Editorial Preface

From the Desk of Managing Editor…

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

Thank you for Sharing Wisdom!

***Abstract*—Electronic Data Interchange is a popular platform for sensitive business transactional data transmission over the local to public network. It requires Value Added Network to communicate local data from one endpoint to another. In this paper, we proposed a value-added network design and deployment using the Virtual Local Area Network. The Value Added Network over a virtual Local Area Network eases the burden of managing the network and its functional devices. This proposed network provides the solution of data traffic as per demand required network path for the Electronic Data Interchange applications. This advanced deployment model of Value Added Network over a virtual Local Area Network also offers more robust security to the network entities and traffic. This proposed Virtual Local area network has been deployed with the Cisco environment, and all the specifications have been successfully implemented and tested for optimal security for Electronic Data Interchange. Virtual Local Area Network deployed with four different methods such as transferring packets with backbone, virtual Local Area Network using the tagging method, implementing virtual Local Area Network using Time Division Multiplexing, and by user-defined frame field. All these deployments are successfully done, and the secure platform for Electronic Data Interchange data exchange from one end local network to the other local network has been optimized.**

Keywords*—*Electronic data interchange; value added network; virtual local area network; data link layer; time division multiplexing

I. Introduction

Electronic Data Interchange is the common medium of business-sensitive data transmission from one entity to another over a public network such as the Internet. Third-party Value-Added Network (VAN) provides the solution to the local network for EDI application to transmit the sensitive EDI application data from a local network of a business firm to another end of other industries. The virtual LAN is considered the more secure and automated network for EDI applications and data communication between the local network of one business entity to another.

The virtual LAN requires switches to constantly contact the VMPS server, requesting configuration information when an EDI host or EDI network client connects to a switch participating in the virtual LAN network [1][2]. A VMPS database can also be configured with more information to handle more hosts' requests for participation under the virtual LAN. Virtual LAN flexibility can be achieved by connecting more than one EDI host on one dynamically configured port as long as all EDI hosts are part of the same virtual LAN. The defined virtual LAN includes several physical segments per logical subnet. Hence this reduces the burden of management of physical segments and maintenance of network tables.

Virtual LANs are defined with two layers for EDI applications. The layers are virtual LAN Layer 2 and Layer 3 as per the basic working at the respective Open System Interconnection (OSI) layers [3]. Layer 2 virtual LAN is defined based on information at the Data Link Layer (DLL). Each port of the switch constitutes a switch port to form a single virtual LAN segment.

Virtual Local Area Network (Virtual LAN) is a mechanism that allows the same physical network topology to use more than one virtual network simultaneously. The networks of each category are separated for the security enhancement of EDI applications [4]. A special kind of routing is required when one device or workstation wants to reach another device or workstation from one virtual LAN segment to another virtual LAN segment for EDI. The switch determines that the client machine belongs to a virtual LAN. Suppose an EDI client requests a connection from port one on a switch assigned VAN 2; the EDI client cannot change anything behind this as the requested EDI client is indifferent or the same virtual LAN. The assignment of the switch port to virtual LANs is performed in two different ways. One mode of assignment of ports to virtual LAN is followed statistically, which means that the administrator must manually configure each port of the switch to assign the virtual LANs [5].

Some switch ports connect multiple end stations, while others have only one. All the workstations connected to ports associated with virtual LAN share a common broadcast domain, and all workstations of another virtual LAN segment are part of a different broadcast domain. The traffic between the segments of virtual LANs must have to pass through the router.

When multiple EDI end workstations are, by default, part of the same virtual LAN, moving a user to a different switch is considered a problem, with the administrator assigning the end user workstation to a different switch port. This problem is being avoided through the administrator end by establishing a one-station-to-one switch port architecture. This elaborates a good idea behind the usability of virtual LAN technology as per the requirements under the networking and infrastructure optimization of any type of network system for users. This also needs to replace all the hubs currently used under the network by switches, but this poses a problem of cost and expense. However, fewer end stations can be taken to connect directly to each switch port to provide greater flexibility in virtual LAN [6].

Layer 3 virtual LAN uses the network layer addresses to implement virtual LANs. Each end workstation within a given virtual LAN is assigned the same subnet address. The witches read the address and use it to forward packets to destinations under the networks inside and outside to the external world. In this layer, three virtual LAN, a particular subnet is treated as a bridge group which is traffic bridged at layer two within the virtual subnet virtual LAN and routed at layer three virtual LAN [7].

This virtual LAN method segments an extensive network into virtual LANs based on the network layer information contained in each packet coming from the workstations or servers of the network [8]. A switched network acts as a router-segmented network. However, one big difference is that multiple end workstations are attached at the same switch port and still work as members of separate virtual LANs that can be defined for different protocol groups, such as the Internet Protocol (IP).

The main important point for this layer 3 Value Added network is that it is protocol dependent and sensitive to the protocol used with this network. It is also mandatory for the layer three virtual LAN switch to read the different protocol formats that will be used over the virtual LANs. The universal use of the IP makes IP-based virtual subnets the most helpful implementation model of layer three virtual LANs. The switches of layer three virtual LANs use only the subnet portion of the network address to switch the packets at the destination address and do not require much processing at the router level [9].

II. Related Work

EDI needs the secured and advanced virtual LAN to form the VAN for reliable data communication. The data exchange should automate to communicate the data between two or more entities effectively [10]. The entities can use an application based on EDI to communicate the data among them securely and timely, as the proposed work provides the automated communication management of the interchange of data. The VAN based on the virtual LAN provides the secured interchange and adds value, such as prioritizing the particular entity to perform ordered communication.

An inter-organizational system enhances the relationship between the business partners and reduces product development life cycle challenges. This also increases the quality of products. The EDI application creates the VAN over the virtual LAN in each organization to effectively communicate inter-business data [11]. The authors mentioned the implementation strategies for EDI and also classified it. The adoption of EDI, Integration of EDI, and the EDI suitability for small-scale industries over the virtual LAN. The network performance requirements and others are the key aspects for implementing EDI successfully.

EDI and its requirements are constantly increasing in the field of business. Almost all business organizations and government entities prefer EDI as a secured and automated information technology platform to process and communicate vital data among business partners and others. The authors performed a meta-analysis of various research in EDI and VAN and developed a theoretical framework for contextual outcomes associated with adoption to usability [12]. Per management perspectives and standpoints, VAN should have defined guidelines to automate data exchange without considering any network processes.

A real-time and decentralized communication network has interconnecting data nodes that can host the artifacts and services. This type of real-time decentralized network adds value to the artifacts and creates the VAN. The event notification-based VAN with the linked data specification provides advanced services, such as automated communication between the given nodes, which is best suitable for the EDI [13]. The experiments performed by the authors provide an advanced framework that can create a network with nodes that interact with each other. Based on the application scenarios, node registration, re-registration, collaborative certification, and awareness are achieved for value-added services such as EDI and other services.

III. Advanced Design Scheme of Virtual LAN

The advanced design scheme of virtual LAN includes all the aspects of the network, messages, algorithms, and protocols.

A. *Proposed Model of Message Format and Encapsulation*

Fig. 1 shows the virtual LAN message and protocol layering. Conceptually program used IP to transmit and receive. Virtual LAN message, the header, and data are encapsulated in a frame [14]. Finally, the network interface layer embeds the datagram into a frame sending it from one machine to another. The format of the frame depends on the underlying network topology.

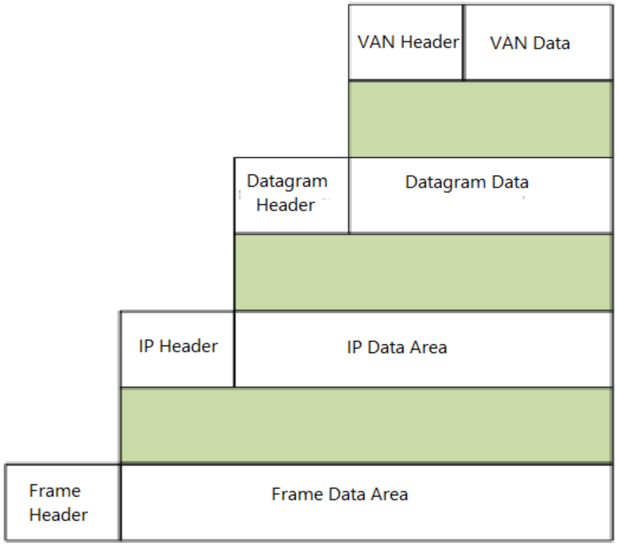

Fig. 1. Virtual LAN message format.

On input, when a packet arrives at the lowest layer of network software and is processed from lower to higher layers. Each layer removes one header before the massage so that all headers are removed by the time the highest layer passes data to the receiving process.

When the net server receives a request for an IP address, it checks for the IP address and sends it to the virtual LAN agent for virtual LAN idea mapping; the virtual LAN agent then checks its node table; if the IP and virtual LAN ID mapping is not available, it sets validity-bit equal to pending and sends back a wait message to the server, the server sends wait message to the node which will be displayed on screen [15].

The virtual LAN manager then replies to the virtual LAN agent with a virtual LAN ID. The virtual LAN agent updates and replies to the server and a node. After random time virtual LAN agent checks its table and sends an updated table to the virtual LAN manager [16]. So that the virtual LAN manager also remains up to date. This is required because after some time, a node that is not in, for some time, its entry from the Ethernet switch is automatically deleted. The second case is when updating is required when a node is in powered condition but whose entry from the cache is removed. It starts reassessing the virtual LAN. Its entry from the node table is updated.

B. Proposed Model of Broadcast by Virtual LAN Manager

The virtual LAN manager repeatedly broadcasts the table, generally after a period of time, which is longer than the previous interval. All virtual LAN agents update their tables after listening to the broadcast [17].

- Virtual LAN Protocol Message Format-1

It is needed to design this format to maintain the node table, as shown in Fig. 2, and details of fields are given Just after Fig. 2.

<table>
<tr><td>Preamble</td><td>Msg Type</td><td>Sec. Bit</td><td>HType</td><td>HLen</td><td>HCPS</td></tr>
<tr><td></td><td></td><td>1 VM
0 VA</td><td colspan="2">1 Intra VLAN 1 = 100 Mb Ethernet
2 = 100 Mb Ethernet</td><td>6 Ethernet</td></tr>
<tr><td colspan="6">VAGENT IP Address VA IDDR</td></tr>
<tr><td colspan="6">VAGENT HA Address VA Haddr</td></tr>
<tr><td colspan="3">VAH addr 32 - 47</td><td colspan="3">VAGENT IP Address VA IDDR</td></tr>
<tr><td colspan="6">VMANAGER IP Address – VM iaddr</td></tr>
<tr><td colspan="6">VMANAGER HA Address – VMH addr</td></tr>
<tr><td colspan="3">VM Address 32- 47</td><td colspan="3"></td></tr>
<tr><td colspan="6">Table</td></tr>
<tr><td colspan="6"></td></tr>
<tr><td colspan="6"></td></tr>
<tr><td colspan="6"></td></tr>
<tr><td colspan="6">END Flag</td></tr>
</table>

Fig. 2. Virtual LAN message format.

Preamble: 1 Octet having left most bit is 1; it indicates b/c.

Msg Type: 0 Indicates this message is from a virtual LAN agent.

Sec bit: 1 Indicates intra-virtual LAN traffic.

Htype: is one octet in length of Hardware address type.

Hlen: 1 octet for hardware address length.

Hops: 1 octet optionally used by relay agents when booting via relay agents.

Vaiddr: Virtual LAN agents IP address filled in by VLAN agent in the request message to virtual LAN manager or server.

Vahaddr: virtual LAN agents hardware address six octets long for Ethernet.

Vmiaddr: Virtual LAN manager's hardware address.

Table: node entries in the table with virtual LAN ID address mapping.

End Flag: indicates the end of the virtual LAN message, a fixed number.

The scheme of the virtual LAN Management is depicted in Fig. 3, assuming that the EDI workstation node in the network is already booted.

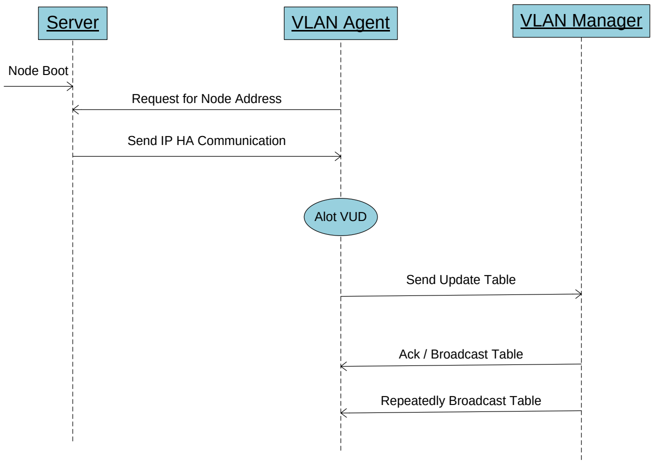

Fig. 3. Scheme of the virtual LAN to manage the EDI workstation.

- Virtual LAN Protocol Message Format-2

Virtual LAN agents request the server for node address; then, the node sends the IP and hardware address combination to virtual LAN agents. Suppose a virtual LAN ID is not allowed on that node. In that case, the agent sets the validity bit equal to pending and sends a wait message to the server. The virtual LAN agent requests the virtual LAN manager for virtual LAN ID allocation. After the virtual LAN ID request from the virtual LAN agent virtual LAN manager checks the table for the virtual LAN ID entry, then allocate the virtual LAN ID and adds it to the table and sets the validity bit equal to clear, and sends the virtual LAN agent [18]. Also, virtual LAN managers repeatedly broadcast the table to all VAN agents with time intervals which is more than the aging time.

The specified design of the virtual LAN message protocol with different fields is shown in Fig. 4 just after it.

Preamble	Msg Type	Sec. Bit	HType	HLen	HCPS
		1 VM 0 VA	1 Intra VLAN 1 = 100 Mb Ethernet 2 = 100 Mb Ethernet		6 Ethernet
VAGENT IP Address VA IDDR					
VMANAGER Address VM iaddr					
Table					
END Flag					

Fig. 4. Virtual LAN message protocol with different fields for VAN.

Preamble: 1 octet. In which if left most bit is 1, it indicates b/c.
Msgtype : 0 Indicates this message is from the Virtual LAN manager is from VLAN manager.
Msgtype: 1. Indicates this message is from a Virtual LAN agent.
Sec bit: -1, Indicates intra Virtual LAN traffic.
Htype: is one octet in length. Hardware address type. For example, 1 for 10 Md Ethernet.
Hlen :1 octet. Optionally used by relay agents when booting via relay agents.
Vaiaddr: Virtual LAN agent's IP address, filled in by the Virtual LAN agent in the request message to the Virtual LAN manager or server.
Table: node entries in tables with address mapping, Virtual LAN ID.
End Flag: Indicates the end of the Virtual LAN message, which is a fixed number.

The scheme of the virtual LAN Management with the dynamic allotment of valid at the time of booting scheme is shown in Fig. 5.

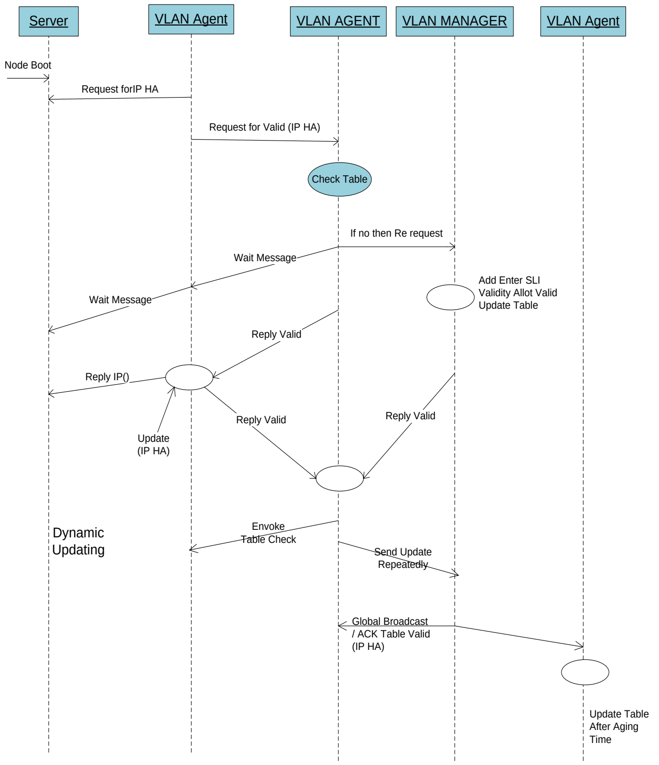

Fig. 5. Scheme of virtual LAN Management with dynamic allotment.

- Proposed Algorithms for Virtual LAN for EDI Services

The message flows between the EDI Node, virtual LAN Agent, and virtual LAN Manager are broadcasted through an algorithm [19] [20]. The design and specification of algorithms are given in Sections III and IV.

IV. Virtual LAN Agent Functional Algorithm

The message between the virtual LAN Agent and Node is defined concerning the algorithmic steps.

```
1.  Check for requests from the node for virtual.
    LAN ID for the node which just came up.
2.
    a. read MAC, the IP address of nodes from the request message.

    b. Send a wait message to nodes.
3. Check the nodes table for
    a. Check mapping of IP, MAC, and virtual LAN ID for node.
4. if (virtual LAN ID for a node is found in the table)
    a. sends it to requesting node.
    b. Accept ACK from the node.
    c. Inform the virtual LAN ID mapping to the virtual LAN manager.
else
    (Evoke virtual LAN manager)
    a. Set validity bit as pending.
    b. Send a request to the virtual LAN manager for virtual LAN ID allotment.
5. Wait for a reply/ack from the virtual LAN manager.
6. Accept virtual LAN ID allotment message from virtual LAN manager.
7. Read the virtual LAN ID from the message
8. Update the virtual LAN agent's node table.
9. send virtual LAN ID to be requesting node.
```

V. Virtual LAN Manager Functional Algorithm

The algorithm for message flow or broadcast has been the dynamic virtual LAN Agent and Manager.

```
1.  Accept request message from virtual LAN agent for
    virtual LAN ID allocation. Set the message type equal to
    zero.
2.  Check the entry for the given IP address in the table.
3.  If (entry of node's IP address is not present)
        a. allocation virtual LAN ID for that node.
        b. Update the virtual LAN manager table with the
           allotted virtual LAN ID.
        c. Set virtual LAN ID bit equal to clear.
4. Send virtual LAN ID to virtual LAN agent by setting
    message type equal to 1.
5. Send a global broadcast on the virtual LAN network to
    inform all of the updated statuses of the virtual LAN ID
    table for synchronization.
```

VI. Proposed Deployment and Implementation Methodology

Meta studies and dynamic virtual LAN design applications are used to collect data. The real-time simulations of dynamic virtual LANs are more helpful in collecting and analyzing the data with the available tool. High-quality lenses tried and tested in industries, are used for the analysis. The Virtual LAN design structure in Cisco Simulator is presented in Fig. 6.

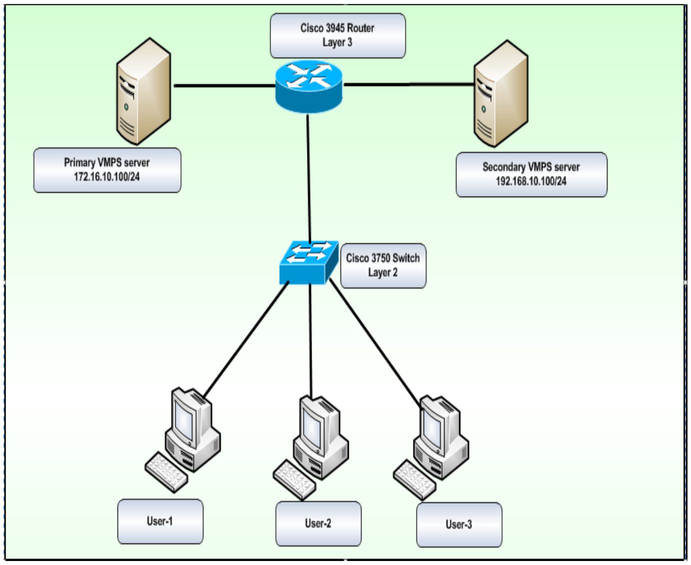

Fig. 6. Virtual LAN design structure in Cisco.

VII. Virtual LAN Implementation & Results

The Ethernet virtual LAN, which functions on layer two, is manually defined by software using which network administrator groups the switch ports into a high bandwidth, low latency switched group [21]. Each virtual LAN with a unique identification number identifies the virtual LAN for network management purposes.

Layer 2 virtual LANs are based strictly on a bridging technique that transmits data using media access control (MAC) and destination addresses. Traffic within virtual LANs is switched using these addresses [22] [23]. Traffic between virtual LANs is carried out by a router that imposes the filtering of packets to provide security and traffic management. The router is either a standalone box-based system or a card integrated into the switch or a node. Routing is handled by a switch that is from the virtual LAN switching logic. The implementation model is given in Fig. 7 with all details of the three virtual LANs, with Cisco Catalyst switch modules with enterprise router interface and external switch interface.

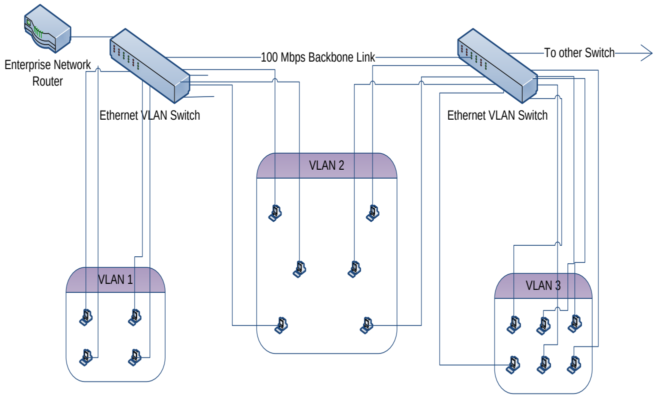

Fig. 7. Virtual LAN implementation using Cisco catalyst switch.

After defining the layer two virtual LANs, each switch reads incoming frames and learns the MAC address associated with each virtual LAN. If the end station or node sends broadcast or multicast frames, it is forwarded to all ports in that end station or node of virtual LAN [24][25][26]. The ports are spread across any number of switches connected to the backbone. All segments in LAN in a port group are bridged, whether they are on the same switch or separated by backbones.

- Transferring Packets over Backbones

Supporting Layer 2 virtual LAN port groups on a switch is transparent. Pure Ethernet switches store MAC addresses and information about which port each address is to. With a virtual LAN switch, a virtual LAN no. and MAC address and port information are stored in the switch's forwarding table. I observed that these tables grow up to 1,000 bytes or sometimes more than this. On layer 2 VLANS, the virtual LAN messages are sent across shared media backbones using frame tagging and time division multiplexing [27].

- Virtual LAN Using Tagging Method

This method places a unique identifier in each frame's header as that frame enters the switch fabric. With the frame tagging process, a short tag is appended at the beginning of every frame that crosses the backbone; the tag tells which virtual LAN the frame belongs to. The switch permanently stores the port group and is valid [28]. Since a virtual LAN number is carried in each frame, each switch examines the identifier before transmitting it to other switches, routers, or end stations [29].

Fig. 8 elaborates on implementing dynamic virtual LAN using the tagging method. Switch such as Cisco Catalyst and tag filed options with switch interface is mentioned under the figure to detail the tagging method for implementing dynamic virtual LAN.

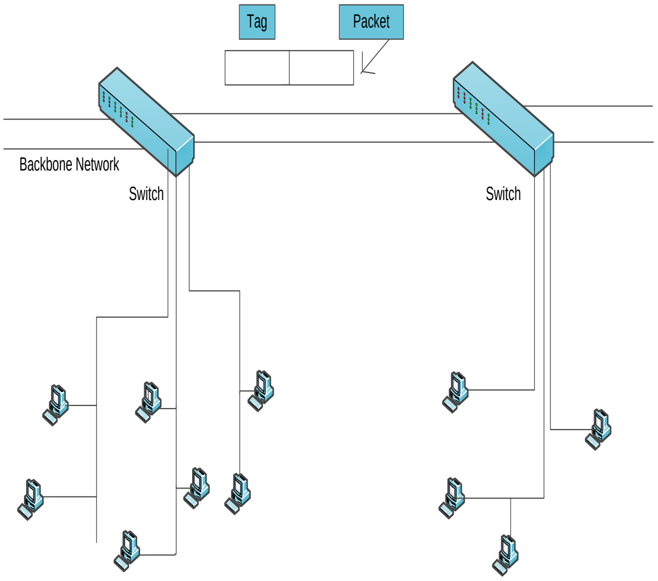

Fig. 8. Virtual LAN implementation using the tagging method.

We received that packet tagging provides a meager latency for assigning and processing frames throughout an enterprise switching fabric, including routers and fast Ethernet backbones [29]. Also, we found one drawback to frame tagging overhead. The frame carries a few bytes of extra baggage.

- Implementation of Virtual LAN using TDM

The implementation and issues related to dynamic virtual LAN using the time division multiplexing mechanisms are considered in this section. Virtual LAN information crosses the campus bus using this technique in layer two virtual LAN. The backbone is divided into 100 Mbps slots, and every virtual LAN is assigned one or more of these time slots, which are used only by virtual LANs. Switches are configured with the information needed to port groups to TDM channels [28][29]. Lan traffic is divided into a separate time slot and reduces the need to use frame tags using which packets are checked. Due to this, network stability increases, and the network load is reduced. As broadcast, one virtual Lan does not affect other virtual LANs. However, I found in this case disadvantage is that other virtual LANs cannot use the bandwidth unused by any Lan. Using this type of virtual LAN requires constant traffic monitoring, ensuring time slots are allocated efficiently. Table I illustrates the implementation data with dynamic virtual LAN using the time division multiplexing mechanism.

TABLE I. VIRTUAL LAN IMPLEMENTATION USING TDM

LAN	Channel Allotted
Virtual LAN 2	Slot 1
Virtual LAN 1	Slot 4
Virtual LAN 3	Slot 2

- Implementation of Virtual LAN User-Defined Frame Field

We studied one different method which uses a layer user-defined frame field in layer 2 Dynamic virtual LAN. Virtual LANs defined by common subnet address, protocol type, and other parameters are defined by the value in the user definition frame field [28]. This creates many possibilities, as virtual can be created based on frame values. As port grouping is eliminated, users can move around; there is no network concern for the port it is connected to.

The problem with the frame field method is that it requires storing information on protocols such as Bit mask offset and another routing (switch) software detail [14]. This method allows different stations on a single switch port to be part of different virtual LANs. Also, the Virtual Lan-based group shares a common server or applications [18]. This aspect of port grouping would require switches that are capable of reading and decoding server names, numbers, and other application-specific fields.

- Using MAC address List

A different dynamic virtual LAN model is designed on the MAC address list, and the list is defined manually. This address list sets up protocol and port-independent switched dynamic virtual LANs. For example, node terminals use non-routable protocols to separate Virtual LANs where each dynamic virtual LAN corresponds to a MAC address list. We found that the MAC address lists technique is more sophisticated than the layer two-port group, as a user can shift to any port in the network and add in proper virtual Lan without reconfiguring the port. The user-defined field under the MAC structure for dynamic virtual LAN MAC is represented in Fig. 5. We observed that this method gives a concrete tool for traffic management. But for extensive networks list becomes lengthy, and if the list is lengthy, it requires more effort.

VIII. Conclusion and Future Work

Virtual LAN is the complex local network structure and more secure local network. The deployment of dynamic virtual LAN needs the design and structuring of the network equipment, such as layer three switches, network routers, and many more. In this paper, we have proposed a deployment and implementation model of virtual LAN for VAN of EDI by considering the different factors. The design is so robust that the network function is optimum per the given details. Also, we tested the network functions concerning functional optimization and found that the designed and deployed network is working per the given specifications.

The proposed research work includes the EDI and VAN over the virtual LAN. The applications and other facts related to the research are very clearly specified and deployed over the Cisco simulation. The functional aspects of the given algorithm for VAN and EDI functionalities are very straightforward. They can be taken as an opportunity to advance the current given processes and get the dynamic protocols with existing automated service-based VAN for EDI. This advancement will bring the opportunity to EDI organizations by reducing the network management overhead. So the organization's cost for information technology support will be drastically reduced.

***Abstract*—The current intelligent evaluation methods for English teaching quality are inefficient and have poor evaluation accuracy for effective assessment. The paper suggests an evaluation model based on an upgraded Back Propagation Neural Network to overcome the aforementioned issues. First, the principal component analysis is utilized to lessen the dimensionality of the index system as we build an English teaching quality evaluation index system with reference to the results of the existing study. Then, we adopt a multi-strategy improved dragonfly optimization algorithm to evaluate Back Propagation Neural Network for its defects; an algorithm to improve it. Finally, to increase the efficacy and objectivity of English teaching quality evaluation, an intelligent evaluation model based on IDA-BPNN is developed. The experimental results demonstrate that the IDA-BPNN model has an evaluation accuracy of 98.96%, an F1 value of 0.950 on the training set and 0.968 on the test set, a Recall value of 0.948 on the training set and 0.966 on the test set. The aforementioned indicators are all superior to the most recent state-of-the-art approaches for evaluating teaching quality. The aforementioned findings thus demonstrate that the model suggested in the study has high performance and can successfully improve the accuracy and efficiency of English teaching quality evaluation, which has a positive impact on the development of English teaching careers.**

Keywords—Teaching quality evaluation; English; BPNN; intelligent evaluation; dragonfly optimization algorithm

I. Introduction

The importance of English education is increasing as globalisation picks up speed. English teaching(ET) nowadays is a course that is offered in most majors in most universities, aiming to cultivate more and better educated English professionals for the society and market [1,2]. As a result, numerous parties have paid attention to the standard of ET at universities, including school leaders, students' parents, students themselves, and major enterprises. An essential component of ET is quality evaluation (QE), which can assist teachers in identifying areas of weakness in their instruction and working to raise standards to increase effectiveness [3]. Because of its straightforward structure, broad applicability, and superior learning capacity, BP Neural Network (BPNN) is currently a popular tool in the machine learning industry [4]. Some researchers have successfully used BP neural networks for ET QE studies, with promising results. However, the commonly used Analytic Hierarchy Process (AHP) and Fuzzy Comprehensive Evaluation methods in teaching quality evaluation are inefficient and highly subjective, which can affect the results. The performance of traditional BPNN has shortcomings, which have a negative impact on the reform of ET, resulting in poor QE of ET based on BPNN [5]. In order to improve the objectivity and scientificity of English education quality evaluation, provide data support and improvement guidance for English education reform and innovation, this study proposes an improved dragonfly algorithm as the basic basis, and combines BPNN to establish an intelligent evaluation model for English education quality. Principal component analysis is used to reduce the dimensions of the indicator system. The research is innovative in two ways. The first is to implement an intelligent evaluation of ET quality using the enhanced BPNN, which increases the objectivity, accuracy, and effectiveness of ET QE. The second objective is to provide appropriate methods for addressing the DA's flaws and to optimise the BPNN using the enhanced DA, which enhances the functionality of the BPNN model. The research content mainly includes five parts. The first part is a review of the current research status of English education and BPNN. The second part, divided into three sections, constructs an English education quality evaluation model based on the IDA-BPNN model. The first section constructs an English education quality evaluation index system, the second section extracts common factors, and the third section discusses the BPNN optimization of the improved Dragonfly algorithm. The third part analyzes and evaluates the performance of the quality evaluation model. The fourth part discusses the results obtained in the study and fifth part draws the conclusion of constructing an English education quality evaluation model based on the IDA-BPNN model.

II. Related Works

English is the most commonly spoken language in the age of globalisation, and demand for English majors has skyrocketed internationally. Education in English (ET) is a crucial position for developing students' English skills at universities. In this context, ET in universities has received attention from various researchers, and many scholars have put forward their own insights and strategies for ET. Turan et al. comprehensively compiled and analyzed the recent related literature, so as to explore the application path, application effect and development prospect of flipped classroom in ET, which has positive significance for the advancement of ET quality [6]. To increase the quality of ET and provide new ideas to the training of English teachers, Ng investigated the role of synchronous online teaching for pre-service English instructors [7]. By using the Arab League nations as an example, Hazaea et al. examined the drawbacks of the remote ET model based on computer technology as well as the potential solutions [8]. Goodman et al. examined the shift from code-switching to cross-linguistic perspectives in English teacher education, providing empirical and theoretical guidance [9]. The necessity and course of the shift to flexible learning, which has implications for English language teaching during the epidemic, was examined by Tarrayo et al. [10] using a state university in the Philippines as an example. They also looked at the development of ET models during the New Coronation epidemic. Based on a thorough analysis of the most recent research literature on English language teaching, Rose et al. studied the state of English and language teaching globally. They then discussed the difficulties that English language teaching is currently facing, provided solutions for those problems, and then talked about the direction and future of English language teaching [11]. Using videos based on multimedia technology in the teaching process and looking into the effects of video teaching, Waluyo et al. researched the effects of multimedia technology in ET and the requirement of its implementation [12]. An extensive analysis of ET in higher education was presented by Block et al., which prompted an examination of STEM lecturers as non-English teachers' self-positioning was investigated and analysed [13]. This analysis has theoretical ramifications for the advancement of English language instruction in higher education.

The use of machine learning techniques has impacted all facets of daily life and employment, and they are crucial in numerous professions. Numerous researchers have focused on BPNN because of its straightforward structure, superior classification performance, and broad variety of applications. In order to optimise research performance management, Chen et al. first analysed the BPNN's structural makeup. Based on this analysis, they applied BPNN to the problem, effectively raising the bar for research and advancing modern science and technology [14]. The necessity and significance of enterprise financial management risk prediction in the context of the digital economy were examined by Li et al., who realises the intelligent prediction of enterprise financial management risks [15]. The traditional BPNN structure was modified by Li et al., who then used the enhanced BPNN model to create a smart city building information model [16]. In order to improve the performance of BPNNs, Wu Y et al. created a model based on genetic algorithms (GA) improved Simulated Annealing (SA) algorithm and used GA-SA. In order to increase forecast accuracy and ensure production safety, a coal and gas protrusion prediction model was built using the enhanced BPNN [17]. Tang et al. proposed corresponding strategies to improve the BPNN for its defects and implemented medical image segmentation using the improved BPNN, thus assisting clinical diagnosis and treatment. Finally, the effectiveness of the model was verified by using color fundus image retinal vascular image as an example [18]. To improve the performance of BPNN and create GA-BPNN, Wang et al. applied the GA algorithm [19]. The improved adaptive GA algorithm proposed by Yan et al. was used to find the best BPNN parameters and boost model performance. Finally, a vehicle insurance fraud identification model based on the improved BPNN was built, offering fresh perspectives on how to safeguard consumers' rights [20]. In order to provide data assistance for investors' decision-making, Zhang et al. examined the application path and impact of BPNN in stock price pattern classification and prediction [21].

Nowadays, academics from many nations are paying close attention to ET, and BPNN application and study are very in-depth. ET QE is a crucial basis for assisting teachers in identifying areas of weakness and raising teaching standards. Despite the fact that there have been several studies on the subject, the majority of these findings are primarily theoretical and based on human judgment. This results in the teaching of QE being ineffective and lacking objectivity, which has an impact on the correctness of the teaching of QE. To address the aforementioned issues, the study develops an IEM of ET quality based on the development of BPNN in order to achieve an objective, scientific, and effective evaluation of ET quality. This will provide data support for reform and innovation of ET as well as for quality improvement, and will also show the direction of improvement, which is important for the advancement of English education in China.

III. English Education Quality Evaluation Model Construction using the IDA-BPNN Model

A. Construction of English Education Quality Evaluation Index System

Teaching QE is a vital responsibility with the goal to improve the calibre and effectiveness of ET education. And in order to carry out ET QE, a sensible, reliable, and efficient ET QE index system must be created. To ensure that the ET QE index system is functional and that the ensuing ET QE is accurate, it is essential to undertake ET QE index selection in accordance with scientific, developmental, and process-oriented principles. In light of the foregoing, the study chose language teaching QE indices on the basis of the five dimensions of teaching [22]. Following completion, 19 secondary indicators were attained, and Table I's ET QE index system was created.

In Table I, the ET QE index system constructed in the study contains five dimensions and 19 indicators, which is relatively complex. However, there are some variances in how certain factors affect the quality of ET in the actual ET. Therefore, studying some indicators that have a minor impact on the quality of ET requires more effort, but does little to increase the accuracy of that assessment. Additionally, if there are a lot of indicators, building more input nodes for the BPNN model will be necessary, which will make the model more complex. This is because adding the corresponding indicator data to the BPNN model for learning will result in a lot of dimensions of the input vector features. The length of the model's training process and accuracy both suffer as a result of the model's increasing complexity. The ET QE index mechanism needs to be simplified in light of the aforementioned. In order to score the ET QE index system, the study recruited 25 specialists, including 5 students, 15 English teachers, and 5 ET researchers. After that, values based on

AHP were assigned to each of the 19 indicators in Table I. The top 10 weight values for the indicators were chosen in order to reconstruct the ET QE index system, and Table II displays the simplified ET QE index system.

TABLE I. EVALUATION INDEX SYSTEM FOR ET QUALITY

Dimension		Indicators	
Code	**Name**	**Code**	**Content**
X1	Teaching ability	U1	Clear and fluent language with Standard Mandarin
		U2	Thoroughly analyze the problem
		U3	Clear organization of courseware
		U4	Correctly Understanding the Teaching Village
X2	Teaching attitude	U5	Adequate lesson preparation
		U6	Strict teaching mode
		U7	Carefully listen to students' opinions
		U8	Patient in answering questions
X3	Teaching contents	U9	Focusing on Theory and Practice
		U10	Having scientific and ideological qualities
		U11	Correct teaching content
X4	Teaching method	U12	Emphasize induction and summary
		U13	Reasonable course arrangement
		U14	Multimedia teaching
		U15	Proficient in various teaching modes
X5	Teaching effectiveness	U16	Achieve teaching objectives and complete teaching tasks
		U17	Active classroom atmosphere
		U18	Students can apply what they have learned
		U19	Improving academic performance

TABLE II. SIMPLIFIED EVALUATION INDEX SYSTEM FOR ET QUALITY

Dimension		Indicators	
Code	**Name**	**Code**	**Content**
X1	Teaching ability	U1	Thoroughly analyze the problem
		U2	Correctly Understanding the Teaching Village
X2	Teaching attitude	U3	Strict teaching mode
		U4	Carefully listen to students' opinions
X3	Teaching contents	U5	Focusing on Theory and Practice
		U6	Having scientific and ideological qualities
		U7	Correct teaching content
X4	Teaching method	U8	Reasonable course arrangement
		U9	Proficient in various teaching modes
X5	Teaching effectiveness	U10	Improving academic performance

To assess the validity and dependability of the ET QE index system created by the study, Table II underwent reliability and validity testing. Table III displays the test results.

TABLE III. RELIABILITY AND VALIDITY TESTING

Project		Value
KMO inspection		0.864
Bartlett sphericity test	Approximate chi-square	7714.853
	DF	0.772
	Significance	0.000

The validity and feasibility of the study to create an ET QE index system are confirmed in Table III and suggest that the next stage can be carried out in accordance with Table II. Table III shows that the reliability and validity tests of the ET QE index system given in Table II are good.

B. Public Factor Extraction

Following the simplification, the ET QE index system is lowered from 19 to 10 indicators, thus lowering the BPNN model's complexity and raising the model's accuracy. The BPNN model still needs to build 10 input nodes after the streamlining, and this adds to the model's complexity. The dimensionality of the ET QE index system needs to be further lowered with the goal to increase the model's accuracy in assessing ET quality. In Table IV, this stage is accomplished by the study using principal component analysis (PCA) for public factors, as indicated.

The cumulative total variance contribution of the three public components in Table III was 78.05%. There are three factors with a combined value larger than 1 in Table III. These three public factors' variables therefore have a lot of explanatory power and can accurately and thoroughly depict the standard of ET. The constructed factors were extracted by descriptive statistics operation, and then a factor component matrix was obtained. Through this factor component matrix, the correlation between the public factors extracted by the study and the indicators can be described, so that the indicators corresponding to the public factors can be selected. Table V displays the factor component matrix that was culled for the investigation.

TABLE IV. PCA EXTRACTION RESULTS

Composition	Initial Characteristics			Extract the Sum of the Squares of the Load		
	Total	*Percent Variance/%*	*Cumulative contribution rate/%*	*Total*	*Percent Variance/%*	*Cumulative contribution rate/%*
1	3.925	39.25	39.25	3.925	39.25	39.25
2	2.026	20.26	59.51	2.026	20.26	59.51
3	1.854	18.54	78.05	1.854	18.54	78.05
4	.854	8.54	86.59	-	-	-
5	.759	7.59	94.18	-	-	-
6	.254	2.54	96.72	-	-	-
7	.203	2.03	98.75	-	-	-
8	.093	0.93	99.68	-	-	-
9	.025	0.25	99.93	-	-	-
10	.007	0.07	100.00	-	-	-

The content of Table IV shows that the indicators corresponding to public factor 1 are U$_{10}$: Improving academic performance; U$_7$: Correct teaching content; U$_6$: Having scientific and ideological qualities. These are the three indicators mentioned above Therefore, the data corresponding to the above three indicators are input into BPNN, which effectively reduces the input nodes of BPNN.

TABLE V. STUDY THE EXTRACTED FACTOR COMPONENT MATRIX

Indicator code	1	2	3
U$_1$	-.162	.102	.351
U$_2$	.013	.134	.056
U$_3$	.154	-.052	-152
U$_4$	.155	.335	.174
U$_5$	-.253	-.103	.068

U$_9$	.092	.353	-102
U$_{10}$	.953	.405	.147

C. BPNN Optimization-based on Improved Dragonfly Algorithm

The accuracy and training effectiveness of BPNN will be directly impacted by its initial weights and thresholds. In order to better and more efficiently obtain the best parameter selection for BPNN, the study uses DA to find the optimal model parameters. An optimisation algorithm known as DA, which simulates the behaviour of dragonfly populations, was recently presented. Due to its superior efficiency, DA offers a wider range of applications in diverse optimisation issues. In the population of DA, it is generally divided into two kinds of populations, one of which is a static population, mainly the other is the dynamic population, which is mainly responsible for migratory behavior. In DA in Eq. (1), the separation behavior of the population S_i is shown.

$$S_i = -\sum_{j=1}^{n} X - X_j \tag{1}$$

The dragonfly individual is located at X, the first j neighbouring individual is located at X_j, and the number of neighbours is given by n in Eq. (1). The alignment behavior A_i is calculated by Eq. (2).

$$A_i = \frac{\sum_{j=1}^{n} V_j}{n} \tag{2}$$

In Eq. (2), V_j represents the flight rate of X_j . The aggregation behavior C_i is expressed as in Eq. (3).

$$C_i = \frac{\sum_{j=1}^{n} X_j}{n} - X \tag{3}$$

Foraging behavior F_i See Eq. (4).

$$F_i = X^{+} - X \tag{4}$$

In Eq. (4), X^{+} is the location of the food the dragonfly is searching for. The avoidance behavior of E_i is shown in Eq. (5).

$$E_i = X^{-} + X \tag{5}$$

In Eq. (5), the natural enemy's position is represented by X^{-}. During the DA iteration, the direction of flight of the dragonfly is determined by the step vector ΔX of the individual dragonfly. During the next iteration, the step vector ΔX_{t+1} is shown in Eq. (6).

$$\Delta X_{t+1} = \left(sS_i + aA_i + cC_i + fF_i + eE_i\right) + w\Delta X_t \tag{6}$$

In Eq. (6), s, a, c, f, e is the weight of the individual's separation, alignment, aggregation, foraging, and avoidance behaviors; w is the inertia weight. On this basis, it is possible to obtain the vector X_{t+1} of the individual's position at the next iteration, see Eq. (7).

$$X_{t+1} = X_t + \Delta X_{t+1} \tag{7}$$

The initial population diversity and worldwide search capabilities of DA are both lacking. To remedy this drawback, the study introduces an inverse chaotic mapping strategy based on Tent chaotic sequences, which optimizes the initial population of DA. If the population individuals have d dimensions, when the population initialization is performed, the individuals of d dimensions are generated X_{id}, which are mapped into some space based on the chaos mapping theory to obtain CX_{id}. As shown in Eq. (8).

$$\begin{cases} X_{id} = X_{\min d} + rand\left(X_{\max d} - X_{\min d}\right) \\ CX_{id} = X_{\min d} + X_{\max d} - X_{id} \end{cases} \tag{8}$$

In Eq. (8), $X_{\max d}, X_{\min d}$ are the lower and upper limits of the values. Let the initial population of DA be X, and the population obtained by chaotic mapping be CX; merge the two to obtain a new population with $2n$ dragonflies. To determine the top n individuals to create the new beginning population, the fitness values of every individual in the population are calculated. In DA, the traditional inertia weight convergence strategy is linear descent. However, the algorithm's rate of convergence differs from the rate at which the inertia weights converge, which has a detrimental effect on the algorithm's rate of convergence. In order to control the algorithm's convergence, the study suggests a nonlinear decreasing inertia weight technique. Equation (9) illustrates the nonlinear inertia weight lowering technique.

$$w = w_{\min} + \left|w_{\max} - w_{\min}\right| \exp\left(\frac{-\alpha t}{t_{\max}}\right) \tag{9}$$

In Eq. (9), $w_{\max}, w_{\min}$ are the maximum and minimum values of the set inertia weights; α is the adjustment coefficient; and $t_{\max}$ is the maximum number of set iterations. Fig. 1 depicts the enhanced inertia weight modification method.

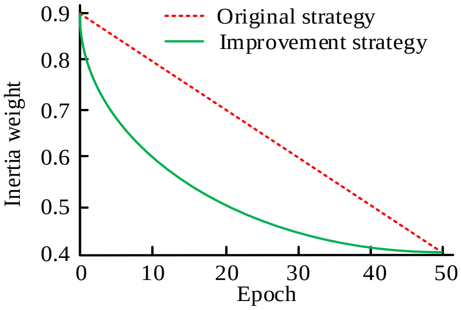

Fig. 1. Improved inertia weight adjustment strategy.

The study's better inertia weighting approach is nonlinearly reducing in Fig. 1. Under this strategy, the inertia weights are basically consistent with the convergence trend of the algorithm, which improves the convergence of DA. Based on the foregoing, IDA is created, used to optimise BPNN, and integrated with the preceeding materials to create an ET quality assessment model that uses IDA-BPNN in order to achieve intelligent evaluation of ET quality and increase ET efficacy.

IV. Performance Analysis of IDA-BPNN ELT Quality Assessment Model

To give a wise, scientific, and impartial evaluation of ET quality, the study suggests an IDA-BPNN ET quality assessment methodology. To create the experimental data set, the necessary index data were pulled from a university's education administration system with the leaders of the school's consent. The experimental data set was divided in a 7:3 manner. The two main cutting-edge algorithmic models used in the current intelligent evaluation of ELT quality are the BPNN model (IPSO-BPNN) based on Improved Particle Swarm Optimisation (PSO) and the BPNN model (GWO-BPNN) based on Grey Wolf Optimisation Algorithm (GWOA) optimisation. In IDA-BPNN, the number of iterations is 200, the learning factor is 0.3, the input layer is 4, the hidden layer is 20, and the output layer is 1. As a result, the effectiveness of the IDA-BPNN, IPSO-BPNN, and GWO-BPNN models is contrasted. The effectiveness of the three common factors extracted based on the PCA method is first investigated using the gravel plot analysis, as shown in Fig. 2. The slope of the curve is greater in the first three common components, as seen in Fig. 2. While in the other public factors except the first three public factors, the slopes of the curves at their positions are smaller and the trends are flatter. The above results show that the three public factors extracted by the study can reflect the ET situation more accurately, comprehensively and effectively, which proves the validity of the public factors extracted by the study.

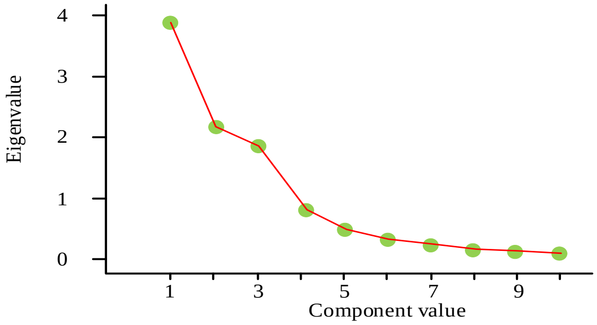

Fig. 2. Gravel diagram of common factors.

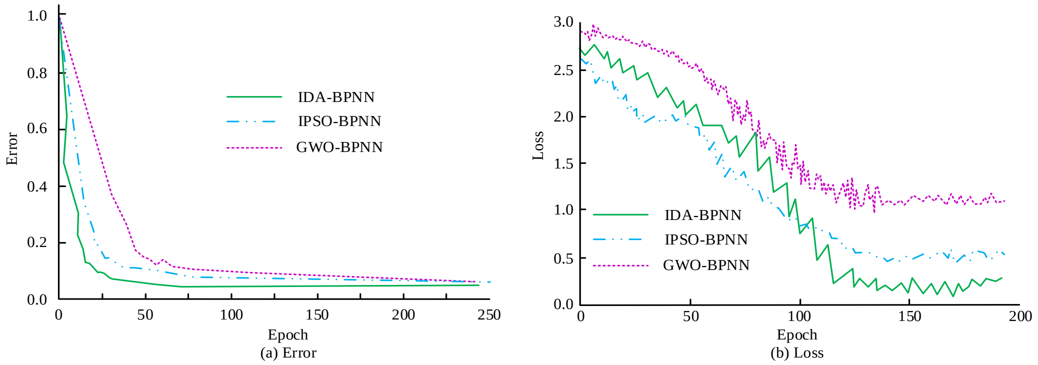
Fig. 3 displays the changes in error and loss values for the IDA-BPNN, IPSO-BPNN, and GWO-BPNN models on the training set. In Fig. 3, the error values and Loss values of the models are dropping, which suggests that the performance of the models is improving during the iterative learning process. The model has reached its optimal performance at this point. When a particular number of iterations is reached, the error and loss values of the model do not vary significantly. The error value of the IDA-BPNN model in Fig. 3(a) is 0.08, which is 0.02 and 0.03 greater than the error values of the IPSO-BPNN model and the GWO-BPNN model, respectively. The Loss value of the IDA-BPNN model in Fig. 3(b) is 0.3, which is 0.2 and 1.0 lower than the Loss values of the IPSO-BPNN model and GWO-BPNN model, respectively.

Fig. 4 displays the F1 value variations for the training and test. The F1 values for the IDA-BPNN, IPSO-BPNN, and GWO-BPNN models on the training set are displayed in Fig. 4(a). In comparison to the IPSO-BPNN model and the GWO-BPNN model, the F1 value of the IDA-BPNN model is 0.950, which is 0.005 and 0.007 higher, respectively. The F1 values for the test set for the IDA-BPNN, IPSO-BPNN, and GWO-BPNN models are displayed in Fig. 4(b). Models for the change of F1 values include the IDA-BPNN model, IPSO-BPNN model, and GWO-BPNN model. In comparison to the IPSO-BPNN model and the GWO-BPNN model, the F1 value of the IDA-BPNN model on the test set is 0.968, which is 0.006 and 0.008 higher, respectively.

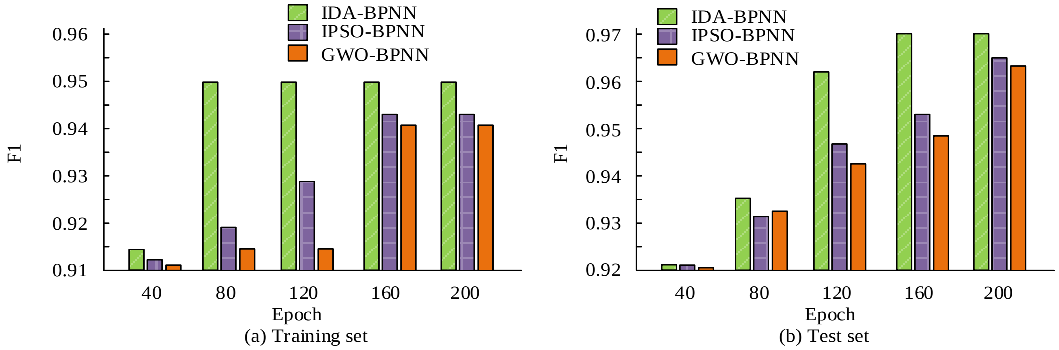
Fig. 5 displays the changes in recall values for the IDA-BPNN, IPSO-BPNN, and GWO-BPNN models on the training and test sets. Fig. 5(a) displays the Recall value changes for the training set for the IDA-BPNN, IPSO-BPNN, and GWO-BPNN models. On the training set, the IDA-BPNN model's Recall value is 0.948, which is 0.007 and 0.012 higher than the values for the IPSO-BPNN model and the GWO-BPNN model, respectively. Fig. 5(b) displays the Recall values for the test set for the IDA-BPNN, IPSO-BPNN, and GWO-BPNN models. Value shifts. The IDA-BPNN model has a Recall value of 0.966 on the test set, which is 0.011 and 0.014 higher than the corresponding values for the IPSO-BPNN model and the GWO-BPNN model, respectively.



(a) Error

(b) Loss

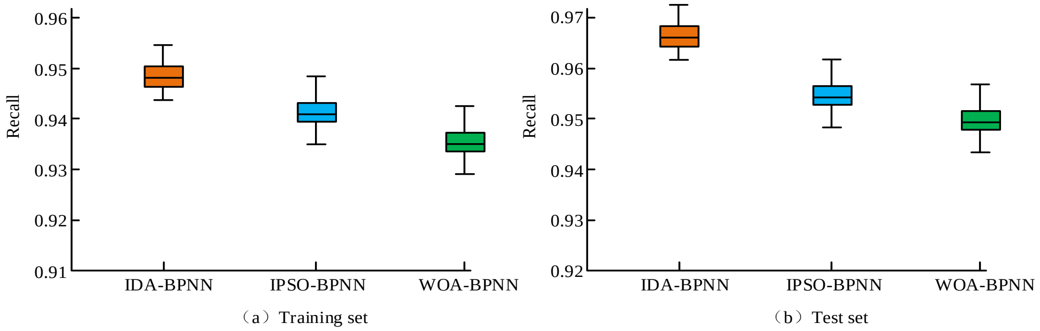
Fig. 3. Changes in model error and loss values.



(a) Training set

(b) Test set

Fig. 4. Change in F1 value of the model.



（a） Training set

（b） Test set

Fig. 5. Change in Recall value of the model.

Use the aforementioned model to evaluate the ET data in the university's educational system, analyse the disparities between the model's evaluation values and the actual values, and determine the model's evaluation correctness. Fig. 6 displays the evaluation accuracy of many models. As can be seen, the IDA-BPNN model outperformed the IPSO-BPNN model and the GWO-BPNN model in terms of assessment accuracy, with 98.96% on the test set, which is higher by 1.02% and 1.24%, respectively.

Fig. 7 illustrates how the MAE values of the IDA-BPNN model, IPSO-BPNN model, and GWO-BPNN model change on the test set after all models have been fully trained using the training set. It is clear that the MAE values of the models have been trending downward over the rounds. The IDA-BPNN model's MAE value after 40 iterations is 0.752, which is 0.048 and 0.097 less than that of the IPSO-BPNN model and the GWO-BPNN model, respectively. In conclusion, the IDA-BPNN ET QE model developed by the study has high evaluation accuracy and efficiency, can perform ET QE objectively and efficiently, and has favourable implications for the development of English professionals as well as for the growth of ET.

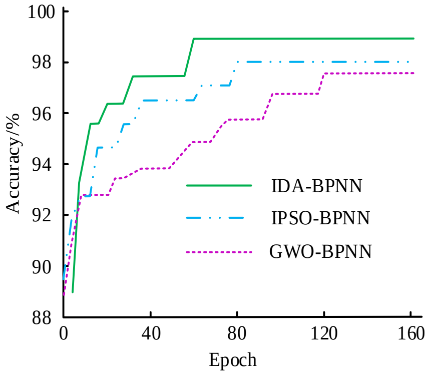


Fig. 6. Accuracy of ET QE.

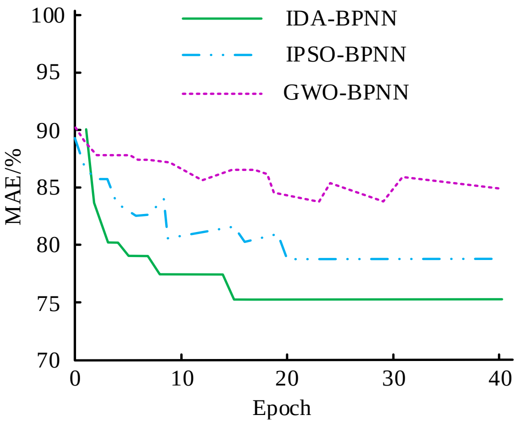

Fig. 7. Change in MAE value of the model.

V. Discussion

Among the first three common factors, the slope of the curve is relatively large, indicating that the three common factors extracted in the study can accurately, comprehensively, and effectively reflect the ET situation. The error value of the IDA-BPNN model is 0.08, which is 0.02 and 0.03 greater than the error values of the IPSO-BPNN model and GWO-BPNN model, respectively. The loss value of the IDA-BPNN model is 0.3, which is 0.2 and 1.0 lower than the loss values of the IPSO-BPNN model and GWO-BPNN model, respectively. The F1 values and recall rates of the IDA-BPNN model are 0.950 and 0.948 on the training set, and 0.968 and 0.966 on the test set. The evaluation accuracy of the IDA-BPNN model is 98.96% on the test set. All the data used in the experiment came from the same university, and the sample range is limited, which may lead to accidental factors in the experiment. Future research should expand the sample size to further enhance the credibility of the study.

VI. Conclusion

Teachers can recognise their own teaching weaknesses and enhance the quality of their ET by doing intelligent evaluations of it. To enhance the assessment of ET quality, the study created the IDA-BPNN ET QE model. In accordance with the experimental findings, the IDA-BPNN model's error value is 0.08, the Loss value is 0.3; the IPSO-BPNN model and the GWO-BPNN model, which have F1 values of 0.005 and 0.007, respectively, respectively, the F1 value on the training set is 0.950. On the training set, the Recall value of the IDA-BPNN model is 0.948; the F1 value on the test set is 0.968; On the test set, the evaluation accuracy of the IDA-BPNN model is 98.96%, which is higher than IPSO-BPNN model and GWO-BPNN model. The recall value of the IDA-BPNN model is 0.966, which is 0.011 and 0.014 higher than IPSO-BPNN model and GWO-BPNN model, respectively. At 40 iterations, the MAE value of the IDA-BPNN model is 0.752, which is 0.048 and 0.097 lower than the IPSO-BPNN model and the GWO-BPNN model, respectively. In conclusion, the research-built IDA-BPNN ET QE model has high assessment accuracy and efficiency, can evaluate the quality of ET objectively and efficiently, and promotes the development and reform of ET while having favourable effects on the training of English professionals. All the data used in the experiment came from the same university, and the sample range is limited, which may lead to accidental factors in the experiment. Future research should expand the sample size to further enhance the credibility of the study.

VII. Fundings

The research is supported by Education Project Civil Aviation Adninistration of China: First Class Curri culum Construction of CAFUC (MHJY2022005).

Determinants of Medical Internet of Things Adoption in Healthcare and the Role of Demographic Factors Incorporating Modified UTAUT

Abdulaziz Alomari, Ben Soh
Department of Computer Science and IT, La Trobe University Melbourne, Australia

***Abstract*—Medical Internet of Things (mIoT) is the IoT sub-set with vast potential in healthcare. However, the adoption of eHealth solutions such as mIoT has been a critical challenge in the health sector of the Kingdom of Saudi Arabia. Therefore, this study was conducted to explore the mIoT adoption determinants in Saudi public hospitals. Methods: A total of 271 participants were recruited from public hospitals in Riyadh, and a modified UTAUT model named UTAUT-HS was developed in this study to test its relevance with respect to mIoT adoption. Results: Ten path relationships were tested in this study, out of which six showed significant results. Similarly, three variables (Computer and English Language Self-efficacy or CESE, Performance Expectancy or PE and Social Influence or SI) showed a significant direct relationship with the behavioural intention to adopt mIoT. Furthermore, CESE showed the strongest relationship and emerged as a major sub-set of Effort Expectancy (EE) for mIoT adoption. However, moderator analysis showed substantial variations between different study demographic groups. In particular, the current study findings unravelled a comparatively novel relevance of Perceived Threat to Autonomy (PTA) for mIoT adoption for clinical and non-clinical and for older and younger participants. Conclusion: The study concludes that UTAUT-HS is an adequate model to explain the mIoT adoption in healthcare. However, it also suggests conducting future large-scale studies in KSA and elsewhere to validate the relevance of UTAUT-HS in other contexts and with much more confidence.**

Keywords*—Medical internet of things; eHealth adoption; modified UTAUT; demographics and IT adoption

I. Introduction

The term "Internet of Things" (IoT) was coined by Kevin Ashton in 1999, who was a British technology pioneer and worked at the Massachusetts Institute of Technology [1,2]. IoT has many definitions; however, in broad terms, it can be defined as a combination of different components, such as smart devices or machines that communicate with each other over the Internet, gather information, and make decisions without human intervention [3]. Medical Internet of things or mIoT is the application of IoT in healthcare and simply can be defined as a consolidation of devices and applications that can link to information technology systems in healthcare using a range of networking technologies [4]. mIoT has tremendous capabilities in healthcare and it ranges from reducing healthcare costs, load on clinicians and medical errors [5,6, 7] to improving treatment outcomes, compliance by patients and overall quality of healthcare [8,9].

However, despite a wide range of advantages, a recent systematic review on IoT adoption suggests that the inclusion and acceptance of IoT in healthcare is still low [10]. It is important to note that successful implementation and adoption of new technologies such as mIoT is not an easy process and is affected by many main interrelated factors, namely social, personal, technical, and organisational factors [11]. However, it has been suggested by many researchers that the greatest challenge of mIoT and AI adoption in healthcare is not the efficacy of the technology but the acceptance by the clinicians [12,10]. The adoption of any new technology in any society is a complex process and the process becomes more challenging if the society is comparatively restrictive in nature, such as the Kingdom of Saudi Arabia and the technology has enormous disruptive power, such as mIoT.

Moreover, in KSA, the resistance to change and to adopt new technology, lack of compliance by the healthcare staff and inadequacies in the policies to introduce and implement new IT-based solutions have created already bad condition worse for the introduction of more complex eHealth solutions such as mIoT [13]. For instance, the past eHealth research (Electronic Health Record {EHR} systems) conducted in the Kingdom suggests that there was underutilisation of EHR functionalities across the board in the hospital [14]. Moreover, healthcare professionals have reported data entry time, lack of adequate IT training and support, the complexity of technology, lack of customizability option of the EHR systems, and disturbance in communication between doctors and patients as grave barriers linked with EHR adoption [14]. Therefore, it is likely that the introduction of mIoT in the Kingdom will experience significant resistance and interruptions. Also, no quantitative studies are available investigating the adoption determinants of mIoT in Saudi hospitals. Thus, research focused on understanding the adoption dynamics of mIoT in the Kingdom of Saudi Arabia should be conducted to support the smooth uptake of these technologies.

To achieve the aim of this study, a brief description of prevailing technology adoption theories is provided to propose the current study framework. Detailed information pertaining to each component of the proposed framework, along with the rationale for their inclusion, is provided in the following sections. Moreover, the relevance of the selected moderators in the current study framework is also established in the subsequent sections.

A. Past Theories Related to the Adoption of New Technologies

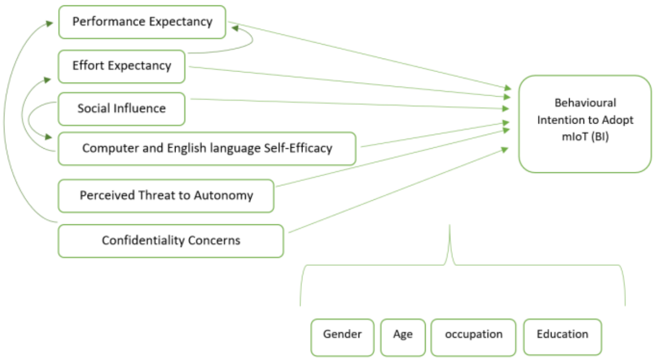
A significant body of research has been conducted to determine the factors associated with the adoption of new innovations/ technologies and aspects related to human behaviours. The most famous theories incorporated by researchers investigating the adoption of new technologies include the Theory of Reasoned Action (TRA) proposed in 1975, The Technology Acceptance Model (TAM) proposed in 1989, The Theory of Planned Behaviour (TPB) proposed in 1991, The Unified Theory of Acceptance and Use of Technology (UTAUT) proposed in 2003 and The Unified Theory of Acceptance and Use of Technology 2 (UTAUT2) proposed in 2012 [15,16,17,18,19].

The Unified Theory of Acceptance and Use of Technology or UTAUT was proposed in 2003 and was based on eight past theories, which included TRA, TAM, TPB, Innovation Diffusion Theory (IDT), Combined TAM-TPB (C-TAM-TPB), Social Cognitive Theory (SCT) and Model of PC Utilization (MPCU) [18]. UTAUT included four main constructs; Performance Expectancy (PE), Effort Expectancy (EE), Social Influence (SI), and Facilitating Conditions (FC). Along with these four constructs, UTAUT also incorporated four moderators (age, gender, experience and voluntariness), which were assumed to influence the constructs [15]. However, it is essential to note that only PE, EE and SI were directly linked with Behavioural Intention to Adopt Technology (BI), while FC was majorly linked with the actual use of the technology.

Since the development of UTAUT, it has been used by various studies from a broad range of disciplines to explore and explain the adoption of technology majorly at an individual level [20]. Moreover, it has been suggested that the variance explaining power of UTAUT is about 70% and it has outperformed all the other past eight models (eight models explained between 17% and 53% of the variance in BI) that were used to construct UTAUT [18].

II. Proposed Framework for the Current Study - The Unified Theory of Acceptance and Use of Technology for Hospital Staff (UTAUT-HS)

Comparing the characteristics of the past study models, the current study considered UTAUT as the most suitable model to develop the current study framework (Fig. 1). The original UTAUT model proposed four key constructs: PE, EE, SI and FC. However, FC is considered to be affecting the actual use of IT and not directly linked with the adoption or acceptance of IT in the original UTAUT model. Thus, it was excluded from the current study proposed framework. Further, based on the literature search conducted on the adoption of IT technologies in the Saudi healthcare system and elsewhere, three additional components, Computer and English language Self-Efficacy (CESE), Perceived Threat to Autonomy (PTA), Confidentiality Concerns (CC), were included in the current study proposed framework. Similarly, two moderators; gender and age, were adopted from the UTAUT model and two more; occupation and education, were included in the proposed framework.



Performance Expectancy
Effort Expectancy
Social Influence
Computer and English language Self-Efficacy
Perceived Threat to Autonomy
Confidentiality Concerns
Behavioural Intention to Adopt mIoT (BI)
Gender
Age
occupation
Education

Fig. 1. Study framework - The Unified Theory of Acceptance and Use of Technology for Hospital Staff (UTAUT-HS).

A. Performance Expectancy (PE)

Performance Expectancy is defined as the extent to which a particular technology brings about effectiveness in work performance and this concept is similar to Perceived Usefulness (PU) from TAM [21,18,17]. Gao et al. [22] suggested that when healthcare consumers believe that the introduction of IoT will enable them to improve effectiveness, they are more likely to accept the technology. As far as eHealth is concerned, PE has been reported by many studies to be a significant contributing factor for technology adoption among healthcare professionals [23,24,25]. Moreover, the lack of PE of information technology was also observed to be a crucial hurdle in healthcare, and the literature concerning the adoption of EHR in KSA has suggested lack of Perceived Usefulness (PU) or PE to be contributing 15% of all barriers [26].

H1: Performance Expectancy (PE) will have a positive influence on the Behavioural Intention to Adopt mIoT (BI). Age, gender, occupation, and education will moderate the influence of PE on BI.

B. Effort Expectancy (EE)

Effort Expectancy (EE) is regarded to be clearly linked with the ease of use of Information technology and it is similar to the Perceived Ease of Use (PEOU) from TAM [27,15]. In other words, it refers to the extent to which an individual considers the use of technology free of effort. A range of past studies has endorsed the substantial influence of PEOU and it has been reported that EE plays a positive role in the adoption or acceptance of healthcare information systems, clinical decision support systems, adverse event reporting systems and many more [28,29,30,31]. The significance of PEOU is also supported by Alqahtani et al. [27], who suggested that 15% of all EHR adoption barriers in the KSA were linked to PEOU [26].

H2: Effort Expectancy (EE) will have a positive influence on the Behavioural Intention to Adopt mIoT (BI). Age, gender, occupation, and education will moderate the influence of EE on BI.

H3: Effort Expectancy (EE) will have a positive influence on Performance Expectancy (PE).

C. Social Influence (SI)

Social influence is defined as the perception of an individual about a product, technology or services, which is substantially influenced by the perception of people around him/her and it is similar to the subjective norm from TRA and TBP [32,33,19]. In the case of IoT or mIoT technology, the majority of the potential users lack adequate information about it. Thus, the impact of SI is even amplified in the decision-making process [32]. The social network has a crucial role in the adoption or acceptance of IoT technologies since it has been a general observation that IoT users seek assistance and advice from family, peer and colleagues to clear uncertainties about the product [34].

Moreover, in the healthcare context, many studies have found a substantial role of SI on technology acceptance among doctors and physicians [24,35]. Similarly, it is also hypothesised that the norms will affect the expectations linked with the Computer and English Self-efficacy of healthcare professionals. Since, KSA is conventionally considered a reserved culture and a lot of significant changes are introduced under the progressive 2030 Vision approach, thus there is more significant uncertainty about the influence of SI on the intention to adopt mIoT [36,37,38,39].

H4: Social Influence (SI) will positively influence the Behavioural Intention to Adopt mIoT (BI). Age, gender, occupation, and education will moderate the influence of SI on BI.

H5: Social Influence (SI) will have a positive influence on the Computer and English Self-efficacy (CESE).

D. Computer and English Language Self-Efficacy (CESE)

Self-efficacy is defined as the self-evaluation of an individual to conduct a particular task and in terms of mIoT adoption, CESE is associated with the self-evaluation of computer skills and English language proficiency [40]. In the healthcare context, mIoT technology adoption remains a significant issue and is substantially associated with technological skills and abilities [22]. Moreover, past literature has indicated the lack of familiarity of doctors with information technology to be a significant barrier obstructing the adoption and use of those technologies [41,42]. The Kingdom of Saudi Arabia has also witnessed this issue and has reported it in many past studies conducted in the healthcare environment [43,44,45,46].

Despite the fact that many studies in KSA have highlighted this issue, only a few studies have explored the role of this issue in the acceptance of information technologies by healthcare professionals [43,44,45,41,42]. Concerning English language proficiency, a vital link has also been found with eHealth use in the Kingdom [44,45].

H6: Computer and English language Self-Efficacy (CESE) will positively influence the Behavioural Intention to Adopt mIoT (BI). Age, gender, occupation, and education will moderate the influence of CESE on BI.

H7: Computer and English language Self-Efficacy (CESE) will have a positive influence on the Effort Expectancy (EE).

E. Perceived Threat to Autonomy (PTA)

Perceived Threat to Autonomy (PTA) is not a new concept as [47] Walter & Lopez (2008) described PTA as the extent to which an individual thinks that incorporating a particular technology or system will compromise his/her control over the procedures, policies and functions of their work [47]. However, this concept has become substantially relevant with respect to the adoption or acceptance of mIoT. Conventionally, it is believed that healthcare professionals and in particular, doctors hold a high level of professional autonomy and the introduction of mIoT can affect the power dynamics in the healthcare environment [48,47]. Safi et al. [49] noted that the doctors in their study highlighted the possible interference of technology with their autonomy in their diagnostic process. The doctors showed high concerns related to the use of eHealth tools by the management to control them. These perceptions ultimately led to a negative attitude toward the acceptance of change brought by the technologies [49].

Carcary et al. [50] asserted that one of the key reasons for resistance to IoT is its very different nature from other eHealth technologies. The key new component in IoT is AI or machine learning (which has not been a major part of past technologies). AI is perceived as a direct threat because of its capability to replicate the human performance. The research conducted in the Saudi healthcare environment has shown the understating of this barrier by healthcare professionals, especially doctors. The studies by Abdullah and Fakieh [51] and Qurashi et al. [52] have reported that doctors and other healthcare employees are worried about their job security due to AI. Moreover, the qualitative study by Alsulame et al. [48] concluded that healthcare professionals are resistant to the adoption of eHealth technologies due to the fear that they might lose their privileges, which suggests a loss of respect and autonomy. Therefore, the following hypothesis was developed.

H8: Perceived Threat to Autonomy (PTA) will have an influence on the Behavioural Intention to Adopt mIoT (BI). Age, gender, occupation, and education will moderate the influence of PTA on BI.

F. Confidentiality Concerns (CC)

Confidentiality Concerns (CC) can be defined as the extent to which the use of a particular technology can increase the risk of loss of personal or important information. Past research conducted in the Kingdom of Saudi Arabia has frequently reported CC causing major hurdle in the acceptance of eHealth technologies [53,54,55,44,45]. For instance, the study by Albarrak et al. [53] found that 90% of the doctors showed concerns about patient privacy (among other concerns) for the adoption of telemedicine. Similarly, Alqahtani [54] study noted privacy and security issues as major obstacles preventing Saudi healthcare from adopting IoT technology. Moreover, past research has also identified an association between CC and PE, which suggests the indirect effect of CC on the acceptance of technology [56].

Among all healthcare professionals, doctors are believed to be concerned about CC the most, even more than the patient themselves [41]. This could be because they are at the frontline and feel more responsibility for patient information protection. It is visible from the observation that doctors who use even basic eHealth technologies such as EHR have suggested an increased risk of confidentiality and security issues while comparing EHR with paper-based record systems [41]. Even though many past studies in KSA have highlighted CC to be a significant obstacle to mIoT and e-health adoption and use, the literature investigating the influence of CC on the adoption intention of mIoT is limited, highlighting the need for CC to be included in the current study framework [55,44,45].

G. Moderators in the Framework

1) Gender: Hoque [57] argues that gender as a moderator of technology adoption have received less attention compared to other demographic factors age, experience or culture. However, past studies conducted on the adoption of technology have found significant influence of gender [58,59,60]. Despite this some of the most commonly used technology acceptance models such as TAM have made no reference of the impact of gender on the IT acceptance model [57]. Overall, it has been suggested that male possess less suspicions about technology and hold more positive views them, while female lack confidence in computer usage [57,61]. However, with respect to mIoT, the study by Karahoca et al. [62] found out that male showed more privacy and healthcare vulnerability concerns than females. While other studies have suggested that male’s provided higher score on PU Or PE and PEOU or EE compared to females [63].

However, again these patterns are not consistent and varies substantially from technology to technology or region to region. For instance, the Bangladeshi study on mHealth adoption showed that male provided higher scores on PEOU than females (0.6556 versus 0.1445, $t = 3.784$), while females provided higher PU scores (0.3244 versus 0.0140, $t = 2.104$) [57]. However, the key standpoint behind the role of gender on technology adoption is associated with the social roles rather than any biological mechanism and there is major discrepancy among male and female societal roles in KSA, therefore this aspect is quite important for the Kingdom [64].

H9: Confidentiality Concerns (CC) will have a negative influence on the Behavioural Intention to Adopt mIoT (BI). Age, gender, occupation, and education will moderate the influence of CC on BI.

H10: Confidentiality Concerns (CC) will have a negative influence on Performance Expectancy (PE).

2) Age: Age is another noteworthy factor that may influence the adoption of mIoT. Sivathanu [65] conducted a study to evaluate the adoption factors for IoT-based healthcare wearables. The study found that older individuals experience mainly three types of barriers (traditional, usage and risk barriers), which are related to age and can influence (reasons against) the adoption of IoT-based healthcare wearables [65]. Similarly, the study found that elderly participants were more inclined toward visiting doctors in person rather than conducting online consultations. They believe that doctors provide more personalised healthcare services in person and also believe that the use of eHealth or wearable healthcare devices is a challenging task. Given that the current study is aimed to be conducted in KSA, the aspect of age become significantly important due to the rapidly changing cultural environment in the Kingdom, which might increase the generational gap and consequently widen the perceptual gap towards mIoT technology [66,67].

These presumptions related to elderly participants are also proved by various past studies conducted in the healthcare domain. For instance, the study by Parthasarathy et al. [68], focus on the concerns associated with the adoption of EMR, showed that negative beliefs and attitudes towards the use of computers and inadequate motivation to change readiness negatively influenced IT adoption among nurses. The research concluded that these negative factors were most commonly found among older nurses. Moreover, it was asserted that a one-size-fits-all training style is inadequate in healthcare for adopting new technologies [68]. The study by Al Otaybi et al. [69] is one of those few studies which showed that age difference in healthcare is a determining factor with respect to EMR satisfaction. Hence, age is considered a predisposing factor in technology adoption, and healthcare organisations are often challenged to provide a wholistic environment that can meet the needs of all, support change readiness and enhance the digital competency of all healthcare professionals [70].

3) Occupation: Hospitals include a range of staff members, which includes but not limited to doctors, nurses, pharmacists, IT staff and management employees. Further, among doctors, there are various categorizations based on their skills and qualifications. Therefore, the difference in the field of practice may produce a difference in attitude towards the adoption of the same technology. This inference is supported by the systematic review conducted by Boonstra et al. [71] on the adoption of EHR in hospitals. The review suggested that the leadership has to focus on the work conducted by different healthcare professionals and the impact of health information technology on the flow of those works to ensure a smooth technology transition [71].

It is essential to consider that a particular occupation in the hospital encompasses specific roles, responsibilities and duties, determines the level of interaction with other colleagues and patients and requires certain level of education [72,73,74]. All these factors can influence the knowledge and perception towards e-health technologies or more precisely, towards mIoT. For instance, the study by Afolaranmi et al. [75] found a significant correlation between good EHR knowledge and different hospital professions. Among clinical professions, pharmacists showed the highest positive knowledge of EHR, followed by resident doctors and nurses/midwives. Thus, these aspects are essential and occupation should be included as a moderator for the adoption of mIoT.

4) Education: Similar to gender, age and occupation, education is another significant determinant that can act as a substantial moderator in the current study. Past studies have indicated a significant role of the level of education on technology awareness and perception in the healthcare sector [76,45,77]. Healthcare professionals holding a master's or above education have been identified to be significantly more eHealth aware than their counterparts with a bachelor's or below education [76,45,77]. Similarly, Saudi research by Hasanain et al. [45] indicated a statistically significant association between EMR literacy, computer literacy, English language proficiency level and healthcare professionals' education level. Thus, the inclusion of education as a moderator was important for the current study.

III. Methodology

The current study aimed to evaluate the determinants that were associated with the adoption of mIoT among hospital care staff in Saudi Arabia. To achieve this aim, Ministry of Health (MOH) hospitals in Riyadh were selected for the recruitment of the participants. MOH hospitals are public entities, providing 60% of the total healthcare services in the Kingdom [78]. The selection of Riyadh was made because it is the biggest city in the Kingdom and is at the forefront to receive technological innovation in the country [44]. Thus, 271 participants, including doctors, nurses, pharmacists, and non-clinical personals i.e., IT individuals, technicians and managerial personnel working in the MOH hospitals in Riyadh, were recruited. Before the recruitment, relevant ethics approvals were sought from the Latrobe University, Melbourne, Australia (ethics no HEC19482) and from the MOH of Kingdom of Saudi Arabia (ethics no: 21-79 E).

A. Data Analysis

Model testing is an integral part of research as it allows the researcher to identify the relationship between different variables included in the study model. Therefore, structural equation modeling (SEM) using SmartPLS version 3 was incorporated in this research for model testing. SEM is a complex multivariate statistical analysis technique that permits researchers to examine the nature and significance of relationships among various exogenous and endogenous variables [79]. Also, conducting SEM using SmartPLS is particularly beneficial as it requires no assumptions related to the distribution of the study data and is suitable for a comparatively small sample size [80,81].

IV. Study Model Validation – Main Results

To check the indicator reliability, SmartPLS version 3 was used to calculate the Factor loadings (Table X in Appendix) of the indicators included in each variable. Henseler et al. [82] suggested that a factor loading of 0.7 or higher is considered highly satisfactory, whereas the value of 0.5 or above is considered acceptable [83]. Table I demonstrates that all outer loadings were above 0.7; hence the acceptance criterion was fulfilled. The second parameter for model evaluation was the assessment of construct reliability which was carried out by measuring Cronbach's Alpha and Composite Reliability (CR) (Table I). The value of Cronbach's Alpha and CR above 0.7 is considered adequate to establish internal consistency reliability [83]. Table I shows that all values for Cronbach's Alpha, CR and rho_A (similar to CR calculated by SmartPLS) were higher than 0.7; hence this criterion was also fulfilled.

For the assessment of validity, the variables were evaluated for convergent and discriminant validity. Convergent validity measurement was carried out by calculating the Average Variance Extracted (AVE) through SmartPLS [83]. [83] Hair et al. (2011) suggested that an AVE value of greater than 0.5 is considered acceptable to determine the convergent validity of the variables. Table I illustrates that all variables had an AVE value of greater than 0.5; hence no adjustment was required.

Discriminant validity is another significant factor that is required to be evaluated to assess the quality of the measurement model. Discriminant validity measures the extent to which the indicators are different from each other empirically [84,85]. The discriminant validity can be measured by using the Fornell & Larcker criterion method, the Heterotrait-monotrait (HTMT) ratio of correlation, and by evaluating the cross-loadings of the indicators. The latent variable should explain better variance of its own indicator compared to the variance of other latent variables. Thus, the values in the Fornell-Lacker method for each latent variable should be higher than the correlation with other latent variables. Table II illustrates that the AVE square root values for each latent variable were greater than all the other correlations; hence this criterion was satisfied [84,85].

TABLE I. Internal Consistency, Reliability and Validity Results for the PLS-SEM Measurement Model

	Cronbach's Alpha	rho_A	Composite Reliability	Average Variance Extracted (AVE)
BI	0.927	0.928	0.965	0.932
CC	0.933	0.933	0.957	0.882
CESE	0.949	0.949	0.963	0.868

PE	0.699	0.538	0.715	0.837	0.882		
PTA	0.761	0.873	0.813	0.749	0.630	0.890	
SI	0.768	0.728	0.797	0.810	0.742	0.851	0.944

The other method to assess the discriminant validity includes the evaluation of HTMT ratios of correlation [84,85]. [82] Henseler et al. [82] suggested that this method is superior to the Fornell-Lacker method as it can achieve higher rates of specificity and sensitivity. The acceptable threshold of the HTMT ratio ranged between 0.85 and 0.90, and anything above these values can indicate issues of discriminant validity [86,87]. Table III demonstrates a PTA-CC HTMT ratio of 0.957, which required treatment. To identify the point of concern, cross-loadings were checked [84,85].

TABLE III. HTMT RATIO FOR DISCRIMINANT VALIDITY TESTING

	BI	CC	CESE	EE	PE	PTA	SI
BI							
CC	0.678						
CESE	0.863	0.732					
EE	0.815	0.691	0.880				
PE	0.760	0.581	0.770	0.902			
PTA	0.811	**0.957**	0.856	0.791	0.669		
SI	0.813	0.769	0.835	0.851	0.792	0.900	

Three issues were identified in the indicator 36, 39 and 42, because their cross-loadings were higher in other latent variables compared to theirs, thus these were dropped. HTMT ratios were checked again, and it showed that the issue was resolved (Table IV).

TABLE IV. RE-CHECKING HTMT RATIO FOR DISCRIMINANT VALIDITY TESTING

	BI	CC	CESE	EE	PE	PTA	SI
BI							
CC	0.683						
CESE	0.863	0.744					
EE	0.815	0.691	0.880				
PE	0.760	0.564	0.770	0.902			
PTA	0.733	**0.895**	0.760	0.714	0.583		
SI	0.813	0.734	0.835	0.851	0.792	0.835	

Note: Indicators 36, 39 and 42 were dropped because their cross loadings were higher in other latent variables compared to theirs.

A. *Structural Model Results*

The structural model evaluates the strength and significance of the relationship between independent and dependent variables by assessing the R square, path coefficient (β) and its significance level, which is assessed through the t-test and p-value [88]. R square provides the extent of variance explained by the independent variable, while β explains the strength of an effect from the independent variable to the dependent variable. Similarly, a t-value of above 1.96 and a p-value of below 0.05 suggests the significance of the relationship [88].

Fig. 2 and Table V demonstrate the path coefficients (β) and the corresponding significance levels. It can be observed that out of six independent variables for the Behavioural Intention to Adopt mIoT (BI), only three variables showed a significant relationship. Three variables - CESE, PE and SI positively influenced the BI. Also, out of these three, CESE had the strongest effect ($\beta = 0.437$, $p < 0.001$), followed by SI ($\beta = 0.175$, $p = 0.024$) and PE ($\beta = 0.148$, $p = 0.032$). Further, CESE -> EE, EE -> PE and SI -> CESE showed a significant strong positive relationship. Of these three, EE -> PE showed the strongest relationship ($\beta = 0.858$, $p < 0.001$). Further, 71.2% variance in BI was explained by the independent variables, which suggests a good fit. Similarly, 70.1% variance in PE was explained by EE, 69.4% variance in EE was explained by CESE and 63.6% variance in CESE was explained by SI.

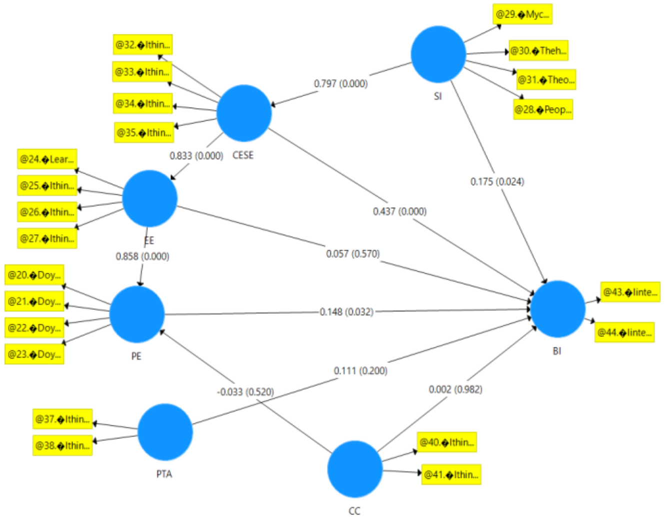

Fig. 2. Overall structural model results including path coefficients and (p values).

TABLE V. OVERALL, PATH COEFFICIENTS, T STATISTICS AND P VALUES OF THE MODEL

	Path coefficients	T Statistics	p values
CC -> BI	0.002	0.023	0.982
CC -> PE	-0.033	0.644	0.520
CESE -> BI	0.437	5.798	0.000
CESE -> EE	0.833	19.175	0.000
EE -> BI	0.057	0.568	0.570
EE -> PE	0.858	17.713	0.000
PE -> BI	0.148	2.139	0.032
PTA -> BI	0.111	1.281	0.200
SI -> BI	0.175	2.255	0.024
SI -> CESE	0.797	20.413	0.000

B. *Moderator Analysis*

1) Gender: Sub-group analysis was conducted for gender, which included separate analyses for male and female participants. Table VI illustrates that out of six independent variables for the BI, two variables showed a significant relationship for male (CESE and PE) and only one showed a significant relationship for female (CESE) participants. Also, the strength of relationships between CESE and BI and PE and BI were stronger for male participants compared to female and overall results (Table VI). Moreover, SI -> CESE, CESE -> EE and EE -> PE showed significant positive relationships for both male and female participants, however, male participants showed comparatively stronger relationships. With respect to R square values, 81.2% variance in BI was explained by the model for male participants, while this percentage was only 51.9% for female participants.

TABLE VI. Path Coefficients and P Values of Male and Female Participants

Gender	Male		Female	
	Path coefficients	p Values	Path coefficients	p values
CC -> BI	-0.021	0.844	0.003	0.974
CC -> PE	-0.064	0.306	0.000	0.997
CESE -> BI	0.537	0.000	0.379	0.002
CESE -> EE	0.877	0.000	0.739	0.000
EE -> BI	0.072	0.544	-0.019	0.917
EE -> PE	0.867	0.000	0.816	0.000
PE -> BI	0.178	0.045	0.110	0.353
PTA -> BI	0.115	0.364	0.080	0.407
SI -> BI	0.103	0.362	0.252	0.079
SI -> CESE	0.825	0.000	0.718	0.000

2) Age: Sub-group analysis was conducted for age and separate analysis for participants aged 18 to 35 years and 36 to 70 years was conducted. Table VII shows that out of six independent variables, three variables (CESE, PE and PTA) showed a significant positive relationship for the 18 to 35 years group and two variables (CESE and SI) showed a significant positive relationship for the 36 to 70 years group with BI. Similarly, the 18 to 35 years group showed a significant positive relationship between PTA and BI (β = 0.258, p = 0.031), which is not shown by the overall results. On the other hand, the 36 to 70 years showed a non-significant negative relationship between PTA and BI. Moreover, the strength of CESE with BI was much stronger for the 36 to 70 years group compared to the 18 to 35 years group (β = 0.536 vs 0.353, respectively) (Table VII).

The variables CESE -> EE, EE -> PE and SI -> CESE showed a significant positive relationship for both groups (Table VII). Also, the 36 to 70 years group showed a significant negative relationship between CC -> PE (Table VII). With respect to the R square, 78.6% variance in BI was explained by the model for the 36 to 70 years group, while this percentage was 64.6% for the 18 to 35 years group.

TABLE VII. Path Coefficients and P Values of 18 To 35 and 36 To 70 Years Old Participants

Age	18 to 35		36 to 70	
	Path coefficients nts	P Values	Path coefficient s	values
CC -> BI	-0.020	0.856	0.049	0.584
CC -> PE	0.076	0.423	-0.112	0.043
CESE -> BI	0.353	0.000	0. 536	0.000
CESE-> EE	0.826	0.000	0.821	0.000
EE -> BI	0.048	0. 708	0.012	0.944
EE -> PE	0. 760	0.000	0. 904	0.000
PE ->BI	0.162	0.043	0.151	0.192
PTA ->BI	0.258	0.031	-0.053	0.653
SI -> BI	0.106	0.338	0.269	0.036
SI -> CESE	0.751	0.000	0.821	0.000

3) Education: Sub-group analysis was conducted for education and bachelor and above (high education) and diploma and below (low education) groups were analysed. Table VIII shows that out of six independent variables, two variables showed a significant relationship with BI for both groups. However, the nature of variables varied between groups – CESE and PE showed a significant positive relationship with BI for the high education group. In contrast, CESE and SI showed a significant positive relationship with BI for the low education group. Moreover, the strength of CESE with BI was much stronger for the low education group compared to the high education group (β = 0.442 vs 0.366, respectively). The variables CESE -> EE, EE -> PE and SI -> CESE showed a ssignificant positive relationship for both groups. With respect to the R square, 82.2% variance in BI was explained by the model for the low education group, while this percentage was 60.5% for the high education group.

TABLE VIII. Path Coefficients and P Values of High and Low Education Groups

Education groups	Bachelor's and above		Diploma and below	
	Path coefficients	p Values	Path coefficients	p values
CC -> BI	-0.010	0.933	0.003	0.971
CC -> PE	-0.026	0.775	-0.040	0.423
CESE -> BI	0.366	0.001	0.442	0.000
CESE -> EE	0.851	0.000	0.808	0.000
EE -> BI	0.050	0.720	0.161	0.257
EE -> PE	0.773	0.000	0.925	0.000
PE -> BI	0.236	0.007	-0.063	0.603
PTA -> BI	0.110	0.372	0.134	0.247
SI -> BI	0.139	0.231	0.279	0.017
SI -> CESE	0.728	0.000	0.884	0.000

4) Occupation: Sub-group analysis was conducted for occupation and clinical and non-clinical groups were analysed. Table IX shows that the variables CESE and SI showed a significant positive relationship with BI for the clinical group, while CESE, PE and PTA showed a significant positive relationship with BI for the non-clinical group. Moreover, the strength of CESE with BI was stronger for the non-clinical group compared to the clinical group (β = 0.525 vs 0.424, respectively). Also, the non-clinical group a significant positive relationship between PTA and BI (β = 0.340, p = 0.017), while the clinical group showed a non-significant negative relationship (β = - 0.100, p = 0.368).

The variables CESE -> EE, EE -> PE and SI -> CESE showed a significant positive relationship for both groups. With respect to the R square, 84.5% variance in BI was explained by the model for the non-clinical group, while this percentage was 60.7% for the clinical group.

TABLE IX. PATH COEFFICIENTS AND P VALUES OF CLINICAL AND NON-CLINICAL GROUPS

Occupation	Clinical		Non-clinical	
	Path coefficients	p Values	Path coefficients	p values
CC -> BI	0.077	0.356	-0.078	0.491
CC -> PE	-0.013	0.848	-0.060	0.387
CESE -> BI	0.424	0.000	0.525	0.000
CESE -> EE	0.779	0.000	0.887	0.000
EE -> BI	0.006	0.973	-0.021	0.831
EE -> PE	0.839	0.000	0.877	0.000
PE -> BI	0.131	0.235	0.242	0.003
PTA -> BI	-0.100	0.368	0.340	0.017
SI -> BI	0.314	0.019	-0.002	0.989
SI -> CESE	0.764	0.000	0.823	0.000

V. MODEL DISCUSSION

This study model explained 71.2% variance in BI, which demonstrates a good fit and shows that the majority of the factors predicting mIoT adoption were included in the model. Also, the variance explained by the current study model is very similar to the potential of the original UTAUT model [89]. In total, ten path relationships were tested in this study and results concluded six significant relationships (hypothesis supported), out of which three variables showed a significant direct relationship with the behavioural intention to adopt mIoT.

Three variables - CESE, PE and SI positively influenced the BI. Also, out of these three, CESE had the most potent effect ($\beta = 0.437$, $p < 0.001$), followed by SI ($\beta = 0.175$, $p = 0.024$) and PE ($\beta = 0.148$, $p = 0.032$). The current study did not show the significant effect of EE on BI. However, a very strong effect of CESE on EE ($\beta = 0.833$, $p < 0.001$) was observed in this research. This concludes that computer and English language competence is a major sub-determinant of the overall Effort Expectancy of mIoT use. There is very limited research available regarding IoT adoption among healthcare professionals; thus, the current study's findings were compared with IT adoption by healthcare professionals. The strong influence of CESE or self-efficacy is supported by [90,91,92]. These studies concluded that self-efficacy, including but not limited to computer skills, had a strong impact on the Perceived Ease of Use and subsequent indirect effect on the adoption of technologies.

The findings regarding the strongest influence of CESE (considering CESE as a major sub-part of EE) on BI are also well aligned with the previous research. Gagnon et al. [24] conducted a study with physicians and concluded that EE or Perceived Ease of Use had the strongest impact on EHR acceptance. Similarly, Chen & Hsiao [90], conducted a study with hospital staff and concluded similar results with respect to health information systems adoption. However, the Saudi studies conducted on nurses and physicians suggested that PU or PE was more important than PEOU or EE in determining professionals' acceptance of EHR [93,54]. The reason for this discrepancy could be due to the nature of the technology. EHR systems are mainly operated by humans and require effort to enter data. However, mIoT majorly relies on wearable devices to upload and AI to analyse data without human involvement, which suggests the transformation of EE from the user point of view.

Similarly, another reason could be due to the unfamiliarity of the participants with the technology, as the hospitals are not using it on a full scale. Thus, they perceived computer and English skills as the most crucial component (as these are the most integral component of all previous technologies). This inference is supported by the previous research by Alsahafi et al. [94], where EE was the most significant predictor of behavioural intention to use National Electronic Health Records by the respondents who were actually non-users of the technology in KSA. This proposes a key finding of this study as the previous dominance (major predictor) of PE or even overall EE on IT adoption is not supported in this one of the early mIoT acceptance research in KSA. Hence, other reported factors of EE, such as time required for data entry, interruption in workflow, the influence of technology on the communication between professionals and patients and many others (El Mahalli [14]), are not important for the adoption of mIoT for this study cohort. This is an essential consideration for policymakers as understanding key adoption determinants can tailor the efforts in the right direction and even assist product developers about the consumers' expectations.

The second significant determinant for the adoption of mIoT reported in this study was SI ($\beta = 0.175$, $p = 0.024$). However, SI also showed a strong effect ($\beta = 0.797$, $p < 0.001$) on the CESE (which showed the strongest effect); thus, it is just to conclude that the total effect of SI on the adoption would be more. This inference is supported by Tsourela & Nerantzaki [95], where SI was found to influence PEOU or EE and PU or PE, which influence attitude, and behavioural intention to adopt IoT technologies. SI is very important for the adoption of mIoT, especially in KSA [96]. The reasons for this are the nature of the technology (wearable devices, apps providing live data feed to the patients, improving control of patients over their health data, etc.) and Saudi society's nature. IoT products can be considered health and fashion products with aesthetic qualities, which could allow customers to articulate their characters and values [95]. This is supported by Yang et al. [97], where social image (SI) showed the strongest ($b = 0.303$, t-value = 4.66, $p < 0.001$) influence on the customers' intention to use of wearable devices.

With respect to society, Saudi Arabia is considered a conservative and enclosed community and the citizens are substantially influenced by their native culture and therefore prefer face-to-face interaction to virtual one [98]. However, this has changed due to the ruler's (Prince Muhammad bin Salman) progressive approach and the COVID-19 epidemic. There is a difference in the findings of the research conducted before and after COVID-19 in KSA and post-COVID-19 research shows that Saudi health consumers are happy with the transition toward e-health during the epidemic [99,100,101]. Thus, it is reasonable to conclude that the influence of Saudi society has inclined more towards e-health or IoT. Hence, SI is a significant predictor of mIoT adoption. This conclusion has substantial value for the IT managers and individuals responsible for the introduction of new technology in Saudi hospitals. Considering the role and value of SI, they can develop strategic plans highlighting the links between the role of mIoT and SI in the hospital to support the smooth transition towards mIoT.

Performance expectancy showed the lowest influence on BI ($\beta = 0.148$, $p = 0.032$), however, a very strong effect of EE on PE ($\beta = 0.858$, $p < 0.001$) was reported in this study, which the CESE also influenced (CESE -> EE, $\beta = 0.833$, $p < 0.001$). This relationship supports the TAM factors developed by Davis as it shows the strong impact of EE or PEOU on PE or PU. This is also supported by the previous Saudi research on EMR and EHR adoption with healthcare professionals [93,92]. However, the strength of the relationship between PE and BI in the current study is comparatively weaker than the previous studies conducted in Saudi Arabia [54,93]. The reason for this discrepancy could be due to the composition of this study cohort (comparatively fewer doctors and more non-clinical participants) or could be the nature of the technology. As mIoT is different from EMR or EHR, it is quite probable that participants cared more about the computer and English skills directly influencing EE rather than the performance concerning adoption. This is supported by Chen & Hsiao [90], where PU has substantially less impact than the PEOU on health information system acceptance by healthcare professionals.

A. Gender and Study Model

Sub-group analysis of the model showed differences in the relationships due to gender, which is supported by the original UTAUT model [18]. Out of six independent variables for the BI, two variables showed a significant relationship for male (CESE and PE) and only one showed a significant relationship for female (CESE) participants. Past research on gender and technology suggests that males incline more toward task accomplishment than females; therefore, as an illustration, PE tends to be more significant for males, whereas females are more concerned with effort in adopting new technology [18]. Also, the strength of the relationship between CESE and BI and PE and BI were stronger among male participants compared to female and overall results. The study by Hoque [57] found similar results where male participants showed stronger relationships than females (0.6556 versus 0.1445, $t = 3.784$) between PEOU and m-Health adoption.

This indicates that EE, as suggested by other researchers, is a substantial factor for the adoption of mIoT among women. However, for men, both EE and PE were important. This is also supported by Tubaishat [92], where male Jordanian nurses were found to have a 0.19 higher PU of EHR than females, controlling for other variables in the model. Similar findings regarding the stronger link between PU and intention to use mHealth among men compared to women were also shown by a Western study suggesting a universal moderating trend of gender on technology adoption [102].

B. Age and Study Model

Sub-group analysis of the model was conducted for age and a separate analysis for participants aged 18 to 35 years (younger) and 36 to 70 years (senior) was conducted. The study findings showed that out of six independent variables, three (CESE, PE and PTA) showed a significant positive relationship for the younger group, and two (CESE and SI) showed a significant positive relationship for the senior group with BI. Moreover, the strength of CESE with BI was much stronger for the senior group compared to the younger ($\beta = 0.536$ vs 0.353, respectively). This stronger relationship for the older group is well supported by Venkatesh and Morris [103], who suggested that EE or CESE is more salient for older participants for IT adoption. The weaker computer skills of the middle-aged and older participants expressed through computer anxiety and less computer self-efficacy [104,105] could be the main reason for this stronger relationship. It is to assume that the participants will put more emphasis (hence a stronger relationship) on the determinants that retain the most significance for them.

PE did not show a significant relationship with BI for the senior participants, and it could be due to low mIoT knowledge among them or due to lower expectations from mIoT performance. As Al Otaybi et al. [69] showed, healthcare participants above 50 were more satisfied with EMR performance in KSA than their blow 35 years counterparts. SI only showed a significant relationship with BI for the senior participants. The reason for this could be the rapid cultural transformation occurring in KSA, which has influenced the youth, but the elderly are still intact with their culture and rely on each other, and value the opinion of the people when it comes to technology adoption [94]. The influence of aging and the role of social influence on the adoption of new technologies is also evident in the Western culture, where elderly participants expressed feelings of inadequacy in comparison to younger generations and lack of social interaction as a major barrier to the use new IT technologies [106].

Apart from these, PTA was another major factor that showed a moderate positive relationship with BI ($\beta = 0.258$, $p = 0.031$) for the younger group. In contrast, the other group showed a non-significant negative relationship between PTA and BI. This is a significant finding of our study. In contrast to past research [48, 51] PTA is not a barrier to mIoT adoption for younger participants, but it might still be for the middle-aged and elderly. This discrepancy could be explained by the power difference dynamics in the hospital environment. Younger staff in KSA, especially nurses, usually hold working or sub-managerial positions in the hospitals and they are often mismanaged or scolded by senior staff or their managers [107]. Increasing control of the top management and reducing the privacy of the behaviour conducted by the senior staff through mIoT might give a sense of transparency and reassurance to the junior employees. Hence, they perceived PTA as a significant positive determinant for adoption, which can assist them in reporting unseen misbehaviour to the top management [108].

On the other hand, senior staff might believe that mIoT can expose their professional misconduct and or can reveal their professional in-competencies and hence perceive PTA as a barrier. Also, the senior group showed a significant negative relationship between CC -> PE, which aligns with the previous research related to security concerns [13,10]. Moreover, the lack of significant effect of PE on BI for the senior group might also be explained by this finding as CC did not show any significant relationship for the overall or any other sub-group analysis.

C. Education and Study Model

The sub-group analysis of education showed that out of six independent variables, two variables showed a significant relationship with BI for both groups. However, the nature of variables varied between groups – CESE and PE showed a significant positive relationship with BI for the high education group (bachelor and above). In contrast, CESE and SI showed a significant positive relationship with BI for the low education group (diploma and below). This discrepancy could be due to the difference in the role of professionals in Saudi hospitals based on their education. It is most likely that participants with higher education were working in managerial or assistant managerial positions; as noted by Aboshaiqah & Alharbi [109] 72% of nursing managers had master's qualifications. Managers have a specific focus on performance and that is why the high-education group showed a significant effect of PE for BI [110]. Moreover, the strength of CESE with BI was much stronger for the low-education group than the high-education group ($\beta = 0.442$ vs 0.366, respectively). Again, it could be due to the varied computer skills among our study participants (high education better skills and vice versa), which is also supported by past research [111,45].

D. Occupation and Study Model

Sub-group analysis for occupation showed that out of six independent variables, two variables (CESE and SI) showed a significant relationship with BI for the clinical group, and three (CESE, PE and PTA) showed for the non-clinical group. This difference is well explained by the nature of the job of the clinical professionals [112]. Compared to other professionals in the hospitals doctors, nurses and other clinical staff are directly connected with the patients and have more potential for interaction with their colleagues; thus, SI holds substantial significance for them. In contrast, the non-clinical staff, which includes the administrators and IT personnel, have the duty of care for performance [74,110] and hence, they prioritised PE.

Moreover, the strength of CESE with BI was stronger for the non-clinical group than the clinical group ($\beta = 0.525$ vs 0.424, respectively). This could be due to the better understanding of the non-clinical participants about the computer skills required for mIoT use. Also, the non-clinical group showed a significant positive relationship between PTA and BI ($\beta = 0.340$, $p = 0.017$), while the clinical group showed a non-significant negative relationship ($\beta = - 0.100$, $p = 0.368$). Again, this is a noteworthy finding of our study as it shows that the non-clinical group, which included administrators and IT personnel perceived PTA as a significant facilitator for BI as it can increase their control and support transparency in work done mainly by clinical professionals [112,108]. While as previously supported and hypothesised by the current study, PTA is a negative determinant of BI for the clinical participants, which can compromise their professional freedom and autonomy in the hospital [48].

VI. Study Contributions

This study makes a substantial contribution to the subject of mIoT adoption by hospital care staff in KSA. The findings and inference concluded in this research hold critical importance for the Saudi Ministry of Health as it is the first-ever quantitative study conducted on mIoT in Saudi hospitals and it aligns with the inclusion of the latest technology in healthcare, which is an integral part of the Saudi 2030 vision. Apart from that, the study findings are important for hospital administrators, IT managers, mIoT developers, vendors, and researchers. The following sub-sections elaborate the significance for each stakeholder.

It is strongly advised to the mIoT developers and vendors to incorporate an option of multiple languages in the mIoT systems. The current study participants showed a very strong relationship between CESE and mIoT adoption. Thus, this factor should be addressed and be prioritised.

It is recommended that the hospital administrators tailor the mIoT training program according to the demographic needs of the staff. The current study showed a disparity between the hospital staff regarding mIoT adoption as different demographic groups have shown different priorities and interests towards mIoT adoption determinants. To support equality and equity and to avoid conflict of interest among hospital staff, this study suggests the following.

It is advised to give special focus to the female, middle-aged hospital staff with low education, such as diploma and below, and clinical professionals in the hospital during awareness and training program sessions. It is likely that these identified groups might require some extra assistance to understand the concepts related to mIoT. It is also possible that they might not ask for assistance by themselves due to peer pressure and perceived shame. Thus, if it is possible, two versions (beginner and intermediate) of mIoT awareness and training program sessions should be introduced in the hospital, so the participants can choose according to their self-perceived abilities.

Based on demographic differences, the study participants showed varying preferences and expectations toward mIoT. For instance, young and non-clinical participants have shown PTA as a significant facilitator for the adoption, while older and clinical participants have indicated otherwise. Thus, this element should be considered carefully and moderated opinion should be promoted regarding PTA to accommodate both groups. Although PTA is a relatively new determinant for the adoption of e-health, it holds substantial importance for mIoT due to the nature of the technology. Therefore, hospital administrators have to be very careful about their presentation and explanation to the staff.

VII. Limitations and Research Implications

This research provides a substantial basis to future mIoT studies in the Kingdom of Saudi Arabia and elsewhere in the Gulf region. The study incorporated a modified UTAUT model and named it UTAUT-HS. The model showed significant variance (above 70%), which indicated that it was a good fit to explain the mIoT adoption behaviour. In addition, the model also showed some interesting findings, which as per the researchers' knowledge, have yet to be observed in any mIoT studies.

These findings include the most decisive role of CESE in adopting mIoT. Though CESE can be considered a subset of EE, based on the current study findings, it has narrowed the scope of EE to CESE, which can help future researchers tailor their research direction toward more targeted needs. However, the current study must assert that the UTAUT-HS model should be tested with a much larger sample (including many doctors from different specialisations and hospitals) as the current study speculates some other EE concerns (which are not shown in the current study) from the physicians. Furthermore, PTA is another factor that is initially not included in any of the original past technology adoption models (TRA, TPB, TAM, UTAUT, etc.). Now, this factor is substantially crucial with respect to mIoT and again, it should be tested with a large sample, including a sufficient number of doctors.

Also, it is suggested that more direct questions (e.g., 'mIoT including AI can make me redundant' etc.) should be included in PTA, which may overlap with the job security factor or perhaps another construct of job security can be included in the model to explore the severity of this matter. Apart from the current research, some other recent qualitative studies have highlighted these concerns. Another noteworthy finding concerning the UTAUT-HS model was the moderators' significant influence, including age, gender, education, and occupation. The current study found a wide range of significant differences among different demographic groups. While most of the differences were related to the degree (in one direction) to which a factor was known or perceived (e.g., males knew more about mIoT than females), some were in the opposite direction. PTA positively influenced BI for the younger participants, while it was non-significantly negative for the older counterparts.

Unexplored and unreported contrasting findings concerning a comparatively sensitive construct such as PTA can have grave consequences for the stakeholders responsible for introducing mIoT in the Kingdom. Thus, it is suggested that future studies include all potential demographics as moderators in the model to identify these conflicting perceptions. However, as asserted before, a much larger sample size would be required to execute these suggestions. Last, but not least, the UTAUT-HS may have universal relevance concerning mIoT adoption. Thus, researchers conducting studies in healthcare outside the Kingdom, particularly in the Western world, are suggested to employ UTAUT-HS to test its relevance.

VIII. Conclusion

The study concludes that CESE, PE, PTA and SI are the significant determinants that can influence the adoption of mIoT among the hospital care staff in the Kingdom of Saudi Arabia. The model (UTAUT-HS) included in the study showed a 71.2% variance in BI, which demonstrated a good fit and showed that the majority of the factors predicting mIoT adoption were included in the model. Among all determinants, CESE demonstrated the most substantial effect suggesting that computer and English language competence is a significant sub-determinant of the overall Effort Expectancy for mIoT adoption and should be prioritised during the development and introduction of these technologies. However, the element of PTA cannot be disregarded as it provided critical insights related to occupation and power dynamics in the hospitals and respective attitudes towards mIoT adoption. Future large-scale studies are recommended in KSA and elsewhere to validate the relevance of UTAUT-HS for mIoT adoption in the healthcare sector.

Apache Spark in Riot Games: A Case Study on Data Processing and Analytics

Kanhaiya Sharma[1], Firdous Hussain Mohammad[2], Deepak Parashar[3]
Symbiosis Institute of Technology Pune, Symbiosis International (Deemed University), Pune, India[1, 3]
Computer Information System, University of the Cumberland’s, Williamsburg, Kentucky, USA[2]

***Abstract*—This case study examines Riot Games' use of Apache Spark and its effects on data processing and analytics. Riot Games is a well-known game production studio. The developer Riot Games, best known for the well-liked online multiplayer game League of Legends, manages enormous volumes of data produced daily by millions of players. Riot Games handled and analyzed this data quickly using Apache Spark, a distributed computing technology that made insightful findings and improved user experiences. This case study explores Riot Games' difficulties, the company's adoption of Apache Spark, its implementation, and the advantages of utilizing Spark's capabilities. We evaluated the drawbacks and advantages of adopting Spark in the gaming sector and offered suggestions for game creators wishing to embrace Spark for their data processing and real-time analytics requirements. Our study adds to the increasing body of knowledge on the use of Spark in the gaming sector and offers suggestions and insights for both game producers and researchers.**

Keywords—Riot games; Apache Spark; data processing; real-time analytics; distributed computing technology

I. Introduction

Riot Games, a prominent player in the online gaming industry since its inception in 2006, has achieved unprecedented success with its flagship game, League of Legends, which has garnered a staggering 100 million active players worldwide. The company faces the daunting task of managing and extracting insights from the massive volume of data generated by the game, which includes player behavior, gameplay patterns, and performance metrics.

To address this challenge, Riot Games has adopted Apache Spark, a cutting-edge distributed computing framework that efficiently processes large-scale data. The study [1] outlines the advantages of Apache Spark, such as its ability to handle both batch and streaming; data and its ability to seamlessly integrate with other big data tools. By utilizing Apache Spark, Riot Games can effectively process and analyze the vast amounts of data generated by League of Legends to derive insights that can be used to improve the game and enhance the player experience continuously.

Moreover, Apache Spark's in-memory processing capabilities allow for faster data processing and analytics, making it a suitable choice for Riot Games. In their research, [2] discusses the benefits of in-memory computing for data-intensive applications, such as online gaming. By leveraging Apache Spark's in-memory processing capabilities, Riot Games can process data more quickly and efficiently, allowing real-time analysis of player behavior and gameplay patterns.

In summary, Riot Games has harnessed the power of Apache Spark to effectively process and analyze the vast amounts of data generated by League of Legends. By doing so, the company can continuously improve the game and provide a better experience for its players. In this study, we propose to explore the use of Apache Spark in the gaming industry through a case study analysis of Riot Games.

The remaining sections of this study are organized as follows. In Section II, a detailed description about role of Hadoop framework in processing Riot games is discussed. Literature review is presented in Section III. Section IV describes various aspects of Riot game and its processing with big data. The suggested framework is provided in Section V. The conclusion of the paper is provided in Section VI.

II. Apache Spark in Riot Games

A. Apache Spark

Apache Spark is an open-source distributed computing framework that offers a fast and efficient method for processing large volumes of data. Developed by the Apache Software Foundation, Apache Spark has emerged as a popular alternative to Hadoop Map Reduce for big data processing, providing a more versatile and flexible interface. In their research paper, [1] outlines the advantages of Apache Spark, such as its ability to handle both batch and streaming data and integrate with other big data tools seamlessly. Apache Spark's scalability and fault tolerance capabilities make it ideal for processing large volumes of data, even during hardware failures or network disruptions. Additionally, its easy-to-use interface enables users to process data in various programming languages, including Java, Scala, and Python. In [3] discuss the advantages of using Apache Spark for large-scale data processing, such as its ability to perform iterative algorithms efficiently and its support for in-memory computing.

B. Hadoop

Apache Hadoop is an open-source distributed computing platform that enables the processing large-scale data sets using thousands of independent machines and large amounts of data.

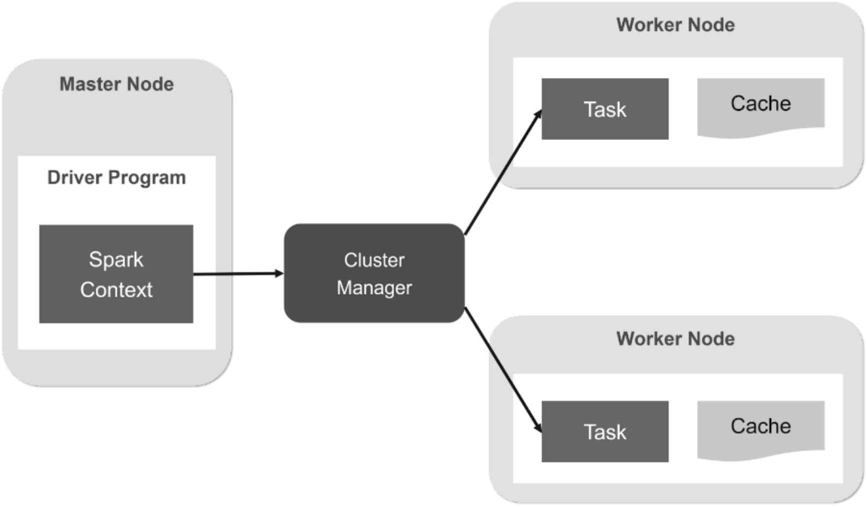

Fig. 1. Architecture of Apache Spark.

The platform includes a framework that offers tools for distributed processing, such as Hadoop Distributed File System (HDFS) for distributed storage and Apache MapReduce for distributed processing. Hadoop was initially based on Google MapReduce and the Google File System (GFS). Hadoop's distributed computing capabilities have made it popular for big data applications, such as social media analysis, predictive modeling, and machine learning. Its open-source nature and a large community of contributors have also contributed to its popularity. In their research, [4] describes HDFS's architecture and design, including its scalability and fault tolerance capabilities. The study [5] provides an overview of Hadoop's features and advantages for big data analytics, its limitations, and potential future developments. Fig. 1 shows architecture of Apache Spark.

C. Architecture of Riot Games

The architecture of Riot Games can be broadly divided into four main components, as described in [6]:

Game Servers: The game servers manage the game logic, handle player inputs, and update the game state. Riot Games uses a distributed server architecture, where multiple servers work together to run game sessions. This architecture allows for better scalability and fault tolerance, as the load can be distributed across various servers. If one server fails, the game session can be migrated to another server [7]. API Platform Architecture and High-level Architecture are shown in Fig. 2, and Fig. 3, respectively.

Matchmaking: Riot Games' matchmaking system pairs players together for games. The matchmaking system uses a complex algorithm to match players based on various criteria, such as skill level, playing history, and other factors. This ensures players are matched with opponents of similar skill levels, leading to more enjoyable gameplay experiences. As outlined in a [8], Riot Games' matchmaking system is continuously being updated and refined to provide the best possible experience for players.

Data Storage: Riot Games uses a variety of data storage solutions to manage the vast amounts of data generated by their games. This includes databases for player accounts and game data and distributed file systems for storing game assets like textures and sound files. As described in [9], Hadoop Distributed File System (HDFS) is used for processing and analyzing large volumes of data.

Game Clients: The game clients are the software that runs on players' computers or devices, allowing them to interact with the game servers. Riot Games' game clients are built using a combination of C++, Lua, and other technologies and are designed to be highly responsive and optimized for low-latency gameplay. As outlined in [10] developed a network optimization system called "Riot Direct" to improve network performance and reduce latency for players. Overall, Riot Games' architecture is designed to provide a scalable and fault-tolerant platform for their online games, ensuring that players enjoy seamless gaming experiences.

D. Apache Spark in Riot Games

Riot Games has effectively leveraged Apache Spark, an open-source distributed computing framework, for various data analysis tasks supporting their online game services. According to [11], Riot Games has utilized Apache Spark to analyze large volumes of data from their online game, League of Legends, to extract insights on player behavior, gameplay patterns, and performance metrics. The real-time processing capabilities of Apache Spark have enabled Riot Games to analyze player behavior and game performance in real time, allowing them to quickly identify and address issues that may impact the game experience. Furthermore, [12] shows that Riot Games has utilized Apache Spark to build machine-learning models that can improve game performance and player experience.

In addition, Riot Games has used the stream processing capabilities of Apache Spark to analyze real-time game data streams, helping the company quickly detect and respond to issues such as server downtime and player disconnects. This was demonstrated in [13], where Apache Spark was used by Riot.

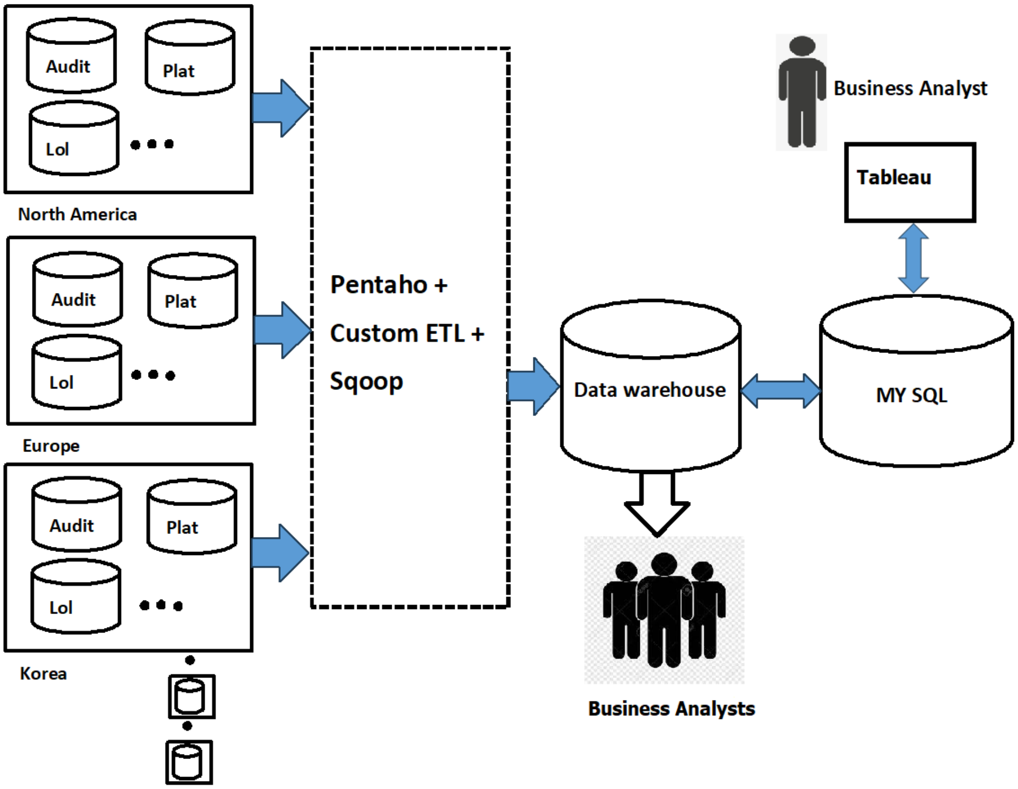

Fig. 2. Riot game data processing and analysis architecture.

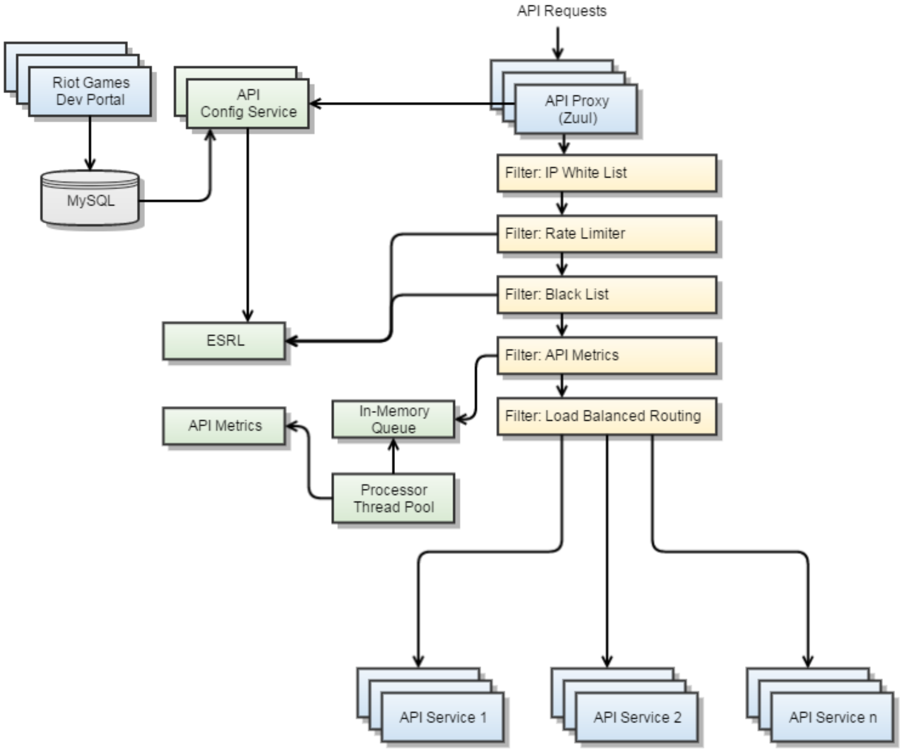

Fig. 3. API platform architecture [14].

(b)

Fig. 4. (a) Graphic settings [18], (b) Client-side logic view [18].

Games detect and diagnose network issues in real time, enabling them to respond and mitigate the issues quickly. Overall, Apache Spark has been a vital tool for Riot Games in analyzing and processing the massive volumes of data generated by their online games, enabling them to improve the gaming experience for players while maintaining the stability and reliability of their online game services. How Riot Games Reworked Its Software Infrastructure Using Open Source: Even under the best conditions, developing a software architecture supporting hypergrowth is challenging. Riot Games faced several obstacles last year, including the need for the company to switch from a traditional SQL database to Hadoop and to create better real-time monitoring tools.

Graphic Settings and Client-Side Logic are shown in Fig. 4(a) and Fig. 4(b), respectively [17], [18]. The company is behind the hugely well-liked online game League of Legends and has offices in Santa Monica and St. Louis. The game, released four years ago, currently boasts 32 million active players who play for over a billion hours each month. However, the game's craze was giving their software team fits. Barry Livingston, Director of Engineering at Riot Games, said, "It took us too long to gain insights into our software performance, and our database servers were sluggish." "You wouldn't think a five-year-old company would have legacy software issues, but we did because we have proliferated," he said in a July presentation at the St. Louis Stampede conference. For its data warehouse, Riot Games started with a monolithic SQL platform. It necessitated numerous manual, custom-coded procedures. Most of the reporting was done in Excel, and queries were developed in MySQL. Game screen is shown in Fig. 5 whereas, Fig. 6 shows the working of Database.

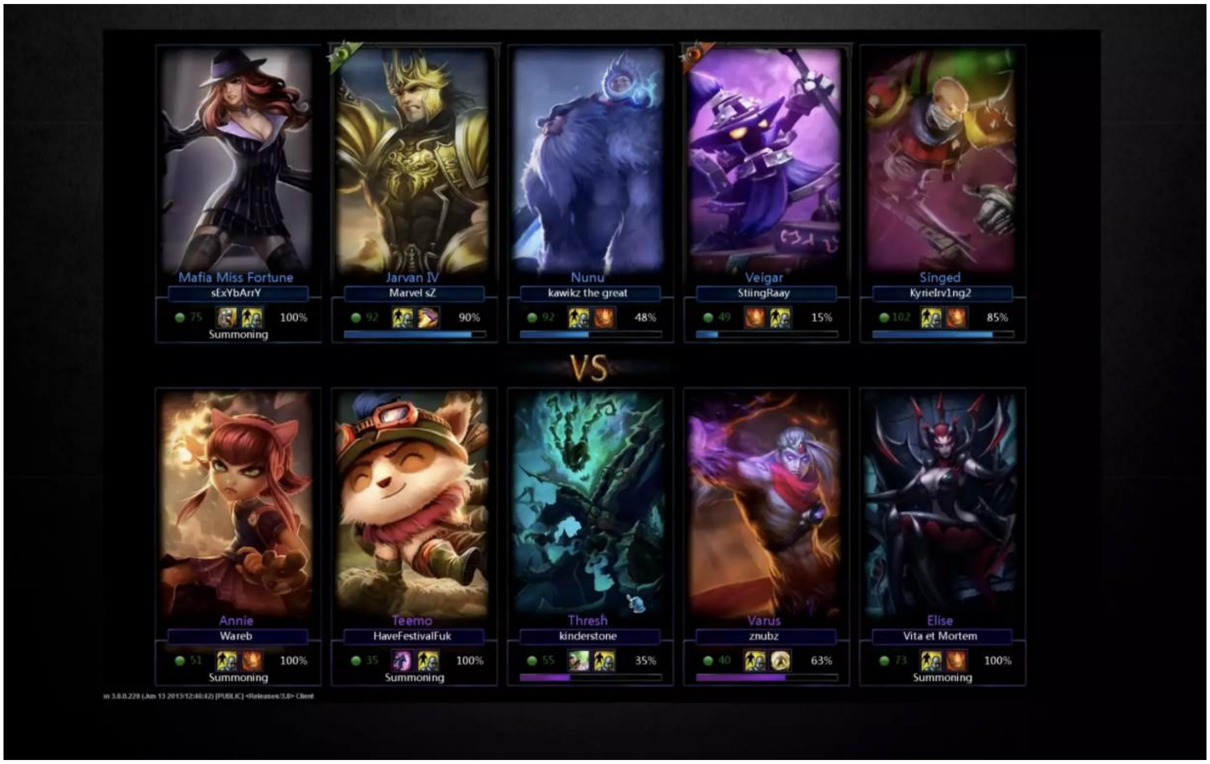

Fig. 5. Game screen.

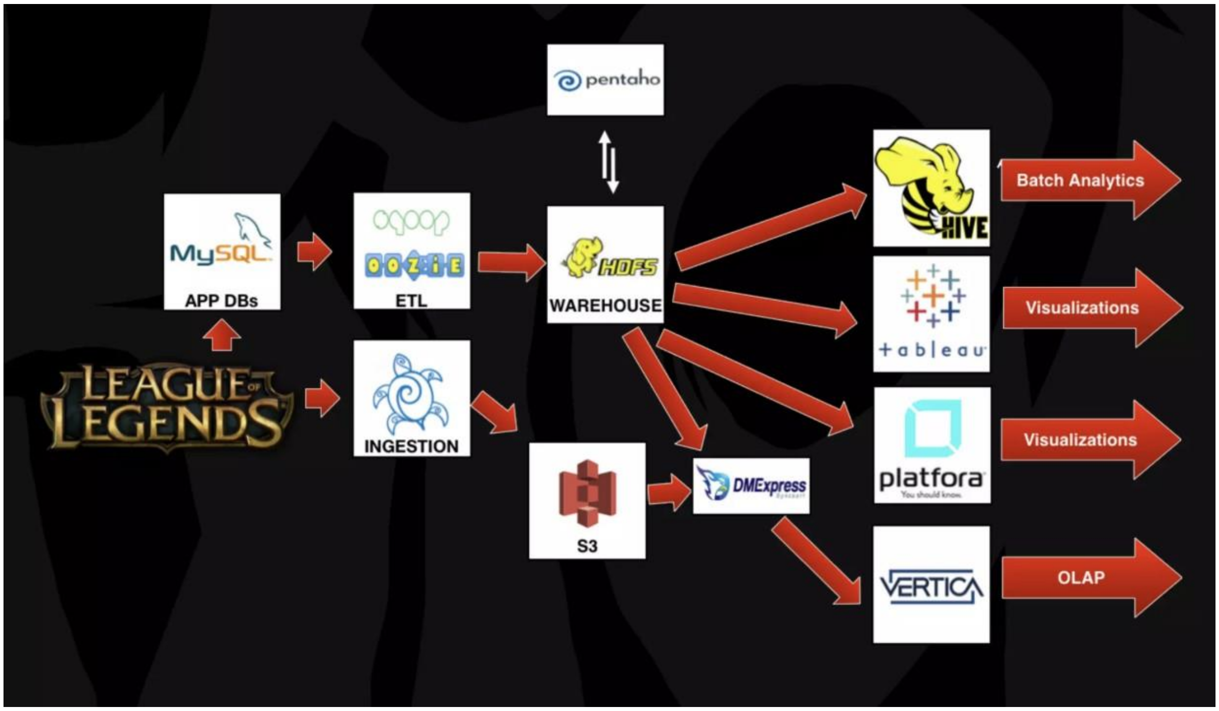

Fig. 6. Working of database.

Riot Games' senior employees concluded that they needed new software data architecture last year since they had reached a critical point. "The time to arrive at insights was taking too long, and ours. The solution required too many dev team members to make changes to our data schemas or other updates," the developer claimed. They also had two more objectives they sought to achieve. The first goal was to democratise data access by making player statistics and gameplay analysis available to a larger group of our workers. For our employees to more easily do updates and address issues, we also needed to produce meaningful insights about the game's underlying software components.

It was necessary to integrate Hadoop, a cloud-based data warehouse, and an end-to-end automated software development pipeline to improve the software infrastructure. The Hadoop transformation involved several add-on programmers and tools for different purposes:

- Honu: A pipeline for collecting streaming logs and processing events.
- Analysis and visualization of BI on Platfor Workflow job scheduler Oozie.
- Data warehouse and queries using Hive.
- Chef: Code distribution and configuration administration.
- Version control and Programme tracking of GitHub.
- Build system management with Jenkins Service discovery process, eureka.

III. Literature Review

Apache Spark is a distributed computing framework that has gained significant popularity in big data processing and analytics. It is known for its speed, scalability, and flexibility and has been widely adopted by companies across various industries. In particular, the gaming industry has been a significant adopter of Apache Spark due to its ability to handle large volumes of gaming data generated by millions of players worldwide.

Riot Games, the developer of the popular game League of Legends, is one such company that has adopted Apache Spark for its data processing and analytics needs. Riot Games has a massive player base generating vast amounts of data related to gameplay, user behavior, and other metrics. The ability to process and analyze this data in real time is essential to maintaining a high-quality gaming experience for players. Fig. 7 shows Riot with Spark & Hive [9].

In a case study [15], Riot Games discussed its implementation of Apache Spark for data processing and analytics. Riot Games used Spark to handle real-time data processing, providing insights into game server performance and player behavior. The company also used Spark's machine learning capabilities to develop predictive models that improved the gaming experience for players. Other studies have also demonstrated the effectiveness of Apache Spark in gaming data processing and analytics. For example, [16] used Spark to process and analyze massive amounts of gaming data generated by online games. Their study found that Spark could effectively identify user behaviors, preferences, and patterns, allowing game developers to improve game design and enhance the player experience.

Similarly, [17] used Spark to analyze user behavior data in mobile games. Their study demonstrated that Spark could be used to identify patterns in user behavior, helping game developers optimize game design and improve user engagement. The literature suggests that Apache Spark is a valuable tool for gaming data processing and analytics. Spark in Riot Games' data processing and analytics pipeline has enabled the company to handle large volumes of data in real time, identify issues quickly, and develop predictive models that enhance the player experience. Spark in the gaming industry has also been shown to be effective in identifying patterns in user behavior, optimizing game design, and improving user engagement.

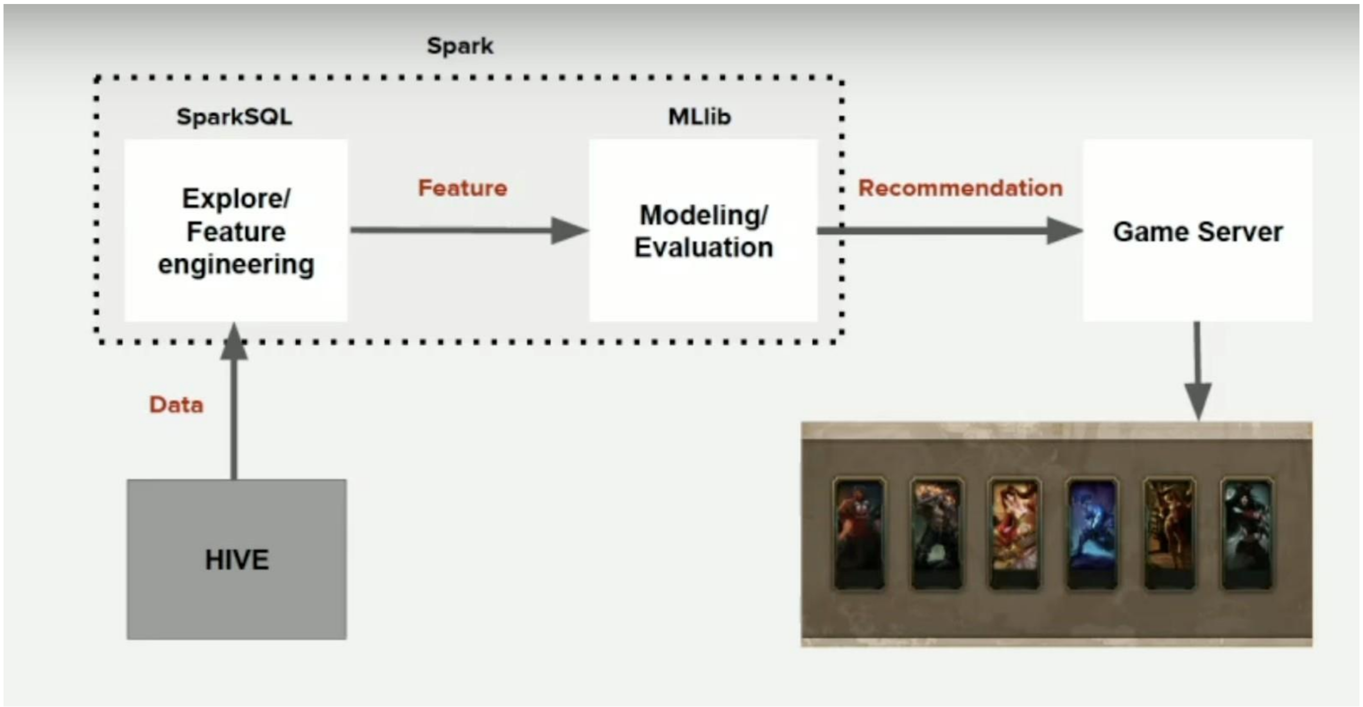

Fig. 7. Riot with spark & hive [9].

IV. Observation

This research paper explores the use of Apache Spark in the gaming industry, focusing on Riot Games. By analyzing a case study and reviewing the literature on the topic, we found that Spark is a powerful tool for handling extensive data generated by games and improving the player experience. Our analysis revealed that Spark's real-time data processing capabilities enable quick issue identification and predictive modeling, leading to more accurate decision-making and better user engagement. Furthermore, our literature review showed that Spark had been widely adopted in the gaming industry for data processing and analytics, with numerous studies demonstrating its effectiveness in identifying user behavior patterns and preferences, optimizing game design, and improving user engagement. Overall, our research provides valuable insights into the benefits of Apache Spark in the gaming industry, demonstrating its potential for data processing and analytics. The findings of this study can help game developers adopt Spark for their data processing and analytics needs, leading to a better user experience and improved business outcomes [19-21].

1) Problem definition: Riot Games encountered several data-related challenges, including: Massive data volume: The game generates a staggering amount of data, including player interactions, in-game events, and performance metrics, resulting in petabytes of data.

- Real-time processing: Riot Games required the ability to process and analyze data in real-time to derive actionable insights promptly.
- Scalability: Traditional data processing solutions struggled to handle the scale and complexity of Riot Games' data, leading to performance bottlenecks and increased processing times.
- Diverse data formats: The data generated by the game encompassed structured, semi-structured, and unstructured formats, making it challenging to handle with conventional tools.

2) PC variability: Hardware and OS profiles are significantlydifferent even with regions:

- OS and patch models
- CPU
- Memory
- Video Card(GPU)
- Video Card Memory
- Drivers

3) Client-side logic: The client-side logic of Riot Games' games is complex and varies depending on the specific game. However, The author can provide some general information about how client-side logic works in online multiplayer games like those developed by Riot Games.

At a high level, the client-side logic of online multiplayer games is responsible for managing the game state on the player's computer or device. This includes the player's position in the game world, health and mana levels, inventory and equipment, and any other relevant data. The client-side logic communicates with the game server, which is responsible for managing the game state for all players. The server sends updates to the client about the state of the game, such as the position of other players, the location of items, and the outcome of actions like attacks or spells.

4) Game load screen: Here are some potential ways that Riot Games could improve game load times:

- Optimize game assets: One way to improve load times is to optimize the game's assets, such as textures and models. By reducing the size of these assets without sacrificing quality, the game can load faster.
- Implement asynchronous loading: Asynchronous loading allows the game to load resources in the background while the player does something else. This can help reduce load times by allowing the player to start playing sooner.
- Use compression: Compressing game files can reduce their size, leading to faster load times. Riot Games could explore using compression algorithms like LZMA orZlib to reduce the size of game assets.
- Prioritize loading: Riot Games could prioritize loading critical assets required for gameplay, such as maps and character models. By loading these assets first, the player can start playing sooner.
- Improve network performance: Load times can also be affected by the quality of the player's internet connection. Riot Games could work to improve network performance by optimizing their netcode and using content delivery networks (CDNs) to reduce latency.

V. Suggested Framework

In this study, we propose to explore the use of Apache Spark in the gaming industry through a case study analysis of Riot Games. Our proposed work will involve the following steps:

1) Conducting a comprehensive literature review to identify the existing research on using Apache Spark in the gaming industry. This will involve reviewing academic papers, industry reports, and other relevant sources.

2) Collecting and analyzing data on Riot Games' use of Apache Spark for data processing and analytics. This will involve interviewing key stakeholders, reviewing internal documentation, and analyzing gaming data.

3) Identifying the key challenges and successes of using Apache Spark in the gaming industry. This will involve analyzing the impact of Spark on key performance indicators such as user engagement, revenue, and game design.

4) Providing recommendations for game developers looking to adopt Apache Spark for their data processing and analytics needs. This will involve identifying best practices and potential use cases for Spark in the gaming industry.

5) Evaluating the potential for Apache Spark to be used in other areas of the gaming industry beyond data processing and analytics, such as fraud detection and customer support.

Overall, our proposed work will provide valuable insights into the use of Apache Spark in the gaming industry, focusing on Riot Games. By conducting a case study analysis and literature review, we aim to provide practical guidance and recommendations for game developers looking to adopt Spark for their data processing and analytics needs. The findings of this study can help drive better decision-making and improved business outcomes in the gaming industry.

Method: Riot Games turned to Apache Spark, a robust distributed computing framework designed for big data processing and analytics, to address these challenges. Spark offers the following advantages:

- Speed and scalability: Spark's in-memory processing and distributed computing capabilities enabled Riot Games to handle large datasets with significant speed improvements over traditional batch processing systems.

- Real-time analytics: Spark Streaming, a component of Apache Spark, facilitated real-time data processing, enabling Riot Games to monitor and respond to in-game events and player interactions in near real-time.

- Fault tolerance: Spark's resilient distributed datasets (RDDs) ensured fault tolerance, enabling continuous processing and reducing the risk of data loss.

- Versatile data processing: Spark's support for various data formats, including structured (Spark SQL), semi-structured (Spark DataFrames), and unstructured (Spark Streaming), made it an ideal choice for handling Riot Games' diverse data requirements.

- Rich ecosystem: Spark's extensive library ecosystem, including machine learning (MLlib) and graph processing (GraphX), offered additional capabilities for advanced analytics and insights.

- Experimental work: Riot Games adopted a multi-phased approach to implementing Apache Spark, focusing on the following key areas:

- Data ingestion: Data from various sources, including game servers, user interactions, and telemetry, were ingested into a data lake using Apache Kafka and Apache Flume.

- Data processing pipeline: Apache Spark was integrated into the existing pipeline, leveraging its ability to handle batch and real-time streaming data processing.

- Data analytics: Spark SQL and Spark Data Frames were utilized to perform ad-hoc queries, generate reports, and extract valuable insights from the processed data.

- Machine learning: Spark's MLlib library was employed to develop and deploy machine learning models for player behavior analysis, fraud detection, and more.

VI. Conclusion

Our research paper examined the use of Apache Spark in the gaming industry, with a case study analysis of Riot Games. Our study showed that Spark could provide significant benefits to game developers regarding data processing and analytics, enabling them to gain valuable insights into user behavior and game performance. We identified the challenges and successes of using Spark in the gaming industry and provided recommendations for game developers looking to adopt Spark for their data processing and analytics needs. Our research contributes to the growing body of research on using Spark in the gaming industry, providing practical guidance and insights for game developers and researchers alike. With its well-liked games and burgeoning e-sports industry, Riot Games, a well-known video game developer, has a bright future. Providing speed and scalability for real-time analytics and machine learning applications, Apache Spark, a distributed data processing engine, is poised to play a significant role in the big data landscape.

***Abstract*—Authorship attribution (AA) is defined as the identification of the original author of an unseen text. It is found that the style of the author's writing can change from one topic to another, but the author's habits are still the same in different texts. The authorship attribution has been extensively studied for texts written in different languages such as English. However, few studies investigated the Arabic authorship attribution (AAA) due to the special challenges faced with the Arabic scripts. Additionally, there is a need to identify the authors of texts extracted from livestream broadcasting and the recorded speeches to protect the intellectual property of these authors. This paper aims to enhance the detection of Arabic authorship attribution by extracting different features and fusing the outputs of two deep learning models. The dataset used in this study was collected from the weekly livestream and recorded Arabic sermons that are available publicly on the official website of Al-Haramain in Saudi Arabia. The acoustic, textual and stylometric features were extracted for five authors. Then, the data were pre-processed and fed into the deep learning-based models (CNN architecture and its pre-trained ResNet34). After that the hard and soft voting ensemble methods were applied for combining the outputs of the applied models and improve the overall performance. The experimental results showed that the use of CNN with textual data obtained an acceptable performance using all evaluation metrics. Then, the performance of ResNet34 model with acoustic features outperformed the other models and obtained the accuracy of 90.34%. Finally, the results showed that the soft voting ensemble method enhanced the performance of AAA and outperformed the other method in terms of accuracy and precision, which obtained 93.19% and 0.9311 respectively.**

Keywords*—*Authorship attribution; acoustic features; fusion approach; deep learning; CNN; ResNet34

I. Introduction

As Authorship attribution (AA) refers to the process of identifying the authorship of a document that has not yet been seen, given a list of potential writers and a list of documents that have already been described and tagged by each potential author [1, 2]. AA can be seen as a classification problem, when the training is done on a given set of training texts of known authors (labels). Using a collection of characteristics taken from the text in the training set, we can identify the authors for the testing set. The main characteristics employed during the classifier's training are the style, sentiment, and subject [3]. The authors' individual writing styles are examined in order to extract the stylometry features. Although the writing style of the author might vary depending on the topic, certain persistent and unchecked habits, but the writing styles of the authors cannot be too different over the time [1]. Previously, the authors' attribution was conducted by hand to recognize the authors of unseen texts, but with the huge amount of the texts available online, it is hard to perform this task manually. Several studies addressed this issue in the literature such as [4].

Different statistical and machine learning-based techniques were recently applied on AA [4]. These techniques included Naive Bayes [5, 6], Support Vector Machine (SVM) [7–12], Bayesian classifiers [13], k-nearest neighbor [14, 15], and decision trees [16]. The authorship attribution for texts written in English, Spanish and Chinese has been studied well in the literature; however, less attention was given to the texts written in Arabic because of the complexity of Arabic scripts [17].

To address the Arabic authorship attribution (AAA) issues, several machine and deep learning methods have been applied. For instance, Al-Sarem et al. [17] applied the ensemble machine learning methods with multi-attribute decision making method (TOPSIS) that identifies the base classifier on two Arabic enquires (Fatwa) datasets. The findings showed that AdaBoost and Bagging methods achieved the highest accuracy for the two used datasets. Similarly, Al-Sarem, Alsaeedi, and Saeed [18] applied deep learning-based methods for AAA. The findings showed that the performance of deep learning method outperformed the state-of-art methods.

A recent study by Alqahtani and Dohler [19] reviewed the authorship attribution for Arabic texts. They found that the findings of AAA tasks vary based on the used dataset and features. Also, it was found that few challenges were faced when dealing with pre-processing of Arabic texts because of the scripts' concatenative morphology. For Arabic scripts, all the datasets presented in the previous studies were in texts format and the majority of the currently published studies rely on machine learning techniques. Few studies have previously examined the effectiveness of deep learning for AAA tasks. Therefore, the purpose of this study is to address this gap by examining how deep learning techniques can be used for enhancing Arabic authorship attribution detection. In addition, to the best of our knowledge, we found that no previous studies investigated the authorship attribution of texts extracted from livestream broadcasting and the recorded Arabic speeches. Therefore, the main contributions of this paper are:

- Scraping data from livestream weekly livestream Arabic sermons as well as the recorded sermons and available publicly on the official website of Al-Haramain in Saudi Arabia (https://www.alharamain.gov.sa/ last access: May 8, 2023).
- Extracting acoustic features and stylometric features directly from the livestream broadcasting and the recorded mp3 files.
- Combining the extracted features using different fusion approaches and Applying different deep learning models for AAA.
- Conducting a rigorous analysis on the applied DL models in terms of different performance evaluation metrics.

This paper is organized as follows: Section II gives an overview of the state-of-the-art methods for detecting authorship attribution. The description of the proposed model's architecture can be found in Section III. Section IV describes the research methodology, including the dataset, preprocessing methods, evaluation metrics, experimental design, and evaluation process. The experimental results were presented in Section V. In Section VI, we summarize the contributions and conclude the paper.

II. Related Studies

Several studies addressed the authorship attribution for Arabic language. For instance, Jambi et al. [20] investigated the feasibility of predicting authorship in Arabic short-microblog content using modern classifiers. To forecast the accuracy of the chosen classifiers, they used three frequently language features—character, lexical, and syntactic—in an incremental approach. Another developing area of machine learning is deep learning, which performs better than classical machine learning in several areas [21] and does not need the use of feature engineering. Although authorship attribution has been a topic of discussion in different languages such as English [22], German [23], Spanish [24], and Chinese [25], only a few studies have specifically addressed the authorship attribution in the context of Arabic [16].

Different deep learning models have been studied in the literature, including the Deep Belief Network (DBN), Convolutional Neural Network (CNN), Recurrent Neural Network (RNN), and Long Short-Term Memory (LSTM). Deep neural networks have recently been used to build authorship attribution systems [26–29]. Usually, input for neural networks takes the form of a list of words or a string of letters. Most techniques focus on lexical aspects, even though lexical-based language models are not scalable when dealing with authorship covering a range of themes [30, 31]. The syntactic features are based on content, more robust, and effective against topic volatility. Sari et al. [26] utilized continuous representation via a neural network together with a classification layer to determine the authorship. In [32], the IMDB62 dataset was used and 94.8% accuracy rate was achieved. According to [30, 33], CNN model was used for authorship identification. They tested their approach using a variety of text data, including emails, reviews, blogs, and tweets, and they were able to get outstanding accuracy scores between 85.0% and 95.0%. The authorship-attribution problem of brief postings was addressed by Shrestha et al. [28] using CNN based on a string of character n-grams. They assessed their methodology using the dataset shown in [34].

To address the issue of authorship attribution, Hitschler et al. [35] used a single author from an anthology reference corpus [36] using POS tags and CNN approach. To achieve proper results from a corpus of scientific papers, they replaced unusual terms with their POS tags in order to create a better generalization. The researchers in [37] used a number of embedding structures based on character, word, n-gram, and POS tags in a CNN model to accurately identify the writing styles used by authors of tweets and posts on Weibo and Twitter. Zhang et al. [29] proposed to encode the syntax parse tree of phrases which contributed towards addressing the authorship attribution problem. By combining lexical characteristics and CNN, they were able to achieve accuracy results of 96.16%, 81.00%, and 56.73% on the IMDB62, CCAT50, and Blogs50 datasets, respectively. Jafariakinabad and Hua [30] used similar datasets and achieved accuracy values of 73.83% and 82.35% on the Blogs50, CCAT50 datasets, respectively, by encoding the syntactic and semantic structures of sentences in texts, and employing a hierarchical neural network based on attention. In [38], a large corpus of blogs with author-provided demographic information was used to study how writing style and content vary by age and gender. It identifies significant differences in vocabulary use and topics among different groups and shows how they can be used for authorship attribution. Moreover, Murauer and Specht [39] applied multiple well-established pre-trained language models to reach better generalization outcomes on the authorship attribution problem. Specifically, they employed variety of language models such as bidirectional encoder representations from Transformers (BERT) [40], a pre-trained general-purpose language representation of DistilBERT [41], and a robustly optimized BERT pre-trained model (RoBERTa) [42] on a large number of extremely diverse authorship-attribution datasets.

Post-authorship attribution is an unresolved research issue because of the numerous inherent uncertainties that text snippets present. On the foundation of a convolutional neural network, a technique for character-level authorship identification was suggested by Modupe et al. [43]. The suggested approach can effectively extract lexical, syntactic, and structural representations from a given post to determine the authorship of dubious materials. Four benchmark experimental datasets were used to compare the performance of this approach to thirteen state-of-the-art approaches.

A character-level RNN was used by Bagnall [44] to model the language of each author in the training set received from the PAN 2015 author verification problem [45]. Additionally, Shrestha et al. [46] used a three-layer CNN model to determine who posted a tweet. The suggested model was used at the character level since tweets are generally brief in duration. Furthermore, a hierarchical attention-based neural network was also employed by Verma and Srinivasan [47]. The semantic and syntactic structural features are extracted and encoded using the suggested model. Next, document representations were created by combining these features. They used a collection of convolutional layers in their attention-based model to represent a phrase at the word level. While the structural patterns were recorded using an attention based RNN. Moreover, RNN was used by Jafariakinabad et al. [48] to identify a document's syntactic patterns. They used various combinations of DL models to explore both long-term and short-term dependency (POS) tags in phrases. They concluded that the LSTM-based POS are faster than CNN-based POS in capturing the authorial writing style of short texts. Further, Rhodes [49] investigated the effectiveness of the CNN model using a dataset that included 28 English novels written by 14 writers and eight English books written by six authors, both taken from the PAN2012 Authorship Identification competition. The model was used at the sentence level and achieved an accuracy rate of 76% for the books dataset and 20.52% for the PAN2012 English novels.

Ruder et al. [50] examined how different CNN setups affected the impact of attributing various post types. The best performing technique was a character-level CNN, which were compared to other conventional approaches. In addition, a feedforward neural network language model was applied by Ge et al. [51] to train a classifier to attribute a dataset with only a little amount of data. In comparison to n-gram baselines, the model trained a representation for each word using a window of four grams and achieved an accuracy of 95%.

According to the conducted review of the literature, there are few state-of-the-art techniques for identifying Arabic language writers, especially for the text extracted from livestream broadcasting and the recorded speeches. Most of the existing studies investigated the machine learning methods for AAA. Therefore, this study aims to investigate how to apply deep learning for solving Arabic authorship attribution using religious texts extracted from livestream broadcasting and recorded speeches. The dataset was collected from the official website of Al-Haramain for several authors (scholars) in Saudi Arabia.

III. Proposed Approach

As mentioned earlier, this paper aims to enhance the performance of the authorship attribution detection. For this purpose, a combination of acoustics and stylometric features were extracted and combined, and deep learning methods were applied. Generally, the proposed approach consists of the following stages: feature extraction, data preprocessing, detection and classification, and ensemble learning-based techniques.

Fig. 1 shows the overview of the proposed approach used for extracting the required features and applying the classification. The full description of the proposed approach stages are given in the subsections.

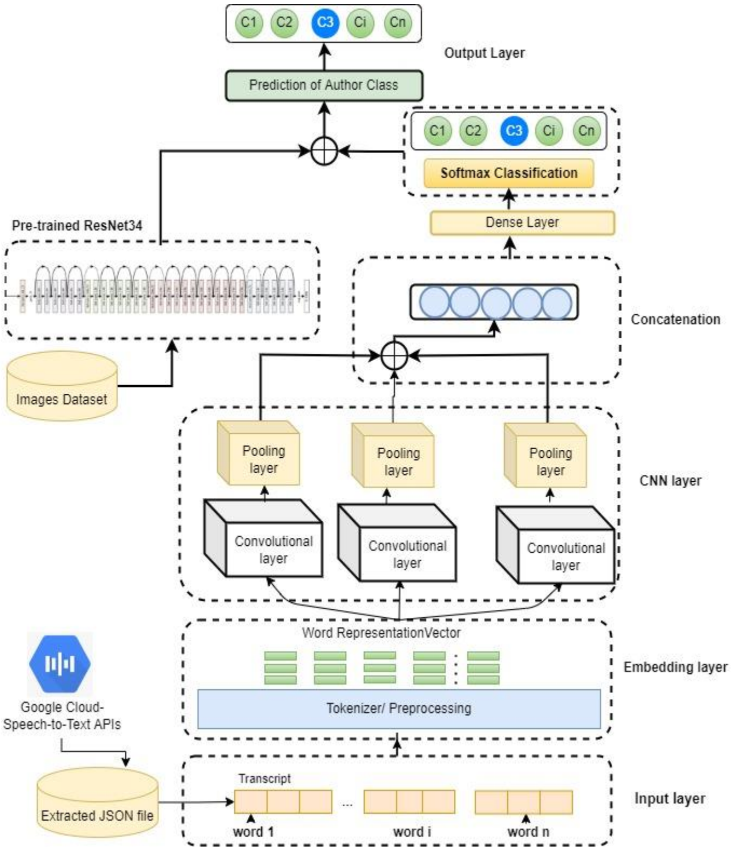

Fig. 1. The proposed approach for detecting the class of authors.

Cloud Function (Transcribe speech to text)
Cloud Storage (Transcription files in JSON)

Fig. 2. Transcription speech to text within Google Cloud storage. The process shows two scenarios: (i) the video files and (ii) audio files.

A. Extraction Stage

In this stage, a set of acoustic features, textual and stylometric features are extracted from the weekly live stream of Arabic sermons and the recorded speeches in mp3 files that are available publicly on the official website of Al-Haramain. We collected the dataset from this source because the Modern Standard Arabic (Fusha) is used in all sermons' texts and recorded speeches. The google cloud APIs were used to extract audio files from the livestream videos and to transcribe speech to text.

The final transcription is stored in JSON format and then passed to the next stages. Fig. 2 shows the process of extracting the acoustics and stylometric features using google cloud APIs. The process of extracting the raw textual data from the audio file after converting it to FLAC format is summarized in Algorithm 1. Also, Table I shows a fragment of JSON file obtained as the output of the Google cloud API and the JSON request file fired in Google cloud. For determining the SampleRateHertz of an audio file, we used Apache Tika tool[1].

Algorithm 1: Extraction textual data from audio files

```
    Input: livestream Arabic sermons $ArS$ ; recorded mp3 files $AudioF$
    Output: JSON file
Initialize: FileMetadata= [] // empty list
For (every $ArS$ and $AudioF$) do
        ConvertToFlac( )  // convert file to FLAC format
        FileMetadata ← GetMetadata() // get file metadata including
                                     // SampleRateHertz by
                                     // Apache Tike tool
        JSON_file = ConstructJSON (FileMetadata)
        End
    Return JSON_file
```

B. Data Preprocessing

1) Preprocessing the textual data: Before feeding the raw textual data into the proposed DL model, a set of preprocessing techniques were applied. This is a necessary step to enhance the quality of the DL model. AL-Sarem et al. [52] investigated the importance of the preprocessing techniques in increasing the performance of ML models. The preprocessing phase includes data cleansing techniques, stemming and tokenization techniques. In terms of the used cleansing techniques, since the textual data is obtained directly from the JSON files that were generated by the Google speech-to-text APIs, the only necessary steps are fixing the spelling errors, stop word removal, and completing the words that might truncated due to the non-complete video frame splitting (this is because the video frames had a fixed length and we set them to 30 second per a frame). In addition, we performed the stemming process using the porter stemmer as recommended in [53].

2) Preprocessing the audio files: We treated the audio files as the source for obtaining the acoustic features such as waveforms, spectrogram, spectral roll-off and chroma features. The audio waveforms are represented as spectrograms, which depict the intensity of a signal over time at various frequencies. Fig. 3 to 6 show a sample of waveform, spectrogram, spectral roll-off and chroma images that were obtained when we passed the same sliced audio signal to the acoustics feature extractor.

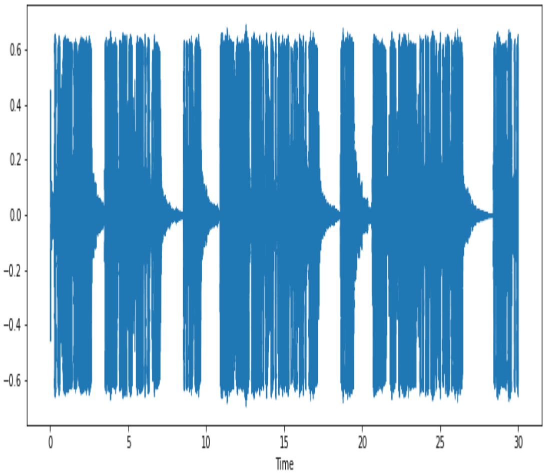

Fig. 3. Wave form that was obtained from the sliced audio signal.

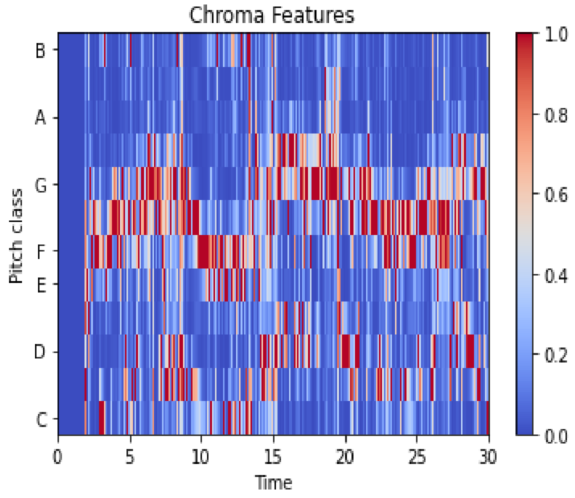

Fig. 6. Chroma that was obtained from the sliced audio signal.

C. Detection and Classification Stage

For the detection and classification stage, the textual data that were extracted as JSON file by the google speech-to-text APIs and prepared at the second stage were fed into the deep learning-based models. DL-based techniques possess the main advantage that no feature engineering is needed [54, 55]. In the training phase, DL classifiers extract and obtain useful features from the input data directly. In this section, we described the models that were applied in this study such as CNN architecture and its pre-trained ResNet34. In addition, this section explains how we used multi-input word embedding as a text representation. For the acoustic features, the pretrained ResNet34 model was fine-tuned and trained using the spectrogram images dataset obtained from the audio files. Then, the outputs of both models (multi-input CNN-based models and the pre-trained ResNet34 model) were combined. Finally, different ensemble methods were used to obtain more accurate results.

1) Multi-input word embedding model: The concept of word embedding (WE) refers to a technique of a text representation in which words having the same meaning are represented similarly. *Word2vec*, *GloVe*, and *FastText* are some recent word-embeddings that are commonly used with ML and DL models. In the proposed multi-input channel CNN model, we used the *Keras* embedding layer. The proposed model processes textual data in three channels with four, six, and eight grams of input. The word-embedding vector has an output dimensions size of 100 with a maximum length of sequences (input length) computed directly from the input textual data.

2) Architecture of the proposed CNN model: As shown in Fig. 1, the word embedding layer was connected to three parallel CNN blocks. Each block (channel) composes of the following:

- The length of input sequences.
- A layer of embedding set with 100-dimensional real-valued representations.
- A convolution layer with 32 filters and a kernel size set to the number of words to be read simultaneously.
- Max Pooling layer to consolidate the output from the convolutional layer.
- Flatten layer to reduce the dimensional output before concatenation phase.

Finally, we concatenated the output from the three channels into a single vector and processed it through a dense layer and an output layer. Table II summarizes the configuration of each CNN block.

TABLE II. CNN LAYERED ARCHITECTURE

CNN Block	Output Dimension	Kernal Size	Filter	Dropout Rate	Activation Function
Block No. 1	100	4	32	0.5	relu
Block No. 2	100	6	32	0.5	relu
Block No. 3	100	8	32	0.5	relu

3) ResNet34 model: ResNet34 model is an image-based pre-trained CNN model with 34 convolution layers, one *MaxPool*, and one average pool layer. Unlike the CNN-based models which commonly experience vanishing gradients during backpropagation, the skipping connections in the ResNet34 [56] are used to solves this issue.

As shown in Fig. 7, the first convolutional layer in ResNet34 model has filter with kernel size of 7x7 followed by a *MaxPool* layer (the stride is set to 2, which is indicated as "/2" in the Figure). Next, a group of convolution layers were connected using skip connection which is jumping every two layers. The layer of the first group (colored in grey) has kernel size of 3×3 and filters of 64. This layer is repeated three times and layered between the *MaxPool* layer and the layers of the second group. The layers of the second group have filter of 128 and *Kernal* size of 3x3 and these are get repeated on this time four times keeping the same skip connection length. In this manner, we continue until we reach the *avg_pooling* and *softmax* functions. Each time, the number of filters gets doubled.

4) Ensemble learning-base fusion strategies: Ensemble learning is a technique for merging the outputs of different ML models to improve the overall performance [57-59]. The empirical results show that when different ML/DL models work together, the performance is improved compared to the performance of standalone single model. Armed with this concept, two ensemble learning strategies: the hard voting and soft voting were implemented to combine the output of the multi-input channel CNNs models and the ResNet34 model.

a) Hard voting approach: The hard voting approach follows the majority voting concept in which a class with the most n votes is considered as the final output class. In general, each classifier $\mathrm{c} \in \mathbb{C}$, makes its own prediction, and a vector size of n store the results, where n is the number of classifiers that participate in voting pool: $[\mathrm{C}_1\ (\mathrm{x}), \mathrm{C}_2\ (\mathrm{x}), \dots, \mathrm{C}_\mathrm{n}(\mathrm{x})]$. The output class y, is then, predicted by applying the formula presented in Equation (1).

$$y = mode[C_1\ (x), C_2\ (x), \dots, C_n(x)] \quad (1)$$

b) Soft voting approach: Unlike the hard voting, soft voting determines the output class by projecting probability p of all classifiers [57]. Then, the average probability is computed for each class as follows:

$$P_{max}(i_n|x) = \frac{1}{n}\sum_{k=1}^{n} Pm_k\ (i_j|x)$$

$$Y\ =\ argmax[Pmean\ (i0\ |x), \dots, Pmean\ (ij\ |x)]$$

Then, taking into consideration the greatest probability, the output class y is determined according to the formula in Equation (2) as follows:

$$y = argmax[P_{max}(i_0|x), P_{max}(i_1|x), \dots, P_{max}(i_n|x)] \quad (2)$$

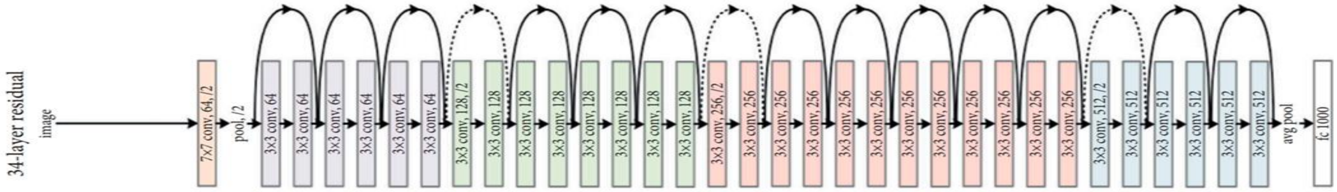

Fig. 7. ResNet34 model architecture, "skip connection" among the layers was depicted as a black curved arrow.

IV. EXPERIMENTS

This section presents and analyses the finding results of the proposed model and the ensemble learning-based fusion techniques that applied to dataset of textual and acoustic-based features.

A. Experimental Setup

In this study, an Intel(R) Core (TM) i9-10980HK CPU @ 2.40 GHz and an NVIDIA GeForce MX graphics card run on Windows 11 with 32 GB RAM to implement the proposed methods. All the tested DL models were encoded using Python 3.9 using the *Jupyter* Notebook (available online: https://jupyter.org). It is also provided by Anaconda distribution (available online: https://www.anaconda.com). In addition, we employed the open-source *PyTorch* library (available online: https://pytorch.org) to implement the ResNet34 and tune the multi-input channel CNN models. Since the main aim of the proposed model is to enhance the performance of classifying the authors of Arabic scripts and live stream or recorded Arabic sermons, a set of different DL architectures over 35 epochs was trained. Later, we compared the performance of these models to the proposed model. In addition, the models applied the Adam optimizer and the cross-entropy loss function at 1e-3 learning rate. The Spectrogram images of the audio signal with size of (224 × 224) pixels and batch size of 64 were used for training the ResNet34. Table III summarizes the hyperparameters used for models training.

TABLE III. CONFIGURATION PARAMETERS OF THE RESNET34

Parameters	Values
Epochs	35
Batch Size	64
Learning rate	1e-3
Optimizer	Adam Optimizer
Spectrogram image size	(224x224)
Loss function	Cross-entropy

B. Dataset

As mentioned earlier, the dataset was scrapped directly from the official website of Al-Haramain in Saudi Araiba (https://www.alharamain.gov.sa/) and its official YouTube channel (https://www.youtube.com/watch?v=o5tC9aWaQ80/*).*

The size of scrapped data was about 2 GB. Table IV shows some statistical characteristics of the dataset. Since the dataset is imbalanced in terms of number of videos (see Fig. 8), we assumed a Gaussian distribution over the candidate authors.

In addition, the dataset contains 14,912 spectrogram images size of (224x224) representing five distinct classes. In the experimental part, we split the dataset into 70% for training, 20% for validation, and 10% for testing.

TABLE IV. SOME STATISTICAL CHARACTERISTICS OF DATASET

Author	No. of videos	Average video length in (Min)	Total Size in (MB)
AAl AlShaikh	42	18.24	344
Ahmed Hameed	20	15.38	153
Albaejan	43	17.32	308
Alhudaify	68	24.55	775
AlQaseem	49	20.46	482

C. Performance Metrics

For any classification problem, the performance of ML and DL models can be evaluated by computing the classification accuracy, precision, recall, and F1 score. In this paper, to precisely assess the proposed method, the experiments were conducted and validated using 5-fold cross-validation method. The confusion matrix (refer to Table V for more details) is presented to demonstrate how the statistical metrics (accuracy, precision, recall, and f1-score) can be computed.

$$Accuracy = \frac{TP+TN}{TN+FP+FN+TP} \quad (3)$$

$$Precision = \frac{TP}{TP+FP} \quad (4)$$

$$Recall = \frac{TP}{TP+FN} \quad (5)$$

$$F1 - score = \frac{2*Precision*Recall}{(Precision+Recall)} \quad (6)$$

TABLE V. CONFUSION MATRIX

	Predicted Negative	Predicted Positive
Actual Negative	True negative (TN)	False positive (FP)
Actual Positive	False negative (FN)	True positive (TP)

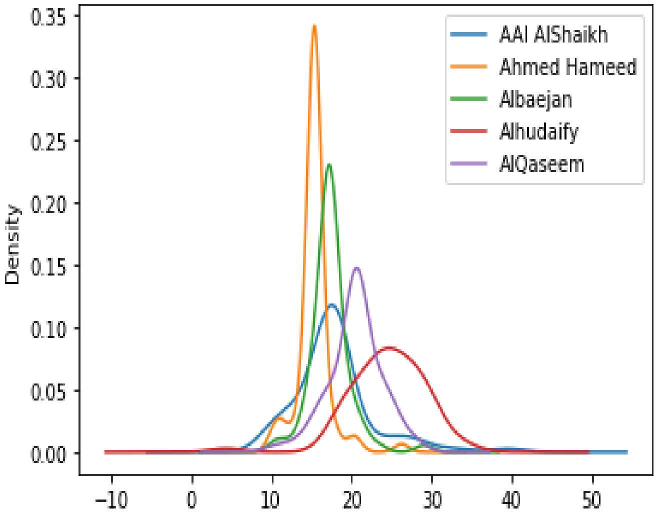

Fig. 8. Distribution of video length as per an author class.

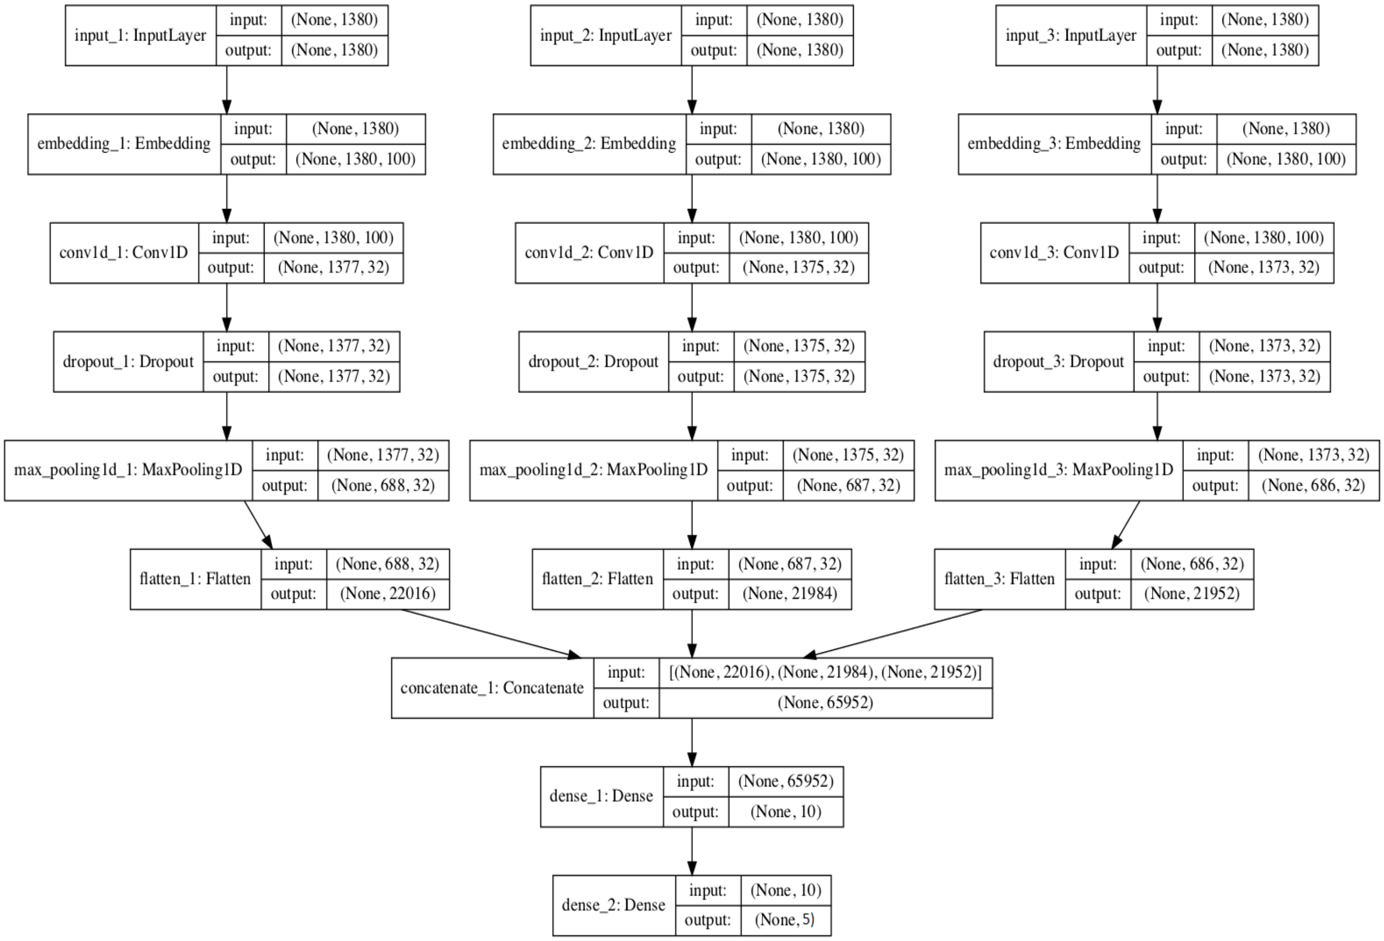
V. RESULTS

The subsections below summarize the findings of the experiments performed on the used dataset. We first presented the results obtained by employing only the extracted textual data. Then, the performance of ResNet34 model was highlighted. Later, we showed the results of fusing both features using the two fusion strategies. It is important here to mention that the results presented in the following subsections are the average value of each experiment that was repeated five times independently.

A. Evaluation with Textual Data

To show the impact of the proposed CNN model with multi-input channels, different kernel size input layer was implemented. Table VI shows the performance of the CNN model with different input channels. The results of CNN model with the multi-input channel are highlighted at the bottom of the table. In addition, the structure of the proposed CNN model with multi-input channel is depicted on Fig. 9.

The results show that the use of textual data yields an acceptable performance in terms of all measuring metrics. However, when the CNN model was restructured and the multi-input blocks were added to the original CNN model, a notable improvement was observed in terms of all metrics which encourage us to keep this structure and test it after the fusion with ResNet34 model.



input_1: InputLayer | input: (None, 1380) | output: (None, 1380)
input_2: InputLayer | input: (None, 1380) | output: (None, 1380)

Fig. 9. Architecture of the proposed CNN model with the multi-input channel.

TABLE VI. THE PERFORMANCE OF CNN MODELS WITH DIFFERENT INPUT CHANNELS

CNN model	Accuracy	Precision	Recall	F1-Score
Block No. 1	85.26%	0.856	0.853	0.853
Block No. 2	85.10%	0.851	0.851	0.851
Block No. 3	85.42%	0.856	0.854	0.854
The proposed Model	**86.57%**	**0.864**	**0.861**	**0.861**

B. Evaluation with Spectogram Images

The acoustic features that were extracted from the audio files are fed into the ResNet34 model. As we mentioned earlier, several acoustic features can be extracted as images from each audio file such as waveforms, spectrogram, spectral roll-off and chroma features. The spectrogram-based images were used. To illustrate the performance of *ResNet34*, two other pretrained DL models were also implemented namely *Xception* Model [60] and VGG-19 model [61]. Table VII shows the performance of the deployed DL models achieved when the spectrogram images were used as a training set. The results show that the *ResNet34* model overcomes other models and yields accuracy of 90.34%, and 0.903, 0.899, and 0.901 in terms of precision, recall, and F1-score respectively.

TABLE VII. PERFORMANCE OF CNN-BASED MODELS USED IN THIS PAPER

CNN model	Accuracy	Precision	Recall	F1-Score
VGG19	79.12%	0.789	0.801	0.795
Xception	85.31%	0.850	0.860	0.850
ResNet34	**90.34%**	**0.903**	**0.899**	**0.901**

C. Fusion Model

In the previous subsections, the experimental results proved superiority of multi-input channel CNN model and ResNet34 model in detection and classification the authors' class using the textual data and the acoustic-based features. The next step is to examine the impact of fusing both models using various learning strategies. Both the hard and soft voting approaches have been investigated. Table VIII presents the performance results of the proposed model with respect to the used ensemble learning strategies.

TABLE VIII. PERFORMANCE RESULTS OF THE PROPOSED MODEL WITH RESPECT TO THE ENSEMBLE LEARNING STRATEGIES

Ensemble Learning	Accuracy	Precision	Recall	F1-score
Hard voting	92.75%	0.9258	**0.9287**	0.9272
Soft voting	**93.19%**	**0.9311**	0.9271	**0.9291**

In addition, the results show the superiority of the combined models over the individual models. The results show that soft voting approach clearly outperforms the hard voting approach in terms of accuracy and precision and both approaches obtained similar results in terms of recall and F1-score. As a result, the soft voting approach is the recommended assembling strategy.

VI. CONCLUSION

This study proposed an Arabic authorship attribution approach that includes five main stages: feature extraction, data preprocessing, detection and classification, and ensemble learning-based fusion strategies. In the first stage, a set of acoustic, textual and stylometric features were extracted from different Arabic live stream sermons and recorded Arabic speeches files for five authors. In the data preprocessing, several techniques were applied for data cleansing, stemming and tokenization. The audio waveforms were represented as spectrograms, which depict the intensity of a signal over time at various frequencies. Next, in the detection and classification stage, the extracted data were fed into the deep learning-based models (CNN architecture and its pre-trained ResNet34). Then, hard and soft voting ensemble methods were applied for combining the outputs of the applied models to improve the overall performance. The experimental results showed that the use of textual data with CNN yields an acceptable performance in terms of all evaluation metrics. Then, when the acoustic features were extracted from the audio files and fed into the ResNet34 model, the results show that the ResNet34 model overcomes other models and yields accuracy of 90.34%, and 0.903, 0.899, and 0.901 in terms of precision, recall, and F1-score respectively. Finally, when the outputs of the multi-input channel CNNs models and the ResNet34 model were combined using hard and soft voting ensemble methods, the results show the superiority of the combined models over the individual ones. The results show that soft voting approach clearly outperforms the hard voting approach in terms of accuracy and precision (93.19% and 0.9311 were obtained respectively). Future works can investigate the application of the proposed model on different datasets and apply different CNN architectures and pre-train models. Different fusion methods can be applied and lead to obtain more enhancements for the detection of AAA.

ACKNOWLEDGMENT

The authors extend their appreciation to the Deputyship for Research & Innovation, Ministry of Education in Saudi Arabia for funding this research work through project number IFP-IMSIU202106.

FUNDING

This research is funded by the Deputyship for Research & Innovation, Ministry of Education in Saudi Arabia through project number IFP-IMSIU202106.

CONFLICTS OF INTEREST

***Abstract*—A speech-music classification method according to a developed neural system and beat spectrum is proposed to achieve accurate classification of speech-music through pre-emphasis, endpoint detection, framing, windowing and other steps to preprocess and collect vocal music signals. After fast Fourier transforms and triangle filter processing, the Mel frequency cepstrum coefficient (MFCC) is obtained, and a discrete cosine transform is performed to obtain the signal MFCC characteristic parameters. After calculating the similarity of feature parameters through cosine similarity, the signal similarity matrix is obtained, based on which the vocal music beat spectrum is obtained. The residual structure is optimized by adding Swish and max-out activation functions, respectively, between convolutional neural network layers to build residual convolution layers and deepen the number of convolution layers. The connected time series classification (CTC) is used as the objective loss function. It is applied to the softmax layer to build a deep optimization residual convolutional neural network for speech-music classification model. The pitch spectrum of vocal music is used as the input information of the model to realize the vocal music classification. The experiment proves that the classification accuracy of the design model is higher than 99%; when the iteration reaches 1200, the training loss approaches 0; when the signal-to-noise ratio is 180dB, the sensitivity and specificity are 99.98% and 99.96%, respectively; the accuracy of voice music classification is higher than 99%, and the running time is 0.48 seconds. It has been proven that the model has high classification accuracy, low training loss, good sensitivity and special effects, and can effectively achieve the classification of speech-music.**

Keywords—Vocal music; classification model; beat spectrum; feature parameter extraction; cosine similarity; convolutional neural network

I. Introduction

With the rapid development of the network and computer field, multimedia information such as audio and video has gradually become the mainstream of information. Audio media is the most important media form besides visual media, accounting for over 20% of the total information [1]. Faced with the huge scale of media databases and the large amount of audio content generated by users daily, it is also difficult for people to find the information they want [2]. The traditional text-based conventional information retrieval technology has been unable to meet the users' retrieval requirements, so how to effectively retrieve this information is a critical error to be resolved. Audio classification is an effective means to achieve rapid audio information retrieval [3]. Speech and music are two of the most common signals in audio. The classification of speech and music signals not only plays an important role in audio retrieval but also plays an important role in speech recognition, beat tracking and other fields [4]. For instance, in speech signal processing, first, determine the type. If it is a speech type, the following steps can evaluate the language, gender, etc. [5]; If it is music, the following steps can evaluate the music type, beat tracking, etc. [6]. This shows that the classification of voice and music is very important, and accurate classification can set a solid base for the next retrieval and other work.

In recent years, many scholars at home and abroad have done a lot of research on audio classification issues, such as vocal music, and have made certain research achievements. For example, Sun HF et al. [7] proposed a vocal music classification algorithm based on zero crossing rate and spectrum. After endpoint detection and subsection preprocessing of voice and music signals, this algorithm combines each audio segment's zero crossing rate and spectrum amplitude characteristics for classification and recognition processing. Finally, the classification of voice and music signals is realized by calculating the probability of becoming voice or music; Zhang X L [8] and others combined the residual network and random forest methods to convert the vocal music audio data of one-dimensional time domain signal into two-dimensional data form of Mel spectrogram and pre-trained the residual network to obtain a network model with high accuracy as the characteristic extractor. The network figure is used to extract the deep features in the audio, and then the random forest algorithm is used to achieve the vocal music classification in the audio; In [9] first proposed an adaptive Mel filtering algorithm to extract the Mel spectrogram with higher discrimination and then proposed a cyclic residual structure, combined with migration and fine-tuning methods, to construct a cyclic residual network spectrum classifier, aiming at the problem that the classification accuracy of voice, music and audio signals in a small sample environment needs to be improved urgently, Combining adaptive Mel filtering algorithm and cyclic residual network spectrum classifier, an audio signal classification model mainly used in small sample environment is generated, through which vocal music in audio can be classified. Although the above three methods play a role in classifying audio, such as vocal music, they also have some defects. The first method ignores the extraction of signal features before the vocal music classification. Although the last two methods extract the signal features of vocal music, they do not consider the music's rhythmic characteristics in the audio, which leads to inaccurate extracted features, and thus affects the classification results of the overall audio signal.

The neural network is an algorithm network composed of multiple neurons with strong self-learning features, associative storage performance and the ability to figure out optimal answers at high speed [10]. The convolutional neural network is a network obtained by improving the neural network. It is a feedforward neural network with convolution calculation and depth structure. It belongs to one of the representative algorithms of depth learning. It has the ability to represent learning and can translate and classify the input information according to the hierarchical structure [11]. Beat is an organization form representing a fixed unit's time value and the law of strength and weakness in audio. Its focus is on the relationship between the strength and weakness of each audio bar, as well as the length of time between beats. The beat in music has the characteristics of a periodic cycle. Although some research has focused on music classification, with the popularity of streaming music services, real-time music classification has become increasingly important. For this reason, according to the characteristics of neural network and beat, this paper proposes a vocal music classification model based on improved neural network and beat spectrum, that is, first obtain the beat spectrum of the audio signal of vocal music, and input it into the classification model as the intake characteristic of the audio classification figure. The classification model uses a convolutional neural network, takes the connection timing classification as the objective optimization function, and integrates the residual structure into the convolution layer; Swish and max-out activation functions will be used to improve it, and finally, an end-to-end vocal music classification model based on deep optimization residual convolutional neural network will be formed. This model has good classification performance and strong applicability.

II. Classification Model of Vocal Music

A. Feature Extraction of Vocal Music Signal Based on Beat Spectrum

Voice and music are two very important audio signals, but they have different characteristics. In the music signal, there are periodic laws with a strong beat, while most of the voice is irregular, and the beat is not obvious. Beat refers to the combination rule of downbeat and downbeat, which is composed of downbeat and downbeat in a certain sequence. In music, the beat uses a strong, weak relationship to organize the music. Therefore, the characteristics of vocal music signals are extracted based on the beat spectrum.

1) MFCC feature parameter extraction of vocal music signal: Generally, if the vocal music signal is directly analyzed, the signal resolution will be very low. However, if the voice parameters of the vocal music signal are extracted and analyzed, the recognition rate will be greatly improved [12]. Mel frequency cepstral coefficients (MFCC), to a certain extent, simulate the characteristics of speech processing by the human ear [13], have good performance in auditory perception, and also have good robustness in the case of channel noise and spectral distortion [14]. The principle of MFCC is to use a group of band-pass filters to filter the sound signal according to the frequency bands of different frequencies and the bandwidth length to obtain the output signal of each band-pass filter [15]. For example, the output signal obtained by filtering the vocal music signal through the band-pass filter is used as the basic feature of the vocal music signal, which can be used as the characteristic parameters of the vocal music signal after transformation and processing [16].

In order to facilitate the study of the human ear's perception characteristics of different frequencies of speech, Mel frequency can be used. 1Mel is 1/1000 of the tone perception degree of 1000Hz. Formula (1) is the conversion formula of frequency f and Mel frequency F :

$$F = 3322.23\lg(1+0.001)f \tag{1}$$

MFCC is proposed based on the above Mel frequency concept. The process of extracting MFCC feature parameters of vocal music signals is represented in Fig. 1.

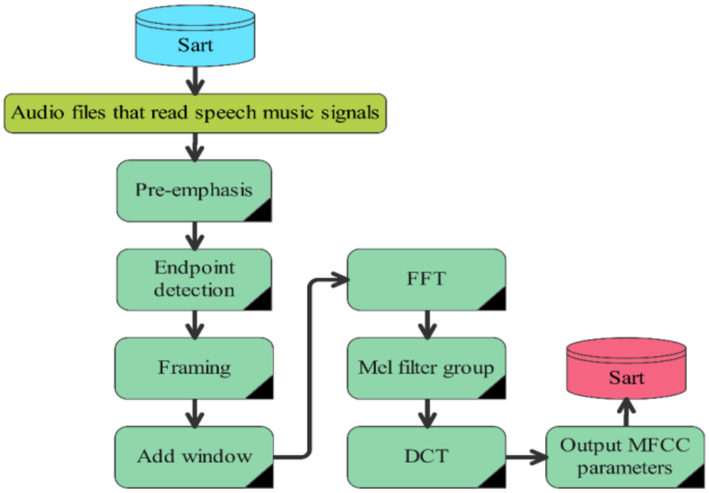

Fig. 1. Extraction flow chart of MFCC feature parameters of speech and music signals.

The specific steps for extracting MFCC feature parameters of vocal music signals are as follows:

Step 1: Read the audio file of the vocal music signal

Input the vocal music audio file into the Matlab tool, read the data and sampling frequency of the audio file using the audio read function, select the wav format for the audio file, and record the read vocal music signal as $r(n)$.

Step 2: The pre-emphasis processing of vocal music signal is aa.

Since the travelling wave propagation distance of treble is smaller than that of bass, and the energy is smaller than that of bass, it is easy to be masked by bass, so it is necessary to pre-emphasize the high-frequency signal. The pre-emphasis filter s is used to amplify the high-frequency signal to avoid the loss of high-frequency signal. The transfer function $H(s)$ of filter s is Formula (2):

$$H(s) = 1 - \ell s^{-1} \tag{2}$$

Where, $\ell \in [0.9,1]$ is generally 0.97 or 0.95.

The pre-emphasis function is Formula (3):

$$R(n) = r(n) - \ell r(n-1) \tag{3}$$

In the formula, n is the number of data points in the vocal music signal, usually 1 to 200K.

Step 3: Vocal music signal endpoint detection

Endpoint detection is an important part of vocal music recognition. Effective endpoint detection methods can not only reduce data storage and processing time but also eliminate noise interference in silent segments, making vocal music recognition more accurate. In this paper, short-time energy is used to detect the endpoint of the vocal music signal, and the start frame and end frame of the whole audio segment are determined to reduce the amount of data and calculation of subsequent audio feature extraction and improve the stability of the system.

