- The entire modelling of the proposed scheme is carried out to support the scheme's decentralization applicability, which is not exhibited by either of the existing methods, irrespective of their accomplished outcomes. This is a significant novelty of the proposed scheme, which leads to the practical ground of implementation in urban traffic systems.
- Without using any sophisticated or iterative learning principle, the proposed scheme offers higher accuracy than existing methods without compromising the other performance attributes shown in Table IV.
- The proposed algorithm has reduced dependencies of iterative computation while it is more progressive, providing a speedier algorithm processing time. This is a significant accomplishment of novelty attributes of the proposed scheme compared to existing schemes where complex approaches are used.
- The proposed approach also offers very low computational complexity, contributing to other novel features. The prime reason behind this is the formulation of algorithms emphasising optimal data quality in predictive operation. Further, the adoption of shared memory makes it a more lightweight operation.

VII. CONCLUSION

A closer look into the proposed experimental analysis showcases that the proposed scheme can consider the input of multiple streams of ITS traffic data via various data nodes. This is a practical scenario where a gateway node can collect the traffic data and subject it to analysis. Further, the information is subjected to various rounds of processing, right from transformation to the final stage of knowledge discovery. All these individual blocks of operation can be carried out in distributed form. Yet, owing to the inclusion of a unique indexing mechanism, all the data are closely synced with each other. Further, the benchmarking over the accomplished outcome clearly states the distinguishable performance for each supervised machine learning scheme. This shows that the proposed scheme can act as a robust and highly flexible evaluation platform for analyzing the ITS traffic data with cost-effective measures without affecting data transmission performance. The proposed scheme presents a novel architecture capable of performing an efficient analytical operation over complex traffic data in ITS. The contribution of the proposed study is as follows:

1) The proposed model can transform the raw and complex stream of traffic data into highly structured data rendering it with higher suitability for analytical processing,

2) The proposed model offers the implementation of the highly decentralized scheme of the analytical process considering streams of multiple traffic data from different origins followed by a unique data fusion,

3) The proposed model can identify the position of artefacts in massive data sizes followed by eliminating the artefacts using cost-effective statistical correlation-based analysis.

4) The proposed scheme also introduces a joint test-bed benchmarked with multiple machine learning models to show the best-fit model towards predictive analytical operations in the ITS environment.

5) Quantification of outcome states that the proposed model, when executed with the RF model, shows improvement in accuracy by 20%, reduction in communication overhead by 14%, minimization of delay by 13%, and diminished processing time by 7% in comparison to other machine learning approaches (e.g., ANN, SVM, LR, and NB model).

Future work will be carried out toward further optimizing the learning model by including network-based parameters involved in the assessment. An assessment model can be constructed to investigate the impact of different network types, storage types, and communication standards on analytical operations. Further, work can be extended to understand the adoption of different data formats toward predictive accuracy.

***Abstract*—This study describes the search for optimal hyperparameter values in rainfall data in 49 cities in Australia, consisting of 145,460 records with 22 features. The process eliminates missed values and selects 16 numeric type features as input features and one feature (Rain Tomorrow) as output feature. It is processed using the Multi-Layer Perceptron (MLP) and Support Vector Machine (SVM) methods based on Three Best Accuration (3BestAcc) and Best Three Nearest Neighbors (3BestNN). The results showed that the SVM kernel linear method gave an average accuracy value of 0.85586 and was better than the MLP method with an accuracy of 0.854.**

***Keywords*—Rainfall; MLP; SVM; optimal**

I. INTRODUCTION

Weather is the condition of the air at a certain time and place. Weather conditions are related to sunlight, air temperature, humidity, wind, and other conditions and play a significant role in various areas of life, such as changes in the quantity and quality of water, changes in forest habitat and agricultural land, and other changes. The weather for a short time must use the values of the weather elements that exist at that time. Meanwhile, weather statements in a more extended unit of time must use the values of weather elements with the lowest, highest, or most felt levels by the five senses as in [1].

Rain is one of the parameters and weather phenomena that comes from the evaporation of air containing water vapor and forms clouds at certain temperatures. Rain can be measured as a parameter, and rain can be seen visually as a phenomenon, such as fog, smoke, and others. Rainfall data information is very important for planning, especially for water structures such as irrigation, dams, urban drainage, ports, and docks, so data analysis is needed to predict it. In [2], rainfall is the amount of water that falls on a flat ground surface during a certain period which is measured in millimeters (mm) above the horizontal surface. Rain can also be interpreted as the height of rainwater that collects in a flat place, does not evaporate, does not seep, and does not flow.

One of the solutions for predicting rainfall is to analyze big data from the information obtained using the correct method to get the best accuracy. Big Data is a collection of data with super large data volumes and has a high diversity of data sources, so it needs to be managed with methods and assistive devices whose performance is appropriate as in [3]. However, the implementation of big data is still not good or requires a relatively long time to obtain the desired accuracy value, so it is necessary to reduce the feature dimensions by utilizing the Linear Discriminate Analysis and Principle Component Analysis methods to optimize the computational process.

This study will explain predictions of rain status based on a collection data set over a 10-year period that describes meteorological information from 49 different cities in Australia. Furthermore, the data is processed by eliminating missed values and selecting 16 numeric type features as input features and one feature (Rain Tomorrow) as output features and analyzed using the Support Vector Machine (SVM) and Multi-Layer Perceptron (MLP) methods. Then to get optimal results (maximum accuracy), an algorithm was developed to obtain hyperplane parameters using K-Fold cross-validation and developed through two schemes. The results of this study are the level of prediction accuracy in each city, which can be used as a supporting medium in urban planning and anticipation. In addition, the overall average accuracy can also be used as material for consideration in further research.

II. PREVIOUS RESEARCH STUDY

Many methods have been used to predict rainfall data, including the Extreme Learning Machine Method on Artificial Neural Networks to predict rainfall in the Poncokusuma area of Malang district, using data from 2002 to 2015. The results of this study obtained a MAPE of 3.6852% with 4 features, 2 hidden layers, and the proportion of training data is 80% as in [4]. Research on clustering rainfall predictions in Australia using the K-Means algorithm in the WEKA and RStudio applications. The results obtained are the number of cluster 2 with an SSE of 28.0%, which is an ideal cluster to predict rainfall in Australia as in [5][6]. Research on rainfall prediction in Australia using Machine Learning by comparing the level of accuracy using several methods. The methods used are K-Nearest Neighbors, Decision Trees, Random Forests and Neural Networks. The results obtained by the best method are from Neural Networks with an accuracy rate of 85.5% as in [7].

- Multiple Face Detection Research using Hybrid Features with SVM Classifier: The data used is from two databases, namely the BAO database and the CMU database. The SVM classification method can recognize faces with an accuracy of 89% as in [8].

- Liver Cancer Analysis Research using SVM Data Mining Algorithm in MATLAB: The processed data is in images in the UCI machine learning repository. The accuracy obtained is 86.7% as in [9].

- Comparative Research of Naive Bayes and SVM Algorithms Based on Sentiment Analysis using Dataset Review: The data used is a dataset collected from the Twitter API. The SVM method achieves 77 per cent better accuracy than Naïve Bayes as in [10].

Research on hyperplane-parameter tuning for SVM, namely Hyper-parameter Tuning for Support Vector Machines with Distribution Algorithm Estimation, has been carried out using various methods, including Genetic Algorithms, Particle Swarm Optimization (PSO), Grid Search, and Random Search. This study will estimate hyperplane-parameter estimation using the Univariate Marginal Distribution Algorithm (UMDA) and Boltzmann Univariate Marginal Distribution Algorithm (BUMDA). Both methods are stochastic optimization techniques by building and taking samples from probabilistic models. The study's results obtained the best method using the Boltzmann Univariate Marginal Distribution Algorithm (BUMDA) as in [11].

Parameter optimization in SVM using the Taguchi Method for High Dimensional Data. In this study, optimal parameters were selected using the Taguchi method, which provides an increased level of accuracy compared to the Grid Search method as in [12]. Support Vector Machine (SVM) for Rainfall Forecasting on the Johor River, namely forecasting rainfall as a warning in the event of heavy rainfall resulting in flash floods. The data for the 60-year study period came from rainfall data in the Malaya Gum Field, Kota Tinggi, Johor, Malaysia. The method used is SVM. The research results on the SVM method with the Radial Basis Function RBF kernel has the best performance compared to sigmoid, linear and polynomial. The Root Mean Square Error (RMSE) value for the RBF 67.70 kernel is the best compared to other kernels as in [13]. Research on rainfall forecasting using the Support Vector Machine (SVM) has been conducted. The method used to predict rainfall is SVM regression. The research data used is rainfall data in Khurda District Orissa. The kernel that has the minimum Mean Square Error (MSE) is the Linear kernel which produces a minimum MSE average of 15.04% as in [14].

Sustainability plays an important role in enhancing the industry's competitive advantage. Continuous performance and application assessments face high dimensional data, robustness and imprecision. Machine learning is pressured to implement. This study aims to design a machine learning model to assess sustainability performance using SVM. Hyperplane-parameter tuning and k-fold validation are included for improved performance in SVM models. The research object was carried out in the bioenergy industry. The validation was carried out ten times. Tuning the hyperplane parameters gets 98.32% in testing the data. The final results show that SVM with a polynomial kernel model can classify sustainability performance accurately as in [15].

Problems related to hyperparameter tuning are still an interesting topic to be studied. Some of them are aspect-based sentiment analysis of iPhone users on Twitter using the SVM and GridSearch methods for hyperparameters C, gamma, and kernel as in [16], hyperparameter tuning of supervised learning algorithms for classification of families receiving rice food assistance using the grid search method, random search, and Bayesian optimization as in [17], and indoor pollutant classification modeling using relevant sensors under thermodynamic conditions with multilayer perceptron hyperparameter tuning using the GridSearch method as in [18].

III. Material and Methods

A. *Materials*

The data used in this study is secondary data related to daily rainfall in 49 different cities in Australia over a 10-year period Australia. The dataset was obtained from the kaggle.com platform accessed February 2, 2023. The sample data is 145,460 which consists of 22 (twenty-two) features.

