal solution is the lowest, 4687.5 kg. The computational time of the optimization model designed in this study is lower than all the comparison models. The experimental data show that the optimized model for the self-weight optimization of the bridge inspection vehicle arm structure designed in this study has good optimization effect and has some application potential.

Keywords—Genetic algorithm; Bridge inspection; Structural optimization; Finite element model; BP neural network

I. INTRODUCTION

Currently, the design of mechanical structures in China is generally completed through manpower, specifically relying on the personal experience and professional knowledge of engineers to complete the preliminary design of products [1-3]. This approach highly relies on the personal abilities of the designer, and the design cycle is long, and the design efficiency is also relatively low [4-6]. For large construction machinery such as excavators and bridge inspection vehicles, in most cases, their structural optimization design goal is to minimize the weight of the structure as much as possible while meeting the stress requirements, thereby improving the operational efficiency of the mechanical structure, saving energy and reducing emissions, and reducing construction risks caused by excessive mechanical self-weight [7-9]. As an important part of transport infrastructure, bridges play an irreplaceable role in maintaining traffic safety and ensuring economic development [10-12]. Periodic inspection and maintenance are essential during the operation of bridges [11-13]. As the main equipment for bridge inspection, the design and optimization of the bridge inspection vehicle arm directly affect the effectiveness and efficiency of bridge inspection [14-16]. With the rapid development of artificial intelligence technology represented

by neural networks, applying artificial intelligence technology to mechanical structure design has become one of the development trends in mechanical structure design [17-19]. Some previous research has attempted this type of method, but there are still some shortcomings, such as insufficient automation of the designed method and the need to incorporate a certain degree of expert experience into the method. The main reason for this phenomenon is that the parameters in mechanical structure design are complex and numerous, and it is difficult to model using a high level of automation. Therefore, this study attempts to combine finite element model analysis with artificial intelligence algorithms to explore a fast and sufficiently accurate lightweight design method for bridge inspection vehicle arm structures, and uses genetic algorithms to assist in searching for the optimal solution in the optimization model. In addition, considering the inherent drawbacks of genetic algorithms such as being prone to falling into local optima and having poor stability in optimization results, this study innovatively improves the selection operator, mutation, and poor probability calculation methods of genetic algorithms, which is also the importance of this study.

II. RELATED WORKS

Various artificial intelligence algorithms, including BP neural network algorithms, have been applied to a variety of industries and mechanical structure optimization design. Wang D et al. found that the traditional tunnel inspection and reconnaissance methods have high workload and high risk factor. Considering the high mobility of micro-rotor UAV, the authors designed an autonomous tunnel reconnaissance UAV incorporating information from multiple sensors such as inertial measurement units, vision and LIDAR, and used convolutional neural networks to optimize the self-weight of the UAV. The test results show that the optimized UAV reduces its self-weight by 15.7% compared to the pre-optimized UAV, which effectively improves the UAV's endurance [20]. The current additive design capability of Patel D's research team could not meet their production requirements well, so they designed an intelligent additive design system using two neural network architectures, and the test found that the system effectively improved the design efficiency of additive materials [21]. Kien DN et al. constructed a structural defect detection method for mechanical components using Alex neural network and tested that the method resulted in an 8.2% improvement in the accuracy of detecting production defects in mechanical structure design [22]. Li Y et al.

*Corresponding Author.

designed a lightweight optimization model for battery structure using radial-based neural network in order to solve the problem of lightweight design of automotive batteries. The experimental results showed that the application of the model reduced the mass of the designed battery pack by 17.62% and the maximum deformation by 30.78% [23]. Fan Y's research team found that the geometry of high-temperature sealed ceramic parts has a significant impact on their compressive resilience performance, so an accurate and large-scale artificial neural network was built to match the relationship between structural parameters and mechanical properties of ZrO_2 parts fabricated through 3D printing. The prediction results show that the combination of artificial neural network and finite element is a better method to optimize the structure and guide the 3D printing method to fabricate complex ceramic parts [24]. Han X et al. proposed a fast, efficient and convenient method to optimize the shape design of centrifugal pump impeller and worm housing by combining genetic algorithm and back propagation neural network. The experimental results showed that the optimized impeller increased the head and efficiency by 7.69% and 4.74%, respectively, at the design flow conditions, while the optimized power was reduced by 2.56%. The hydrostatic pressure across the optimized impeller is more uniform, and the hydraulic performance of the centrifugal pump with the optimized impeller exceeds that of the original centrifugal pump at low and design flow conditions [25]. To AC et al. proposed a new topological optimization method that uses a neural style to simultaneously optimize the mechanical structural performance and geometric similarity of the reference design for a given load condition; this method pre-trains the convolutional layers of the neural network and extracts the geometric similarity. This method also pre-trains the convolutional layers of the neural network and extracts quantitative features from the reference and input data to perform structural optimization. Test results show that the use of this method to optimize the design of mechanical components resulted in the production of components with a 16.7% reduction in dead weight with only a 2.82% increase in maximum stress [26].

In summary, experts in artificial intelligence and mechanical design have conducted extensive research to analyze the possibility and effectiveness of using intelligent algorithms for automatic design of mechanical components. The ideas behind designing these methods may have some inspiration for this study, which is also the connection between this study and previous studies. However, there are still some shortcomings in previous studies, such as insufficient automation of design methods, a certain degree of expert experience still needs to be incorporated into the method. At the same time, the application of this approach to the lightweight design of bridge inspection vehicle structures in previous studies is quite rare. At the same time, the automatic lightweight design of bridge inspection vehicle structures is of great significance in improving the work efficiency of bridge inspection vehicles, saving operating energy consumption, and even reducing the possibility of potential accidents caused by excessive self-weight of inspection vehicles. This is the

purpose or objective result of this study. The research may provide some improvement suggestions for the design and manufacturing of future bridge inspection vehicles, which is the impact of this study on the future.

III. MODEL DESIGN FOR WEIGHT OPTIMIZATION OF TRUSS BRIDGE INSPECTION VEHICLE ARM STRUCTURE

A. Finite Element Modeling of the Structure of the Inspection Arm of the Truss-type Bridge Inspection Vehicle

In order to optimize the arm structure of the inspection vehicle, the arm structure needs to be abstracted and modeled first, specifically by establishing its finite element model, in order to remove elements that have no or little influence on the optimization problem and highlight the computational elements that determine the structural optimization results [27]. The loading arm system of truss bridge inspection vehicle consists of gear slewing structure, telescopic working platform, inner and outer working platform, vertical lifting tower and lower slewing truss. The truss bridge inspection vehicle, which is commonly used in bridge construction projects, was selected as the object of this study, and the dimensions of the components to be optimized in its design structure are shown in Fig. 1.

In the optimization problem of truss bridge inspection vehicle arm structure, since the total length of the inner and outer telescopic working platform of the arm truss and the parameters of the lowering depth of the lift tower are determined through the working conditions, it is more reasonable to choose the constructed interface size as a design variable here. Specifically, the sheet thickness and profile dimensions of the interface are selected as design variables. Here, the design variables are first treated as continuous variables to solve the optimization problem, and then the values of the optimal solution are rounded to obtain the appropriate discrete values according to the actual situation. The distribution of design variables of interface dimensions for each type of carriage arm truss rod is shown in Fig. 2.

Fig. 1. Common truss bridge inspection vehicle core structure dimensions.

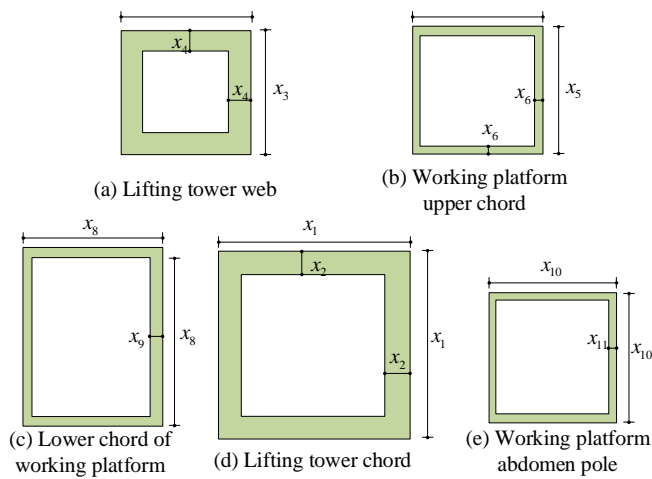

Fig. 2. Distribution of design variables of the arm section of truss bridge inspection vehicle.

The specific meaning of each section design variable, the range of variables, and the initial value of each section design variable of the truss bridge inspection vehicle arm truss in Fig. 2 are shown in Table I. The value range of each variable in Table I is obtained by referring to the corresponding design range of truss bridge inspection truck arm trusses in the industry, and the respective initial values are determined according to the most common values of the same type of products on the market.

TABLE I. DESIGN VARIABLE SPECIFIC INFORMATION DISPLAY TABLE

Parameter number	Variable Symbols	Initial Value	Value range/mm	Variable Meaning
*01	x_1	82	[60,90]	Lifting tower chord cross-sectional dimensions
*02	x_2	11	[5,15]	Cross-sectional material thickness of lift tower stringers
*03	x_3	50	[40,60]	Lifting tower web cross section size
*04	x_4	7	[5,17]	Lifting tower web material thickness
*05	x_5	50	[45,60]	Cross-sectional dimensions of stringers on workbench
*06	x_6	3	[1,8]	Material thickness of stringers on the workbench
*07	x_7	67	[42,75]	Cross-sectional dimensions of the lower chord of the working table
*08	x_8	22	[10,33]	Cross-sectional dimensions of the lower chord of the working table
*09	x_9	5	[2,10]	Material thickness of the lower chord of the working table
*10	x_{10}	45	[25,60]	Cross-sectional dimensions of the lower web of the working table
*11	x_{11}	2.5	[1,8]	Thickness of material of lower web bar of worktable

Considering all kinds of possible working conditions of the inspection vehicle, the most dangerous working condition was selected to carry out the study, i.e. the working condition when the vertical lift tower descends to the lowest position. In this case, the vertical relationship between the telescopic inspection platform and the bridge is vertical, the load borne by the inspection vehicle is 300 M/kg, and the safety factor is 1.5 according to industry regulations.

The parametric model of the truss structure of the inspection vehicle is designed again below. Considering the actual structure of the inspection vehicle arm, it is stipulated that the contact points between the guiding and positioning rollers and the lift tower flange plate are connected by fixed constraints, and the upper and lower end plates of the arm structure are connected by using the gears and bolts of the slewing structure. Although the rotating truss is also connected to the slewing structure and the inner and outer table lap joints using bolts, this part of the modeling is too complex and will significantly increase the number of finite element units and nodes, so the connection structure is ignored and the connection between them is considered as direct coupling. Using the established finite element model to carry out structural statistics and static calculations, it was found that the total mass of the model was 5519.48 kg, and the maximum equivalent stress of the structure was 250.4 MPa, which appeared at the bolt hole of the lower end plate of the rotary structure, while the stress at other locations was much smaller than this value. The strength requirement is satisfied. The maximum displacement of the structure is 98.58mm in the vertical direction of the arm truss, which also meets the structural requirements.

B. Mapping Relationship Model and Mathematical Model Design for Structure Optimization

The computational efficiency of using manual debugging of design variables and then running the finite element model to calculate the optimization target values is particularly low. Therefore, this study uses a BP neural network to construct a mapping relationship between the structural design variables and the optimization objective, i.e., the structural weight of the arm, in order to achieve the goal of fast optimization. The reason for using BP neural network instead of other more complex and advanced neural network algorithms to construct the mapping relationship model is that the target problem in this study is not complicated in terms of features and does not require repeated and high-latitude abstraction extraction, which would substantially increase the computational and training time of the mapping model. And it is difficult to provide a large number of data samples that can make the latter training effective in this study. Before building the mapping model, it is also necessary to select a suitable training sample set. Now, we choose to use the orthogonal test method to obtain the sample data because it generates data samples with neat comparability and balanced distribution, i.e., it is possible to obtain a data set with as complete a distribution as possible with fewer samples.

The orthogonal table $L_{50}(5^{11})$ is chosen to obtain the training samples, which contains 5 levels, 50 samples and 11 design factors, as shown in Table II. As shown in Table II, the truss self-weight, maximum deformation and maximum equivalent

force of the model structure are taken as the output in turn, and the required calculation results can be quickly generated by using the finite element model of the inspection vehicle arm.

TABLE II. $L_{50}(S^{11})$ ORTHOGONAL TEST DETAILS

Design Variables	Level 1	Level 2	Level 3	Level 4	Level 5
x_1	81	82	84	85	88
x_2	10	11	12	13	14
x_3	49	51	54	55	57
x_4	8	10	11	12	13
x_5	49	51	55	57	59
x_6	3.0	3.5	4.0	4.5	5.0
x_7	61	62	64	65	68
x_8	21	22	25	27	29
x_9	4.0	4.5	5.0	6.0	6.5
x_{10}	43	44	47	48	51
x_{11}	3.0	3.5	4.0	4.5	5.0

Therefore, the size of the designed BP neural network input data is fixed to 11×50 , and the output is the maximum equivalent force and overall mass of the model. Since some of the design variables vary greatly in order of magnitude and may even be out of oversaturation, thus slowing down the convergence or even failing to complete the convergence, the input data need to continue the normalization process. The BP neural network in the mapping model adopts the classical four-layer organization structure, and after several debugging, each layer is substituted with S-type tangent function, S-type logarithmic function, and pure linear function as the transfer function in turn.

The mapping model can be used to quickly calculate the predicted optimization results of the opposing structural solution for the input design variables, but the output value is not the global optimal solution. Therefore, it is also necessary to perform an optimization search operation on the neural network mapping model. The following is a mathematical model of structural optimization required for the optimization search process.

The optimization objective of the mathematical model is to minimize the total weight of the structure while satisfying all the constraints, so as to achieve the effect of improving the efficiency of the drive system and the whole vehicle. Therefore, the objective function and constraints of the structure optimization mathematical model of the detection vehicle are shown in formula (1) and (2), respectively, by calling the three trained BP neural network implicit functions.

$$\min f(x) = \text{sim}(\text{net } G, x) \quad (1)$$

$$\begin{cases} \sigma = \text{sim}(\text{net } S, x) < [\sigma] \\ f = \text{sim}(\text{net } f, x) < [f] \end{cases} \quad (2)$$

In formula (1), $f(x)$ and $\text{net } G$ are the self-weight function and auto-implicit function of truss respectively, the former is calculated by finite element model and the latter is obtained by BP mapping network training; in formula (2), σ and f are structural stress and vertical displacement respectively, $[\sigma]$ and $[f]$ are allowable stress and allowable stiffness respectively, $\text{net } S$ and $\text{net } f$ are structural stress implicit function and vertical maximum displacement implicit function respectively. The input data x satisfy the relationship of formula (3).

$$x \in X = [x_1, x_2, \dots, x_{11}]^T \quad (3)$$

C. Design of Optimization Model Solving Method Based on Improved Genetic Algorithm

Genetic algorithm is an optimization algorithm designed after biological genetic rules, which has excellent adaptive ability and large solution set coverage, so it is widely used in solving various complex optimization problems. This time, genetic algorithm is also chosen as the mapping model optimization method, but the traditional genetic algorithm has the following disadvantages. Firstly, the traditional genetic algorithm population initialization is carried out randomly, which may make the mapping model miss the optimal solution, secondly, due to the complex computational content of the mathematical model for structural optimization of the detection vehicle, it will lead to slow convergence of the algorithm, and finally, the traditional genetic algorithm also has the problem that it may fall into local convergence. To alleviate these problems, this study improves the traditional genetic optimization algorithm in many aspects, and the improvement process will be analyzed in detail below.

In the iterative process of genetic algorithm, variation probability and crossover probability play a significant role in the calculation results of the algorithm, and it is necessary to optimize these two parameters because they may even directly lead to the failure of optimization if they are not set properly. In classical genetic algorithms, the variation probability and crossover probability change with the increase of iterations, thus increasing the genetic diversity of the population and reducing the possibility of falling into local optimum. For the classical genetic algorithm, when the fitness of an individual is greater than the average fitness of the population, it means that it is a good individual, and the corresponding variation and crossover probabilities are both a small value, making it easier to save to the next generation. On the contrary, it means that the current individual is a poor adaptor, and its variation and crossover probability are larger values, aiming to improve the quality of its offspring. However, if the individual fitness is equal to the maximum fitness of the population, the corresponding two probability metrics will be reduced to 0. Although this internal regulation model is more reasonable in the later stages of the iteration, when the majority of individuals in the population are excellent and the impact of variation adjustment should be minimized. However, in other stages of the iteration, this approach makes the evolution and convergence process too slow, and this is the optimal individual may not be the global optimum. To address the

drawbacks of this adaptive adjustment, previous work has improved the calculation of the crossover probability P_c and the variance probability P_m , as in formulas (4) and (5).

$$P_c = \begin{cases} P_{c1} - \frac{(P_{c1} - P_{c2})(f' - f_{avg})}{f_{max} - f_{avg}}, & f' \geq f_{avg} \\ P_{c1}, & f' < f_{avg} \end{cases} \quad (4)$$

$$P_m = \begin{cases} P_{m1} - \frac{(P_{m1} - P_{m2})(f_{max} - f)}{f_{max} - f_{avg}}, & f' \geq f_{avg} \\ P_{m1}, & f' < f_{avg} \end{cases} \quad (5)$$

In formulas (4) and (5), P_{c1} , P_{c2} , P_{m1} , and P_{m2} are the parameters to be set, and f' , f_{avg} , and f_{max} represent the fitness values of the individuals to be mutated, the average fitness of the population, and the maximum fitness, respectively. This improved calculation method uses an elite retention strategy, which protects the best individuals in each generation. However, the parameter of the number of iterations of the population needs to be added to ensure that the two probabilities will change dynamically, so this study adjusts the calculation of the crossover probability and the variation probability to formulas (6) and (7).

$$P_c = \begin{cases} P_{c1} \left(1 - \cos^2 \left(\frac{f' - f_{avg}}{f_{max} - f_{avg} + \lambda} - 1 - \frac{\pi}{2} \right) \right), & f' \geq f_{avg} \\ P_{c1}, & f' < f_{avg} \end{cases} \quad (1)$$

$$P_m = \begin{cases} \frac{1}{\sqrt{n}} P_{m1} - \left(1 - \cos^2 \left(\frac{f_{max} - f}{f_{max} - f_{avg} + \lambda} - 1 - \frac{\pi}{2} \right) \right), & f' \geq f_{avg} \\ \frac{1}{\sqrt{n}} P_{m1}, & f' < f_{avg} \end{cases} \quad (2)$$

In formulas (6) and (7) λ is a very small positive number, which is added to prevent the occurrence of a situation in the population where the average fitness is equal to the maximum fitness. n , for the number of iterations, the two probabilities are combined with the number of iterations and the trigonometric function, so that they satisfy both non-zero and changeable with the fitness to avoid the situation of falling into local optimum. The selection operation is an indicator to judge whether an individual can be inherited or not. In the optimization problem of this study, the size of the adaptation degree of the optimized solution is closely related to its total structural weight, which means that when the total structural weight is too large, the corresponding solution should be eliminated. For this characteristic, elite retention and roulette selection methods can be chosen to screen genes. The roulette selection strategy allows individuals with greater fitness to be preferentially selected for inheritance to the next generation, facilitating the process of optimization and iteration, which is more common and will not be repeated here. The elite selection

strategy can make the better individuals not be destroyed by the hybridization strategy, so the elite selection strategy is chosen as the selection operator of the algorithm. The specific treatment of the elite selection strategy is that when the best individual appears in the population, it is directly copied to the next generation and the subsequent steps are skipped.

The mutation operation serves to increase the genetic richness of the population and prevent the algorithm from early convergence. For the characteristics of the inspection vehicle arm structure weight optimization problem, the mutation operation was chosen to be carried out in this genetic algorithm using the inversion mutation method. The specific processing method is shown in Fig. 3.

However, the disadvantage of this mutation algorithm is that there is no way to know whether the mutated chromosome is superior to the parent, and if the mutated chromosome becomes worse instead, it will instead increase the possibility of local convergence of the algorithm. To avoid this situation, the validity of this mutation needs to be judged after the inversion mutation operation is finished. Here, we choose to use fitness as an indicator to judge the level of chromosomal excellence of the offspring. If the judgment result shows that the chromosome fitness of the offspring is smaller than that of the parent, the mutation operation is deleted, and the result is accepted on the contrary. The improved genetic algorithm was designed by combining the above improved results, and its computational process is shown in Fig. 4. As shown in Fig. 4, firstly, the mapping model based on BP neural network was input into the algorithm, and then the binary coding method was applied to encode the parameters of the improved genetic algorithm, in which several populations were randomly generated, and the fitness function was used to calculate the genetic probability of each individual. Before carrying out the chromosome crossover mutation operation, it is necessary to retain a few good individuals according to the elite strategy, and then judge whether the current operation is inbred, because if it is inbred, it will bring serious adverse effects to the optimization results. If the judgment result is "yes", reselect the operation object and judge again. If the answer is "no", crossover and mutation operations are performed on all individuals according to formulas (6) and (7) to generate new offspring, and finally determine whether the current population and algorithm parameters meet the stop iteration condition, and if so, stop the iteration and output the optimal individual, i.e., the optimal detection vehicle arm structure optimization scheme, and if not, return to the calculation of genetic probability. Step to continue running the algorithm.

This completes the design of the optimized model for the weight of the arm structure of the truss bridge inspection vehicle.

IV. OPTIMIZE MODEL PERFORMANCE TESTING

In order to verify the effect of the optimization method designed in this study on the optimization of the bridge inspection vehicle arm structure, the optimization model designed was implemented using Python language, and its input interface with the finite element model calculation data was built. After several tests and adjustments, the experimental BP neural network model was selected from Trainlm learning method, the maximum number of training steps was fixed to 1000, and the target error was set to 1×10^{-10} . At the same time, the Faster-Regions with CNN features (Faster-RCNN) neural network algorithm, which is widely used in current application scenarios and has excellent performance, was selected to form a comparison model, and finally The following four optimization model schemes are formed: classical genetic algorithm + BP neural network, improved genetic algorithm + BP neural network, classical genetic algorithm + Faster-RCNN neural network, improved genetic algorithm + Faster-RCNN neural network, hereinafter referred to as CGA+BP, IGA+BP, CGA+FRCNN, IGA+FRCNN, respectively.

In order to verify the reasonableness of using neural network algorithm instead of finite element model, after constructing and training the mapping model based on BP and Faster-RCNN, five groups of data different from the training samples were randomly selected to carry out the simulation test, and the test results are shown in Fig. 5. The horizontal axis in Fig. 5 shows each prediction model and the prediction index of the output, the left vertical axis represents the total structural self-weight of the output of various models, and the right

vertical axis represents the maximum structural stress of the output of each model. The right vertical axis represents the maximum structural stress output of each model, and the data with percent sign in the figure is the absolute value of the relative error of the output value of the prediction model relative to the output value of the finite element model. As can be seen in Fig. 5, the predicted mean structural dead weight and maximum structural stress of the predictive models based on BP neural network and Faster-RCNN for the five groups of test design variables are 5164.8 kg, 5170.4 kg, 223.63 MPa, 223.95 MPa, and 0.81%, 0.92%, 1.62%, 1.48% respectively. It can be seen that the absolute values of the average relative errors are within the allowed range (less than 5%), indicating that the two selected prediction models can be used. Although the relative error of the structure maximum self-weight prediction value of the Faster-RCNN-based prognostic model is smaller than that of the BP network-based one, the fluctuation of the former prediction is significantly larger, so it is reasonable to select the BP algorithm to construct the prognostic model.

The following analysis of the BP and Faster-RCNN neural network training process in the structural optimization model is shown in Fig. 6. The horizontal axis is the number of model iterations and the vertical axis is the value of the loss function, with different line shapes representing different optimization models. Since the loss function decreases extremely fast in the early stage of model training, the vertical axis is shown in segments. The loss function values after convergence of the two models IGA+BP and IGA+FRCNN constructed using the improved genetic algorithm are significantly lower than those of the other two models, and the former is higher than the latter, at 1.52 and 3.15, respectively, indicating that the global search capability of the algorithm is indeed significantly enhanced after improving the genetic algorithm along the lines of this study. From the perspective of the number of iterations, the model using BP neural network converged significantly faster than the model using Faster-RCNN neural network, for example, IGA+BP and IGA+FRCNN converged after 91 and 169 iterations, respectively.

Fig. 5. Comparison of the prediction results of the prediction models.

Fig. 6. Comparison of the training process of each optimization model.

In the following, the calculation results of the optimal solution parameters output from each model corresponding to the circular integer value scheme are compared again, as shown in Table III. Observing Table III, it can be seen that after the calculation and processing of each optimization model, some of the design variables of the four optimal integer solutions derived have increased compared to the initial values, but most of the design variables have a significant decrease. From the perspective of maximum stress and maximum deformation, the IGA+FRCNN model is the smallest with 213.9 MPa and 74.64 mm, respectively, followed by the IGA+B0P model with 219.50 MPa and 79.31 mm, respectively. But the maximum stress and maximum deformation of the optimal integer solutions of all the optimized models are smaller than the initial design values and lower than the allowable values. From the perspective of measuring the total structural weight of the measuring arm, the IGA+B0P model has the lowest total structural weight of 4687.5 kg.

Finally, the computational efficiency of each optimization model is analyzed, so different groups of design variables are input and the statistics are obtained in Fig. 7. The horizontal axis in Fig. 7 represents the number of groups of design variables processed by the model consecutively, and the vertical axis represents the total computational time spent. Different curve types represent different optimization models, and the gray vertical lines are auxiliary lines. As can be seen in Fig. 7, the computational time of the model incorporating the FRCNN algorithm is significantly more than that of the model constructed based on the BP algorithm, mainly because the former has a complex structure and more computational levels. Also the computation time of the model using the improved genetic algorithm is significantly lower than that of the model using the same prediction algorithm but without the improved genetic algorithm. For example, when the number of groups of variables with computation is 50, the computation time of each scheme of CGA+BP, IGA+BP, CGA+FRCNN, and IGA+FRCNN is 5.88s, 4.62s, 10.24s, and 9.57s, respectively.

To further compare and study the designed methods, a bridge inspection vehicle optimization method based on incremental algorithm is designed here, and the parameters in

the algorithm are determined through multiple debugging methods. The data obtained from the experiment is relatively simple, and it is described in text here. According to the statistical experimental data, it was found that the optimal structural parameters optimized by the IGA+BP model designed in this study still have lower self-weight than the incremental algorithm, indicating that the optimization effect of the latter is worse than that of the former.

TABLE III. COMPARISON OF OPTIMAL INTEGER SOLUTIONS FOR EACH OPTIMIZATION MODEL

Name	Initial design value	CGA+BP	IGA+BP	CGA+FRCNN	IGA+FRCNN
x_1 /mm	82	74	67	71	69
x_2 /mm	11.00	6.00	6.00	6.00	6.00
x_3 /mm	50	61	58	60	59
x_4 /mm	7.00	7.50	6.50	7.00	6.50
x_5 /mm	50	56	58	58	60
x_6 /mm	3.00	2.50	2.00	2.50	2.50
x_7 /mm	67	52	50	52	50
x_8 /mm	22	16	15	15	16
x_9 /mm	5.00	4.50	4.00	5.00	4.50
x_{10} /mm	45	54	60	62	60
x_{11} /mm	2.50	3.50	4.00	4.00	4.00
Maximum stress/MPa	250.48	227.1	219.50	224.8	213.9
Maximum deformation/mm	101.36	96.49	79.31	87.15	74.64
Self-weight/kg	5574.2	5271.0	4687.5	5188.3	4962.3

Fig. 7. Comparison of the computational efficiency of each optimization model.

In summary, the difference between the self-weight and maximum structural stress of the inspection vehicle designed in this study using neural networks instead of the finite element model output and the finite element model is less than 2%. In the engineering application environment of bridge inspection vehicles, this degree of error can be considered more accurate. The main reason for this situation is that neural networks have strong nonlinear relationship search and extraction capabilities, and there is indeed a complex nonlinear mapping relationship between the structural parameters of the bridge inspection vehicle and the corresponding structural self-weight and maximum stress. From the perspective of algorithm training speed, the IGA+BP model designed in this study has a slightly faster training speed than the comparison algorithm, because the BP neural network that makes up the algorithm itself is a three-layer structure, and the parameters to be optimized and the number of samples required for training are smaller than neural network algorithms such as Fast-RCNN. From the optimized parameter results, it can be seen that the optimal solution output by the design algorithm in this study corresponds to a significantly smaller self-weight than other algorithms, and the maximum stress and strain of the structure has not significantly increased compared to other methods, indicating that this method has certain application value in optimizing the structural parameters of bridge inspection vehicles.

V. CONCLUSION

In order to reduce the self-weight of the bridge inspection vehicle boom structure, this study designed an improved genetic algorithm and built an intelligent optimization model of the inspection vehicle boom structure by combining the BP neural network prediction model and the finite element model. The simulation experimental results show that the prediction value of the output of the test design variables from the prediction model constructed based on BP and Faster-RCNN neural network is less than 5% relative error to the calculation result of the finite element model, and can be used for the prediction model. The values of loss functions after convergence of the two models constructed using improved genetic algorithm, IGA+BP and IGA+FRCNN, are significantly lower than the other two models, and the former is higher than the latter with 1.52 and 3.15, respectively. Analysis of the optimal integer solutions of each optimized model reveals that the IGA+FRCNN model is the smallest in terms of maximum stress and maximum deformation, with 213.9 MPa and The maximum stress and maximum deformation of the IGA+FRCNN model are 213.9 MPa and 74.64 mm, respectively, followed by the IGA+BOP model with 219.50 MPa and 79.31 mm, respectively, which are lower than the allowable values of the material. From the perspective of measuring the total structural weight of the measuring arm, the IGA+BOP model has the lowest total structural weight of 4687.5 kg. Also the computation time of the model using the improved genetic algorithm is significantly lower than that of the model using the same prediction algorithm but without the improved genetic algorithm. When the number of groups with computational variables is 50, the computation time of CGA+BP, IGA+BP, CGA+FRCNN, IGA+ The computation time of each scheme is 5.88 s, 4.62 s, 10.24 s, and 9.57 s,

respectively. It can be seen that the optimization model designed this time can obtain better self-weight optimization results of the bridge inspection vehicle arm structure quickly. However, the optimization effect of the model on other uncommon types of bridge inspection vehicles was not analyzed in the study, and this part will be added in the subsequent study.

A Real-Time Automated Visual Inspection System for Printed Circuit Boards Missing Footprints Detection

Xiaoda Cao*

Laboratory Management Department, Northeast Agricultural University, Harbin, Heilongjiang, 150030, China

Abstract—Visual inspection systems (VIS) are vital for recognizing and assessing parts in mass-produced products at the fabricating lines. In the past, item review was carried out physically, which made finding imperfections repetitive, moderate, and prone to error. VIS may be a strategy to abbreviate preparing times, boost item quality, and increment fabricating competitiveness. For the reason of reviewing lost components on uncovered printed circuit sheets, a visual inspection framework is required. The assessment assignment has become more challenging to accomplish the specified quality due to the more compact and complex surface of structured electronic components. This study proposes a real-time visual inspection system to assess lost impressions on Printed Circuit Boards (PCB). This system is composed of hardware and software frameworks. The main contribution of this study is the proposed software framework. The software framework consists of components region analysis and missing detection using image processing, cross-correlation, and production rules. Experimental results show the viability and achievability of the proposed system for PCB missing component detection.