Set the short-time energy of each frame of data in the music signal to ℓ as the Formula (4):

$$e = \sum_{m=1}^{u_b} y^2(m) \tag{4}$$

Where, $y(m)$ is the amplitude of the mth frame of the vocal music signal, u_b is the frame length, and $m = 1, 2, \cdots b$.

Step 4: Vocal music signal framing operation

If the voice of the whole vocal music signal is directly Fourier transformed, it is easy to cause a loss of timing information. However, suppose the signal is divided into several frames, and a fast Fourier transform (FFT) is performed on each frame with a fixed duration. In that case, the loss of information can be effectively avoided. Because a speech signal is a non-stationary time-varying signal, its quasi-stationary feature can only be considered as a stationary process in a short period (generally speaking, the speech signal between 10ms and 30ms is considered a stationary signal). Therefore, the voice signal can be divided into one short time segment. Each short-time segment is called a frame, and each frame contains N sampling points, usually 256 or 512 for N; thus, the framing operation is completed.

Step 5: Windowing processing of vocal music signals

After the vocal music signal is divided into frames, the periodicity of a small signal segment will not be obvious. At this time, a Hamming window needs to be added so that the vocal music signal in a window will show periodicity. In order to avoid losing the dynamic change information of voice and music signals, there must be an overlap area between every two adjacent frames. The length of the overlap area is generally 1/2 or 1/3 of that. Multiply each frame by the Hamming window so that the continuity of each frame's left and right ends can be increased.

Set the vocal music signal of the m frame as $R(n,m), n = 0, 1, \cdots, N-1$, and the vocal music signal $R'(n,m)$ after Hamming window processing is the Formula (5):

$$R'(n,m) = R(n,m)\left[0.54 - 0.46\cos(2\pi n/(N-1))\right] \tag{5}$$

Where, $0 \le n \le N-1$.

Step 6: Fast Fourier Transform (FFT) of speech-music Signal

The function of the FFT transform is to convert the time domain of the vocal music signal to the frequency domain [17], which can better reflect the characteristics of the signal and facilitate its analysis.

The frequency spectrum of the mth frame of vocal music signal after FFT transformation is Formula (6):

$$R(k,m) = \sum_{n=0}^{N'} R'(n,m)\exp(-(2\pi nk/N')) \tag{6}$$

Where, N' is the window width of FFT. After taking the modulus square of the spectrum of the vocal music signal, the power spectrum of the vocal music signal can be obtained.

Step 7: Filtering operation of vocal music signal

The obtained power spectrum of vocal music signal is filtered by a triangle filter with Mel frequency average distribution to obtain a group of coefficients $d_1, d_2, \cdots$, which are the energy output by each filter and also MFCC coefficients.

Step 8: Discrete Cosine Transform of speech-music Signal

MFCC coefficients have a high correlation. Discrete Cosine Transform (DCT) can reduce the dimension of their correlation. Calculate the MFCC coefficient using the discrete cosine transform to obtain the L dimension MFCC parameter $A_l, l = 1, 2, \cdots, L$, as shown in Formula (7):

$$A_l = \sum_{k=1}^{p} \lg(d_k)\cos\left[(kl - (1/2)l)(\pi / p)\right] \tag{7}$$

Where, p is the number of triangular filters. After DCT, MFCC characteristic parameters of vocal music are obtained.

2) Beat spectrum of vocal music signal: Beat spectrum is a measure of acoustic self-similarity and a function of time delay. A highly structured or repetitive concert has a strong beat spectrum peak, which reveals the relative intensity of rhythm and a specific beat. Therefore, different kinds of rhythms of the same beat can be distinguished. The pitch spectrum of vocal music first needs to use cosine similarity to calculate the similarity between two pairs of MFCC feature parameters of vocal music [18] to obtain a similarity matrix and then obtain it by evaluating the autocorrelation of the similarity matrix.

The MFCC parameter of vocal music is regarded as the feature vector of the vocal music signal. The alikeness among them is evaluated by evaluating the cosine value of the angle between the two vectors. The cosine value of 0° is 1, while the cosine value of any other angle is not greater than 1, and the minimum value is - 1. Music has the characteristics of rhythm, which makes it repeatable to calculate its similarity, while voice does not. The cosine value is Formula (8):

$$\cos\theta = (A_l(i)A_l(j)) / (\|A_l(i)\| \times \|A_l(j)\|) \tag{8}$$

In the formula, $A_l(i)$ and $A_l(j)$ represent the two eigenvectors of the vocal music signal respectively, and $\cos\theta$ represents the calculated cosine value.

Using the cosine parameter of the included angle of the feature vector, the similarity matrix of the vocal music signal is evaluated through Formula (9). The autocorrelation of its similarity matrix calculates the beat spectrum of the signal to obtain the Formula (10):

$$X(i, j) = (A_l(i)A_l(j)) / (\|A_l(i)\|\|A_l(j)\|) \tag{9}$$

$$C(g,h) = \sum_{i,j} X(i, j)X(i+g, j+h) \tag{10}$$

Where, $A_l(i)$ and $A_l(j)$ are the eigenvectors of the i and j frames, respectively, $X(i, j)$ is the similarity matrix, $C(g,h)$ is its symmetric matrix, and the beat spectrum $C(h)$ is obtainable by adding them by row or column.

B. Speech-Music Classification on the Basis of Convolutional Neural Network

The neural network has the characteristics of distributed storage, parallel processing and self-learning skill, so it has a wide application view in data processing, pattern identification, classification and other areas. Convolutional Neural Networks (CNN), as an improved neural network, is one of the commonly used speech-music recognition models at present. Its unique convolution structure ensures the translation invariance of speech-music signals in time and frequency domains.

1) Convolution neural network: CNN is an algorithm for learning multilayer neural network structure, which is created of the input layer, convolution layer, pooling layer, full connection layer and output layer [19].

The sparse interaction and parameter sharing of CNN is able to decrease the number of training principles and network complexity [20]; the invariance of data scaling and translation is conducive to optimizing the network structure, making the model have a stronger generalization ability in feature extraction [21]. The network structure of CNN is shown in Fig. 2.

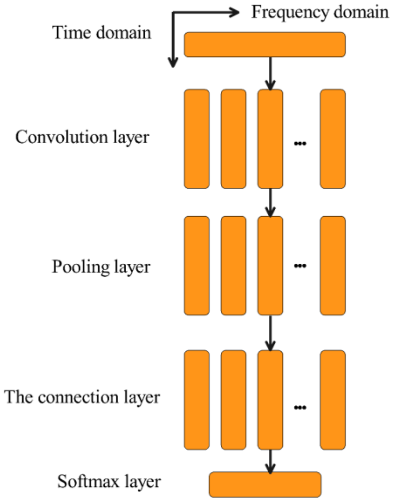

Fig. 2. Structure of convolutional neural network

CNN convolution layer has the characteristics of weight sharing and local connection [22]. Set $Q_{a(i')c(j')}$ as the i' neuron on the input a feature plane, and output the connection weight value between the j' neuron on the c feature plane. Then there is Formula (11):

$$Q_{a(i')c(j')} = Q_{a(i'+1)c(j'+1)} = Q_{a(i'+2)c(j'+2)} \quad (11)$$

In CNN, the output feature surface of each roll-up layer uniquely corresponds to the output feature surface of the pooled layer. The commonly used activation function is the Sigmoid function [23]. Through pooling operation, the features of vocal music signals are further extracted. Common pooling methods include the mean and maximum pooling methods [24]. After the convolution pooling operation, the obtained features enter the full connection layer. Each neuron in the fully connected layer is connected to each neuron in the previous layer, and the fully connected layer can receive all local information in the previous layer.

2) Residual convolutional neural network for depth optimization: Using the idea of a residual network for reference, the input of the upper layer is directly transmitted to the lower layer by adding a congruent mapping layer. This paper combines the input feature x beyond the convolution operation with the outcome after the convolution operation as the intake of the subsequent activation function. Then it outputs new information to build an optimized residual convolution layer. Aiming to raise the number of layers of the depth convolution neural network, Swish and max-out activation functions are introduced to optimize the residual structure, which can directly transmit the input information of the network to the output and improve the degradation and gradient disappearance problems of the network.

The formula of the activation function Swish is $f(x) = x * \mathrm{sig\,mod}(x)$, which is non-monotonic, smooth and unsaturated.

The function of the activation function max-out is similar to that of the activation function layer in the network structure of the convolution layer and pooling layer. It is attached in front of each output neuron. The highest value of the node outcome of the same group of the hidden layer is taken, and the output of each node in the hidden layer is calculated as Formula (12):

$$W = \varphi(o), o = \omega \times x + \partial \quad (12)$$

In the formula, the linear activation vector o of the neuron is calculated by inputting the sample data vector x, the weight coefficient vector ω and the offset term coefficient ∂. Then the nonlinear transformation is performed through the max-out activation function, where $\varphi(o)$ represents $\max(o,0)$. Maxout divides the M hidden layer units of the specified layer into I groups. If each group contains V units, the output of the i group is Formula (13):

$$W_{i'} = \max_{v=0}^{V-1} z_{iV+v}, i = 0,1,\cdots,I-1 \quad (13)$$

Since the piecewise linear function can fit any convex function with any precision, and the V hidden layer neuron nodes taken by max-out also have the characteristics of linearity, the operation of taking the maximum value also has the characteristics of piecewise linearity, where the number of segments is related to the size of V value. The max-out activation function has a very strong fitting ability and can fit any convex function [25].

The building of the deep optimization residual convolutional neural network is shown in Fig. 3.

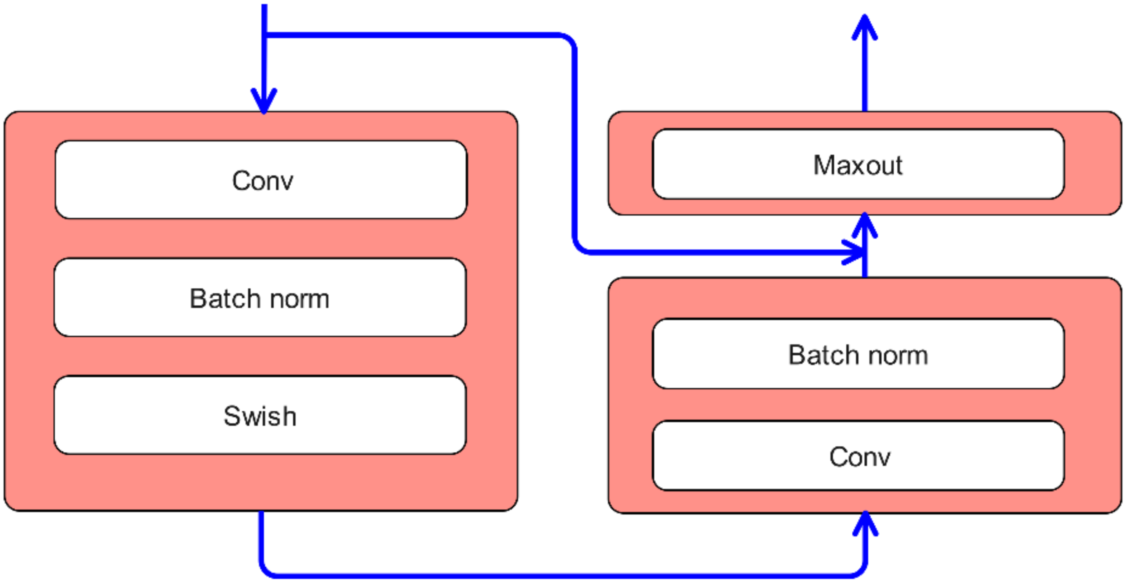

Fig. 3. Building of deep optimization residual convolutional neural network.

Since the max-out function has no weight sharing, it is easy to overfit, so only the max-out activation function is added to the external output of the residual structure. In contrast, the internal convolution layer activation function uses the Swish function to replace the ReLU function. Although both Swish and ReLU function images have no upper and lower bounds, they can increase the nonlinear mapping performance of the network model from the input feature space to the high-dimensional space. The difference is that Swish has the characteristics of non-monotone and smooth. When the sample data of the input dimension is negative, the gradient of the ReLU activation function is 0, and the network model parameters cannot be updated effectively, resulting in the problem of gradient disappearance. However, the first derivative of the Swish activation function is smooth and will not produce saturation. The network model parameters can be updated normally to avoid the disappearance of the gradient, which can improve the training effect of the depth model to a certain extent.

The above depth optimization residual convolutional neural network process can be expressed as follows: Firstly, the acquired vocal music signal beat spectrum is input into the convolutional neural system. Following the convolution process, batch normalization and Swish activation function processing, it is summed with the original input that has not undergone the convolution operation of this layer. The output results obtained are used as the input of the max-out activation function of the next layer, thus forming a group of optimized residual convolutional network structures; a complete depth optimization residual convolutional neural network model is constructed by superimposing the layers of multilayer optimization residual convolutional network structure.

3) Classification of the connection sequence: In the process of vocal music recognition, vocal music generates a real value of training during training, which is in comparison with the anticipated value in the vocal music type. The loss function in the output layer is used to anticipate the degree of inconsistency between the anticipated and the real value. The loss function represents the robust performance of the established model. The smaller the loss function, the better the robust performance of the model.

CTC is a loss function which is used to measure the difference between the input sequence data and the real output after passing through the neural network [26]. CTC introduces an empty node, which does not require full alignment of voice frames. CTC is applied to the speech-music classification in this paper. As the objective function of the softmax layer, CTC will optimize the likelihood between the input and output target sequences.

CTC adopts the maximum likelihood function as Formula (14):

$$B(q) = \sum_{(x,z)\in q} B(x,z) \tag{14}$$

The CTC loss function is defined as Formula (15):

$$B(q) = -\ln \prod_{(x,z)\in q} P(z|x) = -\sum_{(x,z)\in q} \ln P(z|x) \tag{15}$$

Where, $P(z|x)$ represents the probability of the output sequence z for a given input x, and q is the training set. When the input is given, the function of CTC is to find the output sequence with the highest probability.

4) Speech-music classification model based on DCNN-CTC: The convolution layer and pooling layer structure in the convolution neural network can help the model accurately recognize the slight deformation and displacement of the input features. As an end-to-end structure, CTC can resolve the issue of sequence misalignment in the recognition procedure of vocal music. However, the disadvantage of the shallow neural network model is that the feature information extracted by the convolution neural network is not significant enough, which affects the final classification and recognition effect. Therefore, this paper proposes a new DCNN-CTC classification model based on the optimized depth residual convolutional neural network. The model raises the number of convolution layers through the residual structure and constructs the end-to-end model structure of the deep convolution neural network, which is created of six convolution layers, a pooling layer and two filled connection layers. The DCNN-CTC vocal music classification model is shown in Fig. 4.

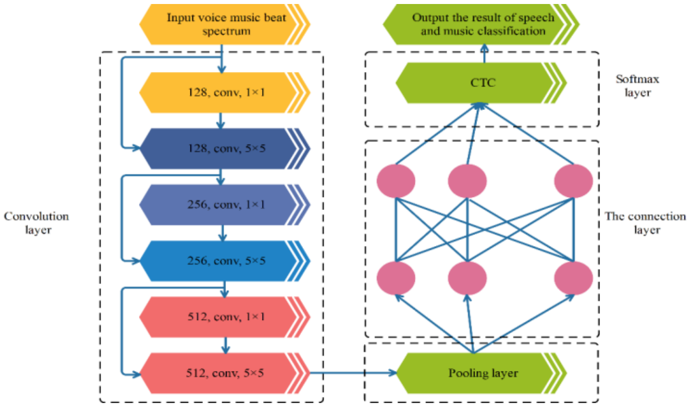

Fig. 4. Speech-music classification model of DCNN-CTC.

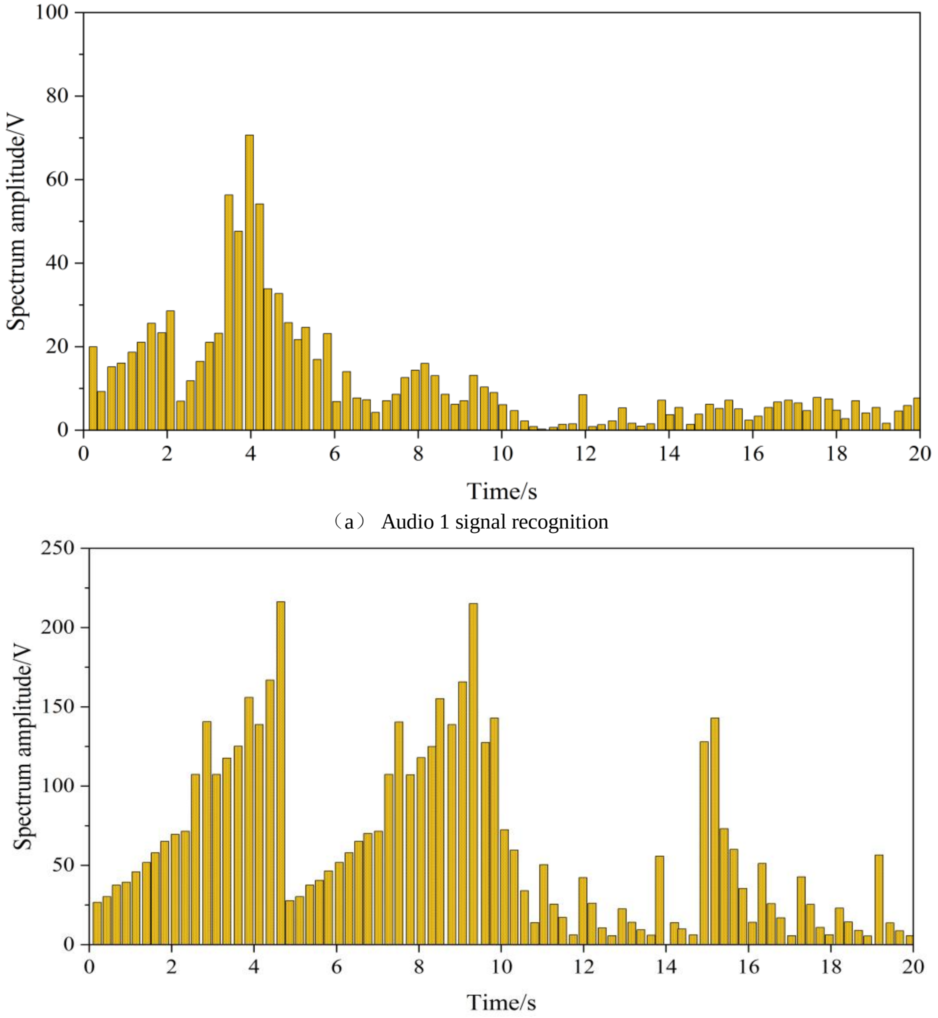
When using the DCNN-CTC vocal music classification model for training, the pitch spectrum of the vocal music signal is first input into the depth convolution neural network. The convolution layer uses the residual structure. After six layers of convolution operations, the pitch spectrum of the original vocal music is extracted for depth features so that the local information of the audio features can be fully integrated. The step size of the convolution layer is set to 1×1. The first convolution layer in the residual structure is to reduce the dimension of the vocal music signal. The size of the convolution core is 1×1. Then the output of the convolution layer is imported to the pooling layer for sampling through maximum pooling. The full connection layer of the two layers has 1024 nodes, and its activation function is maxed out. The softmax layer adopts an end-to-end CTC structure to classify the input vocal music. The end-to-end CTC structure can further improve the robustness of the model, speed up decoding, and obtain the state output of features after classification. The supervised gradient descent method is used for model training in this paper.

III. Experimental Analysis

Take two audio segments in a radio station as the experimental object, and the time length is the 20s. In order to confirm the validity of this type, the test accomplished a classification test on this segment of vocal music. First, the vocal music signal is pre-emphasized and windowed by frames. Set the frame length to 30, the frameshift to 15, and add 0 if the frame length is less than 30. The window function is Hamming window. After MFCC feature parameter extraction and cosine similarity calculation, the vocal music beat spectrum is obtained. Input the acquired vocal music beat spectrum into the model in this paper. The convolution layer of the model in this paper is set as 6 layers. After three residual block structures, the extracted characteristics are compressed and extracted through the maximum pooling method. Finally, they are transferred to the softmax layer by two filled connection layers, which use the CTC loss function. The supervised random gradient descent method is used for model training, with 128 iterations and an initial learning rate of 0.01. After the experiment, the classification results of this segment of vocal music are shown in Fig. 5 and Table I.



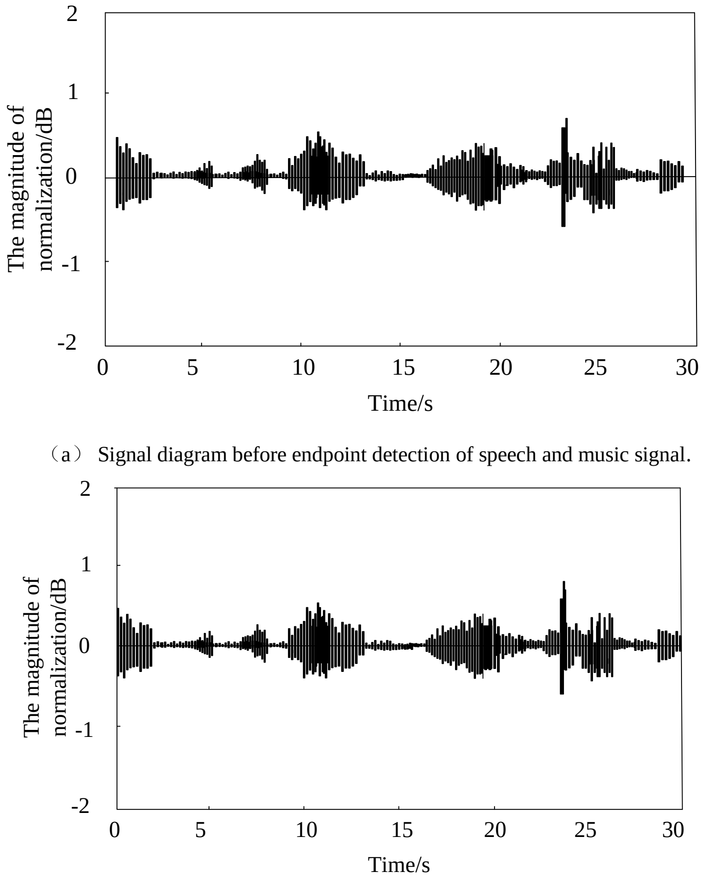
（a） Audio 1 signal recognition

（b） Audio 2 signal recognition

Fig. 5. Recognition results of speech and music signals.

TABLE I. AUDIO CLASSIFICATION RESULTS

The name of the audio	The classification results
Audio 1	Speech signal
Audio 2	Music signals



（a） Signal diagram before endpoint detection of speech and music signal.

（b） Signal diagram after endpoint detection of speech and music signal.

Fig. 6. Signal comparison before and after endpoint detection of speech and music signals.

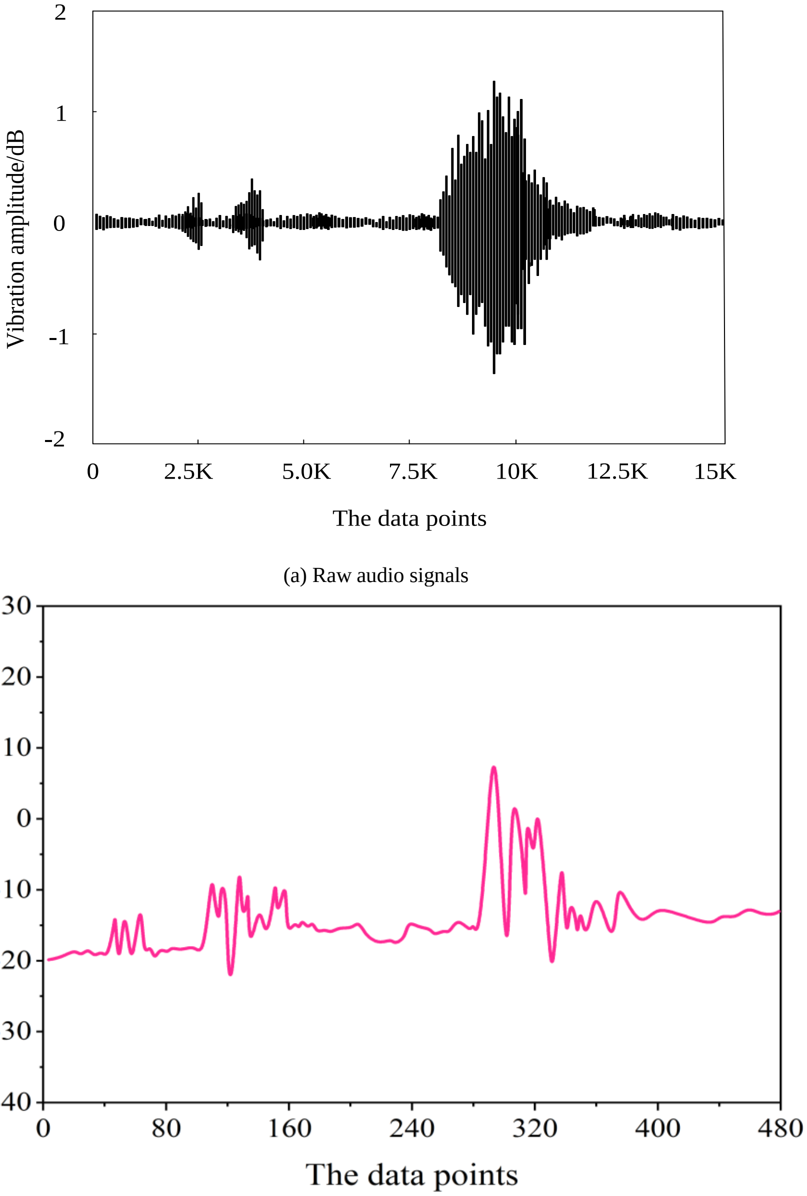
Due to the periodicity of the music signal, it has a strong beat, while most of the voice is irregular, and the beat is weak. It is perceivable from Fig. 5 that the peak value in the vocal music signal obtained by using the model in this paper corresponds to its main rhythm component, and the amplitude of different peaks reflects the strength of the corresponding rhythm of the signal. In addition, the peak value change of some vocal music signals with a strong sense of rhythm will be relatively obvious. In contrast, the peak value change of vocal music signals with a weak sense of rhythm will be slightly weak, which is able to invert the main features of the vocal music signal better. It can be seen from the identification diagram of audio 1 signal that the signal has no regularity and a weak beat; it can be seen from the identification diagram of audio 2 signal that the signal changes periodically, with a regular period from 0s to 9.6s and a regular period from 9.7s to 20s, and the beat is strong.

Through the above analysis, it shows that this model is effective for the vocal music classification.

In order to measure the effect of endpoint detection on the vocal music signal mentioned in this paper, the experiment collected a section of vocal music signal on the radio station. The sampling frequency is 8kHz, the accuracy is 16bit, and the duration is 30s. The result of endpoint detection of this signal is shown in Fig. 6.

It is perceivable from Fig. 6 that after endpoint detection of the vocal music signal using the model in this paper, the audio period with low head and tail energy of the signal is removed. The start frame and end frame of the whole audio signal are determined, which can effectively reduce the amount of data and calculation of subsequent audio feature extraction and improve the stability of the model.

To judge the excellence of MFCC characteristic parameter extraction proposed in this model, an audio file intercepted from the radio station is input into the Matlab tool in the experiment. The audio file data and sampling frequency are read using the audio read function, and the audio file is in wav format. Set the audio frame length to 256 points, frameshift to 80, filters to 24 groups, and dimensions to 12. Use this model to extract the MFCC feature parameters of this audio, and the results are shown in Fig. 7.



(a) Raw audio signals

(b) Audio signal after MFCC feature parameter extraction

Fig. 7. Audio signal comparison before and after MFCC feature parameter extraction.

In Fig. 7, comparing the collected original signal with the signal after MFCC feature parameter extraction, we can see that the collected original signal has 15K data points, and the audio signal data points after MFCC parameter extraction are only 480. After amplification and comparison, the audio signal waveform after MFCC parameter extraction is more consistent with the trend and trend of the original signal waveform; after MFCC parameters are extracted, 480 data points completely reflect the characteristics and change trend of 15K data points. From this, it can be seen that the MFCC feature parameter extraction proposed in this model can reflect the characteristics of the entire audio signal, which is conducive to subsequent analysis of the signal and lays a good foundation for the next step of speech-music classification.

The convolution layer is an important part of feature learning and extraction in the convolutional neural network structure. Different convolution layers will lead to different feature representations. Therefore, the experiment tests the performance of the residual convolutional neural network with depth optimization when the convolution layer is 3, 4, 5 and 6 layers. The preprocessed vocal music signal data set is divided into a training data set and a test data set at a ratio of 7：3 for experiments to determine the number of convolution layers with the best classification performance. The experiment sets the input length, the characteristic dimension and the number of iterations obtained by the full connection layer as 150, 3600 and 1200, respectively. It obtains the classification accuracy and training loss of the depth-optimized residual convolutional neural network under different convolution layer structures, as shown in Fig. 8 and Fig. 9.

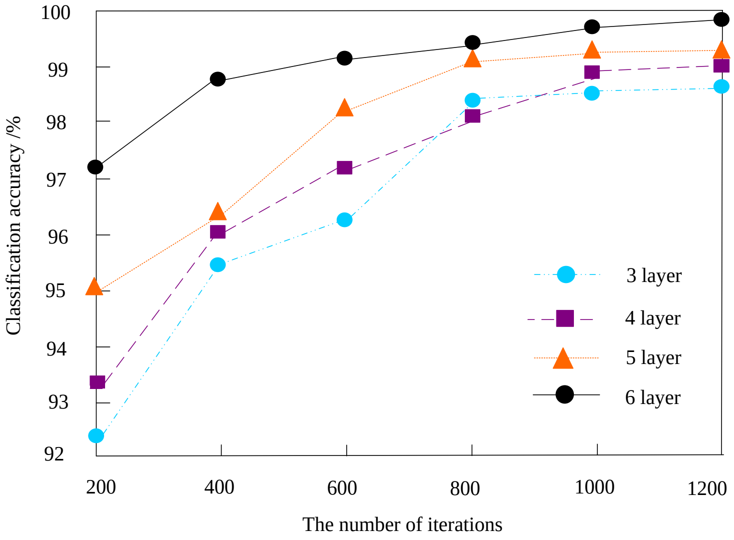


Fig. 8. Comparison of classification accuracy of deep optimized residual convolutional neural networks with different convolutional layer structures.

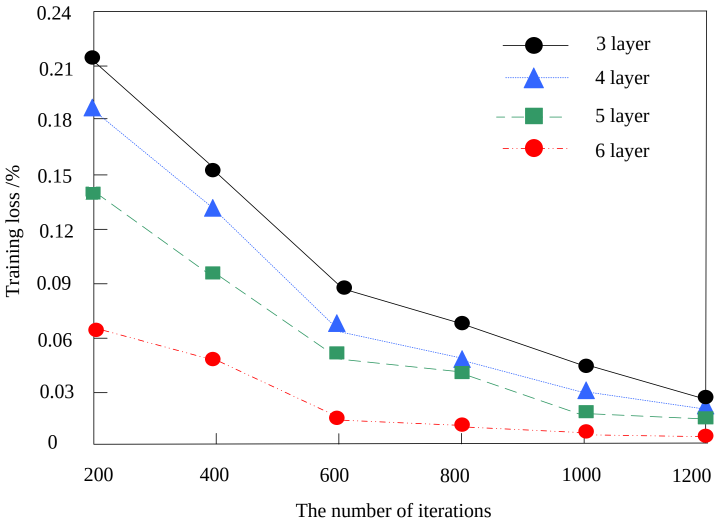

Fig. 9. Comparison of training losses of deep optimization residual convolutional neural networks with different convolutional layer structures.

It is perceivable from Fig. 8 that for the depth-optimized residual convolutional neural network figure with a 6-layer convolution layer structure, when the number of iterations is 600, the classification accuracy has reached more than 99%; when the number of iterations is 1200, the classification accuracy has reached 99.87%, approaching 100%; while for the depth optimized residual convolutional neural network model with other hierarchical structures, the performance in classification accuracy is slightly worse, which shows that, When six convolution layers are set in the depth optimization residual convolutional neural network model, it has a strong classification ability.

It is perceivable from Fig. 9 that when the number of iterations is between 400 and 600, the training loss of the deep optimization residual convolutional neural network decreases the most, especially for the convolution neural network with six convolution layers; the training loss is only about 0.01 at this time. By the time the number of iterations is 1200, the training loss is close to zero, and the training loss of other hierarchical networks is inferior to that of the convolution neural network with six convolution layers; at the same time, it also shows that the network can better avoid the overfitting phenomenon.

In conclusion, when the convolution layer of the depth optimization residual convolutional neural network model proposed in this method is 6 layers, it performs well both in classification performance and training loss. It is superior to other hierarchical convolution neural networks, with good classification performance.

For classification models, sensitivity and specificity are two important performance evaluation indicators. Sensitivity represents the proportion of all positive samples to be paired, which measures the recognition ability of classification models to positive samples; Specificity represents the proportion of all negative samples divided into pairs and measures the recognition ability of classification models to negative samples. The sensitivity and specificity are Formula (16) and (17), respectively:

$$sensitive = \frac{TP}{P} \tag{16}$$

$$specificity = \frac{TN}{N} \tag{17}$$

Where, P represents a positive sample, N represents a negative sample, TP represents a positive sample classified as a positive sample, and TN represents a negative sample classified as a negative sample.

The experiment selects 100000 vocal music audios from the audio database of the radio station as the sample set, of which 46000 are voice audio, set as positive samples, and 54000 are music audio, set as negative samples. Under the conditions that the signal-to-noise ratio is 20dB, 40dB, 60dB, 80dB, 100dB, 120dB, 140dB, 160dB, and 180dB, the model in this paper is tested from the perspective of sensitivity and specificity. The final results are shown in Fig 10.

It is perceivable from Fig. 10 that under different signal-to-noise ratios, the method in this article has a good performance both in sensitivity and specificity. When the signal-to-noise ratio is 100dB, the sensitivity and specificity reach 99%. When the signal-to-noise ratio is 180dB, the sensitivity and specificity reach 99.98% and 99.96%, respectively. It is perceivable that the model in this article has good recognition ability and classification effect for speech-music.

To measure the function of the model in this article further, for vocal music classification, the experiment selects different types of audio from the audio library of the radio station as the sample set; the sampling rate is 32kHz, the format is PCM format, the whole number of demos is 30min, in which the voice duration is 18min, including the pronunciation of men and women of different ages, different speakers, and different sentences; The music lasts for 12 minutes, including various instrumental music, such as violin, piano, zither, flute, etc. 70% of the samples in the sample set were chosen as training demos and 30% as test demos. The experiment compares the classification model of zero crossing rate and spectrum in reference [7], the classification model of the residual network and random forest in reference [8], and the classification model of Meyer spectrum and cyclic residual in reference [9]with the model in this paper, and analyzes the classification results of different models for vocal music, as presented in Table II.

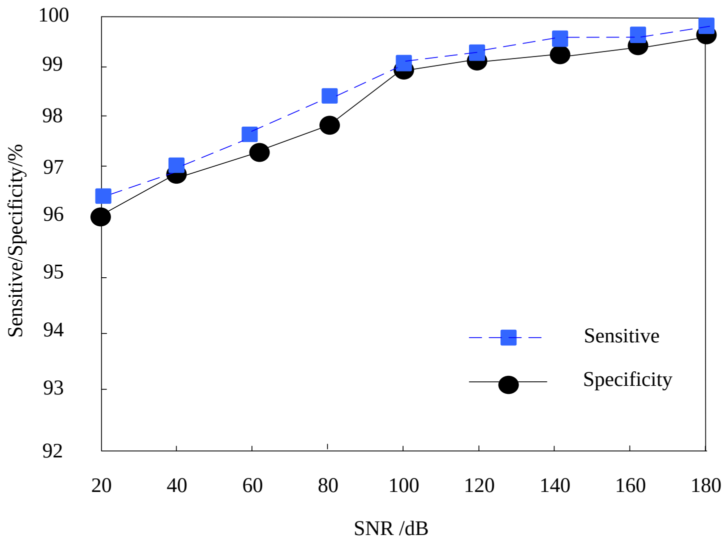

Fig. 10. Sensitivity and special effect of the proposed model under different SNR.

TABLE II. COMPARING CLASSIFICATION ACCURACY OF DIFFERENT MODELS

Methods	Audio type	The total number of samples	Number of corrected samples	Number of wrong samples	Classification accuracy /%	The average classification accuracy /%	Running time /s
Model in reference [7]	Voice	273	265	8	97.07	95.47	0.75
	Music	147	138	9	93.88		
Model in reference [8]	Voice	273	269	4	98.53	97.23	0.59
	Music	147	141	6	95.92		
Model in reference [9]	Voice	273	259	14	94.87	93.35	0.67
	Music	147	135	12	91.84		
In this paper, the model	Voice	273	272	1	99.63	99.82	0.48
	Music	147	147	0	100.00		

It can be seen from Table II that different models are used to classify different types of vocal music. The accuracy of the model in this paper for music recognition reached 100%, and there was only one error in speech recognition, with an average classification accuracy of 99.82%. It has been proven that the proposed model has good classification performance and the running time is the shortest compared to other algorithms, only 0.48s. While the average classification accuracy of the reference [7] model for vocal music is 95.47%, the running time is 0.75 seconds, the mean classification correctness of the reference [8] model is 97.23%, and the running time is 0.59 seconds. The mean classification correctness of the reference [9] model is 93.35%, and the running time is 0.67 seconds. It can be seen from the above data that compared with the other three models, the vocal music classification in this model is the most accurate, and the classification speed is the fastest. It has a good classification function and convergence effect.

IV. Discussion

The speech-music classification model based on improved neural networks and beat scores is a research aimed at improving the accuracy and efficiency of music classification. This study designed a novel model that achieved impressive results by combining an improved neural network architecture and beat spectrum feature extraction method.

Firstly, the model in this study performed well in terms of music classification accuracy, achieving an accuracy rate of over 99%. This means that the model can highly accurately classify different types and styles of music, providing users with more accurate music recommendations and personalized experiences.

Secondly, after 1200 iterations of training, the training loss of the model approaches zero. This indicates that the model can fully learn and adapt to music datasets, and has strong learning and generalization abilities.

In addition, the model exhibits very high sensitivity and specificity at high signal-to-noise ratio (180dB), reaching 99.98% and 99.96%, respectively. This means that even in noisy environments, the model can still accurately recognize and classify music, providing users with stable and reliable classification performance.

Finally, the study also focuses on the runtime of the model. After optimization, the running time of the model is only 0.48 seconds, which means that the model has high efficiency and practicality, and can quickly classify music in real-time applications.

In summary, the speech-music classification model based on improved neural networks and beat scores is an exciting research topic. By designing models with high accuracy, low training loss, high sensitivity, and special effects, and completing classification tasks in a short running time, this study has made significant contributions to the development of music classification and provided strong support for music recommendation systems and other related applications.

V. Conclusion

With the development of cloud storage and Internet technology, more and more multimedia data, such as audio, has entered people's lives. In order to save local storage space, many individuals and enterprise users store multimedia data in the cloud, which increases the technical burden of multimedia data retrieval. Classifying audio is an effective means to achieve fast retrieval. As the two most important types of audios - voice and music, their classification has important application value in content-based audio retrieval, video retrieval and summarization, and voice document retrieval. It is an important preprocessing work in sound signal processing. Therefore, this paper proposes a vocal music classification model based on an improved neural network and beat spectrum. This model combines CTC and residual network design ideas, proposes an improved depth optimization residual convolutional neural network structure, and introduces the beat spectrum as the model's input. The model in this paper effectively solves the problem of model overfitting and improves classification accuracy. The innovation work of this paper mainly includes:

1) Design the pitch of vocal music. In the characteristic extraction of the original audio signal, the beat feature is added to enhance the precision of characteristic extraction.

2) The introduction of residual structure. The residual structure is introduced into the convolutional neural network to increase the number of convolution layers and increase the number of convolution layers to 6 layers, which deepens the depth of the network model, extracts the features of deeper vocal music signals, and better enhances the classification correctness of the network figure.

3) Introduction of CTC. The softmax layer of the convolutional neural network adopts an end-to-end CTC structure, which can resolve the issue of sequence misalignment in the recognition procedure of vocal music, improve the robustness of the model, speed up decoding, and obtain the state output of features after classification.

Through experiments, it has been proven that the application of this model can effectively achieve accurate classification of speech and music, with small errors, high accuracy, and fast speed.

In order to further improve the performance of the design in practical applications, in-depth research will be conducted in the following aspects in the future:

1) Dataset expansion: Find more datasets for training and evaluating model performance. These datasets can contain different types and styles of music, as well as different language and cultural backgrounds.

2) Model architecture optimization: try different neural network architectures, such as Convolutional neural network (CNN), Recurrent neural network (RNN) or attention mechanism, to improve the modeling ability of the model for music features.

3) Multimodal learning: Combining audio data with data from other modalities (such as images or text) to improve the performance of music classification models. For example, audio data can be combined with lyrics or album cover images for joint training.

DATA AVAILABILITY

The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation.

CONFLICTS OF INTEREST

The authors declared that they have no conflicts of interest regarding this work.

A Method for Evaluating the Competitiveness of Human Resources in High-tech Enterprises Based on Self-organized Data Mining Algorithms

Sun Zhixin*
Anyang Vocational and Technical College, Anyang, Henan, 455000, China

***Abstract*—The level of human resources competitiveness of high-tech companies affects the efficiency and effectiveness of enterprises to a particular extent. To achieve sustainable development of high-tech enterprises, an evaluation method of human resource competitiveness of high-tech enterprises based on a self-organized data mining algorithm is proposed. The fuzzy clustering algorithm is used to select five first-level indexes for the evaluation of HR competitiveness of high-tech companies, including human capital power, human resources policy incentive power, and human resources performance manifestation power, and to construct the initial evaluation indicator setting. The self-organized data mining algorithm is used to identify the key attributes related to the human resource competitiveness of high-tech companies within the initial assessment indicator setup, reduce the complexity of the indexes and construct the final rating index system. The multi-level fuzzy evaluation method is applied to calculate the evaluation index weights and fuzzy evaluation matrix to obtain the assessment results of HR competitivity of high-tech enterprises. The experimental results show that the information contribution rate of the evaluation index system constructed by this method is higher than 95%, which can accurately evaluate the human resource competitiveness of high-tech enterprises.**

***Keywords*—Self-organized data mining algorithm; high-tech enterprises; human resources; competitiveness evaluation; multi-level fuzzy evaluation method**

I. Introduction

Human resources are the physical and mental workers who can promote social and economic development and create material and spiritual wealth for society [1, 2]. High-tech enterprises are organizations based on high technology. As creativity, information, and technology become more and more constituents of products, the knowledge content in products and services increases and the development of enterprises depends to a large extent on the ability to create knowledge and the level of technology possessed, thus human resources as carriers of knowledge and skills become strategic resources of enterprises [3-5]. The competitiveness of the human resources of a high-tech enterprise refers to the ability to integrate the strengths of the human resources of a high-tech enterprise with the process of human resource integration, which mainly emphasizes the ability to attract, invest, develop, utilize, and generate economic performance of HR of high-tech companies under the effective human resource management mechanism, to achieve the rapid and sustainable development of high-tech enterprises and open the gap with other high-tech zones [6]. However, high-tech enterprises still have the problem of a low overall level of human resource competitiveness in human resource management, so it is of considerable theoretical and practical importance to research how high-tech enterprises manage human resources and integrate human resource quality to bring into play the competitive advantage of enterprises.

Collins [7] examined how scholars in the field of strategic human resource management have utilized the resource-based view of the firm to contend that an HR strategy centered around high commitment can result in a competitive edge by establishing exclusive and valuable employee-centered resources at the firm level. Nevertheless, previous research has not clarified why variations in employee-centered resources remain among firms that adopt the same HR strategy, nor have they taken into account the significance of aligning employee-centered resources with other organizational abilities. The author suggested that the cognitive abilities of the CEO, social capital, and human capital can help clarify when a pursuit of a high commitment HR strategy leads to an increase in employee-centered resources and when firms can effectively handle and use them for competitive advantage. Utilizing Grey Relational Analysis (GRA) to analyze data from the CGSS and the China Health Statistics Yearbook for 2013 and 2015, Peng et al. [8] investigated the determinants of public satisfaction with the health system in China. The findings revealed that the percentage of total healthcare expenditure allocated by the government is the most critical factor for public satisfaction in both years. Moreover, out-of-pocket expenses were identified as a significant factor in 2013, while hospital beds per thousand population were crucial in 2015. The importance of healthcare workforce per thousand population increased from 2013 to 2015. The study's results indicated a transition in priority from economic affordability to more people-centric services in recent years. However, the research also highlighted persistent regional disparities and gaps that require attention in future healthcare reform endeavors. Geng and Hengxin [9] aimed to shed light on the evolution and contemporary environmental management practices of industrial parks in China. Industrial parks have played a pivotal role in China's economic advancement, particularly in terms of attracting foreign investment. The paper outlined the characteristics of industrial parks in China, delineated the principal site selection criteria, and highlights crucial factors for foreign investors. It also underscored the necessity of pursuing sustainable development in industrial parks, given their historical contribution to environmental pollution. The authors advocated for the adoption of eco-industrial development as a fresh developmental approach for industrial parks. Overall, the paper contributed to a more comprehensive comprehension of the current state of affairs and management outlooks concerning the growth of industrial parks in China.

In order to understand the competitiveness of enterprises, provide direction for human resource improvement in high-tech enterprises, and compare with competitors, the evaluation method of human resource competitiveness of high-tech enterprises based on a self-organized data mining algorithm is investigated. Follow the following approach for research:

1) Build an evaluation index system for human resource competitiveness of high-tech enterprises, comprehensively consider the weights and contributions of different indicators, and form a comprehensive evaluation result to provide a comprehensive and objective evaluation of human resource competitiveness.

2) Based on self-organizing data mining algorithms, key indicators are selected to determine human resource competitiveness evaluation indicators suitable for high-tech enterprises.

3) Evaluate the human resource competitiveness of high-tech enterprises by constructing a factor set, determining the weights of each indicator layer, constructing grade evaluation standards, determining membership relationships, constructing a fuzzy evaluation matrix, and determining a fuzzy subset vector;

4) Design experiments to verify that the proposed method can accurately evaluate the human resource competitiveness of high-tech enterprises.

The idea of self-organized data mining is the first milestone in developing mining theory and method. The self-organized data mining algorithm can use complete and incomplete induction algorithms to achieve the automatic selection of the optimal model. Through the research of this method, it is hoped to optimize human resource allocation, motivate employee motivation, improve employee satisfaction and retention rate, and promote the formation of innovation and learning culture. These benefits help enterprises improve their human resource management level, enhance competitiveness and sustainable development capabilities.

II. Materials and Methods

A. *Construction of the Evaluation Index System for Human Resources Competitiveness of High-tech Enterprises*

In constructing the evaluation index system for the human resources competitiveness of high-tech enterprises, the fuzzy clustering algorithm is used to select evaluation indexes. Cluster analysis is a young branch of numerical taxonomy [10], which classifies indexes according to the degree of affinity of representative sample indexes in nature. In the assessment of the identifying the components of HR competitiveness of high-tech enterprises, because of the degree of reflection of various evaluation elements on the evaluation of HR competitiveness of high-tech enterprises, the boundaries of each other are not obvious. They have a certain degree of fuzziness [11], so employing fuzzy mathematical methods to deal with them is more appropriate.

The stages of using a fuzzy clustering algorithm to select the assessment indexes of HR competitivity of high-tech enterprises are as follows.

Step 1: Characterize the theoretical domain

The assessment elements of HR competitivity of high-tech enterprises are used to be classified as a thesis domain, $B=\left\{b_1,b_2,\cdots b_i,\cdots,b_m\right\}$, where b_i is characterized by a set of rating data, i.e., $b_i=\left\{b_{i1},b_{i2},\cdots,b_{ij},\cdots,b_{in}\right\}$.

Step 2: Determine the fuzzy relationship

The importance of various evaluation elements is fuzzily scored according to the specified scoring criteria to form the evaluation element scoring matrix $X\left(x_{ij}\right)_{m\times n}$. On this basis, the scoring matrix is normalized to calculate the correlation coefficient r_{ij} between different evaluation elements and establish the fuzzy similarity matrix R on the domain B. The most common method to determine the similarity coefficient r_{ij} is the closeness method. The closeness of u_i to u_j is $r_{ij}=N\left(x_i,x_j\right)$. When N takes the distance closeness, $r_{ij}=1-c\sum_{k=1}^{m}\left|x_{ik}-x_{jk}\right|$

Step 3: Calculate the fuzzy equivalence matrix

This fuzzy similarity relation matrix $R=\left(r_{ij}\right)_{m\times n}$, satisfies only self-reflexivity and symmetry but not transferability. To perform fuzzy clustering analysis, a Boolean multiplicative transfer closure operation is performed on R up to $R^k=R^{2k}\left(k=2,4\cdots.2^n\right)$. Taking $R^*=R^k=t\left(R\right)$, $t\left(R\right)$ is the fuzzy equivalence relation matrix, and the fuzzy equivalence relation matrix $t\left(R\right)$ satisfies self-reflexivity, symmetry, and transferability [12].

Step 4: Clustering

The fuzzy equivalence matrix $r\left(R\right)$ is used to find its intercept matrix under different thresholds ϕ, and the intercept matrix ϕ is used to analyze the similarity of the evaluation elements [13, 14] so that the indexes of each evaluation element can be clustered.

Step 5: Determine the optimal threshold ϕ

The intercept matrix of the fuzzy equivalence relation matrix $t(R)$ under different thresholds ϕ is $t(R)_\lambda = \lambda(r_{ij})$, where

$$\phi(r_{ij}) = \begin{cases} 1, r_{ij} \ge \phi \\ 0, r_{ij} < \phi \end{cases} \tag{1}$$

Different values of ϕ will get different truncation matrix R_ϕ. Generally, when ϕ gradually decreases from large to small, the classification becomes coarser from fine, forming a dynamic cluster analysis picture. Through this cluster analysis picture, the best ϕ value is selected according to the actual problem's needs, the classification objects' master-slave ranking can be realized, and the identification and analysis of the components of the HR competitiveness of high-tech companies can be realized.

Based on the principles of comparability, operability, the composition of qualitative and quantitative, dynamism, comprehensiveness, and complexity [15-18], the comprehensive index system of initial high-tech enterprises' HR competitiveness is constructed by combining the specifications of high-tech companies themselves. This index system mainly consists of five primary indexes, 16 secondary indexes, and 32 tertiary indexes, as presented in Table I.

The human resource competitiveness of high-tech enterprises mainly consists of five parts: human capital power, human resource environment attractiveness, human resource policy incentive power, human resource investment competitiveness, and human resource performance manifestation power, with the goal of reflecting both the existing competitiveness and the future competitive potential. Human resource environment attractiveness, human resource policy incentive power, and human resource investment competitiveness are the direct manifestation of human resource competitiveness of high-tech zone, and human capital power is the bridge between human resource environment attractiveness, human resource policy incentive power, and human resource investment competitiveness and human resource performance manifestation power.

B. *Selection of Key Indexes Based on Self-organized Data Mining Algorithm*

Since the initial human resource competitiveness evaluation index system of high-tech enterprises contains a large number of indexes, using all the indexes to evaluate the competitiveness of high-tech enterprises will consume a lot of time and space resources, so in order to improve the evaluation efficiency, it is necessary to analyze the indexes in the initial human resource competitiveness evaluation index system of high-tech enterprises, identify the key attributes related to the competitiveness of high-tech enterprises, and use them as the basis to design the assessment setup of high-tech companies' human resource competitiveness. In order to improve the evaluation efficiency, it is necessary to analyze the indexes in the initial evaluation index system of high-tech enterprises, identify the key attributes related to the competitiveness of high-tech enterprises, and design the evaluation system of human resources competitiveness of high-tech enterprises based on this.

In the process of identifying the key attributes related to the competitiveness of HR in high-tech companies, the objective system analysis (OSA) way in the self-organized info analysis algorithm is used to extract the key attributes [19]. The objective system analysis method in the self-organized data mining algorithm automates the following steps objectively.

1) Divide the observed sample data into training and detection sets.

2) Generate the system to be selected at each stage by different variables and growing complexity [20].

3) Estimate the unknown parameters on the training set for the parameters of high-tech enterprises' human resource competitiveness evaluation system.

4) Select some optimal human resource competitiveness evaluation systems for high-tech enterprises at each stage using data from the testing set.

5) When repeating steps (2) to (4), the complexity of the assessment setup of HR competitivity of high-tech enterprises grows gradually as the number of HR of high-tech companies increases. Otherwise, the final optimal evaluation system of human resources competitiveness of high-tech companies is selected.

According to the basic principles of the OSA algorithm, the key attributes related to the competitivity of HR of high-tech enterprises are identified in the following steps.

(1) Divide the initial data set of HR competitivity evaluation indexes of high-tech enterprises W into two groups with the same sample size γ and λ so that $W{=}\gamma\bigcup\lambda$. The data lengths of γ and λ are both N, and $P{=}\{1,2,\cdots,m\}$, $Q{=}\{1,2,\cdots,N\}$.

(2) Let $k=1$. For the i-th variable (initial evaluation index data of high-tech enterprise's human resource competitiveness), parameter estimation is performed by the least squares method on the full set of samples [21]to obtain:

$$x_i = \gamma_0 + \lambda x_0 \quad i \in P \tag{2}$$

Then perform parameter estimation using least squares on the data sets γ and λ, respectively, to obtain:

$$x_i^\gamma = \gamma_0^\gamma + \lambda^\gamma x_0 = \gamma_0^\lambda + \lambda^\lambda x_0 \quad i \in P \tag{3}$$

Calculate the minimum deviation criterion value [22].

$$\eta_{1i} = \frac{\sum_{k=1}^{N}\left(\frac{x_i^\gamma(k) - x_i^\lambda(k)}{x_i(k)}\right)^2}{N} \quad i \in P$$

Let $\eta_1 = \min(\eta_{1i})$

$$\text{Let } k = k+1 \tag{4}$$

TABLE I. INITIAL EVALUATION INDEX SYSTEM OF HR COMPETITIVENESS OF HIGH-TECH COMPANIES

Target layer	First-level indexes	Secondary indexes	Tertiary indexes
Evaluation index system of HR competitiveness of high-tech companies	Human capital	Number of human resources	Total number of employees
			Proportion of R&D personnel
			Proportion of foreign students
		Human resource quality	Proportion of personnel with bachelor's degree
			Proportion of personnel with master's degree
			Proportion of personnel with doctor's degree
			Proportion of personnel with intermediate professional titles
			Proportion of personnel with senior professional titles
	Attractiveness of HR and environment	Perfection of human resources market	Human resource flow system
			Human resources entrepreneurship service satisfaction index
			Free flow index of human resources
		Economic improvement of HR	Per capita disposable income
			Contribution rate of high-tech industry
			Internationalization trend
		HR life comfort	Housing accessibility
			Transportation convenience
			Air environment index
			Cultural Leisure Index
		Intelligence intensity of HR	Number of colleges and universities per square kilometer
			Amount of scientific study institutions per square kilometer
			Amount of college students per square kilometer
	Human resources policy incentives	Attraction of HR policy	
		Incentive degree of human resources policy	
		Incentive degree of human resource flow policy	
		Perfection of human capital property rights system	
	Human resources investment competitiveness	Perfection of education and training system	Training input index
			Training efficiency index
		Health Care Security Index	Health insurance index for medical treatment
			Social security rate
		Investment in innovation	Funds for technical development activities
			Per capita scientific research funds
	Human resources performance demonstration	Scientific and technological achievements	Independent intellectual property rate
			technical income
		Economic performance	Per capita GNP
			Gross industrial output per capita
			Per capita profit and tax
		External benefit system of human resources	

Within the m independent variables, take any k different attribute variables $x_i, x_j, \cdots, x_r \left(i, j \cdots, r \in P\right)$, least squares estimate the parameters on the full set of samples to obtain a system of k -Formulas.

$$\begin{cases} x_i = \gamma_{01} + \gamma_{11} x_i + \cdots \gamma_{(k-1)1} x_r + \lambda_1 x_0 \\ x_j = \gamma_{02} + \gamma_{12} x_i + \cdots \gamma_{(k-1)2} x_r + \lambda_2 x_0 \\ \vdots \\ x_r = \gamma_{0k} + \gamma_{1k} x_i + \cdots \gamma_{(k-1)k} x_r + \lambda_k x_0 \end{cases} \tag{5}$$

Then carry out the parameter estimation for $x_i, x_j, \cdots, x_r \left(i, j \cdots, r \in P\right)$ using least squares on γ and λ, respectively, to obtain:

$$\begin{cases} x_i^{\gamma} = \gamma_{01}^{\gamma} + \gamma_{11}^{\gamma} x_i + \cdots \gamma_{(k-1)1}^{\gamma} x_r + \lambda_1^{\gamma} x_0 \\ x_j^{\gamma} = \gamma_{02}^{\gamma} + V_{12}^{\gamma} x_i + \cdots \gamma_{(k-1)2}^{\gamma} x_r + \lambda_2^{\gamma} x_0 \\ \vdots \\ x_r^{\gamma} = \gamma_{0k}^{\gamma} + \gamma_{1k}^{\gamma} x_i + \cdots \gamma_{(k-1)k}^{\gamma} x_r + \lambda_k^{\gamma} x_0 \end{cases} \tag{6}$$

$$\begin{cases} x_i^{\lambda} = \gamma_{01}^{\lambda} + \gamma_{11}^{\lambda} x_i + \cdots \gamma_{(k-1)1}^{\lambda} x_r + \lambda_1^{\lambda} x_0 \\ x_j^{\lambda} = \gamma_{02}^{\lambda} + \gamma_{12}^{\lambda} x_i + \cdots \gamma_{(k-1)2}^{\lambda} x_r + \lambda_2^{\lambda} x_0 \\ \vdots \\ x_r^{\lambda} = \gamma_{0k}^{\lambda} + \gamma_{1k}^{\lambda} x_i + \cdots \gamma_{(k-1)k}^{\lambda} x_r + \lambda_k^{\lambda} x_0 \end{cases} \tag{7}$$

Calculate the minimum deviation criterion value for each system of Formulas.

$$\eta_{ij\cdots r} = \frac{\eta_{ki} + \eta_{kj} + \cdots + \eta_{kr}}{k} \tag{8}$$

In Formula (8), calculate $\eta_{ki}, \eta_{kj}, \cdots, \eta_{kr}$ according to Formula (4), denoted as $\eta_k = \min\left(\eta_{ij\cdots r}\right)$.

(4) Compare η_k with η_{k-1}, if $\eta_k \le \eta_{k-1}$, go back to step (3); otherwise, stop the algorithm and record the minimum deviation criterion value $best\eta = \eta_{k-1}$. The variables in the set of Formulas corresponding to the minimum deviation criterion value of η_{k-1} are the characteristic variables of the system [23]. The attributes corresponding to these characteristic variables are the key attributes for evaluating the competitiveness of HR of high-tech enterprises.

The obtained key attributes of the human resource competitiveness of high-tech companies are used to construct the final applied assessment index setup of HR competitiveness of high-tech enterprises, according to which the fuzzy comprehensive assessment process is applied to design the assessment project of human resource competitiveness of high-tech enterprises and obtain the evaluation results of human resource competitiveness of high-tech enterprises.

C. Evaluation of Human Resource Competitiveness of High-tech Enterprises

In the process of evaluating the competitiveness of human resources in high-tech enterprises, there are several elements to be assumed, and they are able to be parted into various layers and groups [24]. When conducting a comprehensive evaluation of such an object, in order to facilitate the distinction of the act and effect of the ultimate assessment of distinct elements and to receive the data that all elements collected more comprehensively, the number of elements is dividable to various groups based on particular features [25], with a small number of factors in one category and a comprehensive evaluation of each type first, followed by a high-level synthesis of the evaluation results between the classes. Therefore, the assessment of HR competitivity of high-tech enterprises is achieved by a multi-level fuzzy comprehensive evaluation method.

a) Construction of Factor Sets

The theoretical factor domain U is divided into m disjoint subsets according to different attributes, i.e., $B = \bigcup_{i=1}^{m} B_i$, and $B_i \cap B_j = \phi\left(i \ne j\right)$, and $B = \left\{B_i\left(i = 1, 2, \cdots, n\right)\right\}$ is called the first-level indicator set; each first-level indicator is further divided and $B_i = \left\{B_{ij}\left(i = 1, 2, \cdots, n; j = 1, \cdots, m\right)\right\}$ is called the second-level indicator set. Similarly, a set of indicators can be obtained at three or even more levels.

b) Determination of the Weights of Each Index Layer

The design of the weights of each level of indexes mainly uses the hierarchical analysis method to calculate the weights of tertiary, secondary, and primary indexes, in turn. The comparison matrices are constructed for different indicator levels, and the weights of each indicator are calculated [26], and then the consistency test is performed. If they pass the test, the weights can be determined; if they do not pass the test, the comparison matrix is reconstructed, the weights of each indicator are calculated, and the consistency test is conducted again until they pass the test so that the weights of each indicator can be scientifically determined.

c) Construction of Grade Evaluation Criteria

The evaluation level set is a collection of various evaluation results that evaluators may make about the competitivity of HR in high-tech enterprises, i.e., $V = \left\{v_1, v_2, \cdots, v_e\right\}$.

d) Determination of the Affiliation Relationship to Construct the Fuzzy Evaluation Matrix

The fuzzy assessment matrix for every element of the second level is created based on the third-level indexes. The factors of the third level index B_{ijk} are evaluated according to the rank of the evaluation set $V = \left\{v_1, v_2, \cdots, v_e\right\}$, and the affiliation degree of B_{ijk} to v_e is evaluated by $R_{ie}\left(i = 1, 2, \cdots, n; \mathrm{e} = 1, 2, \cdots, f\right)$, thus forming the evaluation matrix of the factors of the second level index R_{ij}.

$$R_{ij} = \begin{bmatrix} R_{11} & \cdots & R_{1e} \\ \vdots & \vdots & \vdots \\ R_{i1} & \cdots & R_{ie} \end{bmatrix} \tag{9}$$

R_{ij} denotes the fuzzy matrix corresponding to the factors of the 3rd level subset under the factor i at the 2nd level, i shows the number of elements of the 3rd level indexes under the 2nd level indexes, e is the number of human resource competitiveness level of high-tech enterprises, where: $R_{ie}\left(i = 1, 2, \cdots, n; \mathrm{e} = 1, 2, \cdots, f\right)$ denotes the affiliation degree of the f-th level comments made to the i-th evaluation index, i.e., later than using professionals to score the assessment outcomes, it can get v_{ie} level comments v_e for the i-th evaluation index, then:

$$R_{ie} = \frac{v_{ie}}{h} \tag{10}$$

Where, h is the number of experts.

e) Determination of the Fuzzy Subset Vector

The single-factor assessment matrix R_{ij} and the weight vector A_{ij} of the three-level index set $U_{ij} = \left\{U_{ijk}\right\}$ are used to do the fuzzy comprehensive assessment. The fuzzy integrated assessment vector of the three-level indexes is attained and normalized ("~" indicates normalization, same below).

$$P_{ij} = A_{ij} \cdot R_{ij} \sim \left(b_{ij}^{e}\right), \left(i = 1, \cdots, n;\ j = 1, \cdots, m; \mathrm{e} = 1, 2, \cdots, f\right) \tag{11}$$

Where, p_{ij}^{e} is the value of the affiliation function of the comprehensive evaluation P_{ij} taken at the e-th comment. The fuzzy operation "$\cdot$" here uses the $M\left(\cdot, \underset{+}{\wedge}\right)$ operator. That is, $p_{ij}^{e} = \overset{n}{\underset{+}{\wedge}}\left(a_{ij}, r_{ij}^{e}\right), \left(i = 1, \cdots, n;\ j = 1, \cdots, m; \mathrm{e} = 1, 2, \cdots, f\right)$, where $\underset{a+b}{\wedge} = a + b - a \cdot b$.

In the same way, the comprehensive evaluation of the second-level indicator set and the first-level indicator set is done again. Eventually, the single-factor assessment matrix R and the weight vector A of the first-level indicator $B = \left\{B_i\right\}$ are used to do the fuzzy comprehensive assessment, and the comprehensive assessment vector P of the first-level indicator is attained and normalized; according to the above model, the fuzzy comprehensive evaluation results of human resources competitiveness of high-tech enterprises P_{ij}, P_i and P can be obtained, which are the fuzzy subset vectors on V.

$$\begin{cases} P_{ij} = A_{ij} \cdot R_{ij} = \left(P_{i1} \cdots P_{im}\right) \\ P_i = A_i \cdot R_i \\ P = A \cdot R \end{cases} \tag{12}$$

Thus, the results in assessing the HR competitiveness of high-tech enterprises are obtained.

III. Results

A. Experimental Setup

To confirm the applied impact of the HR competitiveness evaluation method of high-tech companies according to the self-organized data mining algorithm studied in this article in the evaluation of the human resource competitivity of actual high-tech enterprises, eight high-tech enterprises in a first-tier city are used as the research objects. The overview of the research objects is shown in Table II.

The human resource competitiveness of each research subject is evaluated using the methodology of this paper, and the outcomes attained are shown hereby.

B. Info Clustering Results

In this paper, the fuzzy clustering algorithm is used to obtain the initial evaluation index system by clustering the research object's human resource-related data. Assuming that several human resource-related data points are random distribution, as shown in Fig. 1(a), where the noise points occupy 8% of the data, the number of clusters in this paper is set to 5. The clustering results of human resource-related data obtained by the method in the paper are shown in Fig. 1(b).

Analysis of Fig. 1 shows that the boundaries of various evaluation elements of the evaluation of HR competitiveness of high-tech enterprises are not obvious and have certain fuzziness. The method in this paper applies the principle of cluster analysis that "the indicators with similar properties are classified into one category, and the indicators with large differences are classified into different categories, so that the indicators within the category have high homogeneity, and the indicators between the categories have high heterogeneity," which can better shield the impact of noise and outlier data, and accurately reflect the spatial set characteristics of HR-related data. The initial assessment indicator arrangement of HR competitiveness of high-tech enterprises has been constructed, which has a positive impact on improving the application efficiency of human resource-related data.

C. Selection of Key Indexes

The method in this paper uses self-organized data mining algorithms to identify key attributes related to the competitiveness of high-tech enterprises on the basis of the initial evaluation index system of high-tech enterprise's human resource competitiveness, thus generating the final used evaluation index system for high-tech enterprise's human resource competitiveness, as shown in Table III.

In order to analyze the scientific of the evaluation index system of HR competitiveness of high-tech companies finally used, the principle of data variance describing the information content of evaluation indexes is used as the basis to set the analysis criteria for the scientific of evaluation index system construction. In and S are taken as the information contribution rate of the filtered evaluation indexes to the initial evaluation indexes and the covariance matrix of the evaluation index data, respectively, then.

$$In = \frac{trS_s}{trS_h} \tag{13}$$

In Formula (13), tr is the trace, and s and h are the number of filtered evaluation indexes and the number of initial evaluation indexes, respectively.

Formula (13) can describe the ratio between the overall variance of the screened evaluation indexes and the overall variance of the initial evaluation indexes so that the information on the initial indexes described by the screened evaluation indexes can be obtained. In general, if the screened indexes can reflect more than 90% of the initial indexes, it means that the evaluation index system constructed by the screened evaluation indexes is scientific.

The overall variance of the assessment indicators screened by way of this paper and the overall variance of the initial 32 evaluation indexes are brought into Formula (13) to obtain the results of the scientific analysis of the evaluation index system constructed by way of this article, as presented in Fig. 2.

Analyzing Fig. 2, we can get that after identifying the key attributes of the evaluation indexes in the initial evaluation index system, and the information contribution rate reaches more than 95% when the number of evaluation indexes reaches 17, which indicates that the assessment indicator setup constructed by the method of this paper has high scientific. Although the information contribution rate also increases under the condition that the number of evaluation indexes continues to increase, the complexity and redundancy of the evaluation index system also increase.

D. Evaluation Results

Taking enterprise, A as an example, the evaluation index weights are calculated using this paper's method, and the results are shown in Fig. 3.

Analyzing Fig. 3, it can obtain that the weight of each level of the evaluation index is calculated using the method of this paper, and the highest weight of human capital power (B1) reaches 0.26. The lowest weight of human resource investment competitiveness reaches 0.15 (B4).

Fig. 4 shows the evaluation results of the methods in this article, studies [7], and [8] for each research object, as well as the comparison between the evaluation results of this article's method and the actual human resource competitiveness of each research object.

Analyzing Fig. 4, it can be seen that the human resource competitiveness of the selected research object does not have significant advantages and is generally at a moderate level. There is a significant deviation between the evaluation results obtained using the methods of studies [7] and [8] and the actual human resource development potential of the research object. This method can effectively obtain the evaluation results of the human resource competitiveness of the research object, and the evaluation results obtained are basically consistent with the actual human resource development potential of the research object. The major cause for the variance in the assessment outcomes of enterprise B maybe since the main direction of enterprise B is new materials and application technology and advanced manufacturing technology. The two technologies are related but relatively opposed to each other, so there is a certain duplication and redundancy in acquiring human resource information, which causes a certain deviation in the final evaluation results. Still, this deviation is within a manageable range. The above data fully demonstrate that the method of this paper can evaluate the competitivity of HR of high-tech enterprises more accurately.

TABLE II. OVERVIEW OF RESEARCH OBJECTS

Research object	Survey
Enterprise A	The main research direction is electronics and information technology
Enterprise B	Main research directions are new materials and application technology and advanced manufacturing technology
Enterprise C	The main research direction is modern agricultural technology
Enterprise D	The main research direction is aerospace technology
Enterprise E	The main research directions are new technologies for environmental protection and new energy and efficient energy-saving technologies
Enterprise F	The main research direction is nuclear application technology
Enterprise G	Main research directions are bioengineering and new medical technology
Enterprise H	The main research direction is marine engineering technology

E. *Discuss*

In today's fiercely competitive business environment, the human resource competitiveness of high-tech enterprises is crucial for innovation and sustainable development. However, accurately assessing and measuring human resource competitiveness has always been a challenging task. Traditional evaluation methods often rely on subjective judgment and limited data, making it difficult to fully reflect the actual situation of the enterprise. Therefore, the evaluation method based on self-organizing data mining algorithm provides a more scientific and objective way for relevant research to evaluate the human resource competitiveness of high-tech enterprises.

The advantage of self-organizing data mining algorithm lies in its ability to automatically discover and select key evaluation indicators from a large amount of data, without the need for prior assumptions or manual intervention. This method can help identify factors that play a crucial role in human resource competitiveness, which may be overlooked or less noticeable in traditional methods. Through self-organizing data mining algorithms, key indicators that have a significant impact on the human resource competitiveness of high-tech enterprises can be extracted from massive data, providing a more accurate and comprehensive basis for evaluation.

In addition, evaluation methods based on self-organizing data mining algorithms can provide more reference and decision support. By analyzing and mining the selected key indicators, we can gain a deeper understanding of the correlation and degree of impact between these indicators. This in-depth analysis can help understand the complex relationships in human resource management and provide more targeted improvement and optimization suggestions for enterprises. For example, by identifying a positive correlation between employee satisfaction and innovation ability, companies can place greater emphasis on improving employee satisfaction to promote innovation and enhance competitiveness.

Overall, the evaluation method for human resource competitiveness of high-tech enterprises based on self-organizing data mining algorithms has obvious advantages and potential benefits. It can automatically discover and select key indicators from a large amount of data, provide comprehensive, objective, and accurate evaluations, and provide direction for improvement and optimization for enterprises. However, when applying this method, attention needs to be paid to issues such as data quality, algorithm selection, and comprehensive analysis of results. By overcoming these challenges and limitations, we can better evaluate the human resource competitiveness of high-tech enterprises, improve their competitiveness and sustainable development capabilities.

IV. Conclusion

This paper studies the assessment method of HR competitivity of high-tech enterprises based on a self-organized data mining algorithm that constructs an evaluation index system by using a fuzzy clustering algorithm and self-organized data mining algorithm and uses multi-level comprehensive fuzzy evaluation method to comprehensively evaluate the human resource competitiveness of high-tech enterprises, so as to determine the level of human resource competitiveness of high-tech enterprises, thereby judging the strength and weakness of human resource competitiveness of high-tech enterprises and discovering the defects of high-tech enterprises, which can provide a reference for measuring and improving the competitiveness of high-tech enterprises' human resources, and provide a reference for promoting the comprehensive, all-round and coordinated development of high-tech companies' HR competitivity. With the arrival of the era of Big data, more and more data exist in unstructured forms, such as text, image and audio data. Future research can explore how to use Natural language processing, image recognition, sound analysis and other technologies to incorporate these unstructured data into the evaluation model to obtain more comprehensive evaluation results.

A Novel Internet of Things-enabled Approach to Monitor Patients' Health Statistics

Xi GOU*
School of Electronics and IoT Engineering, Chongqing Industry Polytechnic College, Chongqing, 400020, China

***Abstract*—Leveraging Internet of Things (IoT) technology in healthcare systems improves patient care, reduces costs, and increases efficiency. Enabled by IoT, telemedicine allows remote patient monitoring, vital sign tracking, and seamless data accessibility for doctors across multiple locations. This article presents a novel IoT-enabled approach that utilizes artificial neural networks with radial basis functions to detect patients' positions. This real-time tracking mechanism operates even without cellular connectivity, providing timely diagnoses and treatments. Our research aims to develop a smart and cost-effective healthcare approach, revolutionizing patient care. Mathematical analysis and experiments confirm the effectiveness of our proposed method, particularly in predicting patient location for the upcoming smart healthcare solution.**

***Keywords*—Internet of things; healthcare; telemedicine; artificial neural network**

I. Introduction

In today's world, with the ever-increasing advancement of technologies, sharing data related to old systems is cumbersome and often weak. For example, sharing health data with others in old systems is difficult due to different formats and parameters and is not suitable for the urgent needs of modern users [1]. In addition, the relationship between healthcare experts and patients has always been a one-way path. For patients and experts, the current system is incredibly slow, inflexible, and unclear. These problems are equally evident in all stages. When a patient needs services, health plans are used to determine the amount of money they will pay. To determine this fee, as opposed to the agreement between the patient and the health plan, the health plan must validate the services received from the provider and then share the results with the provider [2]. This only happens if the application provider is online. For a provider to be considered online, a complex agreement must be negotiated, which adds significant overhead to the provider's administrative costs. Part of these costs are related to billing and insurance costs, which include activities such as updating the database and maintaining records of the services provided [3]. Normally, this whole process takes between one to two weeks if done electronically and three to five weeks if done on paper. In addition, this process is full of spots where it is possible that an error can occur. In order for sponsorship to actually take place, many people have to check multiple old agreements compared to multiple records. The result is an ineffective and unclear process that causes profiteers and patients to feel confused and pessimistic [4].

Recent advancements in wearable health technologies have opened new avenues for telemedicine and have made it possible to monitor one's health remotely and continuously. These sensors can collect a wide range of data, including heart and respiratory system data and several more vital signals. Using artificial intelligence and signal processing techniques, these signals can be automatically analyzed and categorized. In the event of detecting unusual signal patterns, notifications are promptly sent to both patients and doctors. This innovative approach to telemedicine provides a valuable and rewarding experience for individuals needing medical assistance [5]. Internet of Things (IoT), humanitarian logistics, meta-heuristic algorithms, nonlinear complementarity, silicon nanostructure arrays, machine learning, Markov-modulated regime-switching market, and artificial intelligence play crucial roles in the field of telemedicine, revolutionizing healthcare delivery and improving patient outcomes.

The integration of IoT in telemedicine allows for remote patient monitoring, real-time data collection, and seamless communication between healthcare providers and patients. This connectivity enhances the accessibility and effectiveness of healthcare services, especially in remote or underserved areas [6-8]. Humanitarian logistics leverages technology to optimize the delivery of medical supplies and resources during emergencies or humanitarian crises. It ensures timely and efficient distribution, minimizing supply chain disruptions and saving lives [9]. Meta-heuristic algorithms provide efficient solutions to optimization problems in telemedicine, helping healthcare providers in resource allocation, scheduling, and decision-making. These algorithms can optimize complex systems and improve the utilization of healthcare resources [10, 11]. Nonlinear complementarity and silicon nanostructure arrays are emerging technologies with potential for telemedicine. They enable advanced diagnostics, drug delivery systems, and personalized medicine, enhancing the accuracy and effectiveness of medical treatments [12, 13]. Machine learning and artificial intelligence enable predictive analytics, risk assessment, and decision support systems in telemedicine [14-16]. They can analyze vast amounts of patient data, identify trends, and assist healthcare professionals in making informed decisions [17-21]. The markov-modulated regime-switching market model provides insights into the dynamics of telemedicine markets, helping stakeholders understand market behavior and optimize healthcare service provision [22].

Furthermore, telemedicine makes medical services more available at lower costs by using modern communication tools. Additionally, telemedicine virtually provides easy access to medical services for people in rural areas [23]. This easy access cannot be limited to just one country, and different people in different countries can use these medical services. Doctors and

*Corresponding Author

patients can communicate with each other online using computers or smartphones. Doctors can check the patient's file and test results remotely. Patients also visit their doctor at their homes and receive diagnoses and treatment through telemedicine software without waiting for an appointment. Easy and reliable use, smart characteristics, no time loss, high security, and low cost are some advantages of telemedicine [24]. Although telemedicine is still a new concept for users and doctors, advances in technology and medical innovation have expanded its use. Despite the provision of many advantages through this technology, its use is expected to increase in the coming years. "Telemedicine" includes maintenance, care, diagnosis, consultation, and treatment, while at this stage, the focus is on transferring medical data and educational goals. Also, in a more comprehensive and complete view, it can be said that, in general, "telemedicine" is the use of medical and communication technologies to exchange any data, including data, voice or video communications between a doctor and a patient or a doctor and healthcare experts in separate geographical locations as well as creating the possibility to exchange medical, healthcare, research and educational concepts [25].

The convenience of using remote medical services, low waiting time, high-quality medical diagnosis and treatment, and cost reduction are among the advantages of this technology. Also, the presence of the patient's medical record online makes it possible to diagnose and treat the disease more accurately and with higher quality. Another advantage is the lower costs of telemedicine compared to the traditional method. With this method becoming common, insurance companies also will include telemedicine services in their insurance plans, and this process will lead to a reduction in the costs of telemedicine services. Telemedicine services only require a webcam (or smartphone) and a secure online system to connect the patient with the doctor and store medical records. In addition to ensuring the patient's privacy and safe keeping of medical records, the professional competence of doctors should also be ensured through the examination of documents [26]. Moreover, the challenges facing the current medical care system, which is often accompanied by cumbersome laws that slow down medical services, can include data dispersion in the health system, patient disobliging, misdiagnosis, and false medical data, security risks for patient data, and lack of transparency. Researchers and healthcare professionals are faced with a number of new challenges as they attempt to understand and utilize new developments in the field of information technology. Wireless communication platforms and their application to the development and interconnection of smart devices have revolutionized the landscape where the first electronic healthcare systems were conceived. The use of network-enabled devices has become widespread, covering a wide range of items from household items and cars to health and care management systems in what has been referred to as IoT [27].

The purpose of modern information and communication technologies (ICTs) in the healthcare system is traditionally to provide promising solutions that facilitate the efficient delivery of healthcare services, referred to as e-health, including personalized diagnostic, telemedicine, and electronic record tools. In the developed world, however, the rapid increase in longevity has led to the fact that an increasing proportion of the population is over the age of 80. Consequently, traditional healthcare systems need to be designed and developed in a more cohesive and ubiquitous manner in order to provide excellent patient-centered services [28]. In recent years, the emergence of wearable gadgets and smartphones has enabled IoT technology to revolutionize healthcare by changing a traditional hub-based model to a personalized one. With the effective implementation of IoT into customized healthcare services, preventive care becomes timelier and safer, costs are reduced, and patient-centered care is improved. As IoT becomes increasingly prevalent, highly customized healthcare services will be able to provide enhanced and customized access to extensive healthcare information and facilitate clinical decision-making for each patient through the use of unobtrusive, continuous monitoring and sensing [29]. We conduct research on the remotely monitored healthcare system as it plays a vital role in the medical field. A change in lifestyle is also leading to new diseases appearing in the modern age. Further, the COVID-19 epidemic shows the global community our deficiencies regarding healthcare services. A large number of people need health care services at the same time, and adequate resources, equipment, and space are required. Remote health monitoring offers several advantages for elderly and ill patients who are unable to visit medical facilities for periodic checkups. This will ultimately improve the efficiency of the entire healthcare system and allow critical patients to receive the necessary care. The main contributions of the paper are centered around addressing the energy efficiency and decision problems related to location tracking for remote health monitoring. The specific contributions can be summarized as follows:

- Problem identification and analysis: The paper identifies and analyzes the energy efficiency and decision challenges associated with location tracking in the context of remote health monitoring. By understanding these challenges, the researchers lay the groundwork for developing solutions that optimize energy consumption and improve decision-making processes.

- Development of a location tracking system: The researchers design and develop a system that is capable of collecting patients' location data for remote health monitoring. This system incorporates a mobility management model to efficiently track the patients' movements and gather relevant location information.

- Feature extraction based on movement: In order to accurately predict the patients' location, the paper introduces a novel approach for feature extraction. By analyzing the movement patterns of the patients, relevant features are extracted from the location data. This step is crucial for improving the accuracy of location prediction.

- Utilization of radial basis function neural network: The paper proposes the use of radial basis function neural network as a learning algorithm to process the extracted features and predict the patients' location.

- Enhanced prediction of patient location: The combination of the mobility management model, feature extraction, and radial basis function neural network learning enables an efficient and accurate prediction of patients' locations. This advancement in location tracking facilitates seamless information gathering of patients' health data in remote monitoring scenarios.

II. Related Work

A mobility-aware, IoT-enabled healthcare security framework has been proposed by Moosavi, et al. [30]. The system consists of three main components: interconnected gateways that provide robust mobility, an ad-hoc protocol that supports resuming sessions, and a certificate-based DTLS handshake protocol for user authentication and authorization. Smart gateways serve as an intermediary computing layer between cloud services and IoT devices. With the computing layer, there is no need to reconfigure the device for ubiquitous mobility. The framework is demonstrated using simulations and a full prototype of both hardware and software. Compared to existing approaches, this framework significantly reduces the delay between end users and smart gateways by 17% and the amount of communication overhead by 25%.

Data generated by medical devices with sensors is often referred to as big data, which is a combination of structured and unstructured data. The complexity of the data makes it difficult to analyze and process big data in order to find relevant information to aid decision-making. Security of data is an essential requirement for healthcare big data systems. This issue was addressed by Manogaran, et al. [31] by creating a new architecture for incorporating the IoT into healthcare for storing and processing scalable sensor data (big data). The suggested architecture is based on two main underlying models, namely Grouping and Choosing (GC) and Meta Fog-Redirection (MFR). MFR collects and archives sensor data (big data) generated by a variety of sensors. The proposed GC architecture integrates fog computing and cloud computing. MapReduce-based prediction models are also used to predict heart disease. Based on performance measures such as f-measure, precision, robustness, and efficiency, the proposed architecture and prediction model are evaluated.

Pal, et al. [32] have proposed an IoT-based system for controlling access to constrained healthcare resources. Using this approach, trusted users will have access to the services while unauthorized users will not be able to access valuable resources. The authorization design utilizes attributes, roles, and capabilities in a hybrid manner. Role membership is assigned based on attributes, and permissions are evaluated based on attributes. Capabilities are granted by membership in roles. User capabilities may be granted according to additional attributes when accessing specific services provided by IoT devices. Consequently, the number of policy instances necessary for specifying access control criteria is significantly reduced. It is implemented and evaluated based on an initial proof-of-concept. There was minimal additional overhead associated with this approach when compared to other solutions that incorporate access control functions within the Internet of Things.

IoT technology has revolutionized the healthcare industry, resulting in smart medical applications. A system for monitoring urine-based diabetes (UbD) at home has been presented by Bhatia, et al. [33]. In order to predict and monitor diabetes-related urinary tract infections, a four-layer system is proposed. Diabetes measures are regularly tracked and a prediction procedure is conducted to enable precautionary steps to be taken at an early stage of the disease. Furthermore, a Recurrent Neural Network (RNN) was used to obtain a probabilistic measure of UbD monitoring by calculating the Level of Diabetic Infection (LoDI), a measure of diabetes infection. Simulation results demonstrated that the proposed system was more accurate, robust, and consistent than state-of-the-art decision-making techniques.

In the design of any information and communication technology (ICT) infrastructure, interoperability and connectivity play an important role. By integrating IoT technologies into medical systems, people will be able to receive timely, cost-effective, and ubiquitous healthcare services. Currently, a complex ecosystem of devices, databases, and communication technologies provides a wide range of healthcare services. Healthcare information systems must integrate and collaborate with these technologies and resources to ensure that healthcare is provided efficiently. By providing connectivity for billions of devices worldwide, IoT technology improves healthcare delivery and quality. The potential benefits of IoT-based connectivity for healthcare are discussed by Zeadally and Bello [34]. An overview of recently implemented IoT-based healthcare systems is provided. Lastly, they discuss the potential uses of the IoT for enhancing healthcare solutions.

A new IoT-based reliable healthcare monitoring approach was proposed by Jacob, et al. [35]. To collect vital parameters, such as deviations in body temperature, multiple sensor nodes are implanted into the body of a patient as a first step. After preprocessing the dataset in order to eliminate redundant and irrelevant attributes, the normalization procedure is applied. Cancers are classified based on their features using a convolutional neural network (CNN). Based on sensor input, the CNN model calculates the cancer risk of a patient. Once the results have been received by the hospital management, they are analyzed. Rivest-Shamir-Adleman (RSA) encryption is primarily used in this study in order to achieve high assurance security, simplicity of deployment, and simplicity of use. A modified version of the RSA algorithm, utilizing the double encryption-decryption process and n prime numbers, is presented in this paper. Based on experimental results, the proposed method demonstrated superior performance when compared to other approaches.

III. Proposed Method

A. Network Model

System performance and network architecture are critical to the success of an IoT-based healthcare system. The ability to process large amounts of data quickly and accurately is essential for IoT-based healthcare systems to work properly and provide accurate diagnoses and treatments. Additionally, the network architecture of an IoT-based healthcare system must be robust enough to handle the large amounts of data being transferred between various devices and systems. By placing sensors in the patient's body and transmitting the data to the monitoring end, various processes are undertaken, which require careful observation of the locations of the sensors, the hardware configurations, and the control of the energy usage of the monitoring devices. An industry-specific IoT environment incorporating significant parameters was used to design the network architecture for optimal data transmission and energy consumption according to the patient or node locations. Assumptions and approximations are outlined below.

- Sensor nodes operate continuously and communicate via cellular networks.
- According to the Rayleigh distribution, the signal magnitude varies randomly or fades.
- Rayleigh fading channels are considered throughout the communication process.
- Continuous sensing, transmission, and reception are characteristics of sensing operation.
- Patients' bodies are continuously monitored by heterogeneous sensors that collect data such as temperature, blood sugar, etc.
- Patients are equipped with sensors, and they are mobile.

As illustrated by Fig. 1, the present design comprises a mobility management strategy for collecting location information, followed by a radial basis function neural network-based learning method used to predict the node's location to ensure uninterrupted communication. Fig. 2 illustrates the network architecture. In this system, mobility management is used to determine the patterns of movement of nodes as a set of locations. As shown in Fig. 2, these data are used to train the proposed model with location feature maps for each time instant. Based on the training output, nodes or patients' positions are predicted and localized. Localized nodes collect observations estimated from the previous data gathered over time.

B. Mathematical Modeling

The proposed system begins with tracking patient location information. Thus, a patient movement scheme is designed to estimate at first the positions of N patients based on their movements. The number of locations (n) is assumed to be fixed in proximity to the individual's residence or the locations he/she frequently visits. It is also assumed that there are m unknown places that must be investigated to determine how patients move two-dimensionally. Throughout the range of transmission radius R, sensing devices can communicate omnidirectionally with each other. The direction and speed experienced by a patient from any fixed position can be used to determine their relative locations. Sensor location changes over time are primarily a function of rapid node movements, and displacement is measured as a Gaussian random variable with mean 0 and variance 1. The following equations can be used to illustrate the randomness of the movement:

$$|u(r)| = \eta|u(r-1)| + (1-\eta)\phi_{|u|} + \gamma|u|\sqrt{1-\eta^2}\,h_{|u(r-1)|} \tag{1}$$

$$d(r) = \eta d(r-1) + (1-\eta)\phi_d + \gamma d\sqrt{1-\eta^2}\,h_{d(r-1)} \tag{2}$$

In the above Equations, u(r) represents time-dependent displacement, whereas d(r) represents displacement direction concurrent with the movement of the sensor nodes. In this situation, the probability of the sample depends on η ranging from 0 to 1 and on the proportional average speed based on the scale factor of r→∞.

C. Pattern Definition and Feature Assignment

The random movement of patients makes it difficult to recognize certain patterns. Patients move from one location or provider to another, and their care may be fragmented, making it hard to determine a consistent care pattern or evaluate the effectiveness of interventions. Additionally, patients may not have the same healthcare access, making it difficult to identify patterns. However, using historical location records, relationships are formed, and feature mapping is conducted. This feature mapping can then be used to identify potential gaps in care and areas where healthcare providers can intervene to improve patient outcomes. It can also help reduce the burden of fragmented care by helping providers identify the most effective treatments. In a high-dimensional space, locations of patient i can be mapped at different time intervals t, as follows:

$$L_{x_i} = \{x_i(1), x_i(2), \dots, x_i(r)\}$$

$$L_{y_i} = \{y_i(1), y_i(2), \dots, y_i(r)\} \tag{3}$$

In a g-dimensional space, patients' positions can be mapped separately in the x- and y-axes. By plotting points on the graph in the x- and y-axes, it is possible to map out the position of each patient within the given space. This allows for more accurate tracking and analysis of the patient's movements over time. Thus, both feature spaces can be expressed as follows:

$$W_{x_i} = \{W_{x_i}(1), W_{x_i}(2), \dots, W_{x_i}(v), \dots, W_{x_i}(r-g+1)\}$$

$$W_{y_i} = \{W_{y_i}(1), W_{y_i}(2), \dots, W_{y_i}(v), \dots, W_{y_i}(r-g+1)\} \tag{4}$$

The feature vectors assigned to each patient are bound in the g dimension and stored in feature spaces WXi and WYi, respectively. These features provide sensor movement characteristics and can be used as training data for predicting a sensor's future location.

D. Feature Learning

Machine learning techniques are the most effective in terms of optimizing and approximating functions accurately, making them a valuable tool for prediction. Among the various machine learning approaches used to train systems, the radial basis function neural networks are unique in their ability to approximate functions and classify them. As shown in Fig. 3, radial basis function neural networks are able to linearize nonlinear data.

Fig. 3 illustrates an architecture in which three layers are present: input, hidden, and output. The input layer takes the input data and passes it on to the hidden layer. The hidden layer processes the input data with mathematical operations and passes the processed data to the output layer. The output layer produces the desired output, such as a prediction or classification. A radial basis function is used in the hidden layer to convert the nonlinear to linear data. In most cases, nonlinear kernels are used as Gaussian kernels in radial basis function neural networks based on Euclidean distance. The radial basis function neural network is trained to learn the input characteristics in the form of $v = 1, 2, \dots, (r - t(g - 1))$, which are output components to be $Q_{X_i(v)}$ and $Q_{Y_i(v)}$.

E. Place Estimation

The last step in our approach involves obtaining predictions based on our assumptions. The predicting procedure is initiated, and the position is estimated if the mobility management solution cannot identify the point of interest because of excessive communication interference. At first, the model considers the initial coordinates of the last place and searches for the next possible location. During the prediction process, this assumption was based on the non-availability of the model for mobility management. According to our assumptions, m is the predicted number of locations or steps associated with our experiment and $V_P(p)$ denotes an input vector for (p = 1, 2, . . ., m). Suppose that the output results for (P = X, Y) during the prediction will be $S_P(p)$. Therefore, it can be calculated as follows:

$$S_P(p)=\sum_{j=1}^{z} k_j . \phi(V_P(p), c_j) \tag{5}$$

In other words, with respect to $S_P(p)$, the anticipated position ith individual can be shown by:

$$\hat{L}_i(r + p) = \hat{x}_i(r + p), \hat{y}_i(r + p) \tag{6}$$

In this manner, the latest position corresponds to the following location on the axis of $\hat{x}_i(r + p)$, $\hat{y}_i(r + p)$. Neurons are updated periodically in order to predict future locations in accordance with certain rules. The incoming points for the pth vector are expressed matrixial in the following way.

$$V_X(p) = \begin{bmatrix} x_i(r - t(g - 1) & \dots & x_i(r)) \\ \hat{x}_r & \dots & \hat{x}_i(r + p) \end{bmatrix} \tag{7}$$

$$V_Y(p) = \begin{bmatrix} y_i(r - t(g - 1) & \dots & y_i(r)) \\ \hat{y}_r & \dots & \hat{y}_i(r + p) \end{bmatrix} \tag{8}$$

This is our setup for converting high-dimension states into low-dimension ones in order to predict them. The prediction outcome is as follows:

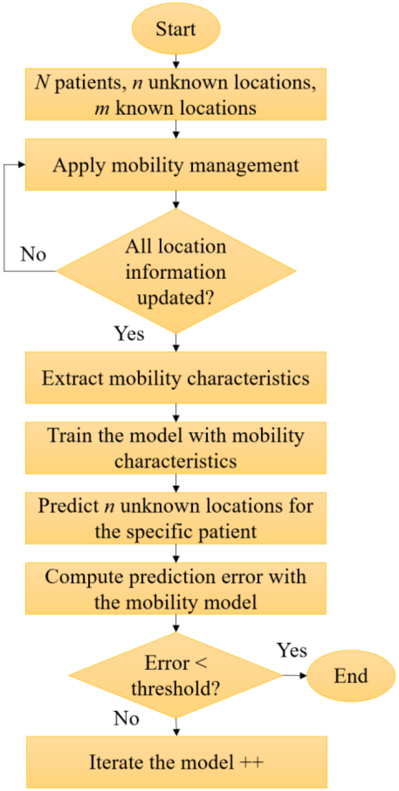
$$\hat{L}_i = \{\hat{L}_i(r + 1), \hat{L}_i(r + 2), \dots, \hat{L}_i(r + p), \dots, \hat{L}_i(r + m)\} \tag{9}$$

In order to determine the prediction error, the actual number of patient places traveled by the mobility management scheme can be compared to the prediction error. According to the prediction-based algorithm, known locations can be expressed as follows:

$$L_i^0 = \{L_i^0(r + 1), L_i^0(r + 2), \dots, L_i^0(r + p), \dots, L_i^0(r + m)\} \tag{10}$$

In this regard, the expected error value can be calculated as follows:

$$e(p) = \frac{1}{N}\sum_{i=1}^{N} \sqrt{(L_i^0 - \hat{L}_i)^2} \tag{11}$$



Start
N patients, n unknown locations, m known locations

IV. Experimental Results

This section presents the numerical analysis and provides a detailed analysis of the experimental findings to evaluate the effectiveness of the proposed mechanism. The experiments were conducted using a MATLAB simulator, and Table I outlines the parameters used for the simulation tests. The dataset consisted of 2400 data points, capturing position information for 600 locations over different time periods, which were used for both training and testing purposes. To assess the accuracy of the suggested technique, an average error was calculated, as depicted in Fig. 4. In the traditional method, a simple range error is employed as the basis for the mobility management model. As the number of prediction steps increases, the average error becomes more pronounced. The error rate rises when the number of prediction steps is reduced and when an individual remains outside the range of the cellular network for an extended period. However, our proposed method demonstrates fewer errors compared to conventional methods. Unlike the traditional approach, which relies on a fixed number of prediction steps and exhibits increased error rates when the patient is out of range for longer durations, our method leverages machine learning algorithms to better predict the patient's movements, resulting in a reduction in the average error rate.

TABLE I. Simulation Parameters

Parameter	Value
Network dimensions	80 × 80 m2
Number of simulations	500
Simulation time	1000 seconds
Number of prediction steps	20
Range of sensors	30m
Locations for training	500 locations

Furthermore, the proposed method is compared to a conventional mobility management model in Fig. 5. The primary objective of our research is not only to predict patients' locations but also to monitor their health with precision. Therefore, it is crucial to verify that the developed system can obtain accurate and timely patient data to a significant extent. Fig. 5 illustrates that our prediction model provides additional data and information compared to traditional approaches. As a result, the proposed approach enables more accurate and real-time prediction of patient positions.

Additionally, Fig. 6 shows the minimal response time achieved by our proposed algorithm compared to the conventional method [36]. The results demonstrate that our algorithm can handle a greater number of requests in less time. This improved performance is attributed to the efficient utilization of resources and optimal request routing. The use of at least 10 prediction steps and a minimum time interval of one second between locations contribute to the algorithm's superior performance. It is important to note that modifying these parameters may result in a smoother transition between the performance of the proposed method and the traditional approach.

The experimental results provide quantitative evidence of the proposed mechanism's effectiveness in terms of efficiency, accuracy, and response time. The findings highlight the superiority of our approach over conventional methods, emphasizing the potential impact and benefits it can offer in the field of healthcare monitoring and patient management.

V. Conclusion

In this paper, a neural network-based radial basis function algorithm is presented for the prediction of a patient's location in a remote healthcare system. The movement characteristics of the patients are trained using a radial basis function neural network, and their locations are predicted whenever they move outside of their range of cellular devices. The training of the system is based on a mobility management model. Simulated results indicate that the proposed method is faster and consumes less energy than the existing method. Also, the proposed work shows good results regarding the average error for predicting the position. As a result, the proposed system can reliably and accurately track the locations of patients while maintaining low energy consumption and fast response times. This makes the proposed system an ideal choice for applications in healthcare and monitoring patient mobility, as it offers optimal performance. While radial basis function neural networks have faster training times, their classification process can be slower compared to multilayer perceptron networks. This is primarily due to the computation of the radial basis function in each node of the hidden layer before the input sample vector can be classified. To overcome this limitation and enhance the system's ability to learn new categories and update the classification system in real-time, we propose incorporating transfer learning in future work. Transfer learning is a technique that utilizes pre-trained models as a starting point for learning new features while preserving the existing knowledge. By leveraging transfer learning, we intend to take advantage of the knowledge acquired by the back-end network of the radial basis function neural network. This approach allows for a more efficient adaptation of the network to new categories without disregarding the valuable information that has already been learned.

Abstract—**Software Defined Networking (SDN) is utilized to centralize network control within a controller, but its reliance on a single control plane can make it vulnerable to attacks such as DDoS. This highlights the importance of developing effective security mechanisms and using proactive measures such as detection and prevention strategies to mitigate the risk of attacks. Many DDoS attack detection technologies within SDN focus on detecting and mitigating the attack once it has occurred in the controller, which leads to more seconds of exposure, diminished precision, and high overhead. In this work, we have developed an Automated Modified Grey Wolf Optimizer Algorithm (AMGWOA) to design the detection of this malicious activity in an SDN environment to prevent the attack in the controller. Our methodology involves the development of the AMGWOA, which incorporates a mechanism to facilitate the blocking of malicious requests while reducing detection time and minimizing the use of storage and data resources for detection purposes. The results obtained show that our model performs well, with an ability to minimize a very large number of malicious requests in a minimum of time of less than 1 second compared to Grey Wolf Optimizer and particle swarm optimization algorithms evaluated using the same datasets.**

I. Introduction

Prior to very recently, communication service providers (CSPs) used proprietary physical equipment and devices to carry out network activities, making security a crucial component of wireless communication systems. This typical network design does not provide a scalable and manageable solution for such big and complicated networks, and as user needs rise, more hardware devices are needed to satisfy consumer expectations [1].

With 5G and edge computing, software-defined networking (SDN), which separates the control plane from the data plane, can be used to deliver more adaptable and dynamic services across the wireless communication network [2].

Although this SDN technology has several significant advantages, such as flexibility and economical, effective administration, it also introduces new risks [3]. The SDN controller serves as the brain of the system. The entire network will be at risk if the controller is compromised, or worse, destroyed. The SDN paradigm is vulnerable to DDoS attacks from malicious users, according to a number of recent research studies [4] [5] [6]. This attack is characterized by a large number of puppet hosts controlled by the controller launching an attack on the targeted system, rapidly depleting its resources and threatening its continued operation.

When a DDoS attack affects an SDN network, the switches generate a flood of incoming packet messages for the controller to process. This places a strain on the controller's assets. causes the switch routing table to grow and potentially compromises the integrity of the encrypted connection between the controller and the switches. This has the potential to bring the whole SDN network down.

If the DDoS happens in SDN, communication channels might be quickly blocked, and controller resources would be used up, drastically reducing service quality.

In this research, we provide a novel model based on the Grey Wolf optimization technique that acts in an automated way to prevent DDoS attacks in the SDN network.

Mirjalili [7] describes the Grey Wolf Optimizer (GWO), a novel population-based algorithm motivated by the hunting strategies of a wolf pack. While other evolutionary computation-based methods, such as particle swarm optimization (PSO), fast evolutionary programming (FEP), and the gravitational search algorithm (GSA), achieve comparable performance, GWO has the advantage of requiring fewer adjustment parameters [7].

The design of an improved algorithm based on an automated modified grey wolf (GWO) is the contribution of this paper. This modified GWO will identify the most malicious requests and facilitate blocking them by the SDN Controller, which will minimize the risk of dealing with a critical DDoS attack, minimize the latency, and maintain the continuous availability of the controller for legitimate users.

This work is organized as follows: The background of the research is provided in Section II. Section III gives a brief summary of previous work. Section IV presents the design of our proposed algorithm (AMGWOA) for DDoS detection in SDN. Section V contains the experimental methodology and findings. Section VI is the concluding section of the paper.

II. Background

A. Overview of the SDN Concept

The control and infrastructure layers of conventional networks function as a single unit. The control layer is responsible for determining the best route for data packets to take across the network, while the Infrastructure layer is responsible for carrying out those instructions. In software-defined networking (SDN), the Infrastructure land control layers are two distinct entities, with the control layer controlling several data planes. Through "softwarization," it can centrally monitor and regulate the network. The architecture of this new software technology is shown in Fig. 1.

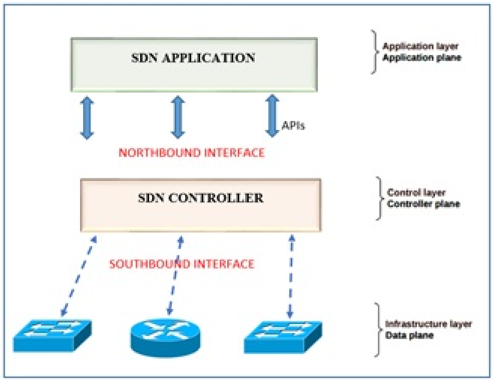

Fig. 1. A three-layer software-defined networking (SDN) architecture.

1) Application layer: It contains network applications like firewalls, load balancing, monitoring, and routing. The management plane is in charge of establishing regulations and guidelines.

2) Control layer: It is responsible for setting up the forwarding devices. The program that interacts with the hardware and software parts of the network in an SDN is called a controller. It is a focal point of the network since it coordinates information transfer between northbound and southbound APIs and connects the data plane and application plane.

3) Infrastructure layer: In the data plane, a physical network architecture is defined. Switches and routers are examples of forwarding devices, and they can communicate with one another using either wired or wireless means. In the data plane, the header, match, and actions fields constitute the main part of forwarding tables. The ternary content addressable memory (TCAM) contains the flow entries into tables for the data plane. Another name for it is a forwarding plane (FP).

4) Northern connection: This connection interface is called the northbound interface. Communication between the management plan and the control plan. It gives the southbound interface low-level instructions. It's also known by its alternate name, the Management to Control Plane Interface (MCPI). As of yet, there are no agreed-upon protocols for the northbound interface [8, 9].

5) Southern connection: The southern interface is known as the southbound interface. it provides a means of communication between the control and infrastructure layers, made possible by a protocol called OpenFlow. The control plane and data plane are separated by the OpenFlow standard protocol for SDNs [10].

B. DDoS Attacks in Software Defined Networks

when the processing power of the network is centralized, one central point of vulnerability is created. In simpler terms, the network will fail if the state of the SDN controller is compromised or cannot fulfill the requests of the switches. The DDoS attack in SDN illustrated in Fig. 2 aims to overwhelm the target host resources in order to disrupt the benign host.

The following possible attack scenarios could be carried out by attackers:

1) Attack on the application plane: The attack takes place via the applications that are present in the application plane. The rogue application uses up all the resources, hurting honest users.

2) Attack on the controller: The controller would be able to handle all of the packet requests sent by the attacker, which would result in a malfunction. As a result, all requests from respectable users suffer.

3) The transmission path of information transfer between the control plane and the data plane: An attacker could attempt to assault the communication channel connecting the control and data planes by sending many Packets as requests.

4) Attack using a table overflow: Innocent users are harmed when an attacker utilizes phony IP sources to fill the switch flow table to its maximum capacity. As a result, a decent traffic sender will be denied access to the services.

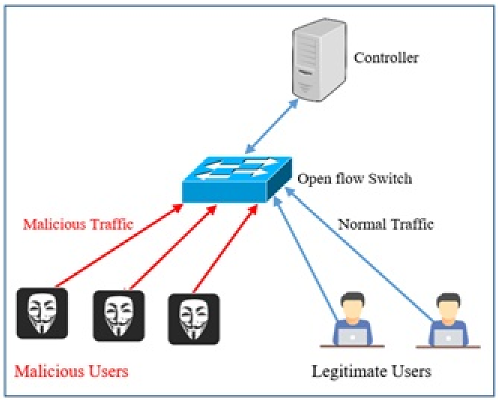

Fig. 2. DDOS attack scenario in SDN an example.

C. Overview of the Grey Wolf Optimizer

Grey wolves tend to move and hunt in packs of 10 to 17 individuals, and this social behavior inspired GWO, a population-based metaheuristic algorithm [11],[12],[13],[14],[15]. Grey wolves have a distinct social hierarchy. Wolves at the top of the social hierarchy of a pack are called alphas. In the hierarchy, Beta, Delta, and Omega are ranked second, third, and fourth, respectively. When to get up, where to sleep, and when to go hunting are all decisions made by the Alpha.

The rest of the wolves must follow the decision of the Alpha. Beta wolf provides assistance to the Alpha wolf when making decisions and will take over if the Alpha dies or is incapacitated.

The Beta defers to the Alpha's decision but gives orders to lower-ranked wolves. Sentinels, scouts, elders, and caregivers are all examples of Delta wolves. The Omegas are at the bottom of the list and should be consumed last. Omega wolves take orders from all wolves. In the same pack, the delta wolf, in turn, dominates omega but follows the instructions of alpha and beta.

Grey wolves are sociable animals with many shared traits, including group hunting. Grey wolves will follow, pursue, and approach their prey first. The target will then be pursued, encircled, and harassed until it stops moving.

Wolves will then attack their prey in the final phase of the hunt.

The GWO algorithm mimics two social behaviors typical of wolves: social hierarchy and collective hunting. Each of the individual wolves represents various strategies for achieving optimal performance. Alpha (α) is the best possible response, while beta (β) is the second, and delta (δ) is the third choice. These three competitors are leading and being followed by the hunt. Every other option is assumed to be the omega (ω) solution. The wolves encircling behavior is modeled analytically using Equation (1).

$$\overrightarrow{Y}(t+1) = \overrightarrow{Y}_p(t) + \overrightarrow{B} \cdot \overrightarrow{E} \tag{1}$$

$\overrightarrow{Y}_p$ is the position of the prey, $\overrightarrow{Y}$ is the position of the grey wolf, and $\overrightarrow{E}$ is as stated in equation (2), t is the iteration number,$\overrightarrow{B}$ and $\overrightarrow{D}$ are coefficient vectors as defined in equations (3) and (4).

$$\overrightarrow{E} = |\overrightarrow{D} \cdot \overrightarrow{Y}_p(t) - \overrightarrow{Y}(t)| \tag{2}$$

$$\overrightarrow{B} = 2a \cdot \overrightarrow{r_1} - a \tag{3}$$

$$\overrightarrow{D} = 2\overrightarrow{r_2} \tag{4}$$

where a is reduced linearly from 2 to 0 over iterations and r_1 and r_2 are random vectors in $[0, 1]$. The alpha, beta, and delta are said to have superior knowledge of the likely whereabouts of prey in order to mimic the hunting behavior of grey wolves. Once the best search agents' locations have been determined (alpha, beta, and delta), the positions of the other wolves will be updated accordingly. The wolves' positions are updated in accordance with equation (5).

$$\overrightarrow{Y}(t+1) = (\overrightarrow{Y_1} + \overrightarrow{Y_2} + \overrightarrow{Y_3})/3 \tag{5}$$

Where $\overrightarrow{Y_1}$, $\overrightarrow{Y_2}$)and $\overrightarrow{Y_3}$ are defined in equations (6), (7) and (8).

$$\overrightarrow{Y_1} = \overrightarrow{Y_\alpha} - \overrightarrow{B_1} \cdot (\overrightarrow{E_\alpha}) \tag{6}$$

$$\overrightarrow{Y_2} = \overrightarrow{Y_\beta} - \overrightarrow{B_2} \cdot (\overrightarrow{E_\beta}) \tag{7}$$

$$\overrightarrow{Y_3} = \overrightarrow{Y_\delta} - \overrightarrow{B_3} \cdot (\overrightarrow{E_\delta}) \tag{8}$$

where $\overrightarrow{Y_\alpha}$, $\overrightarrow{Y_\beta}$ and $\overrightarrow{Y_\delta}$ are the positions of the first best three solutions, $\overrightarrow{B_1}$, $\overrightarrow{B_2}$ and $\overrightarrow{B_3}$ are defined in equations (6), (7) and (8) and $\overrightarrow{E_\alpha}$, $\overrightarrow{E_\beta}$, and $\overrightarrow{E_\delta}$ are defined in equations (9), (10) and (11).

$$\overrightarrow{E_\alpha} = |\overrightarrow{D_1} \cdot \overrightarrow{Y_\alpha} - \overrightarrow{Y}| \tag{9}$$

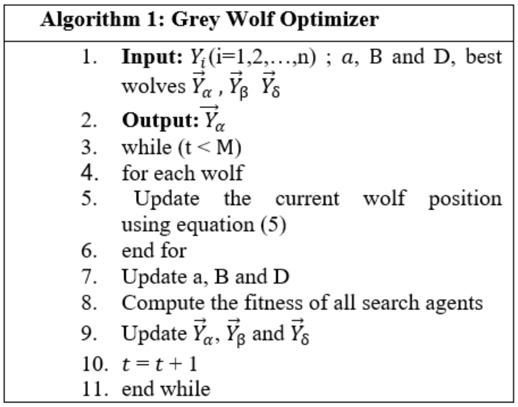
$$\overrightarrow{E_\beta} = |\overrightarrow{D_2} \cdot \overrightarrow{Y_\beta} - \overrightarrow{Y}| \tag{10}$$

$$\overrightarrow{E_\delta} = |\overrightarrow{D_3} \cdot \overrightarrow{Y_\delta} - \overrightarrow{Y}| \tag{11}$$

Where $\overrightarrow{D_1}$, $\overrightarrow{D_2}$and $\overrightarrow{D_3}$ are as defined by equation (4). The parameter a, which controls the balance of exploration and exploitation, is updated based on equation (12).

$$A = 2 - \frac{2t}{M} \tag{12}$$

where t is the number of iterations and M is the maximum number of iterations. The pseudocode for the GWO algorithm is represented by Algorithm 1.



Algorithm 1: Grey Wolf Optimizer

```
Input: $Y_i$(i=1,2,…,n) ; $a$, B and D, best wolves $\vec{Y}_\alpha$ , $\vec{Y}_\beta$  $\vec{Y}_\delta$
Output: $\overrightarrow{Y_\alpha}$
while (t < M)
    for each wolf
        Update the current wolf position using equation (5)
    end for
    Update a, B and D
    Compute the fitness of all search agents
    Update $\vec{Y}_\alpha$, $\vec{Y}_\beta$ and $\vec{Y}_\delta$
    $t = t + 1$
end while
```

III. Related Works on DDOS Detection in SDN

There has been a lot of discussion about the security risks that SDN faces. DDoS attacks are the most frequent and well-known SDN attacks. Numerous DDoS detection algorithms have been proposed thus far, but only a selected few are presented here.

A. The Detection Methods Based on Information Entropy

In [16] DDoS is detected by evaluating the unpredictability of incoming packets and using two elements: window size and threshold. The entropy of packets is calculated and if it goes below a threshold, the attack is detected. This strategy merely identifies the DDos attack, but does not eliminate it.

Authors in [17] proposed a fusion entropy method. In this method, the benefits of log energy entropy and information entropy are combined to achieve complementarity. Attackers can take advantage of fusion entropy's ease of detection and the transparency of its entropy value variations. Since it is challenging to discern between normal network traffic and low-rate DDoS attacks when they occur, this method makes it more challenging to detect low-rate DDoS assaults.

Low-rate and high-rate DDoS attacks against the controller are both detectable using an entropy-based DDoS attack detection method, which the authors of [18] and [19] assess in terms of detection rate (DR) and false-positive rate (FPR), as well as whether the attacks originate from a single host, multiple hosts, or both. Eight different scenarios were tested, each representing a different level of traffic rate during a distributed denial of service (DDoS) attack on the controller. Experimental results show that the average DR for identifying high-rate DDoS attack traffic is improved by 6.25% points, 20.6% points, 6.74 % points, and 8.81% points using the entropy-based method.

These information entropy detection-based techniques fail to optimize most of the limited resources of the controller.

B. Detection Based on Machine Learning

DDoS attacks can be detected with SDN security. Machine learning-based detection approaches are used more frequently than those based on information entropy [20].

Relevant feature selection methods for DDoS detection using ML are discussed in [21]. The final feature selection is based on the classification accuracy of the machine learning methods and the efficiency of the SDN controller. Comparative research on feature selection and machine learning classifiers for SDN attack detection has also been conducted. Using a subset of features determined by the Recursive Feature Elimination (RFE) approach, the Random Forest (RF) classifier is able to train a model with an accuracy of 99.97 %, as shown by their experimental findings.

In [22] authors proposes a deep learning (DL) based ensemble solution to address the problem of DDoS attack detection in SDN. In order to enhance SDN traffic classification, four hybrid models have been provided that combine three ensemble methodologies with three distinct DL architectures (convolutional neural network, long short-term memory, and gated recurrent unit). The CICIDS2017 flow dataset served as the basis for the experiments. The findings demonstrated high detection accuracy (99.77%). This method has a higher controller resource requirement because it uses four distinct hybrid models.

The authors in [23] have studied several machine learning models for DDoS detection in SDN. The question of how to improve the accuracy of DDoS attack detection has been studied using a well-known DDoS dataset called CICDDoS2019. In addition, the DDoS dataset has been preprocessed using two main approaches to obtain the most relevant features. Four machine learning models have been selected for the DDoS dataset. According to the results obtained from real experiments, the Random Forest machine learning model offered the best detection accuracy with (99.9974%), with an enhancement over the recently developed DDoS detection systems.

Authors in [24] attend to detect DDoS attacks by classifying the normal and malicious traffic. The study solves the data shift issues by using the introduced Decision Tree Detection (DTD) model encompassing of Greedy Feature Selection (GFS) algorithm and Decision Tree Algorithm (DTA). Initially, the gureKddcup dataset is loaded to perform preprocessing. After this, feature selection is performed to select only the relevant features, removing the irrelevant data. The results of the investigation revealed that the proposed system achieved an accuracy of 98.42% in the test data. this technique is based on the decision tree, which often involves higher time to train the model, which is costly in terms of detection time.

The authors of [25] use machine learning algorithms in conjunction with Neighborhood Component Analysis (NCA) to categorize SDN traffic as either benign or malicious. The project leveraged a publicly available "DDoS attack SDN dataset," which had a total of 23 features. Through feature selection, the NCA algorithm reveals the most important features, allowing for accurate categorization. The acquired dataset was then categorized using the k-Nearest Neighbor (kNN), Decision Tree (DT), Artificial Neural Network (ANN), and Support Vector Machine (SVM) methods, after the preparation and feature selection phases. The experimental findings demonstrate that DT achieves a perfect 100% classification rate, which is far higher than any of the competing methods. This method could not be continued with other types of high-volume datasets because DT is sometimes unstable, meaning that a small change in the data can lead to a large change in the optimal decision structure.

Authors in [26], did a study that was focused on DDoS attack detection using machine learning-based methods. The primary goal of the study was to reduce misclassification error in DDoS detection and this was made possible by using Mutual information and Random Forest Feature Importance. From the features selected, Random forest, Gradient Boosting, Weighted voting ensemble, and KNN were applied and they had better accuracy when using the features selected. Random Forest, performed better in DDoS attack detection and only misclassified 1.

Although the aforementioned studies are grounded in machine learning, the most majority rely on inefficient, time-consuming, and costly fixed detection approaches that require immediate control.

C. Detection Based on Optimization Algorithms

In order to create an innovative solution, the modern new approach to DDoS detection in SDN relies on optimization algorithms techniques. The study in [27] designed an efficient and low-power SDSN topology by using the Degree Constrained Topology Generation (DCTG) algorithm and a novel formulation of the optimization target. The primary purpose of the method is to design a topology for a Software-Defined Satellite Network (SDSN) that minimizes power consumption. In addition to considering all possible link states, the proposed method strives to reduce the aggregate power usage of the network.

The authors of [28] proposed a satellite network topology optimization technique that incorporated NIDS (Network Intrusion Detection System) using federated learning distributed NIDS in STN. This program Could evaluate and filter harmful traffic as well as fairly distribute resources across each domain. Additionally, it can reduce malicious packet tracking challenges brought by frequent network changes. Malicious traffic could be identified with greater accuracy than typical NIDS, yet with less CPU usage.

Defending DDoS attacks with a metaheuristic strategy, the authors of [29] presented a whale optimization algorithm-based clustering for DDoS detection (WOA-DD). The WOA is a metaheuristic algorithm that takes inspiration from nature. With this historical data, WOA-DD hopes to distinguish between typical traffic and malicious DDoS attacks. After the clusters have been created, any incoming requests will be distributed among them at random. WOA-DD prevents DDoS attacks, but the technology has a major drawback: the clustering process significantly slows down decision-making.

In conclusion, the SDN ecosystem is abundant with DDoS attack detection solutions that aim to identify and counteract the issue of data memory. This requires the creation of a memory-efficient, computationally straightforward, and network overhead solution.

The Optimization techniques have been utilized by many researchers to solve the network Intrusion problem. These techniques will be employed in solving the DDoS attack in the proposed method. Several optimization issues have recently been solved successfully with the help of metaheuristics (e.g., Facial emotion recognition, disease diagnosis, gene selection, and intrusion detection systems) [30]. In contrast to exact search mechanisms, metaheuristics deliver exceptional performance, because unlike full search algorithms, they don't need to traverse the entire search space to find the optimal solution, which is an advantage in terms of computational complexity and memory.

IV. Automated Modified Grey Wolf Optimizer Algorithm (AMGWOA) for DDOS Detection in SDN

A discussion of the proposed technique is presented in this section. It is based on the Grey Wolf algorithm and applied in blocking malicious requests from the controller.

The algorithm is based on the concept of pack intelligence and uses a grey wolf optimization model to identify the best combination of attack detection techniques.

The Grey Wolf algorithm detects suspicious traffic patterns and DDoS attacks by employing a set of heuristics. The algorithm analyzes traffic input to look for specific characteristics. These traits are used to detect malicious behavior. If any predefined characteristics are found in the data, the system flags the traffic as suspicious and takes proactive measures to block it to protect the network.

To formulate the proposed policy, we define the objective function (fitness function) is defined as follows:

A. Design of AMGWOA

$$\min Z = \sum_{i=1}^{n} Req_i^m \tag{13}$$

subject to:

$$Req^{\gamma} = \tau,\ \tau \in [20, 50]$$
$$\sigma^t = \mu,\ \mu \in [0.01, 1]$$

Where Req^m represents the targeted malicious requests to be minimized. The objective function Z is linked to two main constraints:

- A set of requests Req^{γ} targeting the same resource (service/application).
- An instantiated time window σ^t (in seconds), in which requests are received.

B. Core Components of AMGWOA

To solve the proposed objective function, combine the GWO with a Resource-Constrained (RC) management. This latter tends to classify the received requests based on a threshold (λ) where each request is classified in regards to the three best solutions of GWO. Accordingly, this threshold is defined through the computation of the fitness function, which can be used to identify three classes:

- The Alpha class: it represents the first best solution where in our context is associated to the next Req^m that will be dropped in case of the condition $\omega \leq \lambda^-$ is attained.
- The Beta class: it represents the second best solution. The Req^m will be dropped in case the condition $\omega \in [\lambda^-, \lambda^+]$is satisfied.
- The Delta class: it represents the third best solution. Similar to the previous classes but with the following condition $\omega \geq \lambda^+$, the request will be blocked.

We note that the condition ω is calculated as the following $\omega = Bw/C$ where Bw is the measured bandwidth in the network (bits per second) and the capacity C represents the number of bits that a cable can transfer. The two thresholds λ^+ and λ^- (i.e., upper bound and lower bound values) are initialized based on the constraint σ^t where the defined time range is partitioned into three periods: $[20 - \lambda^-]$, $[\lambda^- - \lambda^+]$ and $[\lambda^+ - 50]$. The overall algorithm as shown on algotithm2 of our modified GWO is described on the following:

C. Implementation of AMGWOA

As shown on algorithm 2 the implementation of Automated modified Grey Wolf is described on the following:

The proposed AMGWOA algorithm will act by minimizing the fitness function, which is the total of the requests, to find the best possible solution.

When the sum of new requests arrives, each request will be examined to ensure that it is not an attack before being sent. That is to say that if it does not respect the pre-established conditions (range and time), it will be automatically blocked and not forwarded to the controller.

V. Experimental Setup and Results Discussions

In this section, we discuss our experimental setup and report our findings from testing the proposed methodology.

A. Experimental Setup

Our Simulation was done using Matlab R2020a. Due to the availability of diverse Matlab is selected because it has diverse mathematical functions.

Experiments are carried out on a personal computer PC HP Pavilion X360, Windows 10 OS with 8GB DDR4, Core i7, 10th generation CPU, and 512 GB SSD.

B. Results Discussion

In this implementation, we set the population size to 35 and the maximum number of iterations to 500 in the proposed Automated Modified Grey Wolf algorithm (AMGWOA).

Algorithm 2: Proposed Automated Modified Grey Wolf Optimizer (AMGWOA)

```
Initialize the GWO population (solution): $Y_i$ ($Y = 20$) ;   /* number of requests considered before blocking the next request. */
Initialize $a, \overrightarrow{B}, \overrightarrow{D}, \lambda^+$ and $\lambda^-$. $t = 0$;
Calculate the fitness of each solution $\overrightarrow{Y_i}$ (e.g., $i = 1 \cdots 20$);
$\overrightarrow{Y_\alpha}$: the first malicious request;
$\overrightarrow{Y_\beta}$: the second malicious request;
$\overrightarrow{Y_\delta}$: the third malicious request;
while ($t < M$) do
    foreach agent do
        if (number of requests = $\tau$ & time window = $\mu$) then
            Update the position of the current agent using equation (1);
            if (the sum of $Req^\gamma$ in the Alpha class is greater than the sum of $Req^\gamma$ in the other two classes) then
                Block the next request;
            else
                Forward the request;
            end
    end
    Calculate the fitness value of each candidate solution (malicious requests);
    Update $\overrightarrow{Y_\alpha}, \overrightarrow{Y_\beta}, \overrightarrow{Y_\delta}$;
    $t \leftarrow t + 1$;
end
Return $\overrightarrow{Y_\alpha}$;
```

1) AMGWOA compared with standard GWO and Particle Swarm(PSO): To verify the performance of our approach, AMGWOA is compared with standard GWO [7] and PSO [31] algorithms. For a fair comparison among the three algorithms, they were tested using the same settings of the parameters, specifically, a population size of 35 and a maximum number of iterations of 500 for all test functions. The performance of the algorithms is compared using the following metrics: Objective function values (Best solution) and running times.

Comparison parameters for the three algorithms AMGWOA, GWO, and PSO are shown in Table I below.

It can be seen from Table I that compared to standard GWO and PSO our proposed AMGWOA produces the best score (lowest) objective function value represented by equation (13) This is in fact due to the tolerable iterations of the algorithm. In terms of running time Compared with the GWO algorithm, AMGWOA reduces execution time by 96.7% and 89.9% with PSO. Compared to GWO The PSO does not take much running time, but it does not converge, giving the best optimal “Minimum” values compared to AMGWOA.

Fig. 3 displays the average value of a test function as a function of the number of iterations of the standard GWO,PSO and AMGWOA algorithms. The graph demonstrates that compared with GWO and PSO, AMGWOA converges much faster.This is because of the two parameters $[\lambda^-, \lambda^+]$ that are introduced into GWO initialization, which improve its exploration ability and enhance global convergence.

TABLE I. AMGWOA COMPARED WITH STANDARD GWO AND PSO

Algorithm	Best solution	Running time(seconds)	% Time Improvement
AMGWOA	696	0.008	
GWO	873	0.238	96.7 %
PSO	814	0.079	89.9 %

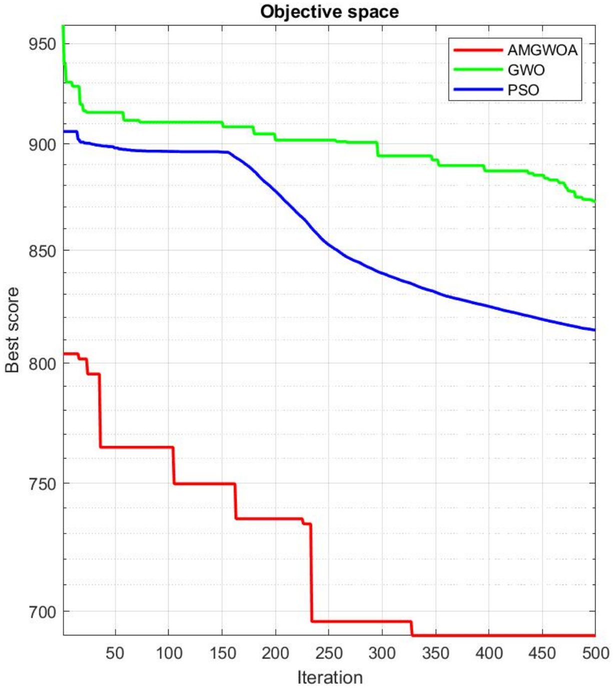


Fig. 3. Comparison of convergence curve for AMGWOA and PSO.

2) Comparison of DDoS detection graphs with and without our proposed method: Fig. 4 and Fig. 5 show the results of a comparison between the use of our AMGWOA model and a standard detection system for fraudulent requests. The number of requests is plotted along the horizontal axis, and the time at which those requests are expected to arrive is plotted along the vertical axis.

The results in Fig. 4 and Fig. 5 represent the classification of the sum of the requests in the Controller before and after AMGWOA Optimization. From Fig. 4 and Fig. 5, it can be observed that the detection of DDoS in the proposed method is superior to the current methods; as a result, the number of requests in the controller within the time window μ is reduced significantly. In Fig. 4 the number of requests is 600 whereas in Fig. 5 the requests are increased to 1200. The figures show that when the number of requests increases, the performance of our method AMGWOA also increases under the same circumstances. It can be noted that before classification the number of incoming requests is huge and exceeds the time that is allocated to them but after optimization, it is shown that whatever the number of requests their sums are minimized, and those that respect the conditions as defined in the constraints $\tau \in [20, 50]$ and, $\mu \in [0.01, 1]$ are maintained as normal requests. The results in Fig. 6 show the normal requests We can see that they do not overflow unlike malicious queries and respect the defined range $[20, 50]$ and time $\mu \in [0, 01, 1]$. The requests after this range and time are not visible because they are blocked and dropped by the algorithm automatically.

Our solution AMGWOA metaheuristic algorithm has been shown to be more effective than Standard GWO optimizer and other competing optimization methods such as PSO in preventing unauthorized requests.

In general, the exploration and exploitation capacity of a population-based metaheuristic algorithm determines its performance [32], [33]. If we further increase the initialization parameters threshold λ^- for our suggested approach, we are increasing the possibility that zombie hosts will pass as regular hosts by significantly altering their query pattern. However, the system's efficiency will drop if we put any otherwise healthy hosts into the zombie host group by lowering the value of the threshold λ^+. Therefore, it is essential to select an accurate threshold value for AMGWOA.

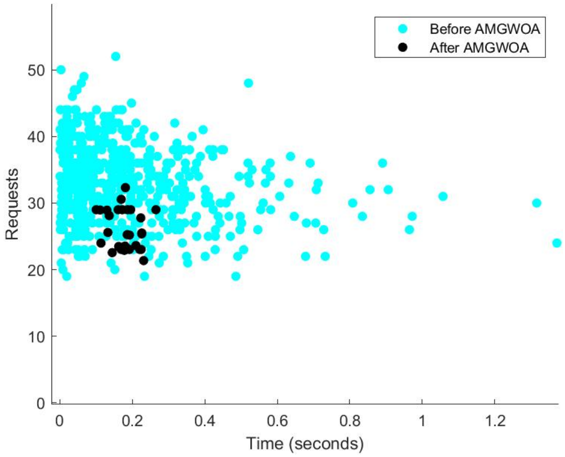

Fig. 4. 600 Requests versus time.

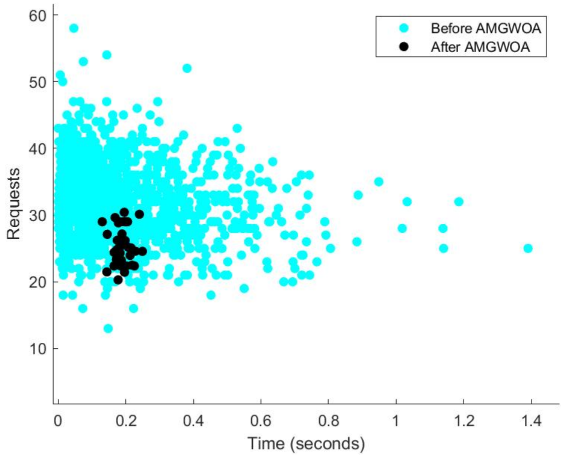

Fig. 5. 1200 Requests versus time.

VI. Conclusion

In this paper, we have developed an automated efficient Grey Wolf optimizer algorithm to prevent the DDoS attack on SDN. The results of our simulations demonstrate the relatively minimal time and space complexity of our approach. Most of the previously proposed methods for detecting and mitigating attacks once happen. These methods necessitate a huge quantity of data storage, which might be problematic for devices with limited memory and exposes the controller to high risks because some of the attacks once they enter the system have immediate effects before their detection. Our solution limited the number of flows without using up a lot of storage or processing space to separate the fraudulent requests from the legal ones.

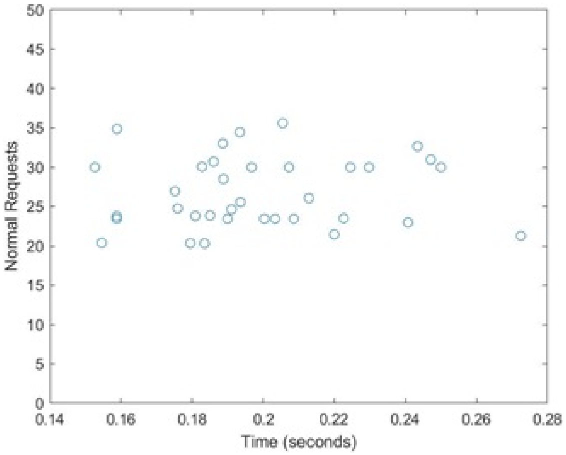

Fig. 6. 1200 Requests versus time.

The experimental findings demonstrate the efficacy of our method because the graph of the fitness function for malicious requests has been minimized while keeping the normal requests that respect the range [20, 50] and the time $\mu \in [0.01, 1]$ allocated to them.

In future work, we will implement our architecture using hybrid metaheuristic algorithms for more accuracy and compare the results obtained.

Acknowledgment

The authors would like to thank the Electrical Engineering (Telecommunications) option of the Pan African Institute of Basic Sciences, Technology and Innovation (PAUSTI) in Kenya for all their technical and financial support in carrying out this research project.

School of Computing, University of Portsmouth, England, United Kingdom[6]

***Abstract*—This paper explores the risks prevalent in the poultry farming industry, drawing upon an extensive examination conducted by researchers over the past decade. Employing a bibliometric analysis approach, a comprehensive search of the Scopus database was conducted using relevant keywords related to poultry farming risk and technology utilization. The search spanned from 2002 to 2022, yielding 345 pertinent documents. This study presents an overview of the current state of publications concerning poultry farming risk and its intersection with technology utilization. It delves into citation patterns, prevalent themes, and authorship analysis, focusing on the role of technology in mitigating risks. The comprehensive citation analysis highlights the impact of technology-related studies in the field. Frequency analysis employed Microsoft Excel, while VOSviewer facilitated data visualization. Harzing's Publish or Perish software was used for citation metrics and analysis. The findings reveal a consistent increase in publications on risk in poultry farming since 2002, particularly in relation to technology utilization. The United States emerges as the most active country in this area of research, with Wageningen University from the Netherlands identified as the most prolific institution contributing significantly to risk in poultry farming research, including technology applications. The research involved 32 scholars from 70 different countries and 32 distinct institutions, reflecting the multi-authorship and multicultural nature of the research. It is important to note that this paper focuses solely on the Scopus database, while future researchers may consider alternative databases for new studies, recognizing the expanding role of technology in addressing risks in the poultry farming industry.**

***Keywords*—Poultry farming risk; poultry farming industry; bibliometric analysis; Harzing's Publish or Perish; VOSviewer**

I. INTRODUCTION

Poultry farming is the practice of raising domesticated birds such as chickens, turkeys, ducks, and geese for their meat, eggs, and feathers [1]. The poultry farming industry refers to the commercial production of these birds on a large scale to meet the demands of the market [2]. In this industry, chickens are the most farmed bird due to their fast growth rate and high meat and egg production [3]. The industry involves breeding, hatching, raising, and slaughtering poultry birds in large numbers using modern farming techniques, equipment, and facilities. Poultry farms can be categorized into two main types: broiler farms and layer farms. Broiler farms focus on raising chickens for meat production, while layer farms focus on raising chickens for egg production [4]. In both types of farms, the birds are kept in large sheds or cages, which are designed to provide them with the ideal conditions for growth and development. Poultry farming has become a significant industry worldwide, with billions of birds raised each year to meet the demands of the global market. The industry has seen significant growth in recent years due to advancements in technology, improved genetics of the birds, and increased demand for poultry products. In general, there are three types of households where poultry are raised: close farming systems, semi-intensive farming systems, and intense farming systems [5]. The backyard poultry industry has transformed into a significant supplier of poultry meat and eggs by embracing modern breeds, advanced housing and equipment, and efficient marketing systems. In the past, backyard poultry solely relied on local, low-yield, and unremarkable poultry breeds, which had limited productivity [6].

As increasing demand for food by the world's population has resulted in tremendous growth in agricultural productivity in recent years [7] and this will cause a lot of issues or risks for this industry that need to be controlled to ensure production can be maximized. Moreover, farmers need to increase their work efficiency to improve the quality of the poultry product while still focusing on animal welfare, environmental sustainability, and public health [8]. According to [9], livestock sector faces numerous challenges, including diseases, climate change, inadequate management practices, genetic issues, farmer capacity and skills, marketing challenges, infrastructure limitations, and a lack of information for effective decision-making. Consequently, the current production rate does not meet the projected demand. Conducting a bibliometric analysis allows us to observe the patterns and trends discussed by researchers regarding these issues. Furthermore, utilizing bibliometric analysis can serve as a valuable guide for farmers and researchers alike. It enables us to identify the key issues being discussed among researchers, shed light on the most prominent researchers who have published on the topic, and gain insights into the specific topics they have explored, including potential solutions and recommendations. This analysis offers a comprehensive overview of the scholarly landscape, providing guidance and informing future directions for both farmers and researchers in addressing the identified challenges. Bibliometric analysis is frequently employed to evaluate trends and impact, encompassing factors such as publishing countries, subject categories, journals, and author keywords [10]. The objective of this study is to examine trends and advances to better inform researchers about the viewpoint of risk research in poultry farming. A forward-looking analysis that can anticipate the author's contribution, both presently and in the future, is imperative. This study serves as a heuristic tool to assess the literature on poultry farming risk to provide practitioners and researchers with the most recent developments in pedagogy. In order to shed light on the topic at hand, this study endeavors to answer the following research questions (RQs):

- RQ1: What is the current status of research publications on the topic of poultry farming risk?
- RQ2: How are publications on poultry farming risk being cited in current literature?
- RQ3: Which themes related to poultry farming risk are receiving the most attention and interest among scholars?
- RQ4: What patterns can be observed in terms of authorship in publications on poultry farming risk?

II. Method

This paper employs bibliometric analysis to examine trends and productivity in research on poultry farming risks. The study's methodology encompasses the data gathering and filtering processes, culminating in the analysis-ready dataset. The objective is to identify the topic and scope of the study, encompassing all available research on risk in poultry farming within the Scopus database. The paper presents various bibliometric indicators and utilizes network visualization techniques. The research protocol used to guide the selection of the documents acquired for this study was shown in Fig. 1.

A. *Bibliometric Analysis*

The aim of this study is to utilize bibliometric analysis as a quantitative technique to uncover the prevailing trend in poultry farming risk. Bibliometric analysis involves statistical measurements and enables the examination of published articles or bibliographic units, providing insights into the distribution and characteristics of the literature in the field [10], [11]. The analysis has the capability to identify descriptive patterns in the articles generated based on various factors such as domain, field, country, or time [12]. There are three categories of bibliometric study indicators include quantity, quality, and structural indicators [13]. The quantity indicator in bibliometric analysis refers to the productivity of researchers, which can be measured by factors such as the number of publications or citations per year [14]. On the other hand, quality indicators assess the performance of researchers based on metrics like the overall h-index, g-index, and citation score, which reflect the impact and recognition of their work. Structural indicators, on the other hand, focus on the relationships between publications, authors, and research fields, shedding light on the interconnections within the scholarly landscape [15]. Additionally, employing a systematic methodology necessary for conducting bibliometric analysis can reveal valuable insight, including information about the authors, frequency of keywords and citations [16].

B. *Source and Data Collection*

The Scopus database was selected as the main data source that being used in this paper to achieve paper's objective since it is known for being the "largest single abstract and indexing database ever developed and the largest searchable citation and abstract literature search list." [17], [18]. Moreover, Scopus database also is the largest database of peer-reviewed literature, including books, journals, and conference proceedings [19] and the database has over 36 000 titles from nearly 11000 publishers, mostly from peer-reviewed journals, and it covers the social, physical, health, and biological sciences [16].

The search query of the poultry farming risk topic was applied in the Scopus data based within search by keyword and with the 345 documents were produced for the next further analysis. Besides, other tools also have been utilized for gathering the document for example, Microsoft Excel, Harzing's Publish and Perish software and VOSviewer.

The data was obtained from the Scopus database on November 6, 2022. The documents are restricted to the topic based on the poultry farming risk title. To fulfill our objective, we executed a query with the KEYWORD term 'poultry farming risk.' This query yielded a total of 477 documents. Through a thorough data cleaning process, we identified and eliminated 132 duplicate or irrelevant documents not pertinent to our topic. The data collected from the Scopus database was then exported into comma-separated values (.csv) and research information systems (.ris) formatted files, ensuring a standardized and organized dataset.

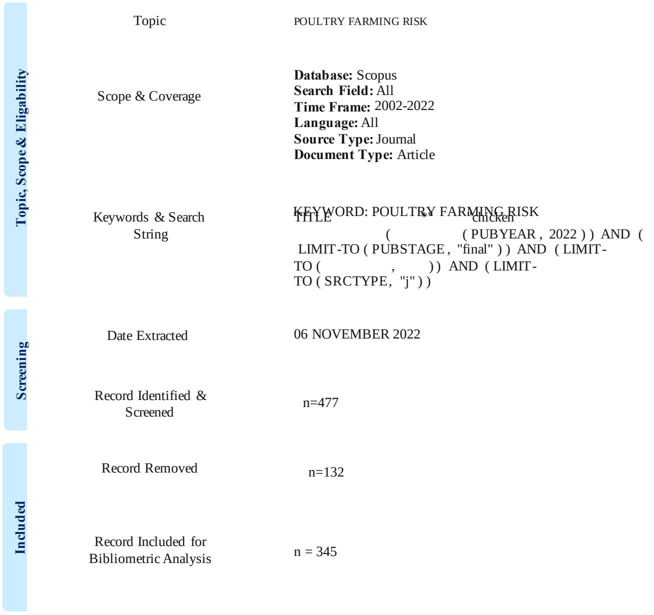

Fig. 1. Flow diagram of the search strategy.

This study utilized the bibliometric method to analyze the research trends in the field of poultry farming risk. The database provides a comprehensive range of publication details, encompassing information such as publication type, year, language, subject area, keywords, country, affiliation, citations, and authorship of the documents. Data analysis was conducted using Microsoft Excel and Harzing's Publish or Perish software, while VOSviewer software was utilized for data visualization. In this study, the VOSviewer software played a key role in conducting the mapping analyses [10]. When representing the nodal network, VOSviewer employs two uniform weights to create a graphical visualization: the quantity of connections and the collective strength they possess. The relevance and power of the links are reflected in the network size and network-connecting interlinking lines.

III. Result and Finding

To acquire an overview of the research related to poultry farming risk, data sets are provided. All articles that met the search query were evaluated for current publication such as year, language of publications, subject area, distribution of publications by countries, most active authorship, keywords, and citation analyses.

A. *Current State of Publication in Poultry Farming Risk*

In order to investigate RQ1 (What is the current state of publication in poultry farming risk?), a thorough analysis was conducted to examine the publication trends in this field. The analysis encompassed several key dimensions, including the total number of publications by year, document type, publication source title, country of publication, affiliated institutions, language, and subject area. To perform this analysis, we utilized the bibliographic data collected from the Scopus database, allowing for comprehensive calculation and evaluation of the relevant data.

- Publication by year

Examining documents by publication year allows the researcher to track the pattern and popularity of the research topic through time [27-33]. Table I summarises the total publications for poultry farming risk since 2002. In the early topic of poultry farming risk there were three articles about this topic that were publish in 2002 that were written by [20]–[23] . Nevertheless, analysis of these papers revealed that in 2002 were justified as the pioneers of publication as these paper that was written by [21] was cited 259 times. According to the records, between 2005 and 2015, the number of publications had an inconsistent pattern, with fluctuations in both increases and decreases. However, starting from 2016, there was a noticeable growth in the number of articles being published. This trend continued, and in 2020, there was a record high of 35 publications, accounting for 10.14% of the total. This significant increase indicates a peak period in the practice of the poultry farming risk approach adopted by educators worldwide (Fig. 2). This observation becomes clearer when analysing the trends of countries participating in research.

TABLE I. Year of Publication

Year	TP	%	NCP	TC	C/P	C/CP	h	g
2002	3	0.87%	3	777	259.00	259.00	3	3
2003	9	2.61%	8	288	32.00	36.00	5	9
2004	5	1.45%	5	740	148.00	148.00	5	5
2005	14	4.06%	13	326	23.29	25.08	9	14
2006	12	3.48%	11	282	23.50	25.64	6	12

2020	35	10.14%	34	387	11.06	11.38	11	18
2021	27	7.83%	20	112	4.15	5.60	6	9
2022	16	4.64%	7	23	1.44	3.29	2	4
Total	345							

TP total number of publications, NCP number of cited publications, TC total citations, C/P average citations per publication, C/CP average citations per cited publication, h h-index, and g g-index

- Document type

The term "document type" pertains to the categorization of documents into various categories, including conference papers, articles, book chapters, reviews, and books. Table II provides a summary of the distribution of documents published on poultry farming risk, classified into seven document types. Notably, a significant majority of the publications (84.06%) were classified as articles.

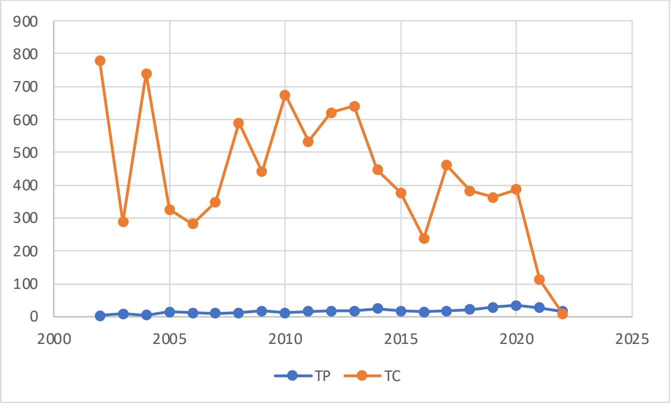

Fig. 2. Publication and citation trend of poultry farming risk.

TABLE II. Document Type of Poultry Farming Risk

Document Type	Total Publications (TP)	Percentage (%)
Article	290	84.06%
Review	23	6.67%
Letter	14	4.06%
Note	10	2.90%
Conference Paper	4	1.16%
Editorial	3	0.87%
Short Survey	1	0.29%

- Publication by country

There are top 10 listed as the most productive countries (see Table III). United States was dominated in publishing this topic with a total of 81 (23.48%) documents followed by United Kingdom (56: 16.23%) and China (50: 14.49%). The United States' leading position in poultry farming publications is unsurprising, as their publications have garnered the highest number of citations, indicating extensive recognition worldwide.

TABLE III. COUNTRY

Country	TP	%	NCP	TC	C/P	C/CP	h	g
United States	81	23.48%	76	2894	35.73	38.08	31	52
United Kingdom	56	16.23%	51	1688	30.14	33.10	25	40
China	50	14.49%	49	1439	28.78	29.37	18	37
Netherlands	28	8.12%	28	1428	51.00	51.00	16	28
France	26	7.54%	26	702	27.00	27.00	12	26
Australia	18	5.22%	17	401	22.28	23.59	9	18
Italy	18	5.22%	17	441	24.50	25.94	13	18
Germany	14	4.06%	14	414	29.57	29.57	9	14
Thailand	14	4.06%	12	262	18.71	21.83	7	14
Belgium	12	3.48%	12	601	50.08	50.08	11	12

TP total number of publications, NCP number of cited publications, TC total citations, C/P average citations per publication, C/CP average citations per cited publication, h h-index, and g g-index

- Publication by institution

Table IV depicts the top five institutions that publish on Poultry Farming Risk. Based on the result, it stated that Wageningen University is the highest institution that were publish in this topic with total 20 publications with the average citation per year 32.00. Even though it has the highest publication, National Institute for Public Health and the Environment that were in Netherlands has the highest citation per year (88.36) compared to other institution. When institutions were ranked according to h-index, the Wageningen University and Royal Veterinary College University of London top institutions that lead the publications on poultry farming risk.

- Languages of the document

There are four languages used for publications that were mostly published in English languages (342: 98.84%) (See Table V). The extensive use of a wide range of languages, including major ones, in publications signifies the diverse global involvement and breadth of research on poultry farming risks across nations.

TABLE IV. INSTITUTIONS MOST AFFILIATED WITH POULTRY FARMING RISK

Institution	TP	%	Country	NCP	TC	C/P	C/CP	h	g
Wageningen University	20	5.80 %	Netherlands	20	640	32.00	32.00	13	20
Royal Veterinary College University of London	14	4.06 %	United Kingdom	13	546	39.00	42.00	9	14
Centers for Disease Control and Prevention	12	3.48 %	United States	11	870	72.50	79.09	8	12
National Institute for Public Health and the Environment	11	3.19 %	Netherlands	11	972	88.36	88.36	7	11

- Subject Area

Based on all the documents gathered from the Scopus database, poultry farming risk covers almost all subject areas especially in medicine. Table VI shows that between this period (2002–2022), the most written subject in these topics is medicine (48.41) % as almost the half of the publications were published for this topic.

TABLE VI. THE MOST WRITTEN SUBJECT AREAS

Subject Area	Total Publication	Percentage
Medicine	167	48.41%
Veterinary	86	24.93%
Agricultural and Biological Sciences	79	22.90%
Environmental Science	69	20.00%
Immunology and Microbiology	63	18.26%

B. *Citations Pattern on Poultry Farming Risk*

Our second research question (RQ2) aims to identify the most influential articles on poultry farming risk and visualize the citation patterns using data obtained from the Scopus database. The analysis involved examining the citation metrics and networks of 345 articles to address RQ2. Citation analysis was conducted to measure the impact of documents on poultry farming risk using relevant citation metrics. Data analysis was performed utilizing Harzing's Publish or Perish and VOSviewer software. Table VII presents the citation metrics for the retrieved documents as of 06 November 2022. Among the 345 articles, an average of 452.35 citations per year was observed, with a total of 9,047 citations reported.

Table VIII displays comprehensive information, including the overall number of total citations and the average number of citations per year for all retrieved publications. Based on Scopus data, the top five most cited articles are listed. Notably, the article titled "Antimicrobial residues in animal waste and water resources proximal to large-scale swine and poultry feeding operations" by [20] has garnered the highest number of citations, with 395 citations or an average of 19.75 citations per year.

Fig. 3 illustrates the network visualization map, which reveals the citation connections among countries. It is worth noting that "Citations attribute indicates the number of citations received by a document or the total number of citations received by all documents published by a source, an author, an organization, or a country" [23]. Out of the 71 countries considered, 68 have met the minimum thresholds for both the number of documents and citations attributed to an author. To interpret Fig. 3 effectively, it is essential to refer to the corresponding data in Tables VII and VIII, which provide specific information on the number of citations received by each country. Notably, the United States, United Kingdom, and China have received a substantial number of citations in the domain of poultry farming risk.

C. *Theme in Poultry Farming*

- To address RQ3 (Which themes involving poultry farming risk are the most popular among scholars?), we conducted co-occurrence analysis using the keywords data obtained from the Scopus database. Co-occurrence of keywords indicates the presence of a relationship between two concepts when they appear together in an article [26]. We performed the co-occurrence analysis and keyword evaluation based on the understanding that author keywords provide a meaningful representation of an article's content [27]."

TABLE VII. CITATION METRICS

Metrics	Data
Papers	345
Citations	9047
Years	20
Cites Year	452.35
Cites Paper	26.22
Cites Author	2016.29
Papers Author	91.13
Authors Paper	5.61

g index	80

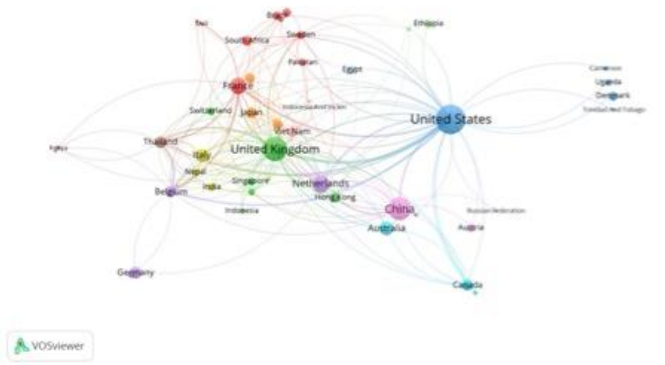

Fig. 3. Network visualisation map of the citation by countries.

TABLE VIII. HIGHLY CITED ARTICLE

No.	Author(s)	Title	TC	C/Y
1	[21]	Antimicrobial residues in animal waste and water resources proximal to large-scale swine and poultry feeding operations	395	19.75
2	[22]	Routes for salmonella contamination of poultry meat: Epidemiological study from hatchery to slaughterhouse	148	7.4
3	[23]	Risk of influenza A (H5N1) infection among poultry workers, Hong Kong, 1997-1998	234	11.7
4	[24]	A comparison between leg problem in Danish and Swedish broiler production	48	2.53
5	[25]	Survey of effects of radiofrequency electromagnetic fields on production, health, and behavior of farm animals	4	0.21

Undoubtedly, author keywords are of great importance for researchers seeking to identify research trends. Additionally, [28] emphasize the significance of author keyword analysis in measuring the development of research topics. After eliminating duplicate keywords resulting from spelling variations (e.g., Poultry farming, poultry farm, poultry), our analysis reveals the top 10 frequently used author keywords in relation to this topic (see Table IX).

Subsequent analysis involved the mapping of all keywords using VOSviewer, a software tool specifically designed for constructing and visualizing bibliometric networks (refer to Fig. 4). For this purpose, a comprehensive approach was adopted, considering a minimum threshold of ten occurrences for each keyword out of a total of 3,716 keywords. Consequently, 188 keywords met the specified criteria. Employing these settings, VOSviewer generated the network visualization depicted in Fig. 4, where the colors, circle sizes, font sizes, and line thicknesses indicate the strength of the relationships between the keywords [26]. In Fig. 4, each color corresponds to a distinct cluster identified in the visualization map. Initially, four clusters were observed. However, by adjusting the cluster size criterion to include a minimum of 50 items in each cluster, three clusters remained. Cluster one, represented by red, comprises 60 items centered around the theme of avian influenza. Cluster two, depicted in green, encompasses 54 items associated with the non-human theme. Cluster three, highlighted in blue, includes 53 items related to the poultry farming theme.

TABLE IX. TOP KEYWORDS

Keywords	TP	%
Poultry Farming	285	82.61%
Article	257	74.49%
Animals	234	67.83%

D. Authorship Analysis

Besides, this paper also analyses the most active authors who published the documents on this topic as stated in Table X. All the data that was analysed, is based on the active author who published at least more than three documents on poultry farming risk. Even though there are four authors who have same total publications, author Gilbert, Marius is the most active author who published research article in this topic; as his article journal consists of the highest citation per year and h-index compared to others.

TABLE X. MOST PRODUCTIVE AUTHOR

Author's Name	Affiliation	Country	TP	NCP	TC	C/P	C/CP	h	g

IV. Conclusion

Bibliometric analysis can be used to analyze the trend in Poultry Farming research. It also can analyze the productivity of research and other specific research domains. According to [34] the insights obtained from bibliometric analysis can provide an understanding of the factors that influence the research output and contribution within different fields of study. These findings can guide researchers in conducting meaningful and impactful research. However, it is important to note that the scope of this study is confined to the publications related to poultry farming risk available in the Scopus database. Based on the results that had been conducted by using Harving's Publish or Perish software and VOSviewer we can see that all the research question have been answered. Overall, there were 345 total documents that were found from Scopus database using the defined search query. The author in [27] is the most active author who published research articles on this topic in six total publications and had 300 of total citation. Besides, English is the most common language that has been used in this topic and Medicine is the subject area that is the most written subject are covered for this research study. Regarding the country, the country with most publications, covered in this research, is United States as the total publications based on this topic were 81. Based on the analysis of the top five most cited articles, it can be inferred that a significant portion of the publications focused on the topic of diseases in the poultry farming industry. This finding suggests that despite advancements in management practices, disease outbreaks remain a critical risk that necessitates continuous monitoring and attention. Finally, there are still more opportunities for research related to this topic that can be conducted in future. Due to the distinctive nature of the bibliometric analysis, the study has limitations that should be addressed to provide readers with a clear understanding of the paper and to improve future research. First, the results were limited to a single keyword, such as poultry farming risk, based on the document's title. As a result, the results of the search query on other fields, such as article title and abstract, have been left out of this analysis. The main reason for this is because by using search query for article title, the documents are not enough to be analyzed using bibliometric. By using search query for keyword, even though some included a term linked to the search area yet might not be related with the topics, but by using data cleaning we manage to get at least certain amount of documents to analyze. But the only disadvantage is that there is a lot of filtering and cleaning to be done before the analysis can begin. It is likely that future research will be expanded into it. Finally, being the primary source of documents, this study is solely focused on the Scopus database. Web of Science, Google Scholar, and Dimensions are some of the other databases that could be used in future research. Combining all these databases will almost certainly result in more interesting and useful findings. Despite these limitations, this study has added to the body of knowledge by describing the current state of poultry farming risk. This study also uses a bibliometric technique to enhance and augment prior findings on poultry farming risk literature and provide valuable insights into the trend of previous publications.

Adaptive Style Transfer Method of Art Works Based on Laplace Operator

HaiTing Jia
Academy of Fine Arts, Jiaozuo Normal College
Jiaozuo, Henan 454001

***Abstract*—In order to improve the image quality of artworks after style transfer, the adaptive style transfer method of artworks based on the Laplace operator is studied. Through three steps of expansion processing, corrosion processing and multi-scale morphological enhancement, the image edge of the content of artworks is enhanced. The colour and brightness of the artworks with edge enhancement are transferred, and the transfer results are input into the convolution neural network simultaneously with the style image. According to the improved Laplace operator, the Laplace operator loss term of the convolution neural system is counted, the style losing term of the style picture of the art image is determined, and the total loss function is constructed. According to the determined loss function, a convolution neural network is used to output paintings' adaptive style transfer results. The experiential outcomes indicate that this technique is able to realize the adaptive style transmission of paintings. After style transfer, the picture quality of paintings is high, and the adaptive transfer of artworks can be realized within 500ms.**

Keywords—Laplace operator; artworks; adaptive style transfer; brightness migration; convolution neural network

I. Introduction

With the development of computer technology, the task of image art creation can be accomplished excellently with the help of a computer's image processing ability. Convolution neural network is a powerful and effective model in image processing [1]. Deep learning is a heavyweight machine learning algorithm [2] with a huge hyperparametric space and requires strict computational efficiency in practical applications. To a large extent, it restricts the further promotion of the image style transfer method of deep learning in practical applications. Deep learning is still a black box inside, and the mathematical meaning of its hyperparametric space is still incomprehensible [3, 4]. The process of applying the style of one style image to another content image [5, 6] is an artistic creation and image editing technology. Deep learning has made great breakthroughs in computer vision in the fields of image processing, intelligent robots, natural language processing, data mining and unmanned driving. Image style transfer algorithm is an application of depth neural network [7]. The appearance of an image style transfer algorithm can make the generation of a master artist's painting become a reality in a short time.

At present, many researchers have carried out research on image migration methods. Yuchi et al. [8] performed K-means clustering matching on transition images and obtained the optimal energy equation for color transfer through two methods: hierarchical transfer and global transfer. This method can achieve effective color transfer of images, but after color transfer, the image quality is poor; Deng et al. [9] studied a tapestry based adaptive perceptual domain style transfer algorithm based on semantic segmentation, combining semantic segmentation tasks with adaptive perceptual domain style transfer algorithms, and proposing new content loss and style loss. Although this method can achieve effective image migration, there is a problem of unprotected content and image structure, and the results of graphic migration are not ideal; Sun et al. [10] proposed a local style transfer method based on residual neural networks. Generate an image that only completes style transfer for the target area through deconvolution. This method has high local style conversion ability and high execution efficiency, but there is a problem of losing the main structure of the content image, resulting in poor visual effect of stylized images.

In mathematics and physics, the Laplace operator is differential. The Laplace operator has many uses, and it is also an important example of an elliptic operator. The function that is zero by the Laplace operator is called a harmonic function; the Laplace operator is the core of Hodge's theory and is the result of De Rham's cohomology. Laplace operator can extract the edge information in the image, and emphasize the details and texture of the image. In the style transfer of art works, by performing Laplace filtering between the original image and a reference image with a specific style, the transferred image can retain the original content while maintaining the artistic style of the reference image. Therefore, in order to promote art creation and technology development, provide more possibilities for art creation, and apply the potential of this technology in different fields, research the adaptive style transfer method of art works based on Laplace operator. The motivation of using the Laplace operator for style transfer is that it can help artists achieve more accurate style conversion, making the transferred works more consistent with the expected artistic effect. The main ideas of this study are as follows:

1) Firstly, edge enhancement is performed on the content images of art works through dilation processing, corrosion processing, and multi-scale morphological enhancement algorithms.

2) After edge enhancement, Convolutional neural network is selected as the main framework of adaptive style transfer of art works.

3) The improved Laplace operator algorithm is studied, which combines Laplace operator with Convolutional neural network; then design an adaptive style migration network structure based on color, brightness and semantic information, and apply it to the adaptive style migration of art works to achieve migration.

4) Through experiments, it has been verified that this study can improve the transfer level of art works and obtain user satisfactory adaptive style transfer results.

II. Materials and Methods

A. Edge Enhancement Algorithm of the Content Image of Artworks

1) Dilation processing: The expansion operator's task is to solve the maximum local value of the pixel in the artwork image. The structural element is used to calculate the area covered by the expansion operator in the artwork [11], find the maximum value of the pixel, and then input the calculated value into the element specified in the centre of the artwork structural element.

If $f(s,t)$ is the original artwork image, the artwork image after dilation processing is:

$$f_e(x,y)=(f\oplus b)(s,t)=\max\{f(s-x,t-y)+b(x,y)\} \quad (1)$$

In formula (1), b is a structural element; D_f and D_b are definition fields; $f\oplus b$ is the result of b dilating the original artwork image f

2) Corrosion processing: Contrary to the expansion operator, it is the task of the erosion operator to solve the local minimum value of pixels in the picture of paintings. The structural element is used to calculate the area of the artwork covered by the expansion operator, find out the minimum pixel value of each area of the corresponding artwork, and then input the calculated value into the element specified in the centre of the structural element. Corrosion processing is conducive to filtering noise [12], preserving the original information in the picture of paintings, making the edges smooth, and the extracted picture of paintings more continuous.

The picture of the artwork after corrosion processing is as follows:

$$f_c(x,y)=(f-b)(s,t)=\min\{f(s+x,t+y)-b(x,y)\} \quad (2)$$

In formula (2), $f-b$ is the result of corrosion operation on f

3) Multi-scale morphological enhancement algorithm: The selection of structural elements is very important to the edge detection results of artworks. Selecting only one structural element will result in discontinuous edge information of the detected artwork and generally cannot get a relatively complete edge contour of the artwork [13]. Using multi-scale structural elements can effectively solve the problem of edge discontinuity in artworks. Structural elements with different scales are used to calculate the image of artworks, and large-scale structural elements can effectively filter the image of artworks; Small-scale structural elements can be targeted to detect the contour of target features of artworks [14]. Two structural elements of different scales are combined to detect the edge of the image of the artwork.

The expression for defining multi-scale structure elements is as follows:

$$nB=B_1\oplus B_2\oplus\cdots\oplus B_n \quad (3)$$

In formula (3), n is the scale parameter; B is a structural element.

Using multi-scale and multi-structure element morphological edge detection operators, the expression for processing artworks is as follows:

$$f_B(x,y)=\frac{1}{2}\{\,[\,f_c(x,y)\Theta b_i(m,n)\oplus nB\,]\,\oplus f_e(x,y) \quad (4)$$

In formula (4), $f_B(x,y)$ is the image of artworks after multi-scale mathematical morphology processing; b_i is a structural element.

The circular structure element with the size of 3×3 and the rectangular structural element with the size of 6 ×2 are used as the structural element of the edge enhancement for the image of the artwork. The expression of the structural element is as follows:

$$b_1=\begin{bmatrix}1&0&0\\0&0&1\\0&1&0\end{bmatrix} \quad (5)$$

$$b_2=\begin{bmatrix}1&1&1&1&1&1\\1&1&1&1&1&1\end{bmatrix} \quad (6)$$

$$b_3=\begin{bmatrix}1&1&0&1&0&1\\0&0&1&1&1&1\end{bmatrix} \quad (7)$$

According to the structural element expression of formula (5) to (7), the circular structure element with the size of 3×3 is firstly used to expand and erode the image of the artwork. Then the rectangular structure element with the size of 6×2 is used to expand and erode the image of the work of art and complete the edge enhancement of the image of the artwork.

B. Style Transfer Network Structure of Convolution Neural Network

The convolution neural network is selected as the deep learning algorithm for the adaptive style transfer of artworks. A convolution neural network is a series of feedforward neural networks with depth, including convolution operation. Convolution neural network has strong learning ability because of their unique network structure [15]. Unlike the full connection strategy of traditional neural networks, each neuron of the convolution neural network is only connected with some neurons of other layers, and the parameters of the convolution kernel are shared, making the operation simple and efficient, and can learn on large data sets [16, 17]. A convolution neural network comprises the input layer, convolution layer, activation function [18], pooling layer [19] and full connection layer. Among them, the selection of the activation function in the activation layer greatly impacts the migration result of the adaptive style transmission of paintings. The ReLU function is selected as the activation function in the activation layer of the convolution neural system. The ReLU function is a function with the maximum value. The calculation formula of the ReLU function is as follows:

$$f\left(x\right)=\max\left(0,x\right) \tag{8}$$

The ReLU function mimics the biological neurons in the human brain and has the characteristics of dispersion and sparsity. The ReLU function is the most commonly used activation function at present. When the convolutional neural network uses the ReLU function as the activation function, there is no problem of gradient disappearing.

Maximum and average pooling are two common pooling ways of pooling layers in convolutional neural networks. The maximum pooling method is selected as the pooling operation of adaptive style migration of artworks. The full connection layer acts as a "classifier", mapping the learned features of artworks to the sample space. Full connection operation will cause a huge amount of parameters, so it is generally only used in the last few layers of the convolutional neural system to exploit the feature vectors of artworks to complete some classification tasks.

C. Laplace Operator and its Improvement

1) Laplace operator: The Laplace operator is an important algorithm in the adaptive style transfer processing of artworks. The Laplace operator is an edge point detection operator independent of an edge direction. It responds more strongly to isolated pixels in the picture of paintings than to edges or lines [20]. Before applying this operator to the adaptive style transmission of paintings, it needs to smooth the image of artworks. The Laplace operator is a second-order differential operator. Let the artwork image be a continuous, binary function $f\left(x,y\right)$, and its Laplace operation is defined as:

$$\nabla^2 f=\frac{\partial^2 f}{\partial x^2}+\frac{\partial^2 f}{\partial y^2} \tag{9}$$

The Laplacian operator of the image of artworks can be simplified as follows:

$$g\left(i,j\right)=4f\left(i,j\right)-f\left(i+1,j\right)-f\left(i-1,j\right)-f\left(i,j-1\right) \tag{10}$$

Formula (10) can also be expressed in the form of convolution, and the expression is as follows:

$$g\left(i,j\right)=\sum_{r=-k}^{k}\sum_{s=-t}^{l}f\left(i-r,j-s\right)H\left(r,s\right) \tag{11}$$

In formula (11), the sampling of $H\left(r,s\right)$ is as follows:

$$H_1=\begin{bmatrix}0 & -1 & 0\\ -1 & 0 & -1\\ 0 & -1 & 0\end{bmatrix} \tag{12}$$

In the process of adaptive style transmission of paintings, the Laplace operator of the function is realized with the help of templates. The effect of template sampling will directly affect the effect of adaptive style transfer of artworks.

2) Improved Laplace operator: The Gaussian function improves the Laplace operator, and the log operator represents the improved operator. The log operator is used to improve the application performance of the Laplace operator in the adaptive style transfer of artworks. The log operator is an improved operator based on the Laplace operator. The log operator first performs Gaussian convolution filtering on the artwork image to reduce noise [21], then uses the Laplace operator to detect the edge of the artwork image after noise reduction. The expression of the Gaussian convolution function $G\left(x,y\right)$ used to improve the Laplace operator is:

$$G\left(x,y\right)=\exp\left[-\frac{x^2+y^2}{2\sigma^2}\right]/2\pi\sigma^2 \tag{13}$$

In formula (13), x and y respectively represent the row coordinates and column coordinates of the pixel points of the artwork image; σ represents the standard deviation of pixels.

The original artwork image $f\left(x,y\right)$ is first convolved with the Gaussian function $G\left(x,y\right)$ to obtain the smoothed artwork image $g\left(x,y\right)$. The smoothed artwork image $g\left(x,y\right)$ is solved with the Laplace operator differential of the convolution. The expression of the operation process is as follows:

$$g\left(x,y\right)=G\left(x,y\right)\otimes f\left(x,y\right) \tag{14}$$

$$\nabla^2\left[f\left(x,y\right)\otimes G\left(x,y\right)\right]=f\left(x,y\right)\otimes\nabla^2 G\left(x,y\right) \tag{15}$$

$$\nabla^2 G\left(x,y\right)=\left(\frac{x^2+y^2-2\sigma^2}{2\sigma^2}\right)\exp\left(-\frac{\log\left(x^2+2y\right)^2}{2\sigma^2}\right) \tag{16}$$

In formula (14) to (16), $\otimes$ is a convolution symbol; ∇ is the differential sign; $\log$ is an improved Laplace operator.

Because the edge detected by the log operator is not very smooth and has a lot of noise [22], on the basis of using the operator detection, the two-dimensional digital filter is used again to filter and detect the image of the work of art. The detection process is as follows:

1) The filtered artwork image $y(n)$ can be expressed as:

$$y(n)=h(n)\times x(n)=\sum_{k=0}^{K-1}h(k)\times x(n-k) \tag{17}$$

In formula (17), $h(n)$ is the non-recursive filtering coefficient, $h(k)=\log(x,y)$; $x(n)$ is the input artwork image; K is the filter length, and the order is $K-1$. The coefficient matrix of the two-dimensional digital filter is rotated 180 ° to create a convolution kernel [23], and obtain the convolution kernel expression as follows:

$$H_i=\begin{bmatrix}0 & 1\\ 1 & 0\end{bmatrix}M_i \tag{18}$$

In formula (18), H_i is the convolution kernel created by rotating the filtering coefficient matrix of the two-dimensional digital filter by 180 °; M_i is the edge operator.

2) Two-dimensional convolution is used to realize the filtering operation of artwork images. The expression of the two-dimensional convolution operation of artwork images is:

$$C_i(s,t)=\sum_{m=0}^{M_r-1}\sum_{n=0}^{M_c-1}H_i(m,n)\otimes B(s-m,t-n) \tag{19}$$

In formula (19), $C_i(s,t)$ is the artwork image after filtering operation; M_r and M_c are the number of rows and columns of convolution kernel H_i, respectively; The number of rows and columns s and t of the picture of the artwork meet the requirements of $0\le s<M_r+N_r-1$, $0\le t<M_c+N_c-1$; N_r and N_c are the number of rows and columns of the input artwork image matrix B.

3) The filtered data of the artwork image are added, and the expression is:

$$S=\sum_{i=1}^{4}C_i(s,t)=\sum_{i=1}^{4}\sum_{m=0}^{M_r-1}\sum_{n=0}^{M_c-1}H_i(m,n)\otimes B(s-m,t-n) \tag{20}$$

In formula (20), S is the sum result of the filtered data of the artwork image.

Through the above process, the threshold segmentation of the artwork image is completed, and the edge contour information of the artwork image matrix B is obtained.

D. *Adaptive Style Transfer of Artworks Based on Color and Brightness*

In the stylized result graph of artworks, some of the generated results of the stylized transfer algorithm of the traditional neural network have color confusion, which affects the overall artistic effect of adaptive style transmission of paintings in visual effect. Inspired by the color migration algorithm in style migration [24], in the process of adaptive style transmission of paintings, the color details and brightness details of the content picture of paintings are retained by using the migration of color and brightness.

X_C represents content image, X_S represents style image, X_J represents after color matching and migration, $x_i=(R,G,B)^T$ represents the pixel color of the input artwork content image and the input artwork style image. The color matching of the content image X_C of the artwork is transferred to the style image X_S of the artwork, and gets the new artwork image X_J. Then, before and after the style transfer, the pixel value of the artwork image has the following mathematical mapping relationship:

$$x_{CJ}\leftarrow Ax_S+b \tag{21}$$

In formula (21), A represents a matrix of size of 3×3; b represents a vector of size of 3 ×1; x_S shows the pixel value of the input artwork style picture; x_{CJ} represents the pixel value change result of the artwork image after color style migration.

In order to obtain the pixel value x_{CJ} after color-matching migration when the painting style is transferred, the matrix A and vector b in formula (21) must be determined first. The color-matching migration process of artworks will be described in detail below.

μ_C and μ_S are defined to represent the mean value of each pixel of the input artwork content image and the input artwork style image in RGB color space; σ_C and σ_S represent the covariance of the input artwork content image and the input artwork style image, respectively. According to the definition of mean and covariance, it can get:

$$\begin{cases}\mu=\sum_i x_i/N\\ \sigma=\sum_i(x_i-\mu)(x_i-\mu)^T/N\end{cases} \tag{22}$$

After the color matching of the artwork content image X_C is transferred to the artwork style image X_S, when the new artwork image X_J is obtained, the pixel color mean value and pixel covariance of X_J must be consistent with the pixel color mean value and pixel covariance of X_C, that is, the existing expression is as follows:

$$\begin{cases} \mu_{C_J} = \mu_C \\ \sigma_{C_J} = \sigma_C \end{cases} \tag{23}$$

In formula (23), μ_{CJ} represents the mean value of X_J in the artwork image after color migration; σ_{CJ} represents the covariance of X_J of the artwork image after color migration.

According to the above formula, the mathematical relationship between matrix A and vector b can be obtained as follows:

$$\begin{cases} b = \mu_C - A\mu_S \\ A\sigma_S A^T = \sigma_C \end{cases} \tag{24}$$

According to the above formula and mathematical knowledge, the value of vector b is determined by matrix A. As long as matrix A is determined, vector b can be determined. From the knowledge of matrices, there are many matrices A that meet the above conditions. When solving matrix A, the image analogy method is used. The eigenvalue expression of the decomposition covariance matrix is as follows:

$$\sigma = UAU^T \tag{25}$$

The square root expression of matrix A can be obtained by calculating formula (25) as follows:

$$\sqrt{\sigma} = U\sqrt{A}U^T \tag{26}$$

The expression for obtaining the value of matrix A through formula transformation is as follows:

$$A = 1/\sqrt{\sigma_C}\sqrt{\sigma_S} \tag{27}$$

According to the above mathematical ideas, the color of the content image of the artwork is successfully matched and transferred to the style picture of the painting to avoid the loss of the traditional style transfer method. In the Lab color space of the artwork image, the color value of each pixel is separated into one brightness channel, L and two color channels, a and b, which provide conditions for the color brightness separation of the artwork image's adaptive style migration [25]. The brightness of the content image of the artworks and the brightness of the style image of the artworks are extracted separately in the Lab color space. The brightness information of the content picture of the paintings is transferred to the style image of the paintings so as to match the brightness information of the content image of the artworks with the brightness information of the style picture of the paintings and achieve the purpose of preserving the color of the content picture of the paintings [26], so as to improve the problem of color mixing in the resulting image obtained from the style transmission of paintings.

H_C and H_S represent the brightness channel of the content image and style image of the artworks; H_J refers to the brightness pixel of the style picture of the paintings after the brightness migration; B_C and B_S show the medium brightness of the content picture and the style picture of the paintings; d_C and d_S represent the standard deviation between the content image of the work of art and the style image of the work of art, then the brightness transfer from the content image of the work of art to the style image of the work of art can be expressed as follows:

$$H_J = d_C\left(H_S - B_S\right)/d_S + B_C \tag{28}$$

Through the above process, it can complete the color and brightness transfer process of an artwork's image's adaptive style transfer and improve the level of the artworks image's adaptive style transfer through the color and brightness transfer of the artwork's image.

E. Self-Adaptive Style Transmission of Paintings on the Basis of Semantic Information

1) Determination of loss function: In the process of adaptive style transmission of paintings, to restrict the image transfer of artworks without redundant semantic information, based on the Laplace operator and convolution neural network method, the semantic information transmission of adaptive style transfer of paintings is realized by using Laplace operator to enhance the semantic information method. The method of the Laplacian operator to enhance semantic information increases the deeper information in the convolutional neural system and fully considers the loss of style transmission of artworks. A grim matrix is used to construct the style transfer loss of the convolutional neural network.

The content loss expression of the convolutional neural system for adaptive style transfer is as follows:

$$L_c = L_{lap} + \gamma L_{r_1} + \delta L_{r_2} \tag{29}$$

In formula (29), L_c represents the losing function of the content picture of the artwork, L_{lap} represents the loss function of the Laplace operator, L_{r_1} and L_{r_2} represent the adjustment coefficient of the loss function, and δ and γ are the weights of the latter two loss function terms. In order to prevent the network from over-fitting due to excessive loss during the training of the convolutional neural network, which affects the final generalization effect, both δ and γ are set to 0.5.

The original artwork image P_c and the migrated artwork image P_o are input into the loss network to calculate the mean square loss of the artwork adaptive style transfer so that the forward propagation error of the convolution neural network can be corrected. The structure diagram of the content loss network of the artwork image is shown in Fig. 1.

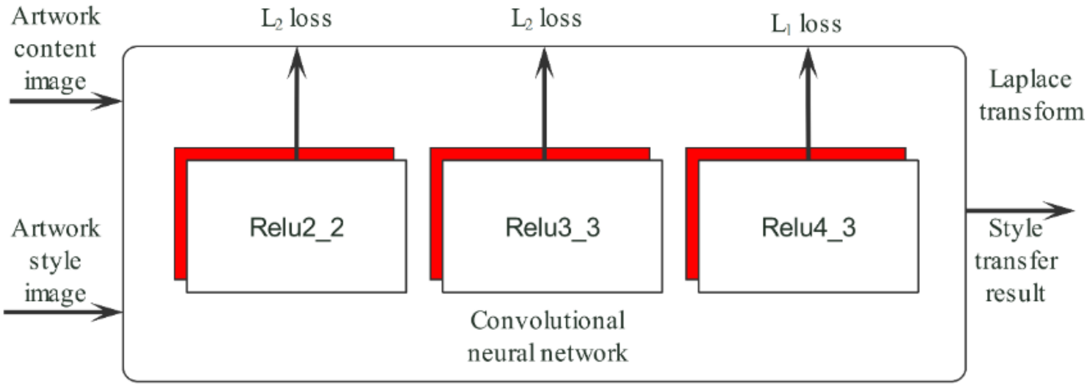

Fig. 1. Graphic content loss network structure of artworks.

In Fig 1, the improved Laplace operator log operator is used to perform the Laplace transform of the artwork image. The loss function L_{lap} of the Laplace operator is calculated as follows:

$$L_{lap} = \frac{C_{l_c}}{W_{l_c} L_{l_c}} \sum_{ij} \left\| lap\left(F_l\left(P_c\right)\right) - lap\left(F_l\left(P_o\right)\right)\right\|_{ij} \tag{30}$$

In formula (30), the value of l_c is Relu4_ 3. The Laplace operator used in the loss function is the improved Laplace operator log operator. P_c is input into the network to output Relu4_ 3. The Laplace operator is used to filter; P_o repeats the above steps. L_1 error is performed by backpropagation to correct the error. The reason for using L_1 error is that L_1 has fewer constraints on the solution, so L_1 error has a better generalization effect than L_2 error.

Using the Laplace operator as the loss function that emphasizes the feature extraction of the convolution neural network will not modify the original artwork image with the Laplace operator, so adding this loss item will not affect the actual quality of the artwork image after style transfer. In the last two terms of the loss function, the Relu2_ 2 and Relu3_ 3 of the convolution neural network are the standards to judge the loss of the content of artworks. The deeper features of the artwork can be obtained using the deeper convolution neural network output. Suppose the deeper image features of the original artwork are consistent with the image features of the artwork after style transfer. In that case, the artwork's image features better constrain the original image's semantic content. After adaptive style transfer, the image of the artwork will be closer to the original artwork image to constrain the artefacts unrelated to the original artwork's image semantics due to style transfer.

The calculation method of L_{r_1} in formula (29) is as follows:

$$L_{r_1} = \frac{C_{l_c}}{W_{l_c} L_{l_c}} \sum_{i,j} \left\| F_l\left(P_c\right) - F_l\left(P_o\right)\right\|_{ij}^2 \tag{31}$$

The calculation method of L_{r_2} is the same as that of L_{r_1}. The only difference between the two is that the value of l_c and is Relu2_ 2 and Relu3_ 3, respectively.

2) Structure design of adaptive style migration network: The overall structure of the adaptive style transfer method of artworks based on the Laplace operator is shown in Fig. 2.

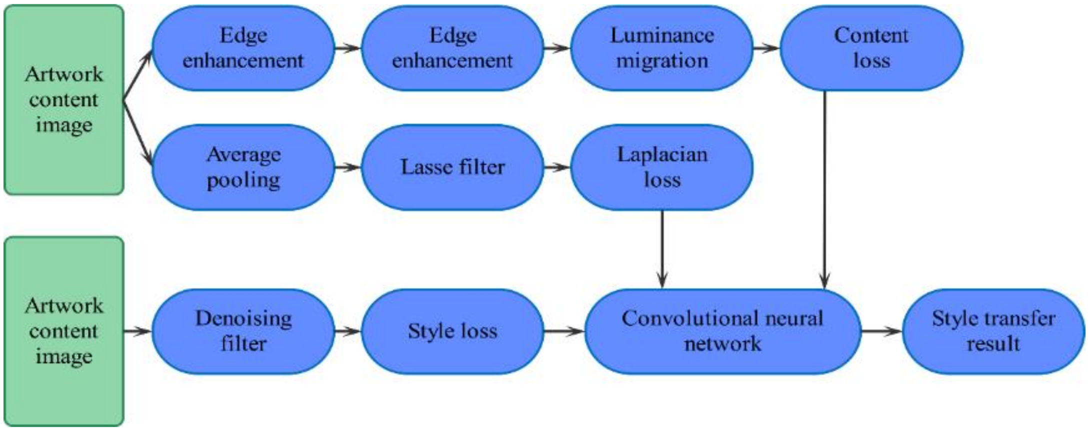

Fig. 2. Adaptive style transfer structure diagram.

It can be seen from the structure chart of adaptive style transfer of artworks in Fig. 2 that the Laplace loss term between the content image of paintings and the stylized picture of paintings is taken as the control dimension of the stylized detail feature of artworks image and added to the total loss function of adaptive style transfer. At the same time, the impact of the color brightness information of the content image and style image on the stylized visual effect is comprehensively considered. Detailed analysis of the specific implementation steps of adaptive style transfer of artworks images is as follows:

1) Input the artwork content image and artwork style image and carry out edge enhancement processing on them; during the edge enhancement process, effectively filter the noise in the artwork image and reduce the impact of the noise in the artwork image on the subsequent adaptive style migration process and the calculation of each loss item.

2) Convert the content image and style image of the artwork from RGB space to Lab space, realize the separation of image brightness channel L and colour channels a and b, transfer the brightness information of the content image of the artwork to the style image of the artwork, and retain the colour information of the content image of the artwork.

3) Input the content image of the artwork after the brightness transfer and the initial stylized result map into the convolution neural network, and carry out the statistics of the content loss items of the convolution neural system to obtain the loss function of the content picture of the artwork.

4) Make statistics of Laplace operator loss term of convolution neural network.

5) Evaluate the style losing function of the style picture of the art picture after denoising.

6) Construct a new total loss function and optimize iteratively in the convolution neural network; use the gradient descent method for continuous iteration of the convolution neural system; and output the adaptive style transfer result chart of paintings. In the process of style transmission of paintings, all loss items are calculated simultaneously.

III. RESULTS

In order to verify the adaptive style transfer method of artworks based on the Laplace operator and the effectiveness of adaptive style transmission of paintings, the paintings collection in the network is selected as the test set, which contains 254 artworks in total. The artworks collection is divided into the content of the artworks set and the artworks style set, which contain 185 images and 69 images, respectively. The method in this paper is programmed by Matlab software, which is run to test the adaptive style transfer of the test set of artworks.

In this paper, a convolution neural network is used as the method of adaptive style transmission of paintings. The ReLU function is selected as the activation function of the convolution neural network. The curve of the ReLU function is shown in Fig. 3.

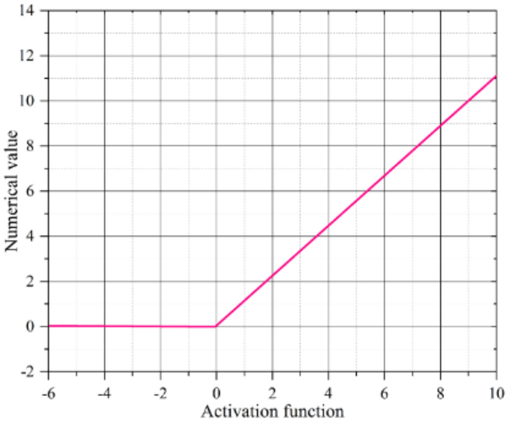

Fig. 3. Schematic diagram of ReLU activation function curve.

The method in this paper is used for adaptive style transmission of paintings. The loss curve changes during the operation of the method are shown in Fig. 4. At the same time, in order to verify the effectiveness of the proposed method, the residual neural network method in the same method reference [10] and the original Convolutional neural network are selected as the comparison method, and the loss curve is generated at the same time.

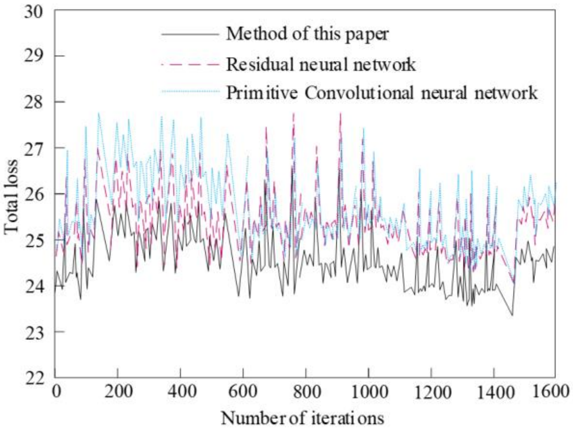

Fig. 4. Loss curve analysis.

A content picture of artwork is selected from the content set of the artwork test set. The content image of the original artwork is shown in Fig. 5.

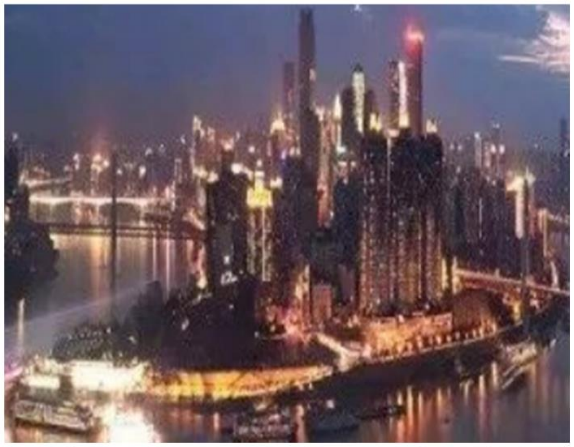

Fig. 5. Original artwork content image.

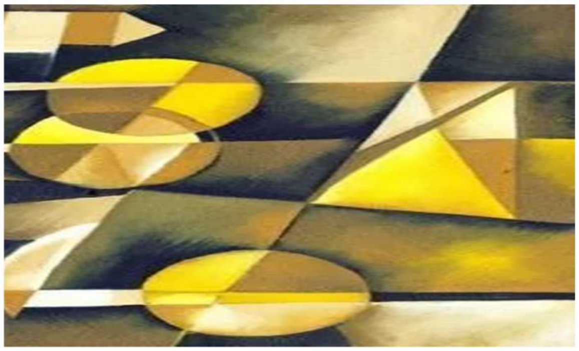
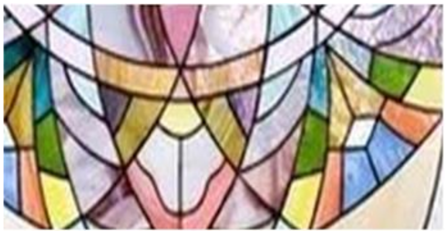
Two artworks style images are selected from the content set of the artworks test set. The style image of the original artwork is shown in Fig. 6.



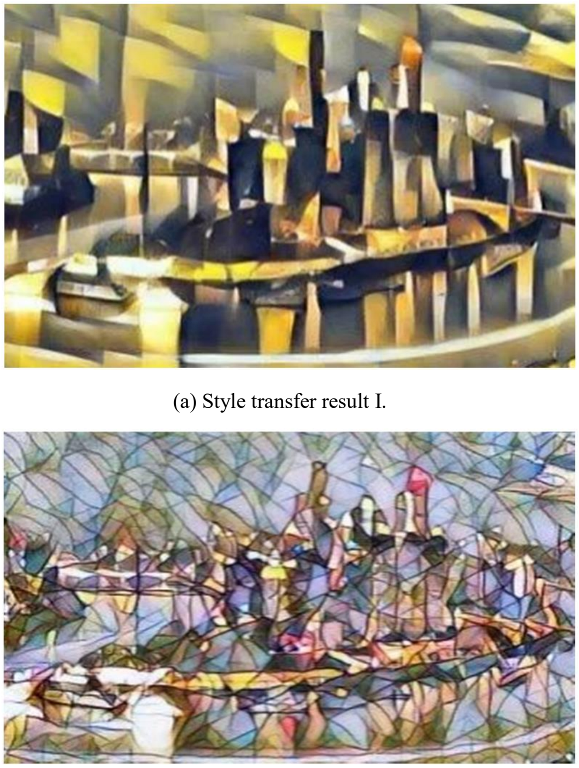
(a) Style image one.



(b) Style image 2.

Fig. 6. Original art style image.

The method in this paper uses the Laplace operator to conduct adaptive style transmission for paintings. The results of adaptive style transfer are shown in Fig. 7.



(a) Style transfer result I.

(b) Style transfer result II.

Fig. 7. Results of adaptive style transfer of artworks.