They are the location of weather stations, minimum temperature (C), maximum temperature (C), recorded rainfall amount (mm), evaporation in 24 hours, number (hours) of bright sunlight in 24 hours, the direction of strongest wind gust in 24 hours, strongest wind speed (km/h) in 24 hours, wind direction at 09.00 local time, wind direction at 15.00 local time, wind speed at 09.00 local times, wind speed at 15.00 local time, humidity (per cent) at 09.00 local times, humidity (per cent) at 15.00 local time, atmospheric pressure (hpa) which decreases to an average sea level at 09.00 local times, reduced atmospheric pressure (hpa) to mean sea level at 15.00 local time, part of the sky covered with clouds at 09.00 local times. The unit size used is octas (a unit of eight), which records the number of clouds, the part of the sky covered by clouds, at 15.00 local time. The unit size used is octas (a unit of eight), which records the number of clouds, temperature (C) measured at 09.00 local time, temperature (C) measured at 15.00 local time, today's status (rain, notated 1 or not raining, given the notation -1), tomorrow's status (rain, given the notation 1 or not raining, given the notation -1).

B. *Methods*

Based on the data obtained, the steps for preprocessing and analyzing the data are compiled as follows:

- Collect a data set over a 10-year period that describes meteorological information from 49 different cities in Australia and consists of 145,460 records with 22 features.

- At the preprocessing stage, the process carried out is the elimination of miss values and the selection of 16 features of a numeric type as input features and one feature (RainTomorrow) as an output feature. In the Python program, to delete all data miss values from a feature (e.g., the MinTemp feature), suppose df is a logical file containing the results of reading all data, with the statement: you can use the statement:

df = df.loc[df[‘MinTemp’].isna()==False] then the new df contains data with no missed values in the MinTemp feature. This process is carried out on all features.

- Using the Support Vector Machine method to determine the value of C that gives the best average accuracy, and the Multi-Layer Perceptron method to determine the hidden layer structure.
- Based on the data records that have been cleaned (data cleaning), the data will be divided using the k-cross validation principle into one part of the data (training and data validation). In contrast, the rest will be used as test data. The training and validation data will be divided into folds, fold1, fold2, fold3, fold4, and fold5, each containing random and different data (not intersecting) with the same number of records.
- Create a tuning method algorithm for Linear Kernel SVM and MLP with the principle of the three best accuration (3BestAcc) to find the 3 best accuracy values in a discrete hidden structure and three best nearest neighbor (3BestNN) to find the 3 best accuracy values in an interval.
- Displaying the Contour of the SVM method by carrying out the Principle Component Analysis (PCA) transformation so that two features are obtained, namely principal component 1 and principal component 2, which are used as abscissa and ordinate on a two-dimensional graph (cartesian graph). Based on the results of an experiment on 100 data, it was found that the contour hyperplane is a dividing line between the status of the two classes shown in Fig. 1.

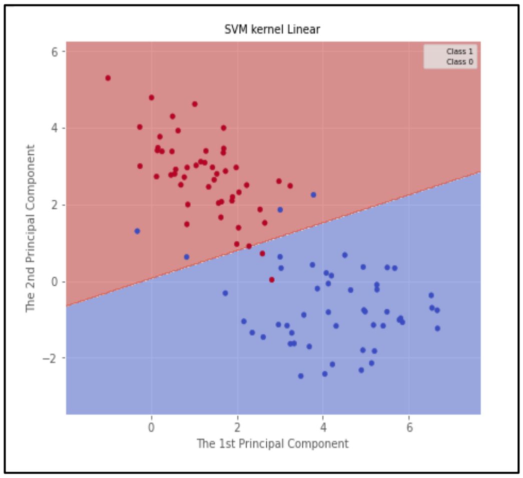

Fig. 1. Contour linear kernel hyperplane.

- Displaying the Histogram of Test Data Distribution by transforming 16 numeric features in the collected data into one feature, which will be used as the abscissa of the histogram created while the ordinate axis represents the frequency of data in a value. The transformation used in this study is Linear Discriminant Analysis (LDA). The distribution of data classes includes rain status for tomorrow in blue and non-rainy status for tomorrow in red. The histogram of the class distribution of tomorrow's rain status data is shown in Fig. 2.
- Output analysis is carried out after obtaining histogram graphs, accuracy, and Mean of Square Error (MSE) to obtain interpretations and conclusions from the results obtained.

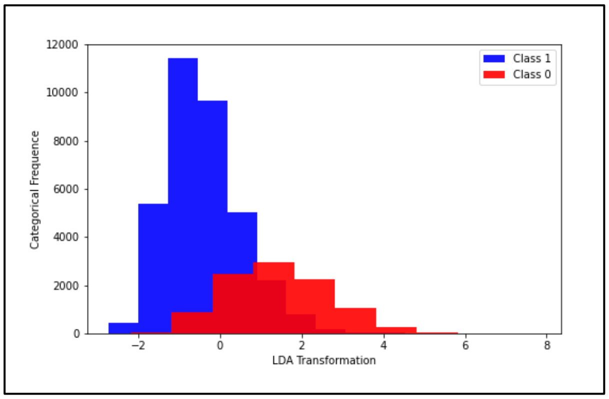

Fig. 2. Histogram of tomorrow's rain status distribution.

IV. RESULTS

A. Research Data

The data retrieved from kaggle.com is divided into three parts. A total of 50,000 records were used as data (training and validation), and 6,420 records were used as test data. Of the 50,000 records used as training data and validation data with a ratio of 80:20. With the K-Cross Validation method, the data is divided into five folds of the same size, which are randomly generated. Each fold contains 10,000 data records. One of the five folds is used as validation data, and the other four are used as training data. Of the 56,420 datasets, there are two classes: Rain Status with 12,427 records and no rain status with 43,993 records.

B. Support Vector Machine

The algorithm implemented in this study uses the Python SVM function in scikitLearn by Belete et al. as in [19]. The selected parameters are:

kernel='linear',

C=kC(input from user)

The default parameters of the system:

(*, C: float = 1, kernel: str = "rbf", degree: int = 3, gamma: str = "scale", coef0: float = 0, shrinking: bool = True, probability: bool = False, tol: float = 0.001, cache_size: int = 200, class_weight: Any | None = None, verbose: bool = False, max_iter: int = -1, decision_function_shape: str = "ovr", break_ties: bool = False, random_state: Any | None = None) -> None.

In obtaining the accuracy value of a certain linear C kernel SVM model, one fold is used as validation data and the other four folds as training data. This process was repeated five times to get average accuracy. This study used C ∈ (0.16), and the accuracy values were calculated at various initial intervals, as shown in Fig. 3. The C value with the highest accuracy is

0.08272, with an accuracy of 0.8538. This value is obtained from one of the folding compositions. If the composition of the wrinkles is different, it is possible to get other Cs, but the accuracy values are almost the same. The accuracy value for data testing is 0.85586; this average value is higher than the accuracy value for obtaining optimal parameters. This value is increasing by 1.586% compared to the results as in [20].

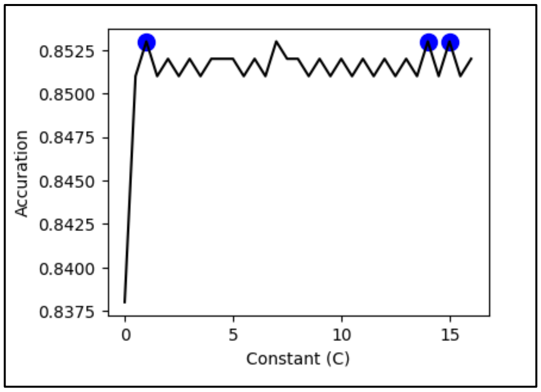

Fig. 3. Graph of accuracy calculation at interval [0.16].

C. Multi-Layer Perceptron

The hyperparameter optimization (HPO) optimization steps for the MLP method use the three highest accuracy values or Three Best Accuration (3BestAcc) starting from the initialization of the data and functions to be used. Then from the 16 inputted numeric data, three nodes with the highest accuracy will be selected (best1, best2, best3) with 6 Hidden layer structures consisting of (best1, i), (i, best1), (best2, i), (i, best2), (best3, i), (i, best3), (i=1,2,3,…,30). Next, three structures with the highest accuracy were taken for each structure so that 18 arrangements were obtained.

The algorithm implemented in this study uses the Python MLPClassifier function in scikitLearn as in [21]. The modified parameters are:

- Hidden_layer_sizes contains the number of hidden layers and the number of nodes of each Hidden Layer

- random_state=1

- solver = "adam"

- learning_rate_init = 0.001

- max_iter=300

- toll = 0.000001

for other parameters, the default of the system.

Calculations are made from hidden layer 1 to hidden layer 12 because the accuracy value tends to decrease starting from hidden layer 9, as shown in Fig. 4, so the process is stopped at hidden layer 12.

Hyperparameter tuning is performed on the Multi-Layer Perceptron method on the parameters of the number of hidden layers and nodes. The process of getting one model accuracy value (number of hidden layers and number of nodes) uses one fold as validation data and the other four folds as training data. This process is repeated five times to obtain the average accuracy. The hidden layer structure that provides the highest accuracy is (19, 24, 25, 25, 15, 3, 3, 26) so it is obtained that the optimal MLP model has eight hidden layers with the number of nodes in the hidden layer 1 being 19, the number of nodes in hidden layer 2 is 24. and so on. This structure is obtained from one of the fold compositions. However, if the fold composition is different, it is possible to obtain a different Hidden Layer structure arrangement but still has the highest accuracy in the fold arrangement. The accuracy value for testing data is 0.85586; this average value is higher than the accuracy value for obtaining optimal parameters, which is 0.854. This value is 1.4% greater than the results as in [20].

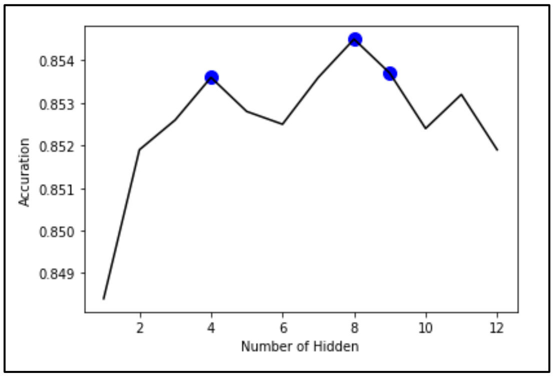

Fig. 4. Graph of the maximum accuracy value for each hidden layer.

TABLE I. ACCURACY PER STATION

No	Station	Record	SVM Accuracy	MLP Accuracy
1	Darwin	3062	0,857	0,859
2	Perth	3025	0,897	0,893
3	Brisbane	2953	0,856	0,853
4	Melbourne Airport	2929	0,839	0,826

Table I shows the average accuracy value for each station of the SVM methods and MLP methods. The accuracy information for each station can be used to determine which method to use for maximum accuracy. SVM kernel method C=0.08272, an accuracy of 0,85586 was obtained, while for the MLP method with a hidden layer structure (19, 24, 25, 25, 15, 3, 3, 26), an accuracy of 0,854 was obtained. Thus it can be concluded that the SVM kernel linear method is better than the MLP method with a difference of 0.00186.