Keywords—Automated visual inspection; Printed Circuit Boards (PCB); quality control; image processing

I. INTRODUCTION

Printed circuit boards (PCBs) are a pillar of the electronic manufacturing sector [1,10]. The process of PCB inspection is challenging to perform manually because the surface of electronic goods is increasingly compact and complicated. This makes it harder for electronic boards to achieve quality control on the final products. The AVIS is the answer to boosting productivity and avoiding the challenges of manual inspection and mostly used in smart manufacturing [2,11]. Although many studies have been done on PCBs inspection, the issue of missing footprints has received less attention. When a "Printed Circuit Board" is created and released onto the market, the consumer of the board needs footprints (component shapes) in order to locate the location of the electronic component on the board [3,7].

The methods of human-based inspection for finding flaws depend on the expertise of the inspectors utilizing conventional tools, which makes finding flaws tedious, sluggish, and prone to mistakes [12]. This study thus concentrated on PCB footprint verification utilizing machine vision in the production line. These footprints are categorized by the AVIS utilizing a rule-based classifier and a machine vision system based on print quality [1,8]. As the global marketplace demands more

emphasis on quality, automated visual inspection of industrial items for quality control plays an increasingly important role in the manufacturing process [2,9]. Most of the time, people still do visual examinations for quality purposes. However, human-based inspection suffers from many challenges: low inspection speed and accuracy fluctuations.

This study presents an automatic visual inspection system for PCB missing component detection. This work is based on pure image processing algorithms which provide efficient and less computation cost techniques to represent and detect faulty PCB products. The categorization of fault types is done using a proposed production rule. Additionally, the finished footprints on the PCB are identified using Template matching.

In following section, related works are reviewed in Section II. The proposed method describes in Section III. Section IV presents the experimental result. Finally, the paper concludes in Section V.

II. RELATED WORKS

This section presents related works on automated visual inspection systems in the PCB quality control process.

Wu et al. [1] developed a method for automatic visual examination based on characteristics of solder connections on PCBs, such as their location, shape, and logical aspects. The suggested technique may be used to identify various PCB defects, including no solder, surplus solder, incorrect or missing components, and damaged components. The characteristics will be retrieved based on several locations and the geometry of the solder connections once the solder joints have been localized. From solder junctions, they obtain occupancy ratios for the area, color, center of gravity, and continuous pixels. The logical features are recovered by examining the tight relationships between form, location, and colour dispersing factors.

Matsushima et al. [2] proposed a neural network-based visual inspection solution for PCB solder connections. For the learning and inspection phases, input data characteristics are retrieved using principal component analysis (PCA). The camera angles and the light source determine the circumstances for capturing images. There are two phases in a neural network visual inspection system: learning and inspection. In the learning phase, the neural network system produces two outputs, the defect degree and the good degree of the sample, based on the inputs retrieved from a good or defective sample.

The neural network's input for the learning phase is the Principle Component Analysis (PCA) generated as a feature from the sample pictures.

After placing wet solder paste on a printed circuit board, Zhang et al. [3] created a real-time visual assessment method of the solder paste quality. In this approach, the extraction of the region of interest, which includes the solder paste and pad regions, begins with a segmentation procedure. The categorization of five kinds of solder pastes as Good, Excess, Insufficient, Horizontal displacement, and Vertical displacement is then performed using a neural network algorithm.

Brunetti et al. [4] proposed a solder connection flaw detection system using automatic optical inspection (AOI) for PCBs produced using the surface mounting method (SMT). The neural network technique solves this diagnostic as a pattern recognition issue. The pictures are obtained using horizontal, vertical, and correlation coefficients. Each region of interest is assessed using three different types of feature vectors: geometric features (G-feature), wavelet features (W-feature), and the combination of the two features (GW-feature). According to their experiment, the best recognition rate was attained using a Multi-Layer Perceptron (MLP) network and GW features.

Lin et al. [5] developed a method to inspect printed circuit boards more quickly and accurately. The inspection process consists of two steps. Only one image characteristic is abstracted from the picture in the first step, and it is utilized as a screening index to filter out most typical components quickly. The neural network is then used as a classifier along with picture indices such as the histogram index, correlation coefficient, high contrast index, and regional index.

III. PROPOSED SYSTEM

The architecture of the systems that are suggested in our study is shown.

A. Hardware Framework

Fig. 1 shows the hardware framework's organizational structure. It incorporates the web camera used for picture

acquisition, a conveyor belt, a light source, and a laptop system with image processing software.

The AVIS framework aims to classify the footprints into complete and incomplete shapes related to LED, Resistor, IC, Capacitor, and Transistor footprints. The specific algorithms are detailed in the paragraphs that follow. The camera, light source, and conveyor belt, which make up the three main parts of our real-time imaging system, are calibrated in simulated settings. Fig. 2 depicts the hardware for the suggested AVIS model and is explained in the following subsections.

As shown in Fig. 3, a webcam is used to capture images. The PCBs are moved along the conveyor belt at the chosen pace and in the desired direction, from left to right, simulating a true industrial setting. The stand is used to secure the camera to the conveyor belt and allows for up-and-down movement of the webcam. Additionally, the camera is fixed to a pedestal and is positioned in the middle of the conveyor belt. The webcam is best positioned in the center to catch the PCBs as they go along the conveyor belt. The actual capture of the picture, segmentation, and classification are done on the computer.

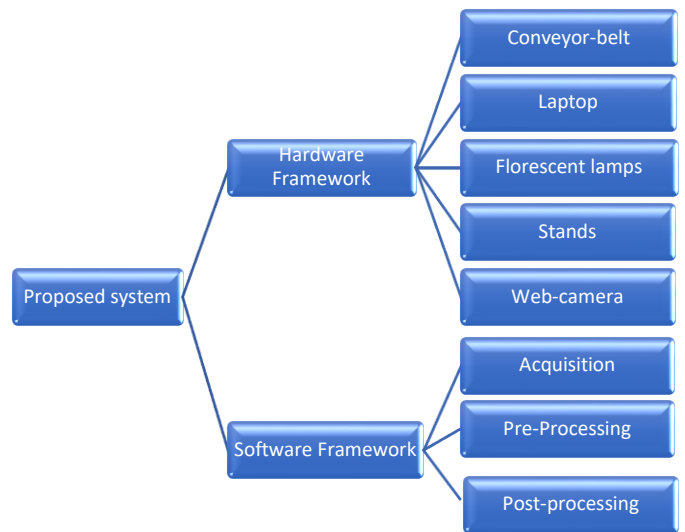

Fig. 1. The proposed system.

Fig. 2. The proposed hardware framework.

Fig. 3. AVIS model hardware in the real environment.

B. Software Framework

The software diagram depicted in Fig. 4 represents the proposed AVIS software framework. The processes for object detection and picture processing are included. Feature extraction, board location, segmentation of footprints, and image collection are the first five processes. The images are then categorized in terms of their geometrical features using a production rules method.

1) *Image acquisition*: The acquisition systems feature a mechanical positioning tool to move the camera or the product

being tested to a fixed position and acquire the picture. The program displays the outcome and waits for the following acceptable image. The program recorded RGB frame-by-frame photos of PCBs traveling on the conveyor belt at a set conveyor belt speed.

2) *Image segmentation*: The pre-processing stage consists of two steps of image segmentation. The first image segmentation step is to extract the board under inspection from the acquired images, while in the second step, the image of the footprint is obtained from the board image. We have explained the two steps in detail.

a) *Board localization*: The work carried out in this stage of pre-processing is the extraction of the board from the obtained image. In any instance, a procedure to lessen or eliminate discrepancies between the obtained picture and the ROI must be included in the pre-processing [4]. In this case, we used a connected component to locate the board from the collected picture. In this project, the connected-component labeling procedure will use an 8-connectivity pixel since it is assumed that forms are frequently far from one another. As a consequence, calculation complexity can be avoided [6]. The largest component among those found to be connected is then extracted from the group based on size, and in this case, the largest component is the whole board, as shown in the obtained image. The steps of board localization are depicted in Fig 5.

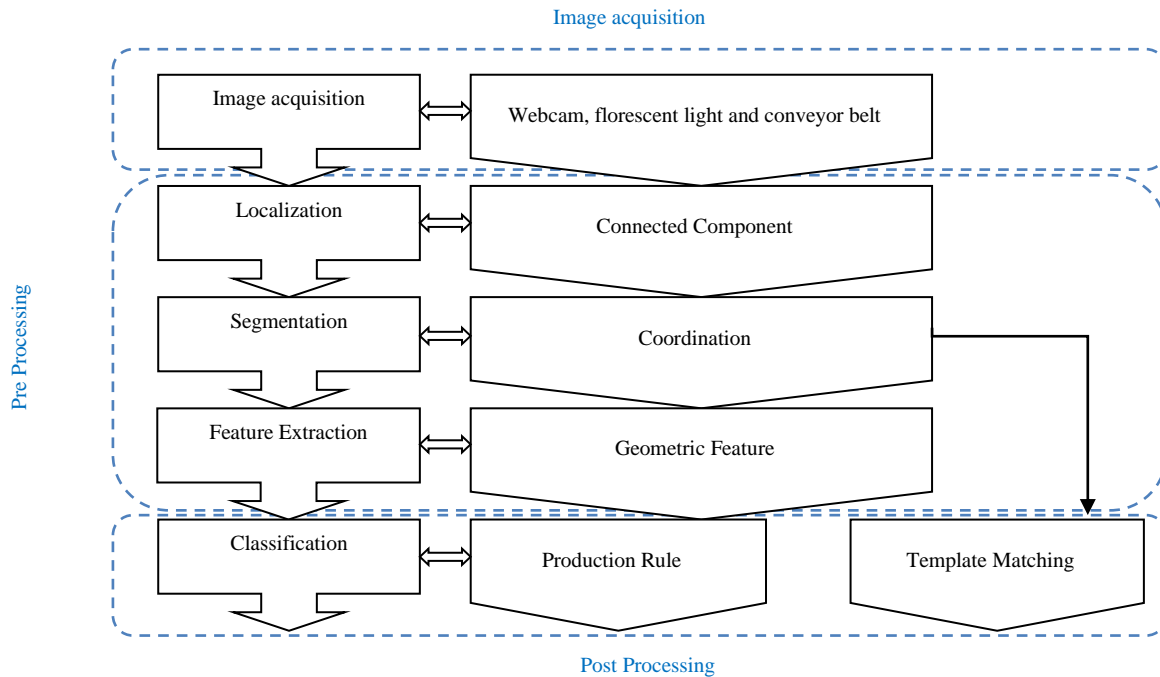

Fig. 4. The software framework.

Fig. 5. The steps of board localization.

b) *Footprint segmentation*: In this step, each region of footprints is cropped based on its coordination in terms of PCB's size. In this instance, we cropped the bounding box using four parameters: X_{min} , Y_{min} (Coordination), width, and height. First, the segmented image's energy will be assessed. If the segmented image's energy is greater than 15 pixels, the following stage will be to assess the printing quality. The entire footprint would be missing if the energy level were below 15.

3) *Feature extraction*: The feature extraction stage of image processing is crucial. The application and success of every classification method in the next phase depend on choosing the most appropriate characteristics. The subsequent phase of our procedure is feature extraction. From linked components on the footprint that were acquired by segmentation, a geometric feature [4] has been retrieved in this part. This method investigates two types of significant geometric properties, Area and Perimeter, for each item in the image based on the previously given information.

4) *Classification*: Image classification is the last phase of the proposed software framework. When the features are retrieved, a classification may be made using a set of known features in this step. In this study, the area and perimeter

characteristics are the geometrical features chosen for the classifying footprint. Production guidelines are used to categorize the footprints into four groups in this step: 25%, 50%, 75%, and 100% for each type of footprint. Different types of footprints on a PCB are dealt with by the models for detection and categorization (Variable resistor, IC, Capacitor, LED, Transistor). Tables I, II, III, IV, and V show the types of footprints.

5) *Production rules* : In this work, the classifier is rules-based. An effective and simple system is founded on rules. The IF-Then structure states that IF can develop a set of rules that can achieve a high classification rate for these specified classes of footprint and can then claim that rule-based systems are feasible. Calculated rule-based output takes the form of rules based on the area and perimeter of forms. The variable resistor takes just Area. Each object can get one of the values: (25%, 50%, 75%, and 100%). Table VI shows the features and values in each segmented image. Fig. 6 shows the inference engine of the production rule for four classes of footprints.

The V1 to V6 represent the perimeter of shapes in a segmented image. The V7, V8, V9, and V10 represent the Area of shape in a segmented image. The values of perimeter and area are different for each type of footprint.

IV. EXPERIMENTAL RESULT

This section discusses and presents the results of each module using a standard for evaluating computer software. Each module's step's performance is calculated. These procedures comprise capturing the picture, board localization, segmentation, and classification of the footprint. When the PCBs are in the webcam's field of view, the program instructs the webcam to take a picture by using a region of interest

(ROI). Using three criteria, the program evaluates the ROI for each frame. The image's top, bottom, and middle thirds are our focus areas. Three regions' total quantity of white pixels will be determined. The PCB picture was taken in ROI by the technique chapter's instructions. Using a set threshold in the region of interest, the collected image's outcome is shown in Fig. 7. Table VII shows how well this technique performed.

Fig. 7. The captured image.

TABLE VII. PERFORMANCE OF THE METHODOLOGY USED IN IMAGE ACQUISITION

Number of images	Number of Correct capturing	Performance of capturing step
211	207	98%

A. Image Segmentation Module

1) *Board localization*: The 8-connectivity component was utilized in this stage to sort every component found to be linked. Then, from the acquired picture displayed in Fig. 8, select the largest one among them based on its area, which is the entire board. The result of board localization is shown in Fig. 9. Table VIII shows the results of board localization.

2) *Footprint segmentation*: We cropped each footprint's bounding box depending on its coordination and the size of the PCB. Boxes with footprints for capacitors, variable resistors, integrated circuits, LEDs, and transistors are shown on the PCB in Fig. 10. The results of the segmentation process are displayed in Table IX.

B. Image Classification Module

The suggested AVIS model's performance was assessed in this study using the 207 photos for each proposed classification technique. Five different footprint kinds are included on each PCB. On the PCB, we fully show eleven footprints. The number of footprints on the PCB is displayed in Table X.

The boards include different kinds of uncompleted footprints as follows the footprints that are missed and four classes of footprints in percentage (25%, 50%, 75%, and 100%). Table XI shows the number of each class of footprint in 207 images.

The 207 photos are utilized in this manner, as indicated previously. One PCB has eleven (11) examined footprints. Production rule methodology is employed to execute real-time inspection in a real-world setting.

If the suggested system properly detects the form in a segmented picture, the accuracy value equals the percentage of footprints. Each component's footprint is assessed independently by the suggested segmentation. Finally, using the formula below, we demonstrate how the production rule performs for each footprint type.

$$\text{Accuracy of production rule} = \frac{\sum \text{correct classification of footprints}}{\text{number of related footprints}} \times 100$$

In the 207 photos, we counted the production rule accurate classifications, and Table XII shows the results. The final tables and figures, Table XIII and Fig. 11, show how the production rule performed.

In summary, an automated visual inspection technique for finding missing PCB components is presented in this paper. This study is built on pure image processing algorithms that offer effective and low-cost methods for representing and identifying defective PCB devices. A proposed production rule is used to classify the different sorts of faults. Additionally, template matching is used to identify the completed PCB footprints.

V. CONCLUSION

This study presents a real-time automated visual inspection system using an image processing technique to detect the missing footprint components on printed circuit boards. This system consists of hardware and software components. The software involves pre-processing and post-processing stages. The capture step is finished, and the picture is segmented, localized, and extracted of its characteristics during the pre-processing stage. In order to categorize the footprints using the production rule, the post-processing step focuses on leveraging the feature extraction from the previous stage. Thus, we may conclude that the entire intelligent real-time machine vision system, whose design is presented in this study, can be utilized to enhance industrial quality control procedures.

Abstract—Most researchers are beginning to appreciate the use of remote sensing satellites to assess PM_{2.5} levels and use machine learning algorithms to automate the collection, make sense of remote sensing data, and extract previously unseen data patterns. This study reviews delicate particulate matter (PM_{2.5}) predictions from satellite aerosol optical depth (AOD) and machine learning. Specifically, we review the characteristics and gap-filling methods of satellite-based AOD products, sources and components of PM_{2.5}, observable AOD products, data mining, and the application of machine learning algorithms in publications of the past two years. The study also included functional considerations and recommendations in covariate selection, addressing the spatiotemporal heterogeneity of the PM_{2.5}-AOD relationship, and the use of cross-validation, to aid in determining the final model. A total of 79 articles were included out of 112 retrieved records consisting of articles published in 2022 totaling 43 articles, as of 2023 (until February) totaling 19 articles, and other years totaling 18 articles. Finally, the latest method works well for monthly PM_{2.5} estimates, while daily PM_{2.5} and hourly PM_{2.5} can also be achieved. This is due to the increased availability and computing power of large datasets and increased awareness of the potential benefits of predictors working together to achieve higher estimation accuracy. Some key findings are also presented in the conclusion section of this article.

Keywords—AOD; machine learning; PM_{2.5}; remote sensing; pollutant

I. INTRODUCTION

Interest in the study of PM_{2.5} (particulate matter aerodynamic diameter $\leq 2.5 \mu\text{m}/\text{m}^3$) concentration estimates from various outdoor and indoor particle sources has increased dramatically recently, as evidenced by the number of academic journals that have published articles on it. Studies identified the impact of PM_{2.5} contamination on humans as the initial problem of various adverse effects on the health of fetal growth during pregnancy to early death [1]. Direct and long-term exposure can significantly impact climate change, visibility degradation, ecosystem disruption, and social, ecological, and economic impacts [2]–[4].

PM_{2.5} monitoring is a critical need for public health, especially in densely populated areas, where exposure to airborne particles poses significant health risks [5]. Ground station monitoring is the most direct and accurate method of PM_{2.5} monitoring. However, it is impossible to fully identify the spatial distribution and obtain historical measurements of PM_{2.5} concentrations across the region. Most researchers are

beginning to appreciate the use of remote sensing satellites to assess PM_{2.5} levels. Estimating PM_{2.5} concentrations using Aerosol optical depth (AOD) as a remote sensing satellite derivative can be used to fill the gap of spatial and temporal data gaps left by ground stations [6]. Various remote sensing satellite sensors, such as Moderate Resolution Imaging Spectrometer (MODIS) [7], [8] The Visible-infrared Imaging Radiometer Suite (VIIRS) [9], [10], the Advanced Himawari Imager [11], [12] the Advanced Geosynchronous Radiation Image (AGRI) [13], [14] have been applied to estimate PM_{2.5} concentrations.

Models for predicting PM_{2.5} concentrations can be useful for filling data gaps from existing monitoring networks. Air pollutant concentration prediction methods can generally be classified into three categories: numerical, statistical, and artificial intelligence (AI) models. Numerical models simulate the physical and chemical changes and transport processes of atmospheric pollutants by specifying and solving complex differential equations. Recent representative numerical models include Community Multiscale Air Quality (CMAQ) and Weather Research and Forecasting coupled with Chemistry (WRF-Chem). The accuracy of these models relies heavily on detailed emission data from pollutant sources, which often need to be made more precise and available. In addition, the complex modeling process requires more time and computing power [15]. Therefore, it is necessary to develop a faster and more accurate model to improve the prediction of air pollutants.

Statistical models have not involved complex physical changes, chemical reactions, and transportation processes. Statistical models rely entirely on data-driven mining of internal relationships to historical data. Therefore, the computational effort is significantly lower compared to numerical models. It is easy to implement classical statistical models such as autoregressive integrated moving average (ARIMA) [16] and autoregressive moving average (ARMA). However, these models are suitable for small data sets and univariate time series models. In addition, these models are based on linear assumptions that require strict stationarity of the data. Therefore, capturing nonlinear relationships in the data is inherently complex. These limitations greatly restrict the performance and applicability of classical statistical models in air pollution forecasting.

In contrast, adopting machine learning models in remote sensing is considered the optimal solution for predicting PM_{2.5} concentration time series due to its advantages of flexible

nonlinear regression capabilities and classification features based on large data sets with complex data relationships between many variables. [17], [18]. The initial study that utilized a Neural Network (NN) to tackle the intricate correlation between AOD-PM_{2.5} [19]. Since the 1990s, Machine Learning algorithms have been used to automate the collection, understand remote sensing data, and extract previously unseen data patterns [20], [21].

Machine learning capabilities make it possible to non-parametrically examine the relationship between predictors of pollutant concentrations and measured pollutant concentrations [22], [23]. A number of research investigations have indicated that machine learning [17], [24], [25] such as deep learning [26], Random Forest [27], and deep ensemble models [28], have a remarkable ability to estimate PM_{2.5} concentrations at various temporal and spatial scales. Several models have been developed to predict indoor [29] and atmospheric PM_{2.5} concentrations based on data obtained from air quality monitoring stations, such as meteorological variables from weather stations such as air temperature (T), relative humidity (RH), wind speed (WS), wind direction, Precipitation (PRE). Land variables, such as NDVI. Variables related to population) such as population density, road network density, height, and the number of buildings, and others, including data on PM_{2.5}, carbon monoxide (CO), ozon (O₃), nitrogen oxides (NO), nitrogen dioxide (NO₂), and sulfur dioxide (SO₂) [10], [11], [14], [26], [30].

The success of PM_{2.5} concentration estimation studies using machine learning and satellite remote sensing data depends on the quantity and quality of the researcher's domain knowledge, regional knowledge, and time spent. This review article aims to summarize the literature on the use of machine learning and satellite remote sensing in estimating large-scale and long-term PM_{2.5} concentrations. This literature review includes articles from 2022 to 2023 related to this crucial topic. However, some articles that can provide insights into various remote sensing technologies on PM_{2.5}, air pollution, and other specific studies were also added without being limited by the year of publication period. Specific search terms and study selection are illustrated in the second section to summarize the current state of development in estimating PM_{2.5} concentrations. The third section investigates factors affecting PM_{2.5} concentrations, levels, and model measurements. The following section is a personal presentation on using machine learning models.

II. LITERATURE SEARCH AND SELECTION

In line with the multidisciplinary research topics, several other disciplines, ranging from computer science, forestry, remote sensing, atmosphere, and disaster, which intersect with the main topic without being limited by the year of publication period to provide additional insight, are included. Four general stages of literature search and determination were conducted, such as:

- Identification: The initial set was conducted by identifying keywords to search for articles relevant to the topic of this literature review from electronic databases Web of Science, Google Scholar, and sources of Elsevier, ScienceDirect, and Springer, both from

National and International journals. Based on the topic raised, this study needs to summarize (1) literature from indoor PM_{2.5} concentration research, (2) specific indoor PM_{2.5} sources (cooking, cigarettes, vacuum cleaners, and more.), and (3) monitoring via landline networks. Application of keywords as follows: "Estimating PM_{2.5}", "machine learning," "satellite remote sensing," "PM_{2.5}", and "outdoor." Findings of article titles corresponding to the research topic were then stored and evaluated. The search continued by checking for other articles cited or quoted in this set and removing double-identified documents. Due to the core topic of this literature review, we focused on published articles from January 2022 to February 2023.

- Screening: The articles found were screened by labeling them as relevant or not to this study after checking the abstracts. These potential papers were then carefully reviewed to ensure their eligibility as references in this literature review.
- Eligibility: Eligibility was determined by reading the main findings, use of data, results, and discussion. The authors considered journal articles and books published by reputable publishers as high-quality research and included them in summary. The authors used "Scimago Journal & Country Rank" to check the rankings of the included articles.
- Inclusion: The research then lists literature articles that correspond to the main topic.

Our initial search yielded 112 articles. After passing the initial screening to eligibility assessment, this study used 61 primary and 18 other articles.

is a summary flowchart of the following literature search and selection statistics:

Fig. 1. Literature search and selection flow chart.

illustrates the number of references in the literature review. The collected articles from 2022 totaled 43 articles, 2023 (up to February) totaled 19 articles, and the other years totaled 18 articles.

Fig. 2. Number of literature review references.

III. REMOTE SENSING TECHNIQUE

A. Moderate Resolution Imaging Spectroradiometer (MODIS)

MODIS is an instrument on the Aqua and Terra satellites capable of detecting small changes in surface reflectance due to changes in $PM_{2.5}$ concentrations. Reflectance changes estimate $PM_{2.5}$ concentrations through a statistical approach that does not require calibration or data collection from ground-level locations. In addition, this method is more resistant to noise than other methods [31]. The MODIS instrument captures data from 36 spectral bands with wavelengths ranging from 0.4 to 14.385 μm and observes the entire Earth's surface every one to two days. The Terra satellite follows a north-south orbit and crosses the equator in the morning, while the Aqua satellite travels in the opposite direction and flies over the equator in the afternoon. Various sources provide various MODIS data products:

- MODIS level 1 data, geolocation, cloud mask and atmospheric products: <http://ladsweb.nascom.nasa.gov/>
- MODIS ground products: <https://lpdaac.usgs.gov/>
- MODIS cryosphere products: <http://nsidc.org/daac/modis/index.html>
- MODIS ocean color and sea surface temperature products: <http://oceancolor.gsfc.nasa.gov/>

MODIS images have spatial resolutions of 250 m, 500 m, and 1km. The range of wavelengths between 0.47 and 2.12 μm in various channels is utilized to determine aerosol properties, specifically AOD, in order to estimate $PM_{2.5}$ [7], [8]. A research study based on theoretical analysis of data gathered by a multiangle imaging spectrometer aboard the Terra satellite in the US has shown that the range of particle sizes appropriate for AOD retrieval, which closely corresponds to the particle size range of $PM_{2.5}$, falls between 0.1-2 μm in the visible and near-infrared wavelength bands.

B. Himawari-8

The Japan Meteorological Agency (JMA) operates Himawari-8, a geosynchronous weather satellite. The satellite was launched on 7 October 2014, and is stationed at 140.7 degrees east longitude, providing uninterrupted observations over the Asia-Pacific region, which includes Southeast Asia, Australia, Japan and the Western Pacific. Himawari-8 carries a

suite of advanced instruments to observe the Earth's atmosphere and weather systems. These instruments include the Advanced Himawari Imager (AHI), which provides high-resolution images of the Earth's surface and clouds, and the Himawari Cast data collection system, which receives data from other weather satellites and ground-based weather stations [32]. Himawari-8 can be used to measure Aerosol Optical Depth (AOD) to investigate the diurnal variation of air pollution with high temporal resolution. [12]. Recently, some studies have started to estimate hourly ground-level $PM_{2.5}$ in real-time from Himawari-8 AOD products [33]–[35].

C. Sentinel 5-P

The Sentinel-5 Precursor Satellite (Sentinel-5P) was launched on October 13, 2017, carrying the following Tropospheric Monitoring Instrument (TROPOMI) to generate global high-coverage total/tropospheric vertical columns of precursors (e.g., NO_2) for $PM_{2.5}$ and PM_{10} . TROPOMI has a legacy to the Ozone Monitoring Instrument (OMI) as well as the Scanning Imaging Absorption spectroMeter for Atmospheric CartographY (SCIAMACHY) TROPOMI is a single instrument from the Sentinel-5P spacecraft covering wavelengths from ultraviolet (UV) to ShortWave InfraRed (SWIR). This hyperspectral spectrometer is designed to provide routine observations of key atmospheric constituents including ozone, NO_2 , SO_2 , CO , CH_4 , CH_2O and aerosol properties at high spatial resolution using passive remote sensing methods. [36]. The typical pixel size (near nadir) is defined as $7 \times 3.5 km^2$ for all spectral bands except UV1 ($7 \times 28 km^2$) and SWIR band ($7 \times 7 km^2$). In terms of accuracy, the evaluation results show that the quality of the TROPOMI atmospheric product meets the requirements in $PM_{2.5}$ pollutant estimation [37], [38].

IV. PREDICTORS USED FOR ESTIMATION OF $PM_{2.5}$ CONCENTRATIONS

A. Sources of $PM_{2.5}$

There are several types of outdoor $PM_{2.5}$ sources originating from the combustion of fossil materials, such as automotive vehicle exhaust emissions, coal, and biomass combustion [39], industrial activities, soil dust, secondary combustion, secondary nitrates, as well as through release into the volcanic atmosphere [40]. The sources and concentrations of $PM_{2.5}$ can vary significantly between locations due to the different characteristics of climatic conditions, emission sources, and distribution patterns [41]. Black carbon, aryl hydrocarbons, polycyclic aromatic hydrocarbons, volatile organic hydrocarbons, biological materials, heavy metals, minerals, inorganic ions, and organic compounds are the primary constituents of $PM_{2.5}$, which account for around 79-85% of the entire mass when considered together [42].

B. Explanatory Variables of $PM_{2.5}$

Two characteristics of variables used in $PM_{2.5}$ research are dependent and independent variables. The dependent variable contains $PM_{2.5}$ values ($\mu g/m^3$) obtained through air quality measurements using ground stations. On the other hand, the independent can contain co-pollutant, meteorological, and anthropic information that can significantly improve the model's accuracy. Regarding this critical difference,

independent data is essential information to help estimate $PM_{2.5}$, including AOD.

1) *Aerosol optical depth*: (AOD is a quantitative measure of the reduction of light by aerosol particles in the Earth's atmosphere. AOD describes how much light from the sun is reduced or blocked by aerosol particles in the atmosphere. The higher the AOD value, the more significant the attenuation of light caused by aerosol particles. AOD can be measured using devices such as spectrometers or photometers [43]. Thus, AOD is an essential predictor of $PM_{2.5}$, according to the close relationship with AOD.

The starting point for knowing satellite AOD about surface $PM_{2.5}$ is through Equation (1) [44], which shows the dependence of $PM_{2.5}$ and cloud-free AOD relationships on various factors:

$$AOD = PM_{2.5} \times H \times f(RH) \times \frac{3Q_{ext,dry}}{4\rho r_{eff}} = PM_{2.5} \times H \times S \quad (1)$$

where H is the boundary layer height (*BLH*), $f(RH)$ is the ratio of the ambient and dry extinction coefficient to the relative humidity (RH), ρ is the aerosol mass density ($g\ m^{-3}$), $Q_{ext,dry}$ is the Mie extinction efficiency, and r_{eff} is the effective radius of the particle. S is the specific extinction efficiency ($m^2\ g^{-1}$) of the aerosol at ambient RH . This equation assumes the aerosol is homogeneously distributed throughout the BLH .

The relationship between $PM_{2.5}$ and AOD could take the form of a multivariate function that is linked to numerous meteorological and spatial factors that influence it. [45], [46]. AOD is a variable that includes changes in $PM_{2.5}$, resulting from a comprehensive combination of emissions, chemical reactions, and others. However, there are still three main differences between AOD and $PM_{2.5}$ data:

- AOD is a unitless value that reflects the total light blackout effect of the aerosol in the column, while $PM_{2.5}$ is the mass concentration at the soil surface.
- In the presence of moisture, water-soluble particles will become more prominent through the water absorption process, thus affecting the light-extinguishing ability of the aerosol.
- $PM_{2.5}$ is only part of aerosols with a diameter equal to or less than $2.5\ \mu m$, but this does not apply to all aerosols.