In order to further verify the adaptive style transfer performance of the method in this paper for artworks, the structural similarity index is selected as a measure of the structural similarity of artworks before and after style transfer. In order to verify the consistency of the structure of the artwork image and the original artwork image after the adaptive style transfer, structural similarity is used to determine the similarity between the two images. The calculation formula of structural similarity is as follows:

$$SSIM(x,y)=l(x,y)c(x,y)s(x,y) \tag{32}$$

In formula (32), $l(x,y)$ is the brightness estimation, $c(x,y)$ is the contrast estimation, and $s(x,y)$ is the structure estimation. The method in this paper is used to conduct adaptive style transfer for artworks. The statistical results of structural similarity are shown in Fig. 8.

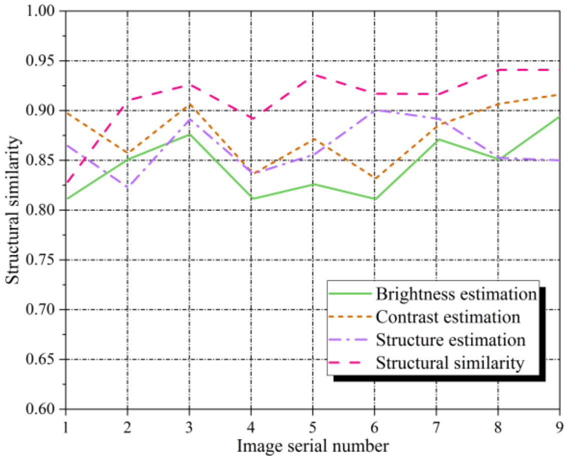


Fig. 8. Statistical results of structural similarity.

Stylization is an art editing work, and the quality of artistic works varies from person to person, so evaluating the quality of stylized images is a very subjective task. As scientific research, the image adaptive style transfer method should have rigorous and quantifiable evaluation indicators. The method in this paper is used to conduct adaptive style migration of artworks. The peak signal-to-noise ratio and migration time of style migration results are shown in Table I.

TABLE I. PERFORMANCE TEST RESULTS OF ADAPTIVE STYLE MIGRATION

Content image number	Style image number	Style transfer result	
		Peak signal-to-noise ratio /dB	Migration time /ms
1	A	35.6	354
2	A	33.4	285
3	A	31.5	415
4	B	32.8	365
5	B	34.5	385
6	B	32.9	346
7	C	31.5	456
8	C	33.7	395
9	C	34.5	405

IV. DISCUSSION

It can be seen from Fig. 3 that when the ReLU activation function inputs a negative value, the output result is 0, which means that only some neurons are activated at the same time, which makes the convolutional neural network more sparse. When this method is used for adaptive style transmission of paintings, the convolution neural network is set up, and the ReLU function is used as the activation function. When the adaptive style transfer of artworks, there is no problem of gradient disappearing. The convergence speed is fast, the calculation is simple, and the efficiency is high, effectively improving the effectiveness of the adaptive style transfer of artworks.

From the experimental results in Fig. 4, it can be seen that the total loss of this method in adaptive style transfer of art works is relatively low. The total loss of the residual neural network method in reference [10] is relatively high, and the total loss of the original Convolutional neural network is the highest among the three methods. This proves that the introduction of Loss function and Laplace operator in the process of adaptive style transfer of art works in this method reduces the loss in the process of adaptive style transfer of art works, and improves the style transfer performance of art works. The experimental results in Fig. 4 show that the adaptive style transfer of artworks using the method in this paper can improve the visual quality of the adaptive style transmission results of paintings and have better performance of minimizing the loss function.

From the experimental results in Fig. 7, we can see that using the method in this paper can achieve adaptive style transmission of paintings. The migrated paintings effectively retain the content of the original artworks content image and the style of the artworks style image. The artworks after style transfer can meet the user's adaptive style transfer needs. This method can achieve style transmission of paintings for different styles, and the effectiveness of style transfer is high.

As an art editing work, evaluating the style transmission effect of paintings is a highly subjective task. In addition to ensuring that the subject information is prominent, detailed information is also an important standard to measure the quality of a good work of art. In addition to preserving the prominent areas in the content image of the artwork, the contour information and line information of the objects in the content image should also be depicted in the stylized image. The method in this paper is used for adaptive style transmission of paintings, and its structural similarity is higher than 0.8. It is verified that the method in this paper can carefully constrain the detailed information of objects in the content image and stylized image, making the generated stylized image lines clearer and the visual effect more refined. This method achieves a balance between the preservation of image structure and the transfer of style elements, so the effect of style transfer is good.

The experimental results in Table I show that the peak signal-to-noise ratio is higher than 30 dB, the image quality is higher, and the style transfer time is less than 500 ms. From the perspective of the quality and time of style transfer image, the method in this paper has a high speed of style transfer, a high quality of style transfer, and a stable effect of style transfer, which can better balance the style and content of artworks. The content and style boundary of the composite image is clear, and the picture effect is good. The quality of the synthesized image is very high, which improves the clarity of the image's content structure and the style's expression ability. The 500ms migration time achieves the real-time migration effect without affecting the user experience of style migration. This method achieves a balance between style transfer time and image quality and achieves real-time high-quality style transfer effect.

V. CONCLUSION

As an excellent neural network in deep learning, convolution neural network has achieved remarkable results in target detection, classification and recognition, especially in image style transfer. Therefore, this article offers an adaptive style transmission method for paintings on the basis of the

Laplace operator. The combination of the Laplace operator and convolution neural network can better retain the semantic information of the content image in the stylized image and improve the visual effect of the stylized image. The experimental results show that the proposed method can obtain ideal style transfer results on the premise of ensuring the quality of style transfer images. The visual effect of style transfer is largely subjective, so the next step will be to add more objective experiments to verify the effectiveness and practicality of the method.

Application of Virtual Reality Technology in the Design of Interactive Interfaces for Public Service Announcements

Rong Hu
College of Visual Arts, Hunan Mass Media Vocational and Technical College, Changsha, 410100, China

***Abstract*—With the development of technology, more and more public service announcements are being designed with interactive interfaces. There are many different ways to interact with interactive interfaces, and using appropriate design methods can expand the impact of PSAs. The study incorporates image pre-processing methods based on virtual reality, using the cvtColor grey scale function and median filtering method to process the images, an iterative approach to camera positioning method design, and subsequent performance testing of the research algorithms. The test results showed that the peak signal-to-noise ratio of the research method was 13.390dB in the image pre-processing process and 35.635dB on lightly shaded images; in the error test, the rotational mean error of the research method was approximately 4.2degrees at four reference points; and in the image plane reprojection test, 70% of the points of the research method almost coincided with the original point position. The method generated 1203 designs with 40 reference points. The experimental results show that the research method can effectively design interactive interfaces for PSAs in virtual reality environments, and can propose more design solutions, and has better performance in virtual reality environment positioning.**

I. INTRODUCTION

With the increasing abundance of entertainment content on the Internet, people's acceptance of advertising is becoming lower, which puts forward higher requirements for the dissemination form of public service advertising [1]. Public service advertising has a certain degree of specificity, and traditional advertising forms and communication methods lack interaction with the audience, often making it difficult to achieve the expected promotional effect [2]. At present, the purpose of public service advertising is not only to disseminate information, but more importantly, to awaken the public's sense of social responsibility and promote social civilization and progress [3]. How to design public service advertisements that can stimulate public emotions and increase participation has become an urgent problem to be solved. At present, common interactive design methods for public service advertisements include socialized interaction, emotional guidance, etc. However, due to the limitations of communication carriers and audience groups, the design effect of public service advertisements is not ideal. With the continuous development of virtual reality technology, its application in various fields is becoming increasingly widespread. Virtual reality technology provides a new interactive experience that can bring users into a virtual real world, providing a more realistic and immersive experience [4]. The application of virtual reality technology in the interactive interface design of public service advertisements can not only improve the user experience, but also allow users to have a deeper understanding of the information that public service advertisements are intended to convey [5]. In virtual reality technology, visual positioning is a very important technology, and more realistic positioning can improve the immersion and realism of virtual reality. Therefore, a study on the interactive interface design of public service advertising has proposed an interface design method that integrates virtual reality technology and visual positioning, in order to provide more reference solutions for the interactive interface design of public service advertising.

The research mainly focuses on four aspects. The first part discusses the current research achievements in interactive interface design and virtual reality technology. The second part elaborates on the technical methods used in the research and design of interactive interface design methods for public service advertisements that integrate virtual reality technology. The third part is to test the performance of the research method. The last part is a discussion and summary of the entire text.

II. RELATED WORKS

Public service announcements (PSAs) are one of the most important tools for spreading healthy moral values in society, and the large number of PSAs being broadcast has led experts to realise the value of applying interactive interfaces to PSAs. A number of experts have conducted research on interactive interface design, and Zong J and others have proposed a system based on Lyra 2 to address the problem that interactive graphic interface design is limited to static output. The process uses a trial-and-error approach to define the attributes of interaction and then represent the interaction on the editorial visualisation. Experimental results show that the proposed method is effective in expressing interactions in multiple types of interface design and has a high runtime speed [6]. Oulasvirta A et al. propose a combinatorial optimisation approach to the problem of coding in the design of interactive GUIs. The process identifies the problem type, selects the focus of the design goals and formulates the functionality specifically. Experimental results show that the proposed approach has good human-computer interaction and can effectively design interactive interfaces [7]. Latif S et al. propose a correlation method to support the tight coupling of data text and diagrams for the adoption of complex data for graphical text interfaces. The process developed a hybrid active interface to enable users to construct interactive interface references between the chart texts. The end result shows that the method is an effective way to provide a wide range of users with the ability to write interactive data documents [8]. Leung J and Cockburn A propose a structured design framework for improving the control and application performance of salient display techniques in user interface design, involving parameter control and highlighting constructs (PCCH). The process collected and reviewed a range of potential human factors and effect measures regarding the interactive impact of highlighting techniques. The results show that the framework is effective in improving the user's understanding of salient information[9]. Two scholars, Jianan L and Abas A, analyse human-computer interaction and the safety and comfort of car driving. The process provides an effective analysis of future human-machine interaction modes and proposes a method for designing human-machine interface interactions with cars based on existing technologies, providing some reference for future car human-machine interface design [10].

There have also been studies on virtual reality technology by experts. Qiu W et al. propose a parallel hierarchical control method based on virtual reality in order to be able to construct a large-scale high-fidelity traffic scene simulator. The process modifies and generates the original data of the traffic elements and assigns all the data to the corresponding taskers based on the proposed spatially parallel slicing method. The results show that the method can effectively ensure the fidelity of the visual scene and better allocate computational resources [11]. Hite R L et al. propose an effective combination of three-dimensional modelling (3D), support for haptic feedback (HE) and interactive virtual reality (VR) in order to assist all K-12 learners in their curriculum on human heart and physiology, and apply it to the curriculum. The results show that the application of 3D-HE-VR technology can effectively provide learners with powerful system representations and student-driven interactions, significantly driving system learning forward [12]. Gu K et al. propose a virtual reality-depth image based rendering (DIBR) method for effective assessment of the quality of synthetic images. To accomplish this goal, the study introduced a new blind image quality assessment (IQA) method developed through multi-scale natural scene statistical analysis (MNSS). The results show that the method has a more comprehensive performance [13]. Rockcastle S et al. designed an experiment for illumination perception in a real space using a series of illuminators in order to make valid observations of images in real and simulated spaces. The process invited 53 people to perform immersive perception. The results showed that there was little difference between the perceived ratings of the designed virtual reality scene and people in the real space in a well-lit scene, which had a more realistic effect [14]. Yeh H C et al. used virtual reality technology in order to enable students to better grasp the language content and language skills in English and to reform the curriculum with virtual reality, interactive, audio and structured teaching. The results showed that students were better able to learn cross-culturally with VR technology and significantly improved their own English language learning skills [15].

In summary, although virtual reality technology has been studied and applied in many fields, there is a lack of research in the field of interactive interface design for public service announcements. In view of this, the study proposes an interactive interface design method for public service announcements that incorporates virtual reality technology in order to effectively design interactive interfaces for public service announcements and provide more references for the interactive interface design industry.

III. Research on the Interactive Interface Design Method of Public Service Advertisement Integrating Virtual Reality Technology

A. *Design of Visual Orientation Methods for Interactive Interfaces*

Interaction design supports people to communicate and interact with tools and objects in their working lives. In the Internet+ environment, PSAs are increasingly focused on interacting with their audiences to enhance the interest and content richness of functional PSAs [16-17]. Virtual reality technology is widely used in interactive games and software, and can be effectively applied to the design of interactive interfaces for PSAs due to its immersive nature and the variety of ways in which it can be used [18-19]. The main reference elements for interactive design are shown in Fig. 1.

As shown in Fig. 1, there are six principles and four elements to be considered when designing interactions. The four elements are: the object is the target user of the interaction; the behaviour is the action of the user during the interaction; the function is the interaction module and scenario that can be provided to the user during the interaction; and the technology is the implementation of the interaction. The technology is the control system and information algorithm that realises the interaction. Public service announcements (PSAs) have certain characteristics that differentiate them from ordinary advertisements in terms of planning and filming because of their special meaning of existence. The characteristics of an interactive PSA are shown in Fig. 2.

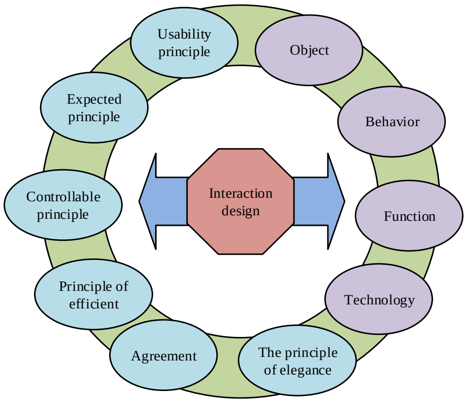

Fig. 1. Reference principles and elements of interaction design.

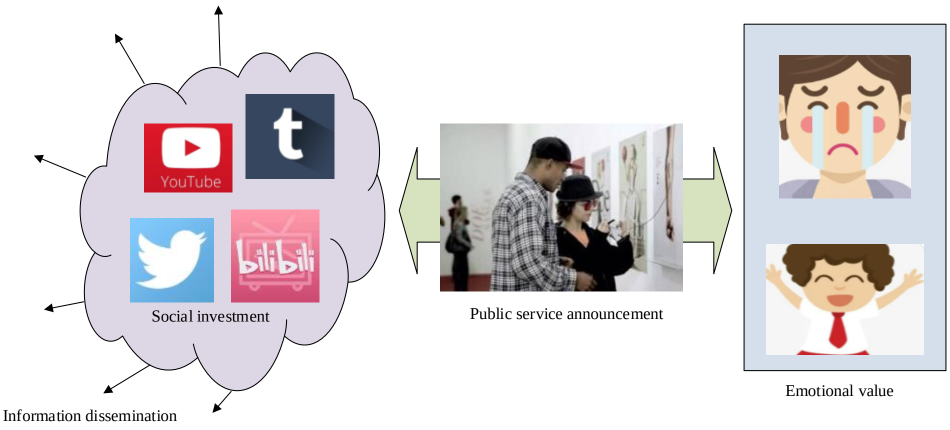

Fig. 2. Features of interactive public service announcement.

As can be seen from Fig. 2, interactive PSAs are a type of PSA, and so, like other PSAs, have two main characteristics: social input and emotional brewing. The development of the Internet has enabled information to spread faster and over a wider area, and social interaction has given rise to numerous information platforms through which the public can access public service information and play a supervisory role over social welfare. Public service announcements (PSAs) are more emotionally charged than ordinary advertisements, and interactive PSAs are richer in ways of communicating emotions, bringing a wider variety of emotional experiences to viewers as they interact with each other [20-21]. When designing interactive PSAs using virtual reality technology, the first step is visual positioning, analysing the information with location markers and solving for camera position and pose [22]. Before virtual reality can be used for spatial positioning, 2D markers need to be created. 2D markers are deformed in 3D space due to perspective, and 2D markers captured by the camera are more likely to be trapezoidal in shape, requiring a coordinate system conversion for recognition. In the pixel and image coordinate system, the dimensions of a single pixel on the u and v axes are shown in Eq. (1).

$$\begin{cases} u = x / d_x + u_0 \\ v = y / d_y + v_0 \end{cases} \tag{1}$$

In Eq. (1), d_x represents the unit size of a single pixel on the x-axis; d_y represents the size of a single pixel on the y-axis; u_0 and v_0 represent the coordinates of the centroids in the image coordinate system. The matrix relationship between pixels and images is shown in Eq. (2).

$$\begin{bmatrix} u \\ v \\ 1 \end{bmatrix} = \begin{bmatrix} 1/d_x & 0 & u_0 \\ 0 & 1/d_y & v_0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \\ 1 \end{bmatrix} \tag{2}$$

In Eq. (2), the matrix is normalised by u and v. The relationship between a point in the world coordinate system and its position in the camera coordinate system is shown in Eq. (3).

$$P_c = RP_w + t \tag{3}$$

In equation (3), P_c represents the coordinates of the point in the camera coordinate system; P_w represents the coordinates of the point in the world coordinate system; and R is the rotation matrix. After the rotation of the coordinate system by the rotation matrix, the relationship is matrixed and normalised to obtain the coordinate matrix, as shown in Eq. (4).

$$\begin{bmatrix} X_c \\ Y_c \\ Z_c \\ 1 \end{bmatrix} = \begin{bmatrix} r_{11} & r_{12} & r_{13} & t_x \\ r_{21} & r_{22} & r_{23} & t_y \\ r_{31} & r_{32} & r_{33} & t_z \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} X_w \\ Y_w \\ Z_w \\ 1 \end{bmatrix} \tag{4}$$

In Eq. (4), X_c, Y_c and Z_c represent the coordinates of the point in the three axes of the camera's coordinate system respectively; X_w , Y_w and Z_w represent the coordinates of the point in the three axes of the world coordinate system respectively. Since the camera lens uses a convex lens, there is bound to be aberrations when recording the image and the image needs to be corrected. With the centre of the aberration as the central point, the deviation along the radial direction is the radial aberration, and the radial aberration error is shown in Eq. (5).

$$\begin{cases} \varepsilon_{ur} = u(k_1 r^2 + k_2 r^4 + k_3 r^6) \\ \varepsilon_{vr} = v(k_1 r^2 + k_2 r^4 + k_3 r^6) \end{cases} \tag{5}$$

In Eq. (5), ε_{ur} is the radial error of the point position on the u-axis of the pixel coordinate system; ε_{vr} is the radial error of the point position on the v-axis of the pixel coordinate system; k represents the radial aberration coefficient. The deviation along the tangent line with the centre of distortion as the centre point is the tangential distortion, and the tangential distortion error is shown in equation (6).

$$\begin{cases} \varepsilon_{tu} = 2p_1 uv + p_2(r^2 + 2u^2) \\ \varepsilon_{tv} = p_1(r^2 + 2v^2) + 2p_2 uv \end{cases} \tag{6}$$

In Eq. (6), p represents the tangential aberration factor; ε represents the aberration error of the coordinate axes. Thin lens aberrations occur when the camera lens is not parallel to the CDD, and the thin lens aberration error is shown in Eq. (7).

$$\begin{cases} \varepsilon_{cu} = s_1(u^2+v^2) \\ \varepsilon_{cv} = s_2(u^2+v^2) \end{cases} \tag{7}$$

In Eq. (7), s represents the thin lens aberration parameter.

B. Design of an Interactive Interface Camera Positioning Method Based on Image Pre-processing

In the interactive interface of a PSA, the camera needs to extract the logo image for visual positioning, and using a higher resolution image can increase the accuracy of the extraction. However, the higher the resolution of the image, the more storage space it takes up and the greater the pressure on the system when processing the image [23]. The 2D logo used in the study is only in black and white, so the logo image can be extracted by greyscaling the image, which does not affect the visual localisation of the camera and reduces the amount of extra information contained in the image. The study uses the cvtColor greyscale function, which comes with the OpenCV vision library, to greyscale the images. The camera converts the image colour during imaging in the RGB domain, resulting in the appearance of non-linear noise[24]. The median filtering method takes care of bright and dark point noise and removes sharp signals from the signal. When performing telecoded image processing, reference points need to be extracted and the maximum contour containing all points is calculated as shown in Eq. (8).

$$\begin{bmatrix} (x_1,y_1) & \cdots & (x_1,y_n) \\ \vdots & \ddots & \vdots \\ (x_m,y_1) & \cdots & (x_m,y_n) \end{bmatrix} \in \max Quad\left((x_l,y_m),(x_n,y_o),(x_p,y_q),(x_r,y_w)\right) \tag{8}$$

In Eq. (8), $\max Quad$ represents the maximum contour that contains all points. As the operator interacts, the captured image will change due to the operator's actions and the study uses a perspective transformation to process the image. The principle of the perspective transformation is shown in Fig. 3.

As can be seen in Fig. 3, the captured image differs from the real one in shape in the final two-dimensional form because of the angle formed between the lens and the surface of the object and the perspective changes in the lens field of view, which are large near and far away. The coordinates of the original image and the pixel points of the transformed image are established, and the coordinates of the perspective transformed image are obtained after linear and translational transformations, as shown in Eq. (9).

$$\begin{cases} X^p = \dfrac{a_{11}X + a_{12}Y + a_{13}}{a_{31}X + a_{32}Y + a_{33}} \\ Y^p = \dfrac{a_{21}X + a_{22}Y + a_{23}}{a_{31}X + a_{32}Y + a_{33}} \end{cases} \tag{9}$$

In Eq. (9), X^p and Y^p represent the coordinates of the pixel points on the X and Y axes respectively. The Z-axis coordinates are both 1 after the transformation. In order to reduce the computational pressure of extraction, the 2D logo is rotated so that the logo is at a computationally convenient angle. The rotation angle of the logo is calculated as shown in Eq. (10).

$$angle = arc\left(\frac{y_2 - y_1}{x_2 - x_1}\right) \tag{10}$$

In Eq. (10), $angle$ represents the rotation angle; x_1 and y_1 are the centroid coordinates of the top left corner; x_2 and y_2 are the centroid coordinates of the top right corner. When locating near-code images, only the pixel coordinates of the image centroid need to be extracted. However, when searching for near-code image finding, the position image and the parent contour can interfere. The study uses an iterative method to mitigate the interference by establishing a hierarchical relationship for each contour and then removing the position image. This is shown in Fig. 4.

As seen in Fig. 4, the complete labelled image contour contains three position contours as well as the parent contour. The position contours are the first to be removed by the iteration as they differ most from the near-code image. The separate small squares in the near-code image are combined while the parent contours are removed, resulting in an image containing only the near-code image. The complete image pre-processing process is shown in Fig. 5.

As can be seen from Fig. 5, in the first half of the pre-processing process, the colour and interference noise of the image are processed, and the outline of the 2D logo is extracted and the area of the maximum outline is calculated. The maximum contour area is used as the judging condition, and the area requirement is met before entering the second half of the processing process for the far-code and near-code images, and when the maximum contour area exceeds the judging value, the image is judged as a near-code image, otherwise it is judged as a far-code image. After the extraction of information from the far code image or the near code image, the image pre-processing of the 2D logo is completed. The 3D reference point on the camera coordinate system is shown in Eq. (11).

$$P_i^c = RP_i^w + t \tag{11}$$

Fig. 5. 2D identification image preprocessing process.

In Eq. (11), P_i^w represents the coordinates of the 3D reference point on the world coordinate system; R is the rotation matrix obtained after the reference point enters the camera coordinate system; t is the translation of the reference point after it enters the camera coordinate system. The reference point is subject to some error in actual positioning, and the study iterates over the object-squared residuals to complete the estimation of the camera's position pose. The object-squared residuals are calculated as shown in Eq. (12).

$$E_g = \left\| \dot{p}_i - \dot{p}_i^{'} \right\| = \left\| p_i - \frac{R(P_i^c - C)}{R^3(P_i^c - C)} \right\| = \frac{1}{Z_i^c} \left\| P_i^c - P_i^{'c} \right\| \tag{12}$$

In Eq. (12), $P_i^{'}$ and $P_i^{'c}$ are the reference estimation points; $\dot{p}_i$ represents the flush coordinates of the image reference point; $\dot{p}_i^{'}$ represents the flush coordinates of the estimation point; C represents the coordinates of the origin on the world coordinate system; and Z_i^c represents the depth value of the reference point on the camera coordinate system. The object-squared residuals and image-squared residuals are shown in Fig. 6.

As seen in Fig. 6, the depth of the spatial reference point affects the object residuals when the image residuals are the same, the deeper the object residuals the greater the object residuals. When performing the orthogonal iteration, the error between the theoretical point and the reference point in the 2D plane is calculated as shown in Eq. (13).

$$w_{ki} = \frac{1}{n} \sum_{i=1}^{n} \left(\frac{(u_i - \bar{u}_i)^2}{\bar{u}_i - u_0} \right) \tag{13}$$

In Eq. (13), u represents the coordinates of the point after the distortion effect. The translation vector and rotation matrix are calculated by introducing the Kronecker product for matrix operations, as shown in Eq. (14).

$$\begin{cases} A \otimes (B + C) = A \otimes B + A \otimes C \\ (A \otimes E_1)(E_2 \otimes B) = A \otimes B \\ vec(ABC) = (C^T \otimes A) vec(B) \\ P_i^W \leftarrow P_i^W - \bar{P}_i^w \end{cases} \tag{14}$$

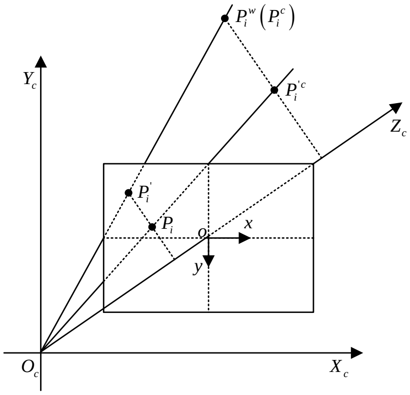

Fig. 6. Object residual and image residual.

In Eq. (14), $\overline{P}_i^w$ is the average of all spatial reference points. Decompose the matrix m as shown in Eq. (15).

$$\begin{cases} m^{(k)} = \left[\sum_{i=1}^{n} w_i \left(P_i^w \otimes \left(P_i^w \right)^T \otimes V_i^{'} \right) + \sum_{i=1}^{n} \left(P_i^w \otimes V_i^{'} \right) \left(G \right) \right] H^{(k)} \\ m = UDV^T \end{cases} \tag{15}$$

In Eq. (15), $m^{(k)}$ and $vec\left(M^{(k)}\right)$ are equal and are obtained by regularising the projection points. After calculating the translation vector and combining it with the rotation matrix, the objective function is obtained, as shown in Eq. (16).

$$\begin{cases} E\left(R,t\right) = \sum_{i=1}^{n} w_i \left\| \left(T - V_i^{'} \right) \left(\left(P_i^w \right)^T \otimes I + G \right) H \right\|^2 = H^T J_{9\times9} H \\ J = \sum_{i=1}^{n} w_i \left(\left(P_i^w \right)^T \otimes I + G^T \right) \left(I - V_i^{'} \right) \left(\left(P_i^w \right)^T \otimes I + G \right) \end{cases} \tag{16}$$

In Eq. (16), the matrix at G is considered a constant matrix; $E(R,t)$ represents the final camera position. Once the technical framework has been constructed, the design of the appearance and interactive functionality of the interactive PSA interface can be carried out.

IV. Performance Testing of an Interactive Interface Design Method for Public Service Announcements Incorporating Virtual Reality Technology

In order to verify the feasibility and effectiveness of the research design virtual reality technology when applied to the design of interactive interfaces for public service announcements, the performance of the system was tested. The basic hardware environment setup for the experiment is shown in Table I.

The testing started with performance testing of the functions in the first half of the process. The performance of the study using the greyscale algorithm was tested and compared with other greyscale algorithms and the results are shown in Fig. 7.

As can be seen in Fig. 7(a), the smallest result in the peak signal-to-noise ratio test was obtained by the component method at 12.980dB, while the largest result was obtained by the cvtColor used in the research method at 13.390dB. 39.053; the study method is not the largest, but the value of 39.021 is very close to the maximum. This shows that the research method produces the clearest images, with higher image contrast and higher computational efficiency. The performance of the denoising algorithm was tested and compared with other denoising algorithms and the results are shown in Fig. 8.

As seen in Fig. 8(a), the test was conducted using lightly shaded images, moderately shaded images, and heavily shaded images. In the signal-to-noise ratio test, the median filter reaches a value of 35.635dB on the light shaded image, much higher than the Gaussian filter and the mean filter at 28.595dB and 28.526dB; the median filter is the same as the mean filter on the medium shaded image, both at 25.673dB, slightly lower than the Gaussian filter at 25.841dB, but the difference is negligible; the median filter reaches a value of 38.145dB on the heavy shaded image, much higher than the Gaussian filter and the mean filter. As can be seen from Fig. 8(b), the mean square error of the median filter on the light, medium and heavy shaded images is lower than 14, and the lowest mean square error of the Gaussian filter and the mean filter is 24.666, which is much higher than that of the median filter. This indicates that the research method can provide good denoising of images in light, medium and heavy shading environments. After completing the testing of the first half of the process function, the performance of the research method was tested. The noise was fixed at 3pixel and 1000 experiments were performed for each reference point. The error of the research method when the number of reference points was varied was tested and the results are shown in Fig. 9.

TABLE I. THE EXPERIMENT'S BASIC ENVIRONMENTAL PARAMETERS

Parameter variables	Parameter selection
Operating system	Windows 10
Operating environment	MATLAb 2020a
System PC side memory	16G
CPU dominant frequency	2.62Hz
GPU	RTX-2060
Central Processing Unit	Intel ⑧CoreTM i5-10500

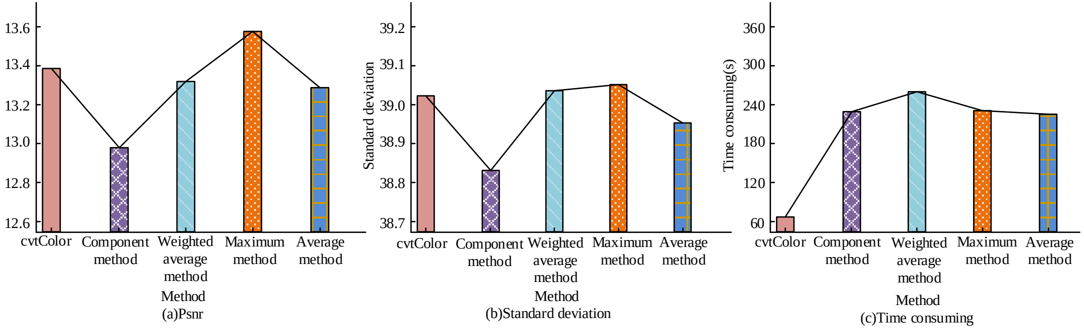

Fig. 7. Comparison of grayscale algorithm performance.

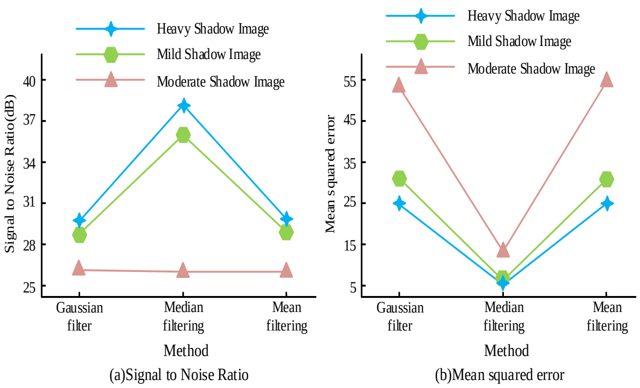

Fig. 8. Noise reduction effect test.

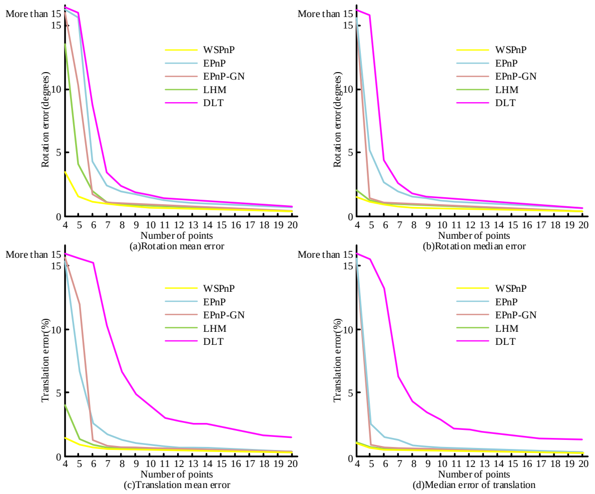

Fig. 9. Rotation error and translation error.

As can be seen from Fig. 9, the errors of all methods gradually decrease as the number of reference points increases. As seen in Fig. 9(a) and Fig. 9(b), the curves for all methods show a sharp decrease in the first few times and a slow decrease towards a stable shape in the later stages in terms of rotational mean error and rotational median error. The rotational mean error of the study method at 4 reference points is about 4.2degrees, much lower than the other methods, and the rotational median error at four reference points is about 2.1degrees, slightly lower than the LHM and much lower than the other remaining methods. At reaching 20 reference points, the rotational mean error of the study method stabilises around 0.7degrees, slightly lower than the other methods; the rotational median error of the study method stabilises around 0.6degrees, slightly lower than the other methods. As can be seen from Fig. 9(c) and Fig. 9(d), the curves of all the methods show a sharp decline in the first few times and a slow decline towards stability in the latter part of the curve for both the translational mean error and the translational median error, with the DLT declining at a slightly slower rate. The mean error of translation at 4 reference points is slightly lower than the LHM and much lower than the remaining methods, while the median error of evaluation is slightly lower than the LHM and much lower than the remaining methods. When reaching 20 reference points, the translation mean error of the study method and all other methods except DLT are stable at around 0.5%, and the translation median error is stable at around 0.4%. This indicates that the error of the research method is less affected by the number of reference points and has a much lower error. The effect of Gaussian noise on the positioning accuracy was tested and is shown in Fig. 10.

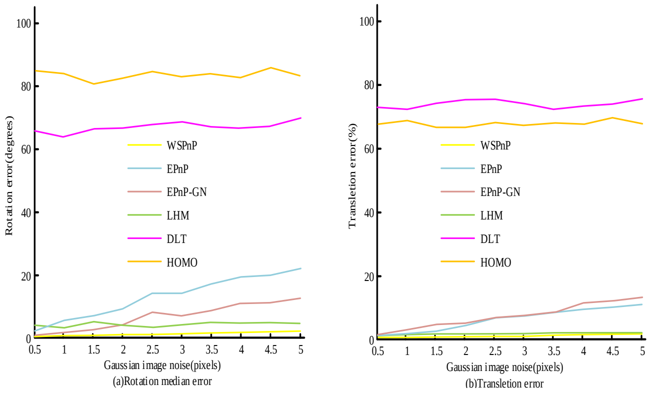

Fig. 10. The influence of Gaussian noise on location accuracy.

As can be seen in Fig. 10, DLT and HOMO consistently remain at a high error level when performing localisation, with the other methods resulting in increasing errors as the Gaussian noise increases. In terms of rotation error, the rotation error of the study method is about 0.3degrees at 0.5pixels, rising to about 1.8degrees when reaching 5pixels, which is significantly lower than the other methods. In terms of translation error, the translation error of the research method is about 0.1% at 0.5pixels and rises to about 1.2% at 5pixels, which is closer to LHM and significantly lower than other methods. This indicates that the de-noising performance of the research method is good, and the performance advantage of the research method becomes more obvious when the Gaussian noise is larger. Ten 3D reference points were set, and the camera coordinates for the 3D reference points were solved and reprojected, as shown in Fig. 11.

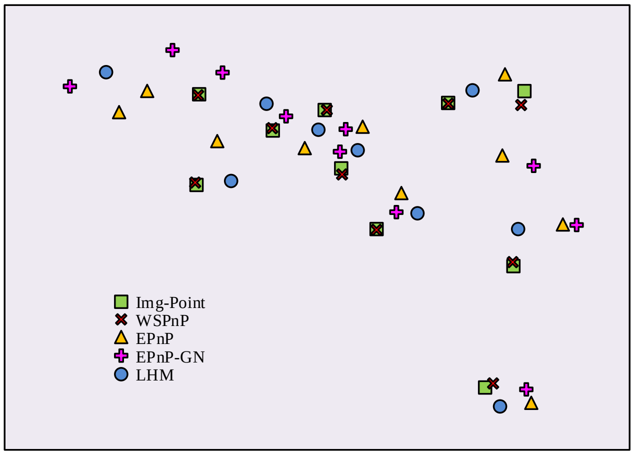

Fig. 11. Image plane reprojection.

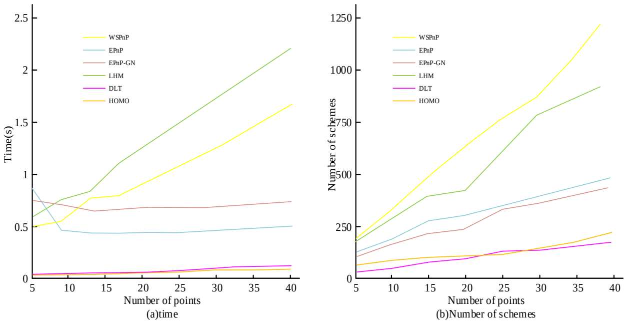
As can be seen from Fig. 11, the 10 original image points are randomly distributed in the image plane, the reprojection position of EPnP-GN deviates more, only 6 points are closer to the original image points; EPnP and LHM have more points closer to the original image points, but no points almost coincide with the original points. All the points of the research method are close to the original points, and seven of them almost coincide with the original points. This indicates that the research method has good performance in solving the coordinates and produces less variation in position. The research method was tested with different numbers of reference points, as shown in Fig. 12, to ensure the computation time and number of solutions when using the research method for PSA interactive interface design.



(a)time

(b)Number of schemes

Fig. 12. Calculation time and number of generated solutions.

The computation time of EPnP-GN and EPnP does not depend much on the number of reference points, while the computation time of other methods including the research method increases with the number of reference points. The computation time of EPnP-GN and EPnP is basically stable at 0.6s and 0.8s. DLT and HOMO are linear solution methods with obvious advantages in speed, but lacking in accuracy. The computation time of the research method is about 0.5s at five reference points, rising to about 1.6s when 40 reference points are reached, more than EPnP-GN and EPnP when the number of reference points is higher, and in all cases lower than LHM, which also uses orthogonal iteration. The research method generates 212 solutions at five reference points and rises to 1203 solutions at 40 reference points, which is more than the other algorithms. This indicates that the research method does not have a significant speed advantage when designing interactive interfaces for PSAs, but it can generate more solutions and provide a richer choice when conducting subsequent designs.

V. Conclusion

The interactive interface design of public service advertising directly affects the quality of public service advertising. In the environment of virtual reality technology, the visual positioning method is designed first, and then when the camera positioning method is designed, the image is preprocessed to reduce the computational burden, the Iterative method is introduced to reduce the interference in image positioning, and finally the object residual is iterated to complete the camera position pose estimation. The results show that the research method only requires 65.804ms for image graying, while other methods require over 200ms; The Mean squared error of research methods on light, medium and heavy shadow images is lower than 14, far lower than other methods; In a noisy environment of three pixels, the translation mean error of the research method is around 0.5%, and the translation median error is around 0.4%, which is lower than other methods; In the Gaussian noise environment of five pixels, the rotation error of the research method is 1.8 degrees, which is significantly lower than other methods; When designing research methods, using five reference points can generate 212 schemes, which is more than other methods. It shows that the research method has good technical performance guarantee under the virtual reality technology environment, and can provide more options for the design of other content such as the Look and feel of subsequent public service advertisements. However, the research was tested in a simulated environment and lacked data reference to the real environment. In the future, real machine testing will be conducted to enrich experimental data and optimize it.

Institute for Q-shu Pioneers of Space, Inc. (iQPS), Fukuoka, Japan[2, 3]

***Abstract*—A method for image quality evaluation of satellite-based Synthetic Aperture Radar: SAR data is proposed. Not only geometric fidelity but also signal to noise ratio, frequency component, saturated pixel ratio, speckle noise, optimum filter kernel size and its filter function are evaluated. Through experiments with SAR so called QPS-SAR_2 (Q-shu Pioneers of Space SAR the second) of imagery data, all these items are evaluated, and it is confirmed that the geometric and radiometric performances are good enough. Also, geometric fidelity of QPS-SAR_2 is compared to Sentinel-1/SAR European Space Agency (ESA) provided data which is obtained on the same day of QPS-SAR_2 data acquisition.**

Keywords—Image quality; synthetic aperture radar (SAR); geometric fidelity; signal to noise ratio; frequency component; saturated pixel ratio; speckle noise; optimum filter kernel size; filter function for speckle noise reduction

I. Introduction

Institute for Q-shu Pioneers of Space, Inc.: iQPS has realized a mass of 1/20 and a cost of 1/100 of the conventional X band SAR satellite by using a lightweight antenna for small satellites developed in-house, and a 100 kg class high-definition small SAR. It was the first successful SAR mounted small satellite in Japan. Currently, we are aiming to launch 36 small SAR satellites and build a constellation early after 2025, and to provide a quasi-real-time ground observation data service about every 10 minutes. To realize this project, we were able to work on the development, manufacture, and launch of two satellites, "Izanagi" and "Izanami" which play the role of technology demonstrator. The first unit "Izanagi" was launched in December 2019, and the second unit "Izanami" was launched after February 2021.

The satellite called "Izanami" which was developed and manufactured by iQPS and about 20 local companies in Kyushu was launched by the flagship rocket "Falcon 9" of the American space development company "SpaceX" on January 25, 2021 (Monday). It was launched at 1:14 a.m. and set to the altitude of about 525 km. Then, on the same day, the first communication was successful, the retractable antenna was deployed on the 30th of January (Saturday), and the first image acquisition was announced on 3 March (Wednesday), about one month after the launch. After that, Izanami continued to observe steadily every day, and succeeded in acquiring an image with an azimuth resolution of 70 cm and a range (ground range) resolution of 70 cm in a high-definition mode (spotlight mode)[1] with a resolution of 70 cm.

The need for high-definition images in the market is extremely high, and the successful acquisition and demonstration of technology at Unit 2 Izanami (QPS-SAR_2) is a major step toward the full-scale data provision service business. In the future, we will further stabilize the image quality and proceed with the development of the usage platform with a sense of speed.

There are many papers which deal with SAR image quality evaluation methods. Not only geometric fidelity but also signal to noise ratio, frequency component, saturated pixel ratio, speckle noise, optimum filter kernel size and its filter function can be evaluated with the previously proposed methods. Cross comparison between two different SARs which are onboarded the different satellites and observe in a same day is conducted. This is a new method for the SAR imagery data quality evaluation in this paper. Two different SARs observed the same ground cover target with the different off-nadir angles. Therefore, layover, shadowing, foreshortening is different each other of SAR imagery data results in some processing is required for tie point matching. Otherwise, pixel-to-pixel comparisons cannot be performed. The purpose of this paper is to propose SAR image quality evaluation methods such as spatial resolution, signal to noise ratio, modulation transfer function, pixel geolocation accuracy (geometric fidelity), etc. Through the experiments, it is found that the proposed method works well for image quality evaluation.

In the next section, related research works are described followed by research background and theoretical background. Then, the proposed system is described at first followed by some experiments are described together with conclusion and some discussions.

II. Related Research Works

The following are the SAR related papers,

A method for Ground Control Point: GCP acquisition using simulated SAR derived from Digital Elevation Model: DEM is proposed [1] together with GCP acquisition using simulated SAR imagery data and evaluation of GCP matching accuracy with texture features [2].

[1] There are normal mode (stripmap mode) with a resolution of 1.8m (azimuth resolution 1.8m x range resolution 0.7m) and high-definition mode (spotlight mode) with a resolution of 70cm.

Speckle noise removal of SAR images with DEM is attempted [3]. Meantime, a method of speckle noise reduction for SAR data is proposed [4]. Meanwhile, SAR image classification based on Maximum Likelihood decision rule: MLH with texture features taking into account a fitness to the probability density function is proposed [5]. A new method for SAR speckle noise reduction (Chi-Square Filter: CSF) is proposed and validated [6] together with a new method for SAR speckle noise reduction based on CST filter [7].

Decomposition of SAR polarization signatures by means of eigen-space representation is attempted [8]. On the other hand, evaluation of vector winds observed by NASA Scatterometer: NSCAT in the ocean of Japanese vicinity is conducted [9].

Polarimetric SAR image classification with maximum curvature of the trajectory in eigen space domain on the polarization signature is proposed [10] together with polarimetric SAR image classification with maximum curvature of the trajectory in eigen space domain on the polarization signature [11]. Meanwhile, polarimetric SAR image classification with high frequency component derived from wavelet Multi Resolution Analysis: MRA is proposed [12].

Comparative study of polarimetric SAR classification methods including proposed method with maximum curvature of trajectory of backscattering cross section in ellipticity and orientation angle space is conducted [13]. On the other hand, wavelet MRA and its application to polarimetric SAR classification are proposed [14].

Sentinel-1A SAR data analysis for disaster mitigation in Kyushu, Japan is conducted [15]. Also, flood damage area detection method by means of coherency derived from interferometric SAR analysis with Sentinel-1A SAR is proposed [16]. GCP generation from simulated SAR image derived from Digital Terrain Model: DTM and its application to texture feature extraction is conducted [17].

Meanwhile, there are the following not only SAR but also optical sensor image quality evaluation related papers,

Report on vicarious calibration and image quality evaluation of LISA/LISAT[2] is presented and issued [18]. Also, methods for vicarious calibration and image quality evaluation of LISA/LISAT are proposed [19].

On the other hand, there are the following papers which deal with frequency component analysis,

Polarimetric SAR image classification with high frequency component derived from wavelet multi resolution analysis: MRA is proposed [20]. Meanwhile, hearing aid method by equalizing frequency response of phoneme extracted from human voice is proposed [21].

Meanwhile, the following papers deal with noise analysis,

On the other hand, sensitivity analysis of Fourier Transformation Spectrometer: FTS against observation noise on retrievals of carbon dioxide and methane is conducted [22].

Noise suppressing edge enhancement based on Genetic Algorithm: GA taking into account complexity of target image measured with Fractal dimension is proposed [23]. Meantime, a method for aerosol parameter estimation error analysis is proposed with a consideration of noises included in the measured solar direct and diffuse irradiance [24].

Method of noise reduction in passive remote sensing is proposed for noise and clutter rejection [25]. On the other hand, speckle noise removal of SAR images with DEM is proposed [26]. Flood damage area detection method by means of coherency derived from interferometric SAR analysis with Sentinel-1A SAR is proposed [27]. Furthermore, Ground Control Point: GCP generation from simulated SAR image derived from Digital Terrain Model: DTM and its application to texture feature extraction is also proposed and validated [28]. Meanwhile, method for frequent high resolution of optical sensor image acquisition using satellite-based SAR image for disaster mitigation is proposed [29].

III. Theoretical Background and Proposed Method

Not only geometric fidelity but also Signal to Noise ratio: S/N, frequency component, saturated pixel ratio, speckle noise, optimum filter kernel size and its filter function can be evaluated with the previously proposed methods.

As for the geometric fidelity, GCPs which are derived from geographic maps can be used. S/N can be evaluated with the ratio of mean and standard deviation of certain homogeneous areas. Frequency component can be evaluated with Fast Fourier Transformation: FFT, Discrete Cosine Transformation: DCT and so on.

On the other hand, saturated pixel ratio can be evaluated with histogram analysis. As for the speckle noise evaluation, visual perception can be used for identification of saturated pixels. Meanwhile, optimum filter kernel size and its filter function for speckle noise reduction can be estimated with trial and errors through visual perception.

Cross comparison between two different SARs which have onboarded the different satellites and observed in a same day is conducted. This is a new method for the SAR imagery data quality evaluation in this paper. Two different SARs observed the same ground cover target with the different off-nadir angles. Therefore, layover, shadowing, and foreshortening are different from each other in SAR imagery data, resulting in the need for some processing to be done for tie point matching. Otherwise, pixel-to-pixel comparisons cannot be performed.

IV. Experiments

A. *Examples of Acquired QPS-SAR_2 Imagery Data used for Image Quality Evaluation*

Fig. 1 shows examples of acquired QPS-SAR_2 imagery data used for image quality evaluation. Fig. 1(a) and 1(b) are SAR images of Osaka, Japan (34.69N, 135.50E) (these are referred to Osaka scenes hereafter) which are acquired at 9:24 p.m. (Japan time) on 4 May 2021 (Tuesday) while Figure 1(c) to (g) are SAR images of Tokyo, Japan (N35 40', E139 46') (these are referred to Tokyo scenes hereafter) which are acquired at 9:06 p.m. (Japan time) on 23 March 2021 (Friday).

[2] https://www.eoportal.org/satellite-missions/lapan-a3#overview

In Fig. 1(a), "Senri Chuo Station" (Located in 1-chome Shinsenri Higashimachi (34.81N, 135.49E), Toyonaka City, Osaka Prefecture, it is a station on the Kita-Osaka Kyuko Railway Namboku Line and the Osaka Monorail Main Line.) is a little to the right of the central part. In Fig. 1(b), the steel tower and a part of the electric wire in the upper left, the Ferris wheel "OSAKA WHEEL" and "Panasonic Stadium Suita" with a height of 123m in the lower left, and the monorail stopped in the garage near the center are identified. The detail locations of Toyonaka and Osaka wheel are shown in Fig. 1(c).

As for Fig. 1(f), since the roof of the Tokyo Dome (35.71N, 139.75E) can be seen through, you can even see the electric bulletin board. Meanwhile, in Fig. 1(g), you can see Ueno Onshi Park (35.72N,139.77E) and Shinobazu Pond (35.71N, 139.77E) while you can identify the freight container in the lower right in Fig. 1(h). The detail locations of Tokyo Marunouchi buildings (35.68N, 139.76E), Minami Senju (35.73N 139.80E), Tokyo dome and Ueno Onshi Park are shown in Fig. 1(i).

Through comparisons between geographic maps and QPS-SAR_2 imagery data, it is found that the spatial resolution (equivalent to ground range) of QPS-SAR_2 is confirmed as 70cm (Azimuth resolution 70cm while range resolution 70cm).

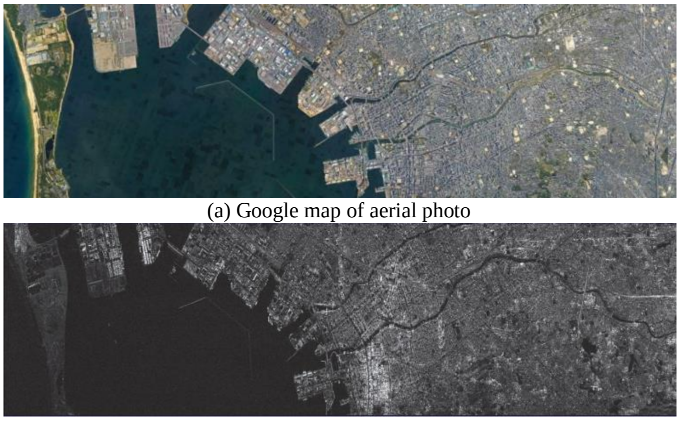
Fig. 1. Examples of the acquired QPS-SAR_2 imagery data.

From the QPS-SAR_2 image, edge responses are reduced. Then, differentiations of the responses are calculated. After that, frequency component analysis is made for the differentiations result in spatial resolution.

B. Geometric Fidelity

This significantly high spatial resolution is one of specific features of QPS-SAR_2. Therefore, geometric performance has to be evaluated. By comparing QPS-SAR_2 images to geographic maps, geometric fidelity can be evaluated. Google map of aerial photos derived GCPs can be a good reference of the geometric performance evaluation, pixel size, pixel-to pixel distances.

Fig. 2 shows Google map of aerial photo of Fukuoka, Japan (33°36’47.13”N, 130°24’36.08”) and QPS-SAR_2 image which is acquired at 21:23 on 23 February 2021. Since Google map was created using advanced surveying techniques including aerial surveying, it was considered to have high geometric fidelity, and the instrumental fidelity of QPS-SAR_2 was measured with reference to this.



(a) Google map of aerial photo

(b) QPS-SAR_2

Fig. 2. Comparison of aerial photo and QPS-SAR_2 image.

The following two GCPs are selected for evaluation of pixel-to-pixel distance performance,

GCP1: 33°36’33.03”N, 130°23’24.88”E, Alt=4m

GCP2: 33°36’13.36”N, 130°22’50.28”E, Alt=1m

Yellow colored points (two end points of pixels are colored in yellow) are indicated the locations of GCPs in Fig. 3. Fig. 3 shows superimposed image between QPS-SAR_2 image and Google map. As the result, it is found that the distance between two GCPs is 5.41 km ± 2m. Therefore, it is concluded that geometric fidelity of QPS-SAR_2 is around 2m.

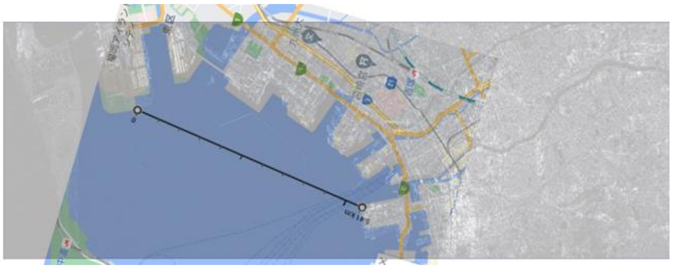


Fig. 3. Locations of GCPs and the distance between two GCPs (Fukuoka).

Same experiment is conducted with the following GCPs for Tokyo scene (Tokyo dome area) of QPS-SAR_2 image,

GCP3：35° 42’ 08.40” N, 139° 45’ 18.27” E 6m

GCP4：35° 04’ 29.71” N, 139° 44’ 12.59” E 2.6m

As shown in Fig. 4, white colored line shows the distance between two GCPs and indicates 2.11 km± 2m. Therefore, geometric fidelity of QPS-SAR_2 is around 2m.

On the other hand, an attempt is made for estimation of off-nadir angle and SAR radio wave irradiation direction with Google Earth which can change azimuth and elevation of look angle. Fig. 5 shows the resultant image of superposed Tokyo Dome image of QPS-SAR_2 image on Google Earth derived aerial photo. Because the Tokyo Dome area is almost flat so that there is no shadowing, layover, and foreshortening. Therefore, the two images are almost perfectly matched. Thus, it is found that estimation of off-nadir angle and radio wave irradiation direction can be done with Google Earth. Geometric fidelity is defined as pixel geolocation knowledge which can be determined by the geometric parameters of off-nadir angle of SAR antenna, satellite nadir location (satellite position determination accuracy), Earth curvature at the footprint of SAR antenna pattern. Using image rotation (azimuth and elevation angles) and translation functions of Google Earth, QPS-SAR_2 image and Google Earth image can be matched. This implies that the rotation angle and translation pixels are almost same as the predicted value from the pixel geolocation knowledge, which is determined by satellite position knowledge, off-nadir angle, compliant Earth spheroidal model of WGS84[3].

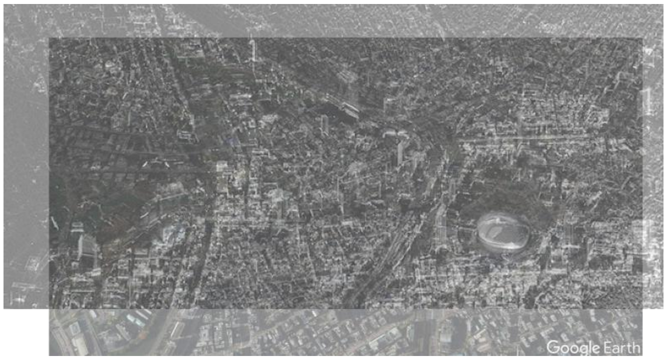

Fig. 5. Resultant image of superposed Tokyo Dome image of QPS-SAR_2 image on Google Earth derived aerial photo.

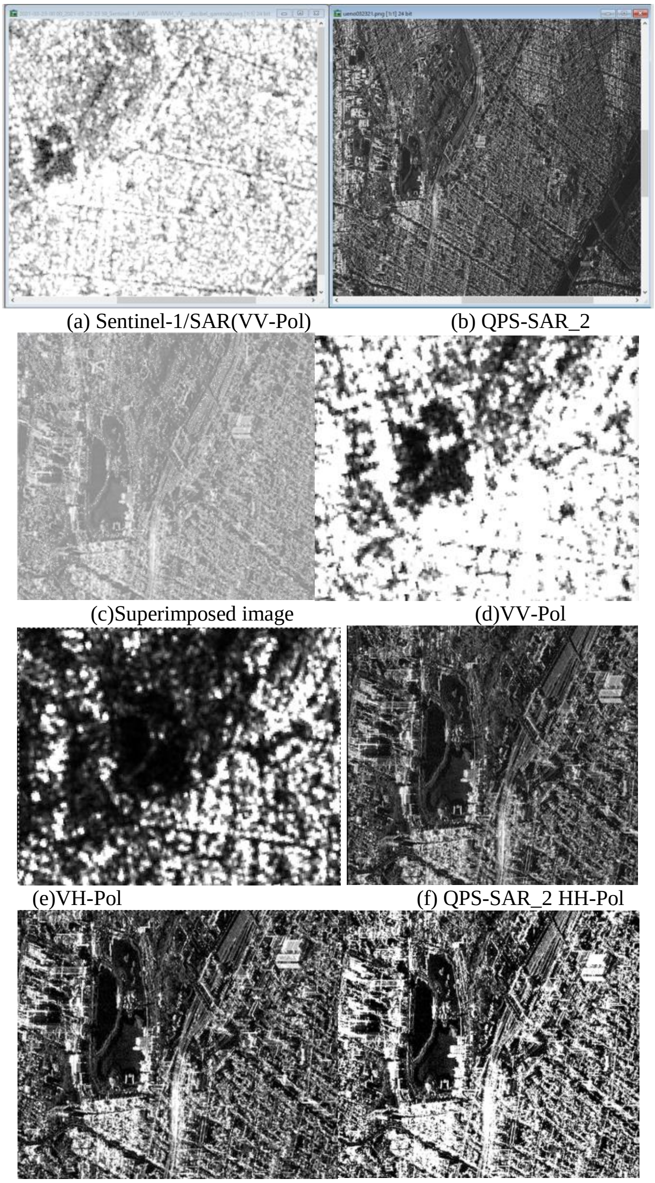
C. Saturated Pixel Ratio

On 23 March 2021 (Friday) of the QPS-SAR_2 data acquisition, the Sentinel-1 of SAR data is acquired Tokyo scene. Therefore, cross comparison between both images can be done. Fig. 6 shows the Tokyo scene of QPS-SAR_2 (a) and Sentinel-1/SAR images (b) and the superimposed QPS-SAR_2 image onto Sentinel-1/SAR image (c). On the other hand, Fig. 6 (d) to 6(h) show Sentinel-1/SAR VV polarization, VH polarization, QPS-SAR_2 HH polarization, simulated VH polarization and VV polarization. Although QPS-SAR_2 is essentially HH polarization, through the regression analysis[4], it was found that the VH and the VV polarization of QPS-SAR_2 can be derived from the following equations,

$$\text{VH-Pol} = 1.478\ \text{HH-Pol} + 15.24 \quad (1)$$

$$\text{VV-Pol} = 2.49\ \text{HH-Pol} + 21.32 \quad (2)$$

As shown in Fig. 6, the most visual difference between both is saturated pixels.



(a) Sentinel-1/SAR(VV-Pol) (b) QPS-SAR_2

(c)Superimposed image (d)VV-Pol

(e)VH-Pol (f) QPS-SAR_2 HH-Pol

(g) QPS-SAR_2 VH-Pol (h) QPS-SAR_2 VV-Pol

Fig. 6. Tokyo scene of QPS-SAR_2 and Sentinel-1/SAR images.

[3] The World Geodetic System 1984 (WGS 84) is a 3-dimensional coordinate reference frame for establishing latitude, longitude and heights for navigation,

[4] https://jp.mathworks.com/discovery/linear-regression.html

Saturated pixel ratios of the two different SAR imagery data are evaluated. As shown in Fig. 7, the saturated pixel ratio of Sentinel-1/SAR is 233.07/255=91.4 (%) while that of QPS-SAR_2 is 81.78/255=32.07 (%). Therefore, this QPS-SAR_2 image is much informative than that of Sentinel-1/SAR image in terms of non-saturated pixels. Since Sentinel-1/SAR has VV and VH polarizations, the saturation rate at VV becomes high. If the VV saturation rate is lowered and the dynamic range setting is matched to VV, the dynamic range of VH will be narrowed.

D. Frequency Component Analysis

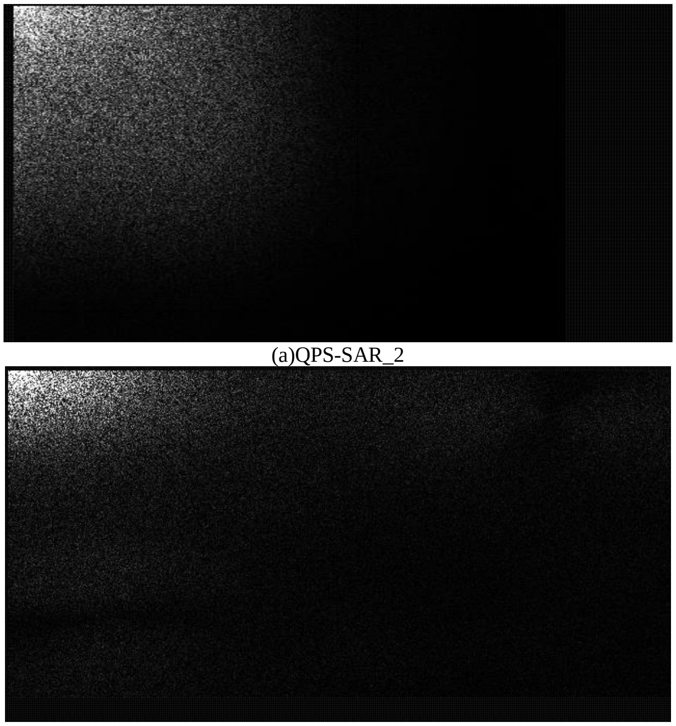
Fig. 8 shows frequency components of QPS-SAR_2 and Sentinel-1/SAR imagery data of Tokyo Dome scene. As shown in Fig. 8, it is clear that the QPS-SAR_2 image shows much wider frequency components in comparison to that of the Sentinel-1/SAR image. The top left corner of the Fig. 8 shows zero frequency component, and the horizontal/vertical axis shows horizontal and vertical frequency components, respectively.

From the results of the aforementioned two experiments, following is found:

1) Sentinel-1/SAR concentrates on frequency components that are about 10 times lower than QPS-SAR_2.

2) It is reasonable because the spatial resolution of QPS-SAR_2 is 10 times smaller than that of Sentinel-1/SAR.

3) Saturation rate (average pixel value / 255): Sentinel-1/SAR VV-Pol is about 38.69 times higher than QPS-SAR_2 HH-Pol (Sentinel-1/SAR VV-Pol has many saturated pixels).



(a)QPS-SAR_2

(b)Sentinel-1/SAR

Fig. 8. Frequency component comparison between QPS-SAR_2 and Sentinel-1/SAR.

E. Singal to Noise Ratio

Signal to noise ratio (S/N) depends on the intensity level, backscattering cross section.

Therefore, S/N is evaluated at low, middle and high levels of Fukuoka scene of QPS-SAR_2 image. As shown in Fig. 9, it is found that the low level of S/N=44.18/3.25=13.59, the middle level of S/N=55.52/6.72=8.26, and the high level of S/N=148.33/38.91=3.18. Noise component is mainly caused by speckle noise of which the footprint composed with multiple targets (Due to radio wave interference from multiple targets). In comparison among the low, the middle and the high levels of QPS-SAR_2 image, the number of pixels which composed with multiple targets for the low levels of image is small and that for the middle level of image is middle in between small and large as well as that for the high level is large.

F. *Speckle Noise Reduction*

When observing a distributed target, speckle noise is generated by the fading phenomenon caused by the random presence of a large number of scatterers in the resolution cell, so this detection and reduction is necessary. The important thing of the speckle noise reduction is filter kernel size and filter function. In this paper, comparisons are made between 3 by 3 and 5 by 5 of kernel sizes for median filter, as well as between circle and Gauss filter functions. The circle and the Gauss filters are well known and widely used typical kernel spatial filter functions without edge preservation. On the other hand, the median filter with the kernel size of 3 and 5 are edge preserving filter. Frequency component is degraded depending on the kernel size and the kernel functions. Fig. 10 shows the resultant images of the comparisons. As the result, it is found that the best filter kernel size is 3 by 3 and the filter function of Gauss is much better than the circle filter function through visual comparison. From the point of view of spatial frequency component preservation, the median filter with 3 by 3 filter kernel shows the best performance, obviously.

(c) Circle function (d) Gauss filter function

Fig. 10. Comparisons between 3 by 3 and 5 by 5 of kernel sizes for median filter, as well as between circle and Gauss filter functions.

V. Discussion

Although SAR image quality evaluation methods such as spatial resolution, signal to noise ratio, modulation transfer function, pixel geolocation accuracy (geometric fidelity), etc. are confirmed through the experiments, speckle noise reduction is not good enough. Multiple or single target in the footprint is the issue of the speckle noise reduction. Therefore, further thoughts considering the causes of the speckle noise are required for improvement of noise reduction performance.

VI. Conclusion

Method for image quality evaluation of satellite-based SAR data is proposed. Not only geometric fidelity but also S/N, Frequency component, saturated pixel ratio, speckle noise, optimum filter kernel size and its filter function are evaluated. Through experiments with Q-shu Pioneers of Space: QPS-SAR_2 imagery data, all these items are evaluated, and it is confirmed that the geometric and radiometric performances are good enough. Also, geometric fidelity of QPS-SAR_2 is compared to Sentinel-1/SAR of ESA provided data which is obtained on the same day of QPS-SAR_2 data acquisition.

In more detail, the S/N of QPS-SAR_2 was found to be 3.18 to 13.59 for the Fukuoka image and 1.96 to 5.10 for the Tokyo image. Also, it was found that the wind size suitable for speckle noise removal is 3x3, and Gauss is suitable for the filter function. Furthermore, Sentinel-1/SAR concentrates on frequency components that are about 10 times lower than QPS-SAR_2. Moreover, spatial resolution is about 10 times lower for Sentinel-1/SAR than for QPS-SAR_2. Meanwhile, saturation rate (average pixel value / 255): Sentinel-1/SAR is about 38.69 times higher than QPS-SAR_2 so that Sentinel-1/SAR may have more saturated pixels than QPS-SAR_2.

Future Research Works

In the future, we will evaluate layover, shadowing, fore shortening, and signal to ambiguity ratio, main lobe / first side lobe ratio, spatial resolution, radiometric resolution, etc. using QPS-SAR_2 images which observe corner reflectors and with ground test data.

Acknowledgment

The authors would like to thank Professor Dr. Hiroshi Okumura and Professor Dr. Osamu Fukuda for their technical discussions.

Kohei Arai, He received BS, MS and PhD degrees in 1972, 1974 and 1982, respectively. He was with The Institute for Industrial Science and Technology of the University of Tokyo from April 1974 to December 1978 also was with National Space Development Agency of Japan from January 1979 to March 1990. During from 1985 to 1987, he was with Canada Centre for Remote Sensing as a Post-Doctoral Fellow of National Science and Engineering Research Council of Canada. He moved to Saga University as a Professor in Department of Information Science in April 1990. He is now an Emeritus Professor of Saga University since 2014. He was a council member for the Aeronautics and Space related to the Technology Committee of the Ministry of Science and Technology during from 1998 to 2000. He was a councilor of Saga University for 2002 and 2003. He also was an executive councilor for the Remote Sensing Society of Japan for 2003 to 2005. He is a Science Council of Japan Special Member since 2012. He is an Adjunct Professor of University of Arizona, USA since 1998 and is an Adjunct Professor of Nishi-Kyushu University as well as Kurume Institute of Technology/AI Application Laboratory since 2021. He was Vice Chairman of the Science Commission "A" of ICSU/COSPAR since 2008. He is now award committee member of ICSU/COSPAR. He wrote 78 books and published 695 journal papers as well as 560 conference papers. He received 77 of awards including ICSU/COSPAR Vikram Sarabhai Medal in 2016, and Science award of Ministry of Mister of Education of Japan in 2015. He is now Editor-in-Chief of IJACSA and IJISA. http://teagis.ip.is.saga-u.ac.jp/index.html

A Multi-label Filter Feature Selection Method Based on Approximate Pareto Dominance

Jian Zhou*, Yinnong Guo
School of Management Engineering, Qingdao University of Technology, Qingdao, China

***Abstract*—The Pareto dominance has been applied to resolve the issue of choosing significant features from a multi-label dataset. High-dimensional labels will directly result in the difficulty of forming Pareto dominance. This work proposes a multi-label feature selection approach based on the approximate Pareto dominance (MAPD) to address this issue. It maps the multi-label feature selection to the problem of solving the approximate Pareto dominant solution set. By introducing an approximate parameter, it is possible to efficiently cut down on the amount of features in the chosen feature subset while also raising its quality. To verify the performance of MAPD, this research compares the MAPD algorithm with alternative approaches in terms of Hamming loss, accuracy, and chosen feature size using nine publicly available multi-label datasets. The findings indicate that the MAPD method performs better in terms of classification accuracy, Hamming loss, and the amount of features that may be chosen.**

Keywords—Approximate Pareto dominance; multi-label data; feature selection

I. Introduction

Feature selection is a process of removing noisy information and selecting the most significant feature subset, which is commonly considered as a pre-process of building a classifier machine learning model [1]-[3]. The multi-label feature selection problem is more universal in application than the single-label feature selection problem [4], [5]. For example, it might be necessary to simultaneously judge the geographical location, weather conditions, and image content of a figure in the process of image recognition [6], [7]. When processing the text categorization, we may need to judge whether the text belongs to multiple bibliographic categories [8], [9]. It also might be necessary to judge whether a protein has multiple different functions in the field of bioinformatics in the same manner [10].

The multi-label feature selection methods could be classified as the filter methods [11]-[13], the wrapper methods [14], [15], and the embedded methods [16], [17]. Since the increase of label dimension would lead to higher time complexity of the feature selection processing, this paper only focuses on the filter feature selection methods that are more efficient compared with the wrapper and embedded methods.

In the current literature, the multi-label feature selection problem can be resolved primarily in two ways. The first strategy is to convert the multi-label data into single-label data and then choose feature subsets using single-label feature selection techniques [18], [19]. However, such methods create an abundance of labels with only a limited number of observations which is not beneficial for establishing a classifier model. In order to improve the disadvantages of such methods, a method called pruned problem transformation (PPT) is proposed, and it ignores the labels with observations lower than the given threshold [20]. This method can ensure that each converted single-label has enough observations to establish a classification model, but this irreversible conversion may lose some label information [21]. The second method involves choosing a feature subset using a specific multi-label feature selection algorithm [22]-[25]. For example, an approximating mutual information (AMI) method is proposed, and it uses the feature selection criterion as maximizing the mutual information between features and labels and minimizing the mutual information among features [26]. A multi-label feature selection strategy based on a scalable criterion for a large label collection (SCLS) is proposed, which can evaluate the conditional correlation between variables more accurately through an extensible correlation evaluation process [27]. Due to the information loss issue of the first way, it is believed that the second way has better performance under several evaluation criteria, such as classification accuracy and Hamming loss [28].

Recently, scholars have applied the concept of Pareto dominance to multi-label feature selection problems. For resolving the multi-label feature selection problem, the Pareto dominance concept is appropriate, since it can transform this problem into a more manageable issue. Specifically, a multi-label feature selection technique based on the Pareto dominance concept (ParFS) is proposed [29]. The ParFS algorithm treats each label as a dimension of Pareto dominance, and thus the issue of multi-label feature selection becomes a Pareto dominance problem. The key point of this algorithm is that the original feature set is viewed as a solution set. Each feature in the original feature set is viewed as a solution, and the evaluation function of the solution is regarded as a feature's and a label's correlation vector. Then the feature selection problem is transformed into how to delete those non-Pareto optimal solutions. In fact, high-dimensional data refers not only to the high-dimensional features of the data, but also to its high-dimensional labels. High-dimensional labels increase the difficulty of using the ParFS algorithm to resolve issues of multi-label feature selection [30], [31]. Specifically, the increase of label dimensions will directly lead to the increase of the dimensions to be considered in Pareto dominance, which results in the difficulty of forming Pareto dominance, causing the Pareto-dominance-based algorithm to fail to finish the multi-label feature selection task. Consequently, it's essential to improve the multi-label feature selection method based on Pareto dominance concept.

In this paper, a multi-label feature selection strategy based on approximate Pareto dominance is proposed (MAPD). Approximate Pareto dominance requires that one solution is superior to the others in most dimensions, but not in all dimensions. Compared with the existing concept of Pareto dominance, the concept of approximate Pareto dominance introduces a new approximate parameter. This parameter can reduce the difficulty of forming approximate Pareto dominance between two solutions under the evaluation function of high-dimensional solutions, and ensure that the scale of approximate Pareto dominance solutions is within an acceptable range. The three main contributions are as follows:

1) A new concept called approximate Pareto dominance is proposed. By introducing an approximate parameter, it can solve the problem when Pareto dominance is difficult to form in the case that the evaluation function dimension of the solution is high.

2) Approximate Pareto dominance is applied in the multi-label feature selection, and the multi-label feature selection issue is mapped to the challenge of determining the approximate Pareto dominance solution set.

3) Based on the approximate Pareto dominance, MAPD is built for the high-dimensional multi-label feature selection problem, and it is proved to be competitive compared with the existing methods.

The remainder of the paper is organized as follows: Preliminaries of this work are presented in Section II. The proposed approximate Pareto dominance concept and multi-label feature selection method is discussed in Section III. Experimental studies and discussion are presented in Section IV, and the paper is concluded in Section V.

II. Preliminaries

A. Problem Description

Given a dataset, $\boldsymbol{X}=[\boldsymbol{X}_1,...,\boldsymbol{X}_m]$ denotes the feature observation space, and its corresponding *l*-dimension label space is $\boldsymbol{Y}=[\boldsymbol{Y}_1,...,\boldsymbol{Y}_l]$, where $\boldsymbol{X}_j=[x_{1j},\cdots,x_{ij},\cdots,x_{nj}]^T$ is the *j*th feature in $\boldsymbol{X}$, x_{ij} denotes the *i*th observation of the *j*th feature, $\boldsymbol{Y}_t=[y_{1t},\cdots,y_{it},\cdots,y_{nt}]^T$ is the *t*th label in $\boldsymbol{Y}$, y_{it} is the *i*th observation of the *t*th label, $y_{it}=\{0\}\ or\ \{1\}$, $i=1,2,...,n$, $j=1,2,...,m$, and $t=1,2,...,l$. To create the classification machine learning model, the multi-label feature selection in this study aims to identify the best feature subset from all feasible subsets.

B. Symmetrical Uncertainty

Symmetrical Uncertainty which abbreviated to SU is a measure of the degree to which two variables are related [32]. In essence, SU measures the information that the two variables exchange and is a standardized representation of the mutual information. In other words, SU quantifies how much one variable's uncertainty is reduced when the other variable is known, and the higher the degree of SU, the more knowledge the two variables have in common. The formula for calculating SU is given below [33].

$$SU(\boldsymbol{U},\boldsymbol{V})=2\frac{H(\boldsymbol{U})-H(\boldsymbol{U}|\boldsymbol{V})}{H(\boldsymbol{U})+H(\boldsymbol{V})}, \quad (1)$$

$$H(\boldsymbol{U})=-\sum_{i=1}^{n}p(u_i)\log_2(p(u_i)), \quad (2)$$

$$H(\boldsymbol{U}|\boldsymbol{V})=-\sum_{j=1}^{n}p(v_j)\sum_{i=1}^{n}p(u_i|v_j)\log_2(p(u_i|v_j)), (3)$$

In the above equation, $\boldsymbol{U}$ and $\boldsymbol{V}$ denote two variables with n observations. $H(\boldsymbol{U})$ and $H(\boldsymbol{V})$ are respectively the entropy of $\boldsymbol{U}$ and the entropy of $\boldsymbol{V}$. $H(\boldsymbol{U}|\boldsymbol{V})$ is the conditional entropy of $\boldsymbol{U}$ under $\boldsymbol{V}$.

C. Pareto Dominance

The following definition of Pareto dominance is used to compare the results of two solutions to a particular problem.

Definition 1 (Pareto Dominance [34]): If $s_1(s_{11},s_{12},...,s_{1n})$ and $s_2(s_{21},s_{22},...,s_{2n})$ are two solutions of a given problem, and $g(s_i)=(g_1(s_i),g_2(s_i),...,g_m(s_i)), i\in\{1,2\}$ is the evaluation function of m dimensions of the given problem,

1) we define that the solution $s_2(s_{21},s_{22},...,s_{2n})$ is Pareto dominated to the solution $s_1(s_{11},s_{12},...,s_{1n})$ if and only if $g_j(s_1)>g_j(s_2), j\in\{1,2,...,m\}$ is satisfied;

2) we define that the solution $s_2(s_{21},s_{22},...,s_{2n})$ is weakly Pareto dominated to the solution $s_1(s_{11},s_{12},...,s_{1n})$ if and only if $g_j(s_1)\geq g_j(s_2), j\in\{1,2,...,m\}$ is satisfied;

3) we define that the solution $s_1(s_{11},s_{12},...,s_{1n})$ and solution $s_2(s_{21},s_{22},...,s_{2n})$ have no differences under the Pareto dominance if and only if $g_j(s_1)>g_j(s_2)$ and $g_k(s_1)<g_k(s_2),\ j\neq k\in\{1,2,...,m\}$ are satisfied.

It can be inferred that the conditions required for Pareto dominance are relatively strict, which requires that one solution is superior to another solution in each dimension of the evaluation function. Considering the increased evaluation function dimensions of the solution, we assume that all the evaluation function dimensions of the solutions are independent with each other, and the difficulty of forming Pareto dominance will increase exponentially. Therefore, for the high-dimensional evaluation function of the solutions, one solution is hard to be Pareto dominated to another solution.

We concentrate on the Pareto dominance relationships between one solution and other solutions when there are more than two possible solutions to the problem. The set of Pareto optimal solutions is defined as follows.

Definition 2 (Pareto Optimal Solutions Set [34]): If $S=\{s_1,s_2,...,s_n\}$ is a solutions set of a specific problem and $s_l\in S$ is not Pareto dominated to any other solutions in S, then we propose that $s_l\in S$ is a Pareto optimal solution. All the Pareto optimal solutions in S is called as the set of Pareto optimal solutions.

According to Definition 2, we suggest that the set of Pareto-optimal solutions can partially substitute for the set of original solutions as the remaining solutions are all inferior to a certain solution in the Pareto optimal solutions set.

III. Approximate Pareto Dominance and Multi-Label Feature Selection

A. Multi-label Feature Selection Based on Pareto Dominance

Given a multi-label dataset with *m* features, *l* labels and *n* observations, the original features are denoted as a set of solutions of the feature selection problem, and each feature in the original feature set is denoted as a solution of the feature selection problem. The *l*-dimensional evaluation function of the solution is defined as the symmetric uncertainty between the feature and its *l* labels. In this way, choosing a feature subset from the original feature set is analogous to choosing the Pareto optimal solutions set from the initial solution set.

As mentioned in Definition 1, Pareto dominance strictly requires that one solution is superior to another solution in each dimension of the evaluation function of the solution. In particular, with the increased dimensions of the evaluation function of a solution, it is challenging to come up with a solution that is superior to another solution in all the dimensions of the evaluation function. As such, most solutions in the solution set become Pareto optimal solutions. In this case, most features in the original feature set are preserved in the feature selection process. Pareto dominance might cause the inefficiencies of the feature selection process because useless features cannot be removed. Therefore, to cope with the multi-label feature selection issue, this study proposes the approximate Pareto dominance based on the Pareto dominance to avoid the above circumstance.

B. Approximate Pareto Dominance

Based on Pareto Dominance, this study proposes approximate Pareto dominance and the set of approximate Pareto optimal solutions.

Definition 3 (Approximate Pareto Dominance): If $s_1(s_{11}, s_{12}, ..., s_{1n})$ and $s_2(s_{21}, s_{22}, ..., s_{2n})$ are two solutions of a problem, and $g(s_i) = (g_1(s_i), g_2(s_i), ..., g_m(s_i)), i \in \{1, 2\}$ is the evaluation function of m dimensions of the given problem,

1) we define solution $s_2(s_{21}, s_{22}, ..., s_{2n})$ is approximate Pareto dominated to solution $s_1(s_{11}, s_{12}, ..., s_{1n})$ if and only if $\sum_{j=1}^{m} \delta(g_j(s_1) > g_j(s_2)) > \alpha m$ is satisfied;

2) we define solution $s_2(s_{21}, s_{22}, ..., s_{2n})$ is weakly approximate Pareto dominated to solution $s_1(s_{11}, s_{12}, ..., s_{1n})$ if and only if $\sum_{j=1}^{m} \delta(g_j(s_1) > g_j(s_2)) \geq \alpha m$ is satisfied;

3) we define solution $s_1(s_{11}, s_{12}, ..., s_{1n})$ and solution $s_2(s_{21}, s_{22}, ..., s_{2n})$ have no differences under approximate Pareto dominance if and only if $\sum_{j=1}^{m} \delta(g_j(s_1) > g_j(s_2)) < \alpha m$ and $\sum_{j=1}^{m} \delta(g_j(s_2) > g_j(s_1)) < \alpha m$, $j \neq k \in \{1, 2, ..., m\}$ are satisfied.

Note that $\delta(x)$ is a conditional discriminant function and $0.5 < \alpha < 1$ is the approximate parameter. When condition x is satisfied, $\delta(x) = 1$; otherwise $\delta(x) = 0$.

Definition 4 (Approximate Pareto Optimal Solutions Set): If $S = \{s_1, s_2, ..., s_n\}$ is a set of solution of a given problem and $s_l \in S$ is not approximate Pareto dominated to any other solutions in S, then we define that $s_l \in S$ is an approximate Pareto optimal solution of the given problem. All the approximate Pareto optimal solutions in S are called the approximate Pareto optimal solutions set.

Compared with Pareto dominance, the approximate Pareto dominance introduces an approximate parameter. The higher the value of the approximate parameter is, the more dimensions of one solution are required to be superior to another solution in all the evaluation function dimensions, and the closer the approximate Pareto dominance is similar to the Pareto dominance. The upper bound of the approximate parameter is 1. When the approximate parameter approaches to the upper bound, the approximate Pareto dominance is equal to Pareto dominance. The lower bound of the approximate parameter is 0.5, which means that when one solution is approximate Pareto dominated to another solution, it is dominant in more than half of the dimensions. This approximate parameter can avoid the situation that two solutions are mutually dominant.

C. Multi-Label Feature Selection Algorithm

We build a multi-label feature selection algorithm (MAPD) based on approximate Pareto dominance for feature selection with high-dimensional labels, which is shown in the following Algorithm 1, where the SU_{ij} is the symmetrical uncertainty of the *i*th feature and the *j*th feature; the set *S* is the selected feature subset; $\delta(\cdot)$ is the conditional discriminant function; s_j is the *j*th solution in the original solution set (namely the *j*th feature); $g_p(s_j)$ is the *p*th dimension of the evaluation function of the *j*th solution; α is the approximate parameter. Approximate parameter α can keep the number of approximate Pareto dominance solutions in an acceptable range.

Algorithm 1 contains three important steps: (1) calculating the symmetrical uncertainty between one feature and one label (see lines 1-5 of Algorithm 1); (2) initializing the selected feature set as an empty set, treating each feature as a solution and the symmetric uncertainty between the feature and each label as one dimension in the evaluation function. We detect the approximate Pareto dominant relationship between each two features. If one feature is the approximate Pareto dominant solution of the original solution set, the feature is merged into the selected feature set until all features are checked (see lines 6-17 of Algorithm 1). (3) Output the selected feature set (see line 18 of Algorithm 1).

Algorithm 1 MAPD

Input: The approximate parameter α, the dataset ***X*** with *m* features, *l* labels and *n* observations;
Output: The finally chosen feature subset *S*.

```
for $i = 1 : l$
    for $j = 1 : m$
        $SU_{ij} = SU(\boldsymbol{X}_i, \boldsymbol{X}_j)$
    end
end
$S = \varnothing$
for $i = 1 : m$
    $k = 0$
    for $j = 1 : m$
        if $j \neq i \cap \sum_{p=1}^{l} \delta(g_p(s_j) > g_p(s_i)) > \alpha l$
            $k = k + 1$
        end
    end
    if $k = 0$
        $S = S \cup i$
    end
end
Output $S$
```

IV. Experimental Studies and Discussion

A. Parameter Setting

To evaluate the effectiveness of the suggested MAPD technique, we employ nine publicly available multi-label datasets (http://mulan.sourceforge.net/datasets-mlc.html). The datasets have been used in many studies, e.g., [35]-[37].

Given a dataset with *m* features, *l* labels and *n* observations, $\boldsymbol{y}_i = (y_{i1}, y_{i2}, ..., y_{il})$ is the real label of the *i*th observation, $\boldsymbol{y}'_i = (y'_{i1}, y'_{i2}, ..., y'_{il})$ is the predicted label of the *i*th observation based on the classification model. To assess how well multi-label feature selection approaches work in terms of precision, we use two criteria of Hamming loss and accuracy, which can be calculated as follows [38], [39]:

$$Hamming\ loss = \frac{1}{n}\sum_{i=1}^{n}\frac{\sum_{j=1}^{m}\delta(y_{ij} \neq y'_{ij})}{l} \tag{4}$$

$$Accuracy = \frac{1}{n}\sum_{i=1}^{n}\frac{\delta(\sum_{j=1}^{m}\delta(y_{ij} = y'_{ij}) = m)}{l} \tag{5}$$

According to Equation (4), Hamming loss analyzes each dimension of an observation's real label and prediction label and focuses on the prediction accuracy of a certain dimension. Then Hamming loss calculates the average error prediction rate of all observations in all dimensions. According to Equation (5), accuracy strictly requires that the real label and the prediction label should be exactly the same, and calculates the accuracy prediction based on all observations.

This study uses the average values of the accuracy and the Hamming loss of 5-fold cross validation of five times as a measure of how well feature selection techniques operate. Specifically, 5-fold cross validation means that the observations are randomly divided into five subsets. For a total of five tests, one of which is chosen as the testing set and the other four as the training set, and the average performance of these five times' tests is taken as the performance of 5-fold cross validation. A higher value of accuracy (or a lower value of Hamming loss) means that the feature selection method is more efficient.

B. Result Analysis

A summary of the nine public multi-label datasets is presented in the following Table I. As shown in Table I, the nine multi-label datasets come from many different fields, such as image, text, and biology, etc. These datasets' label counts range from 6 to 374. There are from 593 to 7395 observations and from 72 to 1836 features are present. We use these multi-label datasets to test the performance of the MAPD method.

TABLE I. CHARACTERISTICS OF THE NINE MULTI-LABEL DATASETS

Name	Abbr.	*n*	*m*	*l*	LCard	LDen	Field
scene	Sce	2407	294	6	1.074	0.179	image
emotions	Emo	593	72	6	1.869	0.311	music
yeast	Yea	2417	103	14	4.237	0.303	biology
birds	Bir	645	260	19	1.014	0.053	audio
genbase	Gen	662	1186	27	1.252	0.046	biology
medical	Med	978	1449	45	1.245	0.028	text
enron	Enr	1702	1001	53	3.378	0.064	text
bibtex	Bib	7395	1836	159	2.402	0.015	text
corel5k	Cor	5000	499	374	3.522	0.009	image

Note: LCard means label cardinality; LDen means label density.

Label density is a standardized way to calculate label cardinality by dividing the total number of labels, where label cardinality is the average number of labels marked for each observation. The following formulas can be used to calculate label cardinality and label density: (Kashef and Nezamabadi-Pour, 2019):

$$LCard = \frac{1}{n}\sum_{i=1}^{n}\sum_{j=1}^{m}\delta(y_{ij} = 1) \tag{6}$$

$$LDen = \frac{1}{n}\sum_{i=1}^{n}\frac{\sum_{j=1}^{m}\delta(y_{ij} = 1)}{l} \tag{7}$$

In the MAPD algorithm, we first analyze approximate the Pareto dominance of different approximate parameter *α*. Considering the range of the approximate parameter is 0.5<*α*<1, we set four groups of tests, i.e., *α*=0.6, *α*=0.7, *α*=0.8, and *α*=0.9. The results of Hamming loss for different approximate parameters are listed in Table II.

As shown in Table II, when the value of the approximate parameter decreases, the average of Hamming loss for the nine datasets decreases. Specifically, successively subtracting two adjacent items in the last row of Table II, we can see that the reduction of Hamming loss is 0.36%, 0.22%, and 0.07% for each 0.1 reduction of the approximate parameter α, respectively. Therefore, the proposed MAPD algorithm has a trend of continuous reduction and convergence in the Hamming loss criterion. Specifically, the average of the Hamming loss is optional when the approximate parameter α=0.6. The optimal Hamming loss is obtained on 7, 5, and 3 of 9 datasets when the approximate parameters are α=0.6, α=0.7, and α=0.8, respectively. The standard deviations of Hamming loss are stable for all approximate parameters.

TABLE II. HAMMING LOSS FOR DIFFERENT APPROXIMATE PARAMETERS

Datasets	***α*=0.6**	***α*=0.7**	***α*=0.8**	***α*=0.9**

Cor	**0.3089** (0.00265)	0.2952 (0.00246)	0.2430 (0.00113)	0.1664 (0.00283)
Mean	**0.7359** (0.00293)	0.7250 (0.00332)	0.6769 (0.00267)	0.6151 (0.00319)

The results of accuracy for different approximate parameters are shown in Table III. When the values of the approximate parameter reduce, the average value of the accuracy for the nine datasets increases. Similar to the calculation in Table II, for each 0.1 reduction of approximate parameters, the accuracy will increase by 6.18%, 4.81%, and 1.09%, respectively. The accuracy criterion of the proposed MAPD algorithm has an increasing and converging trend. Specifically, the mean value of the accuracy is optimal for the approximate parameter *α*=0.6. When the approximate parameters are *α*=0.6, *α*=0.7, and *α*=0.8, 6, 3, and 1 of 9 datasets get the optimal accuracy, respectively. The standard deviations of the accuracy criterion are stable.

Fig. 1 displays the outcome of the number of features chosen for various approximation values. We use the natural based logarithm of the size of the selected features when plotting the histogram. As the number of the selected features calculated by the proposed algorithm is 1 for several datasets (e.g., Gen, Cor and Yea), the scale of the chosen features in the Fig. 1 is zero. As shown in Fig. 1, when approximate parameter decreases, the number of chosen features by the proposed multi-label feature selection algorithm decreases. This finding is consistent with the definition of the proposed approximate Pareto dominance. When the value of the approximate parameter decreases, the number of dimensions that need to be satisfied is reduced for determining if one solution is better than the other or not. This makes it relatively easy to satisfy the concept of approximate Pareto dominance between solutions in the original set of solutions, decreasing the number of approximate Pareto dominated solutions and, in turn, the number of the chosen features of the suggested MAPD technique.

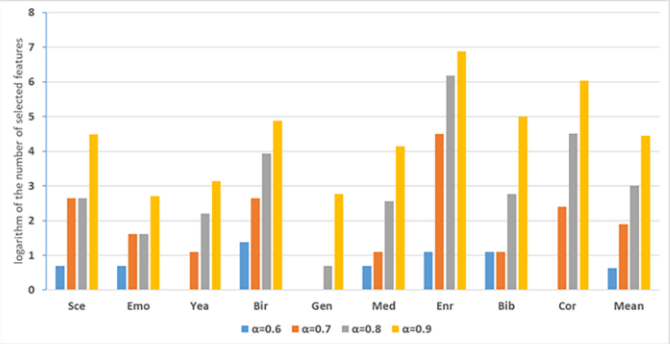

Fig. 1. Influence of different approximate parameters on the scale of the chosen features.

We also compare Hamming loss of the proposed MAPD method with other feature selection methods, i.e., ParFS, SCLS, and AMI. As shown in Table IV, the average value of Hamming loss of the proposed algorithm (MAPD) is optimal (0.0102). Compared with the Hamming loss values of ParFS, SCLS, and AMI algorithms, the Hamming loss of the MAPD method is reduced by 0.68%, 0.56%, and 0.18%, respectively. Specifically, the proposed MAPD algorithm obtains the optimal Hamming loss for the six multi-label datasets (i.e., Sce, Emo, Med, Enr, Bib, and Cor). However, other feature selection methods have a low performance of Hamming loss. Specifically, ParFS algorithm obtains the optimal Hamming loss for Yea dataset; SCLS algorithm obtains the optimal Hamming loss for Gen dataset; AMI algorithm obtains the optimal Hamming loss for Bir dataset. Moreover, for Cor, Bib, Enr and Med datasets with the highest number of labels, the proposed MAPD algorithm obtains the optimal Hamming loss.

Thus, it follows that datasets with high-dimensional labels are more suited for the suggested MAPD method. Compared with ParFS, SCLS, and AMI algorithms, the reduction ranges of Hamming loss of the proposed MAPD method are -0.02% ~ 20.99%, -0.15% ~ 2.36%, and -0.67% ~ 1.42%, respectively. The standard deviation values of the MAPD algorithm are similar to the other algorithms.

TABLE IV. HAMMING LOSS PERFORMANCE OF DIFFERENT METHODS

Datasets	ParFS	SCLS	AMI	MAPD

Bib	0.2006 (0.00195)	0.2216 (0.00127)	0.4077 (0.00321)	**0.6127** (0.00275)
Cor	0.1596 (0.00291)	0.2666 (0.00455)	0.2730 (0.00529)	**0.3089** (0.00265)
Mean	0.6020 (0.00238)	0.6288 (0.00405)	0.6779 (0.00310)	**0.7359** (0.00293)

We compare the accuracy of different multi-label feature selection methods (see Table V). As shown in Table V, the proposed MAPD algorithm obtains the optimal average value of accuracy of nine datasets (0.7359). Compared with ParFS, SCLS, and AMI algorithms, the accuracy value of the proposed MAPD algorithm has increased by 13.39%, 10.71%, and 5.80%, respectively. The proposed MAPD algorithm obtains the optimal accuracy value for six datasets, i.e., Sce, Emo, Med, Enr, Bib, and Cor. ParFS algorithm obtains the optimal accuracy value for Yea dataset; SCLS algorithm obtains the optimal accuracy value for Gen dataset; AMI algorithm obtains the optimal accuracy value for Bir dataset. Moreover, for Cor, Bib, Enr and Med datasets with the highest number of labels, the proposed MAPD algorithm obtains the optimal accuracy value. Compared the ParFS, SCLS, and AMI algorithms, the increase ranges of the MAPD algorithm on the nine datasets are -1.09% ~ 41.21%, -1.37% ~ 39.11%, and -4.71% ~ 25.45%, respectively. In terms of the standard deviation, all algorithms are similar.

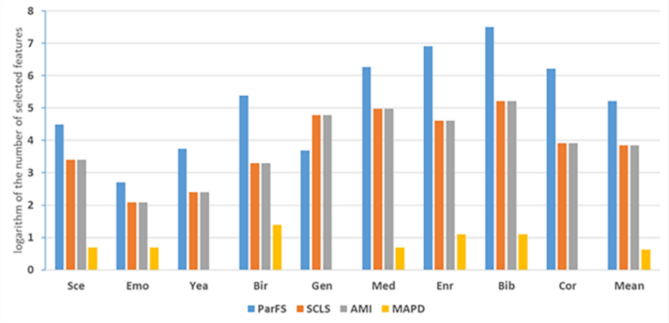

Fig. 2. The number of selected features of different methods.

In Fig. 2, the scale of the chosen features of the MAPD algorithm is much lower than the scale of the chosen features of the other three methods. When the dimensions of the labels increase, the advantage of the MAPD algorithm is strengthened.

V. CONCLUSIONS

For the high-dimensional feature selection problem with multi-label dataset, a concept called approximate Pareto dominance is presented, which can be used to compare the qualities of two solutions. Compared with the traditional Pareto dominance concept, with the help of the approximate parameter, the proposed approximate Pareto dominance can solve the problem that Pareto dominance cannot do well when the evaluation function dimension of the solution is high. Then, using this concept, the feature selection problem with multi-label data is mapped to the problem of finding the set of approximate Pareto dominance solutions. Based on this transformation, we propose a method called MAPD to solve it.

The MAPD algorithm is tested on nine public multi-label datasets from different fields. Experiment results show that the proposed MAPD algorithm has a higher level of classification accuracy, a lower level of Hamming loss and a lower number of the selected features compared with the existing methods. Specifically, compared with ParFS, SCLS and AMI methods, the Hamming loss evaluation index is reduced by 0.68%, 0.56% and 0.18%, respectively. The proposed MAPD method obtains the optimal Hamming loss on six of nine datasets. On the accuracy evaluation index, the proposed MAPD algorithm also obtains the best classification accuracy on six of nine datasets; compared with ParFS, SCLS and AMI methods, the classification accuracy increased by 13.39%, 10.71% and 5.80%, respectively.

Dynamic Allocation Method of Incentive Pool for Financial Management Teaching Innovation Team Based on Data Mining

Huang Jingjing[1], Zhang Xu[2]
School of Financial Management, Hefei University of Economics Hefei 230011, China[1]
Zhengqi Holding Co., Ltd Hefei 230011, China[2]

***Abstract*—In order to reasonably allocate the amount of incentive pool and promote the unity of members of the financial management teaching innovation team, a dynamic allocation method of incentive pool for the financial management teaching innovation team based on data mining is proposed. This method constructs the incentive pool allocation index system by analyzing the principles of risk and income correlation, income and contribution consistency, individual and overall profit consistency, as well as the actual contribution of the financial management teaching innovation team, members' efforts and other factors that affect the allocation of incentive pool. After determining the index weight, the maximum entropy model is used to establish the incentive pool function of the financial management teaching innovation team project. The incentive pool scale decision model is established according to the prospect theory. After outputting the scale of the financial management teaching innovation team's incentive pool using the construction model, the incentive pool model of the financial management teaching innovation team is obtained. Based on the asymmetric Nash negotiation model, the allocation model for the incentive pool model of the financial management teaching innovation team is established, the improved artificial colony algorithm in the data mining algorithm is used to solve the model, and the dynamic allocation result of the incentive pool of the financial management teaching innovation team is obtained. The experiment shows that this method can effectively calculate the size of the incentive pool and allocate the incentive pool. The members of the financial management teaching innovation team have a high degree of satisfaction with the allocation result of the incentive pool, with allocation satisfaction consistently fluctuating around 96%.**

Keywords—Data mining; financial management; teaching innovation team; incentive pool; dynamic allocation; artificial colony

I. Introduction

Financial personnel need to predict risks in advance and conduct effective control in time [1, 2]. The incentive pool is an incentive mechanism that takes part of the project income to motivate team members, retain core members and stimulate members to engage in work actively [3]. In the financial management teaching innovation team, the innovation input, actual contribution, and effort level of all participants change with the actual situation of the project [4]. A single profit distribution scheme is easy to lead to the unfair distribution of surplus target costs [5], which affects the internal harmony of the financial management teaching innovation team, and even leads to team breakdown. Therefore, scientific and reasonable dynamic allocation of incentive pool [6] is an effective means to improve the stability and enthusiasm of the financial management teaching innovation team. Now many scholars are studying the dynamic allocation method of incentive pools.

Study [7] proposed a transaction incentive mechanism for the V2G market, considering dynamic loss aversion. This method considered the incentive margin and liquidated damages when allocating incentives and proposed a minimum incentive strategy. This incentive pool allocation method needs to deduct a certain amount of incentive margin. Therefore, team members have a small number of funds in the incentive pool, which has a poor incentive effect. Research [8] proposed a dynamic incentive mechanism in mobile group intelligence perception. This method allocated the incentive pool based on the contribution degree of team members by evaluating the contribution degree of team members. However, this method is ineffective in evaluating team members' contribution degree, so its allocation effect is not good. Wu Z. et al. proposed an unbalanced fund allocation method, which only distributed the unbalanced funds in the team incentive pool. When the amount in the team incentive pool is large, and the unbalanced funds cannot be divided, it cannot complete the allocation of the incentive pool. In [9] authors proposed the reconstruction method of fund allocation standard based on the extended energy model. This method used the expansion energy synthesis model to calculate the premium value of the incentive pool project funds. It allocated the funds in the incentive pool according to the premium value. However, in the application process of this method, due to the iterative influence of the expansion energy synthesis model, its calculation of the capital premium value of the incentive pool project is not accurate enough, resulting in its poor final application effect. The authors in [10] proposed a matching method for the working capital of the supply chain incentive pool. This method used a dynamic discount decision to allocate the incentive pool capital by calculating the working capital's operating cycle and cycle income. However, this method is affected by the long operating cycle of the capital, resulting in the insufficient balance of the allocation of the incentive pool capital.

In response to the problems in the above research, team members are unable to complete the allocation of incentive pool funds due to the small amount of funds allocated in the incentive pool, which has a poor incentive effect. When the amount of funds in the team incentive pool is large and unbalanced funds cannot be divided, the allocation of incentive pool funds is not balanced enough. This article studies the use of data mining methods to solve the problem. Utilize data mining techniques to analyze data related to team members' contributions, performance, and motivational effects, and establish appropriate models to evaluate the value and potential of team members. This can more accurately determine the amount of incentive funds that each member should receive, in order to improve the effectiveness of incentives. Data mining based methods can help identify imbalances among team members and optimize the allocation of incentive pool funds. By considering factors such as member contributions, performance, and overall team goals, data mining algorithms can be used to optimize fund allocation, making it more balanced and fair. Data mining technology can analyze historical data and make predictions, helping to predict the potential and performance of future team members. Based on these prediction results, the allocation of funds in the incentive pool can be dynamically adjusted to adapt to changes in team members and achieve better incentive effects and balance. Data mining technology can provide personalized incentive strategies based on the characteristics and needs of team members. By mining and analyzing the data of members, incentive plans suitable for their personal characteristics and goals can be designed for each member to improve their participation and job satisfaction.

Data mining [11, 12] refers to the non-trivial process of revealing hidden, previously unknown and potentially valuable information from a large amount of data in the database. Data mining [13] is a decision support process, which is mainly based on artificial intelligence, machine learning, pattern recognition, statistical database, visualization technology, etc., which can make a highly automated analysis of enterprise data, inductive reasoning, mining out potential patterns, and helping decision-makers adjust market strategies, to reduce risks, and make correct decisions. Data mining is a technology to find rules from a large amount of data by analyzing each data. It involves three steps: data preparation, rule finding and rule representation. Data mining tasks include association analysis, cluster analysis [14], classification analysis, anomaly analysis, specific group analysis and evolution analysis. The research purpose of dynamic allocation of incentive pool for financial management teaching innovation teams is to explore an effective incentive mechanism to stimulate teachers' enthusiasm and creativity in financial management teaching innovation. This study aims to establish a mechanism that can dynamically allocate incentive resources based on teachers' contributions and performance, in order to improve teachers' job satisfaction, teaching quality, and teaching innovation level. By dynamically allocating incentive pools, teachers can be given corresponding rewards and incentive measures based on their performance and contribution in financial management teaching innovation. This can motivate teachers to actively participate in teaching innovation activities, improve teaching effectiveness and students' learning experience. Here, based on data mining technology, this paper proposes a dynamic allocation method of incentive pool for financial management teaching innovation teams based on data mining to improve the dynamic allocation effect of incentive pool. The framework and main content of this study are as follows:

1) Clarify the basic principles for constructing incentive pool allocation models.

2) Analyze the factors that affect the allocation of incentive pools, and construct an incentive pool allocation indicator system and determine the indicator weights.

3) On the basis of clarifying the relevant principles, the paper constructs the incentive pool function of financial management teaching innovation team based on the maximum entropy model, and designs the Decision model of incentive pool size based on the prospect theory.

4) Implement the financial management teaching innovation team incentive pool allocation decision based on data mining from three aspects: constructing objective functions, calculating constraint conditions, and constructing models.

5) The effectiveness of the proposed method was verified through experimental analysis.

II. Dynamic Allocation Method of Incentive Pool for Financial Management Teaching Innovation Team

A. *Basic Principles for the Construction of the Incentive Pool Allocation Model*

First of all, the distribution of the incentive pool of financial management teaching innovation team is still the distribution of project profits in essence, which still needs to follow the general principles of the enterprise profit distribution model; secondly, according to the cause of formation of incentive pool and its distribution function, its distribution principle has a particularity. By summarizing the allocation scheme proposed by scholars and the practical experience of foreign financial management teaching innovation team projects, the allocation of incentive pool for financial management teaching innovation team projects should follow the following basic principles:

1) Principles related to risks and benefits: The potential profits and losses of all participants in the financial management teaching innovation team should be related to the real risks they bear [15].

2) The principle of consistency between income and contribution: The actual contribution of the financial management teaching innovation team and the contribution of each participant to the project are positively correlated with the profits obtained.

3) The principle of consistency between individual and overall profits: Whether the participants of the financial management teaching innovation team are profitable should be consistent with whether the project is profitable as a whole. The result of profit distribution can only lead to common profits or common losses, not profits of one party and losses of the other.

4) The principle of limited liability for financial management teaching innovation team participants: The potential losses of the members of the financial management teaching innovation team should be capped at the normal profits of each participant, the company's indirect costs and the share of profits, and the owner should bear the risks in excess.

5) 100% sharing principle: The members of the financial management teaching innovation team have 100% right to share the excess profits of the project. The above principles link the interests of participants with the interests of the project and encourage participants' behaviour to develop in a direction conducive to the project's overall profitability [16]. This paper will select indicators based on the above principles.

B. Analysis of Factors Affecting Incentive Pool Allocation

Based on the analysis of the characteristics of incentive pool allocation, this paper uses the all-factor method to comprehensively evaluate the contribution of the participants of the financial management teaching innovation team to the project surplus target cost from five aspects of the actual contribution, effort, risk and dynamic factors of the financial management teaching innovation team, combined with the design of specific indicators.

1) The actual contribution of the financial management teaching innovation team: The actual contribution of the financial management teaching innovation team is mainly reflected in the role of the internal members in the project profits. Drawing on the four major control objectives of enterprise project management, the financial management teaching innovation team members' completion of the part of the project they are responsible for is measured from the four aspects of quality, progress, safety and profit, reflecting the distribution principle of "distribution according to work" [17].

2) The degree of effort of the financial management teaching innovation team members: The effective cooperation and active innovation of the financial management teaching innovation team are the source of creating excess profits. The distribution system that only pays attention to the results without considering the efforts of the financial management teaching innovation team members is difficult to motivate the members of the financial management teaching innovation team to participate in project management and technical innovation actively. Therefore, this paper evaluates the efforts of enterprises from the perspective of project management and innovative activities.

3) The financial management teaching innovation team bears risks: The principle of "risk sharing and profit sharing" in the enterprise operation mode determines that the profit distribution mode should match the risks borne by the financial management teaching innovation team members. This paper sets three secondary indicators, namely, the degree of awareness, the control cost and the reduction of losses, from the perspective of risk control, to evaluate the contribution of the risk factors borne by the participants to the excess profits.

4) Dynamic factors: Enterprise projects usually have large investments and long cycles. When allocating excess profits, we should consider the spillover effect of the financial management teaching innovation team's investment income and special resource investment on the project.

C. Determination of Incentive Pool Allocation Index System and Index Weight

Based on the analysis of the factors affecting the allocation of the incentive pool in the financial management teaching innovation team, the indicator system and weight are determined. Firstly, 17 second-level indicators are refined according to the four first-level indicators of the financial management teaching innovation team's actual contribution, degree of effort, risk-taking and dynamic factors, and a consultation letter is sent to five scholars for indicator screening opinions; after three rounds, the indicators tend to be consistent, and then a consultation letter on the weight of indicators is issued. Both stages of consultation require respondents to evaluate their own judgment and familiarity and empower experts with the basis of their judgment and familiarity with the financial management teaching innovation team project through the analytic hierarchy process: knowledge of relevant references and cases (1), the experience of similar projects (0.75), theoretical analysis (0.5), personal intuition (0.25); Very familiar (1), familiar (0.75), average (0.5), not familiar (0.25). The calculated credibility of this consultation is 0.81; the Familiarity coefficient is 0.75; The overall authority level is 0.78, and the result is relatively reliable. The final indicator system and indicator weight are shown in Table I.

According to the indicator system in Table I, it can evaluate the contribution of team members to the incentive pool fund during the implementation of the financial management teaching innovation team project. The scores of the members of the financial management teaching innovation team project in the evaluation system in Table I are normalized and recorded as l_{ij} , then the evaluation of the financial management teaching innovation team members' profit contribution is as follows (1):

$$B = \sum_{i=1}^{n} \sum_{j=1}^{n} \xi_i \xi_{ij} l_{ij} \tag{1}$$

In equation (1), B represents the profit contribution evaluation of the members of the financial management teaching innovation team; ξ_i is the weight of the first-level indicator; ξ_{ij} is the weight of the first-level indicator.

TABLE I. PROJECT INCENTIVE POOL INDEX SYSTEM OF FINANCIAL MANAGEMENT TEACHING INNOVATION TEAM

Influencing factor layer	Primary index	Secondary indicators
Actual contribution	Quality contribution (0.1)	Project quality qualification rate (0.4)
		Number of quality accidents (0.6)
	Progress contribution (0.1)	Progress contribution rate (0.5)
		Return and shutdown frequency (0.5)
	Profit contribution (0.2)	Profit contribution rate (0.5)
		Profit loss rate (0.5)
	Safety contribution (0.1)	Accident loss (0.7)
		Accident frequency (0.3)
Effort	Project management (0.15)	Project management plan (0.6)
		Decision cycle (0.4)
	Innovation investment (0.05)	Professional training rate (0.5)
		New technology (0.5)
Risk factor	Risk compensation (0.2)	Cooperation risk (0.3)
		Capability risk (0.3)
		Investment risk (0.4)
Dynamic factors	Input resources (0.1)	Capital investment (0.8)

D. Construction of Project Incentive Pool Model for Financial Management Teaching Innovation Team

The construction of the incentive pool has played a very good role in risk sharing and incentive compensation under the financial management teaching innovation team model. However, the size of the incentive pool, that is, the amount of funds invested in the incentive pool, has become the key issue of subsequent research and the prerequisite for allocating the incentive pool. If the number of incentive pools is too high, it may cause the enterprise to exceed the project's budget range and cannot save costs on the premise of encouraging all participants. If the number is too low, it will weaken the role of the incentive pool, make the setting role of the incentive pool not obvious, and cannot bring power to the financial management teaching innovation team to maximize the project benefits and save costs, and also make the tense relationship between the members of the financial management teaching innovation team. It brings difficulties to the subsequent research on the allocation of incentive pools [18], so how to determine the size of the incentive pool is very important for maximizing project benefits.

The project incentive pool model of the financial management teaching innovation team consists of three parts, namely C1, C2 and C3, as shown in Fig. 1.

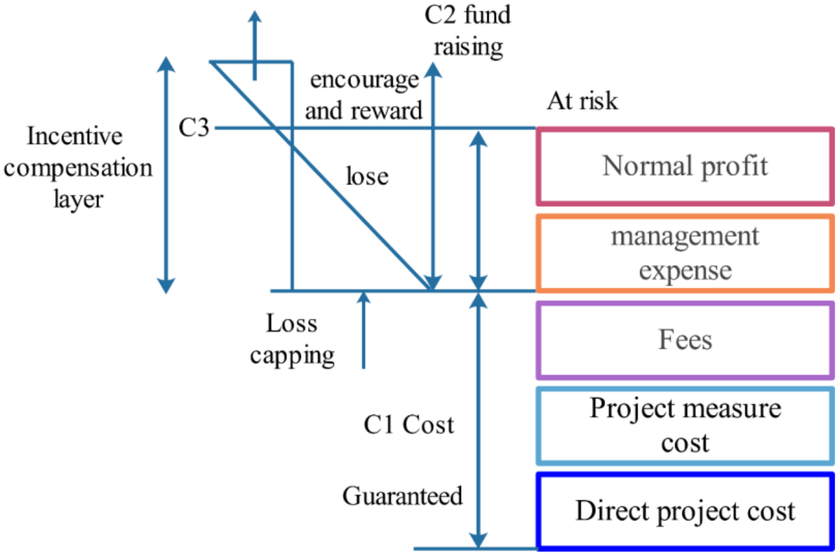

Fig. 1. Project incentive pool model of financial management teaching innovation team.

According to the division of enterprise project costs, the C1 layer is the first part, which is the project cost, including the direct project cost, project measure cost and regulation cost of the project. The cost of this part is guaranteed, and these costs are placed at the first level because the project partner will never let his direct project cost and site management cost bear the risk. The C2 level is the second part, which is the project remuneration, including the project management fee and normal profits. Because this part may suffer losses, if any, it will be borne by all financial management teaching innovation team members, so this part is reflected in the risk sharing. The C3 layer is the third part, that is, the compensation layer for project risk incentives, including the loss value for failing to reach the target and the bonus for exceeding the target. The amount of this part of rewards or punishment mainly depends on the final actual output of the project. If the benefit exceeds the expected target, it will be rewarded, and if it is lower than the expected target, it will be punished. Here we introduce two keywords, target cost (TOC) and actual cost (AOC). TOC represents the project target cost agreed upon by all participants at the initial design stage [19]. AOC refers to the actual total cost after the completion of the project, which is equal to the actual direct project cost plus the project measure cost and regulation fee. There are four cases to analyze the model:

1) If the target cost is equal to the actual cost, the incentive compensation level is equal to the initial incentive value, the project is completed as scheduled, and there is no loss or surplus. The financial management teaching innovation team members can be rewarded as expected.

2) If the target cost is less than the actual cost, but the target cost plus the initial incentive value is greater than the actual cost, the incentive compensation level is equal to the initial incentive value minus (actual cost - target cost), the project loss, cost overrun, and the members of financial management teaching innovation team jointly bear the loss.

3) If the target cost is greater than the actual cost, the incentive compensation level is equal to the target cost minus the final cost and plus the initial incentive value so that the project gains benefits, reduces costs, saves expenses, and members of the financial management teaching innovation team can get corresponding benefits.

4) If the target cost plus initial incentive value is less than the actual cost, there is no incentive compensation; that is, the incentive compensation level is equal to 0.

Based on the above analysis, this paper uses the maximum entropy model and prospect theory to determine the size of the incentive pool.

a) Construction of incentive pool function of financial management teaching innovation team based on maximum entropy model: The maximum entropy theory was put forward by Jaynes in 1957, which is one of the data mining algorithms. The maximum entropy theory is a mining algorithm that, under the premise of a certain number of probability distributions, the maximum probability expression of other location distributions is reached when the entropy value of the whole population is maximum, and the maximum entropy value is obtained to obtain the optimal results. The maximum entropy objective function is shown in equation (2):

$$h(x_i) = -B\int_{x_1}^{x_2} f_x(x)\ln f_x(x)dx \tag{2}$$

In equation (2), x_i represents the i-th state value; $h(x_i)$ is the maximum entropy objective function; $f_x(x)$ is the probability density function of the variable x; x_2 and x_2 represent the upper and lower limits of the maximum differential entropy.

The constraint conditions for setting equation (2) are as follows:

$$h(x_i)\int_{-\infty}^{+\infty} f_x(x)dx = 1 \tag{3}$$

$$\int_{x_1}^{x_2} f_x(x)F_i(x)dx = \varepsilon_i \tag{4}$$

In the above equation, $F_i(x)$ is a distribution function of a random variable x, which represents a prior condition before solving the maximum unknown distribution probability of x; ε_i is a set of constants.

According to the characteristics of the project delivery model of the financial management teaching innovation team, it is assumed that the utility value of the financial management teaching innovation team can be approximated as the sum of the utility values of all members. The random variable x can represent the utility of each member. The function of the size of the incentive pool of the financial management teaching innovation team is $x_n(sca)$, and the proportion of the incentive pool to the utility fluctuates within the range of 0-1. sca is the size of the incentive pool, $n=1,2,\cdots$ is the number of members in the financial management teaching innovation team, $h(x_i)$ is the entropy value of any member of the financial management teaching innovation team to maximize it. $x_n(sca)$ is substituted into the above model, and the size function of the incentive pool model of each member's utility financial management teaching innovation team is taken as a random variable to obtain the relationship function that best conforms to the random probability density distribution. In this paper, several Lagrange multipliers, such as $a_0, a_1, \cdots, a_i$, are introduced to form a new Lagrange function by combining the constraint function and the objective function. The extreme value of the original function is obtained by solving the stationary point. The incentive pool model of financial management teaching innovation team can be expressed as equation (5)

$$G(X)=-\int_0^1 f_{x_n}\left[x_n(sca)\right]\ln f_{x_n}\left[x_n(sca)\right]+h(x_i)\sum_{i=1}^{k}F_i(\varepsilon_i,f_{x_n}\left[x_n(sca)\right])dx\sum_{i=1}^{k}a_i dx \tag{5}$$

In equation (5), $G(X)$ represents the incentive pool model of the financial management teaching innovation team, and $k=1,2,\cdots$ represents the different roles of members in the financial management teaching innovation team project.

To calculate the differential at both ends of the above equation and assign the initial value to 0, the functional relationship between the utility of the financial management teaching innovation team's members and the size of the incentive pool can be obtained as equation (6):

$$x_n(sca)=G(X)\int_0^1 x_n f_{x_n}\left[x_n(sca)\right]dn \tag{6}$$

b) Incentive pool size decision model based on prospect theory: Prospect theory is a psychological concept that studies the criteria for people making decisions from a psychological perspective. This theory believes that the estimation of events with different probabilities is different. After this paper uses the maximum entropy model to obtain the functional relationship between the utility of each participant in the IPD project and the size of the incentive pool, the best scheme of the size of the incentive pool can be solved by applying the prospect theory, introducing the value function and the weight function. Its specific mathematical expression is:

$$U(x,p)=x_n(sca)\sum_{i=1}^{k}w(p_i)\sum_{i=1}^{k}V(\pi_i) \tag{7}$$

$$w(p_i)=\begin{cases} p^r\cdot\dfrac{1}{\left[p^r+(1-p)^r\right]^{\frac{1}{r}}},\text{earn profit} \\ q^\delta\cdot\dfrac{1}{\left[q^\delta+(1-q)^\delta\right]^{\frac{1}{\delta}}},\text{damage} \end{cases} \tag{8}$$

$$V(\pi_i)=\begin{cases} \pi_i^\alpha & \pi_i>0 \\ -\tau(-\pi_i)^\beta & \pi_i<0 \end{cases} \tag{9}$$

In the above equation, $U(x,p)$ represents the overall value of the incentive pool, and $i=1,2,3\cdots$ represents the possible future, $w(p_i)$ represents the weight function of the foreground i; $V(\pi_i)$ represents the value function of the prospect i. α and β represent the risk attitude coefficient of the members of the financial management teaching innovation team, τ represents the loss aversion coefficient of each participant, and r and δ represent the adjustment coefficient of the weight. Assuming there are two prospects u' and u'', under the prospect u', the financial management teaching innovation team successfully completes the project and gains profits. Under prospect u'', the project is incomplete, and all financial management teaching innovation team members lose. Then the decision model of the size of the incentive pool is shown in equation (10):

$$\max U=U(x,p)\sum_{i=1}^{k}\frac{p^r\left[u'_i(sca)\right]\alpha}{\left[p^r+(1-p)^r\right]^{\frac{1}{r}}}+\tau\sum_{i=1}^{k}\frac{q^\delta\left[u''_i(sca)\right]\beta}{\left[q^\delta+(1-q)^\delta\right]^{\frac{1}{\delta}}} \tag{10}$$

In equation (10), $Max\ \ U$ represents the decision model of the size of the incentive pool.

Set the constraint conditions of the decision model for the size of the incentive pool as equation (11):

$$s.t.\begin{cases} \int_0^0 f_{u'}\left[u'(sca)\right]du'=1 \\ \int_0^0 f_{u'}\left[u'(sca)\right]F_i\left[u'(sca)\right]du'=\varepsilon_i(sca) \end{cases} \tag{11}$$

E. Construction of Incentive Pool Allocation Model Based on Asymmetric Nash Negotiation Model

1) Principle of asymmetric Nash negotiation model: The last section mainly introduced the method to determine the size of the incentive pool of the financial management teaching innovation team. After having an incentive pool of appropriate size, the project participants implemented and completed the entire financial management teaching innovation team project according to their scope of rights and responsibilities and achieved the expected results. However, the rational allocation of funds in the incentive pool will enable all parties to have sufficient motivation to work hard to achieve the project objectives without being jealous because of the excessive distribution of other parties [20], which is the main consideration of the members of the financial management teaching innovation team after the completion of the project implementation. This paper then proposes a mathematical model of an incentive pool allocation system based on the asymmetric Nash negotiation model, which is based on the risk preference and risk decision-making weight of the financial management, teaching innovation team members in the project implementation process to solve this problem quantitatively. The Nash negotiation model is a mathematical model for finding a Nash equilibrium solution. This equilibrium solution makes the strategy adopted by each player to other players optimal. The equilibrium solution was put forward and improved by Nash during his PhD study (1950, 1951). Before that, there was only a cooperative game in the simple game theory, and the game hypothesis that all parties in the game participated in cooperation made the game theory not develop rapidly. With Nash putting forward the concept of a non-cooperative game and providing a method to find an equilibrium solution that can satisfy all parties, the non-cooperative game problem that can have more extensive application space has been developed and improved in the long run. In the research process in recent years, with the deepening of the research on Nash negotiation theory, there are two game forms, symmetrical game and asymmetric game [21], and different optimal strategy sets can be obtained according to the Nash negotiation model. The mathematical expression of the asymmetric Nash negotiation model is shown in equation (12):

$$C=\max U\prod_{i\in n}\left[x_i\omega_i-g_i\omega_i\right] \tag{12}$$

In equation (12); $n=1,2,\cdots$ refers to the participants in the negotiation; x_i represents the result of the negotiation, and g_i represents the starting point of the negotiation; ω_i is the weight coefficient of negotiator i.

Set the constraints of the asymmetric Nash negotiation model, as shown in equation (13):

$$s.t.\begin{cases} \\ x_i\geq g_i \\ x_i\in\Omega \\ \sum_{i=1}^{n}\omega_i=1 \end{cases} \tag{13}$$

In equation (13), Ω represents the project negotiation domain.

2) Construction of incentive pool's allocation objective function of financial management teaching innovation team: Based on the above asymmetric Nash negotiation principle, the objective function of incentive pool allocation for financial management teaching innovation teams is established. When the financial management teaching innovation team members participate in the project, each member's position is different, and the role of undertaking the project and the number of resources is different. It should be more suitable for the asymmetric Nash negotiation model [22]. The Nash equilibrium solution obtained with the goal of maximizing each member and taking the project's own conditions as constraints is the most reasonable allocation proportion of the incentive pool of the financial management teaching innovation team. The objective function of incentive pool allocation for the financial management teaching innovation team is shown in equation (14):

$$D=\max C\prod_{k\in n}\left[c_k\omega_k-g_k\omega_k\right] \tag{14}$$

In equation (14), c_k represents the utility value of each member considering risk sharing; g_k refers to the utility value when no agreement is reached, and the difference between the first two items is the increase in the interests of each participant minus the risk cost; ω_k refers to the decision-making weight of the project participants in the risk sharing process.

3) Calculation of constraint conditions of incentive pool allocation objective function

a) Calculation of individual utility and group utility: According to the assumption of individual utility, this paper assumes that the members of the financial management teaching innovation team are in line with the mean-variance expected utility function [23]; that is, their individual utility function can be expressed as equation (15):

$$c_k=E(x_k)-0.5H_k\sigma^2(x_k) \tag{15}$$

In equation (15), $E(x_k)$ represents the utility expectation of each participant, $\sigma(x_k)$ is the utility variance value of each participant, H_k represents the absolute risk aversion coefficient of each participant.

ζ_k represents the distribution proportion of the financial management teaching innovation team members in the incentive pool. The group utility of the members of the financial management teaching innovation team can be expressed as equation (16):

$$\sum_{k=1}^{n}c_k=E(x_X)-(0.5\sum_{k=1}^{n}H_k\zeta_k^2)\sigma^2(x_X) \tag{16}$$

In equation (16), $E(x_X)$ represents the utility expectation of the financial management teaching innovation team; $\sigma(x_X)$ represents the utility variance of the financial management teaching innovation team.

b) Absolute risk aversion coefficient setting: The concept of the risk aversion coefficient [24] was first developed in finance, investment and other fields. When the risk aversion coefficient is greater than 0, it indicates that the evaluated person is risk averse; that is to say, the existence of risk does not affect their decision-making. When the risk aversion coefficient is greater, the evaluated person's risk aversion degree is also higher; when the risk aversion coefficient is 0, the evaluated people are said to be risk-neutral. They do not care about the variance of the utility they can achieve but only about the expected utility they can achieve. Such people are theoretical model people that do not exist in reality; when the risk aversion coefficient is less than 0, the assessed can be defined as risk preference. The smaller the risk aversion coefficient is, the more risk they chase. For the financial management teaching innovation team, the different positions of the members in the project, the different workloads they undertake, and the different levels of development of their enterprises lead to different ways of evaluating their risk aversion. This paper adopts the definition standard of risk aversion coefficient in the US investment and wealth management industry. The value is between 2 and 6; that is, the greater the value of H_k is, the more risk-averse the financial management teaching innovation team is, and the smaller the value of H_k is, the more risk-averse the financial management teaching innovation team is.

4) Incentive pool allocation decision model for financial management teaching innovation team based on data mining: According to the objective function and constraint conditions of the incentive pool allocation of the financial management teaching innovation team, the incentive pool allocation decision model of the financial management teaching innovation team is constructed, as shown in equation (17):

$$T = \max c_k \prod_{k=1}^{n} \left[DE(x_X)\omega_k - 0.5\sum_{k=1}^{n} H_k \zeta_k^2)\sigma\left(x_X\right)\omega_k \right] \tag{17}$$

The constraint conditions for solving the incentive pool allocation decision model of the financial management teaching innovation team are equation (18):

$$s.t. \begin{cases} x_X = \sum_{k=1}^{n} x_k \\ \sum_{k=1}^{n} \zeta_k = 1 \end{cases} \tag{18}$$

According to the constraints of equation (18), the improved artificial swarm algorithm of data mining algorithm is used to solve the incentive pool allocation decision model of the financial management teaching innovation team, that is, the numerical value of ζ_k, as a reasonable incentive pool allocation proportion, which can ensure that the members of financial management teaching innovation team can reach the Nash equilibrium solution when the project is completed.

The artificial bee colony algorithm is a bionic intelligent optimization algorithm that simulates bees searching for honey sources in space. The algorithm has fewer control parameters in the calculation process and good global convergence. The detailed steps of the incentive pool allocation decision model of the financial management teaching innovation team based on the improved artificial bee colony algorithm are as follows:

Step 1: Use equation (17) to get the solution of the incentive pool allocation decision model of all financial management teaching innovation teams, and then import it into the artificial bee colony algorithm.

Step 2: After setting the colony boundary conditions, use the incentive pool allocation decision model of the financial management teaching innovation team a_k to generate the initial colony N_p, then the position value y_{ij} of the i-th solution in the colony in the j-th dimension is as shown in equation (19):

$$y_{ij} = Ty_{j\min} + \psi y_{j\max} - \psi y_{j\min} \tag{19}$$

In equation (19), i represents the bees in N_p, that is, the solution of the incentive pool allocation decision model of the financial management teaching innovation team; $j = 1, 2, \cdots, D$ represents the dimension of the solution, D represents the total dimension, $y_{j\max}$ and $y_{j\min}$ represent the maximum and minimum fitness values of the j-th dimension respectively; ψ is a random constant.

Step 3: After calculating the position value of the solution of the incentive pool allocation decision model of all the financial management teaching innovation teams by using equation (19), sort the solution according to the size of the value, and select the solution of the incentive pool allocation decision model of the financial management teaching innovation teams corresponding to the first $\frac{N_p}{2}$ fitness as the employment bee of the bee colony. Take the hired bee as a discrete random variable and calculate its entropy, as shown in equation (20):

$$R(fit) = -y_{ij} \sum_{i=1}^{n} o_i \ln o_i \tag{20}$$

In equation (20), $R(fit)$ represents the employment bee entropy, o_i represents the probability of occurrence of the state.

According to the result of equation (20), the artificial bee colony is allowed to select the honey source following bee proportion $\dot{\alpha}$ and the optimal honey source selection probability $\dot{\beta}$ within an appropriate range, as shown in equation (21):

$$\begin{cases} \dot{\alpha} = \frac{R(fit)_{\max}}{R(fit)_{\max}} - R \\ \dot{\beta} = 1 - \frac{R(fit)_{\max}}{2R(fit)_{\max}} - R \end{cases} \tag{21}$$

In equation (21), R represents the initial entropy of the colony; fit_i represents the limit value of swarm sway.

Step 4: hire bees to update the honey source location according to equation (21).

Step 5: After the honey source location of the hired bees is updated, calculate the probability of the current status of each hired bee. According to this probability value, the hired bees search for new honey sources in their neighboring areas and greedily choose while recording the solution at this time.

Step 6: Judge whether all the employed bees in the current artificial bee colony have been allocated. If not, terminate the solution process. If yes, proceed to the next step.

Step 7: Set the number of honey source location updates ϖ. When the number of honey source location updates is lower than the time ϖ, a new honey source will be randomly generated.

Step 8: Record the optimal solution generated by the current artificial bee colony algorithm, and set the maximum iterative threshold u of the artificial bee colony algorithm. When the number of iterations reaches the maximum threshold, stop the iteration and output the current optimal solution. Otherwise, continue the iteration.

After the above steps, the artificial bee colony algorithm transmits the optimal solution of the financial management teaching innovation team's incentive pool allocation decision model. It obtains the incentive pool allocation result of the financial management teaching innovation team.

III. Experimental Analysis

Taking the financial management teaching innovation team as the experimental object, the financial management teaching innovation team is composed of 11 teachers who have innovative teaching concepts, are aggressive, are determined to reform, and are good at cooperation. The team members are from Nankai University, Shanghai University of Finance and Economics, Xi'an Jiaotong University, Jilin University, Chinese Academy of Social Sciences and other well-known universities. The professional title structure, educational background structure, age structure and academic background structure of the teaching team are reasonable. It is a high-level, highly educated, old, middle and young teachers' team with an optimized structure. The team has played an effective role in planning, organizing and coordinating the company's project promotion. It has effectively improved the company's project revenue by using the experience and wisdom of team scholars. The teaching hours and incentive amount of the 11 financial management teaching innovation team members participating in the company's projects are shown in Table II.

This article mainly adopts three methods: asymmetric Nash negotiation, data mining, and artificial bee colony algorithm when implementing dynamic allocation of incentive pools for financial management teaching innovation teams based on data mining. To ensure the effectiveness of the experiment, set the parameters of the corresponding algorithm:

- Asymmetric Nash negotiation:

Initial strategy setting: The initial strategy for each team member is [0.2, 0.3, 0.5], indicating the proportion they expect to be allocated to the incentive pool.

Objective function setting: The objective function is to maximize the average incentive value.

Game theory parameter setting: the number of participants is 3, and the strategy space is [0, 1].

- Data mining:

Dataset selection: Use a financial management teaching innovation team dataset that includes data on member contributions and performance.

Feature selection: select the performance indicators of members and participation in teaching innovation activities as the characteristics for analysis.

- Artificial bee colony algorithm:

Bee quantity setting: Set 10 bees to search for incentive pool allocation schemes.

Parameter settings: foraging distance is 2, memory factor is 0.8, and local search range is 0.2.

A. *Generalization Performance Test of Incentive Pool Decision Model*

The subjects' working characteristic curve, also known as the ROC curve, is one indicator describing a model's generalization ability. A model's generalization ability is good, indicating that the model has a strong calculation ability. The generalization ability of the financial management teaching innovation team and historical decision-making model built by the method of this paper is verified in the form of a ROC curve. The test results are shown in Fig. 2.

TABLE II. Teaching Hours and Incentive Amount of Financial Management Teaching Innovation Team Members

Team member code	Teaching hours	Follow up the teaching content of the project	Expected incentive amount/10000 Yuan
1	109	Financial management	4.6
2	128	Enterprise Finance Theory	5
3	156	Cost control	10
4	98	Strategic cost management	8.5
5	69	Financial analysis	5
6	70	Financial decisions	6.5
7	90	Tax administration	9
8	115	Assets and liabilities	6.5
9	137	Profit management	4.5
10	164	Profit and loss assessment	7.8
11	103	Owner's equity	6.2

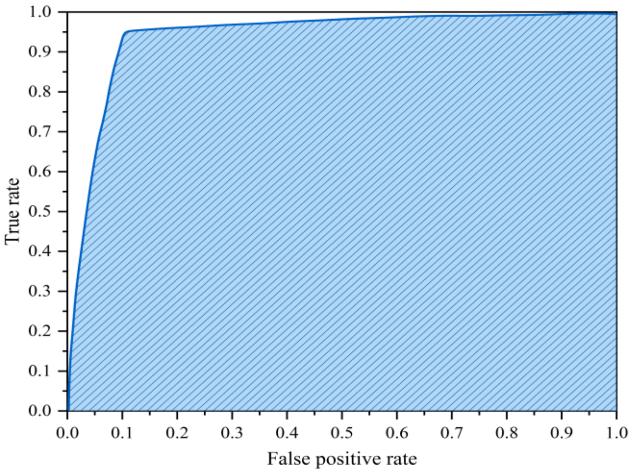

Fig. 2. Financial management teaching innovation team and historical decision-making model generalization ability.

The analysis of Fig. 2 shows that the real rate value of the ROC curve of the model in this paper can reach more than 0.96, and the maximum value of the false positive rate value is only about 0.1. In contrast, the coverage area under the ROC curve is large. The above results show that the model in this paper can effectively adapt to new measured samples in the application process, with strong adaptability, good generalization ability, and more accurate output results.

B. Ability to Build Incentive Pool Allocation Index System

The reliability and validity of the incentive pool allocation indicator system selected are taken as the measurement index to analyze the reliability and validity of the different influencing factors of the incentive pool allocation of the financial management teaching innovation team and verify the ability of the method of this paper to select the incentive pool allocation indicator system of the financial management teaching innovation team. The test results are shown in Fig. 3.

According to the analysis of Fig. 3, the reliability and validity values of different influencing factors of the incentive pool allocation of the financial management teaching innovation team are 0.94, which shows that the incentive pool allocation indicator system of the financial management teaching innovation team constructed by the method in this paper is good. The incentive pool can be reasonably allocated according to this indicator system.

C. Calculation of Incentive Pool Size of Financial Management Teaching Innovation Team

After the financial management teaching innovation team is responsible for the company's project profitability, it generates its incentive pool. It uses the method in this paper to calculate the scale of the incentive pool during the project promotion cycle. The calculation results are shown in Fig. 4.

It can be seen from the analysis of Fig. 4 that with the increase of the project cycle, the incentive pool of the financial management teaching innovation team has gradually increased, but in the process of increasing, the scale of the incentive pool has also decreased, because when the enterprise project is promoted, its internal capital liquidity is strong. There is a situation of a loan of profit funds in the project cycle. However, as the project continues to advance, the scale of the incentive pool of the financial management teaching innovation team continues to increase, which indicates that the project is profitable. The incentive amount that can be allocated to the financial management teaching innovation team members continues to increase. To sum up, the method in this paper can effectively calculate the size of the incentive pool of the financial management teaching innovation team and provide a basis for the subsequent allocation of the incentive pool.

D. Incentive Pool Allocation Results

When the enterprise project is completed, the incentive pool of the financial management teaching innovation team is allocated, and the allocation results are shown in Fig. 5.

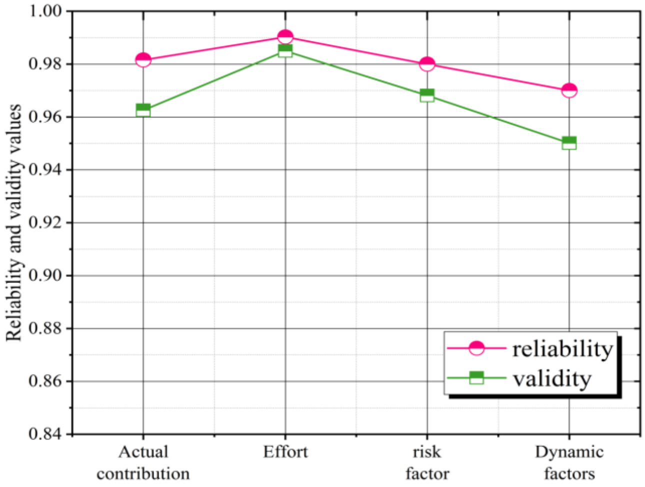

Fig. 3. Reliability and validity of incentive pool allocation indicator system.

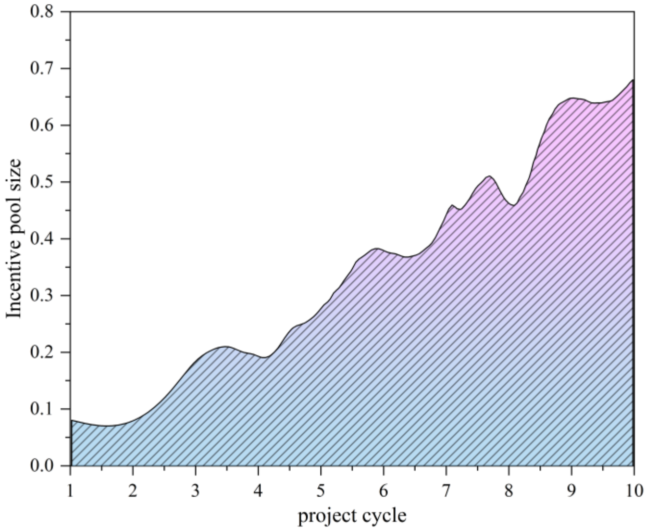

Fig. 4. Calculation results of incentive pool size under different project cycles.

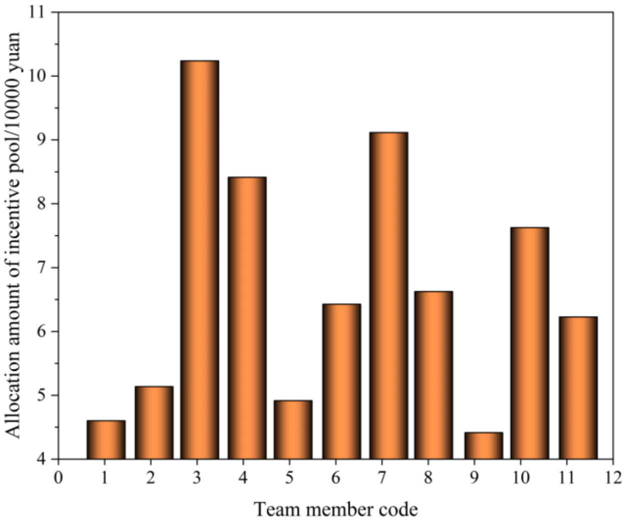

Fig. 5. Distribution results of incentive pool of financial management teaching innovation team.

It can be seen from the analysis of Fig. 5 that using the method in this paper can effectively allocate the incentive pool amount of the financial management teaching innovation team, and compared with the incentive amount of the team members in Table II, the allocation results meet the expected amount of the team members. Some team members allocate the incentive amount higher than their expected amount. The above results show that this method can effectively allocate the incentive pool of the financial management teaching innovation team. Its allocation result is more consistent with the team members and their results, with good application effect.

To further verify the allocation ability of the method in this paper to the incentive pool of the financial management teaching innovation team, it takes the satisfaction of the members of the financial management teaching innovation team with the allocation result of the incentive pool as a measure, to test the ability to allocate the amount of the incentive pool when the number of incentive pools is different. In order to make full use of the experimental results, the methods of reference [7], reference [8], reference [25], reference [9], and reference [10] are used to carry out the test. The test results are shown in Fig. 6.

It can be seen from the analysis of Fig. 6 that when the number of incentive pools allocated by the method in this paper is different, the satisfaction of the members of the financial management teaching innovation team with the allocation of incentive pools has always fluctuated around 96%, which shows that the results of the allocation of incentive pools are in line with the expected values of the members of the financial management teaching innovation team. When allocating incentive pools according to the method of reference [8], when the number of incentive pools is small, the satisfaction of team members with the allocation results is high. Still, when the number of incentive pools is large, the satisfaction of team members with the allocation results shows a downward trend. The satisfaction value of team members is lower than that of the method in researches [7], [25], [9] and [10] when allocating different rate incentive pools. The above results show that the method of this paper can not only effectively allocate an incentive pool, but also team members are satisfied with the allocation results of the incentive pool, and its application effect is good.

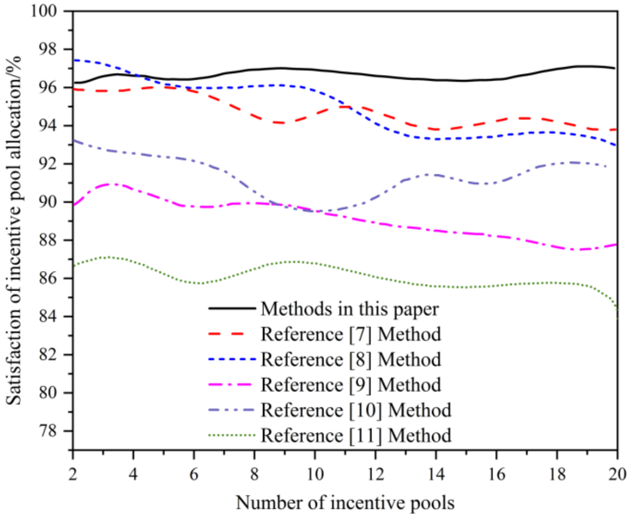

Fig. 6. Test results of satisfaction with the allocation of incentive pool of financial management teaching innovation team.

IV. Conclusion

When the amount of incentive pool is distributed unevenly, it will seriously affect team unity and lead to the poor effect of the team following up on the enterprise project. Therefore, this paper proposes a dynamic allocation method of incentive pool for financial management teaching innovation teams based on data mining. Taking the actual enterprise project and financial management teaching innovation team as the experimental object, the method in this paper has been fully verified. The verification results show that the method in this paper has a relatively significant application effect. However, the method in this paper still has some shortcomings. For example, it is difficult to determine the amount of funds in the incentive pool in the early stage of the project promotion. There are many unpredictable factors in the project promotion process. The calculation of the size of the incentive pool is usually carried out in the late stage of the project promotion. However, the calculation results of the method in this paper calculate the size of the incentive pool in each project cycle, and there is a certain deviation. Although the method of dynamically allocating incentive pools was proposed in the study, it may face some challenges in practical applications. For example, factors such as resource constraints, organizational structure, and culture may affect the actual allocation and execution of incentive pools. Therefore, when applying research results to practice, it is necessary to consider these practical feasibility issues. In the future, in the process of applying the cumulative prospect theory, according to the actual implementation of the project and the risks and changes that may be encountered, the risk prospect with more dimensions and different probability of occurrence will be set. When applying the cumulative prospect theory model, the risk prospect of the project can be judged from different angles, and the more suitable incentive pool size can be solved.

A Hybrid Federated Learning Framework and Multi-Party Communication for Cyber-Security Analysis

Fahad Alqurashi
Computer Science Department-Faculty of Computing and Information Technology,
King Abdulaziz University, Jeddah 21589, Saudi Arabia

***Abstract*—The term "Internet of Things" (IoT) describes a global system of electronically linked devices and sensors capable of two-way communication and data sharing. IoT provides various advantages, including improved efficiency and production and lower operating expenses. Concern about data breaches is constantly present, for example, since devices with sensors capture and send confidential data that might have dire effects if leaked. Hence, this research proposed a novel hybrid federated learning framework with multi-party communication (FLbMPC) to address the cyber-security challenges. The proposed approach comprises four phases: data collection and standardization, model training, data aggregation, and attack detection. The research uses the UNSW-NB15 cyber-security dataset, which was collected and standardized using the z-score normalization approach. Federated learning was used to train the local models of each IoT device with their respective subsets of data. The MPC method is used to aggregate the encrypted local models into a global model while maintaining the confidentiality of the local models. Finally, in the attack detection phase, the global model compares real-time sensor data and predicted values to identify cyber-attacks. The experiment findings show that the suggested model outperforms the current methods in terms of accuracy, precision, f-measure and recall.**

I. Introduction

IoT defines the interconnection between physically moving objects through the internet integrated with the sensors, system memory, electronic chips, and other hardware [1]. In an IoT network, things interact with other nodes, which can be managed and controlled remotely [2]. This interconnectivity between the nodes enables them to gather and exchange information with other connected devices [3]. The IoT system provides ubiquitous connectivity to various intelligent systems, service industries, cloud computing, and applications [4]. Moreover, the IoT system enhances the number of communication networks and the amount of big data shared using the cloud architecture [5]. Recently, IoT-assisted approaches have had numerous applications in smart cities, online shopping, health care, banking, industries, etc., to protect human beings [6]. However, IoT systems are vulnerable to open attacks available on the network. Furthermore, the increased usage of IoT devices made them more vulnerable to cyber-attacks, making it essential to develop efficient mechanisms for predicting these threats [7]. The traditional techniques to detect and prevent cyber-attacks in IoT include conducting risk assessment, execution of authentication system, utilization of secure protocols, data encryption, etc., [8]. The risk assessment involves the evaluation of security controls to predict the vulnerabilities and cyber-attacks in the IoT system [9]. The implementation of the authentication system includes the usage of biometric authentication, password policies, and factor authentication technique to enable authorized user access in the IoT network [10].

In data encryption, the collected IoT data was encrypted using different algorithms during the data transmission [11]. However, conventional algorithms cannot offer higher security to IoT devices. Moreover, it cannot deal with the huge volume of data generated by IoT devices [12]. To address these challenges, Artificial Intelligent (AI) techniques are utilized to predict malicious events in the IoT network [13]. Machine learning (ML)-based methods are trained to identify data patterns and malicious events without requiring explicit protocols [14]. Hence, they have emerged as an effective attack detection tool in real-time IoT systems. Several types of ML techniques exist, such as supervised, unsupervised, and reinforcement learning [15]. The supervised learning technique utilizes a labeled database to train the algorithm to identify the patterns and categorize data into various classes, like benign or malicious [16]. But then, unsupervised learning does not require a labeled dataset to predict the data pattern or malicious data [17]. On the other hand, the reinforcement learning technique learns from experience and makes decisions to predict and prevent cyber-attacks in IoT networks [18].

Utilizing ML approaches in cyber-attack detection earned more advantages, like greater detection accuracy, improved speed, and faster response [19]. In addition, it enables the system to classify the types of cyber-attacks present in the data [20]. Moreover, it minimizes the human workload and allows them to detect complex cyber threats. However, the existing ML-based techniques face limitations and challenges, such as lack of labeled data, inconsistent data quality, storage, data privacy, etc. Moreover, recently various approaches such as supervised machine learning [21], false-data injection using ML model [22], Ensemble deep learning model [23], Deep learning-based IDS [24], Federated Learning-based IDS [26], etc., are designed to protect the network data from cyber-security attacks. However, these approaches are limited to generalizability that is these techniques cannot recognize the patterns of unknown attacks. Moreover, the performances of these models rely on dataset availability for training, and acquiring such a database is challenging. In addition, the techniques including deep learning and machine learning algorithms are computationally expensive and resource intensive. Also, training and deploying these techniques require more computational power, memory, and time, thus making them less effective for resource-constrained environments. Addressing these issues and challenges is important to develop a reliable and robust cyber-security framework. To address these challenges, federated learning with an intelligent MPC system was developed in this article. The basic concept of the proposed model is combining the advantages of Federated Learning and MPC algorithms to predict attacks and malicious events in IoT networks. The key contributions of the presented research work are described below:

- We develop an integrated Federated learning-based Multi-Party Computation approach to protect the IoT network data from malicious attacks.
- The network data was pre-processed using the z-score normalization approach enabling data standardization and effective training across subsets.
- Each IoT device trains a local model on its subset of pre-processed data using the federated learning approach. Then, the local models are encrypted using the MPC to confirm data security.
- The central server collects the encrypted models, and secure model aggregation was performed using the intelligent MPC approach to ensure privacy of the individual models.
- Finally, the performances of the developed model were analyzed and evaluated with existing techniques in terms of accuracy, f-measure, recall, and precision.

The organization of the presented article is described as follows, the current research related to cyber-security is described in Section II, the existing cyber-security model and its challenges are illustrated in Section III, the proposed methodology is explained in Section IV, the outcomes of the proposed work is analyzed in Section V, and the conclusion of the article is summarized in Section VI.

II. Related Work

Some of the research articles related to the proposed work are listed below:

IoT defines the interconnection between different devices or objects, enabling the devices to collect, exchange and share information over the Internet. However, the tremendous growth of the IoT makes it more vulnerable to privacy and security risks. These security risks result in the limitation of energy resources and reduce the scalability of IoT devices. Hence, Yakub Kayode Saheed *et al.* [21] proposed an ML-supervised approach-based Intrusion Detection System (IDS) to address the security and privacy risks of the IoT. The developed model was tested and evaluated with the publicly available UNSW-NB15 dataset. The developed model utilizes the Principal Component Analysis technique to reduce the dataset dimensionality and minimum-maximum normalization concept to extract features. The implementation outcomes illustrate that the presented model earned greater accuracy of 99.9% for the UNSW-NB15 dataset. However, training the labeled dataset using the supervised technique consumes more time and increases the implementation cost.

The wide acceptance of the Industrial Internet of Things (IIoT) system resulted in various limitations like security, privacy, etc. The primary security threat affecting the IIoT system's function is the False Data Injection (FDI) attack. The primary concern of the FDI attacks is to mislead the industrial design by faking its sensor measurements. Mariam M. N. Aboelwafa *et al*. [22] developed an innovative FDI attack prediction algorithm. This method utilizes auto-encoders to detect the FDI attacks accurately. Initially, the sensor data was collected from the industrial sector and pre-processed to detect false data. Further, denoising auto-encoders are used to clean the falsified data. Finally, the performance of the developed design was evaluated and compared with existing techniques. The developed model is more effective in recovering the clean data from the injected dataset. However, the presented approach cannot handle highly dynamic and complex datasets.

The incorporation of IoT devices and communication networks in industrial control systems makes them vulnerable to cyber-attacks, making the system produce devastating results. Typically, IDS schemes are developed to assist the Information Technology (IT) system in predicting cyber-attacks. These models are pre-defined algorithms and are trained to identify the specific cyber threat. However, the traditional IDS design needs to consider the inconsistent nature of the industrial control system, which results in low accuracy and a high false positive rate. Abdulrahman Al-Abassi *et al.* [23] designed a Deep Learning (DL)-based IDS framework to overcome these issues. The proposed model builds a balanced demonstration of the imbalanced database and passes it to the ensemble DL attack prediction scheme. The developed algorithm integrates the deep neural network (DNN) and Decision tree classifier to predict cyber-attacks accurately. However, this approach cannot specify the cyber-attacks in the industrial control system.

The ultimate goal of the stakeholders from IIoT is its sustainability and trustworthiness to prevent loss. A secured IIoT network enables trust, security, privacy, safety, and reliability to the stakeholders. However, conventional security models are ineffective in protecting the network from security threats. Fazlullah Khan *et al*. [24] designed a reliable and accurate supervisory control and data acquisition (SCADA) system-based attack detection. The developed model integrates the DL-based recurrent units and decision tree classifier to predict the cyber-attacks in the IIoT system. The nonlinearity of the presented recurrent unit eliminates the irrelevant data. Thus it enhances the detection rate of the system. The proposed technique was validated with 15 different SCADA datasets. The experimental analysis illustrates that the presented algorithm outperforms the traditional attack detection schemes. However, it cannot process large-scale databases.

In the IIoT system, a tremendous amount of data processing occurs at the edge or cloud server to perform various analytics. Hence, various DL-based data analytic models are developed to effectively process the hue IIoT data. However, the learning process must be trustworthy and reliable to overcome the vulnerability of the IIoT networks. Therefore, Sharmistha

Nayak *et al.* [25] developed a DL-based routing algorithm for attack prediction in IIoT networks. This model deploys adversarial training to identify the injected attacks. Furthermore, the Generative Adversarial Network-Classifier (GAN-C) is designed to specify the type of attack that occurred in the IIoT system. The developed model utilizes parallel learning and prediction design to minimize the computational complexity of the system. The performance analysis demonstrates the usage of GAN-C significantly reduces the training time and increases accuracy. But the GAN-C is biased towards certain data types, making the system more complex.

Othmane Friha *et al.* [26] presented a federated learning (FL)-based IDS for providing security to the agricultural IoT architectures. The developed model protects the agricultural data through local learning in which the devices benefit the knowledge and share to enhance the detection accuracy. The presented model utilizes three different DL classifiers: convolutional neural network, recurrent neural network, and deep neural network. The performance of the developed algorithm was evaluated on other datasets such as InSDN, MQTTset, and CSE-CIC-IDS2018. The results illustrate that the presented technique outperforms the non-federated learning techniques. However, the communication cost in the proposed method is high compared to other techniques.

III. Problem Statement

Even though the Internet of Things (IoT) has undoubtedly improved our everyday lives in many ways, its dispersed and decentralized architecture has also opened the door to novel cybersecurity risks. Methods based on Machine Learning (ML) have shown a lot of promise in spotting these dangers. The limitations of the traditional approaches include dependency on central servers for data processing and transmission; hence, these models cannot perform in a decentralized IoT environment. The existing model faces privacy problems, as they share sensitive data with the central server; this leads to data unauthenticated access to user-sensitive information. Moreover, these models transfer the large volume of data to the server, which is time-consuming, poses computational overhead, large energy consumption, and leads to poor resource utilization. As a result, improved collaboration methods for threat detection across IoT devices that respect users' security and privacy are required. Federated learning with MPC may provide a safer and more private solution for IoT devices to work together on threat detection [27]. The motivation behind the proposed work is the benefits of federated learning and MPC to handle the decentralized and distributed nature of the IoT environment. The federated learning approach enables each IoT device in the network to train a local model using its data, confirming that the sensitive data remains on the device and is not shared with the central aggregator. This decentralized framework preserves data privacy and addresses the concerns interconnected with centralized data aggregation. Moreover, the distributed and decentralized feature of federated learning minimizes the amount of data transmission, thus it reduces the computational overhead and energy consumption issues faced by the existing models. Further, by aggregating the local models' knowledge through MPC, the global model benefits from the collective intelligence of all participating IoT devices. This collaboration enables the system to leverage diverse data sources and insights, leading to more accurate and robust threat detection. Moreover, the MPC approach confirms that the data transmitted during collaboration remains encrypted and makes it inaccessible to unauthenticated users. Thus, the designed framework addresses the problems faced by the existing models.

IV. Proposed FLbMPC Approach For Cyber-Attack Detection

A novel hybrid cyber-security framework was developed in this article to predict attacks or malicious events in the IoT network. This model integrates the Federated Learning algorithm [28] and intelligent multi-party computation (MPC) [29] technique to secure network data from cyber-security threats. The federated learning is an algorithm, which enables multiple IoT devices to collaboratively train the model without sharing the raw data. On the other hand, the MPC is a cryptographic algorithm, which allows secure collaboration and computation on encrypted data. Initially, the cyber-security dataset was collected from the standard site and imported into the system. The raw dataset was pre-processed using the z-score normalization technique, and the dataset was partitioned into multiple subsets in which different parties own each subset. Further, each IoT device trains a local model on its subset of pre-processed data.

The local model can be an ML design trained using the federated learning algorithm. After the completion of local model training, it is encrypted using the MPC to confirm that the privacy of the local model is preserved. Then, the encrypted local model is sent to the central server for aggregation.

The central server gathers the encrypted local models from all the IoT devices and aggregates them to form a global model. The proposed work performs the model aggregation using the MPC algorithm. Finally, the global model is utilized to predict cyber-attacks in real-time by comparing sensor readings from each IoT device to the expected values detected by the model. If there is a difference from the expected values, it is represented as a cyber-attack. Finally, the performances of the proposed work are estimated in model evaluation in terms of accuracy, precision, recall, and f-measure. The proposed framework is explained in Fig. 1.

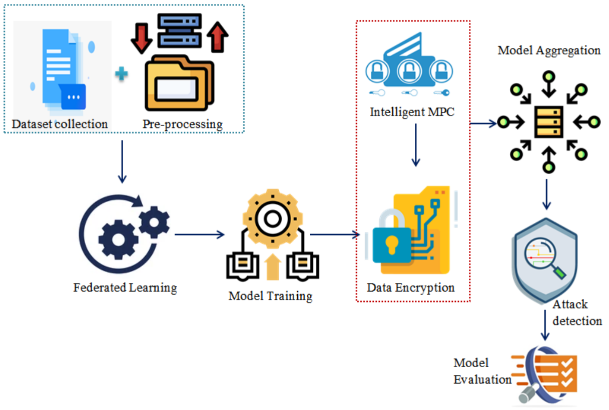

Fig. 1. Proposed hybrid federated learning framework with multi-party communication.

A. Data Pre-processing

The cyber-security dataset containing the network traffic logs from numerous IoT devices is initially collected. Each log contains information regarding the device, log time, port numbers, IP addresses, packet sizes, etc. In the proposed work, the UNSW-NB15 cyber-security dataset was collected from the Kaggle site and imported into the system. The dataset initialization is expressed in Eq. (1).

$$D_{un} = \{d_{a1}, d_{a2}, ...d_{an}\} \tag{1}$$

Where D_{un} denotes the input dataset, d_a the data present in the dataset, and n the number of data present in the dataset. Then the raw dataset was pre-processed using the z-score normalization technique. Z-score normalization is a data pre-processing approach deployed in ML to convert numerical attributes to mean and standard deviations of 0 and 1, respectively. The mean and standard deviation calculation for each feature in the dataset is expressed in Eq. (2), and (3).

$$M_e(D_{un}) = \frac{1}{n}\sum(f_i) \tag{2}$$

$$S_D(D_{un}) = sqrt\left(\frac{1}{n} * \sum(f_i - M_e)^2\right) \tag{3}$$

Here S_D represents the standard deviation, M_e denotes the mean value, and f_i indicates the value of the i^{th} feature. The dataset normalization is formulated in Eq. (4).

$$N(f_i) = \frac{(f_i - M_e)}{S_D} \tag{4}$$

In this approach, the mean of the feature is subtracted from each value in the feature, and the result is divided by the feature's standard deviation. The outcome values have a mean and standard deviation of 0 and 1, which enables the ML algorithms to learn easily from the data.

B. Model Training

The model training was performed using the federated learning algorithm in the proposed framework. Federated learning is a ML-based algorithm that performs model training using the data distributed across multiple devices without the necessity of centralized data collection. Initially, the pre-processed dataset was partitioned, and then local model training was performed to train the models for cyber-attack detection. The dataset was partitioned into multiple subsets and distributed across the IoT devices. In the developed work, random partitioning was deployed to divide the dataset into approximately equal sizes of subsets. The formulation of data partition is expressed in Eq. (5).

$$D_{un} = \{D_{un1}, D_{un2}, D_{un3}, ...D_{unK}\} \tag{5}$$

Where K denotes the number of IoT devices. In federated learning, the data is partitioned so that each party owns a data subset, and the subsets are non-overlapping. For example, the party p owns a subset of data D_{unp} .

The local training model begins after the completion of data partitioning. It is the process of training a ML design on the data subset owned by each party in the network.

In the proposed work, each party trains a local model on its own data subset without sharing the data with other parties. Here, each party p trains a local model M_p with its own data subset D_{unp} in a decentralized manner and L_p denotes the local model on the device.

C. Model Aggregation

After the completion of local model training, it is encrypted using the MPC approach to confirm the security and privacy of the model. The local model is encrypted using cryptographic techniques like MPC. The encryption of local models is expressed in Eq. (6).

$$E_n(L_p) = Ef_{Ke}(L_p) \tag{6}$$

Where E_n denotes the encryption process, Ef refers to the encryption function, and Ke represents the key. Further, the central server gathers the encrypted local models from all the IoT devices and aggregates them to form a global model. In the proposed work, the model aggregation was performed using MPC. The global model was utilized to predict cyber-attacks in real time by comparing sensor readings from each IoT device to the expected values detected by the model. If there is a variation from the expected values, it predicts a cyber-attack. It is represented in Eq. (7).

$$D'_p = \left|S_p - S'_p\right| \tag{7}$$

where D'_p indicates the deviation between the actual and expected values, S_p denotes the sensor reading on the device p , and S'_p the expected value detected by the global model. If the deviation value exceeds the predefined threshold value T_R , it is predicted as an attack. Otherwise, the central server updates the global model, which is expressed in Eqn. (8).

$$R' = R - \lambda\sum\left(D'_p - \nabla L_p\right) \tag{8}$$

Where R' denotes the updated global model, R indicates the previous global model, λ refers to the learning rate, and ∇L_p defines the gradient of the local model on the device p . This process continues until the global model achieves the desired accuracy.

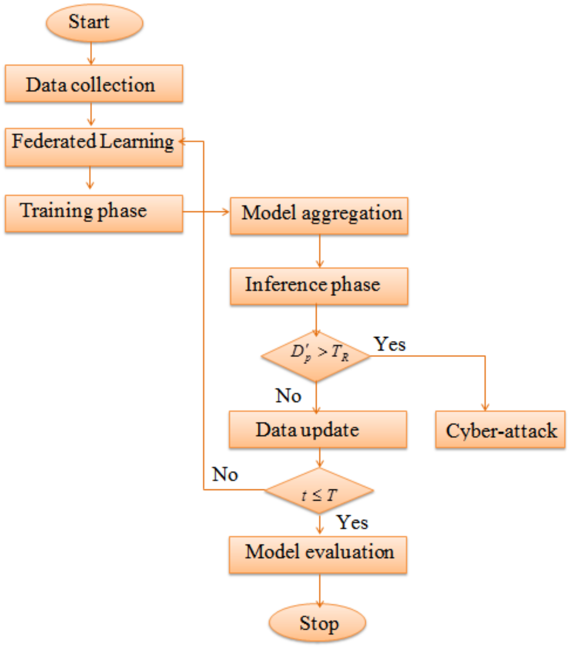

Fig. 2. Flowchart of the proposed framework.

The flowchart of the proposed work is displayed in Fig. 2. In addition, the step-by-step procedure of the proposed model is illustrated in pseudo code format in algorithm 1.

Algorithm pseudo-code of the proposed model (Algorithm 1)

```
start
  {
  Initialize the machine learning model with random weights $R_w$
  Initialize the number of training rounds, IoT devices
  Initialize the batch size and learning rate for local training
  for $(t=1, t \le T; t++)$
    {
      Partition the dataset: $D_{un1,} D_{un2}, D_{un3}, .....D_{unK}$
      Each IoT device p trains the local model $L_p$ with its subset. $D_{unp}$
      $En = encrypt(L_p)$ // encrypt the local model using the MPC algorithm
      Send the encrypted model to the central server.
      $L_p = encrypt(En)/N$ // aggregate the local model to form a global model
      $If(D'_p > T_R)$
      {
      "Cyber-attack" //The system predicts a "cyber-attack."
      }
      else (data update);
    }
  }
end
```

V. Results and Discussion

This research proposed a hybrid intelligent cyber-security mechanism to detect cyber-attacks in the IoT system. The model utilizes federated learning and MPC to predict cyber-attacks effectively. The input dataset was initially collected and pre-processed using the z-score normalization approach. Further, a federated learning algorithm was designed to partition the normalized dataset. Moreover, it enables the system to train the local model in a decentralized manner (without sharing the raw dataset). Moreover, an intelligent MPC was developed to encrypt the local models, enabling it to preserve the privacy of the local models.

Finally, the encrypted local models are sent to the central server for model aggregation. The model aggregator combines them to form a global model. The global model predicts cyber-attacks by analyzing expected and actual sensor readings deviation. The presented work was implemented in MATLAB software, version R2020a, and the results are analyzed. The parameters and their description are tabulated in Table I. In addition, a comparative assessment was carried out to manifest the effectiveness of the proposed work.

A. Dataset Description

The presented model was trained and tested with the UNSW-NB15 dataset. It is a cyber-security dataset that was developed to help the researchers on IDS and network security. It consists of a massive collection of network traffic data, including the different types of cyber-attacks such as DoS, Probe, U2R, R2L, etc. Table II illustrates the attack types and number of records in the UNSW-NB15 dataset. The dataset contains ten different attack types indicated by a separate class label.

TABLE I. Parameter and Specification

Parameters	Specification
Tool	MATLAB
Version	R2020a
OS	Windows10
Dataset	UNSW-NB15
Dataset size	1.9GB

TABLE II. Dataset Description

Attack Type	*Number of records*
Normal	221,876
Analysis	2,244
Backdoor	18
DoS	122,846
Exploits	445,104
Fuzzers	242,720
Generic	188,220
Reconnaissance	104,13
Shellcode	1,571
Worms	130

In addition, it includes 49 different features like port numbers, protocol types, source and destination IP addresses, byte counts, etc. The University of New South Wales researchers in Australia created the dataset. It comprises nearly 2.5 million network packets in which 175,341 records are selected for training and 82,332 records are chosen for testing.

B. Case Study

The working procedure of the proposed work is explained in this case study. Initially, the input cyber-security dataset was collected from the standard site and imported into the system. In the present study, the UNSW-NB15 dataset was collected and fed into the system for further processing. After data initialization, the raw dataset was pre-processed using the z-score normalization technique. Further, a federated learning setup was established for performing data partition and local model training. Initially, the pre-processed dataset was partitioned into approximately equal-sized subsets and distributed to IoT devices.

Federated learning helps the system divide the dataset so that each party owns a data subset, and the subsets are non-overlapping. In local model training, each party trains a local model with its own data subset without sharing the data with other parties. Further, the trained local models are encrypted using the MPC algorithm to ensure the privacy and security of the models. After encryption, the central server collects the encrypted local models from all the IoT devices and aggregates them into a global model. The global model was used to detect cyber-attacks by matching the real-time sensor reading with the expected values predicted by the model. If the difference between actual and estimated values is greater than the threshold value, it is predicted as Attack. Else, the central server updates the global model.

This process is continued until the system achieves the desired accuracy. Finally, the performances of the proposed technique were estimated by implementing it in the MATLAB tool. In addition, a comparative assessment was performed to validate the outcomes of the proposed work. The implementation results of the proposed work are tabulated in Table III.

The performance analysis illustrates that the proposed model earned greater performances, such as 99.98% accuracy, 100% precision, 99.8% recall, and 99.87% f-measure. In addition, the presented model achieved a less computational time of 2.34ms.

C. Performance Analysis

In this module, the performances of the proposed work are examined in terms of accuracy and loss relative to the increasing number of epochs. The training and testing accuracy of the proposed framework over increasing epochs count is demonstrated in Fig. 3. The training accuracy denotes the model accuracy on the train dataset which is how accurately the designed model detects the attacks on the train set. In addition, it measures how efficiently the designed model learns the attack patterns during the training phase. On the other hand, the testing accuracy measures how well this approach works on unseen data. The designed framework achieved an approximate training accuracy of 0.99, which demonstrates that the developed model works well on the training dataset and quickly learns the interconnection between the normal and attack data. Consequently, the presented approach attained an approximate testing accuracy of 0.97; this shows that the designed framework predicts cyber-attacks on unseen data effectively.

Similarly, the training and testing losses were over increasing epochs. Fig. 4 portrays the evaluation of training and validation losses. The training loss represents the difference between the actual and predicted results on the training dataset. It measures how well the proposed model fits the training set and learns the relationship between network data and attack patterns. This approach attained an average training loss of 0.003, which shows that the proposed model fits well on the training dataset.

TABLE III. PERFORMANCE ANALYSIS

Metrics	*Values*
Accuracy (%)	99.98
F-measure (%)	100
Recall (%)	99.8
Precision (%)	99.87
Processing time (ms)	2.34

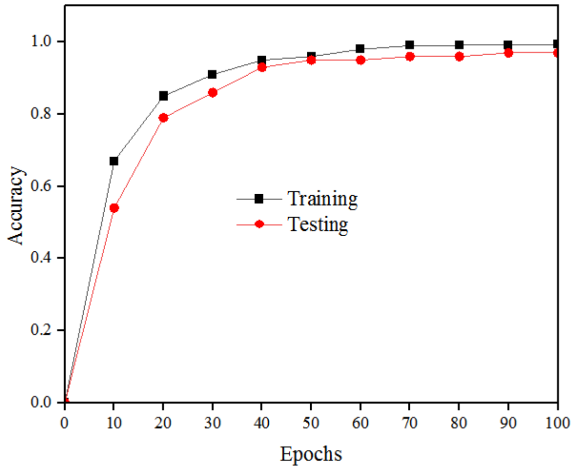

Fig. 3. Training and testing accuracy evaluation.

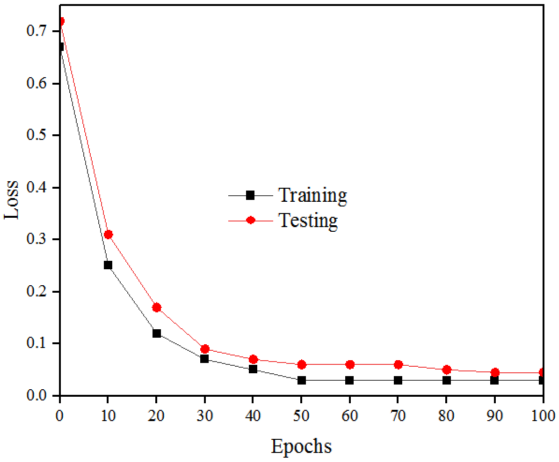

Fig. 4. Training and testing loss evaluation.

The testing loss defines the model's generalization ability on unseen data (unknown attack patterns). This approach earned a testing loss of 0.045, which indicates that the proposed model accurately classifies cyber-attacks in real-world scenarios.

Furthermore, to evaluate the effectiveness of the proposed work on real-world scenarios the system performances such as attack detection accuracy, computational time, and energy consumption are analyzed for increasing number of participants and data size in the network.

Here, the model accuracy was evaluated by increasing the data size and number of users in the IoT network and it is graphically represented in Fig. 5. When the network user count is 20, the proposed model earned an average accuracy of 99%. Further, on increasing the network users to 40, 60, 80, and 100, the designed model obtained an approximate accuracy of 99.5%, 99.6%, 99.7%, and 99.99%. The increase in system accuracy over increasing network users and data size is because of the ability of the proposed model to compare the sensor readings with the expected values. This makes the system more refined and attuned to the attack patterns owing to improved accuracy over increasing network users and data size.

Error rate defines the discrepancy between the actual and predicted results. This metric determines the efficiency of the model in detecting the attacks. Fig. 6 illustrates the error rate over increased network users and data size. The proposed model earned a minimum error rate of 1%, 0.9%, 0.8%, 0.6%, and 0.5%, respectively for 20, 40, 60, 80, and 100 network users at increasing data size from 50MB to 500MB. The lowering of the error rate illustrates that despite the increased network users and data size the proposed model correctly detects the attacks and normal events.

The computational complexity over increasing network users and data size is illustrated in Fig. 7, the computational time of the system was examined at different network user counts and the increasing data size (50 to 500MB). When a user in the network is 20, the proposed system consumed an average computational time of 1.75ms. Consequently, on increasing the network users to 40, 60, 80, and 100, the designed model consumed an approximate time of 2ms, 2.25ms, 2.5ms, and 2.75ms, respectively. From the analysis, it is observed that the computational time increases with increasing the number of users and data size in the IoT network. However, the computational time consumed by the presented model is relatively small, which is achieved by integrating federated learning and MPC. The local model training using the FL approach significantly reduces the amount of data transmission over the network; this minimizes the computational overhead and leads to faster communication. The integration of these techniques optimizes the computational process and reduces the time complexity.

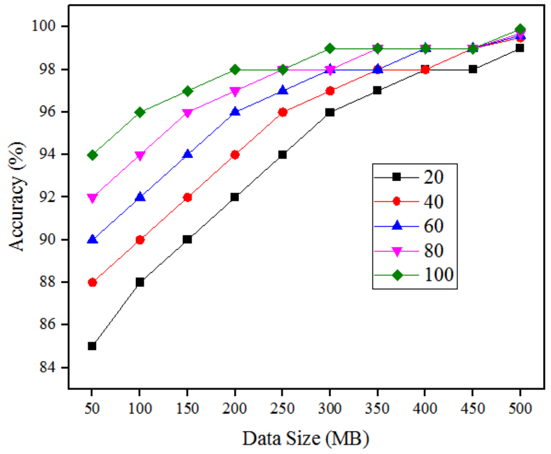

Fig. 5. System accuracy over the increasing number of network users and data size.

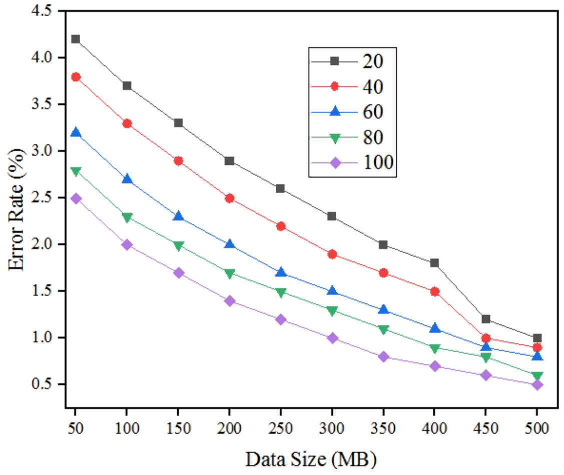

Fig. 6. Error rate over the increasing number of network users and data size.

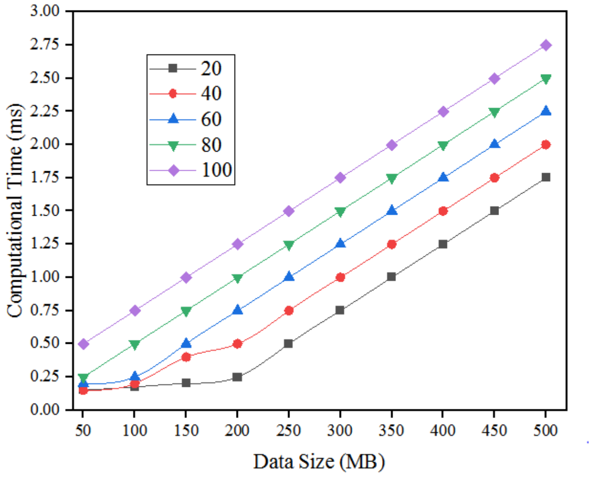

Fig. 7. Computational complexity over increasing network users and data size.

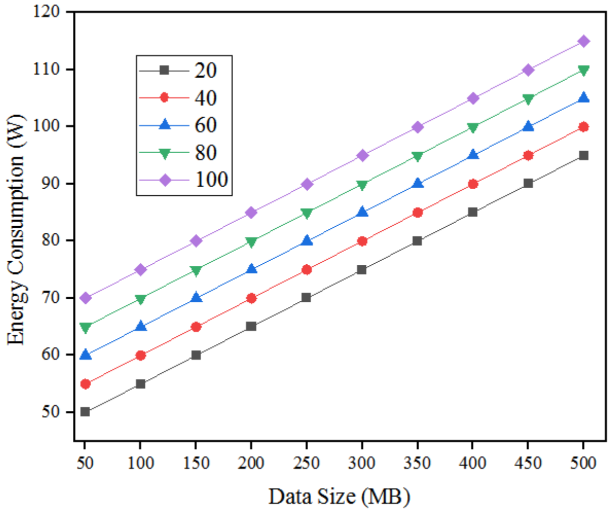

Fig. 8. Network energy consumption over increasing network users and data size.

The energy consumption of the system over increasing data size and network users is graphically represented in Fig. 8. Typically, on increasing the network user count and data size the energy consumption of the IoT network increases. Similarly, energy consumption increased with the increase in user count and dataset size. When the user count is 20, the model attained an average energy consumption of 95W over increasing data size (50 to 500). Consequently, the proposed model obtained an approximate energy consumption of 100W, 105W, 110W, and 115W, respectively for 40, 60, 80, and 100 network users. Similar to the traditional model the energy consumption of the network increases over increased network user and dataset size. However, the energy consumption of the system is comparatively lower than other models. This is due to the incorporation of the FL method in the proposed model. The FL technique in the designed model enables collaborative training that is it does not require a centralized server and instead of transferring the raw data to the central server, the proposed framework transmits only encrypted local models for aggregation. This process significantly reduces the energy consumption for data transmission. This comprehensive performance analysis manifests that the developed model efficiently predicts the attacks or malicious events on the IoT network.

D. Comparative Analysis

In this section, the performances of the proposed model are compared with existing techniques for validation purposes. The current methods such as Deep Belief Network-based Intrusion Detection System (DBN_IDS) [30], Deep Convolutional Generative Adversarial Network (DCGAN) [31], Distributed Convolutional Neural Network (DCNN) [32], Feed-forward neural network (FFNN) [33], and Vector convolutional deep learning (VCDL) [34] are used in comparative performance. The outcomes of these techniques are evaluated by implementing them in the MATLAB tool for the UNSW-NB15 dataset.

1) Accuracy: Accuracy defines the percentage of correct classification of instances. It is defined as the proportion of the sum of true positives and negatives to the total number of instances[35]. Moreover, it represents how exactly the system performs a cyber-attack detection function. The accuracy calculation is formulated in Eq. (9).

$$A_{sy} = \frac{w^+ + w^-}{w^+ + w^- + z^+ + z^-} \tag{9}$$

Where A_{sy} defines the system accuracy, w^+ w^- z^+ and z^- denotes the true positive, true-negative, false-positive, and false negative, respectively.

To manifest the accuracy of the proposed technique, it is compared with existing cyber-security models. Fig. 9 shows the comparison of accuracy. This section uses existing models such as VCDL, FFNN, DCNN, DCGAN, and DBN_IDS for comparative analysis. The accuracy earned by the conventional approaches is 94.72%, 89.43%, 95.45%, 91.78%, and 95.65%, respectively. But the developed technique attained greater accuracy of 99.98%, which is higher than existing techniques. The highest accuracy obtained by the designed model illustrates that it predicts cyber-attacks accurately.

2) Precision: Precision represents the proportion of true positives out of the total positive instances classified by the system[36]. It is also defined as the system's ability to correctly predict cyber-attacks without creating false positives. The precision calculation is represented in Eq. (10).

$$Pi_{cs} = \frac{w^+}{w^+ + z^+} \tag{10}$$

Where Pi_{cs} represent the precision percentage. The high precision defines that the proposed system accurately identifies the cyber-security threats with fewer false positives.

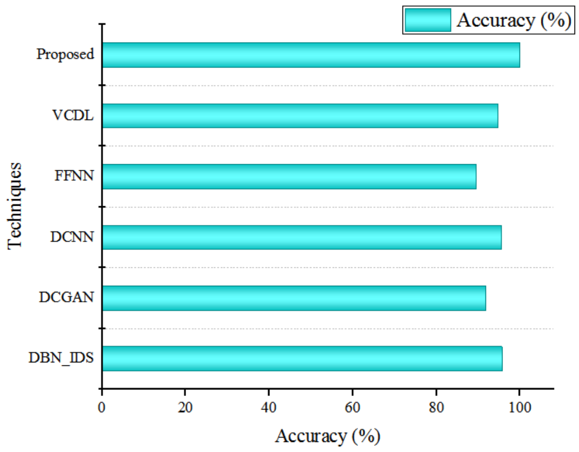

Fig. 9. Comparison of accuracy.

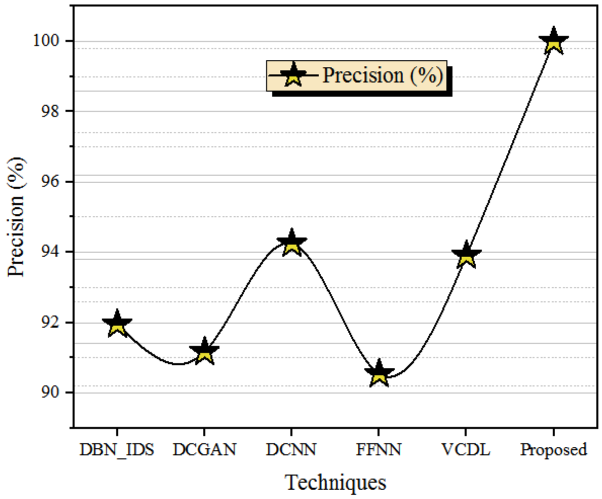

Fig. 10. Precision validation.

In model evaluation, a comparative analysis is important to identify the strength and weaknesses of the proposed techniques. Here, the precision percentage of different machine learning algorithms for predicting cyber-attacks on the UNSW-NB15 dataset was compared with the proposed technique. The existing ML techniques like VCDL, FFNN, DCNN, DCGAN, and DBN_IDS earned precision percentages of 93.91%, 90.54%, 94.25%, 90.17%, and 94.95%, respectively. However, the proposed technique obtained a higher precision percentage of 100%, which is comparatively greater than existing techniques. The comparison of precision is illustrated in Fig 10.

3) Recall: The recall is a performance metric that measures the proportion of true positives out of a total number of actual positive instances[37]. It denotes the system's capability to classify cyber-security threats irrespective of false positives correctly. The recall calculation is expressed in Eq. (11).

$$\mathrm{Re}_{ll} = \frac{w^{+}}{w^{+} + z^{-}} \tag{11}$$

Where Re_{ll} denotes the recall. The high recall rate defines that the system exactly predicts most of the actual cyber-attacks.

The comparison of recall is shown in Fig. 11. The recall is compared with the existing techniques such as VCDL, FFNN, DCNN, DCGAN, and DBN_IDS. The proposed technique attained a recall percentage of 99.8%. On the other hand, the recall percentage attained by the conventional methods is 92.24%, 88.56%, 93.41%, 91%, and 94.16%, respectively. The comparative performance of recall describes that the developed model achieved a better recall percentage than existing techniques.

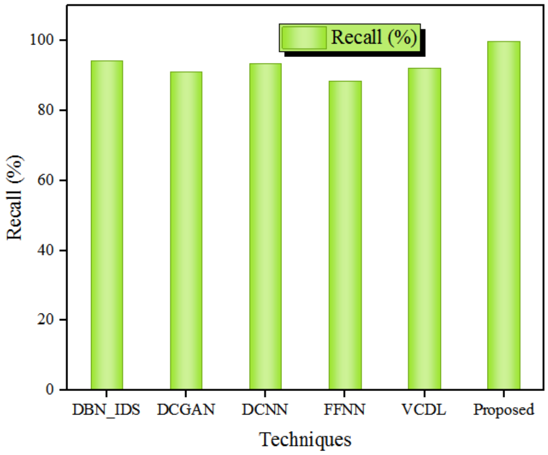

Fig. 11. Comparison of recall.

4) F-measure: F-measure is the metric that combines both precisions and recalls into a single score. It is evaluated as the harmonic mean of these two metrics[38]. The system achieves greater f-measure value only when both recall, and precision score is high. The f-measure calculation is represented in Eq. (12).

$$Fm_{sc} = 2\left(\frac{Pi_{cs} * \mathrm{Re}_{ll}}{Pi_{cs} + \mathrm{Re}_{ll}}\right) \tag{12}$$

Where Fm_{sc} refers to the f-measure.

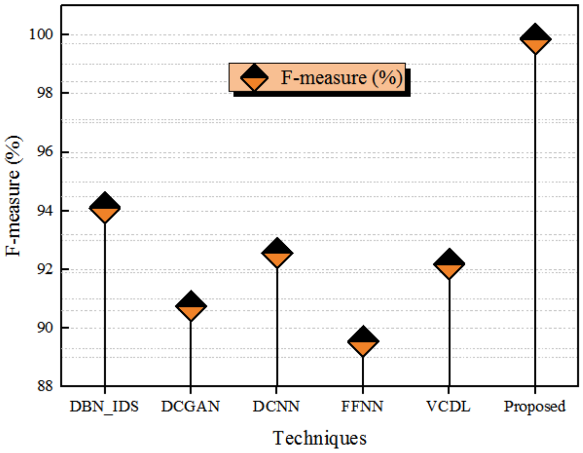

Fig. 12 Comparison of f-measure

To validate that the proposed model gained more f-measure, it is compared with existing techniques like VCDL, FFNN, DCNN, DCGAN, and DBN_IDS. Fig. 12 shows the comparison of the f-measure percentage. The f-measure obtained by the existing techniques is 92.18%, 89.54%, 92.56%, 90.75%, and 94.10%, respectively, less than the f-measure earned by the proposed model. This shows that the developed model balances the precision and recall metrics optimally.

TABLE IV. COMPARATIVE PERFORMANCE OF DIFFERENT MODELS

Techniques	*Accuracy (%)*	*Precision (%)*	*Recall (%)*	*F-measure (%)*
DBN_IDS	95.65	94.95	94.16	94.10
DCGAN	91.78	90.17	91.00	90.75
DCNN	95.45	94.25	93.41	92.56
FFNN	89.43	90.54	88.56	89.54
VCDL	94.72	93.91	92.24	92.18
Proposed	99.98	100	99.8	99.87

The comparative performance of different cyber-security models with the proposed technique is tabulated in Table IV.

5) Computational time: Computation time defines the time taken by the system to perform tasks such as data pre-processing, encryption, data transmission, decryption, etc. The computational time of the system is tabulated in Table V.

TABLE V. COMPUTATIONAL TIME EVALUATION

Component	*Time (ms)*
Encryption time	0.5
Key generation time	0.2
Decryption time	0.6
Data processing time	1.04
Total computational time	2.34

The computational time of the system was compared with an existing model including the VCDL, FFNN, DCNN, DCGAN, and DBN_IDS for validation purposes.

TABLE VI. COMPUTATIONAL COMPLEXITY OF DIFFERENT MODELS

Techniques	*Computational time (ms)*
DBN_IDS	16.02
DCGAN	21.96
DCNN	16.93
FFNN	20.5
VCDL	17.92
Proposed	2.34

Table VI lists the computational complexity of different models. The above-mentioned models consumed 16.02ms, 21.96ms, 16.93ms, 20.5ms, and 17.92ms, respectively. The time taken by the proposed model is 2.34ms, which is comparatively less than the existing techniques. The comprehensive comparative assessment proves that the developed model outperformed the existing techniques.

E. Discussion

This research article presents an integrated framework to detect attacks or malicious events in the IoT network. The developed strategy combines the advantages of Federated learning and MPC algorithms. To begin with, a cyber-security database was acquired from a standard source and fed into the system. This collected database acts as the basis for training the models and predicting potential cyber-attacks. Before training, the raw data was pre-processed using the z-score normalization method. The data normalization confirms that the data was standardized and ready for further analysis. Further, the standardized database was partitioned into multiple subsets, with each subset being owned by different parties (IoT devices). Each party trains the local model using the FL model on its subset of pre-processed data. The utilization of the FL approach for training ensures that the sensitive information owned by IoT devices remains secure and confidential. Moreover, this distributed training minimizes the computational overhead on individual IoT devices and overcomes the drawback of centralized training in which a single server is responsible for training the entire dataset. In addition, it improves scalability and ensures efficient resource utilization.

After local model training, these models are encrypted using the MPC algorithm; this ensures that the model's sensitive data remains confidential and prevents unauthorized data access. Consequently, the encrypted local models are transmitted to the central server for aggregation. The central server receives the encrypted local models from all IoT devices and combines them to form a global model using the MPC, without having direct access to the data. This step permits secure and privacy-preserving collaboration among the different parties. Finally, the global model containing the collective knowledge of all local models is employed to detect cyber-attacks. The real-time prediction ability of the global model improves the system’s capacity to respond promptly to cyber-attacks and mitigate potential damages.

The presented approach was evaluated with the publically available network data named UNSW-NB15 and the performances are analyzed in terms of accuracy, computational time, error rate, and energy consumption. Moreover, the developed model performances are examined in real-time scenarios over increasing network users and data size. This intensive performance evaluation demonstrates the effectiveness of the proposed model in handling real-time applications. Thus, the integration of federated learning with the MPC permits the data to remain on the IoT devices, and only encrypted gradients are sent to the central server. This enables the system to preserve security by ensuring that sensitive information is not transmitted to the central server and reduces the risk of data breaches. In addition, the proposed model minimizes the latency, especially in scenarios with limited network connectivity. Moreover, it enhances the robustness to device failures. Since the training is distributed across multiple devices, the failure of one or more devices does not necessarily lead to the failure of the entire system. Furthermore, to manifest the robustness of the developed model the obtained results are compared with the existing techniques. The comparative analysis demonstrates that the proposed model outperformed the existing models in terms of accuracy, recall, f-measure, and precision.

VI. CONCLUSION

This paper proposed a ML-based cyber-security framework to secure IoT networks from attacks and malicious activities. The proposed framework integrates the FL technique and MPC algorithm to preserve security in the IoT. Federated learning partitions the pre-processed data into equal size subsets. Further, each IoT devices train a local model on its subset of data. Then the trained local models are encrypted using the MPC approach to preserve the model's privacy. Finally, the central server gathers the encrypted local model and forms a global model to predict the cyber-attacks in the system. The developed model is implemented in the MATLAB tool on the UNSW-NB15 dataset. Moreover, a comparative analysis was performed to illustrate the robustness of the proposed algorithm. The comparative analysis shows that performance like precision, accuracy, recall, and f-measure are improved by 5.05%, 4.33%, 5.64%, and 5.77%, respectively. Thus, the designed model accurately predicts the cyber-attacks in IoT networks. Although the proposed framework provides high privacy, it cannot handle large-scale federated learning scenarios. In addition, the proposed framework is vulnerable to adversarial attacks, such as model poisoning or data poisoning attacks. Since IoT systems are composed of devices and sensors from different vendors and manufacturers, making interoperability a critical issue. Moreover, this approach may face scalability issues when handling large-scale federated learning scenarios, and maintaining the inherent trade-off between privacy and utility is a challenging factor. Therefore, in the future, developing ML-based techniques with multi-objective optimization and advanced privacy-preserving approaches will provide enhanced privacy and increases the scalability and efficiency of the system.