D. Data Analysis for each Region

Processing rainfall data at each station helps predict conditions where the results obtained are compared to obtain results with the best accuracy. Fig. 3 and Fig. 4 shows several stations whose station test data accuracy values are higher than the average accuracy of the SVM and MLP methods. In addition, Table II shows that the SVM method has a higher average accuracy than the MLP method, where the data for the "Rain" status is less than the data for the "No Rain" status. Therefore, the amount of testing data on the "Not Raining" status is used as much as 1.5 times of the "Raining" status data. An example is the data at the Darwin station, which consists of 789 data records for the “Rain” status. The number of testing data is 1.5 x 789 = 1183 records. The total number of records is 3062, so the total training data is (3062-1183) = 1879. Then the 1879 records are divided into five folds with the same number of records, each containing (1879/5) = 376 records.

TABLE II. STATION WITH AN ACCURACY OF MORE THAN 0.85586

No	Nama Kota	Metode
1	Alice Springs	SVM
2	Cobar	SVM
3	Darwin	MLP
4	Mildura	SVM
5	Moree	MLP
6	Nuriootpa	SVM
7	Perth	SVM
8	Perth Airport	SVM
9	Townsville	SVM
10	Wagga Wagga	MLP
11	Woomera	SVM

V. CONCLUSION

This research results in the MLP method hyperparameter tuning with the 3BestAcc method. The 3BestAcc method can be used to find the structure of the Hidden layer Multi-Layer Perceptron which gives optimal results. The working principle of 3BestAcc is to select three structures in the hidden layer with the highest accuracy, and then these three structures are used to determine the structure of the next hidden layer. Further development of the 3BestAcc method still requires a lot of time, so algorithms can be developed to make the selection of the hidden layer arrangement more time efficient. Another research that might be developed is to look for the highest accuracy value at specific intervals. Further research is also possible on the dataset. Because the data records are extensive, the preprocessing stage can select representative data, reduce feature dimensions, or select the most influential features so that the MLP model processes fewer data.

Table II provides information that the SVM kernel linear method (C=0.08272) provides a better average accuracy value than the MLP method with a hidden layer structure (19, 24, 25, 25, 15, 3, 3, 26).

***Abstract*—Vehicle type classification has an extensive variety of applications which include intelligent parking systems, traffic flow-statistics, toll collecting system, vehicle access control, congestion management, security system and many more. These applications are designed for reliable and secure transportation. Vehicle classification is one of the major challenges of these applications particularly in a constrained environment. The constrained environment in the real world put a limit on data quality due to noise, poor lightning condition, low resolution images and bad weather conditions. In this research, we build a more practical and more robust vehicle type classification system for real world constrained environment with promising results and got a validation accuracy of 90.85 and a testing accuracy of 87%. To this end, we design a framework of vehicle type classification from vehicle images by using machine learning. We investigate the deep learning method Convolutional neural network (CNN), a specific type of neural networks. CNN is biologically inspired with multi-layer feed forward neural networks. It can learn automatically at several stages of invariant features for the particular chore. For evaluation, we also compared the performance of our model with the performance of other machine learning algorithms like Naïve Bayes, SVM and Decision Trees.**

Keywords—Vehicle classification; intelligent transport system; deep learning; machine learning; CNN; digital image processing

I. Introduction

Vehicle classification and detection has emerged as an integral part of the Intelligent Transportation System (ITS). The aim of ITS is to provide public safety, improve travel and transit information, minimize blocking, produce cost funds to tragedies operators. To cope with the rising demand of surface transportation system, the ITS technologies assist cities, states and towns nationwide. The effectiveness of an IT system is generally based on the performance of vehicle detection and classification technology. It collects all or part of the information which is used in an efficient ITS. In the development of ITS, traffic monitoring is one of the significant applications encompassing the categorization and detection of vehicles. Vehicle type classification has an extensive variety of applications which include intelligent parking systems, traffic flow statistics, toll collecting system, vehicle access control, congestion management, security system and many more. These applications are designed for reliable and secure transportation. Vehicle classification is one of the major challenges of these applications. Many researchers from different domains have been involved in this area to overwhelm the primary transportation issues.

In recent past, the research in vehicle type classification and detection from static images has achieved huge attention because of its essential role in an enormous variety of applications [1], [2]. Vehicle type classification and detection from still images is a demanding job. Because of their great intraclass distinctions, numerous vehicle types fitting into similar classes have features of several shapes and sizes. Furthermore, shadow, lighting, noise, and obstruction make the classification job more demanding [1]. Moreover, there can be some constraints on image quality while working with limited computing resources. These types of complications can be determined by using efficient and reliable vehicle classification systems for such constrained environment.

Several image-based techniques have been presented until now and the majority of them comes under into two groups: appearance-based methods and model-based methods. To classify vehicle type, appearance-based method uses appearance features (for example SIFT [3], sobel edges [4]) from either vehicle side view or front view image for classifying vehicle type. Model-based methods [5], [6], [7], [8] retrieve the 3D parameter of the vehicles just like height, length, and width for classification. To define the vehicle shape and structure 3D models are used. In 3D models, the main features to deal with are faces, point, lines and topological structures. The vehicle classification is generally performed using a combination of hardware and software-based approaches. The hardware used for this purpose mainly includes radars, magnetic detectors, infrared detectors, ultrasonic detectors, acceleration detectors and many more. But this capable hardware cannot be used without having automated vehicle classification software embedded in their backend. The focus of all the previous works as well as this work is also to develop such a capable software that when embedded in any capable hardware, can provide accurate vehicle classification results. The core Idea behind the development of automated vehicle classification software's is automated intelligence. This also goes the other way around. If a capable software gets developed that can accurately classify

*Corresponding Author, email id- mkkamran@uj.edu.sa vehicle classes, it will not be able to do anything until it is embedded into a capable hardware to provide real time monitoring, surveillance, and other activities.

Nowadays, many real-world applications like auto controlling traffic are totally dependent on vehicle classification and detection. Several methods have been proposed for vehicle classification. Vehicle classification is very complicated area in computer vision because it requires high accuracy which may lead towards complex algorithm. Until now various works have considered for this classification, some of the work has been done on the limited scenarios. There are some challenges which must overcome for the accomplishment of this task like image quality, size, image scale and color [9], [10]. Moreover, existing research works on vehicle image classification using deep learning have made significant progress in achieving high accuracy and robustness. However, they also exhibit certain limitations that need to be addressed. One limitation is the lack of diverse and comprehensive datasets, which may lead to biased or overfitting models. Additionally, the focus on specific regions or vehicle types in some studies limits the generalizability of the proposed methods. Another limitation is the heavy reliance on manual annotation and labeling, which can be time-consuming, subjective, and prone to errors. Furthermore, the computational complexity and resource requirements of deep learning models pose challenges for real-time applications and resource-constrained environments. The interpretability and explain ability of deep learning models in the context of vehicle image classification also remain areas of concern. Addressing these limitations will contribute to the advancement of vehicle image classification research and enable more accurate and efficient solutions in real-world scenarios.

The main motivation behind our proposed work is that in real world scenarios, due to bad weather conditions and moving of the camera and/or vehicles, the images are sometimes not clear enough to distinguish between types of vehicles automatically. We believe that the need to address this problem is very important; particularly, in case of lack of high-end cameras that could provide a good quality image. Also, there can also be other factors like more than one vehicle in a single image and various angles of the vehicle when the image was captured. Furthermore, image rotation also presents a challenge for accurate classification of vehicles.

The vehicle images captured by camera are blurry (or not clear) if the shutter speed while capturing the images is not according to the vehicle speed (or stationary vehicle and moving camera). The image clearness is usually measured by its sharpness. A clear image has a high degree of sharpness; while on the other hand, a blurred image is less sharp. In our work we are concerned with motion-blurriness caused by the motion of vehicle and/or camera. So, a robust method would yield accurate results on blurred images as well. Deep learning based CNNs have revolutionized image processing and computer vision. They excel in extracting meaningful features directly from raw data, eliminating the need for manual feature engineering. CNNs leverage their hierarchical and localized approach to capture complex patterns and structures in images. They are adept at tasks like object recognition, image classification, and segmentation. Deep learning models handle large-scale datasets, ensuring scalability and generalization across different domains. With their ability to automatically adapt and learn from image data, deep learning and CNNs have significantly advanced applications such as autonomous driving, medical imaging, and video analysis. In this context, we propose a more practical and robust vehicle classification system with a promising accuracy rate. We recommend a structure of vehicle classification from vehicle images by using a machine learning system. Convolutional neural networks are the machine learning methods. They are specific neural networks. CNN is biologically inspired by that multi-layer feed forward neural network. It is capable to automatically learn several phases of invariant features for the chore. CNN has good ability of learning features in face detection [11], image classification [12], video classification [13], facial point detection [14], and human attribute inference [15]. CNN have verified great success in these kinds of tasks. For large scale image recognition task it has become the most popular architecture. Convolutional neural networks have a layered structure and each layer could learn the demonstration of the input. This capability is called feature learning. Feature learning is a method through which machine learns from raw data. In image classification, the raw data of the image is represented by an array of pixels. These arrays of pixels fed to the CNN and then CNN learns the useful features of the image to resolve the machine learning problem [16]. The major contributions of the work presented in this paper are as follows:

- Development of the algorithm proposed for automatic vehicle type classification in constrained environment.
- Modeling the vehicle classification system as a problem to be solved by using CNN algorithm.
- Performance analysis of the proposed technique using experiments.

The rest of this paper is organized as follows. Section II presents the current relevant techniques with their limitations. A detailed explanation of the proposed technique is presented in Section III. Details about experimental setup and results has been given in Section IV. Future directions have been provided in Section V and finally, this paper has been concluded in Section VI.