Some AOD products that can be found:

a) *AERONET AOD*: The Aerosol Robotic Network (AERONET) is a global aerosol monitoring network widely recognized as the benchmark for evaluating satellite source AOD products. It provides long-term AOD ground measurements with low drift (0.01-0.02) and high time resolution (15 minutes). AOD measurements in the 550nm band are not available through AERONET. However, to estimate AOD in this band, the Angstrom exponent is typically used to interpolate AOD values between 440nm and 675nm. AERONET AOD is currently categorised into three quality levels: L1.0, L1.5, and L2.0, which represent unfiltered data, filtered and quality-controlled data, and quality-assured data, respectively. Version 3 of the database is currently under

development, which will feature more stringent quality control measures, particularly for cirrus cloud pollution [47].

b) *DT AOD*: The development of the Dark Target (DT) Algorithm is enabled to obtain AOD values in high vegetation cover, dark soil, and low sea surface albedo environments at 10 Km or 3 Km spatial resolution. DT selects dark pixels with atmospheric reflectance (TOA) of 0.01-0.25 in the 2.12 μm channel to retrieve AOD. DT provides fine (low, medium, high) and coarse three-surface aerosol models. Furthermore, it selects from these three models according to the season and geographical conditions [45]. Collection 6 DT AOD (C6 DT AOD) was established in early 2014 and has completed updates to calibration, cloud mask, and land/ocean symbols. Subsequently, the C6-based C6.1 DT AOD was released to address the continuous changes in surface reflectivity caused by the rapid growth of tall buildings worldwide [48]. Specifically, in a pixel network covering an area of 10km \times 10km, consisting of $\geq 50\%$ coastal pixels or $\geq 20\%$ water pixels, C6.1 DT will reduce the capture quality to zero and modify it with surface reflections in certain AOD areas [48]. The observed rise in value confirms a 2.17% increase in the correlation coefficient between C6.1 DT and AERONET AOD in certain urban locations, suggesting that C6.1 DT AOD provides a more accurate representation of the urban situation. The unfiltered product for AOD C6.1 DT, lacking quality detection, is denoted as "Image_Optical_Depth_Land_And_Ocean," whereas the filtered product with Quality Assurance (QA) greater than 1 (for ocean) and QA equal to 3 (for land) is denoted as "Optical_Depth_Land_And_Ocean."

c) *DB AOD*: The Deep Blue (DB) algorithm is designed to capture AOD at 10 km spatial resolution for environments with high surface albedo in deserts, drylands, and cities. It can overcome the defects of the DT algorithm on shiny surfaces. Contrary to DT, DB first picks up aerosols at 1Km resolution, and then combines the 10Km pixels. The Collection 6 DB AOD (C6 DB AOD) product is named "Enhanced Deep Blue" to differentiate it from C5 and extend to other global layers beyond snow and ice C6.1 DB has the following improvements over C6: (1) reduction of artefacts from heterogeneous terrain, (2) improved elevation terrain surface models, and (3) updated seasonal or regional aerosol models and better smoke detection [48]. The product without quality detection in AOD C6.1 DB is named "Deep_Blue_Aerosol_Optical_Depth_550_Land" and filtered by QA=2 and QA=3 is named "Deep_Blue_Aerosol_Optical_Depth_550_Land_Best_Estimate".

d) *MAIAC AOD*: MAIAC AOD refers to the atmospheric aerosol optical depth (AOD) product generated by the Multi-Angle Implementation of Atmospheric Correction (MAIAC) algorithm. The MAIAC algorithm is a sophisticated technique for atmospheric correction of satellite imagery, which allows for the retrieval of high-quality AOD data. MAIAC AOD is derived from the Moderate Resolution Imaging Spectroradiometer (MODIS) instrument on board the Terra and Aqua satellites, which are operated by the National Aeronautics and Space Administration (NASA). MAIAC AOD

provides high-resolution AOD data with spatial and temporal coverage, making it a valuable tool for studying air pollution and its impacts on human health and the environment. Therefore, MAIAC has a high level of quality (L2) [49], [50]. In addition, the 1 km resolution is another important feature of MAIAC AOD. MAIAC has uncertainties under extreme conditions, indicating that MAIAC cannot obtain AOD accurately at high altitudes (>4.2 km). Lyapustin [51] showed that MAIAC could not get the AOD accurately at altitudes (>4.2 km). Tao [49] showed that daily bias varies dramatically in areas where airborne transportation and dusting occur. Otherwise, Lyapustin [51] compared MAIAC products with different surface cover types and found significantly different detection precision. The miscalculation of regression coefficients of surface reflectance at different wavelengths caused MAIAC to be systematically overestimated due to particle scattering properties in northwest China's desert areas.

e) Other AOD products: In addition to the aforementioned AOD products, several radiometers offer satellite-based AOD products, such as the Climate Change Initiative (CCI) products from the European Space Agency (ESA), which include AATSR Dual View (AATSR-ADV), AATSR Swansea University (AATSR-SU), AATSR Oxford-RAL Retrieval of Aerosol and Cloud (AATSR-ORAC), and AATSR-ENSEMBLE (AATSR-EN), as well as AOD products from other sensors, including the Advanced Very High-Resolution Radiometer (AVHRR), Multi-angle Imaging Spectroradiometer (MISR), Sea-viewing Wide Field-of-view Sensor (SeaWiFS), Visible Infrared Imaging Radiometer (VIIRS), and Polarization and Directionality of the Earth's Reflectance (POLDER) [52] and Advanced Himawari Imager (AHI). Some AOD products are not widely used for PM_{2.5} estimation due to low time resolution, poor overall accuracy, or limited application range.

2) Co-pollutant and meteorological variables: When hydrocarbons (HC) and nitrogen oxides (NO_x) react in sunlight, they produce the secondary pollutants ozone (O₃) and secondary organic carbon (SOC). The photochemical reaction of gaseous precursors of primary organic carbon (POC) results in the formation of SOC [53]. Meteorological factors affect the dispersion and transport of fine particles. Commonly used meteorological variables are relative humidity (RH), temperature (TEMP), u/v wind, surface pressure (SP), and wind direction (WD) [54]. Additional studies based on observation have demonstrated that the correlation between PM_{2.5} and AOD is influenced by the Planetary Boundary Layer Height (PBLH). When the PBLH is greater, the AOD is also higher; however, the PM_{2.5} concentration is lower. [55]. RH changes aerosol particles, affecting AOD by increasing humidity, hygroscopicity (the ability of a substance to take up water molecules from its surroundings, either by absorption or adsorption), and aerosol particles. Furthermore, evaporation has a strong positive correlation with temperature ($R > 0.6$) and a strong negative correlation with relative humidity ($R < -0.6$).

The survey results summarize the various source variables and individual chemical constituents of the data set used for the PM_{2.5} study. The chemical sources were divided into the categories of natural and anthropogenic-biogenic [42]:

- Natural Sources
 - Biomass (Potassium (K))
 - Sea spray aerosols (Sodium (Na))
 - Coal burning (Aluminium (Al), Selenium (Se), Cobalt (Co), Arsenic (As))
 - Soil and road dust (Aluminium (Al), Silicon (Si), Calcium (Ca))
 - Volcanic dust particles and wild land fire particles (Potassium (K), Zinc (Zn), Lead (Pb))
- Anthropogenic-biogenic sources
 - Diesel, petrol and coal combustion (Elemental carbon (EC), Sulfates (SO₄))
 - Heavy industry—high temperature combustion (Iron (Fe), Zinc (Zn), Copper (Cu), Lead (Pb), Nitrates (NO₃))
 - Fertilizer and animal husbandry (Ammonium (NH₄))
 - Oil burning (Vanadium (V), Nickel (Ni), Manganese (Mn), Iron (Fe), Organic carbon (OC))

3) Anthropogenic variables: According to existing research on PM_{2.5} forecasting, road and rail density, population density, and proportion of land use (agricultural land and forest land) as human influencing factors of PM_{2.5} [56], [57]. Land use variables have always been the conventional choice in PM_{2.5} driving research, representing the degree of landscape modification by humans and as a proxy for local emissions and background air pollution levels. Land use variables approximate air pollutant emissions, often at the kilometer or sub-kilometer scale. Land use can be (1) type of land use coverage, (2) distance to the nearest highway, (3) distance to the coastline, (4) elevation, and (5) NDVI (normalized vegetation difference index). (6) The distribution of PM_{2.5} is influenced by elevation due to the difficulty of reaching PM_{2.5} at a higher elevation above the earth's surface from sea level [58].

Land use variables are potential sources of PM_{2.5} and are the areas of most significant concern. Existing studies on the dependence of land use variables on AOD or PM_{2.5} show significant differences between lower and higher areas. Grassland, shrubs, water bodies, and artificial surfaces positively depend on AOD (maximum partial dependence of about 0.63) and are insignificant on PM_{2.5} [43]. Since land cover properties can be assumed to change gradually, missing values at the temporal scale are then replaced through linear interpolation between adjacent values [59].

Nighttime (Night Light (NLT)) population density variables, such as road network density, height, and number of buildings, are used to identify the degree of population agglomeration and urbanization in the scale of urban industrial development [30]. For example, coal, forest fires and vehicle emissions can be a

major source of haze, as the larger composition of released fine soot particles affects the higher AOD and PM_{2.5} measurements in MODIS. Another study showed that NLT has an increased MSE: about 30 n plots with partial dependence on PM_{2.5} generally increase slowly as NLT increases [60]. This suggests that high NLT represents densely populated areas and still operating factories. However, the impact of emissions in a short period is not very influential on high PM_{2.5}. Studies by [61] have shown that population density is significantly positively correlated with AOD, with PM_{2.5} concentrations increasing sharply near population density = 6 (people/KM) then increasing slowly. This pattern shows the contribution of population density to PM_{2.5} concentrations, which can rise above pollutant limits due to high human activity.

C. Analysis of Variables Affecting PM_{2.5}

Understanding the variables that trigger PM_{2.5} is essential. The study by Su [56], adopted spatial autocorrelation analysis to explain the spatial correlation of PM_{2.5} in the study area and period. This study uses spatial cluster and outlier methods to analyze the distribution and spatial-temporal variation of the PM_{2.5} surface. Meanwhile, the Random Forest algorithm was used to analyze the influence variables on PM_{2.5}. The relationship between PM_{2.5} concentration and the explanatory variables was well modeled, and the explanation level of the drivers to PM_{2.5} was more than 0.9. Temperature, rainfall, and wind speed are the main driving forces of PM_{2.5} emissions. The impact of forest fires is also slowly influencing the driving force of PM_{2.5} concentration [61]. Another study related to the importance of explanatory variables in explaining PM_{2.5} variations, using ensemble models (deep learning (DL), Random Forest Distribution (DRF), and Gradient Boosting Machines (GBM)) by explaining PM_{2.5} variations such as wind speed, inversion strength, and aerosol optical depth (AOD) to be the most influential in DRF and GBM models. For the deep learning algorithm, wind direction emerged as the most influential, followed by the land cover variable [62].

D. Missing Values

The relationship between AOD and PM_{2.5} varies considerably across regions, seasons, and time periods. Hence, studies that employ a single machine learning technique to estimate PM_{2.5} concentrations over a vast area require some enhancements in spatial distribution. Additionally, the accuracy of machine learning methods for PM_{2.5} estimation is linked to the training sample used. Since satellites cannot detect atmospheric aerosols below the clouds, it has a gap of missing values in the spatial distribution.

The advantages of atmospheric model data are fully utilized to obtain comprehensive coverage results. Therefore, the map produced by the interpolation analysis of PM_{2.5} concentration distribution using measured values from each monitoring station can be evidence of the validity of the PM_{2.5} concentration prediction technique. To obtain values for unknown spatial data, a spatial interpolation approach can be used. Various researchers have referred to standard spatial interpolation methods such as Trend Surface (TS) interpolation, Collaborative Kriging (CK), Inverse Distance Weighted (IDW) interpolation, Ordinary Kriging (OK) interpolation [56], and radial basis function.

1) *The OK*: interpolation method assumes that the spatial correlation of surface changes can be explained based on the distance or direction between sampling points, and it adjusts a mathematical function at all points to determine the value of each outlet by considering a certain number of nearby points or a certain radius. Calculated through Eq. (2) as follows:

$$z_v^*(x) = \sum_{i=1}^n \lambda_i Z(x_i) \quad (2)$$

Where $Z(x)$ is the measurement of position i , λ_i is the unknown weight of the measurement value at a position i , is the predicted position, and n is the number of measurements. Wong [56] used the OK method to generate continuous air pollutant concentrations and meteorological factors covering Taiwan.

2) *The IDW*: interpolation method calculates pixel values by linearly combining a series of sample points, with the goal of minimizing the distance between the mapped variable and the sample locations. Calculated through Equation (3) as follows:

$$z = \left[\sum_{i=1}^n \frac{z_i}{d_i^k} \right] / \left[\sum_{i=1}^n \frac{1}{d_i^k} \right] \quad (3)$$

This formula represents the calculation of the inverse distance weighting (IDW) method, which is a spatial interpolation technique used to estimate values at unsampled locations based on the values of neighboring sampled locations. In the formula, "z" represents the estimated value at the unsampled location, "n" is the number of neighboring sampled locations, "z_i" is the value at each neighboring sampled location, "d_i" is the distance from the unsampled location to each neighboring sampled location, and "k" is a power parameter that determines the influence of the distance on the estimated value. The formula calculates the weighted average of the neighboring sampled values based on their distances to the unsampled location, where the weights are determined by the inverse of the distances raised to the power of "k", and divides the sum of the weighted values by the sum of the weights to obtain the estimated value. Chae [63] used the IDW method to interpolate the missing values uniformly and generate grid-shaped data in the Convolutional Neural Network (ICNN) Interpolation prediction model in South Korea from January 1, 2018, to December 31, 2019, with PM_{2.5} and PM₁₀ measurements [63].

3) *The TS*: method involves applying statistical techniques to create continuous mathematical surfaces by matching them to known spatial points to examine patterns of change in regional and local geological variables. It is calculated through Equation (3) as follows:

$$z = \beta_1 + \beta_2 + \beta_{13y} + \beta_{4x^2} + \beta_{5xy} + \beta_{6y^2} + \dots \quad (4)$$

Where Z is the address variable, x and y are the coordinates of the observation point.

The CK method refers to kriging interpolation, which is a geostatistical method based on variogram theory and structural analysis. It is considered an unbiased and optimal estimation

method for regional variables [64], [65]. Liu [66], employed the CK Method to generate simulation maps depicting the spatial distribution of PM_{2.5} mass concentration on Changsha's Third Ring Road. Furthermore, an additional interpolation analysis map was generated using the measured values from each monitoring station, to serve as a reference for the map generated using predicted values. The aim is to validate the PM_{2.5} concentration prediction method, which uses the CK method. This method uses one or more secondary variables to interpolate the primary variable of interest. The method assumes that the correlation between these variables can improve the accuracy of the primary predictor [66]. Usually, some measurement points correspond to a normal distribution. To estimate each unknown point, the estimator is expressed as a linear combination of the valid sample values. In other words, a linear combination of valid sample values is used as an estimator for each unknown point to be estimated:

$$\hat{Z}(S_i) = \sum_{j=1}^n \lambda_j Z(S_j) \quad (5)$$

where $\hat{Z}(S_i)$ is the estimated value of the variable at location S_i , $Z(S_j)$ is the observed value of the variable at location S_j , λ_j is the weight assigned to the observed value at location S_j , and n is the total number of observed values used in the estimation.

One way to guarantee that the model provides unbiased estimates is by:

$$\sum_{j=1}^n \lambda_j = 1 \quad (6)$$

The value of $\hat{Z}(S_i)$ can be determined while ensuring that the kriging variance is kept at a minimum.

V. APPLIED MACHINE LEARNING MODELS

Advanced machine learning models have been applied to PM_{2.5} forecasting by developing methods that reflect transport and formation characteristics in suitable algorithms. Compared to classical statistical models and generalized additive models that have been used to calculate empirical models of PM_{2.5}[67], machine learning has become a popular method for developing satellite-based AOD-PM_{2.5} models due to its advantages in selecting and using many independent factors that can affect the dependent variable to be estimated [62], [68].

The feed-forward neural network [69] and Recurrent Neural Network (RNN) [41] are some of the fundamental algorithms to simulate the temporal variation of PM_{2.5} concentration by describing the stratigraphic characteristics of the predicted area. Observation data from monitoring stations in the forecast area and surrounding areas are utilized to develop Convolutional Neural Network (CNN) and Graph Neural Network (GNN) models that directly capture transportation characteristics [41], [70]. These models can effectively represent the spatial correlation between the forecast area and the downwind emission source.

Hybrid models that combine CNN and GNN with the temporal property of LSTM, such as CNN-LSTM and GNN-

LSTM, can reflect the temporal variation of the forecast area and the transmission of the wind direction area. Theoretically, the convolutional LSTM (ConvLSTM) network structure makes it an ideal algorithm for combining transportation and formation features; however, these features cannot be accurately predicted after 12 hours [71]. The ensemble technique of Deep Neural Network (DNN) [69], RNN, CNN algorithmic models for real-time estimation of PM_{2.5} is considered capable of reducing the average bias and improving the accuracy index of models that are substantially limited by the uncertainties in the input data of anthropogenic emissions and meteorological fields, as well as the inherent limitations of each model [65].

The paper by Wong [56] uses four types of machine learning algorithms GBM, eXtreme gradient boosting (XGBoost), LightGBM, and CatBoost, after influential variables are identified through interpolation models. The results of the study by comparing the ensemble mixed spatial model and LUR showed that the forecast performance increased from 0.514 to 0.895 (from 0.478 to 0.879) during the day and from 0.523 to 0.878 at night [56].

Note that both the LightGBM model [72] and the eXtrem Gradient Boosting (XGBoost) model [72], [73] are decision tree-based Gradient Boosting frameworks. The XGBoost objective function equation is as follows:

$$Ob^{(t)} = \sum_{j=1}^T \left[G_j W_j + \frac{1}{2} (H_j + \lambda) w_j^2 \right] + \gamma T \quad (7)$$

where:

- $Ob^{(t)}$ is the objective function at iteration t
- T is the total number of leaf nodes in the tree
- G_j and H_j are the cumulative sum of the first-order and second-order partial derivatives of the samples contained in leaf node j , respectively
- λ and γ are constants
- W_j is the score value of the j -th leaf node
- w_j is the weight of the j -th leaf node

LightGBM uses the same gain formula $G_j W_j + \frac{1}{2} (H_j + \lambda) w_j^2$ as XGBoost, however, it employs a histogram-based algorithm, as well as techniques like leaf-wise growth with depth restrictions and Gradient-based One-Side Sampling (GOSS) to accelerate the training process. These approaches enable LightGBM to attain better prediction accuracy and lower memory consumption.

The Random Forest (RF) regression algorithm produced a good fit in detecting the relationship between PM_{2.5} and its drivers [61], [74], [75]. Liu [12] utilized RF as a gap filler on the Himawari-8 AOD, using MERRA-2 to estimate hourly PM_{2.5} concentrations, respectively. The results of this random forest study indicate that a set of input variables are used at each node to grow the tree. The algorithm (random forest) used resulted in gap-filling capability with AOD MERRA-2 can

provide reliable spatial and temporal PM_{2.5} predictions and significantly reduce errors in PM_{2.5} estimation [12]. The PM_{2.5} concentration estimation model (night) was also conducted by Ma [77] by integrating Visible Infrared Imaging Radiometer Suite (VIIRS) Day/Night Band (DNB) radiance, moon phase angle, and meteorological data in the Beijing Tianjin-Hebei region. The study developed a NightPMES model using random forests and compared its cross-validation results with those of MLR and DNN models. The NightPMES model achieved an R2 of 0.82, and an RMSE and MAE of 16.67 and 10.20, respectively. In addition, the NightPMES model performed better than most previous models [76].

The general framework for estimating PM_{2.5} concentrations in RF is as follows:

$$f(x) = \sum_{z=1}^Z C_z I(x \in R_z)$$

$$\hat{c}_z = \text{mean}(y_i | x \in R_z) \tag{8}$$

The formula involves the regression tree function, $f(x)$ where the output value is the estimated PM_{2.5} value. The sample (x_i, y_i) is taken from the Z region (R1, R2, ..., Rz), and there are N samples in total. The best estimate of the output mean for the data set is denoted as \hat{c}_z . The RF division strategy is expressed as follows:

$$z_1(m, n) = \{X | X_j \leq N\} \& z_2(m, n) = \{X | X_j > N\}$$

$$\min_{m,n} \left[\min_{x_i \in R_1(m,n)} \sum (y_i - C_1)^2 + \min_{x_i \in R_2(m,n)} \sum (y_i - C_2)^2 \right] \tag{9}$$

$$\hat{c}_z = \text{mean}(y_i | x_i \in R_1(m, n)) \& \hat{c}_2$$

$$= \text{mean}(y_i | x_i \in R_2(m, n))$$

where, m is the splitting variable, n is the split point. Diagrammatic representation of it is given in Fig. 3.

Fig. 3. Random forest based prediction process.

The study by Aguilera [62], used three base learners available within the H2O framework for machine learning: deep learning, random forest (RF), and Gradient Boosting. Each model was trained individually on all response (PM_{2.5}) and independent variables, with the optimal parameters of each machine learning algorithm selected by performing a grid search which was then stacked to find the optimal combination of the set of prediction algorithms (H2O's Stacked Ensemble method). Of the three machine learning algorithms, the optimal

combination of three base learners (RF, deep learning, and gradient boosting) achieved excellent prediction performance (R2 of 0.78 and RMSE of 3.51 $\mu\text{g m}^{-3}$) [62].

Feng conducted a study in the Beijing-Tianjin-Hebei region, where they developed an integrated model using RF and LightGBM after wavelet decomposition of PM_{2.5} observations. The study showed a high degree of consistency between the estimated and actual values. The cross-validation using time-based R2, RMSE, and MAE showed good model performance, with respective values of 0.91, 11.60, and 7.34 [77]. A later study by Falah [73] explored the use of RF and XGBoost models based on the fusion of multiple satellite-borne remote sensing aerosol products retrieved from two platforms (Aqua and Aura), two sensors (MODIS and OMI), and three retrieval algorithms (MAIAC, DB, and OM AE RUV). This study developed thirteen different performance models for each algorithm based on the input data sources MODIS/MAIAC (AOD, aerosol type), MODIS/DB (Angstrom exponent), and OMI (UV Aerosols Index). The UVAI OMI is used to classify aerosols into three categories: scattering aerosols, UVAI < 0.25; mixed-type aerosols, 0.25 ≤ UVAI < 0.25; and absorbing aerosols, 0.25 ≤ UVAI. Similarly, MODIS/DB AE is used to classify aerosols into three size fractions: coarse, e.g., dust, AE < 0.7; mixed mode, 0.7 ≤ AE < 1.3; and delicate, e.g., smoke, 1.3 ≤ AE. Overall, both RF and XGBoost models showed good performance, with variance (RF; R2 0.753 and NRMSE 0.884 - XGBoost R2 0.741 and NRMSE 0.874) explained by high cross-validation and low normalized root mean square error even for the base model (MAIAC AOD: AOD, CWV, PBLH, SP), with both models showing much better overall weighting performance when the model input data is subdivided into categories representing different aerosol types/properties [72].

Mahmud [54] conducted a study that used six supervised machine learning algorithms for regression and classification to predict PM_{2.5} values from 2015 to 2019 in the North Paso region. The variables were analyzed by six different machine learning algorithms using various evaluation metrics. The study showed that the ML model successfully detected the effects of other variables on PM_{2.5}, made accurate predictions, and identified areas of potential risk. The random forest algorithm showed the best performance among all machine learning models with 92% accuracy[54]. This technique has several advantages over other machine learning methods, such as shorter computation time, ease of handling high-dimensional data, strong fault tolerance, and parallel processing, making it suitable even for very high-dimensional data.

Support Vector Machines (SVMs) are flexible and powerful techniques for supervised machine learning, which are used for classification, pattern recognition, and functional regression problems. SVMs find an N-dimensional hyperplane with large margins to classify data into specific groups or labels [78]. A hyperplane divides the class into two, and the margin is used to divide the hyperplane. The predicted value, close to the best margin, is sampled to one of the classes. The predicted output includes one of the high-dimensional spaces as class 1 or 0, which concludes the prediction as traffic or less traffic area.

Recent research indicates that artificial neural networks are effective in both classification and regression tasks. One approach to predict areas with high levels of air pollution is by utilizing support vector machines (SVM), which aim to identify an N-dimensional hyperplane that maximizes the separation gap (margin) for the training data points. The optimal hyperplane is located at the center of the margin, and the data points located close to this hyperplane are known as support vectors. SVMs use kernel functions, such as linear, radial basis function, polynomial, Fisher, and Bayesian, to bridge linearity to non-linearity. In Masood's work [25], kernel functions were found to be crucial in this process. This study employed both linear and polynomial kernel functions. A visual representation of the SVM approach is shown in Fig. 4.

$$\text{Linear Kernel} = k(X_i, X_j) = x_j^T x_i \quad (10)$$

$$\text{Polynomial Kernel} = k(X_i, X_j) = (1 + x_j^T x_i)^p \quad (11)$$

Where X_i and X_j are independent random vectors, and p is a polynomial kernel order.

The efficacy of the SVM kernels depends on the calibration of controlling parameters such as kernel width (σ), regularization parameter (C), and gamma parameter (γ). In this research, two kernels (linear and polynomial) were employed for modeling. The SVM_lin model had NSE, RMSE, IA, R2, and R values of 0.938, 22.733, 0.983, 0.938, and 0.968, respectively, for the training phase, and 0.896, 29.634, 0.970, 0.923, and 0.961 for the testing phase. For the SVM_poly model, the NSE, RMSE, IA, R2, and R values for the training phase were 0.934, 23.334, 0.982, 0.935, and 0.967, respectively, and for the testing phase, they were 0.893, 30.071, 0.939, 0.840, and 0.916. Overall, the results of the SVM_lin and SVM_poly models were satisfactory for both the training and testing phases, indicating their ability to accurately predict PM2.5 concentrations. [25].

Fig. 4. This diagram illustrates the ideal hyperplane that effectively separates the data points, with the support vectors located near it.

A. Model Validations and Predictions for the Model

Statistical indicators such as coefficient of determination (R2, the higher, the better), correlation coefficient (R), Mean percentage error (MPE, the lower, the better), root means squared prediction error (RMSE, the lower, the better), index of agreement (IA), Mean Absolute Percentage Error, (MAPE

the lower, the better), mean absolute error (MAE) and Nash-Sutcliffe efficiency index (NSE), are evaluation metrics typically used for model evaluation. The mathematical expressions of these metrics are given as follows:

$$1) \text{ Determination coefficient } (R^2) \\ R^2 = \frac{\sum_{i=1}^N (I_o - \bar{I}_o) (I_p - \bar{I}_p)}{\sum_{i=1}^N (I_o - \bar{I}_o)^2 \sum_{i=1}^N (I_p - \bar{I}_p)^2} \quad (12)$$

$$2) \text{ Correlation coefficient } (R) \\ R = \frac{N \sum I_o I_p - (\sum I_o) (\sum I_p)}{\sqrt{N(\sum I_o^2) - (\sum I_o)^2} \sqrt{N(\sum I_p^2) - (\sum I_p)^2}} \quad (13)$$

$$3) \text{ Root mean square error } (RMSE) \\ RMSE = \sqrt{\frac{\sum_{i=1}^N (I_p - I_o)^2}{N}} \quad (14)$$

$$4) \text{ Index of Agreement } (IA) \\ IA = \left(\frac{\sum_{i=1}^N (|I_o - I_p|)^2}{\sum_{i=1}^N (|I_p - \bar{I}_o| + |I_o - \bar{I}_p|)^2} \right) \quad (15)$$

$$5) \text{ Mean Absolute Percentage Error } (MAPE) \\ M = \frac{1}{n} \sum_{t=1}^n \left| \frac{A_t - F_t}{A_t} \right| \quad (16)$$

$$6) \text{ Mean Absolute Error } (MAE) \\ MAE = \frac{1}{n} \sum_{i=1}^n |y_{true} - y_{predict}| \quad (17)$$

$$7) \text{ Nash-Sutcliffe efficiency index } (NSE) \\ NSE = 1 - \left(\frac{\sum_{i=1}^N (I_o - I_p)^2}{\sum_{i=1}^N (I_o - \bar{I}_o)^2} \right) \quad (18)$$

VI. CONCLUSIONS

Although ground stations are considered precise for measuring PM2.5 concentrations, obtaining values that reflect the overall situation is challenging due to their uneven presence. As a result, many researchers are turning to satellite remote sensing to fill in the gaps in spatial and temporal data left by ground stations. AOD, a satellite remote sensing derivative, has been utilized to calculate PM2.5 concentrations due to its relationship-based nature. However, satellite products have limitations such as being unable to detect atmospheric aerosols below clouds and the variation of AOD and PM2.5 relationship between regions, time, and seasons. To address this, researchers commonly use spatial interpolation methods like OK, IDW, TS, and CK to obtain missing spatial data.

In recent years, machine learning has become popular for predicting unknown values at spatial and temporal scales, and to establish the relationship between PM2.5 concentrations and AOD values at each grid. Many new methods, ensembles, and refinements of existing methods have been applied to PM2.5

estimation based on the derived satellite data. Large datasets, increased computing power, and awareness of the potential benefits of predictors working together have contributed to achieving higher estimation accuracy at different scales and spatial-temporal resolutions.

To support our explanations, we reviewed relevant papers, including classic papers, in this study. Key findings include:

- The distribution of ground-level PM_{2.5} observatories is generally uneven, which makes PM_{2.5} estimates less reliable in areas with fewer stations compared to those with more stations. This also raises concerns about the effectiveness of the commonly used cross-validation approach based on ground stations, as the observational data used for training and validation are concentrated in areas with more stations.
- Several factors determine the accuracy of PM_{2.5} estimates, including the specific conditions of the study area, the resolution of the source data, the use of predictors in a particular model, and the details of the methods used to estimate PM_{2.5} concentrations.
- The low consistency between independent and dependent variables in the same atmospheric environment can affect the estimation results. Therefore, it is essential to have different data as predictors to increase confidence in the results obtained. However, data availability is a challenge. In some research areas, the potential for predicting the temporal variation of PM_{2.5} based on satellite AOD needs to be further explored in the future.
- The use of classical methods to estimate PM_{2.5} concentrations is known to be not as accurate as those obtained using new methods. On the other hand, to estimate PM_{2.5} concentrations, there are more and more models and ensemble methods that can be implemented for various conditions.
- A simple and fast method is a spatial interpolation. Several improvements and integrations to various methods have been made to obtain more accurate results. However, the accuracy of these methods is relatively low compared to more complex methods (machine learning).
- Currently, research on PM_{2.5} concentration estimation models is starting to lead to the use of deep learning models. In some recent studies, especially those published in 2023, deep learning models dominate many studies.

From the importance of variables and correlations between variables in different articles, the following conclusions can be drawn:

- Meteorological variables are a class of predictors that make an essential contribution to PM_{2.5} after AOD;
- The contribution of land use variables has a low correlation with meteorological variables;

- The importance of population-related variables depends on the economic development of the study area.