Abstract—**Machine learning determines patterns from data to expedite the process of decision making. Fact-based decisions and data-driven decisions are specified by the industry specialist. Due to the continuous growth of machine language models in healthcare, they are breeding continuous complexity and black boxes in ML models. To make the ML model crystal clear and authentically explainable, AI accession came in prevalence. This research scrutinizes the explainable AI and capabilities in the Indian healthcare system to detect diabetes. LIME and SHAP are two libraries and packages that are used to implement explainable AI. The intimated base amalgamates the local and global interpretable methods, which enhances the crystallinity of the complex model and obtains intuition into the equity from the complex model. Moreover, the obtained intuition could also boost clinical data scientists to plan a more felicitous composition of computer-aided diagnosis. Importance of XAI to forecast stubborn disease. In this case, of stubborn diabetes, the correlation between plasma versus insulin, age versus pregnancies, class (diabetic and nondiabetic) versus plasma glucose persisted with a strong relationship. The PIDD (PIMA Indian Diabetic Data set) with the SHAP value is used for concise dependency, and LIME is applicable when anchors and importance of features are both required simultaneously. Dependency plots help physicians visualize independent relationships with predicted disease. To identify dependencies of different attributes, a correlation heatmap is used. From an academic perspective, XAI is very indispensable to mature in the near future. To estimate the presentation of other applicable data set correspondence studies are very much apprenticed.**

Keywords—Explainable Artificial Intelligence (XAI); diabetes; interpretability; machine learning; chronic disease management

I. INTRODUCTION

In developing countries such as India, one of the top ten causes of death related to the disease is diabetes. The researchers are working on the project to find the earliest way to detect the disease at a very early stage. Type 1 and type 2 are the two main types of diabetes. Type 1 diabetes causes a shortage of insulin, which affects increases in blood sugar levels. Whenever humans eat any food that is broken down into glucose, blood sugar in the blood stream increases [1]. The pancreas cell emancipates insulin as the revolt of blood sugar levels, and as a result, it furnishes us to zeal for every day's task [2]. If the cell ceases to produce insulin in the body, it may cause extravagant blood sugar to be sustained in the bloodstream. Significant health issues, such as blurred vision, kidney disease and heart disease, may be sustained as a result of the excessive presence of blood sugar. The symptoms of diabetes are delayed healing, itching, weaknesses, stiffness of muscle, polydipsia and blurred vision [3]. Millions of deaths are caused by diabetes, which is a metabolic condition throughout the year with various health issues. Approximately 84 million to 238 million diabetic cases will be diagnosed within 2030 around the world, which will impose a consequence load on the health care system [4, 5].

Glucose level changes are the main reason for diabetes. Maintaining a healthy lifestyle, a balanced diet and regular medical check-ups are the most preventive ways to restrict diabetes. Based on laboratory tests and disease symptoms, an intelligent system might be an important tool for diabetes prevention and detection.

Patient trust is the main dispute of an AI system. Without any explanation and without any reason to provide the output of the system is an opaque AI system. Especially in the health care system, the machine provides the output without any explanation, which makes it very difficult for the patient to believe the machine properly. To overcome this situation, explainable AI is rapidly used today to diagnose the disease fairly and correctly without any errors. Artificial intelligence adds a layer where the output can be defined clearly, which is known as explainable AI.

Interpretability as well as transparency can be escalated through XAI in the medical field. There is no legal right, which is reflected in the literature. XAI enhances the exposure of service by obliging end users to rely on the decision that AI makes correct decisions. The scope of AI is to make faster and correct decisions regarding the patients' diagnosis and treatment and make it most trustworthy. The main goal of XAI is to generate a high-performance level explainable model. XAI will provide a detailed description of the AI technique, which helps to make AI algorithms more illuminate and translucent by depending on diagnosis with treatment protocols, drug research, medicine patterns, tests, etc.

Addressing XAI, the two important features are interpretability and explainability. The interpretability defines how the output will be changed when the corresponding input parameters are changed. The term explainability defines a clear conception about a modern model, including certain assumptions made by the model and why.

This research aims to furnish interpretability of ML models and boost the performance of prediction to detect diabetes. The contributions of this work are as follows:

- Explainable AI now a day provides us with a “Black Box” nature, which releases more transparency and accuracy in the detection of disease and heightens the confidence of users.
- Shapley Additive Explanations (SHAP) and Local Interpretability Model-Agnostic Explainable (LIME) have been used widely in decision processes.
- A detailed analysis in the SHAP and LIME framework has been used to divulge significant perceptions to make a complete decision process considering all risk factors.

The remaining elements of the research discussion are organized as follows: briefs of similar papers are in Section II that use different categorizations of XAI technologies to forecast chronic disease. Section III describes the methodology used. The implementation of XAI techniques discussed in Section IV and in Section V describes the XAI upgrading of the health care system. The research effort is concluded in Section VI.

II. Literature Review

To diagnose diabetes, various types of machine learning algorithms have been used in [6,7-12]. In [9], PIDD missing values are replaced by mean values. A decision tree classifier is used for the classification. For the same data set, the researcher use different classification algorithms in [10], and the support vector machine provided the best result compared to other classification algorithms.

In another work with the PIDD data set [11], the models were developed using three different machine learning algorithms where SVM provided 70% accuracy with an accuracy of 80 of the trained data set. The same data set provides 78.9% accuracy using theXGBoost algorithm [8] by Tiwari and Singh.

The imbalanced classes and lack of preprocessing in the data set resulted in poor accuracy in these studies [13, 14, 15, 16]. In Fitriyaniet al. [17], these constraints are overcome.

In [18], the researcher developed a commission model amalgamation model to detect heart disease, which is an improved version of [6]. In [19], training set a split for detecting diabetes that scored high accuracy.

For several reasons [20], academic research findings and fruitful applications in medical practice have a remarkable distance. The most recent methodologies and techniques are not reliable by the physician [21, 22]. Black box methodology is not accepted by most medical practitioners due to its lack of explanation [23]. With the sacrifice of higher accuracy [24], clinical ML keeps away from complex models [25-27].

Due to the lack of explainability and biased accuracy, diabetes detection [28-30] and progression have become challenging. This research provides interpretability of the machine learning model and boosts the prediction performance using cross-validation, which helps to predict disease more reliably, accurately and effectively.

III. Methodology

Fig. 1 demonstrates the workflow of the overall model. PIMA Indian Diabetic Data set (PIDD), which contains eight attributes with values that the system has made use of. Then, the data are reprocessed to remove any missing or void values. Next, for training validation and testing, the data set was separated. For the implementation of separation, random sampling was used. As a result, the training and testing division will be unbalanced. To eliminate this problem, stratified sampling was used with a training size of 20% and a training validation size of 80%. After that, different machine learning models were put into action using the Scikit-Learn package. Next, the results were evaluated and explained with the LIME package and SHAP tool to make a complete decision process considering all risk factors. Table I describes the statistical description of the PIMA database.

TABLE II. STATISTICAL DESCRIPTION OF DATABASE

	Preg	Plas	Pres	Skin	Insu	Mass	Pedi	Age	Class
Count	768.00	768.00	768.00	768.00	768.00	768.00	768.00	768.00	768.00
Mean	3.8451	120.8945	69.1055	20.5365	79.7995	31.9926	0.4719	33.24	0.3490
Std	3.3696	31.9726	19.3558	15.9522	115.2440	7.8842	0.3313	11.7602	0.4770
Min	0.0000	0.0000	0.0000	0.0000	0.0000	0.0000	0.0780	21.0000	0.0000
25%	1.00	99.0000	62.0000	0.0000	0.0000	27.3000	0.2438	24.0000	0.0000
50%	3.00	117.0000	72.0000	23.0000	30.5000	32.0000	0.3725	29.0000	0.0000
75%	6.00	140.2500	80.0000	32.0000	127.2500	36.6000	0.6263	41.0000	1.0000
Max	17.00	199.0000	122.0000	99.0000	846.0000	67.1000	2.4200	81.0000	1.0000

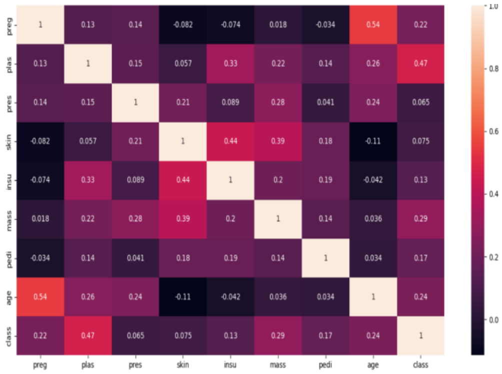

Fig. 2. Correlation coefficient matrix of diabetes.

All diabetes feature correlation coefficient matrices are displayed in Fig. 2. The calculation is based on the linear relationship of measures and features; -1 to + 1, the correlation coefficient value ranged. Values closer to 0 indicate a weak relationship, and values higher than 0 indicate a strong relationship. The correlations between plasma versus insulin, age versus pregnancy, and class (diabetic and nondiabetic) versus plasma glucose were strong.

A. Data Description

An auspicious disease is diabetes with its barrier. Mentioning the present health care system, it is very important to detect the disease properly. Table II explains the dataset description of proposed machine learning system. The present PIDD(https://www.kaggle.com/datasets/kumargh/pimaindians diabetescsv) is a tabular data set containing 768 data points with two classes (diabetic and nondiabetic). In AI-based solutions in the area of healthcare, XAI is a censorious tool for predicting disease more accurately. The personalized description of XAI solves constraints such as the proper interpretations of model features, performances, explanations of the data set, and knowledge of the model with associations of trained data.

TABLE III. DATA SET DESCRIPTION OF PROPOSED MACHINE LEARNING SYSTEM

Attributes Abbreviation	Attributes	Attributes Types
Preg	Pregnancies	int 64
Plas	Plasma Glucose	int 64
Pres	Diastolic Blood Pressure	int 64
Skin	Triceps Skin Fold Tickness	int 64
Insu	Insulin(2Hrs serum insulin)	int 64
Mass	Body Mass Index	int 64
Pedi	Diabetic Pedigree Function	int 64
Age	Person's Age	int 64

The characteristics of the XAI technique can be explained by LIME, SHAP and personal dependency plots with the diabetic data set in Fig. 3. The scatter plot in Fig. 4 represents the classifications of 768 patients into two classes, diabetes, which is class 1, and nondiabetes, which is class 0, according to the two important features plasma and insulin. It can be inferred that most of the patients belong to Class 0 nondiabetes. From this plot, low plasma and high insulin are less likely to be predicted as diabetes.

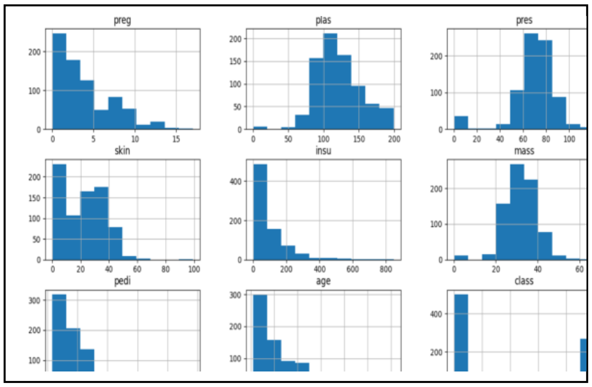

Fig. 3. Histogram of data set features.

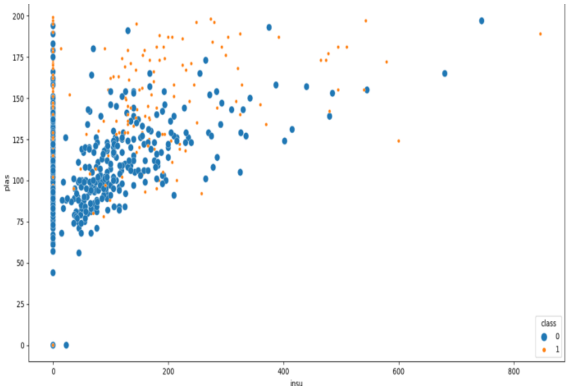

Fig. 4. Scatter plot of two classes.

IV. Implementation of XAI Techniques

XAI process accomplishment helps researchers understand the system properly and expedites the process of diagnosing chronic disease properly with supportive results.

A. *Platform and Language*

XAI techniques can be easily implemented by using the Python programming language, which is an object-oriented, asynchronous interpretive high-level programming language with lower maintenance cost. ML with AI is very much in the Python language for the following reasons:

- Substantial libraries

Actualization of AI algorithms with ML is very difficult to implement, cumbersome and time-consuming. Python libraries and frameworks are used in programming and reduce the complexity of the program, which makes it simpler and more flexible.

- Compact and Elementary

Python acknowledges the programmers to develop a solution that is trustworthy instead of highlighting the practical.

B. *SHAP (SHapley Additive Explanations)*

In XAI techniques, SHAP is a very functional tool that can be used to evaluate the precise value of an attribute in forecasting. The SHAP values represent the difference between the actual forecasting of the result and the average forecasting of the model. The altar in the forecasting of the predicted model is represented by the SHAP values for each and every attribute when forcing the condition on a feature.

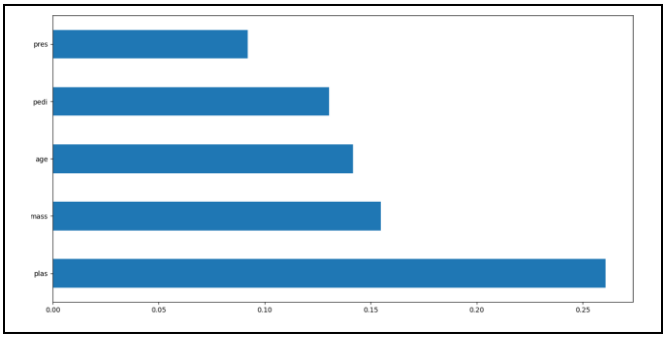

Fig. 5. Global variable importance.

In Fig. 5, it is clearly observed that the plasma glucose variable has the highest influence in the model, followed by mass and age and Fig. 6, describes the SHAP values with all attributes with two classes.

Fig. 7 clearly depicts how individual attributes subscribe to the average or standard model forecasting on a global level. The y-axis on the right side represents whether the relevant value of the feature is low or high. The instances of data are represented by each dot sign.

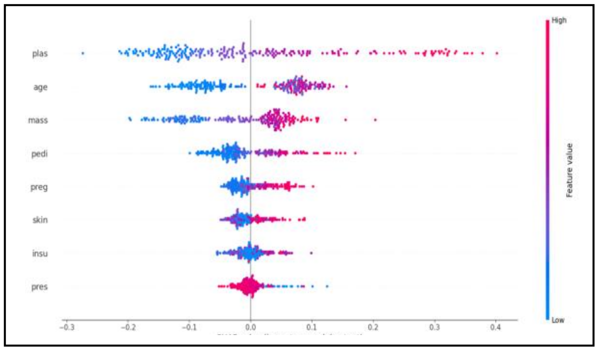

Fig. 6. Mean SHAP value.

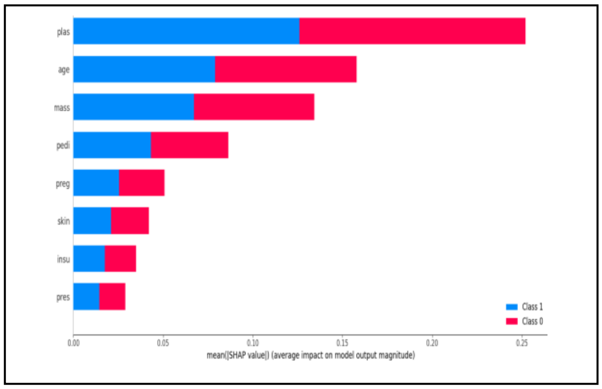

Fig. 7. SHAP value of the model.

C. *LIME (Local Interpretable Model-Agnostic Explanations)*

What ML model is currently being used by the programmer that will be explained by a tool is known as LIME. LIME endeavours to embrace the model by making differences in input data and scrutinizing the revised prediction in altered input data. The questionnaires below are the key ingredients of LIME.

- Which attribute steers to predict a particular specimen of data and changes the entire output as an alteration?
- Why did this anticipation take place?

The Fig. 8 describes here the class names that tested positive and tested negative and fit the explainer on the training data set using the lime tabular explainer and perform the explanation on the 8th instance in the test data, Fig. 9. The output describes the local LIME model intercept of 0.3580, and LIME model prediction is 0.3960 (Prediction local). The original random forest model prediction is 0.3051 and with the prediction explanations of intercept 0.3644 and prediction local is 0.3892.

V. Using XAI upgradation of Health Care System

- Conventional Health Care System

This healthcare system provides care and proper planning for the treatment of chronic diseases. This system provides a plan for proper care and treatment and accomplishes the goal of boosting the care of patients. It may consist of several important components as follows:

Information system based on clinical data

Organizational health system

Treatment system design

Right decision support system

Self-decorum action

Resource management of the community

- Obstacles with Traditional Healthcare Systems

It may consist of several important components -

Mistakes and lapses in clinical reports

Financial obstacles of patients

Lack of self-caring patients

Insufficient knowledge and a lack of proper training of health workers

- Usage of Explainability

XAI may be implemented in the following ways with auspicious technology for the management of chronic health care.

By using ML models, we can minimize errors and improve the accuracy precision.

Chronic healthcare management can be properly managed by a decision support system, as all the components are explainable.

Explainable AI optimizes the cost and provides relevant inferences and predictions with proper explanations for accurate results.

Explainable AI also suggests hypothetical information that notifies about the applicable alteration in a feature for accuracy.

Therefore, it is necessary, such as in India, to build an XAI system in hospitals for the proper diagnosis of chronic diseases such as diabetes.

VI. Conclusion

Importance of XAI is that XAI helps to predict the diagnosis of chronic disease. In the case of diabetic pregnancies, plasma glucose and age have been identified as the most important features based on the Pima Indian Diabetes Data set (PIDD), and the SHAP value is used for concise dependencies and visualizations of trends. LIME is applicable when anchors and importance of features are both required simultaneously. A correlation heatmap helps to identify dependencies of different attributes. Dependency plots help doctors visualize independent relationships with predicted classes.

The present work explains the utility of the XAI technique with only 768 limited clinical data. In future research wishing to work with more clinical data in different ways, XAI may be used for automatic diagnosis.

From an academic perspective, XAI works are far from the authentic medical framework, which is essential for development in the near future. Correspondence studies are necessary to estimate the presentation of recommended proposals in other applicable data sets. To a greater extent, refinement in the accomplishment of the model and explainability will endeavor using various algorithms in machine learning to furnish different types of accumulation models.

Research on the Text Classification of Legal Consultation Based on Deep Learning

ZuoQiang Du
School of Computer and Information Engineering,
Harbin University of Commerce,
Harbin, China

***Abstract*—In view of the existing traditional legal service, practitioners are unable to meet the huge demand; a large number of citizens are unable to determine the scope of the problems when they encounter infringement or require various legal assistance. Based on this, an automatic classification model of legal consultation based on Deep Learning is proposed in this paper. A KP+BiLSTM+Attention model is proposed. The Keyword Parser is introduced to extract key information. TF-IDF and part of speech tagging are used to filter out the important information in the user's legal problem description. The extracted keywords are given a weight value, and the other information weights are set to zero. The text information is transferred into two parallel word vector embedding layers. One of the word vector embedding layers transfers the results to the fusion layer for splicing, difference and point multiplication after the key information is converted into vector form. The output results are respectively connected with the results obtained from the other embedding layer as residuals. The final results are transferred to the BiLSTM+Attention model for training. The test results show that KP+BiLSTM+Attention model has significantly improved the accuracy and F1 value of the best benchmark method for text classification tasks of legal consulting. Therefore, KP+BiLSTM+Attention method has better performance in dealing with the classification of legal consulting issues.**

Keywords—Text classification; legal consultation; deep learning; KP+BILSTM+ATT model; word embedding layer

I. Introduction

Legal consultation is to determine the scope of the problem encountered by the public and to provide legal solutions applicable to the relevant field. How to put forward effective opinions and suggestions quickly and effectively for their own problems is the focus of people's attention, and it is also an important issue facing the popularization of legal awareness [1][2][3]. In view of this problem, the demand of users is classified correctly for lawyer advice is the first task. Because it can complete automatically the classification and recognition of text information [4][5][6], Deep Learning (DL) is widely used in the field of Natural Language Processing (NLP) [7][8][9][10]. The problem category is determined accurately after adaptive training according to relevant information of legal provisions and customer problem descriptions [11][12][13].

Text classification is a basic work in the field of NLP, which aims at classifying text information [14][15][16][17]. Salton [18] proposed the word vector space model. However, this model needed to define a large number of rules for each category which were highly dependent on the professionals. The Q-AND-A method based on knowledge graph had achieved good results in the fields of public security information analysis, medical consultation and drug prescribing [19]. Zhang [20] used the fine-granularity question and answer model based on Bi-LSTM+CRF to select entities. Li [21] used the entity recognition model based on Bi-LSTM+CNN+CRF to establish a human-computer interactive question and answer system to improve the employment rate. In the legal field, a question and answer system was proposed based on the legal field by Huang [22], which introduced a small number of samples and a transfer learning model. Zhang et al. [23] introduced DL into the legal judgment task, and a better effect was achieved in the open data set of the real legal judgment prediction task.

In this paper, the original word segmentation algorithm TF-IDF is improved, and combined with the DL model. The brand new Keyword Parser (KP) is proposed based on common keyword extraction approach. Firstly the Chinese word segmentations are calculated based on TF-IDF, and the weights assigned according to the degree of importance. Then, it enhances the extracted key information according to part-of-speech screening, and the important words in each piece of data can be further screened and retained. The retained information is passed to two embedding layers at the same time. The fusion layer embedded in one embedding layer will process the incoming data by splicing and dot multiplication, and the results will be passed to the other Embedding one as the residual connection to improve the credibility of the information. Finally, the classification results were obtained by training Bi-LSTM+Attention model. Based on the legal consultation database, comparing common Machine Learning (ML) text classification models and DL text classification models, the experimental results show that KP-BiLSTM+Att model performs better on the legal consulting data set.

II. Structure of KP-BiLSTM-Att Model

A. Chinese Segmentation

Unlike English words, which are naturally separated by spaces, Chinese takes words as the basic unit and there is no obvious separation mark between words [24]. The main task of Chinese word segmentation [25] is to divide a complete sentence into individual words. There are three main types of mainstream Chinese word segmentation methods: word segmentation based on string matching, word segmentation based on understanding and word segmentation based on statistics [26]. In this paper, jieba segmentation is used as a word segmentation tool, and the sentence is cut into data information *X* using the built-in precise mode.

B. Structure of Legal Consultation Text Classification Approach Based on KP-BiLSTM-Att

The overall structure of the legal consultation text classification approach based on KP-BiLSTM-Att proposed in Fig. 1.

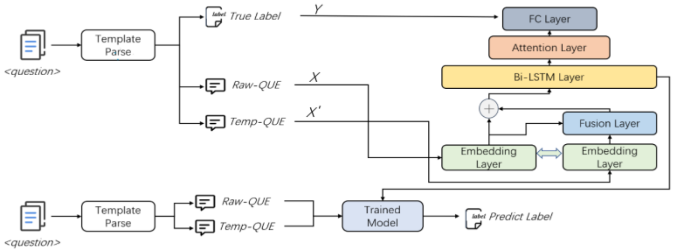

Fig. 1. Structure of the legal consultation text classification based on KP-BiLSTM-Att.

The text information *X* which has not been processed and the information *X*` which has been processed by keyword processors are passed into the two embedding layers for vectorization operations. A fusion layer is added to the embedding layer that is responsible for dealing with *X*' to carry out vector operations on the vectorization results of *X* and *X*', and then the results are connected with *X* as residuals. The vector results are passed into the BiLSTM+Attention model for training. The training results were used by linear layer and softmax function to predict the scope of legal consulting problems. Finally, Focal Loss is introduced to solve the unbalance problem of all kinds of samples in the dataset.

III. Model Training Stage

There are four modules during model training stage: Keyword Parse, two parallel embedding layers, Bi-LSTM layer and attention layer.

The main task of the KP is to receive the pre-processing results, and obtain the keyword information of the problem description by TF-IDF algorithm and [mask] label. Two parallel word embedding layers receive the original word segmentation result *X* and the keyword information *X′* after processing by the KP respectively. Meanwhile, a fusion layer is added the word embedding layer which is receiving *X*' to calculate the output vector information of two embedding layers. The final calculation results are passed into Bi-LSTM layer and attention layer for training.

A. Keyword Parser

In this module, the text information obtained after data preprocessing is received by the parser, and the weight value of each word in the word segmentation result about the category is calculated based on TF-IDF. The importance of each word for the category is obtained. Then, with the idea of part-of-speech tagging [27], all words are labeled with a correct part of speech, that is, each word is a noun, verb, adjective or other part. The part-of-speech tagging method based on statistics is adopted in the process of part-of-speech tagging [28].

The parser retains nouns, verbs, and adjectives, and it masks all the results of word segmentation other than the above parts of speech with the [mask] tag to get *X*'. The purpose of masking other parts of speech words is to keep the words that are helpful to the classification accuracy (that is, the words with the high TF-IDF values) and keep their original positions unchanged, so as to avoid the dislocation phenomenon in the subsequent weight addition, and improve the efficiency and accuracy of model training. The operations performed by the KP are shown in Fig. 2.

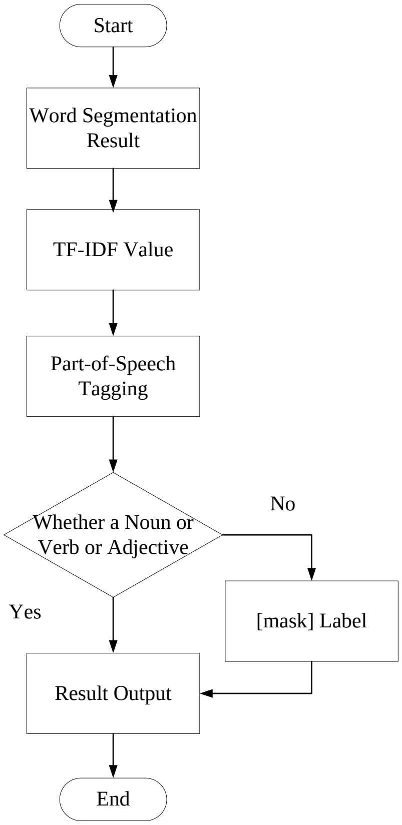

Fig. 2. Operations performed by KP.

B. Word Embedding Layer

The main task of embedding layer is to receive the text information *X*' which is the output by the KP and the unprocessed word segmentation result *X*. The text information of two incoming models make vectorial operation through two embedding layers respectively, and the data from the text information would be transformed to the computer recognizable vector information, meanwhile the relationship vector between different words obtained.

Compared with the traditional high-dimensional sparse feature matrix, the embedding can represent a word with low-dimensional vector and calculate the distance between this one and other words, so as to determine whether the two words are semantically similar.

In this paper, the two embedding layers are used to receive the text information *X* without the KP information and the text information *X*' with KP information respectively. The word embedding layer received *X* information will directly reduce the dimension of the information through the transformation of high-dimensional image and low-dimensional. The other word embedding layer converts *X*' into vector form after random initialization, and passes the results into the fusion layer [29] for concatenation, difference and dot multiplication operations with the vectorization result of *X*. The obtained result and the X result are respectively connected by residual to improve the information weight value.

There are a large number of [mask] labels in *X*', which will be directly set to 0 in the vector during the operation. The difference between keywords and non-keywords has been increased by the operations above, which is conducive to the subsequent model training. The structure of the word embedding layer is shown in Fig. 3.

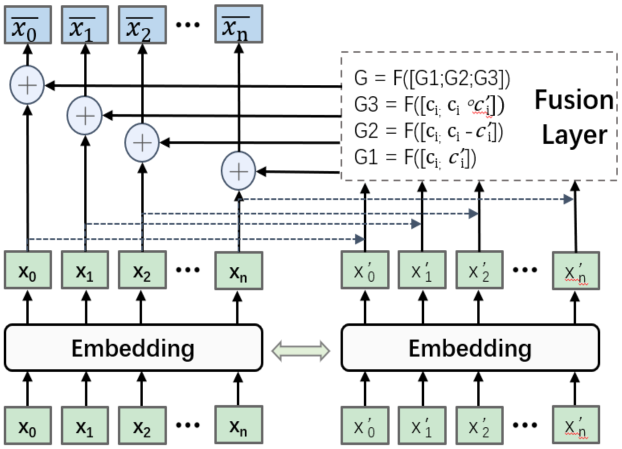

Fig. 3. Structure of the embedding layer.

C. Bi-LSTM+Attention Layer

Bi-LSTM is an improved model based on LSTM. In fact, two LSTM process the sequence from the forward direction and the reverse direction respectively, and the results of the two directions are combined to obtain a new vectorized result which will pass to the attention layer to assign different attention values [34]. Finally, the loss function in the fully connected layer is used to calculate the category. The structure of BiLSTM+Attention layer is shown in Fig. 4.

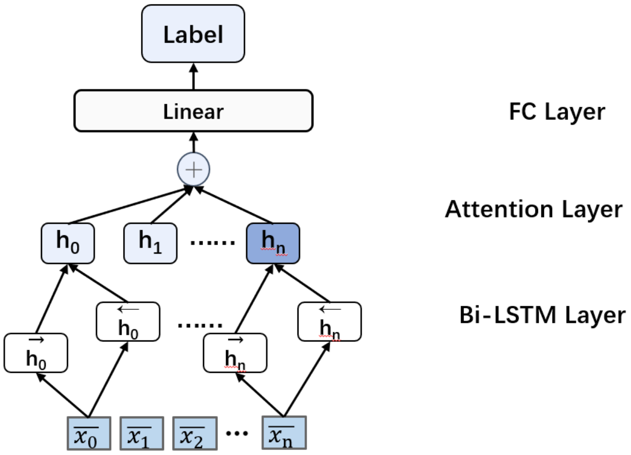

Fig. 4. Structure of BiLSTM+Attention layer.

Bidirectional LSTM is the LSTM Neural Network structure that combines the vector information obtained in the forward direction and the reverse direction on the basis of the LSTM processing sequence information in the reverse direction, and computes the new vector results. Fig. 5 shows the structure of bidirectional LSTM [35].

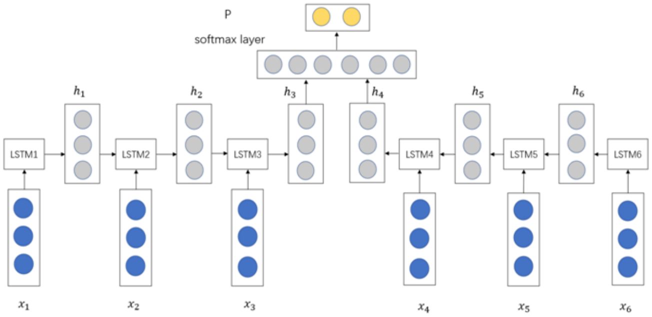

Fig. 5. Structure of bidirectional LSTM.

The new vector obtained by bidirectional LSTM is passed into the attention layer to calculate the attention weight of each word vector through the self-attention mechanism. The self-attention mechanism not only helps the current node focus on the current word, but also obtains contextual semantic information.

Self-attention will calculate three new vectors: Query, Key and Value, which are obtained by multiplying the word embedding vector and the random initialization matrix. Then, Query and Key will be dot-multiplied to get the weight, which is the score of self-attention. When we encode a word, the score of the self-attention determines how much attention is paid to the input sequence:

$$f(Q,K_i)=Q^{\mathrm{T}}K_i \quad (1)$$

The correlation size of each word for the current position will get by a softmax calculation:

$$\alpha_i = soft\max(f(Q,K_i)) = \frac{\exp(f(Q,K_i))}{\sum_j f(Q,K_j)} \quad 2)$$

Value and softmax are multiplied and added together to obtain the attention value of the current node. The units in each sequence are made attention calculating with all the units in the sequence to obtain the self-attention value.

$$Attention(Q,K,V)=softmax(\frac{QK^{\mathrm{T}}}{\sqrt{d_k}})V \quad (3)$$

where QK^{T} is the attention matrix, and $\sqrt{d_k}$ is the conversion from the attention matrix to a standard normal distribution. Multi-Head Attention mechanism is to carry out multiple attention operations, so that the model has multiple attention values with the same structure but different weights.

$$head_i = A(Q,K,V) \quad (4)$$

$$MultiHead(Q,K,V)=Concat(head_1,head_2,\ldots\ldots,head_n)W^Q \quad (5)$$

The vector obtained after vector operation by bidirectional LSTM Neural Network and self-attention mechanism can remember the semantic information of context well, and the accuracy of classification results is higher.

D. Focal Loss Based on Class Balance

Due to the unbalanced distribution of legal problems, Focal Loss [30] is introduced as an effective method to solve the problem of unbalanced quantity of different samples in data sets. Focal Loss can reduce the weight of easily classified samples to make the model pay more attention to difficult classified samples in training. The traditional cross entropy loss should be improved by this approach.

As an example of taking binary classification, the loss function of cross entropy is shown as (6).

$$CE(p,y)=\begin{cases}-\log(p) & \text{if y=1}\\ -\log(1-p) & \text{otherwise}\end{cases} \tag{6}$$

where $p\in[0,1]$ is the classification probability. p_t is the probability that the sample belongs to the true class.

$$p_t=\begin{cases}p & \text{if y=1}\\ 1-p & \text{otherwise}\end{cases} \tag{7}$$

The size of p_t can reflect the degree of difficulty of sample classification. In the training process, the model should pay more attention to hard-to-classify samples, so the proportion of these kinds of samples should be increased.

Focal Loss adds an item to the binary classification cross-entropy loss function to attenuate the original cross-entropy loss, which reduces the weight of easily classified samples to focus on the training of difficult samples. At the same time, in order to solve the imbalance of positive and negative samples, a weight factor $\alpha\in[0\ \ 1]$ will be added to each category of the loss function to coordinate the class imbalance. The improved Focal Loss function formula is shown in (8).

$$FL(p_t)=-\alpha(1-p_t)^{\gamma}\log(p_t) \tag{8}$$

where $\gamma\geq 0$ is an adjustable focusing parameter, and the larger the value of γ, the smaller the loss of easily classified samples, A larger γ will expand the samples range which have small loss. When γ>1, Focal Loss can reduce the loss of easy to classify samples, but not much for difficult to classify samples. When γ=0, the Focal Loss formula becomes a cross-entropy loss function.

E. FGM and R-Drop Based on Confrontation Training

1) FGM: Because of the linear characteristics of Neural Network, it is easily attacked by linear disturbance. The concept of Adversarial training [31] is proposed to improve the robustness of the model. Adversarial training is to add a disturbance r_{adv} to the original sample x, and then train the model with the adversarial sample. The disturbance is increasing in the direction of increasing the loss.

The perturbation definition formula is shown as (9).

$$\mathrm{r}_{adv}=\varepsilon\cdot\mathrm{sgn}(\nabla_x L(\theta,x,y)) \tag{9}$$

where sgn() is the sign function and *L* is the loss function. If the input sample is further moved in the direction of rising loss, the resulting adversarial sample can cause greater loss and improve the error rate of the model, so as to meet the requirement that adding small disturbance to the adversarial sample can make the model judgment wrong.

Madry [32] redefined the problem as a saddle point finding problem from the perspective of optimization:

$$\min_\theta E(x,y)\sim D[\max_{r_{adv}\in S} L(\theta,x+r_{adv},y)] \tag{10}$$

where *S* is the range of perturbations. θ is the internal parameter of the model, *D* is the distribution of input samples, and x and y correspond to the input and output respectively. There are two parts of this formula: the internal loss function maximization and the external empirical risk minimization. The internal maximization is to obtain the disturbance parameter in the most serious case of model misjudgment, and external risk minimization is to find the parameters that make the model the best robust for internal attacks. The disturbance increased by FGM is:

$$r_{adv}=\varepsilon\cdot\frac{g}{\|g\|_2} \tag{11}$$

$$g=\nabla_x L(\theta,x,y) \tag{12}$$

The new adversarial sample is:

$$x_{adv}=x+r_{adv} \tag{13}$$

2) R-drop: Another way to improve model robustness and generalization is R-drop. Although the traditional Dropout is often used to regulate the training of Deep Neural Networks, its practice of randomly dropping some neurons lacks explanation, resulting in inconsistencies between training and reasoning.

R-drop construes the output consistency of the random submodel due to Dropout through KL divergence. The formula for the R-drop method to apply regular constraints on the output prediction is:

$$L_{KL}^{i}=\frac{1}{2}(D_{KL}(P_i(y_i\mid x_i)\,\|\,P_2(y_i\mid x_i))+D_{KL}(P_2(y_i\mid x_i)\,\|\,P_1(y_i\mid x_i))) \tag{14}$$

Since Dropout randomly drops a few neurons at one time, both probability values of $P_1(y_i\mid x_i)$ and $P_2(y_i\mid x_i)$ are predicted probabilities derived from different submodels of the same model. The difference between these two prediction probabilities is constrained with uses the symmetric KL divergence.

$$L_{NLL}^{i}=-\log P_1(y_i\mid x_i)-\log P_2(y_i\mid x_i) \tag{15}$$

The final loss function is:

$$L_{NLL}^{i}=L_{NLL}^{i}+\alpha\cdot L_{KL}^{i} \tag{16}$$

where α is the coefficient used for control L_{KL}^{i}. Compared with the traditional Dropout, a regular constraint term is introduced to improve the robustness of the model and reduce the inconsistency of the model output.

F. GHM Loss and Dice Loss

Although Focal Loss introduced is considered to be more suitable as a loss function to solve the problem of unbalanced sample data sets, the experimental results of the task in this paper are slightly short of the cross-entropy loss function, which may be due to the phenomenon of category imbalance in the data set. However, in the classification process, it is difficult to classify many samples, which leads to a large loss value of Focal Loss, and the small number of samples in individual categories led to the failure of Focal Loss to give full play to its performance.

GHM Loss is an improved approach based on Focal Loss. Focal Loss is mainly the unbalanced distribution of difficult and easy samples [33], while GHM Loss believes that not all difficult samples are worthy of attention. It adopts a gradient harmonic mechanism and abandons some outliers by formula calculation.

A new gradient norm is introduced by binary cross entropy loss function.

$$L_{CE}(p,p^{*}) = \begin{cases} -\log(p) & \text{if } p^{*}=1 \\ -\log(1-p) & \text{if } p^{*}=0 \end{cases} \tag{17}$$

where p=sigmoid(x) is the category probability of the model prediction sample and p* is the label information. The gradient with respect to x can be calculated by the formula (18).

$$\frac{\partial L_{CE}}{\partial x} = \begin{cases} p-1 & \text{if } p^{*}=1 \\ p & \text{if } p^{*}=0 \end{cases} = p - p^{*} \tag{18}$$

The gradient norm is defined as:

$$g = | p - p^{*} | = \begin{cases} 1-p & \text{if } p^{*}=1 \\ p & \text{if } p^{*}=0 \end{cases} \tag{19}$$

Intuitively, g represents the distance between the real values and the predicted ones of the sample. The gradient mode norm distribution after convergence of the binary classification model is shown in Fig. 6.

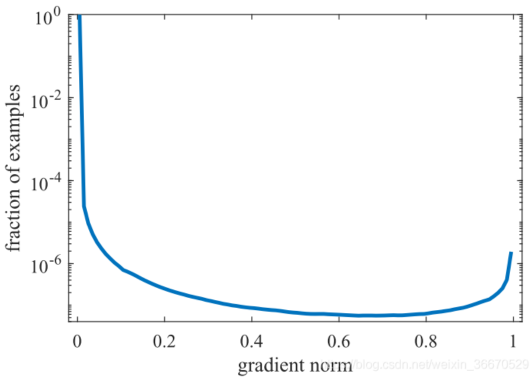

Fig. 6. Gradient norm distribution of the binary classification model.

After logarithmic scaling, the samples close to the y axis are 'easy to classify', while those close to the x=1 axis are 'very difficult to classify', and the middle parts represent 'difficult to classify'.

It is standardized according to the proportion of the gradient mode norm of the samples, so that all kinds of samples have a more balanced contribution to the model parameters. Since gradient equalization essentially changes the contribution by weighting the gradients generated by different samples, and the contribution is added to the loss value can also achieve the same effect. The gradient density is defined as the number of samples distributed within the unit value region.

$$GD(g) = \frac{1}{l_{\varepsilon}(g)} \sum_{k=1}^{N} \delta_{\varepsilon}(g_{k}, g) \tag{20}$$

where g_k represents the gradient of the k sample, and:

$$\delta_{\varepsilon}(x,y) = \begin{cases} 1 & \text{if } \text{y-}\frac{\varepsilon}{2} \le x \le y + \frac{\varepsilon}{2} \\ 0 & \text{otherwise} \end{cases} \tag{21}$$

$$l_{\varepsilon}(g) = min(g + \frac{\varepsilon}{2}, 1) - max(g - \frac{\varepsilon}{2}, 0) \tag{22}$$

Define the density coordination parameter β:

$$\beta_{i} = \frac{N}{GD(g_{i})} \tag{23}$$

where N represents the number of samples. It can ensure that the weight value is 1 when the distribution is uniform or only one unit area is divided, that is, the loss is unchanged. It can be seen that the weights of samples with high gradient density will decrease. The definition of loss function obtained by applying GHM idea to classification problem is shown as (24).

$$L_{GHM} = \frac{1}{N} \sum_{i=1}^{N} \beta_{i} L_{CE}(p_{i}, p_{i}^{*}) = \sum_{i=1}^{N} \frac{L_{CE}(p_{i}, p_{i}^{*})}{GD(g_{i})} \tag{24}$$

According to (24), the weights of the easily classified negative samples and the extremely difficult classified samples in the candidate samples will be reduced, and the loss value will also be reduced and the impact on model training will be reduced. The weight of the normal hard-to-classify samples will be increased, so that the model will pay more attention to the normal hard-to-classify samples to improve the model performance.

However, GHM Loss is more used in binary classification problem of target detection, and there may be errors in judging extremely difficult samples in multiple classification tasks. At the same time, there might exist a problem that too many hard-to-classify samples are discarded as outliers; will lead to inadequate training. Therefore, the training effect of the model is still inferior to that of the cross-entropy Loss function, and even the experimental effect is lower than that of Focal Loss due to the operation of directly discarding outliers.

Dice Loss, inspired by Dice Coefficient (DSC), was first proposed to apply loss function in the field of image segmentation [33] to solve the problem of pixel sample imbalance in image segmentation.

In this paper, the loss function is transferred to the text classification task to verify whether it can be applied to the field of NLP through experiments. The DSC coefficient is used to evaluate the similarity of two sets.

$$DSC(A,B)=\frac{2|A\bigcap B|}{|A|+|B|} \tag{25}$$

where *A* represents the set predicted by the model as a positive category, and *B* represents the set with a true label as a positive class. Dice Loss directly optimizes F1-score:

$$DSC=\frac{2TP}{2TP+FN+FP}=\frac{2\Pr e\times \operatorname{Re} c}{\Pr e+\operatorname{Re} c}=F1 \tag{26}$$

where *TP*, *FP*, *FN* are discrete values, and the DSC coefficient is based on discrete values. For a sample, the continuous form of DSC coefficient can be defined as follows:

$$DSC(x)=\frac{2p_1y_1}{p_1+y_1} \tag{27}$$

where y_1 represents the label value of a positive sample, and p_1 represents the prediction probability of a positive model sample. If the sample is positive, the higher the prediction probability is, the higher the DSC value is. When the sample is a negative class and the molecule is 0. In order to preserve the value of the DSC coefficient of the negative class, the smoothing term γ is added.

$$DSC(x)=\frac{2p_1y_1+\gamma}{p_1+y_1+\gamma} \tag{28}$$

The greater the DSC value is, the more accurate the prediction is, and we convert the formula to a loss.

$$DSC(x)=1-\frac{2p_1y_1+\gamma}{p_1+y_1+\gamma} \tag{29}$$

Since DSC coefficient is a metric function to measure the similarity of two samples, the larger the positive sample *p* is, the larger the DSC value is, indicating that the more accurate the model prediction is, the smaller the loss should be at this time. Therefore, the final form of Dice Loss is shown as (30).

$$DL=1-\frac{2p_1y_1+\gamma}{p_1^2+y_1^2} \tag{30}$$

Dice Loss has a good performance for the scene where the positive and negative samples are seriously unbalanced, and pays more attention to the prediction of the foreground region in the training process. But the value of training losses is highly volatile.

The reason Dice Loss can solve the problem of sample imbalance is mainly because it is a loss related area , that is, the loss of the current pixel is related not only to the predicted value of the current pixel, but also to other points. The intersection form of Dice Loss can be understood as the operation of mask.

Therefore, no matter how large the picture is, the loss value calculated for a positive sample area of fixed size is the same, and the supervision contribution to the network will not change with the picture size.

Experimental results show that Dice Loss is not as good as cross entropy loss function, which may be due to the fact that the loss value calculated by the loss function is not stable enough. When the loss function is used in the case of only foreground and background, the loss value of a small target will change drastically when there is a partial prediction error, resulting in a drastic change in gradient. For example, considering that there is only one positive sample in the extreme case, as long as the prediction is correct, the loss value will be close to 0, while the loss of the prediction error will be close to 1. The cross entropy loss function is equal in dealing with positive and negative samples and averaging the population, so it is more stable than Dice Loss.

In addition, the above three loss functions are first proposed in the field of image processing, and the difference between image information and text information is also the reason for the unsatisfactory results. Therefore, through experiments, it is believed that the cross-entropy loss function combined with the model can achieve the best results of the experiment in this paper.

IV. Example Analysis

A. Subjects

The subjects of our experiments come from the open-source data set on github website. There are a total of 200,000 legal Q&A pairs of 13 types of questions, which are put forward and recorded by customers who need legal consulting services. We mainly conduct classification experiments through two aspects of problem description and problem classification. After deleting some categories with fewer cases in the data set, a total of 190,000 data are retained in the experiment, corresponding to 11 different categories.

The names of 11 categories and their distribution in the training set and test one are shown in Table I. There are a total of 152,000 descriptions of legal issues. The average length is 23.918, among which the descriptions of legal problems with text length of 28 characters is the most, the descriptions with text length of 32 characters account for 81.377%, the descriptions with 50 characters account for 98.204%, and the ones with 150 characters account for 99.926%.

There are 19,000 descriptions of legal problems in the test set, with an average length of 23.723, among which the descriptions of legal problems with text length of 28 characters are the most, the descriptions with 32 characters account for 81.311%, the descriptions with 50 characters account for 98.437% and the ones within 150 characters account for 99.921%. It can be seen that most legal advice texts are within 32 characters.

B. Evaluation Index

In this paper, the classification task of legal consulting texts is modeled as a multi-classification problem. In order to compare the performance of the KP-BiLSTM-Att model method proposed and the baseline model approaches, a unified measurement standard is needed. Therefore, we select the evaluation indexes commonly used in Machine Learning to deal with text classification: Accuracy, Precision, Recall and F1-score.

Accuracy $A(i)$ is the proportion of the number of correctly predicted samples to the total number of samples in the dataset:

$$A(i) = \frac{TP_i + TN_i}{TP_i + TN_i + FP_i + FN_i} \quad (31)$$

The accuracy rate $P(i)$ is the proportion of correctly predicted positive samples to the predicted positive samples in the dataset.

$$P(i) = \frac{TP_i}{TP_i + FP_i} \quad (32)$$

The recall rate R(i) is the proportion of the sample in which the positive sample was correctly predicted.

$$R(i) = \frac{TP_i}{TP_i + FN_i} \quad (33)$$

The $F1(i)$ value is the weighted harmonic average of the $P(i)$ and $R(i)$.

$$F1(i) = \frac{2 \times \mathrm{Re}call(i) \times \mathrm{Pr}ecision(i)}{\mathrm{Re}call(i) + \mathrm{Pr}ecision(i)} \quad (34)$$

C. Analysis of Experimental Results

From four traditional ML methods, we choose Term Frequency–Inverse Document Frequency (TF-IDF), Naive Bayes model (NB), Support Vector Machine (SVM) and Random Forest (RF) as the baseline methods, and three other models of TextCNN, TextRCNN and Transformer models from Deep Neural Networks.

For the implementation of the benchmark approaches, the classification method based on ML is repeated through sklearn library and XGBoost library. In order to make a fair comparison of their performances, the same word segmentation methods were used to divide the data set. The results of various indicators were shown in Table II, Table III, Table IV and Table V respectively.

Table II shows the comparison of the Accuracy results of the KP-BiLSTM-Att approach proposed in this paper with other benchmark methods on the test set. According to the experimental results, the Accuracy of KP-BiLSTM-Att is higher than others in terms. Ours test result is improved by 4.3% of the performance of TF-IDF algorithm, which has the best performance among Machine Learning text classification algorithms. Ours is improved by 1.2% of TextRCNN which has the best performance among DL text classification algorithms.

In addition, we also tried to use TextRNN model in the experiment, but because the problem description content in the data set was too long, TextRNN could not train long-distance text well, resulting in low accuracy. It also confirmed that the effect of BiLSTM Neural Network is better than the commonly used TextCNN and TextRNN Neural Network structure. According to the Accuracy index alone, KP-BiLSTM-Att approach performs better than other benchmark methods in the task of legal consulting text classification

Table III, Table IV, and Table V show the Precision values, Recall values, and F1-score values of KP-BiLSTM-Att approach and other baseline methods in each category.

Since there is a pair of contradictory indicators for Accuracy rate and Recall rate, it is difficult to reach high values at the same time. Therefore F1-score is finally selected as the model performance evaluation index.

According to the experimental results of F1-score, KP-BiLSTM-Att approach proposed in this paper reaches the optimal values in 8 out of 11 categories. In the category of traffic accidents, KP-BiLSTM-Att has increased by 0.8% compared with the baseline model with the best performance. In the category of bond debts, ours has increased by 0.8% compared with the best one; and in the category of marriage and family, this method has increased by 1.4% compared with the best one. In the category of company law, KP-BiLSTM-Att has increased by 3.4% compared with the baseline model with the best performance. Compared with the best-performing baseline model in the contract disputes category, KP-BiLSTM-Att has increased by 2.3%, and compared with the best-performing model in the relocation and resettlement category, ours has increased by 0.3%. In the category of medical dispute, KP-BiLSTM-Att has increased by 13.1%, and it has increased by 0.3% in the category of labor dispute.

In the other three categories that do not reach the optimal value, KP-BiLSTM-Att approach is also stronger than most of the baseline methods, and the weakness stems from an imbalance in the number of samples in different categories. It can be considered that combined with the comprehensive evaluation of Accuracy and F1-score, the superiority of KP-BiLSTM-Att method in the classification task of legal consulting texts is preliminarily confirmed.

Then, weighted average processing is performed for all indicators of the proposed method, and the results are shown in Table VI.

TABLE VI. EVALUATION INDEX BASED ON WEIGHTED AVERAGE

Approaches	Evaluation Index			
	Accuracy	Precision	Recall	F1-core
TF-IDF	0.755	0.750	0.755	0.751
NB	0.682	0.691	0.682	0.637
SVM	0.751	0.743	0.751	0.734
RF	0.721	0.712	0.721	0.725
TextCNN	0.768	0.758	0.769	0.769
TextRCNN	0.787	0.781	0.783	0.782
Transformer	0.783	0.777	0.783	0.779
Ours	**0.798**	**0.782**	**0.798**	**0.794**

Combined with the weighted average evaluation indicators, all evaluation indicators of KP-BiLSTM-Att have reached the optimal values, among which Accuracy index has increased by 1.1%, Precision index by 0.1%, Recall index by 1.5%, and F1-score index by 1.2%. The experimental results prove that KP-BiLSTM-Att approach can achieve better classification performance than the traditional ML text classification method and the common reference method of DL text classification Neural Network model.

V. CONCLUSIONS

In this paper, KP-BiLSTM-Att model is proposed and applied to the task of classifying legal consulting texts. The preprocessed data set text is passed into the Keywords Parser, and all the results of word segmentation are weighted by TF-IDF and the result is defined as *X*. Meanwhile, all the parts of speech of the results of word segmentation are marked, processed by [mask], and the result is output as *X*'. *X* and *X*' are passed into the two word embedding layers respectively, and the adversarial training FGM algorithm is added to add disturbance to the vector quantization results to improve the robustness of the model. The R-drop method was introduced into the BiLSTM structure of deep learning to accelerate model training and improve model generalization ability. Then, the Focal Loss function method based on class balance was introduced to solve the unbalanced data set samples in multiple classification tasks and improve the classification accuracy.

The performance of KP-BiLSTM-Att method is compared with seven popular machine learning and deep learning methods. Experimental results show that the Accuracy index of KP-BiLSTM-Att method is 4.7%, 11.6%, 7.7% and 4.3% higher than that of TF-IDF, NB, SVM and RF algorithm in traditional ML classification methods, respectively. Compared to common DL baseline models, the KP-BiLSTM-Att approach offers a 3.0%, 1.1%, and 1.5% improvement over TextCNN, TextRCNN, and Transformer respectively. The test results show that KP+BiLSTM+Attention model has significantly improved the accuracy and F1 value of the best benchmark method for text classification tasks of legal consulting. It can be seen that KP-BiLSTM-Att method has better performance in the classification of legal consulting texts.

There is still some follow-up work for improvement in this research. 1) Different data sets of legal consulting texts and other commonly used data sets in the field of text classification will be presented to verify the feasibility of this model. At the same time, it is considered whether the model can be applied to other related tasks in the legal field through experiment to test whether better results can be obtained. 2) More advanced deep learning models will be used to improve the overall structure and further improve the classification accuracy and operation efficiency of the model. 3) Other methods will be explored to improve the performance of unbalanced data samples and improve the overall classification accuracy of the model.

***Abstract*—Continuous software engineering is a new trend that has attracted increasing attention from the research community in recent years. In software engineering there are "continuous" stages that are used depending on the number of artifact repositories such as databases, meta data, virtual machines, networks and servers, various logs, and reports. Augmented Reality (AR) technology is currently growing rapidly. We can find this technology in various fields of life, but unfortunately sustainable software engineering for Augmented Reality is not found. The method shown in previous research is a general method in software engineering so that a theory is needed for sustainable software engineering for AR considering that AR is not just an ordinary application but there are 3D elements and specific components that must be met so that it can be called AR. The main idea behind this research is to find a continuous pattern from the stages of the existing method so far. For example, in general the stages of system development are planning, analysis, design, implementation and maintenance. Then after the application has been built, does it finish there? As we know software always grows and develops according to human needs. Therefore, there are continuous stages that must be patterned so that the life cycle process can be maintained. In this paper we present our initial findings about the continuous stages of continuous software engineering namely continuous planning, continuous analysis, continuous design, continuous programming, continuous integration, and continuous maintenance.**

Keywords*—Continuous software engineering; augmented reality; method in software engineering; continuous planning; continuous analysis; continuous design; continuous programming; continuous integration; continuous maintenance

I. Introduction

Continuous software engineering is performed to avoid discontinuities between development and deployment to continuously perform continuous development [1]. Continuously means without interruption, so the application delivery processing time can be maintained [2]. In continuous software engineering, software developers can flexibly implement several changes from coding, testing and deployment so that if there are problems such as detecting bugs, requesting changes and other unexpected actions will be resolved more quickly. In addition, developers can also test more often and implement some changes. Instead of creating new code, developers can leverage code from an already developed version of the software. All changes or additions to the code will be integrated and then tested for functionality. If it passes, the deployment process produces output in the form of the latest version of the application. In this case, all parties are involved in collaborative development until the software is ready for release [3].

A method is a systematic way or technique used to do something. Methods can be applied to one or more of the existing processes in the methodology. Meanwhile, methodology is a unity of methods, rules and stages used by science, art, and other scientific disciplines [4]. From this understanding, systematic and regular steps are needed in solving problems with the purpose of clearly know the procedures and sequences taken [5]. Thus, the results of problem solving can be optimal. To build software engineering, it is necessary to have automatic or semi-automatic support for carrying out the method so that computer-assisted software engineering can be built [6]. In practice, however, it is often the case that using the same methods does not produce the same results or, in other words, does not affect a software project in a comparable way [4].

Augmented Reality is a technology capable of displaying a visual spectrum in real-time which is currently developing rapidly. Its presence not only brings different nuances in the human visual screen but is also able to combine several technologies to bring digital information into visual perception [7]. To build an AR project, a special method is needed because not all digitally enhanced media today is "Augmented" reality. 2D images or Photoshop conversions are not AR. As is the case with images produced from television or films such as "Jurassic Park" and "Avatar" are also not AR. In contrast, a game that uses live feed and provides a real experience is AR. Not all visual searches can be categorized as AR. Therefore, something is said to be AR if it has the main characteristics of the AR system, namely [8]:

- Real time interactivity
- Use of 3D virtual elements
- Mixture of virtual elements with real elements

According to research conducted by Bean [9], the 3D animation industry, such as film, games, television, advertising and visual effects, uses three main stages in each segment that must be carried out. The three stages are pre-production, production, and post-production. In the pre-production stage, the team will think about ideas and make sure to tell a compelling story. Determination of character, environment and other supporting factors need to be made as attractive as possible. At the production stage, if the previous stages have been well structured and mature, the project can be carried out. Then in the post-production stage, 2D visual effects and 3D animations are created. In this stage color correction, sound, and other effects need attention so the project will look fantastic. In addition to these three stages, it is necessary to consider the software and hardware components that will be used to create AR application contexts [10].

II. Literature Review of Software Methods

Software is a computer program that is a key component of most businesses such as products, services, industrial processes, and back-office functions. Responding to changing customer needs and market conditions requires the ability to improve software quality quickly and continuously. This approach is known as continuous software engineering [11].

Continuous software engineering is a paradigm for streamlining software engineering by conducting gradual and continuous delivery of software with the purpose of quickly get feedback from customers and improve software quality according to customer requirements [3]. With this gradual and continuous method, the potential for improvement is easier to plan and strengthen. Smaller portions of software updates allow developers to focus on a collaborative, experience-based business model. The essence of continuous software engineering is continuous integration and delivery. This end principle is expected to cover the entire software engineering process from initiation, analysis, development, integration, validation, verification, delivery, to gathering feedback and planning the next software iteration step.

The stages in the software method generally consist of planning, analysis, design, and programming stages [4]. In the last two decades there has been a change in the stages of software development to address challenges that occur in the field. Based on the results of surveys and interviews conducted by Fitzgerald [1], it is known that only 6% of software developer practitioners apply formally defined methods. The rest do not follow the rules of the established method. Then what causes it? Why is there a difference between the method described and the one implemented? From the results of the literature review there are those who argue that software practitioners do not get sufficient knowledge, are not educated, and do not receive proper training. In the research conducted by Parnas [12] in his writings, he acknowledged that the reasons for non-compliance from software practitioners observed were disciplinary methods and norms.

From the application that has been carried out in previous research it is known that the agile method has the advantage of being more flexible and able to accept change. Its extraordinary adaptability made this method quickly accepted in today's software environment [13]. Very complex software projects require integrated, distributed teams. This plays an important role as a bridge between the developer and other stakeholders so that if there is an error it will be easily detected and immediately corrected. The software development method aims to obtain quality and conformity to user requirements[14]. Currently the need for integrated practice has increased. As an example, for extreme agile methods where their popularity is steadily increasing. Then the DevOps method recognizes that software development and operational deployment must be continuous [15]. From the various results of the literature that has been reviewed, it is known that there is a relationship between business strategy and software development. These two things must be continuously assessed and improved. In research conducted by Fitzgerald [1] the combination of the two is abbreviated as BizDev.

The software development methods commonly used by AR today and which will be used as comparison material are as follows, Table I:

a) Waterfall
b) Agile
c) Scrum
d) RAD
e) Prototype
f) DevOps
g) Kanban
h) Rational Unified Process
i) Spiral
j) 3D Pipeline Production

AR technology is still relatively new for software developers to develop, and it is not easy to choose the right development method. According to Dennis, there are several considerations in choosing a software development method based on several criteria, namely: clarity of user needs, mastery of technology, level of system complexity, level of system reliability, execution time and visibility of the implementation schedule [16]. In research conducted by Fitzgerald [1] on continuous software engineering, it was found that there are four activities, namely, strategy and business planning, development, operation and improvement and innovation. Of the four main activities, there are sub-sections as follows:

Strategy and business planning
- *Continuous planning*
- *Continuous budgeting*

Development
- *Continuous integration*
- *Continuous delivery*
- *Continuous deployment*
- *Continuous verification*
- *Continuous testing*
- *Continuous compliance*
- *Continuous security*
- *Continuous evolution*

Operation
- *Continuous use*
- *Continuous trust*
- *Continuous run-time monitoring*

Improvement and Innovation
- *Continuous improvement*
- *Continuous innovation*
- *Continuous experimentation*

TABLE I. COMPARISON OF EACH METHOD

Method	Superiority	Weakness
Waterfalls	1. Easy in management because almost whole requirements have been identified and documented. 2. Sequential stages linearly, complete identification and documentation, making the process easy understood by all the team involved or project owner.	1. No flexibility to change occurring needs in stage development system. 2. Almost no tolerance errors, especially in stages planning and designing.
Spiral	1. High amount of risk analysis. 2. Good for large projects and mission critical.	1. Can be an expensive model for use. 2. Risk analysis needs very specific skills. 3. Success projects are highly dependent on the risk analysis stage.
Agile Development	1. Method light in accordance small project and medium project. 2. Produce cohesion good team. 3. Emphasize final product. 4. Approach based test for terms and guarantees quality.	1. Not suitable for handling complex dependencies. 2. There is risk to sustainability, maintenance, and time longer. 3. Needed mature plans and roles leader existing project experienced.
Scrums	1. Scrums can help a team finish results project fast and efficiently. 2. Scrum confirmed the use of time and money effective. 3. Developed code and tested during the sprint review. 4. Teams earn clear visibility through scrum meetings. 5. Scrums, with nimble, adopt bait come back from customers and stakeholders' interests. 6. Short sprints possible change based on bait come back with easier.	1. Scrums often lead to scope creep because lack of date definite end. 2. Opportunity failure project high if individual have no committed or cooperative. 3. Only can succeed with members who have experienced team. 4. Meeting daily sometimes makes member team frustrated. 5. Quality difficult applied until team through an aggressive testing process
RAD	1. Efficiency time delivery. 2. Change needs can accommodate. 3. Cycle time can be short with the use of powerful RAD tools. 4. Use tools and frameworks.	1. Complexity management. 2. Suitable for system-based components and measurable. 3. Need involvement users all over cycle system. 4. Requires highly skilled personnel. 5. Dependency high on modeling ability.
Prototype	1. Accurate identification requirements because it has input from the project owner so that the appearance of the resulting prototype can be adjusted to the immediate needs of the user. 2. Errors and redundancies can be minimized because of the good identification process to prototype shape.	1. Each evaluation and input for prototype changes will add to the complexity of the system being developed. 2. Give burden addition to programmers. 3. There is a need for additional costs related to making a prototype display.
DevOps	1. Faster application development and deployment. 2. Be more responsive and fast to market changes. 3. Advantages in terms of software delivery time and transportation costs. 4. Improve customer experience and satisfaction. 5. Simplifies collaboration as all tools are placed in the cloud for customer access.	1. Professionals in the field of DevOps yet adequate. 2. Cost management infrastructure in relative DevOps methods is high. 3. Lack of understanding of DevOps methods can cause problem in integration project continuous automation.
Kanban	1. Kanban's are very simple and easy method understood so that make it easy management company. 2. Kanban method is spot on time or Just in Time (JIT). 3. The Kanban method is a very responsive system and does not cause slowness or delay.	1. Kanban cannot be used as an independent tool. This method is not quite suitable for a single application but can be combined with other methods such as Scrum, JIT, and others. 2. As assignments constantly move between columns of the kanban board, a certain predictive time for the completion of a task or activity becomes difficult. 3. Kanban is not suitable for dynamic environments. 4. Kanban will be very difficult to implement if there are too many related joint activities or tasks in a system.
Rational Unified Process (RUP)	1. RUP is a complete methodology with all easily available documentation. 2. RUP is publicly published, distributed, and supported. 3. Training is available where RUP can guide users through the process with step-by-step tutorials. Many institutions also offer training courses. 4. Requirements Change where proactive resolution of changing client conditions and associated risks. 5. Reduce integration time and effort. 6. The reuse rate becomes higher.	1. The process is too complex, too difficult to learn, and too difficult to apply properly. 2. Integrated process does not capture the sociological aspects of software development and details about how the software develops step by step.
3D Pipeline Production	1. Method This possible 3D animation is shown in a manner realistic, dynamic, and detailed. 2. Method This support technology modern 3D animation possible movement displayed with fluid and very detailed. 3. At the realistic and dynamic rendering stage, 3D animation also has Power strong visual appeal. They have shown for interesting more Lots attention than animation similar in 2D.	3D animation uses more complex techniques than 2D animation. This means it generally takes more time to develop 3d animations. It also requires more expensive software to create 3D animations.

The method shown in Fitzgerald's research [1] is a common method in software engineering. This study tries to explore AR as its focus so that a theory is needed for continuous software engineering for AR considering that AR is not just an ordinary application but there are certain 3D elements and components that must be met so that it can be called AR.

III. Trends Landscape of Software Engineering

The Agile method at its inception was focused on the software development function and was considered only suitable for small businesses or only for small teams [17]. But over time there has been a change with the emergence of many studies which identify that the concept of agile has entered the scale of large companies. The seven general principles of common practice for agile methods are Scrum, XP, DSDM [18]. These seven general principles address the agile approach in several dimensions. In research conducted by Leffingwell [19] said that the experience of organizations adopting agile methods in companies uses agile scale frameworks to explain practices and activities, roles, and artifacts. Basically, the organization must be responsive in responding to environmental changes that occur [20]. The DevOps method emerged because there was a gap in the development and operations functions in the company for large software scales because the bigger the team, the higher the responsibility. Automation, DevOps relies on full automation of build, deploy and test to achieve short lead times, and consequently get rapid feedback from users. Sharing happens on many levels, from sharing knowledge, tools, and infrastructure, celebrating successful releases to bringing development and operations teams closer together.

There are several tools that can be used to practice continuous software engineering, including:

- Jenkins

Jenkins is an open-source tool that is often used especially in the continuous integration/continuous deployment (CI/CD) stage. Jenkins makes it easy to automate the integration and code testing process through features provided to speed up the delivery process introducing automation [17].

- GitLab

GitLab is a complete software development platform that provides a CI/CD pipeline to integrate, test, and deploy code automatically [18].

- Travis CI

Travis CI is a CI/CD tool that provides integration with Git and GitHub repositories resulting in fast integration with various programming languages as well as a flexible testing environment [19].

- Circle CI

Circle CI is a cloud-based tool that provides integrated Git repository features that enable automated testing and deployment and supports multiple programming languages [20].

The tools above are just a few examples while the choice of the right tool depends on the needs of the project and the preferences of the development team.

IV. Proposed Continuous Software Engineering for Augmented Reality

The stages in the software method generally consist of planning, analysis, design, programming, and maintenance [4]. This research proposes additional stages in the software development method for AR, namely continuous planning, continuous analysis, continuous design, continuous programming, continuous integration, and continuous maintenance, Table II.

TABLE II. Proposed Stages of the Software Development Method for AR

No	Stages	Activity	Step in AR
A	Sustainable planning	Continuous planning	Idea, story
		Sustainable budgeting	
B	Continuous analysis	Continuous deployment	Experimental data
		Continuous verification	
C	Sustainable Design	Continuous testing	Animatic and Design
		Continuous compliance	
		Continuous security	
		Continuous evolution	
D	Continuous programming	Continuous use	Research and Development.
		Continuous trust	
		Continuous run-time monitoring	
E	Continuous integration	Continuous release	Interconnected
		Continuous delivery	
F	Continuous Maintenance	Continuous improvement	Correction action
		Continuous innovation	
		Continuous experimentation	

A. Sustainable Planning

In the context of software development, planning is an initial idea that is episodic from the current set of problem formulations [21]. Over time, changes occur, and the business environment does require planning activities to be carried out more frequently to ensure alignment between the needs of the business context and software development. Not only the business environment but covering all areas of human life will certainly always experience changes [22]. In sustainable planning there are stages of continuous planning and sustainable budgeting.

- Continuous planning

The relationship between planning and portfolio becomes important at this stage. Planning must be iterated and released, a portfolio that includes product planning activities must be carried out [23]. However, the portfolio still has the possibility of failure even though the project is generally successful. The portfolio approach tends towards the organization. In previous research, it is known that there are still many cases where the approach to individual project management has received more attention than the portfolio approach [1].

In AR, there are stages in the ideas and stories sections that should always be refreshed so that users always get new findings in the AR applications they use. Periodically new ideas should be rolled out and new story additions or new characters in AR can provide users with an unforgettable immersive experience [24].

- Sustainable budgeting

The budget is a financial plan that is prepared in detail and coordinated from management plans with the aim of achieving targets within a predetermined period [1]. In general, budgeting is an annual or even multi-year event that describes annual events in the 'short term' and for three years or more in the 'long term'. To overcome this, the concept of "sustainable budgeting" is needed so that budgeting becomes more flexible and makes managers more flexible in making operational decisions at their own discretion to deal with unexpected situations that cannot be predicted in the master budget plan[25]. The budgeting system must be open and transparent so that the team can manage finances independently according to a predetermined budget but not limited to the annual cycle [26].

B. *Continuous Analysis*

At this stage it is possible not only to measure the overall behaviour of the mechanism, but also an in-depth analysis of the software engineering being executed. Experimental data to verify the continuous analysis method is strongly recommended [21].

- Continuous deployment

Continuous deployment is the continuous delivery of code changes to applications that are released during software development. This stage must be carried out in a series of predetermined tests. After going through the testing phase, the system will confirm that the software is ready to be released to the customer and that it is in accordance with customer requirements [1].

- Continuous verification

Continuous verification is the discipline of proactive experimentation or the process of monitoring applications for post-deployment anomalies. An anomaly is any interruption in normal operation that may affect application users especially in AR, including [27]:

a) High response latency

b) Server-side error

c) Client-side error

d) Downtime of any application component

e) Unexpected scaling or failover events

The purpose of continuous verification is to collect data from implemented implementations and then analyze them through machine learning and create a basis for good implementations. The benefit of this ongoing verification is to identify that something is wrong and take corrective action—for example, reverting the app to a stable or default version. Precautions should be implemented as quickly and smoothly as possible before the customer becomes aware of the problem [1].

C. *Sustainable Design*

In the sustainable design for AR, design components and final appearance of the project that has been decided can be updated according to market demand. At the beginning of creating AR, designers created conceptual art using media ranging from pens, charcoal, pencils, dyes, or oil paints to using computers such as Adobe Photoshop software. There is no problem using any media if the concept to be conveyed can be understood by users. Artwork often reflects the artist who created it, so the artist's mood and instincts should be an important aspect to pay attention to. The reason why this stage must be continuous is because when making art at the beginning, it is limited by a deadline. So that continuity is needed to ensure the results are delivered in accordance with the desired initial concept and get user feedback. Therefore, updates at this stage need to be done to perfect the design [28].

- Continuous testing

Continuous testing is a software development process where applications are tested continuously throughout the software development life cycle (SDLC). The goal of continuous testing is to evaluate software quality throughout the system life cycle to provide critical feedback earlier and enable faster, higher quality delivery. The advantage of this stage is when the context is still fresh in the mind of the developer and an error occurs, it is quickly resolved before the problem becomes unexpectedly deep and widespread. The benefit to software developers is that testing can be performed effectively and helps reduce overall development time by up to 15%. This is proof that continuous testing can be used as a tool to reduce waste of waiting time [29].

- Continuous compliance

At the beginning of its implementation, Agile methods were considered only suitable for small projects and placed in a crisis context, not safety. However, in recent decades Agile methods have been successfully applied to large, distributed projects. In the research conducted by Fitzgerald [1] there was discussion about adapting the Scrum method to R-Scrum or Regulated-Scrum. This is actually a disguise from a waterfall approach to an agile approach that allows developers to complete projects faster [1].

- Continuous security

Security is a priority in all phases of software development life, even after implementation, security is an important thing that must be done. Security can finally be said to be a non-functional requirement that is often unintentionally delegated to a lower priority. Therefore it is necessary to apply an intelligent and lightweight approach to be able to identify vulnerabilities to security issues [1].

- Continuous evolution

Software evolution is fundamentally dependent on the expertise of the developer as well as the changeability inherent in the software product itself [1].

D. *Continuous Programming*

In continuous programming in AR, it requires continuity in the research and development (R&D). R&D is a component that covers from pre-production to post-production in 3D animation flow [9]. For example, in the animated film Finding Nemo, a team of artists from various components had to think about how to make the water feature look as if it were real. Likewise with other objects that float in the water must really look alive. When it was first released in 2003, there were no 3D animated films depicting water because it was considered especially difficult to render efficiently. Making this film is not easy, it takes years and provides its own challenges for the R&D team. But the resulting effort is well worth it, Finding Nemo succeeds in bringing the animation to life in the expected form [30].

- Continuous use

Continuous use provides advantages in terms of time and cost because the system is not built from scratch but from a continuation of an existing system. This continuous use does not mean that it can be used automatically because there must be some initial consideration and decision to use the software. The cost of acquiring new customers is estimated to be up to ten times that of retaining existing customers [21]. Previous research also stated that developers tend to stick with the system rather than designing from scratch [1].

- Continuous trust

Continuous trust is a process that takes time so that there is confidence that the vendor will do all its expertise to meet customer expectations according to their needs. Continuous use is highly dependent on continued trust where the relationship is a complex relationship. In Hoehle et al [1] research, trust is a very important start to be achieved in a transaction. For long-term activities like Cloud remote services, AWS and others require ongoing trust. Software developers need to pay attention to the issue of trust in sustainability because even if it starts well, the trust itself can erode from the user experience both internally, such as inconveniences in certain features or external factors, such as news regarding vulnerable security issues and others [21].

- Continuous run-time monitoring

A classification scheme is provided to help understand the approach chosen by a system designer with a particular method. This stage can also be used to analyse ongoing projects and consider functional and non-functional aspects that are interesting to study in software development projects [21].

E. Continuous Integration

Continuous integration is defined as a process that is usually triggered automatically and consists of interconnected steps such as compiling code, running unit and acceptance tests, validating code coverage, checking compliance with coding standards and building deployment packages. While some form of automation is typical, the frequency of integration is also important as it needs to be regular enough to ensure rapid feedback to developers. Finally, continuous integration failures are high-profile events that may have several visible ceremonies and artefacts to help ensure that the issues causing these failures are prioritized for resolution as quickly as possible by whoever is held responsible [31].

- Continuous Release

When a component is released, its version number declaration is updated, as well as its dependency declarations, because those dependencies always refer to the component that was also released. This makes the component-based release process recursive. There are significant costs associated with this method of release. The more frequently a dependent component is released, the more frequently a component that depends on it must be released to take advantage of the additional quality functionality it contains. Furthermore, with each dependency release, all components that use it should be tested for integration, before they can be released on their own [21].

- Continuous delivery

Continuous delivery is a prerequisite if developers are going for continuous adoption, but not necessarily the other way around. Continuous delivery focuses on being able to deploy software to multiple environments but not necessarily to customers. As opposed to continuous deployment which is obligatory to release valid software to its users [23].

F. Continuous Maintenance

Continuous maintenance in AR is more focused on maintaining the long-term sustainability of the software both during development and after production. This stage has a series of other advanced stages, namely continuous improvement, continuous innovation, and continuous experimentation.

- Continuous improvement

Continuous improvement activities are efforts to add customer value through reactive initiatives from software developers. Therefore, innovation is needed as a proactive strategy to emphasize customer satisfaction [1].

- Continuous innovation

Innovation in a business context is new ideas that are transformed through processes to create business value for customers. An example of this innovation is discovery plus exploitation[31]. Research on software engineering has conducted a lot of research on innovation and these keywords are the most searched for by software developers and the business community, especially regarding open innovation. The concept of Lean startups is an example of continuous innovation. Testing is done by beta testing which is used to get customer feedback before the official release of a software product. Continuous innovation is a continuous interaction between operations, gradual improvement, learning, and radical innovation to identify added value features aimed at combining operational and strategic effectiveness or known as exploitation and exploration [1].

- Continuous experimentation

Continuous experimentation has another benefit for teams in that it generates measurable metrics of change and progress so that team goals are clearly defined. The application of continuous experiments in several domains requires solutions and challenges that range from infrastructure challenges, measurement challenges and social challenges. These challenges may only be relevant in one domain, but the solutions developed can be applied to other domains. This domain-specific challenge is closely related to the resulting solution [31].

In many publications on perpetual experimentation, the merits of the experiment are mentioned only as a motivation, i.e., improving product quality based on selected metrics. Further studies are needed to determine, for example, if there are more benefits, whether they apply to all companies involved in the experiment, or whether they could be obtained through other means. Another benefit is the potential use of continuous experimentation for software quality assurance. Continuous experimentation can support or even change the way quality assurance is performed for software. Software changes, for example, can only be applied if key metrics are not derived in the associated change experiment. Thus, the loss of quality can become measurable and measurable. Although some papers mention the use of continuous testing for software quality assurance [31].

V. Discussion

When working on AR projects, designers need to weigh quality against time and budget. When using today's rendering engines and shaders, 3D artists must find a happy medium between perfect looks and reasonable render times. New technologies are released every year in various forms—from computer hardware with faster speeds and data transfers, to software with advanced capabilities, and technologies that make workflows smoother. Some of the new trends being pursued by the 3D animation industry include full-body and detail motion capture, stereoscopic 3D output, point-cloud data, real-time workflow capabilities, and virtual studios. Each will provide a faster project turnaround and will allow artists to focus on the art of the project and not the technical hurdles of the production line. Continuous software engineering relies on a basic set of principles that govern every field of technology and includes modelling activities and other descriptive techniques.

VI. Conclusion

In general, the methods in software engineering include planning, analysis, design, programming, and maintenance. In this paper we present our initial findings about the continuous stages of the software method, namely continuous planning, continuous analysis, continuous design, continuous programming, continuous integration, and continuous maintenance then the continuous process of AR system development can be updated according to market demand.

For future work, tool support is available for continuous software engineering but suitable tool support for the whole concept from coding to delivery and data management for decision making needs attention in the future.

***Abstract*—Graph Convolutional Networks (GCNs) have shown remarkable capabilities in learning the topological relationships among electroencephalogram (EEG) channels for recognizing depression. However, existing GCN methods often focus on a single spatial pattern, disregarding the relevant connectivity of local functional regions and neglecting the data dependency of the original EEG data. To address these limitations, we introduce the Local-Global GCN (LG-GCN), a novel GCN inspired by brain science research, which learns the local-global graph representation of EEG. Our approach leverages discriminative features extracted from EEG signals as auxiliary information to capture dynamic multi-level spatial information between EEG channels. Specifically, the representation learning of the topological space in brain regions comprises two graphs: one for exploring augmentation information in local functional regions and another for extracting global dynamic information. The aggregation of multiple graphs enables the GCN to acquire more robust features. Additionally, we develop an Information Enhancement Module (IEM) to capture multi-dimensional fused features. Extensive experiments conducted on public datasets demonstrate that our proposed method surpasses state-of-the-art (SOTA) models, achieving an impressive accuracy of 99.30% in depression recognition.**

Keywords—Electroencephalogram; depression recognition; Local-Global Graph Convolutional Network (LG-GCN); multilevel spatial information; brain regions; multiple graphs

I. Introduction

Depression is a prevalent mental disorder affecting a large population worldwide. According to the World Health Organization (WHO), more than 350 million individuals globally suffer from depression [1]. It is characterized by significant mental impairment and negative emotions, including feelings of sadness, fatigue, and hopelessness. Currently, the primary method for diagnosing depression relies on doctor-patient communication. However, factors such as patient subjectivity, low sensitivity, and denial pose significant challenges to the diagnostic process [2]. Therefore, there is a pressing need for an objective and accurate method for detecting depression.

In recent years, electroencephalography (EEG) has emerged as a widely adopted technique for classifying depression due to its advantages, such as high temporal resolution, low acquisition cost, and ease of operation and recording [3]. It has become a commonly used and effective tool for assessing brain function. Previous approaches have involved models based on recurrent neural networks (RNNs) and convolutional neural networks (CNNs), which analyze EEG signals in the time-frequency domain, extracting features independently from individual channels. However, research has demonstrated that the brainwave patterns of individuals with depression arise from interactions between multiple channels, and EEG electrodes are positioned in a spherical space. Traditional CNNs face limitations in handling irregular and non-Euclidean data. In contrast, graphs, which are effective in handling irregular data, are better suited for modeling signals in a three-dimensional spherical space. In this context, each electrode can be seen as a node in the graph, and the spatial relationships or correlations between electrodes can be represented as edges. Graph Neural Networks (GNNs) leverage the adjacency relationships among nodes to jointly learn the spatial patterns of EEG signals [4].

Integrating prior knowledge derived from neuro-psychological research into the design of Graph Neural Networks (GNNs) presents significant potential for decoding psychological states from EEG signals. In the case of depression, it has been observed that the manifestation of this condition in individuals may involve interactions within specific brain regions [5]. Activation of a particular brain area can also trigger simultaneous activation in other regions. Research has indicated the presence of high-level connections between electrodes on the left and right hemispheres, offering additional insights for biomedical analysis [6]. Ding et al. [7] have demonstrated that many cognitive functions rely on the cooperation between different brain regions rather than being confined to a specific area. While previous research [8] utilized a globally connected adjacency matrix with learnable connections, it failed to consider the local activities within each functional region. On the other hand, the Regularized Graph Neural Network (RGNN) [9] established local connections based on spatial distances between electrodes but struggled to effectively capture the complex relationships between functional regions. Thus, it is crucial to strengthen the connectivity within local functional regions while establishing connection patterns between channels based on global dynamics. Additionally, relying solely on spatial patterns would overlook important discriminative features present in the original EEG data, which are vital for identifying depression in EEG signals. Consequently, our research focuses on appropriately constructing the brain topology based on EEG data and addressing challenges related to information loss.

To tackle the aforementioned issues, we propose an algorithm for depression recognition based on a local-global graph convolutional network (LG-GCN). LG-GCN constructs

*Corresponding Author.

both a global dynamic graph and a local functional graph to explore the multi-level spatial information across EEG channels. To capture adaptive multi-dimensional features of EEG, we introduce an Information Enhancement Module (IEM) that incorporates data dependencies and cleverly integrates them with spatial information. Inspired by brain science research [10], LG-GCN incorporates topological information from both local and global perspectives in the graph convolutional layers. Furthermore, recognizing that the graph structure may not extract all discriminative features from the original signals, we adopt Gated Convolutional Networks to capture the dependency relationships between raw temporal data and advanced features, thereby enhancing the model's performance. Finally, to assess the effectiveness of incorporating prior knowledge into the LG-GCN model, we analyze the differences between various brain region partitioning methods and conduct extensive visualization experiments.

The main contributions of this study are as follows:

1) *Introducing* a local-global multi-graph fusion framework that explores multi-level features of graph topology spaces. This framework overcomes the limitation of insufficient extraction of depression-related information in a single encoding path by utilizing an information enhancement module to adaptively supplement multi-dimensional fused features.

2) *Proposing* an adaptive global dynamic graph and local functional connectivity graph that are integrated into the global graph convolutional network. This integration allows for the incorporation of local information, capturing the multi-level spatial dependencies in EEG data. It effectively associates the spatial distribution of EEG signal channels with depth-encoded depression features, resulting in improved classification performance.

3) *Validating* the effectiveness of the LG-GCN framework on a public dataset, where it achieves state-of-the-art (SOTA) classification performance. Additionally, multiple ablation experiments are conducted, and LG-GCN is compared with other methods, further confirming its efficacy.

The remaining structure of the article is outlined as follows: Section II briefly reviews related works. The proposed framework will be described in detail in Section III. Section IV provides extensive experiments and analyses. Section V provides a discussion of the results obtained, and finally, the study is concluded in Section VI.

II. Related Work

A significant number of previous studies have attempted to use machine learning methods to detect depression. Saeedi et al. [11] used a genetic algorithm to select significant features from linear and nonlinear features and employed an enhanced K-nearest neighbor algorithm to classify the EEG signals of depressed patients. Mumtaz et al. [12] performed time-frequency decomposition of EEG signals based on wavelet transform to construct feature matrices, which were then inputted into an LR classifier. Although machine learning has achieved significant success in classification tasks, it faces challenges in feature selection complexity and high accuracy performance requirements. Therefore, deep learning methods are gradually becoming popular among researchers. Kang et al. [13] proposed transforming the asymmetry of EEG into a matrix image as input to a CNN, but the calculation of electrode spatial positions in the two-dimensional image transformation is challenging. Acharya et al. [14] introduced a 13-layer CNN model based on deep learning, but it has complex training and requires a significant amount of time. Chen et al. [15] used a lightweight DCTNet model, which consists of a six-layer neural network with CNN-LSTM and achieved high classification performance. Compared to machine learning methods that rely on manual feature extraction, deep learning algorithms have better performance in improving the accuracy of depression diagnosis. However, most current deep learning methods focus on mining information in the time-frequency domain, while the spatial distribution information of channels is an important but often overlooked feature.

In recent years, GNN models have shown promising performance in handling graph-structured data, providing new research directions for the development of EEG signal analysis. Zhang et al. [16] proposed a depression recognition framework based on the fusion of time-space ubiquitous EEG features at the feature level. The model selected 19 optimal time EEG features and four optimal spatial metrics features and analyzed the intrinsic connections among EEG signal channels. Zhu et al. [17] modeled correlation using graphs and proposed an attention based GCN that achieved a recognition rate of 96.50% for depression. Wu et al. [18] combined space-time graph convolutional networks (ST-GCN) with a depression-related functional connectivity graph in a deep learning approach, improving the ability to represent spatiotemporal features. Sun et al. [19] used a complex network graph convolutional neural network (CN-GCN) with a multi-branch structure to explore deep information between channels, achieving a recognition rate of 99.29% for depression. However, these models only used one type of functional connectivity in the brain. In this article, the proposed model considered both structural and functional connectivity for the first time. Jang et al. [20] suggested that individuals with depression tend to exhibit greater relative right frontal lobe activity. Mumtaz et al. [21] found that individuals with depression exhibit greater activity in the front EEG. Therefore, in depression research, considering both global brain connectivity and local functional connectivity is critical while constructing multi-channel EEG signal dependency relationships. The proposed LG-GCN model in this paper analyzes the spatial relationships within and between different functional areas, extracting more comprehensive spatial features for more effective depression identification.

III. Methodology

To fully exploit the potential of EEG data, LG-GCN is proposed for EEG-based depression recognition, which consists of a local-global graph convolution module (LG-GCM) and IEM. The overall framework is shown in Fig. 1, which can be divided into the following steps:

1) *Considering* the frequent local connections in the brain network and the need for better differentiation of brain regions in relation to depression, we construct local regions based on prior research, each region's information are aggregated as nodes in the local functional graph, and node similarity are computed to represent functional connectivity.

2) *The* brain network adopts an adaptive adjacency matrix to dynamically calculate the connection strength between channel nodes, dynamically reflecting the information under depression from a global perspective and introducing a GCN to aggregate local-global features.

3) *The* IEM is used to further extract information from the original signal, where the weighted averaging fusion mechanism is used to extract high-dimensional features outputted by the GCN, and then inputted into an adaptive attention fusion network to obtain complementary information. Next, this article will present detailed information related to this.

A. Local-Global Graph Convolution Module

The results of pattern analysis of neuroimaging data indicate that the depression group exhibits distinct patterns related to emotional categories in the activity of the distributed neural system spanning across cortical and subcortical regions [22]. Therefore, to simulate the interconnections between different brain regions, we propose a multi-graph representation, namely LG-GCM. By considering spatial information from different perspectives, the adaptive global dynamic graph can dynamically integrate EEG channel information, while the local functional connectivity graph can characterize static relationships between different brain regions. Finally, multi-layer GCN is introduced to capture multi-graph and multi-level representation features by adaptively fusing local and global spaces.

1) *Local functional graph:* Different regions of the human brain cortex are highly connected and concentrated. Based on prior knowledge from the field of neuroscience [23], we construct two types of local brain regions by aggregating local EEG features to capture more robust features. Fig. 2(a) shows the first partition based on the reference brain cortex anatomy. The brain cortex is typically divided into four lobes: the frontal, parietal, temporal, and occipital lobes, each of which is responsible for different tasks. Due to the importance of electrodes located in the frontal lobe (FP1, FP2, F7, F3, FZ, F4, F8) in depression detection tasks [20], we divide the regions in more detail to meet the needs of structural and functional connectivity. Fig. 2(b) shows another effective method based on the division of regions between the brain's two hemispheres.

(a)7 regions (b)2 regions

Fig. 2. Two different region partition methods for graph coarsening.

We represent multiple graphs as weighted undirected graph G= (V, ε, A), where V is the set of nodes, ε represents the connections between nodes, the adjacency matrix $A \in R^{N\times N}$represents the connectivity between nodes, and N is the number of EEG channels. The region functional graph containing P subgraphs is represented as $G_R^{(1)}, G_R^{(2)} = \left[G_{R_1}, G_{R_2}, \cdots, G_{R_P}\right]$, For kth region functional subgraph G_{R_k}, the input data is denoted as $G_{R_k} \in R^{S\times n_k \times D}$, where S represents the number of samples, n_k is the number of channels in the kth subgraph, and D represents the frequency band, including δ band(0.5~4 Hz), θ band(4~8 Hz), α band(8~13 Hz), and β band(13~30 Hz).These frequency bands have been used in previous studies to investigate differences between patients with depression and healthy controls [24]. In this work, PSD features in the frequency domain of the EEG signals are extracted using the Welch method [19] for each channel node, which can be obtained from the MATLAB software with default parameters. Owing to EEG original data containing noise and redundant information, singular value decomposition (SVD) is commonly used to perform dimensionality reduction and extract relevant information. It can be represented as

$$G_{R_k} = W_{R_k} \cdot G_{R_k}^{b^T} \tag{1}$$

Where W_{R_k} represents the left singular matrix, $G_{R_k}^b \in R^{N_k \times \mu}$ is the channel-level matrix containing advanced channel information, with dimensions of $n_k \times \mu$, Where n_k is the number of channels in the k-th subgraph $(\sum n_k = N)$, and μ represents the number of features for each EEG channel. Furthermore, the local subgraph can be represented as $G_{R_k} = \left[g_{R_k}^1, \cdots g_{R_k}^n, \cdots g_{R_k}^{n_k}\right]$, where $g_{R_k}^n$ is the node feature vector of the local subgraph. The aggregation function aggregates the node feature vectors in each local subgraph, which can be the maximum, minimum, average, etc. This process is known as graph coarsening. In LG-GCN, the average aggregation is selected as the aggregation function. Hence, the output of the local graph, $G_{local}^{(1)}, G_{local}^{(2)} \in R^{P\times\mu}$, can be calculated by

$$\begin{aligned} G_{local}^{(1)}, G_{local}^{(2)} &= \mathcal{F}_{aggregate}\left(\left[G_{R_1}, G_{R_2}, \cdots, G_{R_P}\right]\right) \\ &= \left[\frac{1}{N_1}\sum_{n=1}^{N_1} g_{R_k}^1, \cdots, \frac{1}{N_k}\sum_{n=1}^{N_k} g_{R_k}^{n_k}\right] \\ &= \left[h_{local}^1, \cdots, h_{local}^P\right] \end{aligned} \tag{2}$$

Where p is the index of each node in the local graph, h_{local} represents the latent representation of the local subgraph. Then, the local subgraphs are concatenated to obtain $G_{local} = concat(G_{local}^{(1)}, G_{local}^{(2)}) \in R^{V\times\mu}$, which results in the feature fusion matrix of the two partitioned local subgraphs.

The definition of the local subgraph is incorporated into the basic adjacency matrix of the brain to model the correlation between different brain regions, which is used in the subsequent graph convolutional layers to enhance the feature propagation between more important local edges. The relationships between local graphs are utilized as the edges of the basic global graph. Neuroscience research suggested that activating one specific brain region also tends to activate other regions in the group for advanced cognitive processes [25]. The dot products between local graph representations for each EEG instance are calculated to reflect the relations among local graphs. Thus, we have $A_{global-base} \in R^{V\times V}$, which is calculated as follows.

$$\begin{aligned} A_{global-base} &= \begin{bmatrix} A_{global-base}^{1,1} & \cdots & A_{global-base}^{1,V} \\ & \ddots & \\ A_{global-base}^{V,1} & \cdots & A_{global-base}^{V,V} \end{bmatrix} \\ &= \begin{bmatrix} h_{local}^1 \cdot h_{local}^1 & \cdots & h_{local}^1 \cdot h_{local}^V \\ & \ddots & \\ h_{local}^1 \cdot h_{local}^V & \cdots & h_{local}^V \cdot h_{local}^V \end{bmatrix} \end{aligned} \tag{3}$$

where $\cdot$ operation is dot product. $h_{local}^i \cdot h_{local}^j$ represents the similarity between local subgraphs as the edge weight in the adjacency matrix. $A_{global-base}^{i,j}$ represents the ith row and jth column of the basic adjacency matrix corresponding to the brain. Each local subgraph is treated as a node, forming the basic functional connectivity matrix of the brain. The specific process is as follows.

$$A_{global-base}^{i,j} = exp\left(-\frac{\left\| h_{local}^i - h_{local}^j \right\|^2}{2\sigma^2}\right) \tag{4}$$

Finally, $A_{global-base}$ forms the basic adjacency matrix of the local functional graph. The graph coarsening method aggregates the characteristics of local EEG signals, reducing redundant information and lowering computational complexity, thereby obtaining more robust features.

2) Global dynamic graph: Due to the complex relationships between functional regions of the brain, they exhibit temporal variability and high dynamics [26]. However, existing methods are often restricted by static prior knowledge or weak modification, making it difficult to fully capture the complex dynamic functional connections between brain regions. We aim to learn an adaptive brain network adjacency matrix [27], which is self-learned during the model training process to understand the global connectivity relationships between EEG channels and better understand the interactions between channels. Therefore, we define a non-negative function $F(X_m, X_n)$ to quantify the strength of functional connections between channels, where X_m and X_n respectively represent the features between any two channels.

Function F calculates the connection weight between nodes based on signal differences between channel nodes and can dynamically reflect signal patterns under depression. The formula for calculating function F is shown below.

$$A_{m,n} = F(X_m, X_n) = \frac{exp\left(Relu(W_t|X_m - X_n|)\right)}{\sum_{m=1}^{N}\sum_{n=1}^{N} exp\left((W_t|X_m - X_n|)\right)} \quad (5)$$

where W_t is a learnable parameter, and $|X_m - X_n|$ represents the distance between the features of the two channels. The activation function Relu is applied to constrain weak channel coupling and is applied to the output to ensure that $A_{m,n}$ is a non-negative element. The output of the final global dynamic layer of the brain is a non-negative adjacency matrix A.

3) Multilayer GCNs: Once the local and global graph representations are obtained, we aggregate the information from these two types of graphs and enable global information interaction among the channels of EEG signals using GCN. The global dynamic graph extracts common features of depression patterns under coarse granularity, while the dense local functional graph can better capture functional connectivity features between different regions, containing more detailed information., LG-GCN captures the spatial information of EEG channels at multiple levels and dimensions, thereby extracting topological spatial features that are most favorable for the recognition of depression in EEG.

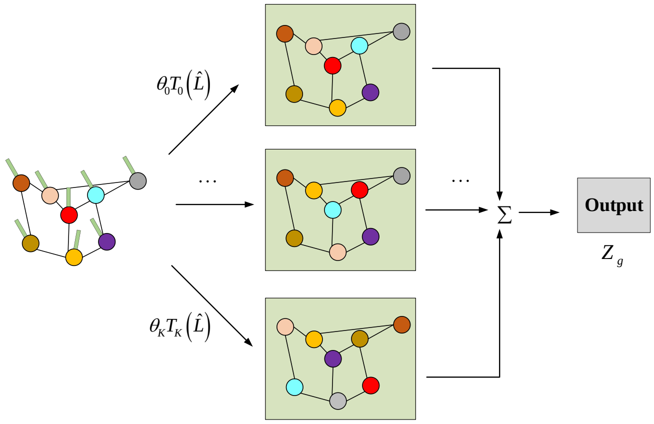

Fig. 3. The structure of graph convolution network.

In terms of node initialization, we use the value of $X^0 = X(G_{local})^T$ as the initialized graph node features of the graph, where X refers to the high-level feature set of the input signal, $X \in R^{N\times\mu}$. The notation $(G_{local})^T$ represents the aggregation relationship of the node features of the local subgraph. Then, we utilize the adjacency matrix A and $A_{global-base}$ to implement multilayer graph convolution and achieve feature propagation of local and global information of EEG signal channels. we first normalize the adjacency matrix A as shown in equation (6), where D is a diagonal matrix with $D_{ii} = \sum_{j=1}^{n} A_{ij}$, Then, we calculate the graph Laplacian matrix $L = D - A$ and perform spectral decomposition to obtain the eigenvalues and eigenvectors corresponding to L, as shown in equation (7), where $U = (\overrightarrow{u_1}, \overrightarrow{u_2}, \cdots \overrightarrow{u_n})$ and Λ is the eigenvalues and eigenvectors of L, respectively, and λ_{max} is set to 2. Assuming that the signal $x \in R^N$ undergoes Fourier transformation as $x = U\hat{x}$, we can calculate the Kth order Chebyshev polynomials $T_{k-1}(\hat{L})$ as shown in equation (8). Given X^{l-1} as the input to the l-th graph convolutional layer, the output X^l can be calculated using equation (9), where θ_k^l is the trainable parameter corresponding to the graph convolutional layer. A key step in GCN is the aggregation of node features, as illustrated in Fig. 3. As the convolutional layers iterate, node features propagate through the graph structure, allowing LG-GCN to obtain the aggregation of global information.

$$A = D^{-\frac{1}{2}}(I_N + A)D^{\frac{1}{2}} \quad (6)$$

$$\hat{L} = U\Lambda U^T = \frac{2L}{\lambda_{max}} - I_N \quad (7)$$

$$T_i(x) = 2xT_{i-1}(x) - T_{i-2}(x), T_0(x) = 1, T_1(x) = x \quad (8)$$

$$X^l = \sigma\left(\sum_{k=0}^{K-1} \theta_k^l\, T_k(\hat{L}) X^{l-1} A_{global-base}\right) \quad (9)$$

Since the multi-channel EEG graph only contains 19 nodes, to avoid the loss of important dynamic information, we do not perform graph pooling and instead directly sum up the outputs of each graph convolutional layer, integrating all node features into one graph representation $Z_g = \sum_{i=0}^{L} X^l \in R^{N\times\mu'}$, μ' is the feature dimension of the hidden layer.

B. Information Enhancement Module

LG-GCN can extract effective multi-graph and multi-level information, but it may ignore some important discriminative features in the raw EEG data. Hence, IEM is proposed to extract the dependency relationships between data and higher-level features, which are adaptively aggregated these features into the graph topology representation to capture a more comprehensive range of information within the EEG signals.

1) Feature Extractor (IEM-FE): To address the noise and high-dimensional characteristics of the raw EEG data and capture its discriminative features, we introduce a gated convolutional network as an FE for capturing enhancing information. The structure of the Gated Convolutional Networks, as shown in Fig. 1, utilizes two types of activation functions. Throughout the entire process, the computation and gate weight adjustment of the gate units are utilized to filter and update the output of the convolutional layers. This allows for the preservation of the ability to extract nonlinear features and further explores the discriminative features dependent on EEG data. Simultaneously, it enhances the network's generalization capability and robustness. Given the reshaped input data $X \in R^{1\times(N*d)}$, the operation of the gated convolution can be expressed as follows:

$$Z_i = S(\Theta_1 \cdot X + b_1) \odot T(\Theta_2 \cdot X + b_2) \quad (10)$$

where Θ_1 and Θ_2 are two 1D convolution operators, b_1 and b_2 are model parameters, $S(\cdot)$ and $T(\cdot)$ denote sigmoid and tanh functions, and $\odot$ is the element-wise multiplication. The output $\odot$ of the gate mechanism is obtained by multiplying the outputs of these two functions, which is used to represent the importance and information gain of each channel at a specific time point.

2) Weighted Average Fusion mechanism (IEM-AF): To obtain more comprehensive information from EEG data, AF mechanism is designed to fuse data-dependent auxiliary information into spatial information. Specifically, we flatten and map the output features Z_i and Z_g to a consistent dimension $\hat{z}_i, \hat{z}_g \in R^{1\times\beta}$, These features are then fused together using the following representation:

$$\hat{z}_f = \omega\left(\hat{z}_i, \hat{z}_g\right) \tag{11}$$

where $\omega(\cdot)$ represents the weighted average fusion function. Subsequently, a fully connected layer is utilized to reduce the dimensionality of the fused spatial features and auxiliary features, denoted as z_g and z_f respectively. These features are then passed through an adaptive attention fusion network to achieve effective feature fusion and extract complementary information. The final representation for EEG depression recognition is as follows:

$$z = \varphi_f \cdot z_f + \varphi_g \cdot z_g \tag{12}$$

where $z \in R^{1\times B}$, B is the binary class number for depression and health. The attention values φ_i and φ_g with embeddings z_i and z_g are self-learned by the proposed model. Specifically, we adopt a non-linear transformation and a shared matrix q to calculate the attention scores using equation (13):

$$AS_f = Q^T \cdot \tanh\left(W \cdot z_f^T + b\right) \tag{13}$$

where W and b are the transformation matrix and bias vector, respectively. Similarly, AS_g is obtained in the same way. We then normalize the attention scores AS_f and AS_g using softmax $(\cdot)$ function, yielding the attention values $\varphi_f, \varphi_g \epsilon R^{N\times 1}$, which represent the importance and relevance of the nodes. This can be expressed as:

$$\varphi_f = \frac{exp\left(AS_f\right)}{exp\left(AS_f\right)+exp\left(AS_g\right)} \tag{14}$$

Ultimately, the embeddings z are normalized by the softmax$(\cdot)$ function to calculate the predicted probabilities $\hat{y}$.

C. *Optimizing LG-GCN*

LG-GCN can extract effective information from EEG data and utilize this information to optimize the model. The construction of the loss function is crucial in this process. To obtain the optimal network parameters, the backpropagation (BP) algorithm is applied to iteratively update the network parameters until the best or suboptimal solution is obtained. The loss function during the training phase consists of a classification optimization term and a spatial regularization term. The classification optimization term uses the cross-entropy loss function, which is defined as:

$$\mathcal{L}_{cla} = -\frac{1}{S}\sum_{i=1}^{S}\sum_{k=0}^{K-1} y_{i,k} log_{\hat{y}_{i,k}} \tag{15}$$

Where S represents the samples and N represents the number of nodes. On the other hand, a spatial regularization term is introduced into the loss function to incorporate the smoothness and sparsity of the learned adjacency matrix, which better considers the spatial relationships among the nodes. This term can be defined as:

$$\mathcal{L}_{reg} = \frac{\lambda}{C}\sum_{i=1}^{C}\sum_{j=0}^{N}\sum_{k=0}^{N}\left|A_{jk}\right| \tag{16}$$

The total loss function consists of the above two terms, that is, $Loss = \mathcal{L}_{cla} + \mathcal{L}_{reg}$. λ represents the regularization parameter that controls the trade-off between the classification and regularization terms.

IV. Experimental Results And Analysis

In this section, we perform EEG-based depression recognition to demonstrate the effectiveness of the proposed LG-GCN model on public datasets. Then, experimental details and results are described, and finally, the ablation experiments and interpretability of EEG-based depression recognition are presented. The training procedure of the proposed model is shown in Algorithm 1.

Algorithm 1 LG-GCN Training Procedure

```
Require: EEG training samples S, ground-truth labels Y, training epoch e, number of partitions P, parameter K in LG-GCM, and learning rate r.
Ensure: Prediction of the model $\hat{y}$
Initialization;
Aggregate node features for each local graph by 1-3;
Calculate the adjacency matrix $A_{global-base}$ by 4;
Compute the global dynamic representation;
for j = 1 → e do
    Aggregate $Z_g$ by 6-9;
    Compute the EEG discriminative features $Z_i$ by 10;
    Conduct fusion to obtain the high-dimensional
      features by 11;
    Compute the final representation by 12;
    Update graph convolution parameters;
end for
return Prediction $\hat{y}$.
```

A. *Dataset*

We evaluate the proposed EEG-based depression diagnosis method using a publicly available dataset provided by Mumtaz et al. [11]. The dataset consists of two groups of participants: 1) 34 patients with major depressive disorder (MDD) (mean age 40.33, SD = ±12.861), and 2) 30 age-matched healthy control (HC) subjects (mean age 38.227, SD = ±15.64). The study is conducted on outpatient participants at the Hospital University Sains Malaysia (HUSM) and record their EEG signals in the resting state with eyes closed (5 min) and eyes open (5 min). The experimental procedures of this study are approved by the HUSM Ethics Committee, and all participants involved in the study have a thorough understanding of the entire process and provide informed consent.

B. *Preprocessing*

In this study, data preprocessing uses the PyCharm software and the MNE tool. Original EEG signals are always accompanied by artifacts and noise, including electrooculogram (EOG), electromyogram (EMG), and noise related to data acquisition. A bandpass filter is applied to extract the frequency band of 0.5-30Hz before applying feature extraction techniques. The independent component analysis (ICA) algorithm is then employed to further remove redundant artifacts and noise in the EEG signals, such as blinking and eye movement. The FastICA algorithm is used in this study. After these steps, clean EEG data is obtained, providing a basis for further analysis.

Considering the inaccuracy of signal boundary values, only the middle portion of the 120s EEG data is retained for analysis. To increase the number of samples and decoding accuracy, a cropping strategy is employed to process the data [28]. First, a sample set is established using all available EC and EO files in the dataset. For each data file, the 120-second data is segmented into 120 samples using a non-overlapping sliding window of 1 second in length, resulting in 240 samples for each participant. Ultimately, there are 8,160 and 7,200 samples for MDD and HC, respectively.

C. *Implementation Details*

We conduct all the experiments on the platform of NVIDIA GeForce RTX 3090 GPU. The proposed model is implemented using the PyTorch framework, a popular deep learning toolkit. The number of graph convolutional layers is set to 2, and the number of gate convolutional layers is set to 1. We use Chebyshev polynomials of order K = 3 for graph convolutions. The electrodes are divided into 7 and 2 regions, respectively. During the training process, we train the model for 200 epochs with a batch size of 256 and a learning rate of 0.01. The LG-GCN model is trained using Adam optimizer [29], which implements the stochastic gradient descent algorithm to update network parameters, weights, and model biases. Adam applies biases to each node in the graph. The training set and test set are set in a ratio of 9:1. Similarly, the validation set is established using 10% of the training set.

D. *Evaluating Metrics*

Due to the existence of false positive and false negative samples, using only accuracy to measure the performance of classifiers is far from sufficient. In previous studies [30], [11], [13], three typical performance metrics, accuracy, sensitivity, and specificity, are used to measure the performance of classifiers. Therefore, this study still chooses these three metrics to facilitate better comparison with other studies. These metrics can be calculated according to the following formulas 17-19:

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \tag{17}$$

$$Sensitivity = \frac{TP}{TP+FN} \tag{18}$$

$$Specificity = \frac{TN}{TN+FP} \tag{19}$$

where TP is the number of MDD patients detected correctly, FN is the number of MDD patients detected as healthy individuals, TN is the number of healthy individuals detected correctly, and FP is the number of healthy individuals detected as MDD patients.

E. *Classification Performance*

To demonstrate the superiority of the LG-GCN algorithm in depression recognition, we carefully select the most representative baseline models by comparing different methods. One category includes traditional machine learning algorithms, namely Support Vector Machine (SVM) [11] and Multi-Layer Perceptron Neural Network (MLPNN) [31]. Another category includes the most popular deep learning algorithms in the field of depression, namely CNN [13] and MDCNN [32]. The last category includes graph-based models. Since GCN has been applied less frequently to EEG-based depression recognition tasks, this paper only lists one of them, namely CN-GCN [19]. Table I presents the performance of LG-GCN compared to these three categories of baseline models on four frequency bands and all frequency bands (using δ、θ、α and β bands together).

TABLE I. ACCURACY ON DIFFERENT FREQUENCY BANDS

Model	**δ band**	**θ band**	**α band**	**β band**	**all（$\delta,\theta,\alpha,\beta$）**
MLPNN	83.33	86.67	91.67	81.67	93.33
SVM	65.52	74.14	81.03	77.55	89.96
CNN	95.50	95.90	98.85	96.07	/
MDCNN	82.31	86.00	87.30	94.10	97.27
CN-GCN	78.09	80.39	78.15	96.68	99.29
Ours	84.36	88.67	91.44	96.90	**99.30**

Our proposed model demonstrates strong advantages in each frequency band. the best accuracy is achieved in the α and β frequency bands. Furthermore, the performance when using all frequency bands together is superior to using the four frequency bands individually. This finding reveal that the overall structure allows for complementation and integration of information from each frequency band, resulting in more comprehensive information for depression recognition. This validates previous works [31].

To further validate the superiority of the proposed model, Table II shows the classification performance of our proposed model compared to existing methods on the same dataset. Mumtaz et al. [12][33][21] manually extracted features, including wavelet features, synchronous likelihood (SL) features, hemispherical asymmetry features, and frequency band energy features, and fed them into traditional machine learning models (LR and SVM) for classification. Mahato et al. [31][34] used frequency band energy and asymmetry features as input features for their classifiers, but their accuracy did not exceed 95%. Similarly, Saeedi et al. [11] considered different band powers and entropies. Dang et al. [32] combined multiple frequency band brain networks with deep learning algorithms, achieving an accuracy of 97.27%. In addition, the results of CN-GCN are comparable to the results of our proposed method, as it learns node features based on the topological connections of the brain network, rather than selecting local features between nodes. Existing studies on building brain networks based on GCN methods only consider the relationship between adjacent nodes, but ignore the activation relationship between brain regions. Soni et al. [35] fused information from three channels in the frontal lobe and used the KNN algorithm to achieve an accuracy of 92.80% in detecting depression. This finding is consistent with the results of this paper and previous studies, demonstrating that the features of depression patients are closely related to the activity in the frontal lobe of the brain.

TABLE II. CLASSIFICATION PERFORMANCE OF OUR PROPOSED METHOD AND EXISTING STUDIES ON THE SAME DATASET

Existing study	Year	Methods or features+Model	Accuracy	Sensitivity	Specificity
Mumtaz et al.	2017	Wavelet features+LR	87.50	95.00	80.00
Mumtaz et al.	2017	SL, coherence,MI+SVM	94.70	98.30	91.40

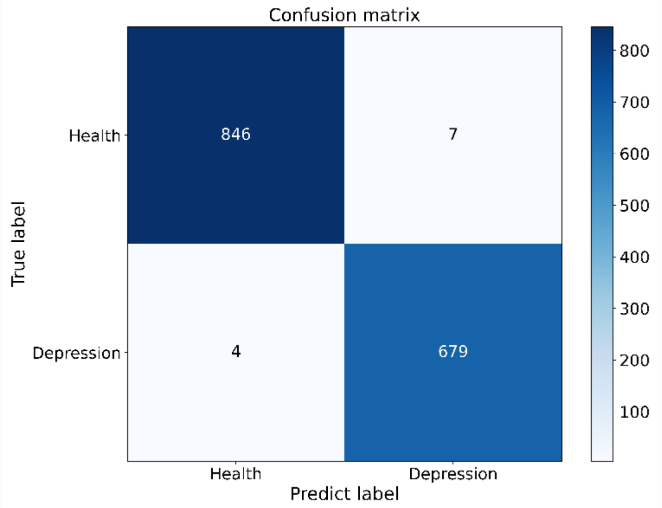

Fig. 4. Confusion matrix of the proposed LG-GCN on the public dataset.

In summary, the LG-GCN model outperforms other methods in depression recognition, with accuracy, sensitivity, and specificity of 99.30%, 99.38%, and 99.16%, respectively. Fig. 4 shows the confusion matrix of the proposed LG-GCN model for EEG-based depression recognition results.

F. *Ablation Experiment*

To better understand the robustness and individual contributions of the local functional graph, global dynamic graph, and IEM in LG-GCN, ablation studies are conducted by removing these modules from the LG-GCN to demonstrate the effectiveness of the model. The results are shown in Table III.

Each module is removed one by one to demonstrate the effectiveness of the combination of multiple graphs. From the results in the first and second rows of the table, Specifically, removing L from LG-GCN and not embedding the global graph led to a performance decrease in terms of Acc, Spe, and Sen. This fully verifies previous research that functional connections between local areas are important for discriminating different human emotional patterns. Hence, we adopt a graph coarsening method to aggregate local EEG features to make the model more robust. Completely removing G and directly performing graph convolution on L with full integration with IEM, results in a decrease in Acc from 99.30% to 97.90%, a decrease of 1.40% in Acc, 1.21% in Sen, and 1.59% in Spe, which highlights the importance of the global dynamic graph.

When the LG-GCN model lacked the IEM and the multi-graph representations were input directly into the GCN, flattened to the fully connected layer and softmax layer for depression recognition, the ACC dropped from 99.30% to 96.62%. This comparison demonstrates the effectiveness of IEM in achieving better performance. Additionally, it indicates that the discriminative features of the original EEG signal data can effectively complement the information captured by the LG-GCN, providing a more comprehensive representation for depression recognition. In conclusion, the information captured by multiple graph representations is crucial, and the ablation experiments strongly validate the necessity of constructing multiple graphs while demonstrating the benefits of extracting multidimensional information for model learning.

TABLE III. THE RESULTS OF ABLATION EXPERIMENTS ON PUBLIC DATASETS USING LG-GCN

L	G	IEM	Acc	Changes	Sen	Changes	Spe	Changes
×	√	√	97.52	-1.78	97.98	-1.43	97.35	-1.82
√	×	√	97.90	-1.40	98.20	-1.21	97.58	-1.59

■Sen(%)	97.35	98.33	97.92	99.17

Fig. 5. Performance comparison of different region partitioning methods.

The local functional graph includes two distinct partition types, one comprising seven brain regions, and the other comprising two hemispheres, to estimate whether there is a significant difference in depression recognition tasks under coarsening at different region scales. We remove the submodules of this local functional graph and present the results in Fig. 5. It can be observed that the performance of classification is lower when the number of regions is fewer. By introducing the 7 region and 2 region subgraphs, the network in the local functional graph enhances some key information features, improving the fitting ability of LG-GCN. This suggests that the functional connectivity between local regions is closely related to depression.

G. Interpretability and Visualization

In this section, to explain that significant connections mainly exist in certain brain regions, which have been found to be related to the pathology of depression. We visualize the distribution of degree centrality in the adjacency matrix of the global dynamics of the brain on four frequency bands in Fig. 6, providing an intuitive mapping of brain functional connections to the brain's topological structure. The degree centrality evaluates the connection strength of a node with the other nodes, which has been widely used to measure the importance of the nodes in a graph [36], calculated as follows:

$$\mathbb{C}_i = \sum_{n=1}^{19} A_{i,n} + \sum_{m=1}^{19} A_{m,i} - 2A_{i,i}, (i = 1, \dots, 19) \quad (20)$$

Based on the distribution of significant electrodes, we can identify brain regions that are favorable for EEG-based depression identification. This finding explains the results in Table II, where the model performs better on the α and β bands, and the connectivity is stronger than in other bands. Especially in the frontal and temporal lobes, as the frontal and temporal lobes are highly related to the onset of depression, the centrality degree is very high. Our study is consistent with [20][21], which found that the coherence of activity in the frontal and temporal regions in depressed patients is significantly higher than in healthy controls. This suggests that considering the connections between local EEG channels is crucial for accurate depression identification.

To display the connections between nodes, Fig. 7 depicts the top five connections learned by the proposed model in the adjacency matrix on the four frequency bands (δ、θ、α and β bands). Unlike the heatmap plot of degree centrality distribution, we remove the diagonal elements and just plot the connections between nodes. The positions of the 19 electrodes are displayed around the circles in the subplots. The lines represent the connections between channels, with darker colors indicating stronger connectivity. It can be observed that the critical connections are primarily located in the frontal and temporal lobes, where nodes corresponding to electrodes in these regions have a higher representation in the brain. This indicates the crucial role of the frontal and temporal lobes in the recognition of depression. In addition, two electrodes of multiple electrode pairs belong to different brain functional regions, indicating that the correlation between these regions not only has local structural connections but also has functional connections from global electrode channels.

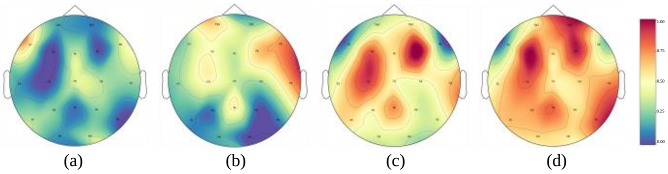

Fig. 6. Degree centrality distribution of the learned global adjacency matrices by LG-GCN over four frequency bands. (a) δ band：0.5-4 Hz (b) θ band：4-8 Hz (c) α band：8-13 Hz (d) β band：13-30 Hz.

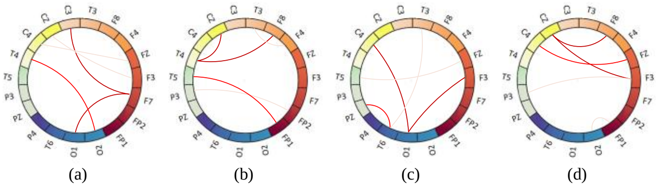

Fig. 7. Visualization of the top five functional connections between EEG channels in the learned adjacency matrices over four frequency bands. (a) δ band：0.5-4 Hz (b) θ band：4-8 Hz (c) α band：8-13 Hz (d) β band：13-30 Hz.

V. Discussion

In this research, we are thoroughly validating the effectiveness of LG-GCN. By partitioning the brain regions into local and global divisions, we discover high-level connections between different brain areas. Through the fusion of locally functional maps from prior research and adaptive adjacency matrices, our graph convolutional model accurately discerns the correlation between brain regions and depression. The fusion of local-global features is playing a crucial role in enhancing the representational power of the features. LG-GCN demonstrates a palpable edge over existing methodologies in data processing and feature extraction. Furthermore, our model evinces exceptional interpretability, elucidating the saliency accorded to specific brain regions and connections. Nodes situated within the frontal and temporal lobes exhibit heightened self-loop weights, indicative of their preeminent roles in the network, forging robust connections with other nodes. This, in turn, culminates in superlative depression identification capabilities.

VI. Conclusion

In this work, we propose LG-GCN, a local-global graph representation that simultaneously explores local brain functional connectivity and global dynamics, constructs the connections between different brain regions with prior knowledge in neuroscience research, and aggregates them into multi-layer GCNs to capture hierarchical dynamic graph topology spatial relations. In addition, IEM enables the proposed model to adaptively include discriminative depression features while retaining high-dimensional information. Extensive experimental results and visualizations demonstrate that the accuracy, sensitivity, and specificity of LG-GCN on public datasets are 99.30%, 99.41%, and 99.17%, respectively. All of these are superior to existing SOTA research, which indicates enormous potential for decoding depression based on EEG signals. However, a challenging issue in EEG-based depression recognition is the inter-individual variability of brain signals. In future work, it is crucial to take this factor into account and construct a common graph structure that is independent of individuals, thus enhancing the generalizability of the model.

ACKNOWLEDGMENT

This work was supported by the National Natural Science Foundation of China (61300098), the Natural Science Foundation of Heilongjiang Province (F201347), and the Fundamental Research Funds for the Central Universities (2572015DY07).

University's Service Delivery Improvement Through a DSS-enabled Client Feedback System

Belen M. Tapado, John Gregory M. Bola, Erickson T. Salazar, Zcel T. Tablizo
College of Information and Communications Technology, Catanduanes State University, Catanduanes, Philippines

***Abstract*—The expansion of products and services on a global scale demands the improvement of an organization's performance. In addition to addressing the challenges of improving product and service delivery, companies must focus not only on meeting customer expectations but also on surpassing them. Consequently, valuing the opinions of clients, giving the best client experience, and measuring client satisfaction are deemed vital not only for the company's survival but also for gaining a competitive edge for the organizations in the wired communities. It is because of these premises that the Client Feedback System was developed in this study for the university's service delivery improvement. This system captured the results of the Client Satisfaction Survey for School Year 2015-2016 to School Year 2020-2021. Interpretation of these captured data were made and action for the improvement of service delivery for each department in this university was recommended using the Decision Support System (DSS) technique. The system was created using the Rapid Application Development (RAD) method and utilized various software and technologies such as HTML, CSS, and JavaScript for the front-end development, MySQL and PHP for the back-end, and Apache as the local server of the system during its development and pilot testing.**

Keywords—Decision support system; client satisfaction; client feedback system; rapid application development; service delivery improvement

I. Introduction

Technological innovation posed an important driver of competitive success for most organizations nowadays to compete successfully and participate in the globalization of markets. Because of this, businesses are under pressure from both domestic and international competition to continuously innovate in order to produce differentiated goods and services.

Many leading companies worldwide place a strong emphasis on prioritizing exceptional customer experiences. They go beyond merely meeting customer expectations and strive to surpass them. Indeed, a world-class performance outcome is necessary so that clients and customers would be satisfied with what the company offers. As a result, it is crucial to evaluate client satisfaction. Client satisfaction describes a customer's perception of the company's quality, value, and expectations. Client satisfaction surveys, a tool used by businesses to gauge how satisfied their clients are with their goods and services, can be used to quantify customer satisfaction [1]. With this system, recognizing dissatisfied clients is just as crucial as identifying those who are really satisfied.

More so, evaluating the satisfaction of customers/clients is needed to understand what the customers expect from the product or service that the company provides. In addition to helping the business retain more customers, doing so enables it to spot and address any critics. A satisfaction survey would allow for the gathering of useful consumer feedback that could be used to ensure total customer experience and satisfaction.

Five benefits of customer satisfaction were presented by Bernazzani [2]. Accordingly, customer satisfaction (a) helps the organization understand where it excels; (b) aids the company in recognizing areas for improvement; (c) leads to higher customer loyalty and advocacy; (d) increases customer retention and reduces stir-up and, (e) increases the client lifetime value. Evaluating customer/client satisfaction indeed can make the organization understand what and where the business is doing well, what business strategy is to be done if the improvement is necessary and what ways could be done in order for the clients to refer new leads to the company and generate more testimonials for their experience. Likewise, satisfied clients will not seek out competition if the company keeps them happy. Customer happiness, therefore, is critical for improving service metrics and ensuring that the firm provides the greatest possible experience.

Assessing client satisfaction was very much imperative in almost all facets of business and service industries such as logistics, food industries, financial institutions, construction industries, hospital general, maternal, and senior health care as well as in educational sectors. Further, businesses and government agencies alike throughout the nation are concerned about the value of exceeding customer expectations. This is embodied in the Philippine Development Plan of the National Economic and Development Authority [3]. The government wants to provide the impression that it is constantly working to make its services cleaner, more effective, and more focused on the needs of its citizens. Similarly, the Civil Service Commission's directives and the Red Tape Act of 2007 [4], include provisions for gathering client satisfaction feedback through surveys.

Higher education from across the globe has long recognized the value of DSS by which it combines data and intelligence, generates the most accurate and likely options and explanations, and fine-tunes uncertain decisions and conclusions, particularly for the improvement of the school's performance [5]. Setting up of DSS is deemed appropriate and well suited for the school's educational mission, cutting-edge research, advanced data collection strategy, and academic activities that are provided to society such as its extension programs. Hence, the use of DSS in higher education's Information and Communication Technology structures would be a cost-cutting measure for the institution and would enable the school to concentrate on the most important issues of drafting and understanding the best decisions, as higher educational systems delegate involvedness.

Likewise, client satisfaction surveys are also carried out at State Universities and Colleges (SUCs) around the nation, just like they do at other government organizations. Several studies on client satisfaction feedback were conducted in academe that had given insights to the researchers to embark on this topic. St. Paul University Philippines (SPUP) conducted customer satisfaction surveys (CSSs) to assess how well it has succeeded in providing quality services and products both to its internal and external customers. This is a routine activity conducted by the university in its quest for standards of quality and excellence in its delivery of service to clientele. This school evaluates the graduates of post-baccalaureate degrees on their satisfaction with respect to the quality of services provided to them by its academic and non-academic support staff, learning support facilities, learning experience, and research-related matters [6]. Likewise, the study of Ventayen and Orlanda-Ventayen [7] regularly measures the satisfaction rating of the students on the Open University Systems in terms of timeliness, access, convenience, and staff attitude. The results of these surveys and actions taken by the institutions are being validated when they apply for quality assurance evaluations, like the Accrediting Agency of Chartered Colleges and Universities in the Philippines (AACCUP) Accreditation, International Standards Organization (ISO), and Institutional Sustainability Assessment (ISA).

Thus, for upholding the Catanduanes State University (CatSU)'s tradition of excellence in service delivery, the researchers conducted this study to assess the effect of client satisfaction evaluations on the performance of the university's offices and departments and improve service delivery using decision support systems (DSS). A computer-based program called a "Decision Support System" (DSS) gathers, organizes, and analyzes data to support good managerial, operational, and planning decision-making. Organizations can identify issues, find solutions, and take choices with the use of DSS analysis [8]. A DSS captures and analyzes data, synthesizing it to produce comprehensive reports. The organization then uses these reports to help in decision-making for the improvement of its goods or services [9].

The following industries use DSS: (a) retail stores to plan strategies to boost sales and advertise their goods; (b) banking institutions to analyze financial data asset reports and income statements; hospitals to improve the workflow of their key medical tasks; (c) farming businesses to plan effective crop-planting procedures; and (d) manufacturing industries to plan out efficient production plans and processes. Universities and academic institutions are also using DSS in order to identify the best course alternatives and provide appropriate amenities, including housing or eating options, and track the number of registered students [10]. Because they help university administrations better plan for student-related expenses, these programs may be especially useful when they create a yearly budget. A DSS system can also be used by administrators to assess students' academic progress, redesign a course's syllabus, or choose which on-campus services to give the highest priority.

Further, using DSS in Higher Educational Institutions (HEIs) resulted in reduced manual work, better data analysis, and ease of decision-making process, thus it helped increased productivity, employee and customer satisfaction, and revenue and profitability. With the COVID-19 pandemic, DSS helped improved the e-learning process by combining students with similar learning styles and assessing student profiles such as gender, age, the number of hours spent on a course, average time spent per week, and the like [11]. Additionally, the use of web technologies and user experience (UX) in enhancing CRM Business Intelligence applications were considered important factors in the study of Gharaibeh [12]. By leveraging web technologies and optimizing the UX, HEIs can improve their business intelligence implementation, leading to more profitable customers and reduced costs.

Given these assumptions and the significance of implementing DSS in HEIs, this study, therefore, developed an automated web system for collecting information on client satisfaction survey results, performing data analysis, and providing comments or recommendations for improving the university's service delivery using decision support system (DSS). The system developed in this study captured client satisfaction survey results from School Years 2015-2016 to 2020-2021. It likewise stored, organized, and analyzed the data gathered in a database system. From the interpreted result, the system presented a corresponding decision and recommendation for the improvement of the university's service delivery to its clientele.

II. Related Works

Continuous performance evaluation of an organization enables management to determine if anything has improved or worsened the way clients see a company's business. Meaningful reward and recognition systems can only operate in businesses where there is an accurate and visible process of performance feedback and discussions. The integration of a Decision Support System further improves business processes by recommending valuable actions based on actual data from client satisfaction surveys. The following were the studies reviewed relative to the use of such system. Articles in relation to the use of Decision Support Systems specifically in client satisfaction research were scarce during the time of gathering related articles of this study. Hence, articles relative to Decision Support System, in general, were considered in this paper.

A decision support model was proposed in the study of Dweiri, Kumar, Khan, & Jain. Their model was for supplier selection in the automotive industry. The model was based on the analytic hierarchy process (AHP). The criteria considered in the model were price, quality, delivery, and service. Sensitivity analysis checked the robustness of the decision using Expert Choice software. The suppliers were selected and ranked based on sub-criteria. Sensitivity analysis suggested the effects of changes in the main criteria on the suppliers ranking [13]. The use of AHP in supplier selection gives the decision-maker confidence in the consistency and robustness of the developed system throughout the process.

A platform that utilized the Decision Support System approach had also been done by Yazdani, Zarate, Coulibaly, & Zavadskas [14]. Their paper proposed a decision support system for selecting logistics providers based on the quality function deployment (QFD) and the technique for order preference by the similarity to the ideal solution (TOPSIS) for the agricultural supply chain in France. The proposed model looked at the decision problem from two points of view which were technical and customer perspectives. The main customer criteria that were considered were confidence in a safe and durable product, emission of pollutants and hazardous materials, and social responsibility while the main technical factors were financial stability, quality, delivery condition, and services. The outcome of this research was a group decision-making system that put into account decision-makers and customer values to aid agricultural partners and investors in the selection of third-party logistic providers. Likewise, the fuzzy linguistic variables enabled to assist agricultural parties in uncertain situations. The integrated decision support system overall enhanced the quality and reliability of the decision-making of the agricultural supply chain.

Similarly, a decision support model was designed by Kucukaltan, Irani, & Aktas for the identification and prioritization of key performance indicators in the logistics industry. The authors designed a stakeholder-informed Balanced Scorecard (BSC) model with the use of the Analytic Network Process (ANP) method to identify key performance indicators as well as various stakeholders in the logistics industry and analyzes the interrelationships among the indicators. The results show that educated employee (15.61%) is the most important indicator of the competitiveness of logistics companies [15].

While the reviewed articles on decision support systems in industries and logistics services demonstrated positive outcomes in enhancing service delivery particularly in logistics services and automotive industries, no article was found and reviewed on client satisfaction survey systems utilizing the DSS approach specifically for higher educational institutions. The integration of this approach to business processes, however, instills greater confidence in decision-makers, as it enables them to make informed decisions based on accurate data as processed by the system. This study, therefore, filled this gap by developing a DSS-Enabled Client Feedback System specifically designed for implementation at Catanduanes State University. The system ensured the accuracy and reliability of suggestions or recommendations by utilizing actual data from client satisfaction surveys conducted every semester.

III. Methods

This study employed the systems development method and documentary analysis. System development is a process of developing a software or application that will answer the user’s needs, particularly on client satisfaction feedback that employed the DSS concept [16], [17]. In their study on the suitability of agile development methodologies for Decision Support Systems (DSSs), Gharaibeh & Abu-Soud discussed the use and effectiveness of agile development methodologies [18]. Being a progressive agile method, the researchers specifically employed the Rapid Application Development model in developing the application for this study.

The results of a customer satisfaction survey were recorded and used in a documentary analysis for the academic years 2015-2016 through 2020-2021. System development was utilized in the conceptualization, prototyping, and actual development of the system. The system created and recorded the customer satisfaction survey results for the relevant academic year and provided recommendations for the college's or department's service performance.

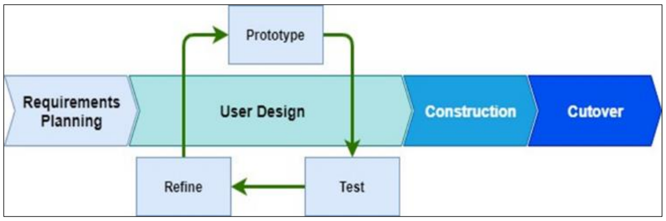

Fig. 1. RAD model.

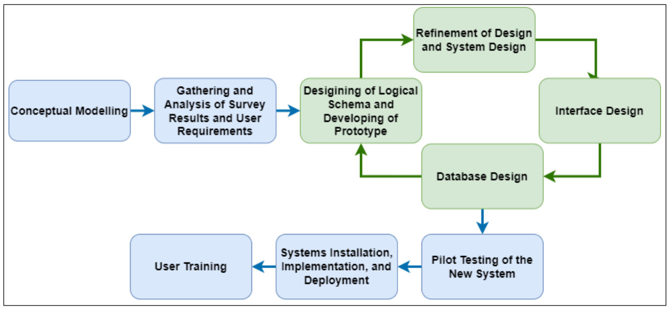
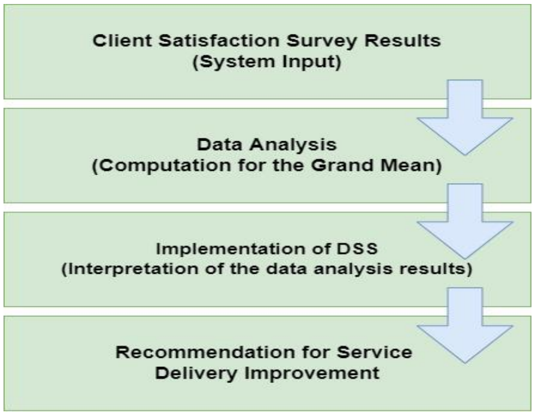
The development approach used in the study adopted the Rapid Application Development method of Requirements Planning, User Design (iterative method of Prototype, Test, and Refinement), Construction, and Cutover [19], [20], [21], [22]. However, the steps were customized to the actual processes undertaken during the development of the system. Fig. 2 illustrates the activities undertaken in the actual development of the system in this study that was adopted through the RAD model presented in Fig. 1. It could be gleaned from the figure that seven (7) steps were carried out to conceptualize present the finished product and have the user accept them. These steps were: (1) Conceptual Modeling; (2) Gathering and Analysis of Survey Results and User’s Requirements for the system; Step 3 is an iterative process of (3-a) Designing of Logical Schema and Developing of Prototype; (3-b) Refinement of the Design and Systems Design; (3-c) Interface Design and (3-d) Database Design; (4) Pilot Testing of the New System; (5) Systems Installation Implementation and Deployment; and (6) User Training.



Refinement of Design and System Design
Conceptual Modelling
Gathering and Analysis of Survey Results and User Requirements
Desigining of Logical Schema and Developing of Prototype
Interface Design
Database Design
User Training
Systems Installation, Implementation, and Deployment
Pilot Testing of the New System

Fig. 2. Step-by-step approach in the development of the system.

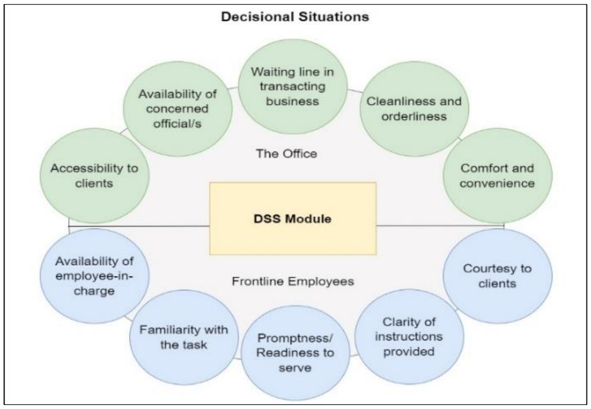
The process flow of the system is shown in Fig. 3. From the figure, the client satisfaction survey results were then put through statistical testing using frequency counting, weighted means, and percentages. To establish the system-wide mean for each customer evaluation, these tests were included as part of the system’s process. The system calculated the grand mean for the client satisfaction rating received per semester from all the client evaluations, and from there it calculated the grand mean for each indication or parameter. The method derived an interpretation from the grand mean based on the study's 5-point Likert Scale. The grand mean result was interpreted using DSS. The system would specify a general impression. Likewise, the Lowest Rating and Highest Rating for each parameter would be specified while highlighting the department's or college's service strengths and flaws. The suggestions/recommendations made by the system through its DSS notion would be taken into consideration by a department when deciding what to do or for some corrective actions to make.



Client Satisfaction Survey Results
(System Input)
Data Analysis
(Computation for the Grand Mean)
Implementation of DSS
(Interpretation of the data analysis results)
Recommendation for Service
Delivery Improvement

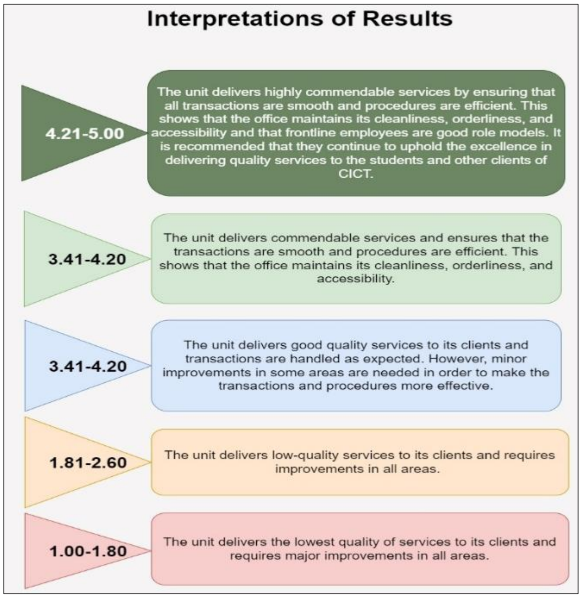
Fig. 3. Process flow of the system.

In addition, the process of capturing, data analysis, and providing recommendations for the system as shown in Fig 3 could be interpreted as follows: (a) it starts with entering the client satisfaction survey results through the user interface, which would be automatically stored in the Database. These results would serve as the knowledgebase of the DSS. The knowledgebase is the information used as basis in the interpretation and implementation of DSS; (b) The system would then analyze this information and then obtain the overall mean for each parameter and the grand mean for each semester; (c) Through the data analysis results, the system would be able to make an interpretation and its DSS part would be recommending actions for the service delivery improvement of the unit. The areas of application of the DSS module and basis of interpretation for the results of data analysis are shown in Fig. 4 and Fig. 5, respectively.



Decisional Situations
Availability of concerned official/s
Waiting line in transacting business
Cleanliness and orderliness
Accessibility to clients
The Office
Comfort and convenience
DSS Module
Availability of employee-in-charge
Frontline Employees
Courtesy to clients
Familiarity with the task
Promptness/ Readiness to serve
Clarity of instructions provided

Fig. 4. Areas of application of the DSS module.



Interpretations of Results

4.21-5.00	The unit delivers highly commendable services by ensuring that all transactions are smooth and procedures are efficient. This shows that the office maintains its cleanliness, orderliness, and accessibility and that frontline employees are good role models. It is recommended that they continue to uphold the excellence in delivering quality services to the students and other clients of CICT.
3.41-4.20	The unit delivers commendable services and ensures that the transactions are smooth and procedures are efficient. This shows that the office maintains its cleanliness, orderliness, and accessibility.
3.41-4.20	The unit delivers good quality services to its clients and transactions are handled as expected. However, minor improvements in some areas are needed in order to make the transactions and procedures more effective.
1.81-2.60	The unit delivers low-quality services to its clients and requires improvements in all areas.
1.00-1.80	The unit delivers the lowest quality of services to its clients and requires major improvements in all areas.

Fig. 5. Range and interpretation of client satisfaction survey results.

The developed system was flexible, maintainable enough, and could easily be migrated to another environment. The system was implemented in CatSU's College of Information and Communications Technology (CICT) for pilot testing purposes. Positive responses and feedback were obtained from end-users; hence, this was recommended to be utilized in the entire university.

IV. Results

The problem proffered in this study was about the development of the Decision Support System for the client satisfaction survey feedback results for bettering the offered services of the departments in the university. As mentioned in the Methods section of this article, the development of the system followed the Rapid Application Development (RAD) approach as specified in Fig. 1. This software development model suggests constant meetings with the end-users during the development process. Before the actual development of the system, prototypes were designed and presented to the end-users. Modifications and refinements were done with the prototype to suit the needs of the users. The actual development of the system commenced after the prototype and its refinements were approved by the users.

Fig. 6 below shows the integration of the DSS and its components into the system developed in this study.

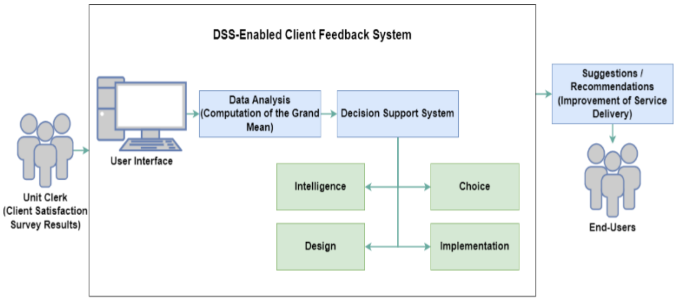


Fig. 6. Integration of the decision support system.

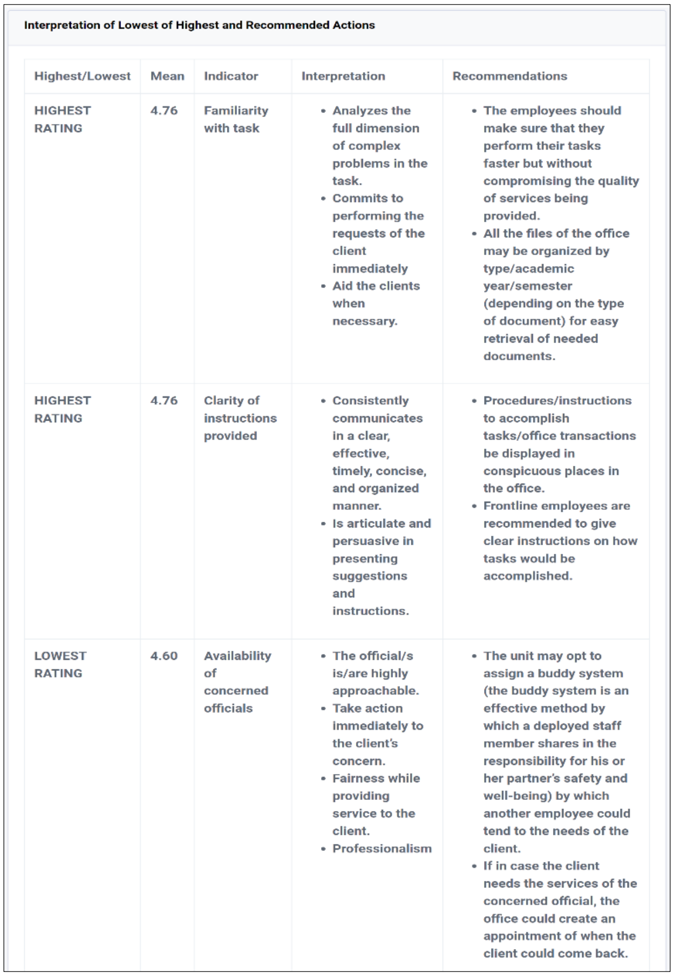
Input to the system was the client satisfaction survey results of the unit through the user interface, which could be done by the unit clerk. These inputs were analyzed by the system to provide the necessary data for the DSS such as the grand mean. The DSS was then implemented to provide suggestions/ recommendations for the service delivery improvement of the unit. The DSS module was based on the development framework by Juneja which was comprised of four (4) basic stages, namely Intelligence, Design, Choice, and Implementation [23]. The following are the stages undertaken in the development and integration of the DSS into the system:

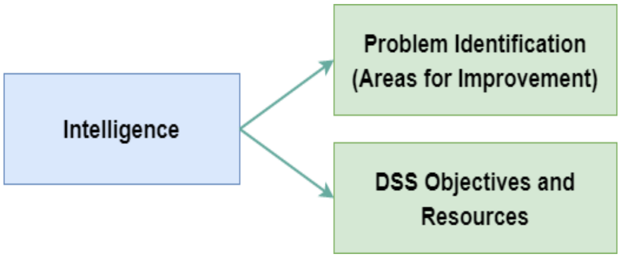
Stage 1: Intelligence. The DSS module started after the data analysis of the system. Fig. 8 shows the components of the Intelligence stage which were the Problem Identification (Areas for Improvement) and DSS Objectives and Resources. The DSS was designed to identify the areas where the unit has the highest and lowest rating. The areas identified were then given interpretations based on what the unit needs. The areas were also categorized into two, as shown in Fig. 5, which were “The Office” and “Frontline Employees”. This is to ensure that the recommendations and interpretations given by the DSS were specific to its areas. Fig. 7 shows an actual screenshot of the system which shows the lowest and highest rating and its corresponding interpretation and recommendation for service delivery improvement.



Interpretation of Lowest of Highest and Recommended Actions

Highest/Lowest	Mean	Indicator	Interpretation	Recommendations
HIGHEST RATING	4.76	Familiarity with task	• Analyzes the full dimension of complex problems in the task. • Commits to performing the requests of the client immediately • Aid the clients when necessary.	• The employees should make sure that they perform their tasks faster but without compromising the quality of services being provided. • All the files of the office may be organized by type/academic year/semester (depending on the type of document) for easy retrieval of needed documents.
HIGHEST RATING	4.76	Clarity of instructions provided	• Consistently communicates in a clear, effective, timely, concise, and organized manner. • Is articulate and persuasive in presenting suggestions and instructions.	• Procedures/instructions to accomplish tasks/office transactions be displayed in conspicuous places in the office. • Frontline employees are recommended to give clear instructions on how tasks would be accomplished.
LOWEST RATING	4.60	Availability of concerned officials	• The official/s is/are highly approachable. • Take action immediately to the client’s concern. • Fairness while providing service to the client. • Professionalism	• The unit may opt to assign a buddy system (the buddy system is an effective method by which a deployed staff member shares in the responsibility for his or her partner’s safety and well-being) by which another employee could tend to the needs of the client. • If in case the client needs the services of the concerned official, the office could create an appointment of when the client could come back.

Fig. 7. Recommendations for the service delivery improvement of the unit.



Intelligence
Problem Identification (Areas for Improvement)
DSS Objectives and Resources

Fig. 8. DSS development framework: intelligence.

Stage 2: Design. The design stage of the DSS development was broken down into two components, namely the System Design and System Structure, as shown in Fig. 9. System Design included identifying all the necessary technical requirements for the DSS and finalization of the User Interface (UI). This was also where all possible courses of action or recommendations for service delivery improvement were established. System Structure, on the other hand, includes the planning of the development and integration of the DSS into the UI. Having the system browser-based (run using a browser such as Chrome, Opera, Firefox, and the like), integrating the DSS required programming in the back-end using scripting languages such as PHP and JavaScript.

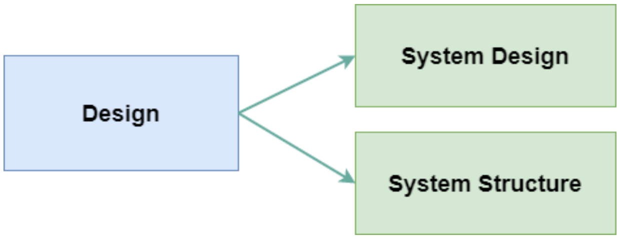


Fig. 9. DSS development framework: design.

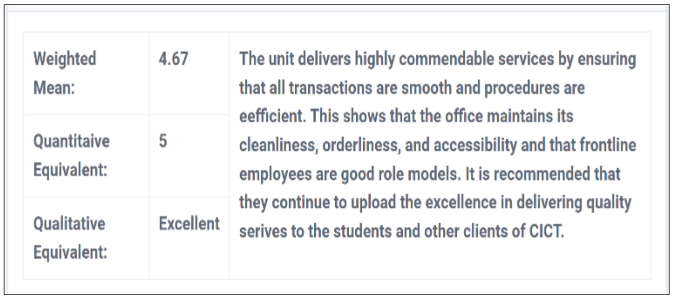
Stage 3. Choice. Once all the possible actions or recommendations were identified, integration of DSS took place in this stage. Sets of recommendations were stored in the Database for easy retrieval. The DSS used the client satisfaction survey results and its grand mean to identify the areas with the lowest and highest ratings. The system then provided a general impression of the grand mean. It also provided the best possible actions to better the unit’s service delivery by providing its interpretation and recommendations for the areas with the lowest and highest rating, as shown in Fig 8. Fig. 10 shows the actual screenshot of the system showing the grand mean of the unit’s results together with the general impression provided in the system.



Weighted Mean:	4.67	The unit delivers highly commendable services by ensuring that all transactions are smooth and procedures are eefficient. This shows that the office maintains its cleanliness, orderliness, and accessibility and that frontline employees are good role models. It is recommended that they continue to upload the excellence in delivering quality serives to the students and other clients of CICT.
Quantitaive Equivalent:	5	
Qualitative Equivalent:	Excellent	

Fig. 10. General impression of the system with the grand mean.

Stage 4. Implementation. The system was deployed in the CICT for pilot testing. During the pilot testing, comments, suggestions, and recommendations for the improvement of the system were sought from the faculty and were integrated into the final deployment of the system for the university. The screenshots of the developed system are shown below. Fig. 11 displayed the login process.

V. Conclusion and Recommendations

The study captured data relative to Client Satisfaction Survey Results for School Year 2015 -2016 to School Year 2020-2021, developed, deployed, and tested the system. The system does interpretations as to the overall mean for each Client Satisfaction Indicator and computed for the grand mean. From the grand mean, a general impression and recommendation as to better the service for a certain department in this university. Employment of DSS enables the system to recommend action to do for the improvement of the service delivery of each department in this university. For each Client Survey Indicator, the system is also recommending action to do. Recommended action of the system served as a guide for the improvement of the delivery of the service for a department in this university. The developed system was pilot tested in one of the colleges of the university and the positive results of the pilot testing enabled the university to adopt it. Adoption of the system as the university's gauge to evaluate a department's performance as perceived by the client had brought an advantage to the university's performance in its external performance evaluators.

The following recommendations were drawn for this study: (1) Valuing the opinions of customers, giving the best customer experience, and measuring customer satisfaction, especially with the utilization/integration of Information and Communications Technology and the DSS principle must be among the top-priority of every government office in this country to constantly improve their manner of service delivery; (2) The system developed should be utilized in full for each department since the system would be of help in the betterment of the service delivery of the entire university; and (3) The recommended actions by the system developed for improving the service delivery of each unit in the university should be put into life (action) to ensure a total client satisfaction or perhaps even exceeding expectations of clients.

Acknowledgment

The authors would like to acknowledge and express their gratitude to all those who had been part of the conceptualization, development, testing and improvement, and acceptance of the system for use in this study.

Development of a Two-dimensional Animation for Business Law: Elements of a Valid Contract

Sarni Suhaila Rahim[1*], Hazira Saleh[2], Nur Zulaiha Fadlan Faizal[3], Shahril Parumo[4]
Fakulti Teknologi Maklumat Dan Komunikasi, Universiti Teknikal Malaysia Melaka (UTeM), 76100 Melaka, Malaysia[1, 3, 4]
Politeknik Melaka, No. 2, Jalan PPM 10, Plaza Pandan Malim, 75250 Melaka, Malaysia[2]

***Abstract*—Elements of a valid contract is an important topic in corporate law. Since there are so many elements and related case studies, some students have difficulty remembering all the elements. Therefore, an animation will contribute to explaining all the elements in simpler terms, help the students remember the relevant case studies, and help lecturers teach students in an easier and more interactive way. An investigation on a 2D animation design and its effectiveness for corporate law and commerce learning is presented in this article. This paper aims to examine the 2D animation principle in animated explainer videos. In addition, the objective of this research is to develop an animation and evaluate the effectiveness of the 2D animation for Business Law teaching and learning. A comprehensive analysis of the 2D animation used in Business Law learning which focusing on spreading the importance of student understanding and motivation in Business Law course using a 2D animated approach is the expected outcome of this paper. The project collaborates with the Department of Commerce, Politeknik Melaka, Malaysia, for content expertise and testing. The Multimedia Production Process is the methodology used for the development of this research work, and the ADDIE Model is applied for the instructional design. The application is developed using Adobe After Effects, Adobe Premiere Pro, Adobe Media Encoder, and the Audacity platform. The contribution of this study is obvious, as the resulting outcomes can be used as guidelines for best practises of learning styles. The implications of this study will impact teaching and learning and increase understanding. This research is expected to improve teaching delivery while also increasing user understanding and motivation to learn.**

Keywords*—*2D animation; business law; elements of a valid contract; teaching and learning; multimedia

I. Introduction

Elements of a valid contract is one of the many topics delivered in corporate law that every business and commerce student should be aware of. It has a lot of key factors and a number of case studies that need to be related to each of the elements [1], making it harder for students to understand and memorise each element and their relevant cases. It also gets progressively harder for lecturers to provide a simpler way for their students to understand the topic. This work is to develop a 2D animation that acts as a medium for business students and lecturers to effectively remember relevant cases based on the elements of a valid contract. Elements of a valid contract is a crucial topic in corporate law that every business student must understand and memorise. Due to the many elements and relevant case studies [3, 4], some students are having a hard time memorising all the elements. This animation that will be delivered will focus more on explaining all the elements in simpler terms, helping them remember the relevant case studies, and helping the lecturers teach the students in a simpler and more interactive way.

This animation provided simplified descriptions of the Elements of a Valid Contract to facilitate the retention of important case studies among business law students and to assist lecturers in delivering interactive and comprehensive lessons. It is envisaged that the proposed work would assist in providing an effective teaching delivery to the students and lecturers in the form of 2D animated video.

The organisation of this paper is as follows: The existing system and related work on Business Law and two-dimensional animation are presented in Section II. Section III defines the overall methodology of this research work in detail. The implementation of the research work is presented in Section IV, while Section V presents the discussion. Finally, Section VI presents the conclusion and future work.

II. Literature Review

Elements of a valid contract consist of six essential elements, which are offer, acceptance, consideration, intention of making legal relation, certainty of the contract, and capacity and legality [1]. All these elements make up one valid contract.

Meanwhile, animation is a technique that manipulates figures to make them appear to move. Most animations today are created using computer-generated imagery, which has allowed multiple storytellers to deliver their stories in a more creative and fun way. Visibly, it provides a whole new method of expression and innovation, but on a more practical level, the evolution of movement attracts more attention than static images [2]. Visual designers can expand their creativity far beyond what the world allows them to do through liveliness. They can create sketches that draw a crowd as well as sketches that help the group understand the world better. Other researchers have presented materials that can assist in law education. For example, Boulton vs. Jones case is presented in [3], while the case between Hyde and Wrench is presented in [4]. The case between David and Noorazman is presented in Malayan Law Journal Reports [5], also Balfour v Balfour case is reported in [6]. Other cases, such as Karuppan Chetty v Suah Thian and Tan Hee Juan v The Boon Keat are reported in [7] and [8], respectively. Meanwhile, there are a lot of research works reporting on the animation usage, mainly for educational purposes. The development and evaluation of a 2D animated for therapy of verbal apraxia have been presented in [9] and [10]. An interactive content development using a 2D animation for depression awareness among tertiary students is explained in [11]. Meanwhile, the usage of animation in education and report generation are presented in [12] and [13]. A related domain to this proposed work which is the production process of an animated explainer video is discussed in [14].

Also, there have been several literature reporting the development of law education resources. Three existing systems will be discussed here: the David Jaroszewski videos on Youtube, Malaysia Company Law: Principles and Practices, and Introduction to the Law of Contract.

David Jaroszewski is a lawyer who practises law in Texas and has 40 years of community college teaching and leadership experience as a classroom instructor, department chair, and dean. He opened his YouTube channel back in January 2013 to make videos about various legal topics and teach the community about the basic concepts of each topic [15]. Fig. 1 shows a screenshot of the video.

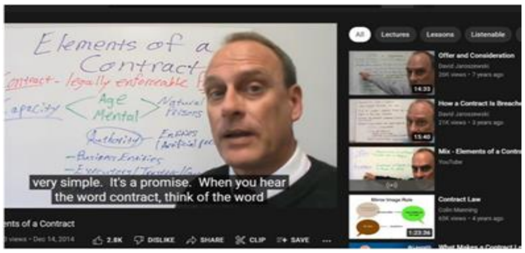

Fig. 1. Elements of a contract.

The Malaysia Company Law: Principles and Practices, 3rd Edition, provides a detailed analysis of the core company law principles, incorporating amendments in 2019 to the Companies Act 2016. The materials cover an extensive number of reported cases with extracts of significant dicta and relevant statutory provisions, combining the discussion of the Companies Act 2016 and the previous Companies Act 1965 [16]. Together with the thoughtful use of tables, diagrams, and flowcharts, this publication enables readers to engage in a critical examination of the law as it is and as it ought to be. Fig. 2 shows the cover page of the Malaysia Company Law book.

Introduction to the Law of Contract by Sarah Field is a user-friendly book that provides a comprehensive, clear, and straightforward account of what is required for the formation of a valid contract [17]. Fig. 3 shows the cover page of the Introduction of the Law of Contract.

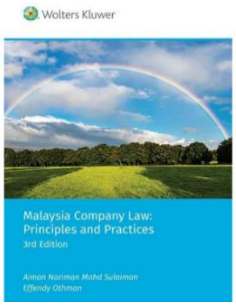

Fig. 2. Malaysia Company Law: Principles and practices.

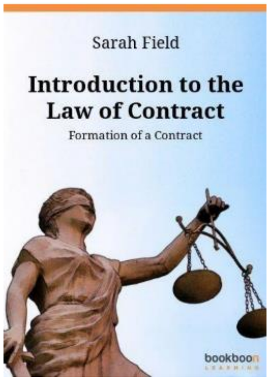

Fig. 3. Introduction to the law of contract.

III. Methodology

Multimedia Production Process is the methodology used in this research work. This model was chosen for this research work because it addresses the use of different media, such as images, text, animation, audio and video, to enhance the impact of message. The goals and objectives of the research work, as well as the intended audience, are all decided during development. Basic aims, objectives, and matrix of an activity would be constructed after settling on a multimedia project theme. Specific aims or general assertions of desired work outcomes are often global in multimedia works, whereas the objectives of work target adding customer association to a two-dimensional animation using the approach of digital animation.

The first phase is pre-production, which includes concept creation, design boards, storyboards, script writing, and character creation. The concept is the first item that is generated. To create a script, everyone involved in the work will explore different ideas for the animation. Before getting too ambitious, it is critical to understand the limitations of the animation and programme used. The animation's authors will write a narrative that will allow the animation to establish a storyline. A script is the foundation of an animation film, and it will serve as a point of reference throughout the animation production process. Captions that summarise the story's outline will be included in the storyboards. This aids in camera location as well as animation timing. It also aids in making decisions about what works and what does not.

The production phase comes next, which entails creating and implementing the storyboard into a multimedia work. During the production phase, the necessary hardware was installed, assets were transferred to the unit, also code was completed, among other things. Multimedia element utilised will be implemented, and flow charts also storyboards developed on this work will determine the technology to be used, as well as an existing system analysis and the current system limitation, all of which are the requirement part.

Lastly, there is the post-production stage, where the video's final appearance is determined. The full process of developing and modifying sound mixing, background music, and visuals, including lower thirds, is referred to as postproduction. When the video is finished, the multimedia program goes to alpha testing and beta testing. After it has been tested and updated, the developed application transfers to the stage called packaging. It may be available through a DVD or CD-ROM, or could be made available on the Internet and shared on sites like YouTube.

A. Analysis

A YouTube video called ‘Elements of a Contract’ made by David Jaroszewski and the Malaysia Company Law book will be the inspiration for this animation work. The reason for this is that their content is very simple to understand but lacks graphic content to assist students who are visual learners in memorising and understanding the context of the video. Table I presents the comparison of existing systems.

It can be concluded from Table I that various applications were proposed in order to produce an efficient and interactive learning tool. However, these applications still have lacunae or spaces for improvement. The contents of the listed research works, for example, are delivered in non-interactive video and manual books. In addition, the usage of multimedia elements is not fully implemented in those applications. Therefore, this proposed research implements a 2D animation approach for delivering the contents. The implementation of animation is necessary to overcome the limitations of the current delivery method. The proposed techniques in this research will most notably benefit the realm of multimedia in a number of areas or ways that include the provision of an interactive method for effectively displaying complex contents in the commerce and law fields.

The project specifications look at the framework that will be built. It will detail the actions, procedures, and other requirements that must be met by the work. The specifications will then be judged according to the gathered requirements also the project's methodology. One of the requirements of the project is a clear task understanding that must be accomplished.

The gathering requirements is among the most vital step for the process of data organisation and transmission. An interview was performed with a corporate law lecturer from Politeknik Melaka, Malaysia as the subject matter expert. All the work's features, including proposed interactions, source analysis and raw data were addressed during requirement collection. This work's basic methodology will be investigated as well. The study's findings will be used to further the field of animation.

The duration of this proposed application is about five minutes to help the students understand the content of the video even better. The storyline of the work is that there would be a businesswoman who would be telling the relevant cases in a storytelling way to make it easier to understand. All the characters and objects will be designed. As a result, during the analysis process, the researcher should conduct requirements consumer, target user, and stockholder. For this work, the researcher interviewed a lecturer from a local college who teaches that specific subject. The interviewee's information is listed in Table II.

B. Design

During the design phase, the animator will create and structure the animation. The animator and viewer will be able to get a general idea of the project interface by sketching the concept, layout and design. This phase also goes over storyboard design which is necessary for animation because it serves as a reference until the production process is completed. This stage is crucial for determining all the research work’s specifications.

In delivering the message to the viewer, characters play an important role. If the character fails to do so, the story will turn into ineffective and dull. Adobe Illustrator was used to create the design for better quality. Amongst the important character profiles designed for this work are businesswoman, defendant, plaintiff, third party, Mrs. Balfour, teenager, land, money, housing estate, handshake for agreement, goods, contract and court.

TABLE I. COMPARISON OF EXISTING SYSTEM

Comparison	David Jaroszewski videos	Malaysia Company Law: Principles and Practices, 3rd Ed	Introduction to the Law of Contract	2D Animation Business Law: Elements of a Valid Contract
Interactive	Non-Interactive	Non- Interactive	Non-Interactive	Non-Interactive
Types of Product	Video explainer	Book	Book	2D animation
Interface	Simple	Basic	Basic	Attractive and Simple

Position:	Principal Lecturer

C. Implementation

This part details the media creation, where it will cover the processes of media creation and media component editing before incorporating them in the media integration section later. Audio, graphics, text, and animation will be produced as part of this process. The storyboard of all the modules and the characters profiles are presented below in Tables III and IV, respectively.

TABLE III. STORYBOARD OF ALL MODULES

 BUSINESS LAW ELEMENTS OF A VALID CONTRACT RELEVANT LAW CASES	Scene: Main Title Description: Business Law:Elements of a ValidContract (Relevant Cases) Sound: Background Music Time: 6 seconds
 ↑ animate - slide up OFFER what is being proposed? A willingness to do/give something of desired	Scene: Module 1 Description:Offer definitions Sound: Background Sound
 Boulton v Jones ↑ up This is Jones [Defendant] order Brocklehurst [3rd Party] BUT Boulton [plaintiff] sell now a store owner	Scene: relevant case 1 Description: Boulton vJones Sound: Background Sound
 sends order receives WHY? B didn't inform J about change of owner Jones refused to pay Boulton! B was not liable for the price! Because no identification of person before contracting Contract Invalid!	Scene: relevant case 1 Description: continuationof the case and case issue Sound: Background Sound
 ACCEPTANCE ↑ up does everyone agree? ∴ action of consenting to receive / undertake contract offered	Scene: Module 2 Description: Acceptancedefinitions Sound: Background Sound
 Wrench Defendant Plaintiff Hyde Has a need sell to sell for $1000 no! $950! $1000?	Scene: relevant case 2 Description: Wrench v Hyde Sound: Background Sound
 P rejected original offer = no longer capable of accepting the original offer counter offer made = destroy original Contract Invalid	Scene: relevant case 2 Description: case issue and why the contract invalid Sound: Background Sound
 CONSIDERATION what's in it for you > other party ∴ act done/abstained by one person in return for promise	Scene: Module 3 Description: Consideration definitions Sound: Background Sound
 promise to help obtain approval for turn Wong Hon Leong pay RM 268,888 repay promise Noorazman Adnan promise exchange = mutual consideration = Good! Contract Valid!	Scene: relevant case 3 Description: Wong Hon Leong v Noorazman Adnan and case issue Sound: Background Sound

 INTENTIONS TO CREATE LEGAL RELATIONS are the parties interested in partnering together ∴ person signifies willingness to do / abstain from doing anything	Scene: Module 4 Description: Intentions to Create Legal Relations definitions Sound: Background Sound
	Scene: relevant case 4 Description: Balfour v Balfour Sound: Background Sound
 P & D had ✗ intention on making legal relations to each other agreement purely domestic contract invalid !	Scene: relevant case 4 Description: case issue andwhy the contract invalid Sound: Background Sound
 CERTAINTY is the contract clear? ∴ clear that any agreements in which terms or meaning of the agreement. ∴ no doubt or confusion in the contract	Scene: Module 5 Description: Certainty definitions Sound: Background Sound
 owns rents Karuppan Chetty Suah Thian he can stay as long as he likes for RM 35 Mr. Chetty have his house back and Mr. Suah Thian needs to leave the house Contract void	Scene: relevant case 5 Description: Karuppan Chetty v Suah Thian Sound: Background Sound

contract wasnot certain on its terms	Scene: relevant case 5 Description: case issue andwhy the contract invalid Sound: Background Sound
 CAPACITY & LEGALITY are the parties fit to enter an agreement ∴ person is a subject, has a sound of mind and is not disqualified from contracting by any law	Scene: Module 6 Description: Capacity & Legality definitions Sound: Background Sound
 Tan Hee Juan minor Teh Boon Keat I want to buy! → has a show wants to sell applied to set aside transfer contract void! contract invalid !	Scene: relevant case 6 Description: Tan Hee Juanv Teh Boon Keat Sound: Background Sound
 Tan Hee Juan was ✗ competent for a contract because he was a minor transaction = void tan hee juan keep the money	Scene: relevant case 6 Description: case issue andwhy the contract invalid Sound: Background Sound

TABLE IV. CHARACTER PROFILES

Profiles	Character
Host	Defendant	Plaintiff	Third Party (Module 1)	Mrs Balfour (Module 4)	Teenager (Module 6)	Land	
Money	
Housing estate	
Handshake for agreement	
Goods (Module 1)	
Contract	CONTRACT Sign
Court	

1) Text production: Text is vital to the creation of this animation, as it provides all the information needed for the viewers to understand the context of the work. In this venture, the words and sentences are simplified in order to make them clearer and more precise. The text was created using Adobe After Effects. For this animation, the font types Times New Roman, Georgia, and Impact are chosen in order to create the typewriting style.

2) Graphic production: The process of editing and design is in production of graphic for a two-dimensional animation, in which graphics or images are used. The characters and bitmap images are formed as a two-dimensional image using Adobe Illustrator, while some characters were taken from the Freepik website. The 2D images were used for this animation.

3) Animation production: In this section, the storyline and characters were created according to the storyboard that had already been done in the pre-production phase. All the characters were formed, colored, and edited in Adobe Illustrator. Then, the movements of the characters are done using Adobe After Effects. Then, the animation is saved as a clip of movie format. For all the objects and characters designed in this animation work, some have been done to make the animation process easier. All the assets are then saved in Adobe Illustrator. Besides, transitions are used for the movement of the characters as a way to make the characters move smoothly onto the canvas and make up the animation. The combining of movie clips and files is implemented in Adobe Premiere Pro, and the rendering file is an mp4 file. The targeted audience can then play this project on any sort of device, whether it be a laptop or their smartphones.

4) Audio production: This application has a voiceover that is recorded using the Audacity software, which is then imported into the animation using Adobe Premiere Pro. The background audio is taken from a non-copyrighted sound from the Internet.

5) Product configuration management: This work made use of Adobe Illustrator for illustration and the objects and characters were drawn in layers called vector layers. The characters and objects will then be animated frame by frame in the same software after they have been finished drawing. This is where all the coloring and shading takes place. After finishing the animation process, the animation is later exported to a software named Adobe After Effects to be animated. Finally, the animation will then be exported as an mp4 video format.

The status of implementation aims to keep track the process of development for the developed work. It will discuss the progress of development using the Gantt chart. Table V will show the status of development.

TABLE V. IMPLEMENTATION STATUS

Module	Duration	Description
Character design and modelling	1 week	The character and object that will be used will be designed
Animation scenes creation	3 weeks	The frame by frame animation using Adobe After Effects will be created
Background input and sound effect	1 week	Sound effect and sound for background will be chosen and input into the animation
Scene compiling in Adobe Premiere Pro	1 week	The animated scenes will be compiled to Premiere Pro

IV. DEVELOPMENT

V. Discussion

This paper presented the essential phases of analysis, design and development of the Business Law two-dimensional animation. A comprehensive explanation of the evaluation phase of the application is presented in [18]. The evaluation comprised five major evaluation components, including learnability, usability, accessibility, functionality, and effectiveness. The findings of the usability testing performed revealed that the majority of respondents were pleased with the outcomes of the animation. Also, the findings of the testing in [18] indicate that the outcomes of the 2D animation may facilitate and overcome the limitation from the current work proposed by other researchers in [15-17]. It is envisioned that this proposed animated video will assist teachers and students as an effective teaching and learning platform.

The main aim of this work is to help the students achieve a better understanding of the Elements of a Valid Contract topic and provide a way of memorising the relevant cases in each element. In a nutshell, this method of learning is proven to be able to assist students in understanding the Elements of a Valid Contract topic and memorising its relevant cases more effectively, hence the objective is reached.

VI. Conclusion

To conclude this research work, the animation was indeed proven to be successful. Despite a little shortcoming, the demand for the animation work was well addressed. Throughout the analysis phase, the animation and systems were investigated to determine the elements that could be required to build an effective teaching animation system.

The proposed techniques in this research will mostly notably benefit the realm of multimedia in a number of areas or ways that include the provision of an interactive method for effectively displaying complex contents in the social sciences field. The proposed work will be a benchmark and can be enhanced in other major complex study fields and topics in order to assist course delivery among tertiary students and lecturers. The application could be enhanced with other advanced approaches for more convenient accessibility and wider usability.

A few enhancement suggestions made in order to improve the application capabilities and execution in the future, such as making a separate video for each Element of a Valid Contract and different character designs for different character names that are featured in each different case. Besides, it is suggested to improve the sound quality of this animation by slowing down the narration to produce clearer and more precise explanation.

ACKNOWLEDGMENT

This research is funded by Universiti Teknikal Malaysia Melaka (UTeM) through Teaching and Learning in TVET Short Term Research Grant (PJP/2022/FTMK/TVET/S01952). The group of authors are thankful to all respondents who took part in the final survey and testing phase, and we would like to express our thoughtful appreciation to them.

An Improved Lane-Keeping Controller for Autonomous Vehicles Leveraging an Integrated CNN-LSTM Approach

Hoang Tran Ngoc, Phuc Phan Hong, Nghi Nguyen Vinh, Nguyen Nguyen Trung,
Khang Hoang Nguyen, Luyl-Da Quach
Software Engineering Department, FPT University, Cantho City, Vietnam

***Abstract*—Representing the task of navigating a car through traffic using traditional algorithms is a complex endeavor that presents significant challenges. To overcome this, researchers have started training artificial neural networks using data from front-facing cameras, combined with corresponding steering angles. However, many current solutions focus solely on the visual information from the camera frames, overlooking the important temporal relationships between these frames. This paper introduces a novel approach to end-to-end steering control by combining a VGG16 convolutional neural network (CNN) architecture with Long Short-Term Memory (LSTM). This integrated model enables the learning of both the temporal dependencies within a sequence of images and the dynamics of the control process. Furthermore, we will present and evaluate the estimated accuracy of the proposed approach for steering angle prediction, comparing it with various CNN models including the Nvidia classic model, Nvidia model, and MobilenetV2 model when integrated with LSTM. The proposed method demonstrates superior accuracy compared to other approaches, achieving the lowest loss function. To evaluate its performance, we recorded a video and saved the corresponding steering angle results based on human perception from the robot operating system (ROS2). The videos are then split into image sequences to be smoothly fed into the processing model for training.**

Keywords*—*End-to-end steering control; convolutional neural network; LSTM; nvidia model; MobileNetv2; VGG16

I. Introduction

For over a decade, autonomous driving techniques have captured significant attention from both academic and industrial research and development sectors. During the initial phases of autonomous driving research, the predominant strategies employed were rule-based, primarily focused on image processing. In these approaches, perception, and control were treated as distinct functional modules, operating independently from each other [1]-[9]. However, with the advent of deep learning technologies, there has been a notable shift towards end-to-end vehicle control as a leading research area in autonomous driving [10]-[12]. This approach integrates perception and control into a seamless system, leveraging the power of deep learning to optimize autonomous driving performance.

In 2016, Nvidia introduced the pioneering end-to-end driving model for steering angle control [13]. This model employs Convolutional Neural Networks (CNN) to directly predict the steering angle using raw pixel data from a single frame obtained from a front-view camera. Subsequently, other research studies emerged, exploring various CNN architectures like MobileNetV2, ResNet50, and VGG16, with the aim of enhancing the accuracy and speed of steering angle estimation. These papers are presented with different definitions. [14]. However, these end-to-end driving models have neglected temporal information by focusing solely on individual frames.

In recent years, LSTM has been considered and incorporated into the CNN structure to learn continuous information from the image sequences of the past. Eraqi et al. [15] presented a C-LSTM (CNN with Long Short-Term Memory) model that captures both visual and dynamic temporal dependencies in driving. By incorporating both a CNN and an LSTM network, this model utilizes multiple frames from the front-facing camera input to estimate the steering angle. In a similar vein, Xu et al. [16] proposed an end-to-end architecture called FCN-LSTM, which not only predicts the steering angle but also aims to understand the scene simultaneously. In addition, Yang et al. [17] proposed a multi-modal multi-task network that takes an end-to-end approach and aims to simultaneously predict the steering angle and speed. However, the utilization of the conventional combination of CNN and LSTM in these methods limits their accuracy. With the continuous development and progress of processing hardware, CNN architectures with millions of parameters have been developed and successfully employed to achieve higher accuracy. In light of this, we present a novel approach in this paper by integrating the VGG16 model with LSTM to enhance the estimation accuracy. We leverage the relevant information from input image sequences to improve performance. Through a comparison with traditional methods, we demonstrate the exceptional accuracy achieved by our proposed approach. It is important to note that the implementation of this model will be carried out in a ROS2 simulation environment.

The structure of this paper is outlined as follows: Section II presents an overview of the proposed method. In Section III, we provide a detailed explanation of the CNN-LSTM architectures incorporated into our proposed model. Section IV introduces the experimental system, dataset, evaluation metrics, and the corresponding results, followed by a comprehensive discussion. Finally, Section V concludes the paper, summarizing the key findings and contributions.

II. Proposed Method Overview

The system being developed within the ROS2 robot simulation environment comprises a vehicle model equipped with an RGB camera mounted on the front chassis. Our proposed synthetic neural network, which integrates VGG16 and LSTM networks, is utilized to estimate the steering angle based on input from the camera. The VGG16 model processes each frame of the camera image individually, extracting relevant features. These features are then fed into the LSTM network to capture temporal dependencies, as explained in the next section. The steering angle prediction is obtained from the output classifier following the LSTM layers. Upon completing the training process, the model will be saved and applied for testing on the vehicle model.

To train the proposed model network, we utilize the VGG16 architecture for feature extraction by including the current image (t) and the four preceding images from (t-1) to (t-4). This creates a sequence of 5 images captured within one 0.16s, which will serve as a sample sequence. The LSTM network will then analyze the temporal relationships among these images to estimate the steering angle based on contextual information. During training, the estimated steering angle at the time (t) will be compared with the corresponding ground-truth steering angle at the time (t), and the error will be used in the backpropagation algorithm [18] to update the model's parameters. During the training phase and after saving the model, the proposed system can be visualized through a block diagram, as shown in Fig. 1. This diagram outlines the flow of data and processes involved in the system's operation during both the training and running phases.

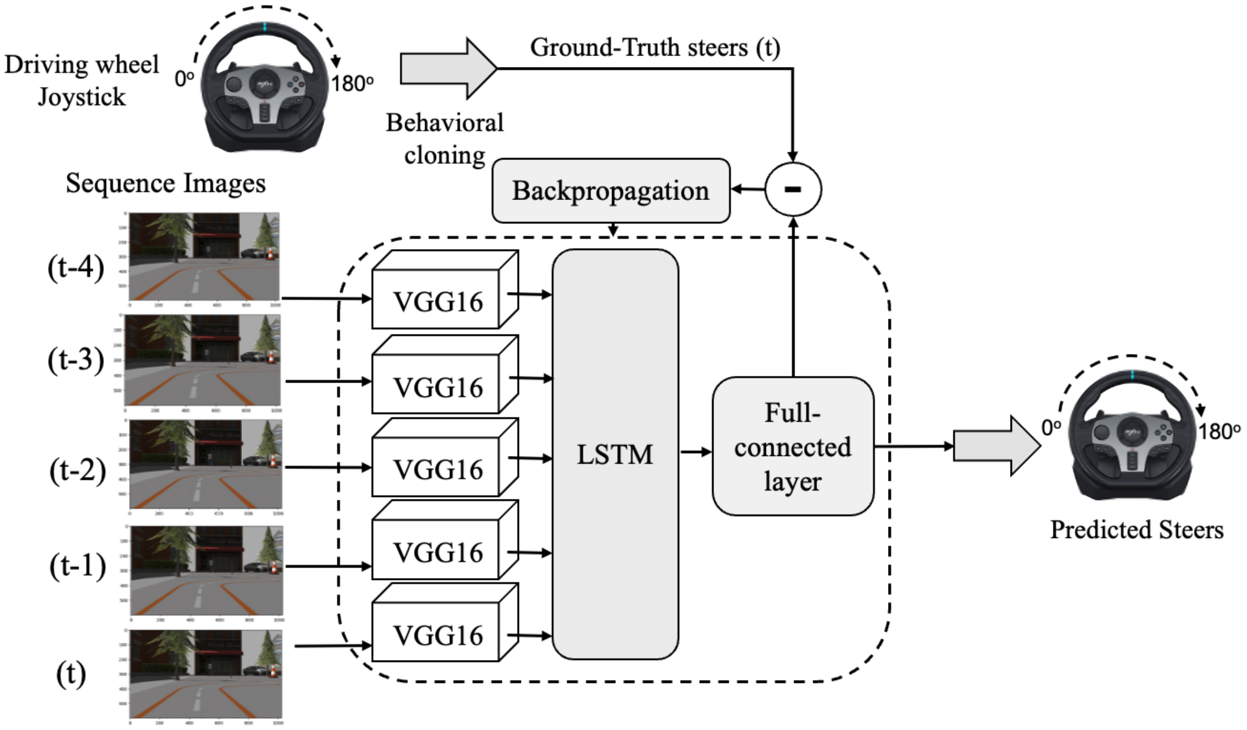

Fig. 1. Block diagram of the proposed system.

III. CNN-LSTM Architectures

In this section, we will introduce the CNN architecture and its integration with LSTM to extract relevant features and combine them over time. This integration allows us to process the input data in a sequential manner and pass it through a fully connected layer to obtain the predicted steering angle.

A. *Nvidia CNN-LSTM Model*

The Nvidia model, introduced by Nvidia [10], utilizes convolutional neural networks (CNNs) and is specifically engineered to predict the steering angle by processing raw pixel information obtained from a front-facing camera. This model takes advantage of the visual information captured by the camera to directly predict the appropriate steering angle for autonomous driving. By training on a large dataset of images and corresponding steering angles, the Nvidia model learns to extract relevant features from the images and make accurate predictions. We have separated the convolutional feature map of the Nvidia model. Then, we integrated it with LSTM, as shown in Fig. 2, to process the image data sequence by first extracting the features individually before reassembling them using LSTM.

B. *MobileNetV2-LSTM Model*

The MobileNetV2 model is a lightweight CNN architecture that focuses on efficient computation [19]-[20]. It utilizes depthwise separable convolutions, which divide the convolutional operation into separate depthwise and pointwise convolutions.

Fig. 2. Nvidia CNN-LSTM structure.

This approach reduces the number of parameters and computational complexity, making it suitable for resource-constrained environments such as mobile devices or embedded systems. The MobileNetV2 model is also trained on image sequences and corresponding steering angles to learn the relationship between visual inputs and steering control. However, we have replaced MobileNetV2 with the Nvidia CNN model to extract features from the input image sequence. The architecture of MobileNetV2 integrated with LSTM and a fully connected layer is depicted in Fig. 3. We will proceed with training on the dataset obtained from driving videos in the ROS2 environment to evaluate the results.

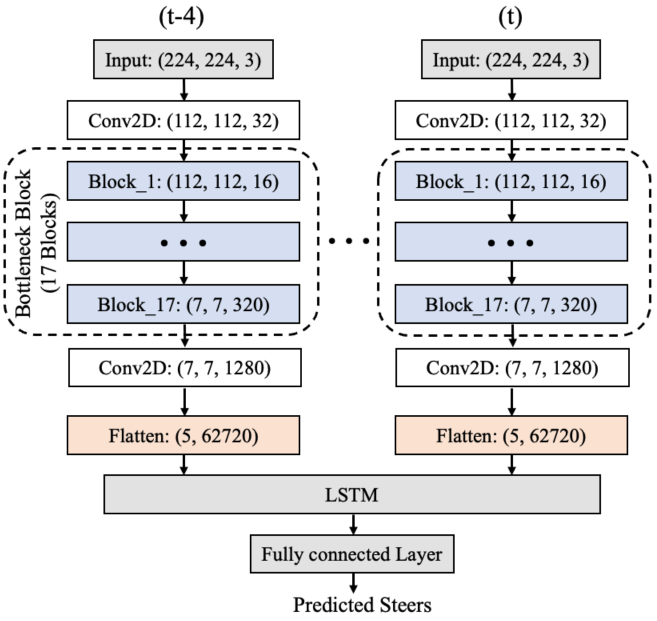

Fig. 3. MobileNetv2-LSTM structure.

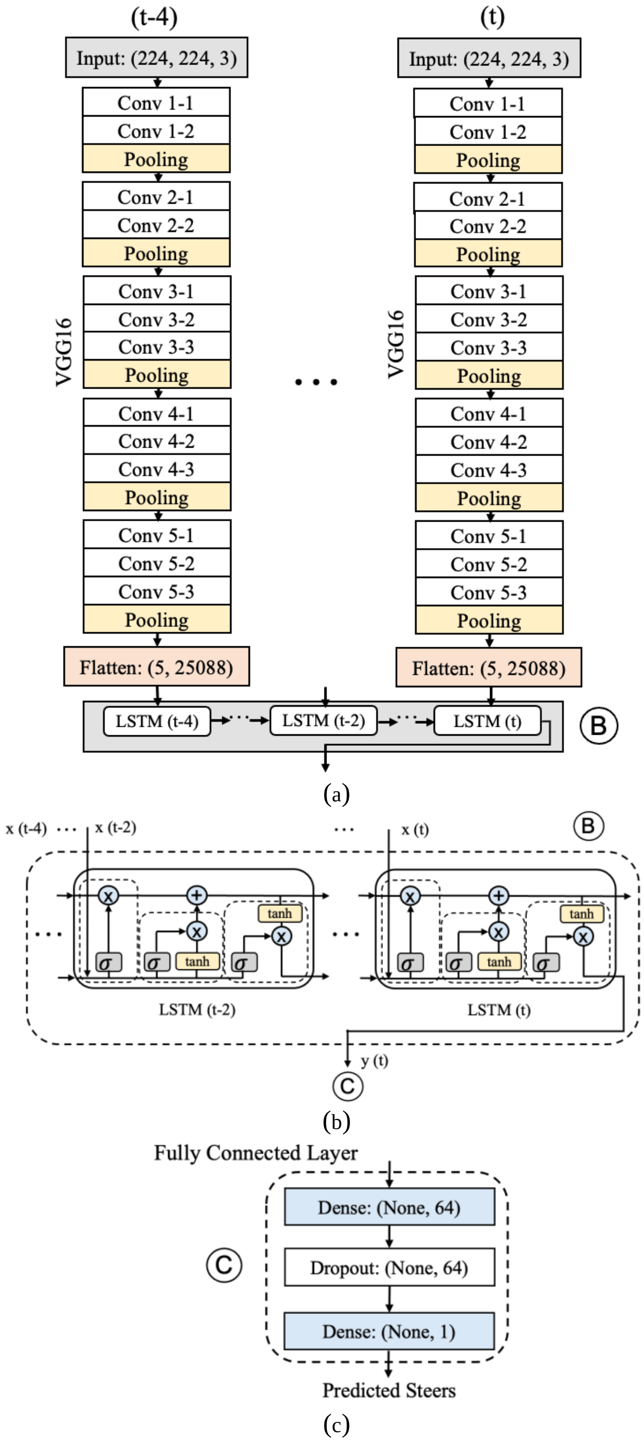
C. Proposed VGG16-LSTM Model

The proposed VGG16-LSTM driving model, presented in Fig. 4, consists of two main components: the feature-extracting network and the steering angle prediction network. In this model, the input comprises the previous five frames, ranging from frame t-4 to frame t, which serve as inputs for the driving model.



(a)

(b)

(c)

Fig. 4. Proposed VGG16-LSTM structure.

In this study, the VGG16 architecture [21]-[22] is utilized as the feature extraction component. VGG16 is composed of several convolutional layers and pooling layers, which are employed to extract relevant features from images.

The network receives a sequence of five images, each having dimensions of 224x224x3, as input. These images are processed through the feature extraction layers of VGG16, resulting in a feature map with a predetermined size. Following that, a Flatten layer is utilized to convert the output of VGG16 into a vector shape. This vector will be fed into an LSTM network to store temporal information. The LSTM network will handle sequential data and retain previous information for estimating the steering angle.

In the LSTM model with multiple inputs and one output, the network takes in 5 input vectors corresponding to x(t-4), x(t-3), x(t-2), x(t-1), and x(t) as shown in Fig. 4(b). These vectors represent past temporal information. The LSTM model is designed to process and analyze sequential data. To accomplish this, the LSTM model utilizes activation functions, specifically the sigmoid function and the hyperbolic tangent (tanh) function. The sigmoid function is used for the input, forget, and output gates, ensuring controlled information flow within the model. On the other hand, the tanh function facilitates the storage and updating of continuous-valued information within the memory cell.

The output y(t) of the LSTM model is further processed by passing it through the final layers, which consist of two fully connected layers and one dropout layer as shown in Fig. 4(c). These layers contribute to refining the predicted steering angle estimation. The fully connected layers serve as a mapping function, transforming the input from the LSTM into a suitable output format for the desired steering angle estimation.

Every neuron is interconnected with all the neurons in the preceding layer, enabling the learning of intricate relationships and patterns. In the following chapter, we will proceed with the training and compare the accuracy of these models.

IV. Experimental Results

A. Experimental Setting

The virtual environment, illustrated in Fig. 5, is constructed and designed using the Gazebo/ROS2 software. Within this simulation world, a donkey car and a two-lane map are present, serving as the training and testing environments for self-driving mode. Human experts control the donkey car through joystick input, and the captured images are saved and used for training the proposed models. The training process utilized a dataset comprising 10,000 images and was executed on a computer equipped with macOS Ventura 13.4, an ARM-based M2 CPU, a 10-core GPU, and 32 GB RAM. Our algorithm was implemented in Python 3.10, utilizing the Tensorflow 2.12.0 and Keras 2.12.0 libraries. The optimizer used in this study is ADAM [23]. For the experiments conducted, the initial learning rate is set to 0.001.

The VGG16-LSTM model has a total of 45,994,177 parameters, including both trainable and non-trainable ones. Out of these, 40,128,641 parameters are trainable, representing weights and biases that will be updated during training, while 5,865,536 parameters are non-trainable and remain fixed. By freezing the last 8 layers of the VGG16 base with a "trainable" attribute set to False, their weights and biases are preserved, leveraging pre-trained knowledge from the ImageNet dataset. The architecture and parameters of our proposed steering angle prediction model, which was based on transfer learning using VGG16-LSTM, are shown in Fig. 6.

B. *Dataset and Evaluation Metrics*

1) Dataset: The vehicle is equipped with a front-facing camera that captures images, and the ROS2 controller records both the steering angle from the joystick and the corresponding camera images. The data is collected at a rate of 30 frames per second, resulting in five consecutive frames captured within a duration of 0.16 seconds. For this particular study, the dataset used consists of 10,000 images, which is equivalent to 2000 sequences of images. Each sequence contains five consecutive images. The dataset is continuously collected along with the corresponding steering angle information, which is obtained through human perception.

To access the dataset used in this study, you can visit the following link: (https://www.kaggle.com/datasets/ngochoangtran1992/steering-angle-prediction). The input images have a size of 1024x600 before being fed into the training model, and they undergo normalization to align with the input size of VGG16. Fig. 7 illustrates a sequence of five images, showing them before and after normalization, which prepares them for training.

2) Evaluation metrics: During the training process for estimating steering angles using a VGG16 model combined with LSTM, the Mean Squared Error (MSE) equation (4) is commonly used as the loss function and evaluation metric. The MSE measures the average squared difference between the predicted steering angles and the ground truth values provided by human perception.

$$MSE(\hat{y}[t], y[t]) = \frac{1}{N}\sum_{i=1}^{N}(\hat{y}[t]_i - \ y[t]_i)^2 \tag{4}$$

where $\hat{y}[t]_i$ and $y[t]_i$ are the predicted and true steering angles at the current time and the i^{th} sequence.

By minimizing the MSE loss, the model aims to accurately estimate the steering angles, ultimately improving the alignment between the predicted and actual values, as perceived by humans.