II. Related Work

Zhen dong et al. in [17] worked on the vehicle classification by using a semi supervised CNN. They used the front view of vehicle images. As an input, the network is given the vehicle image and then it outputs the vehicle class to which the vehicle belongs. Their technique achieves overall classification accuracy of 96.1% in the daylight images and 89.4% accuracy on the nighttime images. Similarly, in [18], a multi type vehicle classification system is established. For this purpose, they used Bag of Visual Words (BOVWs) and Random Neural Networks (RNNs). Their BOVW-RNN classification system achieves 95.63% accuracy which is higher than the LIVCS who achieve 91.21% accuracy. Another approach proposed in Yiren zhou et al. [19] uses Deep Neural Network (DNN) approach for the vehicle detection and classification problem. Their approach has the capability to be used for training on restricted size datasets and can be extended to diverse lighting condition cases. However, as opposed to the proposed work these techniques do not consider the images taken under the constraint environment. For vehicle classification, the authors in [20] used an immovable camera to detect and classify the vehicles. They located the camera on the height of the road surface. They used an algorithm which has two phases: In the first stage they obtained mobile vehicles in the traffic location, removed background from the image and performed morphology operations and edge detection. In the second stage, they captured the vehicle through camera and processed the feature extraction method. The classification rate for their proposed method is 90% of the whole data. In [21], Wei Wu et al. used a novel method by using neural networks and parameterized models for vehicle classification. They captured their own real vehicle images through CCD camera installed on toll collecting station. They took the vertices and their topological structure as the main feature. To recognize vehicle, they used a classifier which is based on the multi-layer perception network (MLPN). In this classifier they used a learning technique which is based on the gradient descent for the least exponential function error (LEFE). They achieved approximately 91% accuracy. The authors in [22]] proposed the appearance-based model for vehicle type classification. They used front view of the vehicle and SoftMax regression for classification. They used convolutional neural network and by using this network their method automatically learned good features for classification. Their method is relatively effective for the classification of vehicle types. For automatic vehicle classification, the method in [23] is based on the fusion classical neural network (CNN) and of fast neural network (FNN). They used FNN as the main classifier and CNN as a final classifier. Their proposed method produced 95.83% accuracy. However, all these techniques do not account for images taken under the constrained environment. The author addresses the limitations of single vehicle detection methods due to a lack of high-quality labeled training samples. They propose using the YOLO-v5 architecture for vehicle detection and classification, employing transfer learning by fine-tuning pre-trained weights. Extensive datasets collected by the authors, including various traffic patterns, occlusions, and weather conditions, are manually annotated to enhance training. The proposed YOLO-v5 model surpasses traditional methods in terms of accuracy and execution time, demonstrated through simulations on PKU, COCO, and DAWN datasets. The findings highlight the effectiveness of the proposed method in challenging scenarios [24].

The author aims to solve the problem of traffic density estimation for effective traffic management by utilizing deep learning techniques. They collect data from open-source libraries and label vehicles in images into six different classes. To address the imbalanced dataset, data augmentation techniques are applied. The proposed model is based on an ensemble of the Faster R-CNN and Single-shot detector (SSD) models, trained on processed datasets. Experimental results demonstrate that the proposed ensemble outperforms base estimators on FLIR thermal dataset, achieving a higher mean average precision (mAP) of 94%. The ensemble model shows promising results compared to other estimators, with better performance on thermal images. The proposed model also exhibits significant potential for traffic density estimation, offering valuable insights for traffic management [25]. The author aims to develop a method for in-vehicle passenger detection using MIMO radar. They propose a CNN-LSTM model that accurately detects, counts, and classifies passengers in five-seater vehicles. The model combines CNN for feature extraction and LSTM for temporal prediction. Reliable datasets collected from different car models are used to evaluate the model, which achieves high accuracy in detecting unattended infants/children (over 95%), counting passengers and identifying occupied seats (89% accuracy), and classifying passengers (over 74% accuracy). The results demonstrate the generality of the proposed method for deployment in any five-seater vehicle [26]. A vehicle classification system based on low cost triaxle anisotropic magneto resistive sensor was proposed in [27]. To detect the vehicle within a segment and single lane the vehicle signals effectively, a fixed threshold state machine procedure is presented. Through experimentation it is concluded that the detection accuracy of the presented technique can reach up to 99.05% and the overall average classification accuracy is almost 93.66. These results show the efficiency of presented technique for low-speed congested traffic, but authors did not test their technique in the constrained environment. In [28], author presented a vehicle classification problem based on laser scanner profiles, which is found as a part of electronic tolling systems. Vehicle shapes are extracted from laser scans and then explore them as multi-dimensional shapes. The presented technique explores identical and non-identical shapes for discovering typical shapes then classified using global alignment of shapes. This technique shows state of art results by overcoming per class error by 4 to 17%. In military operations, nighttime multi-vehicle detection over a long distance is essential. The visual characteristics of automobiles are hard to identify at night due to inadequate lighting, which leads to numerous missed detections. Based on Gm-APD LiDAR intensity images and point cloud data, this work [29] suggests a two-level detection strategy for long-distance nighttime multi-vehicles. There are two layers to the approach. The first level is 2D detection, which raises the brightness of weak and small objects and improves the local contrast of the intensity image. The detection result of more than the threshold is reserved as a dependable item when the confidence threshold is set, while the detection result of less than the threshold is a suspicious object. The suspicious object region from the first level of 3D recognition is translated into the appropriate point cloud classification judgment in the second level, and the object detection score is achieved by thorough judgment. The method outperforms current state-of-the-art detection techniques, according to experimental data, achieving a detection accuracy of 96.38% and effectively enhancing the detection accuracy of multiple cars at night.

LiDAR point cloud semantic analysis accuracy is necessary for autonomous cars to interface with the actual world. By fusing 3D global Hough features and 2D local Hough features with a classification deep learning network, this work [30] suggests a hybrid 2D and 3D Hough Net. First, the global Hough features are extracted from the 3D object point clouds by mapping them into the 3D Hough space. For training global features, the 3D convolutional neural network receives the generated global Hough features as input. To limit the calculation of duplicate points, a multi-scale critical point sampling approach is created to extract crucial points in the 2D images projected from the point clouds. A grid-based dynamic nearest neighbors' method is created by exploring the important locations' neighbors to extract local information. To classify objects, completely connected layers that are input into the two networks are then connected to the full connection layer. The experiments show that the classification accuracy achieved 97.6% by allocating the 25 × 25 × 25 cells for the 3D Hough spaces and specifying 0.25 as the unit size of the local Hough spaces. The results of the studies demonstrate that by assigning the 25 25 25 cells for the 3D Hough spaces and choosing 0.25 as the local Hough spaces' unit size, the classification accuracy was increased to 97.6%.

As per the research carried out [31], numerous automated traffic monitoring systems have been created because of the growing number of cars circulating in various urban cities. Roadside camera traffic monitoring systems are being widely used because they provide crucial technological benefits over other traffic monitoring systems. The performance of the entire system is significantly impacted by the methods used for vehicle identification and traffic congestion categorization, which are the two primary processes for video-based traffic congestion detection systems. Investigate four chosen vehicle recognition techniques in two contexts: urban and highway, including the Gaussian Mixture Model (GMM), GMM-Kalman filter, optical flow, and ACF object detector. Additionally, three classification approaches for traffic congestion are examined. The comparison of the various approaches enables us to select the ones that will function best when incorporated into the framework suggested for addressing the traffic problems on the Bizerte Bridge. For mobile robots in industrial sectors with dusty environments, the author [32] seeks to develop noise-filtering algorithms that can remove dust from LiDAR sensory data. It was created as an intensity-based filter (LIDROR) based on a thorough examination of the characteristics of dust point clouds detected by a LiDAR sensor in order to accomplish the desired result. To the best of our knowledge, the suggested approach and the previously created LIOR are the first initiatives in this industry to design a de-dust filter utilizing non-AI method.

Utilizing 3D Light Detection and ranging, this work focuses on the issue of vehicle detection and tracking for an autonomous vehicle (LiDAR). A new clustering approach is suggested [33] to get vehicle candidates from preprocessed point cloud data gathered by the LiDAR to improve the accuracy of vehicle detection and tracking. To distinguish automobiles from vehicle candidates, a support vector machine (SVM) trained classifier is used. Vehicles are tracked using the Kalman filter and the global nearest neighbor (GNN) method, and the tracking data is used to further increase the accuracy of the vehicle detection results. A testing platform has been used to validate the suggested technique. In this study [34], a hierarchical approach based on RCNN was presented for the detection and recognition of vehicles and vehicle license plates. The tasks were related to RCNN's complexity. Multiple complicated level RCNNs can be used in the same system in this fashion. For intelligent traffic monitoring, a sample vehicle detection system was created as an example. The license plate recognition RCNN was then taken into consideration for vehicle identification. Authors in [35] suggested a simple, cooperative object classification framework for CAV that protects user privacy and focuses on the object classification problem. The framework's main novelty is the inclusion of the P-CNN model, which analyses encrypted images sent from cars and, when combined, yields accurate classification results. To protect the image during storage and transmission, extra image distortion is used. In P-CNN, our safe protocols based on the additive secret sharing technique execute the operations in the original CNN model (VGG16). The outcomes of the experiments show that P-CNN provides precisely the same classification outcomes as the VGG16 model without requiring vehicles to provide raw image data directly, which might contain private information. Additionally, the communication overhead and processing cost on two edge servers are reasonable.

The study [36] utilizes data from naturalistic driving to calculate the driver-vehicle volatilities. This work intends to forecast the occurrence of safety-critical events and deliver appropriate feedback to drivers and nearby vehicles by integrating and fusing several real-time streams of data, such as driver distraction, vehicle movements and kinematics, and instability in driving. The naturalistic driving data, which was gathered from more than 3500 drivers, includes 7566 normal driving events, 1315 severe events (such as crashes and near-crash situations), car kinematics, and driver behavior. Long Short-Term Memory (LSTM), 1DCNN-LSTM, and 1D-Convolutional Neural Network (1D-CNN) are used to capture the local dependency and volatility in time-series data. The input parameters include driving volatility, vehicle kinematics, and distracted driving impairment. The findings show that the 1DCNN-LSTM model performs best, with an accuracy of 95.45% and a precision of 95.67% for predicting crashes that would occur in 73.4% of cases. The CNN layers extract additional information and consider the temporal dependency between observations, assisting the network in learning driving patterns and volatile behavior. A recent trend in research using deep learning [37], [38], [39], [40], [41] has shown its tremendous potential for vehicle classification. However, these techniques mostly did not consider the constrained environment where their restrictions of data quality or hardware constraints. Similarly, some of the techniques presented in [42] does not consider constrained environments as considered in the proposed work in this paper.