Developing A Predictive Model for Selecting Academic Track Via GPA by using Classification Algorithms: Saudi Universities as Case Study

Thamer Althubiti, Tarig M. Ahmed, Madini O. Alassafi

Department of Information Technology-Faculty of Computing and Information Technology,
King Abdulaziz University, Jeddah 21589, Saudi Arabia

Abstract—The main motivation of any educational institution is to provide quality education. Therefore, choosing an academic track can be clearly seen as an obstacle, for students and universities, which in turn led to imposing a mandatory preparatory year program in Saudi Arabia. One of the main objectives of the preparatory year is to help students discover the right academic track. Nevertheless, some students choose the wrong academic track which can be a stumbling block that may prevent their progress. According to the tremendous growth of using information technology, educational data mining technology (EDM) can be applied to discover useful patterns, unlike traditional data analysis methods. Most of the previous research focused on predicting the GPA after the students choose an academic track. On the contrary, our research focuses on using classification algorithms to develop a predictive model for advising students to select academic tracks via prediction of the GPA based on the preparatory year data at Saudi Universities. Then, compare classification algorithms to provide the most accurate prediction. The dataset was extracted from a Saudi university containing preparatory year data for 2363 students. This work was carried out using five classification algorithms: Gradient Boosting(GB), K-Nearest Neighbors (kNN), Logistic Regression (LG), Neural Network(NN) and Random Forest(RF). The results showed the superiority of the Logistic Regression algorithm in terms of accuracy over the other algorithms. Future work could add behavioral characteristics of students and use other algorithms to provide better accuracy.

Keywords—Data mining; educational data mining; classification algorithms; logistic regression; neural networks; gradient boosting; k-nearest neighbors; predicting students' performance

I. INTRODUCTION

In light of scientific progress and the development of communication and information technologies, there is a huge amount of data stored in database management systems (DBMS)[1]. It does not end with the ability to store this data, but it is more important how to use it in the production of knowledge [1] [2]. Recently, there is an increasing interest in science of data mining (DM). The concept of DM is simply a combination of artificial intelligence, statistics, machine learning, and databases [3] [4]. DM techniques can be used to discover unique patterns and hidden relationships. Data mining outcomes contribute to problem-solving, decision-making, and planning for organizations and companies [3]. It also plays a

key role in various fields such as economy, healthcare, and education [4].

Educational data mining (EDM) is interested in discovering hidden relationships in data obtained from educational institutions or learning management systems (LMS). This area of research is used to take advantage of the data to better understand the students and what they learn. EDM is mainly used to predict students' academic performance to help them choose their study track [5]. This helps in making the right decision at the right time.

All countries seek to increase the quality of education. The increasing concern with the quality of education can be clearly seen in the Ministry of Education of Saudi Arabia as it acquires the highest share of the country's budget. According to the budget report, the Kingdom of Saudi Arabia's education budget amounted to 189 billion riyals, representing 18% of the total general budget in 2023 [6]. Additionally, applied of the preparatory year program was started in Saudi universities in 2009 [7]. The preparatory year, the first year of a student's university journey is considered to be the most important in a student's academic study. One of its aims is to prepare the students to choose an academic track based on their results [7] [8].

Due to the increasing number of academic tracks in universities, sometimes students choose a track that is not suitable for them, even if the results of the preparatory year qualify them for this track. This causes the failure of students or graduating with an unsatisfactory GPA. Furthermore, some students have to change their academic tracks after studying for several years, causing wasted effort. A research study conducted by M.J. Foraker at Western Kentucky University (WKU) in 2012 found that 25% of the students changed an academic track once, and 5% more than once [9].

This research aims to predict the academic via GPA of students in Saudi universities. It can help teachers and academic advisors modify students' study plans and improve academic performance. For the purposes of this study, reliance was made on a data set extracted from a Saudi university. It contains data for the preparatory year, by employing five classification algorithms: Gradient Boosting(GB), kNN, Logistic Regression (LG), Neural Network(NN) and Random Forest(RF). In addition, the model is evaluated by comparing the algorithms in terms of accuracy and area under the

curve(AUC). To predict students' academic performance, we must get answers to these research questions.

1) How can we predict the right academic track via the GPA and preparatory year data of students in Saudi universities?

2) Which classification algorithm has the highest accuracy in predicting the right academic track for Saudi students?

Our paper is arranged as follows: Section II provides an overview of previous academic work in the field of predicting the academic performance of students in general and Saudi universities in particular and reviews the selected algorithms. Section III explains the methodology and materials used in preparing this paper to predict the academic track based on the GPA. It also describes the contents of the dataset and the tool used to extract the results and methods for evaluating the results of the proposed model. Section IV presents the results of predicting the GPA and the factors affecting students' academic performance in Saudi universities. We conclude our paper with Section V, in which we discuss the experimental results and answers to the research questions and offer the conclusion and future work.

II. BACKGROUND

A. Predicting Academic Performance for Students

In Nigerian universities, the duration of the study is five years in engineering colleges. Adekitan and Salau [10] questioned about the possibility of predicting the last cumulative GPA based on the results of the first three years. They developed a model by using the KNIME application that experiments with six data mining algorithms (PNN, Random Forest, The Decision Tree, Naive Bayes, Tree Ensemble, and Logistic Regression). The dataset contains a record of 1842 students from different engineering departments. The GPA of the first three years, the first year of academic study, and the department were considered as input. The results showed that the GPA of the third year was the most effective in the prediction of the last cumulative GPA. They also showed that the Logistic Regression algorithm provides higher accuracy than the other algorithms, with an accuracy of 89.15%.

Ginting and Rahman [11] presented a prediction system for the GPA of university students. The proposed system uses an Artificial Neural Network and combines it with a supervised Backpropagation algorithm. The system consists of 18 nodes at the input layer with 24 hidden nodes to produce one node in the output layer. The dataset contains 591 records of students who graduated from an Indonesian university. The system was tested using four different methods, each method changes the number of test and training data. The accuracy of the proposed system was 97.2%.

Zollanvari et al. [12] applied the maximum-weight dependence tree to propose a GPA prediction model. The proposed model is based on the behavioral characteristics of the students. A questionnaire containing 20 questions was distributed in order to find out the behaviors that affect GPA prediction. These questions are based on the educational objectives. The number of students in the dataset is 82 students. The accuracy of the proposed model was 65.85%. Better

results can be achieved by increasing the number of students in the dataset and incorporating academic performance with behavioral characteristics.

Putpuek et al. [13] compared the decision tree algorithm and data mining techniques to predict the students' GPA based on personal factors. The selected algorithms were (C4.5 and ID3) and the techniques were (Naïve Bayes and K-NN) and personal factors such as (gender, skills, type of acceptance, etc.). The dataset contains data of 2,281 students graduating from the same college in different years. The results showed the superiority of the Naïve Bayes techniques, as it achieved an accuracy of 43.18%. While ID3, C4.5, and K-NN achieved 41.65%, 42.88%, and 43.05% accuracy results, respectively.

In order to explore factors affecting the students' academic performance, Hamoud et al. [14] proposed a model that compares the algorithms of the Decision Tree (J48, Random Tree, and REPTree). The study was conducted on the students at Computer Science College at the Basra University in Iraq. Data was collected from 161 students' answers to a questionnaire containing 60 questions in different fields. The results showed the superiority of J48. The results also showed that the factors such as the GPA, the father's job, and the quality of food have a high effect on the students' performance. On the contrary, factors such as gender and age have a weak effect.

Pallathadka et al. [15] analyzed four machine learning algorithms to find out the most accurate one. The used algorithms are SVM, C4.5, ID3, and Naive Bayes. Examinations were conducted on the UCI machinery student performance dataset available online. The dataset contains 649 records and 33 factors. The results showed that the SVM algorithm is the most accurate.

B. Predicting Academic Performance for Students in Saudi Universities

In order to solve the problem of students graduating with a low GPA in Saudi Arabia and help through early intervention Alyahyan and Düşteör[16] developed a model predicting the final GPA based on the results of the first year after the preparatory year. This model is based on decision tree algorithms (Rep Tree, Random Tree, and J48). The dataset contains the record of 339 students and 15 factors such as gender, nationality, subjects' grades, and final GPA. According to the results, the J48 algorithm achieves the highest predictive ability of up to 69.3%.

Al-Barrak and Al-Razgan [17] applied the J48 algorithm on a dataset of 239 female students majoring in computer science at a Saudi university. In order to find which courses, have the most impact on the final cumulative GPA. The dataset contains 16 compulsory computer science courses. Based on the results of the experiment, it was found the two courses' Software Engineering-1 and JAVA-2' have the greatest effect on the final grade.

In order to measure the ability of classification algorithms to predict the GPA Mueen et al. [18] proposed a predictive model based on a student's record in only two courses. They used three classification techniques (Naive Bayes, C4.5, and MLP). This study was conducted on King Abdelaziz

University students in two courses (Programming and Operating Systems). Everything related to the subject, including assignments, tasks, tests, etc., were collected through the Learning Management System LMS. The results showed the superiority of the Naive Bayes classifier over the classifiers, and it achieved a prediction ability to 86%.

Altujjar et al. [19] presented a predictive model to the performance of undergraduate students in the College of Computers at King Saud University using classification algorithms. The model aims to identify important courses that have a significant impact on academic achievement. The ID3 algorithm was used to build the model for each academic year. The dataset consists of 100 student records. The dataset was split into 75% for training and 25% for testing. The results showed that the courses (IT 221), (CSC111), and (CSC113) have a significant and clear impact on the students' academic performance.

Hilal Al-Murabaha [20] analyzed the data of Saudi university students by using classification techniques. The objective is to predict student performance during the undergraduate semester. The dataset contains the record of 225 students and 10 features such as (midterm exams, attendance, final exam score, previous exams score, science experiments, projects, etc.). Five classifiers are applied to analyze student data (Naive Bayes, Bayesian Network, ID3, J48, and Neural Network) using the WEKA tool. The results showed the superiority of Bayesian Network over other classifiers, with an accuracy of 92% also, the amount of data affects the accuracy of the results.

C. Classification Algorithms

1) *Neural Networks (NN)*: Additionally referred to as artificial neural networks (ANNs) or simulated neural networks (SNNs), are at the top of deep learning algorithms. Their call and shape are inspired by the way of the human brain, mimicking the manner that biological neurons signal to each other [21] [22].

(ANNs) re-constructed from node layers, containing an enter layer, one or more hidden layers, and an output layer. each node, or artificial neuron, connects to some other and has an associated weight and threshold [21] [22]. If the output of any individual node is above the specified threshold fee, that node is activated, sending information to the following layer of the group, otherwise no information is surpassed.

2) *Gradient Boosting (GB)*: The Gradient Boosting algorithm is commonly used in the field of machine learning and is often used to build prediction and classification models. It aims to build a strong model using a succession of weak models. At each stage, a new model is built by improving the mistakes of the previous model, achieved by training the new model on the errors of the previous model. This procedure helps reduce bias errors in the final model [23] [24].

3) *K-Nearest Neighbors (kNN)*: In k-NN classification, the output is a class membership. An object is classed via a plurality vote of its pals, with the object being assigned to the class most commonplace amongst its okay nearest neighbors. If

$k = 1$, then the item is without a doubt assigned to the class of that single nearest neighbor [24][25].

4) *Logistic Regression (LR)*: This type of statistical version is regularly used for type and predictive analytics. Logistic regression estimates the possibility of an occasion taking place, together with voting or did not vote, based on a given dataset of impartial variables [26] [27] [28]. Because the final result is a possibility, the structured variable is bounded between 0 and 1. In logistic regression, a logit transformation is implemented on the odds this is the chance of fulfillment divided by way of the probability of failure. that is also typically referred to as the log odds or the natural logarithm of odds [26] [27] [28].

5) *Random Forest (RF)*: This classifier is the most popular. The primary dataset is used to construct a subset of random trees. Each tree contains a different set of features and data to predict a decision. In the end, the most common and frequent decision is chosen [24] [26] [29].

III. RESEARCH METHOD AND MATERIAL

In the method section, we present the data mining phases that we went go through to develop a predictive model for the academic tracks via GPA based on the preparatory year data in Saudi universities. Our research methodology consists of six phases (Fig. 1) as follows:

Fig. 1. Research methodology.

A. Data Collection

We obtained the dataset from a Saudi university, which preferred not to be named with taking care of the privacy of students and concealing any data indicating their personality. The dataset contains records of the preparatory year for the scientific subjects (Chemistry, Statistics, Math, Physics and BIO), the final GPA upon graduation from the university and the college to which the student is registered. All these records belong to students graduating from a university in the same year. The structure of the data set was not suitable for the data mining process. The number of records is 12393, and each student had five records in the data set, with each record representing a subject, as shown in the following Fig. 2:

2	1064702746	Female	IT	Statistics	A+	4.77
3	1064702746	Female	IT	BIO	A+	4.77
4	1064702746	Female	IT	Physics	A+	4.77
5	1064702746	Female	IT	Math	A+	4.77
6	1064702746	Female	IT	Chemistry	A+	4.77
7	1064702759	Male	Engineering	Math	A+	4.38
8	1064702759	Male	Engineering	Chemistry	B	4.38
9	1064702759	Male	Engineering	Physics	B+	4.38
10	1064702759	Male	Engineering	Statistics	B+	4.38
11	1064702759	Male	Engineering	BIO	B+	4.38
12	1064702761	Male	Engineering	Math	A+	4.95
13	1064702761	Male	Engineering	Statistics	A+	4.95
14	1064702761	Male	Engineering	Physics	A+	4.95
15	1064702761	Male	Engineering	BIO	A+	4.95
16	1064702761	Male	Engineering	Chemistry	A+	4.95

Fig. 2. Pure dataset.

Students are evaluated in each subject out of one hundred marks distributed as in the following Table I.

TABLE I. STUDENT EVALUATION

Mark	Grade symbol
From 95 to 100	A+
From 90 to less than 95	A
From 85 to less than 90	B+
From 80 to less than 85	B
From 75 to less than 80	C+
From 70 to less than 75	C
From 65 to less than 70	D+
From 60 to less than 65	D

B. Data Pre-Processing

1) Data cleaning and data reduction: During this phase, we made sure that all students took the same courses, so we deleted the data of students who transferred from other universities.

To increase the balance of the dataset and because of the large difference between the number of students graduating from some colleges we have deleted the data of students graduating from the following colleges (Table II):

TABLE II. DELETED COLLEGES

Deleted colleges	Number of students
Arts	23
Law and Political Science	7
Media	4

2) Data transformation: At this stage, the data has been transformed into a format that accepts modeling. The dataset structure for each student was five records. Each record represents a subject. Also, we changed the GPA formula from a numeric to a categorical as follows (Table III):

TABLE III. GPA SYMBOL

GPA	GPA symbol
From 5.00 to 4.50	Excellent
From 4.49 to 3.75	Very_Good
From 3.74 to 2.75	Good
From 2.74 to 2.00	Pass

After that, we added a new column named (OUTPUT). The students were divided into two values. Any student who achieved a GPA greater than or equal to four will be given in OUTPUT feature a value (RIGHT), and a student with a cumulative GPA of less than four will be given a (WRONG) value in the OUTPUT feature as Table IV.

This procedure helps us to form our hypothesis "When a student achieves a GPA higher than 4.00, then the academic track is correct".

TABLE IV. STUDENT OUTPUT SYMBOL

GPA	OUTPUT
From 4.00 to 5	RIGHT
Less than 4.00	WRONG

After completing the data pre-processing stage, we extracted a data set containing 2363 records in Excel format for this study. The features are the following (Table V):

TABLE V. FEATURES ON A DATASET

Features	No. of types	Type
Gender	2	Male, Female
College	12	Applied_Medical_Sciences, Dentistry, Design_and_Built_Environment, Eco_and_Admin_Sciences, Engineering, Home_Economics, Geology, IT, Medicine, Nursing, Pharmacy, Science
BIO	6	A+, A, B+, B, C+, C
Math	6	A+, A, B+, B, C+, C
Chemistry	6	A+, A, B+, B, C+, C
Physics	6	A+, A, B+, B, C+, C
statistics	6	A+, A, B+, B, C+, C
GPA		
Graduation Grade	4	Excellent, Very_Good, Good, Pass
OUTPUT	2	RIGHT, WRONG

Fig. 3 shows the structure of the final dataset.

Gender	College	BIO	Chemistry	Math	Physics	Statistics	GPA	Graduation Grade	OUTPUT
Female	IT	A+	A+	A+	A+	A+	4.77	Excellent	RIGHT
Male	Engineering	B+	B	A+	B+	B+	4.38	Very_Good	RIGHT
Male	Engineering	A+	A+	A+	A+	A+	4.95	Excellent	RIGHT
Male	Eco_and_Admin_Sciences	C	D+	B	C+	C	3.09	Good	WRONG
Female	IT	A	B+	B	C+	A	4.13	Very_Good	RIGHT
Female	IT	B+	A	A+	A	B+	4.61	Excellent	RIGHT
Female	Applied_Medical_Sciences	B+	C+	B+	B	B+	4.55	Excellent	RIGHT
Female	Science	A	A	A+	A+	A+	4.65	Excellent	RIGHT
Male	Engineering	B	A	A+	A+	B+	4.02	Very_Good	RIGHT
Male	Engineering	B+	B+	A+	A+	C+	4.17	Very_Good	RIGHT
Male	Engineering	B+	A	A+	A+	A+	4.78	Excellent	RIGHT
Male	Engineering	C	B	A+	A+	B	3.84	Very_Good	WRONG
Female	Home_Economics	C+	B+	A+	A+	A	4.89	Excellent	RIGHT
Female	Science	D	A	A+	A+	B	4.57	Excellent	RIGHT
Male	Engineering	B+	A	A+	A+	A+	4.37	Very_Good	RIGHT
Female	Science	B	A+	A	A+	B+	4.0	Excellent	RIGHT
Male	Engineering	A	A	A+	A+	A+	4.0	Excellent	RIGHT
Male	Science	D	D	C+	D+	B	2.75	Good	WRONG
Female	Engineering	A	A+	A+	A+	A+	4.13	Very_Good	RIGHT
Female	Science	D	D+	B+	A	C+	3.72	Good	WRONG

Fig. 3. Dataset after pre-processing.

C. Classification Algorithms Selection

After several experiments and an understanding of the characteristics of the classification algorithms, to achieve the best possible results from the data set, the following classification throws were used with default parameters values:

- Neural Network (ANN)
- Gradient Boosting (GB)
- K-Nearest Neighbors (kNN)
- Logistic Regression (LR)

- Random Forest (RF)

D. Experiments (Training and Testing)

We chose the Orange Data Mining software to conduct the experiments. Orange data mining is written in Python and is open-source. It was developed at the University of Ljubljana. The program's graphic interface offers an easy experience in handling and ease of learning [30] [31]. It supports several operating systems such as Windows and Linux. It provides the possibility to test algorithms, validation, and prediction.

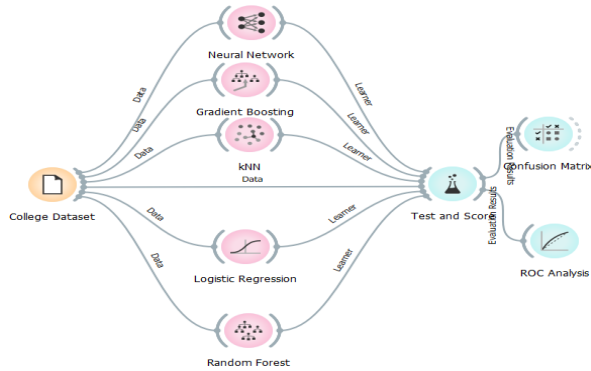

Fig. 4. Orange data mining model.

The data set was used for each student record with nine characteristics. Fig. 4 shows the model created in the orange data mining tool. To explain how the model works, the data set has been loaded and the feature to which each class of data belongs, and which feature of this data is the target as in Fig. 5.

Name	Type	Role	Values
1 Gender	☑ categorical	feature	Female, Male
2 College	☑ categorical	feature	Applied_Medical_Sciences, Dentistry, Design_and_Built_Environment, ...
3 BIO	☑ categorical	feature	A, A+, B, B+, C, C+, D, D+
4 Chemistry	☑ categorical	feature	A, A+, B, B+, C, C+, D, D+
5 Math	☑ categorical	feature	A, A+, B, B+, C, C+, D, D+
6 Physics	☑ categorical	feature	A, A+, B, B+, C, C+, D, D+
7 Statistics	☑ categorical	feature	A, A+, B, B+, C, C+, D, D+
8 GPA	☒ numeric	skip	
9 Graduation Grade	☑ categorical	skip	Excellent, Good, Pass, Very_Good
10 OUTPUT	☑ categorical	target	RIGHT, WRONG

Fig. 5. Model specifications.

In this model, the OUTPUT was determined as the target and the rest were as features and skipped GPA and Graduation Grade features as in Fig. 3 to 5. Then the data set was linked to the previously selected algorithms widget, as well as to the "Test and Score" widget to display the results. This procedure provides training and testing of all algorithms at the same time which saves a lot of time and effort rather than testing the algorithms individually. CROSS VALIDATION was used to split the data into test and training data. Cross-validation divides the data into several groups called FOLDS. This method splits the dataset randomly into 10 subsets [32]. The model training phase uses nine subsets, while the testing phase uses the final subset. This process is repeated 10 consecutive

times each time a different subset is selected in the testing phase [32].

E. Hypothesis

When the student graduates with a GPA greater than or equal to (4.00), this means that the academic track chosen by the student is correct and commensurate with the characteristics chosen in the dataset. On the contrary, when a student achieves a GPA less than (4.00), the academic track chosen by the student is wrong.

F. Validation

To evaluate the performance of the model, we will rely on the Accuracy, Area under the curve (AUC-ROC), and confusion matrix.

- Area under the curve (AUC-ROC):

Gives an idea of the effectiveness of the model and the AUC score is used to compare the different algorithms. Each classifier will predict either a true or false result. Whenever the AUC value was greater than 0.5 the classifier was able to separate the two results and give a correct result and vice versa if the AUC value were less than 0.5 the classifier would have predicted an opposite outcome. That is, the actual positive is expected to be negative. The use of AUC is used when the data set is unbalanced [33].

- Accuracy:

In machine learning and data technology, the term accuracy is inevitable almost in every category assignment. this is the most popular measurement or metric used to assess models [31]. We calculate the accuracy by using the equation:

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN}$$

- Confusion Matrix :

A confusion Matrix is one way to measure the performance of classification models. It can be used when the outputs are two or more classes. The result is an extracted table with four areas. Each area represents the expected and actual value [27] [34] [35] . as shown in Fig.6 are prescribed.

		Actual Values	
		Positive (1)	Negative (0)
Predicted Values	Positive (1)	TP	FP
	Negative (0)	FN	TN

Fig. 6. Confusion matrix.

IV. EXPERIMENTS AND RESULTS

In this section, we will do the experiments based on the database described in the previous section and using Orange Data Mining Tool. The classification algorithms will be used with default parameters. The algorithm will be evaluated based on the following criteria: accuracy, an area under the curve (AUC-ROC) and a confusion matrix. The goal of the experiments will be to predict the student's GPA based on five subjects studied in the preparatory year by using classification

algorithms. To reach the answer to the question, "Is the academic track chosen by the student right or wrong?" The results were as follows in Table VI:

TABLE VI. RESULTS OF THE GPA PREDICTION MODEL

Model	AUC	CA	F1	precision	Recall	Specificity
GP	0.850	0.789	0.789	0.789	0.789	0.788
kNN	0.804	0.749	0.749	0.749	0.749	0.745
LR	0.854	0.791	0.791	0.791	0.791	0.790
ANN	0.846	0.786	0.786	0.786	0.786	0.784
RF	0.817	0.755	0.755	0.755	0.755	0.749

The results of the experiments showed that the LG algorithm provides the best performance with a slight distinction from the GP algorithm. The accuracy and AUC-ROC values for the LG algorithm were 79.1% and 85.4%, respectively. While the GB algorithm attained up to 78.9% accuracy and an AUC-ROC value of 85%. In the same context, the kNN algorithm performed the weakest with an accuracy of up to 75% and an AUC-ROC value of 80.4%. The performance of all algorithms used in the experiment is compared in Fig. 7.

Fig. 7. Comparison performance metrics of algorithms.

The confusion matrix is constructed as shown in Table VII. Where diagonal entries reflect successfully categorized samples, and the remaining entries represent misclassified ones. The results demonstrate that, according to the LG algorithm, actually 1015 predicted the right academic track and 853 the wrong academic track.

TABLE VII. CONFUSION MATRIX FOR ALL ALGORITHMS

LG Algorithm			GB Algorithm		
Actual	Prediction		Actual	Prediction	
	Right	Wrong		Right	Wrong
	Right	1015		262	Right
Wrong	233	853	Wrong	236	850
NN Algorithm			kNN Algorithm		
Actual	Prediction		Actual	Prediction	
	Right	Wrong		Right	Wrong
	Right	1015		262	Right
Wrong	244	842	Wrong	300	786
RF Algorithm					
Actual	Prediction				
	Right	Wrong			
	Right	1001	276		
Wrong	327	759			

V. DECISION AND CONCLUSION

The main objective of this research was to develop a model to predict the right academic track Via GPA by using classification algorithms for Saudi university students. Therefore, we used a dataset of Saudi university students containing five scientific subjects studied in the preparatory year in addition to the student's gender, college, and final GPA. We made sure that all students studied the same subjects. Five classification algorithms serve as the basis for the proposed model: gradient boost, kNN, logistic regression, neural network, and random forest. We assumed that when the student achieves a GPA greater than or equal to 4.00 which means the academic track is correct. But if the student achieved a GPA less than 4.00, the student chose the wrong academic track. The results show that the logistic regression algorithm is the most accurate and able to predict correctly. It achieved an accuracy of 79.1% and an AUC of 85.4%. It can be seen that the accuracy of the model is somewhat low. This is due to the small number of features and their confinement to the academic subjects and the gender of the student. Other features can affect the accuracy of the model, such as behavioral characteristics, high school results, and Aptitude and achievement tests. The results justify the validity of the hypothesis that it is possible to predict the academic track based on the GPA where the proposed model was able to predict the final GPA that the student will achieve if he joins a specific academic track. The results of this study are expected to help educational institutions in early intervention to guide students who are struggling to choose the right academic track. Future research can improve accuracy by relying on additional

variables including behavioral characteristics, results from aptitude tests, and grades from high school.

College of Science, Zhongyuan University of Technology, Zhengzhou 450007, Henan, China¹
University Hospital, Zhongyuan University of Technology, Zhengzhou 450007, Henan, China²

Abstract—Generating a three-dimensional (3D) reconstruction of tumors is an efficient technique for obtaining accurate and highly detailed visualization of the structures of tumors. To create a 3D tumor model, a collection of 2D imaging data is required, including images from CT imaging. Generative adversarial networks (GANs) offer a method to learn helpful representations without annotating the training dataset considerably. The article proposes a technique for creating a 3D model of lung tumors from CT scans using a combination of GAN and LSTM models, with support from ResNet as a feature extractor for the 2D images. The model presented in this article involves three steps, starting with the segmentation of the lung, then the segmentation of the tumor, and concluding with the creation of a 3D reconstruction of the lung tumor. The segmentation of the lung and tumor is conducted utilizing snake optimization and Gustafson–Kessel (GK) method. To prepare the 3D reconstruction component for training, the ResNet model that has been pre-trained is utilized to capture characteristics from 2D lung tumor images. Subsequently, the series of characteristics that have been extracted are fed into a LSTM network to generate compressed features as the final output. Ultimately, the condensed feature is utilized as input for the GAN framework, in which the generator is accountable for generating a sophisticated 3D lung tumor image. Simultaneously, the discriminator evaluates whether the 3D lung tumor image produced by the generator is authentic or synthetic. This model is the initial attempt that utilizes a GAN model as a means for reconstructing 3D lung tumors. The suggested model is evaluated against traditional approaches using the LUNA dataset and standard evaluation metrics. The empirical findings suggest that the suggested approach shows a sufficient level of performance in comparison to other methods that are vying for the same objective.

Keywords—3D tumor reconstruction; lung cancer; LSTM; Generative adversarial network; ResNet

I. INTRODUCTION

Among men, lung cancer is the cancer type that occurs the second most frequently. In recent times, a number of data-based tools have been created by researchers to assist in the diagnosis and treatment of this condition. The ability to comprehend the 2D/3D shape of a tumor is crucial for visualizing the progression of its growth and for surgical purposes. 3D images offer comprehensive insights into the form and structure of the tumor [1].

CT is the favored imaging method for the detection of lung tumors among a variety of diagnostic imaging methods. Despite the fact that CT provides valuable information about

tumors, evaluating an increasing number of images can pose a challenge for radiologists, potentially creating risks. Consequently, it is crucial to create intelligent diagnostic approaches that can aid radiologists and doctors in making faster and more accurate judgments than those reliant exclusively on CT images [2].

Recently, several studies have been conducted on 3D tumor healing with a special focus on healing brain tumors. Although these methods have achieved promising results, they fail to offer a high-quality 3D reconstruction of lung tumors. This is due to the fact that tumors may have complex and random shapes. Additionally, high-quality 3D reconstruction heavily relies on the availability of accurate data in all three dimensions. To the knowledge, the most recent study [3] utilizes conventional methods to reconstruct lung cancer in three dimensions. In this study, significant characteristics are identified from a two-dimensional shape during the reconstruction process. This method includes multiple stages, such as surface reconstruction and smoothing, which can be computationally intensive. As a result, applying this approach in real-world situations where time is a crucial factor may be impractical. Furthermore, the proposed approach is tailored exclusively to lung tumors and may not be readily adaptable to other types of tumors or organs. Convolutional neural networks (CNNs) are capable of automatic feature extraction. Nonetheless, teaching CNNs necessitates a substantial quantity of classified information, which may be lacking, particularly in the medical sector. The processing power and memory requirements for CNNs training may also be high. Transfer learning (TL) may be used instead of training from scratch to deal with these difficulties. In TL, CNNs parameters are set to the values that have been trained on large-scale datasets. Many TL networks, particularly ResNet, have achieved satisfactory results in medical imaging applications [4]. The use of GAN in medical image reconstruction is not extensively studied [5]. Wang et al. [6] developed an U-Net model with skip connections that are sparse by merging two GAN methods, an encoder-decoder method, and an U-Net method, to enhance imaging quality and decrease the size of imaging equipment. Meanwhile, Yang et al. [7] created a generator network with skip connections based on the U-Net architecture, and they also incorporated a refinement learning approach to ensure the stability of GAN training and facilitate faster convergence with less parameter tuning. Despite achieving satisfactory results in their respective tasks, these methods lack the ability to perform 3D reconstruction of lung tumors.

To produce a 3D image, it is vital to extract a comprehensive representation from a series of 2D images in the form of a single vector that encapsulates all the necessary details. Recursive networks, such as LSTM [8], can address this challenge and have been found to be suitable for sequence data in previous studies [9, 10]. LSTM utilizes special blocks called cells. Each cell has three gates: input, output, and forget [11]. The input gate handles the storage of new information in the cell. The output gate is responsible for selecting which portion of the cell state should be transmitted to the cell's output. The forget cell is responsible for forgetting (throwing away) data as time passes, which helps with the vanishing gradient problem [12].