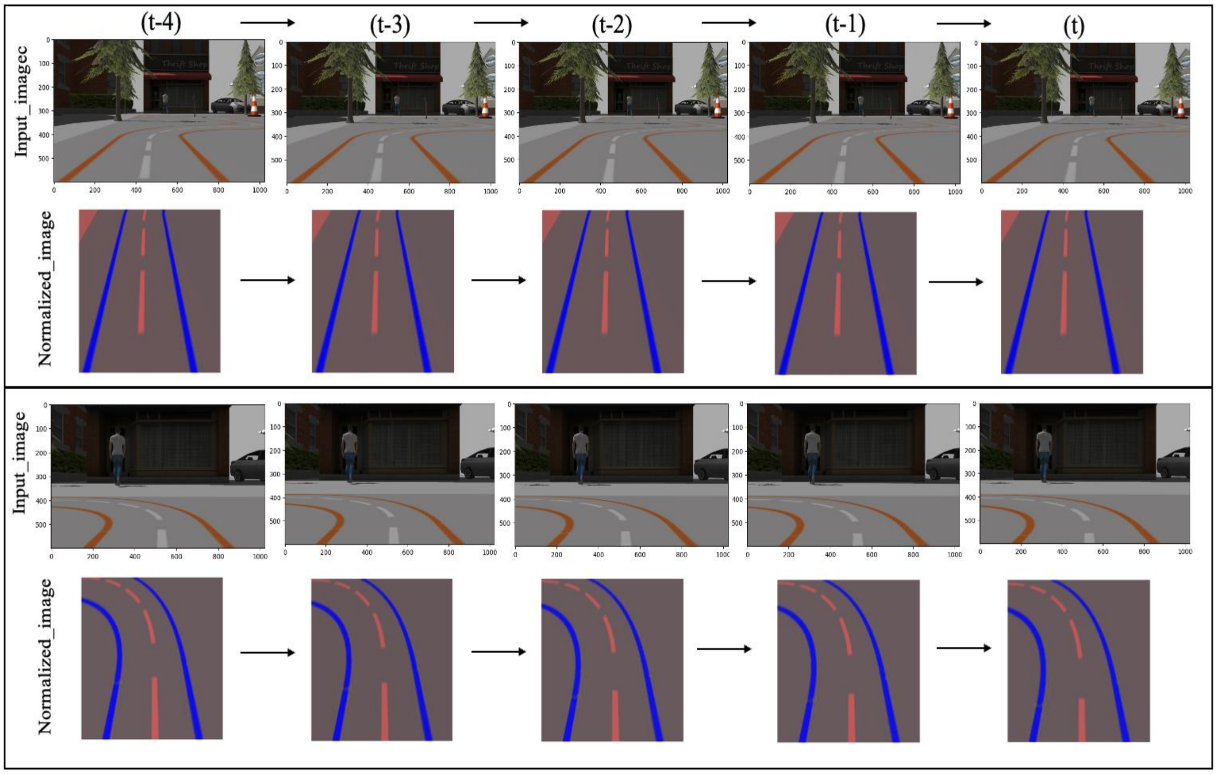

Fig. 7. Sequences of five images before and after normalization of our datasets.

3) Results: The results and comparison of four models, namely Nvidia-CNN, CNN-LSTM, MobileNetv2-LSTM, and the Proposed method (VGG16-LSTM), were evaluated based on their loss values and validation loss values. The Nvidia-CNN model achieved a loss value of 314.03 and a validation loss value of 1268.70. The CNN-LSTM model obtained a loss value of 198.95 and a validation loss value of 479.37. The MobileNetv2-LSTM model demonstrated a loss value of 164.37 and a validation loss value of 244.32. Lastly, the Proposed method (VGG16-LSTM) outperformed the other models with a loss value of 65.07 and a validation loss value of 198.08. These results indicate that the Proposed method (VGG16-LSTM) achieved the lowest loss values, both in training and validation. This suggests that the VGG16-LSTM model performs better in estimating the steering angles compared to the other models, as it exhibits significantly lower loss values. The decrease in loss values indicates a stronger correlation between the predicted and actual steering angles, demonstrating enhanced precision and effectiveness in estimating steering angles. The comparison results of the models are depicted in Table I, and Fig. 8 and Fig. 9 visualize the training outcomes and accuracy assessment of these models throughout 20 epochs.

TABLE I. EXPERIMENTAL RESULTS OF THE PROPOSED MODEL AND OTHER COMPARATIVE METHODS

Val_Loss	1268.70	470.37	244.32	198.08

Fig. 10 shows the comparison between the steering angle predictions of various models with the proposed approach. It is readily apparent that the proposed method's steering angle predictions exhibit an accuracy level of approximately 95% when compared to the ground truth values. Achieving this level of accuracy involves implementing a method that utilizes a series of input images and incorporates information from previous frames to estimate the steering angle.. The VGG16 and LSTM networks are utilized to extract significant features, ensuring the highest possible precision in the predictions.

V. Conclusion

By combining VGG16 CNN and LSTM, our proposed approach successfully captures the temporal aspects of visual information and the dynamics of control. This integration sets it apart from other models, as it achieves an exceptional accuracy rate of approximately 95% when predicting steering angles. The results obtained in the ROS2 simulation environment are highly promising, suggesting significant potential for practical applications. This advancement represents a substantial improvement in the precision and dependability of autopilot systems, enhancing their ability to navigate real-life scenarios with greater accuracy and reliability.

Lane Road Segmentation Based on Improved UNet Architecture for Autonomous Driving

Hoang Tran Ngoc, Huynh Vu Nhu Nguyen, Khang Hoang Nguyen , Luyl-Da Quach
Software Engineering Department, FPT University, Cantho City, Vietnam

***Abstract*—This paper introduces a real-time workflow for implementing neural networks in the context of autonomous driving. The UNet architecture is specifically selected for road segmentation due to its strong performance and low complexity. To further improve the model's capabilities, Local Binary Convolution (LBC) is incorporated into the skip connections, enhancing feature extraction, and elevating the Intersection over Union (IoU) metric. The performance evaluation of the model focuses on road detection, utilizing the IOU metric. Two datasets are used for training and validation: the widely used KITTI dataset and a custom dataset collected within the ROS2 environment. Simulation validation is performed on both datasets to assess the performance of our model. The evaluation of our model on the KITTI dataset demonstrates an impressive IoU score of 97.90% for road segmentation. Moreover, when evaluated on our custom dataset, our model achieves an IoU score of 98.88%, which is comparable to the performance of conventional UNet models. Our proposed method to reconstruct the model structure and provide input feature extraction can effectively improve the performance of existing lane road segmentation methods.**

Keywords*—*Local binary patterns; feature extraction; UNet; semantic segmentation

I. INTRODUCTION

There has been a growing interest in autonomous driving research due to its significant impact on traffic management, the economy, and the development of self-driving cars.

The purpose of these vehicles is to imitate human driving actions through intelligent decision-making and executing various tasks such as switching lanes, preventing collisions, detecting objects, and issuing warnings for lane departure [1],[2],[3],[4],[5]. The design of autonomous driving cars involves three essential components: perception, path planning, and control [6],[7],[8],[9]. Recent advancements in sensor technology have greatly improved perception capabilities. While cameras are commonly used, the integration of additional sensors like GPS, radars, or LIDARs enhances the performance of self-driving systems [10]. The focus of autonomous navigation is on accurately detecting and identifying traffic participants, including cars, pedestrians, and surrounding objects/areas.

In particular, road detection and segmentation are crucial for autonomous driving and intelligent transportation systems as it ensures safe and efficient vehicle operation. Solutions in this area aim to reduce accidents, alleviate traffic congestion, and improve fuel efficiency.

Precise detection and recognition of roadways, encompassing boundaries and lanes, empower intelligent decision-making and enhance navigation efficiency. These advancements have the potential to greatly enhance overall transportation systems. Various datasets such as KITTI [11], Berkeley DeepDrive [12], A2D2, or those generated by the CARLA simulator [13] are utilized for a range of autonomous driving and lane segmentation tasks. Teichmann et al. Research was carried out to measure the computational time required for semantic segmentation tasks using the KITTI dataset [14]. Neven et al. focused on scene understanding using the Cityscapes dataset [15]. Similarly, real-time efforts utilizing the Cityscapes dataset involved the development of an ENet architecture [16]. Wang et al. utilized 3D LiDAR point clouds and the PointSeg architecture for real-time semantic segmentation [17]. Bai et al. explored time-critical task performance in road segmentation using the KITTI benchmark [18]. Additionally, Jang et al. aimed to explain and reduce the end-to-end delay for self-driving cars in their work [19].

In recent years, UNet is a fully convolutional network architecture that has gained popularity for lane segmentation in autonomous driving. It utilizes a U-shaped network design for accurate identification and delineation of road lanes. Studies have demonstrated its effectiveness, comparing it favorably to other methods in terms of accuracy and efficiency [20]-[21]. Giurgi et al. introduce a real-time implementation workflow for neural networks in autonomous driving, specifically focusing on road segmentation using the UNet structure with the KITTI dataset [22]. UNET's potential for improving autonomous driving systems may be seen in activities such as lane departure alerts and autonomous lane holding. However, when autonomous cars operate in tough traffic settings with high levels of noise and interference from elements such as dust, vibrations, rain, and wind, these algorithms become susceptible to disruptions, resulting in decreasing lane segmentation accuracy. The existence of these external elements severely impairs the effectiveness of lane segmentation algorithms, resulting in less than ideal results.

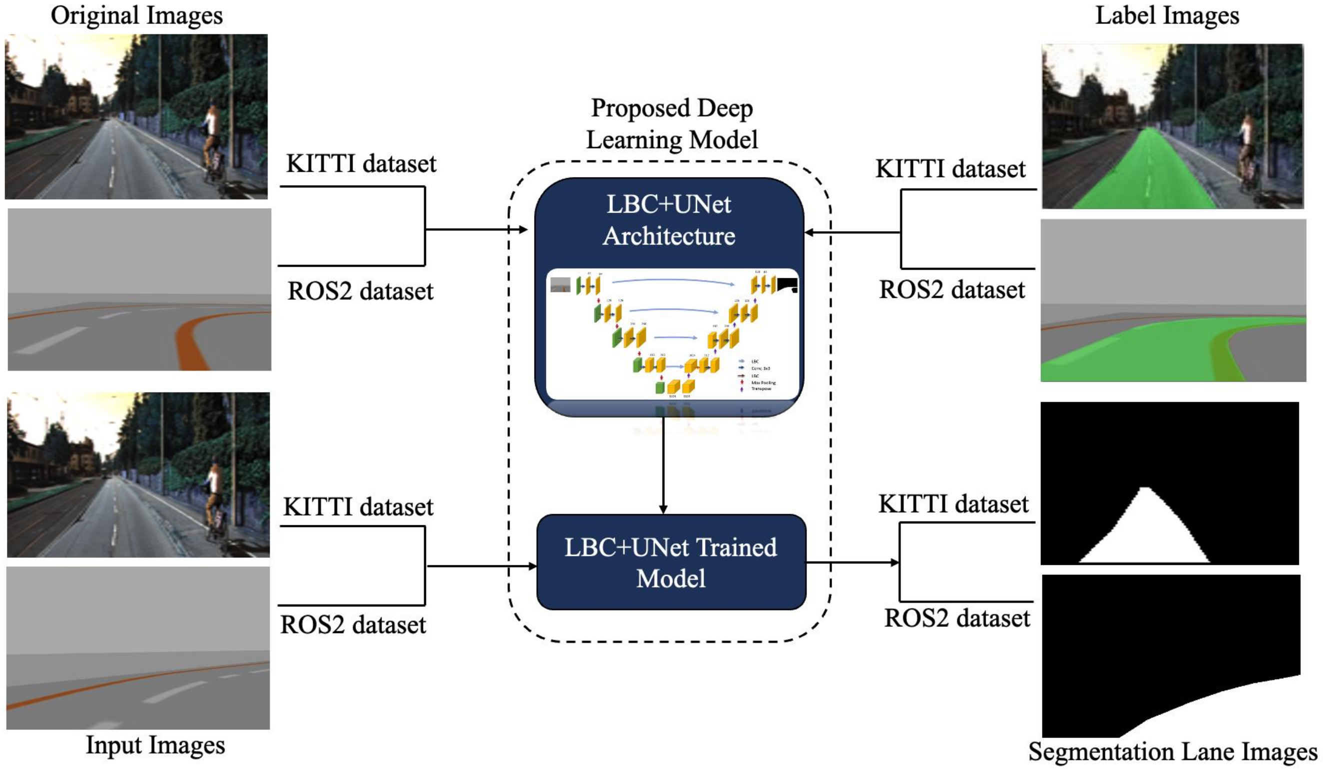

Fig. 1. Our proposed system.

To address these challenges, we propose the combination of LBC layers with UNet in this paper to improve lane segmentation performance in noisy traffic environments. The LBC layers integrate local binary patterns into the convolutional neural network (CNN) architecture [23], enhancing the ability to extract fine-grained structural information and model image representations. These layers have shown potential in applications that require robust feature extraction and learning, particularly in scenarios with limited training data or noisy environments. We will compare the performance of the proposed method to earlier approaches in order to quantify the improvement in accuracy on two datasets: KITTI and our own gathered dataset in a ROS2 robot simulation environment. Fig. 1 describes our proposed system.

The subsequent sections of the paper follow the following structure. Section II provides an introduction and summary of relevant research pertaining to lane segmentation. Section III describes the model's architecture in detail, outlining the integration of LBC and skip connections to enhance local feature extraction. Section IV focuses on the experimental implementation, dataset utilization, and a comparative analysis of various models. Finally, the paper concludes by summarizing key findings and proposing future avenues for advancement.

II. RELATED WORK

In recent years, there have been several advancements in the field of road lane segmentation. One notable approach is the DeepLab method proposed by Chen et al. [24], which combines deep convolutional nets with fully connected conditional random fields for accurate semantic image segmentation. Another approach is the ENet architecture introduced by Paszke et al. [25], specifically designed for real-time semantic segmentation tasks. Additionally, Pan et al. [26] proposed LaneNet, a spatial CNN architecture for traffic scene understanding, focusing on lane segmentation. Fu et al. [27] presented SCNN, a parallel CNN model that explores the road scene in depth for precise road segmentation. In a recent study, Giurgi et al. developed a unique method employing the UNet architecture, which demonstrated appreciable increases in lane segmentation accuracy. These studies are a limited exploration of image segmentation in the complex context of autonomous vehicles. Lane recognition is a crucial task in autonomous driving, and existing approaches confront difficulties owing to the complexities of the input pictures. To address this, we propose the use of LBC layers to reduce complexity and increase processing speed. Building upon this, we present an enhanced UNet model incorporating skip connections and LBC layers for improved lane markings recognition while minimizing training time. Comparative analysis and evaluation metrics, such as IoU, Dice coefficient, and precision, are employed to assess the accuracy and efficiency of the proposed models. Our study focuses on developing efficient and accurate segmentation models for lane recognition in autonomous driving scenarios.

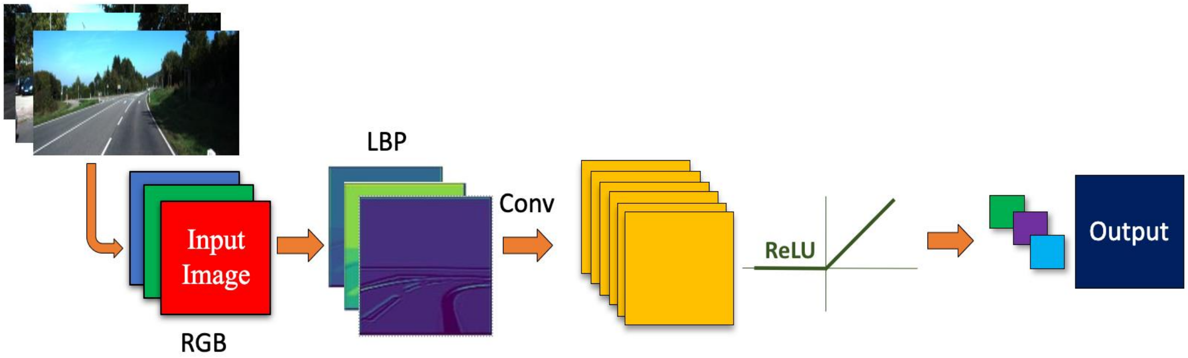

Fig. 3. Basic module local binary convolution.

III. Proposed Method

A. Local Binary Pattern and its Convolution Variants

1) Local binary patterns: Local Binary Patterns (LBPs) is an image processing technique used for capturing local patterns by comparing pixel values in small neighborhoods [28]. It is commonly employed in face recognition and object detection. LBPs operate by selecting a neighborhood around each pixel and converting the pixel values into a binary string. By comparing the values of surrounding pixels with the central pixel, the binary string is constructed. The equation for calculating the brightness intensity of LBPs can be described as follows:

$$LBP_P = \sum_{p=0}^{P-1} s(g_p - g_c)2^p \tag{1}$$

$$s(z) = \begin{cases} 1, & if\ z\ \geq 0 \\ 0, & if\ z\ < 0 \end{cases}$$

where g_p is the neighbor pixel intensity value; $g_c$is the center pixel intensity value. P is the number of neighbor pixels. Z is the result of g_p minus g_c.

This string represents the local spatial patterns within the neighborhood. Analyzing the distribution of these binary patterns provides valuable insights into local variations in brightness, which can be utilized for tasks like contrast enhancement and object recognition. LBPs are a compact representation of local patterns and find wide usage in computer vision applications. Fig. 2 illustrates the basic operation of LBPs, demonstrating their functionality for each pixel in an image with local dimensions of 3x3 and 5x5.

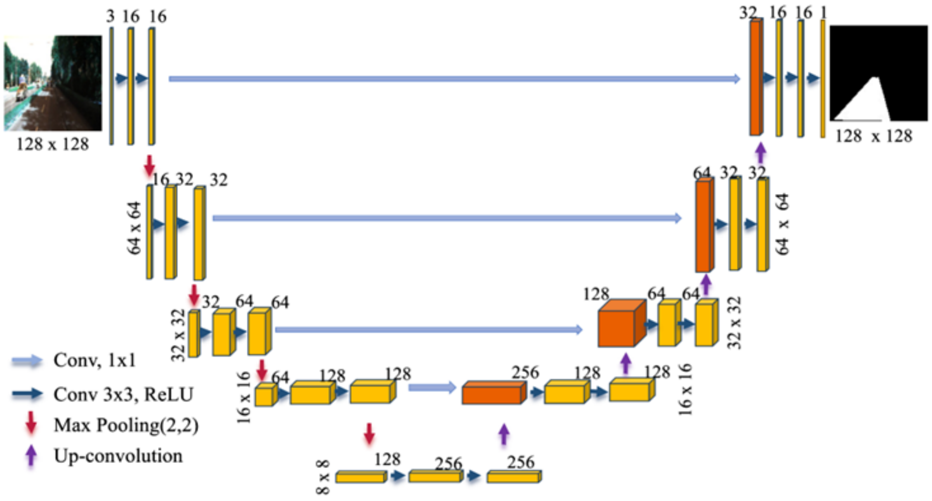

Fig. 4. Conventional UNet architecture.

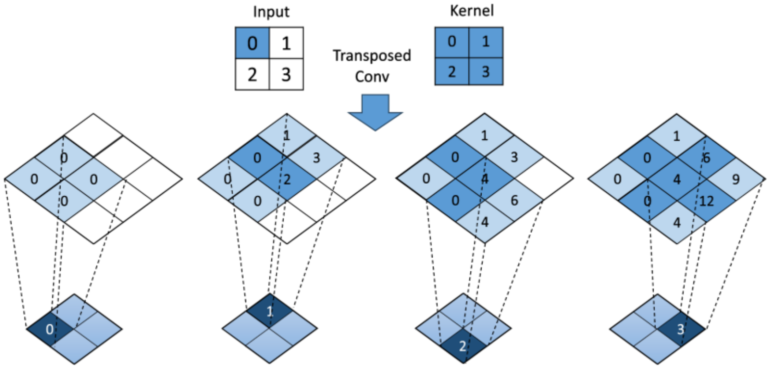

Fig. 5. Transposed convolution with a 2x2 kernel.

2) *Local binary convolution:* The Local Binary Convolution (LBC) layer convolves a filter over an input image, converting pixel values into binary patterns called Local Binary Patterns (LBPs). These patterns record structural, morphological, and textural information. During training, gradients can be backpropagated through the layer's anchor weights, while the learnable 1x1 filters are updated. The anchor weights can be generated deterministically or stochastically, allowing for diversified filters and fine-grained control overweight sparsity. The LBC layer efficiently extracts meaningful features for tasks like object detection and recognition in computer vision. In Fig. 3, we present the basic model of LBC that we use in this paper. The input image is first separated into three RGB channels through the LBP 3x3 local dimensions. After that, a convolutional layer is used for additional processing, followed by the ReLU activation function to extract key traits of road segments.

B. *Improved Lane Road Segmentation*

1) *Conventional UNet model*

a) *UNet architecture:* UNet is an architecture for semantic segmentation introduced by Olaf Ronneberger et al. [23]. This is a widely used architecture for road segmentation that combines encoding and decoding paths. It utilizes max pooling for down-sampling and transposed convolution for up-sampling. Skip connections play a crucial role in preserving information between the encoding and decoding stages.

Fig. 4 illustrates the structure of basic UNet architecture. It is made up of a left side encoding path and a right-side decoding path. Max pooling techniques are used in the encoding process to gradually lower the spatial resolution while raising the number of feature channels. This helps extract abstract features related to road structures. The decoding path employs transposed convolutions to up-sample the feature maps and increase the spatial resolution. This results in a dense output map representing the road segmentation mask. Skip connections establish direct connections between corresponding encoding and decoding layers, allowing detailed information to flow between them. This facilitates the reconstruction of accurate road segmentations.

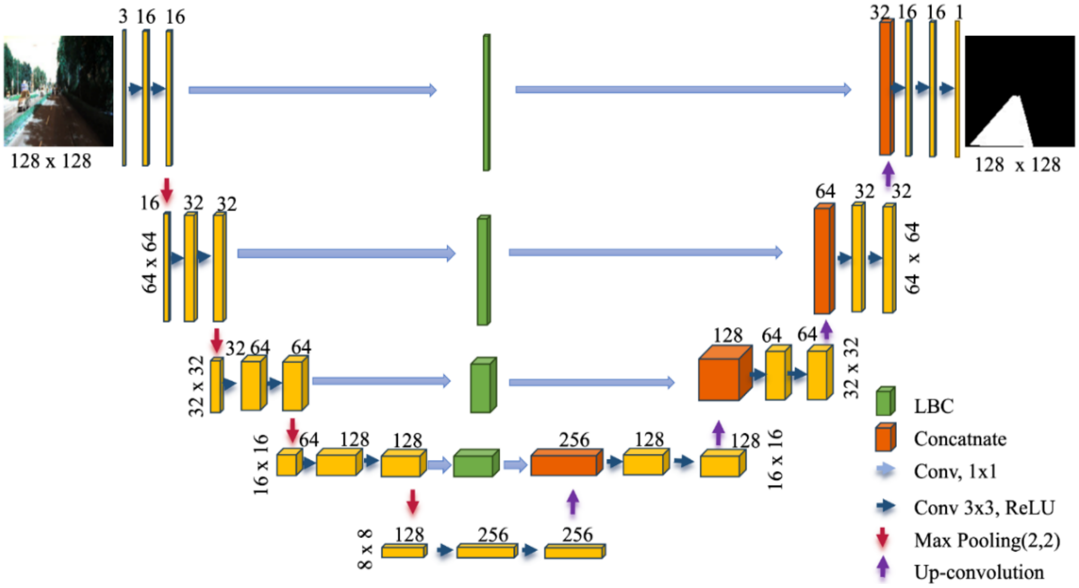

Fig. 6. Proposed UNet architecture.

UNet's combination of encoding and decoding paths with skip connections enables exceptional performance in road segmentation. It effectively captures both local and global context information, enabling precise delineation of road regions in images.

b) Up-convolution with transposed convolution approach: Transposed convolution, also known as deconvolution or fractionally stridden convolution, is a technique used to up-sample feature maps in convolutional neural networks. It is the reverse operation of the standard convolution operation and is commonly used in the decoding path of architectures like UNet. Fig. 5 shows the operation of Transposed Convolution with a 2x2 kernel. The parameters required to design a Transposed Convolution to achieve the desired output size can be described using (2):

$$O_{\text{size}} = (T_{\text{size}} - 1) \cdot s + H_{\text{size}} - 2 \cdot p \qquad (2)$$

where O_{size} is the desired size of the output feature map; T_{size} refers to the size of the input feature map; s is the stride value used in the Transposed Convolution operation; H_{size} represents the size of the kernel used in the operation; and p refers to the padding applied to the input feature map. However, in noisy and challenging environments such as transportation, a lane segmentation system with a robust feature extractor needs to be investigated. Therefore, we have developed an algorithm that we propose in the next section.

2) Improved design of the UNet model: The improved design of the UNet model aims to enhance the segmentation accuracy compared to the classic UNet architecture. To achieve this, we have introduced the Local Binary Convolution (LBC) layer into the skip connections of the UNet model. The design structure is illustrated in Fig. 6.

The encoding structure (left side) consists of four blocks. Each block includes a series of convolutional layers with ReLU activation, followed by max-pooling operationsThe output of each block is created by gradually applying the pooling and convolutional layer operations. The LBC layers are integrated into the skip connections of the UNet model to capture local binary patterns and improve the segmentation performance. These skip connections establish direct connections between the corresponding encoder and decoder layers. The four blocks handle the up-sampling and concatenation operations necessary for the skip connections. They take the inputs from the corresponding pooling layers and transpose convolutional layers to up-sample the feature maps. Finally, the model is compiled with the Adam optimizer and binary cross-entropy loss. The metrics used for evaluation include the Intersection over Union (IoU). This improved UNet model with LBC layers in the skip connections offers enhanced capabilities for accurately segmenting road images. In the upcoming section, we will evaluate the results and accuracy of this model using two datasets. The purpose is to demonstrate the superiority of the proposed method in comparison to existing approaches.

IV. Experimental Results

A. Experimental Setting

The experiments were conducted to train and evaluate multiple models using two distinct datasets. Each model underwent 100 epochs of training, and performance was assessed based on metrics such as IOU, Validation IOU, Loss, and Validation Loss. The training process utilized a computer with Ubuntu 20.04, an Intel i7 3.4 GHz CPU, an Nvidia GTX 3060 Laptop, and 32 GB RAM. The implementation was carried out in Python 3.9.13, employing the Conda 22.9.0, CUDA 11.7, Tensorflow 2.10.0, and Keras 2.10.0 libraries.

d) e) f)

Fig. 7. Comparison of segmentation performance among DeepLabv3, UNet, and proposed model based on IOU, Validation IOU, Loss, and Validation Loss. a), b), c) using KITTI dataset, and d), e), f) using Gazebo/ROS2 dataset.

B. *Datasets and Evaluation Metrics:*

1) Datasets: The research paper utilizes two datasets, namely KITTI [29] and a dataset created from simulated lanes in the Gazebo/ROS2 environment of our laboratory. The KITTI dataset is employed primarily for unmarked lane segmentation in urban areas, comprising 800 training images and 200 test images. On the other hand, the second dataset involves the Donkey self-driving car, which operates in the Gazebo/ROS2 3D simulation environment. The car is controlled using a driving wheel joystick to maintain lane position. The car is equipped with a front-facing camera that captures images, and the ROS2 controller records these images at a rate of 5 frames per second for training data. A total of 1000 images were collected for this dataset. The data split ratio is 80% for training data and 20% for validation data.

2) Evaluation metrics: In image segmentation, Intersection over Union (IoU) [25] is a primary metric used to evaluate the accuracy of models. Unlike in object detection, where IoU serves as a supplementary metric, it plays a crucial role in the pixel-level analysis of segmentation masks. The definitions of true positive (TP), false positive (FP), and false negative (FN) differ slightly in image segmentation, considering the pixel-wise intersection and logical operations between the ground truth and segmentation masks. IoU is determined in image segmentation by dividing the intersected area by the sum of the ground truth and prediction areas using the TP, FP, and FN areas, or pixel counts.

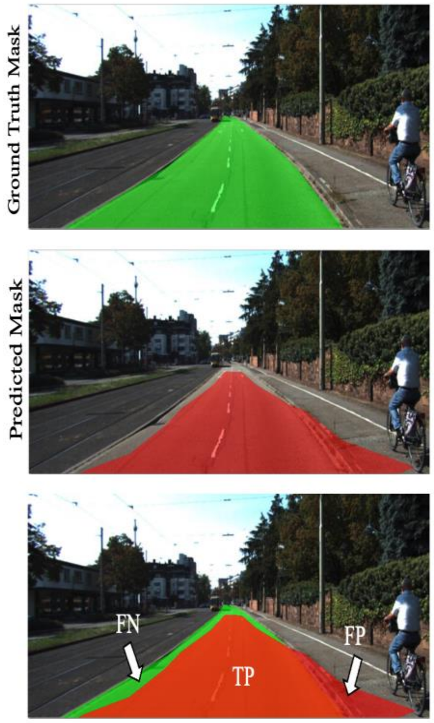

Fig. 8. Example of the IOU equation.

This metric helps assess the effectiveness of models in accurately segmenting objects and regions of interest in images. The equation is shown below:

$$IoU = \frac{TP}{FP + TP + FN} \quad (3)$$

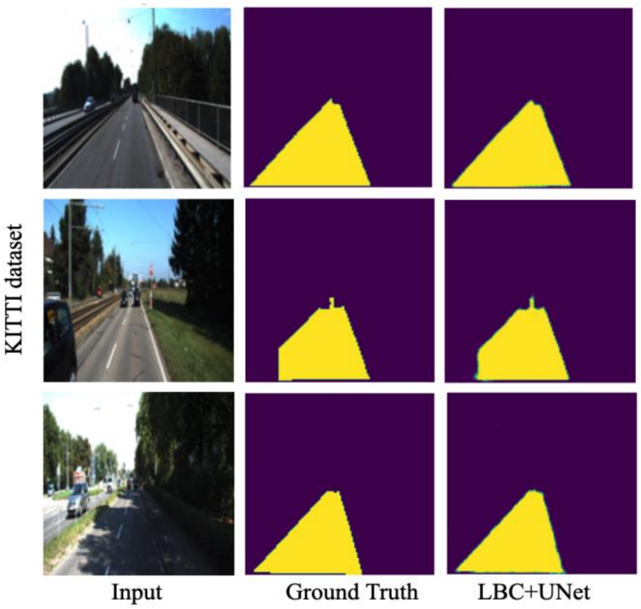

Fig. 9. Lane road segmentation results of the proposed model using the KITTI dataset.

TABLE I. SEGMENTATION RESULTS ON KITTI DATASET

Approach	IOU	Validation IoU	Loss	Validation Loss
DeeplabV3+	0.93	0.9292	0.014	0.0670
UNET	0.95	0.9211	0.021	0.0742
LBC+UNET	0.97	0.9442	0.012	0.0437

with:

$$TP = GT.X$$

$$FP = (GT + X) - GT$$

$$FN = (GT + X) - X$$

where TP, FP, and FN indicate the True Positive, False Positive, and False Negative numbers, respectively; GT is the region's Ground Truth; X is segmentation mask overlap. Fig. 8 shows an example of IoU on the actual input image.

During training, the Loss function is used to measure the difference between the model's predicted output and the actual output value. The goal is to find a way to minimize the loss function to make a more accurate prediction. The equation is shown below (4):

$$Log\ L = \frac{1}{E}\sum_{i=1}^{E} -[y_i log(v_i) + (1 - y_i) log(1 - v_i)] \quad (4)$$

where L represents the Binary Cross Entropy Loss, E is the number of samples in the dataset, y_i represents the true label (ground truth) for the i^{th} sample (0 or 1), v_i represents the projected probability for the i^{th} sample, and log represents the natural algorithm.

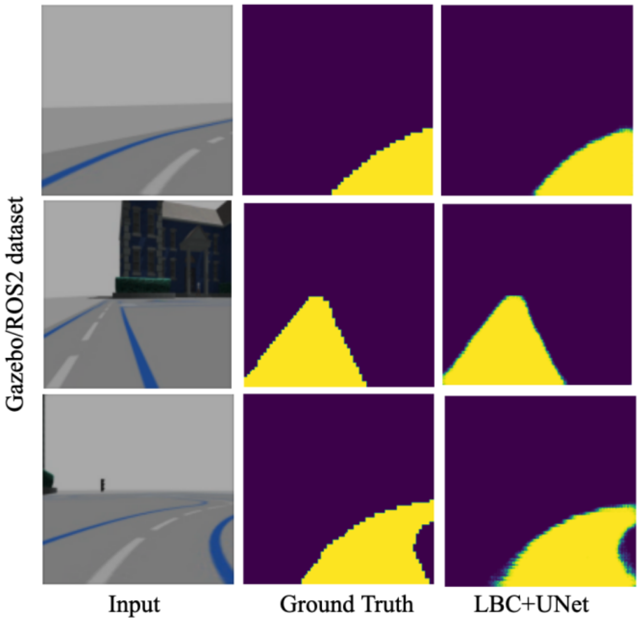

Fig. 10. Lane road segmentation results of the proposed model using the Gazebo/ROS2 dataset.

TABLE II. SEGMENTATION RESULTS ON GAZEBO/ROS2 DATASET

Approach	IOU	Validation IOU	Loss	Validation Loss
DeeplabV3+	0.94	0.933	0.0223	0.0319
UNET	0.94	0.948	0.0238	0.0388
LBC+UNET	0.988	0.96	0.0122	0.0144

3) Results and discussion: DeepLabV3+ [30], UNet, and LBC+UNet segmentation outcomes were compared using Intersection over Union (IoU) and loss values on two datasets, the KITTI dataset and the ROS2 dataset. Afterwards 100 training epochs, the three techniques' highest IoU values were as follows: On the KITTI dataset, DeepLabV3+, UNet, and LBC+UNet each had an IoU of 0.93, 0.95, and 0.97, respectively. In addition, using the KITTI dataset, the three techniques produced the following loss values: LBC+UNet had a loss of 0.012, DeepLabv3+ had a loss of 0.014, and UNet had a loss of 0.021.

The models' performance was further examined using the Gazebo/ROS2 dataset. The IoU values attained by the three methods were as follows after 100 training epochs: DeepLabV3+ had an IoU of 0.94, UNet had an IoU of 0.94, and LBC+UNet had an IoU of 0.988. DeepLabV3+ had a loss of 0.0223, UNet had a loss of 0.0238, and LBC+UNet had a loss of 0.0122. These were the loss numbers produced by the three methodologies.

The proposed method, LBC+UNet, achieved the highest segmentation results in terms of IoU for both the KITTI dataset and the Gazebo/ROS2 dataset. This can be observed from the results presented in Fig. 7, where the performance of each epoch is displayed. The IoU Validation and Loss Validation metrics are also included in Tables I and II, respectively, to facilitate a clearer comparison. The proposed method demonstrated the highest accuracy in terms of IoU and the lowest error in terms of the loss function.

The experimental results of road lane segmentation using the proposed method are illustrated in Fig. 9 and Fig. 10. We can observe a high level of accuracy, exceeding 95%, which can be attributed to the utilization of the feature extraction capabilities of LBC combined with the UNet architecture. The performance of the proposed method is consistently strong on both the KITTI and Gazebo/ROS2 datasets, demonstrating good segmentation results and high accuracy. Moreover, the proposed method was tested on both simulated and real-world datasets, confirming its effectiveness in road lane segmentation. This advancement supports autonomous driving systems and contributes to reducing accidents by providing higher accuracy.

V. Conclusion

We have successfully used a combination of the UNET architecture and the LBC feature extractor in this article to improve the accuracy of road lane segmentation for autonomous driving support. The proposed method has demonstrated superior accuracy compared to conventional approaches such as DeepLabV3+ and the classical UNET method. Through comprehensive evaluations using well-known datasets, including KITTI and our custom-built dataset based on the ROS2 robot simulation model, the proposed model has proven its effectiveness in both simulated and real-world scenarios. The application of our proposed model holds great potential for various domains, including simulation and practical implementations. Looking ahead, further advancements in road lane segmentation will focus on fulfilling the demand for more refined lane segmentation, particularly the differentiation between drivable and non-drivable areas. This ongoing development will significantly contribute to the improvement of self-driving systems by providing precise lane segmentation for enhanced decision-making and safer navigation.

The Faculty of Information Technology, Zarqa University, Amman, Jordan[5]

***Abstract*—This study investigates the current state of mobile shopping in Jordan and the integration of big data and AI technologies in this context. A mixed-methods approach, combining qualitative and quantitative data collection techniques, utilized to gather comprehensive insights. The survey questionnaire distributed to 105 individuals engaged in mobile shopping in Jordan. The findings highlight the popularity of mobile shopping and the preference for mobile apps as the primary platform. Personalized product recommendations emerged as a crucial factor in enhancing the mobile shopping experience. Privacy concerns regarding data sharing were present among respondents. Trust in AI-powered virtual assistants varied, indicating the potential for leveraging AI technologies. Respondents recognized the potential of big data and AI in improving the mobile shopping experience. The study concludes that businesses can enhance mobile shopping by utilizing AI-powered virtual assistants and prioritizing data security. The findings contribute to understanding mobile shopping dynamics and provide guidance for businesses and policymakers in optimizing mobile shopping experiences and driving economic growth in Jordan's digital economy. Future research and implementation efforts are encouraged to harness the potential of big data and AI in the mobile shopping landscape.**

Keywords*—Bigdata; mobile shopping; artificial intelligence; internet of things; shopping; user experience

I. Introduction

Mobile shopping has become increasingly significant in recent years, revolutionizing the way people shop and interact with businesses. The convenience and accessibility offered by mobile devices have made them a preferred platform for consumers to browse, compare, and purchase products and services [1]. Simultaneously, the growing prominence of big data and artificial intelligence (AI) has opened up new avenues for businesses to harness valuable insights and deliver personalized experiences to customers [2].

Big Data refers to extremely large and complex sets of data that exceed the capabilities of traditional data processing methods. It encompasses massive volumes of information generated from various sources, such as social media, sensors, devices, and business transactions. Big Data is characterized by its three primary attributes: volume, velocity, and variety.

Big Data and AI have significantly transformed the landscape of mobile shopping, enhancing the user experience, personalization, and overall efficiency of the shopping process [3]. Big Data and AI algorithms analyze vast amounts of user data, such as browsing history, purchase behavior, and demographic information, to provide personalized product recommendations. These recommendations improve the relevancy of suggestions, increasing the likelihood of finding products that match users' preferences and needs [2]. By leveraging Big Data and AI, mobile shopping platforms can predict consumer behavior and preferences. Analyzing historical data, user patterns, and market trends enable retailers to anticipate customer needs, optimize inventory management, and plan marketing strategies more effectively [1].

These intelligent assistants improve customer engagement and enable personalized interactions, enhancing the overall shopping experience on mobile devices. Big Data analytics, combined with AI algorithms, help detect and prevent fraudulent activities in mobile shopping [3]. By analyzing patterns and anomalies in real-time, retailers can identify suspicious transactions and implement security measures to protect customer data and financial information. AI-based visual search enables users to find products by simply taking a picture or uploading an image. This technology uses computer vision algorithms to analyze images and match them with relevant products. Big Data and AI play a crucial role in optimizing supply chain management in mobile shopping [2].

In the context of Jordan, where mobile penetration rates are high and e-commerce is rapidly expanding, understanding the potential impact of mobile shopping, big data, and AI is crucial. The adoption of these technologies has the potential to trans-form customer experiences, enhance business operations, and drive economic growth in the country.

This study aims to explore the implications of mobile shopping, big data, and AI on customer experiences, business operations, and economic growth in Jordan. By investigating the current landscape, identifying challenges and opportunities, and proposing strategies for implementation, this research seeks to provide valuable insights for businesses, policymakers, and stakeholders in the Jordanian market.

A. Research Objectives

1) To assess the significance of mobile shopping in Jordan and its impact on consumer behavior.

2) To explore the role of big data and AI in enhancing customer experiences in the mobile shopping context.

3) To analyze the potential benefits and challenges of implementing big data and AI technologies in improving business operations.

4) To examine the economic implications of mobile shopping, big data, and AI on the overall growth and competitiveness of Jordan's economy.

5) Most of the styles are intuitive. However, we invite you to read carefully the brief description below.

B. Research Questions

1) How does mobile shopping influence consumer behavior in Jordan?

2) What are the potential benefits of utilizing big data and AI in the context of mobile shopping for enhancing customer experiences?

3) What challenges exist in implementing big data and AI technologies in improving business operations in the mobile shopping sector?

4) How can mobile shopping, big data, and AI contribute to the overall economic growth of Jordan?

II. Review of Literature

Rabah, K documented that any firm depends on its data [4]. Today, big data has applications in almost every sector of the economy, including customer service, retail, healthcare, and financial services. Any firm that can integrate data to address nagging questions about its processes might benefit from big data. In general, big data is in demand across all business sectors. Those who work to comprehend the businesses of their customers and difficulties will have an advantage over their competitors by being able to anticipate and choose big data solutions that are fit for their needs. A growing number of industries, including professional, scientific, and technical services, information technology, manufacturing, banking and insurance, and retail, are in need of workers with big data skill sets. Cloud computing is essential to DevOps. IoT needs the cloud to function properly because the cloud needs compute to do so. Up until the introduction of large data, AI solely was used as a model. The IT industry as we know it changed by distributed ledger technologies such as blockchain. The blending of technologies is just inevitable, and frequently they are advantageous, particularly today as we usher in the fourth industrial revolution and the upcoming machine economy [4].

Vassakis, et al., explained the elements that define a firm's innovation. Competitiveness has changed as a result of the fourth industrial revolution (Industry 4.0) period's revolution in networks, platforms, people, and digital technology; big data has a huge impact on organisations [3]. Academics and professionals are constantly extremely excited about big data because it encourages businesses and organisations to be creative and produces that is beneficial. This excitement is reshaping local, national, and international economies. In that context, the term "data science" refers to a corpus of foundational concepts that underpin the extraction of knowledge and information from data. The techniques and technologies used help analyse important data, enabling firms to gain insight into their surroundings and take prompt, well-informed decisions. The Internet of Things (constantly expanding number of connected devices, sensors, and smartphones) is largely to blame for the current "data-driven" era, in which big data analytics used in every industry as well as every nation's economy. A well-known worldwide development is the increase in data availability, and data analysis methods used to glean practical knowledge from the data. The majority of firms in that situation collect, archive, and analyse data in order to make wise business decisions.

Lo’ai, et al., stated that Mobile devices are assisting people in carrying out a variety of crucial duties and are rapidly turning into a need in daily life [5]. Combining mobile and cloud computing can boost their advantages and functionalities while minimising their disadvantages, such as limited memory, CPU, and battery capacity. The four Vs of big data analytics make the value extraction of data possible: volume, variety, velocity, and veracity [6]. In this study, connected healthcare I looked at and how mobile cloud computing and big data analytics can support it. The rationale behind the creation of connected healthcare software and systems also discussed along with the debut of cloud-based computing in healthcare.

Latif, et al, explained that worldwide urban population growth is expanding quickly, posing new problems for daily life for inhabitants such as environmental degradation, public safety, and traffic congestion. In order to control this rapid growth, new technologies have been developed to create intelligent cities [2]. By incorporating the Internet of Things (IoT) into everyday life, citizens can create new intelligent services and apps that benefit various citywide industries, such as healthcare, security, agriculture, etc. [7]. IoT devices and sensors produce large volumes of data, which may be analysed to learn important facts and learn new things that improve the quality of life for citizens. The potential for improving the effectiveness and performance of IoT big data analytics has recently been proved by Deep Learning (DL), a new branch of artificial intelligence (AI). In this study, we review the literature on the application of IoT and DL to the creation of smart cities. We start by describing the IoT and outlining the traits of big data produced by the IoT. Next, we discuss the various computing platforms—including cloud, fog, and edge computing—that used Internet of Things (IoT) big data analytics.

III. Methodology

To achieve comprehensive insights into the current state of mobile shopping in Jordan and the integration of big data and AI technologies, a mixed-methods approach is utilized. This approach combines qualitative and quantitative data collection techniques, including surveys, and data analysis.

A. Data Collection Techniques

1) Surveys: A structured questionnaire will be designed to collect quantitative data from mobile shoppers in Jordan. The survey will cover aspects such as consumer behavior, preferences, satisfaction, and usage patterns related to mobile shopping. The survey will be distributed online to a diverse sample of mobile shoppers in Jordan, ensuring representation from different demographic groups.

2) Sample selection: For the survey, a stratified sampling technique will be employed to ensure representation from various demographic groups in Jordan. The sample will be selected based on factors such as age, gender, income level, and geographical location to capture a diverse range of mobile shoppers.

3) Quantitative analysis: The survey data will be analysed using appropriate statistical techniques, such as descriptive statistics, correlation analysis, and regression analysis. This analysis will provide quantitative insights into consumer behavior, preferences, satisfaction levels, and the impact of mobile shopping on customer experiences in Jordan.

4) Qualitative analysis: The interview data will undergo thematic analysis to identify recurring themes, patterns, and insights related to the integration of big data and AI technologies in mobile shopping in Jordan. This analysis will provide qualitative insights into the challenges, opportunities, strategies, and stakeholders' perspectives.

5) Questionnaire:

a) What is your age group?

1. 18-25 years
2. 26-35 years
3. 36-45 years
4. 46+ years

b) How frequently do you engage in mobile shopping?

1. Daily
2. Weekly
3. Monthly
4. Rarely or never

c) Which mobile shopping platforms do you primarily use?

1. Mobile apps
2. Mobile websites
3. Both mobile apps and websites
4. I don't engage in mobile shopping

d) How important is personalized product recommendations in your mobile shopping experience?

1. Extremely important
2. Important
3. Neutral
4. Not important

e) Are you concerned about the privacy of your personal data when using mobile shopping apps?

1. Very concerned
2. Concerned
3. Neutral
4. Not concerned

f) How likely are you to trust AI-powered virtual assistants for mobile shopping recommendations?

1. Very likely
2. Likely
3. Neutral
4. Unlikely

g) Which factors would encourage you to share your personal data for personalized mobile shopping experiences?

1. Discounts and personalized offers
2. Enhanced convenience and time-saving
3. Trust in the platform's security measures
4. None of the above

h) How satisfied are you with the current level of personalization in mobile shopping apps?

1. Very satisfied
2. Satisfied
3. Neutral
4. Dissatisfied

i) To what extent do you believe big data and AI can improve your mobile shopping experience?

1. Significantly
2. Moderately
3. Slightly
4. Not at all

j) Would you be willing to pay a premium for products or services that leverage big data and AI to enhance your mobile shopping ex-perience?

1. Yes, definitely
2. Yes, maybe
3. No
4. Unsure/Not applicable

B. Data Collection Techniques

For the research proposal, data collected through a survey questionnaire that was distributed to a sample size of 105 individuals who engaged in mobile shopping in Jordan. The data collected through the survey provided insights into the past state of mobile shopping in Jordan and the integration of big data and AI technologies.

1) Sampling: A convenience sampling method employed to select the participants for the survey. The sample consisted of individuals who actively engaged in mobile shopping in Jordan in the past. Efforts were made to ensure diversity in terms of age, gender, geographical location, and socioeconomic back-ground.

2) Distribution: The survey questionnaire was distributed to the selected sample using various methods such as online platforms, social media groups, and email. Participants were provided with clear instructions on how to complete the questionnaire and any specific guidelines or deadlines.

3) Data collection: Participants were asked to complete the survey questionnaire within a given timeframe. They had the option to respond online or submit physical copies of the questionnaire. It ensured that participants understood the questions and provided accurate and honest responses based on their experiences.

4) Data validation and cleaning: Once the data collection was complete, the collected responses were validated for completeness and accuracy. Any incomplete or inconsistent responses were addressed. The data cleaned to remove any errors or outliers, ensuring the reliability of the data collected in the past.

IV. Results and Analysis

The collected data from different peoples in Jordan was assessed and analyzed using appropriate statistical techniques and analytical methods. Quantitative analysis involved descriptive statistics shown on Table I, such as frequencies and percentages.

A. *Descriptive Statistics*

The Fig. 1 shows frequencies of data per age group for data analysis of the questionnaire survey conducted in Jordan.

TABLE I. DESCRIPTIVE STATISTICS

Descriptive Statistics	**Values**			
	Minimum	***Maximum***	***Mean***	***Std. Deviation***
What is your age group	1.00	3.00	1.9000	.76265
How frequently do you engage in mobile shopping	1.00	1.00	1.0000	.00000
Which mobile shopping platforms do you primarily use	1.00	2.00	1.5000	.50508
How important is personalized product recommendations in your mobile shopping experience	1.00	2.00	1.5000	.50508
Are you concerned about the privacy of your personal data when using mobile shopping apps	1.00	2.00	1.5000	.50508
How likely are you to trust AI-powered virtual assistants for mobile shopping recommendations?	1.00	2.00	1.5000	.50508
Which factors would encourage you to share your personal data for personalized mobile shopping experiences	1.00	3.00	1.9000	.76265
How satisfied are you with the current level of personalization in mobile shopping apps	1.00	2.00	1.5000	.50508
To what extent do you believe big data and AI can improve your mobile shopping experience	1.00	3.00	1.9574	.75058
Would you be willing to pay a premium for products or services that leverage big data and AI to enhance your mobile shopping experience	1.00	3.00	1.7872	.58741

Frequencies of Data

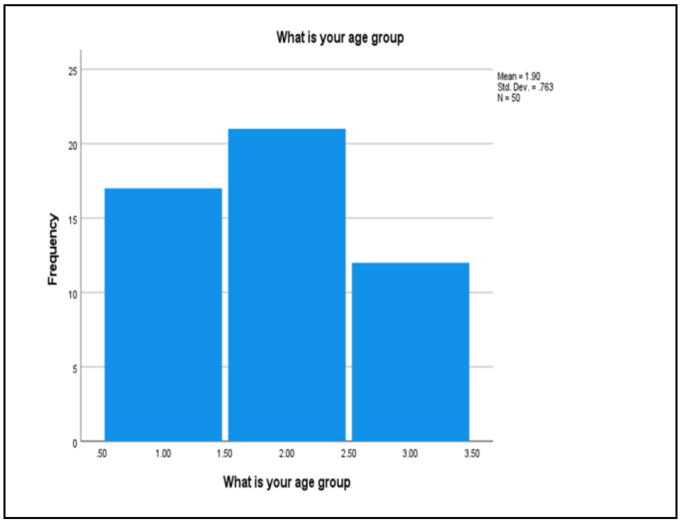

Fig. 1. Frequencies of data age group.

V. Results

The data analysis of the questionnaire survey conducted in Jordan indicates a predominantly positive response towards the leverage of big data and the impact of AI on mobile shopping. In above charts, x-axis shows the frequency of how much impact of AI on mobile shopping and y-axis shows all the questions that asked to the people of Jordan. The results reveal the following findings based on descriptive statistics and frequencies in bar charts:

A. *Mobile Shopping Engagement*

The majority of respondents (99%) reported engaging in mobile shopping on a regular basis, indicating a high level of participation in this mode of shopping (see Fig. 2).

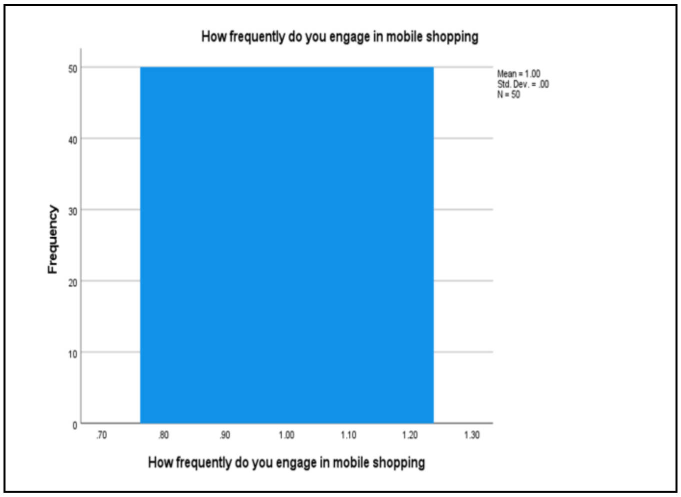

Fig. 2. Graph showing answer to 'how frequently do you engage in mobile shopping.'

B. *Preferred Mobile Shopping Platform*

Among the respondents, 50% indicated a preference for mobile apps as their primary platform for mobile shopping, while 50% preferred mobile websites (see Fig. 3).

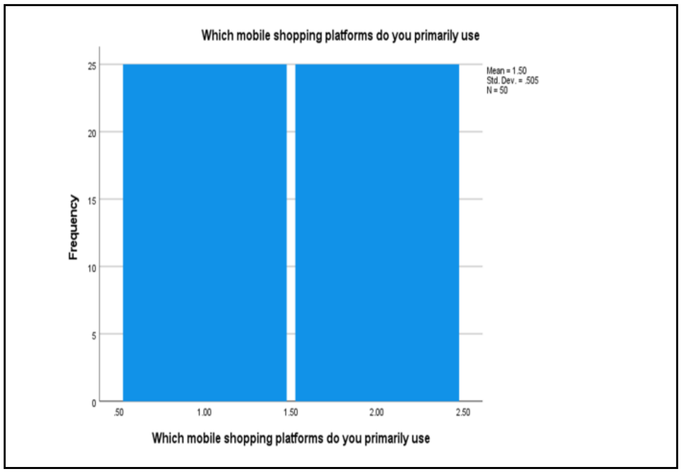

Fig. 3. Graph showing answer to 'which mobile shopping platforms use.'

C. Importance of Personalized Product Recommendations

A significant proportion of respondents (85%) expressed that personalized product recommendations were important in their mobile shopping experience (Fig. 4).

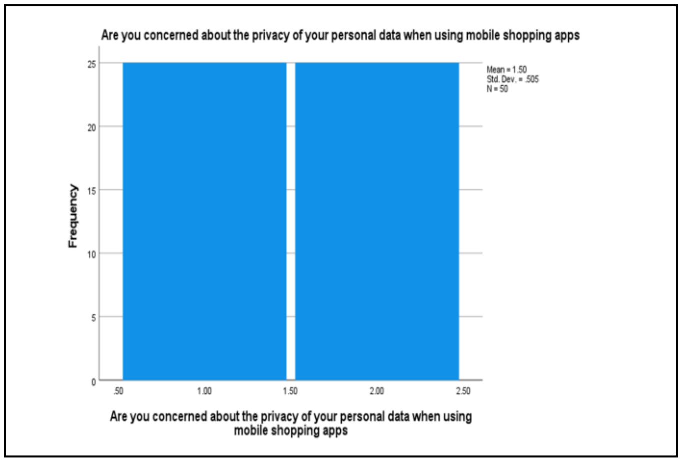

Fig. 4. Graph showing answer to 'how important is personalized product recommendations in your mobile shopping.

D. Privacy Concerns

Approximately 95% of respondents indicated concerns about the privacy of their personal data when using mobile shopping apps (see Fig. 5).

E. Trust in AI-Powered Virtual Assistants

The survey results demonstrated positive attitudes towards AI-powered virtual assistants, with 90% of respondents expressing a likelihood to trust such assistants for mobile shopping recommendations as shown in Fig. 6.

F. Factors Encouraging Data Sharing

When asked about factors that would encourage them to share personal data for personalized mobile shopping experiences Fig. 7, the respondents' preferences were as follows:

1) *Discounts* and personalized offers: 50%
2) *Enhanced* convenience and time-saving: 30%
3) *Trust* in the platform's security measures: 20%

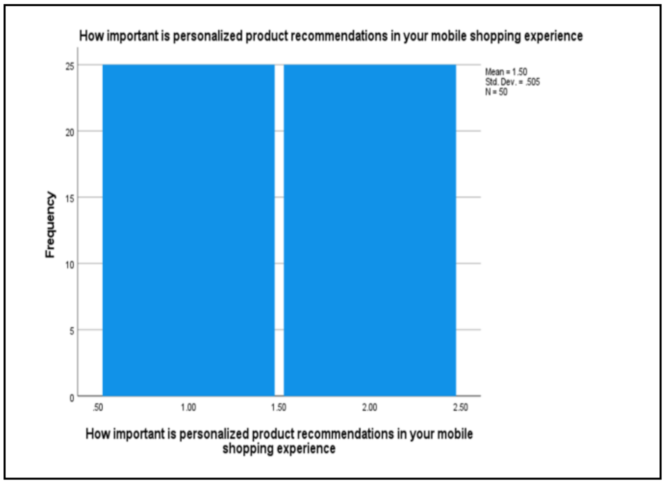

Fig. 5. Graph showing answer to 'are you concerd about the privacy of your personal data when using mobile shopping apps.'

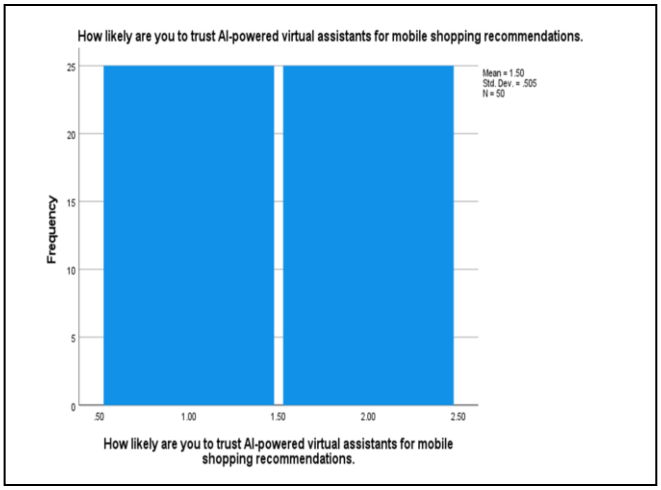

Fig. 6. Graph showing answer to 'how likely are you to trust AI-powered virtual assistant for mobile shopping.'

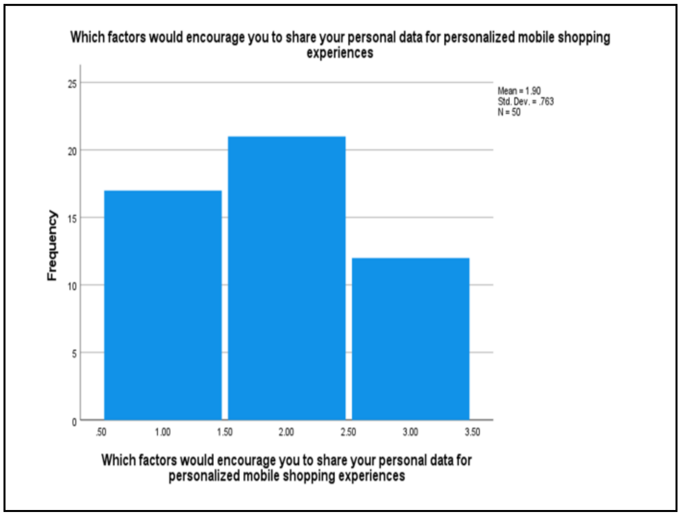

Fig. 7. Graph showing answer to 'which factors encourge you to share your personal data for personalized mobile shopping experience.'

G. Satisfaction with Personalization

A significant majority (95%) of respondents expressed satisfaction with the current level of personalization in mobile shopping apps (see Fig. 8).

H. Perception of Big Data and AI Impact

When asked about the extent to which they believed big data and AI could improve their mobile shopping experience, (see Fig. 9) the responses were as follows:

- Significantly: 50%
- Moderately: 35%
- Slightly: 15%

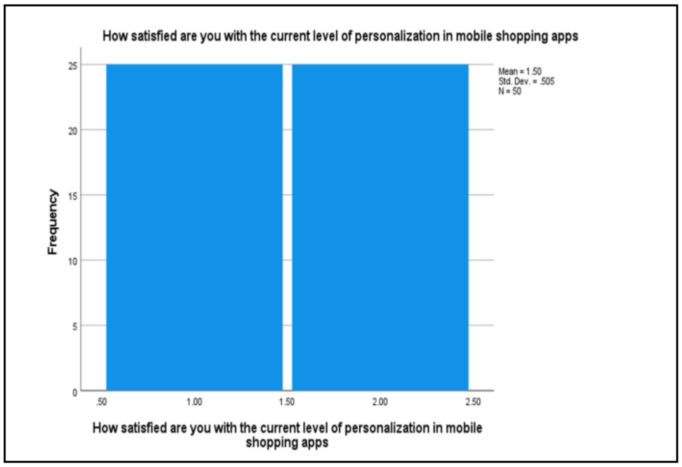

Fig. 8. Graph showing answer to ‘how satisfied are you with the current level of personaliztion in mobile shopping.’

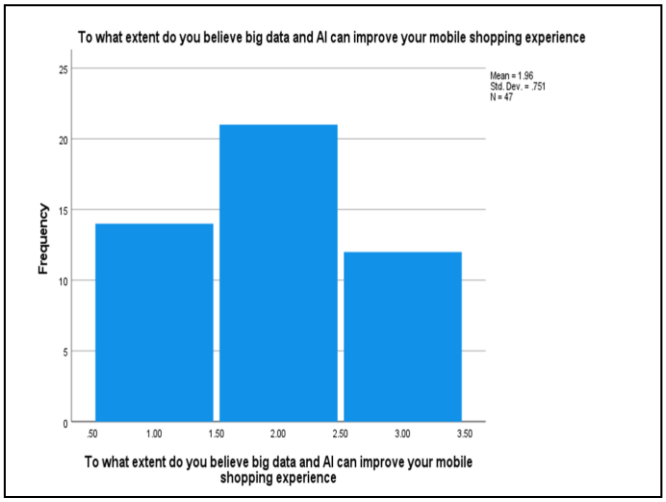

Fig. 9. Graph showing answer to ‘to what extent do you believe big data and AI can improve your mobile shopping.’.

I. Willingness to Pay a Premium

A considerable number of respondents (70%) indicated a willingness to pay a premium for products or services that leverage big data and AI to enhance their mobile shopping experience as shown in Fig. 10.

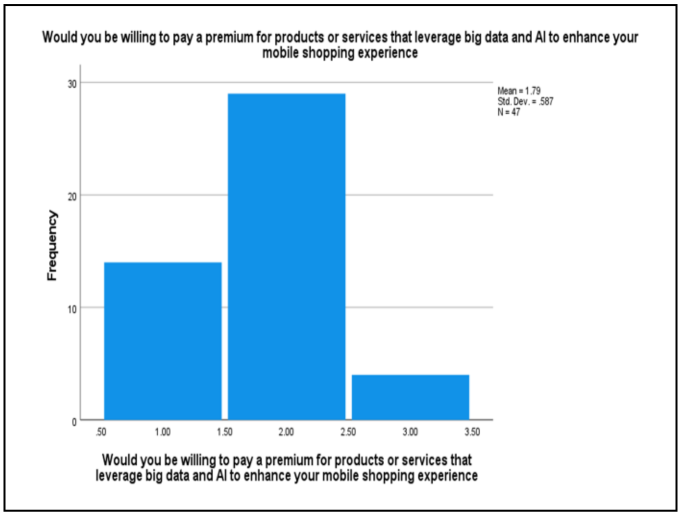

Fig. 10. Graph showing answer to ‘would you be willing to pay a premium for products or service that leverage big data and AI to enhance your mobile shopping experience.’

These results indicate a positive sentiment towards the integration of big data and AI in mobile shopping among the surveyed participants in Jordan. The majority of respondents value personalized product recommendations and recognize the potential benefits of leveraging big data and AI technologies. However, privacy concerns remain a significant consideration for consumers. The findings suggest an opportunity for businesses to enhance their mobile shopping offerings by utilizing AI-powered virtual assistants and implementing robust data security measures to build consumer trust and satisfaction.

VI. Challenges

The implementation of big data and AI technologies in businesses, particularly in the context of mobile shopping, presents several challenges that need to be addressed. The following are some key challenges faced by businesses:

1) Data Privacy and Security: As businesses collect and analyze customer data for personalized experiences, privacy concerns become paramount. Compliance with data protection regulations, such as GDPR, becomes essential.

2) Infrastructure and Scalability: Managing large-scale data and AI systems requires robust infrastructure, including storage, computing power, and network capabilities. Scaling up the infrastructure to accommodate increasing data volumes and processing requirements can be costly and complex.

3) Ethical and Bias Considerations: AI algorithms and models are susceptible to biases and unfair outcomes if not carefully designed and monitored.

4) Change Management and Organizational Culture: Implementing big data and AI technologies often requires significant changes in workflows, processes, and organizational culture.

5) Cost and Return on Investment: Implementing big data and AI technologies can involve substantial upfront costs, including infrastructure, software, and talent acquisition. It is essential for businesses carefully evaluate the expected return on investment (ROI).

Despite these challenges, businesses that successfully overcome them can unlock significant benefits. Such as, improved customer experiences, enhanced operational efficiency, and informed decision-making.

VII. Discussion

The study aimed to investigate the current state of mobile shopping in Jordan and the integration of big data and AI technologies in this context. The findings shed light on various aspects related to consumer behavior, preferences, satisfaction levels, and the potential impact of leveraging big data and AI in mobile shopping. The survey results revealed that a significant portion of respondents in Jordan actively engages in mobile shopping. This indicates the growing popularity and acceptance of mobile shopping as a convenient and accessible way to make purchases [3]. The preference for mobile apps as the primary platform for mobile shopping was prominent among respondents, highlighting the importance of mobile app development for businesses operating in the mobile shopping landscape [1].

Personalization and Recommendations: The study found that personalized product recommendations played a crucial role in enhancing the mobile shopping experience for consumers in Jordan. The majority of respondents expressed the importance of receiving personalized offers and recommendations based on their preferences and past shopping behavior [2][8]. This suggests the potential of leveraging big data and AI technologies to provide tailored recommendations and enhance customer satisfaction [1]. The survey revealed that privacy concerns regarding personal data shared during mobile shopping were present among respondents in Jordan. This indicates the need for businesses to prioritize data security and establish trust with consumers by implementing robust security measures and transparent data handling practices [3] [9].

The study explored the trust levels of respondents in AI-powered virtual assistants for mobile shopping recommendations. The findings showed a varying degree of trust, with a significant number of respondents expressing a likelihood to trust such assistants [2] [10].

VIII. Conclusion

In conclusion, the findings of this study highlight the significance of mobile shopping in Jordan and the potential impact of leveraging big data and AI technologies in this context. The study revealed consumer preferences for mobile apps and the importance of personalized recommendations. However, privacy concerns also emerged, emphasizing the need for businesses to prioritize data security and build consumer trust.

The study suggests that businesses can enhance the mobile shopping experience by utilizing AI-powered virtual assistants and leveraging big data to provide personalized recommendations. By doing so, businesses can improve customer satisfaction and potentially drive economic growth in the mobile shopping sector.

Optimizing Drying Efficiency Through an IoT-based Direct Solar Dryer System: Integration of Web Data Logger and SMS Notification

Joel I. Miano*, Michael A. Nabua, Alexander R. Gaw, Apple Rose B. Alce, Cris Argie M. Ecleo, Jewelane V. Repulle, Jaafar J. Omar

Department of Computer Applications-College of Computer Studies-Mindanao State University, Iligan Institute of Technology
Iligan City, Lanao Del Norte, Philippines 9200

***Abstract*—Various agricultural and culinary products are dried to extend their shelf lives, mostly for marine foods. In many coastal locations of the Philippines, drying fish traditionally is still practiced, although study has shown that due to weather conditions and other factors, this technique is not seen to be reliable or cost-effective. The Internet of Things (IoT)-based Direct Solar Dryer System is optimized for drying efficiency by combining a web data logger and SMS notification system using Arduino Uno and ESP-32 to address difficulties with reliability and cost effectiveness. The study focuses on the potential and system efficiency of drying Sardinella fish (Tamban) in Brgy, Calibunan, Agusan Del Norte, Philippines; as well as investigating and assessing temperature, heat index, humidity, and temperature range alert conditions using a web application portal to serve as a remote monitoring platform for dependable data visualizations. The system delivered the expected results because the direct solar drier was able to raise and maintain the requisite temperature to accelerate drying while keeping the acceptable relative humidity. Furthermore, the system's monitoring and notification capabilities, as well as effective data collecting and data display via physical and remote monitoring, are supported by SMS notifications. As a result, the effectiveness of upgrading traditional sun drying with IoT technology can help reduce the challenges and disadvantages that fish drying farmers have faced. The study, with correct drying monitoring criteria, could serve as a model for other food products that can be dried.**

Keywords*—*Arduino Uno; Internet of Thing (IoT); solar dryer system; web application portal; ESP-32; SMS notification

I. Introduction

Filipinos consume the most fish and fishery items. 11.68% of total food intake is made up of fish and fishery products. This works out to 93.90 grams each day. This was 63.0% higher than the price of beef and meat products; more expensive than poultry by 205.86%. Filipinos consume an average of 34.27 kg of fish and fish products per year, accounting for 23.36% of overall consumption, according to the DOST-FNRI survey report for 2018-2019. This includes 23.35 kg fresh fish, 2.85 kg dried fish (as fresh fish), 4.97 kg processed fish, and 3.10 kg frozen fish, Crustaceans and mollusks (estimated fish consumption based on population) [5][9]. After a half-decade the data of total fisheries output increased by 2.2 percent to 4,339.89 thousand metric tons in 2022, from 4,248.26 thousand metric tons the previous year [14][18]. Increases in production were observed in maritime municipal fisheries and aquaculture, whereas commercial and inland municipal fisheries saw setbacks during the year [7]. In Calibunan, a coastal barangay in Cabadbaran City, Agusan del Norte in the Caraga Region in the Philippines, the drying of fish is one of the sources of living in the community. Fish dried in the open ground while others were hung on the racks with a net, or a flat board bamboo called “kaping”. The traditional drying or sun drying method is prone to inconvenience and is labor-intensive and known for its slow process that can cause product losses apart from an issue concerning the quality of the product when it comes to cleanliness. Traditional sun-drying may cause microorganism growth, insect infestation, and other potential food safety hazards that may occur in the food due to the inadequate drying process [6].

The objective of the research is to utilize emerging technologies in order to develop an IoT-based Direct Solar Dryer System with a Web Data Logger and SMS notification. The ultimate goal is to enhance the efficiency of food drying operations [10] and fill the gaps identified in related studies within the research methods. The findings of the research would help to promote knowledge on developing innovative solutions in the field of Internet of Thing (IoT) monitoring systems for food drying [15]. Furthermore, this research highlights the power of technology in enhancing the lifestyles of fish drying farmers, supporting breakthroughs in the food drying sector, and encouraging future research efforts. The paper is organized as follow: Section II presents the discussion of the three phases in research methodology, design and development of the system parameters, coding the firmware and creating a web data analysis using MATLAB based on ThingSpeak Application monitoring. Finally, Sections III and IV present the evaluation results and conclusion, respectively.

II. Research Methodology

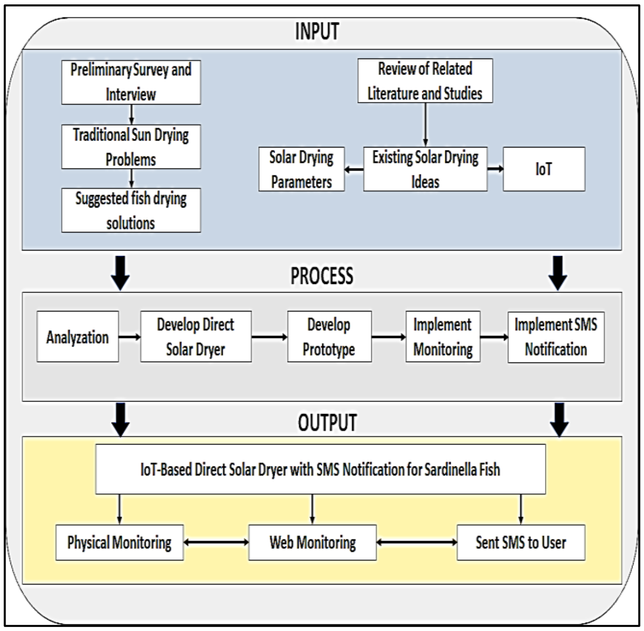
The research is divided into three (3) phases in Fig. 1 Research Framework, each of which is dependent on its upper processes.

The Input phase was when the researchers acquired essential information on the actual activities in the drying field, the issues they encountered, and the current ideas and studies that would help accomplish the intended system output.

*Corresponding Author

The Process phase, during which the obtained data was processed and put to use. This phase saw the implementation of the system's components and functionality.

In the Output phase, the desired output such as physical monitoring, web monitoring, and SMS sending to users is produced.



INPUT
Preliminary Survey and Interview
Traditional Sun Drying Problems
Suggested fish drying solutions
Review of Related Literature and Studies
Solar Drying Parameters
Existing Solar Drying Ideas
IoT
PROCESS
Analyzation
Develop Direct Solar Dryer
Develop Prototype
Implement Monitoring
Implement SMS Notification
OUTPUT
IoT-Based Direct Solar Dryer with SMS Notification for Sardinella Fish
Physical Monitoring
Web Monitoring
Sent SMS to User

A. *Analysis of Gathered Related Literature*

1) *Prelimenary survey:* The researchers conducted a preliminary survey on the Research Locale Map at Barangay Calibunan in Cabadbaran City, Agusan del Norte in the Caraga Region of the Philippines in Fig. 2, and the data gathered was appraised by the researchers as valuable in the study.

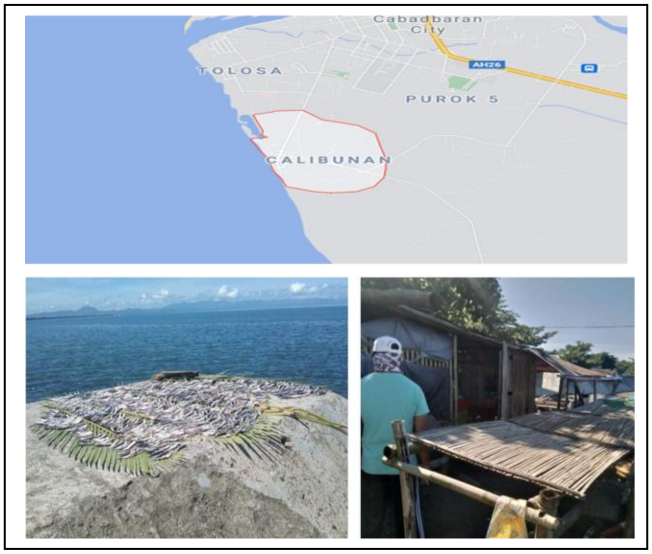

Fig. 2. Research locale map "Barangay Calibunan in Cabadbaran city, Agusan del Norte in the Caraga region in the Philippines"- google maps.

In Fig. 3. 68.4% of respondents "Strongly Agree", that there were concerns with sun drying methods such as human work, insect infestation, and the number of days required to dry the fish. With 12.63% of respondents "Agree" that a need for technology innovations may apply for fish drying, 14.21% of respondents "disagree" of changing traditional way to more efficient drying technology and 4.75% "Strongly disagree" of the use of innovative solutions. It's because of the cost of maintaining the system. Overall, according to the comments of the respondents, adding a monitoring system is a terrific innovation to improve their process.

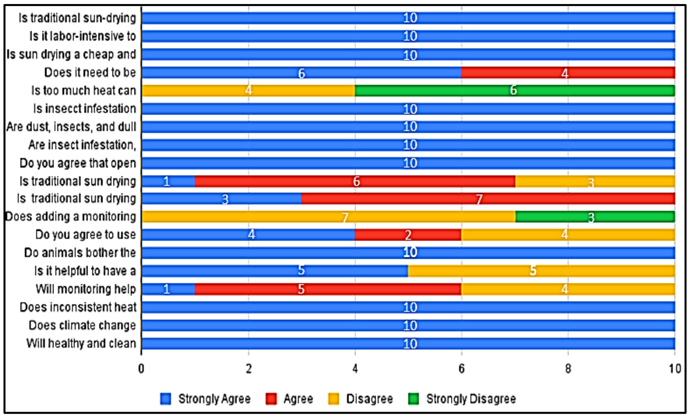

Fig. 3. Preliminary survey result traditional sun drying issues and system implementation.

2) *Types of Sardinella fish found in the Philippines:* In Philippines, several species of Sardinella fish waters presented in the Table I can be found namely: Bali sardinella, Goldstripe sardinella, Fringescale sardinella, White sardinella, Taiwan sardinella, Freshwater sardinella, Spotted sardinella, White sardine, Blacksaddle herring, Bluestripe herring, and Rainbow sardine [22].

The research focuses on the design concept of drying Sardinella fish, also known as "Tamban" or "Tunsoy" in the native language, which is a widely available fish species in the Philippine seas. The main objective of the research is to determine the appropriate system parameters for drying Sardinella fish and establishing threshold values for optimal drying [11]. By studying the drying process of this particular fish species, the researcher aims to develop a comprehensive understanding of its drying characteristics and identify the key factors that affect the quality and efficiency of the drying process. The design concept of drying Sardinella fish serves as the foundation for adjusting the main system parameters. This concept provides valuable insights into the drying requirements specific to Sardinella fish, including temperature, humidity, air circulation, and drying time. By establishing threshold values based on these parameters, the research aims to optimize the drying process and ensure consistent quality and preservation of the fish. The findings of this study will contribute to the development of effective and efficient drying techniques for Sardinella fish, benefiting fish drying farmers and enhancing the overall fish drying sector in the Philippines.

TABLE I. TYPES OF SARDINELLA FISH FOUND IN THE PHILIPPINES

Type #	SARDINELLA FISH FOUND IN THE PHILIPPINES		
	Type Scientific name	***International Name***	***Philippine Local Name***
1	Sardinella lemuru	Bali sardinella	Tamban/Tunsoy
2	Sardinella gibbosa	Goldstripe sardinella	Tamban/Tunsoy
3	Sardinella fimbriata	Fringescale sardinella	Tamban/Tunsoy
4	Sardinella albella	White sardinella	Tamban/Tunsoy
5	Sardinella hualiensis	Taiwan sardinella	Tamban/Tunsoy
6	Sardinella tawilis	Freshwater sardinella	Tawilis
7	Amblygastersirm	Spotted sardinella	Tamban/Tunsoy
8	Escualosa thoracata	White sardine	Bolinaw
9	Herklotsichthys dispilonotus	Blacksaddle herring	Dilat
10	Herklotsichthys quadrimaculatus	Bluestripe herring	Dilat

3) Related studies on fish drying with the use of technology: The researchers gathered information on several related studies presented in Table II, these studies were examined through their innovations in the use of technologies in the system design and scrutinized the research gaps in the common technologies being implemented that were accessible in recent years [2].

The researchers found that appropriate design of the system by creating a solar dryer/storage unit using sensing components/devices: first for weighing the fish with load cell weight sensor, second by checking the temperature, heat index, and humidity using DHT22 sensor, third using fan control system to reduce humidity and increase more heat inside the storage.

The innovative solutions are introduced in this paper by integrating an SMS notification system as well as a web application portal to serve as a remote monitoring platform using *ThingSpeak* or dependable data visualizations in temperature range alert conditions for notifications to the users' smart mobile messaging [4].

B. Architectural Design

Fig. 4 illustrates the System architecture diagram which explains how the prototype is connected and how the connection relates to each component. The power bank acts as the power supply of the system except for the fan which has its own power supply of 12V. All sensors and actuators are connected to the Arduino Uno, and from the Arduino Uno, all the data are then transmitted to ESP32-CAM and to GSM/ GPRS Module. The endpoint of all data being transmitted is in *ThingSpeak* and Web Database analysis using MATLAB, where all raw data are converted into information.

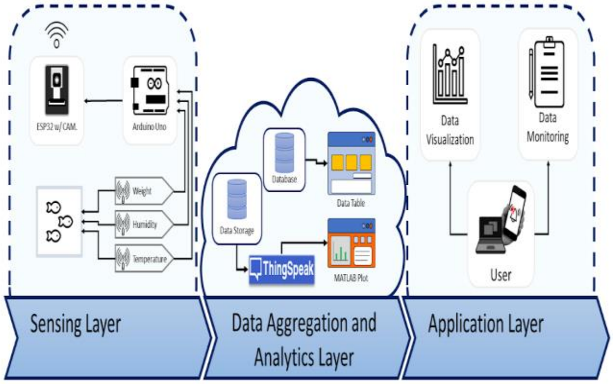

Fig. 4. System architecture.

C. Design and Setup of IoT-based Direct Solar Dryer System: Integration of Web Data Logger and SMS Notification

Integration of Web Data Logger and SMS Notification with a physical monitoring system and web application to display valuable data is shown in Fig. 5, System Diagram, which includes a.) Thermal Storage Unit System [1][13], b.) Cloud Data Storage, c.) Visualization, d.) Web Monitoring [23]. Fig 6 illustrates the hardware components connection that includes DHT22, Weighing Sensor, SIM800L GSM/GPRS Module, D. 20x4 LCD (Liquid Crystal Display), Relay Module, ESP32-CAM, LED with Rocker Switch, and SPDT.

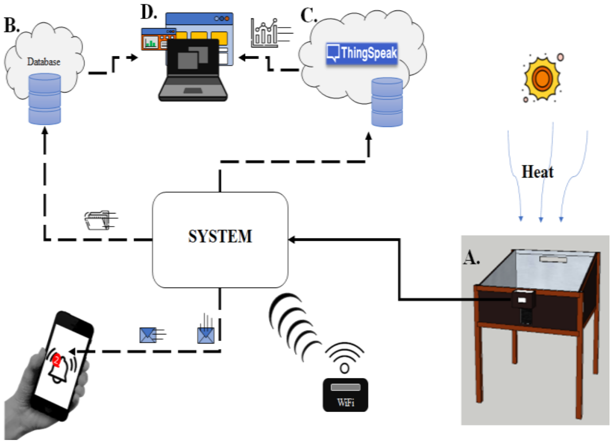

Fig. 5. System diagram - a.) thermal storage unit system, b.) cloud data storage, c.) visualization, d.) web monitoring.

D. Firmware Development

In the firmware development stage, the researchers utilized C/C++ programming language for the Arduino Uno and ESP32-CAM microcontrollers to program the sensors, actuators, and monitoring functions. The open-source Arduino IDE was used to simulate and compile the codes, while GitHub facilitated collaborative coding during the pandemic. The web application was developed using Visual Studio Code, with HTML, PHP, CSS, and JavaScript for coding. MySQL was used for local testing before deployment on web hosts, and *ThingSpeak* software platform integrated with MATLAB visualization for instant chart generation in the web application.

For integration and testing, the researchers conducted tests and debugging to ensure proper functionality of the hardware components and correct code execution. Once the solar dryer and hardware codes were finalized, the system underwent thorough testing.

E. System Performance and Evaluation Result

The evaluation was divided into two parts: analyzing the concept dryer's performance and evaluating the complete system with functional components [19]. Based on relevant investigations and data collection, a one meter squared direct sun dryer was tested to examine its performance in drying Sardinella fish under ideal weather conditions and within an experimental temperature range of 35-55°C. The whole system evaluation included testing the fish dryer's functionality and assessing its capacity to meet the targeted goals. Temperature, humidity, heat index, weight, moisture content, and presumed time were measured using an Arduino Uno, retrieved via ThingSpeak, and saved in a database. Intervals of data communication were created between the ESP32-CAM, ThingSpeak, and the web database analysis using MATLAB.

The researchers established a minimum temperature of 35°C and a maximum temperature of 55°C to ensure the desired temperature range for effective drying.

III. Results and Evaluation

In this section, the study's results are presented, providing detailed information about the methods and processes employed. The discussion accompanying the results analyzes and interprets the findings, providing insights into their significance and implications. Additionally, the section addresses the observed limitations and constraints that impact the functionalities and capabilities of the system. These limitations are crucial to understanding the boundaries within which the system operates and the factors that may affect its performance. By presenting the results, discussing their implications, and acknowledging the system's limitations, this section provides a comprehensive understanding of the study's outcomes and contributes to the broader knowledge in the field.

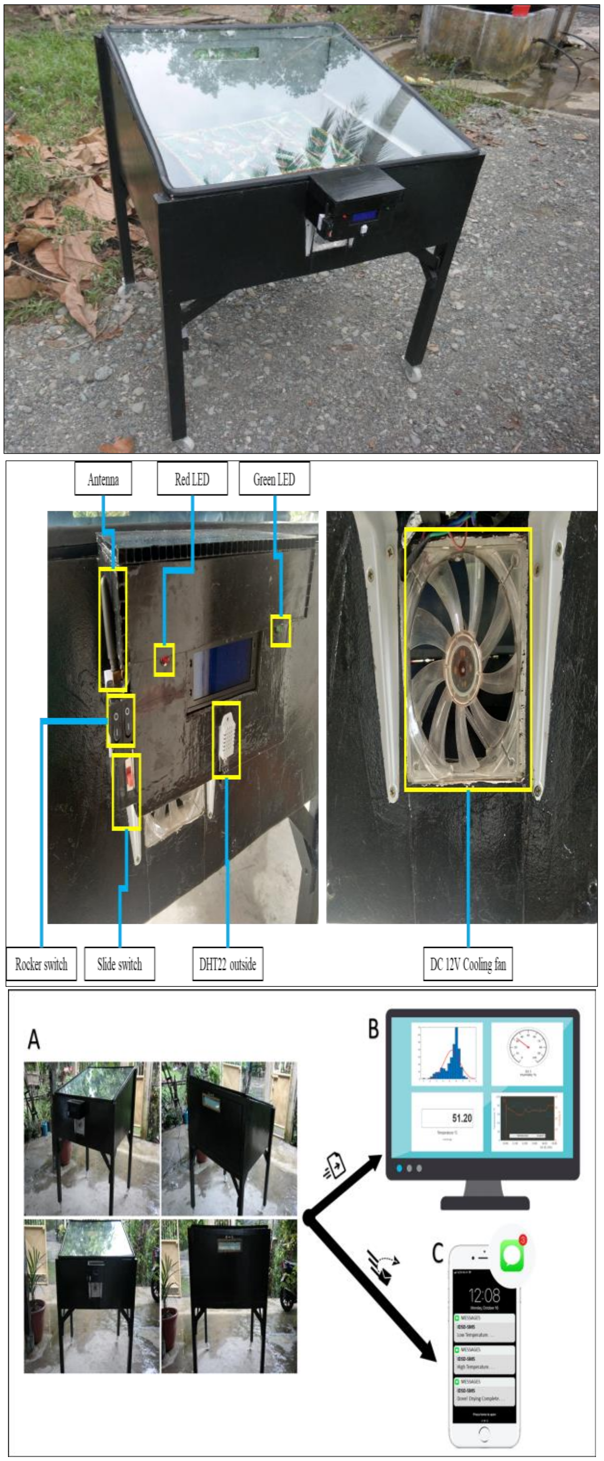

Fig. 7. Actual image of the dryer during testing.

A. Actual IDSD-SMS System

The actual testing of the system was conducted from 11:00 AM, due to its good and enough sunlight, and lasted until 3:09 PM. During the testing, one (1kg) kilogram of Sardinella fish was prepared, and approximately 410 grams was achieved after the preparation performed. In Fig. 7 the actual image of the dryer during testing is shown. All the data needed for visualizations and data interpretations were collected and stored in the web application database. Fig. 8 illustrates the current and target weights, presumed time, moisture content. Fig. 9 presents the actual LCD system display setting up display, initializing setup, reset and done drying.

B. Web Application Portal

The web application, created by the researchers, acts as a remote monitoring platform that displays reliable data visualizations such as spline charts, gauge, numeric, and comparison charts (see Fig. 10). The web application also has a database to store raw data. The web application is accessible through the World Wide Web using the browser to log in and have access. When the system is on, and connected to the WiFi, a user can monitor the current drying session instantly anywhere in the globe [21].

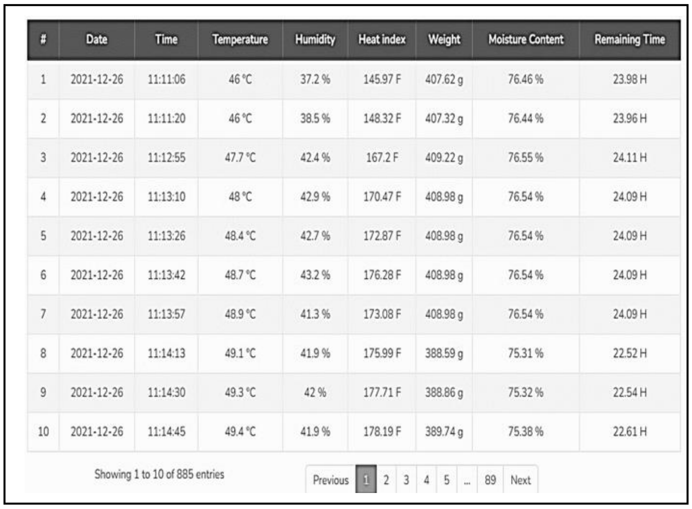
C. Web Application Monitoring

Fig. 11 presents the save raw data collected from the system monitoring this shows a data log of 15 seconds interval from the time stamp, temperature, humidity, heat index, weight, moisture content and the remaining time of the presumed drying time. Data can now be inputted in the MATLAB analysis algorithm to output the data visualizations.

D. Comparison of the Temperature Inside and Outside the Dryers

Fig. 12 using MATLAB visualization data analysis shows the comparison between the inside and outside temperature during the conduct of the study. Based on the chart, the temperature inside was always greater than the temperature outside, as expected ranging from 45.37 - 56.9 °C which is organoleptically excellent quality according to Reza (2002)[16]. The system recorded the inside highest temperature of 56.9 °C and 46 °C on the outside, while the lowest temperature was observed at 45.37 °C on the inside and 26.33 °C outside.



#	Date	Time	Temperature	Humidity	Heat index	Weight	Moisture Content	Remaining Time
1	2021-12-26	11:11:06	46 °C	37.2 %	145.97 F	407.62 g	76.46 %	23.98 H
2	2021-12-26	11:11:20	46 °C	38.5 %	148.32 F	407.32 g	76.44 %	23.96 H

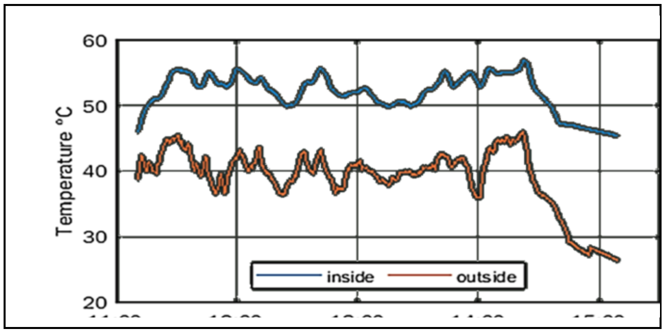

Fig. 12. Inside and outside temperature comparison (chart retrieved from web application visualization).

E. Weight and Moisture Content Relationship

The weight and moisture content are the most critical aspects in terms of drying foods. Throughout the drying session, the weight and moisture content were monitored. As Fig. 13 illustrates using MATLAB, the weight was proportional to the moisture content which means that for every loss of weight, there was also a loss in the moisture content. The researchers started drying with a total weight of 407.83 grams and its target weight of 95.96 grams which was considered safe and dry as it reached a moisture content of 15%. The desired weight was achieved after 4 hours of drying due to the high and constant temperature the fish receives. The temperature slowly goes down from 2:40 PM onwards.

Throughout the drying session, the web application collected and displayed data. The interval of receiving data from the system to the web application took about every 15 to 16 seconds depending on the network speed or/and latency. The researchers use three different kinds of devices such as the laptop, tablet, and mobile phone in monitoring the web application.

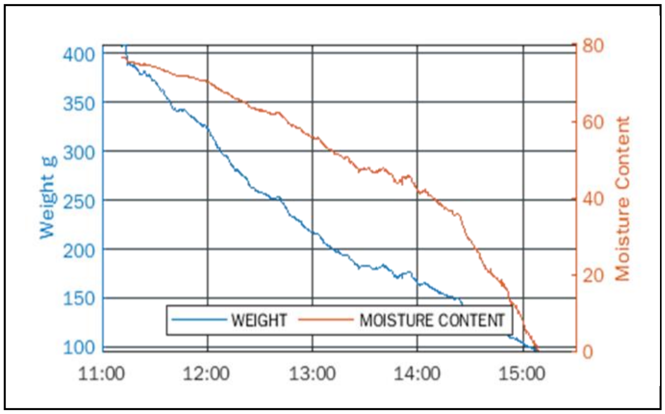

Fig. 13. Weight and moisture content relationship (chart retrieved from web application visualization).

F. Screenshots of the Received SMS

Fig. 14 shows the screenshots of the received SMS *"High Temperature 55.10°C"* or above during the actual testing first trial from 11:28am to 1:42pm and second trial triggered at 2:04pm to 2:22pm. This shows that the SMS alert notifications were repeated if triggered throughout the drying session. The user received in every 5-10 seconds delay interval depending on the providers signal strength on the user's area receptions.

G. Comparison of Two Drying Sessions

Table III shows the different drying sessions with different total and Achieved weights, the date and time the drying session started and ended as well as the hours and minutes it took to dry. The table shows that both drying sessions were successful and achieved the target weight. The Drying session 2 lasted longer compared to drying session 1. The duration of drying will always depend on the condition of the weather; and, the more fish is being dry, the longer it takes.

In comparing traditional sun drying to solar drying, it was found that solar drying dried faster than traditional drying as it only took 4-5 hours to dry a small fish at normal weather conditions compared to traditional outdoor sunlight at temperatures up to 37°C, the fish drying will take about 3 days.

TABLE III. TYPES OF SARDINELLA FISH FOUND IN THE PHILIPPINES

Drying Session No.	**COMPARISON OF TWO DRYING SESSION**				
	Total Weight	**Achieved Weight**	**Date and Time started**	**Date and Time started**	**Duration of Drying**
Drying Session 1	407.82 grams	95.96 grams	12-26-22 11:00 AM	12-26-22 3:09 PM	4 Hours & 9 mins
Drying Session 2	482.82 grams	110.53 grams	01-06-23 9:45 AM	01-06-23 2:31 PM	4 Hours & 46 mins

IV. CONCLUSION

The system IoT-based Direct Solar Dryer System: Integration of Web Data Logger and SMS Notification was able to achieve the desired results based on the conducted testing conditions in Optimizing Drying Efficiency. The direct solar dryer was able to increase the temperature up to 23% and maintain the temperature which can speed up the drying time while achieving the recommended relative humidity ranging from 24.9% up to 58.71%. The physical and remote monitoring was successful in gathering and displaying the needed information for the drying process. Moreover, the system was able to send SMS notifications to the user and the fan worked well according to its intended task. Therefore, the efficacy of improving the traditional sun drying with the use of technology can help alleviate the difficulties and disadvantages of the fish drying farmers.

ACKNOWLEDGMENT

This research work is done by the undergraduate students of Bachelor of Science in Computer Applications through the advice and support of the Department of Computer Application, College of Computer Studies MSU-IIT faculties and with the researcher's collaboration to Local Drying Farmers of barangay Calibunan in Cabadbaran City, Agusan del Norte in the Caraga Region in the Philippines.

Anti-Spoofing in Medical Employee's Email using Machine Learning Uclassify Algorithm

Bander Nasser Almousa, Diaa Mohammed Uliyan
Department of Information and Computer Science(ICS)-College of Computer Science and Engineering,
University of Ha'il (UOH), Hail, Kingdom of Saudi Arabia

***Abstract*—Since the advent of COVID-19, healthcare and IT cybersecurity have been an issue. Digital services and foreign labor have increased cyberattacks. July 2021 saw 260,642 phishing emails. 94% of 12 countries' employees experienced epidemic cyberattacks. Phishing attacks steal sensitive data from spam emails or legitimate websites for profit. Phishing spam uses URL, domain, page, and content variables. Simple machine-learning methods stop phishing emails. This study discusses phishing emails and patient data and healthcare employee accounts cybersecurity. This paper covers COVID-19 email and phishing detection. This article examines the message's URL, subject, email, and links. Uclassify classifies content, spam, and languages and automates emails. Semi-supervised machine learning dominates healthcare. The Uclassify algorithm used multinomial Naive Bayesian classifiers. Document class is [0–1]. This article compared Multinomial Naive Bayesian in two experiments with other algorithms. Experiment 1 achieved an MNB accuracy of 96% based on a database from Kaggle Phishing. Experiment 2 showed that the Multinomial Naive Bayesian system accurately predicted URL and hyperlink targets based on PhishTank data. 96.67% of respondents correctly identified URLs, and 91.6% did so for hyperlinks. These two experiments focused on Tokenization, Lemmatization, and Feature Extraction (FE) and contained an internal feature set (IFS) and an external feature set (EFS). MNB is more exact than earlier methods since it uses decimal digits and word frequency. MNB only takes binary inputs. MNB can detect phishing and spoofing.**

Keywords—Spoofing; phishing; machine learning; Uclassify algorithm; medical employee's email

I. Introduction

The Internet's quick services affect the world. Consumers can shop and bank anytime with improved Internet infrastructure. Despite its benefits, internet security and privacy are issues. Phishing, malware distribution, and privacy exposure are all possible with the Internet's anonymity[1]. Emergency and patient care services require healthcare workers to exchange electronic health information with patients. This data is one of the most sensitive. Therefore, special measures must be taken regarding threats to confidentiality, integrity, and availability (CIA)[2]. Healthcare should prepare for cyberattacks. Attackers have used email to target healthcare companies since the COVID-19 outbreak began [3]. The pandemic increased health cybercrime. Digital change encourages "telework" or "work from home," which boosts email efficiency [4]. Remote operators must be trained for safety. More than 3,000 employees in 12 countries have experienced remote working, and 94% have experienced cyberattacks during the pandemic, according to a report by the International Association of IT Asset Managers (IAITAM) [5]. The Anti-Phishing Working Group (APWG) says there were 260,642 phishing attacks in July 2021, the most ever seen in one month. It rises from 44,008 in the first quarter of 2020 to 128,926 in the third quarter [6]. Phishing emails steal any account credentials. Banks and hospitals were attacked the most [7]. Spoofing deceives victims into divulging passwords, usernames, and personal information. Scammers entice recipients to visit fake websites or download viruses [1]. 16% of 2015 FTC complaints were about identity theft. Phishing and social engineering steal data. Phishing online fraud using a fake website and email [8].

URIs hurt or redirect phishing victims. Second, domain length, numbers, spelling, and brand name may impact Phishing—status, domain owner, and age impact URLs. Reputation determines page believability. Content-based domain scanning—hidden, body, meta, and pictures—estimates daily, weekly, or monthly page views, average page visits, internet traffic, domain category, and similar websites. Finally, scanners check page type, user, and registration [9].

A. Problem of Phishing Attack Detection

Study email security. Email security avoids loss, theft, and hacking. Spam, phishing, and malware utilize email to transfer sensitive data and access networks [10] Phishing persists despite email security. Phishing is inevitable. This thesis tests copyright checking without email sender server settings [11]. The goal: Email is often attacked. Inconsistent protocols, roles, and services compromise email security [12]. Spoofing websites steal customer data—most often fake websites. Machine learning detects spam and phishing sites [13].

These research questions are addressed in this paper as follows:

1) Which machine learning methods are used to create phishing detection models?

2) What datasets are used for phishing email detection models?

3) How can modern datasets and resources recognize phishing emails?

4) Which email features use Phishing detection emails?

5) What are the early stages of phishing and the current trend of phishing emails?

To answer these questions or to address these issues, the findings in the research could be:

1) *SVM*, LR, and DT recognize fake emails, whereas k-means clustering does not [14]. Multinomial Naive Bayesian classifiers power Uclassify ML. Its feature vector classifies input into the most likely class. This algorithm considers all input data irrelevant. Data sets are unaffected by changes.

2) *ML-based* model training and testing require a dataset. Phishing detection methods were developed utilizing pooled datasets. Producers often update long-lived datasets. 2021 revised Nazario's dataset. 2010 spam email, 2005 phishing corpus, 2006 Enron spam, and 2002 spam assassin datasets are updated routinely [15].

3) *Classify* creates ten category numerical values after phishing using ML and web services—health. Uclassify web API will categorize questions by feature vector subject for this study. Uclassify contains ML classifiers for sentiment, themes, language, age, gender, and more.[16]. Customer emails initiate phishing. This malicious email links to an attacker-based website. Reassures email recipients:

a) The sender and email address are not from "UMass Amherst it@umass.edu>," despite the assertion.

b) Phishing emails are misspelled. This email's colon should not precede the comma.

c) Phishing emails employ urgency. It spurs action.

d) The message URL is UMass Amherst's webpage. Hovering reveals a different page.

e) UMass Amherst and Microsoft Corporation are impersonated in the letter. Again, bogus if the sender needs to know who they are.

f) The email link leads to a bogus SPIRE-phishing login page at "tantechhold-ings.com." [6].

4) *Extracting* features from raw data entails retaining the original data set while converting it into numerical portions that can be processed. BoW, IG, and Word2vec are text characteristics in phishing email detection research. The research also utilized latent Dirichlet allocation, part-of-speech tagging, PCA, and LDA [6].

5) *Phishing* targets psychology and emotion. They employ social engineering and technology. Attackers' personalization, clever phishing, and tactics increase prevention [17].

II. Literature Review

A. Introduction

Digital healthcare providers fear cyberattacks. Social engineering targets individuals. This lengthy research shows how cyber threat ignorance impacts healthcare—technical and organizational healthcare cyber security. Table I shows the authors' five questions to classify literature by subject. Healthcare cyber defense was examined first. All personnels are studied [18].

Table I outlines this systematic review's research questions and background [18].

TABLE I. SYSTEMATIC REVIEW'S RESEARCH QUESTIONS AND BACKGROUND

Background	Research Questions
Social engineering cyberattacks against healthcare workers are the most effective. These assaults use social media data.	RQ1: What are the prevalent social attacks perpetrated against individuals by healthcare organizations?
Data governance, encompassing data security, privacy, and IT infrastructure security, protects organizations against cyberattacks. Several methods prevent DDoS assaults. WannaCry has increased healthcare data leaks.	RQ2: Which policies and governance mechanisms have strengthened healthcare organizations?
Cyber risk assessment improves healthcare. Data breaches are expected as healthcare becomes more complicated. IT security dominates risk assessments. Social engineering requires reassessing healthcare cyber threats from insecure human behavior.	RQ3: How does an organization's cybersecurity risk assessment incorporate human elements in cybersecurity?
Healthcare companies now train on cybersecurity—for example, phishing email training. Given recent examples of using social media data to target healthcare practitioners, raising awareness of this evolving, dangerous environment is vital.	RQ4: How can training raise healthcare workers' cyber threat awareness, and how can we quantify an organization's training and awareness efforts?
Europe needs healthcare infrastructure. Outages may generate national emergencies. ENISA advises on cyber resilience. Multi-nation cyberattacks have had enormous economic and human repercussions.	RQ5: Which national and international organizations offer cyber defense strategies to boost cyber resilience?

Fig. 1 illustrates a phishing email, whereas Fig. 2 describes its essential elements. PhishTank hosts samples and notes.

Dear First Generic Bank user,

As a courtesy to our valued customers, First Generic Bank conducts regular account information verification processes. During the most recent process, we found that we could not verify your information.

In order to ensure your account information is not made vulnerable, please visit http://www.firstgenericbank.com.account-updateinfo.com.

Please click on the above link to our Web site and confirm or update your account information. If you do not do this within 48 hours of receipt of this e-mail, you will not be able to use your First Generic Bank account for 30 days. This is an extra precaution we take to ensure your account remains secure.

Sincerely,

First Generic Bank

Fig. 1. Phishing email example[8].

The phishing domain

Fig. 3. Phishing website [8].

The phisher's email connects to a bogus website (Fig. 3). This fake website was created to deceive email recipients. The attacker may utilize Fig. 3's remote data input area. Phishers then emailed and messaged AOL subscribers. Phishers asked AOL users for their account numbers. AOL's TOS couldn't track attackers' AIM accounts, worsening the issue. Finally, AOL sent emails and instant messages pushing users to withhold vital information [8].

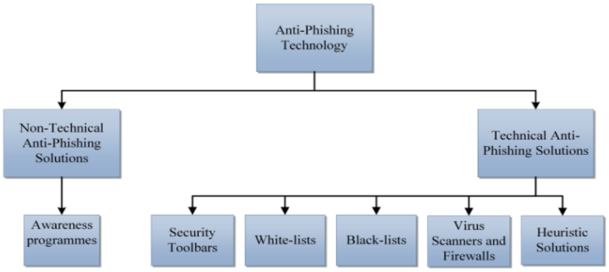

Fig. 4. Phishing prevention technology [8].

Blacklisting and whitelisting virus scanners safeguard internet users (see Fig. 4). Commercial software combats zero-day phishing. Microsoft, Google, and PhishTank blacklists let researchers test solutions. Anti-phishing may block and whitelist phishing URLs on the client's PC or server. Users trust whitelists. Zero-day phishing detection takes accuracy. Whitelists may mistake good websites for phishing. AIWL records user-irritating visual effects and manual white-list maintenance. Multinomial Naive Bayesian classifiers monitor AIWL logins. AIWL whitelists login URLs. The hardest part is picking a trustworthy site from a fraud list. Finally, blacklists and heuristics may whitelist. Avoiding trustworthy websites may expedite phishing detection. URL blacklists stop Phishing. Anti-phishing blacklists URL-verified phishing. Blacklists' low false-positive rate and simplicity make them famous. The research discovered that blacklist software missed 80% of zero-day phishing assaults. Blacklist users enjoy its simplicity and low false positive rate. Blacklists' low false-positive rate and simplicity make them popular [8].

B. *Definition of the Spoof*

The official definition is masquerade: "A type of threat action whereby an unauthorized entity gains access to a system or performs a malicious act by illegitimately posing as an authorized entity" and Spoof: "Attempt by an unauthorized entity to gain access to a system by posing as an authorized user" and phishing attack is: "A technique for attempting to acquire sensitive data, such as bank account numbers, through a fraudulent solicitation in email or on a website, in which the perpetrator masquerades as a legitimate business or reputable person" [19].

C. *Related Works*

Technology introduces security vulnerabilities. In the 1960s, "phone hacking" developed access control and encryption. AOL hackers coined "phishing" in 1996 after obtaining private data. Phishing emails verified AOL customers' credentials. Many provided hackers their login details to purchase items. Customers pay millions. eBay, HSBC, and others fight phishing. These techniques identify fake emails and websites. Despite its effectiveness, only some read online phishing prevention literature. ML finds fraud. Dots, domain ages, and links checked URLs for Spoofing or Phishing. Consumer education prevents phishing emails [20]. For five years, they analyzed US public sector data concerns. Only US public sector international concerns are studied. Targeted personnel cause 22% of security breaches, and hackers 45%. Social dishonesty increases. The Email Sender Centre prevents phishing and impersonation as threats rise. Scammers may be caught. Scam emails conceal [21]. COVID-19 phishing was examined. Cyberattacks grow. Backup data, secure remote worker networks, communicate with IT, and educate staff in the attack. COVID-19 and $6 trillion hacking by 2021 ended it. This article covers multifactor login, VPNs, new hacking regulations, and IT-employee communication. Pandemic hackers targeted hospitals. Phishing, ransomware, homework, and government attacks boost hacking threats. Education, VPNs, multifactor authentication, firmware upgrades, and a firm safety policy decrease these hazards. Spoofing needs numerous countermeasures: Fake COVID-19 affects ML [5]. Phishing and impersonation use distinct strategies. Fig. 5 shows Internet and phone; email, IM, and social media work well. Theft motivates these assaults. It accurately detects phishing emails, URLs, IPs, and images [5].

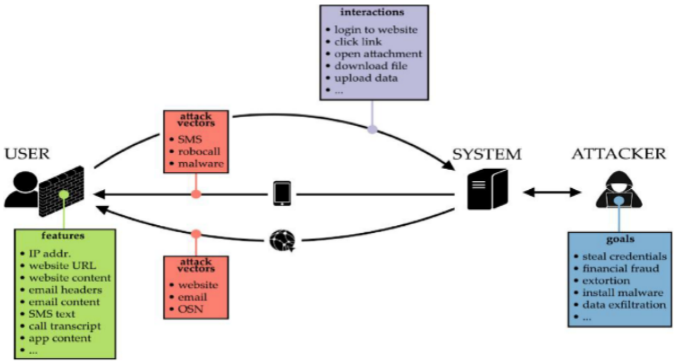

Fig. 5. Phishing attack [5].

SMTP is the Internet protocol for transmitting email. Fig. 6 depicts the three essential email message submission processes [22].

1) The sender's MUA sends the message to the service provider's MSA through STMP or HTTP/HTTPS (MSA).

2) The recipient's email provider receives the message via SMTP from the sender's MTA.

3) The user receives the message over HTTP/HTTPS, POP3, or IMAP via the Mail Delivery Agent (MDA) (IMAP) [22].

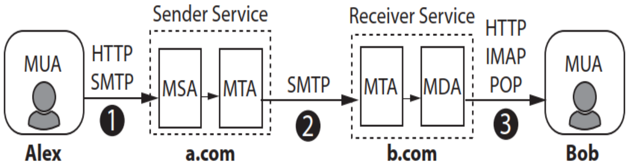

Fig. 6. Alex and bob's email transmission [22].

III. Research Methodology

4.5 billion people use the Internet. Email is trusted online. Fraudulent emails include malware or unsafe URLs. Even with better filtering, spam emails' constantly shifting content makes them hard to distinguish. Corporate email, commercial antispam services, and end-user training filter spam, yet this deadly trap caught non-experts. It trains SVM, Multinomial Naive Bayesian, CNN, and LSTM spam email detectors. This article offers different ML models sans spam email datasets. CNN and LSTM utilize Model Loss and ROC-AUC; MNB and SVM need precision, recall, and f-measure. Finally, all models are compared for great accuracy and DL and ML model evaluation parameters. English and spam detection enhanced [23]. Phishing detection has been improved. ML algorithms shine. ML algorithms will be studied with an accuracy of 94.4%. Content-based filters identify fake emails [24]. ML-based spam classification. Uclassify's own naive polynomial Bayesian classifier. Classification limits are calculated using the document category probability 0-1 [25]. The proposed solution considers the detection aspects of phishing attacks, URLs, and domains. ML will fight phishing attacks Fig. 7 depicts the Phases of a typical Spear-phishing attack [26].

Fig. 7. Phases of a typical Spear-phishing attack.

An attacker gathers as much sensitive target information as possible during preparation (S1). Leak social media and databases. Knowing the victim eases persuasion. Spam-detecting email infrastructure demands technological skills—clean, succinct, balanced email content (S2). The attacker then wants S3 opened. Email subjects matter. Secure email. The reader gets balanced (S2). The attacker then wants S3 unlocked. Email subjects matter. Secure email. Email motivates. Certain emails may create confidence. Avoid downloading attachments (S4). Preventing assaults requires security measures. Antivirus and OS updates protect. S5 attacks browsers, devices, and credentials [26]. Table II outlines our suggestions. "Use of @ symbol," "right-click blocked," and "hiding suspicious links" are three of the seventeen traits we are eliminating. RFC engineers and computer scientists accept @, ", and # in URLs. Browsers no longer allow status bar changes to turn off right-clicking and hide suspicious links. Invalid characteristics. 54-character URLs are questionable. Most bogus URLs are under 54 characters [32]. It impairs judgment. We verified the URL length. Chrome and IE allow 2083-character URLs. Thus, a URL with 1000–1750 characters is suspicious, but phishing with more.

TABLE II. Features of the Website and its Description [27]

#	Feature	Description
1	**IP domain names**	Using IP address in domain part is phishy because attacker is trying to disguise name with numbers.
2	**Long URL**	Long URLs disguise questionable keywords. URLs over 1750 are phishy.
3	**'-' symbol**	The domain's "-" indicates legitimacy. Example: Pay-Pal.com
4	**Sub-domain(s) in URL**	Phishing URLs have several subdomains.
5	**Use of HTTPS**	HTTPS secures URLs.
6	**Request URL**	The URL domain should load all text and graphics.
7	**URL of anchor**	All <a> tags should have domain-matching links.
8	**Server form handler"SFH."**	User data may be transferred. Checking Server Form Handler prevents this.
9	**Abnormal URL**	The URL's WHOIS data confirms its identity—no phishing website.
10	**Redirect page**	Links sometimes redirect users to other pages. Phishy redirects exceed four.
11	**Using pop-up Window**	Pop-up password entry is unethical. Pop-up sites are phishing.
12	**DNS record**	Phishy URLs lack DNS records.
13	**Website Traffic**	Website traffic visits. Websites without traffic records are fishy.
14	**Age of domain**	Domains age from registration. Phishing site registered under one year.

D. Research Design

Businesses and people email. Spammers make money. Bio-inspired machine learning identifies fake emails in this study. A study analyses how to use varied datasets for successful results. Genetic and Particle Swarm Optimization improved classifier performance. Features or automatic parameter selection may assess spam categorization algorithms. Comparing recommended and basic models will determine whether parameter changes enhance them [28].

E. Dataset

The detection approach is crucial to the proposed system, but the datasets used by the authors to test and train their algorithms affect their credibility. Website detection datasets match email detection datasets, showing no concerns. Spam and viruses sometimes are utilized. However, the papers discuss fraudulent email detection. These publications are harmful (the spam dataset contains spam email URLs). Online datasets for fraud detection algorithms are available—Table III lists prevalent phishing and ham datasets.

TABLE III. PRESENTS THE FEATURES OF THE DATASET [6]

#	Dataset feature	Description
1	**Dataset source**	The generally utilized data sources of legitimate and phishing websites, along with the approaches that grip every head, are mentioned; however, the insufficient understanding regarding the methodologies used in collecting and preserving every source results in no concord with all regarding the quality of various origins.
2	**Dataset size**	The evaluation dataset size differs between various approaches. As seen, the reliable outcome depends on the size of the dataset; the bigger the better
3	**Dataset redundancy**	There is not sufficient information in the literature regarding dataset redundancy. Although numerous presentations and overly between various sources of datasets, particularly of phishing websites, can be seen
4	**Dataset timeliness**	Although if a similar source of data and size of the dataset is utilized in two plans, their phishing website's information might not be the same. The phishing blacklist supplier generally amends their data hourly, because phishing websites last for short terms.
5	**Ratio of legitimate to phishing websites**	The ratio of legitimate to phishing examples displays the level at which experiments portray an actual world distribution (≈100/1)
6	**Training set to testing set ratio**	The extensibility of the approach is seen in the ratio of training to testing examples.

This study uses the 2020 Akashsurya156-revised Kaggle Datasets Phishing Email Collection. 22 traits, 21 predictors, and one target variable define email authenticity. Each feature improves model learning. The most deceptive electronic communication phrases were found—525,754 emails in CSV. Spam and fake emails are rare, skewing the classification dataset. Campaigners tested fake and real emails. These two groups balance actual and fraudulent emails in training models [29]. Fig. 8 shows information used for spoofing URL recognition [30].

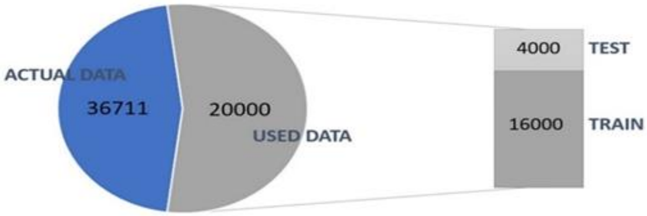

Fig. 8. Information used for spoofing URL recognition.

Phishing and URL data are needed for ML model training. A phishing crawler's program that gathers phishing URLs from the PhishTank website only records the web address if the site is active. Phish Search finds phony URLs that change. BeautifulSoup pulls page code. Using "identifiers" and queries, we may identify the request's absolute phishing URL. 10,000 phishing and 10,000 non-phishing URLs were crawled from the dataset. The training uses 8,000 URLs and evaluation 2,000. Table IV summarizes the study data. Fig. 8 depicts data distribution [30].

TABLE IV. DATA ON PHISHING AND LEGITIMATE URLS [30]

URL	Actual Data	Used Data	Train	Test
Benign URL	17058	10000	8000	2000
Phishing URL	19653	10000	8000	2000

F. Detection Method of Phishing Attack Through Email

Semi-supervised ML identifies bogus emails and impersonation. Fig. 12 depicts categorization. Semi-supervised learning employs small labeled and unlabeled examples. Binary classification identifies phishing emails. The automatic categorization is increasing ML-detected phishing. ML vectors describe emails and web pages. Fake emails and sites are 1. Label 0 denotes a valid email or page. Semi-supervised teaching detects and evaluates phishing emails and web pages. Fig. 11 shows the planned steps. Detect spoofing, phishing, and impersonation emails. These safeguard data and prevent fraud—these secure critical data. Establish email components.

Fig. 10. The format of an email message [31].

From, To, Subject, and Message-ID—the message's content—make up the email header. Fig. 9 and 10 exhibit email taxonomy and arrangement. Emails to scam websites. Email URLs trick consumers into providing critical information. Many studies have revealed email spoofing characteristics and methods to identify fake emails. Primary, latent topic, and dynamic Markov chain features. Researchers found anti-phishing techniques. Machine learning, deep learning, word embedding, and NLP are discussed [31].

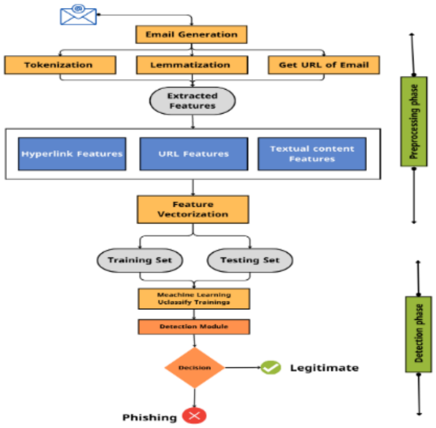

Fig. 11. The general structure of the proposed methodology.

1) Tokenization: Computationally splitting a text into words or tokens [32]. Thus, it trims the input text word by word. Next, filtering removes unnecessary words from token results and finds the root term of each filtered word. Tagging then finds the root form of a preceding word or stem word. Finally, analyzing texts finds word relationships [33].

2) Lemmatization: Removing inflectional suffixes from words returns the base form. Thus, it turns words into their roots. This removes the inflectional ending and restores the root. It uses lexical and morphological analysis to find a word's root form, unlike stemming. The word "better" means "excellent." [32, 34].

3) Feature Extraction (FE): Lexical components, conceptual frameworks, and linguistic phrases make text categorization difficult. Thus, learning from a large dataset takes a lot of work. Therefore, it's computationally expensive. Extraneous and redundant features also impair categorization algorithm accuracy and effectiveness. Use just the key elements to simplify and accurately classify data with little duplication [35].

Our classification has two main goals: 1. Extracting multi-view characteristics from each email that classifiers can manage; 2—applying a disagreement-based semi-supervised learning method to automatically identify and use unlabeled data. Fig. 12 displays our high-level email categorization model. Plan, train and classify. Initialization sorts incoming emails by our standard so an ML classifier can handle them (each email has unique attributes). Research and public spam datasets examined subject length, message size, attachment size, and word count. These studies describe email. 14 criteria were used to categorize emails using the variables above. Email techniques like route tracing and content recording may gather and compute the information. Creating two attribute sets—an internal feature set (IFS) and an external feature set (EFS)—from standard features. IFS contains email content properties, whereas EFS includes routing and forwarding [36]. Table V shows the email categorization model's multi-view data and disagreement-based semi-supervised learning architecture:

- Internal Feature Set (IFS): Email body features include subject length, message size, number and kind of attachments, wings, words in subject and message, and several embedded photos [36].
- External Feature Set (EFS): Unlike IFS, EFS affects email routing, forwarding, confirmations, replies, importance, frequency of sending and receiving emails, and sender name length [36].

TABLE V. TWO FEATURE SETS FOR EMAIL CATEGORIZATION MODELS[36]

	Internal Feature Set (IFS)	External Feature Set (EFS)
1	subject length	the number of receipts
2	message size	the number of replies
3	total attachments	the level of importance
4	type of attachments	email frequency
5	size of attachments	frequency of email receipt
6	words in the subject	sender name length
7	message word count	
8	embedded images	

Uclassify ML detects phishing emails: Fig. 12 shows semi-supervised ML. Classical ML improves predictions. The main methods include unsupervised, semi-supervised, and reinforcement learning. Scientists forecast data through supervised, semi-supervised, or reinforcement learning. Semi-supervised ML partly marked inputs. ML handles real-world learning issues. Semi-supervised ML employs unlabeled primary data and little human input. Labeled datasets are harder to obtain, costly, and may need topic expertise. Thus, fewer are preferable. Unlabeled datasets are cheaper and more straightforward.

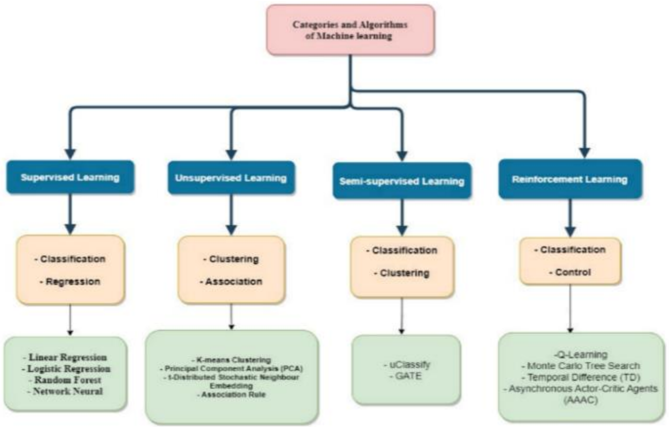

Fig. 12. ML phishing detection methods.

Semi-supervised ML trains unsupervised algorithms. Unsupervised ML uncovers input dataset structures. Supervised ML approaches use the best-unlabeled data predictions on new data. Unlabeled data re-rank or re-evaluate labeled data. Semi-supervised ML assumes smoothness, cluster, or manifold for unlabeled training data. Hybrid learning architectures integrate "discriminative" and "generative" learning. HDNs integrate architectures. Action banks increase human activity recognition. Semi-supervised ML rules healthcare. It processes audio and data. Image and voice analysis improves [37].

1) Uclassify detection method: We chose the Uclassify algorithm, a free web service for ML that facilitates creating and using text classifiers. Local Classification Server runs classification engine. Technically, our classification engine runs on the Amazon cloud Specification [38]:

- Windows service-based.
- Sockets to XML.
- Multiple uses
- Accurate but forgetful
- Fast parallel request processing
- Transactional integrity
- 0-1 outcomes

2) Architecture: The classification server operates as a Microsoft Windows service, functioning through XML calls transmitted via sockets, facilitating seamless integration with diverse Operating Systems. The system also provides XML-formatted responses. The application programming interface (API) exhibits high similarity to a freely accessible web API. Thread-safe classifiers (Readers/Writers lock) allow dynamic input class and training data. Low-resource C++ servers manage massive data sets. Important classifiers categorize requests quickly. We batch-processed 2.4 KB of blog entries using five primary classifiers on a contemporary PC for speed. 3,600,000 messages/hour! One core. Many threads handle queries. It is unbreakable. No paging file, repair errors. Transactional conduct avoids classifier writing errors. We need to remember classwork. Multinomial Hybrid complementary MNB, class normalisation, and exceptional smoothing improve Multinomial Naïve Bayesian classifiers. Sort [0–1]. Set limitations—90%+ spam. CPU classifies. Removes text and class-untrained classifier spam. Retraining the spam message on the spam class may solve it. Spam groups. Fig. 13 shows the pseducode of Uclassify algorithm.

Fig. 13. Pseudo code of Uclassify.

a) Multinomial naïve bayes: The Naïve Bayes model addresses classification predicaments by applying probability methodologies. Equation-1 represents the Naïve Bayes algorithm in this article [28].

$$\mathrm{P}(\text{ Class } | \text{ WORD }) = \frac{\left(\mathrm{P}(\text{ WORD} \mid \text{Class })\times \mathrm{P}(\text{ Class })\right)}{\left(\mathrm{P}(\text{ WORD })\right)} \qquad (1)$$

The present study involves the identification of WORD, which is a set of (word $_1$, word $_2$,.. word $_n$) extracted from an uploaded email. The variable' Class' indicates the email's classification into 'Spam' or 'Ham.' The algorithm computes the likelihood of a given class based on the bag of words supplied by the program. The expression P(Class | WORD) represents the posterior probability, while P(WORD | Class) denotes the likelihood, and P(Class) signifies the prior probability, as stated in reference. Assuming that the variable 'Class' represents the category of 'Spam,' one could rephrase the equation to identify spam emails based on the provided text. It can be subsequently expressed as a more concise equation, denoted as equation (2) [28].

$$\mathrm{P}(\text{ Class } | \text{ WORD }) = \frac{\Gamma_{i=1}^{n}\mathrm{P}(\text{ word\_i i}| \text{ Spam })\times \mathrm{P}(\text{ Spam })}{\mathrm{P}(\text{ word\_1, word\_2 ,... word\_n })} \qquad (2)$$

Multinomial, Gaussian, and Bernoulli are the three varieties of Nave Bayes algorithms. The Multinomial Naive Bayesian algorithm has been chosen to identify spam emails because it is text-related and outperforms the Gaussian and Bernoulli distributions [28]. Multinomial Nave Bayes (MNB) is a classifier that employs Multinomial Distribution for each feature, focusing on term frequency. Equation (3) represents the Multinomial Naive Bayesian model.

$$P(p \mid n) \propto P(p) \prod_{1\le k\le nd} P(t_k \mid p) \qquad (3)$$

The representation of the number of tokens as "nd" and the calculation of $P(t_k \mid p)$ where "n" denotes the number of emails, are the subject matters under consideration.

$$\mathrm{P}(\mathrm{t_k} \mid \mathrm{p}) = \frac{(\mathrm{count}(\mathrm{t_k}|\mathrm{p})+1)}{(\mathrm{count}(\mathrm{t_p})+|\mathrm{V}|)} \qquad (4)$$

Equations (3) and (4) denote the conditional probability for MNB as $P(t_k \mid p)$. The variable $P(p)$ stands for the prior probability, while t_k stands for the presence of spam terms in an email. The algorithm designates 1 and |V| as the smoothing constants. The Scikit-learn library was utilized to load the MNB module to test the algorithm. The parameters of this model are discretionary. Without any specified values, the default settings for the Alpha parameter are '1.0', for the Fit Prior parameter are 'True,' and for the Class Prior parameter are 'None.'

The pseudocode for Multinomial Naïve Bayes is introduced as a spam classifier as shown in Fig. 14. We have two datasets: Tr is defined as Training dataset and Te is defined as Testing dataset. The $\hat{\mathrm{P}}(t_k \mid p)$ is a predicting variable also identified as the conditional probability.

```
Initialise Input Variables;
N ← No. of samples;
X ← Datapoints;
y ← Target Inputs;

Calculate $\hat{P}(t_k \mid p)$
Calculate the Accuracy;
Return $t_k$ ;
```

Fig. 14. Algorithm-multinomial Naïve Bayes.

G. Experimental Results

The findings of the experiments, Multinomial Naive Bayesian (MNB), is the algorithm that outperformed all others. The various types of datasets, the Enron, Spam Assassin, and Ling-Spam datasets, provided greater depth by removing certain features from the emails, thereby allowing the optimization techniques more search space. However, the numerical datasets could have been more extensive, despite effectively enhancing the precision of some split sets. Considering the distinct datasets, the Spam Assassin dataset performed exceptionally well with MNB Nave Bayes Algorithm. The MNB performed better after being automatically tailored by bioinspired algorithms, and because it utilizes feature vectors, it performs exceptionally well with text-based datasets. [28]. Using our variables, they created a dataset to test our email categorization model (Table V). 7133 emails from two well-known companies were randomly marked and unlabeled. Three institution security professionals labeled the confidential dataset, leaving 2,300 instances unlabeled. Discord SSL employs MNB, IBK, and J48 with a 0.75 "majority vote" threshold. They tested voting strategy categorization accuracy after 60 and 100 rounds. They were comparing votes. "Majority vote" overcomes "best opinions." They reached our single-view EM semi-supervised learning method to determine how multiple-view data influences email categorization. Table V emphasizes that the EM semi-supervised learning method should train using a unique display dataset with all attributes. Our technique with multiple displays improves classification accuracy over single displays. Our practice also improves classification accuracy after numerous training rounds. Our approach changes after 60 repetitions [36]. Researchers encounter phishing websites. Blacklisting reduces hazards. Non-blacklisted websites cannot detect fraud—ML outcomes. Improve traffic, search engines, and third parties. In this work, machine learning using webpage URLs and email feature extraction—client-side, no-external services—identifies fraudulent websites rapidly and accurately. URLs link to the content [39].

H. Research Findings

1) Experiment 1: Categorization algorithm implementation outcomes. It compares feature analysis algorithms to 525,754 Kaggle phishing emails—2020 Kaggle Datasets Phishing Email Collection updated by Akashsurya156. The collection includes fake and real emails. Fig. 15 shows that 90% of phishing emails were categorized correctly. All Random Forest metrics are 99.4%. Like Random Forest, AdaBoost offers 99% accuracy. Multinomial Naive Bayes logistic regression achieves F1 scores and recalls accuracy > 98%. SVM accuracy was 92%. Despite its poor recall and F1 score, it must outperform other classifiers [29].

According to the research, Multinomial Naive Bayes, AdaBoost, Logistic Regression, and Random Forest correctly recognized Phishing and authentic emails. MNB has 96.91% accuracy. In Fig. 16, the Random Forest classifier had the best accuracy, whereas the other classifiers did not vary. The Support Vector Machine algorithm's lowest accuracy rate was 16.85%, making it unsuitable for unbalanced dataset categorization [29].

	Naive Bayes	Support Vector Machine	AdaBoost	Logistic Regression
F1	0.975	0.278	0.993	0.984
Precision	0.982	0.923	0.992	0.985
Recall	0.969	0.168	0.993	0.987

Fig. 15. Compares models based on their F1 score, precision, and recall [29].

	Naive Bayes	Support Vector Machine	AdaBoost	Logistic Regression	Random Forest
■ Accuracy	96.91%	16.85%	99.28%	98.72%	99.44%

Fig. 16. Accuracy of state-of-art methods compared with Naïve Bayes [29].

According to the data below in Fig. 17, Random Forest is the most widely used classification model for identifying phishing emails. Compared to the other classifiers used in the study, it shows the highest true positive rates and the lowest false positive rates, thus establishing its status as the most reliable classifier [29].

	Naive Bayes	Support Vector Machine	AdaBoost	Logistic Regression	Random Forest
🟦 TP	99.33%	93.75%	99.54%	98.85%	99.52%
🟥 FP	72.21%	99.40%	19%	22.67%	7.26%

Fig. 17. Compares models based on their accuracy [29].

2) *Experiment 2:* ML-based bogus website detection. PhishTank analyses were actual and fake websites. First, the URL method features train and assess the ML model and compare its predicted output to the actual task. Precision, recall, accuracy, and F1-score support the conclusions. Fig. 18 presents metrics for the three models. SVM has 98.05 percent accuracy and KNN 95.67 percent. SVM had 98.24% specificity and KNN 94.40%. SVM recall 97.86%, KNN 96.99%. SVM precision values are 98.25%—F1 score. The KNN, NB, and SVM models provide 95.65, 96.66, and 98.05 percent F1 scores, respectively [30].

	Accuracy	Specificity	Recall	Precision	F1-Score
🟦 KNN	95.675	94.4063	96.9929	94.348	95.6522
🟥 SVM	98.05	98.2403	97.8618	98.2526	98.0568
🟩 NB	96.675	96.2339	97.1241	96.2019	96.6608

Fig. 18. Efficiency metrics of the ML model utilizing URL-based FE data [30].

ML model testing uses the Hyperlink method—ML model predictions vs. outcomes. Fig. 19 compares the three models' metrics. SVM has 94.55% accuracy and KNN 89.87%. KNN 90.7% and SVM 93.76% specificity. SVM recalls 95.36, KNN 88.87%. SVM's 93.64% accuracy is good—final F1-score analysis. KNN and NB have 89.72% and 91.41% F1 scores, respectively, while SVM has 94.49%.

	ACCURACY	SPECIFICITY	RECALL	PRECISION	F1-SCORE
🟦 KNN	89.875	90.8772	88.8778	90.7332	89.7959
🟥 SVM	94.55	93.7653	95.3642	93.6468	94.4977
🟩 NB	91.6	92.1829	90.9969	91.8378	91.4154

Fig. 19. Compares models based on their true and false positive rates[30].

I. *Findings Analysis*

SVMs classify email spam best. Fig. 20 compares the Multinomial Naive Bayes Classifier and SVM with different-sized training emails. (Fig. 20). Most training data categorizes spam. 95.5% of emails are SVM. MNB ignores email word order. Support Vector Machines find the best hyperplane to discriminate classes from predictions, unlike MNB Classifiers [40].

	1,000	2,000	3,000	4,000	5,000	6,000
🟦 Naïve Bayes Classifier	87.0%	91.5%	92.5%	93.0%	93.5%	94.5%
🟧 Support Vector Machine	90.5%	91.5%	95.0%	94.0%	94.5%	95.5%

Fig. 20. A comparison of the accuracy of the Multinomial Naive Bayes classifier and the Support Vector Machine [40].

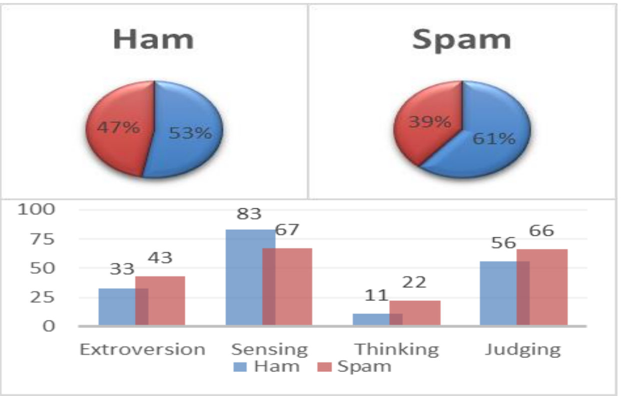

Fig. 21. Dataset personality recognition and sentiment analysis descriptive experiment [24].

This experiment uses CSDMC 2010 Spam corpus. TREC 2007 verifies. Descriptive evaluation Sentiment analyzers and personality recognition algorithms reveal in Fig. 20. BLR and DMNBtext for InfoGainAttributeEval attribute selection [24]. Everyone understands email spam. "Is this email genuine or spam?" Non-spam is shorter and snappier. Personality identification separates messages. The personality analysis creates a new dataset. Communication personality data concludes. Text type affects personality model dimensions. Emails differ. Spam and ham are different. Selected sentiment classifiers analyze message polarity. Derived polarity, like personality, adds three new datasets (one for each classifier). Fig. 21 shows spam positive and ham negative.

J. *Discussion*

Organized emails involve complex multi-view data production and email classification. The IFs and EFs evaluate email structure and word sequences, while numerous two-feature dataset creation methods and unlabeled data selection have shown good classification accuracy stability. Unlabeled samples were examined, which reduced classification accuracy. It is algorithmic. Well-designed biometric authentication and malware detection classifiers attract deep learning projects [36]. Experiment 1 focused on improving security measures for email phishing avoidance, as humans often struggle to detect potential hazards. Machine learning (ML) was utilized to successfully catch spam emails. However, since phishing emails are relatively rare, this skewed the email data, leading to the need for a more realistic model training. The detection model employed several algorithms, including Random Forest, Multinomial Naive Bayes, Support Vector Machine (SVM), AdaBoost, and Logistic Regression. Among these, Random Forest achieved the best classification rate for phishing emails at 99%. AdaBoost, Multinomial Naive Bayes, and Logistic Regression achieved a precision rate of 96%. On the other hand, SVM could only identify 16.85% of phishing emails [29]. In Experiment 2, the focus was on phishing attacks, where cybercriminals create fake websites to deceive users and obtain passwords and financial data. Phishers copy legitimate websites, making it challenging to differentiate between real and fraudulent sites. The effectiveness of anti-phishing measures diminishes in such cases. To address this issue, an ML model was developed using URL- and hyperlink-based feature extraction, which involved examining strings to identify patterns. Two feature extraction methods (URL-based and hyperlink-based) were employed to process the raw input data. Experimentally, the URL-based feature extraction in combination with SVM exhibited the highest accuracy (98.05%), specificity (98.24%), recall (97.86%), precision (94.34%), and F1-score (95.65%) [30].

IV. Conclusion

The Uclassify algorithm is one of the best machine learning algorithms to detect phishing and emphasize internal and external features; Uclassify can classify the message as phishing or not phishing. Based on the results, we determined that Uclassify outperforms some existing algorithms. It can detect phishing or spoofing. This algorithm was evaluated on three databases: Kaggle Phishing, Email Collection and PhishTank.

V. Future Works

Email saves photos, links, directions, and metadata. Email integration may enhance performance. K-nearest neighbors and neural networks will be compared to the current system [40]. Experiment 1 conclusions may help future researchers pick a classified [29]. In future work, we intend to add new features to detect malware-containing fraudulent websites. Our approach could not detect malware affixed to fraudulent web pages. Today, blockchain technology is more prevalent and is an ideal target for phishing attacks, such as blockchain-based phishing schemes. Blockchain is an open and distributed ledger that can effectively register transactions between receiving and sending parties, demonstrably and continuously, making it popular among investors. Detecting phishing schemes in the blockchain environment thus requires additional research and development. Detecting phishing attacks on mobile devices is also an essential topic in this field, as the prevalence of smartphones has made them a common target for phishing attacks [39]. Our model classifies emails well. Many unsolved questions may affect email classification. Email settings affect IFs and EFs' word order and email series. Unknown data selection intrigues. Unlabeled datasets may be "weak" if randomly selected. It may impair classification precision [36].

***Abstract*—Now-a-days, the increasing number of smartphones has caused the immediate sharing of photographs capturing current events on social media. The sentimental content of pictures from social events starts to be obtained from visual material, so visual sentiment analysis is a vital research topic. The research aims to reach valuable criteria to modify the visual sentiment prediction model based on event concepts and object detection techniques. In addition to adapting the approach for designing the method for predicting visual sentiments in a social network according to concept scores and measuring the performance of the model for predicting visual sentiments as accurately as possible, approach obtains a visual summary of social event images based on the visual elements that appear in the pictures which exceed sentiment-specific features. By this method, attributes (color, texture) are assigned to sentiments with discovering affective objects that are used to obtain emotions related to a picture of a social event by mapping the top predicted qualities to feelings and extracting the prevailing emotion connected with a photograph of a social event. This method is valid for a wide range of social events. This strategy also demonstrates the social event's effectiveness for a difficult social event image collection by using techniques for classifying complicated event images into sentiments, whether positive or negative.**

I. Introduction

Online social networks have integrated significantly into our daily lives. It is being designed to become a crucial resource for gathering and disseminating information in a variety of industries, including politics, business, entertainment, and crisis management. Social media Big Data is the result of the enormous increase in social media usage [1], which has resulted in a growing accumulation of data from which we are unable to profit. Numerous options for data formats are available on social networking sites like Instagram, Flickr, Twitter, and Facebook, including text, photographs, videos, sounds, and geospatial data.

Social media network users share a vast amount of written and visual content to communicate their emotions and thoughts, allowing us to construct a large collection of feelings and opinions. Analyzing user-generated material can aid in understanding and forecasting user behavior and emotions. Examining this information is crucial in the behavioral sciences, including areas like opinion mining, affective computing, and sentiment analysis. These disciplines strive to comprehend and anticipate human decision-making, enabling various practical applications such as monitoring brands, predicting stock market trends, and forecasting political voting patterns. As a result, scholars have recently become interested in these topics, and much research has been conducted in the "sentiment analysis" age of web mining. in light of the explosive spread of camera-enabled smartphones and the growth of social media and online visual content. It became easier than ever to create and share images. This led to an increase in the volume of images on the web, which continues to grow exponentially. Images have great power; they are more impactful than text, memorable, more engaging, and more likely to be shared and re-shared. This is due to the fact that the human brain is built for visual communication. Humans handle visual elements faster and remember them longer, and they elicit a stronger emotional response. In fact, visuals are processed 60,000 times faster than text. It's also more efficient for the person who is communicating.

Opinion mining, also referred to as "sentiment analysis," is an automated approach [2] to identifying opinions expressed in text. The increasing prevalence of mobile devices with cameras and social media platforms like Facebook, Twitter, and Weibo emphasizes the significant role played by multimedia content such as images and videos in conveying people's sentiments and opinions within social networks.

In recent years, numerous innovative concepts have emerged in the promising field of visual sentiment analysis. One notable advancement in artificial intelligence is deep learning, which has made significant strides [3, 4, 5, 6]. Researchers have begun to utilize deep learning techniques for sentiment analysis across various forms of social media data.

Traditionally, sentiment analysis has primarily concentrated on analyzing textual content. However, images, as a vital element of multimedia web data, play a significant role in conveying, expressing, communicating, comprehending, and illustrating people's opinions or sentiments to viewers. The increasing significance of image sentiment analysis, or predicting sentiments from images, is becoming increasingly apparent.

Sentiment analysis refers to the computational process of classifying and categorizing sentiments expressed in "multimedia web data," including both textual and non-textual elements. Its objective is to determine the attitude or opinion of a speaker or writer regarding a specific topic [7], as well as the overall contextual polarity or emotional response towards a document, image, interaction, or event.

Deep learning and machine learning are two interconnected fields that have become increasingly important in various domains [8, 9, 10]. Here are some key reasons for their significance as data-driven decision-making tools where deep learning and machine learning algorithms enable organizations to analyze and make sense of large amounts of data. They can uncover patterns, extract valuable insights, and make data-driven decisions. This is particularly crucial in today's era of big data, where traditional methods of analysis may not be sufficient for automation and efficiency. Machine learning algorithms can automate repetitive tasks and streamline processes, leading to increased efficiency and productivity. For example, in industries like manufacturing and logistics, machine learning can optimize supply chains, predict maintenance needs, and improve overall operational efficiency. In personalization and recommendations, deep learning and machine learning algorithms power personalized recommendations in various applications, such as e-commerce, streaming services, and social media platforms. These algorithms analyze user preferences, behaviors, and historical data to deliver tailored suggestions, enhancing the user experience and increasing customer engagement.

Recognizing attitudes elicited by photos from social media is more challenging than many other visual identification tasks, such as object categorization, scene recognition, and so on. For visual sentiment prediction, a diverse range of cues must be considered. Visual sentiment analysis is the process of identifying an object, scene, or activity and their emotional context.

Visual sentiment analysis has recently become one of the areas of computer vision, and it is a clue to solving the picture sentiment prediction problem. The most powerful computer vision approaches improve the process of recognizing human sentiment from low-level features to high-level features. The state-of-the-art in traditional computer vision tasks has lately experienced fast transformations as a result of deep learning techniques such as convolutional neural networks (CNN), which are utilized for image recognition activities. The network employs a multi-layered architecture that, through layer-wise processing, can represent features from raw pixels. This led to the application of similar techniques to forecast visual sentiment, in which we strive to recognize the emotion that an image would elicit in a human observer. In visual recognition, CNN models are reaching human-level performance. Several researchers have also used CNN to classify image sentiment and determined the difference between the amazing performance of deep features and hand-tuned features for sentiment classification. As a result, image sentiment analysis is regarded as an essential topic of research in online multimedia big data. However, visual sentiment analysis research is still in its infancy.

The paper's contributions are as follows: an approach to predicting the sentiment of complex event photographs using visual content and event concept detector scores with object detection, with no text analysis on test images required; Without extracting sentiment-specific information from the photos, the method outperforms state-of-the-art sentiment prediction algorithms. We conducted extensive tests on a difficult social event image dataset that has been tagged with sentiment labels (positive and negative) from different social media engines.

II. Related Work

Yang, J., et al. [11] addressed the difficulty of automatically recognizing sentiments in images. A framework is suggested to find out affective regions and gather information through CNN, inspired by the observation that the entire image as well as local sections have the ability to convey that sentimental information, which is most important. Considering both the objectless score and the sentiment score, the level of sentiment content in some region can be measured, noticing that the objectless score typically contains rich texture information, and that the sentiment score analyses the sentiment of that region at the affective level. The experimental results demonstrated that the proposed strategy outperformed state-of-the-art methods on common emotional datasets. Campos, V. et al. [12] performed extensive tests to compare different fine-tuned convolutional neural networks (CNNs) for visual sentiment prediction. The results demonstrated that deep architectures have the ability to learn new features and effectively understand the visual sentiment conveyed in social photos. The researchers developed multiple models that surpassed the current state-of-the-art performance on a dataset consisting of Twitter photos. They also highlighted the significance of pre-training in model initialization, particularly when dealing with small datasets. Furthermore, the researchers provided visualizations of the network's learned local patterns, which helped in understanding how these models perceive visual positivity or negativity and provided insights into their recognition capabilities. Ahsan, U., et al. [13] introduced a framework based on visual content alone to predict complicated image sentiment. They presented a dataset of an annotated social event and demonstrated that the features of the suggested event can be effectively assigned to sentiments. Accordingly, there was a proposed method to predict complicated image sentiment using visual content and event detector scores without having to analyze text on tested images. Not only did this proposed approach classify complicated event images into sentiments in a way surpassing state-of-the-art approaches, but it also demonstrated the effectiveness of a dataset of challenging social event images. Islam, J., and Zhang, Y. [14] introduced a novel framework for visual sentiment analysis using a transfer learning approach. They employed hyperparameters obtained from a highly deep convolutional neural network as the initialization for their network model. This choice aimed to mitigate overfitting issues. The researchers conducted a comprehensive set of experiments on a dataset of Twitter images, showcasing the superior performance of their proposed model compared to the current state-of-the-art approaches in sentiment analysis. Wang, Y., et al. [15] focused on the task of recognizing human sentiments using a combination of image features and contextual social network information, such as friend comments and user descriptions, within a large collection of Internet images. They developed a novel technique for visual sentiment analysis that leveraged various forms of prior knowledge, including sentiment lexicons, sentiment labels, and visual sentiment strength. The researchers devised a two-stage method for universal affective norms for pictures (ANPs), which involved detecting mid-level qualities to bridge the "affective gap" between low-level image features and high-level image emotions. They introduced a multiplicative updating technique to identify optimal solutions for model inference and demonstrated its convergence. Through experiments conducted on two large-scale datasets, they demonstrated that their proposed model surpassed previous state-of-the-art approaches in both sentiment inference and fine-grained sentiment prediction. You, Q., et al. [16] used the recently developed convolutional neural networks to find a solution to the problem of visual sentiment analysis. A new architecture wasn't only designed but also new training strategies, and that was a way to overcome the noisy nature of the large-scale training samples. The results emphasized that the proposed CNN surpassed not only classifiers that use predefined low-level features but also those with mid-level visual attributes. And its performance in image sentiment analysis was superior to that of other competing algorithms. Chen, T., et al. [17] introduced a hierarchical system that focuses on modelling object-based visual sentiment concepts, such as "crazy car" and "shy dog," to extract emotion-related information from social multimedia content. This system operates in an object-specific manner, enabling sentiment concept classification and addressing the challenge of concept localization. By leveraging an online commonsense knowledge base and introducing novel classification techniques to model concept similarity, the proposed framework significantly improved classification performance compared to previous approaches, achieving up to a 50% improvement. Moreover, the system identifies discriminative features, enabling the interpretation of the classifiers.

III. Approach

An overview of the model is described in the following sections: The proposed method contains four phases, as shown in Fig. 1. The model consists of four main steps: A) elicit social networking images; B) discover affective objects; C) perform feature extraction; and D) make sentiment predictions.

A. *Elicit Social Networking Images*

Collect images from popular social networking sites to assess the proposed method. The dataset includes pictures from user content, which is collected using eight sentiment categories as keywords on social websites.

B. *Discovering Affective Objects*

Localize the object regions in the input image. Then, for these regions, extract features. using object recognition techniques. Finally, the region that has a high score of object recognition indicates an affective object. The phase consists of three steps:

1) *Object detection:* This step used techniques to generate a set of candidate windows that detect visual objects with a rigid structure, such as a car or bike, and non-rigid objects, such as pedestrians and dogs. During the past decades, the object detection problem has been handled by many object proposal methods. These methods are Deformable Part Model (DPM), EdgeBoxes, and BING. The model used EdgeBoxes to detect objects.

2) *Object feature:* During this stage, object recognition techniques are employed to extract features from the objects detected within the bounding box regions. Deep learning algorithms, such as convolutional neural networks (CNNs), have become widely utilized for object recognition. These models have the ability to automatically learn the intrinsic properties of objects and can distinguish between different categories, such as cats and dogs, by analyzing large volumes of images and identifying distinguishing features. In addition to deep learning, machine learning techniques offer alternative approaches to object detection. Examples of traditional machine learning methods include using histogram of oriented gradients (HOG) features in combination with support vector machine (SVM) models, as well as employing bag-of-words models such as SURF and MSER. Another well-known algorithm, the Viola-Jones algorithm, can recognize various objects, including faces and upper bodies. The model used the (HOG) features in combination with support vector machine (SVM) models, as well as employing bag-of-words SURF model to object feature selection.

3) *Object recognition:* Recognizing objects inside the bounding box region and determining the accuracy of the object recognition. The region that has a high score of object recognition indicates the affective object.

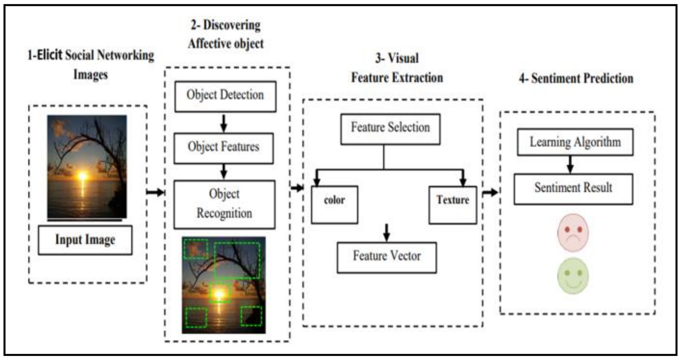

Fig. 1. The proposed approach is divided into four stages.

C. *Visual Feature Extraction*

The affective object region was identified in the previous phase. This phase [18] seeks to extract visual elements (such as color, texture, and form) from this region that reflect image appearance and can also predict image sentiment. A single feature cannot discriminate among a homogeneous group of photos, hence a vector including all retrieved image features is required to describe the image. Color, texture, and shape are examples of mid-level visual elements retrieved. Color is the most effective feature; color retrieval methods include color histograms and color correlograms. There are also various image retrieval methods based on Block Truncation Coding (BTC), which use encoding data in RGB color using BTC to recover image features. The texture of an image [19] is an important quality that describes not only the properties of an object's surface but also its relationship to its surroundings. The wavelet transforms and Gaborfilters are two of the most prominent tools for detecting picture texture; these measures attempt to capture elements of the image relating to changes in specific directions and the scale of these changes. Following that, employing feature [20] selection approaches to choose the most significant, best, most important, and most optimal subset of features collected from the region. Also used to remove irrelevant or redundant properties without changing the data, resulting [21] in increased efficiency, improved accuracy, and reduced data complexity. The output features are then combined to form a feature vector that represents the sentiment features for the affective object region.

D. *Sentiment Prediction*

Classify images and predict sentiment from those images (positive or negative). Sentiment prediction models can be easily trained by using learning algorithms. There are various algorithms used for learning models, such as the logistic regression model, which leads to better performance than SVM classifiers with sentiment features.

IV. Experiments

The images dataset is mentioned in this section, and the study aims to generate sentiment labels for the dataset as well as an experimental setup to predict event photo sentiments on the test set.

A. *Dataset*

To conduct the experiment, using eight event categories as search queries, retrieve public pictures from social media engines. These events are broad, encompassing both planned and unexpected events and including both personal and community-based activities, getting about 11,000 photos labelled as (1) positive and (2) negative. A dataset consisting of annotated event images. The dataset was divided into different sentiment classes.

B. *Experimental Setup*

For each class, 70% of the images were randomly selected as positive training data, while an equal number of images from the remaining mood classes were chosen as negative training data. The remaining 30% of images from each class were reserved for testing purposes. During testing, an equal number of negative training data points from sentiment classes other than those being tested were included. This ensured that the baseline accuracy for sentiment prediction was always 50%. The experiment was repeated five times, and the sentiment prediction accuracy for each class was averaged to obtain the final accuracy. In this stage, different techniques are employed to effectively detect objects within the bounding box regions. utilized EdgeBoxes for object detection. Once the objects were detected, extracted their features within the bounding box region using HOG feature extraction in combination with an SVM machine learning model. Additionally, employing a bag-of-words model with features like SURF to further enhance object recognition. Furthermore, the Viola-Jones algorithm, known for its capability to identify various objects like faces and upper bodies, was also utilized. By recognizing objects within the bounding box region and assessing the accuracy of object recognition, we were able to determine the affective object. The region with a high score of object recognition indicated the presence of the affective object. After that, select features such as color and texture. Color is regarded as the most effective feature; numerous approaches for picture retrieval based on Block Truncation Coding (BTC) extract image features from BTC that store data in RGB color. The texture of an image is an important attribute that describes the surface properties of an object and their relationship to its surroundings. The wavelet transforms and Gaborfilters are two common methods for identifying picture texture and the model used Gaborfilters. These methods attempt to capture image components with respect to changes in particular directions and the scale of the changes. Following that, employing feature selection techniques to identify the most significant, best, most important, and most optimal subset of characteristics collected from the region also used to remove irrelevant or redundant features without transforming the data, resulting in increased efficiency, improved accuracy, and reduced data complexity. The output features are then combined to form a feature vector that represents the sentiment features for the affective object region. To calculate event scores on the images, we utilized the Caffe deep learning framework. Specifically, we extracted features using the activations from the seventh layer ('fc7') of a CNN (Convolutional Neural Network) known as AlexNet. This CNN architecture was pre-trained on HybridCNN, which incorporates knowledge from a pre-training phase on 978 object categories from the ImageNet database and 205 scene categories from the Places dataset. The extracted features from the 'fc7' layer were 4096-dimensional, capturing rich representations of the images. The last step is to classify images and predict sentiment from those images (positive, negative). Sentiment prediction models can be easily trained using a logistic regression model.

V. Results and Discussion

Table I shows the sentiment prediction accuracies for our proposed event features and many powerful state-of-the-art baselines, and our proposed approach surpasses the state-of-the-art for not only all the sentiment classes but also the overall average sentiment prediction.

TABLE I. FOUR CLASSIFICATION MODELS AND THE PROPOSED EVENT CONCEPTS WITH OBJECTS DETECTION MODEL FOR PERFORMANCE EVALUATION

Models	Accuracy	F1-score	Recall	Precision
Hybrid CNN	66.38	66.01	65.70	65.38
SentiBank	67.73	67.55	67.40	66.70
Deep SentiBank	70.69	70.40	69.60	69.50
Event concepts	73.06	73.01	72.60	72.10
Event Concepts with Object Detection	74	74.02	73.59	73.20

As seen in Table I, the events with objects model outperformed all other models, achieving an accuracy of 74%, an f1-score of 74.02%, a recall of 73.59%, and a precision of 73.20%. Fig. 2 displays the accuracy of the five approaches and the proposed events with the object model.

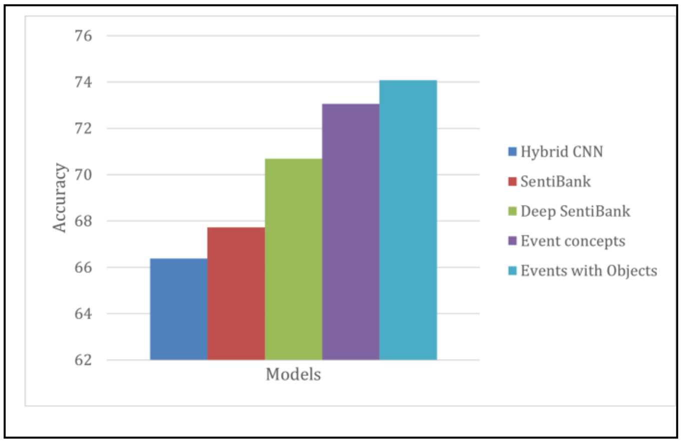

Fig. 2. Comparison between the proposed events with objects model and different models in the term of accuracy.

VI. Limitations and Future Work

The proposed approach has limitations that have been identified. While the taught model can accurately recognize positive images when the visual cues are strong, it tends to make mistakes when differentiating between positive and negative sentiments. In summary, the observation of a disparity between human perception of events (e.g., assuming all photographs of the Nepal disaster should be negative) and the actual images that exhibit diverse emotions influenced by those events. However, we believe that the proposed method adequately captures the nuanced nature of how an event impacts the emotional content of an image. In future developments, expanding the richness of social event data by incorporating more test data and richer labels into the sentiment recognition pipeline could potentially enhance the classifier's performance and address confusion between the three sentiments.

VII. Conclusion

Through event concepts and object detection approaches, we present a system for predicting complicated image sentiment using visual content, presenting an annotated social event dataset and demonstrating that suggested event concepts and object detection approaches can be efficiently mapped to sentiment. Comparing this method to state-of-the-art approaches, it outperforms them by a wide margin. Also investigated the proposed method's generalizability and validity by testing its performance on an unseen dataset of photos encompassing events not covered in model training.

***Abstract*—The emergence of Vehicle Ad hoc Networks (VANET) in 2003 has brought about a significant advancement in mobile phone networks and VANETs enable cars on the road to communicate with each other and the infrastructure on the street through a set of sensors and Intelligent Transport Systems (ITS). However VANETs are a low-level trust environment, making them vulnerable to misbehavior attacks and abnormal use. Thus, it is crucial to ensure that VANET systems and applications are secure and protected from cyber-attacks. This research aims to identify security challenges and vulnerabilities in VANET and proposes an algorithm that checks vehicle identity, location, and speed to detect and classify suspicious behavior. The research involves a study of the structures, architecture, and applications using VANET technology, the interconnection processes between them, and the types of architecture, layers, and applications that can pose a high risk. The research also focuses on the Confidentiality, Integrity and Availability (CIA) information security triangle and develops a program that uses machine learning to classify and analyze risks, attacks. The proposed algorithm provides security and safety for everyone on the road by identifying harmful behaviors of vehicles through knowledge of their location and identity. Overall, this research contributes to the development of a stable and secure Vehicular ad hoc network environment, enabling the integration of VANET security with smart cities.**

Keywords*—*Vehicular Ad hoc Network (VANET); Mobile Ad hoc Network (MANET); machine learning; random forest; linear regression

I. Introduction

The Internet of Things, machine learning, and artificial intelligence have gained immense importance. Vehicular ad hoc network (VANET) is being used in various sectors, including business, industry, and military, and it will soon be available in the civil sector as well. Since machines will replace humans in performing tasks, it is crucial to ensure that they can perform their duties swiftly and accurately to avoid errors.

The underlying chapter is based on providing an overview of different areas that form the basis of this research. The areas that will be covered in this chapter include providing background of the research along with performing an evaluation of the problem that is being studied. Apart from that, the chapter will provide illustrations about the key definitions and the questions of research that are intended to be studied through the completion of this study.

The topic that is under consideration is about identifying Vehicle Ad hoc Networks and how to make this environment safer and less risky. The purpose of choosing this particular topic is because of the importance of the telecom sector and the growth within the level of technology that has been witnessed over the years in this particular industry. However, there have been concerns related to the safety of the use of this technology as well which has created the need to study this particular problem in a detailed manner.

Network and communication scientists are also dedicated to developing these technologies in a way that facilitates the process of their use and reduces errors in them with the ability to transfer data to many networks at high speed. One of the areas that use technology is the Intelligent Transport System (ITS). As per WHO, approximately 1.35 million people are killed each year worldwide by road crash accidents, costing countries 3% of the Gross Domestic Product (GDP) [1]. In Saudi Arabia, the 2019 Saudi Ministry of Interior statistical report [1] reported a total number of 352,646 road crash accidents, with a mean of 40.2 road crash accidents each hour. Of all road accidents, the number of people injured in the accidents was 17,295, and the number of people injured was 30,217. On the other hand, the number of car accidents where people died was 4,780, and the number of actual deaths was 6,025. The report showed that more car accidents (60.91 %) occurred within cities than outside cities. Most (61.08 %) occur in the morning compared to the evening. These statistics highlight the importance of activating ITS applications to support drivers to make the right decisions to decrease road accidents. And we can say that these vehicles can communicate with each other on the road through a connected network of smart systems and applications, and this is what is done with VANET technology, as this technology focuses on road safety and reducing accidents with more efficiency. This technology is classified as a type of wireless network that falls under the umbrella of Mobile Ad hoc Networks (MANETs)[2].

Privacy is also a significant concern in Vehicular ad hoc network (VANET)s, as they can potentially track the movements of vehicles [31]. VANETs must also scale up quickly and efficiently to support large numbers of vehicles on the road. Additionally, interoperability can be challenging due to different communication protocols used by different vehicles [32].

A. Vehicular Ad Hoc Network (VANET) Architecture

Vehicular ad hoc network (VANET)s rely on a reliable infrastructure, which can be costly and challenging to maintain in some areas. Fig. 2 shows the components of VANET architecture in this technology [4], which are three main components that must be available when used on the road.

1) The communication of vehicle ad hoc network: VANET has two-channel communications groups. The safety messages are conducted in the control channel and non-safety messages on the services channel. Vehicles generate ten safety messages every second to other vehicles within a range of 300 meters. These messages aim to help other vehicles stay informed about the situation.

2) Vehicle to Vehicle communication (V2V): The vehicles use three types of communication between them. This type of communication involves the use of a vehicle's computer, which has GPS and radar capabilities. Second is Vehicle-to-Vehicle (V2V) exchange of information [5, 7]. It enables the interchange of speed data, data sharing, and position sharing by allowing cars to communicate with one another and perform its upkeep and secure[6,8].

3) Vehicle to Infrastructure communication (V2I): The third type of communication V2I, which is based on providing data to roadside infrastructure devices such as RSUs. Communication is utilized to deliver customized services like internet access and particular service requests. V2I communication allows cars to request information or services from RSUs and some other roadside infrastructure. For example, a car may inquire about the location of the closest petrol station or cafe, and utilize the RSU may respond. V2I communication may also be utilized to offer internet connection to network devices[5].

The goal of this application was to create a simulation that will perform misbehaving attacks on a certain vehicle. After that, the application will extract the data that it needs, such as the type, speed, and location of the vehicle.

The researchers used a machine learning tool known as WEKA to analyze the data and develop a strategy to identify and prevent misbehavior attacks. We utilized various methods to analyze the collected data, such as the Random tree, the Nave Bayes algorithm, and the Logit Boost method.

Our research aims to know the requirements for achieving security using Vehicular ad hoc network (VANET) and making it a secure and more reliable environment.

1) Develop an application to identify a VANET cybersecurity attack.

2) Improve the Vehicular ad hoc network (VANET) environment to make secure and trust it.

3) A proposed algorithm checks parameters such as vehicle identity sequence of location and speed.

4) Detect the attack and close all vulnerabilities of security holes.

There are a number of cyberattacks that target vehicles on the road, and the VANET environment is not devoid of cyberattacks, like many systems and applications in the world of technology and security challenges.

- There are several questions about this right, the most prominent of which are, what are the examples of the attacks that this environment faces? Among those attacks are Sybil, DDos or Dos attacks, and spam via mail that may affect the work of Vehicular ad hoc network (VANET).
- How to identify these attacks on the Vehicular ad hoc network (VANET) environment which may affect the movement of vehicles, their locations, and the identity of other vehicles?
- Types of attacks that attack the vehicle's identity and location.
- What are the tools used to create a virtual environment for Vehicular ad hoc network (VANET), extract data and analyze the results?

In order to enhance and make this technology safer to use, this paper seeks to analyze cyber security issues and vulnerabilities in the VANET environment, create a safer and more reliable environment, and protect vehicles and their passengers while using it.

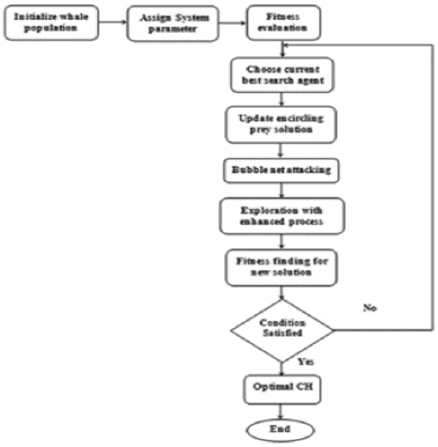
II. Literature Reviews

This section seeks to undertake a quantitative analysis of Vehicular ad hoc network (VANET) research conducted between 2007 and 2019. Then, provide an overview of the previous studies in VANET in terms of architecture, simulations, security, and communication protocols focusing on the cybersecurity issues facing VANET [8]. The massive number of publications in the VANET field discusses the various topics related to VANET, such as MAC Layers Issues (MAC-PHY), service, routing, data, tools, mobility, and applications [9].

"NS-2" is the highest level of network simulation software used in the research. Several studies have discussed issues related to the safe and reliable connection of VANETs [10,11].

The vehicle protocol should be reviewed in accordance with the geographical position [12]. Further, the challenges of designing protocol locations based on VANET, including non-DTVANETs, DTVANETs, and hybrids [13,15].

The algorithms mentioned below were created as a result of research and analysis done on the VANET. A Cluster Head (CH), as shown in Fig. 1, is the best option since it optimizes network settings and arranges the structures so that they function with the Adaptive Clustering Protocol (AWCP). Since it provides a protocol for analyzing the movement, position, and speed of the vehicle, the Enhanced Whale Optimization Algorithm (EWOA), one of the modern algorithms, is crucial to the VANET technology.



Initialize whale population
Assign System parameter

Optimal CH
End

Fig. 1. Flowchart of Optimal CH [18].

Cooper C et al. have conducted a comprehensive study of clustering algorithms designed for VANETs [3]. They proposed classification approaches to address cluster head voting, cluster relationship, and cluster controlling issues, as illustrated in Fig. 2. Furthermore, they evaluated the performance of clustering algorithms and identified the need for practical vehicle channel modeling. Finally, they highlighted the importance of stringent and regulated vehicular channel models.

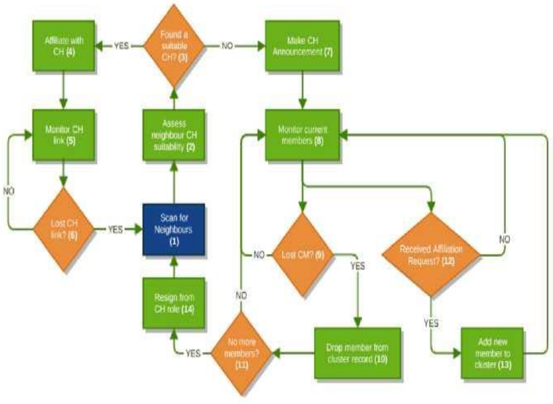

Fig. 2. Flow of a Clustering Algorithm [4].

As a trend, some researchers focused on cyber-attacks and challenges that may face the VANET. For example, R. Engoulou et al. present various architectures and characteristics of VANET. Moreover, they introduced the VANET challenges as time constraints they listed the selection security architecture, requirements, and threads after that. Finally, the authors proposed VANET global security architecture [19].

P. Tyagi et al. examine the routing protocols' features in security and pertinently. Moreover, they proposed an algorithm that focuses on the performance and effort in the most two common protocols used in VANET, named: DSR and AOVD. The protocols mentioned above aim to detect and address a specific type of attack on VANET known as a base black hole attack. The algorithm proposed aimed to enhance AOVD security and detection techniques. Using the proposed algorithm increases the ITS security and reduces the number of malicious nodes.

C. Sowattana et al. showed in Fig. 3 a sample that presents how the Sybil nodes located in the street, propose a distributed technique that detects the Sybil attack by using the messages spread among the nodes. This technique will consider all node positioning locations inside two communication rings as Sybil nodes if it is not acknowledged by one node. [21]

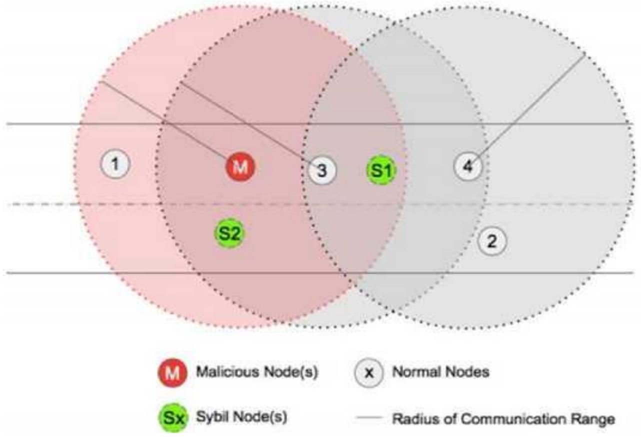

Fig. 3. Sybil attack detection method [20].

M. Hamid et al. [17] present the security issues in VANET communication among the groups. Also, they propose a new solution for man-in-the-middle attacks that may happen in the VANET environment. In [23], authors discuss Invasion of security goals (confidentiality, integrity, availability).

ML is a branch of AI that entails teaching computers to execute tasks and evaluate data. To automate data analysis and processing, ML algorithms employ computer model and decision tools such as decision trees, natural language processing, and neural network models. AI encompasses data exploration and extraction, with machine learning (ML) teaching computers how to use data in decision-making. In this context, data mining is equally significant since it looks for relevant data to execute the task.

ML algorithms are classified into two types: unsupervised and supervised learning. People provide input along with output during training, and the algorithm makes predictions once it has done learning. Unsupervised learning, on the other hand, employs an iterative method nicknamed deep learning which doesn't require the same amount of human input. Unlike supervised learning systems, these algorithms are utilized for more complicated processing tasks. Machine learning techniques are comparable to predictive modeling, but with a concentration on data search [26,28].

This study was conducted with five classifiers from different classification families. It was chosen because they have shown varying ratios in accuracy and timing.

Moreover, the VANET application has found that these classifiers are in line with the results that were found. Five classifiers were used in this study [29-30].

The paper [33] proposes a machine learning-based approach for detecting Sybil attacks in VANETs through collaborative learning. The approach achieves high accuracy in real-time and can be easily integrated into existing VANET security solutions, highlighting the importance of collaboration between network nodes to enhance security.

The study findings [34] show that existing mechanisms use different detection techniques such as time synchronization, trust-based systems, and clustering algorithms to detect Sybil attacks in VFC environments.

The author in [35] proposes a lattice-based group signature scheme for VANETs that offers forward security and efficient authentication. Through a lattice-based group signature, an efficient and forward-secure authentication protocol can be established for VANETs as is discussed. The proposed scheme is shown to be more efficient than existing schemes in terms of computation time and communication overhead.

A. Summary and Research Gaps

This type of technology is considered a modern type that needs to be studied first, and in these areas, the development is rapid or accelerating. In particular, it may cause dangers and problems that may have unimaginable consequences and lead to the death of some people.

Therefore, it is important for the researcher to work on studying and securing vehicles in order to ensure public security and cyber security in this sector. Additionally, there is a need for more research into secure communication protocols that can be used to protect data exchanged between vehicles. Finally, there is a need for improved methods of detecting and responding to malicious activities in Vehicular ad hoc network (VANET)s. Mapping between the related article and cybersecurity majors is shown in Table I.

TABLE I. MAPPING BETWEEN THE RELATED ARTICLE AND CYBER SECURITY MAJORS

Paper	Finding	Security	Threats	ML/AI	Attack
[14]	Existing VANETs' security concerns and the current strategies for tackling these. They explain how well each solution meets security needs such as identity, integrity, confidentiality, or vehicle revocation.	No	No	Yes	Yes
[16]	Suggested that w identify the Sybil attack in the system using ML employing majority voting.	No	No	Yes	Yes
[18]	suggest an efficient mutual strong authentication for safe Vehicular communications on VANETs	Yes	No	No	Yes
[36]	Proposed framework combines multiple detection sources and achieves a high detection rate with low false positives.	Yes	Yes	No	Yes

III. CYBER SECURITY IN VEHICULAR AD HOC NETWORK (VANET) ATTACKS

The first segment covers four different types of attacks that are designed to interrupt the positioning and identity of vehicles. These attacks can lead to a reduction in the speed of moving vehicles and a decrease in road safety. The misbehaviors that seek to locate or identify cars are covered in the second segment. These can cause a decrease in the comfort level of drivers and the safety of road user [24-25].

A. Experimental Setup on the Simulation.

This section outlines the setups employed in the simulations of the experimentation. The road design is a 10km lengthy roadway with two driving directions and countless tracks in each. The experiment used a total of 12,000 vehicles to replicate. The random speed ranges from 10 km/h to 180 km/h. In addition, the app, VMC, M-VMC, VPMC, or M-VPMC, can be subjected to the misbehavior threats. These designs are adaptable to individual requirements.

B. Examine Simulation Data from VANET Attack

The dataset was created by the VANET information security attack simulation software. The dataset created via simulation has a total of 15594 occurrences. To avoid overfitting, the timestamp, and steps are removed. Each sample contains an ID that can detect the vehicle's identification and position x and y to identify the vehicle's location in the simulation. It is adjustable and dependent on the vehicle's x and y speeds. Furthermore, the type property indicates whether the vehicle is normal, attacker, or virtual. Also, the dataset has been labeled (multi-class) and contains four types of attacks in the column.

C. Types of cyberattacks on vehicles, on the road.

1) Vehicle manipulated coordinates (VMC): An attacker creates or duplicates the ID of the vehicle or several virtual vehicles on the road. This type of attack publishes messages for vehicles with a fake site to a BMS message, so that other vehicles are deluded by the presence of an actual vehicle in the same The left path, the attacker also uses random locations with different time periods.

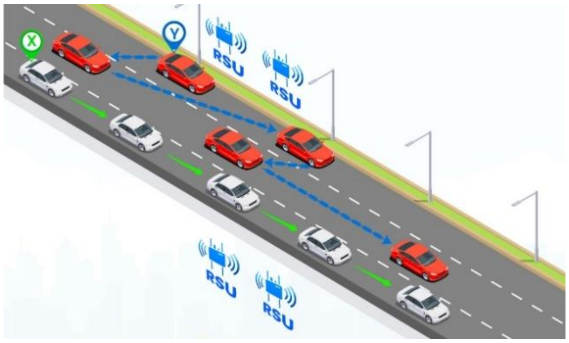

Fig. 4. Vehicle manipulated coordinate.

2) Multi-Vehicle Manipulated Coordinates (M-VMC): The attack in multi-vehicle manipulated coordinates (M-VMC) begins with the creation of a manipulated coordinate's identifier and uses a second vehicle identifier that impersonates a genuine car on the road.

In addition to the fact that this attack works on changing the location of the vehicle in a random manner on the same path as the vehicle on the road, also the same location is used by multiple virtual vehicles for each of them, but they don't use it again, Fig. 5.

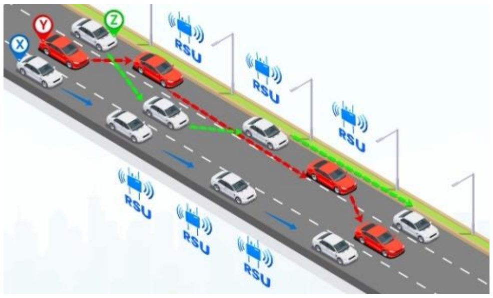

Fig. 5. Multi-vehicle manipulated coordinates.

3) Vehicle Path Manipulated Coordinates (VPMC): A bad type of attack is the vehicle path manipulated coordinates (VPMC) attack. It is an ID-reincarnating virtual vehicle and sends BMS messages as a real vehicle to the vehicles on the road. This type of attack determines its location in advance, similar to a routine traffic.

Fig. 4 to 7, there are two vehicles, X and Y. The real vehicle in red and the arrow is solid, and it is the vehicle X, and its movement path shows the action in different time periods. Stronger, on the other hand, is the virtual vehicle Y in white with a dashed arrow showing its trajectory and virtual movement on the road at different time periods.

In Fig. 6, vehicle X repeats its identification and vehicle Y coordinates are predefined.

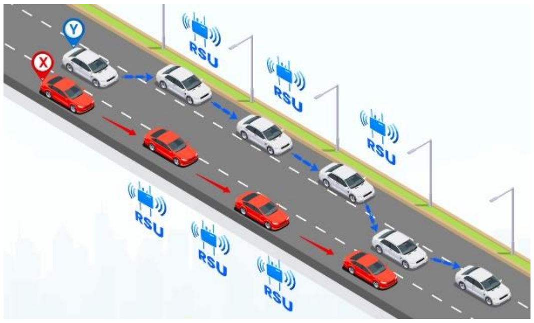

Fig. 6. Vehicle path manipulated coordinates.

a) Multi-Vehicle Path Manipulated Coordinates (M-VPMC): This attack is considered close or similar to VPMC, as it is a bad attack that is difficult to find if it occurs, may cause problems and dangers in traffic safety; and perhaps the most important thing that this attack does is create fake traffic on the road, which causes traffic disruption and delay time Vehicle arrival, The Multi-vehicle path manipulated coordinates (M-VPMC) attacker uses a vehicle and creates broadcast. The attacker can specify the coordinates of the virtual vehicles, bearing to mind that he cannot use a coordinate twice.

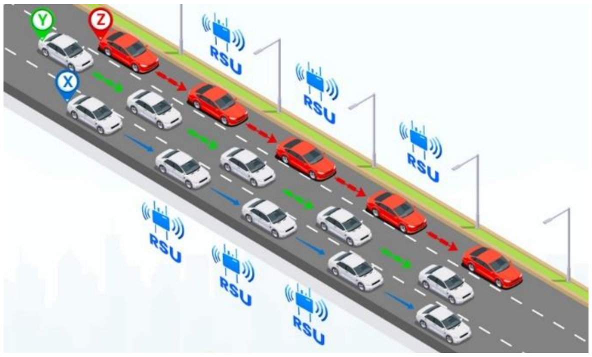

Fig. 7. Multi-vehicle path manipulated coordinates.

D. The Experiment Attack of Vehicular Ad Hoc Network (VANET)

The tools used in this study are discussed in this section. The data collected from the VANET simulation and the experiment are also presented. They are then analyzed using a machine learning tool.

E. The Experiment and Configuration of Simulation

The details of the road configuration used in the experiment are presented in this section. The simulation was conducted on the highway spans a 10-kilometer area divided into two road paths with multiple tracks. The random speed of the 12,000 vehicles that were used during the experiment was set at between 10 and 180 kilometers per hour.

F. The Machine Learning Implementation.

The study was carried out using WEKA, an easy-to-use machine learning tool [26]. It does not require any proficiency in math or programming. In addition, it has a library that can be utilized by developers.

G. Classification Algorithms

The study utilized a classification algorithm that can handle different kinds of circumstances. Some of the systems featured in the experiment are Logit Boost, J48, Naïve Bayes, and Bagging, among others [27-28]. The training phase involves creating a model that will be used on a set of instances. After the model has been trained, it can then be evaluated to see how it performs.

H. The Dataset

The dataset was created using the VANET software. It simulated an information security attack. The dataset created via simulation has a total of 15594 occurrences. To avoid overfitting, the timestamp, and steps are removed. Each sample contains an ID that can detect the vehicle's identification and position x and y to identify the vehicle's location in the simulation. It is adjustable and dependent on the vehicle's x and y speeds. Furthermore, the type property indicates whether the vehicle is normal, attacker, or virtual. Furthermore, the dataset has been labeled (multi-class) and contains four types of attacks in the column.

IV. Result and Analysis

This section aims to talk about the attack described in Section III. It will also discuss the classification tools and the generated dataset.

A. Nave Bayes Output

The first classifier discussed is Naive Bayes, with TP rate representing true positive rate, FP rate representing false positive rate, precision indicating the percentage of true positive designations among all positive categories, recall indicating the percentage of true positive categorizations among all actual positives, and F-measure indicating the normalized harmonic mean of precision and recall. While the Table II, includes these metrics for each class as well as a weighted average of all classes, it does not explain how the statistics were calculated or what they indicate.

TABLE II. RESULT OF NAÏVE BAYES

Class	TP Rate	FP Rate	Precision	Recall	F-Measure	MCC	ROC Area	PRC Area
None	100.00%	0.00%	100.00%	100.00%	100.00%	100.00%	100.00%	100.00%
M-VPMC	53.70%	15.10%	32.40%	53.70%	40.40%	31.40%	86.40%	33.80%
VPMC	23.20%	6.60%	30.40%	23.20%	26.30%	18.70%	86.20%	31.50%
M-VMC	22.30%	5.20%	27.00%	22.30%	24.40%	18.70%	85.80%	24.50%
VMC	12.00%	3.10%	24.20%	12.00%	16.10%	12.50%	85.20%	22.60%
Weighted Avg.	73.20%	3.20%	72.80%	73.20%	72.40%	69.80%	94.60%	72.70%

Similarly, for the additional classifier VMC, the model performs best on the "None" class with 100% TP rate and precision, while the other classes have lower performance metrics. The weighted average of all classes shows that the model has a TP rate of 73.20%, precision of 72.80%, and F-measure of 72.40%, indicating decent overall performance (Fig. 8). In conclusion, this accuracy report provides a comprehensive summary of a machine learning model's performance for a multi-class classifier with five classes, highlighting both the strengths and weaknesses of the model in categorizing examples for each class.

B. Random Forest Outcomes

Fig. 9 illustrates the results of the random tree classifier. The proportion of genuine positive predictions in each class is represented by the TP rate, whereas the proportion of false correct cases is represented by the FP rate. Precision is defined as the ratio of true positive predictions to total positive forecasts for each class, whereas recall is defined as the ratio of true positive predictions to total positive occurrences in each class. The role in the quality mean of accuracy and recall is the F-measure. For the "M-VMC" and "VPMC" classes, the Table III, shows for precision and F-measure as these values could not be calculated due to no positive predictions for these classes. The weighted average row shows the average of the metrics weighted by the number of instances in each class.

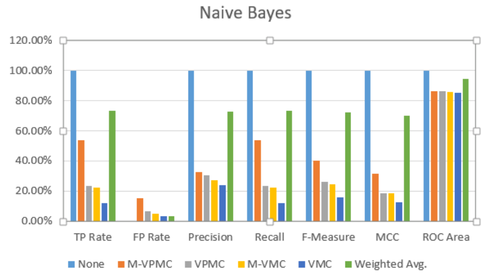

Fig. 8. Result Naïve Bayes.

The classes are listed in the rows of the Table III, with the class name in the leftmost column. The "None" class has the best performance with perfect scores in all metrics. The other classes have varying levels of performance, with M-VPMC having the highest precision but the lowest TP rate and recall, while VMC has the lowest precision but higher TP rate and recall. The weighted average shows that the model has an overall TP rate of 73.0%, precision of 72.5%, and F-measure of 72.4%, indicating decent performance overall.

TABLE III. RESULT OF RANDOM FOREST

Class	TP Rate	FP Rate	Precision	Recall	F-Measure	MCC	ROC Area	PRC Area
None	100.00%	0.00%	100.00%	100.00%	100.00%	100.00%	100.00%	100.00%
M-VPMC	43.40%	11.9%	32.9%	43.40%	37.40%	28.00%	85.60%	33.10%
VPMC	35.6%	10.2%	30.40%	35.6%	32.80%	23.80%	85.70%	31.10%
M-VMC	16.5%	4.3%	24.8%	16.50%	19.80%	14.80%	84.47%	22.80%
VMC	13.00%	3.8%	21.7%	13.00%	16.30%	11.70%	84.60%	21.20%
Weighted Avg.	73.00%	3.20%	72.50%	73.00%	72.40%	69.60%	94.30%	72.40%

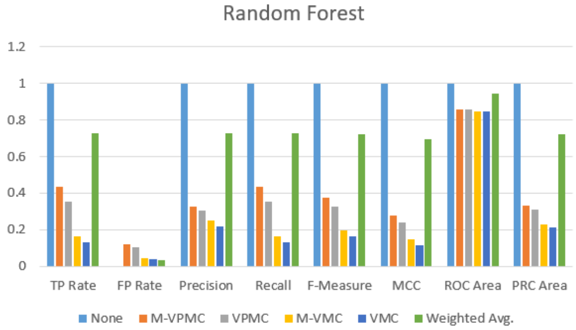

Fig. 9. Result of RF.

C. LogitBoost Classifier Outcomes

The "TP Rate" column (Table IV) displays the true negative rate, which is the number of genuine positives (properly categorized examples) among all positive instances in that class. The "FP Rate" column displays the FPR, which is the amount of false positives (incorrectly categorized occurrences) in comparison to all negative cases in that category. "F-Measure" column represents the F1-score, which is a combined measure of precision and recall. The "Weighted Avg." row at the bottom shows the weighted average of the metrics for all classes.

TABLE IV. OUTPUT OF LOGITBOOST

Class	TP Rate	FP Rate	Precision	Recall	F-Measure	MCC	ROC Area	PRC Area
None	100.00%	0.00%	100.00%	100.00%	100.00%	100.00%	100.00%	100.00%
M-VPMC	43.40%	11.9%	32.9%	43.40%	37.40%	28.00%	85.60%	33.10%
VPMC	35.6%	10.2%	30.40%	35.6%	32.80%	23.80%	85.70%	31.10%
M-VMC	16.5%	4.3%	24.8%	16.50%	19.80%	14.80%	84.47%	22.80%

VMC	13.00%	3.8%	21.7%	13.00%	16.30%	11.70%	84.60%	21.20%
Weighted Avg.	73.00%	3.20%	72.50%	73.00%	72.40%	69.60%	94.30%	72.40%

The second row (M-VPMC) has a true positive rate of 0.434, meaning that it correctly classified 43.4% of the instances for this class, and a false positive rate of 0.119, meaning that it incorrectly classified 11.9% of instances as this class when they are actually from other classes. Its precision, recall, and F-measure are 0.329, 0.434, and 0.374 respectively (Fig. 10). Its MCC, ROC area, and PRC area are 0.280, 0.856, and 0.331, respectively.

The following rows show the performance of the model for the other classes (VPMC, M-VMC, and VMC). The last row (weighted average) shows the overall performance of the model, taking into account the number of instances in each class. The model has an overall weighted average true positive rate of 0.730 and a weighted average precision of 0.725, indicating that it performs well overall. The other evaluation metrics such as weighted average false positive rate, recall, F-measure, MCC, ROC area, and PRC area are also reported in the last row [21].

D. The Outcomes of the Bagging Classification

The metrics for evaluating a classification model are shown in the Table V. The model assumes five classes: M-VPMC, VMC, None, M-VPMC, and VPMC. The TP rate is the proportion of actual positive instances properly categorized as positive by the model, whereas the FP rate represents the proportion of actual negative cases wrongly classified as positive by the model. Precision is the percentage of anticipated positive instances that were really positive, whereas recall is the percentage of immediate valid cases that were properly identified as positive (Fig. 11).

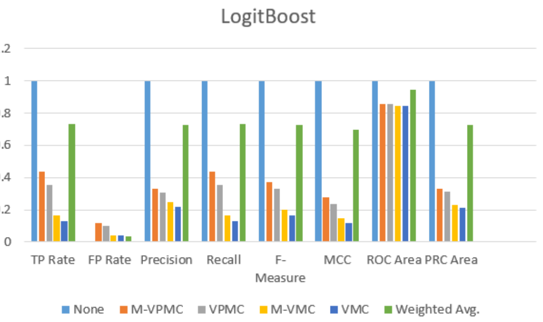

Fig. 10. Output of Logit boost.

TABLE V. OUTCOME OF BAGGING

Class	TP Rate	FP Rate	Precision	Recall	F-Measure	MCC	ROC Area	PRC Area
None	100.00%	0.00%	100.00%	100.00%	100.00%	100.00%	100.00%	100.00%
M-VPMC	41.90%	11.5%	32.9%	41.90%	36.80%	27.40%	85.80%	33.50%
VPMC	35.8%	10.0%	31.0%	35.8%	33.20%	24.20%	85.50%	31.70%
M-VMC	15.00%	4.7%	21.6%	15.0%	17.70%	12.20%	84.40%	22.90%
VMC	15.20%	4.1%	23.0%	15.2%	18.30%	13.40%	84.50%	21.30%
Weighted Avg.	72.80%	3.20%	72.40%	72.80%	72.40%	69.50%	94.30%	72.20%

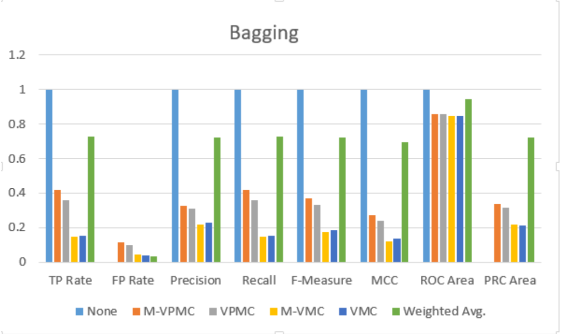

Fig. 11. Output of Bagging.

E. J48 Outcomes

The output of J48 classifier is shown in Fig. 12, presents the performance evaluation metrics for a classification model. For five different classes: M-VPMC, VMC, None, M-VMC, and VPMC. The weighted average of the metrics across all classes is also reported [22].

According to the figure, the model has a greater TP rate and precision for the M-VPMC class than for the other classes, but a lower TP rate and quality for the VPMC class. All the no class has the maximum TP rate and precision, indicating that the model is good at recognizing instances in this class. The total mean metrics(Confusion Metrics) shown in Fig. 13, indicate that the model performs well overall, with a higher TP rate, accuracy, recall, and F-measure, but a smaller FP rate.

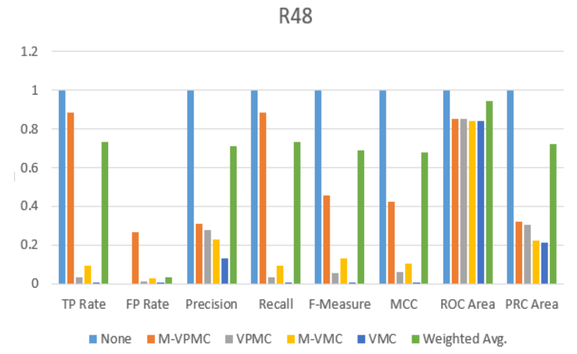

Fig. 12. Output of J48.