According to the literature review, the research that have been conducted for vehicle classification have some limitations particularly in case if constrained environment where either only low-quality images are present (for instance, due to bad weather conditions) or there are some hardware constraints. Some researchers stated their future work as to work with poor training datasets. So, in this work, we created custom dataset with poor quality images with multiples classes such as Car, Bike, Truck, Rickshaw and Bus. Every class used in our project is totally different from each other in terms of model. We take every view of the vehicle like front, back, side, front side and back side to train our network. We conduct our vehicle classification work based on two types of datasets: noisy dataset and a relatively clean dataset. Both these datasets are custom datasets created and collected from real-world images using the image search feature of Google. In this work, the dataset is collected by keeping in view the limitations of the previous work. The most used methodologies of vehicle classification are implemented and evaluated using datasets to analyze their performance in real world environment.

III. PROPOSED METHODOLOGY

In our work, we apply deep learning techniques for the vehicle classification task. The initial step of methods is the data collection technique. The images used in this project are taken from Google images we contribute of ownership protection to prove the ownership of the data. We provide ownership protection systems through watermarking technique. After that for classification purposes the initial step is preprocessing step in which noise is removed from images. After preprocessing is done on images, they can be used to train or to test the network which is also known as recognition step. In the training phase, the preprocessed images are passed to the network with their specified labels so that, for the classification the best network weights can be found. In the testing phase, the network is configured with the set of weights found during the training phase and then the recognition of images is performed. The recognition also outputs the confidence level against each vehicle image. The highest confidence level is used to depict the vehicle class. For increasing the number of training samples, in short for more generalization, the method of synthetic image generation is used during the preprocessing phase (the synthetic images are not being used in testing phase). Fig. 1. presents the general architecture of our proposed framework. A brief description of the proposed technique is mentioned in the following section. It begins with the data collection technique. After collecting the data, ownership protection of that data through watermarking is explained. For classification, preprocessing and the detailed description of convolutional neural network are also presented.

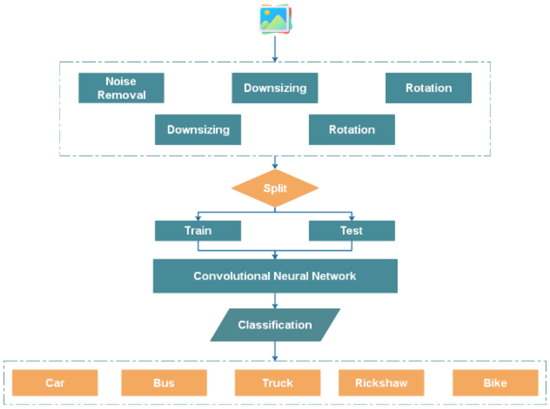

Fig. 1. Proposed framework.

A. Data Collection

In this work, we used the images obtained from Google images. We used “get them all” downloader in chrome to download bunch of images at once. The entire project is executed on a personal computer with restricted computational resources. Our project is also limited to the simple classification of five classes: Car, Bike, Rickshaw, Bus and Truck. Every class is visually different from one another. But our dataset is boundless. Fig. 2 shows the representation of our dataset.

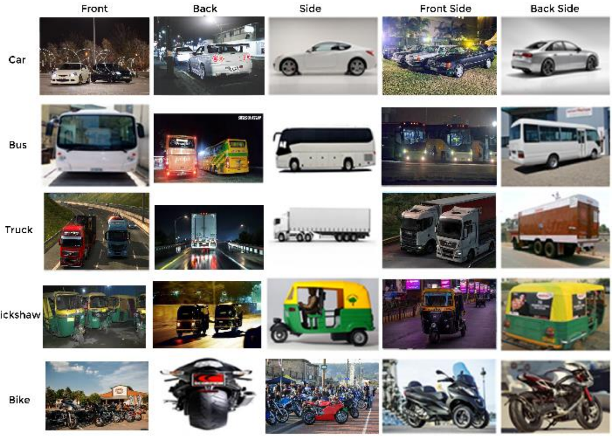

Fig. 2. Dataset representation.

We performed different experiments to achieve maximum accuracy on two types of datasets based: noisy dataset and clean dataset. If one used an immovable camera, mainly CCTV or any other camera that is not generally configured once installed, in any application to detect and classify vehicles, there is a huge chance of noise involvement. This also leads to the foundation of our reason for using images from Google images there is a massive possibility of the involvement of noisy images in them. Moreover, these noisy images contain more than a single desired object in the image, for example, many bikes in a single image and the same issue for remaining classes as well. Therefore, we cleaned our dataset by removing such noisy images. As a result, our finalized dataset contains 4000 images of cars, 3213 images of buses, 4000 images of bikes, 4000 images of trucks, and 1159 images of rickshaws; that is, a total of 16372 images.

These evaluation configuration aims to measure the performance of the system with the vehicle's image database. The database is separated into five groups of non-overlapping classes. To perform experiments, the databases used in each experiment were divided into three sets: The training set, which is used for training the system, the validation set, which is used for dynamically tuning the Meta parameters of the system and then the test set, which is used to measure the accuracy of the system. In all experiments, it is ensured that there is no subject overlap among the three sets.

B. Preprocessing

The images should be preprocessed before it fed into the convolutional neural network. Our preprocessing pipeline consists of various steps as follows:

1) Noise removal: In a bid to work with real-world images with low quality and noise, we used the images obtained from Google images to train the neural network. As images are taken from Google images, there is a massive possibility of the involvement of noisy images and - low-resolution images with lots of variation. In this step, those images contain more than a single desired object in the image --for example, many bikes in a single image and the same issue for the remaining classes as well. At this point, we need to refine whole the dataset. We used certain filters including the Gaussian filter and median filter to refine the images containing multiple objects and those captured in low-light conditions. The unsharp filter is also applied to refine edges and make the objects in ambiguous images clearer thus making it easier for the model to classify such images.

2) Downsizing: The training set contains a diversity of image dimensions as are downloaded from Google images. We resized the images into 32x32 and 64x64 dimensions as required by the model to work with low resolutions. Because images with large dimensions like 256x256 are too time-consuming and sometimes it is very difficult to process them due to hardware limitations or due to the availability of - low-resolution images only in the real-world environment. By using downsize images, there is a chance of information being lost which s to poor results. As in our experiments, the accuracy stuck at 87% by using 32x32 dimension images. When we move towards 64x64 dimension images we get better results approximately 90%. So, if we use high dimension images for training there might be a chance to get better results. We used a light image resizer to resize these all images at once.

3) Rotation: Convolutional neural networks are more suitable to work with huge amounts of data. The network trained well with maximum samples for training. Maximum training allows the network to better learn the variation which is present in the data. To increase the data, data augmentation technique is used. By using this technique, images can be transformed and produced a new image. Rotation is one of the simple transformations through which we can increase our data by just angular rotating the original image. In our approach, we applied 10 different angular rotations. In our dataset, with concern of the different classes, the Bus and Rickshaw chavings has low representation meanwhile the dataset in this phase is unbalanced; therefore, the rotation phase helps in generating additional data through 10 angular rotations. We perform rotations with the angles [-2, 2, -4, 4, -6, 6, -8, 8, 10, -10].

4) Flipping: Several data augmentation techniques can be used to increase the size of training datasets. One of the widely employed techniques is to horizontally flip photographs. Different flipping images can be used to train a model. To double the size of the data, we treat the image that has been flipped as a genuine image. the in this project, we use random flipping to train our model. In our dataset, with the concern of the different classes, the Bus and Rickshaw class is underrepresented meanwhile the dataset in this phase is unbalanced therefore generating additional data through flipping. Color space.

5) Transformation: The source image is used if it has already been colored and is in the RGB color space. Any source images found in the dataset that are not in RGB color space and exist in black and white, grayscale, or any other non-RGB color system are transformed into RGB color space using industry-standard procedures. The convolutional neural network (CNN) only accepts and processes RGB images, hence we have included colored images in the suggested work as well. Red, green, and blue hues are defined by RGB's three channels.

C. Convolutional Neural Network

CNN are the specified neural network. In recent past, much research work regarding image processing and classification has been done by using CNN. The CNN architecture is made up of various kinds of layers. These layers comprise of convolutional layer, pooling layer, and fully connected layers. These layers may contain some supplementary hyper parameters such as size of filter, padding, stride for the convolutional layers and the quantity of neurons used in fully connected layer. The all number of layer types with their supplementary hyper parameters and their consequence on training quality and speed, all these circumstances make it hard to choose architecture. The capacity of learning makes this classifier much superior to other classifiers. It not only learns the weight of features but the features themselves. On universal image classification, CNNs have accomplished revolutionary accuracy. Similar concepts are adjustable for audio and videos as well. In this segment, we define CNN for the processing of images.

Fig. 3 represents the generic architecture of CNN used in the proposed scheme. CNN comprises of numerous convolution layers, pooling layers, and a fully connected layer. After one or several convolution layers, a pooling layer is applied. In this architecture, the convolution layers extract the useful features from the input that produce feature maps. The pooling layers then decrease the spatial size of these feature maps. There are multiple filters used in this architecture with different kernel sizes. It displays the edges of the input image as a result and then this idea of filters for feature extraction is interpreted to CNN. CNN learns these filters as a replacement of hard coded filters.

1) Convolutional layer: As a normal neural network, the convolution layer comprises of units as well, however with a rare arrangement and an unusual connectionism of the units. The main differences between these two networks are based on weight sharing, local connectivity, and three-dimensional arrangement of the unit.

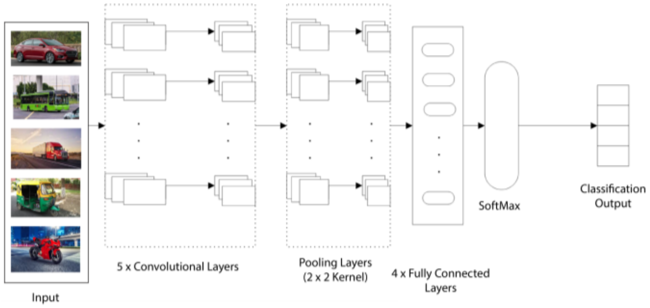

Fig. 3. Architectural flow of CNN on input data.