A GAN is composed of two neural networks, namely a generator and a discriminator. The generator creates synthetic data, and the discriminator attempts to tell actual samples from synthetic ones. The GAN model's capacity to generate superior synthetic data has made it highly popular in academics and business. Promising outcomes have been demonstrated by using GAN in different fields of application, including but not limited to generating high-resolution images, translating text to images, and transforming images to other types of images [13]. Acceptable generalization can be achieved by training DNNs using a combination of limited real data and large amounts of synthetic data generated by GANs. The creative technique of GANs has been employed in diverse medical imaging assignments, such as image partitioning, image enhancement, and image creation. By instructing the generator network on an extensive compilation of images, GANs can produce fresh images that have corresponding attributes to the source dataset. In medical imaging, this has been used to create new images that can help diagnose diseases or assist in surgical planning. On the other hand, the discriminative approach of GANs has been used to improve the quality of medical images. Discriminative GANs aim to distinguish between real and fake images and use this information to improve the generator network. By doing so, discriminative GANs can learn to regularize or normalize images and remove any artifacts or noise that might be present. Both approaches have shown great promise in medical imaging, and researchers are continually exploring new ways to apply GANs in this field. However, challenges remain, such as the need for large datasets and the difficulty of interpreting the outputs of GANs. Nevertheless, the potential benefits of GANs in medical imaging make it an area of active research and development [14].

For this study, a GAN-driven approach is suggested to produce 3D lung tumor reconstructions. The procedure comprises of three steps: segmentation of the lung, segmentation of the tumor, and creation of a 3D representation. The first stage employs the snake optimization method [15] to identify the left and right lungs. The suggested method simplifies the complexity of the issue by dividing it into multiple lower-dimensional problems with search areas that are gradually reduced [16]. The second stage utilizes GK clustering [17] to segment tumors and extract tumor masses from the affected lungs. The third stage involves an LSTM and a GAN. Initially, a pre-trained ResNet model extracts features from 2D lung tumor images, and subsequently, important features are extracted from the tumor sequence using the

LSTM and passed as input to the GAN. The generator uses the LSTM's output to construct the 3D reconstruction, while the discriminator distinguishes between the generated and real images. The proposed approach is tested and evaluated using the commonly used LUNA dataset. The LUNA dataset has been extensively used in lung cancer diagnosis and is considered a standard benchmark for evaluating algorithms related to lung nodule detection and classification. It comprises more than 1,000 chest CT scans, with each scan annotated with multiple nodules. The main contributions are listed below:

- The majority of current approaches for reconstructing 3D tumors concentrate on brain cancer and do not yield satisfactory outcomes for lung cancer tumors. Accordingly, this study concentrates only on the 3D construction of tumors related to lung cancer.
- Afshar et al. [3] conducted the latest research on the reconstruction of lung cancer tumors, which has a relatively high level of computational complexity. However, the suggested technique surpasses Afshar's investigation in regards to effectiveness and computational intricacy.
- Although GAN has the potential to generate high-quality synthetic images, its application in medical diagnosis, particularly for lung cancer diagnosis, has been limited. This investigation seeks to examine the utilization of GAN in constructing three-dimensional lung tumor representations, which is a novel approach in the field.
- In the medical domain, it is frequently encountered to have insufficient labeled training data. To address this, pre-trained models (transfer learning) are often used.
- Reconstructing 3D images of lung cancer tumors involves using a series of 2D CT images. To exploit the sequential nature of this information, recurrent neural networks such as LSTM are utilized.

The paper is structured in the following manner: Section II discusses related work, Section III details the suggested methodology, while Section IV displays the experimental findings, and Section V discusses the results. Section VI concludes the paper and provides future directions.

II. RELATED WORK

A. Generative Adversarial Network

Liao et al. [18] utilized incorrect sampling to reconstruct cone beam CT (CBCT). The model involved the utilization of pyramidal neural networks and computer-generated maps for descriptive discriminants. This approach enabled the reconstruction of results while simultaneously preserving the anatomical structure. MR image reconstruction evaluates k-space data in the frequency domain model. Different loss functions have been employed to identify localized image structures in image restoration, such as coherence loss and cycle consistency loss, when suppressing cardiac CT noise. Wolterink et al. [19] proposed a low-dose CT noise after attenuation of losses in several areas. However, the result prevented the projection of the local image. MRI image

reconstructions are uncommon because they have well-defined back-and-forth formulas such as Fourier transforms.

B. Pre-trained Model

More training data leads to deep models with better performance [20]. That is why significant efforts have been put into gathering and annotating large-scale datasets such as ImageNet, PASCAL VOC, MS COCO, etc [21]. At the start of training, setting the initial parameters of deep models to the parameters of deep models that have already been trained on these large datasets improves the convergence speed of training. It boosts the final performance of the model [22].

3D semantic segmentation is quite common in the medical domain. For example, small organ segmentation in 3D abdominal CT scans has been tackled using an RNN [23]. Most medical 3D image analyses, including [24], train a deep model from scratch, which is challenging due to insufficient annotated data. Alternatively, the model's parameters can be initialized to values pre-trained on a source dataset. The model can then be fine-tuned using (possibly limited) target dataset. To get reasonable results, the distribution of the source and target datasets should be as similar as possible [25]. Therefore, for training deep models on 3D medical images, the model should be initialized to values pre-trained on another 3D medical dataset.

C. 3D Tumor Reconstruction

Lately, 3D models have been created in various medical areas, allowing doctors to provide improved treatment to their patients [26-28]. For example, 3D models were applied to liver resection, assisting surgeons in studying the liver structure [29]. 3D reconstruction of the brain based on magnetic resonance imaging (MRI) [30, 31] has been tackled as well [32, 33]. Amruta et al. [34] proposed a 3D method for brain tumor recovery in which brain tumors were segmented by morphological manipulations and 3D shapes were generated using 3D interpolation. Jaffar et al. [35] considered a multi-step process for segmenting and visualizing brain tumors evaluated on different datasets. Kamencay et al. [36] used the medium screening method to segment the images. For modeling the 3D shape, a combination of the Sum of Squared Differences (SSD) and Speeded-Up Robust Features (SURF) was used to find the corresponding pixels in the image. The method provides an accurate 3D model of the human pelvis. Sun et al. [37] proposed a two-step 3D segmentation that involves identifying active shape models and finding the optimal surface. Several studies have developed valuable methods to address 3D tumor reconstruction [38].

In the context of lung cancer, Afshar et al. [3] recently proposed a method for tumor segmentation and 3D reconstruction of CT images. While this is a significant step towards improving lung cancer treatment, the method has a high computational complexity. This drawback limits its practical applications and motivates the development of new approaches with improved performance and reduced computational costs. Therefore, this study aims to explore a novel approach using GAN for 3D reconstruction of lung cancer tumors, which can potentially overcome the limitations of existing methods.

III. THE PROPOSED MODEL

GANs were first proposed by Goodfellow et al. [39], in which two separate networks are similarly trained: the generator and discriminator networks. The purpose of the generator is to produce data such as images, text, etc. [40], which are structurally similar to real data but are fake. On the other hand, the task of the discriminator network is to strengthen the generator. These two networks engage in a two-player min-max game with a value function $V(D,G)$ [41]:

$$\begin{aligned} \min_G \max_D V(D,G) \\ = E_{x \sim p_{data}(x)} [\log(D(x))] \\ + E_{z \sim p_z(z)} [\log(1 \\ - D(G(z)))] \end{aligned} \quad (1)$$

where x and z represent input data and noise, respectively. G and D denote the generator and discriminator, respectively. $p_{data}(x)$ and $p_z(z)$ show the probability distributions of the input data and the noise, respectively. E represents mathematical expectation.

The objective is to evaluate the 3D morphology of lung tumors using a limited set of 2D CT images. The general outline for the suggested model is presented in Fig. 1. Based on this illustration, the model comprises three stages, namely lung partitioning, tumor partitioning, and 3D rebuilding. Using the snake optimization method, lung segmentation aims to separate two lungs from a CT image. In the tumor localization phase, the region of the tumor in the lung is identified from the healthy region on each 2D slice using snake optimization and GK clustering. Then, a GAN-based model is utilized to reconstruct the 3D model of the tumor. The following sections will be described separately.

A. Lung Segmentation

Segmentation of the lungs is a vital stage in the task and can influence the model's efficacy considerably. The method used for lung segmentation was adopted from a recent study [42].

The approach involves using the snake optimization method to separate the lungs from the background. This method allows the lung outline of one section to serve as the initial outline for subsequent sections in the algorithm [43]. The snake model refers to a curve that starts at a specific point and then moves towards the boundaries of an object. This procedure is referred to as a semi-automated process since it requires some degree of user involvement. This article uses the point-based snake model, which considers a contour as a collection of distinct points, although there are various snake models available [44]. The procedure aims to reduce an energy function [45, 46] that includes internal and external energies, where the internal energy is associated with the form of the contour. On the other hand, external energy relies on image characteristics. Given coordinates $x(s)$ and $y(s)$ in the direction of the contour, where s is a variable between zero and one, the contour can be defined in the following way [47]:

$$v(s) = [x(s), y(s)] \quad (2)$$

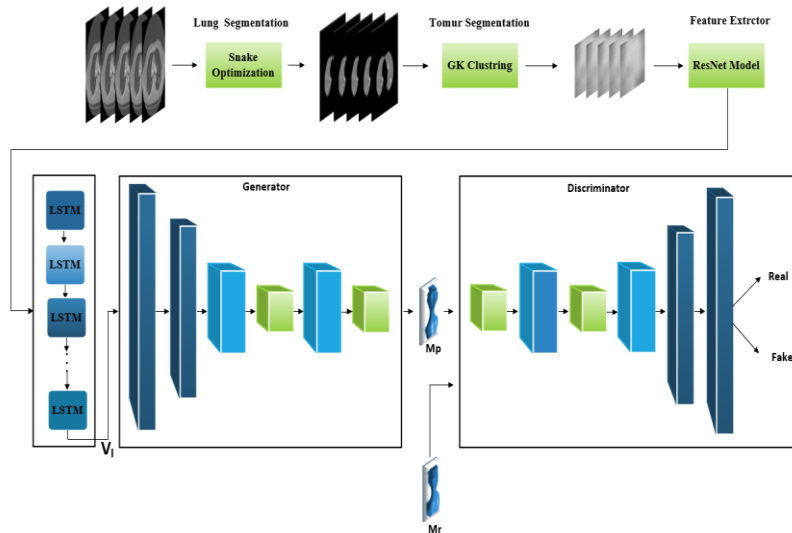

Fig. 1. The proposed model.

Where $v(s)$ represents the snake curve variable, the energy function is defined as follows:

$$E_{snake}^* = \int_0^1 E_{snake}^*(v(s)) ds \quad (3)$$

$$= \int_0^1 (E_{int}(v(s)) + E_{image}(v(s)) + E_{con}(v(s))) ds$$

where E_{con} indicates constant external forces. E_{int} and E_{image} denote the internal energy and the image forces, correspondingly, which can be calculated as:

$$E_{int} = \alpha(s) \left(\frac{dv}{ds}\right)^2 + \beta(s) \left(\frac{d^2s}{dv^2}\right)^2 \quad (4)$$

$$E_{image} = -|\nabla I(x, y)|^2 \quad (5)$$

The initial term turns the snake into a membrane. Increasing the value of β results in an increase in the internal energy, while the image energy comprises the energy of edge, line, and terminations. The value of $I(x, y)$ corresponds to the intensity of the pixel located at (x, y) . The negative sign at the beginning of Equation 5 is utilized since the image gradient is more prominent on the object boundary, and the objective of energy minimization is to detect the object boundary. The aim of the energy function with the damping term is to detect object boundaries. The Viterbi algorithm [48], a widely used technique for optimizing energy functions, is used in this study.

B. Tumor Segmentation

After the lung segmentation stage, tumors are segmented utilizing the GK clustering method. GK is a fuzzy-based approach with the benefits of using covariance and distance matrixes to make clusters with various shapes. The objective function of this method is defined as follows:

$$J_m(U, A_k) = \sum_{i=1}^M \sum_{k=1}^K u_{ik}^2 D^2_{ikA_k} \quad (6)$$

Where U stands for the membership matrix, and m is a coefficient describing the degree of fuzziness. A_k shows a regional norm-inducing matrix for each cluster optimized. M and K are the number of data points and clusters, respectively, and D^2 indicates the squared space between data points and cluster centers., which is calculated as:

$$D^2_{ikA_k} = (z_i - w_k)^T A_k (z_i - w_k) \quad (7)$$

The matrix is used to incorporate the topological characteristics of the data structure into the distance norm.

C. 3D Reconstruction Method

In this paper, 3D reconstruction is carried out using a deep learning model. As shown in Fig. 1, the tumor segmentation stage yields N sequences of 2D images. These images are fed to the pre-trained ResNet network to perform feature extraction. The parameters of this network have been determined by training on the ImageNet dataset. The output of the ResNet is used as input to LSTM units, the output of which is fed to a GAN model. GAN aims to reconstruct 3D images from sequences of 2D data fed to it. The GAN discriminator distinguishes between the synthetic images produced by the generator and the real ones.

D. Overall Algorithm

The overall algorithm of the suggested method is displayed in Algorithm 1. Let $Pateints = \{P^1, P^2, P^3, \dots, P^N\}$ be the set of available patients with N examples, where P^i corresponds to the i -th patient. Every P^i contains a collection of S CT images. In every iteration, for every minibatch with size M , the lung segmentation and tumor segmentation operations are performed, respectively. After that, the sequence of selected lung tumors for every patient whose length is L enters the ResNet model. The L -sample sequence outputted by ResNet is fed into an LSTM. Finally, LSTM output comes into the generator to generate a 3D lung tumor. Updating the components, i.e., LSTM, generator, and discriminator, is done based on introduced standard methods.

Algorithm 1 Overall algorithm for the suggested model.

Input: $Pateints = \{P^1, P^2, P^3, \dots, P^N\}$: the set of available patients, $Images = \{X^1, X^2, X^3, \dots, X^N\}$: the set of available real 3D images, N : the number of patients, S : the number of CT images for every patient, G : generator, D : discriminator;
 for the number of training iterations, do
 for every minibatch with size M do
 for $i = 1$ to M do
 for $j = 1$ to S do
 P_t^{ij} : segment P^{ij} using the snake algorithm; // P^{ij} shows the j -th CT image for the i -th patient
 for $i = 1$ to M do
 $\{P_t^{i1}, P_t^{i2}, P_t^{i3}, \dots, P_t^{iL}\}$: select $L(\leq S)$ consecutive samples containing tumors recognized by the GK clustering from
 $\{P_v^{i1}, P_v^{i2}, P_v^{i3}, \dots, P_v^{iL}\}$;
 $\{P_v^{i1}, P_v^{i2}, P_v^{i3}, \dots, P_v^{iL}\}$: extract features every item of $\{P_t^{i1}, P_t^{i2}, P_t^{i3}, \dots, P_t^{iL}\}$ using the ResNet model;
 V_v^i : enter $\{P_v^{i1}, P_v^{i2}, P_v^{i3}, \dots, P_v^{iL}\}$ into the LSTM network and get the latest unit of LSTM;
 update the LSTM network by its stochastic gradient;
 update the generator by descending its stochastic gradient:
 $\nabla_{\theta_g} \frac{1}{M} \sum_{i=1}^M \log(1 - D(g(V_v^i)))$
 Update the discriminator by ascending its stochastic gradient:
 $\nabla_{\theta_d} \frac{1}{M} \sum_{i=1}^M [\log D(x^i) + \log(1 - D(g(V_v^i)))]$

IV. EMPIRICAL EVALUATION

A. Dataset

The suggested method was evaluated using the LUNA subset of a dataset (referred to as LIDA-IDRI) [49]. The LIDA-IDRI is a lung CT scan public dataset, which includes 220 patients with more than 130 slices. The LUNA 2016 dataset was designed to analyze lung nodules and received 888 CT scans with a section thickness of less than 3 mm and 512×512 pixels picture size. The node has a total of 36,378 notes annotated by various radiologists. However, nodes 2290, 1602, 1186, and 777 are annotated by radiologists 1, 2, 3, and 4, respectively. Node annotations approved by at least three radiologists are called valid annotations. Diameter and position annotations are average annotations in LIDA-IDRI. The LUNA dataset originally was not a 3D image, so the 3D image was created manually using Rhinoceros 3D software.

B. Lung Segmentation and Tumor Detection

The lung and surrounding area have been isolated from the images utilising snake optimization. The method was contrasted with fuzzy-based techniques, namely FCM [50], KFCM [51], SAFCM [52], and FRFCM [53]. The evaluation was based on the metrics of Intersection over Union (IoU) [54] and Hausdorff distance [55], and the results are shown in Table I. The FRFCM method performed better than SAFCM and KFCM, with an improvement of approximately 20% and 13%, respectively. However, even though FRFCM is considered a robust algorithm, it still does not match the performance of Snake. The Snake algorithm showed a 22% improvement in the IoU metric compared to FRFCM. Examples of lungs delineated using the Snake algorithm are shown in Fig. 2.

Following the segmentation of lungs with the Snake algorithm, clustering methods including FCM, K-means, and GK were employed to create two clusters for lung tumor segmentation. Evaluation was carried out using the IoU and HD metrics, and the results are presented in Table II. According to the table, GK clustering is the most effective method for segmenting lung tumors. Lung cancers can also be segmented using FCM and K-means clustering, as shown in the table. Fig. 3 illustrates examples of tumor detection with the GK clustering technique.

TABLE I. EVALUATION OF THE SEGMENTATION EFFICIENCY OF DIFFERENT FUZZY ALGORITHMS

Method	IoU	HD
FCM	0.621	1.496
KFCM	0.746	1.715
SAFCM	0.721	1.852
FRFCM	0.785	2.019
Snake	0.831	2.151

TABLE II. ANALYSIS OF THE PROPOSED MODEL IN COMPARISON TO PREVIOUS WORKS

Method	IoU	HD
FCM	0.751	2.122
K-mean	0.780	1.615
GK	0.786	1.419

Fig. 2. The instances of lungs that were segmented using the snake algorithm.

Fig. 3. The samples of identifying tumors using the GK method.

C. 3D Reconstruction

The evaluation of the 3D reconstruction model included comparing four different methods: MC [56], MC and fairing [57], interpolation [34], and MC, and Afshar et al. [3]. The evaluation metrics used were HD and ED, which measured shape accuracy and pixel-wise distance, respectively. The results of the evaluation are presented in Table III, where MC performed the worst with values of 8.50 and 3.21 for HD and ED, respectively. However, the addition of fairing to MC decreased the values to 6.82 and 2.99. Interpolation with MC further reduced the error by approximately 0.555 and 0.855 for the two metrics, respectively. Despite these improvements, the recent work of Afshar et al. outperformed all other methods, including MC and MC + fairing, with values of 5.39 and 1.45

for HD and ED, respectively. Interestingly, the proposed model, which uses a strong GAN to create 3D shapes, outperformed Afshar et al.'s method, even though they had similar lung segmentation and tumor detection. The difference in performance may be attributed to the nature of the methods, as the proposed model relies on GANs, which have proven to be effective in generating complex data distributions. On the other hand, other methods use mathematical operations to create 3D shapes, which may not capture the underlying complexity of the data as well as GANs. In conclusion, the proposed model with a strong GAN is a promising approach for accurate 3D reconstruction, especially for complex medical imaging data.

TABLE III. THE EVALUATION AND COMPARISON OF THE SUGGESTED APPROACH WITH OTHER EXISTING METHODS

Model	HD	ED
MC	8.50	3.21
MC+ fairing	6.82	2.99
Interpolation + MC	5.85	2.57
Afshar et al. [3]	5.39	1.45
Proposed	2.99	1.06

Table IV demonstrates that the model is effective in accurately reconstructing 3D shapes from the provided input images. The reconstructed shapes closely resemble the original ones, and the input images are smooth, which is critical for accurate medical diagnoses. The smoothness issue faced by other methods can lead to incorrect diagnoses, and the generated images by these methods do not resemble the

original ones. The proposed model has successfully addressed these issues, demonstrating its superiority over other methods. Table V shows the computational efficiency of the suggested model and other approaches. The traditional methods take more time because of their lower computational efficiency. Nonetheless, the ResNet model, which is utilized for image recognition, consumes the most time in the proposed model. Despite this, the proposed model still outperforms other methods that use heavy computational operations, indicating its superiority in terms of accuracy and computational efficiency trade-off compared to existing methods. The results suggest that the proposed model has great potential for real-world medical applications. Its ability to generate smooth and accurate 3D images can help physicians make more precise diagnoses, which can lead to improved patient outcomes. Additionally, the model's computational efficiency makes it suitable for use in clinical settings where time is a critical factor.

2	475	527	498	449	410
3	365	336	279	319	230
4	614	595	591	585	563
5	651	639	626	574	480
6	720	661	705	680	621
7	561	538	477	499	425
8	741	729	742	691	670
9	481	507	489	452	430
10	558	579	578	539	500

1) *Analysis of pre-trained models:* The experiments carried out in this research demonstrate the superiority of the ResNet model compared to other pre-trained models, namely AlexNet [58], GoogleNet [59], Inceptionv3 [60], DenseNet [61], and MobileNet [62] (refer Table VI). Although other models have been extensively utilized in diverse image recognition works, they cannot match the ResNet model's performance in 3D reconstruction. The ResNet model significantly outperforms the other models, leading to a remarkable improvement in the HD and ED error metrics. These results highlight the importance of selecting an appropriate pre-trained model for achieving optimal performance in 3D reconstruction. Thus, the experimental findings provide solid evidence for the use of the ResNet model as the feature extractor in the suggested model.

2) *Explore the hidden size:* The LSTM network's hidden vector serves as a practical tool to compress data from a sequence of 2D images and aid in drawing 3D shapes. Increasing the hidden size can add more data to the model, but it may not always be useful. A limited capacity of the hidden size is inadequate to store the required data. Eight different values ranging from 16 to 2056 were evaluated to explore the influence of the hidden dimension on the suggested model. The outcomes are depicted in Fig. 4. Upon examination, it was observed that for HD and ED, the chart shows a descending trend when the hidden size is within the range of [16, 128], and an ascending trend from [128, 2056]. As a result, the optimal hidden size is 128.

3) *Analysis of loss function:* Selecting an appropriate loss function is vital for the success of deep learning models, as neglecting it may cause the model to be trapped in local optima. Therefore, the study aimed to assess how the discriminator's performance was affected by various loss functions. Five functions were selected for this purpose, namely Weighted Cross-Entropy (WCE) [63], Balanced Cross-Entropy (BCE) [64], Dice Loss (DL) [65], Tversky Loss (TL) [66], and Sensitivity Specificity Loss (SSL) [67]. WCE is a modified version of BCE that assigns different weights to examples from one class. Even though DL was originally developed to compare two images, it has been suggested as a loss function. The outcomes of these loss functions are presented in a tabular format in Table VII. Among the examined loss functions, TL exhibited the most superior performance, attaining an ED of 1.06 and an HD of 3.02. Although WCE assigns weights to the samples, TL still outperformed it, improving the error of WCE by approximately 1.64 and 2.50.

TABLE VI. THE RESULTS OBTAINED FOR USING VARIOUS PRE-TRAINED MODELS

Model	HD	ED
AlexNet	3.49	1.98

V. DISCUSSION

The study's proposed approach for 3D lung tumor reconstruction using deep learning techniques offers promising results for medical diagnosis applications. The superior performance compared to traditional approaches on the LUNA dataset demonstrates the potential of deep learning techniques in the diagnosis and treatment of lung cancer. However, the study also highlights several limitations that should be addressed in future work.

One major limitation of the proposed method is the relatively small size of the LUNA dataset, which may limit the model's generalizability. Therefore, future studies could focus on expanding the dataset size to validate the proposed method's effectiveness on a larger scale. Additionally, incorporating other imaging modalities, such as PET scans, could improve the accuracy of the lung tumor reconstruction. Furthermore, the proposed method's generalizability to different datasets and populations should be thoroughly investigated in future studies to assess its practicality in clinical settings. The evaluation of the proposed method was done only on the LUNA dataset, and further evaluation on other datasets would be necessary to validate its performance. Additionally, the proposed method requires a large amount of labeled data for training, and the scarcity of such data in medical imaging remains a challenge. Therefore, further studies could focus on developing techniques for efficient data labeling to improve the availability of labeled data. Lastly, the interpretability of the proposed model could be improved. While the model can generate 3D lung tumor images, it is not always clear how the model arrived at a particular result. Future work could explore ways to make the model more interpretable, such as using attention mechanisms or visualization techniques. This could help

increase the transparency of the model's decision-making process and improve trust among clinicians and patients.

In addition to the limitations discussed earlier, there are also other aspects of the proposed method that could be improved in future work. For instance, the proposed method involves several complex steps, including lung isolation, tumor detection, and 3D lung tumor re-creation. Each of these steps requires careful tuning of hyperparameters and may introduce errors that can affect the overall performance of the model. Therefore, future studies could explore ways to simplify the proposed method by combining some of these steps or using alternative segmentation methods. Moreover, the proposed method assumes that the lung tumor is visible in the input image, which may not always be the case. For instance, small tumors or tumors that are located close to other organs may be challenging to detect using the proposed method. Therefore, future studies could explore ways to incorporate other features, such as patient history or genetic information, to improve the model's sensitivity and specificity. Another disadvantage of the suggested method is the computational cost, which may limit its practicality in clinical settings. While the proposed method shows promising results, it requires substantial computational resources, including high-end GPUs and extensive training time. Therefore, future studies could focus on developing more efficient models that can achieve similar performance with fewer computational resources. Lastly, the ethical implications of the proposed method should also be taken into account in future research. Deep learning models can be used to make critical medical decisions, and it is crucial to ensure that such models are fair and unbiased. Therefore, future studies could explore ways to ensure that the proposed method does not reinforce existing biases or discriminate against certain patient populations.

VI. CONCLUSION

The study proposes a novel method for constructing 3D lung tumors, which combines an LSTM and GAN network with a ResNet model serving as the feature extractor. The technique is divided into three stages: lung isolation, tumor isolation, and 3D lung tumor reconstruction. To achieve lung isolation and tumor isolation, the snake optimization and GK techniques are employed. In the 3D reconstruction phase, the pre-trained ResNet model is used to extract features from 2D lung tumor images, followed by the provision of these features into an LSTM to produce compressed features. The compressed characteristics are then utilized as input for GAN, where the generator is accountable for producing 3D lung tumor images, and the discriminator ascertains the authenticity of the image. The suggested model is evaluated on the LUNA dataset, and standard evaluation metrics are used to compare its effectiveness with conventional techniques.

One potential future work based on this study could be to investigate the proposed technique's applicability to other types of cancer or medical imaging modalities. It would be interesting to see how the proposed model could be adapted and optimized to handle different types of tumors, such as those found in breast or prostate cancer. Additionally, exploring the potential of incorporating other deep learning architectures or loss functions could further enhance the

accuracy and efficiency of the proposed method. Finally, conducting a clinical validation study to assess the proposed model's usefulness in real-world settings would be a valuable next step towards its eventual clinical adoption.

Abstract—Currently, cloud storage in blockchain and federated learning technology provides better security among data transmission and file access. But, in some of the cases, security issues arose. So, to avoid security problems and offer better protection in a cloud environment, a novel optimized buffalo-based Homomorphic SHA blockchain (OBHSB). In this model for accessing the cloud storage data with the key matching method, if any of the unauthenticated users are trying to access the file initially, the system checks the key matching parameter. The proposed model was developed to provide better security in big data presented in the cloud environment. However, the parameters in the proposed model were compared with the existing models to make sure better performance was attained through the proposed model. Attack was considered as an event in this research. In the performance analysis, the performance rate of the proposed model was validated. Subsequently, the case study was developed in this research to explain the working procedure of the proposed design; model performs hashing, encryption, decryption, and key matching mechanisms. The results proposed model is observed to have 100% confidentiality rate after attack.

Keywords—Blockchain; cloud storage; decryption; encryption; federated learning; hashing; homomorphism

I. INTRODUCTION

Federated Learning is a Machine Learning (ML) concept that trains the program through a decentralized edge system having local data [1]. Fig. 1 describes the general architecture of federated learning. The training process does not involve the exchange of data [2]. In conventional ML approaches, the entire local datasets are transferred to a single server/ device, whereas in classical ML approaches, the local dataset is distributed identically [3]. In the federated learning approach [4], the local sample dataset is trained without distributing the information [5]. Therefore, it is widely used in applications to overcome data privacy and security issues [6]. Event detection (ED) involves the investigation of several events to provide a better understanding of social events [7].

The event investigation by analyzing massive heterogeneous datasets such as audio, images, and video is called Multimodal ED [8]. The development of different image processing approaches helps identify various types of events automatically [9]. Unstructured multimedia data are created in recent types to search the data more flexibly [10]. Many different technologies were developed to identify the event in various scenarios, such as ED in the smart city [11], ED in social media [12], ED in road traffic [13], etc. Recently, event identification has been carried out with the help of big

data [14]. Big data is a massive collection of data whose size can be enhanced exponentially over time [15]. The conventional information management tool can store only a limited amount of data [16]. But big data can process and store massive amounts of data in it [17]. Moreover, event detection using big data is highly effective because of its high storage space [18]. However, multimodal event detection is one of the major concerns for machine learning approaches. In this research, the attack is considered as event. Here, we are performing homomorphism concept so single event detection has been performed. Thus, different machine learning-based multimodal ED such as message dissemination model with the assistance of blockchain [19], blade icing identification technique based on blockchain and imbalanced federated learning approach [20], incentive governor for FL approach based on blockchain technology [22] were developed for identifying events from audio, text, image and video. However, they cannot provide effective results. Hence, an optimized federated self-supervised learning for multimodal event classification in big data using blockchain is presented in this article. In this work, some of the recent literature related to this topic was discussed in the second Section. Moreover, the system model as well as the problem statement was presented in Section III, and in fourth section the proposed system model was discussed. Moreover, the result and a discussion of the proposed model were developed in Section V, and the paper was concluded with the conclusion in Section VI.

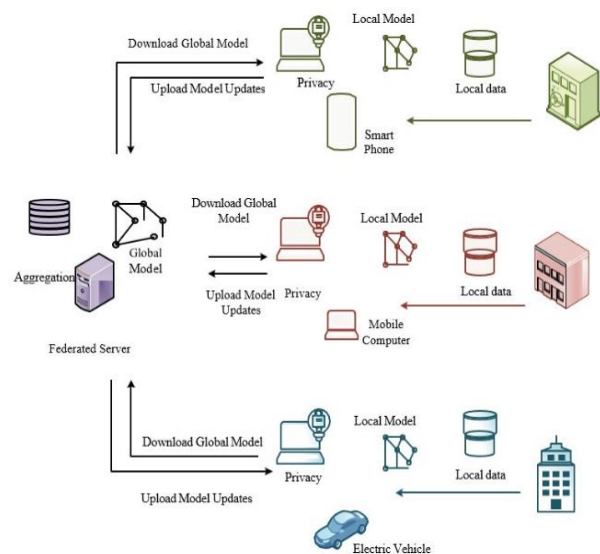

Fig. 1. General architecture of federated learning.

II. RELATED WORK

The recent works associated with this research are summarized below.