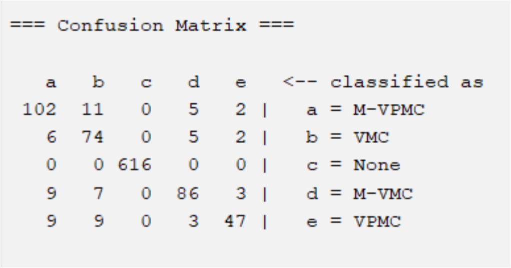

```
=== Confusion Matrix ===

   a   b   c   d   e   <-- classified as
 102  11   0   5   2 |   a = M-VPMC
   6  74   0   5   2 |   b = VMC
   0   0 616   0   0 |   c = None
   9   7   0  86   3 |   d = M-VMC
   9   9   0   3  47 |   e = VPMC
```

Fig. 13. Confusion Matrix for J48

V. Classification and Evaluation

Classification is a well-known ML supervised learning approach that includes predicting a category target variable based on a collection of input characteristics. Generally, the input data is separated into sets for training and testing.

The evaluation process is critical in ML because it determines how well the model is able on unknown data. A classification model's performance may be evaluated using a variety of measures, notably accuracy, precision, recall, F1 score, or ROC curve.

Accuracy: Measures the percentage of correctly predicted instances out of the total instances.

$$Accuracy= TP +TN / TP+TN+FP+FN$$

Precision: Measures the proportion of true positives out of the total instances classified as positive.

$$Precision = TP/TP+FP$$

Recall: Recall measures the proportion of true positives out of the total actual positive

$$Recall = TP/TP + FN$$

F1-Score: The arithmetic mean of accuracy and recall is used to get the F1 score. 2 * (precision * recall) / (precision + recall) is the formula.

A. *VANET Attack Detection Flowchart*

This section will also talk about the attack detection process. It is shown as a flowchart in Fig. 14.

B. *The Generated Dataset*

The generated dataset is presented in this section. The simulation program generated a total of 15594 instances of the attack detection process. There were eleven attributes in the dataset, which were sorted into four categories: type, attack type, location, and speed. The steps, timestamp, and detection reason were not included in the analysis. The classification method was also labeled with two classes: normal vehicle and malicious. Fig. 14 shows the flow chart for attack detection.

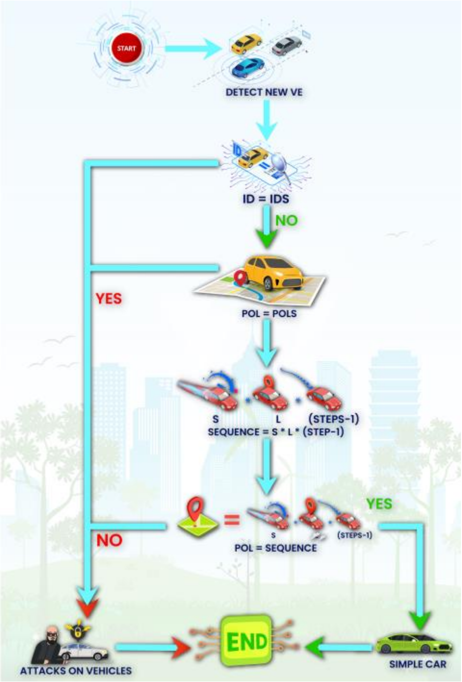

Fig. 14. Flow chart for attack detection.

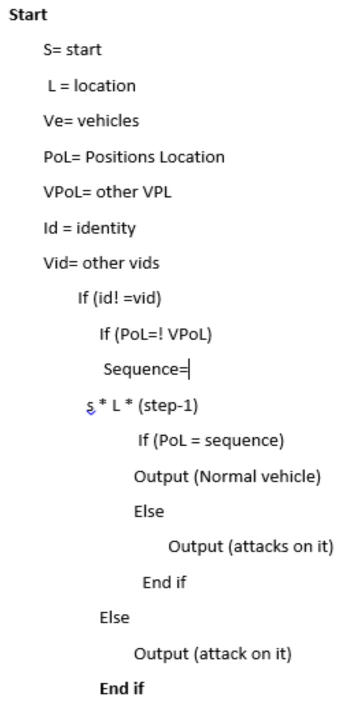
C. *Algorithm for Identifying VANET Attacks*



```
Start
    S= start
     L = location
    Ve= vehicles
    PoL= Positions Location
    VPoL= other VPL
    Id = identity
    Vid= other vids
        If (id! =vid)
          If (PoL=! VPoL)
           Sequence=
         s * L * (step-1)
              If (PoL = sequence)
              Output (Normal vehicle)
              Else
                  Output (attacks on it)
               End if
          Else
              Output (attack on it)
          End if
```

D. Detection’s Time and Accuracy Performance

The accuracy of five distinct classifiers, including: Bagging, Nave Bayes, Random Tree, J48 & LogitBoost classifiers, is assessed in Fig. 15 based on the total number of examples, correct instances, and wrong instances. The accuracy of cases is used to assess the performance of each classifier. Right examples are those that are correctly identified by the classifier, whereas wrong instances are those that are incorrectly classified. The assessment used a maximum of 263,879 examples, and the findings are shown in detail in the figure below [24]. Instance correctness is an important performance metric since it represents the classifier's accuracy in identifying fresh instances or data points. It represents how accurately the classifier identifies fresh instances or data points, which is an important performance metric. Since Reliability and Accuracy are important factors, it is essential to achieve high instances correctness [25].

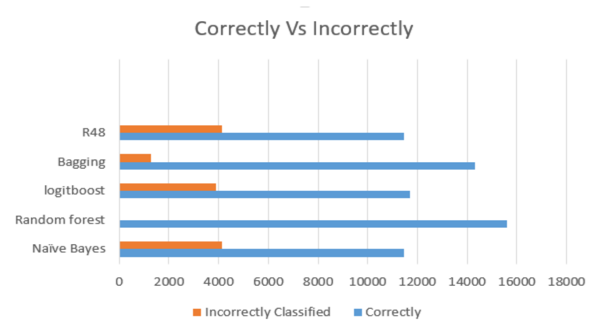


Fig. 15. Accuracy of all classifiers.

The given graph depicts the classification performance of five machine learning algorithms: Naïve Bayes, Random Forest, Logitboost, Bagging, and R48, on a dataset. Each algorithm's table displays the number of correctly and incorrectly classified instances. Random Forest attained the highest accuracy, correctly classifying 15593 instances with no misclassification, whereas Naïve Bayes, logitboost, Bagging, and R48 exhibited varying levels of accuracy and misclassification. The selection of the most suitable algorithm depends on the dataset's characteristics, classification objectives, and available computational resources. Choosing a classifier that generates a model promptly is critical, considering both accuracy and efficiency. [26]. Time accuracy graph is shown in Fig. 16.

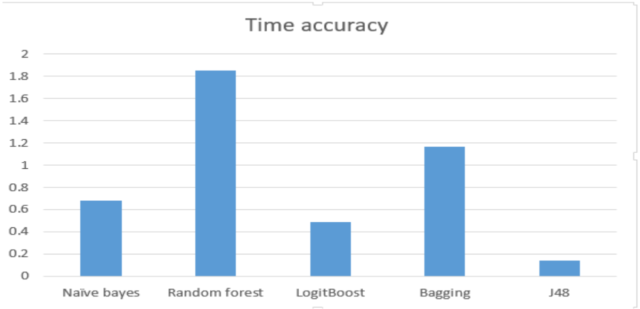

Fig. 16. Time accuracy graph.

VI. Conclusion and Future Work

The present research paper reviews various studies on the security requirements of electronic systems and VANETs (Vehicular Ad Hoc Networks). The paper aims to focus on misbehavior attacks on VANETs, specifically Fake BMS messages that can lead to attacks like M-VPMC, VMC, M-VMC and VPMC. These attacks pose a considerable threat to the security, safety, and comfort of drivers. The study introduces proposed techniques and algorithms to detect misbehavior attacks on identity and location in VANETs. The detection algorithm’s performance is evaluated using five classification techniques, including Na¨ıve Bayes, J48, Random tree, Bagging, and LogitBoost, based on accuracy and time taken to build a model/sec. The results reveal that the Random Tree classifier performs the best with accuracy of 99 percentage. The J48 classifier comes in second, with an accuracy of 99.75 and a time of 7.75 sec. On the other hand, the Bagging classifier reports the lowest performance with a time of 15.15 sec and an accuracy of 98.98 percentage.

Using research and scientific studies, along with journals related to VANET, we gained insight into the requirements and security risks that might affect VANET infrastructure. Using a simulation for vehicles and cyber-attacks, we were able to identify whether these threats were the first of four threats posed to this environment in advance. It is very important for the future. It may lead to infrastructure risks and the safety of the driver and pedestrians. In the future, great prosperity is expected for the VANET field, as it is a developed environment that has received a lot of investments at this time. There are still environmental problems and the environment needs to be protected. In the near future, we expect to find many algorithms that will benefit infrastructure owners and vehicle owners. Research has great prospects.

Optimization Solutions for Solving Travelling Salesman Problem in Graph Theory using African Buffalo Mechanism

Yousef Methkal Abd Algani
The Faculty of Mathematics, The Arab Academic College for Education in Israel, Israel

***Abstract*—The African Buffalo Optimization (ABO), a metaheuristic optimization algorithm created from thorough study of African buffalos, a species of African cows, in African woods and savannahs, is suggested in this study. In its pursuit for food across the African continent, this animal demonstrates unusual intelligence, sophisticated organising capabilities, and remarkable navigational acumen. The African Buffalo Optimization creates a mathematical model based on this animal's behaviour and uses it to tackle several benchmark symmetrical Travel Salesman's Problem and six tough asymmetric Travelling Salesman Problem Library (TSPLIB) instances. Buffalos can ensure the effective exploitation and exploration of the problem space by frequent contact, teamwork, and a sharp mind of previous record discoveries, as well as tapping into the breed's collective exploits, according to this study. The results produced by solving these TSP problems using the ABO were compared to those obtained by utilizing other prominent methods. The results indicate that ABO gently outperformed than Lin-Kernighan and HBMO optimising solutions to the ATSP cases under investigative process, with a slightly higher accuracy of 99.5% compared to 87% for Lin-Kernighan and 80% for HBMO. The African Buffalo Optimization algorithm produces very competitive outcomes.**

Keywords*—African buffalo optimization; solutions; travelling salesman's problem; graph theory

I. Introduction

Profit maximisation and expense reduction never been more essential in social history than they are today. As a result of this need, efficiency has become a popular research topic. As a result of this advancement, a variety of optimization methods were developed. Ant Colony Optimization, Particle Swarm Optimization, Artificial Bee Colony, Genetic Algorithm, and many other techniques are among the most prominent [1]. However, the foregoing methods have a number of disadvantages, including a premature convergent delay in getting the results, the ability to become caught in global minimum, and a complex fitness function with a lot of factors to set up[2]. The construction of the African Buffalo was motivated by a desire to offer remedies to some of these algorithms' flaws.

The ABO is a community stochastic optimization method inspired by the behaviour and attitude of African buffalos, a genus of wild cows comparable to domestic cows that traverse thousands of kilometres through African tropical rainforests and scrubland by travelling together and in large herds of up to a hundred buffalos [3]. Their travel is motivated by a desire to find abundant grazing pastures. They tend to follow the wet weather to find abundant grazing meadows. Because the seasons vary from place to place across Africa's huge expanse, buffalos are constantly on the move in search of their preferred meadows. ABO algorithm is focused to analyse how buffalos use different modes of communication to organise themselves [4]. They have uses various modes of sounds to indicate the danger zone, good and bad area of grazing fields and to encourage their herds to stay and take use of the present resources.

Over the last few decades, there has been a lot of research on the symmetric Traveling Salesman's Problem. It's astonishing how little research has been done on the asymmetrical Travelling Salesman's Problems [5]. This is perplexing because the majority of real-world uses are asymmetric. A postal service official searching for the optimum route to make deliveries to various locations within a specific area is an ideal example. For instance, a bus driver attempting to find the best way to pick up children from schools, delivering meals to residents, and other real-life scenarios illustrate its practical application. Asymmetric solutions are the most probable approach to resolving these challenges [6]. This concept explains this need for research project since it will aim to solve everyday difficulties and, as a result, will have broad applicability. TSP computations are commonly done in the literature using Eucledian or orthodromic distances. The Euclediaa distance is determined using x-y dimensions and the Pythagorean formula, and the range among x and y is clearly symmetrical. But at the other end, the orthodromic range estimates the area between the coordinates of two nodes over a portion of the globe [7]. Though more exact than Euclidean measurements, particularly over vast distances, it does provide genuine real-life measurements when nodes are connected by highways or transport systems, as do unbalanced computations that account for one-way mobility and some other construction related issues [8].

A research gap in the field of optimization solutions for solving the Traveling Salesman Problem (TSP) in Graph Theory is the development of hybrid or integrated approaches that combine multiple optimization techniques. While numerous algorithms have been proposed individually, there is a lack of comprehensive studies that explore the synergistic potential of integrating different methods. By combining the strengths of various algorithms such as metaheuristics, exact algorithms, and machine learning, it may be possible to achieve improved solution quality, faster convergence, and enhanced scalability for solving TSP. Investigating the effectiveness of hybrid approaches and identifying the optimal combinations of techniques for different TSP instances would be a valuable research direction to bridge this gap and advance the field of TSP optimization. The research on the African Buffalo Optimization (ABO) algorithm is of significant importance as it introduces a novel metaheuristic approach inspired by the behavior of African buffalos. By studying and emulating their intelligence, organizational capabilities, and navigational acumen, the ABO algorithm provides a fresh perspective on solving optimization problems. The algorithm's ability to effectively exploit and explore the problem space through teamwork, communication, and knowledge sharing among individuals mirrors the collective intelligence of the buffalo breed. The study demonstrates the algorithm's competitive outcomes by solving benchmark symmetrical Traveling Salesman's Problems and challenging asymmetric TSPLIB instances. By showcasing the potential of bio-inspired optimization, this research contributes to the development of innovative algorithms and expands the range of effective tools available for solving complex optimization problems.

The African Buffalo Optimization and the Traveling Salesman's Problem are introduced in Section II of this work. A Proposed ABO algorithm is presented in Section III. The study's results and discussion are summarised in Section IV.

II. Related Works

The African Buffalo Optimization (ABO), Ant colony optimization (ACO), LinKernighan algorithm and the hybrid Honey Bee Mating Optimization (HBMO-TSP) are the subjects of this research. The truth that all these techniques have some of the greatest outcomes and compare the effects in the research piques our interest in them.

Buffalo optimization approached with various alarms, [7] In its hunting tasks, the newly built African Buffalo Optimization imitate the warning and alarm sounds of African buffalos. The waaa sound alerts buffalos to the existence of attackers or a paucity of pastures, prompting the herds to move on to safety or more profitable regions of the grassland. Once this cry is issued, the animals are instructed to remain vigilant and find a secure or better grazed field. The maaa sounds, on the other side, are being used to advise buffalos to relax because there are plenty of grazing pastures nearby and the environment is suitable to grazing. The herds are able to utilize their seek for food sources using these signals. This ABO is being the solution of various optimised problems for both Symmetric and Asymmetric Travelling Salesman Problems and the numerical benchmark functions. ABO seems that it is old algorithm and weak in process, issues in delay and inefficiency, this optimisation is only helpful for African buffalos.

Ant Colony Optimisation is developed by [9]. This is among the most often used optimization techniques. After some preliminary work on Dorigo and Gambardella's Ant Colony System and Marc Dorigo's Ant System, Marco Dorigo and Di Caro developed the Ant Colony Optimization method in 1999. The spontaneous wandering of ants in looking for food prompted the Ant Colony Optimization. Once a food supply has been found, the ant that identified it transports a particle of it back to the nest; likely take a shorter path and continuously depositing pheromones as a way of reminding additional ants of its progress. Neighborhood ants will probably join the succeeding ant in tracking the food resources if they detect the pheromone's fragrance. Once such ants reach the food resources, they take some food bits back to the home and deposit pheromones to improve the original ant's route. This mechanism attracts other ants by increasing the pheromone content on the preferred shortest route. The swarm of ants is on the most efficient route into and out of the protein source in a short amount of time. The main defects of ACO algorithm is fuel cost minimization, less voltage profile, loss in transmission reduction and this computational algorithm is reduced to find the original paths in graphs.

The Lin-Kernighan algorithm is derived by [7] a common search method that finds solutions by carrying out extensive local searches]. This method searches employing transfers (or moves) that turn one route into another in order to shorten the route duration until the greatest (cheapest) trip is found. The basic rules of the iconic Lin-Kernighan algorithm are as follows: k Only successive transactions with huge progress are allowed; (ii) 'Shuttered' tours are permitted except when k = 2; (iii) A earlier cracked link should not be provided, and a precipitate link should not be cracked; and (iv) Journeys are only registered through the five closest neighbours; (v) If k = 4, no connection, xi, on the route should be destroyed whether it is a common factor of a tiny proportion of remedy routes; (vi) If future attempts do not provide a good outcome, the research for enhancements is ended. Principles (iii) and (iv) are heuristics principles that may decrease the time but it may produce in a degraded approach, as shown. The improved LinKernighan method has enhanced most of the core rules as a result of this: k Choose a different nodes l; (ii) Choose another network l so that k-l is an applicant side and á (k-l) = 0 and k-l relates to the actual best circuit; otherwise, choose l so that k-l is a determined based or choose l from endpoints not yet chosen. Proceed to stage ii if any locations will not be addressed; (iv) Whenever the network size picked in step iii >1, the sequence of the networks chosen includes the initial route. This algorithm provides results randomly because the algorithm begins with random partition.

The Honey Bees Mating Optimization method is a community metaheuristic, simulates the beehive queen's mating rituals. The princess of the bee’s couples with the swarms joining her in flying, dependent on her strength and ability of the queen retains the vehicle's genetics in her spermathecal after pairing, and the swarm is formed when the breeding flight is completed. Part of the answer is the genetics of the drones. A transformation function is utilised to construct the nests. When a progeny is stronger than the queen, this becomes the empress. The leader, labourers, and flyers are the three kinds of bees. The endeavour golden jelly to the offspring, while the flies pair with the monarch and the emperor is the healthiest bee. This is the HBMO algorithm analysed by [10]. Honey Bee Breeding Optimization to Broadening Nearby Search Algorithm (ENST) and Multi-

Phase Nearby Lookup Randomly assigned Flexible Described (HBMOTSP) is a hybrid that combines HBMO with the Broadening Community Search Method (ENST) and the Multi-Phase Nearby Lookup Randomly assigned Dynamic Mapped (MPNS-GRASP). This combination of processes aids HBMO-TSP in reducing calculation time and ensuring effectiveness when addressing Traveling Salesman's Issues. This method, which is based on the Honey Bee Mating Optimizer, has proven to be particularly useful to overcome multimodal optimization issues. This optimisation is mainly based on the matting strategy of bees and the problem solving is very competitive with other state.

III. Proposed ABO Algorithm

ABO was made in an attempt to address problems with certain existing techniques, such as stimulated annealing, Particle Swarm Optimization, Genetic Algorithm and Ant Colony Optimization, such as medium speed, rate of convergence and use of different factors, complex fitness features. The ABO is essentially a replica of the warning 'maaa' contact calls that the herds use to coordinate troops to stay put and utilize a specific grazing field, as well as the warning 'waaa' contact calls that organize the entire species to demand a new or secure grazing position. From this alarm sounds Herds were able to optimise their searches in order to reach food-rich areas [11]. Mathematical representations for these various alarms are shown in Eq. (1) and Eq. (2).

$$M_{x+1} = N_x + St1(pq_{max} - U_x) + St2(pq_{max.x} - U_x) \quad (1)$$

Where, M_x is the “maaa” alarm of buffalo with reference x. $(x = 1,2, \dots\dots..x)$, pq_{max} is the better buffalo in group. $pq_{max.x}$ is the good place found in buffalo herds. $St1, St2$ Are the parameters for learning. M_{x+1} denotes the movement of buffalo from their current position mk to a new location, and it indicates the migration's enormous storage size, Lifestyle. The real behaviour of the animals can be adjusted be accomplished in accordance with Eq. (2).

$$U_{x+1} = \frac{(U_x + N_x)}{\theta} \quad (2)$$

Where, U_{x+1} represents new parameters, U_x is the alert for “waaa” sound and θ is time intervals with respect to the moments of buffalo.

The African buffalos have used these vocalisations to organise together as they navigate through the African woods in pursuit of rich grassy fields to feed their enormous appetites. Each organism's position indicates a solution in the search area in this method. Fig. 1 shows the implementation chart of ABO algorithm. The ABO algorithms are maintaining this structure on every step, it monitors each buffalo's dynamical position as it approaches the pq_{max}. Based on how far the emphasis is applied at a given iteration, x and pq_{max} are used. The training settings have an impact on every animal's efficiency.

A. *Working Procedure of ABO*

The ABO begins by allocating herds to subnetworks in the solution space. The mammals can visit any unpopulated node that is nearest and cheaper to them based on probability. The price of the movement, as calculated by the accessible heuristics in the previous move, influences this decision[12]. The cost heuristics for such manoeuvres, the personal profit of the transfer to the animal as judged by its past experience, and the actual benefit of the specific move to the grassy field all impact further movements [13]. This is expressed by the equation by in a subsequent section. The buffalo’s fitness is then updated by the program. In this method, the method finds the best buffalo's (pq_{max}) location in the herds in respect to the best option. The personal record (pq_{max}) of each individual is also measured. Its parameters are remembered by the buffalos. If a buffalo's strength and conditioning value is higher than(pq_{max}), the method records it as the animal's ideal position, bgmax. Likewise, if a buffalo's present performance is greater than any other in its memories, the system records it as the animal's greatest (pq_{max}).If the pq_{max} matches the exit condition at this point, the algorithm ends and returns the greatest buffalo's position matrix as the perfect result [8]. Or else, it moves on to the next cycle and resumes the procedure till the exiting requirements are met.

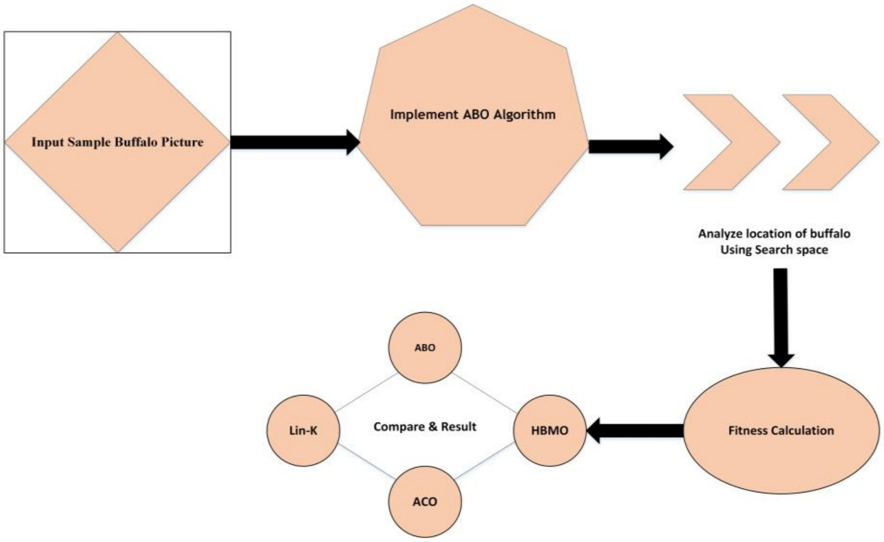

Fig. 1. Implementation of ABO.

Step by step working procedure of African Buffalo (ABO) algorithm is given below:

Step 1-Initialization: Define the population size, maximum number of iterations, and other algorithmic parameters. Generate an initial population of buffalo individuals with random positions.

Step 2-Fitness Evaluation: Evaluate the fitness of each buffalo individual by calculating the objective function value for the given optimization problem. Assign a fitness score to each buffalo based on their objective function value.

Step 3-Selection: Select buffalo individuals from the population based on their fitness scores. The selection process can be based on various strategies like roulette wheel selection, tournament selection, or rank-based selection.

Step 4-Movement and Communication: Simulate the movement and communication behavior of African buffalos. Determine the new positions of the buffalo individuals by considering their current positions, velocities, and movement rules.

Step 5- Local Search: Apply a local search operator to explore the neighborhood of the buffalo individuals' positions. This step helps improve the quality of solutions by making small adjustments to the positions.

Step 6-Update Personal and Global Best: Update the personal best positions and fitness scores for each buffalo based on the newly obtained solutions. Keep track of the global best position and fitness score achieved by any buffalo individual in the population.

Step 7-Termination Condition: Check if a termination condition is met, such as reaching the maximum number of iterations or achieving a satisfactory solution. If the termination condition is met, proceed to the next step. Otherwise, go back to step 3.

Step 8-Output: Once the termination condition is met, output the best solution found, which corresponds to the global best position obtained during the algorithm's execution. The solution represents the optimized solution for the given optimization problem.

ABO Algorithm

```
    Function $P(n) = (P1, P2, \dots \dots . Pn)^k$
    Place buffaloes in solution path
    Input fitness values used Eq. (1)
    $N_{.x} + 1 = N_{.x} + Stx_1\big(pq_{max.x} - U_x\big) + Stx_2(pq_{max.x} - U_x)\big)$
Where, $N_x$ and $U_x$ is exploitation and exploration of x buffalo $(x = 1,2, \dots \dots \dots ..)$, $pq_{max.x}$ is the herds fitness.
    Location Update $pq_{max.x}$ and $pg_{max.x}$
    $N_{x+1} = \theta(M_{.x} + N_{.x})$, where $\theta\ is\ unit\ time$
    If $pq_{max.x}$ provides Yes, then proceed.
    If $pq_{max.x}$ provides No, then back with initial step
    Stopping procedure not performs, and then starts with fitness step
    Get Output.
```

B. Steps to Solve TSP using ABO

The ABO has the benefit of solving difficult optimization issues like the TSP with very basic stages. The basic steps for solving the problem are as continues to follow:

- Initial step to migrate buffalos shown in Eq. (3)

$$f_{xy} = \frac{U^{st1}{xy}^{st2}{xy}}{\sum_{j=1}^{k} u^{st1}{xyz}^{st2}{xy}}, \text{ Here } xy = \pm 0.10 \qquad (3)$$

- Use Eq. (1) and Eq. (2) and update fitness
- Determine $pq_{max.x}$ and max.
- Using value of heuristic and add non- visited cities of buffalos
- If pq_{max} Updated, Yes then proceed
- If pq_{max} Updated, No then back to initial stage
- If reach with exit parameters, Yes then go for output
- If reach with exit parameters, No then back to fitness
- Get best results (output).

Where, Stx_1 and Stx_1 are the parameters values 0.5 and 0.3 respectively. xy takes alternate values on +0.10 and -0.10 iterations. Z is the reinforcement.

Fig. 2 shows the work flow of ABO Algorithm The positive reinforcement warning invitation z informs the creatures to stop and utilize the surroundings because there are ample meadows, whereas the negative reinforcement warning u urges them to continue exploring the area because the current place is not profitable [14]. The possibility St of an animal n migrating from town j to town k is based on a combination of two possible values: the perceived benefits of the transition, as calculated by certain heuristic denoting the attack's prior appeal, and the evaluation advantage of the relocation to the breed, denoting how effective have been in the sense of making that specific travel. The lowest values suggest whether or not that move is desirable [15].

IV. Results and Discussion

The ABO was applied to a set of asymmetric TSP (ATSP) datasets and three sets of symmetric TSP datasets and from TSPLIB95 ranges from 50 to 14470 locations in this research. The first experimental compared ABO's effectiveness in TSP situations to data from a recent survey that included St70, Pr76, Ch150, Eil76, KroA100, Eil101, Berlin52and Tsp225. The following set of studies compared ABO's effectiveness to that of Att48, Rd400, St70, Eil76, Gil262, Pr152, Brd14051, D1291, Pr1002 and Fn14461 in a recent study [16].

The final experiment looked at how well ABO performed in asymmetric TSP scenarios. The findings of the fourth set of trials were compared to those achieved utilising some common Artificial Neural Networks approaches [17]. The following are the variables for the PSO-related phases of testing: 300 people; 2000 iterations (G_{max}); 0.95 inertia weights, $T_1: 2, T_2: 1$ rand $1(0,1)$, and rand2 $(0,1), (0,1)$. The following are the HPSACO research factors: Pheromone parameter (): 1.0; heuristic element (): 2.0; condensation rate (): 0.05; pheromone quantity: 100; people: 300; iterations (G_{max}): 2000; inertia gravity:(0.85); $T_1: 2, T_2: 1$; insects (N): 200; pheromones factor $(\propto)$:2.0; therapeutic factor (β):3.0; condensation variable (ρ): 0.05. The studies were run on a 3.40 GHz Intel Duo Core i7-3770 CPU with 6 GB RAM and MATLAB [18]. The tests on the asymmetrical Traveling Salesman's Problems were run on a desktop or laptop with a 4 Gb Of ram and Pentium Duo Core 1.80 Ghz cpu. Similarly, the ANN experiments were conducted out with MS Virtual C++ 2009 on an Intel Duo Core i6 CPU [9]. We first did research on eight TSP examples to verify the ABO algorithm's accuracy in handling the TSP. Error rate is calculated using Eq. 4 from the average value referred through fitness factor of each ABO algorithm.

$$Error\ Rate = \frac{(Average\ Value - Best\ Value)}{Best\ Value} \times 100 \quad (4)$$

In all of the tests that were conducted, ABO outscored the other methods. For example, the ABO found the best solution to Eil76 and Berlin52. No other technique came close. In addition, as comparing to other method, the ABO found the closest-optimal response to the remainder TSP instances. The ABO continues to have the optimum value of average outcomes obtained from each method. It's odd that the Hybrid Algorithm (HA), it utilizes a storage matrix comparable to the ABO, really cannot come up with a decent result [15]. Because the HA is a mixture of the ACO and the CGAS, this can be traced back to the employment of multiple factors[2].The ABO's superiority may also be demonstrated in the usage of computer capabilities in which the ABO is easily the quickest of the four methods.

Table I shows the comparative results of various optimisation technique involves in TSP. The ABO, for example, is 58,885 times better than the ACO, 1,435 times higher than the ABC, and 30,412 programs are to improve than the Hybrid Mechanism in Berlin52 (HA). This pattern can be found in all of the instances under inquiry [19]. Lin-Kernighan algorithm took 0.283 seconds to complete all of the TSP issues above, compared to ACO's 7356 seconds, ABC's 44.11 seconds, and HA's 3288.27 seconds. But since ABO uses the route methodology, as opposed to the delayed path fabrication used by the ACO, the ABO's speed can be traced back to good storage management strategies. Fig. 3 shows the Error rate graph, which is typically shows how the error rate changes as the problem size increases. It helps in evaluating the efficiency and effectiveness of different algorithms in solving TSP instances of varying complexities. A lower error rate indicates that the algorithm is capable of finding solutions closer to the optimal solution, while a higher error rate suggests larger deviations from optimality. The graph can compare multiple algorithms or optimization techniques, allowing for a comparative analysis of their performance. It can highlight which algorithms perform better in terms of minimizing the error rate and provide insights into their scalability and suitability for different TSP instances. By analyzing the error rate graph, researchers and practitioners can make informed decisions about the choice of algorithm and the potential trade-offs between solution quality and computational efficiency when solving TSP optimization problems.

TABLE I. PERFORMANCE COMPARISON OF ABO, LIN-KERNIGHAN AND HBMO

TSP Samples	**Higher Value**	**African Buffalo Optimization**			**Lin-Kernighan Algorithm**			**Honeybee Mating Optimization**		
		Error rate	**Plus rate (%)**	**Processor Time (secs)**	**Error rate**	**Plus rate (%)**	**Processor Time (secs)**	**Error rate**	**Plus rate (%)**	**Processor Time (secs)**

PR152	47651	0.12	98	0.34	0.75	94	2.5	0.5	92	3
FL417	89675	0.5	100	1.4	1.25	97	2.25	1.5	98	3.5

Fig. 4 plus rate for solving the Traveling Salesman Problem (TSP) in optimization problems represents the percentage of instances or problem instances for which a specific algorithm or optimization technique achieves a solution that is better than or equal to a certain threshold. It provides insights into the algorithm's success rate in finding solutions that meet a desired level of optimality. The plus rate graph allows for a comparative analysis of different algorithms or optimization techniques. It shows how well each algorithm performs in terms of meeting a certain level of optimality for various TSP instances. A higher plus rate indicates that the algorithm consistently achieves solutions that are equal to or better than the specified threshold. By examining the plus rate graph, researchers and practitioners can assess the algorithm's effectiveness in providing high-quality solutions for TSP optimization problems. It helps in evaluating the algorithm's reliability, robustness, and suitability for different problem instances. Fig. 5 shows the CPU rate graph for solving the Traveling Salesman Problem (TSP) in optimization problems represents the computational efficiency or runtime performance of different algorithms or optimization techniques. The CPU rate graph shows how the computational time changes as the problem size increases. It helps in evaluating the efficiency and scalability of different algorithms in solving TSP instances of varying complexities. A lower CPU rate indicates faster computation and better efficiency, while a higher CPU rate suggests longer computational time.

The difference in speed between the ABC and the ABO is related to the CGAS utilisation of multiple parameters. The mix of path creation and path enhancement approaches, as well as the utilisation of numerous factors, could have had an impact on the HA's performance [20].

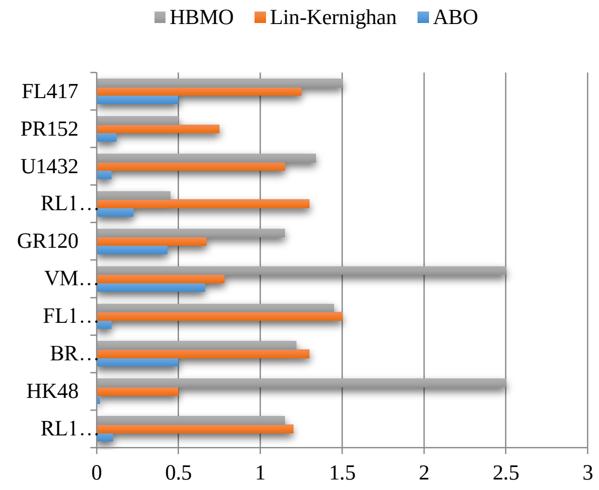

Fig. 3. Error rate comparison of ABO, lin-kernighan and HBMO.

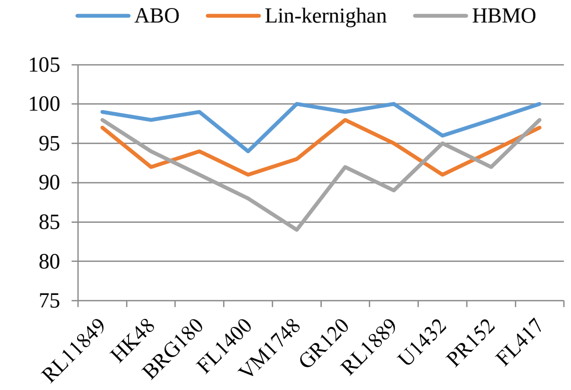

Fig. 4. Plus rate (%) comparison of ABO, lin-kernighan and HBMO.

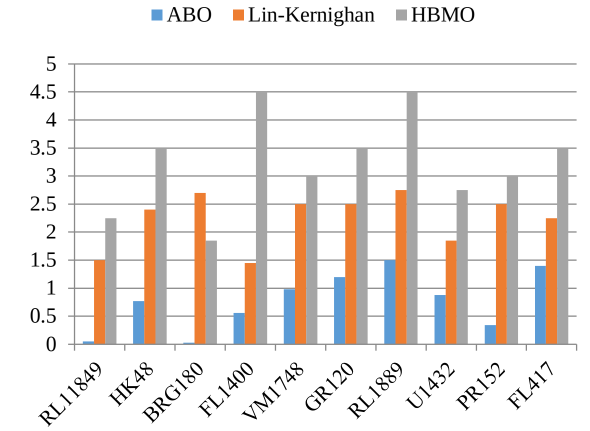

Fig. 5. CPU rate (Secs) comparison of ABO, lin-kernighan and HBMO.

V. Conclusion

Decision has made from the following comparison of ABO, Lin-Kernighan and HBMO algorithm, ABO provides better results on both error and plus rate even CPU rate also. Asymmetric Traveling Salesman's Problems cases have optimum solution. The results indicate that ABO gently outperformed than Lin-Kernighan and HBMO optimising solutions to the ATSP cases under investigative process, with a slightly higher accuracy of 99.5 percent compared to 87 percent for Lin-Kernighan and 80 percent for HBMO. However, HBMO was able to find the best solution in 12 of the 20 examples studied, while the ABO was able to find the best option in all cases and came close in the others. Unfortunately, when it comes to the quickness with which findings must be obtained, the ABO is the best algorithm. Because reliability and efficiency are two of the three main methods for evaluating a superior algorithm the ABO can be recognised a better algorithm than other optimization techniques.

In future work, the optimization solutions for solving the Traveling Salesman Problem (TSP) in Graph Theory using the African Buffalo mechanism can be extended in several directions. There is a scope for refining and enhancing the African Buffalo Optimization (ABO) algorithm by exploring different variations and incorporating additional features inspired by the behavior of African buffalos. The scalability of the ABO algorithm can be investigated to handle larger TSP instances with thousands or even millions of cities. The ABO algorithm can be extended to address variations of the TSP, such as the dynamic TSP where the cities and their distances change over time. Adapting the ABO algorithm to handle dynamic scenarios would enable its application in dynamic routing problems where the optimal route needs to be continuously updated. Analyzing the algorithm's performance guarantees, complexity bounds, and robustness to problem variations will contribute to establishing a solid theoretical foundation for the ABO algorithm.

***Abstract*—Most existing methods do not make full use of different types of information sources to extract effective features for relation extraction. This paper proposes a multi-feature fusion model based on raw input sentences and external knowledge sources, which deeply integrates diverse lexical, semantic, and syntactic features into deep neural network models. Specifically, our model extracts lexical features of different granularity from the original input text representation, entity type features from the entity annotation information of the corpus, and dependency features from the dependency trees. Meanwhile, the dimension-based attention mechanism is proposed to enrich the diversity of entity type features and enhance their discriminability. Different features enable the model to comprehensively utilize various types of information, so this paper fuses these features and train a classifier for relation extraction. The experimental results show that the proposed model outperforms the existing state-of-the-art baselines on the TACRED Revisited, Re-TACRED, and SemEval datasets, with macro-average F1 scores of 81.2%, 90.2%, and 89.4%, respectively, improving the performance by 1.4%, 4.4%, and 2% on average, which indicates the effectiveness of multi-feature fusion modeling.**

I. Introduction

Relation extraction (RE) aims to extract the relationships between entities from free text [1], which can provide support for high-level tasks including knowledge graph construction [2], text summarization [3], question answering [4], and so on. As an important and challenging task, RE has recently received considerable attention from researchers. Specifically, neural relation extraction (NRE) models have emerged and achieved promising performance thanks to the remarkable advancement of deep learning [5-7].

It is essential to fully exploit the different types of features to enhance the performance of the RE task. To utilize rich lexical information in the word sequences, many NRE models have been proposed to extract lexical features, including convolutional neural network (CNN) based [8], recurrent neural network (RNN) based [9], recursive neural network (Recursive NN) based [10], and transformer based [11] models. Most recently, without using any external tools or knowledge, Liang et al. [12] proposed a new model that extracts features from the original input sentences at entity mention, segment, and sentence levels. These methods focus on utilizing the overall or local information within word sequences but do not leverage more specific external knowledge, which may hinder performance of the model.

Besides learning lexical features from the raw data, many recent works also use external knowledge including knowledge graphs [13-14], dependency trees [15], and entity types [16] to construct explicit structured features. To infuse prior knowledge from the existing knowledge graphs, some works [13-14] have tried to integrate large-scale pre-trained models with knowledge bases (KBs) and use the models on numerous downstream tasks. Chen et al. [15] proposed a method that encodes and weights the dependency information by utilizing type-aware map memories (TaMM), which achieved outstanding results on the SemEval dataset [17]. Vashishth et al. [16] improved the performance of the RE model by enriching the features with additional entity type information in the graph structure. However, these methods only use a single form of external knowledge and do not encompass the collaborative use of multiple forms of external knowledge.

Despite their effectiveness, existing methods have the following drawbacks:

1) There are various types of information that can contribute to RE tasks, for example, the word sequences can be a source of rich lexical information, the dependency trees can provide syntactic information, and the entity types can provide constraint information of semantic relations over the entities. However, most of the previous works did not take them into account simultaneously and cannot take full advantage of different types of information sources to extract effective features.

2) A specific relation often constrains the entity types of its target entities. For instance, the place-of-birth relation restricts the entity types of a pair of entities to person and location, respectively. Therefore, entity types are important indicators for a specific relation. However, NRE models usually ignore such auxiliary information without using entity type information to impose constraints when extracting relations. Although a few studies have integrated entity type information into relation extraction, they are resource-centric and highly dependent on knowledge bases [16, 18]. Moreover, previous works often combined the coarse entity types of entity mentions with its contextual features, which suffers from coarse-grained entity types as they may fail to distinguish the relations.

To tackle these limitations, a multi-feature fusion model is proposed for RE. The model exploits both raw text data and external knowledge sources to obtain different types of features, filling the gap left by previous methods that did not simultaneously leverage both word sequences and multiple types of external knowledge. In detail, the model constructs representative original input features from the raw data, and obtains entity type and dependency features from external knowledge sources including entity annotation information in the corpus and dependency tree, respectively. Furthermore, the model employs a dimension-based attention mechanism to improve the diversity and discriminability of entity type features extracted from coarse-grained entity type information, addressing the issue of previous models being unable to distinguish between different relations. Finally, considering that different granularity features have complementary effects, we further fuse these features into a single vector via concatenation and perform relation extraction. The experimental results on the three public datasets demonstrate the effectiveness of our model.

Our contributions are summarized as follows:

3) We propose a multi-feature fusion model for relation extraction. To strengthen the ability to capture different kinds of features with various granularities, the model deeply integrates representative original input features with extra knowledge such as entity type information and dependency information, which can significantly boost the model's performance.

4) We present a dimension-based attention mechanism to enrich the diversity of the entity type features and enhance their discriminability, thus solving the problem of the coarse entity types of entity mentions.

5) We also carry out extensive experiments on the three public datasets. The results verify the benefits of multi-feature fusion modeling, and our model achieves significant improvements over competitive baselines.

The rest of this paper is structured as follows: Section II provides a review of related works; Section III presents the task definition, and Section IV provides the research objective; Section V describes in detail the proposed model; Section VI and VII discuss the experimental setups and results, and Section VIII concludes the paper.

II. Related Works

Early works on RE were mainly based on statistical machine learning. Kambhatla [19] combined a variety of features with a maximum entropy model for relation classification. Zhou et al. [20] incorporated semantic information into the feature-based relation extraction model to further boost the performance. Overall, these works require a significant level of manual design, and the quality of the hand-crafted features has a significant impact on the model's effectiveness.

With the maturity of deep learning technology, neural networks can automatically learn the potential features in a sentence and have been widely adopted in relation extraction tasks. Existing NRE models can be broadly classified into two categories: sequence-based and dependency-based [21].

Sequence-based models work with word sequences and concentrate on encoding the context information of a sentence by neural networks to capture latent features. Many models using various neural network architectures have been proposed to extract effective lexical features from the input. As CNN has achieved competitive performance on many traditional NLP tasks, Zeng et al. [8] employed it to extract features that contain valid lexical information for RE. Nguyen and Grishman [22] designed CNN models with convolutional kernels of multiple window sizes that can automatically learn implicit features in sentences, minimizing the reliance on external toolkits and resources. Zhang and Wang [10] employed RNN to model sentence context, allowing the model to capture both long-term and temporal features for RE. In order to extract multi-type features from input sentences, Wen et al. [23] combined the gate mechanism with the piecewise CNN to capture the features of the sentence.

Dependency-based models, as opposed to sequence-based models, use dependency parsing information to extract syntactic relations. Using dependency trees in RE has become a mainstream trend [24-25]. However, most dependency trees are generated by tools, which will cause a certain amount of noise, so efficient pruning methods are necessary. There are many pruning methods, which can rely on graph neural networks for key information selection [25-26], or specific attention mechanisms to dynamically select the important dependency information [15].

With the recent advancements in pre-trained language models (PLMs), the latest studies often employed popular models such as BERT [27] or XLNet [28] for RE tasks. Hou et al. [29] directly applied BERT to relation extraction and proposed a BERT-based model. Based on the bidirectional transformer, Yamada et al. [30] built a model to obtain contextualized representations of words and entities by treating them as independent tokens. Joshi et al. [31] extended BERT and proposed the SpanBERT model for span selection tasks. Wang et al. [32] used external knowledge to fine-tune the pre-trained model. Overall, the above-mentioned PLMs-based models have achieved promising success for the RE task.

Although the above studies have made significant progress in the field of relational extraction, however, they still have some shortcomings. Some of them [12,22] only use the original input to extract lexical features and fail to make comprehensive use of different information sources, while some of them [13-14] use the knowledge base to extract entity type features, which requires a large-scale external resource for support. Other studies [24-26] use dependency trees to obtain dependency features, but the pruning methods are quite complex.

Different from the existing NRE models, our model provides several feature extractors to explore various information sources and deeply integrates diverse lexical, syntactic, and semantic features in RE tasks. The model comprehensively uses the original input text, entity annotation information, and dependency information to extract features, and the extraction of entity type features is done in a way without relying on external knowledge bases. In addition, the extraction method of dependency features is simple and effective. In summary, the model is a multi-feature fusion model, which can not only effectively utilize various types of features to improve the model's performance but also has the advantage of the low computational cost of feature extraction. To the best of our knowledge, few previous studies have attempted this.

III. Task Definition

We define the sentence-level relation extraction task discussed in this work as follows. Let x={x_1,x_2,…,x_n} be tokens of input. Let e_1 and e_2 be a pair of entities in the sentence. The RE task will learn a function P(r)= $f_\theta(x,e_1,e_2)$, where $r \in R$ and R is a pre-defined relation set.

IV. Research Objective

The objective of this paper is to address the following problems with RE: 1. It is necessary to make full use of the original input text and external information sources to effectively build the relationship extraction model. 2. The cost of introducing information sources should not be too high, and the model should not become heavily resource-dependent. 3. The method of extracting features from external information sources should be simple and effective. To achieve the above goals, we propose a multi-feature fusion model for relation extraction, which explores various information sources and investigates the incorporation of diverse lexical, syntactic, and semantic features in relation extraction. In our model, different from the existing works, the external information sources are easily accessible and do not depend on the large knowledge base, which can reduce time and space requirements and can be flexibly applied to more scenarios.

V. Proposed Model

The motivation of our model is to take full advantage of different types of information sources and fully exploit various types of features to improve performance. Fig. 1 depicts the model's structure as well as details of each component. The model is made up of three components: 1) origin input feature extractor; 2) entity type feature extractor; 3) dependency feature extractor.

The origin input feature extractor is responsible for capturing multi-granularity hierarchical features from the raw input sentences, including sentence level, segment level, and entity mention level features. Specifically, as the multi-granularity feature extractor named SMS proposed in [12] has achieved remarkable performance, we directly use it to construct the original input features and concatenate them with entity type information and dependency information. The entity type feature extractor follows the design of the key-value memory network (KVMN) [33] by constructing two memory slots to store the type information of the corresponding entities and then inputting the feature information of each slot into the model in combination with the dimension-based attention mechanism. The dependency feature extractor encodes dependency information obtained from the dependency parser. Finally, we classify the relation with a fully-connected layer by aggregating all the extracted features.

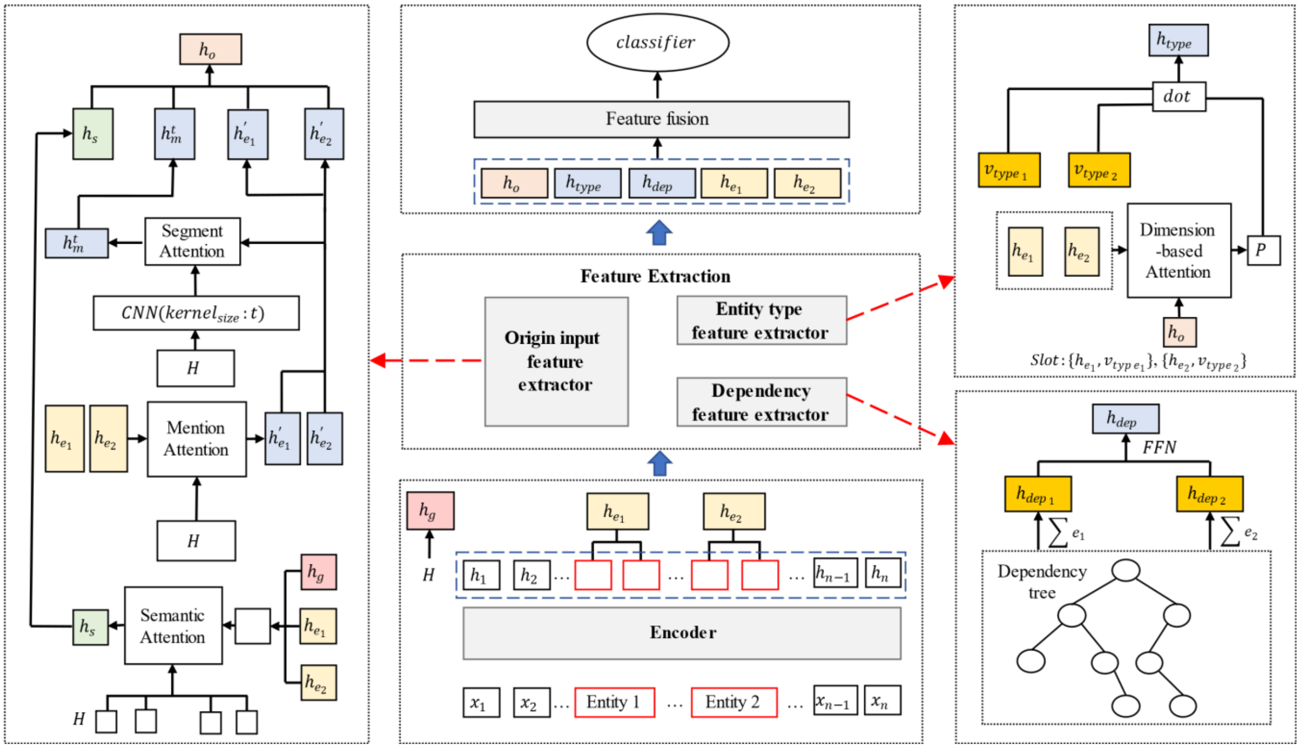

Fig. 1. The structure of our model.

In our model, three kinds of information sources are used to extract features, which are the original input sentences, the entity type's annotation information in the corpus, and the dependency trees of the sentences, respectively. Specifically, the original input sentences provide abundant lexical information, the dependency trees of the sentences carry long-distance syntactic information, and the entity type's information provides constraints information of the relation. For instance, in the sentence "A former Pakistani lawmaker has been arrested" with the marked entities "Pakistani" and "lawmaker", the relation between the two entities is "per:origin". To extract relation, the RE model needs to first capture lexical features of the sentence and the given entities, then catch entity type features and dependency features that are related to a specific relation, by combining the lexical with its syntactic and entity type features, the model can effectively model the contextual information required by RE task and predict the relation. In more detail, the entity types of two entities are helpful to capture the constraints of a specific relation and are important indicators for the relation. As shown in Fig. 2, if the types of the two entities are nationality and person, then there is more likely a "per:origin" or "org:founded_by" relation between the two entities than a "per:age" or "per:parents" relation. Moreover, considering that the dependency between the two entities is compound (compound expression), combined with the word sequence information and entity type information, the model will prefer to classify the relation as "per:origin" rather than "org:founded_by".

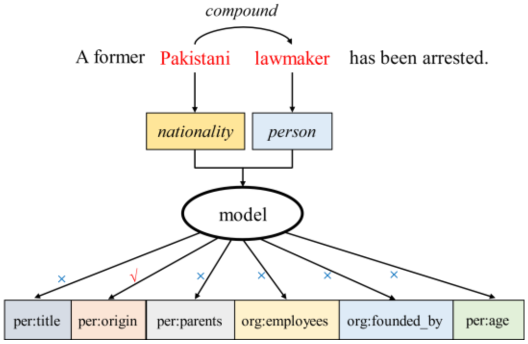

Fig. 2. Illustration of the relation extraction procedure for an example sentence.

A. Origin Input Feature Extractor

For the origin input feature extractor, we employ the SMS feature extractor proposed by Liang et al. [12], which fully exploits the input sentences to attain multi-granularity hierarchical features.

Firstly, a sequence of input tokens is transformed into vector representations using a BERT-related text encoder, which can be described as (1):

$$H = \{h_1, \dots, h_n\} = encoder(x_1, \dots, x_n)\# \quad (1)$$

Based on H, max-pooling operations can be used to get entity and sentence features, as shown in (2)-(3):

$$h_{e_1} = Maxpooling(h_{i:j}), h_{e_2} = Maxpooling(h_{k:l})\# \quad (2)$$

$$h_g = Maxpooling(H)\# \quad (3)$$

Where h_{e_1} and h_{e_2} are the representations of entity pairs, $(i{:}j)$ and $(k{:}l)$ are entity indices which delimit entity e_1 and e_2, and h_g is the input representation which captures global semantic information.

To obtain more information about entities e_1 and e_2 from input sentences, SMS utilizes a mention attention mechanism (Mention Attention in Fig. 1) to extract entity mention level features, as shown in (4):

$$h'_{e_i} = Softmax\left(\frac{H\cdot h_{e_i}}{\sqrt{d}}\right)\cdot H, i\epsilon\{1,2\}\# \quad (4)$$

Where h'_{e_1} and h'_{e_2} are entity mention features which capture more comprehensive entity information than h_{e_1} and h_{e_2} , and d denotes the dimension of vector representation.

To effectively capture the valuable local segments information, based on the n-gram segment level features $\{H_t\}_{t=1,2,3}$ extracted by CNN with different kernel sizes, SMS then utilizes a segment attention mechanism (Segment Attention in Fig. 1) to obtain mention-aware segment level features by combining the entity mention features h'_{e_1} and h'_{e_2} with H_t, which can be described as (5)-(6):

$$h_m^t = Softmax\left(\frac{H_t\cdot(W_m[h'_{e_1};h'_{e_2}])}{\sqrt{d}}\right)\cdot H_t, t\epsilon\{1,2,3\}\# \quad (5)$$

$$H_t = CNN_t(H), t\epsilon\{1,2,3\}\# \quad (6)$$

Where t is CNN kernel size and H_t contains segment level features of 1,2,3-gram, and $\{h_m^t\}_{t=1,2,3}$ contain segments features with different granularity.

Then, SMS utilizes a global semantic attention operation (Semantic Attention in Fig. 1) which uses the concatenation of $[h_{e_1}; h_{e_2}; h_g]$ as the query to obtain the representation h_s, it contains sentence-level features related to entity mentions and captures deeper semantic features from the contextual representation H, as shown in (7).

$$h_s = Softmax\left(\frac{H\cdot(W_s[h_{e_1};h_{e_2};h_g])}{\sqrt{d}}\right)\cdot H\# \quad (7)$$

Where $W_s\epsilon\mathbb{R}^{d\times 3d}$ is a parameter matrix. Finally, SMS aggregates different-granularity features by (8).

$$h_o = ReLU\left(W_o\left[h_s; h'_{e_1}; h'_{e_2}; h_m^1; h_m^2; h_m^3\right]\right)\# \quad (8)$$

Where $W_o\epsilon\mathbb{R}^{6d\times d}$ is a parameter matrix.

B. Entity Type Feature Extractor

The structure of the entity type feature extractor is shown in the upper right corner of Fig. 1. As a new neural network architecture, the key-value memory network (KVMN) [33] can effectively model pair-wisely organized information and has wide application scenarios in NLP tasks ([34-35]). Inspired by the architecture of KVMN, we also utilize a key-value structured memory and construct two memory slots to store the corresponding entity type information. Specifically, KVMN defines the memory slot s_i (i is the index of memory slots) as a pair of vectors $\{k_i, v_i\}$ where k_i is the key and v_i is the value, and stores the context information as a series of memory slots $s_i = \{k_i, v_i\}$. In our work, we build only two slots. $s_1 = \{e_1, entity\_type_1\}$ and $s_2 = \{e_2, entity\_type_2\}$ with *e* referring to the entity and *entity_type* referring to the entity type information. For the entity types which are used to compose features for training the model, there are only a few different types of entities, with entity types such as person or organization appearing more frequently than the remaining entity types such as date, money, etc., which leads to the model use coarse-grained entity types and often concentrates on a few common types, thus losing a certain amount of information diversity. In order to enrich the diversity of entity type features and increase the discriminability of entity type features, we design a dimension-based attention mechanism; it computes the entity type information in each memory slot to ensure that even if the entity types in different inputs are the same, they can have different effects on the model. Dimension-based means it calculates the attention scores for each dimension of the values in each memory slot.

For each memory slot, the keys and values are stored as $\{h_{e_1}, v_{type_1}\}$ and $\{h_{e_2}, v_{type_2}\}$, respectively, where h_{e_1} and h_{e_2} are the representations of entity pairs, v_{type_1} and v_{type_2} are the parameter vectors of the two entity types. The final representations are calculated as shown in (9)-(11).

$$p_i = softmax(W_e \cdot h_{e_i} \cdot h_o), i\epsilon\{1,2\}\# \tag{9}$$

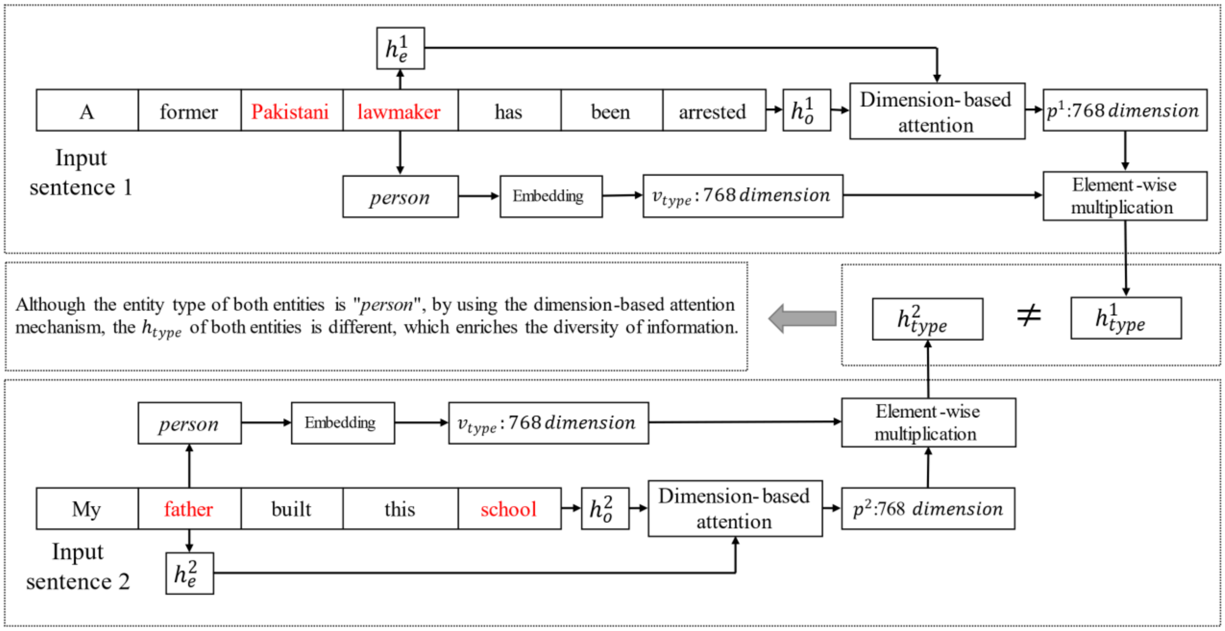
$$h_{type_i} = p_i \odot v_{type_i}, i\epsilon\{1,2\}\# \tag{10}$$

$$h_{type} = W_t[h_{type_1}; h_{type_2}]\# \tag{11}$$

where W_e, W_t are the corresponding parameter matrices, h_{e_i} are the shallow entity features introduced in Section V.A, h_o is the original input feature introduced in Section V.A, p_i indicates the importance score of each dimension of v_{ty} in a single memory slot and ⊙ denotes element-wise multiplication operation.

When utilizing entity type information, the original input features are used to obtain the importance weights of each dimension of the vector for the relevant entity type by using the dimension-based attention mechanism. An illustration of the mechanism is shown in Fig. 3.

In Fig. 3, for example, one sentence contains an entity “lawmaker”, and the other sentence has an entity “father”, both entities belonging to the same entity type “person”, and their parameter vectors of the entity type v_{type} are the same. Assuming that the dimension of the parameter vector is 768, then by combining h_e and h_o, a 768-dimensional weight vector p can be calculated, indicating the importance of each dimension of the parameter vector of the entity type. For entities, “lawmaker” and “father”, the shallow entity features h_e^1 and h_e^2 are different. For sentences 1 and 2, their original input features h_o^1 and h_o^2 are also different. As a result of the varied input contexts, the entity type features h_{type}^1 and h_{type}^2 are characterized differently, resolving the coarse-grained problem of entity types, increasing the diversity of entity type features, and improving the discriminability of entity type features.



Although the entity type of both entities is "*person*", by using the dimension-based attention mechanism, the h_{type} of both entities is different, which enriches the diversity of information.

Fig. 3. Illustration of the dimension-based attention mechanism.

C. Dependency Feature Extractor

The structure of the dependency feature extractor is shown in the lower right corner of Fig. 1. As the existing tools cannot ensure that the auto-generated dependency trees are totally right, a pruning strategy must be used to eliminate as much noise as possible while exploiting valid dependency information. We have tried several alternative approaches which use: 1) dependency information of the whole sentence; 2) dependency information of the whole sentence combined with the dimension-based attention mechanism; 3) dependency information directly related to the entities; 4) dependency information directly related to the entities with the dimension-based attention mechanism. Among these four approaches, approach three achieved good results, while the rest of the approaches failed to meet expectations. Therefore, when extracting the dependency feature, we simply use the dependency information directly related to the entities to prevent the introduction of too much noisy information. Referring to the KVMN, we also construct memory slots to record dependency information.

After getting the dependency parsing results of the input by using the toolkit such as Stanford CoreNLP Toolkit (SCT) or spaCy, for each word in the entity, its memory slot can be expressed as $s_i = \{k_i, v_i\}$, where k_i denotes the original word and v_i denotes the dependency type with its governor obtained from the dependency parse tree. In Fig. 4, as an example, the two entities are "*marrow bone*" and "*cell stem*" respectively, and their direct dependencies memory slot list should be S = [{*marrow*, *nsubj*},{*bone*, *compound*},{*cells*, *dobj*},{*stem*, *compound*}].

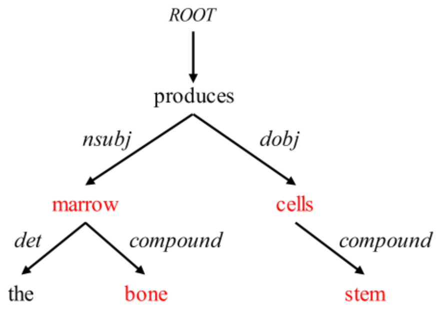


Fig. 4. Dependency tree of the sentence "the bone marrow produces stem cells".

More specifically, for each memory slot, the key is stored as the entity word vector obtained from the transformer encoder, the value is stored as a parameter vector which is obtained by using an embeddings lookup table, and the dependency features are calculated as shown in (12)-(13).

$$h_{dep_i} = \sum_{k=1}^{L_i} v_{dep_k^i}\,, i \epsilon \{1,2\} \# \tag{12}$$

$$h_{dep} = W_d [h_{dep_1}; h_{dep_2}] \# \tag{13}$$

Where L_i is the word count of entity i, W_d is the parameter matrix, $v_{dep_k^i}$ is the value vector obtained from the memory slot of the k-th word of entity i, h_{dep_1} and h_{dep_2} are the dependency features for the two entities. By combing the concatenation of h_{dep_1} and h_{dep_2} with a linear transform matrix, we can get the dependency feature denoted as h_{dep}.

D. Classification

Finally, we aggregate different types of features and output the relation label. In our model, we provide two feature fusion methods. The one method simply concatenates features, as shown in (14).

$$h = [h_o; h_{type}; h_{dep}; h_{e_1}; h_{e_2}] \# \tag{14}$$

The other method involves introducing a gating mechanism for the further fusion of various types of features, as shown in (15)-(17), where W_{type} and W_{dep} are parameter matrixes, b_{type} and b_{dep} are bias parameters, σ is a nonlinear activation function, and $\odot$ denotes element-wise multiplication.

$$h'_{type} = Gate(h_o, h_{type}) = \sigma(W_{type} h_{type} + b_{type}) \odot h_o \# \tag{15}$$

$$h'_{dep} = Gate(h_o, h_{dep}) = \sigma(W_{dep} h_{dep} + b_{dep}) \odot h_o \# \tag{16}$$

$$h = [h_o; h'_{type}; h'_{dep}; h_{e_1}; h_{e_2}] \# \tag{17}$$

Finally, we use softmax function to get the relation label, as shown in (18), where W is a trainable weight matrix and $|R|$ represents the number of relation labels.

$$\hat{r} = argmax \frac{exp(Wh_i)}{\sum_{i=1}^{|R|} exp(Wh_i)} \# \tag{18}$$

VI. Experiments

A. Datasets

We conduct experiments on SemEval 2010 Task 8 (SemEval) [17], TACRED Revisited (Tac-Rev) [36] and Re-TACRED [37] datasets to evaluate our model. Table I summarizes the statistics of the three datasets.

TABLE I. THE STATISTICS OF THE THREE DATASETS

Dataset	Training set	Validation set	Testing set	Relation types
SemEval[1]	8000	-	2717	19
Tac-Rev[2]	68124	22631	15509	42
Re-TACRED[3]	58465	19584	13418	40

Task 8 of SemEval-2010 aims to develop a standard testbed for future research and to provide a public dataset. The dataset contains 10,717 instances: 8,000 of them are released for training and the remainder is kept for testing. There are nine different types of relations in it, plus an additional "Other" type. When the two entities for each of the nine types of annotated relation types appear in the opposite order, it is implied that the phrase conveys the corresponding inverse relation for that type of relation. For example, the relations Entity-Destination(e1,e2) and Entity-Destination(e2,e1) are different from one another. Consequently, there are 19 different relation types in the SemEval dataset.

The TACRED Revisited (Tac-Rev) dataset is based on the original TACRED dataset [38]. Alt et al. [36] conducted an explorative analysis of the label quality for the TACRED dataset and found that a large fraction of the instances was incorrectly labeled by the crowd workers, and they corrected the errors in the Dev and Test sets.

Considering that the Tac-Rev dataset restricts revisions to a small subset of labels, and the majority of TACRED remains uncorrected. Stoica et al. [37] applied a better crowdsourcing strategy to re-annotate the entire TACRED dataset and then released Re-TACRED.

B. Settings

Detailed hyper-parameter settings for each dataset are shown in Table II.

TABLE II. THE HYPER-PARAMETER SETTINGS

	Tac-Rev	Re-TACRED	SemEval
Learning rate	3e-5	3e-5	3e-5
Warmup steps	300	300	-
Warmup rate	-	-	0.06
Epoch	4	4	10
Batch size	64	64	32

PyTorch is used to implement the proposed model. Following the official script, we use the Macro-F1 score to evaluate the models on the Tac-Rev, Re-TACRED, and SemEval datasets. On the Tac-Rev and Re-TACRED datasets, we use the large cased version of SpanBERT as the encoder in the model with its default settings. On the SemEval dataset, we use the uncased version of BERT-base as the encoder in the model with its default settings. Stanford CoreNLP Toolkit (SCT) is used for dependency parsing.

C. Baselines

As PLMs have brought many breakthroughs in various NLP tasks in recent years, to evaluate the effectiveness of our model, we compare it with the following powerful baselines:

1) SMS [12]: SMS is a novel RE model that employs a hierarchical attention mechanism and global semantic attention to fully exploit multi-granularity features, and then aggregates these extracted features to predict the relation.

2) SpanBERT [31]: SpanBERT is a pre-training model that extends BERT using different masking schemes and training objectives. It masks contiguous spans of tokens using a different random process and introduces a span-boundary objective (SBO) that attempts to infer the complete content of the span.

3) KnowBERT [13]: To enhance text representations with structured knowledge, the knowledge-enhanced BERT (KnowBERT) incorporates multiple knowledge bases (KBs) into the BERT model and obtains knowledge-enhanced representations that can be used for a variety of downstream tasks.

4) LUKE [30]: LUKE is a new pre-trained contextualized representation model. By using a huge entity-annotated corpus, it is trained to predict words and entities that have been randomly masked. With regard to a variety of downstream entity-related tasks, LUKE has demonstrated excellent performance.

5) GDPNet [39]: GDPNet creates a multi-view graph to represent various potential relationships among tokens, and the graph is refined through several interactions. Both the refined graph representation and the "[CLS]" token representation of the BERT input sequence is combined to form the input of the softmax classifier, which predicts the type of relation.

6) TaMM [15]: The model uses BERT to encode the input, and then incorporates the dependency information by using a type-aware map memory (TaMM) module. TaMM improves relation extraction performance by leveraging dependency type information with an attention mechanism to obtain each dependency's importance.

7) C-AGGCN [25]: The model uses dependency trees as inputs and utilizes the graph convolutional network to learn tree structure features in an end-to-end way.

8) RECENT [40]: The model introduces mutual restriction of relation and entity type into the relation classification, which can use the entity type to restrict the candidate relations and avoid some unsuitable relations being candidates.

VII. RESULTS AND DISCUSSION

A. Results on Tac-Rev and Re-TACRED

We evaluate our model on the Tac-Rev and Re-TACRED datasets. The experimental results are shown in Table III, and we follow the official train/dev/test split for these two datasets. For our model, feature concatenation is the default feature fusion method. If the gating method introduced in Section V.D is used as the feature fusion method, the model will be denoted as "(with gate)".

Table III demonstrates that our model yields the highest Macro-F1 scores. When compared to the latest SOTA work such as SMS, the proposed model substantially outperforms the baseline with an absolute improvement of 1.4% on the Tac-Rev dataset and 4.5% on the Re-TACRED dataset. As SMS utilizes origin input features extracted solely from the original input sentences, this proves that our model can benefit from extra knowledge and obtain effective features. Compared to TaMM, we also achieve a 3.2% improvement on the Tac-REV dataset, confirming that comprehensive utilization of origin input features and features extracted from extra knowledge is feasible. It is worth noting that our model outperforms the baselines without the use of an external large knowledge base or large corpus. This also demonstrates the flexibility and effectiveness of our model.

To get a better intuition about how our model works, we conduct an ablation study to analyze the contribution of each component. The results are shown in Table IV. In Table IV, "O" denotes the origin input features, "T" denotes the entity type features, "D" denotes the dependency features, "G" denotes the gating mechanism introduced in Section V.D, and “att” denotes dimension-based attention, for example, SpanBERT+O+T+att means that the model employs SpanBERT as the encoder and utilizes the combination of the origin input features and the entity type features with dimension-based attention. Note that in Table IV, since the computation of the dimensional attention mechanism involves both the original input features and the entity type features, we only add the dimensional attention mechanism when both features are used. Similarly, for the gating mechanism, since its computation involves three feature extractors, we only use it when all three feature extractors are used simultaneously.

As can be seen in Table IV, through the incorporation of various types of features, improvements can be achieved for relation extraction. Specifically, among the three features, we can observe that the entity type feature extractor yields the contribution to the performance with a 1.7% (78.00% vs 79.7%) and 3.1% (85.3% vs 88.4%) improvement on the Tac-Rev and Re-TACRED datasets, respectively. This means that entity type features are important indicators for relation prediction. For the other two types of features, we can also see that they are helpful to improve model performance. As a result, we can see that each of our feature extractors can obtain a boost on the basis of the pre-trained language model, which confirms the feasibility of our feature extractors and shows that all three features are essential for relation extraction tasks.

TABLE III. F1 SCORE RESULTS ON TAC-REV AND RE-TACRED

Models	Tac-Rev (%)	Re-TACRED (%)
SMS [12]	79.8	85.7
SpanBERT [31]	78.0	85.3
KnowBERT [13]	79.3	89.1
LUKE [30]	80.6	-

SpanBERT+O+T+att	80.7	89.7
SpanBERT+O+T+D	80.9	89.7
SpanBERT+O+T+D+att	81.2	89.8
SpanBERT+O+T+D+G	81.1	90
SpanBERT+O+T+D+G+att	**81.2**	**90.2**

We can also observe from Table IV that the model performance can also be gradually improved when the three types of features are combined. For example, on the Tac-Rev dataset, when combining the origin input features and the dependency features, compared to SpanBERT+O and SpanBERT+D, the model SpanBERT+O+D achieves a performance improvement of 1.5% (79.5% vs. 81%) and 1.8% (79.2% vs. 81%), respectively. The results also demonstrate that the combination of the three types of features can bring positive gains.

In summary, the performance of the model is gradually improved with the addition of modules, which confirms that each key component of our model plays a vital role in relation extraction, and deep fusion of origin input features and extra knowledge will further boost the performance of the model. In addition, we can see that using the dimension-based attention mechanism along with the entity type feature can also further leads to performance improvement, which also indicates the effectiveness of the dimension-based attention mechanism.

To further analyze why using features extracted from extra knowledge is effective, the statistical analysis of the relation labels on the Tac-Rev dataset and Re-TACRED dataset is performed, as illustrated in Fig. 5 and 6, respectively.

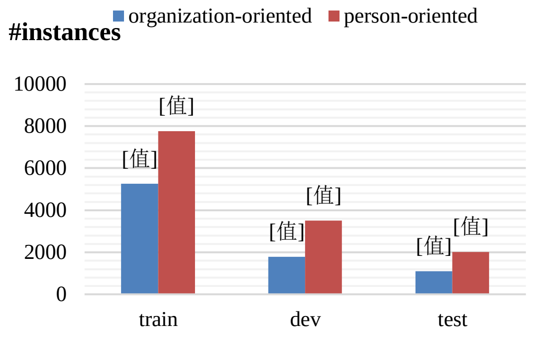

Fig. 5. The statistics of relation labels on the Tac-Rev dataset.

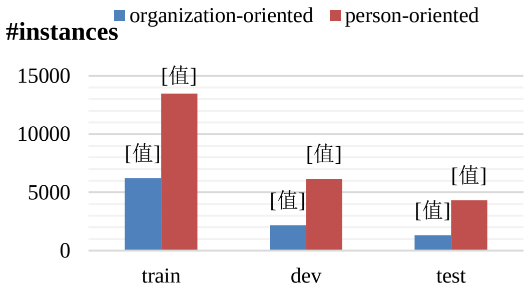

Fig. 6. The statistics of relation labels on the Re-TACRED dataset.

Generally, in these two datasets, each instance is annotated with a person-oriented or organization-oriented relation type, such as per:city_of_birth, per:title, org:employees, and so on, otherwise assigned no_relation for negative instances, and each relation label belongs to the “Person” or “Organization” categories. As the entity types mainly consist of categories such as person, organization, location, and so on. Naturally, inputting the entity type information to the model can play a good hint effect for relation extraction. At the same time, some dependencies also have a significant effect in determining the type of a specific relation. For example, in the sentence “My father built this school”, its' entities are “my father” and “school”, and the dependency between the two entities is obj (Object). When the entity type and dependency information are combined, the model is more likely to predict that the relation type as “org:founded” or “org:founded_by”.

B. *Results on SemEval*

We also conduct experiments on the SemEval dataset. As it is a classical dataset, besides baselines introduced in Section VI.C, the following popular models are adopted as comparison models.

1) LST-AGCN [41]: This model aggregates and transports information about syntactic relations and word features in accordance with the grammatical structure, and directly manipulates the graph to derive the representation for relation classification.

2) DP-GCN [24]: DP-GCN selects relevant information from dependency trees, and each graph convolutional network (GCN) layer contains a selection module that allows it to filter away information that is irrelevant to the target without using any pre-defined rules.

3) C-GCN-MG [26]: The model represents a sentence using multiple sub-graphs and performs graph convolution operations on the sub-graphs to acquire relevant features.

4) C-DAGCN [42]: By appending attention modules over the GCN, C-DAGCN further uses distributional reinforcement to guide the GCN for relational extraction.

5) Two-channel [43]: The model incorporates the benefits of both the Bi-LSTM-ATT and the CNN channel to predict relation.

6) MSML [21]: For the text data, the model constructs feature hierarchy and relation hierarchy and then presents a framework to fully leverage these hierarchies for RE tasks.

7) POS&DP [1]: The model uses both the sequential POS tags and the dependency graph structure for the RE task.

The experimental results are shown in Table V.

TABLE V. F1 RESULTS ON THE SEMEVAL DATASET

Models	**SemEval (%)**
BERT-base	87.9
SMS [12]	88.3
SpanBERT [31]	-
KnowBERT[13]	89.1
LUKE [30]	-
GDPNet [39]	-
TaMM [15]	89.2
LST-AGCN [41]	86.0
DP-GCN [24]	86.4
C-GCN-MG [26]	85.9
C-DAGCN [42]	86.9
Two-channel [43]	85.42
MSML [21]	89.1
POS&DP [1]	87.2
Our model	**89.4**
Our model (with gate)	89.2

From Table V, we can see that our model also achieves the best result on the SemEval dataset. It outperforms 1.1% over SMS and more than 3% improvement over graph convolution network-based models such as LST-AGCN, DP-GCN, and C-GCN-MG. Compared with the latest works such as POS&DP and MSML, our model still achieves better performance.

The SemEval dataset is not a large dataset, its test set has only 2717 items, and each relation label has fewer instances than the Tac-Rev and Re-TACRED datasets. We conduct ablation experiments on the SemEval dataset to understand the relative contribution of each module of the proposed model. The results shown in Table VI demonstrate that our model can benefit from three types of feature extractors. The meaning of these abbreviations, including “O”, “T”, “D”, “G” and “att”, is the same in Table VI as it is in Table IV. Furthermore, we can see that on the SemEval dataset, the contribution of entity type features to our model is smaller than that of the Tac-Rev and Re-TACRED datasets and the dimension-based attention mechanism makes no impression on the performance. One reason is that for the SemEval dataset, the correlation between relation labels and entity types is not as high as the Tac-Rev and Re-TACRED datasets; Another reason is that entity types that are used to compose features for training the model are generated by entity recognition tool rather than manual annotated, and the noise in the automatically generated entity types may harm the performance of the model; The last reason may be that there are some data belonging to “other” label in the SemEval dataset, which accounts for 17.63% of the training set and 16.71% of the test set, and for these data, the effect of entity type features is limited.

TABLE VI. F1 RESULTS OF THE ABLATION STUDY ON THE SEMEVAL DATASET

Models	**SemEval (%)**
BERT-base	87.9
BERT+O	88.4
BERT+T	88.2
BERT+D	88.5
BERT+O+D	88.6
BERT+O+T	88.6
BERT+T+D	88.7
BERT+O+T+att	88.6
BERT+O+T+D	89.2
BERT+O+T+D+att	**89.4**
BERT+O+T+D+G	89
BERT+O+T+D+G+att	89.2

C. *Feature Vector Visualizations*

To verify that the dimension-based attention mechanism can enrich the diversity of entity type features, we use t-SNE [44] to project the vector of entity type features into two dimensions. First, we select four sentences from the Re-TACRED dataset, which all contain named entities of type person and organization, and visualize the entity type feature vectors corresponding to the named entities in these sentences, as shown in Fig. 7.

As can be seen from Fig. 7, the four feature vectors belonging to type person are different, and the entity type feature vectors of person type and organization type appear to show two different clusters, i.e., the feature vectors corresponding to two named entities of the same type have a shorter distance on the graph, while the feature vectors corresponding to two named entities of different types have a longer distance on the graph.

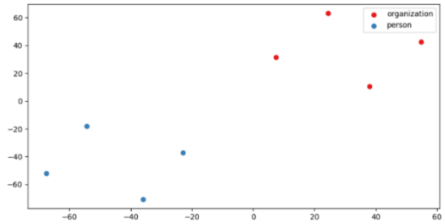

Fig. 7. Visualization of entity type feature vectors from 4 sentences.

Similarly, we select 100 sentences from the Re-TACRED dataset for observation, and the results are shown in Fig. 8.

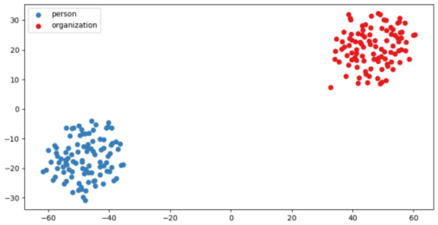

Fig. 8. Visualization of entity type feature vectors from 100 sentences.

From Fig. 8, it can be seen that the feature vectors of type person and organization cluster into two clusters. It indicates that the feature vectors of the same type will be differentiated after applying the dimensional attention mechanism, but the feature vectors of different types can still be clearly distinguished. The visualization results can still meet our expectations when adding more entity types, as shown in Fig. 9. We can see that the dimension-based attention mechanism can effectively increase the discriminability of entity type features, thus solving the problem of the coarse entity types of entity mentions.

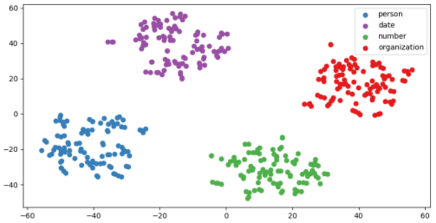

Fig. 9. Visualization of entity type feature vectors from 300 sentences with 4 entity types.

VIII. Conclusion

This paper presents a multi-feature fusion model for relation extraction, which explores various information sources and investigates the merging of different types of features in relation extraction. The resulting model can extract abstract features from raw inputs while benefiting from external knowledge. Our study shows that entity type information is especially useful for RE tasks and contributes significantly to the gain in performance from a semantic aspect, while dependency parsing information provides additional benefits. We also demonstrate that deep integration of different types of features makes the proposed model perform significantly better than strong baselines. The experimental results on the three benchmark datasets show that our model is effective and generalizable.

Moreover, our model is mainly composed of a series of feature extractors with a simple architecture. We can add feature extractors according to new external information sources in subsequent research and flexibly integrate them into our model. While our model has achieved good results on annotated datasets, the limitations of its application to unlabeled data still remain for future exploration and resolution. In future work, we will investigate the way to leverage unlabeled data and extend our work to the semi-supervised setting. We also would like to explore knowledge bases to extract additional features and enhance the performance of relation extraction.

Mobile Apps Performance Testing as a Service for Parallel Test Execution and Automatic Test Result Analysis

Amira Ali, Huda Amin Maghawry, Nagwa Badr
Information Systems Department-Faculty of Computer and Information Science, Ain Shams University Cairo, Egypt

***Abstract*—Now-a-days, numerous mobile apps are developed daily that influence the lives of people worldwide. Mobile apps are implemented within a limited time and budget. This is to keep up with the rapid business growth and to gain a competitive advantage in the market. Performance testing is a crucial activity that evaluates the behavior of the application under test (AUT) under various workloads. Performance testing in the domain of mobile app development is still a manual and time-consuming activity. As a negative consequence, performance testing is ignored during the development of many mobile apps. Thus, mobile apps may suffer from weak performance that badly affects the user experience. Therefore, cloud technology is introduced as a solution that emerges in the domain of software testing. Based on this technology, software testing is provided as a service (TaaS) that leverages cloud-based resources. This overcomes the testing issues and achieves high test quality. In this paper, a cloud-based testing as a service architecture is proposed for performance testing of mobile apps. The proposed performance testing as a service (P-TaaS) adopts efficient approaches for automating the entire process. Efficient approaches for test case generation, parallel test execution, and test results analysis are introduced. The proposed test case generation approach applies model-based testing (MBT) technique that generates test cases automatically from the AUT's specification models and artifacts. The proposed P-TaaS lessens the testing time and satisfies the fast time-to-release constraint of mobile apps. Additionally, the proposed P-TaaS maximizes resource utilization, and allows continuous resource monitoring.**

***Keywords*—Performance testing; mobile apps testing; mobile apps performance testing; automated testing; cloud computing; TaaS; model-based testing**

I. Introduction

The evolution of wireless technology and the development of an immense number of smartphones led to the prosperity of the mobile app development industry [1]. An enormous number of mobile apps are developed and uploaded to different app stores (e.g., Google Play Store) daily. Thus, mobile app testing becomes an urgent matter that must be performed to ensure the application under test (AUT)'s functionality, quality, and reliability before it is released for public use. However, mobile apps usually have a short development life cycle [2]. Thus, many mobile apps are not rigorously tested.

The performance of mobile apps is considered an important concern to users. The prosaic performance of mobile apps roughly affects the user experience [3]. Therefore, mobile app performance testing is considered an indispensable activity. Mobile app performance testing refers to the determination of the AUT behavior under various workloads of concurrent users [4]. This ensures the AUT's responsivity to the concurrent users' instructions as well as discovering AUT vulnerability under various workloads.

At present, cloud computing with its virtualization technologies has become a critical orientation in the information technology industry [5]. The integration of cloud technology with the software engineering domain led to an evolution in the field of software testing. Therefore, the expression of cloud testing appeared. The cloud-based testing frameworks provide an on-demand TaaS for testing any type of software app including mobile app testing [6]. TaaS is defined as a service model that automatically carries out the entire testing process in a cloud-based environment. Then, it submits the test results to the end user. Consequently, the TaaS architecture can be used to provide performance testing as a service (P-TaaS) using cloud-based resources.

However, the challenges found in the literature [7-10] related to performance testing and P-TaaS include the following:

- The majority of researchers focus on discussing functional testing in the context of cloud testing. However, performance testing was relatively rare. Thus, few researchers introduced a comprehensive architecture for automating the entire performance testing process and utilizing cloud-based resources.
- Most of the existing performance testing research focuses on performance test case generation and execution. Few works present systematic approaches to automatically analyze the performance test results.

Therefore, the main contributions of this paper include proposing the following:

- A performance testing as a service (P-TaaS) architecture that automates the whole performance testing process for hybrid mobile apps. Hybrid mobile apps are web apps that are downloaded from mobile app stores and need an internet connection to operate.
- An automated approach for performance test case generation. Thus, no need for skillful testers to design test cases that resemble real users' scenarios when using AUT under various workloads.

- An approach for simultaneous test case execution on multiple virtual nodes. This reduces the time required for the test execution process.
- An automated approach for performance test results analysis that can detect the performance bottleneck in the AUT.

The rest of the paper is organized as follows: Section II presents brief background information. Section III surveys the most relevant work related to performance testing and P-TaaS specifically. Section IV presents the proposed mobile app P-TaaS architecture and a detailed explanation of the functionality of each module. Section V shows the experimental results. Section VI mentions the limitations of the proposed P-TaaS and the differences between the proposed P-TaaS and other relevant tools. The paper is concluded in Section VII. Finally, the future work is presented in Section VIII.

II. Background

This section provides brief background information about concepts that are utilized in the proposed mobile app P-TaaS architecture (i.e. model-based testing and the OCL-based UML diagrams).

The Model-based Testing (MBT) [11] is known as an automatic testing technique that generates performance test scenarios from the AUT specifications that are represented by software models. Unified modeling language (UML) [12] is one of the most widely used methods to model software apps. MBT automatically generates test cases from the software models that represent the behavior and the requirements of the AUT. Then, the software models are converted into test models (e.g., Finite State Machine (FSM)). FSM graph is defined as a set of AUT states, where the inputs trigger each transition and convert AUT from one state to another. FSM graph is traversed to obtain paths. Each path represents a user behavior when using AUT. Thus, FSM graph allows the automation of test case generation.

OCL [13] stands for object constraint language. Generally, OCL is used as a formal language for adding user-defined constraints on the UML diagrams. The OCL as a formal language includes three types of constraints: (i) invariant, (ii) precondition, and (iii) post conditions. The invariant constraint added to any object means that this constraint must be true for the entire lifetime of that object. The precondition constraint added to an operation shall be true before the operation execution. The post condition added to an operation shall be true just after the operation execution.

III. Related Work

Many researchers were concerned with studying mobile app performance testing in a cloud-based environment from different perspectives. The benefits and challenges of mobile app performance testing using cloud-based resources are widely discussed in the literature [5], [6]. Ali et al. [14] reviewed the most recent studies and research gaps related to the performance testing using cloud-based resources. Section III A discusses the most recent mobile apps performance testing frameworks, as well as some of the performance testing tools and services widely used in the market. Section III B introduces relevant studies on the adoption of model-based testing (MBT) techniques in mobile app testing. Section III C discusses the performance test results analysis and interpretation techniques. Finally, Section III D introduces recent studies related to the resource utilization and scheduling approaches adopted in the TaaS domain.

A. P-TaaS Frameworks and Widely Used Performance Services in the Market

Mobile apps performance testing frameworks based on the cloud-based environment were presented in the literature. For instance, Prathibhan et al. [15] presented Android Testing as a Service framework known as (ATaaS). The framework depends on the emulators and Android Application Package (APK) file of the AUT as input to execute test cases. Performance test cases are generated manually by the testers, then test cases are recorded to be executed several times under various workloads. The author did not ensure the efficient utilization of cloud-based resource. The presented ATaaS framework focused only on test case execution and ignored the rest of the performance testing activities.

There are cloud-based performance testing tools and services that are adopted for both small and large businesses with various pricing structures. SOASTA CloudTest [16], LoadStorm [17], and Xamarin Test Cloud [18] were selected from the list of the top 10 extremely used cloud-based performance testing tools in 2020 [19]. SOASTA CloudTest depends on manual test case generation and test results analysis. LoadStorm generates a performance test results analytics report that represents the performance metrics, such as response time and error rate. LoadStorm does not support automatic test case generation. It requires testers to record test scenarios manually. Xamarin Test Cloud allows cross-platform mobile app testing. It supports multiple tenets to execute tests over thousands of devices. Xamarin Test Cloud has limited access to open-source libraries.

B. Model-Based Testing Techniques for Mobile Apps

Model-based testing (MBT) techniques are widely adopted in mobile app testing. Researchers introduced the MBT approach for mobile app test case generation. For instance, Usman et al. [12] adopted UML class diagrams and state machine models in their proposed performance testing approach. The proposed approach generates abstract test cases automatically using UML class diagrams, state machine models, and OCL constraints. The proposed approach was experimented on two different Android apps. The results showed that the proposed approach successfully estimates the performance of apps under test. However, the author only focused on conducting the performance testing of the code related to the business logic code. Additionally, he ignored testing the performance of the GUI.

C. Performance Test Results Analysis and Interpretation

Techniques for performance test results analysis and interpretation were studied in the literature in the field of P-TaaS. Researchers presented frameworks for the automatic analysis of performance test results. Liu et al. [20] proposed a framework for analyzing test results and detecting performance bottlenecks. The proposed framework increased the workload iteratively and monitored the AUT performance metrics simultaneously. The proposed framework was based on cloud infrastructure. However, the author did not discuss issues related to conducting the performance test efficiently using cloud resources. Additionally, the author ignored mentioning the used approaches and tools in test case generation, test execution, and workload generation.

D. Scheduling and Resource Utlization Techniques

There are many researchers presented scheduling approaches to enhance resource utilization, especially in the TaaS field. For instance, the fuzzy sets theory was applied to schedule test cases in the TaaS platform by Lampe et al. [21]. The author applied the fuzzy sets theory as a solution to address the difficulty of predicting the duration of test case execution in advance. This is called uncertainty task scheduling issue. Two algorithms were proposed by the author to handle the uncertainty task scheduling issue. The proposed algorithms are based on simulated annealing (SA). The author used the Q-recent estimate for each test case to estimate the average durations from the history of executions of a given test case.

The metaheuristic methodologies were proposed by Rudy [22]. The author applied metaheuristic methodologies to schedule the parallel test case execution in the context of TaaS. Genetic algorithm (GA) [23] is an example of the metaheuristics methodologies that was used by the author. The presented metaheuristic methodologies assume that the test case execution time is unknown before the test execution. The proposed metaheuristic methodologies have the following drawbacks (i) it needs a long computation time; (ii) the metaheuristics can operate on a limited number of test cases at once (i.e., 300 for SA and 100 for TS and GA).These limitations badly influence the quality of the solution.

Therefore, it observed from analyzing the previous related work that there is no comprehensive framework that conducts the whole performance testing process automatically and leverages the cloud-based environment efficiently.

IV. The Proposed Mobile App P-TaaS Architecture

This paper proposes a P-TaaS architecture for mobile apps. Tester submits a request to the proposed P-TaaS where the entire performance testing process will be automatically processed. The overall architecture of the proposed mobile apps P-TaaS is shown in Fig. 1. The five main layers of the proposed architecture are as follows (1) user interface layer; (2) performance testing layer, (3) service management layer, (4) infrastructure as a service (IaaS) layer, and (5) data repository.

1) User interface layer: The user interface layer is the top web-based layer of the proposed architecture. It is where the testers can interact with the proposed P-TaaS architecture. The tester submits the test input files to accomplish the performance test. Then, the tester receives the test results report through it.

2) Performance testing layer: The performance testing layer is responsible for automatically accomplishing all the performance test activities including test case generation, parallel test case execution, test result analysis and interpretation, and finally the test report generating. The proposed approaches that are applied to each of these activities are discussed in the consequent subsections IV A.

3) Service management layer: The service management layer is concerned with managing, monitoring, and scheduling the test execution tasks among the available resources. The main modules of the service management layer are the scheduler, runtime monitor, and resource allocator. A detailed explanation of each module will be introduced in Section IV B.

4) IaaS layer: The infrastructure as a service (IaaS) layer includes virtual machines (VMs) where the testing process physically occurs. The virtualization technology is applied to provide all needed resources in the proposed P-TaaS architecture.

5) Data repository: The data repository is where the proposed mobile app P-TaaS architecture stores all generated data during its operation. These data include the following: (1) The test cases generated from the test case generation module, (2) The performance measurements generated from the test case execution module, (3) Information produced from the test results analysis module, (4) The test reports obtained from test report generation module, and (5) VMs status (i.e., on, off, or idle) detected by the monitor module.

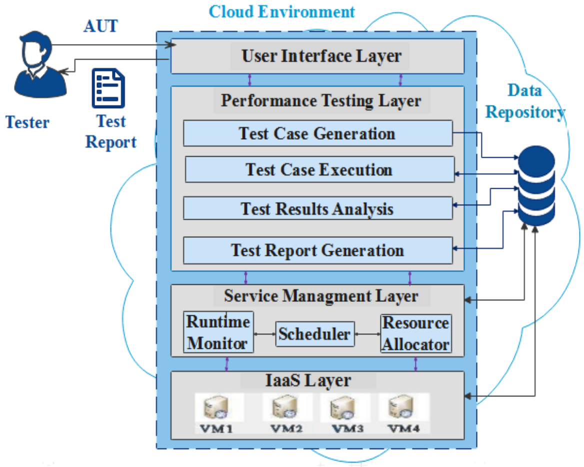

Fig. 1. Mobile apps P-TaaS architecture.

A. The Performance Testing Layer

The performance testing layer is the core layer of the proposed mobile app P-TaaS architecture. In this section, the proposed approaches employed in each module of this layer will be briefly explained.

1) The test case generation module: The test case generation module is responsible for the automatic generation of AUT's performance test cases. Generating test cases is an essential activity of the entire testing process [12]. Performance testing requires a set of appropriate test cases that can evaluate the responsiveness of the AUT under various workloads of concurrent users' accesses [3]. Generally, a performance test case composes of a consecutive set of actions exerted on the mobile app's GUI widgets. Performance test cases should resemble real user scenarios when using AUT. Besides, they should achieve full coverage of all the AUT's GUI actions and activities [4]. Automating the process of mobile app performance test case generation lowers the cost and raises the efficiency of testing. Additionally, it can improve the accuracy of test results.

In this paper, the proposed test case generation approach is based on the MBT methodology. The proposed MBT methodology depends on the OCL activity diagrams. Activity diagrams are used to model AUT's workflows in terms of stepwise activities and actions. The OCL defines the performance requirements formally. The OCL-based activity diagrams become a good candidate for modeling user behavior which allows automated mobile app performance testing. OCL-based activity diagrams are used to represent the AUT flow of actions as well as the performance requirements associated with every GUI action. The proposed approach targets interactive hybrid mobile apps. Interactive hybrid mobile apps [24] perform the requests of users who interact with the apps through the GUI through an internet connection.

The proposed test case generation approach depends on representing each functionality in the AUT by a separate OCL-based activity diagram. Each AUT's functionality will be modeled as an activity diagram. Besides, each activity diagram will have OCL constraints associated with each action in the activity diagram. Thus, the prerequisite inputs of the proposed mobile apps performance test approach are acquired from the analysis and design team. These inputs include: (a) an activity diagram for each functionality in AUT; (b) OCL constraints added to each activity diagram.

For each OCL-based activity diagram, which are submitted by the tester through the user interface layer of the proposed P-TaaS architecture, the steps of the proposed test case generation approach go as follows:

- OCL Based Activity Diagram is parsed into an XM Based Activity Diagram. This is considered the primary step to automate the test case generation process.
- All details included in each XML Based Activity Diagram are extracted and inserted into a Predicate Table. Each XML Based Activity Diagram is converted to its corresponding Predicate Table. Each element included in the XM Based Activity Diagram is shown as a row in the Predicate Table.
- The following information about each element of its corresponding XML Based Activity Diagram are stored in the Predicate Table:
    - Element name.
    - Element type (i.e., action, decision, initial, and final nodes).
    - Performance constraints on this element (i.e. represented with OCL constraints)
    - List of all edges to this element.
    - List of all edges out from this element.

Edges are used to represent the dependency between elements. The dependency between elements is proved by the existence of an edge out from an element which is the same as the edge to the current element.

- A Finite State Machine (FSM) Graph [25] is automatically created from each Predicate Table.
- The Depth First Search (DFS) [26] algorithm is applied to the FSM Graph to find all available Independent Path. The Independent Path refers to any path from the start node to the terminal node of the FSM and has at least one new edge that has not been traversed before.
- The Longest Common Subsequence (LCS) [27] algorithm is applied to filter the previously generated independent paths. LCS is an algorithm that eliminates test paths that are included as a sub-path in another path, to obtain basic paths. Applying the LCS algorithm decreases the number of test paths and ensures high test coverage. Additionally, it guarantees the existence of each GUI component at least once in the obtained basic paths. Thus, the LCS algorithm is used as a test case selection and reduction method.
- Finally, the obtained basic paths as an output of the proposed test case generation approach are considered abstract test cases. Each abstract test case consists of a set of GUI actions that resemble an actual user scenario, as well as an analogy of an entire path inside the AUT.

2) The test case execution module: Test case execution module is responsible for the automatic execution of mobile app performance test cases in a cloud-based environment. In the proposed mobile app P-TaaS architecture, test cases are executed simultaneously on multiple VMs. This leads to a reduction in the overall testing time, cost, and effort. The input to the test case execution module includes: (i) abstract test cases; (ii) Android Application Package (APK) file of the AUT. The tester submits these two inputs to the proposed P-TaaS through the user interface layer. APK file is a file format used by the Android operating system [28]. It assists in the easy distribution and installation of Android apps. The proposed P-TaaS architecture is based on using the APK file of the AUT. Hence, there is no necessity for the AUT's source code.

The automatically generated abstract test cases are converted to test scripts by the tester. The tester records these abstract test cases using the capture and reply test methodology [29]. Then, these test scripts will be executed to measure the AUT performance characteristics and responsivity toward the heavy load of concurrent users' access. During the test case execution, performance response time and error rate are measured. Response time is defined as the time taken by the AUT to respond to a certain action. Thus, response time is the total time between sending the request and receiving the response [3]. The error rate is defined as the ratio of failed requests with respect to the total number of requests [3].

Generally, there are several mobile app performance testing tools for test case execution. Apache JMeter [30] is an open-source tool that is first used to test the performance of web applications. Eventually, Apache JMeter expanded to allow mobile app performance tests as well. Proxy is used by the JMeter tool to record requests to mobile apps. The proxy can be configured on a mobile device. Then, the request will be captured by JMeter. Additionally, the JMeter tool allows the scalability during the performance testing process by providing any number of the virtual workload of concurrent users. Therefore, the JMeter tool is selected in the proposed P-TaaS to simulate different workloads and test the AUT under heavy workloads to detect the performance bottlenecks in the AUT.

The entire process of test case execution is shown in Fig. 2. The steps of the test case execution process are as follows:

a) Firstly, the test case execution module retrieves the automatically generated abstract test cases from the data repository.

b) The tester records the steps included in every abstract test case using the capture and reply test methodology.

c) Test scripts are recorded by the JMeter recording proxy. The recording proxy of the JMeter can record the HTTP requests executed by the tester on mobile devices. This is used for test script generation.

d) Test scripts are stored in the data repository.

e) The test case execution module submits the captured test scripts and APK of the AUT to the assigned VMs to execute test scripts in parallel on multiple VMs.

f) APK file will be installed on the assigned VMs.

g) Then, each test script is executed with a different workload to test the responsivity of the AUT under various workloads and reveal the AUT bottlenecks.

h) Finally, test results are stored in the data repository for further analysis and interpretation.

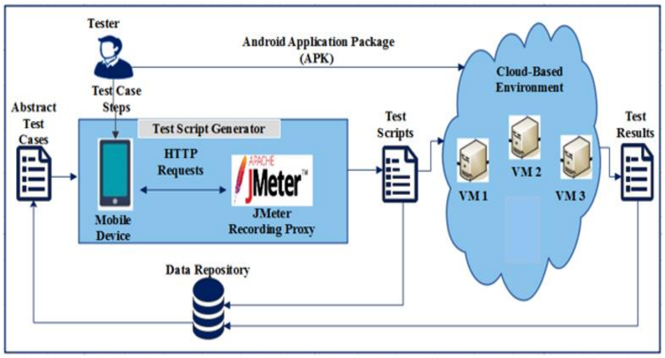

Fig. 2. Test case execution.

3) Test result analysis module: The test result analysis module is responsible for the automatic analysis of test execution results. In this paper, an approach for performance test results analysis is proposed. The proposed approach collects the performance metrics values (i.e. response time and error rate) under different workloads. Then, it interprets these data to determine the performance critical turning point and the heavy workload value. Performance critical turning point refers to a point during the AUT execution under various workloads, where the error rate suddenly increases and the response time of the AUT increases exponentially [20]. This indicates that the performance of the AUT descends sharply and the AUT may crash. When the AUT reaches the performance critical turning point, this implies that a performance bottleneck occurs under this workload. Heavy workload means the value of workload is more than or equal to the workload where the performance critical turning point occurs.

The required input to the proposed performance test results analysis approach includes the minimum and the maximum number of concurrent users defined by the tester. The tester defines the minimum and maximum number of concurrent users that simulate the expected minimum and maximum workloads exposed to the AUT during its production. The test shall consider the expected workloads during daily operations, peak hours on the AUT, and the most popular days the AUT will be used. The performance metrics are measured starting from the minimum number of concurrent users' accesses to the AUT, until the maximum number of users' accesses. During test execution, the response time and error rate are measured at each workload from the minimum to the maximum workload values. Additionally, the Error_Threshold refers to the maximum error rate value that is accepted by the tester. The AUT is considered in an unstable state when its error rate value reaches the Error_Threshold during the test execution. The Error_Threshold is defined by the tester during the proposed performance test results analysis approach.

Fig. 3 shows the pseudocode of the proposed performance test results analysis approach. The steps of the proposed performance the proposed performance test results analysis approach go as follows:

a) Firstly, loop on the number of concurrent users starting from the minimum number to the maximum number. For each iteration, the workload value will be increased by 50.

b) For every workload value:

- Performance metrics (i.e., response time and error rate) are measured.
- The measured performance metrics values are added to Response_Time_Measurements, and Error_Rate lists.
- H_Respone_Time refers to the length of the perpendicular line on the line connecting the first and last value of response time at the minimum and the maximum number of concurrent users, respectively. Fig. 4 shows H_Respone_Time at a certain workload value [20]. Equation 1 shows how to calculate H_Respone_Time at a certain workload x.

$$\text{H\_Response\_Time}[x] = A\_RT[x]Sin(Cos(A\_RT[x]^2 + C\_RT^2 + B\_RT[x]^2)/2 * A\_RT[x] * C\_RT)$$

(1)

- *A_RT* refers to the length of the line between the following two points: the coordinates of the first point are (minimum workload, value of the measured response time at minimum workload) and the coordinates of the second point are (certain workload x, value of the measured response time at this workload x).
- *B_RT* refers to the length of the line between the following two points: the coordinates of the first point are (maximum workload, value of the measured response time at maximum workload) and the coordinates of the second point are (Certain workload x, the value of the measured response time at this workload x).
- *C_RT* refers to the length of the line between the following two points: the coordinates of the first point are (minimum workload, value of the measured response time at minimum workload) and the coordinates of the second point are (maximum workload, and value of the measured response time at maximum workload).
- Sin and Cos refer to the trigonometrical sine rule and cosine rule, respectively.
- Equation 1 is used to calculate the length of the perpendicular line H_Response_Time.
- The perpendicular line H_Response_Time which corresponds to the workload value x. The performance critical turning point [20] is the point with lonest perpendicular line.

c) Secondly, the error rate value that exceeds the Error_Threshold value is determined.

d) Thirdly, the workload value where the error rate exceeds the defined threshold value is captured. The captured workload value is called the Unstable_Workload. It is where AUT starts to crash, and its behavior becomes unstable.

e) Fourthly, RT_Critical_Turning_Point is determined. It refers to the maximum value of response time in the H_Response_Time list. It has a workload value less than the captured Unstable_Workload.

*f) RT*_Critical_Turning_Workload is captured. It refers to the workload value at which the RT_Critical_Turning_Point occurs.

g) Finally, the value of the RT_Critical_Turning_Workload is obtained. This workload value represents the Performance_Critical_Turning_Workload.

*h) Heavy*_Load refers to any workload value more than the value of the Performance_Critical_Turning_Workload.

```
Input: Min_of_Concurrent_Users, Max_of_Concurrent_Users,
Error_Threshold
Output: Performance_Critical_Turning_Workload, Heavy_Load,
Response_Time_Measurements, Error_Rate _Measurements

Start

For (x= Min_of_Concurrent_Users; x < Max_of_Concurrent_Users; x+=50)
  // Loop to execute the test cases on different workloads
 {
   Response_Time_Measurements [x] = Get_Response_Time (x)
 // calculate the response time at workload x

   Error_Rate_ Measurements [x] = Get_Error_Rate (x)
 // calculate the error rate at workload x

  $H\_Response\_Time[x] = A\_RT[x] Sin(Cos(A\_RT[x]^2 + C\_RT^2 + B\_RT[x]^2)/2 * A\_RT[x] * C\_RT$
  }
For (i=0; I < Error_Rate_ Measuremenst.Lenght; i++)
 // Loop to determine the unstable workload where the AUT starts to crash
 {
 If (Error_Rate_ Measurements.Lenght >= Error_Threshold)
         {
         Unstable_Workload = i;
         Break;
         }
 }
For (i= Min_of_Concurrent_Users; i< Unstable_Workload; i++)
 {
 RT_Critical_Turning_Point = Max (H_Response_Time [i]);
 RT_Critical_Turning_Workload = i;
 }
 Performance_Critical_Turning_Workload =
 RT_Critical_Turning_Workload;

 Heavy_Load is more than or equal to the RT_Critical_Turning_Workload

End
```

Fig. 3. Performance test results analysis approach.

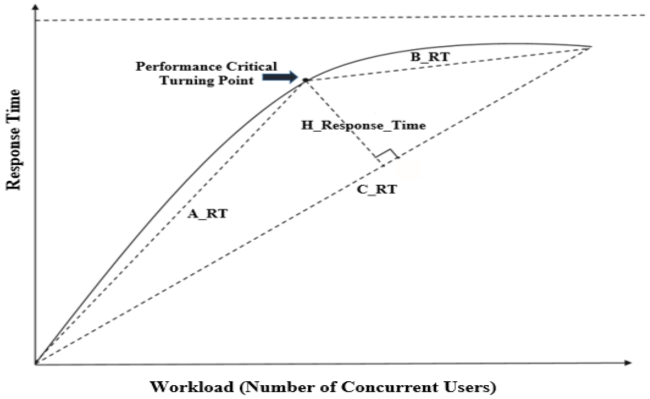

Fig. 4. Performance critical turning point.

4) Test report generation module: The final activity of the performance testing process is to generate the test report and submit it to the tester through the user interface. The test report gathers test results collected from multiple virtual nodes. The test report contains: (i) the automatically generated test cases; (ii) the measured performance metrics (i.e., response time measurements and error rate measurements); (iii) the information produced from test results analysis and interpretation (i.e., performance critical turning point, and heavy workload value). This can be valuable for testers to determine the performance deviations and bottlenecks in the AUT. Consequently, testers utilize this information to resolve performance issues within the AUT.

B. Service Management Layer

The service management layer is responsible for managing and optimizing the cloud-based resources and infrastructure. The aim of this layer includes the following: applying a suitable scheduling approach for simultaneous test case execution; reducing the overall testing time; handling uncertainty issues in scheduling the test case execution; improving the resource utilization; monitoring the runtime status of resources.

The service management layer includes three modules: (1) runtime monitor, (2) scheduler, and (3) resource allocator. An insightful explanation of the role of each module will be mentioned in this section.

1) Runtime monitor module: The runtime monitor module guarantees a high-reliability level. The monitor module is implemented as a local service for tracking the runtime status of all virtual nodes. Then, it stores a list of the available VMs. Additionally, it determines the state of each virtual node (i.e., idle, busy, and fail). The list of available VMs is sent to the scheduler and resource allocator modules, in order to assign tasks to available VMs.

2) Scheduler module: The scheduler module is developed as a local service for sorting and prioritizing test tasks submitted to the proposed P-TaaS architecture [31]. This module aims to achieve efficient utilization of the resources.

Test task duration is hard to predicate before the actual test task execution. Additionally, test task duration varies from one task to another. This is considered an uncertainty scheduling issue [22]. The proposed approach considers the uncertainty scheduling issue. The test task scheduling approach depends on task waiting time and task deadline. Task waiting time is the amount of time between task submission and the current time. The task deadline is the time defined by the tester when the task is submitted to the user interface of the proposed P-TaaS architecture. The task deadline is the predefined time at which the task must be finished and delivered before it.

The proposed scheduler approach goes as follows: firstly, the scheduler module sorts tasks in ascending order according to the task deadline. This means that tasks with an earlier deadline will be executed earlier. Secondly, tasks with the same deadline will be arranged according to their waiting time. For tasks with an equal deadline, the task with a higher waiting time will be executed earlier.

3) Resource allocator module: The resource allocator module aims to achieve a high level of resource utilization and load balance. The resource allocator module receives an ordered list of test tasks from the scheduler module. Additionally, the list of available virtual nodes is sent to the resource allocator from the monitor module. Consequently, the resource allocator module allocates test tasks to certain virtual nodes, in such a way that guarantees the load balance between virtual nodes.

The proposed resource allocation approach goes as follows:

- Each virtual node in the proposed P-TaaS has a waiting queue. It includes a list of tasks assigned to it.
- The length of the waiting queue of each virtual node is calculated.
- Virtual nodes are sorted in descending order according to the calculated waiting queue length.
- The virtual nodes with small waiting queue lengths will be assigned to high-priority test tasks.

V. Experimental Results

Experiments are carried out to assess the applicability of the proposed P-TaaS. In the experiments, three virtual machines are used to simulate a cloud-based environment and support the simultaneous execution of test cases. The three virtual machines are created using VMware workstation [32]. The VMware workstation allows the creation of multiple virtual machines on the same physical machine. The experiments are carried out on a machine with the following specs: processor Intel Core i5, memory 8 GB, and Windows 10 operating system. Thus, three virtual machines are created to suit the specs of this physical machine and allow the simulation of simultaneous test execution of the cloud-based environment. The JMeter performance testing tool [30] runs on virtual machines. MS SQL is used to develop data repositories that store the automatically generated test cases and test results (i.e., performance measurements, test results interpretation, and analysis information). The OCL-based activity diagrams are drawn using the Enterprise Architect tool [33]. In addition, the Enterprise Architect tool parses the drawn OCL-based activity diagrams to XML-based activity diagrams with their corresponding OCL constraints. The experimental environment is the same for executing each task using VMs with equivalent specifications.

Nowadays, Android dominates almost 88% of the mobile device market worldwide [34]. Therefore, our experiments depend on using Android apps as AUTs. The APK files of the android AUTs are installed on the virtual node before the test case execution starts. The objective of the proposed P-TaaS architectures is testing the performance of hybrid interactive mobile apps. Therefore, two hybrid mobile apps were chosen for experiments. They are the SpeedTest app [35] and GoodReads app [36]. GoodReads app looks like an online bookstore, where users can read, browse, recommend, and review books. It is a widely used app worldwide. It is the first ranked app in the category of (Science and Education, Libraries and Museums) in the United States. The total number of visits to the GoodReads apps reached 119.7M [37].

SpeedTest app is an Android app that measures the speed of the internet. It is the most used app for measuring the upload/download speed of the internet. It is used by more than 45 billion times unparalleled. Therefore, GoodReads and SpeedTest apps are selected as AUTs in the experiments.

A. Experimental Results of the Proposed Performance Test Case Generation Approach

The purpose of this experiment was to evaluate the proposed mobile app performance test case generation approach. The proposed test case generation approach is assessed in terms of action coverage, activity coverage, and performance requirements coverage. The action coverage refers to the percentage of actions included in the automatically generated abstract test cases to all actions included in the activity diagrams. Similarly, the activity coverage. Performance requirements coverage refers to the ratio between the performance requirements covered by test cases and all performance requirements in the activity diagrams. The proposed test case generation approach is based on the black box MBT methodology. The experimental results of applying the proposed test case generation approach on the SpeedTest app and GoodReads app are presented in Tables I and II, respectively.

As shown in Table I, the number of automatically generated abstract test cases was 17. They were used to test seven major functionalities of the SpeedTest app. The total time required to automatically generate test cases using the proposed approach was 3.055 seconds. It is observed from Table II that the number of automatically generated abstract test cases was 28. They were used to test 13 major functionalities of the GoodReads app. The total time required to automatically generate test cases using the proposed approach was 6.325 seconds. Additionally, it is observed from Tables I and II that the generated test cases for each functionality cover 100 % of both activities and actions exerted during each functionality. Therefore, it is considered faster than the manual approaches, which need a long time to design, write, and review the coverage of the test cases.

TABLE I. EXPERIMENTAL RESULTS OF THE PROPOSED PERFORMANCE TEST CASE GENERATION FOR SPEEDTEST APP

Functionality	Number of GUI Activities	Number of GUI Actions	Number of Test Cases	Time Spend to Generate Test Cases	% of Covered GUI Activities	% of Covered GUI Actions
1. Measure download/upload speed	2	2	1	0.211 sec	100 %	100 %
2. Show or delete previous results	3	4	3	0.617 sec	100 %	100 %
3. Adjust app settings	3	3	3	0.614 sec	100 %	100 %
4. SpeedTest support	5	6	3	0.540 sec	100 %	100 %
5. Privacy and terms	8	8	5	0.651 sec	100 %	100 %
6. Test the speed of the video	4	4	1	0.211 sec	100 %	100 %
7. Generate map data	2	2	1	0.211 sec	100 %	100 %
Total	27	29	17	3.055 sec	100 %	100 %

TABLE II. EXPERIMENTAL RESULTS OF THE PROPOSED PERFORMANCE TEST CASE GENERATION FOR GOODREADS APP

Functionality	Number of GUI Activities	Number of GUI Actions	Number of Test Cases	Time Spend to Generate Test Cases	% of Covered GUI Activities	% of Covered GUI Actions
1. Search by book name or author name	2	2	1	0.214 sec	100 %	100 %
2. Search by book genre	4	9	2	0.376 sec	100 %	100 %
3. Browse recommended books	4	4	2	0.361 sec	100 %	100 %
4. Browse best-selling books	2	5	1	0.261 sec	100 %	100 %
5. Browse “The Books That Everyone Should Read At Least Once” list	1	2	1	0.261 sec	100 %	100 %

Total	33	50	28	6.325 sec	100 %	100 %

B. Experimental Results of the Proposed Performance Test Results Analysis Approach

This experiment focuses on executing test cases, then analyzing the test results to detect the performance critical point and heavy load of the AUT. The previously generated test cases were executed. Then, the test results were analyzed and interpreted. JMeter tool is used for test execution. The value of the Thread Group variable (i.e., number of simulated concurrent users) starts from 100 users. Then, the Thread Group value increments iteratively by 50, until it reaches 1000. The minimum and the maximum number of concurrent users are defined as a tester input to the proposed P-TaaS architecture. The minimum and the maximum number of concurrent users shall be defined according to the estimation of the owner of the AUT. In the experiments, multiple trials were made to choose the appropriate minimum number of concurrent users. It was noticed that the error rate was 0 % and the response time is very small at workloads less than 100. However, the response time and error rate values began to upsurge starting from 100 concurrent users. Thus, the test results analysis experiments use 100 concurrent users as the minimum number. The maximum workload is defined in the experiments as the number of workloads where the AUT's behavior (i.e., fluctuation and instability) could be observed. Thus, the maximum workload in the experiments was 1000 concurrent users, as shown in Tables III and IV.

Generally, there are dependent and independent variables in any experiment [38]. The goal of the experiment is to monitor the effect of changing the value of the independent variable on the dependent variable. In our experiments, the independent variable is the workload value (i.e., number of simulated concurrent users). The dependent variables are response time and error rate. The value of the H_Respone_Time is a dependent variable on the response time and error rate.

Table III presents the detailed measurements of test execution and result analysis for the first functionality of the GoodReads App (i.e., Search by book name or author name functionality). The first column in Table III includes the number of concurrent users' access to the AUT. The second column includes the measured response time. The third column includes the calculated H_Respone_Time value for the corresponding workload and response time. The fourth column includes the measured error rate value of the AUT under a certain workload. Error rate value indicates the percent of requests submitted to the AUT with error. The last column includes the time spent on executing the test case within the corresponding workload. It is observed from Table III, that at the workload of 1000 concurrent users, response time increases sharply and H_Respone_Time has the highest value. During the test execution, it was noticed that the error rate became 52.7% at the workload of 1000 concurrent users, which exceeds the threshold error value. This implies that the AUT becomes unstable and may crash at any workload of more than 1000 concurrent users. Thus, it is interpreted that the performance critical turning point occurs at a workload of 1000 concurrent users, a workload of more than 1000 will be considered a heavy load. This leads to an exponential increase in the error rate. Besides, the AUT becomes unstable and may crash. Fig. 5 shows the response time measurement for a different number of concurrent users' accesses. It is observed that when the number of concurrent users reaches 1000, the response time increases sharply and reaches its peak.

TABLE III. EXPERIMENTAL RESULTS OF TEST EXECUTION AND ANALYSIS FOR GOODREADS APP

Workload	Response Time (sec)	H_Respone_Time	Error Rate (%)	Test Execution Time (sec)
0	0	0	0	0
100	1,657	1599.1158	0	102
150	1,931	1866.810935	0.333	102

950	15,958	15379.26698	18.79	113
1000	78,602	71702.83435	52.7	610

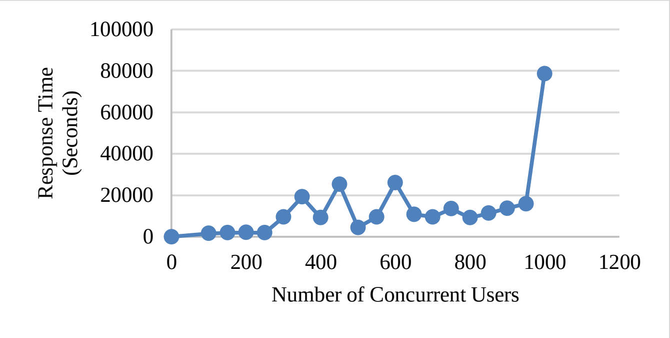

Fig. 5. Response time measurement for several numbers of concurrent users' accesses to the goodreads app.

Similarly, Table IV presents the results for the first functionality of the SpeedTest App (i.e., Show upload/download speed). It is observed from Table IV, that at the workload of 850 concurrent users, the response time increases sharply and the H_Respone_Time has the highest value. During the test execution, it was noticed that the error rate became 56.12 % at the workload of 850 concurrent users, which is the highest error rate that occurred during the experiment. Thus, it is interpreted that the performance critical turning point occurs at the workload of 850 concurrent users. A workload of more than 850 will be considered a heavy load. Fig. 6 shows the response time measurement for a different number of concurrent users' accesses. It is observed that when the number of concurrent users increases, the response time increases sharply and reaches its peak.

TABLE IV. EXPERIMENTAL RESULTS OF TEST EXECUTION AND ANALYSIS FOR SPEEDTEST APP

Workload	Response Time (sec)	H_Respone_Time	Error Rate (%)	Test Execution Time (sec)
0	0	0	0	0
100	663	647.3549	0	99
150	685	681.4788	0	100
200	717	728.3722	0	100
250	609	653.1596	0	100
300	723	776.9281	0	101
350	675	759.3621	0	100
400	706	811.3094	0	101
450	767	889.2544	0	101
500	1,015	1128.796	0	105
550	1,184	1300.434	0	108
600	2,646	2639.006	0	116
650	3,749	3680.732	0	116
700	1,106	589.3899	0	106
750	13,978	13453.63	23.9	236
800	11,976	11538.09	27.12	190
850	20,647	19859.62	56.12	748
900	46,544	44749.01	78.37	258
950	17,977	17301.74	67.3	469
1000	23,779	22873.01	52.4	623

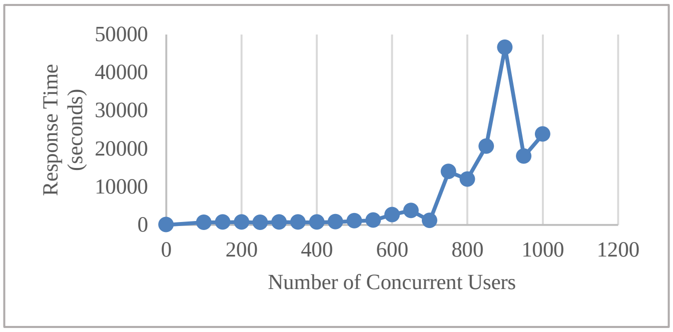

Fig. 6. Response time measurement for several numbers of concurrent users' accesses to the speedtest app.

The experimental results presented in Tables III and IV, and Fig. 5 and Fig. 6 were closely examined. The observations revealed are as follows:

- There is a fluctuation in the response time, especially with workloads lower than the detected heavy load. The fluctuation means that the response time of the AUT is faster than the preceding run. In the experiments, the fluctuation appears more obviously in Fig. 5 than in Fig. 6. For instance, in Fig. 5 the response time was 9,541 seconds at 300 workloads, the response time was 19,226 seconds at 350 workloads, then the response time decreased to 9,246 seconds at 400 workloads. This fluctuation in the response time is expected and is not considered as a problem during the performance test execution. This fluctuation indicates that the AUT does not clean up its resources. The memory usage metric is used to confirm this. If the memory usage remains high after the test is completed, then this implies that the resources are not cleaned-up at the AUT's web server. Thus, there are many other performance metrics (e.g., CPU usage, Memory usage, DB response time) that affect the responsivity of the AUT.

- The response time sometimes decreases under high workloads. However, the error rate values increase exponentially. This occurs despite the expectations of high response time value due to the heavy workload. For instance, in Table IV the response time was 46,544 seconds at 900 workloads and the error rate was 78.37%. However, the response time decreased to 17,977 seconds at 950 workloads and the measured error rate was 67.3%. The reason is that 900 workloads were defined as the heavy workload during the experiment where the AUT became unstable. Thus, the high error rate implies that a considerable percentage of the requests returned failed immediately and the average response time calculated by the JMeter decreased.

C. Experimental Results of the Effect of Utlizing the Simulated Cloud-based Environment in the Proposed P-TaaS

An experiment was conducted to evaluate the effect of utilizing the simulated cloud-based environment in the proposed mobile app P-TaaS. This experiment measures the time spent executing the automatically generated test cases sequentially on one virtual machine. Then, it measures the time spent executing the automatically generated test cases simultaneously on multiple virtual nodes. The experimental results for sequential and simultaneous test execution for the GoodReads app and SpeedTest app test cases are shown in Table V. The sequential execution for GoodReads app test cases takes 25 hours and 52 minutes, but the simultaneous execution only takes 8 hours and 37 minutes. The sequential execution for SpeedTest app test cases takes 18 hours and 18 minutes, but the simultaneous execution only takes 6 hours and 6 minutes. From the results, applying the proposed mobile app P-TaaS shows a vast reduction of time in case of simultaneous test execution.

TABLE V. EXPERIMENTAL RESULTS FOR SEQUENTIAL AND SIMULTANEOUS TEST EXECUTION FOR SPEEDTEST AND GOODREADS APPS TEST CASES

Test Case Execution Approach	SpeedTest	GoodReads
	Total Time	Total Time
Sequential Execution	18 hours and 18 minutes	25 hours and 52 minutes
Simultaneous Execution	6 hours and 6 minutes	8 hours and 37 minutes

VI. Discussion and Limitations of the Proposed P-TaaS Architecture

This section discusses the difference between the proposed P-TaaS architecture and other frameworks presented in literature and are mentioned in Section III. These comparisons show that the proposed P-TaaS architecture fulfill the contributions and handle challenges mentioned in Section I. Additionally, this section discusses the limitations of the proposed mobile app P-TaaS architecture.

The proposed P-TaaS architecture is compared with similar cloud-based performance testing frameworks discussed in literature as well as widely used tools in the market. The comparison includes the following criteria: automatic test case generation with high test coverage, simultaneous test execution on multiple virtual nodes in the cloud-based environment, automatic test result analysis, automatic test report generation that includes the performance metrics (i.e., response time and error rate) collected during the test execution at different workloads, and efficient scheduling and resource utilization. The comparison is shown in Table VI. The first five criteria are related to automating the whole performance testing process. The last criterion in Table VI is related to the efficiency of utilizing cloud-based resources. From the comparison, the proposed P-TaaS is considered a comprehensive framework that conducts the whole performance testing process automatically. Moreover, the proposed P-TaaS leverages the cloud-based environment efficiently.

Table VII shows that the proposed scheduling approach achieves efficient resource utilization. Besides, it guarantees the uncertainty of test execution, load balance between resources, and low complexity. Although, the fuzzy sets theory-based approach proposed by Lampe et al. [21] did not address the issue of uncertainty of test execution time. Lampe et al. [21] depend on knowing the test execution time in advance before starting the test, which is difficult to predict before the test started. Metaheuristic methodologies proposed by Rudy et al. [22] are very complex to implement. Besides, both approaches proposed by Rudy et al. [22] and Lampe et al. [21], have high computation time. The three approaches presented in Table VII balance the load between the available resources. The load balance between resources avoids the downtime and reduces the possibility of losing task productivity.

However, the limitations of the proposed mobile app P-TaaS architecture include: (i) not experimenting with other platforms such as iOS; (ii) not conducting the experiment on a cluster of distributed VMs; (iii) the experiments are conducted on VMs with the same capabilities and configurations using the same performance test tool (i.e., JMeter). However, performance testing is environment dependent. The test environment of the AUT shall mimic the real deployment environment of the application. Changing any factor (e.g., test execution tool, VM capabilities) during the test execution may change the test results.

TABLE VI. Comparison Between the Proposed P-TaaS and Performance Testing Tools in Literature and in the Market

Performance Testing Framework	Automatic Test Case Generation	Simultaneous Test Execution	Automatic Test Result Analysis	Automatic Test Report Generation	Efficient Scheduling and Resource Utilization
The Proposed Mobile Apps P-TaaS	Yes	Yes	Yes	Yes	Yes
ATaaS Framework by Prathibhan et al. [15]	No	Yes	No	No	No
SOASTA CloudTest [16]	No	Yes	No	No	o
LoadStorm [17]	No	Yes	Yes	Yes	Yes
Xamarin Test Cloud [18]	No	Yes	No	Yes	Yes

TABLE VII. Comparison Between the Proposed Scheduling Approach and other Approaches in the Literature

Approach	Uncertainty of Test Execution Time	Load Balance Between Resources	Computation Time
The Proposed P-TaaS Schedule Approach	Exists	Exists	Simple and Low Computation Time
Fuzzy Sets Theory-Based Approach Proposed by Lampe et al. [21]	Not Exists	Exists	Long Computation Time
Metaheuristic Methodologies Proposed by Rudy et al. [22]	Exists	Exists	Complex and Long Computation Time

VII. Conclusion

The performance of mobile apps is significantly important. Performance testing assesses and guarantees the reliability and stability of mobile apps when exposed to different workloads of concurrent users' accesses. The lack of performance testing may lead to degradation in mobile apps. Therefore, more attention from the industrial and academic communities is directed to performance testing as a service (P-TaaS). This paper introduced mobile app performance testing based on the TaaS architecture. It accomplishes the entire performance testing process automatically. The proposed P-TaaS adopts efficient approaches for test case generation, simultaneous test execution, test results analysis, and scheduling of test tasks. The experimental results on two different mobile apps prove the effectiveness of the proposed P-TaaS.

VIII. Future Work

In future work, the proposed mobile apps P-TaaS can be extended to include many directions such as: (i) allowing the performance testing of different types of mobile applications running on different platforms, (ii) including more types of testing as: security testing and regression testing., (iii) using a real cloud-based environment for simultaneous test execution on many VMs (e.g., Amazon EC2).

A Segmentation-based Token Identification for Recognition of Audio Mathematical Expression

SBTI Method for Audio Mathematical Expression Recognition

Vaishali A. Kherdekar[1], Sachin A. Naik[2], Prafulla Bafna[3]
Symbiosis Institute of Computer Studies and Research (SICSR), Symbiosis International (Deemed University),
Pune, Maharashtra State, India

***Abstract*—In human-computer interaction, humans can interact with the computer with the help of text, audio, images, speech, etc. Interacting with the computer using speech, speech recognitions in particularly audio segmentation is a challenging task due to accent or way of pronouncing style. To input mathematical symbols, words, functions, and expressions with the help of a keyboard are tedious and time-consuming. Input this with the help of audio, speeds up the input process. In this paper, an SBTI (audio Segmentation Based Token Identification) algorithm is proposed for the recognition of words in an audio mathematical expression. 6 types of audio mathematical expressions are considered for recognition. The proposed algorithm segments the audio file into chunks and from each chunk temporal and spectral characteristics of audio signals are selected to extract the features. The model is trained using a neural network. The proposed algorithm shows a classification accuracy of 100% for the algebraic, quadratic, area, and differentiation expression, 99% for trigonometric expression, and 92% for summation expression.**

***Keywords*—Audio segmentation; classification; feature extraction; neural network; speech recognition**

I. Introduction

In human-computer interaction, various types of data are used such as text, image, audio, and video. Interacting with the computer with the help of audio data increases the speed of interaction. Now a day’s most devices accept audio data as input but input mathematical data with the help of audio is not available. Existing work reveals that few researchers worked on the recognition of audio mathematical expression. To input mathematical symbols, words, functions, and expressions with the help of a keyboard are tedious and time-consuming. In this paper, a novel methodology is designed for the recognition of audio mathematical expressions. Recognition of mathematical expression is a challenging task because it consists of digits, letters, symbols, functions, etc.

Segmenting audio data is an important step in speech processing as well as audio processing applications such as speech recognition [1]. Segmenting audio data is challenging and a need of the day for applications such as speech recognition. Audio segmentation quality [2] affects the performance of recognition of speech. Segmentation of audio data is the process of splitting the audio data into small segments. Continuous audio signals are fragmented into small segments. To segment a sentence into phonemes, words, and syllables, [3] continuous speech segmentation is used. Based on classification techniques, segmentation is categorized into two types [4], [6], [7] classification-dependent segmentation and classification-independent segmentation. In [5] audio is segmented into the voiced and unvoiced parts with the help of ZCR and energy. The purpose of audio segmentation is to find acoustics variations [7] in the audio signal. Audio is segmented into various components of speech such as voiced part, nonvoiced part, noise, silence [8], etc. Segmentation methods are also categorized into three types [6] model-based segmentation, metric-based segmentation, and energy-based segmentation. In energy-based segmentation, silence is detected by thresholding the energy signals. Statistical models are used to design the model-based segmentation [9]. In metric-based segmentation, a distance function is used to determine the boundaries. Speech segmentation is an important step in speech processing [10]. A phoneme or a syllable or a sub-word, is the basic phonetic unit [11] which is based on the language.

Segmentation can be categorized into [18] acoustic audio segmentation and phonetic audio segmentation. Speech segmentation is also categorized into [19] manual segmentation and automatic segmentation. In Manual segmentation, speech signal waveforms are examined and it is segmented but it is very time-consuming and not produced correct results whereas, in automatic segmentation, speech waveforms are automatically segmented into words. Preprocessing of a speech signal is most important in speech recognition. As speech signals are continuous, the first thing is to convert them into digital form with the help of an analog-to-digital converter. In the audio file when silence is present it has no importance because of the lack of information. Silence removal is significant in speech recognition. Silence in the audio file is removed with the help of energy and the threshold value. In an audio file, speech signals are present in the form of frames through which features are extracted by considering the window size and frame rate. Feature extraction is the process of converting an audio signal into a sequence of features called a feature vector. Feature vector consists of the information of audio signals having temporal and spectral characteristics. The selection of feature sets plays a key role to improve the performance of audio segmentation.

In the proposed work, a novel audio segmentation based token identification algorithm is proposed, features are extracted based on various parameters and accuracy for different types of expressions is reported.

II. Literature Review

There are various challenges in audio segmentation and speech recognition such as separating the audio data into regions, multiple classes will be used for different types of segmentation boundaries [1]. To segment audio data various features are considered such as BIC, Boundary confidence, Warping factor variance, and word length [1] where the MAP decoder framework is presented which is applicable for segment features. It has been observed that many researchers have used various audio segmentation techniques [6, 7, 8, 9,10,14] which are based on either acoustic information or word level timing information [2]. In [7, 8,10] author proposed audio segmentation methods for classifying audio components into speech, non-speech, noise, music, and silence. By combining model-based and metric-based algorithms, a hybrid algorithm is proposed where results indicate that the model-based algorithm gives high precision and moderate recall whereas the metric-based algorithm indicates high recall and moderate precision. Gish distance function is used which improves the performance. Researchers have used various feature extraction techniques for segmentation such as MFCC [1], zero-crossing rate, and energy [5] where authors concluded that ZCR is low and energy is high for the voiced part and ZCR is high and energy is low for the unvoiced part. In [9] author proposed a speech segmentation method for streaming end-to-end automatic speech recognition. In [11] 20 Kannada audio sentences are used where speech signals are processed and framed into 20 milliseconds, the model shows an accuracy of 87.76% using HMM. In [12] 150 Punjabi-connected words are used for the recognition of speech in noisy and noise-free environments. In [13] Voice Input Speech Output calculator is developed for the recognition of Bangla numerals. In [14] weather news data in Myanmar language is segmented and computed the recognition accuracy. In [15] threshold and energy value are used for the segmentation of recognition of English audio. To select voiced and unvoiced parts from audio signal Voice Activity Detectors [16] are used. In [20] author developed the model based on handwritten recognition and speech recognition for 74 mathematical symbols, 39 features were extracted from each frame. The model showed a 50.09% recognition rate for speech recognition and 81.55% recognition rate for handwritten recognition which was developed using SVM classifier. In [21] author proposed a mathematical expression recognition based on handwritten recognition, speech recognition, and fusion method. They used CROHME dataset for handwritten recognition and HAMEX dataset for speech recognition. For automatic speech recognition, each speech signal is filtered, re-sampled and then reframed back. It is segmented into 25 ms frames with an overlap of 10 ms. Results showed that recognition rate of 80% for handwritten recognition, 50% for speech recognition and 98% after fusion. They conclude that bimodal processing gives better results. In [22] author discussed the ICT related needs to study mathematics for disabled persons. They have reported that Human-Computer Interaction in the domain of mathematics is still lagging, creating & editing electronic mathematical content still remains difficult for both able and disabled students, and particularly for people studying "at a distance" and those relying on mobile computing devices such as Smartphones and tablet PCs. In [23] author developed a speech recognition system for speaker-independent isolated words. They have created a database of 200 samples by recording Urdu digits 1 to 20 from 10 speakers at a sampling rate of 16KHz. DWT is used to extract the features and the model is trained using FFANN (Feed Forward Artificial Neural Network).

In [24] author developed a speaker-independent model for the Kannada language. PRAAT software was used to record 10 Kannada words (from 1 to 10) 10 times from one female speaker at an 8KHz sampling rate with some background noise. A statistical method is used to remove the silence from the speech signal. Speech signals are segmented into frames of 160 samples in length with overlapping of 80 samples. Each frame is multiplied by a 160-point Hamming window. Features are extracted using the MFCC technique. They trained the model using two clustering algorithms of the vector quantization method. VQ1 was developed by Juang which is based on a binary splitting algorithm i.e. splitting every cluster into two clusters, and VQ2 is developed by Lipeika, based on splitting a cluster with the largest average distortions into two clusters. The result shows that when the silence removal algorithm is used error rate has decreased from 2.59 to 1.56 in the case of VQ1 clustering algorithm and 2.5 to 1.45 for the VQ2 algorithm. In [25] author proposed a speech recognition model for isolated speaker-independent 300 Gujarathi numerals from age group of 5 to 40. Result shows an accuracy of 78.13% with MFCC features and KNN classifier. To overcome the problem of low accuracy and high computational complexity, [26] proposed a method for speech segmentation.

Based on the above literature, it shows that audio segmentation is challenging [13], and segmenting an audio mathematical expression is more challenging, hence there is scope to work on it. Researchers reported that the syllable counting method can be used in the segmentation [14] process to improve the result. In this paper, we have proposed a segmentation algorithm based on tokens for the recognition of audio mathematical expressions.

Authors have experimented to segment the speech into phonemes with the help of phonemes specialists, results in known as tedious, expensive and subjective [27].

An optimised parameters of automatic speech segmentation has been done into syllable units. This can be developed using time domain energy-based features and static threshold is used to detect the syllable boundary [28].

Speech Recognition technology is challenging because of sensitivity to the environment (background noise) or the weak representation of grammatical and semantic knowledge [29].

The proposed research study is unique because the dataset is generated as it is not available and samples are collected by varied age group. To segment long utterances is challenging. Here, Complex mathematical expressions are executed using the proposed approach, and recognition accuracy is reported.In this experiment the eight different categories of mathematical expressions are considered because of their different spatial and structural representation.

III. Methodology SBTI (Segmentation-based Token Identification)

Fig. 1 shows the methodology used for implementation of the proposed algorithm of segmentation.

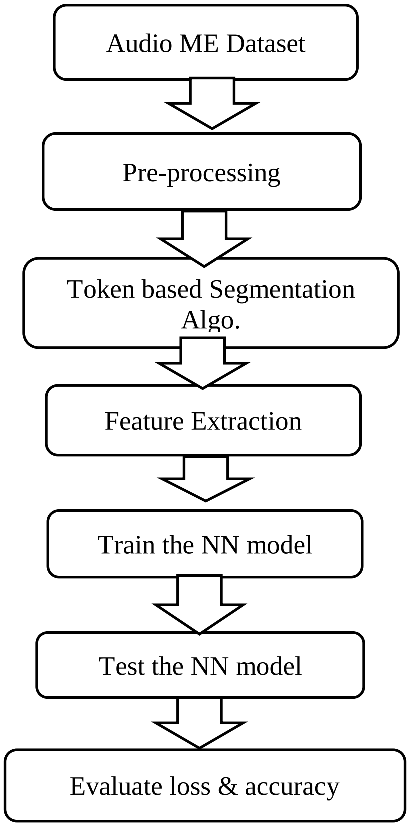

Fig. 1. Methodology

A. Audio Mathematical Expression (AME) Dataset

To perform the experiment we have selected 6 categories of mathematical expression which include algebraic expression, quadratic expression, area formulae, trigonometric expression, differentiation, and summation. To cover the samples from different age groups, people from the age group of 10 to 55 are used to create the dataset. All these expressions are recorded using the Audacity tool and taken in .wav. Table I shows the number of samples used for this study.

B. Pre-processing

In this step, the voiced part from the audio file is selected with the help of ZCR.

C. Segmentation

The proposed segmentation algorithm segments audio mathematical expression by considering the parameters such as the number of tokens, frame rate, and duration of audio mathematical expression in milliseconds. Fig. 3 shows the signal of $x^2 + y^2 = z^2$ audio mathematical expression in .wav format which is given as input to the proposed algorithm.

Proposed Segmentation Algorithm 1: SBTI

```
Input: Audio Mathematical Expression (AME) in .wav format
Output: Segments of  AME
  Start
    D← S/ Fr     // Duration of AME
    Fr ← // Number of samples per second
    T←  // Number of tokens in AME
    Ch← D/T  // Number of chunks
    St←0 //Starting pint
    Lt←0 //Ending point
    For I←1 to T
        Ch (I) ← Seg(St. . Lt )
        St ←  Ch   + I
        Lt ← Lt + Ch
    End loop
    End
```

D. Feature Extraction

From the audio mathematical expression, we have selected the features such as chroma_stft, rmse, spectral_centroid, spectral_bandwidth, roll-off, zero_crossing_rate, and 21 MFCC coefficients. Chromogram features and root mean square energy are features calculated in chroma_stft and RMSE. Root Mean Square Energy for each frame is calculated in RMSE.

Spectral centroid is a frequency-based feature that computes the “Location of mass”. Equation (1) is used to calculate spectral centroid.

$$f_C = \frac{\Sigma_k s(k) f(k)}{\Sigma_k s(k)} \tag{1}$$

where s(k) is the spectral magnitude at frequency bin k, f(k) is the frequency at bin k.

A variation between higher and lower frequencies is calculated using spectral_bandwidth. Spectral_rolloff computes the shape of the signal. It shows the frequency at which high frequencies deteriorate to 0. ZCR is used to check the voiced and unvoiced parts of speech. It is the rate at which the signal changes from positive to negative or vice-versa. It is computed as

$$ZCR = \sum_{n=1}^{N-1} |S[x(n+1)] - S[x(n)]| \,/\, 2(N-1) \tag{2}$$

In MFCC, the first audio signals are divided into short frames. Calculate the Fourier transform for each frame. Find the log of all filter bank energies. Compute the discrete cosine transform of each Mel log power. MFCC coefficients are calculated as

$$\text{Mel (f)} = 2595 * \log_{10}(1 + \frac{f}{700}) \tag{3}$$

There are various applications of neural network present such as Machine translation, speech recognition, sentiment analysis, chatbots, named entity recognition, etc. To study such areas machine learning’s sequence model is very useful.

Sequence modeling consists of data in the form of sequences, a data structure.

It is used in supervised learning algorithms. Sequence models are categorized based on the input and output which may be in the form of scalar, audio, text, image, and video form.

The performance of the model is measured using various parameters such as accuracy, loss, F1-score, precision, recall, etc. The accuracy of the model depends on predicted and observed values. It is computed as

$$\mathrm{Acc(M)} = \frac{TrP+TrN}{Tot_P+Tot_N} \qquad (4)$$

Where TrP and TrN are true positive and true negative respectively. Tot_P is the combination of true positive and false positive samples whereas Tot_N is the inclusion of false positive and false negative.The model's performance is visualized using accuracy-loss graphs.

E. Training and Testing

To recognize the speech for audio mathematical expression, the proposed algorithm is used to segment an audio mathematical expression. Audio mathematical expression in .wav format is given as input as shown in Fig. 2. The frame rate and the number of samples present in each expression are computed. Based on the number of samples and frame rate duration of audio mathematical expression is find out. The number of tokens and duration of audio mathematical expressions are used to segment the audio mathematical expression.

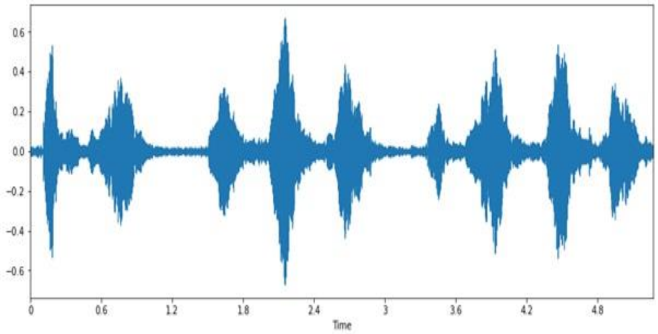

Fig. 2. An Audio signal of the mathematical expression "$x^2 + y^2 = z^2$".

Features such as chroma_stft, rmse, spectral_centroid, spectral bandwidth, roll-off, zero_crossing_rate, and 21 MFCC coefficients are extracted from each segment. The parameters used to train and test the NN (Neural Network) model are RElu and Softmax activation function, sparse_categorical_ crossentropy loss function, adam optimizer, 50 epochs, and 128 batch size. The total number of samples for each expression is split into Training 80% and testing set 20%.

IV. Results and Discussion

Table I, represents the samples used for segmentations alog with its total number of segments and number of labels used. Table II indicates that training accuracy for algebraic expression, quadratic expression, trigonometric expression, and area formulae whereas it is less for summation expression. Testing accuracy is also less for summation expression as compared to another category because of more number of labels. Table II shows testing accuracy for each category of audio mathematical expression. Fig. 3 shows the graph of training accuracy of summation and differentiation expression. It indicates that initially training accuracy is low but gradually it goes on increasing.

Table III shows the comparative result of the proposed model with the existing result for the recognition of words in continuous speech.

TABLE I. No. of Samples used for Segmentation

Expression Type	No. of Samples	No. of Segments	No. of Labels
Algebraic (x2 + y2 = z2)	160	1280	8
Quadratic (ax2 + bx + c)	237	1896	6
Area (πr2)	225	675	3
Trigonometric (Sin2θ + cos2 θ =1)	102	918	7
Differentiation (d/dx x2 =2x)	100	600	6
Summation (∑n = n(n+1)/2)	100	1000	10

TABLE II. Testing Accuracy

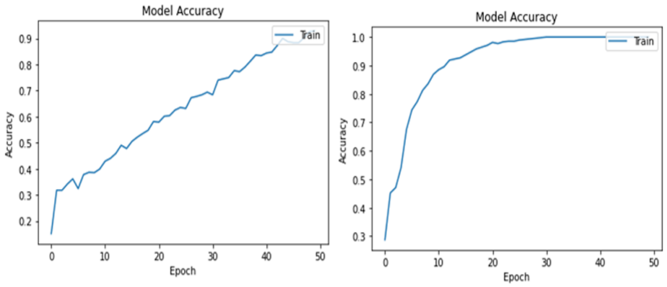
Expression Type		Testing Accuracy
Algebraic	$x^2 + y^2 = z^2$	0.86
Quadratic	$ax^2 + bx + c$	0.91
Area	πr^2	0.91
Trigonometric	$\mathrm{Sin}^2\theta + \mathrm{Cos}^2\theta = 1$	0.85
Differentiation	$d/dx\ x^2 = 2x$	0.89
Summation	$\sum n = n(n+1)/2$	0.60

TABLE III. Comparative Results of the Proposed Model with Existing Results

Ref. No.	Dataset	Language	Recognition Rate
[11]	20 unique sentences	Kannada	87.76%
[12]	150 distinct Words	Punjabi	86.05%
[17]	25 samples of 0- 9 digits, some operators	English	80%
[20]	74 Mathematical Symbols	French	50%
[21]	HAMEX	French	50%
Proposed Algo.	AME	English	85% to 91%

V. Conclusion

In Human-computer interaction, speech recognition plays a vital role, but developing systems for speech recognition is challenging. In this paper, a segmentation-based token identification algorithm is proposed to segment an audio mathematical expression and classify it into symbols, letters, digits, Greek letters, and operators. Chroma_stft, Rmse, Spectral_centroid, Spectral_bandwidth, Rolloff, Zero_crossing_rate, and 21 MFCC coefficients were used to extract the features. Results indicated that the proposed algorithm works accurately for the segmentation of audio mathematical expressions. This study will be useful to speed up the entry of mathematics in documents for normal people as well as for blind persons. It will help the researchers to work on the recognition of speech for expressions used in mathematics.



(a) Summation (b) Differentiation

Fig. 3. Training accuracy of summation and differentiation.

In the future, we would like to expand the proposed segmentation algorithm for audio mathematical expressions having a large number of tokens.

Abstract—**The escalating student numbers in Moroccan universities have intensified the complexities of managing on-time graduation. In this context, Machine learning methodologies were utilized to analyze the patterns and predict on-time graduation rates in a comprehensive manner. Our dataset comprised information from 5236 bachelor students who graduated in the years 2020 and 2021 from the Faculty of Law, Economic, and Social Sciences at Moulay Ismail University. The dataset incorporated a diverse range of student attributes including age, marital status, gender, nationality, socio-economic category of parents, profession, disability status, province of residence, high school diploma attainment, and academic honors, all contributing to a comprehensive understanding of the factors influencing graduation outcomes. Implementation and evaluation of the performance of five different machine learning models: Support Vector Machines, Decision Tree, Naive Bayes, Logistic Regression, and Random Forest, were carried out. These models were assessed based on their classification reports, confusion matrices, and Receiver Operating Characteristic (ROC) curves. From the findings, the Random Forest model emerged as the most accurate in predicting on-time graduation, showcasing the highest accuracy and ROC AUC score. Despite these promising results, it is believed that performance enhancements can be achieved through further tuning and preprocessing of the dataset. Insights from this study could enable Moroccan universities, among others, to better comprehend the factors influencing on-time graduation and implement appropriate measures to improve academic outcomes.**

Keywords—Machine learning; logistic regression; classification reports; on time graduation; Moroccan universities

I. Introduction

The integration of technological advancements within higher education has stimulated a shift towards data-driven strategies to manage burgeoning student enrollments and optimize institutional systems. Particularly, on-time graduation, a significant performance metric, is becoming increasingly challenging to predict and manage [1]. This predicament isn't confined to a single region, as institutions worldwide are contending with it. The case of Morocco, with its unique socio-economic contexts, is even more compelling [2].

This research intends to tackle this critical issue by applying machine learning methodologies to forecast on-time graduation rates at the Faculty of Law, Economic, and Social Sciences at Moulay Ismail University. A comprehensive dataset of 5236 bachelor students who graduated in 2020 and 2021 was utilized. The dataset includes numerous student characteristics such as age, marital status, gender, nationality, socio-economic category of parents, profession, disability status, province of residence, high school diploma attainment, and academic honors. It is posited that the detailed analysis of these variables could reveal valuable insights into the determinants of on-time graduation [3].

To identify the most effective method for predicting on-time graduation rates, a comparative analysis of five machine learning models - Support Vector Machines (SVM), Decision Tree (DT), Naive Bayes (NB), Logistic Regression (LR), and Random Forest (RF) - was conducted. Each model's performance was evaluated based on several statistical measures, including classification reports, confusion matrices, and Receiver Operating Characteristic (ROC) curves.

The implications of this research go beyond academic discourse. The findings could provide actionable insights for higher education institutions, particularly in Morocco, facilitating the formulation of effective data-driven strategies for improving on-time graduation management.

The paper is organized as follows: Post the introduction, the methodology, including data collection and analysis procedures, is detailed. Subsequent sections present a comprehensive discussion of the results, interpreting and comparing the performance of the different machine learning models. Potential implications of the findings are then outlined, offering a practical perspective. Finally, the paper concludes with a summary of the research findings and suggests directions for future research.

II. Related Work

Several studies have addressed the question of predicting student success and on-time graduation using machine learning techniques. These studies, while varying in scope and methodology, provide valuable insights into the potential of machine learning in education.

For instance, Marbouti [4] conducted a study using machine learning to predict the success of first-year engineering students based on high school academic performance. They used logistic regression and decision tree models, highlighting the significant role of high school mathematics grades in predicting success.

Similarly, Delen [5] used decision tree, neural network, and logistic regression models to predict students' graduation status based on demographic and academic data. They found that the neural network model performed best in predicting student graduation status.

In the context of Moroccan higher education, however, the application of machine learning for predicting on-time graduation remains relatively unexplored. This study contributes to filling this research gap by applying machine learning techniques to a dataset from the Faculty of Law, Economic, and Social Sciences at Moulay Ismail University.

Notably, this work extends beyond the previous studies by comparing the performance of five different machine learning models: Support Vector Machines, Decision Tree, Naive Bayes, Logistic Regression, and Random Forest, in predicting on-time graduation. Moreover, a diverse range of student attributes is incorporated, aiming to create a more comprehensive prediction model.

Through this approach, the aim is to further the understanding of the factors influencing on-time graduation and contribute to the development of more effective strategies for academic success in Moroccan universities.

III. Materials and Methods

This section outlines the data collection process, the variables incorporated in the study, the preprocessing steps undertaken, and the machine learning models employed for analysis.

A. *Data Source*

The dataset was derived from the student records of the Faculty of Law, Economic, and Social Sciences at Moulay Ismail University, encompassing 5236 bachelor students who graduated in the years 2020 and 2021. The dataset was collected and anonymized in strict compliance with data privacy regulations.

B. *Dataset Features*

The dataset incorporated a variety of student characteristics (Fig. 1) such as age, marital status, gender, nationality, socio-economic category of parents, profession, disability status, province of residence, high school diploma attainment, and academic honors. The target variable was 'Graduate on Time,' a binary variable indicating whether the student graduated within the standard duration of the program. (Table I) summarizes the main variables of this study.

Fig. 1. Dataframe information.

TABLE I. Student Characteristics

Variable	Definition
Age	Age of the student in years
Marital_status	Marital status of the student
Gender	Gender of the student
Nationality	Nationality of the student
Parents_Categ_soscio	Socio-economic category of the student's parents
Profession	Profession of the student
Disability	Indicates whether the student has a disability
Province	Province of the student's residence
High_School_Diploma	Indicates the type of high school diploma the student has.
Academic_honor	Academic honors achieved by the student
Graduate_on_time	Indicates whether the student graduated on time

C. *Label Encoding*

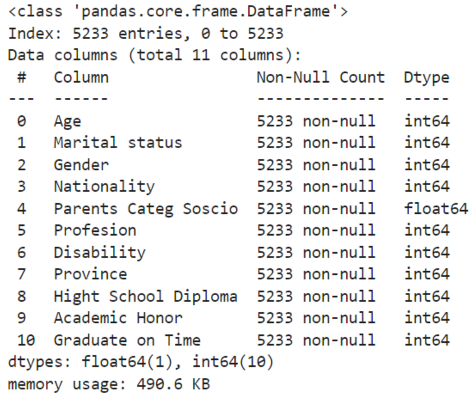
The dataset under consideration encompasses a range of features that capture the student's demographic and academic characteristics. The 'Age' feature represents the age of the student in years. 'Marital_status' indicates the student's marital status, represented by numeric values where 1 signifies being Single, 2 stands for Married, 3 denotes Divorced, and 4 implies a Widower. 'Gender' signifies the student's gender, with 0 indicating Female and 1 representing Male. 'Nationality', 'Parents_Categ_soscio', 'Profession', and 'Province' are represented by IDs corresponding to different nationalities, socio-economic categories of parents, professions, and provinces respectively. 'Disability' is a binary indicator that highlights whether a student has a disability, where 0 denotes No and 1 stands for Yes. 'High_School_Diploma' points to the type of high school diploma the student possesses, represented by different IDs for each type of diploma. Academic_honor' delineates the academic honors a student has achieved, ranging from 1 (Passing), 2 (Good), 3 (Very Good), to 4 (Outstanding). Lastly, 'Graduate_on_time' is a binary variable that indicates whether the student graduated within the standard duration of the program, represented by 0 (No) and 1 (Yes). These features collectively provide a comprehensive profile of the students' demographic and academic landscape (Table II, Fig. 2).

D. *Correlation Features*

The features used in this study have differing levels of correlation with the target variable, 'Graduate on Time'. The correlation values signify the strength and direction of the relationship between each feature and the target [6]. These values were computed and visualized through a correlation matrix. A positive correlation indicates that as the feature value increases, the likelihood of on-time graduation also increases, and vice versa. Conversely, a negative correlation means that as the feature value increases, the likelihood of on-time graduation decreases.

TABLE II. METHOD FOR ENCODING OF VARIABLES

Variable	Definition	Possible Values
Age	Age of the student in years	Numeric values
Marital_status	Marital status of the student	1(Single), 2(Married), 3(Divorced), 4 (Widower)
Gender	Gender of the student	0(Female), 1 (Male)
Nationality	Nationality of the student	IDs corresponding to different nationalities
Parents_Categ_soscio	Socio-economic category of the student's parents	IDs corresponding to different socio-economic categories
Profession	Profession of the student	0 (No), 1 (Yes)
Disability	Indicates whether the student has a disability	0 (No), 1 (Yes)
Province	Province of the student's residence	IDs corresponding to different provinces
High_School_Diploma	Indicates the type of high school diploma the student has.	IDs corresponding to different high school diploma
Academic_honor	Academic honors achieved by the student	1 (Passing), 2 (Good), 3 (Very Good), 4 (Outstanding)
Graduate_on_time	Indicates whether the student graduated on time	0 (No), 1 (Yes)



```
<class 'pandas.core.frame.DataFrame'>
Index: 5233 entries, 0 to 5233
Data columns (total 11 columns):
 #   Column                Non-Null Count  Dtype
---  ------                --------------  -----
 0   Age                   5233 non-null   int64
 1   Marital status        5233 non-null   int64
 2   Gender                5233 non-null   int64
 3   Nationality           5233 non-null   int64
 4   Parents Categ Soscio  5233 non-null   float64
 5   Profesion             5233 non-null   int64
 6   Disability            5233 non-null   int64
 7   Province              5233 non-null   int64
 8   Hight School Diploma  5233 non-null   int64
 9   Academic Honor        5233 non-null   int64
 10  Graduate on Time      5233 non-null   int64
dtypes: float64(1), int64(10)
memory usage: 490.6 KB
```

Fig. 2. Dataframe after encoding.

In the dataset, the 'Academic Honor', 'High School Diploma', and 'Province' are the features that show the highest correlation with on-time graduation as depicted in the correlation matrix (Fig. 3). The 'Academic Honor' feature, representing the academic performance of students, shows a positive correlation, suggesting that students with higher academic honors are more likely to graduate on time. Similarly, the 'High School Diploma' and 'Province' features also have a positive correlation with on-time graduation, indicating that the type of high school diploma and the province of residence can have an influence on graduation times (Fig. 4).

These highly correlated features are particularly beneficial in predictive modeling, as they provide significant insight into the factors that influence on-time graduation. By focusing on these variables in the machine learning models, it becomes possible to make more accurate predictions and gain a deeper understanding of the factors contributing to graduation times.

Fig. 4. Ranking of correlations with graduate on time.

E. Modeling

In this study, the modeling procedure takes place after the data preprocessing stage. This procedure entails training machine learning algorithms to predict whether a student will graduate on time based on their academic and demographic characteristics. Several well-regarded machine learning techniques were employed, including Support Vector Machine (SVM), Naive Bayes (NB), Decision Tree (DT), Random Forest (RF), and Logistic Regression (LR). These classification models are popular and efficient for dealing with such a binary classification task. The models were trained based on attributes such as Academic Honor, High School Diploma, and Province, aiming to classify students into two categories: those who are likely to graduate on time and those who are not. The Python scikit-learn library was used for data analysis and model implementation. The models were evaluated using a split-test method, partitioning the original dataset into a training set (80%) to train the model, and a test set (20%) to evaluate it. This technique is commonly used in machine learning to assess the effectiveness and efficiency of predictive models. By comparing the performance of the different models, the aim is to identify the one that provides the most accurate predictions for on-time graduation among students at the Faculty of Law, Economic, and Social Sciences at Moulay Ismail University. The entire procedure of the experiment is depicted in (Fig. 5).

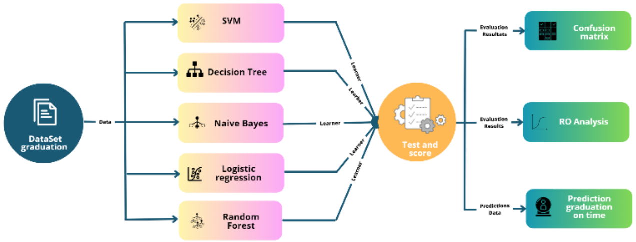

Fig. 5. Model machine learning use.

1) Machine learning algorithms: In this study, we utilized five different machine learning algorithms, each with its strengths and applicable use cases. These include:

a) Support Vector Machine (SVM): SVM is a widely used classification algorithm that finds the hyperplane in an N-dimensional space that distinctly classifies the data points. It is especially useful in high dimensional spaces and situations where the number of dimensions exceeds the number of samples [7].

b) Naive Bayes (NB): The Naive Bayes classifier is a simple and efficient machine learning algorithm often used in text classification, spam filtering, recommendation systems, etc. It is based on applying Bayes' theorem with the "naive" assumption of conditional independence between every pair of a feature [8].

c) Decision Tree (DT): Decision Trees are a type of flowchart-like structure where each internal node represents a feature (or attribute), each branch represents a decision rule, and each leaf node represents an outcome. They are widely used due to their interpretability and simplicity [9].

d) Logistic Regression (LR): Logistic regression is a type of regression analysis used for predicting the probability of a binary outcome. It's a statistical model that uses a logistic function to model a binary dependent variable [10].

e) Random Forest (RF): Random Forest is an ensemble learning method that operates by constructing multiple decision trees during training and outputting the majority vote of individual trees for classification problems or average prediction for regression problems. It's a powerful algorithm known for its robustness and simplicity [11].

F. *Performance Indicators*

In this study, the performance of the various machine learning models was evaluated using several widely recognized performance indicators:

1) Confusion matrix: The Confusion Matrix is another key performance indicator used in this study. It is a specific table layout that visualizes the performance of an algorithm, typically a supervised learning one. The matrix contrasts the actual and predicted classifications of the instances in a dataset to measure the quality of the output of the classifier. Each row of the matrix represents the instances in an actual class while each column represents the instances in a predicted class (Fig. 6).

In general, the confusion matrix provides four types of classification results with respect to a classification target k [12].

- True positive (TP): correct prediction of the positive class $(c_{k,k})$
- True negative (TN): correct prediction of the negative class $\sum_{i,j\in N\setminus\{k\}} c_{ij}$
- False positive (FP): incorrect prediction of the positive class $\sum_{i\in N\setminus\{k\}} c_{ik}$
- False negative (FN): incorrect prediction of the negative class $\sum_{i\in N\setminus\{k\}} c_{ki}$

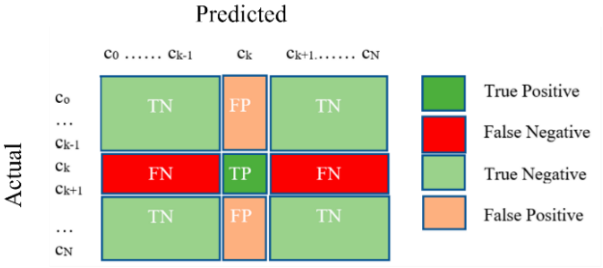

Fig. 6. Confusion matrix for multi-class.

The Confusion Matrix allows us to compute various other classification metrics, including precision, recall, F1-score, and support. By providing a more detailed view of how the classification model is performing, the Confusion Matrix plays a crucial role in understanding the behavior of the model beyond simple accuracy [13].

2) Classification report: A classification report offers a comprehensive synopsis of how well a classification model has performed. It consolidates key performance metrics such as accuracy, precision, recall, F1-score, and support.

a) Accuracy: Defined as the ratio of correctly predicted observations to total observations, accuracy is the most straightforward performance measure [14]. The accuracy of the model is defined as:

$$OverallAccuracy = \frac{(\sum_{i=1}^{N} C_{(i,i)})}{\sum_{i=1}^{N}\sum_{j=1}^{N} C_{(i,i)}} \quad \# \tag{1}$$

b) Precision: Precision, calculated as the ratio of correctly predicted positive observations to total predicted positive observations, indicates the model's ability to correctly identify only the relevant instances [15]. It’s defined as:

$$Precision_{class} = \frac{TP_{class}}{TP_{class} + FP_{class}} \quad \# \tag{2}$$

c) Recall (Sensitivity): Also known as sensitivity, recall measures the model's ability to identify all relevant instances, defined as the ratio of correctly predicted positive observations to all actual positives [16], it’s defined by equation (3).

$$Recall\ _{class} = \frac{TP_{class}}{TP_{class} + FN_{class}} \quad \# \tag{3}$$

d) F1-Score: The F1 score combines precision and recall into a single metric by taking their harmonic mean, effectively balancing the trade-off between the two measures [17]. It's defined by equation (4).

$$F\,1 - Score = \frac{2 * TP_{class}}{2 * TP_{class} + FN_{class} + FP_{class}}\ \# \tag{4}$$

e) Area Under Curve: The Receiver Operating Characteristic (ROC) curve, plotting the true positive rate against the false positive rate, indicates the model's discriminative power. The Area Under the Curve (AUC) offers a single measure summarizing the overall quality of the classifier [18].

G. *Training and Validation*

In this study, the modeling procedure commenced with partitioning the dataset into a training and validation set. As per the widely accepted practices in machine learning research, 80% of the total data was allocated for training the algorithms, while the remaining 20% was set aside for validation [19]. The objective was to ensure a realistic estimate of the models' performance on unseen data, providing a valuable measure of their generalizability.

The training phase of this research implemented five distinct machine learning models: Support Vector Machine (SVM), Naive Bayes (NB), Decision Tree (DT), Random Forest (RF), and Logistic Regression (LR). These models were selected due to their widespread adoption in predictive modeling tasks of a similar nature and their ability to effectively manage binary classification problems [20].

Python's scikit-learn library was utilized for the execution of these models [21]. The training of each model was conducted using the 'fit' function, while model parameters were optimized through the GridSearchCV function, an exhaustive search over a specified range of parameter values [22].

After the training, the models underwent validation using the validation set. Various performance metrics were employed to evaluate model performance, including Accuracy, Precision, Recall, and the F1-score. All of these metrics were featured in the Classification Report [15]. Additionally, the Receiver Operating Characteristic (ROC) curve was graphed for a visual assessment of the model's performance [23].

For this study, a 10-fold cross-validation technique was also incorporated during the training phase [19]. This technique subdivides the training set into 10 subsets, and the model is trained 10 times. In each training iteration, nine subsets are used for training, and one is used for validation. The ultimate model performance is computed as the average performance of the ten models. This method helps generate a more dependable performance estimate and mitigates the risk of overfitting [24].

IV. Results and Discussion

A. *Analysis of Results*

The performance of each model is summarized by highlighting key metrics and visual representations from the classification report and confusion matrix.

The SVM model achieved an overall accuracy of 69%. However, it demonstrated high recall (97%) for class 0 but had a low recall (11%) for class 1. This indicates that while the SVM model was able to identify the majority of class 0 instances correctly, it struggled to correctly classify instances from class 1 (Table III, Fig. 7).

TABLE III. Metric Report for SVM

Metric	Class 0	Class 1
Precision	0.69	0.64
Recall	0.97	0.11
F1-Score	0.81	0.18
Support	705	342

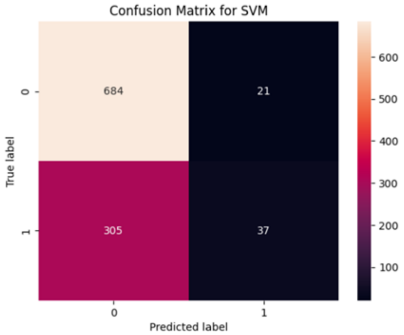

Fig. 7. Confusion matrix for SVM

The Decision Tree model performed better with an accuracy of 74%. It demonstrated a better balance in classifying both classes with a recall of 82% and 57% for class 0 and class 1 respectively (Table IV, Fig. 8).

TABLE IV. Metric Report for Decision Tree

Metric	Class 0	Class 1
Precision	0.80	0.60
Recall	0.82	0.57
F1-Score	0.81	0.59
Support	705	342

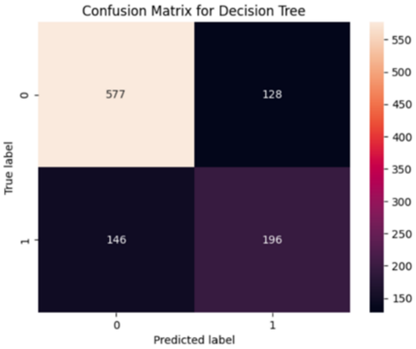

Fig. 8. Confusion matrix for decision tree.

The Naive Bayes model achieved an accuracy of 70%. While it showed good recall for class 0 (85%), it faced difficulties in classifying class 1 instances correctly, similar to the SVM model (Table V, Fig. 9).

TABLE V. METRIC REPORT FOR NAIVE BAYES

Metric	Class 0	Class 1
Precision	0.74	0.55
Recall	0.85	0.38
F1-Score	0.79	0.45
Support	705	342

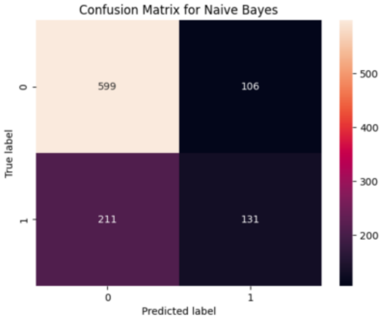

Fig. 9. Confusion matrix for naive bayes.

The Logistic Regression model performed with an accuracy of 75%. It showed a fairly balanced performance for both classes, with a recall of 89% for class 0 and 47% for class 1 (Table VI, Fig. 10).

TABLE VI. METRIC REPORT FOR LOGISTIC REGRESSION

Metric	Class 0	Class 1
Precision	0.78	0.67
Recall	0.89	0.47
F1-Score	0.83	0.55
Support	705	342

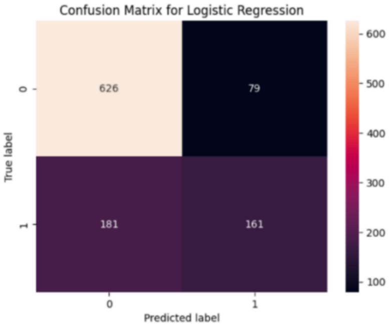

Fig. 10. Confusion matrix for logistic regression.

Random Forest was the top-performing model with an accuracy of 77%. It also demonstrated the most balanced performance with a recall of 85% and 62% for class 0 and class 1, respectively (Table VII, Fig. 11).

TABLE VII. METRIC REPORT FOR RANDOM FOREST

Metric	Class 0	Class 1
Precision	0.82	0.66
Recall	0.84	0.62
F1-Score	0.83	0.64
Support	705	342

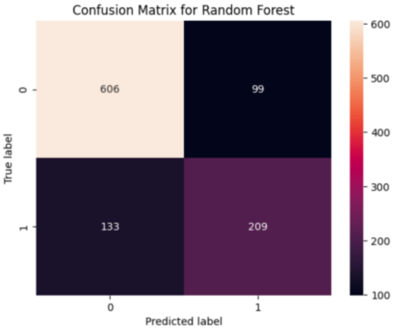

Fig. 11. Confusion matrix for random forest.

ROC and AUC curve

The Receiver Operating Characteristic (ROC) curve, in conjunction with the Area Under the Curve (AUC), offer insightful metrics for assessing the classification performance of a predictive model. In the context of this study, the ROC AUC scores reveal that the Random Forest model surpasses its counterparts, recording the highest score of 0.82. This indicates a superior capacity of the Random Forest model in distinguishing between students likely to graduate on time and those who aren't, across various thresholds.

Following closely, the Logistic Regression model achieved the second-highest ROC AUC score of 0.75. This suggests a commendable proficiency of this model in accurately classifying the students. The Decision Tree model was also noteworthy, with a score of 0.74. The SVM and Naive Bayes models demonstrated similar performance levels, with ROC AUC scores of 0.73 each. Although these scores are lower compared to the Random Forest and Logistic Regression models, they still denote reasonable classification capabilities (Fig. 12).

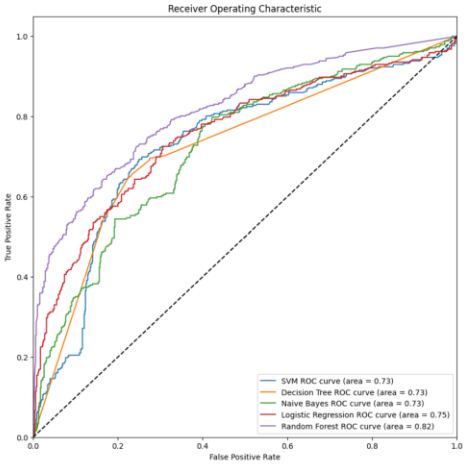

Fig. 12. ROC curve for SVM, DT, NB, LR, RF.

B. Discussion

In this study, the relationship between a variety of features and the ability to graduate on time was investigated. After a careful data transformation and correlation analysis, three features, 'Academic Honor', 'High School Diploma', and 'Province' were selected based on their strong correlation with the target variable.

Several popular machine learning models were used to construct and validate predictive models. These models included Support Vector Machine (SVM), Naive Bayes (NB), Decision Tree (DT), Random Forest (RF), and Logistic Regression (LR). Each of these models was trained using the train-test split method, and their performance was evaluated using a suite of metrics including accuracy, precision, recall, and the F1 score. Also, the ROC-AUC score was calculated to measure the performance of the models under different classification thresholds.

The results clearly demonstrate that the Random Forest model was superior to all other models, achieving top marks in accuracy, precision, recall, and F1 score for predicting timely graduation of students. In addition, it accomplished an ROC-AUC score of 0.82, a clear indicator of its excellent performance. Although the Decision Tree and Logistic Regression models exhibited commendable performance, they were unable to match the outstanding performance of the Random Forest model.

Future work in this area could include the incorporation of more features, utilization of diverse feature selection techniques, and experimentation with alternative machine learning models. Furthermore, additional data should be considered. Ultimately, the goal is to construct a reliable predictive model capable of accurately identifying students at risk of not graduating on time, thereby enabling early interventions to support these students in achieving success.

V. Conclusion

The application of various machine learning models was showcased in this study to predict students' ability to graduate on time. 'Academic Honor', 'High School Diploma', and 'Province' were used as predictors. The central goal was to identify the model that most accurately could assist educational institutions in pinpointing at-risk students and implementing interventions in a timely manner.

Among all the models tested, the Random Forest model stood out as the most effective, achieving the highest precision, recall, F1-score, and ROC-AUC score. The model's ability to manage high-dimensional spaces and generate an internal unbiased estimate of the generalization error distinguished it from the other tested models. Therefore, this study underscores the use of machine learning, and particularly ensemble methods like Random Forest, as potent tools in the educational sector.

As a part of future work, further fine-tuning of the Random Forest model is suggested, along with the exploration of other machine learning models and additional student features. A potential avenue for future research may also include the implementation of this model in other educational contexts, allowing for a more comprehensive understanding of its applicability and robustness.

In conclusion, this study accentuates the potential of machine learning in education to predict student outcomes and enable proactive measures. With the ongoing integration of technology into education, the importance of such predictive tools is projected to rise. Such tools equip educational institutions with better understanding of student needs, enabling them to tailor their support services more effectively and, ultimately, assist more students in achieving their educational goals.

Abstract—**Because of the potential threats it presents to marine ecosystems and human health, beach litter is becoming a major global environmental issue. The traditional manual sampling survey of beach litter is poor in real-time, poor in effect, and limited in the detection area, so it is extremely difficult to quickly clean up and recycle beach litter. Deep learning technology is quickly advancing, opening up a new method for monitoring beach litter. A QSB-YOLO beach litter detection approach based on the improved YOLOv7 is proposed for the problem of missed and false detection in beach litter detection. First, YOLOv7 is combined with the quantization-friendly Quantization-Aware RepVGG (QARepVGG) to reduce the model's parameters while maintaining its performance advantage. Secondly, A Simple, Parameter-Free Attention Module (SimAM) is used in YOLOv7 to enhance the feature extraction capacity of the network for the image region of interest. Finally, improving the original neck by combining the concept of the Bidirectional Feature Pyramid Network (BiFPN) allows the network to better learn features of various sizes. The test results on the self-built dataset demonstrate that: (1) QSB-YOLO has a good detection effect for six types of beach litter; (2) QSB-YOLO has a 5.8% higher mAP compared to YOLOv7, with a 43% faster detection speed, and QSB-YOLO has the highest detection accuracy for styrofoam, plastic products, and paper products; (3) QSB-YOLO has the greatest detection accuracy and detection efficiency when comparing the detection effects in various models. The results of the experiments demonstrate that the suggested model satisfies the need for beach litter identification in real-time.**

Keywords—Beach litter detection; QSB-YOLO; YOLOv7; Quantization-Aware RepVGG; a simple, parameter-free attention module; bidirectional feature pyramid network

I. Introduction

Environmental pollution issues have gotten progressively worse in recent years, and beach litter pollution is unquestionably one of the planet's biggest environmental issues. Beach litter is characterized by wide distribution, persistence, and cumulative pollution, with two main sources, land-based and sea-based, including metal products, plastic products, wood, and paper products, etc [1]. The majority of beach litter is made up of materials that break down slowly, and because of poor waste management, it spreads out uncontrollably into the environment and interferes with marine traffic, damages ships, pollutes the nearshore area, degrades the environment, and results in many accidental injuries and deaths of marine life, etc [2]. Additionally, pollutants that persist and build up in beach litter can have an impact on people through the biological chain [2]. Today, China places a high value on reducing beach litter pollution, has created pertinent laws and regulations, and is actively doing research to improve the quality and cleanliness of beaches [3].

Many researchers have conducted a series of studies on the monitoring, sorting, and recycling of coastal litter. For example, Merlino et al. [4] evaluated the reliability of non-expert citizen scientist operators (CSO) to manually tag and classify marine litter from aerial photographs taken by drones. According to the study, CSO can support drone-based marine litter surveys with the right training programs and the provision of user-friendly guidance software, but the study is always labor-intensive [4]. Due to the labor-intensive nature of artificial beach litter sorting and cleanup, automated beach litter detection is a good solution to the pollution problem. The traditional method of beach litter monitoring is to monitor the amount of litter on the beach, which does not specifically localize or identify the beach litter [58]. The beach litter detection algorithm based on deep learning can simultaneously complete the classification and location of beach litter and feed it back to relevant staff, which can not only improve the detection accuracy of recyclable or non-degradable beach litter but also save a significant amount of manpower and material resources needed for beach litter cleaning and reduce environmental pollution to the greatest extent [910]. Deep learning-based beach litter detection is therefore very important.

In this research, we examined a few deep learning approaches that can be used to detect beach litter. However, the majority of deep learning-based object detection algorithms are designed for object detection in natural situations and do not completely apply to such unique scenarios as beach litter detection. This is due to the fact that the universal target detection model has a large number of parameters and a sluggish detection speed, making it unable to fulfill the speed requirements of actual applications and ineffective in dealing with issues like the mutual occlusion of targets and complicated beach litter backgrounds. Beach litter detection also be quite challenging due to the significant size differences between the targets of the litter.

In order to address the aforementioned issues, we suggest the QSB-YOLO beach litter detection method, which reduces model parameters to meet real-time requirements in practical applications, improves feature extraction capabilities of the

[†] These authors share first authorship

model to address the problem of missed and false detection in complex background, and enhances feature fusion network capabilities to enhance network's ability to acquire multi-scale features. The approach also offers improved detection speed and accuracy. The following are the primary contributions of this paper:

- Combining YOLOv7 with the quantization-friendly reparameterization architecture Quantization-Aware RepVGG (QARepVGG) [11] reduces the model parameters, and accelerates beach litter detection.
- Introducing A Simple, Parameter-Free Attention Module (SimAM) [12] attention mechanism in the YOLOv7, it enhances the features already acquired, gathers more useful information from images of beach litter, lessens the negative effects of complex backgrounds, focuses the model on beach litter objects, and reduces missed and false beach litter detection.
- Using the modified Bidirectional Feature Pyramid Network (BiFPN) [13] to improve the Path Aggregation networks (PAFPN) [14] structure of the original Neck; increases the model's capacity to extract features of various sizes and raises the model's accuracy in the identification of beach litter.

This paper adopts the following aspects to carry on the research. Section II explains the related research of object detection and beach litter detection. Section III introduces the suggested algorithm and discusses the reasons for and advantages of introducing three innovations. Section IV introduces the self-built dataset and discusses and analyzes the experimental results of the algorithm on the self-built dataset. Section V concludes and looks ahead to future work.

II. Related Works

A. Object Detection

Since 2012, deep learning has significantly advanced target detection technology. Deep learning-based target identification algorithms provide the advantages of high accuracy and resilience when compared to conventional target detection techniques. Depending on whether they must create candidate areas or not, deep learning-based target identification algorithms may be split into single-stage target detection algorithms and two-stage target detection algorithms [15].

R-CNN [16] marked the emergence of two-stage object detection algorithms, which first generate candidate regions and then put the candidate regions into the classifier to classify and correct the positions. Next, other two-stage object detection algorithms were put forth one after the other, including Fast Region-based Convolutional Network (Fast R-CNN) [17], Faster Region-based Convolutional Network (Faster R-CNN) [18], and more. However, due to its slow detection speed, two-stage object detection algorithms perform less well in practical applications.

The single-stage target detection algorithm is simple in structure, scalable, and more widely used, does not require candidate regions to generate branches, and detects the candidate frames and classes of targets directly at multiple locations in the image for a given input image. Its representative algorithms, such as the first You Only Look Once (YOLO) version of the target detection algorithm YOLOv1 proposed by Redmon et al. [19] in 2015, which completely discards the candidate region generation step and integrates classification, localization, and detection functions into one network, greatly improving the detection speed, but there are issues with missed and false detection and poor detection of small and multiple targets because of the simple network structure. The Single-shot multi-box detector (SSD) developed by Liu et al. [20] in 2015, which first introduced the idea of multi-scale detection, can improve the model's ability to detect small objects and be designed with a prediction module and a deconvolution module; however, the algorithm sacrifices a larger detection speed in exchange for a significant improvement in detection accuracy. Later, on the basis of YOLOv1, Redmon et al. [21][22] subsequently suggested YOLOv2 and YOLOv3 in 2017 and 2018, respectively. In order to address the issues of low recall and poor localization accuracy, YOLOv2 borrowed the Anchor mechanism of the Faster R-CNN algorithm, removed the fully connected layer from the YOLO network, and used the convolutional layer to predict the position offset of the detection frame and the category information [21]. In order to save computing effort, the YOLOv3 algorithm creates the DarNet-53 backbone network and makes use of only the 1×1 and 3×3 convolutional layers [22]. The YOLOv4 model, developed by Bochkovskiy et al. [23] in 2020, by fusing CSPDarknet53 and SPP to broaden the sensory field, and increases the detection accuracy of tiny objects. By expanding the effective aggregation network, adding the REP layer to facilitate new deployments, and adding Aux_detect for auxiliary identification, the YOLOv7 approach, which Wang et al. [24] introduced in 2022, obtains advantages in both speed and accuracy.

Although the single-stage technique identifies objects more rapidly than the two-stage method does, the detection results are still insufficient in detection with complex backdrops and enormous variations in object size. This study updates the YOLOv7 network using a method that boosts the network's feature extraction power to address these shortcomings and enhance the capacity of beach litter detection.

B. Beach Litter Detection

In 2011 Nakashima et al. [5] used balloon-assisted aerial photography combined with in situ measurements to estimate the amount of large litter on beaches; however, there is a large difference in litter density from place to place, so there is a large error in monitoring the amount of litter on beaches. Jang et al. [6] suggested employing a method that includes color and morphological image processing to compute the generation rate by applying thresholds to drone photographs in order to extract information about beach litter from the images. In 2012, kako et al. [7] built a low-altitude remote sensing system using a remotely operated digital camera suspended from a balloon, combining projection transformation methods and chromatic aberration in uniform color space (CIELUV) to process the resulting images to identify beach or marine litter. In 2018 Bao et al. [8] used remote sensing to apply a two-step threshold filtering method to images obtained by drones to identify and detect the distribution of beach litter. The aforementioned study largely uses imaging techniques and projection transformation methods to monitor beach litter, however, it does not explicitly localize or identify beach litter, instead, it just monitors its amount.

Recently, researchers have started to carry out research and application practices for deep learning-based beach litter identification. In 2022, Rfeiffer et al. [9] investigated and compared the detection performance of two deep learning algorithms (YOLOv5 and Faster R-CNN) on images of beach litter taken by drones. The mAP value of YOLOv5 was 54.2% and the mAP of Faster R-CNN was 32.8%, the experimental findings demonstrate that the single-stage detection algorithm based on deep learning performs better for beach litter detection in terms of detection accuracy and detection speed. In a study of beach litter identification using YOLOv5 and camera acquisition picture data, Song et al. [10] achieved 87% detection accuracy, a notable increase over earlier research. In this investigation, over 90% of the dataset consisted of up-close images of beach litter collected at a height of 0.5 m. The beach litter objects in the close-up images were clear and there was mostly single-object beach litter in a single image, so a high detection accuracy was achieved; however, after using 1335 training photographs with complex backgrounds, the mAP of the plastic category significantly decreased from 88% to 26%, and there were some cases when shells were misclassified as plastic. Although there is a certain amount of misdetection, these experimental results show the immense potential and value of the YOLO model in beach litter detection application scenarios and demonstrate that the model's effectiveness in applications for identifying beach litter is significantly influenced by item morphology and characteristics, hyperparameter settings, and training data.

The analysis above shows that, even though YOLOv7's accuracy and efficiency have greatly improved over the previous YOLO model, more focused optimization is still required to increase the performance and suitability of beach litter detection.

First, it must be addressed that the number of model parameters and detection speed do not meet the needs of the actual applications. Wang et al. [25] incorporated GhostNet into the YOLOv5 model to improve its detection effectiveness. As a consequence, the number of parameters was successfully reduced by 47% and the computational complexity by 49.4%, but the detection accuracy fell by 2.2% compared to the original YOLOv5 model. By pruning the filters corresponding to the low-importance channels of the model to make it simpler to deploy the model to devices for real-time intelligent pedestrian monitoring, Xu et al. [26] obtained CAP-YOLO, which is three times faster inference than the original YOLOv3, but with a 7% reduction in mAP. Many current lightweight network models focus on compromising detection accuracy to boost detection speed, but beach litter detection demands high accuracy, hence this research introduces QARepVGG in YOLOv7 to enhance detection speed while enhancing the accuracy of beach litter detection.

Secondly, the beach litter dataset contains a complex background consisting of leaves, branches, and other kinds of interfering objects, with interfering objects obscuring the target, overlapping between the target and the target, and the problem of fuzzy targets exists. The YOLOv7 algorithm still encounters missed and incorrect detection in such intricate backgrounds. The attention mechanism is often used for complex backgrounds. The Coordinate Attention (CA) mechanism that TCA-YOLO [27] introduced in YOLOv5 to weaken the interference of complex backgrounds has greatly improved the detection accuracy of small targets, but the detection effect of larger targets still requires improvement.

Additionally, in the actual application environment for beach litter detection, the size and form of the litter also vary, and there are many tiny and medium-sized targets. The great variety in target sizes makes detection extremely challenging. Li et al. [28] proposed adding jump connection and multi-structure multi-size feature fusion in feature extraction and feature fusion to improve the detection accuracy but slow down the detection speed.

For efficient and accurate beach litter detection, it is not advisable to sacrifice the detection speed or accuracy. Therefore, considering the practical application scenarios of beach litter detection, this paper optimizes the YOLOv7 model according to the difficulties in beach litter detection and proposes QSB-YOLO for beach litter detection, and tests the optimized QSB-YOLO. The experimental results show that QSB-YOLO not only reduces the number of parameters of the model and improves the detection speed of the model, but also improves the detection accuracy of beach litter.

III. Materials and Methods

Considering the three problems in beach litter detection, we propose the beach litter detection method QSB-YOLO, whose overall network structure is shown in Fig. 1. Different from the original YOLOv7, QSB-YOLO replaces the first E-ELAN module of the YOLOv7 backbone network and the E-ELAN module in the neck with the quantization-friendly QARepVGG, then replaces the MP in the neck with the improved S-MP, and finally combines the idea of BiFPN to improve the original neck's PAFPN.

The beach litter image dataset is input into QSB-YOLO, and the image size is adjusted to 640×640 through input. The adjusted image is input into the backbone for feature extraction, and the obtained effective feature layers C3, C4, and C5 are input into the neck to strengthen the feature extraction of the network. The three outputs P3, P4, and P5 obtained from the neck are then sent to YOLOhead to predict the anchor frame, confidence, and category of beach litter after RepCov adjusts the number of channels.

A. *Combine the Quantization-friendly QARepVGG*

The approach of model compression known as quantization, which successfully reduces a model's number of parameters but also lowers the model's performance, is frequently overlooked in deep neural networks. The reparameterized architecture-based multi-branch design widens the dynamic numerical range, which creates an issue with the difficulty of quantization. But the reparameterization architecture QARepVGG we introduced is simple and efficient.