In weight sharing, the same weights are used for several output units. Basically, the weights are the filters and these filters are used on the entire input to generate the output. In local connectivity, the size of this connectivity is defined by the kernel size. In this connection, all the units of input are not connected with the output unit. The three-dimensional arrangement of the unit arises from the image. Colored image normally comprises of three channels (red, green, and blue). Each channel is defined by a two-dimensional matrix. Consequently, the input and output of the CNN is a three-dimensional matrix. The output comprises of three-dimensional matrix with feature maps of two dimensions and this x times for the filter numbers used in this layer. Each filter creates a feature map. In convolutional layer, the feature map is obtained by convolving a filter across the input volume, adding a term bias. If we represent the k^{th} input feature map of the convolutional layer ash^k and its filter is denoted by w^k and term bias isb^k, then the output which is feature map h^{k+1} is obtained as:

$$h^{k+1} = W^k \times h^k + b^k \qquad (1)$$

Where × shows a convolutional function

2) Pooling layer: The pooling layer is applied after convolution layers. This layer is used to minimize the spatial size of the feature maps. It actually downs samples the feature maps. The spatial dimension of the feature maps is reduced of 75% by one pooling with the stride size of 2*2. Size of sliding over the input channel is called stride. The pooling layer has no activation function or weight to learn because it works independently on each feature map. The max-pooling and average-pooling are the common pooling layers. The max-pooling layer calculates the maximum, which lies on the receptive side of filter and the average-pooling layer calculates the average.

3) Fully connected layer: These layers work identically to hidden layers of a regular neural network. To determine the output scores and arbitrary features, these fully connected layers can be used at the termination of the CNN after numerous stages. As the name shows, in this section all layers of the units relate to the input layer.

4) Training: In this phase, we have a trained set of input vectors with a parallel set of output vectors. The goal is to use training data to train the network's biases and weights so that the network performs good in classifying input. The further training data given to a network, the additional iterations and weight updates can possible and then it came out with improved network architecture which gives better results. Through a training process, the way a computer is capable to adjust its filter values or weights is called back propagation. Backpropagation is an efficient method to propagate back the error to calculate the gradient from the loss function through the network. It computes the gradient referring to the weights. The backpropagation has the following recursively equation to calculate the gradient in respect to the weights.

$$\frac{\partial L(\theta)}{\partial w_{l,k}^{(i)}} = \delta_l^{(i)} . Z_K^{(i-1)} \qquad (2)$$

Backpropagation can be divided into four different segments. Forward pass, loss function, backward pass and weight update. In forward pass, the training images pass through the whole network. In the first training image all the filter values or weights are casually initialized thus output does not give any sensible conclusion about what the classification could be. This leads towards the loss function of backpropagation. Loss function is used to reduce the error. Modest loss function is the mean squared error (MSE) which computes the squared difference between half of the difference between actual and predicted as follows:

$$L\,(\theta) = \frac{1}{2N} \sum_{n=1}^{N} \| f(\check{Y}_n ; \theta) - \check{Z}_n \|^2 \qquad (3)$$

The backward pass in the propagation decides which weights donates maximum loss and it adjusts the weights to decrease the loss. After this in the weight update process, all the weights of the filters got updated.

$$W = W_t - \eta \frac{dL}{dW} \qquad (4)$$

5) Gradient descent: To minimize the loss function, gradient descent method is mostly used. It needs the gradient of the loss function in terms of α. Backpropagation method is used to calculate the gradient. Gradient descent is an iterative optimization algorithm. In this algorithm weights can be updated with the help of gradient.

$$\theta \leftarrow \theta - \eta . \frac{\partial L(\theta)}{\partial \theta} \qquad (5)$$

Where η defines the learning rate. Learning rate is a parameter that is selected by the programmer. High learning rate meant to take higher steps to update the weight.

6) Dropout layer: Dropout layers have a very definite function in neural networks. The idea of dropouts is basic in nature. It is a technique used for decreasing over fitting in neural networks. The units will be arbitrarily dropped for each iteration of the training. Dropout layer is only used in training time. Units are dropped with the probability of p and this p can be different for each layer. It is a method that prevents overfitting. It drops out an arbitrary set of activations in that layer by setting them to zero in the forward pass.

By using dropout, the network should be able to deliver right classification if some of the activations are dropout. In supervised learning, it improves the performance of neural networks. Except loss layer, dropout can be used in every layer and applied during supervised training alongside with end to end back propagation. The option of dropping the unit is random. In dropout, the forward process is defined as:

$$h^{k+1} = M * (w^k \times h^k + b^k) \qquad (6)$$

7) Rectified linear unit: Rectified Linear Unit (ReLu) is the efficient activation function because the network is capable to train a lot faster while not making any significant difference to the accuracy. The value for ReLu can be calculated as:

$$\sigma(y) = \max(0, y) = \begin{cases} 0, & if y < 0 \\ y, & if y \geq 0 \end{cases} \qquad (7)$$

8) Exponential linear unit: Exponential linear unit (ELu) is for negative values. Over the negative activation, the mean activation is near zero and this led towards the faster merging of the network because the input for the next layer has zero mean. The formula for ELu is:

$$\sigma(x) = f(x) = \begin{cases} \alpha.(e^x - 1), & if x < 0 \\ x, & if x \geq 0 \end{cases} \quad (8)$$

Where α>0 and is generally set to 1.

9) SoftMax: SoftMax activation function is used for the encoding of the output. It represents a probability distribution over k classes and hence it is only used in the output layer. The formula of SoftMax is:

$$\sigma(y)_j = \frac{e_j^y}{\sum_{k=1}^{k} e^{z_k}}, for\ j = 1, \ldots..k. (9)$$

IV. Results and Discussion

For experimentation, we used libraries like Tensorflow, Keras, Sklearn, Matplotlib, Scipy, and OpenCV in python language running on a Core i3 processor with 8GB of RAM.

A. Convolutional Neural Network for Vehicle Classification

The proposed architecture of our CNN has been presented in Fig. 3. Various convolutional neural network architectures were used in our implementation. The reason behind this is to pinpoint the architecture that achieved a reasonable accuracy with under restricted environment with respect to computational resources and quality of the data. The network takes an input of 64x64 RGB image and then classifies the given image assigning it a vehicle type. Our architecture of CNN consists of 5 Convolutional layers, 4 fully connected layers and then a softmax output layer. We used ReLUs as activation function. The first CNN layer is a convolutional layer on which we apply Convolutional kernel of 5x5 and results an image of 32x32 pixels. This convolutional layer is then followed by another sub sampling layer that uses max pooling (with 2x2 kernel size) to shrink the image to half of its original size. Then drop out layer is applied with drop out 0.2. The second CNN layer is a convolutional layer on which we apply a Convolutional kernel of 3x3 and results an image of 16x16 pixels. This convolutional layer is then followed by another sub sampling layer that uses max pooling (with 2x2 kernel size) to shrink the image into half of its original size. Then drop out layer is applied with drop out 0.2. The third CNN layer is a convolutional layer on which we apply a Convolutional kernel of 3x3 and results an image of 8x8 pixels. This convolutional layer is then followed by another sub sampling layer that uses max pooling (with 2x2 kernel size) to shrink the image into half of its original size. Then drop out layer is applied with drop out 0.2.The fourth CNN layer is a convolutional layer on which we apply a Convolutional kernel of 3x3 and results an image of 4x4 pixels. This convolutional layer is then followed by another sub sampling layer that uses max pooling (with 2x2 kernel size) to shrink the image into half of its original size. Then drop out layer is applied with drop out 0.2.The fifth CNN layer is a convolutional layer on which we apply a Convolutional kernel of 3x3 and results an image of 2x2 pixels. This convolutional layer is then followed by another sub sampling layer that uses max pooling (with 2x2 kernel size) to shrink the image into half of its original size. Then drop out layer is applied with drop out 0.2.

B. Experiment 1: Noisy Dataset

Since the real-world images are often noisy and blur; therefore, we also tested the performance of our framework on noisy data. Table I shows the detailed dataset of noisy images. As the rickshaw class contains few images so we generated additional data for the rickshaw class to improve the imbalance ratio. Now our new data contains 96273 images.

TABLE I. Noisy Dataset

Class	Number of Images
Car	19333
Bus	18844
Truck	21142
Bike	19374
Rickshaw	15822

1) Model 1: In the first set of experiments, we took 20% of data for training to investigate the results when many images are not available for the training. So, our first split contains 19254 images in the training set. Next, we flipped our training data of 19254 images and generated new 38504 (two times the size of training data) samples through flipping because the training set was quite small as compared to the testing set that contained 80% of the images. Then we again apply the split of 34656 training images and 3848 images for validation; we got a validation accuracy of 74% and validation split accuracy of 73% and testing accuracy of 66% in this set of experiments. Since this accuracy is not good enough, we proceed to the next set of experiments.

2) Model 2: In the experiment set no 2, data is the same as used in the experiment set no 1. But this time we applied the split of 50/50. So, our split A becomes 48136/48137. Now we do not y apply any flipping and the network remains the same we use a split B of 43322 training images and 4814 images for validation. We got a validation accuracy of 75%, validation split accuracy of 76%, and testing accuracy of 62%. Through the results of the experiment set 1 and 2, we conclude that flipping yields higher accuracy on test data. This accuracy can be improved by working with higher resolution images and using a machine with higher computational power, such as a GPU (graphical processing unit) as there are too many samples for normalizing but in this paper, we are examining the results in a constrained environment with hardware constraints and low data quality. This is because the real-world images usually do not have good quality and are at times noisy. Moreover, we are also advocating the case for the importance of increasing the computational resources for better results. In our experimental study, we observed that training samples greater than 80,000 become too computationally intensive for the CPU to normalize data. For 80,000 images with 32x32 image resolution, the normalization function must perform 32x32x3*80,000 computations.

3) Model 3: In the experiment set no 3, the data used was the same as in the previous experiment. We applied a split of 30/70 which is 28881/67392 for the training/testing dataset. Next, we applied -left-right flipping on the training dataset obtaining 57762 images. We split this data again for applying validation during the classification process with a split of 51985 images for training and 5777 images for validation. In this experiment, we got a validation accuracy of 74.8%, a validation split accuracy of 74%, and testing accuracy of 63.4%. In this experiment, we notice that test accuracy is not increasing so we decided to tweak the network architecture further.

4) Model 4: In this set of experiments, data remained same as in experiment set 3 and we only changed the network architecture by adding one convolutional layer and got increased validation accuracy of 77%, validation split accuracy of 75% and testing accuracy of 67%. This motivated us to further investigate the effect of network architecture on overall classification results.

5) Model 5: In experiment set no 5, we again changed the network architecture by adding one more convolutional layer and got validation accuracy of 78%, validation split accuracy of 77% and testing accuracy of 67%. In this experiment, we noticed that adding an additional layer did not help in increasing accuracy.