Nowadays, message dissemination plays a significant role in providing safety to Electric Vehicles (EVS). The messages are transferred among EVs using broadcasting technology. Moreover, high mobility and density in incoming vehicles affect the message dissemination process. To overcome the issues in message dissemination, Ferheen Ayaz et al. [19] developed the message dissemination model with the assistance of blockchain. This technique minimizes the delay and improves the message delivery rate. However, the practical implementation of this model provides inefficient results. Recently, renewable energy resources such as solar, wind, etc., have been widely used in different sectors. Wind energy is one of the rapidly growing renewable sources among these renewable sources. Blade icing is one of the significant concerns in wind power generation. To overcome this issue, data-driven technologies are widely used for blade icing identification. They require substantial resource data. Hence, Xu Cheng et al. [20] developed a blade icing identification technique based on blockchain and an imbalanced federated learning approach.

This technique identifies blade icing issues accurately. However, the implementation cost is high in this technique. Federated learning (FL) is an ML concept mainly used to provide data privacy in different applications. In the federated learning approach, the data is trained in a distributed way where the training dataset is located on the user side. The major problem with the FL approach is that it requires vast resources, and the computation of resources is complex. Hence, LiangGao et al. [21] developed an incentive governor for the FL approach based on blockchain technology to overcome these issues. This technique provides high security by neglecting the attackers. But the computation time is more in this approach.

As network applications are developing faster, it is widely used in different sectors. Thus, providing trustworthy applications to the user is the primary task of the researchers. Therefore, SafaOtoum et al. [22] developed a technique to provide security and network trustworthiness. This technique integrates the features of blockchain architecture and a federated learning approach. Moreover, they provide network trustworthiness by considering the trust of every individual. This method provides high accuracy. However, the detection rate of false statements is low in this approach. This technique integrates the features of blockchain architecture and a federated learning approach. Moreover, they provide network trustworthiness by considering the trust of every individual. This method provides high accuracy. However, the detection rate of false statements is low in this approach.

In a distributed network, the federated learning approach provides high data privacy by training data in a secure manner. It is a type of collaborative learning where the training dataset is located on the user's side to preserve privacy. YajingXu et al. [23] presented the FL approach based on blockchain methodology to identify malicious events in a unified model. This approach's experimental outcome improves FL's

performance on data protection and negative identification. However, malicious events are not neglected in this approach.

The key contribution of this proposed work was described as follows:

- Initially, three different data (audio, image, text) is gathered and trained in the system.
- Moreover, a novel OBHSB has been developed with different security parameters and monitoring functions.
- Then the data transmission from the different users was encrypted to hide the raw data among third parties.
- The encrypted data was stored at central cloud server, the homomorphism function has been performed during file access.
- Finally, the performance of the designed monitoring crypto model is validated by launching a DoS attack.
- The robustness has been measured regarding computation time, confidential rate, resource usage, throughput, and data transfer time.

III. SYSTEM MODEL AND PROBLEM STATEMENT

Cloud computing is the primary memory resource for intelligent digital gadgets because the collected information by the smart devices is stored in the cloud environment. So, the cloud memory must become secure to maximize user trust.

Hence, to secure the data sharing process in the cloud environment, federated learning has been introduced with security mechanisms. Usually, the federated system has security features, but some harmful events have broken the security. So, the blockchain system has been introduced. The blockchain module's main reasons are homomorphic concepts and data integrity validation. But in some cases, the data became injected by malicious events. So, the present work has planned to design the monitoring of the homomorphic blockchain system for cloud environment. Fig. 2 illustrates the system's basic model and common problem. Subsequently, the data transmission to the system with the help of blockchain provides more security because through the use of blockchain, the transmitted data was safer and stored in the cloud. In this proposed model, three different types of data sets were used, so a large amount of data was transmitted in a single transmission.

Fig. 2. System model with problem.

IV. PROPOSED METHODOLOGY

To enrich the security module of the federated learning, a novel Optimized Buffalo-based Homomorphic SHA Blockchain (OBHSB) has been designed with the required security parameters. Hence, to perform the federated learning concept, three different types of data have been considered. Initially, the collected data was trained to the system then a novel OBHSB was designed with the required data hiding and the homomorphic parameters. Here, the buffalo algorithm is incorporated to monitor the malicious activities in the designed federated learning system. Here, we provide three different types of data sets to the system. With the help of the proposed model, the system was monitored to detect malicious activities. The transferred data was stored in the cloud memory for better security. Here, finding the two hash values was termed homomorphism. After that, if the two hash values are the same, then through the help of a key, the file was accessed. Otherwise, the file was not able to access. However, the performance of the system was measured. Attack was launched to validate the proposed model; Fig. 3 illustrates architecture of the proposed model.

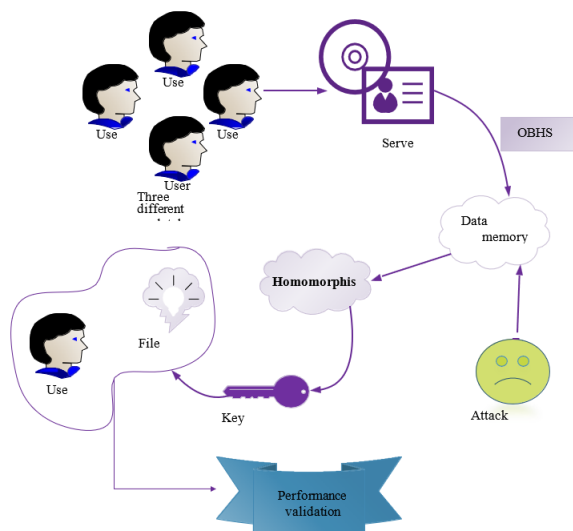

Fig. 3. Proposed architecture.

A. Design of OBHSB Model

The proposed model was designed based on the optimized buffalo algorithm and the Homomorphic SHA blockchain. At first, audio, image, and text data were collected and trained in the system to validate the implemented design. After that, the proposed model was designed to provide security for the ordered data sets. For better security, the data was stored in cloud storage. Moreover, with the help of the proposed model, encryption, decryption, and homomorphism were done. Initialization of the data set was declared through (1).

$$F[B_3] = (a_1 + i_1 + t_1, a_2 + i_2 + t_2, \dots \dots \dots a_n + i_n + t_n) \quad (1)$$

Where $F[B_3]$ defines the initializing parameter of the proposed model, $a_1 \dots a_n$ represents the amount of audio data presented in the data set, $i_1 \dots i_n$ defines the number of image data introduced in the initialized data set, and $t_1 \dots t_n$

refers to the number of test data presented in the dataset.

B. Attack Prediction and Neglection

After initializing the data sets, the system was monitored through the proposed model for detecting the attack. For attack detection, Neglection, and encryption, decryption was done under the proposed technique. While initializing the data, the data set contains both the attacknode and the normal node. Among them, the attack nodes were removed from the system, and the normal nodes were used for different processes. Here, the attack detection expression of the proposed model was declared in (2), (3).

$$Pa * (b_3) = \sum_{i=1}^n (a + i + t, a' + i' + t') \quad (2)$$

$$Na * (b_3) = b_3(a + i + t) - b_3(a' + i' + t') \quad (3)$$

Where $Pa * (b_3)$ defines the attack detecting parameters of the proposed model, $Na * (b_3)$ refers to the attack neglecting parameter of the implemented design, $a+i+t$ represents the normal data presented in the data set, and $a' + i' + t'$ defines the attack nodes of the proposed model.

C. Calculation of Hash 1

Hash 1 function was calculated after removing the attack nodes from the data set. After measuring the hash one value, the obtained value was stored in the cloud for more security. Subsequently, finding the hash one function of the proposed model was declared through the (4).

$$h^* = a \text{ mod } b \quad (4)$$

Where h^* defines the hashing function of the proposed design. Moreover, a describes the plain text and b represents the prime number. Furthermore, the hash one value of the model was used for finding the key matching operation.

D. Data Encryption

In this research, SHA encryption was used to encrypt the data. At SHA encryption, Hexa decimal numbers were chosen for key values. Encryption was done in the data to protect the data from the unauthenticated user. Through the encryption process, the data were protected as private data and sensed data. Moreover, the SHA defies the secure Hash Algorithm used for hashing the data and securing the files. SHA encryption of the proposed model was declared through (5).

$$E^* = a * k \quad (5)$$

Where the parameter E^* defines the encryption parameter of the proposed model and a refers to the plain text and k critical parameter of the SHA encryption.

E. Homomorphism

For finding the hash, two values were mentioned as homomorphism. Hash 2 was measured by encrypting the initialized data. If the hash one and the hash two values are equal. it was mentioned as key matching so the user can access the file. Moreover, the system can access the file while displaying data injection if the two values are not equal. For finding the hash, two value of the proposed model was expressed in (6)

$$h^{**} = \frac{E^*}{k} (a \bmod b) \quad (6)$$

Where h^{**} refers to the parameter used for finding the homomorphism. E^* represents the encrypted data, k refers to the key parameter, and a defines the plain text, as well as the parameter b was the prime number.

F. Key Matching

Key matching was done to find the exact user to access the file. Moreover, if the hash one and the hash two rates were the same, the system accomplishes the file accessing process. If the two values are not the same, then the system displays as data injected. The key matching expression of the proposed model was expressed through the 'if' condition and was declared in (7).

$$k_m = \begin{cases} \text{if } h^* = h^{**}; \text{file accessed} \\ \text{else ; data injected} \end{cases} \quad (7)$$

Where k_m represents the key matching parameter used in the proposed model. h^* Defines the hash one function of the system and h^{**} establishes the hash two parameters of the model.

G. Performance Validation and Attack Launching

The performance of the parameters was validated after finding the hash one and hash two values. Moreover, the proposed model attains a higher rate of parameters with better performance. After that, the robustness was validated by launching the attack. After launching, the attack's performance improved compared to the initial stage performances. After completing the file accessing process, the system was checked for malicious nodes. This research launched the Denial of Service (DoS) attack. Subsequently, the function of this attack was to shut down the system and quit the process when accessing the unauthenticated user, and here the unauthenticated user was considered the malicious node; after launching the attack, if any of the malicious nodes were presented.

The working procedure of the proposed model was developed in the pseudo-code format and represented in Algorithm 1 and the workflow diagram of the proposed model was shown in Fig. 4.

Algorithm 1: OBHSB

```

Start
{
  Initialization()
  int F[B3] = (a1 + i1 + t1, a2 + i2 + t2, an + in + tn)
  //Initialize the audio, image and text data set
  Attack Prediction & Neglection()
  {
    int P a *(b3) , Na *(b3)
    //initializing the attack detecting and neglecting
    parameters To neglect Na *(b3)
    //System was monitored, if the attack was predicted,
    then it was removed, and the attack detected node
    was considered as Na *(b3)
  }
  Hash1 ()
  {

```

```

int h*, a, b;
//initializing the parameters used for calculating the hash
one function
// hash one was calculated from the initialized data set,
and it was stored in the cloud storage for better security
}
Data encryption ()
{
  int E*, a, k;
  //initialize the data encryption parameters
  E* = a x k
  //SHA encryption method was followed for encryption
}
Homomorphism ()
{
  int h**, E*, a, k, b;
  //initializing the parameters for homomorphism

  h** = E*/k (a mod b)
  //hash two value was calculated
}
Key matching ()
{
  int h*, h**;
  //initializing the key matching parameters of the model
  km = { if h* = h** ; file accessed
        else ; data injected
        }
}
}
Stop

```

Flow chart which explains the process of the developed model is illustrated in Fig. 4.

Fig. 4. Flow chart.

The primary aim of this present research was to provide security to the files presented in the cloud memory of the system. Through the proposed model, high security was attained. Consequently, the attack was launched on the cloud memory of the system.

H. Dataset Description

The proposed methodology uses datasets created manually using text dataset form Kaggle stocks data and audio mp4 has been collected randomly from google. The image dataset is created by using the images available on the Internet. Various kinds of images are available on the Internet, and the images suitable for event detection are collected for the proposed event detection process.

V. RESULT AND DISCUSSION

In this research, the proposed model was implemented and executed in the python platform to provide better security to the files. Here, the system provided three different types of data sets for analysis. After initializing the data sets with the help of the proposed model, the plan was monitored to predict the attack/event nodes. If any attack nodes were presented in the datasets, then the system neglected them. For more security, hash one and hash two functions were measured when both values were the same, and the user accessed the file. Subsequently, if not equal means the system displays data injection. However, the required parameters for developing the proposed design were tabulated in Table I.

TABLE I. PARAMETER VALIDATION OF THE DEVELOPED MODEL

Parameters	Requirement
OS	Windows 10
Platform	Python
Version	3.10

The present work was designed in the python software 3.10 version. The performance analysis section mentioned the result after and before attack launching. Moreover, the comparative analysis of the model was evaluated and compared with the existing techniques for assuring the presentation of the implemented model.

A. Case Study

Here, the working procedure of the implemented design was explained in detail. The primary aim of this particular research was to provide security for the files from the attackers. Initially, the system was monitored through the proposed model. The file was accessed only when both the hash values were the same. Consequently, from this method, more security was provided for files. After that, the DoS attack was launched to validate the system's performance. At the performance analysis, the version of the proposed model, such as encryption time, decryption time, confidential rate, throughput, and data transfer time, were calculated. Fig.5. presents the calculated performance metrics.

The total time it takes the system to encrypt and decrypt the data is called encryption and decryption time. The encryption time, decryption time as well as the confidential rate of the proposed model is shown in Fig. 6. Here, the encryption time of the audio signal was about 10.35ms, the encryption time of the image data was approximately 17.56, and the encryption time of the text data was about 5.29ms. Subsequently, in the proposed model, the decryption rate of the audio signal was about 1.6ms, the decryption rate of the

image data was about 28.2ms, decryption rate of the text data was about 6.233ms. Data transfer time was the time needed to transfer the data, and in the proposed model, less time was required to move the high amount of data. Moreover, the data transfer rate of the proposed model is 18.8ms for audio signal, 19.2ms for image data and 3.3ms for text data.

Fig. 5. Performance metrics of the proposed model.

Fig. 6 depicts the rate of throughput in the model.

The system's throughput was calculated based on the rate of exactness and time needed to complete the process. Here, the throughput range was varied at image, audio, and text data sets. However, the throughput range of the image data set was about 73%, throughput attained through the audio data set was about 94% and 85% of the throughput was attained through the text data set.

Fig. 6. Confidential rate and throughput of the model.

B. Comparison Analysis

A higher performance rate was attained through the proposed model, and validating the performance of the proposed model comparison analysis was done. In this section, the proposed model's stability, scalability, and resource usage were compared with the existing models. Moreover, the parameters of the developed model were comparing with the current models like DNN+GRM+MFO, DNN+GRM, CNN+HHO+GRM+MFO, and CNN+GRM+MFO as well as the scalability and the stability rate of the proposed model was compared to the existing models such as Recurrent neural network (RNN), Convolution neural network (CNN), Deep convolution Neural network (DNN), Deep belief network (DBN) as well as the proposed MLFC.

1) Resource usage: Here, the resource usage of the proposed model was compared with the existing models such

as DNN+GRM+MFO, DNN+GRM, CNN+HHO+GRM+MFO, and CNN+GRM+MFO. But, the proposed model uses a lower rate of resources. Moreover, the proposed model uses 8.5MB of audio data, 7.3MB of image resources, and 9.4MB of text data. Based on the time and the performance rate, resource usage was measured. The resource usage was measured through (8).

$$R_u^* = P_y * \Delta t \tag{8}$$

Where R_u^* defines the model's resource usage function, P_y represents the proposed model's performance rate, and Δt defines the time required to complete the process. Consequently, the resource usage comparison of the proposed model was illustrated in Fig. 7. After comparison, the proposed model needs a lower rate of resources to perform the function.

Fig. 7. Comparison of resource usage.

2) *Scalability*: Scalability refers to the overall capability to co-operate and perform well with data given to the model.

$$\sigma = R_u^* * \beta_t \tag{9}$$

Where σ defines the scalability function of the proposed model R_u^* was the resource usage function and β_t represented the model's throughput. Moreover, the scalability of the proposed model was about 153 MB. The scalability of the implemented model was comparing through the existing models like CNN, DCNN, RNN and DBN. Among them, the proposed model attains a better rate of scalability. The stability comparison of the proposed model is illustrated in Fig. 8.

Fig. 8. Scalability comparison.

3) *Stability*: Stability refers to the steadiness of the system as well as the condition of the system. Subsequently, the Stability range of the developed model was comparing with the existing models such as CNN, RNN, DCNN, and DBN. However, the proposed model staining a better stability range was about 99%. Stability helps to find the men's performance within a particular time. For evaluation, the exact increment of performance stability will be used. The stability comparison of the proposed model was shown in Fig. 9.

Fig. 9. Stability comparison.

C. Discussion

In this section, the performance parameters of the proposed model were discussed. In this research, the proposed model attained higher rate of throughput about lower rate of encryption time was achieved through the audio, text, and image data was about 10.35ms, 17.56ms, and 3.29ms. Moreover, the decryption time of the proposed model, also low through audio, image, and text data, was about 11.66ms, 28 2ms, and 6.233ms. A higher rate of confidential rate was achieved through the proposed model through the three different datasets, and the confidential rate was 100%. The proposed model used fewer number resources. The text data rate of resource usage was about 8.5MB, the image resource used was about 7.3MB, and 94MB resources were used through the text data. Moreover, the overall performance rate of the developed model was based on three different data sets were tabulated in Table II.

TABLE II. OVERALL PERFORMANCE OF THE IMPLEMENTED DESIGN

Parameters	Audio	Image	Text
Encryption time	10.35ms	17.ms	5.29ms
Decryption time	1.66ms	28.2ms	6.23ms
Confidential rate	100%	100%	100%
Throughput	94%	73%	85%
Data transfer rate	18.95ms	19.6ms	4.20ms
Resource usage	8.5MB	7.3MB	9.4MB

VI. CONCLUSION AND FUTURE SCOPE

This work was presented to provide security for file access. Moreover, the blockchain and homomorphism methods were used to secure the data from the unauthenticated node. Through this proposed model, more security was provided in the cloud environment. In this work, key matching and homomorphism were considered essential features. Due to

these two features, the data in the cloud was safe without accessing the unauthenticated user. In this model, the encrypted data was stored in the cloud environment for better security, and the percentage of improvement was also added in this section. This proposed model measured the output based on image, text, and the audio data set. Subsequently, through the audio, image, and text data, the proposed model needs a low encryption time was about 10.35ms, 17.6ms, and 5.29ms, and the decryption time of the proposed model is also low with three different datasets was about 11.66ms, 28.2ms and 6.23ms. The amount of resource usage of the proposed model with the audio, image, and text data was about 8.5MB, 7.3MB, and 9.4MB. On comparing with existing models, the developed design needs a lower rate of resources to perform the function. The system attains 94% throughput with the audio data set, 73% of throughput in the image data set, and 85% in the text data set. The data transfer rate of the implemented design along with audio, image, and text data was 18.9MB, 19.6MB, and 4.20MB. Subsequently, the proposed model attains 100% of the confidential rate while processing the audio, image, and text data set. Resource usage of the proposed model was 8.5 MB in the audio data set, 7.3 MB in the image data set, and 9.4 MB in the text data set. Among them, the proposed model developed by 4% in resource usage. The Stability of the system was about 99% comparing with the existing techniques; the implemented design improves 3% of stability rate. Consequently, the overall system scalability range obtained through the proposed model was about 153MB; compared with the existing models, the scalability of the proposed model was developed by 5%. Due to the high confidentiality rate, the system provides more security to the files presented in the cloud environment. In future, the model can be checked with other attacks also to check the stability of the model.

Abstract—Hate speech on social media platforms like Twitter is a growing concern that poses challenges to maintaining a healthy online environment and fostering constructive communication. Effective detection and monitoring of hate speech are crucial for mitigating its adverse impact on individuals and communities. In this paper, we propose a comprehensive approach for hate speech detection on Twitter using both traditional machine learning and deep learning techniques. Our research encompasses a thorough comparison of these techniques to determine their effectiveness in identifying hate speech on Twitter. We construct a robust dataset, gathered from diverse sources and annotated by experts, to ensure the reliability of our models. The dataset consists of tweets labeled as hate speech, offensive language, or neutral, providing a more nuanced representation of online discourse. We evaluate the performance of LSTM, BiLSTM, and CNN models against traditional shallow learning methods to establish a baseline for comparison. Our findings reveal that deep learning techniques outperform shallow learning methods, with BiLSTM emerging as the most accurate model for hate speech detection. The BiLSTM model demonstrates improved sensitivity to context, semantic nuances, and sequential patterns in tweets, making it adept at capturing the intricate nature of hate speech. Furthermore, we explore the integration of word embeddings, such as Word2Vec and GloVe, to enhance the performance of our models. The incorporation of these embeddings significantly improves the models' ability to discern between hate speech and other forms of online communication. This paper presents a comprehensive analysis of various machine learning methods for hate speech detection on Twitter, ultimately demonstrating the superiority of deep learning techniques, particularly BiLSTM, in addressing this critical issue. Our findings pave the way for further research into advanced methods of tackling hate speech and facilitating healthier online interactions.

Keywords—Machine learning; deep learning; hate speech; social network; classification

I. INTRODUCTION

Social media platforms like Twitter have become an essential communication tool in our digital age, enabling users worldwide to share their thoughts, opinions, and experiences with a vast audience [1]. However, the rapid growth of social

media has also given rise to undesirable content, including hate speech. Hate speech is a form of communication that is offensive, malicious, and discriminatory, targeting individuals or groups based on their race, ethnicity, gender, religion, or other attributes [2]. The proliferation of hate speech on social media is a critical issue, as it fosters animosity, threatens social cohesion, and undermines the principles of free expression and respectful discourse. Consequently, the need for effective hate speech detection and monitoring tools is more significant than ever.

In recent years, machine learning techniques have emerged as a promising avenue for addressing the challenge of detecting and mitigating hate speech on social media platforms [3-4]. Machine learning algorithms, both shallow and deep, have demonstrated potential in tackling various natural language processing (NLP) tasks, such as sentiment analysis, text classification, and named entity recognition [5]. This paper aims to investigate and compare the performance of various shallow and deep learning methods in detecting hate speech on Twitter.

Machine learning methods have shown effectiveness in various applications, including spam detection, sentiment analysis, and topic modeling [6]. However, shallow learning algorithms have limitations in capturing the complex semantics and context of natural language, which may hinder their ability to identify hate speech accurately.

Deep learning techniques, on the other hand, have exhibited promising results in multiple NLP tasks due to their capacity for modeling high-level abstractions and capturing intricate language patterns [7]. LSTM and BiLSTM are recurrent neural networks (RNNs) that excel at processing sequential data, making them suitable for analyzing the temporal structure of text. CNNs, originally designed for image classification, have also demonstrated their applicability in text classification tasks by identifying local and global patterns in text through convolutional filters.

To investigate the effectiveness of shallow and deep learning methods for hate speech detection on Twitter, we first compile a diverse and representative dataset of tweets, ensuring

that the dataset encompasses a broad spectrum of online discourse [8]. The dataset is annotated by experts, who label the tweets as hate speech, offensive language, or neutral, thus providing a nuanced classification of the content. By adopting a multi-class labeling approach, we aim to capture the complexity and subtlety of hate speech more accurately.

We then apply a range of shallow learning techniques to the dataset, evaluating their performance in identifying hate speech. We also explore the integration of feature selection techniques. Establishing a baseline performance for these methods allows us to gauge the potential advantages of deep learning techniques.

Next, we implement LSTM, BiLSTM, and CNN models and evaluate their performance against the established baseline [9]. By comparing the performance of deep learning techniques with that of shallow learning methods, we aim to identify the most effective approach for hate speech detection on Twitter. In addition to comparing the overall performance of the models, we also assess their ability to handle various challenges associated with the detection of hate speech, such as understanding context, sarcasm, and semantic nuances.

To further enhance the performance of the deep learning models, we incorporate word embeddings, such as Word2Vec and GloVe, which facilitate the representation of words in a continuous vector space [10]. These embeddings capture semantic and syntactic relationships between words, thus enriching the input features for our models. By leveraging word embeddings, we aim to improve the models' ability to discern between hate speech and other forms of online communication, thereby increasing their accuracy and reducing false positives.

Our results reveal that deep learning techniques, particularly BiLSTM, outperform the shallow learning methods in detecting hate speech on Twitter [11]. BiLSTM demonstrates a superior ability to capture the intricate nature of hate speech by understanding context, semantic nuances, and sequential patterns in tweets [12]. This finding underscores the potential of deep learning techniques in addressing the challenge of hate speech detection and monitoring on social media platforms.

Thus, this paper presents a comprehensive analysis of various machine learning methods for hate speech detection on Twitter. Our findings suggest that deep learning techniques, specifically BiLSTM, hold promise for tackling this critical issue more effectively than their shallow learning counterparts. By identifying the most accurate models for hate speech detection, we contribute to the ongoing effort to develop advanced tools and strategies to combat hate speech on social media and foster healthier online interactions.

Future research directions may include the exploration of additional deep learning architectures, such as transformers, to further enhance hate speech detection performance. Moreover, investigating the impact of transfer learning and pre-trained language models, like BERT or GPT, on the performance of the models may provide valuable insights. Lastly, the development of explainable AI techniques to provide interpretable and transparent predictions in hate speech

detection can improve user trust and facilitate better decision-making in content moderation.

II. RELATED WORKS

The problem of detecting hate speech on social media platforms has been extensively studied in recent years due to its increasing prevalence and the potential harm it can inflict on individuals and communities. In this section, we provide an overview of the related works in the field of hate speech detection, focusing on both shallow and deep learning approaches.

A. Shallow Learning Approaches

Several studies have utilized logistic regression, random forest, and decision tree algorithms for hate speech detection on social media. For instance, [13] employed logistic regression for hate speech detection in online communities, using bag-of-words and paragraph2vec features. Similarly, [14] proposed a multi-class classifier using logistic regression and random forest, which demonstrated improved performance over single classifiers. Study [15] employed decision trees to detect hate speech on Twitter, highlighting the importance of feature engineering in improving model performance.

Naïve Bayes and K-NN classifiers have also been employed for hate speech detection. Like [16] used a naïve bayes classifier to detect cyber hate on Twitter, while [17] proposed a K-NN-based approach for the same task. Both studies indicated the effectiveness of these classifiers in detecting hate speech when combined with appropriate feature extraction techniques, such as bag-of-words and TF-IDF.

SVMs have been widely used for hate speech detection, with several studies demonstrating their effectiveness. For example, [18] used SVM to detect cyberbullying and hate speech on Twitter, leveraging features such as character n-grams, sentiment scores, and syntactic patterns. Similarly, [19] employed SVM for hate speech detection, demonstrating that the inclusion of linguistic and semantic features improved the model's performance.

B. Deep Learning Approaches

LSTM and BiLSTM models have been increasingly employed for hate speech detection due to their ability to capture long-range dependencies in text. The authors in [20] proposed a deep learning approach using LSTM for detecting hate speech on Twitter, demonstrating superior performance compared to shallow learning techniques. On the other hand, [21] used BiLSTM models for the same task, illustrating the effectiveness of bidirectional RNNs in capturing the context and semantics of text. Additionally, [22] used both LSTM and BiLSTM models to detect hate speech on Twitter, finding that the BiLSTM model outperformed its unidirectional counterpart.

CNNs have also been applied for hate speech detection on social media platforms. As [23] proposed a CNN-based model for detecting hate speech on Twitter, leveraging character n-grams as input features. Their approach demonstrated improved performance compared to traditional shallow learning techniques. Similarly, [24] employed a CNN-based model for hate speech detection on Twitter, illustrating the

benefits of incorporating pre-trained word embeddings such as Word2Vec and GloVe.

C. Hybrid Approaches and Ensemble Models

Some studies have explored hybrid approaches and ensemble models for hate speech detection, combining both shallow and deep learning techniques to enhance model performance. The research [25] proposed a hybrid approach that combined CNN with LSTM for detecting abusive language on Twitter, demonstrating that the integrated model outperformed standalone CNN and LSTM models. Similarly, [26] developed an ensemble model combining SVM and LSTM for hate speech detection, which achieved better performance compared to individual models.

Recent studies have highlighted the importance of using word embeddings and pre-trained language models for improving hate speech detection performance. For instance, [27] investigated the impact of using different word embeddings. Their findings revealed that the choice of word embeddings could significantly impact model performance.

The use of pre-trained language models has also been explored for hate speech detection. Like [28] proposed a BERT-based model for detecting hate speech on social media platforms, demonstrating superior performance compared to traditional machine learning techniques. Similarly, [29] employed BERT for detecting hate speech on Twitter, highlighting the model's ability to capture the complex semantics of text and adapt to various linguistic contexts.

III. PROBLEM STATEMENT

It is possible that the problem of early identification of cyberbullying on social networking sites is separate from the difficulty of classifying different types of cyberbullying. In the circumstances presented here, there is a group of social media sessions that we will refer to collectively as "S." As a result, there is the chance that some of them are instances of cyberbullying. A sequence of sessions on a social network may be described using the equation (1), which is as follows:

$$S = \{s_1, s_2, \dots, s_{|S|}\} \quad (1)$$

Where S refers to the total number of sessions, "i" indicates the current session.

The sequence in which submissions are made during a specific session is subject to change at different points in time and is governed by a variety of factors

$$P_s = \left(\langle P_1^s, t_1^s \rangle, \langle P_2^s, t_2^s \rangle, \dots, \langle P_n^s, t_n^s \rangle \right) \quad (2)$$

where the tuple P represents the kth post for the social network session and s is the timestamp of when post P was published.

At the same time, a vector of features is utilized to identify each post in a manner that is completely unique:

$$P_k^S = [f_{k_1}^S, f_{k_2}^S, \dots, f_{k_n}^S] \quad k \in [1, n] \quad (3)$$

Therefore, the objective is to acquire the knowledge necessary to develop a function f that can classify whether or not a text is related to hate speech.

IV. MATERIALS AND METHODS

A. The Proposed Framework

A representation of the model that has been built for the purpose of identifying instances of cyberbullying may be shown in Fig. 1. The following are the steps that make up this model: the preprocessing stage, the feature extraction stage, the classification stage, and the assessment stage. In this part, a significant amount of focus is placed on doing a more in-depth analysis of each stage.

B. Feature Extraction

Term frequency-inverse document frequency: In the context of the paper on hate speech detection using shallow and deep learning methods, Term Frequency-Inverse Document Frequency (TF-IDF) plays an essential role as a feature extraction technique [30].

The product of TF and IDF yields the TF-IDF score, which reflects the importance of a term within a document and across the entire corpus. A high TF-IDF score suggests that the term is significant within the document and infrequent across the corpus, making it a valuable feature for classification tasks [31].

In the context of hate speech detection, TF-IDF can be employed to transform raw text data into a structured representation that captures the relative importance of words or terms [32]. The resulting feature vectors can be used as input for various shallow learning algorithms, to develop hate speech detection models. By incorporating TF-IDF, the models can effectively distinguish between hate speech and other types of communication based on the discriminative power of specific terms.

It is important to note that, while TF-IDF has been proven effective in various text classification tasks, it may not always capture the complex semantics and context inherent in natural language [33]. In such cases, advanced feature extraction techniques, such as word embeddings or pre-trained language models, may be employed to complement or replace TF-IDF in the development of more sophisticated hate speech detection models.