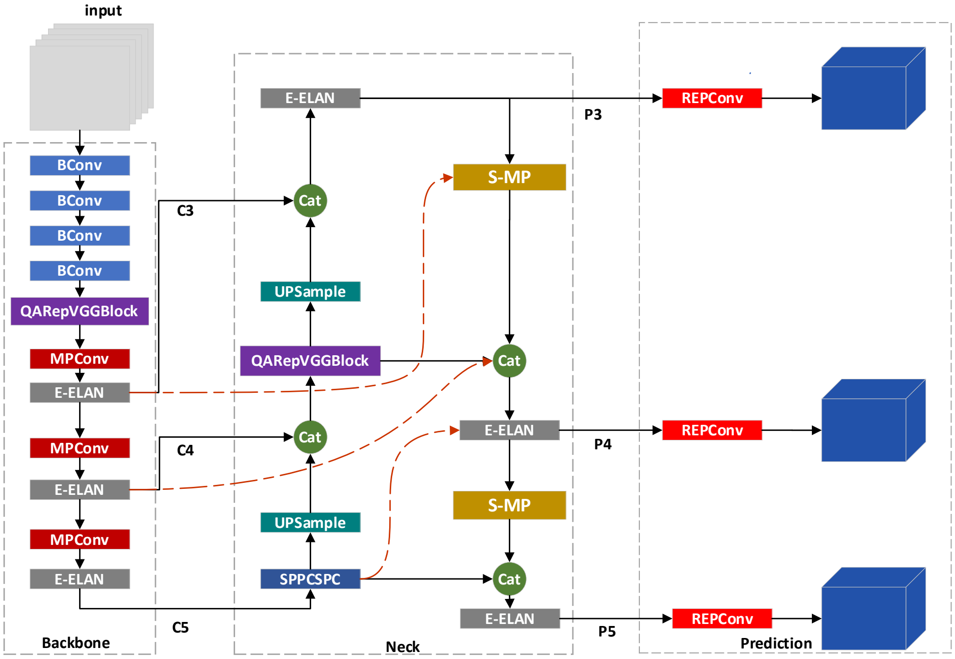

Fig. 1. The network structure of QSB-YOLO.

The custom weight decay design in RepVGG [29] is successful in building a model with a stronger weight distribution, but at the same time the variance of the activation distribution is amplified, the input of the subsequent layer depends on the activation, and the standard deviation rises layer by layer as the depth of the network layer increases, leading to an accuracy decrease. QARepVGG is improved based on RepVGG to solve the problem of quantization failure of RepVGG multi-branch design, which not only reduces the number of parameters of the model but also improves the detection accuracy and detection speed of the model [11]. According to the quantization-friendly features of QARepVGG, in order to improve the efficiency of beach litter detection, we combine QARepVGG in YOLOv7 and prove its effectiveness according to the experiment.

In order to measure quantification error, QARepVGG introduces mean square error (MSE), as in Equation (1).

$$MSE(Q(w,t,n_b),w)=\frac{1}{n}\sum_{i}(Q(w_i,t,n_b)-w)^2 \qquad (1)$$

where Q represents the quantization process, $w\in R^n$ represents the nth channel of the weights, t represents the stage threshold, and n_b represents the number of quantization bits. The output $M_{(2)}$ is:

$$M_{(2)}=BN(3\times 3)+BN(1\times 1)+BN(Identity) \quad (2)$$

$BN(3\times 3)$ is:

$$Y_{(3)}=\gamma_{(3)} □ \frac{M_{(1)} * W_{(3)}-\mu_{(3)}}{\sqrt{\varepsilon+\sigma_{(3)} □ \sigma_{(3)}}}+\beta_{(3)} \quad (3)$$

$Y_{(3)}$ is the output of the 3×3 branch, $\gamma_{(3)}$ is the scale factor of the BN layer after 3×3 convolution, $\mu_{(3)}$ is the mean value of the BN layer after 3×3 convolution, $\sigma_{(3)}$ is the standard deviation of the BN layer after 3×3 convolution, $\beta_{(3)}$ is the deviation of the BN layer after 3×3 convolution. $M_{(1)}$ is input, $W_{(2)}$ is 3×3 convolution kernel, □ is multiplication, ε is the value that ensures numerical stability (The default value is 10^{-5}). This indicates that BN has the effect of stabilizing the variation of the input.

Introduce random variables X and scalars λ, $D(\lambda\mathrm{X})=\lambda^2 D(\mathrm{X})$, and make $\mathrm{X}_{(3)}=M^1 W_{(3)}$, then we have

$$D\left(Y_{(3)}\right)=\frac{\gamma_{(3)} □ \gamma_{(3)}}{\varepsilon+\sigma_{(3)} □ \sigma_{(3)}} □ D\left(X_{(3)}\right) \qquad (4)$$

The variation size of $X_{(3)}$ is controlled by $\frac{\gamma_{(3)} □ \gamma_{(3)}}{\varepsilon+\sigma_{(3)} □ \sigma_{(3)}}$. The reparameterization-based architecture needs to quantify the weight distribution and activation distribution. Friendly quantization refers to having a relatively narrow range of values and a narrow distribution of standard deviations; when one of these features is missing; the standard deviation is amplified, which reduces the model's accuracy [11]. The RepVGG custom weight decay is as in Equation (5).

$$L_{2_{custom}}=\frac{\left|W_{wq}\right|_2^2}{\left|\frac{\gamma_{(3)}}{\sqrt{\varepsilon+\sigma_{(3)} □ \sigma_{(3)}}}\right|_2^2+\left|\frac{\gamma_{(1)}}{\sqrt{\varepsilon+\sigma_{(1)} □ \sigma_{(1)}}}\right|_2^2} \qquad (5)$$

RepVGG reduces the weight loss by enlarging the denominator, but enlarges the standard deviation distribution and amplifies the activation distribution deviation. Based on this, QARepVGG removes the BN in the identity branch and replaces the custom weight decay design in RepVGG with the standard weight decay design (normal L2). As a result, the module successfully completes weight quantization. The output is then rewritten as

$$M_{(2)}=BN(3\times3)+BN(1\times1)+Identity \qquad (6)$$

Let the anticipated values of 3×3 branches and 1×1 branches be

$$E\left(Y_{(3)}\right)=\beta_{(3)}, E\left(Y_{(1)}\right)=\beta_{(1)} \qquad (7)$$

The variance may grow if $\beta_{(3)}=\beta_{(1)}=\beta$, at this point $\mu=0$, $\sigma=0$, $\gamma=1$, $\beta=0$, then $Y_{(3)}$ and $Y_{(1)}$ are in balance. To better stabilize the variance, the BN in the 1×1 branch is further removed, at which time the output is

$$M_{(2)}=BN(3\times3)+(1\times1)+Identity \quad (8)$$

BN has the effect of stabilizing the input variance, and to stabilize the training process, QARepVGG adds batch normalization after three branches. At this stage, the output is

$$M_{(2)}=BN(BN(3\times3)+(1\times1)+Identity) \qquad (9)$$

As illustrated in Fig. 2, the QARepVGG first converts each of the three branches into a single 3×3 convolution, then combines the three into one, and lastly adds the 3×3 convolution with BN to get the final 3×3 convolution. A multi-branch structure is used during training to improve the model's detection accuracy and the network's capacity for representation. To speed up the model's detection, single-branch inference is employed in the inference process.

Fig. 3(b) depicts the topology of QARepVGG in the YOLOv7+QARepVGG backbone network during training, and Fig. 3(a) depicts the E-ELAN module it replaces; the structure of QARepVGG in the Neck of YOLOv7+QARepVGG is depicted in Fig. 3(d), and Fig. 3(c) is its replacement E-ELAN module. When there is no BN versus with BN, the number of parameters for convolution are calculated as shown in Equations (10) and (11), respectively.

$$params=C_o\times C_{in}\times k_h\times k_w+C_o \qquad (10)$$

$$params=C_o\times C_{in}\times k_h\times k_w+C_o\times2 \qquad (11)$$

where, C_o represents the number of output channels, C_{in} represents the number of input channels, k_h denotes the height of the convolution kernel, and k_w represents the width of the convolution kernel.

(c)

(d)

Fig. 3. Schematic diagram of QARepVGG. Comparison of modules before and after improvement. (a) The E-ELAN that was replaced in the backbone, (b) QARepVGG of the backbone during training, (c) The E-ELAN that was replaced in the neck, (d) QARepVGG of the neck during training.

TABLE I. COMPARISON OF THE NUMBER OF PARAMETERS

YOLOv7		**YOLOv7+QARepVGG**	
The sum of all parameters to be changed	value	The sum of all parameters to be changed	value
$params_1 + params_3 + params_5 \times 3 + params_7 \times 2$	1857024	$params_2 + params_4 + params_6 \times 3 + params_8 \times 2$	1067776

The number of parameters for the E-ELAM of the backbone network replaced by QARepVGG in the YOLOv7 is denoted by $params_1$, where Cat has no parameters. In YOLOv7+ QARepVGG, the number of parameters for the QARepVGG in the backbone network is denoted as $params_2$, where the 3×3 convolution has BN operation in QARepVGG, the identity branch has no parameters, and a new BN layer is added at the end. Similarly, the number of parameters for the E-ELAM of the Neck replaced by QARepVGG in the YOLOv7 is denoted as $params_3$, and the number of parameters for the QARepVGG in the Neck of YOLOv7+QARepVGG is denoted as $params_4$.

In addition to the replaced modules, the parameters for the remaining parts of the convolution were also affected. There are three convolutions that are $C_{in} = 256, C_o = 128, k_h = k_w = 1$ in YOLOv7 and become $C_{in} = 128, C_o = 128, k_h = k_w = 1$ in YOLOv7 +QARepVGG, and two convolutions in YOLOv7 that are $C_{in} = 512, C_o = 256, k_h = k_w = 1$ become $C_{in} = 384, C_o = 256, k_h = k_w = 1$ in YOLOv7+QARepVGG, the number of parameters for they are denoted as $params_5$, $params_6$, $params_7$, $params_8$, respectively.

The total number of parameters of the affected modules is shown in Table I. It can be inferred from Table I that after the introduction of QARepVGG, the number of parameters decreased by 789248, or about 2.1%.

B. S-MP

Through the analysis of the self-built beach litter dataset in this paper, we found that there exists a complex background composed of leaves, branches, and other kinds of distractors, the distractors obscure the target, the target overlaps with the target, and there is the problem of the target blurring, which easily causes missed and false detection. To improve this type of situation, this paper proposes to introduce an attention mechanism to attenuate the negative effects of complex backgrounds.

Traditional attention mechanisms, which produce one- or two-dimensional weights along the channel dimension or spatial dimension, focused only on this channel or this space, limit the flexibility of learning attention weights to alter throughout space and channel. Fig. 4 displays the SimAM schematic diagram. In contrast to the traditional spatial attention mechanism and channel attention mechanism, SimAM attention is a three-dimensional attention mechanism that assigns a unique weight to each neuron in space or channel without the use of additional parameters, determines the importance of each neuron, and then enhances the features using the three-dimensional weights. First, SimAM defines the energy function for each neuron as shown in Equation (12).

$$e_t\left(w_t, b_t, y, x_i\right) = \left(y_i - \hat{t}\right)^2 + \frac{1}{M-1}\sum_{i=1}^{M-1}\left(y_0 - \hat{x}_i\right)^2 \quad (12)$$

t represents the target neuron, $\hat{t} = w_t t + b_t$ represents a linear transformation of t. x_i indicates other neurons in the same channel as the input feature $X \in □^{C\times H\times W}$, $\hat{x}_i = w_t x_i + b_t$ is a linear transformation of x_i. i is the index in the spatial dimension, $M = H \times W$ is the number of neurons on the channel, w_t and b_t are respectively the weights and biases of the transformation. When Equation (12) reaches a minimum, the target neuron finds linear differentiability with other neurons in the same channel, at which time $\hat{t} = y_t$, and arbitrary $\hat{x}_i = y_0$. Binary labeling of y_t and y_0, and adding regularization to Equation (12) yields Equation (13).

$$e_t\left(w_t, b_t, y, x_i\right) = \frac{1}{M-1}\sum_{i=1}^{M-1}\left(-1-\left(w_t x_i + b_t\right)\right)^2 + \left(1-\left(w_t t + b_t\right)\right)^2 + \lambda \omega_t^2 \quad (13)$$

$$w_t = -\frac{2\left(t-\mu_t\right)}{\left(t-\mu_t\right)^2 + 2\sigma_t^2 + 2\lambda} \quad (14)$$

$$b_t = -\frac{1}{2}\left(t+\mu_t\right) w_t \quad (15)$$

$\mu_t = \frac{1}{M-1}\sum_{i=1}^{M-1} x_i$ and $\sigma_t^2 = \frac{1}{M-1}\sum_{i=1}^{M-1}\left(x_i - \mu_t\right)^2$ denote the mean and variance of all neurons except for that channel, respectively. The minimum energy is calculated as in Equation (16).

$$e_t^* = \frac{4\left(\hat{\sigma}^2 + \lambda\right)}{\left(t-\hat{\mu}\right)^2 + 2\hat{\sigma}^2 + 2\lambda} \quad (16)$$

$$\hat{\mu} = \frac{1}{M}\sum_{i=1}^{M} x_i \quad (17)$$

$$\hat{\sigma}^2 = \frac{1}{M}\sum_{i=1}^{M}\left(x_i - \hat{\mu}\right)^2 \quad (18)$$

$\frac{1}{e_t^*}$ indicates the importance of each neuron. That is the smaller the value of e_t^*, the more the target neuron is distinguished from other neurons and the greater the importance. Subsequently, feature enhancement is performed according to the definition of attention mechanism as in Equation (19).

$$\tilde{X} = sigmoid(\frac{1}{E}) \Box X \tag{19}$$

To reduce missed and false detection in beach litter detection and enable the model to obtain more useful features without increasing the model's parameters, we introduce the SimAM attention mechanism in the MP module in the neck of YOLOv7.

The MP in Neck is down-sampled in YOLOv7 using both Maxpool and BConv, and the features from each are then combined. As shown in Fig. 5, the SimAM attention mechanism is introduced to replace BConv in the second branch of the MP structure. the input of S-MP is down-sampled by Maxpool in the first branch, and then the number of channels is adjusted by BConv. In the second branch, the features are enhanced by the SimAM attention mechanism while adjusting the number of channels and then down-sampling by BConv. Finally, the features obtained from the two branches are feature fused to obtain the results of the enhanced down-sampling and obtain more effective features.

(b)

Fig. 5. Structure diagram of MP. (a) MP, (b) S-MP.

C. Improved-BiFPN

BiFPN is a feature fusion technique that combines weighted feature fusion with an efficient bidirectional cross-scale connection. The traditional Feature Pyramid Network (FPN) [30] fuses multi-scale features in a top-down manner, and the down-sampling process loses feature information at the highest level, reducing the multi-scale representation capability. A top-down, bottom-up path aggregation network is added by the PAFPN in the YOLOv7 network design. As shown in Fig. 6(a), in order to fuse more features without incurring excessive costs, the idea behind BiFPN is to add an extra edge to the original input and output nodes at the same layer; additionally, each bidirectional path is treated as a layer of the feature network, and the same layer is repeated multiple times to achieve a higher level of feature fusion.

We combine the idea of BiFPN and modify the PAFPN in the YOLOv7 network into the Improved-BiFPN to realize the bi-directional fusion of different network feature layers and enhance the information transfer between different network feature layers. As shown in Fig. 6(b), the three effective feature layers extracted from the backbone network are C3, C4, and C5, which are passed into the Improved-BiFPN to achieve effective bidirectional cross-scale connectivity and weighted feature fusion, resulting in a total of three different scales of P3, P4, and P5 output features.

IV. Results and Discussion

A. Dataset Acquisition and Pre-processing

The beach litter image collection used in this paper was collected from several popular tourist beaches along the coast of South China. A total of 1587 beach litter photographs were captured by cameras during the beach survey, with resolutions ranging from 4000×2250 pixels to 480×360 pixels. To avoid the issue of overfitting brought on by insufficient training samples, data enhancement techniques such as rotation, color enhancement, and contrast enhancement were applied to each image separately, as shown in Fig. 7. After data augmentation, there are 6348 pictures overall, of which 90% are separated into training set and 10% into test set.

The self-built beach litter dataset collected a total of six categories of litter, including plastic products, metal products, paper products, wood, styrofoam, and glasswork, and the examples of each category are shown in Fig. 8. The beach litter image dataset used in this study was manually annotated using LableImg annotation software and saved in YOLO format.

B. Experimental Parameter Settings

In this paper, there are 6348 beach litter image dataset, 5714 images are used as the training set, and 634 images as the test set. The experimental configuration is shown in Table II. The operating system used for training is Ubuntu 18.04.1, the GPU is NVIDIA GeForce RTX 3060 with 12G of video memory, the CPU is 11th Gen Intel(R) Core (TM) i5-11600KF, and the memory is 16G. The batch size is 8, the initial learning rate is 0.1, and 300 Epochs are trained.

TABLE II. HARDWARE EQUIPMENT AND DEVELOPMENT ENVIRONMENT

Equipment	Model
GPU	NVIDIA GeForce RTX 3060
CPU	11th Gen Intel(R) Core (TM) i5-11600KF
Ubuntu	18.04
CUDA	10.2
Python	3.7
Pytorch	1.8
Torchvison	0.7.0

C. Evaluation Indicators

This study evaluates the model using Average Precision (AP), Mean Average Precision (mAP), Parameters (Params), Frames Per Second (FPS), and F1. The value of AP, which measures the typical detection accuracy of a single category of beach litter, is the area of the P-R curve. The accuracy rate and recall rate are the P-R curve's vertical and horizontal coordinates, respectively. Equations (20) and (21), respectively, are used to compute the precision rate, P, and recall rate, R. Equation (22) is used to compute the value of the AP. Equation (23) is used to construct mAP, which is a measure of the average detection accuracy across all categories. The Params is used to measure the size of the model. FPS is a unit used to express how quickly a model can identify an object. The fraction of recalled genuine positive categories is measured by F1, which is determined using Equation (24).

Where TP denotes that the actual result is identical to the expected result, FN denotes that the category of beach litter is judged to be another category of beach litter or to be missed detection, and FP denotes that the non-beach litter target is detected as beach litter.

$$P = \frac{TP}{TP + FP} \tag{20}$$

$$R = \frac{TP}{TP + FN} \tag{21}$$

$$AP = \int_0^1 P(R)dR \tag{22}$$

$$mAP = \frac{\sum_{i=1}^{N} AP_i}{N} \tag{23}$$

$$F1 = \frac{2PR}{(P + R)} \tag{24}$$

D. Analysis of Experimental Results

1) Comparison Experiments Combining QARepVGG: To verify the effectiveness of the quantization-friendly QARepVGG method combined in this paper, RepVGG will be introduced in YOLOv7 to conduct comparative experiments with YOLOv7+ QARepVGG on our beach litter dataset, and the experimental results are shown in Table III.

TABLE III. COMPARATIVE EXPERIMENTS COMBINED WITH QAREPVGG

Model	mAP@0.5	Params	Inference times	FPS(f/s)
YOLOv7	79	37223526	11.8ms	40
YOLOv7+RepVGG	77.7	36434534	8.4ms	56
YOLOv7+QARepVGG	**80.7**	**36434278**	**8.0ms**	**58**

The reparameterized architecture of RepVGG's 1×1 branch at training time than QARepVGG's 1×1 branch has one more BN operation, so the overall number of YOLOv7+ RepVGG parameters is 256 more than YOLOv7+ QARepVGG. The inference time of YOLOv7+RepVGG is 3.4ms faster than YOLOv7, but it is 0.4ms slower than YOLOv7+QARepVGG. The detection speed of YOLOv7+RepVGG is 16 f/s faster than YOLOv7, but 2 f/s slower than YOLOv7+QARepVGG.

RepVGG reduces the inference time and improves the detection speed significantly, but sacrifices the detection accuracy. While reducing the number of parameters in the model and increasing the detection accuracy of beach litter by 1.7%, QARepVGG increases inference speed and detection speed. Therefore, in this paper, we choose to introduce the quantization-friendly QARepVGG for beach litter detection.

2) Comparison experiments with attention mechanisms: In this paper, we combine the Convolutional Block Attention Module (CBAM) [31] and Efficient Channel Attention Module (ECA) [32] with the MP module of Neck in YOLOv7 and compare them with YOLOv7+S-MP for comparison, and the experimental results are shown in Table IV. Where C-MP denotes the use of the CBAM attention mechanism in place of the first convolution of the original Neck's second branch of MP. E-MP denotes that the first convolution of the second branch of MP in the original Neck is swapped out for the ECA attention mechanism.

CBAM is a hybrid attention mechanism, YOLOv7+C-MP detection accuracy is reduced by 3.2% compared to YOLOv7, F1 is reduced by 0.03, and the number of parameters is reduced less. Both ECA and SimAM are parameter-free attention mechanisms, and when the same convolution is replaced, YOLOv7+ E-MP has the same number of parameters as YOLOv7+S-MP. However, when ECA is added, mAP@0.5 is decreased by 10.5%. Beach litter detection on complicated backdrops is not appropriate for either CBAM or ECA, which both decrease the mAP@0.5 of beach litter. While adding the SimAM attention mechanism the mAP@0.5 is increased by 3.9%, F1 by 0.04, and the parameter-free attention mechanism does not negatively affect the number of model parameters.

TABLE IV. COMPARATIVE EXPERIMENTS OF ATTENTION MECHANISMS

Model	mAP@0.5	F1	Params
YOLOv7	79	0.73	37223526
YOLOv7+C-MP	74.8	0.70	37151684
YOLOv7+E-MP	68.5	0.65	**37140838**
YOLOv7+S-MP	**82.9**	**0.77**	**37140838**

3) Comparison experiments of improved enhanced feature extraction network: PAFPN is used as an enhanced feature extraction network in the original YOLOv7's Neck. The Improved-BiFPN is suggested to replace the original PAFPN in this research in order to increase the detection capabilities of the model for various sizes of beach litter in practical applications. The acquired findings are displayed in Table V. When compared to the original model, the Improved-BiFPN increases the network's detection capacity for targets of various sizes, while also increasing mAP@0.5 by 4.1% and the F1 by 0.05. The Improved-BiFPN significantly improves the detection accuracy of the model without a significant increase in the number of parameters and without decreasing the detection speed, therefore we replace the original Neck for beach litter detection.

TABLE V. COMPARATIVE EXPERIMENTS OF NECK

Model	mAP@0.5	F1	Params	FPS(f/s)
YOLOv7	79	0.73	**37223526**	**40**
YOLOv7+Improved-BiFPN	**83.1**	**0.78**	37354598	**40**

4) Comparison Experiment of Beach Litter Classification Results: The AP of each category of various detection models in the self-built beach litter dataset is displayed in Table VI.

Styrofoam, paper products, and glasswork have excellent AP when YOLOv7 is used directly for beach litter detection, whereas the AP of plastic products, metal products, and wood is relatively low. In YOLOv7+QARepVGG, the AP of each category is well balanced, with the exception of metal products, whose AP has decreased by 3.9%. It is clear that the AP of each category has improved after the SimAM attention mechanism was added to the MP module, and glasswork and metal products have the best average accuracy in comparison to the other models in this research. The introduce of improved-BiFPN effectively contributes to the improvement of AP for each category, with the most notable improvement of 12.4% in AP for wood beach litter with high size variation. In QSB-YOLO, the best AP was achieved for styrofoam, plastic products, and paper products relative to all other models, and the AP for glasswork and wood improved by 3.9% and 6.6%, respectively, with only a slight decrease of 2% for metal products. In conclusion, in general, QSB-YOLO is significantly better than the original algorithm.

TABLE VI. AVERAGE PRECISION FOR EACH CLASS OF BEACH LITTER

Model	Styrofoam	Plastic products	Metal products	Paper products	glasswork	Wood
YOLOv7	88.6	69.6	69.4	83	92.7	70.9
YOLOv7+QARepVGG	90.2	77.3	65.3	86.6	92.2	77.5
YOLOv7+S-MP	92.2	71.4	**71.4**	90.4	**98.7**	73.4
YOLOv7+Improved-BiFPN	93.2	77.9	68.1	87.4	88.9	**83.3**
QSB-YOLO	**94.3**	**80.7**	67.4	**92.5**	96.6	77.5

5) Ablation experiments: To verify the effectiveness of each improvement method in this paper, the three improvement modules were added to the original YOLOv7 network structure one by one, and the ablation experimental results are shown in Table VII and Fig. 9.

Table VII shows that, in comparison to the YOLOv7 model, the YOLOv7+QARepVGG model adds the quantization-friendly QARepVGG module, which not only reduces the number of parameters of the model, increases its detection speed and inference speeds, but also contributes to the improvement of the mAP@0.5 of the model. Both YOLOv7+SimAM and YOLOv7 +improved-BiFPN improve the mAP@0.5 and F1 of the model compared to the original YOLOv7. Compared to the original model YOLOv7, QSB-YOLO's mAP@0.5 raises 5.8%, the F1 increases by 0.08, the number of parameters decreases by 281600, the inference speed is accelerated by 3.5ms, and the detection speed of the model is improved by about 43%.

Fig. 9 visualizes the performance difference between each individually added module and YOLOv7 and QSB-YOLO. As can be seen from Fig. 9, the QSB-YOLO model has superior performance and is somewhat advanced in the training process for beach litter detection.

TABLE VII. RESULTS OF THE ABLATION EXPERIMENT ON THE BEACH LITTER DATASET IN THIS PAPER

Model	mAP@0.5	F1	Params	Inference times	FPS(f/s)
YOLOv7	79	0.73	37223526	11.8ms	40
YOLOv7+QARepVGG	80.7	0.75	**36434278**	**8.0ms**	**58**
YOLOv7+S-MP	82.9	0.77	37140838	11.8ms	40
YOLOv7+Improved-BiFPN	83.1	0.78	37354598	11.8ms	40
QSB-YOLO	**84.8**	**0.81**	36941926	8.3ms	57

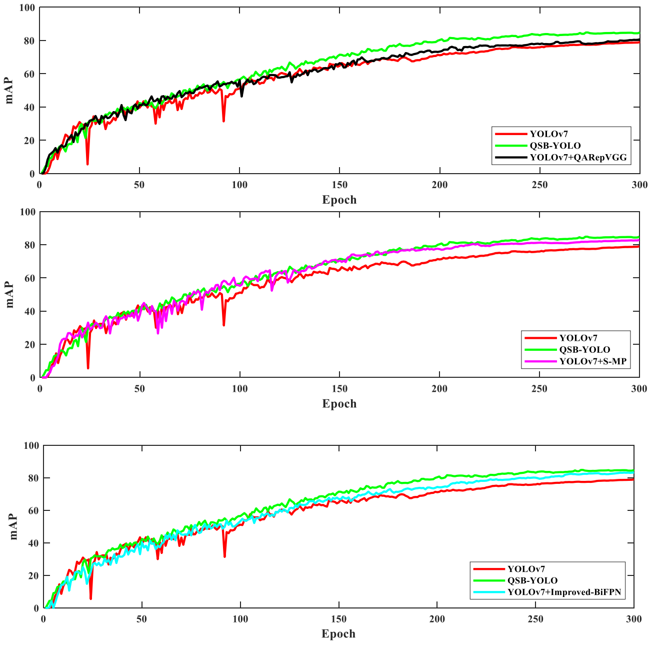

Fig. 9. Comparison chart of ablation experiments.

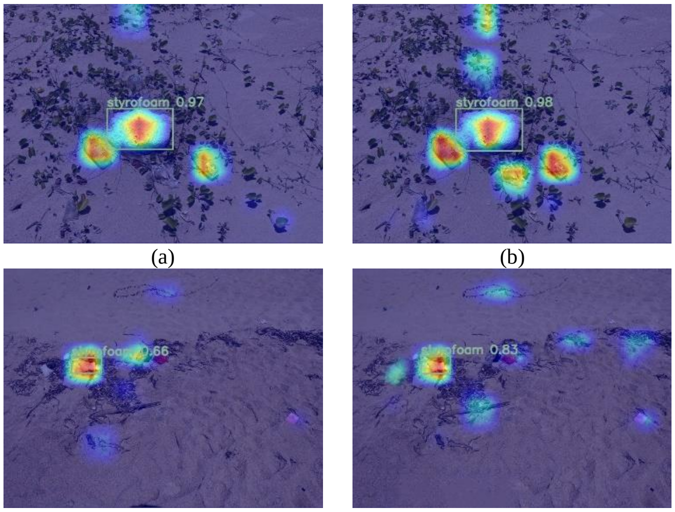

(a) (b)

(c) (d)

Fig. 10. Heatmap visualization results. (a), (c) the heatmap of YOLOv7; (b), (d) the heatmap of QSB-YOLO.

Fig. 10 shows the heatmap of YOLOv7 and QSB-YOLO, where the darker color represents the more attention of the model. We can see that in a complex background, QSB-YOLO has significantly enhance its ablility to focus on beach litter and has focused on some targets missed in YOLOv7.

6) Comparison with other traditional models: To demonstrate its superiority for beach litter detection, we compare the OSB-YOLO with Faster R-CNN, EfficientDet [13], SSD, YOLOv5 [33], YOLOX [34], and YOLOv7 algorithms. The input image size is 640×640, and the framework used is Pytorch. The experimental results are displayed in Table VIII. Under the same experimental setup and beach litter dataset, QSB-YOLO beats other traditional models in terms of detection speed and mAP@0.5.

TABLE VIII. COMPARISON OF DIFFERENT MODEL DETECTION RESULTS

Model	mAP@0.5	FPS(f/s)
Faster R-CNN	50.9	13
EfficientDet	51.6	23
SSD	62.5	28
YOLOv5	76.8	36
YOLOX	77	37
YOLOv7	79	40
QSB-YOLO	**84.8**	**57**

7) Image detection results: To confirm the real detection performance of QSB-YOLO for beach litter in this paper, we compared the detection effects of YOLOv7 and QSB-YOLO, as illustrated in Fig.11.

It can be found in Fig. 11 that YOLOv7 in Fig. 11(a) does not detect the plastic products beach litter which is fuzzy and smaller in size in the distance, and QSB-YOLO successfully locates and identifies the beach litter. Fig. 11(c) misses a plastic products beach litter of smaller size relative to other beach litter, which QSB-YOLO also successfully identifies and locates, and the confidence of QSB-YOLO's prediction frame is significantly higher than the confidence of YOLOv7. The beach litter image in Fig. 11(e) has a complex background, and the leaves obscure some of the targets, and YOLOv7 mistakenly detects the leaves as beach litter, and there are also missed detections. In Fig. 11(f), there is no false detection and three fewer missed detections, and only one plastic products beach litter obscured by leaves is not detected.

In summary, compared with the original algorithm, the detection accuracy of QSB-YOLO proposed in this paper is significantly improved, and the leakage and false detection are reduced.

V. Conclusion

In our study, we apply data augmentation approaches for the beach litter dataset to increase the model's detection range for beach litter in order to avoid overfitting caused by inadequate samples and propose an efficient QSB-YOLO beach litter detection model to address the issues of missed and false detection in beach litter identification. In addition to reducing the number of model parameters, combining with the quantization-friendly QARepVGG also enhance the model's detection precision and speed. The self-built beach litter dataset used has a complicated backdrop, which causes issues like blurred targets and obscured targets. In order to focus the model on the objective of beach litter and improve detection performance while reducing the possibility of missed and false detection, the MP module in the Neck is paired with the 3D SimAM attention mechanism. The original PAFPN is replaced with the Improved-BiFPN to increase the network's ability to learn various size characteristics, address the detection difficulties issue brought on by the large size range of beach litter targets, and enhance the model's detection accuracy.

The experimental results show that the QSB-YOLO suggested in this research is far better than the original YOLOv7 and other traditional target detection models for beach litter identification accuracy and detection speed.

In future work, we plan to expand the beach litter dataset to include more diverse beach litter targets and continue research to solve the difficulties beach litter identification in complicated contexts, so as to further improve the practical application value of the model.

ACKNOWLEDGMENT

Thanks are given for the support of Research on Key technologies of intelligent health diagnosis of reservoir Dams driven by knowledge and data (QiankeheSupport [2023] General 251).

SECI Model Design with a Combination of Data Mining and Data Science in Transfer of Knowledge of College Graduates’ Competencies

Mardiani[1], Ermatita[2], Samsuryadi[3], Abdiansah[4]
Department of Computer Science and Engineering, Universitas Multi Data Palembang, Palembang, Indonesia[1]
Department of Computer Science, Universitas Sriwijaya, Palembang, Indonesia[2, 3, 4]

***Abstract*—One of the methods in knowledge management that can be used is the SECI Model. The SECI Model transfers tacit and explicit knowledge in each quadrant. However, without using tools, the transfer of technical knowledge will experience various obstacles. These obstacles included limited knowledge of the informants, difficulty in translating what was conveyed by the informants, limited time and opportunities, and unclear results obtained. The transfer of knowledge needed by college institutions is in the form of input from graduates who have graduated from college institutions. Graduates' knowledge must be obtained to determine whether their competence is following their respective fields of knowledge. Information technology can help overcome technical problems in transferring knowledge, including the problem of large amounts of data. Data science will deliver results from a combination of technology and mathematics. Meanwhile, data mining, especially with classification, grouping, and association functions, can provide a clear picture of the needs of higher education institutions for the knowledge of their graduates to assess the curriculum that has been provided so far. The design formulation of the SECI model and the implementation of this data mining use an empirical approach through observation and experimentation with quantitative data, as well as theoretical thinking in supporting the development of the model development concept. Data mining and data science will clarify processes in the SECI Model quadrant regarding technological tools in the context of knowledge transfer in a circular manner between tacit and explicit, in order to be more directed and precise. Information extracted from graduate competencies can assist college institutions in formulating future strategies in the academic field, especially the curriculum in study program. This result will impact students in the future, where the developed curriculum will focus more on the results of the input of graduate students.**

***Keywords*—Model SECI; data mining; data science; competence of graduates**

I. Introduction

Competence is defined as knowledge, skills and individual abilities that can directly influence entrepreneurial activity, which is the goal to be achieved [1]. Meanwhile in the field of education, measuring the competence of graduate students can be done using the models that describe the transfer of information, such as the SECI model (Socialization, Externalization, Combination, and Internalization). In [2], the study relates to the design of measuring instruments and means to measure student competence in the enterprise system laboratory and research solutions using the SECI model.

Data science, predictive analytics, and big data have been frequently implemented in various fields. Rigorous academic investigation of this science and method will lead to new areas. Article [3] discussed the results of a recent large-scale survey among supply chain management professionals on this topic. Data analytics and big data are also discussed in the research [4] which review how data mining and learning analytics have been applied to education data. In the last decade, the field of research has grown enormously. Various related terms are used in bibliographies such as academic, institutional, and teaching analytics, data-driven, decision-making, big data, and data science in education.

The data mining functionality helps in predictions of various things such as predicting customer buying behavior in the field of business [5], and predicting the final residual value in education field [6]. Besides prediction, the most frequently used functionality is clustering and classification. In the era of big data, in particular, clustering is a prevalent theme [7]. Finding clusters with different densities is usually tricky because finding clusters with various densities uses a fixed radius. The extended method was used to find clusters with different densities [8]. As in research [9], The K-means algorithm, which considers the distance from each point to each centroid in each cluster, is also commonly used. Decision tree classification is a method that is also commonly used [10]. At the same time, other algorithms in classification techniques are often compared [11].

Outliers in the data sometimes occur, namely when mining is done and patterns in the data that do not match the expected behavior found. Develop work using a statistical approach used to detect outliers [12]. Evaluation of the performance of data mining classification methods, for example, in research [13] that evaluates classification performance in the Internet of Things applications, needs to be done. Related research describes a significant literature survey of Sustainable Smart Cities, Machine Learning, and Data Mining. The most cited relevance and method and feature set data were identified, read, and summarized [14]. In research [15], a survey was conducted, which reviewed and discussed a detailed analysis of 142 research articles using various techniques. This survey will later introduce a model of the various data mining functionalities.

Data collection was necessary for knowledge transfer. A qualitative approach was used to analyze the collected empirical data. Data was collected using various sources, including semi-structured interviews, questionnaires, and internal document processing [16]. Tools were discussed in a study [17] which presents data mining in the data transfer process using the SECI model. However, the discussion was still unclear, there must be a more detailed explanation regarding data mining in each quadrant.

Research conducted with large amounts of data or without special tools would make it difficult for researchers to examine the data. In terms of quantitative data in particular, using tools in the form of technology was very useful in collecting and processing data. Data mining could be used in information dissemination and data processing. In data management, data mining techniques can extract and find valuable and meaningful information from large amounts of data [18]. Implementing information technology, especially data mining, reduces the burden of human error. However, the process still needs to be carried out clearly and in detail, so that every point in the SECI model process can ensure the correctness of the data transfer process.

Graduate competence is very important for Higher Education. Students must be prepared to stand out in the workforce after graduation. Transferring information from graduates can allow college to obtain data and information which can be used as a strategic aspect in future curriculum development. Transfer of graduate knowledge with the SECI Model design was accompanied by improvements to the data mining design in each quadrant of the SECI model can help to overcome the previous model's shortcomings. The design of this research model was a refinement of the previous model, where the SECI model quadrant has data science and data mining which were more detailed in the process and has a special data mining algorithm.

II. Literature Review

A. *Transfer of Knowledge with the SECI Model and Information Technology*

State of the art mapping and knowledge transfer research gaps using the SECI model have been discussed from the discussion of previous preliminary research [18]. Data analysis from related papers were presented generally in the form of bibliographic data analysis using the Vos Viewer as illustrated in Fig. 1 below:

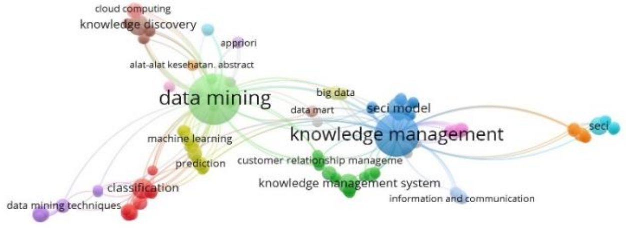

Fig. 1. Bibliometric network visualization output results.

Several studies that show the use of SECI model include designing measuring instruments and determining how to measure with SECI model [2] and managing knowledge using the perspective of SECI model [19]. Then to get something or new results using SECI model was shown in studies that empirically test the analysis to create knowledge models [16] and knowledge transfer using SECI model to create new knowledge [20]. While from a technical point of view, research [21] actualizes and provides empirical consistency to the theory underlying the SECI model.

Information technology as a tool, will facilitate the search for results. Research [22]–[24] uses data mining as a tools to create knowledge management system. Process Knowledge discovery process from databases use data mining techniques, and the SECI knowledge dimension model. Thus, information technology enables the completion of various functions with SECI model.

B. *Slice of Knowledge Mapping Gap*

Information technology can be used for the design of models and frameworks. The framework builts by adding information technology to the knowledge management system [17]. Models can be developed by exploring the adaptation of information technology to the knowledge conversion process [25].

The SECI model helps a lot in transferring information in building a knowledge management system in an organization [16], [20], [21]. With SECI model, knowledge transfer will become more focused and measurable in each quadrant. Research gaps can be seen in weaknesses that arise when tools are not used, as in research [2], where human abilities, understanding, and resources limit the knowledge transfer to the graduates. There are often inconsistent perceptions between respondents and interviewers. Another loophole occurred in research [25] where there were limitations in data collection due to privacy issues related to sources and some informants' refusal to participate in the research.

Research that used technology to assist, is limited by small and inadequate sample of data [26], and not all implementations of information technology fit in every phase of SECI model [24]. Data mining as part of information technology has been implemented in research [17]. However, the discussion is still unclear and concrete; each SECI process must have an explanation in its quadrants. From the deficiencies described, the previous model needs to be corrected and revised, as discussed in several articles. Data mining has more detailed features to explain each data transfer process. Functions that can be used include classification, grouping, and association functions. This function can complement the model created to explain and fill the gaps in previous research. When designing data mining models in the SECI model, relevant and suitable algorithms can be used in the quadrants of the SECI model.

III. Research Methodology

The stages for the research method begin with data collection. Data is used to formulate the problem, which can be done using data collection techniques in the form of a literature study. This data collection technique is carried out by collecting the required data using literature studies and looking for scientific journals related to the research theme. Related journals are built in the form of state-of-the-art to get research gaps. The next stage is direct interviews conducted with the head of the Study Program, the Dean, and Vice Chancellor III of student affairs, as well as distributing questionnaires to respondents, namely graduates—technical data collection using written and computer media tools. The questionnaire was carried out by asking several questions to the respondent, namely graduates who had worked. The questionnaire results are stored in written documents or computerized storage media. This initial stage is the first stage in the SECI model, namely socialization which is the transfer of knowledge from tacit to tacit.

The next step is the Externalization stage, where data transformation is performed. At this stage, hypotheses and conclusions are sought from the data that has been obtained. This process continues to the data cleansing process, which is carried out because the data received is still not clean and must be reprocessed before proceeding with the next data. The Externalization quadrant focuses on data documentation for storing data from tacit to explicit.

After the data is transformed or processed, it is continued to the data analysis stage at the Combination SECI explicit to the explicit stage. Datasets that have gone through the process of transformation and cleansing are then grouped using the K-Means Algorithm before being predicted using the same data. Classification forecasts use the Decision Tree Algorithm to test future possibilities. The third data mining functionality, namely the association, uses the Apriori Algorithm, which adapts transaction data to map graduate competency data with associated attributes. At the data analysis stage, system design and development are in the combination phase. Patterns are extracted from the test data to produce output from training data. Discovery Process describes data mining as the process of disseminating data. Data mining is about finding information or information that was not previously known to exist. Data science plays a role in information extraction, where data science helps extract valuable information from mined data. Data is analyzed from data mining results, identifying relevant patterns, trends, and relationships and exploring insights that can be used for decision-making.

The internalization process is carried out by transferring knowledge from explicit to tacit. This is done after the system is completed, implemented, and tested. This process is carried out by returning explicit knowledge to tacit by sharing the analysis results with users. The results of this analysis can also be strategically used by management.

The following is a draft framework for the SECI model with data mining and data science for graduate competency data, which is given in Fig. 2.

Tests and results can be carried out using statistical methods to test the results of the implementation of data mining and the knowledge management model built whether they are appropriate and suitable, then conclusions are drawn. Testing and evaluation performed with tools to see the relationship between the model results built and user needs.

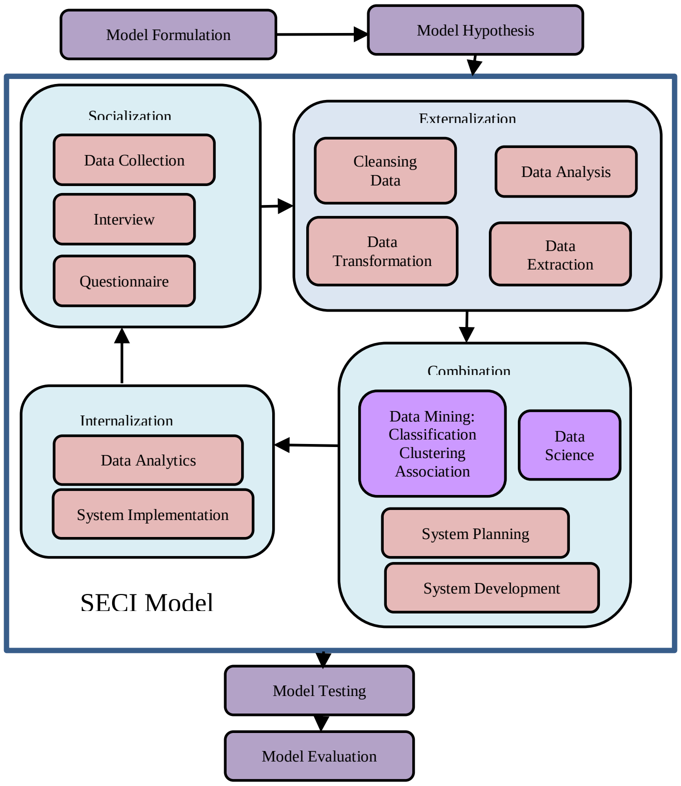

Fig. 2. SECI model framework with data mining and data science.

IV. Result and Discussion

A. Stages of Socialization

The first stage is in the socialization quadrant. Data is collected by tacit to tacit knowledge. Knowledge from related parties who mastered and indeed in their fields to formulate graduate competencies was interviewed. The parties in question are the Head of the Study Program, the Dean, and Vice Chancellor III, who handle students' affairs and graduates. This interview was conducted based on official documents from the government in the form of a Regulation of the Minister of Research, Technology, and Higher Education of the Republic of Indonesia. Government regulations define National Higher Education Standards for various levels of education programs. This research is limited to the undergraduate graduates in two fields of study: computer science and also economics and business.

The competence of graduates is contained in four formulations, namely the formulation of general attitudes and skills, which contain the same formulation for all study programs. The following formulation is specific knowledge and skills tailored to each study program. From interviews with related parties, graduates' competency formulations were obtained and mapped into questionnaire questions aimed at the intended respondents, which is the graduates.

B. Stages of Externalization

The next SECI quadrant is the externalization stage which includes the process of cleansing and transforming data. The data is divided into two types of respondents with questions tailored to their respective fields of knowledge. From a population of 6,536 graduates of a tertiary institution, a sufficient number of samples will be sought. Respondents consisted of graduates from two science fields, computer science, and economics. Respondents from the computer science field consisted of information systems, informatics, informatics management, accounting computerization, and computer engineering study programs. Meanwhile, respondents from economics consisted of management and accounting study programs.

The data from the results of filling out the questionnaire totaled more than 400 respondents. After cleansing, it was found that some data did not meet the requirements, such as blank and double contents. From the cleaning results, clean data for 387 graduates was obtained. According to the Slovin formula, from a total population of N totaling 6,536 graduates and with an error tolerance of e = 0.05, the minimum number of samples of n respondents is obtained as follows:

$$n = \frac{N}{1+Ne^2} \tag{1}$$

$$n = \frac{6536}{1 + 6536 * 0.05^2}$$

$$n = 376.93 \approx 377$$

With this result, this number is sufficient for the minimum number of the total population of all graduates. Then testing the data is done, namely the validity and reliability testing. Validity test is done to see the correlation of each question to other questions. Following are the results of the correlation validity test for each question for the data types of respondents who are graduates of computer science and economics and business, which are presented in Fig. 3 and 4.

From the two pictures above, with an error tolerance of 0.05 from the r table value of 0.1195 for computer science graduate data and 0.1851 for economics graduate data, it can be seen in these figures that the r count meets the r count requirements exceeding the r table value and can be said to be valid.

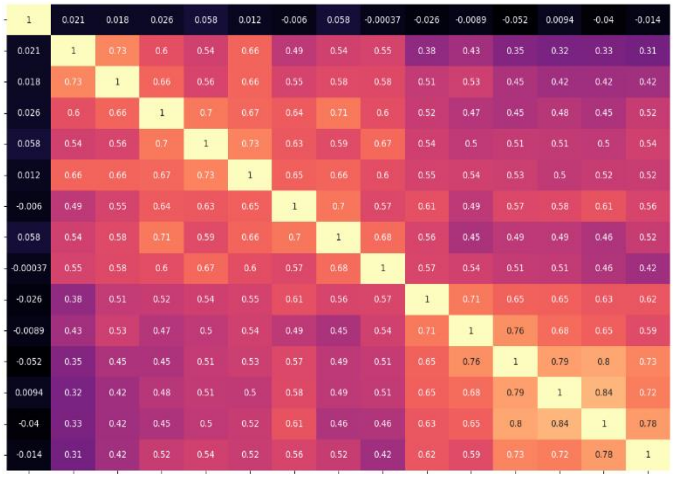

Fig. 3. Data validity of computer science graduates.

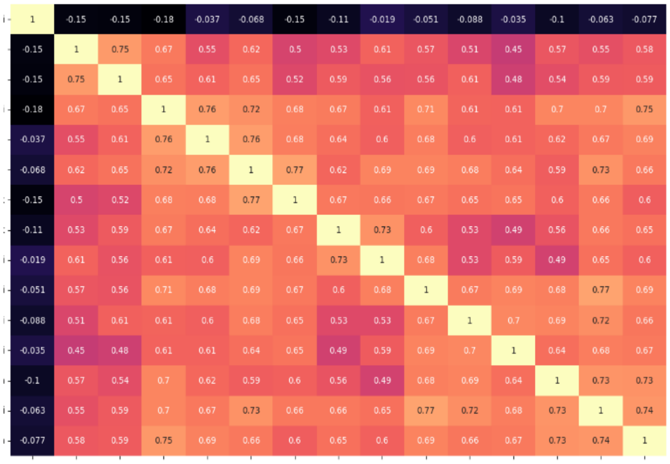

Fig. 4. Data validity of economics and business graduates.

Reliability test for computer science, and economics and business graduate data is presented in Tables I and II below:

TABLE I. RELIABILITY STATISTICS DATA OF COMPUTER SCIENCE GRADUATES

Cronbach's Alpha	N of Items
0.948	14

TABLE II. RELIABILITY STATISTICS DATA OF ECONOMICS AND BUSINESS GRADUATES

Cronbach's Alpha	N of Items
0.961	14

From the results of the reliability test above, it was found that the reliability value was > 0.9. Then the data reliability results are included in the firm and perfect category. The data transformation process adjusts the data format to enter the data mining technical process.

C. *Stages of Combination*

The system was built and designed with data mining at the SECI combination model stage consisting of three primary functions: classification, clustering, and association. The data is divided into three appropriate sections for the three functionalities of classification, clustering, and association. Especially for associations, the data is adjusted to the number of choices of respondents' answers so that the amount of data is no longer the number of respondents but the number of choices.

1) Classification: The classification dataset consists of 14 questions covering three elements of attitude, five elements of general skills, four elements of knowledge, and two unique skills. Because the questions on specific knowledge and skills are divided into two types, the total number of questions is 20. The details of the questions are presented in Table III below:

TABLE III. QUESTIONS IN GRADUATE COMPETENCY QUESTIONNAIRE

No.	Element	Competency Standards
1	Attitude	Deity
2		Nationalism
3		Personal
4	General Skills	Problem Solver
5		Managerial
6		Scientific Communication
7		Relationship Quotient
8		Self-development
9	Knowledge	Literacy Knowledge (Computer/Economics)
10		(Computer/Economics) Basics
11		(Computer/Economics) Knowledge
12		(Computer/Economics) in depth
13	Special Skill	Software Development/General Management and Accounting Concepts and Principles
14		Data and Analytics/Enterprise Analysis

The target variable in the graduate competency dataset is whether the graduate's work is following the field of study according to the study program or not. The algorithms and programming languages used are decision trees and Python programming. The Python libraries used for classification include the Pandas Library, Matplotlib, Numpy, Pydotplus, and Graphviz. Binary decision tree results are obtained up to 23 levels. Fig. 5 below shows the two highest levels of the classification tree.

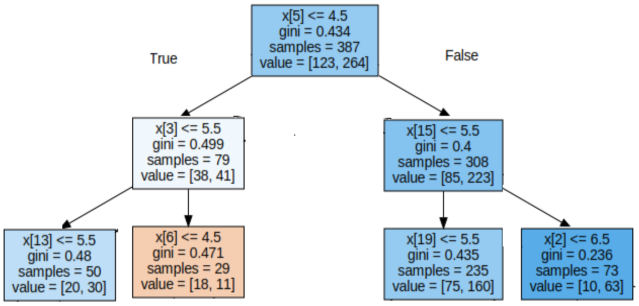

Fig. 5. First and second level classification trees.

The highest branch of the tree, or the 0th tree, is Elements of General Skills: Scientific Communication with a value of ⩽ 4.5, gini = 0.434, samples 387, and value = [123,264], this means:

- For questions with an answer value of 4.5 or lower, the scientific communication elements will follow the True arrow to the left and the rest will follow the False arrow to the right.
- Gini value = 0.434 means that the quality of separation is in this number. The formula for calculating the gini is given as follows:

$$gini = 1 - \left(\frac{x}{n}\right)^2 - \left(\frac{y}{n}\right)^2 \qquad (2)$$

x is target variables that are by the field of science, and y is target variables that are not by the field of science.

- Samples = 387 total datasets.
- Value = [123,264] means that out of a total of 387, 123 will get the "Not suitable" category, and 264 will get the "Suitable" category.

A similar discussion also applies to subsequent branches up to the last branch at the 23rd level.

2) Clustering: The grouping of data will later be connected with segmentation. The data that is suitable for use is the identity of the dataset respondents. Of the many questions, three attributes will be taken, namely age, GPA, and length of study in years. The Elbow method determines the number of clusters and cluster members; the K means algorithm is used.

From the results of coding Python programming with libraries almost the same as classification, we get a recommendation for the number of clusters K = 3 using the Elbow method.

The formula for the distance of two points for three dimensions is given as follows:

$$d(X,Y,Z) = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2} \quad (3)$$

Furthermore, the results of clustering with a 3D plot are obtained as illustrated in Fig. 6 below:

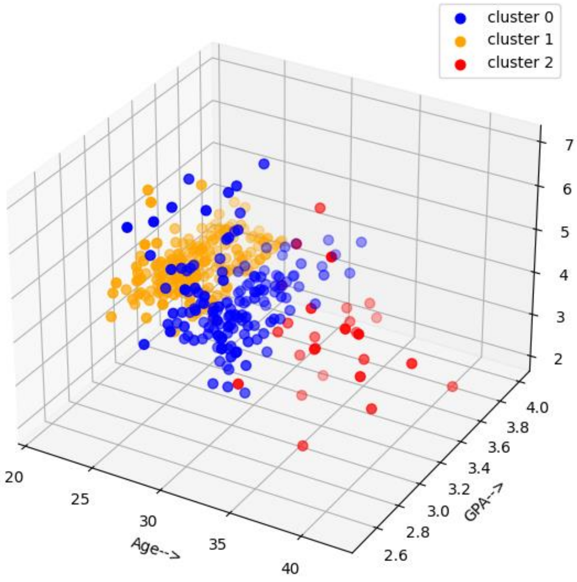

Fig. 6. 3D cluster results.

From the picture above, the following data is obtained:

- Cluster 0: Consisting of 209 data with age distribution under 26 years and a combination of GPA and length of study time.
- Cluster 1: Consisting of 151 data with an age distribution between 27 to 32 years and a combination of GPA and length of study time.

- Cluster 2: Consisting of 27 data with age distribution over 32 years and a combination of GPA and length of study time.

These results indicate that the age attribute of the respondent most influences the cluster results. Meanwhile, the other attributes, namely GPA and length of study, are spread throughout the clusters.

3) Association: The Python library required for association is almost the same as for classification and clustering. The addition is the Apriori Library, which is used for association. Graduate competency data associations are derived from transaction associations. The dataset contains knowledge data from graduates answering eight multiple-choice questions in checklist format, allowing for the selection of more than one option. The number of dataset records corresponds to the number of options selected, rather than the number of respondents. The association questionnaire questions are presented in Table IV below:

TABLE IV. QUESTIONNAIRE ON KNOWLEDGE OF GRADUATES

No.	Graduate Knowledge
1	Theoretical and practical knowledge in the discipline studied
2	Ability to think critically and analytically in analyzing complex problems and situations
3	Knowledge of values, ethics and governance related to the disciplines studied, as well as the ability to apply them in diverse social, political and cultural contexts.
4	Ability to identify, evaluate and use information effectively from a variety of sources
5	Ability to communicate effectively in an appropriate language, both orally and in writing,
6	Ability to work independently or as a team member in different situations, and ability to lead and manage teams on complex projects.
7	Knowledge of social, cultural and environmental diversity, as well as the ability to adapt to differences and respect this diversity
8	The ability to develop life skills, such as the ability to solve problems, make decisions, and learn

The association support formula is as follows:

$$s(X \rightarrow Y) = \frac{(X \cup Y)}{N} \tag{4}$$

Association uses the Apriori Algorithm using a specific support value. With the support of 0.4 of the 1774 selected dataset records, 17 rules are obtained. Detailed rules consist of 15 with two itemsets and two with three itemsets. The rules consist of 3 itemsets, namely the itemsets for questions 8, 4, and 2 and questions 8, 6, and 2.

D. Stages of Internalization

The final stage of the SECI model is internalization, where explicit knowledge returns to tacit. From the results of data mining processing, analysis of the results of data science and analytical recommendations will return to the relevant parties. The results obtained from the three significant functionalities of classification, clustering, and association are given to the Chair of the Study Program, Dean, and Vice Chancellor III for further identification and study to plan future strategies. The strategy in question is to prepare students who are still in college so they can face the world of work after graduating from college, accompanied by sufficient knowledge and competence.

E. The SECI Model with Data Mining and Data Science

The results of three data mining functionality classifications, clustering and association, are then discussed; concerning data science to find the results of data analytics that institutions can later utilize. Data science focuses on extracting, processing, analyzing, and interpreting data to understand phenomena better. The main goal of data science is to identify patterns, trends, and insights contained in data to make better decisions or develop more effective solutions to problems.

In the design model that has been made, with the dataset obtained, for classification, the highest branch obtained is question number 6 (X[5]), namely the Competency Standards for General Skills Elements: Scientific Communication which most influences the suitability of graduates between current jobs, and fields of study obtained from lectures. So from the results obtained, for related parties, both for the Chair of the Study Program, the Dean, Deputy Chancellor III, and graduates. The analytical recommendations can be given so that they can focus more on the elements that influence graduates to be able to work if scientific communication is essential. Various scientific or technical information delivery activities can be carried out, such as seminars or forums, which support students so they can be more involved in scientific journal publications, conference presentations, and scientific discussions.

The cluster results, which consist of the attributes of age, GPA, and length of time in college, tend to be the group most influenced by age. Data science plays a role in segmenting cluster results, where analytical recommendations can be given to respondents based on age. The recommendation is estimated with age groups that are close together; they will likely be in adjacent generations and at almost the same era, so it can be suggested that events involving graduates can be divided by age or generation.

Recommendation analytics for associations depend on the results of the rules. For rules with three itemsets in questions number 8, 4, and 2 as well as numbers 8, 6, and 2, provide an association rule pattern: If graduates have life skills and can recognize information or the ability to work, then graduates will be able to think complexly. Recommendations that can be given to the Head of Study Program, Dean, and Vice Chancellor III are that students can be equipped with sufficient soft skills to face the world of work after graduating from college.

V. CONCLUSION

SECI modeling has been widely used by researchers in transferring knowledge. However, along with the increasingly sophisticated technology, tools will be very helpful in transferring knowledge. With the construction of the SECI model in transferring graduate knowledge with a combination of data mining and data science, it is hoped that it can help related parties. The Head of the Study Program, Dean, and Deputy Chancellor III can use the results of information and knowledge trainers from graduates, both from the results of classification, grouping, and association, to be used as material for future considerations in designing drafting the academic documents, especially curriculum and all matters related to student activities. Recommendations for increasing the competence of graduates from the results of this study include the classification level; the highest branch is scientific communication which most influences the job suitability of graduates. So from these results, college can focus more on preparing the graduates by holding more student activities, such as seminars and workshops on improving students' scientific communication abilities.

From the results of the model modification, several new differences were obtained when compared to the previous model. Modeling modifications with data mining are carried out to understand problems and provide effective and efficient solutions so that the transfer of graduate competence knowledge is more focused. This model is designed to be easy to use and acceptable to all users. The documentation describes the concept, function, and use of the model. Models are compatible with many popular technologies and platforms. Therefore, further model testing must be carried out to test the effectiveness and success of the design model. Caution is required to deal with changes and increase in their use.

Enhancing Cloud Security: An Optimization-based Deep Learning Model for Detecting Denial-of-Service Attacks

Lamia Alhazmi
Department of Management Information System,
College of Business Administration, Taif University,
P.O Box 11099, Taif, 21944,
Saudi Arabia

***Abstract*—DoS (Denial-of-Service) attacks pose an imminent threat to cloud services and could cause significant financial and intellectual damage to cloud service providers and their customers. DoS attacks can also result in revenue loss and security vulnerabilities due to system disruptions, interrupted services, and data breaches. However, despite machine learning methods being the research subject for detecting DoS attacks, there has not been much advancement in this area. As a consequence of this, there is a requirement for additional research in this field to create the most effective models for the detection of DoS attacks in cloud-based environments. This research paper suggests a deep convolutional generative adversarial network as an optimization-based deep learning model for identifying DoS bouts in the cloud. The proposed model employs Deep Convolutional Generative Adversarial Networks (DCGAN) to comprehend the spatial and temporal features of network traffic data, thereby enabling the attack detection of patterns indicative of DoS assaults. Furthermore, to make the DCGAN more accurate and resistant to attacks, it is trained on a massive collection of network traffic data. Moreover, the model is optimized via backpropagation and stochastic gradient descent to lessen the loss function, quantifying the gap between the simulated and observed traffic volumes. The testing findings prove that the suggested model is superior to the most recent technology methods for identifying cloud-based DoS assaults in Precision and the rate of false positives.**

Keywords—DOS attack; cloud database; generative adversarial networks; attack detection; security threats

I. Introduction

Computer networks have become more open to cyber-attacks in recent years due to the expansion of web-associated devices and the rising dependence on internet-based administrations [1]. As shown in Fig. 1, the DoS attack, which involves flooding a targeted network or system with malicious traffic to make it inaccessible to authorized users, is one of the most frequent and disruptive attacks [2]. Network administrators and security experts must identify and prevent DoS attacks [3]. Statistical anomaly detection methods or predetermined signatures are frequently used in traditional forms of identifying DoS assaults [4]. However, these techniques have drawbacks like high false-positive rates, a limited ability to react to changing attack strategies, and a failure to identify previously undetected attacks [5].

Researchers have used deep learning techniques to address these issues, which have shown great promise in areas like PC vision, normal language handling, and discourse recognition [6]. Deep learning models have the potential to properly detect and categorize DoS assaults because they can automatically learn complicated patterns and representations from vast amounts of data [7].

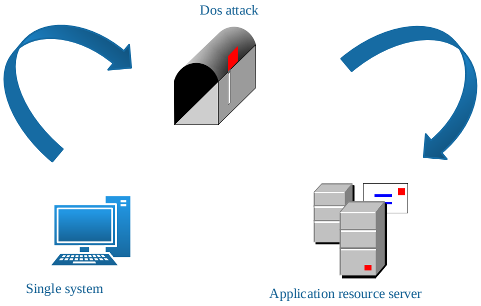

Fig. 1. Basic block diagram of DOS attack.

In this research, we suggest a deep learning model for identifying DoS assaults that are optimization-based. To increase the Precision and stoutness of DoS attack detection, our model takes advantage of deep neural network technology and integrates it with an optimization framework [8]. There are different advantages to recognizing forswearing of administration (DoS) attacks utilizing any procedure, including traditional strategies or state-of-the-art techniques like profound learning: The detection of DoS attacks makes it possible to detect malicious activity before it affects network resources [9]. Network administrators can safeguard the accessibility of essential network resources and services by detecting DoS attacks [10]. Early detection enables prompt remediation, guaranteeing that authorized users may access the network and preventing them from controlling its resources [11]. DoS assaults can significantly disrupt enterprises, resulting in losses in revenue and harm to their brand [12]. Systems for detecting DoS attacks can assist in locating and reducing harmful traffic, enhancing the entire network's performance [13]. It is necessary to filter out malicious traffic to optimally employ the available network resources for legal users and enhance response times and network operations [14].

DoS assaults can differ significantly in power, length, and attack methods. Identifying and correctly categorizing these attacks can be challenging, mainly when dealing with new or emerging attack patterns [15]. DoS attacks are being launched more frequently using encrypted traffic, making detecting and examining illicit activity more challenging [16]. While there are many ways to identify denial of service (DoS) assaults using artificial intelligence (AI), one optimization-based deep learning model that has been applied is based on detecting anomalies. The goal of detecting anomalies is locating odd patterns or actions significantly different from typical network data [17]. Various conventional techniques were employed, such as Particle Swarm Optimization-based Probabilistic Neural Network (PSO-PNN) [18], Recurrent Convolutional Neural Network (RC-NN) [19], Lightweight Random Neural Network (LraNN) [20]; however, not all social media platforms support those.

The key contributions of our proposed work are as follows:

- Initially, the datasets are gathered from the standard web source.
- The system was originally trained using the internet application that contained incursion data.
- Then, the pre-handling stage is completed to eliminate the commotion and blunder values.
- A novel Deep Convolutional Generative Adversarial Network (DCGAN) has been implemented with the necessary characteristics and processing stages.
- Subsequently, the feature extractions are done here; the unwanted features are removed.
- More of the wanted features are trained on the attack prediction model to detect the attack and classify the types of attacks based on the parts.
- Finally, the metrics have been validated and compared with another system through Accuracy, F1- score, Recall, and Precision.

The arrangement of this paper is structured as follows. The related work based on detecting DoS attack is detailed in Section II, and the system model and problem statement are elaborated in Section III. Also, the process of the proposed methodology is described in Section IV. Finally, the achieved outcomes are mentioned in Section V. The results are discussed in Section VI and the conclusion about the developed model is detailed in Section VII. Section VIII gives the future work to be conducted in this area.

II. Related Works

Some of the recent related research works are described below:

Understanding malware's behaviour across the entire behavioural space significantly improves traditional security. Rabbani et al. [21] propose an original technique to upgrade Cloud specialist organizations' ability to demonstrate client conduct. Here he applied a PSO-PNN for the detection and recognition process.

The advantage is that it can be used in safety checking and distinguishing unsafe leads. Since genuine users cannot access resources, they might not be able to find the information they need or take the necessary actions.

The Intrusion detection system is built on an Innovative, custom-optimized RC-NN and the Ant Lion optimization technique, which Thilagam et al. [22] proposed for intrusion detection. The advantage is the high accuracy of the IDS classification model, which raises the rate of detection or error rate. The custom-optimized RC-NN-IDS model has a lower error rate of 0.0012 and an improved classification accuracy of 94%. The most significant disadvantage of deploying an IDS is its inability to respond to or stop attacks once detected.

Samriya et al. [23], to increase, generally speaking, cloud-based registering conditions, another hybridization procedure for interruption location frameworks is proposed. Furthermore, this technique aids in dealing with many types of cloud security challenges. The significant advantage is it reduces computational time and enhances accuracy. The downside of host-based IDS is that it cannot detect network threats against the host.

Kushwah et al. [24] present a DdoS violence finding system based on a Self-Adaptive Evolutionary Extreme Learning Machine (Sae-ELM) that has been improved. The suggested attack detection system outperforms based on the original SaE-ELM and cutting-edge approaches. They overload the system, causing it to fail.

DoS attacks can affect various equipment and technologies used in network infrastructure. Therefore, security systems must be able to recognize these threats. The majority of the methods that have been previously provided employ an individual machine learning model that can pinpoint DoS attacks; however, it appears that combining a variety of learning models will improve the intrusion detection system's detection accuracy and reliability.

Majidian, et al. [25] has developed an Adaptive Neuro-Fuzzy Inference System (ANFIS) to enhance DoS attack detection accuracy compared to existing techniques.

The most alluring invention in the current landscape is probably cloud computing. Lowering the massive upfront cost of buying equipment foundations and processing power provides an expense-effective arrangement. By utilizing a portion of the work that is not registered, decreasing the reaction time at the edge devices of the end client, such as IoT, fog computing provides extra aid to cloud infrastructure.

Sattari, et al. [26] have developed a Software-defined network (SDN) that identifies 99.98% of sophisticated multi-variant bot attacks more accurately than earlier ones, with more excellent performance. Table I lists the difficulties with the existing works.

Ferrag et al. [31] developed a unique Weight-based Ensemble Machine Learning Algorithm (WBELA) to detect aberrant signals in a CAN bus network. Then, he creates a model based on many-objective optimization for CAN bus network intrusion detection. It considerably improves Precision, lowers the false positive rate, and outperforms other approaches. The issue is that the intrusion detection model is not near to the actual CAN bus security protection.

TABLE I. CHALLENGES OF THE EXISTING WORKS

Sl. No	Author Name	Method	Advantages	Disadvantages
1	Rabbani *et al.* [21]	PSO-PNN	The advantage is that it is promising for security checking and distinguishing unsafe leads.	Premature convergence susceptibility, weak local optimization skills
2	Thilagam *et al.* [22]	Recurrent Convolutional Neural Network(RC-NN)	Each pattern can be presumed to be dependent on earlier ones, thanks to the ability of RNN to simulate a collection of records.	The position and orientation of objects are not encoded.
3	Samriya *et al.* [23]	Hybridization Technique	high sensitivity, exact anatomical localization, and quantification potential.	Low rate of good qualities recombining.
4	Kushwah *et al.* [24]	SaE-ELM	Reduce the training time	incorrect data interpretation
5	Majidian, *et al.*[25]	ANFIS	high capacity for generalization	high cost of calculation.
6	Sattari , *et al.* [26]	Software-defined network (SDN)	It enables engineers to reroute networks instantly.	Cost increase brought on by reconfiguration.
7	Ferrag *et al.* [31]	weight-based ensemble machine learning algorithm (WBELA)	Enhancing Predictive Performance	Growing Complexity

III. SYSTEM MODEL

Identifying DoS threats to improve cloud security is crucial. DoS attacks are intended to overburden cloud servers and networks, rendering them inoperable and preventing authorized users from accessing cloud resources. The detection of DoS assaults in cloud systems has several issues: Large volumes of traffic from DoS assaults might be challenging to discern from regular traffic. It can make it difficult to detect and respond to DoS assaults quickly. DoS assaults can spread over numerous computers and networks, making it challenging to pinpoint their origin. The user initiates a request by sending a specific command or action to access a service, browse a website, or communicate with another user. The request is transmitted over the internet. The request reaches the load balancer, which serves as a central entry point for incoming network traffic. The load balancer analyzes the request and determines the most appropriate target server to handle it based on factors such as server health, availability, or predefined load balancing algorithms. Before the request reaches the target server, it passes through the firewall. The firewall examines the request, checking if it complies with predefined security policies and rules. It blocks unauthorized or potentially malicious traffic, protecting the network from potential threats and attacks. Once the request passes through the firewall, it reaches the target server responsible for processing the request. The server performs the necessary operations based on the user's request, retrieves the requested resource or data, and prepares a response to be sent back to the user. The response generated by the target server passes through the firewall. The firewall ensures the response is secure and free from any malicious content or unauthorized data. The load balancer receives the response from the target server and ensures its integrity and consistency.

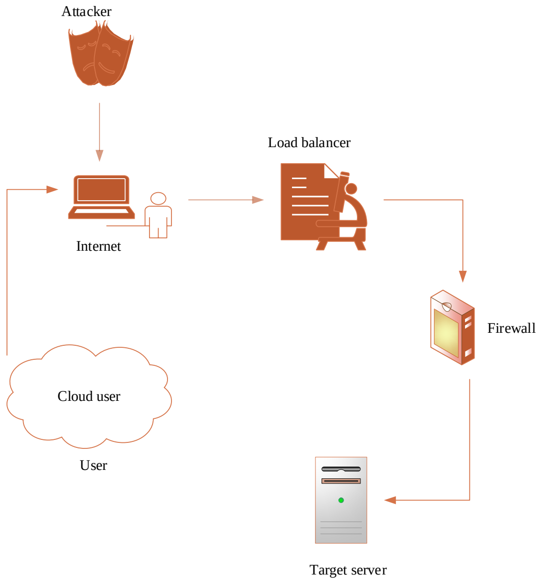

Fig. 2. System model of DOS attack.

It may also perform additional processing or optimization before forwarding the response to the user. The load balancer sends the response back to the user through the internet. The response travels through the network, passing through routers and switches, until it reaches the user's device. The system model is shown in Fig. 2.

Cloud environments are complex and dynamic, with multiple infrastructure, software, and service layers. This complexity can make it challenging to monitor and detect DoS attacks. Monitoring systems may generate false positives, identifying legitimate traffic as malicious and causing unnecessary disturbances in cloud services. So, the presented work has aimed to develop an optimized deep feature-based detecting mechanism for the process.

IV. PROPOSED METHODOLOGY

A novel DCGAN has been developed to detect harmful behaviour in cloud applications. The cloud application containing intrusion data has been purchased and put into the system to evaluate the proposed model. The proposed model employs DCGAN to comprehend network traffic data's temporal and spatial characteristics, thereby enabling the detection of patterns indicative of DoS assaults. Fig. 3 shows the proposed architecture of DCGAN.

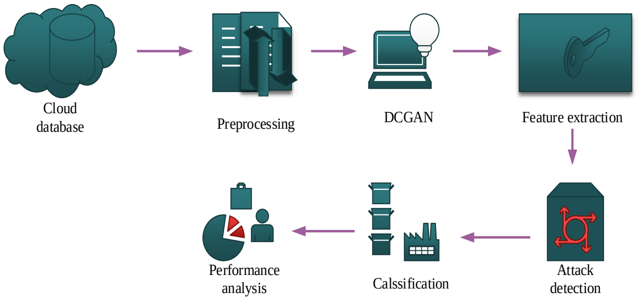

Fig. 3. The proposed DCGAN architecture.

Initially, the datasets are gathered from the authoritative web source. The system was originally trained using the internet application that contained incursion data. Then pre-processing phase is conceded to eliminate the noise and error values. A novel Deep Convolutional Generative Adversarial Network (DCGAN) has been implemented with the necessary characteristics and processing stages. Subsequently, the feature extractions are done here; the unwanted features are removed. More of the wanted features are trained to the attack prediction model to detect the attack and classify the types of attack based on the parts. Finally, the metrics have been validated and compared [32-34] with another system through Accuracy, F1-score, Recall, and Precision.

A. *Pre-Processing*

Pre-process the collected data by cleaning, normalizing, and transforming it into suitable input formats for training the deep learning model [27]. It may involve feature extraction, data augmentation, or encoding techniques specific to DCGANs. The initialization equation is expressed in Eq. (1).

$$A(v) = (v_1, v_2, v_3, ...v_n)Y \tag{1}$$

Where A denotes the collected cloud dataset from the dataset, v indicates the information present in the dataset, Y denotes the features available in the dataset and n represents the total count of data currently in the database [27]. After initialization, the next stage is the pre-processing phase. Here, the input dataset is pre-handled to eliminate the null values present in the dataset. The pre-processing equation is represented in Eq. (2).

$$H_B^*(A) = \frac{1}{n}\sum_{i=1}^{l}\left\|Y_i - L_i\right\|^2 \tag{2}$$

Where H_B^* denotes the pre-processing variable and L_i indicates the null values present in the dataset. Fitness also plays a role in the decision to virtualize the task without compromising the quality of the work. The GAN fitness function creates new data instances that resemble your training data. The fitness function attains less value for an effective result.

B. *Proposed DCGAN*

The features are given to the proposed DCGAN-based convolution neural network classifier for detecting DoS attacks after being appropriately chosen. DoS assaults are often found using intrusion detection systems and network monitoring tools, which can spot changes in network traffic that might indicate a DoS attack. The optimized via backpropagation and stochastic gradient descent model to improve the gap between the simulated and observed traffic volumes [28] [33]. Machine learning models, such as DCGANs, may help these detection efforts by examining network traffic patterns and spotting potential threats. The proposed DCGAN is expressed in Eq. (3).

$$lowhighM(J,R) = E^*_{ndata(Y)}[log\, J\,(x^*)] + E^*_{qc(C)}\left[log\left(1 - J\big(N(C)\big)\right)\right] \tag{3}$$

Where x^* denotes the dataset, c is the generator's blare at the input of the attacks, $n\,data$ is the data delivery, qc is the noise delivery, N is the maker of the cloud attacks and J is the discriminator of the DOS attacks.

C. *Feature Extraction*

The constructed model then moves on to feature extraction after the suggested technique. The valuable characteristics are extracted, and the unnecessary features are removed in the feature extraction module. Consider Y_i^* as the feature present in the pre-processed dataset [27]. The pre-processed dataset contains relevant features F_i and irrelevant features $F_i^{'}$. The feature extraction equation is expressed in Eq. (4).

$$G_B^*(A) = \rho \times Y_i^*\left[F_i - F_i^{'}\right] \tag{4}$$

Only pertinent characteristics remain in the dataset after the feature extraction stage. The dataset is then trained to recognize assaults using the suggested methodology.

D. *Attack Detection and Classification*

To identify known and unknown assaults, deep convolution neural networks are employed to detect noise and other undesirable aspects in the data. The neural network is used to reduce the dimensionality of the data during the training phase. The threshold for conventional traffic data is manually selected, despite the suggested approach lessening the data complexity. Given that it does not clearly show the network abnormality or the sort of attack, the model may be able to identify the device connected to the anomaly, making it suitable for fault detection. An assault that is known to have occurred is indicated in the dataset. Here, the system is trained to recognize attacks in the dataset using an attack trained on a massive collection of network traffic data. Eq. (5) [27] gives the equation for attack detection.

$$P_B^l(A) = \begin{cases} S_Q = 1; & Normal \\ S_Q = 0; & Attack \end{cases} \tag{5}$$

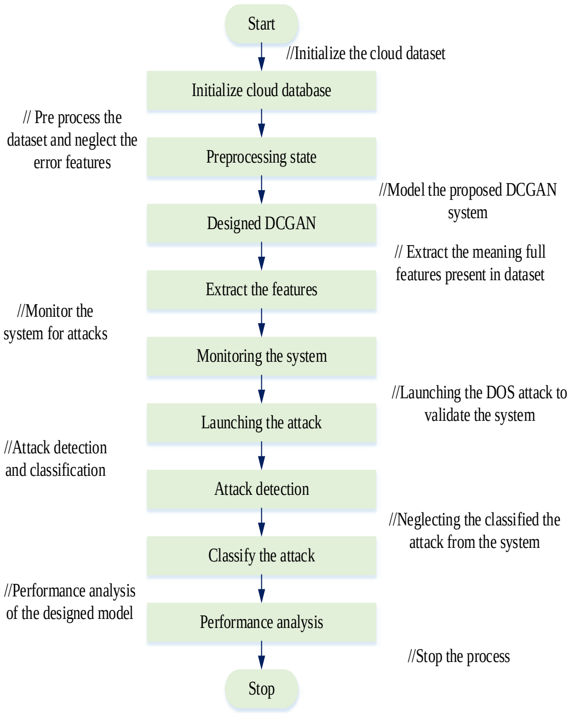
Where P_B^l it indicates the attack detection function and S_Q denotes the trained features, attack features are marked as "0" in this instance, while the standard element in the dataset is designated as "1". As a result, the assaults in the dataset are found [27]. Additionally, to see if the system recognizes and categorizes unidentified attacks like Denial of Service (DoS) launched into the system. The unknown attack detection is expressed in Eqn. (6).

$$P_B^{Ul}(A)=\begin{cases} if\,(A_{on}<80\,Mbs) & ;\ Normal\\ else(A_{on}>80Mbs); & Attack\end{cases} \tag{6}$$

Where P_B^{Ul} denotes the unknown attack detection function, A_{on} indicates overloading data rate. Based on the speed of data overloading, the standard and attack features are identified here. When data overloading rates are above 80Mbs, an assault is recognized. If the rate of data overloading is under 80Mbs, it is recognized as a typical feature [27]. Attack classification is completed after attack detection. The attack classification is expressed in Eq. (7).

$$P_D^{Ul}(A)=\begin{cases} Other & ;\ 80Mbs>A_{on}<100Mbs\\ DoS;\ A_{on}\geq 100Mbs & \end{cases} \tag{7}$$

Where P_D^{Ul} denotes the attack type classification function. The other attack's data overloading rate range is between 80Mbs and 100Mbs. Similarly, if the data overloading rate is more than 100 MB, the attack is classified as a DoS attack. The workflow of the DCGAN approach is shown in Fig. 4.



Start

V. Result and Discussion

The presented method is implemented on the PYTHON platform using an Intel I Core I i5 CPU and 8GB RAM. This section discusses the experimental design and the efficacy of the proposed approach. Several measures, including Accuracy, Precision, Recall, and F-measure with the help of optimization and neural networks, are used to assess the organization's effectiveness.

Case Study: This case study discusses a deep convolution GAN network for DOS attacks to enhance cloud security. The cloud application with intrusion data has been bought and installed in the system. The noise and error values are then removed during the pre-processing step. The proposed system's cloud datasets are gathered from an authoritative web source. Then, cleanse, normalize and convert the obtained data into appropriate input formats before using it to train the deep learning model after carefully selecting the suggested DCGAN-based convolution neural network classifier to detect DoS attacks. And then are the feature extractions carried out; the undesirable elements are eliminated. Additionally, the desired features are trained to help the attack prediction model identify and categorize attacks based on their characteristics. Fig. 5 shows the overall process of GAN.0.

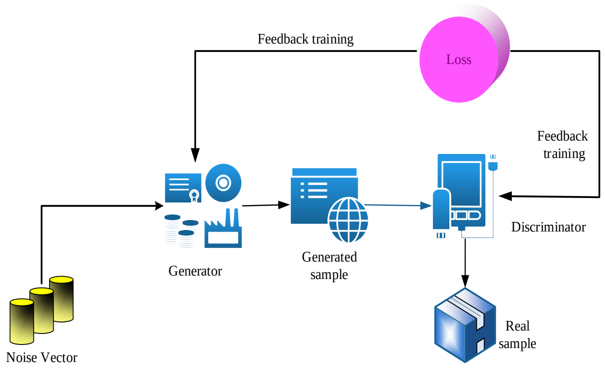

Fig. 5. The proposed GAN process.

A. *Performances Metrics*

The performance metrics are evaluated in terms of Accuracy, Recall, F-measure, and Precision to validate our proposed DCGAN model.

1) Accuracy measure: According to this definition, accuracy is the proportion of outcomes accurately predicted to all the predictions. The machine learning algorithms' performance parameter is most frequently employed [31] [35]. Accuracy is technically defined as the proportion of accurate positive to accurate negative discoveries needed to finish the machine learning model's outputs. Accuracy is expressed in equation (8),

$$A=\frac{TP'+TN'}{TP'+TN'+FP'+FN'} \tag{8}$$

Where, A indicates the accuracy, $TP^{'}$ denoted as true positive, $TN^{'}$ is genuinely harmful, $FP^{'}$ indicates the false positive, $FN^{'}$ is false negative.

2) Precision calculate: By dividing the total of true positives by all optimistic forecasts, Precision can be used to assess whether the model's optimistic predictions are accurate [31]. Precision is expressed in Eq. (9),

$$P = \frac{TP^*}{TP^* + FP^*} \tag{9}$$

3) Recall measure: The Recall is the percentage of positives the model identified adequately out of all potential positives by dividing true positives by the total number of actual positives [31][36]. Recall is expressed in equation (10),

$$R = \frac{TP^*}{TP^* + FN^*} \tag{10}$$

4) F-measure: F-measure represents a weighted average of Recall and Accuracy. The F-measure considers both positive and negative results to keep the balance between Recall and Precision [31][37]. F-measure is expressed in equation (11),

$$\boldsymbol{F - measure = \frac{2(P+R)}{P+R}} \tag{11}$$

Where P represents the Precision, R represents the Recall.

B. Evaluation of Performance

Comparing the constructed model's metrics for Accuracy, Precision, F-measure, and recall to those of other models confirmed its efficacy. The developed model will be implemented in the Python framework. Moreover, the existing techniques like You Only Look Once a Multilayer Perceptron (MLP) [29], Convolutional Neural Network (CNN) [29], Decision Tree (DT) [30], and Support Vector Machine (SVM) [30].

1) Comparison of the suggested with other existing techniques in terms of accuracy

Fig. 6 shows the accuracy of the suggested DCGAN is compared to that of the previous study. The proposed DCGAN accuracy rate is 0.997. While comparing the suggested DCGAN to other existing methods, the accuracy level is more significant. The accuracy rate for the DT method currently in use is 0.86. At the same time, the accuracy level is high compared to other existing methods like MLP, CNN, and SVM.

Compared to other approaches like SVM and CNN, the MLP accuracy level is 0.987, which is a great value. CNN's accuracy level is 0.986, which is poor compared to all other currently used methods. SVM accuracy level is 0.92 compared to other techniques like MLP, CNN, and DT. As a result, the proposed DCGAN performs superior to the other methods already in use.

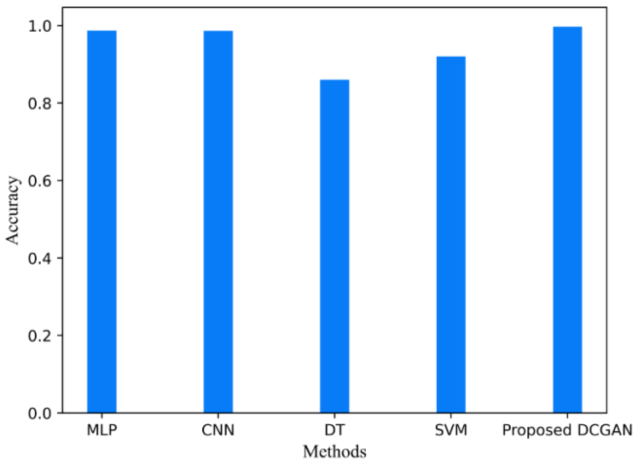

Fig. 6. Comparison of the proposed DCGAN in terms of accuracy.

2) Comparison of the suggested with other existing techniques in terms of Precision

In Fig. 7, the Precision of the suggested DCGAN is compared to that of the previous study. The proposed Convolution-based Buffalo Optimization (DCGAN) precision rate is 0.988. While comparing the suggested DCGAN to other existing methods, the precision level is more significant. The precision rate for the SVM method currently in use is 0.782. At the same time, the precision level is high compared to other existing methods like MLP, CNN, and SVM.

Compared to other approaches like CNN, DT and the MLP precision level is 0.968, which is a great value. The CNN precision level is 0.959, which is poor compared to all other methods currently in use. DT precision level is 0.9159 compared to other techniques like MLP, CNN, and DT. As a result, the proposed DCGAN performs superior to the other methods already in use.

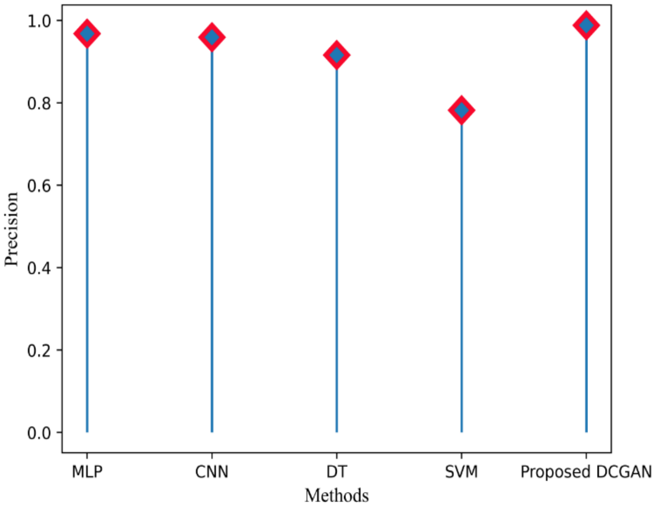

Fig. 7. Comparison of the proposed DCGAN in terms of precision.

3) Comparison of the suggested with other existing techniques in terms of F1-score

In Fig. 8, the F1-score of the suggested DCGAN is compared to that of the previous study. The proposed Convolution-based Buffalo Optimization (DCGAN) F1-score rate is 0.978. While comparing the suggested DCGAN to other existing methods, the F1-score level is more significant. The F1-score rate for the DT method currently in use is 0.7239. At the same time, the F1-score level is high compared to other methods like MLP, CNN, and SVM.

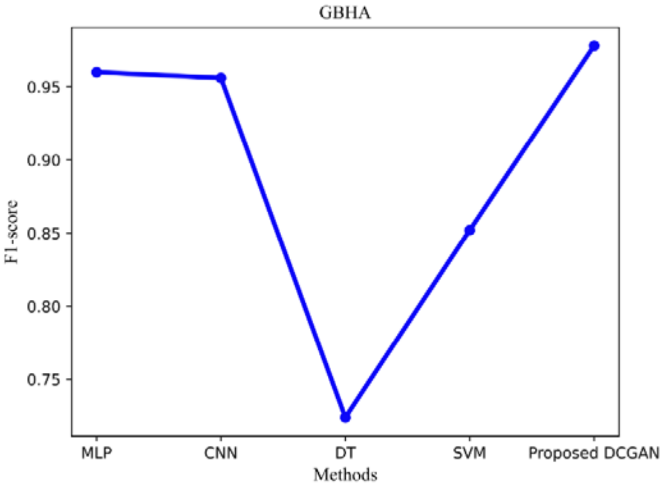

Fig. 8. Comparison of the proposed DCGAN in terms of F1-score.

Compared to other approaches like CNN, DT and the MLP F1-score level is 0.968, which is a great value. The CNN precision level is 0.956, which is poor compared to all other methods currently in use. SVM precision level is 0.852 compared to other techniques like MLP, CNN, and DT. As a result, the proposed DCGAN performs superior to the other methods already in use. The comparison of techniques in terms of accuracy, precision, recall and F1- score data’s are mentioned in Table II.

TABLE II. COMPARISON OF TECHNIQUES

Technique	Accuracy	Precision	Recall	F1-score
MLP	0.987	0.968	0.953	0.96
CNN	0.986	0.959	0.954	0.956
DT	0.86	0.9159	0.6808	0.7239
SVM	0.92	0.782	0.936	0.852
Proposed DCGAN	0.997	0.988	0.96	0.978

4) Comparison of the suggested method with other existing techniques in terms of Recall

In Fig. 9, the Recall of the suggested DCGAN is compared to that of the previous study. The proposed Convolution-based Buffalo Optimization (DCGAN) recall rate is 0.96. While comparing the suggested DCGAN to other existing methods, the F1-score level is more significant. The recall rate for the DT method currently in use is 0.6808. At the same time, the recall level is high compared to other existing methods like MLP, CNN, and SVM.

Compared to other approaches like MLP DT, the CNN recall level is 0.954, which is a great value. MLP recall level is 0.953, which is poor compared to all other currently used methods. The SVM recall level is 0.936 when compared to other techniques like MLP, CNN, and DT. As a result, the proposed DCGAN performs superior to the other methods already in use.

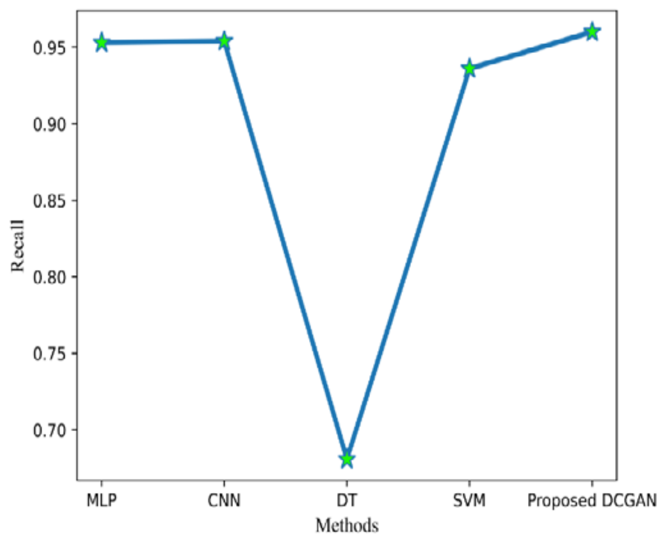

Fig. 9. Comparison of the proposed DCGAN in terms of recall.

Comparative analysis with other machine learning approaches, such as MLP, CNN, DT, and SVM, reveals the superior performance of the DCGAN model in terms of precision, recall, and F1-score. This comparative investigation showcases the advancement of the proposed model over existing techniques and highlights its potential for practical deployment in real-world cloud environments. The DCGAN model's improved precision, robust pattern recognition capabilities and superior performance in comparison to other methods contribute to the enhancement of cloud security measures and offer promising prospects for further advancements in the field.

VI. DISCUSSION

The presented IDS approach was designed and verified in the Python tool. The essential goal of the created model is to distinguish pernicious occasions in the WS organization. The neural network in the proposed approach improves the detection rate and accuracy.

Table III summarizes the performance study of the provided model. For the DCGAN dataset, the designed model attained 0.997 accuracies and 0.988 precision, a recall of 0.96, and an F-score of 0.978 in the developed model. Additionally, findings are compared to current approaches to confirm the great Precision in the calculation period of the developed model. The findings highlight the significance of the DCGAN model in enhancing cloud security by accurately detecting DoS attacks. The improved precision and reduced false positive rate contribute to better protection against service disruptions, data breaches, and financial losses. The study demonstrates the potential of deep learning approaches, specifically DCGANs, in tackling complex security challenges in cloud environments. The results provide valuable insights for researchers and practitioners working on developing effective mechanisms for detecting and mitigating DoS attacks. By addressing the limitations and pursuing future research avenues, the study contributes to advancing the knowledge and practical applications of cloud security.

TABLE III. PERFORMANCE ANALYSIS

Metrics	*Performance*
F-score	0.978
Recall	0.96
Precision	0.988
Accuracy	0.997

The article introduces a novel approach using a DCGAN as an optimization-based deep learning model for identifying DoS attacks in the cloud. This represents a significant contribution to the field by exploring the effectiveness of DCGANs in detecting such attacks. The proposed model leverages DCGAN to comprehend the spatial and temporal features of network traffic data. By analyzing these features, the model can identify patterns indicative of DoS attacks, thereby enhancing the accuracy of detection. To improve the accuracy and robustness of the DCGAN model, it is trained on a large collection of network traffic data. This approach enables the model to learn from diverse attack scenarios and enhances its ability to detect previously unseen attacks. The model is optimized through back propagation and stochastic gradient descent to minimize the loss function, which quantifies the discrepancy between simulated and observed traffic volumes. This optimization process enhances the model's performance and fine-tunes its ability to detect DoS attacks effectively. The article provides testing findings that demonstrate the superiority of the proposed DCGAN model over recent technology methods in terms of precision and the rate of false positives. This comparative evaluation contributes valuable insights into the effectiveness of the DCGAN model for DoS attack detection in cloud environments.

VII. CONCLUSION

By effectively identifying DoS attacks, the optimization-based deep learning model, which utilizes techniques like DCGANs, has the potential to enhance cloud security. The model leverages deep learning to detect anomalies and learn intricate patterns within network traffic data. In this study, the model's performance is evaluated in terms of Recall, Precision, and F1 score for DoS attack detection. A controlled simulation environment is employed to test the model's efficacy in detecting DoS attacks. The obtained results are then compared with existing machine learning approaches such as MLP, CNN, DT, and SVM. The comparative analysis reveals that the developed DCGAN model surpasses other models in terms of performance. Notably, the Accuracy, Precision, Recall, and F1-score values exhibit significant improvements in the proposed DCGAN technique, achieving enhancements of 0.997, 0.988, 0.96, and 0.978, respectively. These results indicate the superiority of the DCGAN model in accurately identifying DoS attacks compared to alternative approaches. Furthermore, in addition to the empirical findings, this study contributes to the field by introducing newly formulated theoretical advancements. The utilization of DCGANs for DoS attack detection in cloud environments represents a novel approach with potential implications for enhancing cloud security. The incorporation of deep learning techniques and the specific architecture of DCGANs contribute to the model's ability to learn complex patterns and identify subtle anomalies in network traffic data. The study may have been limited by the availability of a specific dataset for training and testing the DCGAN model. The results may vary when applied to different datasets or real-world scenarios. The focus of the study was on detecting DoS attacks. The model's performance in detecting other types of attacks or more complex attack patterns was not explored. The study primarily focused on the performance evaluation of the DCGAN model in a controlled environment. The real-time implementation and assessment of the model's effectiveness in practical cloud environments were not addressed. The study thus offers theoretical insights into the application of DCGANs for cloud security and lays the foundation for further research in this area.

VIII. FUTURE WORK

In future it would be seeked to enhance the DCGAN model's ability to detect more sophisticated and evolving DoS attack techniques. This involves exploring novel network traffic features, developing more robust anomaly detection algorithms, and incorporating machine learning techniques to improve the accuracy and effectiveness of the model. Also by integrating the DCGAN model with existing cloud security infrastructure, such as intrusion detection systems, firewalls, or security incident response platforms. This integration can enable a comprehensive security ecosystem, leveraging the strengths of multiple security mechanisms to provide a more holistic and proactive defense against DoS attacks.

***Abstract*—The problem of defects in glass bottles is a significant issue in glass bottle manufacturing. There are various types of defects that can occur, including cracks, scratches, and blisters. Detecting these defects is crucial for ensuring the quality of glass bottle production. The inspection system must be able to accurately detect and automatically determine that the defects in a bottle affect its appearance and functionality. Defective bottles must be identified and removed from the production line to maintain product quality. This paper proposed glass bottle defect classification using Convolutional Neural Network with Long Short-Term Memory (CNNLSTM) and instant base classification. CNNLSTM is used for feature extraction to create a representation of the class data. The instant base classification predicts anomalies based on the similarity of representations of class data. The convolutional layer of the CNNLSTM method incorporates a transfer learning algorithm, using pre-trained models such as ResNet50, AlexNet, MobileNetV3, and VGG16. In this experiment, the results were compared with ResNet50, AlexNet, MobileNetV3, VGG16, ADA, Image threshold, and Edge detection methods. The experimental results demonstrate the effectiveness of the proposed method, achieving high classification accuracies of 77% on the body dataset, 95% on the neck dataset, and an impressive 98% on the rotating dataset.**

***Keywords*—Convolution neural network; glass bottle; defect detection; long shot-term memory; inspection machine**

I. INTRODUCTION

Defect detection plays a vital role in glass bottle production, safeguarding product quality, consumer safety, brand reputation, and value. By investing in robust flaw detection systems and processes, manufacturers can maintain impeccable standards, safe, and visually appealing glass bottles to their customers [1,2]. Common types of defects that can occur in glass bottles include: 1) Stones are foreign stone grains embedded in the glass, degrading the quality of the bottle. 2) Tears are deformed breaks or fractures on the surface of the bottle. 3) Blisters are raised or swollen areas caused by uneven cooling during manufacturing, affecting both strength and appearance. 4) Cracks are breaks in the surface that compromise the structural integrity of bottle.

The inspection machine uses various technologies to detect defects, including cameras, lasers, and sensors. The inspection machine uses cameras to capture images of the products, and the software analyzes these images to detect defects. When defects are detected, the software sends a signal to the control system to remove the faulty product from the production line.

As for the problem with traditional inspection machines, they cannot inspect defects in complex areas and require the use of imaging techniques to visualize the defects. Because these machines utilize image processing techniques and require various parameter settings to be adjusted by users for defect detection. It results in the inability to completely remove defective bottles from the production line, undermining confidence in the manufacturing process. The detection method on inspection machine for detecting the defects must be accurate, precise, capable of recognizing defect well, and fast in the learning process of defect patterns.

This research proposes a new method for detecting defects in glass bottles using a deep neural network for extracting deep features and instance-based classification. The method uses CNN combined with LSTM to recognize distinctive features of defects and extract those features. The training process is designed to create a set of CNNLSTM models with fewer training iterations, helping to reduce the training time. The instance-based classification is used to classify the defect in the images. It reduces parameter settings by users for defect detection, resulting in a reduction in user workload.

The rest of this paper is organized as follows: Section II resents a background study of glass bottle defect detection techniques. Section III explains the glass bottle defect dataset and describes the proposed glass bottle defect classification method. Section IV explains the evaluation methods, the experimental setup, and the experimental outcomes; and finally. Section V suggests directions for future works and concludes the paper.

II. RELATED WORKS

The existing defect detection techniques mainly focused on the defect in glass bottles. The related methods are as follows. Latina et al. [3] presented defect detection method for detecting defects in glass bottles for the purpose of reusing them and highlights the limitations of the manual inspection in micro, small, and medium enterprises (MSMEs). The research introduced a cost-effective deep learning-based method using the SSD MobileNetV2 model to detect various defects in glass bottles. The method used transfer learning and data augmentation techniques to achieve high accuracy, with up to

98.07% overall system accuracy. Gong et al. [4] presented a machine vision system designed for the automatic online inspection of defects in transparent labels on curved glass bottles. The system used an area-array camera and a custom-made blue dome illumination device to capture high-quality still images by minimizing reflection. To address the challenge of distorted curved geometry, a deformable template matching method was employed for precise defect location. The method also included an adaptive threshold selection strategy that effectively detected small scratches by using global and local threshold values along with a Gaussian fitting algorithm. Additionally, techniques such as skeleton extraction and distance transformation were applied to detect the complete edge contour of Chinese characters with a special font, considering the golden edge printing error. Field tests demonstrated an impressive detection accuracy of 99.5% at a speed of 60 bottles per minute, covering over 60,000 bottles. Vitis et al. [5] proposes an algorithm that achieves high detection accuracy while significantly reducing processing time. By using adaptive thresholding and analyzing luminous intensity variations, the algorithm effectively detects blob and airline defects while mitigating the impact of tube curvature, rotation, and vibration. Comparative evaluations demonstrate an 86% reduction in processing time, a 268% increase in throughput, and improved detection accuracy compared to existing methods. The algorithm also incorporates Region of Interest reduction techniques and a tuning procedure for parameter adjustment during production batch changes. The performance of the algorithm was assessed in a real environment, and it successfully identified misclassified tubes, suggesting its practical applicability. Zhang et al. [6] suggested a machine learning-based acoustic defect detection (LearningADD) system to replace manual inspection. The system used an improved Hilbert-Huang transform (HHT) to extract features from acoustic signals and a Shuffled Frog Leaping Algorithm (SFLA) to select features. Five deployment strategies were compared and optimized to improve real-time performance. The LearningADD system was validated using data from a real-life beverage factory. The F-measure of the system reached 98.48%. The proposed deployment strategies were verified using experiments on private cloud platforms. The Distributed Heavy Edge deployment strategy outperformed other strategies, with a defect detection time of less than 2.061 seconds for 99% of bottles. Zhou et al. [7] proposed a surface defect detection framework, which consisted of three main components. Firstly, a novel localization method called entropy rate superpixel circle detection (ERSCD) was introduced. It combined least-squares circle detection, entropy rate superpixel (ERS), and an improved randomized circle detection to accurately identify the region of interest (ROI) on the bottle bottom. The ROI was then divided into two measurement regions: the central panel region and the annular texture region. For defect detection in the central panel region, a method named frequency-tuned anisotropic diffusion super-pixel segmentation (FTADSP) was proposed. It integrated frequency-tuned salient region detection (FT), anisotropic diffusion, and improved superpixel segmentation to accurately detect defect regions and boundaries. For defect detection in the annular texture region, a strategy called wavelet transform multiscale filtering (WTMF) was proposed. It employed wavelet transform and a multiscale filtering algorithm to reduce texture influence and enhance robustness to localization errors. Zhou et al. [8] presented a new apparatus for real-time bottle bottom inspection. The apparatus used a combination of Hough circle detection and size prior to locating the bottom of the bottle. The region of interest was then divided into three measurement regions: central panel region, annular panel region, and annular texture region. A saliency detection method was used to find defective areas in the central panel region. A multiscale filtering method is used to search for defects in the annular panel region. Template matching was combined with multiscale filtering to detect defects in the annular texture region.

The problem with traditional methods of detecting anomalies on glass bottles using image processing is the difficulty in detecting anomalies, especially when there are color and shape variations on the bottles. Inconsistent lighting conditions also pose challenges in detecting anomalies. The disadvantage of using deep neural networks for detecting counterfeit on glass bottles is the complexity involved in building and training the network. Deep neural network-based methods require a large amount of data and longer training time. Additionally, fine-tuning and selecting appropriate parameters for deep networks can be challenging.

III. Methodology

A. Glass Bottle Dataset

There are two main categories of glass bottle inspection machines: straight glass bottle inspection machines and rotary glass bottle inspection machines. Fig. 1 shows an example of an inspection machine for glass bottles. The straight glass bottle inspection machine is an automated system that utilizes advanced technologies, such as computer vision and image processing, to detect and identify defects in glass bottles. It captures images of the bottles from different angles and analyzes them in real-time to ensure product quality and prevent issues during production and transportation. The straight glass bottle inspection machine is depicted in Fig. 1(a). On the other hand, the rotating glass bottle inspection machine is a specialized automated system designed specifically for inspecting glass bottles using a rotating mechanism. By rotating the bottles, it enables a comprehensive examination of the entire surface, ensuring a high level of accuracy in defect detection. The rotating glass bottle inspection machine is shown in Fig. 1(b).

The bottle inspection machine utilizes a vision camera-based inspection method for fully automated visual inspection of glass bottles. The process is as follows. Set the bottles in the designated area on the conveyor belt of the bottle inspection machine. The bottles are properly aligned and spaced to ensure accurate and consistent imaging. Provide proper lighting conditions for capturing clear and well-illuminated bottle images. Set up the camera parameters such as focus, exposure, and white balance to optimize image quality and clarity. Initiate the image capture process using the bottle inspection machine to trigger the camera to capture images of the bottles as they pass through the inspection area. The machine utilizes two cameras to capture images of the bottle: one camera is focused on the neck, while the other is focused on the body of the bottle. Fig. 2 illustrates the composition of the side wall of glass bottles; (a) displays images from the neck dataset, (b) provides an example of the body dataset, and (c) showcases sample bottle images from the rotating dataset. The body dataset for glass bottles comprises 571 images, with 368 images showing defects and 203 images without defects. Similarly, the neck dataset consists of 570 images, including 250 images with defects and 320 images without defects. As for the rotating dataset, it comprises 120 images, with 70 images displaying defects and 50 images representing undamaged bottles. Each image in the body and neck datasets is standardized to a size of 900x800 pixels (width x height), ensuring consistency across the dataset. On the other hand, the images in the rotating dataset are resized to a dimension of 1024x800 pixels (width x height). The captured images are transmitted to the detection system for analysis. If any defects, such as stones, tears, or blisters, are identified on the side wall of a bottle, the detection system generates a signal to reject the faulty bottle. This process ensures that only bottles without defects continue downstream in the production line. Fig. 3(a) is shown tear defect, (b) is a blister, and (c) is stone defect on slid wall of bottle. These defects can appear throughout the bottle.

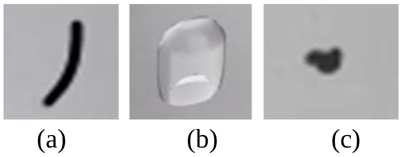
B. The Proposed Method

This section describes the proposed defect detection approach, which is divided into three parts: 1) The network architecture of CNNLSTM for extracting deep features in images, 2) the training process for creating a set of CNNLSTM models and computing the representation of class data, 3) the classification approach that suggests using the extracted deep features from unseen bottle image and applying the distance weight method to classify defect or normal glass bottle images.



(a) (b) (c)

Fig. 3. Defect images. (a) Tear; (b) Blister; (c) Stone.

1) Network architecture of CNNLSTM: CNNLSTM is a convolutional neural network (CNN) combined [9] with LSTM (Long Short-Term Memory) [10] to extract deep features in images. CNNs are effective at extracting spatial features from images, while LSTMs are capable of capturing temporal dependencies in sequential data. The fusion of these two architectures enables CNNLSTM to extract deep features from images. The convolutional layers choose pre-trained deep-learning models available in the Keras library, including VGG16, ResNet50, MobileNetV3, and AlexNet. Using a pre-trained model can reduce the amount of time and resources needed to train a model. It already learned to recognize a variety of features and improve the accuracy of the model. Added LSTM to its convolutional layer. The detail of LSTM unit is shown in Fig. 4.

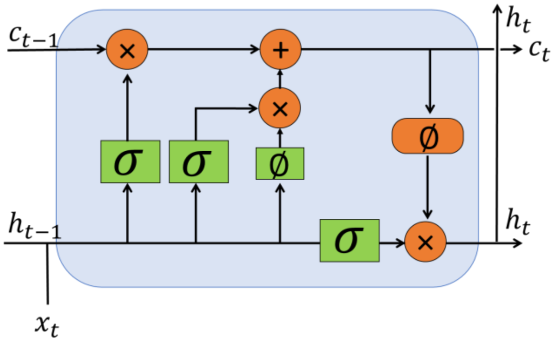


Fig. 4. LSTM.

LSTM comprises multiple memory cells, each consisting of three essential elements: write, read, and forget (delete). During each time step (t), the forget gate unit is updated according to the following process,

$$f_t = \sigma_g\left(W_f \mathbf{x}_t + U_f h_t + b_f\right), \quad (1)$$

$$i_t = \sigma_g(W_i \mathbf{x}_t + U_i h_t + b_i), \quad (2)$$

$$o_t = \sigma_g(W_o \mathbf{x}_t + U_o h_t + b_o), \quad (3)$$

$$c_t = f_t \odot c_{t-1} + i_t \odot, \sigma_c(W_c \mathbf{x}_t + b_c), \quad (4)$$

$$h_t = o_t \odot \sigma_h(c_t), \quad (5)$$

where $\mathbf{x}_t$ is the input data, f_t is the forget gate, i_t is the input/update gate, o_t is the output gate, c_t is the cell state vector, σ is the sigmoid activation function, $\odot$ is the Hadamard product (element-wise product), and h_t is the output of the LSTM unit. In the final representation layer, an LSTM, which is a Recurrent Neural Network (RNN) suitable for sequential data, receives inputs from previous convolutional layers. The LSTM produces a set of 512 outputs, which are then passed to the next layer. The outputs of the convolutional layers are subjected to Batch-Normalization (BN) before they are fed into the LSTM layer. The fully connected layers contain 1,000 hidden neurons. The activation function of all the convolutional layers (with a max pooling size of 2 × 2) is a Rectified Linear Unit (ReLU) [11]. Deep features are extracted from these layers. The output layer contains one output neuron with a sigmoidal activation function. The size of the input images is set as 224 × 224 × 3 pixels. The CNNLSTM is trained using a Stochastic Gradient Descent (SGD) method [12]. The learning rate is set to 0.01, and the batch size is 8 images. The CNNLSTM neural network architecture is shown in Fig. 5.

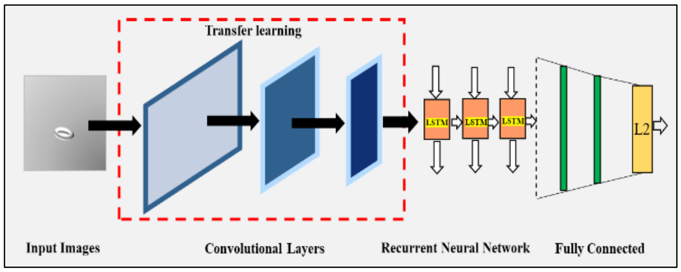

Fig. 5. CNNLSTM.

2) The proposed learning process: Our training process aims to minimize the similarity distance between the extracted deep feature vectors and the centroid of the corresponding class with the same label. Simultaneously, it maximizes the similarity distance between the centroid of good bottles and the centroid of defective bottles.

The overall learning process of creating a set of CNNLSTM and representing class data is proposed in this section. The process of creating a set of CNNLSTM models and generating representations of class data is illustrated in Algorithm 1. The inputs of the learning process include a training dataset **S**, a specified number of sub-training sets K, a threshold value θ, and the pre-trained weight m_{k-1}. The parameter K is a parameter used to determine the number of sub-training sets and the number of CNNLSTM models, which needs to be appropriately adjusted. The value of K affects the number of samples in each sub-training set used for training CNNLSTM and the diversity of CNNLSTM models. θ is a parameter used to define the initial performance of CNNLSTM in each training iteration. The pre-trained weight m_{k-1} helps to reduce training time and resource requirements, improve performance, and enable the model to perform well in limited data conditions.

Algorithm1: Pseudo code of the feature learning network method.

```
Input:
    $S$: A training bottle dataset: $\{(\mathbf{x}_1, y_1), \dots, (\mathbf{x}_N, y_N)\}$
    $K$: The number of the sub datasets
    $\theta$: A performance threshold value
    $m_{k-1}$: The pre-trained model
Output:
    $E$: A set of CNNLSTM models
    $C$: A set of representation of class data

1: Randomly split the training dataset into $K$ sub datasets: $\boldsymbol{S} \rightarrow \{\boldsymbol{s}_1, \boldsymbol{s}_2, \boldsymbol{s}_3, \dots, \boldsymbol{s}_K\}$.
2: For $k = 1, 2, \dots, K$ do:
3:     MSE = 0 and $m_k = m_{k-1}$
4:     While MSE < $\theta$ do:
5:         Train model $m_k$ model with $\boldsymbol{s}_k$
6:         Extract features $\mathbf{F}_k$ in images by $m_k$.
7:         Normalize all features in $\mathbf{F}_k$ with an L2-norm technique.
8:         For $i$ in $y \in \{0,1\}$ do:
9:             Compute the representation of each class data $\mathbf{c}_{ik}$ from $\mathbf{F}_k$.
10:        End For
11:        Evaluate the distances from centroid $\mathbf{c}_{ik}$ to every feature of all $\mathbf{F}_k$instances.
12:        Predicted a bottle is normal or abnormal $(h)$ is based on the minimum distance between $\mathbf{c}_{ik}$and $\mathbf{F}_{k \in N^{ik}}$.
13:        Compute means squared error MSE from $h$ with true label $y$.
14:    End While
15:    $m_k \in E$ and $\mathbf{c}_{ik} \in C$.
16: End For
```

To construct a set of CNNLSTM models, our method involves randomly selecting images in the **S** training dataset and organizing them into several partitions or subsets, i.e., **S** $\rightarrow \{s_1, s_2, \dots, s_k, \dots, s_K\}$. The purpose of creating these sub-datasets is to foster diversity in CNNLSTM models and generate representation vectors for both normal bottles and bottles with defects.

The current s_k is the training bottle images for a CNNLSTM model, m_k. Let the set models is ensemble E. The convolutional layer of the current model uses pre-train weight of previous round. The output of training with five epochs is m_k (Step 5).

In Step 6, deep features vectors $\mathbf{F}_k$ are extracted from the images in s_k. This process involves removing the output layer from the CNNLSTM and obtaining the output features through the fully connected layers. Let the deep feature vector $\mathbf{f}_{jk}$ be an instance extracted from an image in $\mathbf{F}_k$: $\mathbf{f}_{jk} = m_k(\mathbf{x}_{jk})$. The feature vector consists of 1,000 components, which corresponds to the number of hidden neurons: $\mathbf{f}_{jk} = \{v_1, v_2, \dots, v_{nk}\}, \mathbf{f}_{jk} \in \mathbf{F}_k$.

Each feature vector is normalized using an L2-norm technique (Step 7). This normalization technique is commonly used to scale and standardize vectors in machine learning and data analysis. The L2-norm, also known as the Euclidean norm or the L2-norm, is a mathematical measure of the length or magnitude of a vector. In the context of feature normalization, the L2-norm technique calculates the square root of the sum of the squares of each component in the vector, resulting in a normalized vector with a magnitude of 1. Here, we provide an explanation of the concept of L2-norm. Consider a deep feature vector as:

$$\mathbf{F}_k = [\mathbf{f}_{1k}, \mathbf{f}_{1k}, \mathbf{f}_{1k}, \dots, \mathbf{f}_{1k}] \tag{6}$$

where

$$\left|\mathbf{f}_{jk}\right| = \sqrt{\sum_{l=1}^{n^k} |v_{lk}|^2} \tag{7}$$

where v_{lk} represents an extracted feature within $\mathbf{f}_{jk}$, and n^k denotes the total number of extracted features v in $\mathbf{f}_{jk}$. L2 serves as the final output layer of CNNLSTM, producing the extracted features as the output.

The representation of the class data $\mathbf{c}_{ik}$ is computed as the average of all feature vectors in F_k, which have been extracted from instances of the i-th class sample data (Step 9). In this step, we compute the centroids for the two classes: the centroid of the good bottles (class 0) and the centroid of the bottles with defects (class 1): $y = \{0, 1\}$. These class centroids enable the recognition of patterns on the side walls of the bottles. The centroid vector $\mathbf{c}_{ik}$ is calculated as follows:

$$\mathbf{c}_{ik} = \frac{1}{Nik} \sum_{\mathbf{f}_{jk} \in Nik} \mathbf{f}_{jk} \tag{8}$$

where $\mathbf{c}_{ik}$ constrain the average values $a : \mathbf{c}_{ik} = \{a_1, a_2, \dots, a_n\}$; and Nik is the number of all data instances of class i in s_k. The centroids are representation of class data.

Predicted a bottle is normal class or abnormal class (h) is based on the similarity distance between $\mathbf{c}_{ik}$ and $\mathbf{F}_{k \in N^{ik}}$ (Step 12). The similarity distances between each class are compared using the Euclidean distance to predict the category of the bottle. Predict normal or abnormal bottles by minimizing the similarity distance value defined as

$$\mathrm{h}_j = \arg\min_i \left\|\mathbf{f}_{jk} - c_{ik}\right\|_2, for\ \mathrm{j} = 1 : Nk, \tag{9}$$

where Nk is the number of instances in s_k.

To assess the extraction and classification performance of a trained CNNLSTM model m_k, the Mean Squared Error (denoted as MSE) is measured. If the model error (MSE) exceeds an error threshold value (θ), the deep neural model will undergo an additional training process of 5 epochs (proceed to Step 5). If the condition is met, the deep feature vectors $\mathbf{F}_k$ and the centroid c_{ik} are recomputed. Otherwise, the training process is stopped, and the model is obtained. The training iteration k is completed based on the performance condition. The threshold value θ is used to measure the performance and reduce the number of training iterations in each model generation. It serves as a criterion for selecting a set of models that require fewer training iterations compared to the training process of a normal deep neural network. At this point, the model m_k is added to the ensemble E ($m_k \in$ E), and the centroid c_{ik} is included in the set $c_{ik} \in$ C (Step 15). For the next iteration, we used pre-trained CNNLSTM weights from the previous iteration k to learn the current data $m_{k+1} \rightarrow m_k$. This method eliminates the need to reset the weights each time and only requires fine-tuning on the new set of bottle images. The overview of feature learning method is illustrated in Fig. 6.

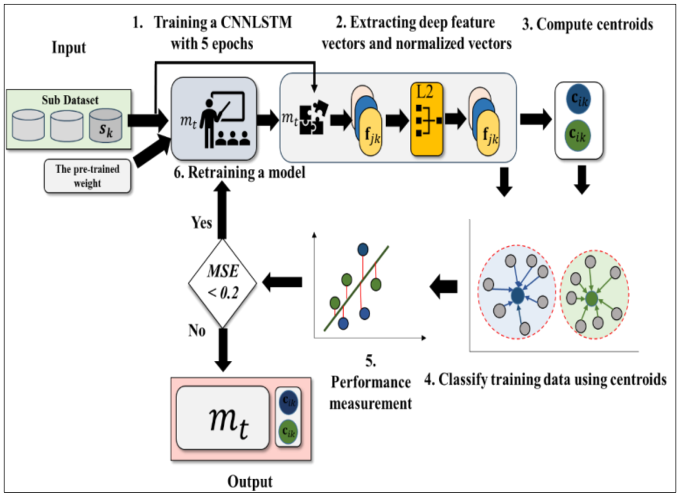

Fig. 6. Over all process of feature learning networks for glass bottle.

3) The classifying process: This section presents a detailed discussion of the proposed similarity voting method. This classification method focuses on utilizing distinctive features of defects for bottle defect detection. The similarity distance is calculated between the representation features of normal bottles and abnormal bottles. The classification steps of our method are outlined in Algorithm 2.

Algorithm2: Pseudocode for classifying bottle defects.

```
Input:
    $E$: A set of CNNLSTM models
    $C$: A set of centroids of class data
    $\mathbf{x}$: A bottle images
Output:
    $h_i = \underset{i}{\operatorname{argmin}} \sum_i \sum_k sd_{ik}$
For $k = 1, 2, \dots, K$ do:
    Extract deep features $\mathbf{f}_k = m_k(\mathbf{x})$
    Normalize the deep feature vectors $\mathbf{f}_k$ by $L2$ -norm
    For $i = 1 : y$ do:
        Calculate the distance $d_{ik}$ between centroid $\mathbf{c}_{ik}$ to features $\mathbf{f}_k$
    End For
    Compute the distance weight $sd_{ik}$
End For
```

The input for Algorithm 2 consists of a set of CNNLSTM models E, the centroid of class data C, and the bottle image $\mathbf{x}$.The models in set E differ from the decision boundary models of the same architecture. Extract features in bottle image using each model in E and combine them to predict the final output. Deep feature vectors are extracted from the bottle image: $\mathbf{f}_k = m_k(\mathbf{x})$ (Line 2). Then, the deep feature vector $\mathbf{f}_k$ is normalized using the L2-norm technique: $\mathbf{f}_k = \text{L2}(\mathbf{f}_k)$ (Step 3). The deep feature vector is normalized to ensure it resides in the same vector space as $\mathbf{c}_{ik}$, enabling the calculation of similarity values. The similarity distance d_{ik} between feature and centroid is expressed as follows:

$$\alpha_{ik} = \|\mathbf{f}_k - \mathbf{c}_{ik}\|_2, for\ k = 1{:}K, \tag{10}$$

where K is the number of ensemble model. Each centroid calculates the similarity distance with the features of the bottle image. The voting weight of each model is computed as follows:

$$sd_{ik} = \frac{\alpha_{ik}}{\sum_i \alpha_{ik}}, \tag{11}$$

where sd_{ik} is the voting weight of class i at model k. The voting weight is determined by calculating the average distance between the centroid and the features of both normal and abnormal bottles (Step 6).

The final output of this method is prediction class that compute as follows:

$$h_i = \underset{i}{\text{argmin}} \sum_i \sum_k sd_{ik}, \tag{12}$$

where h_i is the class or category that the method predicts the input image belongs to base on its defect patterns and relationships from the training bottle images. The proposed classification method is illustrated in Fig. 7.

IV. Experimental Results and Discussion

In this section, we present a comprehensive set of experiments conducted to assess the performance of the CNNLSTM method.

A. Experimental Setup

These experiments used three glass bottle image datasets, namely the body dataset, the neck dataset, and the rotating dataset. These datasets consist of three primary types of defects: stone, tear, and blister. The body dataset of glass bottles comprises a total of 571 images. For the training set, 292 images, consisting of 161 images with defects and 131 images without defects were used to train models. The remaining 279 images constituted the testing set, with 207 images containing defects and 72 images without defects. The neck dataset encompasses 570 images of glass bottles. The training set include 288 images, with 150 images exhibiting defects and 138 images without defects. The testing set includes 282 images, with 100 images containing defects and 182 images without defects. The rotating dataset encompasses 120 images of glass bottles. The training set include 80 images, with 47 images exhibiting defects and 33 images without defects. The testing set includes 40 images, with 23 images containing defects and 17 images without defects. The distribution of each defect type in both the training and testing datasets for body, neck and rotating bottles is presented in Table I.

TABLE I. Number of Training and Testing Images for each Defect Type in the Body, Neck and Rotating Datasets

Defect type	Body		Neck		Rotating	
	Train	*Test*	*Train*	*Test*	*Train*	*Test*
Stone	81	127	80	71	20	10
Tear	30	28	20	17	12	5
Blister	50	52	50	12	15	8
Normal	131	72	138	182	33	17
Total	292	279	288	282	80	40

To assess the effectiveness of our proposed method on the defect dataset, various image processing techniques, including image thresholding and edge detection, along with machine learning models such as Anomaly Detection with Autoencoder (ADA), ResNet50, AlexNet, VGG16, and MobileNetV3 were used to construct models for comparison. Image thresholding, a commonly used technique in image processing using OpenCV, involves setting pixel values to either 0 or a maximum value based on a predefined threshold [13]. Edge detection is a digital image processing technique used to identify and extract edges in an image, representing abrupt changes in intensity or color between adjacent pixels [14]. ResNet50 is a deep convolutional neural network architecture introduced in 2016 [15]. ResNet-50 consists of 50 layers and employs residual blocks, each containing convolutional layers and shortcut connections. It has achieved state-of-the-art performance in various image recognition tasks. AlexNet is a deep convolutional neural network architecture proposed in 2012 [16]. AlexNet comprises eight layers, including five convolutional layers and three fully connected layers. It introduced several key innovations, such as using ReLU as an activation function and applying dropout regularization. VGG16 developed by the Visual Geometry Group (VGG) at the University of Oxford in 2014, is a widely recognized deep convolutional neural network architecture primarily used for image classification [17]. It consists of 13 convolutional layers followed by 3 fully connected layers, and it has demonstrated outstanding performance on numerous computer vision tasks. MobileNetV3, introduced by Google in 2019, is specifically designed for mobile and embedded devices that have limited computational resources [18]. This architecture aims to strike a balance between model size and accuracy, making it suitable for efficient deployment on devices with constrained hardware capabilities. In addition to these models, we also employed the Anomaly Detection with Autoencoder (ADA) technique. ADA detects anomalies by evaluating the reconstruction loss, comparing it to a predefined threshold. If the reconstruction loss surpasses the threshold, the input is classified as an anomaly.

For training our method and deep learning-based models, we used a training set comprising 292 images for the body dataset and 288 images for the neck dataset. The training epochs are set at 500 for VGG16, RestNet50, MobileNetV3, and ADA. The input error threshold, θ, of the proposed method is set to 0.2, and the number of ensemble models, K, is set to 3. All the experiments, including the proposed defect detection method and the comparison methods, were conducted on a personal computer equipped with an AMD Ryzen 7 5000 series processor and an NVIDIA GTX 1650 GPU, allowing for efficient computation and analysis of the results.

B. Experimental Result

Four evaluation metrics are adopted for the analysis: Accuracy, Recall, Precision, and F1-score. These metrics are widely used in image defect detection and provide comprehensive insights into the performance of the methods. They are defined as follows:

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (13)$$

$$Recall = \frac{TP}{TP+FN} \quad (14)$$

$$Precision = \frac{TP}{TP+FP} \quad (15)$$

$$F_1 = 2 \times \frac{Precition \times Recall}{Precition+Recall} \quad (16)$$

TP refers to the number of defect bottles (positive) that are correctly predicted as positive by the model. FN represents the number of defect bottles (positive) that are incorrectly predicted as bottle without defects (negative) by the model. TN indicates the number of the bottles without defect (negative) that are correctly predicted as negative by the model. Lastly, FP signifies the number of the bottles without defects (negative) that are mistakenly predicted as positive by the model.

Fig. 8 presents visualizations of defect classification results of CNNLSTM for the body, neck, and rotation of bottle datasets.

The classification accuracy of various methods on the defect datasets is presented in Table II. The results for the body dataset demonstrate that the standalone VGG16 method outperformed all other methods, achieving an accuracy of 80%. ResNet50 is ranked second in terms of accuracy. Among the CNNLSTM models, CNNLSTM-VGG16 achieved the highest accuracy compared to the other CNNLSTM variants. Conversely, the image threshold method exhibited the lowest accuracy on this dataset.

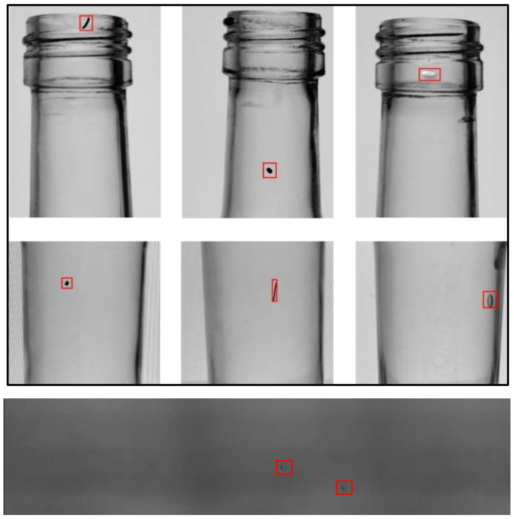

Fig. 8. Examples of classification results of the CNNLSTM.

TABLE II. THE PERFORMANCE ON THE BODY IMAGES, NECK IMAGES AND ROTATING IMAGES DATASETS IN TERMS OF ACCURACY

Methods	Body dataset	Neck dataset	Rotating dataset
	Accuracy (%)	*Accuracy (%)*	*Accuracy (%)*
CNNLSTM-ResNet50	71	**95**	62
CNNLSTM-AlexNet	75	89	97
CNNLSTM-MobileNetV3	64	92	**98**
CNNLSTM-VGG16	77	80	90
ResNet50	79	79	60
AlexNet	74	92	60
VGG16	**80**	85	95
MobileNetV3	70	72	70
ADA	74	75	60
Image threshold	62	65	65
Edge detection	70	72	63

The neck dataset results reveal that CNNLSTM-ResNet50 attained the highest accuracy of 95%, closely followed by CNNLSTM-AlexNet, CNNLSTM-MobileNetV3, CNNLSTM-VGG16, and AlexNet. Among the standalone methods, AlexNet exhibited the highest accuracy on this dataset. Conversely, the image threshold method yielded the lowest accuracy for the neck dataset.

Upon comparing the results of the rotating dataset images, it is obvious that CNNLSTM-MobileNetV3 achieved the highest accuracy. CNNLSTM-AlexNet and the standalone VGG16 also demonstrated good performance with high accuracies. Conversely, ADA exhibited the lowest accuracy percentages on this dataset.

Overall, the results indicate that different methods perform differently on the three datasets. The standalone VGG16 achieved the highest accuracy on the body dataset. CNNLSTM generally achieved the highest accuracy on both the neck and rotating datasets.

In Table III, the performance measures, including Recall, Precision, and F1-score, are presented for the body dataset. VGG16 demonstrates the highest level of correctness, evident from its superior metrics across Recall, Precision, and F1-score. Following closely in terms of correctness, CNNLSTM-AlexNet achieves relatively high Precision and F1-score. On the other hand, Image Threshold exhibits the lowest level of correctness among the methods listed.

TABLE III. THE PERFORMANCE ON THE BODY IMAGES DATASETS IN TERMS OF RECALL, PRECISION, AND F1-SCORE

Methods	Recall (%)	Precision (%)	F1-score (%)
CNNLSTM-ResNet50	80	73	70
CNNLSTM-AlexNet	82	74	74
CNNLSTM-MobileNetV3	71	66	63
CNNLSTM-VGG16	83	75	75
ResNet50	71	75	73
AlexNet	73	74	70
VGG16	**86**	**78**	**77**
MobileNetV3	57	57	57
ADA	51	55	53
Image Threshold	50	53	51
Edge detection	78	72	67

VGG16 outperforms the CNNLSTM method in terms of accuracy on the body image dataset. The VGG16 is advantaged by being pre-trained on a large and diverse collection of images. Its capacity to identify various features associated with bottle defects, coupled with the requirement for a comprehensive and diverse training set, contributes to its superior performance.

Table IV presents the Recall, Precision, and F1-score metrics of the proposed method and the compared methods for neck image datasets. Among the CNNLSTM methods, CNNLSTM-ResNet50 demonstrates the highest recall, precision, and F1-score, indicating its strong performance. CNNLSTM-MobileNetV3 follows closely behind with good recall, precision, and F1-score. Among the individual models, AlexNet demonstrates good performance, achieving high recall, precision, and F1-score. MobileNetV3 exhibits moderate performance with decent recall and F1-score, but its precision is relatively lower. ADA demonstrates moderate performance across all metrics. On the other hand, Image Threshold and Edge detection methods exhibit lower performance, with lower recall, precision, and F1-score.

Table V presents the Recall, Precision, and F1-score metrics of the proposed method and the compared methods for rotating image datasets. Among the CNNLSTM methods, CNNLSTM-MobileNetV3 and CNNLSTM-AlexNet demonstrate outstanding performance, achieving high recall, precision, and F1-score. CNNLSTM-VGG16 also performs well, with consistently high metrics. However, CNNLSTM-ResNet50 exhibits comparatively lower performance across the metrics.When considering individual models, VGG16 stands out with consistently high scores for recall, precision, and F1-score. ResNet50, AlexNet, and MobileNetV3 display varying levels of performance, with some metrics being higher or lower than others. In terms of the additional methods, Image Threshold exhibits relatively high recall but lower precision and F1-score. ADA demonstrates quite low performance across the metrics.

TABLE IV. THE PERFORMANCE ON THE NECK IMAGES DATASETS IN TERMS OF RECALL, PRECISION, AND F1-SCORE

Methods	Recall (%)	Precision (%)	F1-score (%)
CNNLSTM-ResNet50	**95**	**92**	**96**
CNNLSTM-AlexNet	89	85	92
CNNLSTM-MobileNetV3	92	90	93
CNNLSTM-VGG16	80	77	78
ResNet50	79	71	88
AlexNet	92	89	94
VGG16	85	79	90
MobileNetV3	72	62	80
ADA	75	70	75
Image Threshold	65	52	53
Edge detection	72	65	70

Table VI displays the training time and detection time of all detection methods. Among the CNNLSTM methods, CNNLSTM-VGG16 has the longest training time on all three datasets, followed by CNNLSTM-ResNet50. However, CNNLSTM-ResNet50 has the shortest detection time across all datasets, indicating faster inference speed. CNNLSTM-AlexNet and CNNLSTM-MobileNetV3 also demonstrate relatively shorter training and detection times. For the individual models, ResNet50, AlexNet, VGG16, and MobileNetV3 have consistent training and detection times across all three datasets. Among the additional methods, ADA has relatively short training and detection times, while Image

Threshold and Edge detection methods have negligible training times but slightly longer detection times compared to the CNNLSTM and individual models.

Overall, the experimental results demonstrate the effectiveness of the proposed CNNLSTM models for defect detection on all three datasets. The proposed models achieved competitive accuracy and performed well in terms of evaluation metrics. The training and detection times varied among the models, with CNNLSTM-AlexNet demonstrating the shortest training time. These findings can guide the selection of appropriate models based on the trade-off between accuracy and computational time requirements in practical applications.

TABLE V. THE PERFORMANCE ON THE ROTATING IMAGES DATASETS IN TERMS OF RECALL, PRECISION, AND F1-SCORE

Methods	**Recall (%)**	**Precision (%)**	**F1-score (%)**
CNNLSTM-ResNet50	66	71	61

V. CONCLUSION

This research presents an approach for detecting defects in glass bottles using a combination of deep convolutional neural networks with long short-term memory (CNNLSTM) and instance-based classification algorithms. The CNNLSTM combines two types of deep neural networks to extract features and create a representation of class data, which is then used for defect detection. The proposed method is compared with other well-known defect detection methods. Experimental results demonstrate that the proposed method outperforms other defect detection methods in terms of detection performance. Additionally, the proposed method requires less training time, making it suitable for efficient glass bottle defect detection in production lines.

In future work, we intend to extend the application of the proposed algorithm to different types of bottles and explore additional defect types. The flexibility of the CNNLSTM allows for varying the number of models and designing customized detection layers to adapt to specific datasets. Furthermore, there is potential to extend this method to semi-supervised learning, enabling the detection of defects in other product categories. These future directions will further enhance the capabilities and applicability of our approach in defect detection and contribute to the advancement of quality control systems in various industries.

***Abstract*—Anomalous trajectory detection is an important approach to detecting taxi fraud behaviors in urban traffic systems. The existing methods usually ignore the integration of the trajectory access location with the time and trajectory structure, which incorrectly detects normal trajectories that bypass the congested road as anomalies and ignores circuitous travel of trajectories. Therefore, this study proposes an anomalous trajectory detection algorithm using the popular routes in different traffic periods to solve this problem. First, to obtain popular routes in different time periods, this study divides the time according to the time distribution of the traffic trajectories. Second, the spatiotemporal frequency values of the nodes are obtained by combining the trajectory point moments and time span to exclude the interference of the temporal anomaly trajectory on the frequency. Finally, a gridded distance measurement method is designed to quantitatively measure the anomaly between the trajectory and the popular routes by combining the trajectory position and trajectory structure. Extensive experiments are conducted on real taxi trajectory datasets; the results show that the proposed method can effectively detect anomalous trajectories. Compared to the baseline algorithms, the proposed algorithm has a shorter running time and a significant improvement in *F-Score*, with the highest improvement rate of 7.9%, 5.6%, and 10.7%, respectively.**

Keywords*—Anomalous trajectory detection; time periods; popular routes; gridded distance

I. Introduction

With the rapid development of GPS positioning and wireless communication technology, more and more trajectory data have been collected [1, 2]. Detecting anomalous trajectories from a large amount of collected trajectory data has been widely used in various fields, such as fraud detection [3], medical treatment [4], and anomalous trajectory detection [5]. The huge trajectory data generated by vehicle location acquisition also provides an unprecedented opportunity to analyze the anomalies of moving objects and discover some basic rules of their movements [6]. Through timely and effective analysis of these traffic trajectories, the behavior rules of vehicles can be detected, thereby revealing the dynamic changes of certain behaviors and the “special” events hidden behind the vehicle behavior patterns [7]. For example, detours can be detected during taxi driving [8], and traffic jams due to traffic accidents [9] or temporary road closures [10]. This information can better guide the driving of taxi routes and provide early warnings of potential safety hazards, thus improving urban traffic planning.

Anomalous trajectory detection is one of the hot research topics in trajectory pattern mining [11, 12]. Usually, an anomaly means that a data object has a large deviation from the remaining objects in the retrieved dataset due to some of its unusual characteristics. For these different anomalous trajectories, many anomaly detection methods have been proposed. The existing anomalous trajectory detection technology mainly uses the similarity measurement method to find out the trajectory that is highly different from others [13-15]. The LDTRAOD [16], DB-TOD [17], and the ATD-outliers method [18] combine attributes such as distance between trajectory points, local density, and trajectory shape to calculate the abnormal score of trajectories by quantifying the similarity between trajectories. However, the time complexity of these methods is too high, which leads to prohibitive costs. Therefore, trajectory grid processing is often exploited to solve this problem, reducing the computational complexity by mapping the spatial locations of trajectory points onto the grid codes. In addition, it can be seen from the existing methods that the key to anomalous trajectory detection is extracting a representative feature of each trajectory and then using a function based on this to measure the similarity between them. Therefore, a taxi driving a long distance or a trajectory with fewer same driving trends is considered to be an anomalous trajectory. Although this can detect a large number of anomalies, the false positives of the detection results are usually high. Because these methods focus only on the location of the trajectory and do not integrate it with the time period and the trajectory structure, thus incorrectly detect normal driving trajectories of particular time periods as anomalies, and ignore loop driving behavior on normal routes.

For example, a passenger Alice takes a taxi from the starting point *S* to the destination point *D*. There are two routes at fixed starting and ending points, namely R and R_0, where the distance of R_0 is shorter than that of *R*. If the trip occurs during the off-peak period, which means that the traffic volume is relatively low during this period. Therefore, considering the time and fare spent by passengers on the trip, the route R_0 is chosen as the optimal route for this road segment. However, if the trip occurs between 7:00 am-9:00 am, the route R_0 may cause serious road congestion and traffic accidents due to the traffic flow during rush hour. Therefore, in terms of the time peak, the optimal choice for taxi drivers should be *R*.

Obviously, as the dynamics of popular routes change, the anomaly judgment of the trajectory also changes. The driver's choice of route usually changes at special periods or moments when special events occur. Therefore, it is necessary to divide the effective time intervals according to the vehicle travel pattern. However, if the division is performed at very short and fixed intervals, it will consume a lot of unnecessary time and space resources, and the detection results will also contain certain errors. Research [13] pointed out that the taxi trajectory tends to take more time during peak periods than during off-peak periods. Inspired by this, it can be determined that drivers will choose different routes at specific time periods to save passengers' travel time. Therefore, this paper proposes an anomalous trajectory detection method using popular routes in different traffic periods (PRTP). Compared with previous detection algorithms that only consider the location of trajectory points or have large time consumption, the PRTP algorithm divides the time of day into four time periods according to the temporal distribution density of trajectories, thus discovering the dynamic changes of the popular routes and considering the effect of time segmentation and trajectory time span on frequency. Meanwhile, the location and structure of the trajectory are considered comprehensively in the anomaly judgment, which improves the stability and accuracy of detection.

In summary, the main contributions of this study are as follows.

- An anomalous trajectory detection method using popular routes in different time periods is proposed, which divides the time according to the traffic flow and combines the location and time features of trajectories in different time periods to detect anomalies, thus improving the accuracy of anomaly detection.
- By integrating the access location, time, and time span of the trajectory, a calculation method of spatiotemporal frequency is designed, so that the popular routes can be accurately obtained without the interference of temporal anomalous trajectory.
- A grid distance formula is proposed to quantitatively measure the trajectory anomaly distance, which considers both the location and structure of the trajectory, enabling the detection of circuitous driving anomalies of the trajectory in addition to location anomalies. The effectiveness and performance of the PRTP method are empirically evaluated using real taxi trajectories

The rest of the paper is organized as follows. The related work on anomalous trajectory detection is reviewed in Section II. After the problem definitions are given in Section III, the main steps of the PRTP are presented in Section IV. In Section V, the overall experimental setup and experimental results are reported. Section VI discusses the proposed method. Finally, the conclusions are presented in Section VII.

II. Related Work

At present, the field of anomalous trajectory detection has been developed rapidly. Though the existing anomalous trajectory detection algorithm has been well applied in real life, further explorations are still needed. The existing detection methods can be mainly divided into two categories, anomaly detection based on spatial attributes and anomaly detection based on spatiotemporal features.

A. Detection Based on Spatial Features

Among the existing anomaly detection algorithms, the algorithms focusing on the spatial position of the trajectory occupy a larger proportion. These methods focused on considering the spatial attributes of trajectory points, such as position, direction, velocity, etc., and select specific attributes as trajectory similarity criteria to detect anomalous trajectories. Lee et al. [19] proposed a trajectory anomaly detection algorithm TRAOD, which includes trajectory division and trajectory detection. All trajectories are divided into t-partitions according to a novel partition-and-detect framework, and then trajectory partitions are detected by a distance-based method. To detect anomalous from the locally dense trajectory, Luan et al. [16] proposed the anomaly detection algorithm LDTRAOD based on the local density of trajectories, which uses the partition-and-detect framework [19] to determine local anomalous trajectories by calculating the local density and local outlier factors for each t-partition. Although these methods can quantify the similarity between trajectories, anomaly detection based on individual location attribute does not apply to anomalies with complex distributions. To combine multiple features for anomaly detection, San Roman et al. [20] proposed the CaD method which considers the angle difference, Euclidean distance, and the number of points in each trajectory, and effectively detects anomalous trajectories in each cluster by using the unsupervised learning method of the trajectory distance matrix. Sun et al. [21] proposed the TODDT algorithm in combination with dynamic difference threshold to detect anomalous trajectories from multiple perspectives. Considering the trajectory common slice subsequence, Yu et al. [22] proposed a novel trajectory anomaly detection algorithm based on common slice subsequence (TODCSS), which combines features such as direction, position, and continuity to achieve more accurate trajectory anomaly detection. And to detect different patterns of anomalous trajectories, Wang et al [23] proposed a DIS metric. After gridding the trajectories, the DIS values are used to quantify the similarity between trajectories and then assign the anomalous trajectories to different classifications. Considering the special conditions of anomalous trajectories and the motion patterns mined in the massive trajectory data, researchers have also proposed many methods. Inspired by the "few and different" property of anomalous trajectories, Zhang et al. [24] proposed the iBAT algorithm which can effectively detect outliers of trajectories by isolating the number of steps used by the trajectory. Combine the actual inherent travel flow and other information of trajectory data to make abnormal judgment. Yu et al. [25] proposed a multi-level approach that combines association rule techniques to discover moving routes. To mine the special driving patterns of moving objects from trajectories, Zhang et al. [26] proposed an algorithm to discover popular routes from fixed locations. The algorithm meshes the region area into a regular grid to discretize the historical trajectory and finally determines the most popular routes by an ant colony optimization method. Tang et al [27] used the theory of time geography to propose a path-oriented traffic state estimation model to find the most likely road path, link travel time and activity duration at possible intermediate stations.

Real-time performance is the primary requirement of practical applications when detecting trajectory anomalies. Traffic conditions vary at different times and in different locations, exploiting latent patterns in real time can capture anomalous behaviors in real-time and make timely traffic adjustments [28]. Therefore, while overcoming the drawbacks brought by the single spatial attribute algorithm, researchers have investigated anomaly detection for evolutionary trajectories. To reduce the problem of the high false alarm rate of anomaly detection due to complex road conditions, Chen et al. [29] proposed an online anomaly trajectory based on multidimensional criteria for real-time anomaly detection by simultaneously considering multidimensional criteria such as similarity, time, and distance. Ge et al. [30] proposed an evolutionary trajectory outlier detection method TOP-EYE, which continuously calculates the outlier score for each trajectory in a cumulative manner and proposed a decay function to mitigate the impact of historical trajectories on the outlier score of trajectory evolution, thus identifying evolutionary anomalous trajectories at an earlier stage. Using a street-based trajectory delineation approach, Shi et al. [31] proposed RUTOD, an anomaly detection framework for real-time urban traffic. The framework combines an individual anomalous moving object with the group anomalous values generated by various moving objects for anomalous detection.

B. Detection Based on Spatiotemporal Features

In the practical application of anomalous trajectory detection, in addition to various situations where spatial attributes need to be considered, temporal features are also important for anomalous trajectory detection. In recent years, a lot of research and exploration has been conducted on time attributes. Zhu et al. [32] proposed a new time-dependent popular route algorithm TPRO. In this algorithm, the abnormal trajectory is dynamically measured by considering the spatial and temporal characteristics of the motion trajectory. However, the TPRO algorithm is limited to the detection of historical trajectories, and it is not applicable to anomalies of real-time trajectories. Therefore, in the TPRRO [33], a real-time outlier detection algorithm was proposed based on time-dependent popular routes, which can realize efficient detection and evaluation of the testing trajectory through offline preprocessing and online anomaly detection.

Besides, for the detection of more complex anomalous trajectories in the spatiotemporal dimension, Yang et al. [34] proposed a new trajectory clustering algorithm TAD, which is based on the spatiotemporal density analysis of trajectory data to detect the stay of complex trajectories. To detect behaviors such as abnormal parking and stranding of vehicles in the time dimension, He et al. [35] proposed a common subsequence-based spatiotemporal anomaly trajectory detection method (STADCS). This method detects spatiotemporal anomalies by combining spatial features and temporal dimensions of trajectory subsequences. And based on the travel time of the trip, Eldawy et al. [36] proposed a novel real-time anomalous trajectory detection system called FraudMove. When choosing the best route, the FraudMove method takes the popular route as the best choice. Then, an adjustable time window parameter is used to control the detection times of anomaly detection, thus dynamically detecting anomalous taxi behaviors in combination with travel time.

Although most of the above anomalous detection methods combine multiple trajectory attributes to achieve different modes of anomalous trajectory detection, there are still two main limitations. First, if the spatial features or temporal features of trajectories are used alone, such detection results will produce high false positives. Researchers only consider the matching degree of trajectory points when considering the node frequencies in different time periods, the detection accuracy will be reduced by ignoring the influence of other attributes on the node frequencies. Second, most algorithms only consider the location abnormality of trajectories and ignore the change of trajectory structure in the abnormality judgment. Therefore, it is necessary to divide the time periods in anomalous trajectory detection and calculate the frequency in the spatiotemporal dimension, and integrate the trajectory structure with the trajectory position to improve the accuracy of abnormal driving trajectory detection.

III. Problem Definition

This section defines some related terms and provides formal definitions of the problems considered in this paper to facilitate further descriptions.

Definition 1 (Point): given a record, let *x*, *y*, and *t* be longitude, latitude, and timestamp, respectively. Then the spatiotemporal information can be recorded in a triplet, namely (*x*, *y*, *t*), which is a spatiotemporal point formed by the object passing through the position (*x*, *y*) at time *t*.

Definition 2 (Trajectory): a trajectory is denoted by *T*, which consists of a series of trajectory points:

$$T_i = \{p_1, p_2, \dots, p_j, \dots, p_k, \dots, p_{len}\}, \tag{1}$$

the entire trajectory dataset is represented as:

$$TS = \{T_1, T_2, T_3, \dots, T_n\}, \tag{2}$$

|*TS*| is the size of *TS*, i.e., |*TS*|=*n*. p_j is the *j*-th point of T_i, which includes three components *x*, *y*, *t*. The trajectory segment is the line segment between p_j and p_{j+1}.

Definition 3 (Road Network): the road network is represented as a directed graph *G*(*V*,*E*), where V represents the set of nodes (such as the start and end points of a road segment), and *E* is the set of edges (such as a road segment). In this paper, v_i is used to represent a specific vertex in *G*. If v_i and v_j are the two points of the edge *e*, it can be expressed as $e.v_i$ and $e.v_j$.

Definition 4 (Mapped Trajectory): A mapped trajectory *MT* is generated by the function $\phi(T)$, which maps latitude and longitude coordinates to the cell, and generates a series of grid codes $c_1, c_2, c_3, \dots, c_{len}$, where $c_i = \phi(p_i)$.

Definition 5 (Equivalent Cell): Given a grid size of $\mathcal{M}$, the road network is divided into equal cells of size $\mathcal{M}$, and the position of cell is denoted by $\mathbb{C}$. Then, let trajectories pass through the road network regions, if two different trajectory points p_i and p_j fall into the same cell, they are called points with the equivalent cell, which is expressed as $Equcell_{\mathcal{M}}(p_i, p_j)$.

As shown in Fig. 1, there are two trajectories and all their trajectory points have corresponding grid cells. The points p_3' and p_5 on the different trajectories fall into the same grid cell (green grid), so they are called points with the equivalent cell.

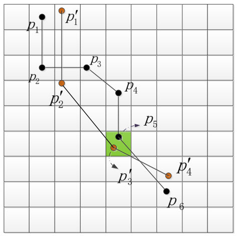

Fig. 1. An illustration of the equivalent cell.

Definition 6 (Time Span): Given a trajectory T_i, the travel time from the source to the destination is defined as the time span, which is denoted by St_i as:

$$St_i = T_i.t_d - T_i.t_s, \tag{3}$$

where $T_i.t_s$, $T_i.t_d$ represent the start time and end time of the trajectory T_i, respectively.

Definition 7 (Route): After matching the trajectory with the city map using ArcGIS, the route is represented by each node cell and its frequency. A route based on cell frequency is represented as:

$$R = \{rc_1, rc_2, rc_3, \dots, rc_m\}, \tag{4}$$

where rc_i=(c_i, f_i), c_i represents the *i*-th node cell on the route, f_i refers to the frequency of passing through the node cell.

Definition 8 (Anomaly trajectory): The trajectory that deviates significantly from the popular routes in the access location or structure is defined as an anomaly trajectory.

As shown in Fig. 2, there are a few trajectories between *S* and *D*, which can be divided into two groups: normal trajectories and abnormal trajectories. T_1 and T_3 are considered abnormal because they deviate from the regular routes at a certain time period.

Problem statement: Given the trajectory dataset $TS = \{T_1, T_2, T_3, \dots, T_n\}$, this study aims to detect anomaly trajectories in TS, for all $T_i \in TS$, if T_i deviates from its corresponding popular routes or drive in a roundabout manner, it is considered an anomaly trajectory.

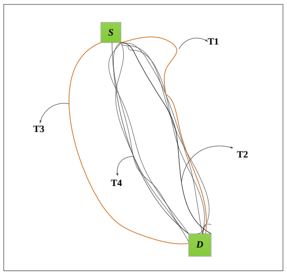

Fig. 2. An illustration of trajectories between *S* and *D*.

IV. PRTP

This section provides an overview of the anomalous trajectory detection framework proposed in this study. The PRTP method consists of two stages: trajectory preprocessing and anomalous trajectory detection. The popular routes acquisition and anomaly judgment constitute the trajectory anomaly detection stage. Fig. 3 shows the working mode of the algorithm.

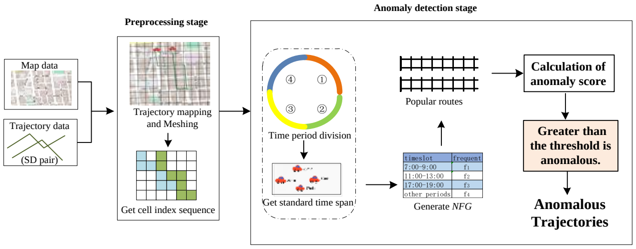

Fig. 3. Overview of PRTP approach.

A. Preprocessing Taxi Trajectory

Since anomalous driving of taxis usually occurs when they are carrying passengers, the first task in the trajectory processing stage of this study is to classify the trajectories according to their occupancy status. As shown in Fig. 4, the figure shows the trajectory of a taxi in a region for one month, in which the red line segment is the trajectory of a taxi carrying passengers and the blue line segment is the trajectory of a taxi without passengers. Therefore, for a more meaningful study, the trajectory represented by the red line segment is extracted as a valid trajectory during the preprocessing of the trajectory data in this paper.

After extracting the valid trajectories from the original trajectories, these trajectories usually contain different starting and ending points, in which there may be a certain starting and ending point between which there are not enough trajectories to form a normal trajectory group, thus causing interference to the anomaly detection. Therefore, in this study, all taxi trajectories that pass through the same *SD* pair are grouped to form the *SD* trajectory dataset (trajectories with the same source and destination). The *S* and *D* regions are 1000m×1000m grid-cells, that is, the source and destination points are satisfy $Equcell_{1000}(MT_{1.s},\dots,MT_{n.s})$, $Equcell_{1000}(MT_{1.d},\dots,MT_{n.d})$ .Then , the city map is divided into grid cells of the same size, and the extracted valid *SD* trajectories are mapped into the grid cells, thus forming a mapped trajectory consisting of a series of grid cell sequences.

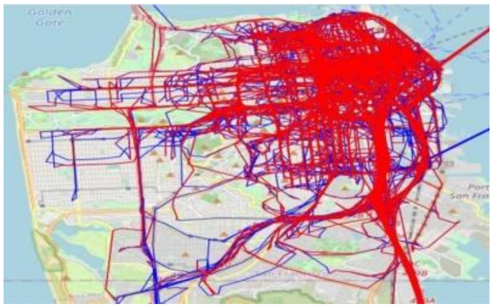

Fig. 4. Trajectories of a taxi in San Francisco during a month.

B. Anomaly Detection

1) Acquisition of popular routes: By extracting a specific SD trajectory dataset from the original dataset and mapping it to the corresponding urban road network, all the routes traversed by the trajectory dataset are obtained. Traversing the trajectory data and calculating the node frequency based on its trajectory point location and time, thus obtaining the node frequency graph (NFG) as shown in Fig. 5. In Fig. 5, $\mathrm{V_s}$ represents the source address, $\mathrm{V_d}$ represents the destination address, and the table corresponding to each node indicates the frequency of that node in each time period. For the division of time periods, the study divides the whole time domain into four time periods according to the peak traffic flow period, namely the morning peak period (7:00 am-9:00 am), the afternoon peak period (11:00 am -13:00 pm), the evening peak period (17:00 pm -19:00 pm), and the time period consisting of the remaining hours, and then performs anomaly detection according to testing trajectory and the popular routes in its time period.

Definition 9 (Equivalent time periods): Given two time periods t_1- t_2 and t_3- t_4, if t_1,t_2,t_3, and t_4 are all in the same pre-divided time period, they are called equivalent time periods.

According to the above analysis, if there are time periods 7:30 am-8:15 am and 8:45 am-9:00 am, because their starting time and ending time are included in the pre-divided morning peak time period, these two time periods are referred to as equivalent time periods in the study. And the trajectories of the equivalent time period have the same popular routes.

The anomalous trajectories are few and different, so the routes chosen by a large number of vehicles are often correct. Therefore, researchers usually determine the popularity of routes in each time period based on the number of times the route is visited. However, when there is a route with a large number of trajectories passing through, if only the number of trajectories is considered, the route must be identified as a popular route. But if all the trajectories on it have time anomalies, then this route is not desirable. So when calculating the frequency values, the study not only considers whether the trajectory points coincide with the nodes but also judges the time anomaly of the trajectories. Therefore, to exclude the influence of time-anomalous trajectories in calculating the frequency of route nodes, this study designs a calculation method for spatiotemporal frequency.

	timeslot	time span	frequency
Vs	7:00-9:00	St_1	f_{s1}
	11:00-13:00	St_2	f_{s2}
	17:00-19:00	St_3	f_{s3}
	other periods	St_4	f_{s4}
...	...		...
	timeslot	time span	frequency
Vd	7:00-9:00	St_1	f_{d1}
	11:00-13:00	St_2	f_{d2}
	17:00-19:00	St_3	f_{d3}
	other periods	St_4	f_{d4}

Fig. 5. An illustration of NFG.

By comparing the trajectory time span with the standard time span, the frequency coefficient of the trajectory is obtained, which is calculated as:

$$fc_i = \begin{cases} 1 - \frac{St_i - \overline{ST_J}}{\overline{ST_J}}, & \text{if } St_i > \overline{ST_J} \ and\ St_i - \overline{ST_J} < \overline{ST_J} \\ 1 & , \quad St_i \le \overline{ST_J} \\ 0 & , \quad else \end{cases} \quad ,(5)$$

where St_i represents the time span of the *i*-th trajectory, $\overline{ST_J}$ represents the standard time span of the *j*-th time period, and the value of *j* ranges from 1 to 4. The standard time span of each time period is obtained by selecting half of the normal trajectories in that time period and calculating the average time span of these trajectories.

After calculating the frequency coefficient of each trajectory passing through the node, the node frequency is defined as:

$$f_v = \sum_{i=1}^{N} fc_i \, , \tag{6}$$

where *N* is the number of trajectories passing through the node, the frequency of node *v* is the sum of the frequencies of *N* trajectories.

To obtain the popular routes of the testing trajectory, the popularity of each route needs to be compared. From the above analysis, the routes popularity can be evaluated by the node frequency values. Therefore, for route popularity comparison, the routes are expressed in the following form, i.e., R=($rc_1.f_1$,$rc_2.f_2$, ... ,$rc_m.f_m$), R'=($rc_1.f_1'$,$rc_2.f_2'$, ... ,$rc_n.f_n'$) . When $rc_x.f_x$ = $rc_x.f_x'$ ($x \in$ {1,2, ... ,p-1}, where p>2), if $rc_p.f_p > rc_p.f_p'$, then the route R is more popular than route R', denoted by $\mathcal{P}_{\mathrm{R}} > \mathcal{P}_{\mathrm{R'}}$.

After the analysis of route popularity, the first *k* high-frequency routes of the testing trajectory are called popular routes (*PR*), that is, if there is a route set *RS*= $\{R_1, R_2, \dots, R_k, \dots, R_q\}$, where $\mathcal{P}_{R_1} > \mathcal{P}_{R_2} > \cdots > \mathcal{P}_{R_k} > \cdots > \mathcal{P}_{R_q}$, then the popular routes *PR*=$\{R_1, R_2, \dots, R_k\}$.

Algorithm 1 Obtain the Popular Routes of the trajectory

Input: Road network *G*, trajectory dataset *TS*, Grid size $\mathcal{M}$, number of popular route *k*.

Output: Popular routes *PR*.

```
gridLabel ← Mesh the road network in $\mathcal{M}$ size
Map the TS to gridLabel to get RS=$\{R_1, R_2, R_3, \dots, R_q\}$
TS is divided into four groups according to the time period of trajectory
for i in RS do
    for j in TS do
        Select trajectory group according to the time period of $MT_j$
        Calculate $\mathrm{St_j}$, $\mathrm{fc_i}$ according to equations (3), (5), respectively
        Calculate f of $R_i$ according to equation (6)
    end for
end for
PR← select the k-popularity routes
return PR
```

The overall pseudo-code for obtaining the popular routes of the trajectory is given in Algorithm 1. First, the trajectories are mapped to the gridded road network to obtain the RS through which the trajectory dataset passes (lines 1-2). Then, the dataset is partitioned and trajectories belonging to the same time period are grouped (line 3). Finally, each trajectory is traversed to find the frequency values of the routes in different time periods, and the popular routes are obtained based on the popularity comparison (lines 4-11). The time complexity of Algorithm 1 is $O(n \cdot q)$, where n is the number of trajectories and q is the number of routes.

2) Perform trajectory anomaly judgment: After the popular routes of the testing trajectory are obtained according to the above steps, the PRTP algorithm performs trajectory anomaly detection by comparing the testing trajectory with the top-*k* popular routes.

In this study, position anomalies and structural anomalies of trajectory are mainly considered in calculating trajectory distance. The position anomaly focuses on whether the visited positions are consistent, and the structure anomaly focuses on the circuitous intersection of trajectories. Before obtaining the trajectory distance, the trajectory and popular route are converted into position access matrixes according to their access position. The elements of the *LocMatrix* are as:

$$LocMatrix_{MT_i}(\mathbb{C}) = \begin{cases} 1, & \text{if } \mathbb{C} \text{ is accessed by } MT_i \\ 0, & \text{else} \end{cases}, \tag{7}$$

where $\mathbb{C}$ denotes the position in matrix.

The structure matrix $StrMatrix_{MT_i}$ is obtained by determining the circuitous access grid through the number of trajectory visits. The elements of the $StrMatrix$ are as:

$$StrMatrix_{MT_i}(\mathbb{C}) = \begin{cases} 1, & \text{if } Num.\mathbb{C} > 1 \\ 0, & \text{else} \end{cases}, \tag{8}$$

where $\mathbb{C}$ denotes the position in *StrMatrix*, $Num.\mathbb{C}$ denotes the number of times the trajectory MT_i visits position $\mathbb{C}$.

In the study, the number of common locations and circuitous visits are focused on, and then define the distance metric of the trajectory with the matrix information. Given the gridded trajectory MT_i and one of the corresponding optimal routes PR_j , transform them into $LocMatrix_{MT_i}$ and $LocMatrix_{PR_j}$, respectively, and determine the $StrMatrix_{MT_i}$ according to the number of trajectory visits. Then the anomaly distance is calculated according to the following defined formulas:

$$LocMatrix_{common} = LocMatrix_{MT_i} \cap LocMatrix_{PR_j}, \tag{9}$$

$$GDDis(MT_i, PR_j) = \frac{\left|LocMatrix_{MT_i} - LocMatrix_{common}\right| + \left|StrMatrix_{MT_i}\right|}{\left|LocMatrix_{MT_i}\right|}, \tag{10}$$

where $|*|$ denotes the summation over the elements of the matrix $*$, $LocMatrix_{common}$ is the matrix of the common position of the testing trajectory access matrix and the popular route access matrix.

Meanwhile, from equation (10), it can be seen that the higher the matching degree between the testing trajectory and popular routes, the greater the value of $|LocMatrix_{common}|$, and the closer the *GDDis* distance is to 0. Therefore, the specific value of the *GDDis* distance can be used to quantify the match between the testing trajectory and popular routes.

In Fig. 6, given the trajectory MT_1 and the route PR_1, three 8×8-sized matrices can be obtained. From the matrix calculation, $\left|LocMatrix_{MT_1}\right|$ =19, $\left|LocMatrix_{PR_1}\right|$ =12, the intersection of the matrices $|LocMatrix_{common}|$=11, and the $\left|StrMatrix_{MT_1}\right|$ =7. Therefore, the $\left|LocMatrix_{MT_i} - LocMatrix_{common}\right|$ =8, the number of abnormal cells is 8+7=15, then, the *GDDis* of MT_1 is 15/19=0.79. However, if MT_1 only considers the anomaly of the access location, the final *GDDis* is 8/19 = 0.42, which may misjudge MT_1 as a normal trajectory. Therefore, through the different results of the above two calculations of MT_1, it can be seen that the study combines structural anomalies with location anomalies improves the detection accuracy of anomalous trajectories.

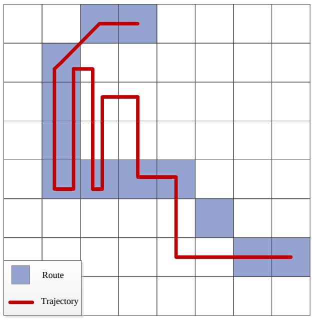

Fig. 6. An access schematic of trajectory and route.

Based on the study [32], there are often multiple alternative routes between two locations, and not all of them have the same popularity. Therefore, when judging the trajectory anomaly, the popular routes should occupy different weights in the anomaly score. Suppose exist popular routes $PRS=\{PR_1,PR_2,...,PR_p,...PR_k\}$, $PR_p=\{rc_1.f_1 ,rc_2.f_2,...,rc_m.f_m\}$, the sum of the frequencies of all nodes for popular route is defined as:

$$SUMPR_p = \sum_{i=1}^{m} PR_p.rc_i.f_i, \tag{11}$$

Since the sum of the node frequencies indicates the route popularity, the popularity weight of the route is defined as:

$$w_{PR_p} = \frac{SUMPR_p}{\sum_{j=1}^{k} SUMPR_j}, \tag{12}$$

where k represents the total number of popular routes, PR_j represents one of the popular routes, and $\sum_{j=1}^{k} SUMPR_j$ represents the sum of the popular routes frequencies.

The anomaly judgment is performed by calculating the anomaly score of the trajectory and its corresponding k routes, which is defined as:

$$Score = \sum_{p=1}^{k} w_{PR_p} * GDDis(MT_i, PR_p), \tag{13}$$

where MT_i represents the testing trajectory, and PR_p represents the *p*-th popular route.

Pseudo-code for the main steps of trajectory anomaly detection is given in Algorithm 2. First, the weights of the popular routes are calculated according to the node frequency (line 2). Then, the corresponding popular routes of testing trajectory are traversed to calculate the anomaly score between the trajectory and the popular route (lines 3-12). Finally, trajectory anomaly judgment is performed by the sum of the anomaly scores between the trajectory and the PRL, where trajectories larger than θ are anomalous (lines 13-17). Meanwhile, from Algorithm 2, it can be seen that the time complexity of the PRTP algorithm mainly depends on two aspects: the loop of trajectory data and the loop of popular routes. Therefore, the time complexity of the PRTP algorithm is O($n \cdot k$), where n represents the number of *SD* trajectory datasets, and *k* represents the total number of popular routes. In most cases, the value of k is usually small, so the time complexity can be approximated to O(*n*).

Algorithm 2 Anomalous trajectory detection method using popular routes

```
Input: gridLabel, top-k Routes PR, Score threshold $\theta$.
  Output: Traanomalous(A dataset of anomalous trajectories).
1.  $Score \leftarrow 0$
2.  WeightList ←Calculate the frequency weights of each
    popular route according to equation (12)
3.  for i in gridLabel do
4.    $PRL \leftarrow$ Get the grid sequences of the popular routes
5.    for j in PRL do
6.      $LocMatrix_{MT_i} \leftarrow$ get the trajectory access matrix
7.      $LocMatrix_{PR_j} \leftarrow$ get the route traversal matrix
8.      Calculate the $LocMatrix_{common}$ according to equation
    (9)
9.      calculate GDDis according to equation (10)
10.     $Score_j \leftarrow$ GDDis ×WeightList[$j$]
11.     Score ←Score +$Score_j$
12.   end for
13.     if $Score > \theta$ than
14.       put trajectory i into Traanomalous
15.     end if
16. end for
17. return Traanomalous
```

V. Experiments

In this section, an empirical evaluation of the proposed method is provided. All experiments are implemented with Python3 and conducted on a computer equipped with an Intel(R) Core(TM) i5-8250U CPU @ 1.80 GHz and 8GB main memory and running Windows 10 operating system.

A. Dataset

This study used the real taxi dataset provided by Piorkowski et al. [37], which contains all spatial locations of more than five hundred taxis in the San Francisco Bay Area in a month. The GPS trajectory records the latitude and longitude, timestamp, and corresponding passenger occupancy status of each taxi location point. In this study, the fixed starting and ending places selected were the airport and the central residential area. To reduce the noise and redundancy in the original trajectory data, it was assumed in the data preprocessing that only the trajectories of occupied taxis are valid. According to the above requirements, three pairs of SD trajectories (T-1 to T-3) were selected from the 463,860 trajectories extracted from 11.22 million GPS points, and whether each trajectory was anomalous or not was manually marked. The marked dataset is used to evaluate the detection accuracy of the PRTP algorithm.

B. Parameter Setting

Trajectory detection is essentially a binary classification problem, and *Recall* and *F-Score* are two important metrics to evaluate its performance. Therefore, these two metrics are used in this paper to judge the effectiveness of PRTP anomaly detection, which are defined as:

$$Precision = \frac{TP}{TP+FP}, \tag{14}$$

$$Recall\ = \frac{TP}{TP+FN}, \tag{15}$$

$$F-Score\ = \frac{2\times Precision \times Recall}{Precision+Recall}, \tag{16}$$

where *TP* (True Positive) denotes the number of detected anomalous trajectories, *TN* (True Negative) denotes the number of detected normal trajectories, *FP* (False Positive) denotes the number of normal trajectories incorrectly detected as anomalous, and *FN* (False Negative) denotes the number of anomalous incorrectly detected as normal [13].

To better investigate the effect of parameter settings in the PRTP algorithm on the detection result, this study conducted parameter setting experiments on the two largest datasets T-1 and T-3. There are three parameters in the detection stage of the PRTP, the grid size $\mathcal{M}$, the number of popular routes *k*, and the Score threshold *θ*. Therefore, this study experimentally investigates the effects of these three parameters on the *Recall* and *F-Score* of detection to determine the optimal values of the parameters.

1) Varying the size of grid cells. The setting of grid cell size determines the cell size when meshing the road network. The smaller the grid cell size, the higher the number of grids in the mapping trajectory. This makes the small differences to be magnified, which affects the detection accuracy. If the grid cell size is too large, there will be more trajectories with the same grid sequence in the dataset, which makes it more difficult to compare the similarity between the trajectory and the popular routes. Therefore, the reasonable setting of grid cell size is crucial to the performance of PRTP algorithm. Referring to previous studies [23,24], the performance variation is considered when the size of grid cells increases from 200m × 200m to 500m × 500m in this experiment. Note that the grid cell size set in this paper refers to the length and width of each small square.

In Fig. 7, the changes in *F-Score* and *Recall* for different grid sizes are illustrated. It can be seen that on the two different datasets, the maximum *F-Score* is obtained when the grid cell size is 400×400m, and the *Recall* also reaches the maximum at this time.

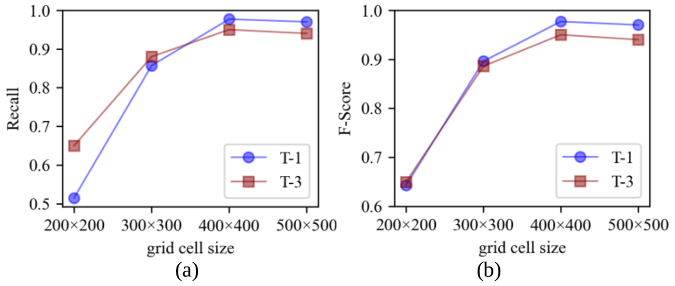

Fig. 7. The Recall and F-Score of grid cells of different sizes.

2) *Varying the number of popular routes.* The number of popular routes *k* is an important parameter in the PRTP algorithm since the value of *k* determines how many routes can be used to calculate the anomaly score of the testing trajectory. Within a certain number of ranges, the detection results may be more accurate when more popular routes are taken for comparison. However, the testing trajectory needs to be compared with the routes one by one during anomaly judgment, so the detection time will increase linearly with *k*. Referring to the previous study [32], the range of *k* is set between 1 and 8.

Combined with the above definitions and calculation equations, it can be known that in the PRTP method, the node frequency is obtained from the node frequency graph of each popular route in advance, and when calculating the *Score* of the trajectory, each popular route is given the corresponding popularity weight and the popular route is also selected according to the order of node frequency. Fig. 8 shows the changes of *F-Score* and *Recall* for different *k* values. The results show that the *Recall* and *F-Score* of anomaly detection in the range of 1 to 6 generally have an upward trend as the *k* increases, when *k*>6, the detection performance gradually decreases as the *k* increases, and it can be seen that when *k*=6, the *F-Score* on the datasets T-1 and T-3 both reach the maximum, and the *Recall* also reaches the peak within the detection range.

3) *Varying the Score threshold.* In the last step of the PRTP algorithm, the parameter *θ* directly determines whether a trajectory is anomalous or not, if the *Score* of the trajectory is greater than *θ*, it is defined as anomalous, otherwise the trajectory is defined as normal. Therefore, it is necessary to study the influence of the value of *θ* on the performance of the algorithm. Fig. 9 shows the distribution of the *Score* values of the trajectories on the two datasets according to equation (13).

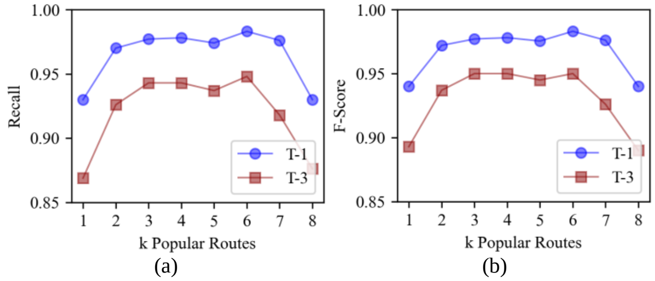

Fig. 8. The Recall and F-Score of different popular routes.

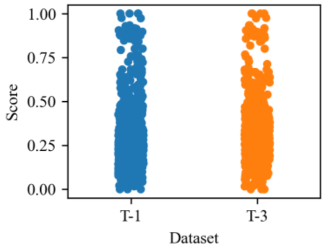

Fig. 9. The Score calculated by the PRTP algorithm.

From Fig. 9, it can be seen that most of the *Score* values on datasets T-1 and T-3 are less than 0.6, so based on the density distribution of *Score* values in the range of 0 to 0.6, 0.3 can be set as the lower limit of the range of *θ*. Moreover, the *Score* values of a small number of trajectories are distributed in the range of 0.6 to 1.0, and these points are likely to be the scores of anomalous trajectories, so 0.8 can be selected as the upper limit of the range of *θ*. Therefore, the article focuses on the effect of *θ* in the range of 0.3 to 0.8 on performance.

It can be seen from Fig. 10 that when the range between 0.3 and 0.6, as the threshold *θ* increases, the *Recall* of anomaly detection on datasets T-1 and T-3 gradually increases. Then, the *Recall* gradually decreases with the increase of *θ*, and when θ=0.6, the Recall achieves the maximum within the detection range of θ. Meanwhile, the *F-Score* shows the same variation trend, and the maximum value is obtained when *θ*=0.6. Therefore, considering the variation trend of the *Recall* and *F-Score*, *θ*=0.6 is chosen as the optimal value of the anomaly threshold.

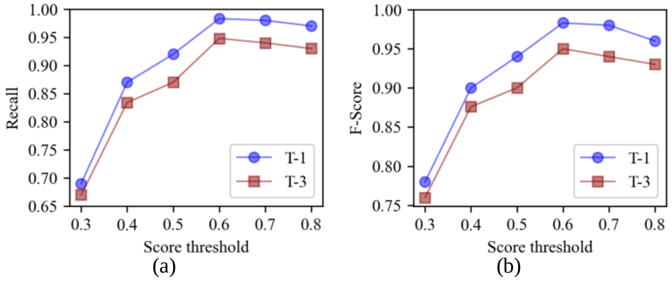

Fig. 10. The Recall and F-Score of different Score thresholds.

Finally, through the above analysis of the three variable parameters and the variation trends of *Recall* and *F-Score*, this paper determines the optimal values of these parameters as $\mathcal{M}$=400×400, *k*=6, and *θ*=0.6.

C. Visual Display of Anomalous Trajectory Detection

Anomaly detection is performed under the optimal values of the parameters. To understand the visualization result more clearly, this subsection selects some trajectories on the two largest datasets T-1 and T-3 for experiments to investigate the accuracy of PRTP. Fig. 11 shows the visualization result of anomaly detection on the real taxi trajectory datasets, where the solid blue lines represent all trajectories in the selected dataset and the solid orange lines show the anomalous trajectories detected by the PRTP algorithm.

It can be seen from Fig. 11(b) and Fig. 11(d) that the PRTP algorithm can fully detect obvious detour anomalous trajectories. Since the PRTP algorithm comprehensively considers the moment of the trajectory point, the time span of the trajectory, and the different frequency values in the detection process, it can correctly detect the local detour anomalous trajectories and global detour anomalous trajectories at different time periods. Therefore, these visualization results confirm the effectiveness of the PRTP algorithm.

(c) The selected trajectories in T-3 (d) The detected anomalous trajectories in T-3

Fig. 11. The result of anomalous trajectory detection on T-1 and T-3.

D. Comparative Evaluation

In the comparative experiments in this paper, to further verify the superiority of the PRTP, the study takes the ATDC [23], TPRO [32], and iBAT [24] as baselines to compare with PRTP. The basic idea of ATDC is to process trajectories by the grid. Then, it uses a distance calculation method to study different anomalous trajectory patterns and adopts an anomalous trajectory detection and classification method for real trajectory data. The iBAT algorithm employs an isolation mechanism to find anomalies in trajectories. Meanwhile, the basic idea of TPRO is to calculate the similarity between trajectories using edit distance in the spatiotemporal dimension. Therefore, the trajectory processing methods and research problems of these three algorithms are similar to this study.

Here, this module focuses on evaluating and comparing the anomaly detection effectiveness of the four algorithms by *F-Score* and *Recall*. From Fig. 12, it can be seen that among the baseline algorithms, ATDC achieves a higher *F-Score* in T-2, which indicates it has a good effect on the detection of global spatiotemporal anomalies. In T-1 and T-3 with more peak trajectories, TPRO shows good detection results due to its spatiotemporal sensitivity. And compared with the baseline algorithms, the PRTP algorithm obtains the highest *F-Score* on all datasets, and has more stable detection results.

Similarly, from Fig. 13, the *Recall* values of the four algorithms show the same trend, PRTP obtains superior detection results on all datasets. It can be seen that the *Recall* of the PRTP algorithm is the most ideal, while the *Recall* of the iBAT algorithm is the lowest, indicating that the iBAT algorithm more incorrectly detects anomalies as normal occurrences on the datasets. Meanwhile, the experiment results show that the PRTP algorithm can play a good role in detecting global anomalies as well as complex local anomalies. Therefore, this group of comparison experiments shows that PRTP can better detect anomalous trajectories compared to the baseline algorithms.

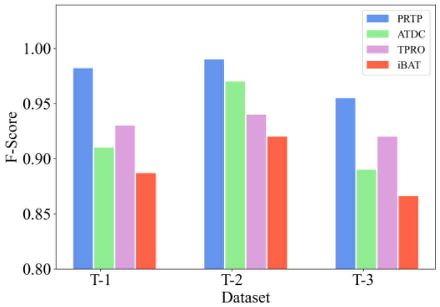

Fig. 12. The F-Score of PRTP, ATDC, TPRO, and iBAT on datasets.

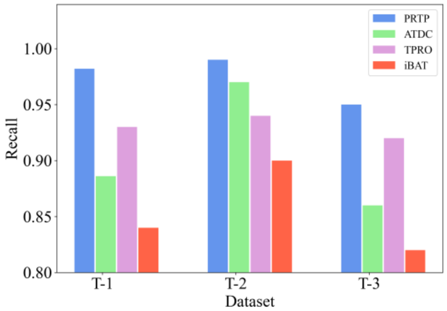

Fig. 13. The Recall of PRTP, ATDC, TPRO, and iBAT on datasets.

In addition to comparing the detection effectiveness of the four algorithms, this paper further compares the time cost of these algorithms. Among them, each algorithm runs ten times in the same environment and the average of the running times is taken as the final result. From Fig. 14, it can be seen that the PRTP algorithm also has an absolute advantage in time consumption. The time loss of ATDC is also ideal, but for the TPRO algorithm, since it chooses a small time interval when dividing the time period, it consumes more time during the whole algorithm detection.

Therefore, with optimal values of the parameters, PRTP achieves high values of both *F-Score* and *Recall* for anomaly detection results on the datasets. Meanwhile, the experimental results also show that the PRTP algorithm has a significant advantage in time loss.

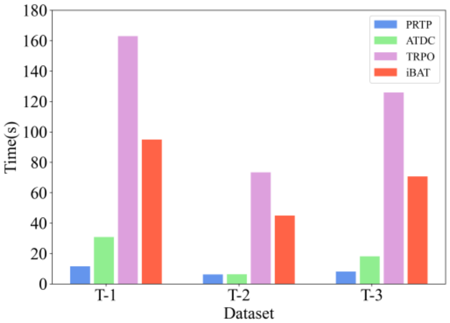

Fig. 14. The running time of PRTP, ATDC, iBAT, and TPRO on datasets.

VI. Discussion

In different application scenarios, most of the existing anomalous trajectory detection methods do not adequately integrate the location, time, and structure of the trajectories, and also ignore the influence of the time period on the route. Traditional algorithms usually compare the similarity of trajectories only in spatial or spatiotemporal dimensions, which is not applicable to anomaly detection of spatial trajectories with complex distribution. Compared with previous studies, the PRTP algorithm fully considers the location, time period, and structure of the testing trajectory in anomaly detection. The trajectory dataset is divided into different groups according to the division of time periods. Through the distribution of trajectories in different groups, the popularity of the route in different time periods is accurately obtained. Among them, to exclude the interference of trajectories with consistent running trend but long time-consuming to the route popularity, this study proposes the calculation method of spatiotemporal frequency, which avoids defining the congested roadway as a popular route. In the anomaly detection stage, to not be limited to the distribution location of the grid cells, this paper combines the location matrix and structure matrix of the trajectory to make anomaly judgments, which effectively detect anomalous spatiotemporal trajectories and loop travel trajectories, and also accurately identify normal trajectories bypassing congested roads. Experiments on real trajectory datasets show that the method can effectively detect trajectory anomalies with higher accuracy. The method can be applied in urban traffic road condition detection and traffic management, providing a new detection scheme for trajectory data mining.

VII. Conclusion

To improve detection accuracy and efficiency, this paper proposes an anomalous trajectory detection method using popular routes in different traffic periods. First, the method grids the trajectories and uses mapped trajectories for the study. Second, different time periods are divided according to the distribution of traffic flow, and the spatiotemporal node frequency values are obtained by combining the trajectory attributes, to obtain the popular routes dynamically. Finally, the distance formula is proposed for trajectory anomaly detection by combining trajectory location and trajectory structure. The proposed method is validated on real taxi GPS data, and it shows remarkable performance in experiments. Also, the method shows its potential in innovative applications such as taxi driving fraud detection.

However, the proposed method has a few limitations. In detecting anomalous trajectories, only the spatiotemporal properties of the trajectories are considered, and the exact location where the trajectory anomaly occurs and the time when the anomaly ends cannot be determined online. Therefore, in the follow-up study, this aspect will be broadened. For example, it is possible to detect anomalous sub-trajectories by combining time windows or decay factors while considering spatiotemporal attributes, to accurately locate where the anomalies occur and classify the anomalies of the trajectories based on the result.

The Model of Stroke Rehabilitation Service and User Demand Matching

Hua Wei*, Ding-Bang Luh*, Yue Sun, Xiao-Hong Mo, Yu-Hao Shen
School of Art and Design, Guangdong University of Technology, Guangzhou 510006, China

***Abstract*—This article focuses on matching stroke rehabilitation services, and patient needs through the interconnection between patient demand and rehabilitation service capabilities. A solution is proposed based on the KJ, fuzzy AHP, and QFD methods to address this problem. Specifically, the KJ method categorizes user needs, and the fuzzy AHP method calculates weights and rankings. Furthermore, rehabilitation service capability indicators are developed, and the QFD method is applied to match customer needs with rehabilitation service capability indicators. The service indicator value is constructed through mapping relationships, and the rehabilitation service capability value is obtained by adding up the results. The best matching scheme is predicted by comparing rehabilitation service capability values of service alternatives. The success of the model has been proven by examining the case. It has helped patients and service organizations find suitable caregivers. The research results illustrate that the proposed model can effectively address the problem of stroke rehabilitation services and patient needs matching and has practical value and potential applications. Therefore, this research is significant in enhancing the quality of stroke rehabilitation services and patient satisfaction and provides a reference value for future studies of similar issues.**

Keywords—Stroke; rehabilitation services; user needs; matching model

I. Introduction

Stroke is a significant public health issue worldwide, significantly burdening patients and society. Early post-stroke rehabilitation is crucial, and studies have shown that inpatient rehabilitation within 14 days after stroke onset could significantly improve daily living activities capabilities [1]. Stroke rehabilitation services accompany the entire rehabilitation process, and effectively meeting patient needs during the rehabilitation service delivery is essential to improve the quality of life and rehabilitation outcomes. Service and demand matching is a critical issue in effectively meeting patient needs.

Researchers have studied user needs matching for the service and demand matching problem. For example, Demain et al. [2] found that understanding and meeting patient needs is vital to alleviating treatment burden, and rehabilitation service providers need to focus on patient's psychological, social, and lifestyle needs. Reichert et al. [3] provided valuable insights into meeting cultural rehabilitation needs and improving the existing rehabilitation services by implementing workplace interventions, specifically through community-driven collaborative needs assessment that facilitated the establishment of responsive rehabilitation institutions. Joshi [4] emphasized the significance of patient-centred care in the success of outpatient surgeries, emphasizing the need for a clear understanding of the diverse needs of different patients. Lu et al. [5] investigated stroke patients' fundamental psychological needs, satisfaction, and influencing factors, focusing on the autonomy, competence, and relatedness aspects of patient needs. The study found that stroke increased patients' satisfaction with their relatedness needs while decreasing their autonomy and competence needs. Saut et al. [6] discussed the mechanisms and structures of patient and family participation in healthcare systems, indicating that reforming open culture and processes may promote service quality. Reforming open culture includes improving service quality through information sharing between patients and professional service providers and achieving a balance of rights between patients and service providers. Trivedi et al. [7], from the perspective of nursing physicians, promoted a smooth transition in post-discharge care by providing nursing education before patient discharge, which helped patients understand their own needs and thus promoted the quality of rehabilitation care.

Therefore, the current ways to match healthcare services with user needs include: providing more appropriate services by understanding factors such as patients' cultural backgrounds, religious beliefs, socioeconomic status, and living environments; continuously optimizing and adapting services through patient feedback and assessment; establishing good communication and trust with family members to better understand patients' needs and provide better services; promoting communication between patients and service providers, educating them about healthcare knowledge, and promoting patients' understanding of their own needs and the positive attitude of service providers. However, there are still many unmet needs in healthcare globally [8]. These unmet needs are because the focus is solely on users' needs in the service-demand relationship, neglecting the service providers' capabilities assessment. The lack of quality in healthcare services is due to insufficient research on user needs and the incorrect evaluation of their service capabilities.

In existing research, the only evaluation of service providers in the context of rehabilitation services is often their caregiving ability. Kardami et al. [9] demonstrated the feasibility and functionality of using a cancer scale to evaluate the caregiving ability of mothers of children with cancer, which can identify the nursing needs of pregnant women. The measurement scale includes five dimensions: effective role-playing, fatigue and subservience, trust, uncertainty, and ignorance of caring for children with cancer. The results showed that the scale had acceptable content, scope, construct

*Corresponding Author.

validity and sufficient reliability. The cancer scale can be used to evaluate the caregiving ability of mothers of children with cancer in Iran. Zhong et al. collected data through the Caregiver Burden Inventory (CBI) and the World Health Organization Quality of Life to construct a caregiver difficulty scale to evaluate the burden on caregivers and the impact on the health of disabled children [10]. O'Malley et al. used the Caregiver Reaction Scale (CRS) to evaluate positive aspects of family caregiving experiences, such as role conflict, challenge, and caregiving, as a multidimensional measure [11].

Thus, the current research on evaluating caregivers' abilities is solely based on their reactions to various tasks, ignoring the link between patients' needs and caregivers' abilities. This study aims to develop a stroke rehabilitation service and user needs a matching model that considers the interplay between patients' needs and rehabilitation service capabilities. The aim is to offer more adaptable services for patients and rehabilitation institutions.

Compared to the statistical methods used in existing rehabilitation service research, the novelty of this study lies in constructing a resolution through a computational model, predicting service outcomes to enhance service quality and efficiency:

Firstly, this research employed the KJ method and fuzzy analytic hierarchy process (FAHP) to construct user demand indicators and assign weights to sort their importance.

Secondly, this research constructed service capability indicators.

Thirdly, this research mapped user demands to service capabilities using Quality Function Deployment (QFD) and used the value of the caregivers' comprehensive ability as the metric to evaluate rehabilitation service capabilities, aiding patients and service providers in matching appropriate service plans.

Finally, this research conducted a case analysis to validate the proposed model's feasibility. Through this case study, researchers demonstrated the feasibility of the model. Researchers helped patients and service providers find suitable caregivers that match patients' needs. Through this research, researchers hope to provide theoretical and practical guidance to optimize rehabilitation services for stroke patients and foster the development of the rehabilitation service industry.

In this thesis, Section I introduces the research problem. Section II briefly discusses related work. Section III describes the primary user needs and care service matching model. Section IV applies the model to a case study involving the selection of caregivers for stroke patients and compares its predictions with actual selection outcomes. Finally, Section V discusses the results of the case study, and Section VI concludes the work.

II. Related Work

A. Fuzzy Analytic Hierarchy Process (FAHP)

The Fuzzy Analytic Hierarchy Process (FAHP) is a multi-criteria decision-making method based on fuzzy mathematics theory, initially proposed by Professor Thomas L. Saaty of Northeastern University in 1970 [12]. It builds on the Analytic Hierarchy Process (AHP). It can convert fuzzy and uncertain information into mathematical quantities, facilitating analysis and processing.

Singh and Özşahin developed an interval fuzzy analytic hierarchy process (IFAHP) model to investigate the key factors influencing the selection of wooden outdoor furniture. They subdivided five major factors into sub-factors and conducted pairwise comparisons, using fuzzy numbers to represent the relative importance of each factor. By computing the weights of each factor, the researchers determined their relative importance in the overall hierarchy. Ultimately, they obtained a prioritization of factors to evaluate and prioritize outdoor furniture selection [13].

Xuan et al. developed an expert automatic cutting tool selection system using an integrated fuzzy analytic hierarchy process approach. They conducted a fuzzy hierarchy analysis evaluation of the distinguishing factors of the cutting tools to determine the priority of tool types. Then they selected the optimal tool type through sorting [14].

Wang proposed a feature-driven triangular fuzzy hierarchy process that obtained a support interval-based triangular fuzzy hierarchy process from the fuzzy multiplication preference relations matrix by establishing three positive definite matrices of feature problems and linear programming based on feature vectors. Additionally, a method for acceptability checks was suggested [15].