Table II summarizes the experimental results obtained while running the experiments on the noisy dataset. The highest testing accuracy we obtained in these experiments is 67 percent. We can get higher accuracy through this dataset by using higher image dimensions but in this paper, we are concerned with low-resolution images and experiments with hardware constraints. The images used in this dataset were taken from Google images to cater for real world scenarios under noisy environment. Some images contain more than a single desired object in the image. For example, multiple bikes in a single image. Same for the other classes as well. At this point, we need to refine all dataset because training with such samples require higher image dimensions such as training with 96x96 images for 40,000 samples took around 2 hours.

C. *Experiment 2: Clean Dataset (32-Bit Images)*

Our data for the previous set of experiments was noisy and we cleaned the data for further experiments. We kept those images which contain a single desired object but again with a low resolution of 32x32. Table III presents the statistics of this dataset.

TABLE II. RESULTS OF CNN ON NOISY DATA

Exp. No.	Split	Flip	Training Data	Validation Acc	Testing Accuracy	F1-Score
1	20/80	Yes	96273	74%	66%	74%
2	50/50	No	96273	75%	62%	75%
3	30/70	No	96273	74.8%	63.4%	74%
4	30/70	No	96273	77%	67%	77.4%
5	30/70	No	96273	78%	67%	76.8%

TABLE III. OVERVIEW OF CLEAN DATASET (32-BIT IMAGES)

Class	Number of images for training	Number of images for testing
Car	4000	2000
Bus	3213	1999
Truck	4000	2000
Bike	4000	2000
Rickshaw	1159	400
Total images	16372	8399

1) Model 1: In experiment set no 1, we applied -left-right flipping on the training data and our data size becomes 32744 images. We trained on 31106 samples and validated on 1368 samples and got a validation accuracy of 84% and a testing accuracy of 80%. From a similar experiment on the noisy dataset, we noticed that test accuracy improves with cleaner data but the bus and rickshaw class is underrepresented. Therefore, we applied rotations for generating additional data for the next set of experiments.

2) Model 2: In experiment no. 2 on the clean dataset, our dataset contains 18690 samples when we applied flipping. We trained on 35511 and validated on 1869 samples and got a validation accuracy of 92.83% and a testing accuracy of 83%. In this experiment, we notice that accuracy further improves by generating additional data. Now in the next set of experiments, we investigate the change in results due to changes in network architecture.

3) Model 3: In this set of experiments, the data is the same as in the previous experiment. We trained on 35511 and validated 1869 samples. However, in this experiment, we changed the network architecture by increasing the filter depth and got a validation accuracy of 89% and a testing accuracy of 86.4%. Increasing filter depth improved testing accuracy. Next, we examine the effect of adding more layers on the overall classification results.

4) Model 4: In this experiment, data is again the same as in the previous experiment. We added one more convolutional layer and got a validation accuracy of 90% and a testing accuracy of 87% which is not significant. So next we add a fully connected layer to see its effect on the results.

5) Model 5: In experiment no. 5, we only added one fully connected layer and got a validation accuracy of 90.85 and a testing accuracy of 87%. The results of these experimental studies have been tabulated in Table IV.

TABLE IV. RESULTS OF CNN EXPERIMENTS ON CLEAN DATASET (32-BIT IMAGES)

Exp. No.	Rotation	Flip	Training Data	Validation Accuracy	Testing Accuracy	F1-Score
1	No	Yes	32744	84%	80%	83.3%
2	Yes	Yes	37380	92.83%	83%	92%
3	No	No	37380	89%	86.4%	89.5%
4	No	No	37380	90%	87%	90.2%

Table IV summarizes the experiments which we performed on a clean dataset of images with a resolution of 32x32. This dataset produces higher accuracy than noisy datasets because in this dataset only desired object is involved. Experiments seem to be giving fine results while using 5 convolutional layers and 4 fully connected layers. But accuracy is stuck here because the images have been downsized to 32x32 and due to this downsizing information has been lost. This motivated us for our next set of experiments with 64x64 images.

D. Experiment 4: Clean Dataset (64-Bit Images)

We performed previous experiments on 32x32 bit images that was a very low image resolution making it challenging to obtain good classification results. To further investigate the performance of CNN on images with slightly better resolution, we performed experiments with 64x64 images. Table V shows the statistics dataset of clean 64x64 images.

TABLE V. OVERVIEW OF CLEAN DATASET (964-BIT IMAGES)

Class	Number of images for training	Number of images for testing
Car	4000	2000
Bus	3213	1999
Truck	4000	2000
Bike	4000	2000
Rickshaw	1159	400
Total images	16372	8399

1) Model 1: In the first experiment set for 64-bit images, to improve the imbalance ratio, we generated some additional data for rickshaw and bus classes and now have 18690 samples. We trained on 17755 samples and validated on 935 samples and got validation accuracy 0f 88% and test accuracy of 86%. We notice that even without flipping 64x64 bit-sized training yielded high accuracy.

2) Model 2: In the experiment set 2, we took the sample size of 16372 and applied rotation; as a result, our data has now images 18690. Next, we apply after flipping and the data now has 37380 images. We trained on 35511 and validated in 1869 and we got a validation accuracy of 92% and a test accuracy of 88%. After this experiment, we observed that flipping the training data improved the accuracy by 2%.

3) Model 3: In experiment no. 3, we changed the convolutional architecture by just adding one more convolutional layer. By changing the architecture, we got a validation accuracy of 93% and a test accuracy of 89% and observed a slight improvement in the results. Next, we investigate the effect of modifying the network architecture a bit further.

4) Model 4: In this experiment set, we changed the convolutional architecture by adding a fully connected layer and got a validation accuracy of 93% and a test accuracy of 90%.

Table VI summarizes the results of experiments that we performed on the clean dataset with the dimension of 64x64. By using 64x64 dimension images, we get 90% accuracy which is higher than for those 32-bit images and noisy images as evident from Tab. 2, 4 and 6. We can safely claim that we can get higher efficiency with our architecture if we work with higher resolution images and better computer power like GPU. However, in this paper, we are investigating the case of real-world noisy images and low-resolution images with hardware constraint; therefore, we did not perform experiments with better resolution, say images with 256x256 resolution.

TABLE VI. RESULTS OF CNN EXPERIMENTS ON CLEAN DATASET (64-BIT IMAGES)

Exp. No.	Rotation	Flip	Training Data	Validation Accuracy	Testing Accuracy	F1-Score
1	Yes	No	18690	88%	86%	88.5%
2	Yes	Yes	37380	92%	88%	91.5%
3	No	No	37380	93%	89%	93.7%

E. Discussion

In the proposed work, different sets are experiments are performed for both noisy and clean images dataset. The reason for doing number of experiments for both the cases is to go through different combinations, data splits and see the impact on performance. The experiments conducted on noisy images dataset explored the impact of different settings and conditions on the accuracy of classification in image processing. The findings revealed that using a smaller portion of the data for training resulted in lower accuracy, emphasizing the need for sufficient training data. Flipping techniques were applied to augment the training data, leading to improved accuracy in some cases. The importance of factors such as image resolution, computational resources, and network architecture were highlighted, with suggestions for further optimization. Overall, the experiments demonstrated the significance of data augmentation, hardware capabilities, and network design in achieving higher accuracy in image classification tasks. Similarly, the findings deducted from experiments performed on clean dataset with 32-bit images concluded that data augmentation techniques, such as flipping and rotations, led to improved accuracy in image classification tasks. Experiment set 1 demonstrated that left-right flipping resulted in a validation accuracy of 84% and testing accuracy of 80%. Further experiments on clean datasets (experiment set 2) showed that additional data generation through flipping enhanced accuracy, with a validation accuracy of 92.83% and testing accuracy of 83%. Changes in network architecture (experiment set 3) by increasing the filter depth led to improved testing accuracy of 86.4%. Subsequent experiments involving the addition of more layers (experiment set 4) and a fully connected layer (experiment set 5) yielded validation accuracies of 90% and 90.85%, respectively, contributing to marginal improvements in testing accuracy. These findings highlight the significance of data augmentation and network architecture modifications in enhancing the classification results of image processing models.

In case of experiment performed on clean dataset with 64-bit images, the conducted experiments revealed interesting findings in image classification tasks. In experiment set 1, the training of 64-bit images without flipping resulted in high accuracy, with a validation accuracy of 88% and test accuracy of 86%. Experiment set 2 demonstrated the benefits of data augmentation through flipping and rotation, leading to an increased sample size and improved accuracy of 92% in validation and 88% in testing. Further modifications in the convolutional architecture, specifically adding one more convolutional layer (experiment set 3), contributed to a slight improvement in accuracy, with a validation accuracy of 93% and test accuracy of 89%. Finally, in experiment set 4, the addition of a fully connected layer resulted in a validation accuracy of 93% and test accuracy of 90%. These findings emphasize the importance of data augmentation and architectural adjustments in enhancing the performance of image classification models.

For comparison purposes, we also ran the experiments using other classifiers such as SVM, Naïve Bayes, and Decision trees on 64-bit images. Table VII lists the results of these experiments. Along with the results represent the dataset which we use for comparative analysis. In this comparison, we compare our result with other machine learning algorithms. For the dataset which gives higher accuracy in CNN, we take that dataset and compute result in SVM, Naïve Bayes and Decision tree.

TABLE VII. PERFORMANCE COMPARISON WITH OTHER CLASSIFIERS

Experiment	**Cell per Block**	**Pixel per cell**	**Feature Vector size**	**Validation Accuracy**	**Test Accuracy**
SVM	2	8	1764	82.9%	83.39%
Naïve Bayes	2	8	1764	71.39%	69.6%
Decision Tree	2	8	1764	50%	50.67%
VGG-16	-	-	1764	56%	55.97%
ResNet-50	-	-	1764	64%	68.52%

We also present the comparison of the performance of CNN with other classifiers: SVM, Decision Tree, and Naïve Bayes in Fig. 4. It is evident from this figure that our convolutional neural network achieves highest accuracy in comparison to other machine learning algorithms. CNN attains 90% accuracy while using 5 convolutional layers and 4 fully connected layers. The results are very conclusive, and CNN shows the highest accuracy rate in comparison to other classifiers.

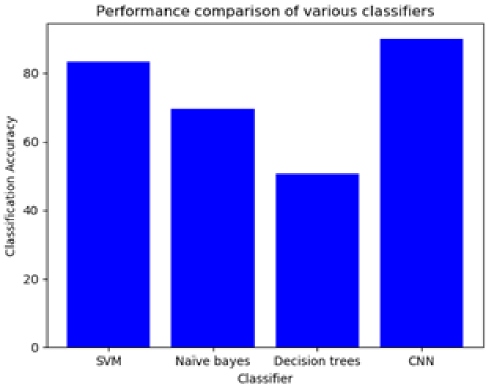

Fig. 4. Comparison of proposed model with other classifiers.