Word2Vec: In the context of the paper on hate speech detection using shallow and deep learning methods, Word2Vec is a significant technique for generating word embeddings. Word2Vec is an unsupervised learning algorithm that converts words into continuous vector representations, capturing semantic and syntactic relationships between words. The technique was introduced by [34] and has since become a widely used method in natural language processing (NLP) tasks, including text classification, sentiment analysis, and machine translation.

Fig. 1. Proposed framework.

In hate speech detection, Word2Vec embeddings can be employed to enrich the input features for both shallow and deep learning models [35]. By leveraging the semantic information captured in these embeddings, models can better discern between hate speech and other types of communication, resulting in improved classification performance. Word2Vec embeddings can be used in combination with other feature extraction techniques, such as TF-IDF or pre-trained language models, to further enhance the models' understanding of the complex semantics and context inherent in natural language.

In this specific piece of study, the weighting method that we make use of is the tf-idf system. For the purpose of calculating the tf-idf weight that corresponds to the i th word in the j th text, the following formula is used:

$$w_{i,j} = TF_{i,j} \times \log\left(\frac{N}{DF_i}\right) \quad (4)$$

Bag of Words: In the context of the paper on hate speech detection using shallow and deep learning methods, the Bag of Words (BoW) model serves as a fundamental text representation technique [36]. BoW is a widely used method in natural language processing (NLP) tasks, such as text classification, information retrieval, and sentiment analysis, as it provides a simple and efficient way to represent text data in a structured format.

In hate speech detection, BoW can be employed to transform raw text data into a structured representation that serves as input for various shallow learning algorithms. However, it is important to note that the BoW model lacks the ability to capture context, semantics, and word order, which may limit its effectiveness in some classification tasks. To address these limitations, more advanced feature extraction techniques, such as word embeddings (e.g., Word2Vec) or pre-trained language models, can be used in combination with or as

a replacement for the BoW model. The goal is to increase the likelihood that, given the following circumstances:

$$\arg \max_{\theta} \prod_{w \in T} \left[\prod_{c \in C} p(c | w; \theta) \right] \quad (5)$$

C. Machine Learning Methods

Decision Tree is a supervised learning algorithm that recursively splits the input space into regions based on feature values, forming a tree-like structure [37]. It is interpretable and handles non-linear relationships well. In hate speech detection, Decision Trees can be employed to make decisions based on extracted text features, such as word frequencies or presence of specific terms.

Naïve Bayes is a probabilistic classifier based on Bayes' theorem, which assumes feature independence [38]. Despite this simplifying assumption, it often performs well in text classification tasks. In hate speech detection, Naïve Bayes can be used to classify tweets by estimating the likelihood of a tweet being hate speech given the occurrence of certain words or phrases.

K-Nearest Neighbors is a non-parametric, instance-based learning algorithm that classifies instances based on the majority class of their K-nearest neighbors in the feature space [39]. In hate speech detection, K-NN can be employed to classify tweets by considering the similarity between their feature representations, such as word embeddings or TF-IDF vectors.

Support Vector Machine (SVM) is a supervised learning algorithm that aims to find the optimal hyperplane separating different classes in the feature space [40]. It is effective in handling high-dimensional data and can be used with various kernel functions. In the context of hate speech detection, SVM can be employed to classify tweets by learning the decision boundary based on the extracted features, such as word frequencies, n-grams, or sentiment scores.

D. Deep Learning Methods

1) *LSTM (Long Short-Term Memory)*: LSTM is a type of recurrent neural network (RNN) specifically designed to address the vanishing gradient problem common in standard RNNs [41]. LSTM networks have memory cells that can store information over long sequences, allowing them to capture long-range dependencies and context within text data. In the context of hate speech detection, LSTM models can be employed to process tweets as sequences of words or characters, enabling them to capture temporal patterns and dependencies that are crucial for understanding the semantics and intent of the text. By using LSTM networks, classification models can better distinguish between hate speech and non-hate speech based on the contextual information present in the tweets. Fig. 2 demonstrates architecture of LSTM network.

Fig. 2. LSTM network.

2) *BiLSTM (Bidirectional Long Short-Term Memory)*: BiLSTM is an extension of LSTM that processes the input data in both forward and backward directions, enabling it to capture both past and future context [42]. In the context of hate speech detection, BiLSTM models can process tweets in a bidirectional manner, capturing the context and dependencies present in the text more effectively. This improved contextual understanding leads to better classification performance compared to unidirectional LSTM models. BiLSTM networks can be combined with other deep learning architectures, such as convolutional neural networks (CNN), to further enhance the model's ability to capture both local and global contextual information in the text. Fig. 3 demonstrates architecture of BiLSTM network.

Fig. 3. BiLSTM network.

3) *CNN (Convolutional Neural Network)*: CNN is a deep learning architecture traditionally used for image processing

tasks but has also demonstrated effectiveness in various NLP tasks, including text classification [43]. CNNs employ convolutional layers to learn local patterns within input data through the application of filters or kernels. In the context of hate speech detection, CNN models can be used to process tweets by treating them as one-dimensional sequences of words or characters. These models can learn local patterns, such as n-grams or specific phrases that are indicative of hate speech. By combining CNNs with other deep learning architectures, such as LSTM or BiLSTM, models can capture both local patterns and long-range dependencies, leading to improved classification performance in hate speech detection tasks. Fig. 4 demonstrates architecture of the convolutional neural network.

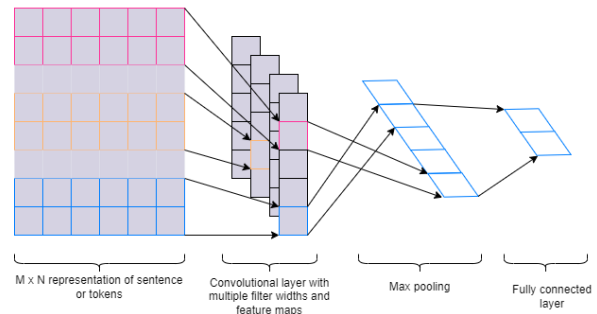

Fig. 4. CNN architecture.

V. EXPERIMENTAL SETUP

A. Evaluation Parameters

1) *Accuracy*: Accuracy is a common metric used to evaluate the performance of classification models. It is calculated as the ratio of the number of correct predictions to the total number of predictions [44]. Although accuracy provides a general overview of a model's performance, it may not be suitable for imbalanced datasets, where one class dominates the other(s), as it can yield misleading results.

$$accuracy = \frac{TP + TN}{P + N} \quad (6)$$

2) *Precision*: Precision is a metric that evaluates the proportion of true positive predictions among all positive predictions made by a classification model [45]. It is particularly useful for assessing the performance of models when the cost of false positives is high, such as in spam detection or medical diagnosis.

$$precision = \frac{TP}{TP + FP} \quad (7)$$

3) *Recall*: Recall, also known as sensitivity or true positive rate, measures the proportion of true positive predictions among all actual positive instances in the dataset [46]. Recall is crucial in situations where the cost of false negatives is high, such as in fraud detection or cancer diagnosis.

$$recall = \frac{TP}{TP + FN} \quad (8)$$

4) *F-score*: F-score, or F1-score, is the harmonic mean of precision and recall, and provides a balanced measure of a model's performance when both false positives and false negatives are important. The F-score ranges from 0 to 1, where a higher value indicates better performance [47]. It is particularly useful for evaluating models on imbalanced datasets, where accuracy may be misleading.

$$F1 = \frac{2 \times precision \times recall}{precision + recall} \quad (9)$$

5) *ROC curve*: The Receiver Operating Characteristic (ROC) curve is a graphical representation of a classifier's performance, plotting the true positive rate (recall) against the false positive rate for various decision thresholds. The area under the ROC curve (AUC-ROC) is a scalar measure of a model's performance, with a higher value (closer to 1) indicating better classification [48]. The ROC curve and AUC-ROC are especially useful for comparing different models and selecting the optimal decision threshold.

B. Experimental Results

Accuracy, Precision, Recall, F-measure, and Area under a Receiver Operating Characteristic (AUC-ROC) are all terms that are used in the field of cyberbullying detection research. The confusion matrices for each of the techniques used in this work and evaluated in the cyberbullying classification dataset are shown in Fig. 5. We are able to clearly show the actual amount of classification results in respect to other classes by using confusion matrices. In the research that we conducted, we found that there are three different classes: cyberbullying, which was given the score of 1, non-cyberbullying, which was given the score of 0, and neutral class, which was given the score of 2.

In Fig. 6, a comparison is made between the model that was suggested and all of the other machine learning and deep learning models that were used. The AUC performance evaluation in each classification is done by finding the area under the receiver operating characteristic curve that includes all extracted attributes. The AUC-ROC curves of all of the strategies that have been implemented as well as the suggested method are compared in Fig. 7. As has been pointed out, deep learning models have been shown to be more valuable than machine learning approaches. According to the figure, the suggested model, which consists of BiLSTM, displays the best AUC-ROC value from the very first iteration and all the way along the graph.

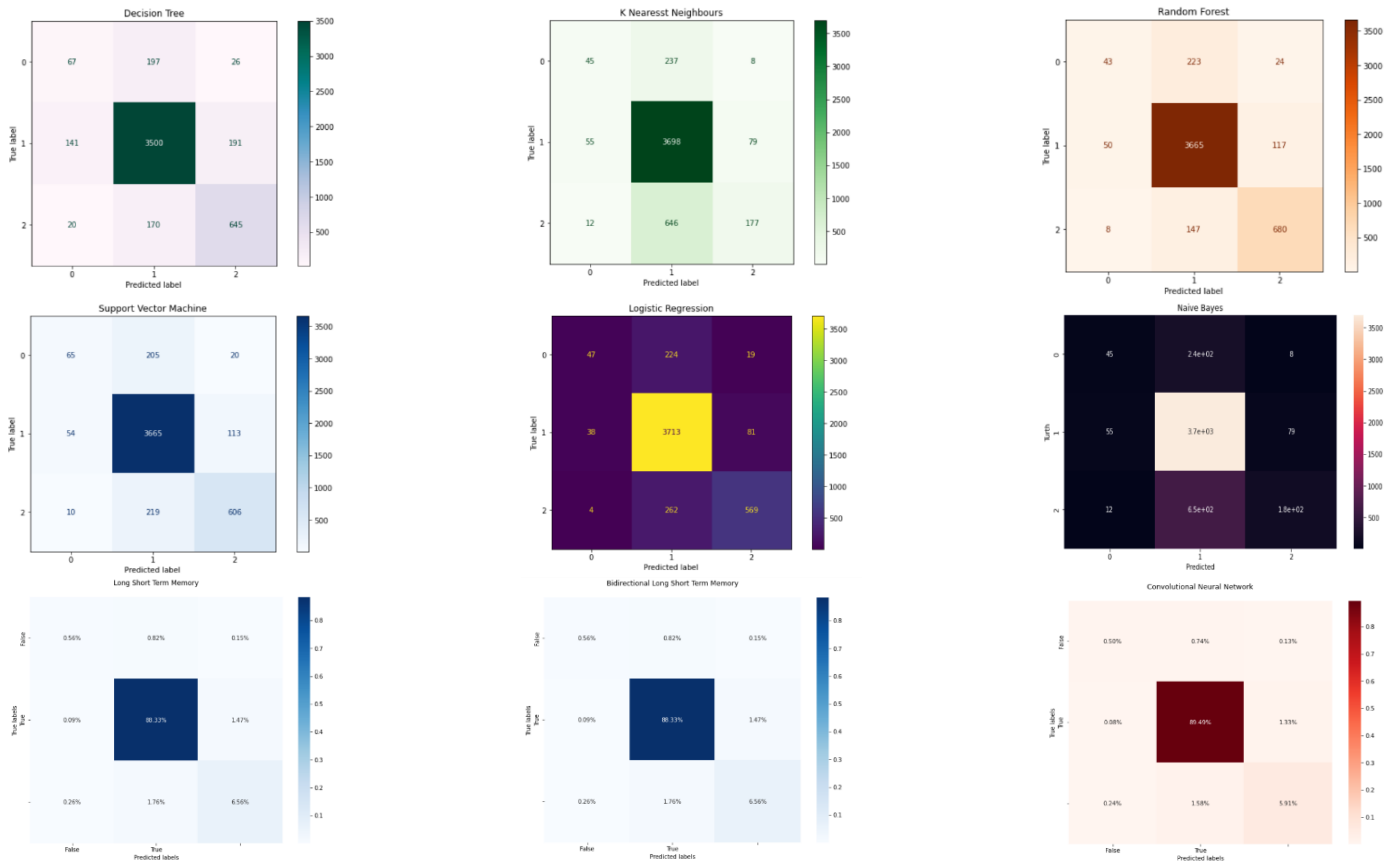

Fig. 5. Confusion matrices for hate speech detection.

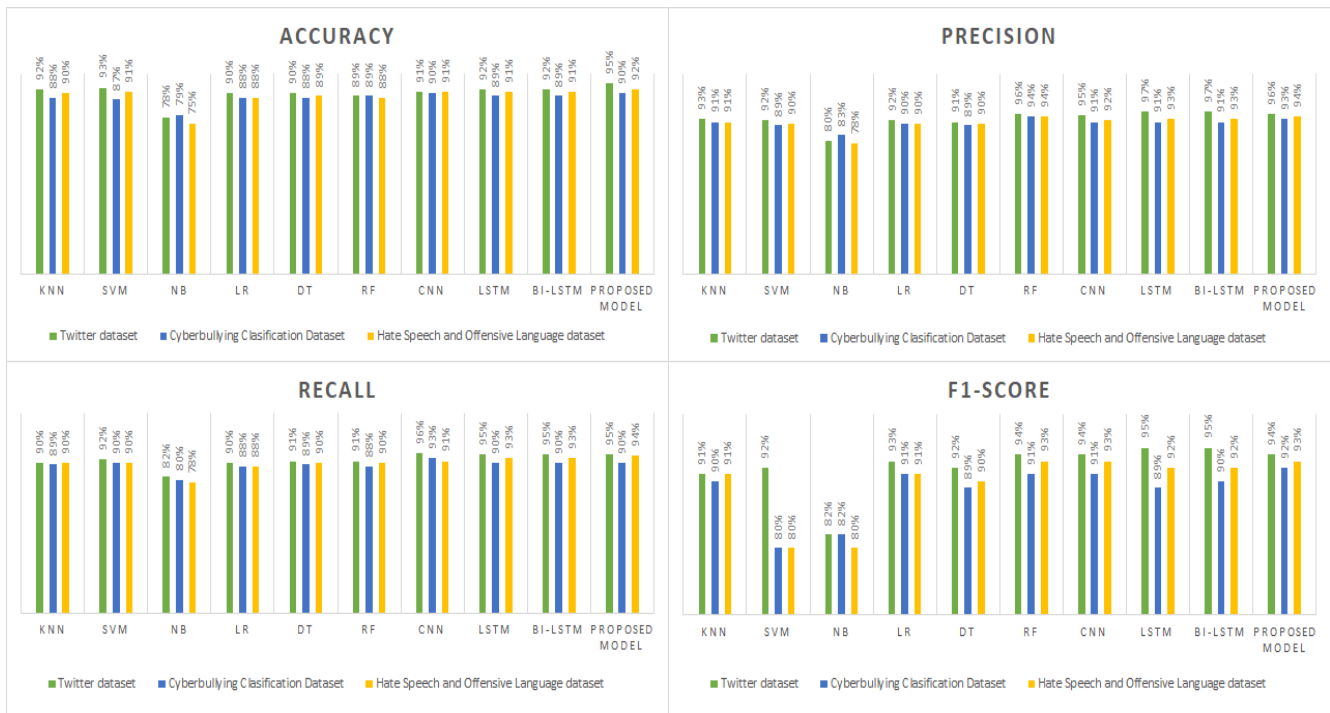

Fig. 6. Evaluation parameters for different datasets.

Fig. 7. ROC curve of applied machine learning and deep learning techniques for hate speech detection.

The categorization findings of cyberbullying are shown in Table I below. These results were achieved by using machine learning and deep learning techniques to three different

datasets. We employed assessment measures such as accuracy, precision, and recall, and F1-score [48-51] to evaluate the approaches of machine learning and deep learning.

TABLE I. COMPARISON OF THE OBTAINED RESULTS

Dataset	Approach	Model	Accuracy	Precision	Recall	F-score	ROC
Hate Speech and Offensive Language	Machine Learning Models	SVM	0.873	0.852	0.862	0.851	0.78
		KNN	0.856	0.839	0.831	0.837	0.92
		NB	0.874	0.832	0.863	0.851	0.80
		DT	0.602	0.524	0.585	0.642	0.65
		RF	0.851	0.854	0.822	0.856	0.77
		LR	0.862	0.853	0.837	0.858	0.78
	Deep Learning Models	CNN	0.892	0.895	0.898	0.896	0.93
		LSTM	0.901	0.896	0.91	0.898	0.93
		BiLSTM	0.902	0.916	0.904	0.899	0.94
Twitter Hate Speech	Machine Learning Models	SVM	0.873	0.852	0.862	0.851	0.75
		KNN	0.856	0.839	0.831	0.837	0.90
		NB	0.874	0.832	0.863	0.851	0.76
		DT	0.602	0.524	0.585	0.642	0.68
		RF	0.851	0.854	0.822	0.856	0.77
		LR	0.862	0.853	0.837	0.858	0.78
	Deep Learning Models	CNN	0.892	0.895	0.898	0.896	0.92
		LSTM	0.901	0.896	0.91	0.898	0.92
		BiLSTM	0.902	0.916	0.904	0.899	0.93
Cyberbullying	Machine Learning Models	SVM	0.873	0.852	0.862	0.851	0.75
		KNN	0.856	0.839	0.831	0.837	0.80
		NB	0.874	0.832	0.863	0.851	0.79
		DT	0.602	0.524	0.585	0.642	0.67
		RF	0.851	0.854	0.822	0.856	0.78
		LR	0.862	0.853	0.837	0.858	0.78
	Deep Learning Models	CNN	0.892	0.895	0.898	0.896	0.91
		LSTM	0.901	0.896	0.92	0.898	0.91
		BiLSTM	0.902	0.916	0.904	0.899	0.93

As a consequence of this, taking into consideration the success rates it has achieved, the suggested strategy may be accepted as a possible method for identifying instances of cyberbullying inside social networking sites. In addition, taking into account all of the criteria used for assessment, the deep neural network that was presented had the greatest performance when it comes to identifying cases of cyberbullying. The usage of the suggested deep neural network for modifying the weights and biases, in addition to a reduction in the amount of time spent training, resulted in favorable outcomes, which can be ascribed to the employment of the proposed technique. The results indicate that the suggested technique using deep neural networks may easily be modified to handle both short and lengthy texts as they are currently used.

VI. DISCUSSION

In this section, we will discuss the advantages, disadvantages, open issues, challenges, and future perspectives of the methods explored in this paper for hate speech detection in Twitter.

A. Advantages of Computational Intelligence in Hate Speech Detection

Shallow learning methods, such as logistic regression, random forest, decision tree, naïve bayes, K-NN, and SVM, offer several benefits, including simplicity, interpretability, and

computational efficiency. These algorithms can perform well on relatively small datasets and are less prone to overfitting compared to deep learning methods.

Deep learning methods, such as LSTM, BiLSTM, and CNN, have the ability to capture complex patterns and long-range dependencies in text data. These methods can learn hierarchical representations of the data, leading to improved classification performance in many NLP tasks, including hate speech detection.

Feature extraction techniques, such as Bag of Words, TF-IDF, and Word2Vec, allow for the transformation of raw text data into structured representations suitable for input to various classifiers. These techniques can capture different aspects of text data, such as word frequencies, term importance, and semantic relationships, providing valuable information for classification tasks.

B. Disadvantages of Computational Intelligence in Hate Speech Detection

Shallow learning methods may struggle to capture complex patterns and long-range dependencies in text data, which can lead to suboptimal classification performance in some cases.

Deep learning methods, despite their ability to capture complex patterns, may suffer from overfitting and require large amounts of labeled data for effective training. Additionally,

these models can be computationally expensive and less interpretable than shallow learning methods.

Feature extraction techniques, while providing valuable information for classification tasks, may not always capture the nuanced semantics and context present in natural language. This limitation can lead to misclassifications, particularly in complex tasks such as hate speech detection.

C. Open Issues and Challenges of Computational Intelligence in Hate Speech Detection

The development of robust and accurate classifiers for hate speech detection remains an open issue, as the nature of hate speech is constantly evolving. New forms of hate speech, including code words, slang, or non-textual elements (e.g., images or emojis), may not be effectively captured by existing models and feature extraction techniques.

The presence of imbalanced datasets, where the number of instances of one class significantly outweighs the other(s), is a common challenge in hate speech detection. Traditional performance metrics, such as accuracy, may be misleading in these situations, and alternative metrics or approaches (e.g., F-score, oversampling, or undersampling) may be necessary for effective model evaluation.

The issue of false positives and false negatives in hate speech detection presents a significant challenge, as the consequences of these misclassifications can be severe, leading to the suppression of free speech or the perpetuation of harmful content. Developing models that strike a balance between precision and recall remains a critical task.

D. Future Perspectives of Computational Intelligence in Hate Speech Detection

Investigating the integration of other deep learning architectures, such as transformers or attention mechanisms, may further enhance the models' ability to capture complex semantics and context, leading to improved classification performance.

The use of pre-trained language models, such as BERT or GPT, can be explored for their potential to leverage large-scale, pre-existing knowledge of language structure and semantics, leading to more accurate and robust hate speech detection systems.

Developing methods for effectively handling imbalanced datasets, such as advanced sampling techniques, cost-sensitive learning, or ensemble methods, may lead to improved model performance and more accurate classification of hate speech.

Exploring techniques for incorporating non-textual elements, such as images or emojis, into hate speech detection models can help address the evolving nature of hate speech and improve the overall effectiveness of classification systems.

Investigating methods for enhancing the interpretability of deep learning models, such as attention mechanisms or explainable AI techniques, can provide valuable insights into the decision-making process of these models, improving trust and adoption in real-world applications.

Collaborating with domain experts, such as sociologists or psychologists, can help in developing a more comprehensive understanding of the complex and evolving nature of hate speech. This interdisciplinary approach can lead to the development of more effective and contextually-aware classification models.

Exploring the potential of transfer learning and domain adaptation techniques can help in developing models that can be effectively applied to different languages, regions, or platforms, broadening the impact and applicability of hate speech detection systems.

In conclusion, the methods and techniques presented in this paper provide a foundation for the development of advanced, robust, and accurate hate speech detection systems. By addressing the open issues and challenges, and considering future perspectives, researchers can contribute to the ongoing effort to create a safer and more inclusive online environment on platforms like Twitter. The lessons learned from these investigations can also be applied to other social media platforms and domains, where hate speech and harmful content pose significant challenges to users and society at large.

VII. CONCLUSION

In conclusion, this paper has presented a comprehensive study of various shallow and deep learning methods for detecting hate speech on Twitter. Shallow learning algorithms, including logistic regression, random forest, decision tree, naïve bayes, K-NN, and SVM, have been explored as effective classifiers for identifying hate speech based on features extracted from text data, such as Bag of Words, TF-IDF, or word embeddings. Additionally, deep learning methods, such as LSTM, BiLSTM, and CNN, have been investigated for their ability to capture complex patterns and long-range dependencies in text, resulting in improved classification performance.

The paper has also discussed the importance of feature extraction techniques in transforming raw text data into structured representations that can be used as input for various classifiers. Techniques like Bag of Words, TF-IDF, and Word2Vec have been highlighted for their ability to capture different aspects of text data, including word frequencies, term importance, and semantic relationships.

In evaluating the performance of the various classifiers, metrics such as accuracy, precision, recall, F-score, and ROC curve have been employed to provide a comprehensive understanding of the models' effectiveness in detecting hate speech. These metrics are crucial in assessing the trade-offs between different models and selecting the most suitable approach for a particular task.

Future research in hate speech detection can explore the integration of other deep learning architectures, such as transformers or attention mechanisms, to further enhance the models' ability to capture complex semantics and context. Moreover, the use of pre-trained language models, such as BERT or GPT, can be investigated for their potential to improve classification performance by leveraging large-scale, pre-existing knowledge of language structure and semantics.

Ultimately, the detection of hate speech on social media platforms like Twitter is of paramount importance in fostering a safe and inclusive online environment. The methods and techniques presented in this paper provide valuable insights and serve as a foundation for the development of advanced, robust, and accurate hate speech detection systems.

Abstract—This research presents a new algorithm for Arabic root extraction, which aims to improve the accuracy of Arabic Natural Language Processing Algorithms by addressing the weaknesses and errors of existing algorithms. The proposed algorithm utilizes a database, that includes a collection of roots, patterns, and affixes, to generate potential derivation roots of a word without eliminating affixes initially. By matching the derived word with patterns to identify potential roots, the proposed algorithm avoids the inaccuracies caused by eliminating affixes based on expectation methods. The study conducted a comparison of the proposed algorithm with three commonly used Arabic root extraction algorithms. The evaluation process is performed on three corpora. Results showed that the proposed algorithm achieved an average accuracy rate of 96%, which is significantly higher than the others.

Keywords—Natural language processing; Arabic root extraction algorithm; Arabic applications; Arabic morphology; Text mining

I. INTRODUCTION

Arabic is a Semitic language with a rich history and culture, and it is spoken by over 420 million people worldwide. The Arabic language is characterized by a unique system of roots, where most words are derived from a three-letter root [1]. Therefore, the ability to accurately extract roots from Arabic words is crucial for understanding the language, conducting research, and developing natural language processing algorithms [2].

In recent years, there has been a growing interest in developing Arabic root extraction algorithms, particularly those based on datasets and rules. These algorithms rely on linguistic rules and datasets to extract the root of a given Arabic word. They have proven to be effective in extracting roots from a variety of Arabic texts, including classical literature, modern newspapers, and social media [3]. The importance of Arabic root extraction algorithms lies in their ability to improve natural languages processing tasks such as machine translation, text classification, and sentiment analysis. These algorithms also play a critical role in the development of Arabic language technologies, including spell checkers, search engines, and speech recognition systems [4]. Despite the challenges posed by the complexity of the Arabic language and its various dialects, researchers continue to explore new techniques and methods for Arabic root extraction. The development of these algorithms is essential for advancing the field of Arabic natural language processing and enhancing our understanding of the language [5].

To effectively extract the root from Arabic words, it is crucial to understand the fundamental concepts of root extraction in Arabic, which include roots, affixes, patterns, and derived words [6]. Until now, not all of the root words and affixes in the Arabic language have been identified. While Arabic scholars have discovered a significant number of them, there is still a need to uncover the remaining ones in order to obtain more precise outcomes when extracting the roots of Arabic words. Thalji et al. [7] have released an Arabic corpus containing 12,000 roots, 430 prefixes, 320 suffixes, 4,320 patterns, and 720,000 word-root pairs. One of the objectives of this paper is to thoroughly comprehend and examine the given corpus, and to extract significant information that can aid in the extraction of Arabic language roots.

This research introduces a new algorithm for Arabic root extraction in Natural Language Processing (NLP). The algorithm utilizes a database and pattern matching techniques to generate potential derivation roots without eliminating affixes initially, resulting in improved accuracy compared to existing algorithms. The evaluation conducted on three corpora demonstrates an average accuracy rate of 96%, highlighting the algorithm effectiveness in accurately extracting roots from Arabic words. This contribution has significant implications for Arabic NLP applications, enhancing the performance and reliability of tasks such as information retrieval, machine translation, and sentiment analysis. Overall, the paper presents a valuable addition to the field of Arabic language processing, advancing the accuracy and reliability of Arabic root extraction in NLP.

II. LITERATURE REVIEW

The literature review summarizes current techniques used in Arabic root extraction, highlighting their strengths and weaknesses, with the goal of identifying gaps in current approaches and proposing areas for future research.

Alfredaghi and Al-Anzi [8] propose a data-base-oriented method for identifying Arabic roots using patterns and root lists. The method is efficient and does not require individual word analysis, but has some limitations such as only returning one root when multiple patterns match, and a relatively short list of patterns.

Al-Serhan et al. [9] propose a statistical approach for extracting Arabic roots based on assigning weights to letters and using mathematical equations. The approach is efficient and doesn't require word analysis, but has limitations such as difficulty in handling the complexities of the Arabic language, and may not provide as accurate results as rule-based

approaches. Additionally, the lack of a clear explanation for root extraction makes it challenging to understand and improve the algorithm.

The Khoja and Garside algorithm [10] is a widely used rule-based approach to Arabic stemming that identifies and removes prefixes and suffixes from Arabic words to produce their root form. It follows a set of rules based on Arabic morphology to identify the prefixes and suffixes that can be stripped from a word to obtain its root. The algorithm is effective but has some limitations, such as mistakenly removing common prefixes and suffixes that are actually part of the root letters, missing certain rules, and providing only one solution for non-vocalized words.

Taghva, Elkhoury, and Coombs [11] developed a rule-based algorithm to extract roots, which aimed to improve Khoja and Garside's algorithm [10] by eliminating the need for a root list. The algorithm did not require a root list, which made the root extraction process faster, but it had limitations, such as ambiguity in affixes, providing only one solution for non-vocalized words, returning meaningless roots, and sometimes failing to extract roots for derived words that contain the "ابدال" rule. Cross-checking with the root list was necessary to minimize the number of erroneous roots.

Ghwanmeh et al. [12] developed a rule-based algorithm to extract the trilateral, quadrilateral, and pentaliteral roots of Arabic words. The algorithm removes affixes and matches the remaining word against a list of patterns. The algorithm still missed many roots, prefixes, suffixes, and patterns. It also faced challenges in dealing with affixes ambiguity problems and returned only one solution for non-vocalized words.

Alkabi [13] proposed a new algorithm for Arabic root extraction to improve the accuracy of Khoja and Garside's algorithm [10]. The new algorithm used additional patterns to supplement Khoja and Garside's patterns and was tested on MSA textual documents from Arabic newspapers websites. The results showed an increase in the accuracy of Khoja and Garside's algorithm from 71% to 76%. The study concluded that expanding the number of patterns can enhance the accuracy of root extraction algorithms.

The Word Substring Stemming Algorithm (WSS), proposed by Yaseen and Hmeidi [14], generates all possible substrings of a word and matches them with a list of known roots to extract Arabic roots. The algorithm achieved an accuracy of 83.9% when tested on the Holy Quran. The algorithm's main strength is its ability to extract all possible roots of derived words. However, it generates a large number of roots, most of which are not related to the original root, and it may mistakenly remove some prefixes and suffixes that are actually part of the root.

Boudchiche et al. [15] presented the second version of AlKhalil Morpho analyzer, a tool for Arabic text processing that analyzes the morphological and syntactic structure of the Arabic language, with improved accuracy and efficiency. The tool can be used for various natural language processing tasks and was evaluated using different methods such as coverage, speed, and an average number of suggested root forms and proposed word stems per word. However, the authors did not

evaluate the precision, recall, and F-measure of the tool due to the unavailability of a corpus with all possible features for each word.