In summary, the fuzzy analytic hierarchy process is valuable for assigning weights and ranking relevant factors through hierarchical division and fuzzy evaluation of sub-factors in complex and multi-criteria screening problems. The differences between studies lie in the formulation of fuzzy rules. The fuzzy analytic hierarchy process was used to assign weights and rank the relevant factors of user needs and rehabilitation service capabilities for this paper's matching problem discussed of the stroke rehabilitation service and patient needs. This method helped to address the uncertainty and fuzziness problems in the analysis process of user needs and rehabilitation service evaluation factors, resulting in a reliable analysis process.

B. Quality Function Unfolding Method

Quality Function Deployment (QFD) is a method that converts customer requirements into product design specifications, aiming to enhance product quality and customer satisfaction by incorporating customer needs into product design and services. The core of QFD involves constructing and analyzing a series of matrices to transform customer requirements into product design specifications, which are then reflected in various aspects of the product.

Kürüm Varolgüneş et al. utilized QFD and AHP to design a thermal hotel building that meets customer needs and improves the quality of building design. The QFD method was employed to gather customer needs and opinions. In contrast, the AHP method evaluated different design options and selected the best one. Combining these two methods can provide a more comprehensive and accurate understanding of customer needs and improve the satisfaction and practicality of the building [16].

Baskir proposed a QFD-AHP model for evaluating after-sales services of automobiles based on customer beliefs. This model converts customer feedback into technical features in lean implementation. Managers, employees, and customers can use belief space evaluation to identify their perception mechanisms and experience how the uncertainty of perception mechanisms affects their decision-making. This model provides a more accurate and comprehensive solution by eliminating ambiguity in poor decision-making based on conceptual change [17].

Shan et al. proposed an optimized design framework combining the quantitative Kano model and fuzzy quality function deployment (QFD) model to best match enterprise service elements under uncertain and imprecise judgment information. This approach improves the quality and customer satisfaction of express delivery services [18].

Combining QFD and other methods, such as AHP and Kano model, provides a more comprehensive and accurate product design and service optimization solution. This application effect highlights the practicality of QFD in helping businesses understand customer needs and convert them into specific product design requirements, thus improving product quality and customer satisfaction. Additionally, combining different methods can further enhance the accuracy and comprehensiveness of analysis and decision-making. This study's combination of FAHP and QFD is feasible for matching the needs of stroke patients with rehabilitation services.

C. Health Care Service Capability

Current research on healthcare service capabilities has primarily focused on evaluating the general abilities of caregivers. Factors such as self-pressure, health management, coping strategies, age, financial status, social issues, self-efficacy, and disease severity have been found to affect caregiver ability [19-20]. However, such evaluations need more direct relevance.

Other studies have shown that caregiver participation in patients' rehabilitation exercises benefits their physical and mental health [21]. While existing research helps to diversify methods related to patient rehabilitation and maintaining caregivers' physical and mental health, it does not provide insights into matching patients with convenient care services.

Research on healthcare services from the perspective of patients and therapists includes rehabilitation therapy methods [22], assessment of rehabilitation outcomes and impacts [23], and the duration and contribution of rehabilitation interventions. However, such research weakens caregiver involvement.

Therefore, it is necessary to propose a model for matching stroke rehabilitation services with user needs from the perspective of patient needs and healthcare service capabilities. This model will provide valuable insights into improving the quality and effectiveness of stroke rehabilitation services.

III. Methodology for the Construction of a Matching Model Between User Needs and Health Care Services

A. User Requirements Acquisition

The matching model between user needs and care services is shown in Fig. 1. A combination of questionnaires, observation, and the Delphi method is used to gather demand information to ensure accurate user requirements. The questionnaire survey method often has low user participation and recall rates, but this can be improved by conducting quick surveys under typical situations. However, users' erroneous responses cannot be resolved. The observation method provides first-hand information but is time-consuming. The Delphi method requires achieving a specific consensus rate in each round through expert evaluations and has limited avenues to obtain indicators [24]. Combining these methods reduces their deficiencies. Since most stroke patients have post-stroke sequelae, it is necessary to interview family members and patients and observe their behaviour to obtain primary needs. The most critical demand indicators are screened by requiring the patient's rehabilitation therapist and the primary doctor to act as Delphi method experts.

B. Fuzzy Hierarchical Analysis Deals with Demand Indicators

1) KJ Method stratified user requirements indicators: Clustering analysis and the KJ method are commonly used for hierarchical requirement analysis. While clustering analysis has the advantage of concise and intuitive data processing, it requires a large sample size [25]. On the other hand, the KJ method is not limited to numbers and is also suitable for text descriptions [26]. Therefore, in this study, researchers opted for the KJ method to classify user requirements hierarchically.

The KJ method is typically conducted in the form of cards. However, researchers encoded the indicators in this study instead of distributing cards. We asked the respondents to use the same code for similar information. Participants, including rehabilitation teachers, nurses, and some patients, were invited to participate in a group study using the KJ method. Researchers finally divided 24 indicators into 3 levels and 4 modules, as shown in Fig. 2.

2) Fuzzy hierarchical analysis (FAHP) quantitative steps

a) Defining fuzzy rules: To achieve precise and accurate outcomes with minimal requirements for periodic modifications to data consistency, we defined a fuzzy scoring interval of [0,1], with adjacent score differences of 0.1. The final score was then selected from the three available values {0,0.5,1} (referred to as "three values" in this study). Specifically, the initial score was compared with {0,0.5,1}, and the value in the three values closest to the actual value was chosen as the final score, resulting in a new fuzzy rule.

b) Demand stratification: Using the KJ method, the research team obtained the target layer G, the quasi-measurement layer Z, and the indicator layer E, forming a three-level fuzzy analytic hierarchy. Researchers first used the three values to construct a fuzzy priority consensus matrix. Then researchers generated a fuzzy judgment consensus matrix using an improved fuzzy analytic hierarchy process [27].

To avoid the need for further consistency evaluations, we took the following measures:

Firstly, to establish the consistency matrix for constructing the fuzzy priority relationship, we used the three values $\{0,0.5,1\}$, which facilitated explicit judgments and avoided confusion. First, we constructed a fuzzy priority relationship matrix a_{ij}, with each position labelled by i and j, where i represents the row number and j represents the column number. In the three values, 0 indicates that j is more critical than i, 0.5 indicates that i and j are equally important, and 1 indicates that i is more critical than j. The consistent matrix factor for the fuzzy priority relationship is obtained by summing the rows to obtain r_i and the columns to obtain r_j, where $i = \{1, \cdots, s\}$ and $j = \{1, \cdots, n\}$, with s representing the number of rows in the matrix and n representing the number of columns. The relationship between the factors in the matrix can be expressed as:

$$a_{ij} + a_{ji} = 1 \tag{1}$$

Secondly, we converted the fuzzy priority relationship consensus matrix into a fuzzy judgment consensus matrix. The formula for constructing the factor b_{ij} in the fuzzy judgment consistency matrix is:

$$b_{ij} = \frac{r_i - r_j}{2s} + 0.5 \tag{2}$$

Thirdly, we calculated and ranked the weights.

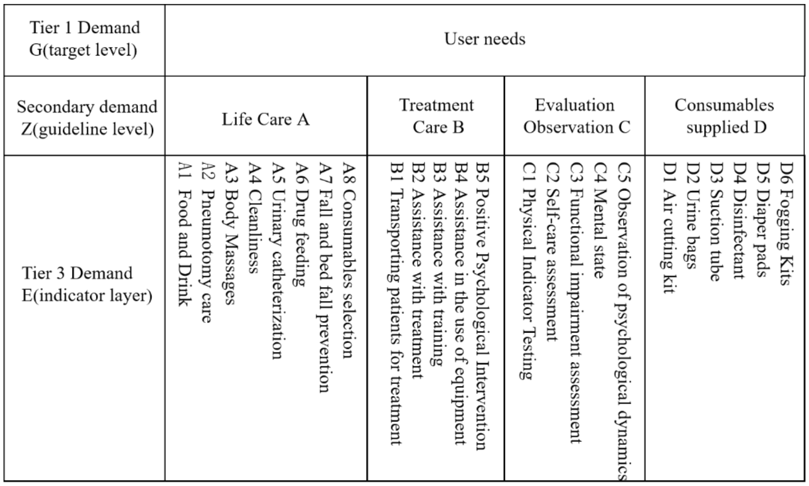
The first step was to calculate the product of the elements in each row of the judgment matrix and then calculate the s-th root of the product. Next, we normalized the eigenvector to obtain the weight vector W_Z. The weight vector W_E represents the relative importance weight of each indicator for the upper quasi-criterion factor, and W is the integral vector. Finally, the ranking was based on the integral weight, and the formula is as follows:

$$M_i = \prod_{j=1}^{n} b_{ij} \tag{3}$$

$$\overline{W_i} = \sqrt[s]{M_i} \tag{4}$$

$$W_i = \frac{\overline{W_i}}{\sum_{i=1}^{s} \overline{W_i}} \tag{5}$$

$$W = W_Z * W_E \tag{6}$$



Tier 1 Demand G(target level)	User needs			
Secondary demand Z(guideline level)	Life Care A	Treatment Care B	Evaluation Observation C	Consumables supplied D

Fig. 2. KJ affinity diagram.

c) Fuzzy Analytic Hierarchy Process (FAHP) was used to calculate weights and rankings.

The expert group was asked to make critical judgments and calculate the average value. Based on the fuzzy rules of this study, the most suitable value was selected from the three values, and the fuzzy priority relationship consistency matrix was constructed and converted into a fuzzy judgment consistency matrix. The fuzzy consistency matrices for the goal layer G, quasi-measurement layer A, quasi-measurement layer B, quasi-measurement layer C, and quasi-measurement layer D are shown in Tables I to V. The indicator layer weight W_E and criterion layer weight W_Z were calculated using formulas (4) - (6). The total weight W was obtained by multiplying the indicator and criterion layer weights, as shown in TableVI.

C. Construction of Indicators for the Evaluation of Health Care Services

After four months of in-depth research in a rehabilitation hospital in Shenzhen, China, semi-structured interviews were conducted with 25 nursing staff and 51 patients and their family members. The results were analyzed, summarized, and organized. Focus group discussions were also held with several frontline rehabilitation therapists. The results showed that the duration of the patient's illness, cultural level, and cooperation level can affect the rehabilitation outcomes. The cultural level, body weight, lifestyle habits, health philosophy, coping skills, time management skills, psychological quality, professional spirit, and caregivers' communication skills can also affect the rehabilitation results.

Compared with existing studies on the comprehensive ability factors of family caregivers, disease-related knowledge, daily and disease-related care skills, coping strategies, self-stress, and health management are used as standards. Some scholars have also added hope level [28] and readiness level [29]. Some scholars aim to improve the effectiveness of rehabilitation nursing interventions by focusing on the sense of interest of caregivers [30]. Understanding disease, daily and disease-related care skills belong to professional abilities; coping strategies are problem-solving skills; self-stress is a psychological quality, and health management is a health concept and lifestyle habit. Hope level and readiness levels are professional ability and time management skills, and the interest of caregivers is a psychological quality. High-quality nursing and efficient care are preparations for good quality of life for patients after discharge.

In contrast, nursing staff can improve the cooperation level of patients through psychological intervention. The key to joint efforts by nursing staff and patients is setting realistic rehabilitation expectations [31]. Patients understand their disease correctly and actively cooperate, leading to a healthy life. Patients and caregivers need to create reasonable rehabilitation expectations. Caregivers should keep in mind the patient's rehabilitation goals. In order to clarify the influencing factors, nursing staff, work, patients and diseases should be studied separately. The patient's cooperation level can represent the caregiver's communication and coping abilities. The indicators of the final rehabilitation serviceability are physical health (I1), lifestyle habits (I2), health philosophy (I3), coping skills (I4), time management skills (I5), psychological quality (I6), professionalism (I7), and communication skills (I8), as shown in Fig. 3.

D. Mapping of User Needs and Wellness Service Capabilities

QFD is often used in product design to convert user needs into technical product characteristics [32]. The user mapping relationship determines the technical importance of needs indicators and technical features. In this study, a scoring method was used to evaluate the rehabilitation service capability under different user needs indicators, and then the weight of user needs indicators was multiplied by the score of rehabilitation service capability indicators. The scoring uses three values $\{0,0.5,1\}$, where 0 represents a low service capability match, 0.5 represents a moderate service capability match, and 1 represents a high service capability match.

A correlation was established between user needs indicators and rehabilitation service capability indicators based on the significance score of the latter. The rehabilitation service capability is measured by the total ability value VA of the caregiver, and the caregiver with the highest VA value can be regarded as the best match. The scoring of the caregiver's ability indicators is evaluated by the hospital or caregiver service institution based on the matching ability of the user needs indicators, forming a fuzzy matrix J. W_n is the weight of user needs indicators, where n is the number of demand indicators and $\in \mathrm{R}^+$. The caregiver's ability indicator is P_k, where k is the number of comprehensive ability indicators of caregivers, and $k \in \mathrm{R}^+$. The matrix J represents the mapping of user needs and caregiver's ability indicators:

$$J = \begin{array}{c} W_1 \\ \vdots \\ W_n \end{array} \begin{bmatrix} P_{11} & \cdots & P_{1k} \\ \vdots & \ddots & \vdots \\ P_{n1} & \cdots & P_{nk} \end{bmatrix} \tag{7}$$

The calculation method of the total ability value VA of the caregiver based on the fuzzy matrix J is as follows:

$$VA = \sum_{K=1}^{k} \sum_{N=1}^{n} W_n * P_{nk} \tag{8}$$

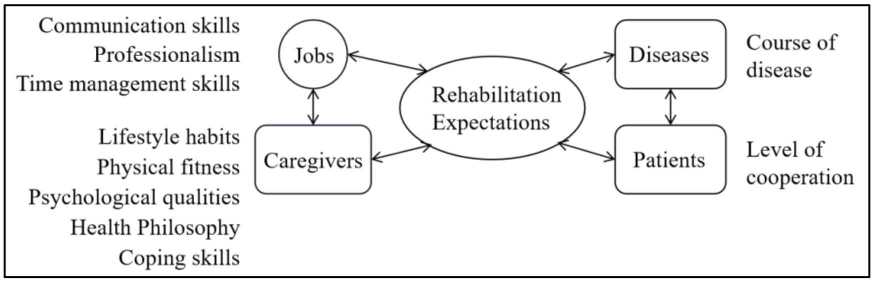

Fig. 3. Caregiver capacity indicators.

IV. Case Study: Choice of Carer for a Stroke Patient

A. Description of the Problem

The feasibility of the matching model proposed in this study was demonstrated using the example of a patient in a rehabilitation hospital in Shenzhen, China, who needed to select a caregiver. The patient was paralyzed due to a stroke and required bedridden care, feeding, urinary catheterization, and other rehabilitation services. As the patient's family members were busy with work, they needed to hire a caregiver with a high degree of matching ability to provide the necessary care. The rehabilitation hospital collaborated with several caregiving service institutions and provided six caregivers for selection. The patient's family members could use the matching model proposed in this study to select the best caregiver based on the patient's demand indicators and the caregiver's ability indicators.

B. Test Rules

This model selects the most suitable caregiver by calculating the comprehensive ability value of six caregivers based on the patient's demand indicators. Then, the six selected caregivers provided one week of rehabilitation services based on their numbers. The patient or their family can evaluate the caregivers' performance during the week and select the most suitable caregiver to continue service. The model's feasibility is determined by comparing the results obtained from the model calculation and essential service. The matching model can be feasible if the caregiver number matches between the two. If the number does not match, an error analysis is conducted using the caregiver's comprehensive ability value. If the error is small, the model can be revised and used; if the error is too large, the model needs to be modified to meet the actual needs better, or it will not meet the actual requirements.

C. Test Method

According to the architecture of the model shown in Fig. 1 and the framework of user demand indicators and caregiving ability indicators built in Section III, six nurses and four rehabilitation therapists were invited as evaluation experts and were evenly divided into two groups: a model group and an experimental group. The model group mainly participated in asking about user requirements, scoring user demand indicators, and scoring the caregiving ability indicators of the six caregivers provided by the rehabilitation institution to provide input for the model calculation. The experimental group mainly discussed and selected a suitable caregiver based on the effectiveness of the caregiver's services and the feelings of the patient and family members. The two groups of experts are not allowed to discuss with each other. The experimental process is shown in Fig. 4.

D. Calculation Results

User demand and caregiving service indicators were constructed, and demand weights and caregiving ability values were calculated based on formulas (1) to (8), as shown in Tables I to VII and Fig. 5. Table I to Table V represents pairwise comparison matrices and their respective weight values for user requirement factors. Table VI represents the comprehensive weight and ranking of user requirement factors. Table VII represents the scores for healthcare service indicators corresponding to user requirements and the total ability value of the caregiver. Fig. 5 represents the comprehensive capability values of different caregivers. Finally, caregiver No. 1 had the highest matching degree, with a comprehensive ability value of 3.320. After the six caregivers provided caregiving services for one week each, the experimental group and the patient's family discussed and decided to keep caregiver No. 1, consistent with the model's prediction.

V. DISCUSSION

In this discussion, researchers try to explore the advancements and significance of our research. The experimental results indicate that the actual selection results are consistent with the predicted results, suggesting the feasibility of the model.

From the calculation data, the patient's demand weight ranking shows that due to being bedridden from paralysis, the patient has a higher demand for living care and rehabilitation training. Therefore, the requirements for service focused on strengthening communication skills, health concepts, caregiver physical fitness, and living habits. The model has performed well in caregiving services, especially caring for patients, through the joint efforts of nurses, rehabilitation therapists, family members, and researchers.

Compared to existing research [6 - 7], the advanced nature of this study lies in its innovative approach, which evaluates and matches user needs and service capabilities from the perspective of the linkage between the two. This mould is done through various methods to meet patients' needs better and improve the quality and efficiency of care services.

In contrast to existing research on demand and capability matching, which uses patient rehabilitation needs quantification [33] and mainly relies on physician experience to predict individual patient discharge pathways, this study stratifies user demand factors, assigns weights, and maps them to service factors. It calculates the degree of match between predicted user needs and services and involves doctors, patients, and third-party service providers in the prediction process. The model developed in this study is more comprehensive in considering the matching relationship and is, therefore, more advanced than existing research.

Moreover, this model has demonstrated practicality in the case study, and we believe it provides more flexible service guidance for patients and rehabilitation institutions. However, the current limitation of this model lies in the fact that its accuracy and reliability depend on the reliability and precision of the data samples. To further improve the model's adaptability, it is necessary to attempt more data analysis.

VI. CONCLUSION

The stroke caregiving service and user demand matching model proposed in this study constructed user demand indicators using the KJ method and fuzzy analytic hierarchy process. They constructed caregiving ability indicators from a service perspective. The model mapped the matching relationship between user demand and caregiving ability indicators using QFD and used the caregiver comprehensive ability value to measure caregiving serviceability evaluation to match suitable caregivers for patients and service institutions and improve the quality and efficiency of caregiving services.

Future research can further optimize the evaluation indicators and parameters of the model to improve its accuracy and reliability. Secondly, this research only focused on stroke caregiving services, and future research can apply this model to other rehabilitation service fields to further verify its practicability and feasibility.

***Abstract*—With the rapid economic development, the government has increased investment in municipal construction, which usually takes a long time, involves many open-air operations, and is affected by cross-construction, traffic, climate and environment, and so on. The safety protection of urban construction workers has been a concern. In this paper, an improved algorithm based on YOLOv5s for the simultaneous detection of helmets and reflective vests is proposed for municipal construction management. First, a new data enhancement method, Mosaic-6, is used to improve the model's ability to learn local features. Second, the SE attention mechanism is introduced in the focus module to expand the perceptual field, strengthen the degree of association between channel information and the detection target, and improve the detection accuracy. Finally, the features of small-scale targets are interacted and fused in multiple dimensions according to the Swin transformer network structure. The experimental results show that the improved algorithm achieves accuracy, recall, and mean accuracy rates of 98.5%, 97.0%, and 92.7%, respectively. These results show an average improvement of 3.4 percentage points in mean accuracy compared to the basic YOLOv5s. This study provides valuable insights for further research in the area of urban engineering security and protection.**

Keywords—YOLOv5s; hard hat; reflective vest; simultaneous detection

I. INTRODUCTION

With the relentless advancement of science and technology, Artificial Intelligence (AI) has emerged as a key player in numerous fields. One such field is municipal engineering, where ensuring the safety of construction workers is of paramount importance. Wearing helmets and reflective vests is an essential measure to ensure their well-being. Combined with artificial intelligence target detection method, it can realize automatic detection and monitoring of whether construction workers are wearing helmets and reflective vests. It is necessary to use artificial intelligence target detection method to detect municipal engineering construction workers wearing helmets and reflective vests [1-3]. First of all, AI target detection method can improve the efficiency and accuracy of site safety monitoring. Traditional safety monitoring methods usually rely on manual inspection, there is a waste of human resources, and blind area coverage is not complete [4]. The use of AI target detection methods, combined with cameras and image processing technology, can monitor the construction site in real time and automatically detect whether there are construction workers wearing helmets and reflective vests. This automated monitoring method can not only reduce the burden of site managers, but also detect and deal with violations in a timely manner, improving the overall safety level of the site [5]. In addition, the AI target detection method can reduce the interference of human factors on safety monitoring results. In traditional safety monitoring, manual judgment can be affected by factors such as subjective awareness, perspective limitations and fatigue, resulting in inaccurate or missing detection results for construction workers wearing helmets and reflective vests. In contrast, AI target detection methods use advanced algorithms and models to quickly and accurately detect target objects without the interference of subjective factors [6, 7]. This ensures more objective and accurate monitoring results for construction workers wearing helmets and reflective vests, effectively improving the reliability of safety monitoring.

The remaining sections of this paper are organized as follows. In Section II, we introduce two deep learning-based detection algorithms and discuss the current state of research in this area, Section III elaborates the basic architecture of the YOLOv5 model and details the optimization part for YOLOv5, Section IV of this paper provides an overview of the dataset sources, the experimental environment, and the model parameter settings. In Section V, we present the experimental results and discuss the performance of the optimized model introduced in the previous section. Experimental tests are conducted for the three optimized parts and compared with the current mainstream algorithms.

II. CURRENT STATUS OF RESEARCH

A. *Introduction of Deep Learning Algorithm*

Deep learning is an advanced and complex machine learning algorithm in the field of AI, which has the advantages of powerful learning ability, high generalization ability, and wide applicability. Deep learning based algorithms in the field of target detection often use a technique where anchor boxes of different sizes are placed on the image to achieve target detection, regressing and classifying the anchor boxes. Based on the way of regression box generation, target detection algorithms can be divided into two main categories: two-stage algorithms and one-stage algorithms [8].

Well-known two-stage target detection algorithms include R-CNN, Fast R-CNN, Faster R-CNN, etc. The two-stage target detection algorithm is a commonly used target detection method, which consists of two main stages: candidate image generation (region proposal) and target classification and localization [9].

Region Proposal Phase: First, a series of candidate frames (often called candidate regions or candidate frames) that may contain targets are generated from the input image by using some advanced techniques such as selective search, Edge Boxes, or deep learning-based methods [10]. The goal of this stage is to generate as many candidate frames as possible to cover the potential targets in the image.

Target Classification and Pinpointing Stage: In this stage, a target classifier is applied to each candidate frame to determine whether it contains the target of interest and to pinpoint the target, i.e., to determine the exact bounding box location of the target. For each candidate frame, the classifier discriminates its extracted features and determines whether it belongs to a specific target class. In addition, the target bounding box can be further fine-tuned to more accurately match the location and shape of the target.

In computer vision, single-stage target detection algorithms are widely used and can be classified as a common type of target detection algorithm. They contrast with another common class of target detection algorithms known as two-stage algorithms. One-stage target detection algorithms have the key feature of performing target detection and localization directly on the image itself. This approach is typically faster and more suitable for real-time application scenarios [11]. The following are some common representatives of single-stage target detection algorithms:

The YOLO (You Only Look Once) family: YOLO is a popular collection of single-stage target detection algorithms. By dividing the image into grids and predicting the location and class of targets within each grid, the YOLO algorithm effectively transforms the target detection problem into a regression problem. The YOLO algorithm performs target localization and classification simultaneously by a single neural network, which is faster, and YOLOv5 is the latest version of the YOLO series.

SSD (Single Shot MultiBox Detector): SSD is another popular single-stage target detection algorithm. The SSD algorithm uses multi-scale feature maps to detect targets of different sizes, and uses anchor boxes of different sizes for target position prediction. The SSD extracts image features through a convolutional neural network and performs target classification through subsequent convolutional layers and bounding box regression.

The following is a detailed description of the YOLO family of target detection algorithms (YOLOv1, YOLOv2, YOLOv3, YOLOv4, YOLOv5):

YOLOv1 is the first release in the YOLO series. YOLOv1 transforms the target detection problem into a regression problem by directly predicting bounding box locations and class probabilities through a single forward pass. A convolutional neural network (CNN) is used to extract features from the image and output predictions through a fully connected layer [12]. YOLOv1 has a fast detection speed, but performs poorly on small and dense targets and has limited effectiveness for scenes requiring high localization accuracy.

YOLOv2 incorporates several enhancements to improve the detection capabilities for small objects, such as the introduction of multi-scale prediction and the implementation of the anchor box mechanism. The network structure used in YOLOv2 is Darknet-19, and a novel loss function is employed to effectively deal with classification errors and bounding box regression errors [13]. YOLOv2 also proposes a data enhancement technique called Random Gamma Adjustment.

YOLOv3 introduced a number of improvements over YOLOv2, including the use of a deeper Darknet-53 network structure, the use of residual connectivity, the application of multi-scale prediction, and the use of more anchor frames. YOLOv3 introduced a Feature Pyramid Network (FPN) structure, which extracts feature maps at different scales and performs target detection. By using feature maps of different sizes for target detection, YOLOv3 can effectively detect targets of different sizes [14]. YOLOv3 achieves a better balance between detection speed and detection performance.

YOLOv4 further improves the network structure and training strategy to increase the detection accuracy and speed. CSPDarknet53 is adopted as the backbone network, and modules such as SAM (Spatial Attention Module) and PAN (Path Aggregation Network) are introduced to improve the feature representation and perception capabilities. YOLOv4 also uses multi-scale inference and multi-scale training strategies by combining different YOLOv4 also uses multi-scale inference and multi-scale training strategies to achieve more accurate target detection by combining feature maps of different scales. The GIoU (Generalized Intersection over Union) loss function is introduced to more accurately compute the overlap between bounding boxes [15].

YOLOv5 introduces some improvements in the network architecture with lighter model architecture while maintaining high detection performance. YOLOv5 introduces a new target detection architecture called CSPNet (Cross Stage Partial Network), which balances model size and performance by reducing computational complexity and improving accuracy. YOLOv5 also introduces more data augmentation techniques to improve model generalization. YOLOv5 achieves faster training and inference through model lightweighting and optimization. Overall, the goal of the YOLO family is to achieve real-time target recognition while balancing speed and accuracy. Each version of YOLO has its own unique contributions and enhancements to improve detection performance and efficiency.

B. *Current Status of Research*

There have been many researchers who have studied helmet detection to propose various optimized detection methods for the above algorithms, for example, Chen et al. presented a novel integration of Retime image enhancement technology into the Faster R-CNN framework. They addressed the challenges posed by various factors such as lighting conditions and distance, which often hinder accurate detection. To overcome these obstacles and improve detection performance, they employed the K-means++ algorithm. By using this approach, they achieved automatic helmet detection with improved accuracy [16]. Guo et al. added a VGG16 feature extraction module to Faster R-CNN to determine whether the helmet is correctly worn using Euclidean distance, which improved the detection accuracy and speed [17]. Song added the R-SSE module to YOLOv3, reduced the network depth, improved the network detection speed and accuracy, and the dual module Res 2 was used to improve the feature reusability and detection efficiency of small target [18]. Chen et al. used a lightweight network PP-LCNet to improve YOLOv4, reduced the model parameters with depth-separable convolution, used a new SIoU loss function, reduced the model size, and improved the speed of helmet detection [19]. To improve the YOLOv5 detector, Jia et al. used triple attention fusion and soft NMS, which can achieve high accuracy and real-time results under complex weather conditions [20]. Jin et al. used K-means++ algorithm and Deep Coordinated Attention (DWCA) mechanism in YOLOv5 to enhance the information propagation between features and improve the accuracy of helmet detection [21].

In summary, although certain results have been achieved in the field of helmet research, there is little research in the field of reflective vest detection. All of the above studies have optimized and improved the algorithms to some extent, but most of the models are more complex and not easy to implement, or the detection accuracy is difficult to meet the demand. In addition, in the urban engineering construction environment, weather conditions and obstacles can significantly affect the reliability of detection, and more in-depth research is required to obtain a good detection model. This paper proposes to combine the two, studies the simultaneous detection and identification methods, and improves and optimizes the speed and accuracy of real-time detection, which can further protect the personal safety of municipal engineering construction personnel.

III. Improved YOLOv5 Model Architecture

A. *Review of the Fundamentals of the YOLOv5 Model*

Backbone Network: YOLOv5 uses CSPDarknet as its backbone network. CSPDarknet is a lightweight convolutional neural network that uses a CSP (Cross-Stage Partial) connection structure to divide the feature maps in the channel dimension and bypass some of the convolutional layers, thus reducing the computational complexity.

Neck Network: Instead of an explicit neck network structure, YOLOv5 introduces multiple cross-level connectivity (PANet) modules in the backbone network. These PANet modules perform spatial pyramidal pooling operations on feature maps at different scales to fuse semantic information at different levels.

Head Network: YOLOv5's head network is responsible for generating predictions for target detection. It has three main components: Spatial Pyramid Pooling (SPP) module, feature pyramid pooling layer, and detection head. SPP Module: The SPP module performs multi-scale pyramid pooling operations on the feature graph to capture contextual information at different scales. Feature pyramid pooling layer: The feature pyramid pooling layer combines feature maps at different scales by upsampling and fusion to produce a feature map that incorporates information from multiple scales. Detection head:

The detection head consists of a series of convolutional layers responsible for predicting the target's bounding box location, category, and confidence score [22]. YOLOv5 uses a multi-scale prediction strategy, i.e., target detection is performed on feature maps at different levels to handle targets of different sizes.

Loss function: YOLOv5 uses a loss function called YOLOv5 Loss, which combines the loss calculation of target position, category and confidence.

In general, YOLOv5 is structured with a lightweight backbone network, cross-stage connectivity modules, and a multi-scale prediction strategy to achieve efficient and accurate target detection. It achieves a good balance between speed and accuracy for a variety of real-time or offline target detection tasks. The schematic structure of YOLOv5 is shown in Fig. 1.

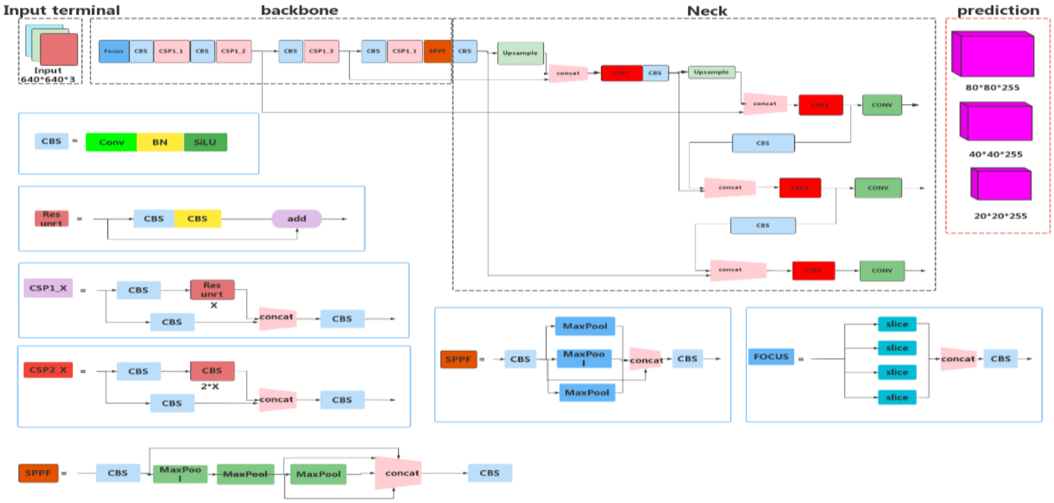

Fig. 1. YOLOv5 principle structure diagram.

B. Improving the YOLOv5 Algorithm

1) Mosaic-6: In YOLOv5, a new data enhancement method called Mosaic has been introduced as a complement to the basic data enhancement techniques. The primary concept behind this method is to randomly crop and scale four images, which are then combined in a random order to create a single image. This method not only enriches the data set, but also increases the number of small sample targets, thus improving the training speed of the network. An important advantage of using the mosaic data enhancement method is that the data from four images can be computed at once when performing the normalization operation, thus reducing the memory requirement of the model [23]. This batch processing reduces memory requirements and allows the model to process large data more efficiently.

By randomly cropping, scaling, and arranging the four images, the mosaic data enhancement method can generate training samples with more diversity and complexity. In this way, the model can better learn how to handle different scenes, scales, and target combinations during training, improving the model's ability to generalize to different situations.

Inspired by the Mosaic data enhancement method, this paper proposes a new data enhancement method called Mosaic-6. In this method, six images are randomly selected for cropping, arranging, and scaling operations to combine them into a new image. The Mosaic-6 detail enhancement is shown in Fig. 2. This can effectively increase the amount of sample data and control the random noise within a reasonable range. In this way, the network model can be improved to distinguish small target samples in images. The final renderings are shown in Fig. 3.

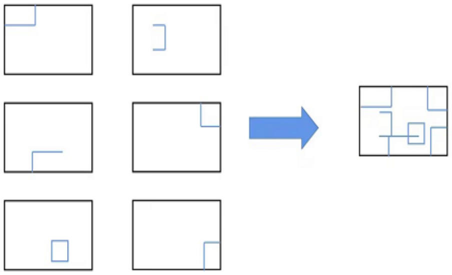

Fig. 2. Mosaic-6 detail enhancement map.

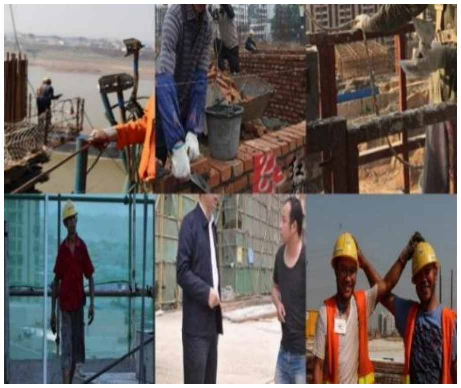

Fig. 3. Mosaic-6 effect.

2) Optimization of attentional mechanisms: Given the nature of the helmet image, where there are numerous small targets that make up a small portion of the overall image, they can be easily influenced by the background and other factors. The original YOLOv5s network tends to lose crucial feature information of these small target helmets during deep convolution, which hinders their effective detection. To enhance the helmet features in the given image, this study introduces a work that assigns different weights to different positions of the image in the channel domain. This approach aims to extract more critical feature information [24]. The paper incorporates the Squeeze-and-Excitation (SE) attention mechanism, which is fused with the input feature map. This fusion produces a feature map with channel attention, which mitigates the loss of information related to small targets in the helmet image.

To ensure the effective functioning of the attention mechanism within the network, the paper integrates the SE attention mechanism into the focus module of the backbone network. This module is located at the front of the network and is placed before the first convolution operation. As a result, the network can prioritize the channel feature information of the target for detection at an early stage, thereby improving its representational capability.

As shown in Fig. 4, the structure of the SEFocus enhanced slicing module consists of two main parts. One part is responsible for slicing the original image to reduce the model computation, as shown in the figure for the slicing module; the other part embeds the channel feature information into the sliced and reconstructed image through the attention mechanism to prevent the channel feature information loss.

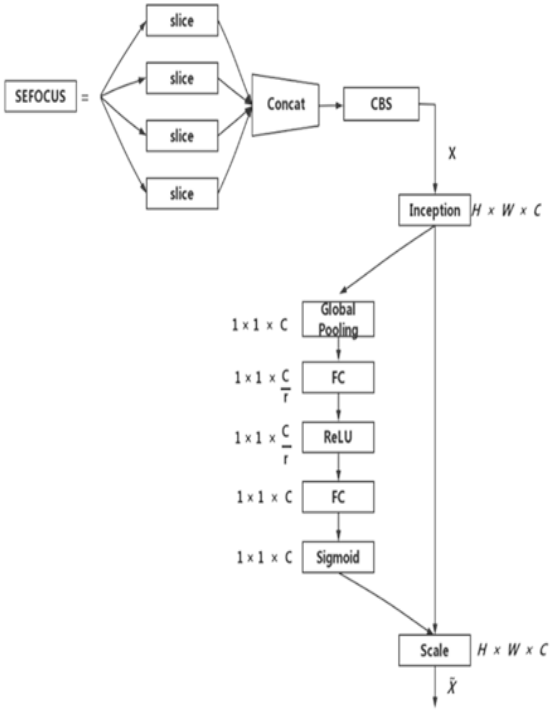

Fig. 4. SEFocus structure diagram.

Transforming the sliced image into an attention image with channel feature information requires three steps. The first step first performs spatial feature compression on the feature map, the second step learns by FC fully connected layer to obtain the channel attention feature map, and the third step outputs the channel attention feature map [25].

In order to reduce the computation, the number of parameters, and the introduction of inter-channel relationships, the squeeze operation is first performed on the input feature map as shown in equation (1), assuming that the input feature map is X with dimensions C*H*W, where C is the number of channels, and H and W are the height and width, respectively.

$$z_c = \mathrm{F}_{sq}(\mathrm{u}_c) = \frac{1}{H \times W} \sum_{i=1}^{H} \sum_{j=1}^{W} u_c(i,j) \qquad (1)$$

This step is completed by two fully connected layers to generate the weight information required in this paper by weight W, which are obtained by learning. Then, the vector z obtained in the previous step is processed through two fully connected layers W_1 and W_2, and the channel weight s is obtained as shown in Equation (2), and after two fully connected layers, the different values in s represent the weight information of different channels, and the channels are given different weights.

$$\mathrm{s}{=}\mathrm{F}_{ex}(\mathrm{z,W}) = \sigma\big(g(\mathrm{z,W})\big) = \sigma\big(\mathrm{W}_2\delta(\mathrm{W}_1\mathrm{z})\big) \qquad (2)$$

Finally, the weight vector s generated in the second step is assigned to the feature map U, and the feature map is obtained as shown in Equation (3), whose size is exactly the same as that of the feature map U.

$$\tilde{\mathrm{x}}_c = \mathrm{F}_{scale}(\mathrm{u}_c, s_c) = s_c \mathrm{u}_c \qquad (3)$$

3) Swin transformer: When YOLOv5s is used for feature extraction, the typical convolutional neural network CSPDarknet53 is selected to expand the perceptual field by continuously stacking convolutional layers to complete the capture of local information into global information. However, the increasingly deep convolutional layers lead to an increasingly complex model, and with the deepening of the network structure, the position information of the small-scale targets in the helmet dataset may be coarse, and the feature information may be easily lost after multiple convolutional operations [26].

This study presents an improved convolutional structure, as shown in Fig. 5, by incorporating the Swin Transformer into the C3 convolution module.

The aim is to enhance the semantic information and feature representation of small targets by utilizing the self-attentive window module in the feature fusion process.

In the Swin Transformer model, after the linear transformation of the input vectors, the resulting matrix is equally divided into three parts, which become the three features of query vector Q, key vector K and position vector V in the Transformer, and the attention mechanism is calculated as shown in equation (4).

$$Attention(Q,K,V) = Softmax\left(\frac{QK^T}{\sqrt{d_k}}\right)V \qquad (4)$$

In the above equation, Attention denotes the attention weight matrix, Softmax denotes the normalized exponential function, QK^T is the matrix obtained by matrix multiplication, d is the feature dimension, and denotes the length of the keyword vector.

The method not only takes into account the displacement invariance, dimensional invariance, perceptual field, and hierarchical relationships characteristic of convolutional neural networks, but also has the ability to extract global information and learn long dependencies. Swin Transformer improves efficiency by limiting self-attentive computation to non-overlapping local windows with moving windows, while allowing cross-window connections [27]. In addition, this hierarchical structure provides the flexibility to model at different scales and improves the ability of the model to capture multiscale information.

In summary, the above three improved methods are applied to the YOLOv5s algorithm, and the improved network structure is shown in Fig. 6.

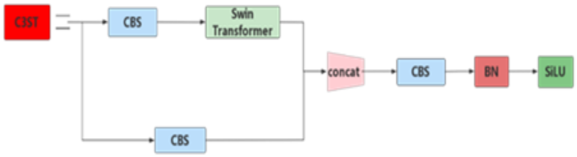

Fig. 5. C3ST structure.

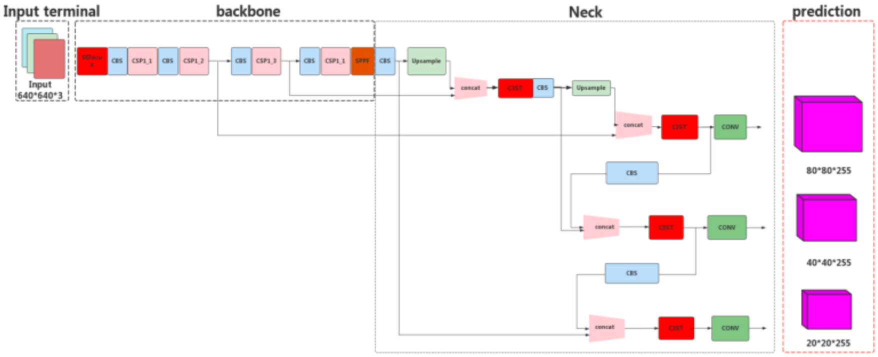

Fig. 6. Improved structure diagram of YOLOv5.

IV. Introduction to the Data Set and Experimental Environment

A. Introduction to the Data Set

1) Dataset sources: In the study of helmet and vest recognition, due to the lack of publicly available large-scale datasets, this paper collects relevant images through on-site photography and from the Internet. On-site photography is a common way to collect data, and this paper chooses to shoot at municipal construction sites and other scenes where helmets and vests are required. On-site photography captures image samples with real environmental backgrounds, different lighting conditions, and different poses, which is very beneficial for the robustness and generality of the algorithm.

In addition, a large number of relevant image resources are available on the Internet. In this paper, we obtain the necessary image information by searching and downloading user-uploaded construction site photos and construction site surveillance video screenshots through engineering websites and social media platforms.

2) Data pre-processing: In the data pre-processing stage, the images that meet the requirements are first converted to .jpg format for further processing and model training. To improve the robustness of the model, some of the positive sample data in this paper are inverted, which can increase the diversity of the data and make the model more generalizable when dealing with mirror image or symmetry problems. The saturation and exposure of the images are also adjusted to further increase the diversity of the data and the adaptability of the model.

Next, manual labeling is performed using the labelImg labeling tool. The construction workers in the image are labeled according to four categories: wearing a helmet (hat), wearing a safety vest (reflective clothes), not wearing a helmet (head), and not wearing a safety vest (other clothes). The labeling tool draws rectangular boxes in the image to frame the target location and assigns the appropriate category label to each box. This creates an XML tag file containing the four coordinates and category information of the target within the frame. The final PASCAL VOC format is obtained, which is a commonly used annotation format for target detection datasets and can be easily compatible and interactive with various deep learning frameworks.

Through the above processing steps, the pre-processed and annotated dataset with a total of 12,000 images is obtained in this paper. Each image has a corresponding image file in .jpg format as well as a tag file in XML format containing the location and class of the target.

B. Experimental Environment and Parameter Settings

In this study, a Linux system was chosen as the experimental development platform and the Ubuntu 18.04 operating system was used.

The experimental environment is equipped with a V100 GPU, and CUDA 10.1 is used as the GPU acceleration library. For the deep learning framework, PyTorch 1.8 was used as the main framework and Python 3.7 as the programming language. To meet the task requirements, the image resolution was set to 640x640, the training batch was set to 16, the training process was set to 100 rounds, and the initial learning rate was set to 0.001. The impulse was set to 0.937.

V. Experimental Results and Analysis

A. Evaluation Metrics

The performance metrics commonly used in target detection algorithms include precision, recall, average precision (AP), mean average precision (mAP), and number of parameters and floating point operations (FLOPs).

Accuracy is the proportion of all samples with a positive prediction that are actually positive. It measures the degree of accuracy of the model in predicting positives. Recall rate, also known as sensitivity or true positive rate, is the ratio of correctly predicted positive samples to the total number of actual positive samples. The formula is shown in equation (5), which measures the ability of the model to detect positive specimens.

$$P = \frac{TP}{TP+FP} \tag{5}$$

Recall is measured by calculating the ratio of correctly detected positive samples (True Positive, TP) to all true positive samples. TP refers to the positive targets that are successfully classified in the model, i.e., the true positive samples that are correctly detected. Equation (6) represents the formula for determining the recall rate.

$$R = \frac{TP}{TP+FN} \tag{6}$$

Here, FN denotes positive samples that were incorrectly classified as negative during the classification process, i.e., true positive samples that were not correctly detected. The recall value, which ranges from 0 to 1, increases as the model becomes better at identifying true positive samples.

Average Precision (AP) is a comprehensive metric that calculates the accuracy of the model at different confidence levels and averages these accuracies. The formula is shown in equation (7) and is used to assess the balance between accuracy and recall of the model.

$$AP = \int_0^1 P(R)dR \tag{7}$$

The mAP is the average of the average accuracies of all categories. It measures the overall performance of the model over multiple categories and is calculated as shown in equation (8).

$$mAP = \frac{\sum_{i=1}^{N} AP_i}{N} \tag{8}$$

The parameter count represents the total number of learnable parameters in the model. Reducing the number of parameters in a model can reduce memory requirements and computational complexity, making model deployment and inference easier. The number of FLOPs quantifies the number of floating point operations required by the model during inference. FLOPs serve as a measure of the computational complexity and inference speed of the model.

B. Presentation of Experimental Results

In this paper, a modified YOLOv5 model is used for security detection in the field of municipal engineering. The effectiveness of the improved model is tested using datasets consisting of homemade helmets and reflective vests to evaluate its detection capabilities. The accuracy, recall, and MAP graphs of this paper are shown in Fig. 7, 8, and 9, respectively.

According to Fig. 7, the accuracy of the proposed algorithm can reach 0.985. The x-axis represents the confidence threshold and the y-axis represents the precision. The overall shape and trend of the curve reflect the detection performance of the algorithm at different confidence thresholds. The improved algorithm in this paper can maintain high precision even at high confidence, indicating good accuracy.

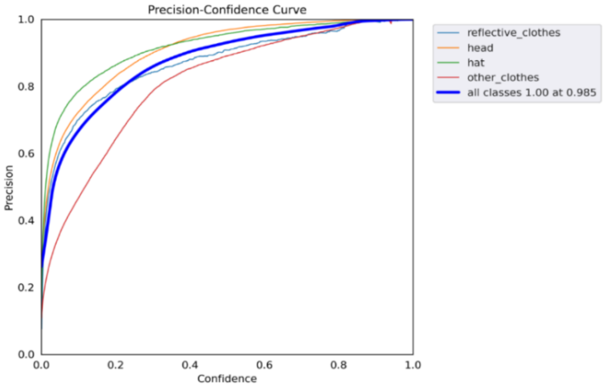

Fig. 7. Accuracy graph.

From Fig. 8, the recall of the proposed algorithm reaches 0.97. The x-axis represents the confidence threshold, and the y-axis represents the recall. The curve describes the recall at different confidence thresholds. Higher recall indicates that the algorithm can detect more targets at a given confidence threshold, but it may be associated with some false positives. Lower recall may indicate that the algorithm misses some targets at a given confidence level, but with a lower false positive rate. The proposed algorithm maintains high recall even at high confidence.

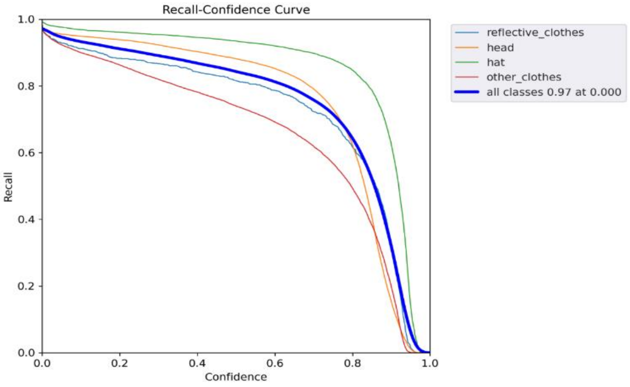

Fig. 8. Recall rate graph.

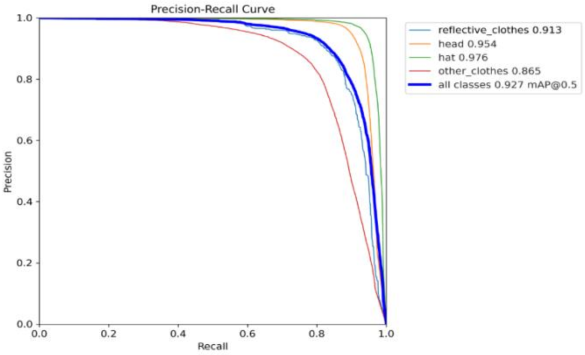

Fig. 9. mAP graph.

According to Fig. 9, the Mean Average Precision (mAP) value in this paper reaches 0.927. The x-axis represents recall and the y-axis represents precision. The curve is plotted by connecting points representing precision and recall at different thresholds. The position of the curve closer to the upper right corner indicates higher precision and recall at different thresholds, implying better performance of the model. This indicates that the model proposed in this paper has good performance.

C. Analysis of Experimental Results

As shown in the table, in this paper, the operation of adding each of the three improvement modules one by one is performed and tested according to the three evaluation metrics of P, R and mAP. Among them, optimization model 1 modified the Mosaic-4 data enhancement method of the original model, optimization model 2 modified the focus structure of the original model, and optimization model 3 modified the C3 module of the feature fusion part of the original model. From the data in the table, the mAP value of Optimized Model 1 is improved by 1.3%, which indicates that the improved Mosaic method enriches the context in which the detection objects appear, which makes the model better learn the local features of the detection objects and optimizes the training of the model. The optimized model 2 mAP value is improved by 2%, indicating that the model can focus on the channel feature information of the target to be detected earlier by adding the SE attention mechanism in the focus part, which effectively reduces the problem of small target feature information loss. The mAP value of the optimized model 3 is improved by 1.8%, which proves that Swin Transformer can effectively improve the global perception of small features of the detected targets. In this paper, the combined use of three enhancement methods, whose P, R, and mAP are improved by 5.3%, 5.7%, and 3.4%, respectively, optimizes the detection effect of small and dense targets in complex scenes.

To better demonstrate the advantages of the algorithms in this paper, the improved algorithms in this paper are compared with several mainstream algorithms for experiments, including Faster R-CNN, SSD, YOLOv3, YOLOv4, YOLOv5s, and the improved algorithms in this paper. To ensure the fairness of the experimental results, the experimental environment, including experimental settings such as input image size, learning rate, and momentum, should be kept identical for the comparative experiments. As shown in Table I, with P, R, mAP, Parameters, and FLOPs as evaluation metrics.

TABLE I. OPTIMIZATION RESULTS OF EACH IMPROVEMENT MODULE FOR YOLOV5S

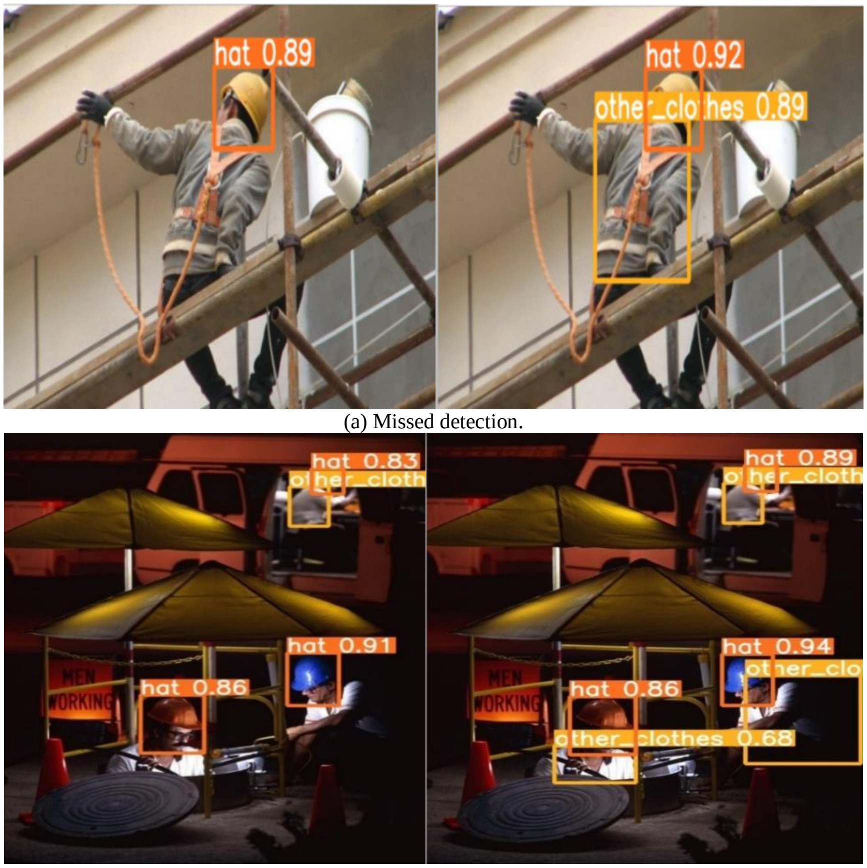
Algorithm model	**Mosaic-6**	**SEFocus**	**Swin Transformer**	**P/%**	**R/%**	**mAP/%**
YOLOv5s				93.2	91.3	89.3
Optimized model 1	√			94.1	91.5	90.6
Optimized model 2		√		95.4	90.6	91.3
Optimized model 3			√	96.4	95.3	92.1
Algorithm in this paper	√	√	√	98.5	97.0	92.7

TABLE II. COMPARISON OF DIFFERENT ALGORITHMS ON THE DATA SET OF THIS PAPER

Algorithm model	**P/%**	**R/%**	**mAP/%**	**Parameters /M**	**FLOPs/G**
Faster-RCNN	87.3	79.5	83.4	136.5	396.2
SSD	82.5	73.6	79.7	24.2	281.3
YOLOv3	84.3	77.4	81.2	116.3	55.1
YOLOv4	85.1	76.3	83.0	101.3	54.7
YOLOv5s	93.2	91.3	89.3	7.05	16.6
Algorithm in this paper	98.5	97.0	92.7	7.6	21.8

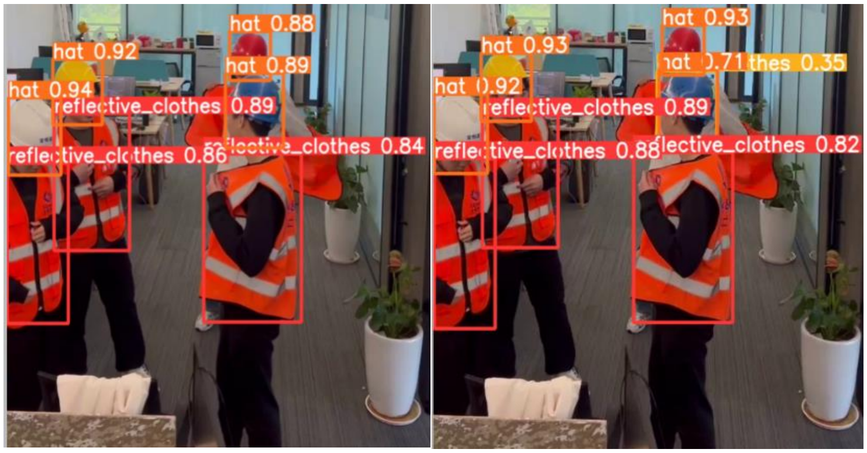
As shown in Table II, the algorithm in this paper has a better detection performance with an average accuracy mAP of 9.3%, 13%, 11.5%, 9.7%, and 3.4% over the constructed helmet and reflective vest datasets than the Faster-RCNN, SSD, YOLOv3, YOLOv4, and YOLOv5s algorithms, respectively. In terms of model computation size, this paper is slightly larger than YOLOv5s, but much smaller than other mainstream algorithms, especially the two-stage detection algorithm. In addition, the algorithm in this paper has a great improvement in accuracy (P) and recall (R). Overall, compared with the YOLOv5s model, the algorithm in this paper is slightly larger in model size, but has a significant improvement in accuracy, and still meets the demand for real-time detection, and also significantly improves the detection performance, with significant overall performance advantages.

In order to visually compare the detection effect, this paper performs the detection of the same image with the YOLOv5 model and the improved algorithm, and shows the comparison results, as shown in Fig. 10. The left side of the figure shows the detection effect of the YOLOv5 model, and the right side shows the detection effect of the improved algorithm. By comparing the results of the two, the performance improvement of the improved algorithm on the target detection task can be clearly observed. Such a comparison helps to illustrate the effectiveness of the improved algorithm proposed in this paper in improving the detection results.



(a) Missed detection.

(b) Dark scenario.



(c) Dense targets.

Fig. 10. Comparative detection.

As shown above, in image (a), the original YOLOv5 model has failed to detect and identify whether reflective vests are worn or not, while the improved model can successfully detect them. The second set of images (b) is a dim scene, and the improved model can detect the protective gear worn by the construction workers even in very low light. The last set of images (c) is dense target detection, and the algorithm is able to accurately identify the presence of personnel occlusion. In short, the improved algorithm has been greatly improved in the case of missed detection, dim scenes and dense targets, which are not conducive to the correct identification of target detection.

VI. Conclusion

This paper proposes a YOLOv5s-based algorithm for the simultaneous detection of helmet and reflective vest wearing, which provides a new technological means for urban engineering supervision. First, the Mosaic-4 data enhancement method used in YOLOv5s is improved, and the Mosaic-6 data enhancement method is used to give synthesized images more complex backgrounds, which is used to enhance the learning ability of the model for local features, thus improving the generalization ability of the whole model. Second, the attention mechanism is introduced in the focus module to enhance the perceptual field of the model and improve the correlation between the channel information and the detection target features. Finally, the feature fusion part of the original model is improved by adopting a new hierarchical construction method inspired by the Swin Transformer. This enhancement aims to improve the semantic information and feature representation of the helmet mini-target by incorporating the window self-attention module, which effectively replaces the C3 module.

The experimental results show that the enhanced approach presented in this research paper is capable of accurately identifying helmets and reflective vests, and the average accuracy can reach 92.7%, which is 9.3, 13, 11.5, and 9.7 percentage points higher than the average of Faster-RCNN, SSD, YOLOv3, and YOLOv4 models, respectively. Li et al. improved the YOLOv5s network structure and loss function. The improved algorithm has a map value of 92.5%, a precision rate of 87.7%, and a recall rate of 86.8% [28]. Compared with this algorithm, the map value is only 0.2% higher. However, our algorithm shows a significant advantage in terms of accuracy, exceeding by 10.8%, as well as recall, exceeding by 10.2%. Although there is a slight increase in model size, the accuracy and recall rates are significantly improved and still meet the requirements of real-time detection with high application value.

VII. Future Outlook

While the improved algorithm in this study has achieved certain results in the detection of safety gear wearing in municipal construction projects, the authors acknowledge that there is still room for improvement. This study focused only on the method for detecting the wearing of safety protective equipment. In practical applications, it is necessary to design and develop a standardized system that includes the interaction interface between the backend algorithm and the frontend system. This will enable real-time detection of construction sites and ultimately establish a complete system. In future work, the authors will continue to strive for higher detection accuracy and explore more effective algorithms and techniques. Additionally, the authors will design and develop the system to ensure the algorithm's compatibility with real-world application environments. By considering both accuracy and real-time requirements, the goal is to provide a high-performance and reliable system that offers a feasible and effective solution for detecting the wearing of safety protective equipment in the field of municipal construction projects.

Acknowledgment

The authors would like to thank the reviewers for taking the time to guide the completion of this paper, and also thank the Education Department of Jilin Province, China for their financial support.

***Abstract*—In recent times, social media has become the primary way people get news about what is happening in the world. Fake news surfaces on social media every day. Fake news on social media has harmed several domains, including politics, the economy, and health. Additionally, it has negatively affected society's stability. There are still certain limitations and challenges even though numerous studies have offered useful models for identifying fake news in social networks using many techniques. Moreover, the accuracy of detection models is still notably poor given we deal with a critical topic. Despite many review articles, most previously concentrated on certain and repeated sections of fake news detection models. For instance, the majority of reviews in this discipline only mentioned datasets or categorized them according to labels, content, and domain. Since the majority of detection models are built using a supervised learning method, it has not been investigated how the limitations of these datasets affect detection models. This review article highlights the most significant components of the fake news detection model and the main challenges it faces. Data augmentation, feature extraction, and data fusion are some of the approaches explored in this review to improve detection accuracy. Moreover, it discusses the most prominent techniques used in detection models and their main advantages and disadvantages. This review aims to help other researchers improve fake news detection models.**

Keywords*—Fake news detection; social media; data augmentation; feature extraction; multimodal fusion

I. Introduction

Social media platforms are now the main source of news consumption for many around the world. Unlike traditional media, social media networks support the rapid spread of posts to a wide audience in a short time and without validation restrictions and costs [1]. This contributes to fake news dissemination on social platforms [2]. Research has indicated that many people have trouble distinguishing between real and fake news. This issue is not related to a specific age or gender and does not depend on education [3]. Researchers observed that fake news spread 70% more than real news [4]. Recent studies have stated that fake news dissemination on social media has become a current-day issue that has attracted global attention that needs intervention and an immediate halt to its spread [5] because this issue is creating social panic and economic unrest [6]. Fake news detection is a difficult challenge. Therefore, the research community has paid much attention to this issue. It is considered one of the modern fields [7], and research in this field is still developing, but constantly increasing. This needs more improvement and exploration of upcoming directions in research to enhance fake news detection methods [1]. However, fake news detection overlaps with several domains [8]. Therefore, this matter has become of interest to many researchers from different disciplines and areas [9]. Based on previous studies, fake news models face many difficulties due to the distinct attributes of this issue These challenges include the lack of standard datasets, their small size, or their imbalanced distribution, which affects detection models' performance. Another issue to be highlighted is how to deal with social media data, the features used, and the improvement of techniques for extracting these features. In addition, developing methods for the fusion of features and making decisions. Although there are many review articles discussing several aspects of fake news detection, most merely review the techniques used in detection models. In addition, they categorize features by type, or group datasets based on labels or domains. What distinguishes this review is that it discusses the challenging aspects that still affect fake news detection models. It also discusses the possibility of increasing detection accuracy by providing future suggestions for improving the techniques used. This review investigates three key and critical aspects of fake news detection studies, namely datasets, extracted features, and data fusion. These aspects affect the accuracy of fake news detection models. Studies published in the following well-known databases and digital libraries in the academic field (Web of Science, ACM Digital Library, Springer Link, IEEE Explore, Science Direct) in English for the period from 2017 to 2023, which dealt with the three aspects referred to above, were covered. The main contributions of this review are as follows:

- Provide an overview of fake news, its types, the impact of its spread, and the role of social networks in disseminating news.
- Highlight the critical parts of the fake news detection model and the most serious limitations related to them.
- Investigate the methods used in several fields that have provided promising results and future suggestions for improvement.

The rest of this review article is arranged as follows: Section II summarizes relevant studies that discuss significant aspects of fake news detection. Section III provides an overview of fake news. Section IV shows the role of social media in disseminating news. Section V reviews the main modules that make up fake news detection models. Section VI investigates the main detection model techniques and their challenges. Section VII discusses the prominent techniques used in Detection models. Section VIII suggests future directions to improve detection models. Section IX concludes this review.

II. Related Works

There are some reviews presented that deal with fake news detection studies. Some reviewed certain aspects, and others investigated others. Cardoso Durier da Silva, Vieira [10] presented a review of studies that dealt with the use of Machine Learning (ML) techniques or Natural Language Processing (NLP) methods in detecting fake news on social networks. While Sharma, and Qian [11] investigated the causes of fake news propagation and ways to reduce it, as well as analyzing the characteristics of standard datasets used in relevant studies. According to Pathak, Mahajan [12], previous studies employing Machine Learning (ML) and Deep Learning (DL)-based models using supervised, unsupervised, and hybrid approaches to rumor detection were reviewed. In addition, they presented in their review the standard datasets used in rumor detection studies and discussed the features used. Vishwakarma and Jain [13] presented a concise review of the methods and datasets used in research on fake news detection. In addition, they categorized fake news in terms of its types. They also investigated the features used in these detection models which are textual content features, and image-based features. In a different context, Zhou and Zafarani [14] published a review examining techniques for identifying fake news from four perspectives: the misinformation it contains, the writing style, the patterns of dissemination, and the reliability of the source. They also highlighted fundamental theories from different fields related to fake news dissemination. In another direction, De Beer and Matthee [15] presented a systematic review discussing the approaches used to detect fake news. These methods included the language, topic-agnostic, machine learning, hybrid, and knowledge-based approach. While Alam, Cresci [16] reviewed misinformation detection research papers divided down by content-based features, including image, speech, video, and network and temporal information. They also mentioned certain difficulties with multimodal detection models. Ansar and Goswami [17] published a comprehensive review of characterizing fake news identification from a data science point of view. They covered the different types of fake news, and the different features used in detection models. They also presented the most significant standard datasets currently available in this area. Studies of COVID-19 misinformation detection were also investigated as a case study. Considering that the issue of detecting fake news is a classification problem, Li and Lei [18] produced a review article that classified research related to fake news detection based on DL based on the data structures used in news classification which are text classification, graph classification, and hybrid classification. An overview of fake news detection studies was presented by Swapna and Soniya [19]. This overview was categorized according to features utilized in these models, such as linguistic and semantic, style, and visual features. Meanwhile, Hu, Wei [20] provided a thorough analysis of DL-based fake news detection techniques that consider many aspects like content, social context, and external knowledge. In their review, several widely used datasets and pertinent studies were presented, in addition to suggesting future work.

III. Fake News Overview

Fake news is perceived as among the most severe dangers to journalism, freedom of expression, and autonomy. It has been proven in studies that in comparison to authentic news, fake news on social media gets more retweets and shares, especially political news [21]. This issue has reduced public confidence in governments, including the controversial “Brexit” referendum, as well as the divisive 2016 U.S. presidential election [22]. The strongest emphasis was placed on the reach of fake news in the crucial months of the 2016 U.S. presidential election movement. Fake news as a term was chosen by the Oxford Dictionary in 2016 as the international word of the year [23]. This nation's economy is susceptible to fake news, which is linked to the fluctuating stock market and big deals. As an example, fake news claimed that US President Barack Obama was injured in an explosion, which led to the erasure of $130 billion worth of shares [24]. In the case of fake news's ability to gain public trust, psychological and social elements play a significant part. They reinforce fake news distribution. It has been proven that people become less reasonable and show vulnerability when authenticity and fabrication are differentiated. At the same time, they are burdened with fake news. Based on research conducted on 1,000 participants in more than 100 experiments in social psychology and communications, a slightly higher human capability of identifying falsehood was recorded compared to possibility with common precision degrees ranging from 55% to 58% and a mean precision of 54% [25]. In the case of news where truth and objectivity are expected, gaining public confidence is easier. People also believe fake news after being exposed to them repeatedly (validity satisfies [26] or if the news satisfies their desirability bias [27], is in line with preexisting principles, bias in confirmation [28] or viewpoints (selective exposure [29]). In some cases, peer pressure could “control” people’s perspectives and conduct (e.g., the bandwagon impact [30]).

A. *Fake News Types*

"Fake news" refers to news items that have been published but contain misleading information to deceive readers intentionally [7] for malicious purposes [31]. Literature shows that there are several types of fake news, as illustrated in Fig. 1. These are rumor, disinformation, misinformation, hoax, and clickbait [7]. A rumor is an unconfirmed or unsupported statement, and it spreads like wildfire [32]. Disinformation is misleading information deliberately posted to deceive people, while misinformation is inaccurate information that is unintentionally shared [7]. When a user publishes false information with malicious intent, it falls under the category of disinformation [33]. It is the users' lack of knowledge of a particular topic or field that causes misinformation to be circulated [7]. One category of fake news is a hoax whose purpose is to intentionally mislead the reader with ill-intention. This includes defrauding users and losing money [34]. According to psychological studies, clickbait is one of the forms of fake news that draws in readers by evoking their interest in learning more about the catchy news headline. It also encourages them to click [35]. The purpose of clickbait is to redirect readers to fake websites to increase traffic to websites containing ads. It is a type of attention-grabbing title that might not reflect the content of the article [34].

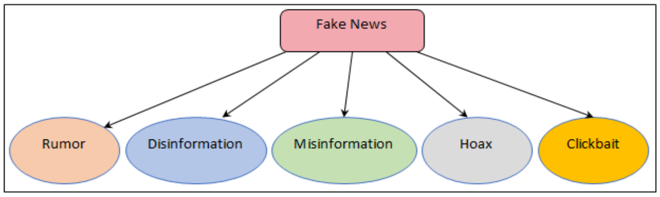

Fig. 1. Types of fake news.

B. Fake News Consequences

Since human society began, fake information has existed. But with the change and recent technological advancements in the global media environment, fake news circulation is growing. Fake news may cause severe consequences in political, social, economic, and health domains. Fake news comes in many forms. Fake news greatly affects the way information shapes our view. We make crucial decisions based on information. Based on the information we hear, we build an opinion about a situation or a collection of people. Contrived, misleading, twisted, or fraudulent information online prevents us from making the right decisions [36]. Fake news has the following main effects:

- Impact on citizens: Rumors about particular people can have a major effect. These individuals can face online abuse. In addition, they can be subjected to insults and threats that may have far-reaching negative effects. Individuals should not directly believe disinformation posted on social media and not make premature judgments about others based on this misleading information.

- Impact on health: People turn to the Internet for health news. Health-related fake news can affect people's lives. This problem has become the issue of the times. In the past few years, misinformation targeting health has had a serious negative impact. As a result, and based on effective lobbying by health organizations, doctors, and health advocates, many social media companies have had to change their policies to prevent and restrict misinformation spread.

- Impact on finances: Currently, fake news is a serious problem in industry and commerce. Fraudulent businessmen publish deceptive information or reviews to increase revenues. Stock prices may drop due to false information. It can destroy a company's reputation. Fake news also impacts customers' expectations. False news can breed unscrupulous commercial practices.

- Impact on democracy: Because fake news was so influential in the US presidential election, the fake news problem has received considerable media attention. Fake news has become a major issue threatening democracy, therefore, its spread must be stopped [37].

IV. Social Media Platforms

In recent years, rapid technological development, particularly in the mobile phone sector has made social media networks like Facebook, Twitter, and Sina Weibo accessible. These platforms have become an integral part of people's daily lives [7]. Social media is now a potent tool for all types of journalism, including sports, medical, and political reporting [15]. Instead of watching traditional media, most people now spend their time on social media to connect, gather knowledge, and share it [7]. Social media is used by many people to post or share news or information. This is because, unlike traditional media, news distribution through networks is real-time and quick, there are no costs involved, and there are no restrictions imposed on validation [4]. For example, in 2012 in the U.S., about 49% of users shared news on social media platforms. The Pew Research Center issued a report in 2016 stating that more than 62% of users daily receive their news from social networking pages [4], while in 2018, a report indicated that two-thirds of adults in the U.S. received their news from these pages [38]. The fact that social media is used on a variety of devices has significantly expanded the amount of data available [15]. Furthermore, it is worthwhile to refer to the issue of the language used in social media. This is because social media users come from all cultural, academic, and age backgrounds. Therefore, many posts on social media contain linguistic mistakes, use acronyms, are written in slang, or include obscene words. Fig. 2 shows a post containing slang and acronyms.

Fig. 2. A colloquial post on a facebook page.

There are drawbacks to these platforms despite their advantages. These platforms are misused by people or organizations to propagate false information for malicious purposes. This may be for financial gain, extremist hatred, or manipulation of people's minds for political reasons. It may also be intended to form biased opinions for electoral purposes [39]. The negative effects of social media as a result of fake news foreshadow a real danger that negatively affects individuals and society. This requires providing models for detecting fake news and limiting its spread [40].

V. Components of the Fake News Detection Model

In this section, the critical parts that make up the fake news detection model and affect its performance and how these elements relate to each other to carry out this task are reviewed. The detection model has three main components: a dataset, features, and a model based on a supervised classifier.

A. Dataset Used in Fake News Detection Models

Fake news detection studies demonstrated that no benchmark dataset is currently available that offers resources for extracting all crucial features. Fake news circulates on social media in various temporal patterns than real news. The dataset is the most significant component of fake news detection, and any model's effectiveness depends on it [34]. The larger size of the dataset [41], more diverse [42], more feature-rich [43], and low-noise [44], leads to improving the model's performance and increases its accuracy in identifying fake news [40]. Many researchers utilize fact-checking websites for data collection [45], because gathering data on fake news is time-consuming [46]. There are several significant challenges facing data gathering. These challenges include the ability to create a large volume of data in high quality, as well as ease of access without privacy restrictions. In addition to the data annotation process [7]. Data collection resources used by the researchers included reliable resources [44] such as government websites and websites of reputable media organizations, which contain information based on the facts [47]. According to researchers Subramani, Michalska [48], collecting, annotating, and labeling data is a laborious process that takes time, cost, and effort. The results are a medium-sized dataset that includes domains not previously investigated and considered acceptable by researchers. Some researchers are compelled to manually gather, annotate, and label data to produce a standard dataset that is checked for quality and reliability by specialists [48]. It should be underlined that facts, not opinions or feelings, must serve as the foundation for gathering ground truth data [44]. Additionally, it is essential to pre-process the dataset to eliminate extraneous data [42]. Future research would take less time, effort, and cost if standard datasets were created for previously unstudied topics, or expanded by adding more information [49]. This would benefit the research community. [50].

The researchers note that the model's accuracy is affected by the balance or imbalance in the dataset structure [51]. When compared to models that use a balanced dataset, models that use an imbalanced dataset produce higher results during training (a bias for one category over another) [52]. This means that these models are biased. Therefore, models that use a balanced dataset perform better [53]. Fig. 3 shows the most significant factors affecting the detection accuracy of fake news detection models.

B. Features Used in Fake News Detection Models

AI-based models for fake news detection rely on some key features, such as content-based, network-based, or user-based. In any case, using all of these features may not increase detection model accuracy. Depending on the nature of the issue, one or more features may be used. The results of the study by Kim, Kim [54] indicated that rumor detection accuracy using user features was the most poor of all. In contrast, rumor detection accuracy using content-only features was significantly higher than utilizing all features at once. According to these researchers, the experiments demonstrated that propagation features and user features were insufficient to identify rumors. Generally, news content (linguistics and visual information) is used as features in news identification [36]. Psychologists say people prefer articles with engaging visuals paired with text and believe them. When an article contains multimedia elements such as images instead of just text, it reaches more users [19]. Therefore, while textual content is essential for news verification, visual content also has a vital function in detecting fake news [17].

C. Fake News Classifiers Based on Supervised Learning

The performance of any model normally relies on the classifiers employed [43], the hyperparameter tuning [48], and the dataset used [34]. The diversity of AI techniques used in fake news detection models in previous research encouraged us to break up related studies based on supervised learning methods applied to detect fake news. Using labeled examples, supervised models learn from a variety of features [20]. Therefore, we list below the previous studies according to their use of ML and DL methods.

1) Machine learning-based models: Many previous research articles have employed Machine-Learning (ML) techniques to identify fake news. Aldwairi and Alwahedi [9] presented a study to detect fake news using a logistic classifier. They scraped their data from web pages. They also applied information gain and correlation attribute methods to rank the attributes according to how they relate. In all their experiments, the accuracy of the results exceeded 99%, and it was unclear whether they were training or test results. While Bhutani, Rastogi [55] proposed a model using Random Forest (RF) to identify fake news by employing sentiment analysis-based features. They utilized TF-IDF with cosine similarity for feature representation. The model was trained and tested on three datasets, each separately. However, there was a disparity in the results between training and testing, which means the model was overfitted. Therefore, the three datasets were combined, and based on them; the proposed model was trained and tested on this merged dataset. The AUC measure was 84.30%. In the same direction, Varshney and Vishwakarma [45] presented a two-stage model, data collection and classification. The data collection stage retrieves claims about statements from rumor-debunking web pages. Based on content similarity to claims, the data classification stage extracts features from web statements that have been retrieved. Claims are classified as real news or fake news by the RF classifier based on content- and sentiment-based features. Faustini and Covões [56] used KNN, RF, NB, and SVM machine learning-based classifiers to identify fake news. SVM and RF outperformed other classifiers, according to experiments. They used five small datasets, and the number of examples in each dataset ranged from 137 instances, as in the btvlifestyle dataset, to 8,981 instances, as in the TwitterBR dataset. Regarding the feature set, the researchers applied the bag-of-words method in their experiments, as well as the DCDistance algorithm to reduce the dimensionality of the features. Although some of the results from some of the datasets examined may be encouraging, the majority of the results are poor. Kim, Kim [54] proposed an Ensemble Solution (ES) based on Soft Voting which consists of RF, XGBoost, and Multilayer perception. In order to determine which ML model was most suitable for creating an ES model, they examined several. To detect rumors, the latter model used the features of content, network, and users, and their model provided the highest F1 score of 79%.

2) Deep learning-based models: For identifying rumors, researchers Rath, and Gao [32] have developed a believability concept-based model that uses the LSTM classifier. Believability is determined based on the level of trust between Twitter users. They formed their dataset by merging two datasets, Twitter15 and Twitter16. LINE embedded the user in the network according to its reply and retweet. Their model provided an accuracy of 73.80%. Li, Hu [57] presented a detection model to identify fake news based on CNN at multiple levels. This model extracts semantic information from articles and represents it based on word and sentence levels. A pre-trained Word2Vec model was utilized for feature vectorization. In addition, they used the TFW method to calculate the weights of sensitive words to improve classification accuracy. They used five small datasets and combined them into two datasets. Their proposed model provided an accuracy of 88.80% and 90.10% on the Weibo and NewsFN datasets, respectively. Furthermore, Alkhodair, Ding [31] created a model that uses the LSTM classifier by plugging it in parallel with the Word2Vec embedding model. The model is constantly updated with new tweets so that the classifier could detect rumors about upcoming topics on Twitter based only on the text of the tweet. The highest score recorded for the suggested model was 79.50% based on the F1 score on the PHEME dataset. In their study, Braşoveanu and Andonie [8] examined several DL-based models to identify fake news using a variety of features from the datasets, such as textual, relational, and meta-features. Textual features were represented by a pre-trained Glove model. The two datasets used are Politifact and Liar, which are small and imbalanced. The results were unsatisfactory for most models with less than 50% accuracy. The highest result was an accuracy of 52.40% on the Politifact dataset and an accuracy of 64.90% on the Liar dataset. This was using the CapsNet model with the attention mechanism using all features. The researchers Guo, Xu [58] developed a CNN-based rumor detection model using Transfer Learning (TL). This proposed model was trained on the small YELP-2 dataset. By copying the basic model's parameter values and then re-adjusting them after the proposed model had been trained on a small Five Breaking News (FBN) dataset to prevent the negative transfer, the TL method addressed the issue of a limited training dataset. Their fine-tuned model produced an 82.50% result based on the F1 score. Regarding Gadek and Guélorget [59], they presented an interpretable text classifier built on CNN architecture with the Class Activation Maps (CAM) method. The classifier identifies fake news in two distinct stages by applying two different datasets. Text analysis is used in the first classification and emotion in the second classification. For their experiments, the Kaggle fake news and Signal-Media datasets were utilized. For the second dataset, they applied an under-sampling method to balance it. To extract the features, a pre-trained FastText model was applied to consider punctuation. The result of detecting fake news relying on textual features was 91.8% of the F1-score, while the result of identifying fake news using sentiment analysis features was 68.3% of the F1-score. While Kaliyar, Goswami [60] proposed a fake news detection model built on Multi-layer DNN. Features based on news textual content and social context were used to identify fake news and were represented by the tensor factorization technique. They conducted their experiments using the BuzzFeed and PolitiFact datasets, and the results on both datasets were 88.37 % based on F1-score. By capturing the connections between rumors and comments on a particular topic, the researchers' Lin and Chen [40] built a Feed Neural Networks (FNN) based model for rumor detection with multi-layer transformer encoding blocks and one fully connected layer. An attention mechanism has been utilized in transformer encoding blocks to improve model performance. They used two datasets Weibo and PHEME for training and testing, and their model provided an accuracy of 84.1% on the PHEME dataset. Consequently, DL is superior to Machine Learning, because of its capacity to extract high-dimensional features [61], automated feature extraction, little reliance on data pre-processing, and improved accuracy [36].

VI. Limitations of Fake News Detection Models

Based on the weak results of Wang's [62] research and the use of high dropout values in the proposed model trained on a fine-grained dataset of 12,800 examples, it can be concluded that the detection model was overfitted and high dropout values were used to eliminate overfitting. Ghanem, and Rosso [63] used an imbalanced fine-grained FNC-1 dataset in their research. They did not address the imbalanced dataset, as their model produced poor results. There is a variation in the results of the Kumar, Asthana [64] study, as the test results were very high for most models on a small test set. However, after testing these trained models on a larger volume of the same dataset from PolitiFact the results were poor. Note that the PolitiFact dataset has the same features as the one used to train the models. This means that their proposed models fell into an overfitting problem, which prevents them from generalizing to the new data. In addition, the FakeNewsNet dataset is multimodal and visual features were excluded from their research. Based on the weak results of Shu, and Mahudeswaran's [65] experiments, it is clear to us that the lack of effective representation of features in detecting fake news, which was represented as a one-hot encoded vector, was one of the reasons for these results. In addition, one of the datasets used, although feature-rich, is small in size, which can lead to overfitting that reduces the generalizability of the model when tested on test data. Raza and Ding [66] used two multimodal datasets in their research, but visual features were not utilized in detecting fake news. In addition, the imbalanced dataset was addressed by the under-sampling method, as the omitted examples may include relevant attributes. In addition, no pre-trained word embedding model was used to enrich the model with features. All of these issues contributed to decreasing the detection model's performance. Elhadad, Li [67] used TF-IDF and N-Gram techniques to extract features and the use of such techniques may lead to the loss of many attributes, including neglecting to capture semantic relationships between words, and this is evident from the research results. Segura-Bedmar and Alonso-Bartolome [68] used the CNN model for feature extraction and did not employ a pre-trained model for visual feature extraction. Also, extracted textual and visual features were directly fused. In addition, they indicated that their model suffered from misclassification due to an imbalanced dataset. If advanced techniques were used, the results would be better. Also, the model presented by Singhal, Shah [69] fused extracted features based on simple concatenation. It was possible to increase accuracy if more focus was placed on data fusion. Kalra, Kumar [70] indicated that their model performed poorly because of the imbalanced fine-grained dataset used. Their model was overfitted and a dropout layer was added after each layer. Moreover, fusing multimodal features from different models directly loses many attributes.

VII. The Prominent Techniques Used in Detection Models

This section highlights some methods and techniques used in other fields. These techniques provided outstanding results, which can be used in fake news detection models to improve these models and increase their accuracy.

A. *Dataset Augmentation Techniques*

Deep Learning-based models are computationally costly and need properly labeled data for high performance. Enhancing the model's performance requires big data to identify the most features. Many researchers utilize fact-checking web pages for data collection, [44], because gathering a dataset related to fake and real news is time-consuming [46]. The ability to provide a big volume of data, its relevance to the research topic, its high quality, rich in features, and its ease of access without privacy limitations, particularly with social media data, are some of the most significant issues facing the data collection process [6]. Moreover, manually labeling this data is labor intensive [71]. The small size of standard datasets or they are available in large sizes but of poor quality, poses the biggest obstacle to developing and evaluating any model's efficacy in identifying fake news [72]. Deep learning-based approaches used for fake news detection require a lot of training data. The size of the data has an impact on the model's accuracy. This is why, the larger the dataset, the better the accuracy of the model [73]. The data augmentation method can create more data from the original existing data. This process leads to increases in the model's accuracy, without human effort to collect data and save time where it is difficult to collect more real data. The data augmentation process is one solution to reduce the occurrence of overfitting and underfitting during the training phase. This is done by increasing the dataset size with synthetically labeled data [74]. The method of data augmentation plays a vital role in the success of DL models, as this augmentation can lead to better detection accuracy for models when using these large datasets [75]. Data augmentation techniques have been widely used in computer vision, and have provided impressive results in image classification [76], in particular using the Generative Adversarial Network (GAN) method. GAN is an effective data augmentation method which is a type of deep network used to generate new examples [77]. In recent years, a trend has emerged for tackling NLP problems via natural language generation models such as LeakGAN. This is a modified GAN to deal with text. This is completely unsupervised or semi-supervised learning for data generation [78].

1) *Generative Adversarial Network (GAN):*

Deep learning-based generative models are called GANs. Their architecture is made up of a generator model for producing new instances and a discriminator model for detecting whether the instances created by the generator model are real or fake. Adversarial networks are frequently utilized to produce images that match observed samples. The generator model creates new images that mimic the original image using features derived from training data. Whether the created image is fake or real is predicted by the discriminator model. In detail, a vanilla GAN is made up of two networks that cooperate during training: Generator and Discriminator as illustrated in Fig. 4. Generator: This network produces images with the same structure as the training set of images when a vector of random values is presented as input. Discriminator: This network attempts to classify observations as "real" or "fake" based on batches of images that include observations from the training set and images created by the generator. The generator output is directly connected to the discriminator input. The generator utilizes the discriminator classification as a signal by using a backpropagation process to update its weights. [79].

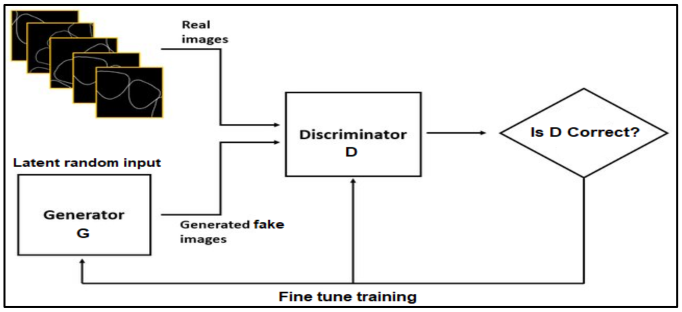

Fig. 4. The basic architecture of GAN.

In a semi-supervised environment, GANs are used to train discriminators and are very effective in generative modeling, which reduces the need for human intervention in data labeling. GANs are also helpful when data contain underrepresented samples or classes. GANs can only generate synthetic data if their foundation is a set of continuous numbers. The GAN technique has been successfully used mostly in image processing to produce real image samples. However, despite the fact that several prominent GANs models have also been suggested for image inpainting, synthesized images still have pixel errors or color inconsistencies throughout the image generation process. These errors are typically called fake textures [80].

2) LeakGAN: Unfortunately, there are two issues with using GAN in NLP to produce sequences. First off, GAN struggles to directly generate sequences of discrete tokens, like sentences, as it is built for producing real-valued, continuous data. For this reason, GAN begins with random sampling before moving on to a deterministic transform controlled by model parameters. The score/ loss for a complete sequence can only be provided by GAN after it has been formed; for a partially generated sequence, it is difficult to reconcile the present performance with the expected score for the entire sequence in the future [81]. However, because all NLP models are based on discrete variables like words, letters, or bytes, GANs cannot be used with NLP data. Novel strategies for training GANs on textual data are needed [36]. Some promising models that address this problem have been presented, such as LeakGAN which handles the problem of generating long text [82]. LeakGAN is a novel algorithmic framework proposed by Guo, Lu [82] that addresses both sparsity and non-informative problems related to previous GAN versions. LeakGAN is an innovative approach that builds on recent developments in hierarchical reinforcement learning. It delivers more information from the discriminator to the generator. A hierarchical generator G has been introduced as shown in Fig. 5, and it comprises a high-level MANAGER module and a low-level WORKER module. Mediation is performed by an LSTM called MANAGER. It gets generator D's high-level feature representation for each step, such as the CNN feature map, and utilizes it to create the WORKER module's guiding objective for that timestamp. Since D maintains its information and plays an adversarial game, it is not supposed to give G access to that information. As a result, it is called a leak of information from D. The WORKER then takes final action in the current state by combining the LSTM output and the goal embedding. This is given the goal embedding created by the MANAGER. This is done by encoding the currently generated words with another LSTM first. Therefore, the guiding signals from D are available to G both at the end in the form of scalar reward signals and during the generation process in the form of a goal embedding vector to help G improve. The discriminator evaluates the created sentence in an adversarial manner once the generator generates the following word. The main innovation is that, in contrast to traditional adversarial training, the discriminator communicates its internal state (feature) during the process to direct the generator more frequently and informatively. Consequently, LeakGAN achieved significant performance gains when generating longer sentences.

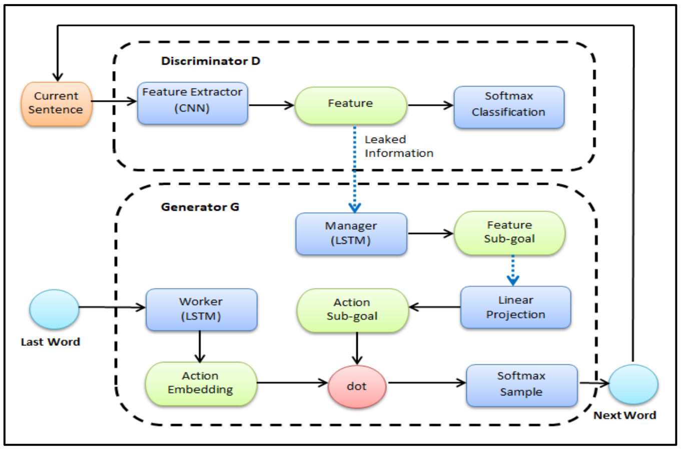

Fig. 5. The LeakGAN architecture.

B. Features Extraction Models

Feature extraction extracts a collection of features, known as a feature vector. This maximizes the prediction rate with the fewest number of elements and produces a similar feature set for several instances of the same symbol [83]. Thus, there is a need for some efficient techniques, such as vectorization, also referred to as word embeddings in the NLP field, and pre-trained image models in the image processing field. In NLP, feature extraction converts each text into a numerical representation in a vector [84], which is the initial stage in training a deep learning model. The word is considered the fundamental building block of documents in NLP [85]. When working with natural languages, the words in the document must be represented grammatically and semantically to obtain the intended results [86]. One of the common and effective techniques used in deep learning models for feature extraction is word embedding. Each word in the text string is transformed into a vector with n dimensions using embedding models, where n is the dimension of the embedding [64]. Word embedding models are distributed feature representations that are dense, low-dimensional, and well-suited to natural language tasks [87], based on deep learning [58]. Based on grammatical and semantic similarity, these models represent words and distribute them in vectors. They also take the word's relations to other terms in the document into account. Words with comparable meanings are represented by low-dimensional vectors [88]. The value of the distance between the two embedding vectors means how close the words are to each other according to the relationship between them [73]. For example, the terms "anxiety" and "depression" are semantically related because they fall under the same class relating to mental health [89] and also the terms "bad" and "good" are closely embedded for the same reason [90]. Word embedding models have proven to be remarkably effective in a variety of NLP tasks [73], including sentiment analysis, text classification, machine translation, and question-answering. This is according to earlier studies [90]. One such effective embedding model is the BERT which was produced by Google. It performed well in classifying, composing, and summarizing texts. The BERT model was used to address the OOV word issue and the problem of polysemy in conventional embedding models and the incorporation of contextual information [91]. However, embedding methods have received increasing interest in extracting textual features and have the potential to develop better representations. As opposed to relationships between words, relationships between visual concepts in images are essential for computer vision (CV) tasks, but challenging to capture. Image-based features are a key component in detecting fake news [92]. There are several neural models based on transfer learning for image-based feature extraction such as AlexNet, VGG16, and VGG19.

1) Bidirectional Encoder Representations from Transformers (BERT): BERT was created to determine the relations among words within a sentence. BERT uses a language representation approach that only utilizes the encoder section of the transformer together with semi-supervised learning. In particular, BERT is built on a multi-layer bidirectional transformer encoder, which efficiently captures information from the left and right contexts of a token at each layer simultaneously [93]. In order to perform the pre-training, an unsupervised prediction operation will be executed using a masked language model (MLM) and a sentence-next predictor by BERT. In MLM, context knowledge comes before word prediction [94]. The BERT model often uses sentences broken up into individual tokens as inputs to produce a sequence of them. The BERT model takes context into account from both sides. Instead of processing each word separately, the transformer analyzes each word in connection with every other word in the sentence. Additionally, BERT's self-attention mechanism supports determining sentence keywords. The pre-trained BERT model could be effectively fine-tuned for advanced performance in various Natural Language Processing (NLP) tasks, proving that BERT models are incredibly adaptable. BERT's tokenizer is built on words and sub-words. Therefore, if a word is absent from the original vocabulary, it will be broken down into a series of sub-tokens that when combined will make up the original word. To ensure OOV tokens do not appear and that all vocabulary units are regularly updated and sufficiently trained during training, the remaining new tokens, those associated with more uncommon words, are simply divided into smaller units [95]. The BERT framework consists of two stages: pre-training and fine-tuning. BERT was trained using unlabeled data from English Wikipedia (2,500M words) and the Books Corpus (800M words). There are two types of BERT models, the BERT large model which consists of 24 layers of encoders, and the BERT base model which consists of 12 layers. Also, there are two versions, cased and uncased [96]. With just one additional output layer, the BERT pre-trained model may be adjusted to handle a variety of NLP-based tasks, including text summarization, sentiment analysis, chatbots, and machine translation. Fig. 6 shows the fine-tuning process for the pre-trained BERT.

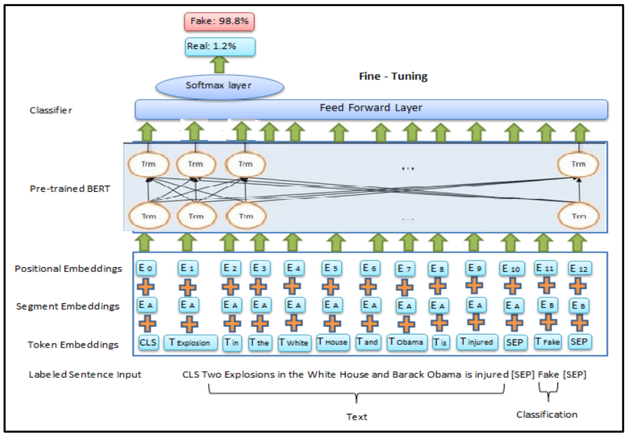

Fig. 6. The fine-tuning of the BERT model.

2) VGG-19 Model: An enhanced variant of the AlexNet architecture is the VGG16-Visual Geometry Group CNN architecture. An improved convolution neural network is implemented by expanding the network depth to 16 or 19 trainable layers. VGG networks in computer vision continue to be favored for many difficult problems [97]. The 143 million parameters of the deep architecture are learned from the ImageNet dataset. VGG receives RGB images in 224 × 224 pixels. The VGG-19 [98] is made up of 19 trainable weight layers, beginning with five stacks of convolutional layers and ending with three fully connected layers (FC) as illustrated in Fig. 7. These convolutional stacking layers carry out the process at each mark, extract image features, and then pass the result to the following layer. The number of filters increases by a factor of two, and all convolution layers employ a 3 by 3 filter size. A max-pooling layer and a Rectified Linear Unit (ReLU) activation function-based layer are followed as a non-linear activation function. Max-pooling layers are applied between each stack of convolution layers after ReLU, using a 2 by 2 kernel filter with 2 strides (pixels).

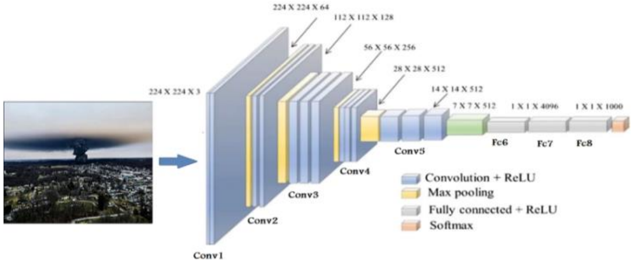

Fig. 7. The standard structure of VGG-19.

Some models, such as AlexNet and VGG-16, have encountered some issues that have been addressed in the improved VGG-19 version, including:

- Model Training: The first completely linked layer will yield a very high number of parameters, according to experiments on the original model VGG-16. This greatly increases the number of calculations and uses up more computational resources which leads to more training time [99].

- Vanishing Gradient (VG): Although network depth is significant, it can be challenging to train a deep network. This is due to the issue of vanishing or exploding gradients that arise when adding more network layers. In addition to gradient problems, if network depths continue to rise, model performance may quickly reach a limit before rapidly declining. Prior to AlexNet, the sigmoid, and tanh activation functions were most frequently utilized. These functions exhibit the VG problem due to their saturation, which makes it challenging for the network to train. AlexNet uses the ReLU activation function, which is immune to VG issues. ReLU aids with vanishing gradient problems, however, because it is unbounded, learned variables may rise excessively [100].

- Model Overfitting: Due to a large number of VGG-16 network parameters, overfitting can easily occur [99].

With the VGG-19 model, some of the previously mentioned problems have been addressed, and it offers higher accuracy than the VGG-16. The VGG-19 network is able to converge after a few iterations because of the implied regularization function of the network depth and the small convolution kernel size [101]. Having a large number of weight layers is the result of the small-size convolution filters in VGG-19, and surely, having more layers results in better performance. Despite this, less trainable variables lead to quicker learning and more resistance to overfitting.

C. *Multimodal Fusion Method*

Fusion is a crucial area of research in multimodal studies because it combines data from various unimodal data sources into a single, condensed multimodal representation. Fusional representations and multimedia are interrelated [102]. Multimodal fusion has generated a great deal of attention among scholars and widespread concern since it is an efficient method of processing multimodal data acquired [103]. Multimodal fusion is used to gain rich features by integrating various modalities [104]. The current challenge is merging and refining information coming from various modalities. Each modality contributes to varying functions. During the analysis of fusion features, the noise must be removed and relevant information extracted [105]. Multimodal fusion combines features from text and image modalities that must be merged before classification can be performed. Multimodal data fusion can produce extra information that improves the outcome precision. For example, compared to a single-modal CNN-based detection model, a multimodal fusion model for autonomous vehicle detection that fuses features of images from cameras with information from Light Detection and Ranging (LiDAR) sensors can attain noticeably improved accuracy by 3.7% over the previous one [106]. Multimodal fusion methods come in a variety of ways as shown in Fig. 8, including:

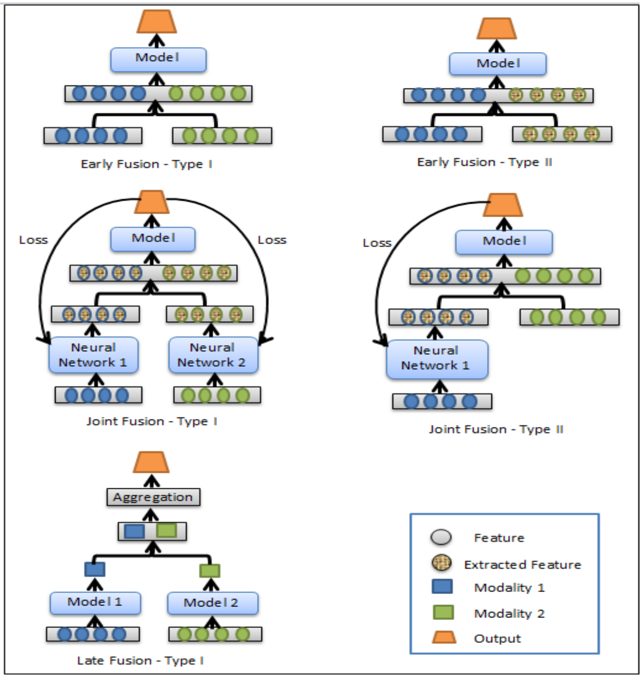

Fig. 8. The types of multimodal fusion.

- Early or Feature-Level Fusion: often referred to as feature-level fusion, it is the task of combining the input of different modalities into a single feature vector before it is presented into a single learning model. There are several techniques to combine input modalities, such as concatenation, pooling, or using a gated unit. Early fusion type I involves combining the original features, whereas type II involves merging extracted features or learned representations from another neural network. The anticipated probabilities are considered as extracted features, making the fusion of features and projected probabilities from several modalities another early type II fusion [107]. Feature-level fusion produced the most effective results for unimodal fusion and reduced processing time [108].

- Joint Fusion or Intermediate Fusion: The technique of combining learned representations of features from the in-between layers of NN with features from other modalities as input to an eventual model is known as joint fusion. The crucial distinction from early fusion is that during training, the loss is returned to the NN for feature extraction. This improves the representation of features for each training iteration. Neural networks are used in joint fusion because they pass on the loss from the prediction model to the feature extraction model. This joint fusion is type I, when feature representations from all modalities are extracted. The feature extraction stage does not always need to be classified as joint fusion for all input features.

- Late or Decision-Level Fusion: Late fusion, often referred to as decision-level fusion, is the task of using predictions from various models to arrive at a final decision. The final decision is typically achieved by using an aggregation function to combine the predictions of various models. Normally, diverse modalities are employed to train individual models. Averaging, weighted voting, majority voting, or a meta-classifier based on each model's predictions are several examples of aggregation functions. Based on the application and input modalities, the aggregation function is typically chosen empirically [107]. This method has the benefit of allowing each modality to learn its features using the best classifier for that modality [108].

VIII. Future Direction

Based on this review, we summarize some of the significant issues in this field that need to be addressed. In addition, we believe there is significant room for further improvement in fake news detection techniques. These issues are as follows:

1) Due to the use of either small or imbalanced datasets, detection models still suffer from significant challenges including underfitting, overfitting, and poor classification that degrade their performance.

2) Image-based features have not been widely used by previous studies in detecting fake news despite their highly critical effect.

3) Despite the vast use of vanilla GANs to generate new samples, they still suffer from some crucial issues, including vanishing gradients, mode collapse, and failure to converge.

4) Although pre-trained word embedding models are efficient at extracting features, they are not able to fully exploit the text's semantic and structural features.

5) Several machine-learning methods have been used to detect fake news. However, lower detection accuracy was provided.

6) The real significance of many modalities cannot be determined by simply concatenating the features. The unique features of each method (text and image) must be preserved while integrating relevant information between the different methods.

IX. Conclusion

This review article presents an overview of fake news, its types, and its consequences. The role of social media platforms in spreading fake news was also discussed. In addition, the most significant factors affecting fake news detection models were highlighted. Among these factors are the dataset, features, and supervised learning classifiers. The critical limitations that still need to be addressed were revealed by reviewing the most promising methods and techniques. These methods provided encouraging results in several areas that can be employed in fake news detection models. Moreover, these techniques were investigated and some of the challenges faced by them were described. This would allow future researchers to improve them and raise fake news detection accuracy.

A Dynamic Intrusion Detection System Capable of Detecting Unknown Attacks

Na Xing, Shuai Zhao, Yuehai Wang, Keqing Ning, Xiufeng Liu
School of Information Science and Technology, North China University of Technology, Beijing, China

Abstract*—In recent years, deep learning-based network intrusion detection systems (IDS) have shown impressive results in detecting attacks. However, most existing IDS can only recognize known attacks that were included in their training data. When faced with unknown attacks, these systems are often unable to take appropriate actions and incorrectly classify them into known categories, leading to reduced detection performance. Furthermore, as the number and types of network attacks continue to increase, it becomes challenging for these IDS to update their model parameters promptly and adapt to new attack scenarios. To address these issues, this paper introduces a dynamic intrusion detection system, Dynamic Unknown Attack Intrusion Detection System (DUA-IDS). This system aims to learn and detect unknown attacks effectively. DUA-IDS comprises three components: Feature Extractor: This component employs CNN and Transformer models to extract data features from various perspectives. Threshold-Based Classifier: The second part utilizes the nearest mean rule of samples to classify known and unknown attacks, enabling the distinction between them. Dynamic Learning Module: The third part incorporates data playback and knowledge distillation techniques to retain existing category knowledge while continuously learning new attack categories. To assess the effectiveness of DUA-IDS, this paper conducted experiments using the UNSW-NB15 public dataset. The experimental results show that DUA-IDS improves the classification accuracy of flow network data with unknown traffic attacks. Can accurately distinguish unknown traffic and correctly classify known traffic. When dynamically learning unknown traffic, the classification accuracy of previously learned known traffic is less affected. This indicates the advantages of DUA-IDS in detecting unknown attacks and learning new attack categories.

***Keywords*—Intrusion detection systems; transformer; DUA-IDS；data playback; variable perspectives features; Knowledge distillation**

I. Introduction

With the increasing prevalence of interconnected devices, the issue of network security has gained significant prominence. Malicious network intrusions or attacks pose a threat to the fundamental elements of computer security policies, namely confidentiality, integrity, and availability. Hackers and cybercriminals continuously innovate their attack methods to steal data, gain control over host computers, and extort money. In order to combat these threats, Intrusion Detection Systems (IDS) have emerged as a major research focus in the field of network security. An IDS serves as a vital component of computer network security. Its primary function is to monitor network traffic for malicious activities, such as distributed denial of service attacks and injection attacks, and respond appropriately to intrusions. When an IDS detects a network attack on a computer, it promptly alerts the security administrator, enabling them to take necessary measures to mitigate the threat.

One of the main challenges in network intrusion detection systems is the ability to detect and recognize unknown events, including risks like zero-day attacks and low-frequency attacks such as worm attacks. Additionally, relying on administrators to manually detect, identify, and address network security issues is both inefficient and time-consuming. The limitations of the signature-based detection method further exacerbate the problem, as it cannot handle unknown threats and requires frequent updates to the signature database. Consequently, the optimal solution lies in equipping machines with the capability to analyze network data and identify suspicious or abnormal behavior.

This paper aims at the two problems mentioned above: detecting unknown events and frequently updating feature database manually. A dynamic intrusion detection system which can detect unknown attacks is proposed.

The rest of this paper is organized as follows: In the Section II, the related work is briefly reviewed. Section III introduces the network model and related algorithms. Section IV introduces the data set used in the laboratory. In the Section V, the experimental setup and results are clarified, and the simulation results are discussed. Finally, conclusions are drawn in Section VI.

II. Related Work

In the early days, IDS algorithms primarily relied on traditional machine learning methods like decision trees, support vector machines, genetic algorithms, and logistic regression. These approaches classified or clustered based on known attack characteristics. For instance, Senthilnayaki et al. [1] introduced an IDS method using the CART decision tree, which enhanced detection accuracy. Wang et al. [2] proposed a feature selection model based on sparse logistic regression, effectively identifying attack data. In recent years, researchers have combined deep learning algorithms with IDS due to their advancements. For example, Xiao et al. [3] developed a CNN-IDS using a convolutional neural network (CNN) that reduced input data dimensions through principal component analysis. The data was then transformed into a grayscale image and fed into the CNN for classification learning. Yan et al. [4] constructed a CNN-based IDS and employed it to generate synthetic attack trajectories against the network. Wang Y et al. [5] proposed a CNN-based network threat detection model that avoided feature selection and manual extraction. They directly converted original traffic data into two-dimensional image data and employed CNN for detection and classification. Yang et al. [6] utilized long-term and short-term memory networks (LSTM) to extract time series characteristics from network traffic, employing an attention mechanism to capture data dependencies. Hassan et al. [7] designed a CNN and LSTM-based model (WDLSTM) with reduced weight. CNN was used for extracting local features, while WDLSTM preserved the time series features and prevented overfitting. HO et al. [8] transformed data streams into RGB images and classified them using a Vision-Transformer model. Yang et al. [9] proposed an improved ViT model, enhancing the local feature modeling capability by incorporating a sliding window mechanism. Wang W et al. [10] presented a robust unsupervised IDS (RUIDS) by introducing a mask context reconstruction module into the self-supervised learning based on Transformers. This approach maintained detection accuracy and improved the model's robustness.

Most IDS algorithms are trained using static datasets, meaning they can only recognize known attacks that were present in the training set. However, when faced with new and unknown attack methods, these models struggle to effectively classify and detect them. To address this issue, researchers have proposed various methods to identify unknown attacks. For instance, Cruz S et al. [11] utilized W-SVM to detect unknown attacks and evaluated their approach using the KDDCUP'99 dataset. Henrydoss et al. [12] introduced an open-set IDS method based on EVM, which achieved higher accuracy compared to W-SVM. Chen et al. [13] proposed a hierarchical detection model based on conditional variational self-coding. Their model learned the classification function for known attacks and the identification function for unknown attacks separately, resulting in good performance. Li et al. [14] developed a network intrusion generation countermeasure network called IDS-GAN. This approach involved scoring the output of normal network data using a discriminator to establish a normal interval. Any data falling outside of this interval was considered an unknown attack. These advancements aim to enhance the ability of IDS algorithms to detect and classify unknown attacks, thus improving their overall performance.

In practical applications, acquiring comprehensive datasets that encompass all types of intrusion detection poses a significant challenge. The collection of network attack types cannot be accomplished at once, as new attack methods continually emerge over time. Confronted with an increasing number of new and unknown attacks, simply categorizing them as unknown attacks can negatively impact the model's detection accuracy. However, retraining a model after merging new data with the original dataset is often impractical. To address this issue, class incremental learning has been proposed [15, 16]. This approach enables dynamic learning and allows for the updating of model parameters based on input from new classes. Li ZZ et al. [15] introduced the LwF model, which mitigates forgetting of previous knowledge by adding a constrained regularization term to the loss function of new tasks. This knowledge distillation technique freezes network layers and aids in retaining old knowledge. Rebeffisa et al. [16] proposed the iCaRL model, which addresses catastrophic forgetting by preserving representative old data and training it alongside new data. Zhang et al. [17] combined the K nearest neighbor clustering algorithm with the nearest class mean classifier to design an intrusion detection system called OCN, which supports class incremental learning. Wu et al. [18] proposed a method for intrusion detection based on dynamic integrated incremental learning (DEIL-RVM), which facilitates a dynamically adjusted integrated intrusion detection model. Zhang et al. [19] developed an incremental intrusion detection algorithm that utilizes an asymmetric multi-feature fusion self-encoder (AMAE) and a classification depth neural network (C-DNN). The confidence of the AMAE result is used to select the final result from the C-DNN output. This approach not only retains the ability to classify old data but also improves the detection accuracy for new categories.

However, the existing methods face limitations in simultaneously detecting unknown attacks and dynamically adding new attack categories. To address these challenges, this paper introduces a novel algorithm called DUA-IDS, which aims to enhance the classification of both old and new attack categories while improving the detection of unknown attacks. The main contributions of this paper are as follows:

1) This paper proposes a feature extraction module that combines a Transformer encoder [20] and a convolutional neural network (CNN). By leveraging the Transformer encoder, this module extracts time series and global features from the training data. The CNN network is employed to extract local features. The integration of these multi-angle features using a self-attention mechanism improves the model's classification capabilities for both new and old data categories.

2) A threshold-based classifier is introduced in this paper. During the training stage, the classifier calculates the threshold for the nearest mean classifier. In the testing stage, if the distance between the test data and the nearest class exceeds the threshold range, it is classified as unknown data. This approach enhances the model's ability to detect unknown data more effectively.

3) This paper presents a dynamic learning method to mitigate the problem of forgetting old data categories. The proposed method utilizes data playback and knowledge distillation techniques, along with the introduction of a spatial distillation loss function. This approach enhances the model's scalability and ability to retain knowledge about previously encountered attack categories.

III. Method

A. System Overview

To enhance the detection accuracy of new attacks, particularly unknown attacks encountered in real scenarios, and to dynamically update model parameters as the number of unknown attacks increases, this paper introduces a novel algorithm called DUA-IDS. The algorithm transforms unknown classes into known classes, thus improving the model's overall performance. The following modules have been designed:

1) Feature extraction module: This module utilizes both a Transformer encoder and a CNN to extract time series information, global information, and local information from traffic data. The extracted multi-angle features are then fused using a self-attention mechanism, thereby improving the model's classification accuracy.

2) Unknown data detection module: This module employs a threshold-based classifier. By calculating the threshold of the nearest mean classifier, the module can determine the distance between the test data and the nearest class. If the distance falls within the threshold range, the data is classified as a known class and further categorized accordingly. Conversely, if the distance exceeds the threshold range, the data is classified as an unknown class.

3) Model dynamic updating module: For the unknown categories identified in the previous module, these categories are marked using other data cleaning algorithms. Based on the principles of data playback and knowledge distillation, the model continuously learns the unknown categories while retaining the detection accuracy for old categories.

These modules collectively contribute to the DUA-IDS algorithm, enabling improved detection accuracy for emerging new attacks and facilitating the dynamic update of model parameters in response to the increasing number of unknown attacks.

The overall framework of DUA-IDS intrusion detection system is shown in Fig. 1.

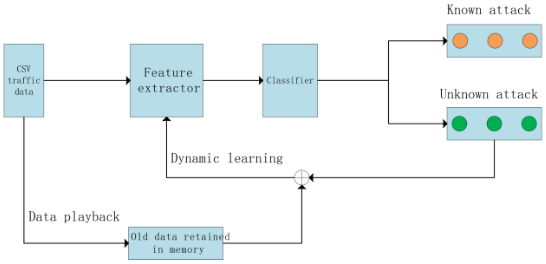

Fig. 1. Overall framework of model.

B. Feature Extraction Module

As shown in Fig. 2, this paper proposes a neural network structure with multi-angle feature fusion. It includes Transformer encoder, CNN and Attention Fusion.

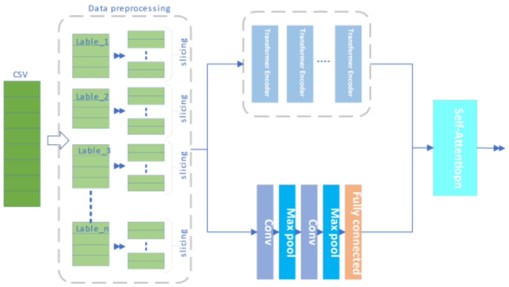

Fig. 2. Feature extractor.

The original Transformer model consists of an encoder and a decoder, but since intrusion detection primarily involves classification, this module only utilizes the encoder component. The encoder is composed of two main sublayers: the Multi-Head Attention mechanism and a fully connected Feed-Forward Network. By incorporating position coding and the self-attention mechanism of the Transformer encoder, it becomes possible to effectively extract global features and time sequence features from each subsequence.

The Multi-Head Attention mechanism serves as the core of the Transformer encoder, enabling the capture of dependencies between data within stream data blocks. This mechanism operates by first linearly transforming the input stream's data block into three vectors: Query, Key, and Value. Next, the attention distribution is computed by comparing the query vector with all the key vectors. Each value vector is then multiplied by its corresponding attention distribution to obtain a weighted value vector. Ultimately, these weighted value vectors are concatenated to form a new feature vector. By utilizing different attention mechanisms, diverse attention representations can be obtained, thereby providing a comprehensive reflection of the information shared among the data within the input data stream block. The calculation formula (1) for the attention mechanism is as follows:

$$\text{Attention}(\boldsymbol{Q},\boldsymbol{K},V)=\text{softmax}(\frac{\boldsymbol{QK}^T}{\sqrt{d_k}})V \tag{1}$$

Where Q, K and V respectively represent three matrices of Query, Key and Value, and dk is the dimension of Key. The calculation formula (2) of multi-head attention is as follows:

$$\begin{cases} Q_i = XW_i^Q, \mathbf{K}_i = XW_i^K, V_i = XW_i^V & i=1,....,n \\ head_i = \text{Attention}(Q_i,\mathbf{K}_i,V_i) & i=1,....n \\ \text{MultiHead}(Q,\mathbf{K},V)=\text{Concat}(head_1,...,head_n)W^o & \end{cases} \tag{2}$$

Where W^Q represents a parameter when Q is calculated for input X, W^K represents a parameter when K is calculated for input X, and W^V represents a parameter when V is calculated for input X.

The CNN component comprises two convolution layers, two maximum pooling layers, and a fully connected layer. The two-dimensional convolution neuron (Conv2D) is primarily employed in the convolution layers for processing. In this study, CNN is predominantly utilized to extract local spatial features from network traffic data.

Subsequently, the attention mechanism is applied to integrate global features, time series features, and local features from multiple perspectives. The feature extraction module enables the consideration of correlations and complementarity among features, thereby enhancing the model's expressive and generalization capabilities.

C. Unknown Data Detection Module

The nearest class mean classifier is a simple and effective classification algorithm that falls under the category of centroid-based classifiers. In this classifier, each class is represented by the mean vector of its training samples, which serves as a prototype for that particular class. During the testing phase, the distance between the test sample and each class prototype is calculated, and the test sample is assigned to the class whose prototype is closest to it.

To be more specific, suppose we have a training set consisting of K classes. Let $\boldsymbol{\mu}_k$ represent the mean vector of class k. The mean vector is obtained by taking the average of all the training samples belonging to that specific class. In order to classify a new test sample $\mathbf{x}$, we compute the distance between $\mathbf{x}$ and each class prototype.

$$d_k = \| \mathbf{x} - \mu_k \| \tag{3}$$

where $|\cdot|$ denotes the Euclidean distance. Finally, the test sample is assigned to the class whose prototype has the smallest distance.

The traditional nearest class mean classifier is limited to classifying known classes only. It determines the class of a test data by calculating the distance between the test data and the centroid of each known class, and assigning it to the class with the closest centroid. Regardless of the actual distance, the test data is always classified into that specific category. This approach poses a problem when encountering unknown categories, as there will always be a known class whose centroid is the closest, even if the actual distance is significantly large. To address this issue, we can enhance the nearest distance calculation. By introducing a threshold on the nearest distance, we can determine whether a test data belongs to an unknown class. If the distance between the test data and the centroid of the nearest class exceeds this threshold, it is classified as an unknown class. The classification calculation method is as follows:

$$\hat{y}_i = \begin{cases} \underset{k\in\{1,\cdots,m\}}{\arg\min}\, d(f(x_i), c_k), & \mathit{if}\ \min d(f(x_i), c_k) < \mathit{threshold}_k \\ m+1, & \mathit{otherwise}. \end{cases} \tag{4}$$

Where $d()$ an example of test data and class centroid is, m is the number of classes, $\mathit{threshold}_k$ is the classifier threshold, c_k is the class centroid of class k and $f(x_i)$ is the result of model output.

In this paper, we utilize a threshold-based classifier, as illustrated in Fig. 3, to identify unknown categories. The threshold for the nearest mean classifier is computed based on the centroids of both known and unknown classes, enabling us to distinguish between them.

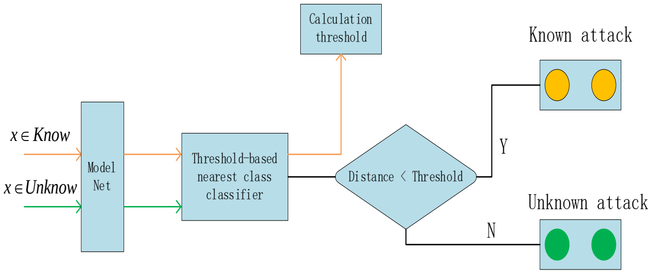

Fig. 3. Process of classifying known categories and unknown categories.

Algorithm1: Calculation threshold

```
Input: Training data x  $x \in know$
Require: Number of each category n  $n = (n_1, n_2, \cdots, n_m)$
Require: Feature extractor $\varphi(x) = model(x)$
FOR $k = \{1, 2, \cdots, m\}$ DO
    $\mu_k = \frac{1}{n_k} \sum_{i=1}^{n_k} \varphi(x_i)$   // Calculate class mean
END FOR
Calculate the minimum distance
   from the center of mass in each category
$Threshold_k = \min_{k=1\cdots m} \| \varphi(x) - \mu_k \|$
$Threshold = \max_{k=1\cdots m} Threshold_k$  // Calculate the classifier
   //threshold
END
```

The threshold calculation algorithm and classification algorithm are shown in algorithm 1 and algorithm 2.

Algorithm 2: Classification algorithm

```
Input: Training data x  $x \in know \& unkonw$
Require: Number of each category n  $n = (n_1, n_2, \cdots, n_m)$
Require: Feature extractor $\varphi(x) = model(x)$
FOR $k = \{1, 2, \cdots, m\}$ DO
    $\mu_k = \frac{1}{n_k} \sum_{i=1}^{n_k} \varphi(x_i)$   // Calculate class mean
END FOR
IF $\min_{k=1\cdots m} \| \varphi(x) - \mu_k \|$ < $Threshold$
    $\hat{y} = \arg\min_{k=1\cdots m} \| \varphi(x) - \mu_k \|$   //Classified as the
        //category closest to the center of mass.
ELSE
    $\hat{y} = m+1$   //unknow attach
END IF
END
```

D. Dynamic Learning Module

When dynamically learning new attack categories, the model often experiences catastrophic forgetting of the known attack categories. The feature extraction module's training objective is to accurately classify the training flow data into a predefined set of categories. However, when a new attack category emerges, the model needs to update its parameters to incorporate the new information. Unfortunately, as the model updates its parameters, it may "over-fit" the new data and forget the previously learned information, resulting in a significant decrease in the detection accuracy of known attack categories. This decline in accuracy occurs because the new data may differ in distribution or feature space from the old data. Consequently, the model might adjust its parameters in a way that sacrifices the performance of old data while improving the performance on the new data. To address this challenge, this paper employs a method based on data playback and knowledge distillation to reinforce the learning of known attack categories.

1) Data playback: Once each task is learned, the data playback method saves a subset of samples from each category for future model training, as depicted in Fig. 4. These saved samples, comprising known attack categories, are combined with the data of new attack categories to update the parameters of the current feature extraction module. In this paper, a sample saving strategy is employed. The total number of saved samples is fixed at K, and the number of samples saved in each category is n=K/m, where m represents the number of currently known attack categories. This approach ensures that the available storage of K samples is utilized efficiently.

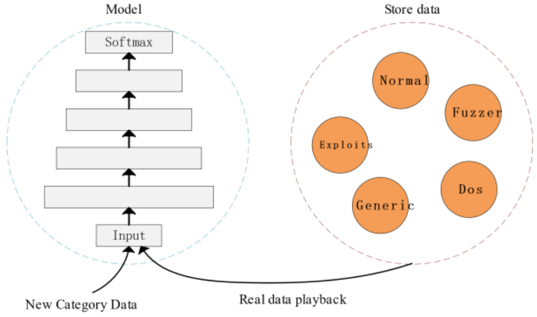

Fig. 4. Class incremental dynamic learning.

Furthermore, this paper employs the "Herding" strategy to select n representative samples from each category. The strategy operates in iterations to choose N samples. In each iteration, a sample is selected from the current training set and included in the saved sample set. This approach aims to ensure that the average feature vector of the saved feature space for known samples closely aligns with the average feature vectors of all training samples. Consequently, the saved set of known samples functions as a priority queue, with the sample order indicating their significance. The specific process of saving the sample set using the "Herding" strategy is outlined in Algorithm 3.

Algorithm 3: Sample preservation based on Herding strategy

```
Input: Training sample set $X=\{x_1,\cdots,x_m\}$ belonging to category y
Require: Number of samples stored in each category n
Require: Feature extractor $\varphi(x)=model(x)$
Initialize: $\mu=\frac{1}{m}\sum_{x\in X}\varphi(x)$
FOR $k=\{1,2,\cdots,n\}$ DO
    $p_k=\underset{x\in X}{\operatorname{argmin}}\|\mu-\frac{1}{k}[\varphi(x)+\sum_{j=1}^{k-1}\varphi(p_j)]\|$
END FOR
$M^y\leftarrow(p_1,p_2,\cdots,p_n)$
```

2) Knowledge distillation: When learning a new model, the knowledge distillation method requires that the output of the new model aligns with the given data in a consistent manner with the old model. The old model refers to the model that learned the previous task (known attack category) and remains unchanged. The new model inherits the parameters of the old model and can be updated for new tasks. During the training process, the new model is optimized to minimize two loss functions: (i) The standard cross entropy loss between the predictions of the new model and the actual labels, and (ii) Distillation loss, which measures the disparity between the predictions of the new model and the soft targets generated by the old model.

The traditional distillation loss primarily focuses on the distillation output of the final feature layer of both the old and new models. However, this paper delves into the distillation calculation of the output from the middle layer of the feature extraction model. By combining the output of the final feature layer with each layer's output, the new model can effectively absorb the knowledge of the old model and mitigate the problem of catastrophic forgetting for known attack categories.

Representation of distillation loss of final characteristic layer:

$$L_{\text{end}}(\mathbf{h}^{t-1},\mathbf{h}^{t})=\left\|\mathbf{h}^{t-1}-\mathbf{h}^{t}\right\|^2 \tag{5}$$

Where h^{t-1} represents the final feature layer output of the old model and h^t represents the final feature layer output of the new model being trained.

Aiming at the feature extraction module in this paper, the data shape after preprocessing the traffic data is as follows: (bitch_size, series, feature_size), abbreviation (B， S， F), For the output of the middle layer of the feature extraction module, the distillation loss is calculated from two dimensions respectively.

Distillation loss in two dimensions.

$$L_{\text{S}}(\mathbf{h}_\ell^{t-1},\mathbf{h}_\ell^{t})=\sum_{f=1}^{F}\left\|\sum_{s=1}^{S}\mathbf{h}_{l,s,f}^{t-1}-\sum_{s=1}^{S}\mathbf{h}_{l,s,f}^{t}\right\|^2 \tag{6}$$

$$L_{\text{F}}(\mathbf{h}_\ell^{t-1},\mathbf{h}_\ell^{t})=\sum_{s=1}^{S}\left\|\sum_{f=1}^{F}\mathbf{h}_{l,s,f}^{t-1}-\sum_{f=1}^{F}\mathbf{h}_{l,s,f}^{t}\right\|^2 \tag{7}$$

$$L_{\text{spatial}}(\mathbf{h}_\ell^{t-1},\mathbf{h}_\ell^{t})=L_{\text{S}}(\mathbf{h}_\ell^{t-1},\mathbf{h}_\ell^{t})+L_{\text{F}}(\mathbf{h}_\ell^{t-1},\mathbf{h}_\ell^{t}) \tag{8}$$

Where h_l^{t-1} represents the characteristic output of the first layer of the old model, h_l^t represents the characteristic output of the first layer of the new model, and S and F represent the intermediate layer loss in the S and F dimensions respectively.

Combining the final characteristic layer output and the intermediate characteristic layer output as the distillation loss of the model.

$$L_{\text{final}}(\mathbf{x}) = \frac{\lambda_c}{L-1}\sum_{\ell=1}^{L-1} L_{\text{spatial}}\left(f_\ell^{t-1}(\mathbf{x}), f_\ell^{t}(\mathbf{x})\right) + \lambda_f L_{\text{end}}\left(f^{t-1}(\mathbf{x}), f^{t}(\mathbf{x})\right) \tag{9}$$

Where the hyperparameter λ_c and λ_f are used to balance the output of the intermediate layer and the output of the final layer, L represents the total number of layers of the feature module, and L-1 is the other intermediate layers except the final layer.

3) Model parameter updating algorithm: Whenever the model acquires new attack data (X_{m+1},...,X_{m+k}) for the new categories (m+1,...,m+k), these data are utilized to update the parameters of the feature extraction module and the cached sample set. Algorithm 4 outlines the steps involved in updating the feature extraction module parameters.

Algorithm 4: Class incremental learning algorithm

```
Input: New category data $X = \{x_{m+1}, \cdots, x_{m+k}\}$
Require: Old data cached in memory $P = \{P_1, \cdots, P_m\}$
Initialize: Training data $X_{train} = X \bigcup P$
FOR $index, x, label$ in $X_{train}$ DO
    Save the output of the middle layer of the feature extractor network. $q[index] = \varphi(x)$
END FOR
Train model one epoch:
FOR $x, y$ in $X_{train}$ DO
    $\hat{y} = \varphi(x)$
    $Loss = Loss_{ce} + Loss_{final}$
    Update parameters
END FOR
END
```

First, the cached data of known attack categories and the input data of new attack categories are combined into a new training dataset. Next, the output results of each layer of the old feature extraction module for the known attack categories are stored. Finally, the parameters of the feature extraction module are updated using the loss function, which is a weighted sum of the classification cross entropy loss and the hierarchical distillation loss.

IV. Dataset Description

A. UNSW-NB15

The dataset used in this paper is the UNSW-NB15[21-26], which is a comprehensive dataset designed by the Australian Cyber Security Center Laboratory in 2015 for network intrusion detection systems. The dataset aims to simulate real attack environments using the IXIA traffic generator, based on vulnerability information technology published on the CVE website. It consists of normal traffic and various types of attack traffic, including Fuzzers, Analysis, Backdoors, DoS, Exploits, Generic, Reconnaissance, Shellcode, and Worms.

The dataset comprises 49 features and 10 labels. These features include basic information such as source IP address, destination IP address, and protocol type, content-related features like HTTP method and URI length, time-related features such as connection duration and average byte rate, as well as other features such as service type and status code. The dataset is available in three versions: full version, training version, and test version. For this experiment, we utilize the full version of the CSV data, which contains 2,540,044 data samples.

Considering the significant imbalance in the number of normal samples compared to other samples, random sampling is applied to reduce the impact of this data imbalance on the classification results. Known classes include common attack types like DOS, Generic, Exploits, and Fuzzers, while the remaining classes are treated as unknown classes. Detailed data can be found in Table I.

TABLE I. NUMBER OF CATEGORIES IN THE UNSW-NB15 DATASET

Categories	Data Size
Normal	200000
Fuzzers	24240
Dos	16350
Exploits	44520
Generic	215480
Backdoor	2320
Analysis	2670
Reconnaissance	13980
ShellCode	1510
Worms	170

V. Experiment

A. Experimental Environment

Experimental configuration: Ubuntu as the operating system, Intel Xeon Gold 5118 as the processor, 32GB of memory, NVIDIA GeForce RTX 3090 as the GPU, Python3.8 as the programming language and Pytorch 1.11.0 as the learning framework.

B. Evaluation Indexes

This experiment is a classification model, using a confusion matrix to evaluate the classification structure. The confusion matrix is shown in Table II.

TABLE II. THE CONFUSION MATRIX

The real situation	Prediction result	
	Positive	***Negative***
True	TP	FN
False	FP	TN

The evaluation indexes used in the experiment mainly include Accuracy, Precision, Recall and F1-score.

Accuracy refers to the proportion of the number of samples that can be correctly classified by the model in the total samples.

$$Acuracy = \frac{TP+TN}{TP+FN+FP+TN} \tag{10}$$

Precision represents the ratio of the number of correctly classified samples to the number of samples retrieved.

$$Precision = \frac{TP}{TP + FP} \quad (11)$$

Recall is the ratio of the number of correctly classified samples to the number of correctly classified samples.

$$Recall = \frac{TP}{TP + FN} \quad (12)$$

F1-score refers to the harmonic mean of Precision and Recall.

$$F1 - score = \frac{2 * P * R}{P + R} \quad (13)$$

C. Results and Discussion

1) Hyperparameter setting: Through many experiments, the values of parameters are adjusted to achieve the best experimental results. In the process of adjustment, the super parameters of the best experimental results are obtained, as shown in Table III.

TABLE III. MODEL HYPERPARAMETER

Hyperparameter	**Value**
Epochs	50
Learning rate	1e-5
Time series	10
Bitch size	10
Number of headers	8
Number of layers	3
Embding size	768
K	2000

2) Experimental analysis of known attack detection: To evaluate the detection performance of DUA-IDS on both known categories and unknown attacks, we have selected several advanced intrusion detection methods as baselines.

a) Methods for detecting unknown attacks:

i) EVM [12]: Extreme Value Machine (EVM) is a classifier that detects unknown attack categories using non-nuclear, nonlinear, and variable bandwidth outlier detection.

ii) IDS-GAN [14]: IDS-GAN defines the normal interval based on the scoring of normal network data by the discriminator. Any data outside this interval is considered an unknown attack.

b) Methods unable to detect unknown attacks:

i) CNN-BiLSTM [27]: This model combines CNN, BiLSTM, and self-encoder to extract high-dimensional traffic features and self-monitoring features, aiming to improve the classification accuracy.

ii) CNN-WDLSTM [26]: CNN-WDLSTM adopts a combination of CNN and LSTM (WDLSTM) with reduced weight. CNN is used to extract local features, while WDLSTM preserves time series features and prevents overfitting, thus enhancing the classification accuracy.

iii) RUIDS [10]: RUIDS is a robust unsupervised intrusion detection system and one of the most advanced closed-set intrusion detection algorithms. It incorporates a shielded context reconstruction module into the self-supervised learning scheme based on the transformer. The self-supervised learning scheme captures internal relationships within the learning context.

Fig. 5 illustrates the loss function of these six groups of models during the training process on known classes using the UNSW-NB15 dataset. The figure demonstrates that all six models exhibit good convergence on the training dataset, yielding optimal parameters. Subsequent experiments will evaluate the model's performance on the test set using these optimal parameters.

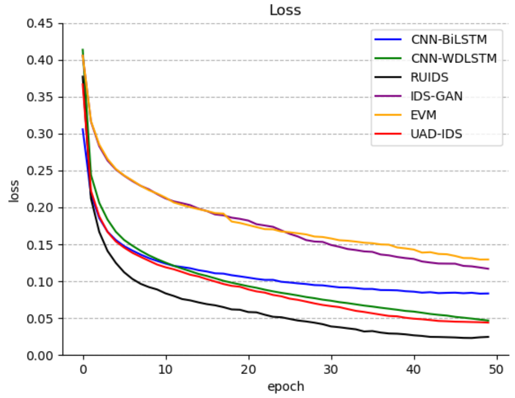

Fig. 5. The loss vs. epoch under different model.

Table IV presents the intrusion detection results of the model proposed in this paper on the test set of the UNSW-NB15 dataset. It compares the classification accuracy of our model with other models of different types on known attack categories. From the data in the table, it is evident that the classification accuracy of intrusion detection algorithms capable of detecting unknown categories in the past is not as high as those based on closed sets (where unknown categories cannot be detected). To enable the detection of unknown categories, our model adopts a non-optimal classification strategy. Consequently, its classification accuracy on known categories is slightly lower than that of closed-set detection models.

TABLE IV. EXPERIMENTAL RESULTS OF THE MODEL ON KNOWN CATEGORIES IN THE UNSW-NB15 DATASET

	UNSW-NB15		
	Acc	**F1**	**Pre**
EVM	0.841	0.8379	0.8345
IDS-GAN	0.8582	0.8627	0.8442
CNN-BiLSTM	0.8689	0.865	0.8582
CNN-WDLSTM	0.8786	0.8725	0.8688
RUIDS	0.891	0.8908	0.8871
DUA-IDS	0.8847	0.8854	0.8794

Compared with other models, EVM adopts the traditional method to classify network flow data based on outliers. In binary classification, it may have better classification accuracy. For multi-classification tasks, the accuracy of multi-classification is weaker than other models.

DUA-IDS is superior to IDS-GAN in the utilization of time series features. DUA-IDS obtains more comprehensive characteristics of network stream data.

Compared with CNN-BiLSTM and CNN-WDLSTM, the Transformer proposed in this paper combines CNN's feature extractor to analyze the time, global and local features of data.

However, the classification accuracy of the model proposed in this paper surpasses that of most closed-set-based intrusion detection algorithms. It is only 0.63% lower than the most advanced closed-set algorithm, RUIDS. This demonstrates the model's strong advantages in feature extraction and classification.

3) Experimental analysis of unknown attack detection: In real-world scenarios, there may be attack categories that are unseen and do not belong to our known training set. To address this, we employ a nearest class mean classifier with a threshold to identify unknown attack categories in this paper. To evaluate the performance of the proposed model in detecting unknown attack categories, we compare DUA-IDS with both closed-set-based intrusion detection models and models capable of detecting unknown categories. The experimental results are depicted in Fig. 6.

	n=0	n=1	n=2	n=3	n=4	n=5
CNN-BiLSTM	0.8689	0.8492	0.8276	0.7305	0.7213	0.7203
CNN-WDLSTM	0.8786	0.8587	0.8369	0.7386	0.7294	0.7284
RUIDS	0.8910	0.8708	0.8487	0.7491	0.7397	0.7386
DUA-IDS	0.8847	0.8840	0.8835	0.8750	0.8810	0.8790

(a)

	n=0	n=1	n=2	n=3	n=4	n=5
EVM	0.841	0.838	0.84	0.83	0.832	0.831
IDS-GAN	0.8582	0.852	0.855	0.845	0.846	0.845
DUA-IDS	0.8847	0.884	0.8835	0.875	0.881	0.879

(b)

Fig. 6. (a). Comparison with the algorithm based on closed-set, (b). Comparison of models for detecting the accuracy of unknown categories.

In this paper, we systematically introduce unknown categories into the test dataset one by one, following the order specified in Table II. The number of added unknown categories is represented as "n=1" in Fig. 6. As depicted in Fig. 6(a), it is evident that our proposed DUA-IDS outperforms the closed-set-based intrusion detection model as the number of unknown attack categories increases. The closed-set model can only recognize data from known categories, and when confronted with new categories, it mistakenly classifies them into known categories, resulting in a continuous decline in classification accuracy. This demonstrates the necessity for intrusion detection models to possess the ability to detect unknown classes.

Fig. 6(b) illustrates the classification accuracy of DUA-IDS and other comparison models, which tends to stabilize as the number of unknown attack categories increases. These models effectively identify most unknown attacks as unknown classes, thereby maintaining high classification accuracy. Notably, the proposed DUA-IDS consistently outperforms the comparison model in classification accuracy, highlighting its superior capability in detecting unknown attack categories.

4) Experimental analysis of dynamic class increment: To evaluate the detection performance of DUA-IDS on both original and new categories after updating the model parameters with the addition of new categories, we compare it with the OCN [17] model in this paper.

OCN: The OCN model combines the concepts of nearest class classifier and K nearest neighbor clustering. It directly incorporates the clustering results into the classifier's category list, enabling incremental learning of categories.

Fig. 7 illustrates the changes in classification accuracy for both DUA-IDS and OCN models when new categories are added. We incrementally introduce one new category at a time, denoted as "n=1" in the figure. As depicted in the figure, as the number of new categories increases, the classification accuracy of both models decreases. However, the proposed DUA-IDS in this paper exhibits a slight decrease in accuracy when new categories are added, while the OCN model experiences a noticeable decline. This indicates that the DUA-IDS model proposed in this paper possesses significant advantages in dynamically updating the model.

	n=0	n=1	n=2	n=3	n=4	n=5
OCN	0.866	0.852	0.843	0.825	0.827	0.8265
DUA-IDS	0.8847	0.88	0.878	0.87	0.868	0.8675

Fig. 7. Comparison of dynamic learning models.

5) Ablation experiment: In the DUA-IDS proposed in this paper, we have incorporated two key elements: a feature extraction module based on transformer and spatial distillation. To further investigate their effectiveness, we conducted ablation experiments focusing on these two aspects.

a) CNN-DUA-IDS: To evaluate the impact of the feature extraction module based on transformer designed in this paper, we conducted a control experiment by replacing it with a simple CNN module. As illustrated in Fig. 8, the utilization of the CNN module resulted in a decrease in overall model accuracy. This clearly demonstrates the significant role played by the transformer-based feature extraction module in enhancing the classification accuracy of the model.

	n=0	n=1	n=2	n=3	n=4	n=5
CNN	0.8527	0.85	0.846	0.84	0.835	0.832
icarl	0.8847	0.872	0.86	0.852	0.843	0.837
DUA-IDS	0.8847	0.88	0.878	0.87	0.868	0.8675

Fig. 8. Comparison of ablation experimental results.

b) icarl-DUA-IDS: To investigate the impact of the introduced spatial distillation loss in this paper, we conducted a control experiment by removing it from the DUA-IDS model. As depicted in Fig. 8, when a new category is added, the classification accuracy of icarl-DUA-IDS noticeably decreases. This observation highlights the substantial contribution of the spatial distillation loss in mitigating the effects of knowledge forgetting.

VI. Conclusion

In the actual network environment, network data is dynamic and will produce new types of unknown network data in real time. The traditional intrusion detection system based on static data can't adapt well to new types of data, which leads to the decrease of classification accuracy. In addition, the increasing number of unknown data also poses a potential threat to the stability of the model.

This paper addresses the challenges of detecting unknown network attacks and dynamically updating models in network intrusion detection. To tackle these issues, a dynamic intrusion detection system capable of detecting unknown attacks is proposed. The model is mainly composed of three parts. Firstly, in the feature extraction module, this paper proposes to combine the multi-angle features of network data by combining Transformer with CNN. Secondly, the nearest class mean classifier based on threshold is used to find the potential unknown attack categories. Thirdly, the unknown class data are updated by class increment method based on data playback and distillation learning. The experimental results show that the method proposed in this paper is effective in detecting unknown data and stable after dynamically learning new types of data.

However, the DUA-IDS model has certain limitations when it comes to handling detected unknown attack categories and incorporating them back into the model. Therefore, additional measures are required to cleanse and label the identified unknown attack data before further learning. Future research efforts will focus on refining the process of handling and relearning unknown data, aiming to achieve automated self-learning in network intrusion detection models.

***Abstract*—Intelligent Transportation System (ITS) is the future of the current transport scheme. It is meant to incorporate an intelligent traffic management operation to offer vehicles more safety and valuable traffic-related information. A review of existing approaches showcases the implementation of varied scattered schemes where analytical operation is mainly emphasized. However, some significant shortcomings are witnessed in efficiently managing complex traffic data. Therefore, the proposed system introduces a novel computational framework with a joint operation toward analytical processing using big data targeting to manage raw and complex traffic data efficiently. As a novel feature, the model introduces a data manager who can manage the complex traffic stream, followed by decentralized traffic management, that can identify and eliminate artefacts using statistical correlation. Finally, predictive modelling is incorporated to offer knowledge discovery with the highest accuracy. The simulation outcome shows that Random Forest excels with 99% accuracy, which is the highest of all existing machine learning approaches, along with the accomplishment of 11.77% reduced overhead, 1.3% of reduced delay, and 67.47% reduced processing time compared to existing machine learning approaches.**

Keywords*—Intelligent transportation system; traffic managemen; machine learning; artifacts; prediction

I. INTRODUCTION

With the proliferation of advancements in network and communication technologies, transportation services have been visioned to incorporate smart features [1]. From this perspective, Intelligent Transportation System (ITS) has evolved in the form of innovative services associated with smart traffic management [2]. The prime agenda of ITS is to offer the user the most valuable information associated with traffic to make the driving experiences safer and well-synchronized [3]. Adoption of ITS is found to offer more reduction of cost owing to the adoption of preemptive preventive measures, minimizes the consumption of resources, and significantly emphasizes accident prevention [4]. Various application of ITS includes smart ports and maritime [5], smart airport [6], smart railways [7], fleet management [8], and smart road [9]. The prime idea of ITS is basically to capture all the essential parameters that connect to road navigation and safety and subject them to specific analytical processing. In contrast, the system's outcome of analytical processing is used to formulate a strategy for effective traffic management [10]. At present, various sets of research are being carried out towards improving the performance of ITS from various perspectives [11]-[15]. However, various scattered challenges are associated with the research-based studies and practical implementation of ITS. The research-based studies on ITS have reported various challenges, e.g., the need for cost-effective analytical processing, faster learning schemes with higher reliability, cost-effective computational modelling, and benchmarked schemes. At the same time, the practical implementation of ITS suffers from different challenges, e.g., constraints of budgets, integration with the conventional scheme, coping with updated standards and technology, rules and traffic regulation of different countries, etc. However, there is no denying that the success factor of an ITS majorly depends upon the accuracy and performance of its analytical capability. At present, the big data approach is the most suitable mechanism to deal with complex data [16]; however, they are in a very nascent stage of development. The various complexities associated with the demanded analytical processing of data in ITS are: i) ITS is characterized by the massive generation of traffic data with higher complexities within it, ii) the point of traffic data generation is multiple, and the rate of transmission is uneven and depends upon various network performance leading to error-prone data, iii) with increasing adoption of artificial intelligence and machine learning, the improvement in the predictive analytical model is significantly less owing to the inclusion of critical size of dynamic constraints. Therefore, the proposed scheme presents a novel computational framework of joint analytical operation using a big data approach to improve ITS knowledge discovery. Unlike any existing approaches reported in the literature, the study contributes toward a novel analytical model capable of extracting knowledge from raw and complex forms of traffic data. Another significant contribution of the proposed scheme is offering quality traffic data by performing a fusion of data and identifying and eliminating artefacts. The scheme implements a novel yet simplified machine learning scheme to optimize the predictive performance of traffic data further. The manuscript's organization is as follows: Section II discusses the existing scheme of analytical operations in ITS and highlights research problems in Section III. Section IV briefs about the research methodology, while an elaborated discussion of system design concerning the algorithm is carried out in Section V. Section VI presents the result and justification of the acquired result in the proposed analysis. At the same time, Section VII makes a conclusive remark about the paper with highlights of novel contributions.

II. Review of Literature

Various work have been carried out to improve the analytical performance of traffic data in ITS. The work by Qi et al. [17] has presented a discussion about the influence of mobility patterns in investigating multiple constraints in traffic management. The study has implemented an ensemble clustering method along with a tensor-based factorization scheme for this purpose. Further adoption of clustering is also witnessed in the work of Huang et al. [18], which emphasizes evaluating the significance of traffic nodes in ITS considering geographic road networks. Liu et al. [19] discuss a unique study model to investigate variability in travel patterns in public transport systems. Analytical modelling is carried out towards quantifying intra-personal variability. Gu et al. [20] have used a deep learning-based approach to predict short-term traffic volume. The study model has used an enhanced Bayesian model integrated with multiple deep learning approaches where correlation analysis is carried out for traffic flow for current and prior time. Chen et al. [21] used the Gated Recurrent Unit (GRU) neural network model to forecast vehicle speed in urban traffic systems. This predictive model facilitates formulating strategies to control traffic and support navigation systems.

All the schemes mentioned above are mainly associated with a single flow of traffic, which are relatively less seen in practical ITS networks. This gap is addressed in the work of Wang et al. [22], where traffic flow estimation is carried out based on trajectories of license plate information embedded with GPS data. The adoption of big data is witnessed in Bakdi et al. [23] work has investigated the possibilities of multiple risk factors associated with ship trials. The study integrated an autonomous identification system with a digital map with a big data approach to realize the spatial and temporal dependencies of various connecting behaviour of vessels. Further adoption of the big data approach is seen in the work of Qin et al. [24], which is meant for tracking routes of vehicles in urban transport systems. The work identifies the vehicle from license plate recognition, while fuzzy logic tracks routes.

It has also been noted that Artificial Intelligence (AI) significantly contributes to the transport system. Besinovic et al. [25] have discussed current insights into railway transport applications using AI. Zhu et al. [26] have presented analytical modelling of traffic data considering transport systems using Hadoop, Spark, and multiple open-source-based software. Predictive analysis is carried out by Long Short-Term Memory (LSTM) and Support Vector Regression (SVR) to investigate various travel-related operations. The work carried out by Gunes et al. [27] has presented an analytical model deployed for the management of traffic lights and scheduling in ITS. The relationship between edge computing and ITS is discussed by Zhou et al. [28], where the study specifies significant challenges in sensing in ITS. The discussion presented by Lucic et al. [29] also stated the usage of Crowdsourcing in ITS. Mirboland and Smarsly [30] developed a novel and simplified information modelling for ITS using a semantic model. Asaithambi et al. [31] have presented a big-data architecture for micro-services for ITS facilitating the processing of both stream and batch of big data. Choosakun et al. [32] have presented insight into cooperative ITS. Yoo et al. [33] have presented an ITS scheme considering sensory data processing using a big data approach based on open-source software. A similar approach is also adopted in the work of Alexakis et al. [34]. Dudek and Kujawski [35] have presented a big data scheme for optimizing route planning and interval of the passage of vehicles considering image features. Table I summarizes the above-mentioned methodologies' effectiveness with respective advantages and limitations. The following section outlines research issues associated with the literature.

TABLE I. Summary of Methodologies Mentioned in Literature

Authors	Method	Advantage	Drawbacks
Qi et al. [17]	Ensemble Clustering, tensor	Simplified evaluation	Highly iterative scheme
Huang et al. [18]	Machine learning, clustering	Effectively identify critical nodes	Induces overhead in increased traffic
Liu et al. [19]	Analytical model	Variability evaluation for travel pattern	Narrowed constraint modelling
Gu et al. [20]	Bayesian, Deep Learning	Higher accuracy	Computationally complex
Chen et al. [21]	Bidirectional GRU	Minimize overfitting, benchmarked	It doesn't deal with user-based data
Wang et al. [22]	Data-driven approach	Supports Multi-fold validation	Dependent on specific data
Bakdi et al. [23]	Autonomous system identification, big data	A practical definition of manifold risk factors	Scope limited to specific forms of traffic
Qin et al. [24]	Big data, fuzzy logic	Satisfactory accuracy	Dependent on rule-sets
Besinovic et al. [25]	Review work	Emergence of AI	Study limited to rail transport
Zhu et al. [26]	LSTM, SVR, open-source software	User-friendly application	No benchmarking
Gunes et al. [27]	Traffic signal management	Offers adaptive control	Applicable only at the intersection
Zhou et al. [28], Lucic et al. [29], choosakun et al. [32]	Review on edge computing, Crowdsourcing, cooperation in ITS	Elaborated discussion	-N/A-
Mirboland & Smarsly [30]	Information model, semantic	A simplified and effective model	No benchmarking
Asaithambi et al. [31]	Big data, stream/batch processing	Improved predictability	No benchmarking
Yoo et al. [33], Alexakis et al. [34]	Open-source Software	Simplified implementation	Cannot reach scalability
Dudek & Kujawski [35]	Image, big data, thresholding	Optimized route planning	Applicable to image data only

III. Research Problem

Existing approaches towards improving analytical operations in ITS reviewed in prior sections offer some of the essential mechanisms; however, some of the shortcomings of the existing schemes are as noted below:

- Non-Inclusion of Complex Traffic Data: Most existing approaches [20]-[35] have considered highly structured and detailed datasets publicly available. However, the practical implementation of multiple devices in traffic monitoring of ITS results in complex traffic data, which are difficult to analyze and occupy a more significant segment of storage units. Existing studies do not address such issues, which are the preliminary steps of any analytical operation in ITS.

- Non-Inclusion of Big Data Characteristics: A larger-sized data with streamed data, including possible artefacts, and less value added is not emphasized for the existing big data-based approach. Some existing approaches have used open-source tools, e.g., Hadoop, to address this, but such software requires more reengineering and is also associated with various reported pitfalls [26].

- Lack of Storage Utilization Aspects: In most existing studies, the traffic data is first subjected to storage, and the claimed analytical algorithms are subjected to them in the same place to acquire knowledge [26][30]. The outcomes are stored in multiple storage containers in this process. Unfortunately, such a process over-utilizes the storage space, adversely affecting the query processing and leading to higher delay.

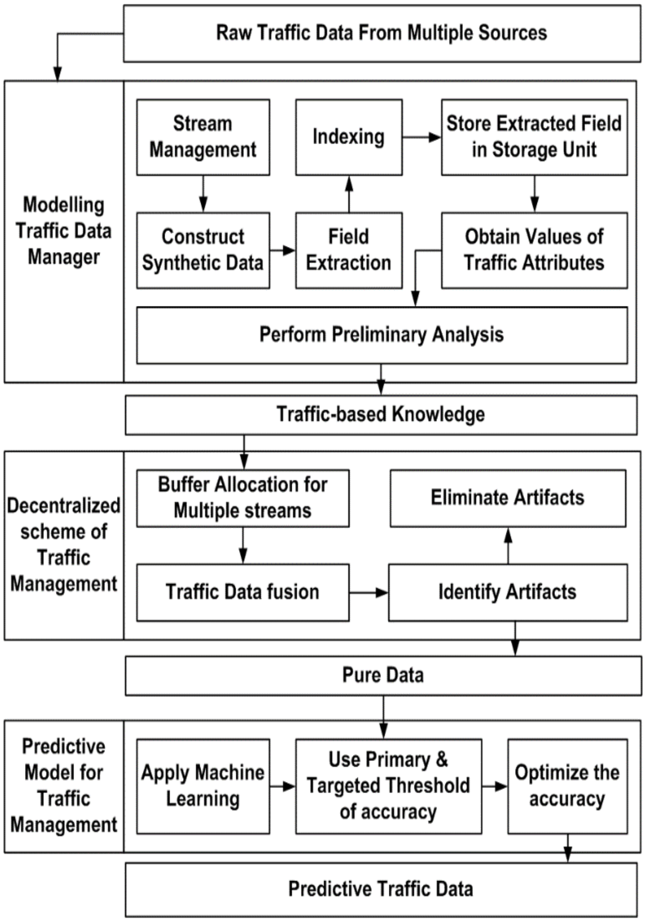
- Adoption of Learning Approaches: There is no denying the fact that machine learning and deep learning significantly contribute to predictive traffic data analysis [21][26]. However, most schemes adopt a complex learning strategy to acquire higher accuracy. Such accomplishment of accuracy is claimed at the cost of highly iterative training operation where higher accuracy is proportional to higher availability of trained error-free data. Confirming error-free data in distributed traffic networks with heterogeneous sensing devices is a computationally challenging task that is not reported to be addressed.

- Lack of Consideration of Model Cost: A model for ITS is required to respond faster, which entirely depends upon a more brilliant construction of its logical condition and lesser usage of traffic attributes with more meaningful insights. This demands a novel and benchmarked strategy implementation towards the knowledge discovery process, considering the decentralized environment of ITS. Very few models are yet reported to accomplish this objective.

All the research problems mentioned above are identified to have concrete solutions; hence, the proposed scheme deploys a novel strategy to address these open-end research problems in ITS. The following section summarizes the methodology adopted to evolve a novel ITS management solution.

IV. Research Methodology

The prime goal of the proposed research work is to introduce a unique knowledge discovery method using a novel big data approach in ITS. The core ideology constructed in the proposed scheme is to acquire a raw form of complex traffic data from multiple sources, followed by performing a decentralized scheme of analyzing the traffic data by uniquely transforming them. The implementation of the proposed scheme is carried out in analytical research methodology, and its architecture is presented in Fig. 1 as follows:



Raw Traffic Data From Multiple Sources
Modelling Traffic Data Manager
Stream Management
Indexing
Store Extracted Field in Storage Unit
Construct Synthetic Data
Field Extraction
Obtain Values of Traffic Attributes
Perform Preliminary Analysis
Traffic-based Knowledge
Decentralized scheme of Traffic Management
Buffer Allocation for Multiple streams
Eliminate Artifacts
Traffic Data fusion
Identify Artifacts
Pure Data
Predictive Model for Traffic Management
Apply Machine Learning
Use Primary & Targeted Threshold of accuracy
Optimize the accuracy
Predictive Traffic Data

Fig. 1. Proposed architecture.

The reasons for adopting the above-mentioned architecture to address the identified problems are manifold.

- A closer look into the research problems showcases that analytical studies towards ITS don’t offer emphasis to address the issues of essential big data characteristics and storage management. Both are considered as two different sets of issues. However, the proposed study introduces a mechanism where both issues are handled simultaneously, exhibiting the cost-effective operational features towards ITS.

- It was also noted that existing analytical approaches demands complex usage of mining or knowledge discovery process overlooking the implementation cost involved in it. However, the proposed architecture offers a single-window operation where indexing, transformation, and progressive knowledge discovery processes are carried out on the same platform. This reduces the dependency on including heavy-weighted analytical algorithms for processing and analyzing large-scale ITS data.

- From the perspective of model cost, it is observed that existing schemes take the input of the complete stream, process the queue, store the raw data in a cloud storage unit and then perform analytical operations. This consumes a lot of processing time and demands the involvement of various resources. At the same time, the proposed architecture can process the stream of ITS data while it stores a part of the data in the cloud and part of the data in a temporary buffer, which reduces the load of processing and storing significantly. Owing to this phenomenon, the filled-up queue can be emptied soon, and the network can process more incoming data. Hence, the proposed architecture offers a practical solution for processing and analyzing extensive ITS data even in peak traffic conditions.

The prime limitation of existing distributed data storage and analytical architecture is that it cannot jointly address the identified research problem. Apart from this, no existing architecture can optimize the spontaneous storage saturation issues in storage units or offer a faster, more progressive, and less iterative knowledge discovery process for evolving ITS data. The architecture exhibited in Fig. 1 offers three explicit blocks of operation toward knowledge discovery of traffic data in ITS. Considering the input of raw traffic data, the first block of operation performs stream management where a series of transformations is carried out over programmatically formulated synthetic data to acquire preliminary traffic-based knowledge finally. The outcome of the first operational block is further subjected to traffic data fusion over a buffer allocated for multiple streams. This operation assists in identifying possible forms of artefacts present in traffic data, eliminating them, and generating pure data. A statistical correlation-based mechanism is adapted to generate the possible value with the highest correlation, followed by substituting the artefact with statistically computed data. The third operational block is finally responsible for retaining the computed data's highest reliability and trustworthiness. A machine learning scheme is applied for this purpose which uses primary and targeted thresholds to assess the genuineness of the accuracy obtained in the outcome of prior block operation. The outcome of this model offers predictive traffic data, a knowledge discovery considered value-added analytical information. The block operation is elaborated and illustrated in the next section.

V. System Design

The proposed scheme's prime idea is to apply a novel analytical operation to offer a value-added ITS performance. An explicit system design using a big data approach has been developed, considering a typical use case for managing and analyzing ITS traffic information streams. The core motive is to develop a simplified and lightweight analytical framework for efficient knowledge discovery of complex forms of traffic data. The description of the proposed system design implemented for the proposed scheme follows.

A. *Modelling Traffic Data Manager*

This is the first module of implementation of the proposed system, which targets minimizing the complexities associated with streaming traffic-related information from various sensing devices installed on roads and vehicles. To carry out an investigation, there are two mechanisms to acquire the traffic-related information, viz., depending on publicly available datasets and acquiring realistic traffic data. There are currently various publicly available datasets for ITS, e.g. [36][37]; however, this dataset does not possess any characteristic of big data complexities of voluminous and various factors and is not featured with uncertainties. Hence, adopting already engineered and processed traffic-related information will not allow the model to be assessed for its capability to process a complex data stream. On the other hand, the acquisition of realistic data demands the involvement of an extensive experimental infrastructure with the inclusion of sensors. Even if small experimental prototyping is done, the outcome cannot be evaluated to prove its applicability for large-scale scenarios.

TABLE II. SAMPLE TRAFFIC DATA

Item	Traffic Attribute	Values
1	Vehicle ID	001
2	Vehicle Type	Car
3	Sensor Type	T1
4	Date	20/02/2023
5	Location ID	NH48
6	Sensor Status	Active
7	Sensor Range	10m
8	Driver Name	John Thomas
9	Driving Experience	The lane is heavily congested

Hence, the proposed scheme develops synthetic traffic data characterized by the complexity attributes of big data in ITS. The complexity is added by streaming the data in massive volume and programmatically making the data highly unstructured, which is challenging for any processor to read and analyze. This scenario can be mapped with complex data acquisition events in a heavy incoming stream of sensed traffic data in ITS. Table II highlights the sample traffic data that are synthetically generated. To ensure better compliance with the significant data form of the repository, the proposed study has visited the existing format for publicly available big data [38] and ensured that synthetic data carry the exact form. The synthetic data is in plain text to ensure that such data could have possible artefacts apart from the autonomous data entry-based errors from the sensing devices. This is done intentionally to ensure the possibility of data with an artefact. Further, the data is programmatically converted to its most complex form as follows:

1VehicleID0012VehicleTypeCar3SensorType

T14Date20/02/20235LocationIDNH486Sensor StatusActive7SensorRange10m8DriverNameJohn

Thomas9DrivingExperienceThelaneisheavilycongested

A closer look into the above data exhibits that such information is highly challenging for a machine to read. Hence, a module of traffic data manager has been evolved to manage such highly unstructured data. The algorithm follows the traffic data manager's overall mechanism.

Algorithm for Traffic Data Manager

```
Input: $s_d$
Output: $k$
Start
1. For $i=1:s_d$
2.     $U_d=f_1(i)$
3.     $f_{ex} \leftarrow f_2(U_d)$
4.     $d=[f_{ex}, d_f, val]$
5.     $F_{ex} \rightarrow s_u(ind(f_{ex}))$
6.     $sem_d=f_2(d(val))$
7.     Apply $f_3(sem_d) \rightarrow d_{int}$
8.     $k \leftarrow f_4(d_{int})$
9.     $k \rightarrow s_u(ind(F_{ex,} k))$
10. End
End
```

The discussion of the algorithmic steps is as follows: The algorithm takes the input of s_d (stream of data) that generates a resultant of k (extracted knowledge) upon processing. The proposed scheme considers a stream of data s_d as an input; however, processing an infinite data stream is infeasible. Hence, sd is considered a sampled data stream based on the number of packets queued. Considering the specific queue capacity, the s_d is sampled and considered an input for the proposed scheme.

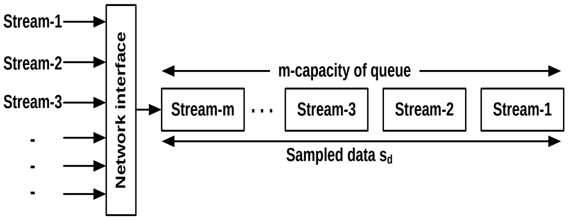


Fig. 2. Preparing for streamed input of traffic data.

Fig. 2 showcases that the proposed scheme considers its input s_d with a size equivalent to the size of the queue capacity m maintained by the service provider or application buffer. Hence, it is technically possible to process the streamed data s_d from different traffic zones (Line-1). The streamed data s_d is then programmatically transformed to unstructured data U_d using an explicit function $f_1(x)$. The prime task of this function is to obtain the stream data and eliminate all white spaces to form $U_{d,}$ which is challenging for the machine to read (Line-2). The following line of execution of the algorithm is to extract significant fields f_{ex} using an explicit function $f_2(x)$ (Line-3). The prime tasks of this function are: i) it reads the complete string of the stream data sd and captures the significant fields f_{ex} (basically the traffic attributes in Table II). Finding and confirming the fields are simple as they will keep repeating in one individual data in s_d (however, their corresponding values *val* will differ), and ii) The function also identifies a differentiator d_f that exists between field (F_{ex}) and value (*val*). Further, a record d is constructed, which retains information about extracted field f_{ex}, differentiator d_f, and corresponding values *val* (Line-4).

The part of the implementation of the proposed algorithm associates it with the preliminary storage optimization. The algorithm stores extracted field f_{ex}, indexes them and stores them in storage unit s_u (Line-5). Hence, the variable f_{ex} and F_{ex} mean original and indexed features, respectively. However, the algorithm doesn't store the corresponding values *val*; instead, it keeps them in a temporary memory where it is further subjected to a transformation process (Line-6). An explicit function $f_2(x)$ is constructed, which uses document tagging for all the corresponding values (as well as indexed extracted features) to generate a semi-structured traffic data sem_d (Line-6). This operation leads to all the intermediate data d_{int}. The term intermediate data d_{int} will mean that each extracted value *val* is mapped with defined contextual factors constructed in the corpus while developing the synthetic data. The core reason behind this is that the last traffic attribute in Table II bears a longer string message which is computationally challenging for the machine to process and analyze. Hence, a small repository of contextual traffic factors is designed and subjected to string comparison with all the individual words in traffic attributes to extract the actual contextual meaning the machine can understand. This operation is carried out using function $f_4(x)$, which finally generates knowledge k (Line-8). The extracted knowledge k is indexed using the self-constructed *ind* method and stored alongside the priorly extracted field F_{ex} (Line-9).

The contribution of this algorithm is as follows:

- This algorithm can process voluminous amounts of traffic-related streamed data, unlike existing approaches applied to static data.
- The algorithm permanently stores a part of iterative message fields in storage and a part of the message for further processing to offer better storage utilization. Existing approaches consider storing entire data and processing where the processed data is kept in different locations while original data is considered meta-data. This increases query processing time in existing approaches.
- A unique indexing mechanism that reduces the processing time for streamed dataset is introduced.

B. *Decentralized Scheme of Traffic Management*

This second implementation module incorporates a decentralization scheme in proposed traffic management. According to the highlights of Fig. 3, the proposed study considers that multiple traffic environments collect traffic information to generate an individual data stream. Upon passing through the network interface using the prior algorithm, the data transform to a streamed data sd, which ultimately generates a knowledge *k*. However, all this knowledge-based information is further indexed and reposited to the storage unit su in the prior algorithm, which is again subjected to analytical data operation. To ensure the practicality of this implementation, it is necessary to introduce a data fusion technique in a decentralized manner over distributed cloud environment. This will further lead to the possibility of artefacts. Hence, this decentralization scheme further assists in identifying the location of artefacts, followed by adopting statistical operations to eliminate the artefacts. This process leads to the generation of pure traffic data.

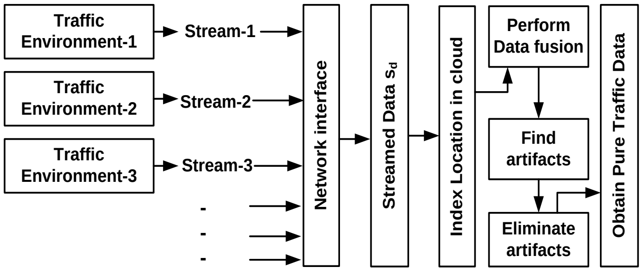

Fig. 3. Decentralized data fusion and quality improvement process.

For this purpose, an algorithm is designed to perform this decentralization operation toward further traffic data management. It is to be noted that this algorithm is explicitly executed in a storage unit on top of the final data (i.e., *k*) collected by the prior algorithm. To optimize computational speed and utilization of storage units, a buffer space matrix is constructed by extracting the available empty spaces of storage units in sharing form from multiple storage units. It will eventually mean that algorithm must be executed in a decentralized manner. Following are the steps of the proposed algorithm:

Algorithm for Decentralized Traffic Management

```
Input: $k$, $s_u$
Output: $d_p$
Start
1. For $j$=1: $k$
2.     alloc $j \rightarrow buf(s_u)$
3.     $d_{art} \leftarrow f_5(s_u, j)$
4.     $c_{sol}=f_6(cell(d_{rt}), s_u(k))$
5.     $d_p \leftarrow arg_{max}(c_{sol})$
6. End
End
```

The discussion of the algorithmic steps is as follows: The algorithm takes the input of k (knowledge) and s_u (index values in a storage unit) that, after processing, yields an outcome of d_p (pure data). A counter variable *j* represents the number of incoming data streams mainly focusing on newly analyzed data of *k* from the prior algorithm (Line-1). Each *j* stream of k data is then allocated to a matrix formulated by a shared buffer from all the available decentralized storage units s_u using method *buf* (Line-2). The prime reason to perform this operation is to ensure that no operation towards fused stream data is carried out directly over storage units, unlike the majority of the existing schemes. Fig. 4 offers a pictorial representation of the allocation of streams over unused memory over existing storage units. The advantage of this mechanism is that it utilizes unused memory from different cloud storage units to process the incoming streams of analyzed data. The following line of operation is associated with identifying errors or artefacts in the data (d_{art}). An explicit function f_5(x) is constructed to identify an artefact in the *j* stream concerning distributed index storage units s_u (Line-3). The outcome will lead to the generation of the location address of the cell in shared memory, which is witnessed with artefacts (d_{art}). The term *artefact* will represent illegitimate or illogical data that offers no significance towards either simplified understanding or could ever be processed.

Such data could be caused due to network or sensor-based errors while propagating the data. Upon identifying the artefacts (dart), the next action step will be eliminating them. The proposed scheme implements a unique artefact elimination process: i) an explicit function f_6(x) is constructed to obtain candidate solution c_{sol}. The variable c_{sol} will represent an alternate solution from different traffic data considering the specific traffic attribute where the artefact has been witnessed, ii) the function f_6(x) performs a correlation assessment between the contextual value of other fields with the field where the artefact is present (Line-4). At the same time, this operation will lead to the generation of multiple correlation values; iii) the correlation value found to be maximum is substituted in the place of artefact dart, leading to the generation of pure data d_p (Line-5).

To offer a clear idea about the proposed identification and elimination of artefacts, a pictorial representation of Fig. 5 further illustrates this process. Fig. 5 showcases that there are series of *m* number of streamed data concerning analyzed data, i.e., $sd_1(k_1)$, $sd_2(k_2)$, …, $sd_m(k_m)$. Although the proposed scheme uses nine explicit traffic attributes (as shown in Table II), this explanation considers five explicit traffic attributes (T1, T2, T3, T4, and T5) to fit the information in pictorial representation. Also, assume that user (node) information present in each stream of data is U_1, U_2, ….., etc. The corresponding values of each user concerning traffic attributes are represented as $v_{1,1}$, $v_{1,2}$, …. Consider that the proposed algorithm, till Line-3 using function f_5(x), found the presence of artefact as $d_{art}=v_{2,3}$ that belongs to second user U_2 in streamed data. In such case, the proposed algorithm obtains candidate correlation for all the user rows to obtain c_{sol1}, c_{sol2}, ….c_{sol99}, c_{sol100}. The algorithm further applies function f_6(x), which upon execution, found multiple possibilities based on correlation analysis. The outcome shows two higher values say $v_{7,3}$ and $v_{97,3}$ belonging to 7th and 97th user respectively. It will mean that the possibility of a better proximal solution in the cell for artefact $v_{2,3}$ resides for either $v_{7,3}$ or $v_{97,3}$. The algorithm compares $v_{7,3}$ and $v_{97,3}$ to find that the higher value is $v_{97,3,}$ which is then substituted in the specific matrix cell for $s_{d1}(k_1)$. That means the older value of artefact $v_{2,3}$ is now eliminated and substituted with the new value of $v_{97,3}$.

Fig. 5. Mechanism of finding and eliminating artifacts.

The novelty of this algorithm is as follows:

- The algorithm can identify the artefacts in more extensive indexed data in simplified steps.
- A non-iterative correlation-based assessment is carried out to obtain the proximal candidate solution, which replaces the artefact value in a specific cell only within the matrix.
- The algorithm is designed to work on artefact identification on massive traffic data.

C. Predictive Model for Traffic Management

The prior module of implementation assists in offering the highest possible data purity using correlation-based analysis statistically. P*ure data* (d_p) refers to a matrix formation of complete information. Each matrix cell is filled with the legitimate or authorized format of individual data complying with the respective traffic attribute. However, on the verge of seamless incoming of stream traffic data, there is still a possibility of accuracy in substituted value in the prior module. Hence, a predictive scheme is introduced in a proposed scheme to assess the degree of accuracy in the obtained data. There are two sets of operations performed in the proposed predictive model viz. i) to identify the degree of accuracy of the newly substituted value based on the learning process, and ii) in case of identification of faulty accuracy score, the predictive model assists in obtaining the actual value with higher accuracy. The operation of the predictive algorithm is as follows:

Algorithm for Predictive Traffic Management

```
Input: $d_p$, Th
Output: $i_{sol1}$
Start
1. For i=1:$d_p$
2.     $i_{sol}=f_7(i)$
3.     If $i_{sol} \geq Th$
4.         flag $i_{sol}$ as true
5.     Else
6.         $i_{sol1}=f_7(i_{sol}, Th_{tar})$
7.         For $i_{sol1} \geq Th_{tar}$
8.             flag $i_{sol1}$ as true
9.             $d_p(d_{art}) \leftarrow i_{sol1}$
10.        End
11. End
End
```

The discussion of those mentioned above predictive algorithmic steps are as follows: The algorithm takes the input of d_p (pure data) and Th (threshold) that, after processing, yields an outcome of i_{sol1} (predicted value). The algorithm considers all the outcomes of the prior module of implementation, i.e., pure data d_p (Line-1), where it subjects all the data to various machine learning approaches. A function $f_7(x)$ is constructed where multiple machine learning approaches are applied to the input data i to obtain an intermediate solution i_{sol} (Line-2). The prime reason behind applying multiple machine learning approaches is to assess the best-fit model toward optimal accuracy. The algorithm then compares the obtained value of i_{sol} with a primary accuracy threshold *Th* (Line-3). The optimal anticipated accuracy of i_{sol} should be more than Th, while the system flags the assessed value of i_{sol}>Th as true accuracy (Line-4). Otherwise (Line-5), the algorithm reform the implication of function $f_7(x)$ to the obtained value of i_{sol} as the second iteration (Line-6). A new target threshold Th_{tar} is set, which is more than the primary threshold Th. The iteration is continued until the objective function towards converging to a new threshold Th_{tar} is met. For optimal solution, the algorithm re-checks the newly obtained value, i.e., isol1 is more than Thtar while the truth condition (Line-7) confirms higher accuracy (Line-8). The obtained value of i_{sol1} is now substituted in the cell recorded with artefact data in the d_p matrix (Line-9). It should be noted that the primary threshold *Th* is fixed by a user based on application/service demand. At the same time, the user can set the value of Th_{tar} by adjusting the prior *Th* value to a slightly higher level. A closer look into the pictorial representation in Fig. 6 of this algorithm will further illustrate the proposed predictive traffic management mechanism.

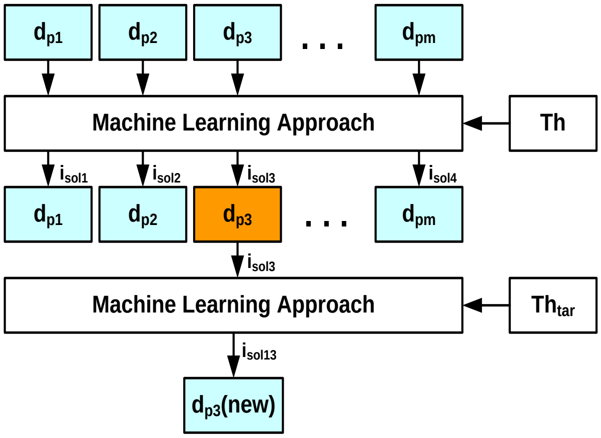

Fig. 6. Mechanism of obtaining predictive value.

According to Fig. 6, the algorithm considers m number of pure data values, i.e., d_{p1}, d_{p2}, ….$d_{pm,}$ subjected to the machine learning model. The respective obtained solution i_{sol1}, i_{sol2}, ….i_{solm} are compared concerning primary threshold Th to find out that one of the data, i.e., d_{p3} is found to under-performed (which means its accuracy is lower than cut-off), while the rest other values (i.e., d_{p1}, d_{p2}, … are found to be optimal, i.e., more than *Th*). Hence, the algorithm is explicitly iterated for d_{p3} with a fine-tuned value of target threshold Th_{tar} (Th_{tar}>Th) that finally leads to the new predictive outcome of $d_{p3.}$ This completes the overall algorithm implementation. The outcome of this model from the viewpoint of the application or service of ITS can be stated as a value-added analytical result, which could assist in more profound insights into the traffic scenario with higher reliability and accuracy.

The novelty of the proposed predictive algorithm is as follows:

- A simplified predictive model doesn't demand any form of the reengineering process towards the ITS framework.
- The accuracy outcome of the model can eventually be fine-tuned by the severity of the application or services demanded in ITS.
- The proposed machine learning algorithm can perform more progressive operations and requires less iteration to obtain optimal accuracy.

A closer look into the entire algorithm implementation shows that the proposed scheme offers a novel and sophisticated learning scheme for traffic management. The following section discusses the results accomplished in the study.

VI. Result Analysis

This section discusses the results obtained by implementing the algorithms discussed in prior sections. The discussion is carried out concerning the assessment environment, and the result is accomplished with more highlights on the result discussion and learning outcome.

A. Strategies for Result Analysis

Before initiating the proposed scheme, 25 records were chosen for a pilot study from the primary dataset as a smaller sample size. The idea was to assess the appropriateness of the proposed algorithm towards data analysis concerning accuracy. With the 25 records, 93.1-98.2% of accuracy has been obtained for almost all the learning approaches. This accomplishment offers a concrete proof-of-concept which is then subjected to the original size of the dataset for further assessment. From the data elicitation process perspective, the proposed scheme develops multiple data nodes responsible for streaming the data to the distributed cloud interface. The proposed scheme develops five distributed ITS data nodes (which can be mapped with a gateway node that keeps track of all traffic data to be disseminated). This information is forwarded as a stream to a standard cloud interface, where further data aggregation, processing, and analysis are carried out. The proposed scheme uses a supervised learning approach where the data points with significant predictive errors can be identified and solved. The implementation environment consists of multiple ITS traffic system data nodes that generate the traffic data and forward it to the core cloud interface. This standard interface is used to aggregate the data, identify with the elimination of the artefacts, perform normalization, and apply semantic and syntactical approaches to discover knowledge. Further multiple supervised learning approach is used for the predictive analysis of ITS traffic data. From the perspective of the balanced dataset, the proposed scheme splits the complete data into ten sets, where each set bears 100 records, and one set is allocated to a single stream. This facilitates effective monitoring of network performance parameters like overhead and delays while attempting to perform data transmission. Further, from the perspective of the learning approach, 70% of the data has been considered for training, while 30% of residual data is considered for testing. Further discussion of the assessment environment follows next.

B. Assessment Environment

A computational framework is constructed in MATLAB to assess the proposed scheme, considering a regular 64-bit Windows machine with i5 processing capability. The raw data from traffic is generated as a stream from multiple sources of traffic environment, which are further subjected to the first algorithm towards accomplishing preliminary knowledge. This output is further subjected to a second algorithm where the artefacts are identified, followed by a statistical correlation-based approach to substitute the specific cell of an artefact with new values to achieve data purity. Further, a set of machine learning algorithms are applied to assess the correctness of obtained outcome of the second algorithm using dual thresholding methods. For simplification in evaluation, the primary threshold (*Th*) for accuracy is maintained at 0.5, while the secondary threshold (Th_{tar}) is maintained at 0.7. The thresholding values can constantly be amended based on service or application severity towards analytical operations. Following is further information on the assessment environment:

1) Dataset: The implementation of the complete work is carried out by constructing a synthetic dataset with nine traffic attributes (e.g., Vehicle ID, Vehicle Type, Sensor Type, Date, Location ID, Sensor Status, Sensor Range, Driver Name, Driving Experience) and their corresponding values. The construction of the dataset is carried out by adhering to the standard format of big data [38]. At the same time, the inclusion of traffic attributes is formulated based on an existing publicly available dataset of ITS [36][37]. A total of 1000 datasets is acquired; each dataset further consists of 100 records of an individual traffic environment. The datasets are maintained in plain-text form, which is further given as input to MATLAB script for further algorithmic operation.

2) Performance Parameters: The performance parameters considered in the proposed assessment are accuracy, communication overhead, delay, and processing time.

3) Comparison with Existing Scheme: The proposed scheme has used multiple machine learning schemes that are reported to be frequently adopted in existing schemes, e.g., Random Forest, Artificial Neural Network, Support Vector Machine, Logistic Regression, and Naïve Bayes. The comparative analysis is carried out with each other adopted machine learning model to investigate the best-fit model towards performing an analytical operation in ITS.

C. Result Accomplished

The numerical outcome of the proposed scheme concerning various learning-based analytical approaches is showcased in Table III with respect to various performance metrics adopted for assessment.

TABLE III. NUMERICAL OUTCOME OF STUDY

Techniques	Accuracy
Random Forest (RF)	99
Artificial Neural Network (ANN)	91
Support Vector Machine (SVM)	86
Logistic Regression (LR)	67
Naïve Bayes	70
Techniques	**Overhead (ms)**
Random Forest (RF)	1.11
Artificial Neural Network (ANN)	2.21
Support Vector Machine (SVM)	2.31
Logistic Regression (LR)	2.37
Naïve Bayes	2.22
Techniques	**Delay (s)**
Random Forest (RF)	0.05
Artificial Neural Network (ANN)	0.31
Support Vector Machine (SVM)	0.12
Logistic Regression (LR)	0.1
Naïve Bayes	0.19
Techniques	**Processing Time (s)**
Random Forest (RF)	3.67
Artificial Neural Network (ANN)	10.56
Support Vector Machine (SVM)	11.21
Logistic Regression (LR)	10.03
Naïve Bayes	9.87

The discussion of the numerical outcomes is further illustrated in graphical form from Fig. 7 to 10 for better inference to the accomplished outcome.

D. Analysis of Accuracy

The proposed scheme computes accuracy by evaluating several correct predictions made by different sets of machine learning approaches toward the analyzed data. The outcome of accuracy is shown in Fig. 7.

The inference of the result exhibited in Fig. 7 is as follows:

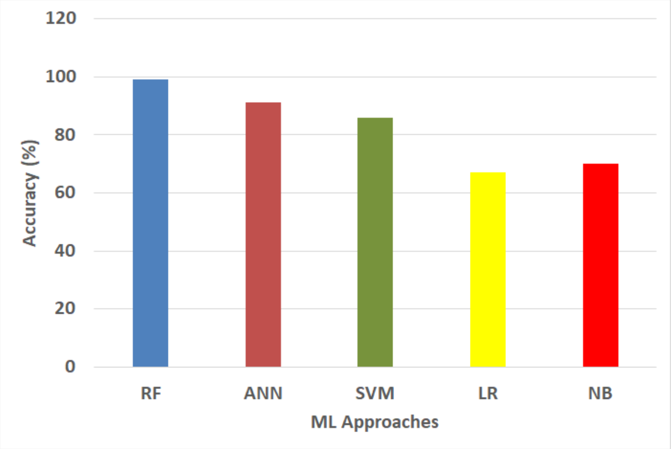

Fig. 7. Comparative analysis of accuracy.

1) Discussion of Results: The outcome showcases that the RF model performs better than others on the accuracy scale. The next exhibit of better performance is from ANN and SVM models, although the SVM model has slightly less accuracy than ANN. LR and NB's accuracy trend is nearly the same, with no significant difference. The prime justification is that the LR method exhibits less reliability when exposed to a continuous data stream and hence witnesses degraded accuracy. At the same time, the assumption of independent predictors in the NB model doesn't map well with the proposed study. Although SVM offers better ranges of classification for heterogeneous traffic data, its accuracy starts to decline when the size of the data increases. In this perspective, ANN performs better than SVM, which performs iterative operations to acquire a higher accuracy state. On the other hand, the RF model can execute both regression and classification, potentially contributing to higher accuracy.

2) Learning Outcome: Based on the result, it can be stated that the RF model is highly suited when exposed to significant streams of ITS applications/services that demand higher accuracy in the prioritized traffic environment. The applicability of ANN and SVM is suited for low-medium scale traffic, which also demands a medium-high range of accuracy. On the other hand, the applicability of the LR and NB model is best suited for performing an analytical operation that doesn't demand instantaneous response delivery or doesn't need higher accuracy.

E. Analysis of Communication Overhead

Communication overhead is computed by evaluating cumulative packets destined to be forwarded from one vehicle to another vehicular node in ITS. A sample of 2500 test packet bytes is used to assess this performance metric. An ITS with an optimal design plan should always keep the communication overhead as low as possible to resist a communication bottleneck situation. The outcome of communication overhead is shown in Fig. 8.

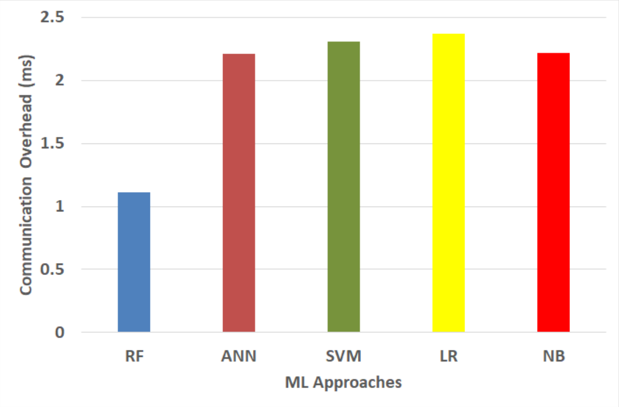

Fig. 8. Comparative analysis of communication overhead.

The inference of the result exhibited in Fig. 8 is as follows:

1) Discussion of results: The outcome in Fig. 8 shows two distinct trends viz. i) lower communication overhead shown by the RF model and ii) higher communication shown by the ANN, SVM, LR, and NB models. Although there is a numerical difference in the outcome among ANN, SVM, LR, and NB models (as shown in Table III), the difference is less significant. The prime justification behind this is as follows: A closer look into ANN, SVM, LR, and NB models shows that they perform quite an iterative analytical process while performing both training and validation operations (especially the training). This fact leads to a more significant communication overhead when exposed to many data packets. It is to be noted that data packets and their sizes are derived from the existing synthetic dataset itself. However, RF models offer a comparatively less iterative process and a more streamlined operation for continuous incoming packets, resulting in less communication overhead.

2) Learning outcome: Based on the outcome, the adoption of RF is more suitable in ITS when it calls for performing analytical operations in dense traffic conditions, whereas other machine learning models are applicable only in lesser dense traffic environments. The reliability of RF processing and analyzing data is relatively higher than others.

F. Analysis of Delay

Owing to the decentralized scheme in the proposed system, it can be assumed that all the algorithmic operations are carried out on different terminals in ITS with higher synchronous operation. Hence, delay is a suitable parameter to justify any form of lag of interval in receiving and analyzing data. The proposed system computes delay by evaluating the duration interval for one module's data packet to reach another.

As the proposed architecture jointly implements three different algorithms, it is anticipated to exhibit a delayed trend as lower as possible. The inference of the result exhibited in Fig. 9 is as follows:

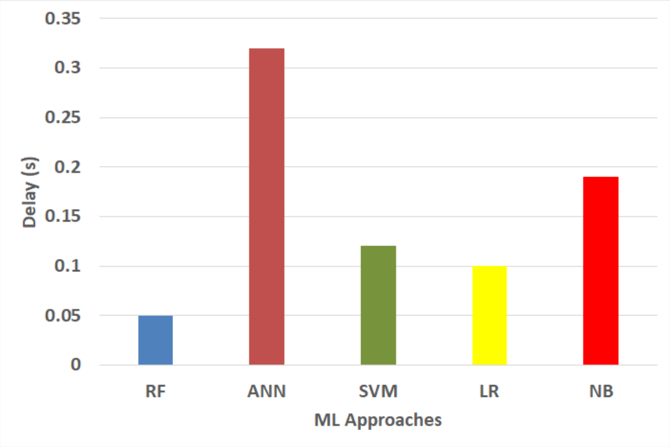

Fig. 9. Comparative analysis of delay.

1) Discussion of results: A unique observation is noted in Fig. 9 concerning delay, which is entirely different from a prior comparison of accuracy and communication overhead. Fig. 9 showcases that RF is the performing model, while the next performing model is SVM and LR. On the other hand, the performance of ANN and NB is shown to consume more delay. The specific reason behind this outcome is mainly associated with increasing training operations in ANN to meet the anticipated accuracy (Th_{tar}). Although NB performs slightly better than ANN, it cannot feature learning from the associated relationship of traffic attributes. From this context, LR and SVM perform better as both can deal with high-dimensional spaces between the data; however, SVM doesn't excel well compared to LR as it demands increasing time for training.

2) Learning outcome: From the outcome perspective, it can be stated that prioritized applications/services in ITS are well-suited when executed with the RF model. In contrast, the application/services of ITS only work well with ANN and SVM if the sample size is reduced. However, it is not practically possible in the genuine environment of ITS.

G. Analysis of Processing Time

Processing time is computed as the time required for the complete algorithm to execute jointly. An effective architecture deployment always demands lower processing time. The outcome of processing time is shown in Fig. 10.

The inference of the result exhibited in Fig. 10 is as follows:

1) Discussion of results: The outcome in Fig. 10 showcases RF to offer reduced processing time compared to other machine learning approaches. A similar justification discussed for another performance metric can be attributed to stating the reason behind this outcome. Lower processing time also refers to lower time complexity stating that the RF model offers a computationally cost-effective analytical process in ITS compared to others.

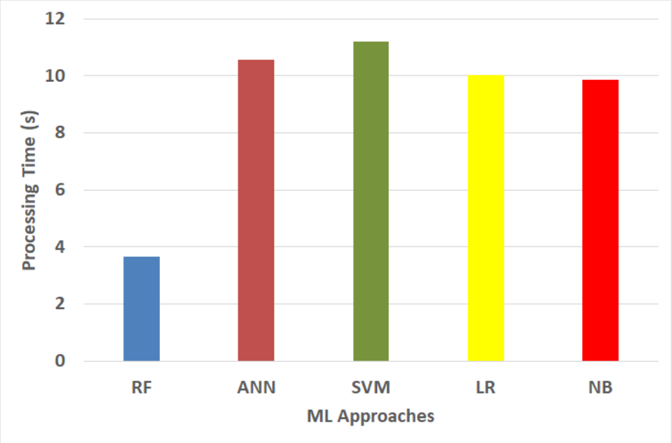

Fig. 10. Comparative analysis of processing time.

2) Learning outcome: As the ITS environment included the usage of multiple resource-constraint devices, it is anticipated that algorithmic operation should not be computationally complex. Hence, the RF model offers better predictive operation on low resource-based devices in ITS, while others are witnessed with higher computational complexity.

Therefore, from the perspective of accomplished outcome, it can be stated that the proposed analytical model is well suited with RF to exhibit a best-fit machine learning model in ITS. However, to understand the efficiency of the proposed scheme apart from standard learning approaches, the proposed scheme also analyzes comparison with existing state-of-art methods, as exhibited in Table IV.

TABLE IV. COMPARISON WITH STATE-OF-ART

Method	A_1	A_2	A_3	A_4
Ensemble Clustering, tensor [17]	No	Low	Medium	High
Machine learning, clustering [18]	No	Low	Low	Medium
Analytical model [19]	no	Low	Medium	High