Atta and Al-Hmouz [16] introduced a rule-based approach to extract Arabic roots using a set of rules and a dictionary containing stop words, affixes, and roots. The algorithm was tested on a set of 480 proverbs in Standard Arabic and achieved an accuracy of 74.11%. The algorithm's strength lies in its attempt to enhance existing algorithms by suggesting new rules and changing the order of rules. However, the algorithm has limitations, such as limited applicability of rules and decreased accuracy as word length increases.

Alnaied et al. [17] proposed a new method called Arabic Morphology Information Retrieval (AMIR) to generate Arabic word stems using a set of rules. AMIR outperformed other systems in terms of mean average precision, but it has some weaknesses, including its inability to extract the root of many words and its tendency to make errors in root extraction by removing some letters that are part of the root.

The research by R. Kanaan and G. Kanaan presents an improved algorithm for extracting trilateral Arabic roots [18]. In their work, Boudlal, Lakhouaja, Mazroui, and Meziane developed Alkhalil morpho sys1 [19], a morphosyntactic analysis system specifically designed for Arabic texts. The system provides detailed analysis and processing capabilities for Arabic linguistic features, aiding in various language processing tasks. In their research, Momani and Faraj proposed a novel algorithm for extracting tri-literal Arabic roots [20]. The algorithm introduces a new approach to accurately identify and extract the core tri-literal roots in Arabic words, contributing to Arabic language processing tasks. In the study by A. Belal [21], comprehensive processing techniques were developed for Arabic texts to extract their roots. The research focuses on providing robust methods for accurately identifying and extracting the roots of Arabic words, contributing to Arabic language analysis and processing tasks. Sonbol, Gheim, and Desouki introduced a new approach for Arabic morphological analysis [22]. The study presents innovative methods and techniques for analyzing the morphological structure of Arabic language, contributing to the field of Arabic language processing and related applications. Hamza, Ahmed, and Hilal provide an overview of Arabic root extraction algorithms in the field of text mining [23]. The study explores various algorithms and techniques used for extracting roots from Arabic texts, highlighting their strengths and limitations. The survey serves as a comprehensive resource for researchers and practitioners interested in Arabic language processing and text mining.

Various algorithms for Arabic root extraction have been proposed in the literature, which aims to suggest new rules, change the order of rules, or increase the dictionaries of data rules. However, these algorithms were tested on specific corpora, and their efficiency decreased when tested on another corpus.

III. METHODOLOGY

In this research paper, the methodology section describes the procedures and techniques employed to conduct the study,

providing a clear and concise explanation of the research dataset and methodology.

A. The Dataset

The research paper utilizes Thalji et al. dataset [7] and discusses the fundamental concepts of root extraction in Arabic. The dataset section is divided into three sections, namely roots, affixes, and patterns in Arabic known as "AWZAN".

1) *Arabic roots*: Arabic roots are the basic building blocks of words in the Arabic language [24]. The roots consist of two or more letters that combine to create a meaning. The roots can be sorted into categories based on their length and the type of letters they contain. The length-based roots are divided into five categories, and the second type of root is divided into two categories based on the type of letters they contain. This categorization helps provide insights into the morphology of the Arabic language and highlights the need for advanced root extraction algorithms to effectively handle the different types of roots. Upon examining Thalji et al.'s corpus [7], the roots can be sorted into categories based on their length and the type of letters they contain, as illustrated in Table I.

TABLE I. TYPES OF ARABIC ROOTS

Category	Sub Category	No of roots	Examples
Length-based root	2	480	(عَض, "add", pride)
	3	8000	(دَرس, drasa, study)
	4	3112	(جَمهر, jamher, mass)
	5	360	(عَظفِر, adanfer, glory)
	6	48	(عَنقَير, ankafeer, skillful)
Type of letters root	Vowel	3000	(يَوم, yawem, day)
	Non-vowel	9000	(دَفَع, dfaa, pay)

2) *Arabic affixes*: Arabic prefixes are added at the beginning of a root word to modify its meaning or function, and can indicate various aspects of meaning [25]. Thalji et al.'s corpus includes 430 prefixes, with lengths ranging from one to six letters, and Table II provides statistical information on a subset of these prefixes. Understanding Arabic prefixes is important for comprehending the language and literature.

TABLE II. TYPES OF ARABIC PREFIXES

Prefixes (length-based)	Number	Examples
1	13	(ي, "yaa", the present tense for the male/s)
2	103	(ال, al, the)
3	146	(وال, wal, and the)
4	103	(ليست, leyasta, the present tense).
5	52	(كالمِن, kaelmon, used for analogy)
6	13	(والاست, walest, used for noun)
Total	430	

The Arabic language has infixes, which are inserted within the root of a word to add more meaning. Thalji et al.'s corpus includes 11 Arabic infixes that are classified by length, ranging from one to two letters. It is important to note that a word may contain one or more of these infixes, or none at all. Table III shows a sample of these infixes and their corresponding statistics.

TABLE III. TYPES OF ARABIC INFIXES

Infixes Subcategory (length-based)	Number of prefixes	Prefixes
1	4	ا, و, ي, ت
2	7	وا, يا, او, يي, وي, يت, تا

Arabic suffixes are added to the end of a root word to modify its meaning or grammatical function. They can indicate various aspects, including tense, aspect, voice, gender, number, and case. The study identifies 320 suffixes in the Arabic language, and Table IV shows the number of suffixes in each length category, along with examples for each type. The identification and understanding of Arabic suffixes are crucial for studying the Arabic language and literature. According to the same table, the length of three letters has the highest number of suffixes, with a total of 183. The length of four letters comes next with 94, and both the length of two and five letters have the same number of 40. The length of one letter has a total of 6, and finally, the length of six letters has only 3 suffixes.

TABLE IV. TYPES OF ARABIC SUFFIXES

Suffixes length	Number	Examples
1	6	(ت, "taa", indicates that the subject of the verb is a singular female)
2	40	(ات, at, indicates that the object is plural female)
3	132	(هما, homa, indicates that the object is dual)
4	94	(ناهم, nahom, indicates that the subject of the verb is a plural and indicates that the object is plural male).
5	40	(كموها, kamoha, indicates that the first object is a male plural and indicates that the second object is singular female).
6	3	(انتان, entyan, indicates that the first object is a dual and indicates that the second object is dual also).
Total	320	

3) *Arabic patterns*: Arabic patterns are important for forming words in the Arabic language [26]. They consist of a sequence of letters added to a root to form a complete word with a specific meaning. The study identified 4320 Arabic patterns, ranging in length from three to twelve letters. The most common pattern length is seven letters, with 1296 patterns, followed by lengths of six and eight letters with almost equal numbers. The length of three letters has only one pattern, while the lengths of eleven and twelve letters have 43 patterns each, as shown in Table V. Understanding Arabic patterns is essential for mastering the language.

TABLE V. TYPES OF ARABIC PATTERNS

Pattern length	Number of patterns	Examples
3	1	(فعل) faal, indicates that one was doing something).
4	86	(يفعل) yafaal, indicates single male is doing something).
5	302	(فعلته) faalatho, indicates single female was doing something).
6	994	(الفعلة) alfealah, indicates singular noun).
7	1296	(يتفعلون) yatfaaloon, indicates plural male are doing something).
8	950	(يتفعلان) yattafaalan, indicates dual male are doing something).
9	475	(واستفعلها) estafalaha, indicates single male was doing something and the object is femal).
10	129	(المفعولتان) almafolatan, indicates the object is dual female and it is noun).
11	43	(واقفعلاتهن) waqfealatehem, indicates that it is noun and plural female).
12	43	(والفوعلايون) waltawalaneyoon, indicates that it is noun and plural male).
Total	4320	

B. Normalization

Before stemming, normalize the Arabic word by applying the following steps:

- 1) Remove diacritics punctuation and the Shadda.
- 2) Replace all distinct forms of Hamza with (أ).
- 3) Replace Madda (آ) with Hamza and Alef (أ).
- 4) Replace Alef Maksura (آ) with Alef (أ).

By applying these normalization steps, the algorithm ensures that all Arabic words are represented in a standardized form, which is essential for accurate and efficient root extraction.

C. Pattern Generation

Generate all possible patterns that match the word. The following template is used for the possible patterns: <prefix> <ف> <infix> <ع> <infix><ل1><ل3><ل2> <ل><suffix>. The format consists of different parts:

- <prefix>: This part represents the letters that come before the root of the word, like in the case of the pattern (المفعلات) for the word (المدرسات), the prefix is (الم). Also, the prefix part can be empty, like in the case of the pattern (فاعلات) for the word (دارسات).
- <ف>: This part corresponds to the first root letter, like in the case of the pattern (المفعلات) for the word (المدرسات), the <ف> letter is corresponding to the root letter (ف). If the root consists of only two letters, the first root letter may not exist, in the case of the pattern (عل) of the word (قف), the initial letter of the original word (وقف) was removed, and this led to the deletion of the letter (ف) from the pattern, resulting in (عل).
- <infix1>: This part represents the infix letters that can appear between the first root letter and the second root letter, like in the case of the pattern (مفتعلون) for the word (منتشرون), the < infix1> letter that appears between the first root letter and the second root letter is (ت). This part may be empty, like in the case of the pattern

(المفعلات) for the word (المدرسات), there is no infix letter between the first root letter and the second root letter.

- <ع>: This part represents the second letter of the root, like in the case of the pattern (المفعلات) for the word (المدرسات), the <ع> letter is corresponding to the root letter (ع). If the root consists of only two letters, the first root letter may not exist, in the case of the pattern (فل) of the word (قول), the second root letter of the original word (قول) was removed, and this led to the deletion of the letter (ع) from the pattern, resulting in (فل).
- <infix2>: This represents any infix letters that can appear between the second root letter and the third root letter, like in the case of the pattern (مفعول) for the word (منتشور), the < infix2> letter that appears between the second root letter and the third root letter is (و). This part may be empty, like in the case of the pattern (المفعلات) for the word (المدرسات), there is no infix letter between the second root letter and the third root letter.
- <ل1>: This represents the third letter of the root, like in the case of the pattern (المفعلات) for the word (المدرسات), the <ل1> letter is corresponding to the root letter (ل). If the root consists of only two letters, the third root letter may not exist, in the case of the pattern (افع) of the word (ارم), the third root letter of the original word (ارمي) was removed, and this led to the deletion of the letter (ل) from the pattern, resulting in (افع).
- <ل2>: This represents the fourth letter of the root, like in the case of the pattern (متفعل) for the word (متدحرج), the <ل2> letter is corresponding to the root letter (ج). If the root consists of three or two letters, the fourth root letter does not exist, in the case of the pattern (فاعل) of the word (دارس), the fourth root letter does not exist.
- <ل3>: This part represents the fifth letter of the root, like in the case of the pattern (فعللل) for the word (سفرجل), the <ل3> letter is corresponding to the root letter (ل). If the root consists of four or fewer letters, the fifth root letter does not exist, in the case of the pattern (فاعل) of the word (دارس), the fifth root letter does not exist.
- <ل4>: This part represents the sixth letter of the root, like in the case of the pattern (فعلللل) for the word (عنقير), the <ل3> letter is corresponding to the root letter (ر). If the root consists of five or fewer letters, the sixth root letter does not exist, in the case of the pattern (فاعل) of the word (دارس), the fifth root letter does not exist.
- <suffix>: This part represents the letters that come after the root of the word, like in the case of the pattern (المفعلات) for the word (المدرسات), the suffix is (ات). Also, the suffix part can be empty, like in the case of the pattern (مفاعل) for the word (مدارس).

D. Remove Non-Patterns

Note that this approach generates all possible patterns that match the word, but not all of them will actually be valid Arabic patterns. Some of the generated patterns may need to be

filtered. The identified patterns are matched against the set of patterns stored in the database. Any pattern that is not present in the database is eliminated.

E. Extract the Roots

Once the potential patterns of the word have been determined, the next step is to identify the root of the word, which can be done by following these instructions:

- The initial letter of the root is the one that corresponds to <ف>. Like in the case of the pattern (المفعلات) for the word (المدرسات), the <ف> letter is corresponding to the root letter(د).
- The second letter of the root is the one that corresponds to <ع>. Like in the case of the pattern (المفعلات) for the word (المدرسات), the <ع> letter is corresponding to the root letter(ر).
- The third letter of the root is the one that corresponds to <ل>. Like in the case of the pattern (المفعلات) for the word (المدرسات), the <ل> letter is corresponding to the root letter(س).
- The third letter of the root is the one that corresponds to <2ل>. Like in the case of the pattern (متفعل) for the word (متدرج), the <2ل> letter is corresponding to the root letter(ج).
- The third letter of the root is the one that corresponds to <3ل>. Like in the case of the pattern (فعلل) for the word (سفرجل), the <3ل> letter is corresponding to the root letter(ل).
- The third letter of the root is the one that corresponds to <4ل>. Like in the case of the pattern (فعللل) for the word (عنقير), the <3ل> letter is corresponding to the root letter(ر).

IV. RESULT AND DISCUSSION

This section presents the study findings by describing the testing and comparison of the algorithm with different algorithms on various datasets.

A. Testing the Algorithm in Different Datasets

The suggested algorithm is tested on three different corpora, and its effectiveness is evaluated using precision, recall, and F1 score metrics based on root length and type. Thalji et al. corpus, which includes 720,000 word-root pairings, is divided into five categories based on root length and two types based on letter type. Alshawakfa et al.'s corpus [27], comprises 27,628,821 word-root pairs. The corpus includes only trilateral roots and is divided into two types of roots based on root letter type: vowel roots (VR) and non-vowel roots (NVR). Alkabi et al.'s corpus [26], which includes 6081 word-root pairs. This corpus is distributed into two root types based on their length, namely TR and QR, and two types of roots based on their letter type: VR and NVR. Table VI summarizes the average results across all corpora and compares the performance of the algorithm on three different datasets. In cases where a particular root type is not listed in a corpus, such as BR in Alshawakfa et al.'s corpus, the column is marked with a "-". The table indicates that the proposed

algorithm consistently produces high values for precision, recall, and F1 score, regardless of the type of corpus used.

TABLE VI. SUMMARY OF THE SYSTEM EVALUATION USING THREE DIFFERENT CORPORA

Roots type	Precision			Recall			F-Measure		
	Thalji	Alshawakfa	Alkabi	Thalji	Alshawakfa	Alkabi	Thalji	Alshawakfa	Alkabi
2	82	-	-	-	-	-	84	-	-
3	81	88	82	93	100	95	87	94	88
4	87	-	86	92	-	88	89	-	87
5	90	-	-	92	-	-	91	-	-
6	93	-	-	85	-	-	89	-	-
Avg.	87	88	84	90	100	92	88	94	88
VR	70	77	71	90	100	82	79	87	76
NVR	90	97	85	94	100	97	92	99	90
Avg.	80	87	78	92	100	90	85	93	83

B. Comparing the Algorithm with other Root Extraction Algorithms

To evaluate the accuracy of the proposed algorithm, a comparison is made with three other Arabic root extraction algorithms, namely Khoja and Garside's algorithm [10], Sonbol et al.'s algorithm [22], and Alkabi et al.'s algorithm [26]. These algorithms are established and respected methods in Arabic language applications and have demonstrated high accuracy performance in their respective studies. The comparison is conducted on the Thalji et al.'s corpus, Alshawakfa et al.'s corpus, and Alkabi et al.'s corpus, and the results are presented in Table VII.

TABLE VII. ACCURACY PERFORMANCE OF THE FOUR ALGORITHMS

The algorithm	Corpus type			Average
	Thalji's corpus	Alshawakfa et al.'s corpus	Alkabi et al.'s corpus.	
Khoja and Garside's algorithm	63%	34%	74%	57%
Sonbol et al.'s algorithm	68%	24%	65%	52%
Alkabi et al.'s algorithm	70%	35%	76%	60%
The proposed algorithm	92%	100%	95%	96%

The proposed algorithm for Arabic root extraction outperformed previous algorithms in terms of accuracy according to Table VI and VII. The proposed algorithm returns all potential roots for non-vocalized words and includes all types of roots, not just one specific type. Previous algorithms returned only one root for non-vocalized words and ignored other possible solutions, resulting in a decrease in accuracy. Additionally, previous algorithms suffered from the reduction of the content of the lists used, ambiguity problems, and the inability to extract roots for words without any consonant letters. Overall, the proposed algorithm had the highest accuracy rate compared to previous algorithms.

The proposed algorithm has limitations in dealing with derived words that consist of only one letter, as they are not considered in the algorithm. These derived words originate from weak roots with three letters, wherein the weak letters are omitted during the derivation process. Moreover, the algorithm's tendency to generate all possible roots can result in confusion when attempting to identify the specific root required, as it primarily focuses on individual derived words rather than considering the context of complete meaningful sentences or paragraphs. Future work can address these limitations by enhancing the algorithm to handle one-letter derived words and incorporating techniques such as natural language processing or linguistic analysis to improve its contextual understanding and accuracy in root extraction.

V. CONCLUSION

This study examined the algorithms used to extract Arabic word roots and found that their accuracy is affected by the lack of comprehensive lists and essential rules. Previous research focused on trilateral roots and ignored other types, resulting in incorrect results for non-vowel roots, which make up 75% of all roots. Weak roots were also found to be a major cause of failure in previous Arabic root extraction algorithms due to their numerous irregular cases.

This study proposes a new algorithm for extracting Arabic word roots and compares its accuracy with three commonly used algorithms. The proposed algorithm generates all potential derivation roots of a word without eliminating affixes first, which is different from previous algorithms. The study uses Thalji et al.'s corpus to utilize the maximum amount of content available in the lists. The proposed algorithm achieves an average accuracy of 96%, which is significantly higher than the accuracy of the other three algorithms.

Abstract—Artificial Intelligence chatbots have shown a growing interest in different domains including e-learning. They support learners by answering their repetitive and massive questions. In this paper, we develop a smart learning architecture for an inclusive chatbot handling both text and voice messages. Thus, disabled learners can easily use it. We automatically extract, preprocess, vectorize, and construct AskBot's Knowledge Base. The present work evaluates various vectorization techniques with similarity measures to answer learners' questions. The proposed architecture handles both Wh-Questions starting with Wh words and Non-Wh-Questions, beginning with unpredictable words. Regarding Wh-Questions, we develop a neural network model to classify intents. Our results show that the model's accuracy and the F1-Score are equal to 99,5%, and 97% respectively. With a similarity score of 0.6, our findings indicate that TF-IDF has performed well, correctly answering 90% of the tested Wh-Questions. Concerning No-Wh Questions, soft cosine measure, and fasttext successfully answered 72% of Non-Wh-Question.

I. INTRODUCTION

The e-learning domain has shown impressive growth in applying AI technologies to enhance the quality of learning. e-Learning platforms are increasingly recognizing the importance of integrating AI to perform tasks effectively while saving time, energy, and cost. Based on AI technologies, the e-learning domain succeeds in (1) personalizing educational content according to each learner's needs and capabilities instead of proposing a standard approach to learning. Hence, the learning strategy becomes dynamic, customized, and individualized to encourage learners. (2) Providing specific information about each learner's progress, strengths, and weaknesses, and even attendance issues. Hence, data analysis on e-learning platforms enhances and improves learning experiences. (3) Developing multilanguage course content by integrating automatic translation tools that offer more speed and efficiency in translating huge amounts of content, thus saving time and offloading teachers from such tasks that consume time and energy. (4) Supporting learners by providing AI chatbots to answer learners' questions. Chatbots are available 24/7. Thus, learners are free to learn at their own pace through multiple devices.

Various chatbots have been created for use in multiple areas, including the e-learning domain. Especially, there is an

exponential interest in AI chatbots in the last few years, especially from 2016 until now [1]. AI chatbots have been used in the e-learning domain to satisfy several needs such as (1) Promoting learners' interaction with online courses. (2) Providing information about administration [2], courses, and exam regulations (3) Sharing exercises and tips/hints to solve them and assist students to master the course knowledge (4) Answering repetitive and massive questions about the course knowledge (5) Recommending learning materials and educational resources according to the learner's need (6) Assessing learners' knowledge by automating exams and assignments (Sreelakshmi et al., 2019) (5) Encourage collaborative learning between learners (El Azhari et al., 2022).

Therefore, e-learning chatbots address several issues facing the e-learning domain, especially since they have succeeded in: (1) Automating repetitive tasks by performing them efficiently. Thus, helping tutors to focus their energies on more complicated tasks rather than answering repetitive and massive questions (El Azhari et al., 2021). Hence, saving time, energy, and cost. (2) Capitalizing knowledge from several sources and storing them as the chatbot Knowledge Base (KB), Thus, assisting learners to quickly find the reliable information needed without wasting time searching in many information sources. (3) Encouraging learners to ask their questions (Moreno-Guerrero et al., 2023) without being afraid of attracting attention from others, being criticized, and having their opinions misinterpreted. (4) Supporting interaction between learners and the chatbot, hence, learners ask their questions at their own pace through multiple devices without waiting for the course session (El Azhari et al., 2022).

Despite the efforts made to integrate AI chatbots in the e-learning domain, there are some drawbacks related to the manual process of creating e-learning chatbots. Specifically, several researchers (M. Verleger and J. Pembridge, 2018; Herrera, Yaguachi and Piedra, 2019; El Janati, Maach and El Ghanami, 2020; H. C. B. Chan and T. T. Fung, 2020; Tamayo et al., 2020; Deepika, Bala and Kumar, 2021a; Nhut Lam, Nhat Le and Kalita, 2022; Singh and Singh, 2022) propose AI chatbots by manually creating pairs of Questions and Answers (Q&As) and storing them as the chatbot's local KB. They manually create learners' intents rather than automatically extracting them. Thus, consuming time, energy, and cost.

In this paper, we will address these issues by proposing an inclusive chatbot called « AskBot » able to automatically understand learners' requests in text and voice formats without the need for prebuilt services in online platforms. Thus, saving

time, energy, and cost. This work differs from existing chatbots by providing an automatic approach to construct the AskBot's KB using the web scraping tool without wasting time in manually collecting Q and As related to the chatbot's domain.

The remainder of this paper is structured as follows: The next section outlines the context and the problem statement of the study. The third section presents related works. The fourth section provides AskBot's architecture, and the implementation process and the last section provides the conclusion and future works.

II. CONTEXT AND PROBLEM STATEMENT

A. Overview of AI Chatbots and NLP Techniques

AI chatbots are based on NLP techniques, especially Natural Language Understanding (NLU) to understand what the user asks for and Natural Language Generation (NLG) to generate the appropriate response and answer correctly. AI chatbots recognize users' needs by applying the NLU technique. They extract two main elements: (1) The intent which means the user's intention behind asking a question or formulating a message. (2) Entities are values extracted from the user's input to understand the information needed. Fig. 1 demonstrates a use case of using AI chatbots to answer learners' questions.

Before understanding the user's request, it's highly recommended to transform it into a vector by applying the word embedding technique. Specifically, each word is converted into a single vector. It considers that a word is characterized by its context, i.e., by the words that surround it. Thus, words that share similar contexts also share similar meanings.

Fig. 1. Example of AI chatbot in an e-learning context.

In this paper, we test four well-known word embedding techniques:

1) *Term Frequency Inverse Document Frequency (TF-IDF)* is a text vectorizer method that aims to transform the text into vectors by combining three main concepts: (i) *Term Frequency (TF)*: It indicates the significance of a particular term by calculating the number of times it appears in a document. (ii) *Document Frequency (DF)*: It refers to the number of documents that include a particular term. It reveals how frequently a term is used. (iii) *Inverse Document Frequency (IDF)* determines the weight of a particular term. It aims to reduce the weight of a term if its occurrences are dispersed over all the documents.

2) *Word2Vec* is based on two-layer neural networks and seeks to learn the vector representations of the words

composing a text. Thus, words with similar contexts are represented by close numerical vectors.

3) *GloVe works based on two main methods*: (i) *Global matrix factorization* is the process of reducing huge term frequency matrices using matrix factorization techniques from linear algebra. (ii) *Local context window methods* are CBOW and Skip-Gram.

4) *FastText* encodes each word as an n-gram of characters rather than immediately learning word vectors. N-grams can be defined as continuous words, symbols, or token sequences in a document.

The chatbot uses the output of the vectorization step to answer given questions. Especially, it measures the similarity between the user's question and all stored questions, then, it returns the response of the most similar question to the user's question. To perform this process, the chatbot needs to measure similarities between questions by using techniques such as Cosine Similarity and Soft Cosine Measure. They are among the techniques widely used. Specifically, they have proven good results in different implementations :

1) *Cosine similarity*: It calculates the cosine of the angle formed by two vectors projected into a multidimensional space. The cosine similarity increases with decreasing angle.

2) *Soft cosine measure*: It assesses the similarity between two publications meaningfully even when they don't share any words. It has been demonstrated that it performs better than several cutting-edge techniques in determining semantic text similarity.

In this part, we introduced an overview of the main concepts used in our work to implement AskBot's architecture. The next part is dedicated to discussing the problem statement of the present work.

B. Problem Statement

The e-Learning domain suffers from a variety of issues, especially, managing learners' questions. Specifically, tutors spend considerable time and energy manually answering repetitive and massive learners' questions. They are unavailable to manually handle them and satisfy all learners' needs [3], [4]. Thus, learners are forced to seek the information they need from several materials: Books, online links, and search engines [5]. Thus, consuming time and energy in filtering relevant and reliable information [6]. Hiring additional tutors might be a solution to handle massive learners' queries. However, it leads to high costs. For that reason, automatically answering learners' questions is needed to offload tutors from repetitive tasks [7]. Thus, they can concentrate their energies on more complicated tasks.

AI chatbots are highly integrated into e-Learning platforms to automatically respond to learners' questions [8]. They automate handling learners' requests by giving the appropriate answers to given queries. Thus, saving time, energy, and cost. As demonstrated by [9], using an AI chatbot positively impacts learner retention. Specifically, they compared learning using AI chatbots and the Google search engine. Outcomes show that learning through the proposed AI chatbot has a positive impact on memory retention and learning outcomes compared to the

learning through Google search engine. Hence, a chatbot is considered an effective tool [10] to support learners and encourage them to freely ask their questions without being evaluated or misjudged.

Several works have been carried out to automatically handle learners' questions. Many researchers propose AI chatbots to automatically answer learners' questions and satisfy their needs by saving time, energy, and cost. However, results are still insufficient and additional efforts are required to enhance AI chatbots in the e-Learning domain [11]. As shown by [11], [12], educational chatbots in the instant messaging application are still limited and need additional AI features. Especially, chatbots in the E-learning domain suffer from manually creating the chatbot's KB. Many researchers construct the KB by manually collecting pairs of Q&As. Thus, consuming time and energy. For that reason, additional efforts are needed to automate the creation process of the chatbot's KB. In addition to that, researchers prefer using platforms such as Dialog flow, IBM Watson, Wit.ai, etc. They facilitate the creation of chatbots through trained AI models. However, they are expensive and lead to high costs.

In this paper, we will address these issues by proposing a smart architecture based on AI technologies. Especially, we will automatically construct the chatbot's KB by scraping reliable and relevant knowledge. Then, automatically classifying intents by using a neural network model rather than wasting time manually creating training phrases. Specifically, the proposed chatbot can automatically understand learners' needs and satisfy them. Thus, saving time, and energy, and reducing costs. To demonstrate the feasibility of the proposed architecture, we will test the chatbot in the Machine learning (ML) domain. Thus, the designed chatbot will answer questions related to the ML domain.

III. RELATED WORKS

Several works have been carried out to develop e-learning chatbots in different learning contexts to satisfy various needs. They support learners by giving them the information needed rapidly and efficiently. They understand learners' needs and respond correctly based on the local KB. In this section, we will present and discuss recent works focused on automatically constructing AI chatbots to assist learners.

Based on our review [11], most studies propose creating chatbots by manually feeding the KB. They propose constructing the chatbot's KB by manually creating a set of Q&As which is time- and energy-consuming [13]–[21]. On the other hand, some papers automate the process of creating e-learning chatbots by using recent technologies such as web scraping, Optical Character Recognition (OCR), and spider robots. The authors in [22] proposed an educational chatbot to answer questions related to the Data Science domain. They automatically extracted the chatbot KB by using the web scraping technique. Study [23] proposed a chatbot to deliver learning materials. They automatically collected relevant documents, indexed them by Elasticsearch, and stored them in Postgre Database. Researchers in [24] proposed an educational chatbot able to assess and evaluate students' knowledge. They used Apache PDFBox and an overgenerating system to automatically construct the local KB. Study [25] proposed a

generative chatbot able to predict answers based on deep learning models. They applied these models to learn from an existing dataset and train the chatbot.

After analyzing previous works, we conclude that few papers proposed automating the creation of the chatbot's KB. They propose the use of web scraping techniques, OCR, or spider robots to automatically collect pairs of Q&As. However, the proposed approaches are still insufficient, and more efforts are needed to automatically understand users' intents without manually creating them. Specifically, they propose using some online platforms such as DialogFlow, IBM Watson, Wit.ai, and Rasa. etc. to facilitate the chatbot's training process without the need for technical knowledge in advanced NLP techniques [26]–[33]. These platforms already integrate NLU and NLG techniques, they reduce the energy needed to understand users' requests and answer them. However, there are some limitations:

1) In these platforms, the integration of Q&As is done manually by adding intent for each question with training phrases (Q&As) to help the chatbot learn from them. The manual integration of intents is time and energy-consuming because AI chatbots require a lot of Q&As to function properly. Otherwise, the chatbot will be restricted to the few Q&As included in training phrases because it is challenging to manually gather a huge number of Q&As.

2) These platforms are expensive, and the number of queries available in their free editions is constrained.

3) These platforms limit the channels to incorporate the chatbot.

The research [34] proposed an approach based on deep learning algorithms, they address the problem of manually creating intents by proposing a generative chatbot. It answers automatically to a user's request by predicting the response via a deep learning model without the need of referring to the KB or classifying the user's intent. Thus, they reduce the time needed to classify Q&As. However, a large amount of data is needed to train generative chatbots. Otherwise, they can result in illogical responses or incorrect answers if the chatbot is trained using little or poor-quality datasets.

In this paper, we aim to automatically handle users' questions through AskBot's architecture. Specifically, we propose a smart architecture to automate the process of detecting intents and understanding the real needs of learners, then, answering correctly without wasting time in classifying intents. Hence, saving time, energy, and cost.

IV. PROPOSED ARCHITECTURE

A. Chatbot's Architecture

In this section, we will present AskBot's architecture, its implementation process, and the role of its main components. As demonstrated in Fig. 2 there are two main layers in AskBot's architecture: (1) the Back-End layer containing the core components of the architecture, namely: (1) Spell Correction, (2) Data Preprocessing, (3) Vectorization, (4) Similarity Measure, (5) Speech To Text, (6) Text To Speech, (7) Small Talk Verification (8) DialoGPT and (9) The knowledge base. They work together to produce the

appropriate answer for a given question. (2) the Front-End layer representing the graphical user interface (G.U.I). It facilitates the interaction between learners and AskBot. Thus, learners can directly ask their questions using its graphical interface.

AskBot's architecture addresses the problem of manually creating chatbots in the e-learning context either by manually constructing the local KB or by manually creating intents for training phrases in online platforms. Specifically, the present work proposes using the web scraping technique to automatically construct AskBot's KB. Hence, saving time and energy. Furthermore, based on our proposed python script, AskBot can detect users' needs without using prebuilt NLP models in online platforms, thus saving time, and energy, and reducing cost.

Fig. 2. Askbot's Architecture.

B. Implementation Process