Although our technique has a unique characteristic of working under constrained environment, comparing it with deep learning-based vehicle-type classification techniques like [34] (proposed by Wang et al.) shows that our technique gives better results as compared to 65.55% accuracy of their work. However, the advantage of [34] over our proposed technique is that the technique of Wang et al. can be used to classify similar vehicles (for instance, cars only) as well. While on the other hand, we considered different types of vehicles like cars, bikes, buses etc.

Table VIII shows the comparison of the proposed with some of the latest works on same domain using similar approaches. The proposed models outperform the existing works in terms of accuracy.

TABLE VIII. COMPARISON OF PROPOSED MODEL WITH PREVIOUS WORKS

References	**Years**	**Accuracy**
[44]	2020	89.50%
[34]	2021	65.55%
[43]	2021	77.55%
[45]	2023	77%
Proposed	2022	**90.85%**

V. LIMITATIONS AND FUTURE WORK

Several limitations are there that effect the streamline vehicle image classification using deep learning mechanisms. One limitation is that the current work was trained and tested on 32-bit and 64-bit datasets, which may restrict the model's efficiency. To address this, the researchers suggest training the model using a higher resolution dataset, such as 256x256 bits, which could lead to improved results. However, they acknowledge hardware constraints and propose the use of GPU clusters for training on larger datasets and more complex neural networks. Gathering more samples from different vehicle classes is also identified as a way to enhance the results and expand the scope of the study. In the future, the researchers aim to overcome these hardware and software limitations to achieve higher accuracy. Additionally, they suggest extending the work by considering vehicle images captured under poor lighting conditions or adverse weather situations. By addressing these limitations, such as utilizing higher-resolution datasets, overcoming hardware constraints, and expanding the dataset size, the researchers anticipate achieving improved accuracy and broader applicability of the classification technique in the future.

VI. CONCLUSION

Data is the most important asset. To explore and extract useful information from this data, the data is also shared with several stake holders via diverse channels. Hence ownership protection of such datasets is very essential. We provide ownership protection systems through watermarking technique. After ownership protection of the data, we have presented an image-based vehicle classification technique from vehicle images by using a supervised learning convolutional neural network. The vehicle image is taken to the network as an input and the network outputs the vehicle class to which the vehicle belongs. For the vehicle classification, we have established our own CNN architecture and compared these CNN results with furthermore machine learning algorithms like Naïve Bayes, SVM and Decision Tree. As the images are taken from Google, we contribute ownership protection to prove the ownership of the data. For this we insert a watermark in our dataset. Binary bits of URL of the images are used as the secret information of ownership. Every image used in our project may lead towards the path where it has been taken from. One limitation of current work is that we trained and tested on 32 bit and 64-bit datasets. In our work we have some hardware constraints. If we trained our model by using 256x256 bit dataset we may lead towards higher efficiency. For much better results GPU clusters are needed to train on large datasets and higher dimensions and deeper neural networks. If we gather more samples from different classes, we can improve our results and increase our scope. In future we are considering coping with all these hardware and software limitations for much better accuracy. Further work can be done by using vehicle images on poor lightning condition or bad weather situations.

ACKNOWLEDGMENT

The authors extend their appreciation to the Deputyship for Research & Innovation, Ministry of Education in Saudi Arabia for funding this research work through the project number MoE-IF-20-07.

Abstract—**Malaria disease mostly affects children and causes death every year. Multiple factors of the disease due to failure in treatment, including anti-malaria drug resistance. The resistance is caused by a decrease in the efficacy of the drug against Plasmodium parasites. Therefore, we proposed a computational approach using deep learning methods to predict anti-malarial drug resistance based on genetic variants of the Plasmodium falciparum through DNA barcoding. The DNA Barcode, organism identification from Plasmodium, is employed as data set for predicting the anti-malaria drug resistance. As a univariate amino acid sequence, it is transformed to numerical value data for building classifier model. It is constructed into a classifier model for prediction using Bidirectional Long Term-Short Memory (Bi-LSTM). This algorithm is extended from LSTM by two directions. In the first stage, the sequence is encoded into numerical data as input data for the method using sigmoid activation loss function. Then binary cross entropy is addressed to define the class, resistance or sensitivity. The final stage is applied by tuning hyper-parameter using Adaptive Moment Estimation optimizer to get the best performance. The experimental results show that Bi-LSTM as the proposed method achieves high performance for resistance prediction including precision, recall, and f1-score.**

Keywords—Drug resistant; plasmodium falciparum; Bi-LSTM; deep learning

I. Introduction

Malaria is a type of infectious disease that is transmitted through mosquito bites or through blood transfusions. This type of disease exists in countries with tropical climates, including Indonesia. Various efforts have been made to reduce the number of deaths from this disease with intensive treatment. One of the causes of this high case is resistance to anti-malarial drugs against the plasmodium parasite. As it is known that the types of anti-malarial drugs are classified as antibiotics, so an appropriate regulation is needed. The development of efficient malaria vaccines is hampered by the inclusion of information about the huge number of genetic variants of this parasite, as many of these alleles avoid the allele-specific immunity elicited by vaccines. Potential vaccine candidate are merozoite proteins 1 and 2 (msp1 and msp2) and glutamate-rich protein from P. falciparum [1]. Resistance of the parasite Plasmodium falciparum to anti-malarial drugs is one of the causes of the high mortality rate in endemic areas.

One of the main causes is a mutation in the gene of the parasite, so that the drug is not right on the target region. Some genes are mutated in the anti-malarial drug Chloroquine (CQ) to the duplication of Mefloquine, it affected the Plasmodium to survive in the host’s body. Several studies related to drug resistance were carried out both in-vivo and in-vitro to in-silico using the bioinformatics method approach to find the characteristics of these parasites. Molecular biology research was carried out in the wet lab to determine the level of polymorphism of the anti-malarial treatment target genes [2], [3]. Furthermore, based on a sufficiently high volume data set, research using a computational approach was conducted, how it is limited to image data (haploid), clinical data, and chemical data analysis to DNA sequence data (genetic variants) using machine learning algorithms [1], [4]–[8]. Therefore, we proposed to conduct research on study of genetic variant analysis against plasmodium parasite resistance in target genes, including the first transporter gene (Pfmsp-1) and second transporter (Pfmsp-1), as well as *Pfglurp* on the anti-malarial drug CQ with a computational approach using the deep learning method. Genetic variants are DNA sequence data from parasites that undergo mutations categorized as time series data. Long Term Sort Memory (LSTM) is a robust deep learning method for time series data. However, the right combination of hyper-parameters from this algorithm affects the performance. Then, this research aims to develop Bi-LSTM algorithm using tuning parameters to purpose a high level of performance.

II. Material and Method

A. Drug Resistance of Anti-Malaria

Treatment of malaria is through drug therapy which aims to eliminate the plasmodium parasite in the host’s body. However, the resistance of the parasite *plasmodium* falciparum to anti-folate resulted in the sequential acquisition of *mutations* in the target gene as shown in Fig. 1. The high mutation rate of this type of Plasmodium parasite species causes resistance, so a combination of anti-malarial drugs is carried out. Including efforts for possible immunity of malaria parasites to anti-malarial drugs, WHO has advised the use of an approved combination of artemisinin, Artemisinin Combination Therapy (ACT) [9].

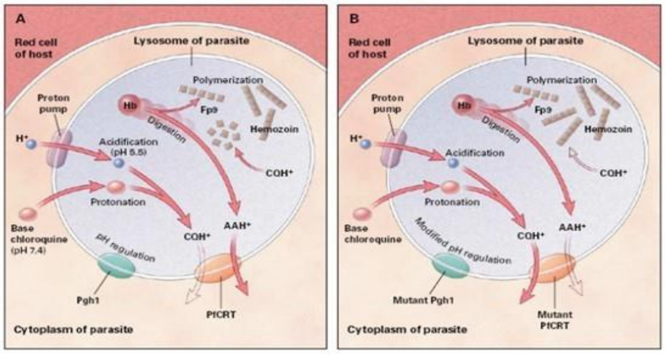

Fig. 1. Illustration of resistance of plasmodium parasite to anti-malarialdrug CQ [9].

B. DNA Barcoding

DNA barcoding is a strategy to recognize and to give auto-validation for living beings. It has a specific region, and the length of the sequence is between 300 and 400 bps. A method for automatically identifying and validating living things is DNA barcoding. The sequence has a specific region and a length between 300 and 400 bps. According to Li, et al. (2018), the barcoding-based protein measuring approach converts protein signals into barcoded oligo probes and amplifies the signals with nucleic acid amplification to achieve ultrasensitive detection down to the single molecule level [10]. With this technique, it is possible to identify rare tumor cells or cancer cells with low abundance surface markers [11]. The Weissleder group developed photo-cleavable DNA- barcoded antibodies that are specifically capable of recognizing multiplexed cell biomarkers [10]. After that, DNA has been cleaved by light (less than 365 nm) and released into solution; gel electrophoresis can be used to analyze it. They also came up with an amplification-free method to profile more than 90 proteins in single cells using DNA-barcoded antibodies and Nano String’s fluorescent readout [12] to study the drug response pathway and inter- and intra-tumor heterogeneity in clinical samples [12], [13]. DNA barcoding can be used to study the resistance of Plasmodium parasites to various anti-malaria drugs. Here are a few examples:

1) Chloroquine was once the most widely used anti-malaria drug, but its effectiveness has been greatly reduced by the emergence of chloroquine-resistant Plasmodium falciparum parasites. DNA barcoding can be used to identify mutations in the parasite’s Pfcrt gene that are associated to chloroquine resistance.

2) Artemisinin and its derivatives are currently the most effective anti-malaria drugs, but artemisinin-resistant parasites have emerged in Southeast Asia. DNA barcoding can be used to identify mutations in the parasite’s K13 gene that are associated with artemisinin resistance.

3) Sulfoxide-pyrimethamine is a combination drug that is used to treat malaria and is also used for intermittent preventive treatment in pregnant women. Resistance to sulfoxide-pyrimethamine is common in many parts of the world. DNA barcoding can be used to identify mutations in the parasite’s *Dhfr* and *Dhps* genes that are associated with sulfoxide-pyrimethamine resistance.

C. Machine Learning

Machine learning is a way of learning from data that has been set up in a way that is supervised or directed. This means that a set of instructions is given to the machine learning algorithm, telling it what to look for and how to interpret it. Unsupervised learning is when the machine learning algorithm is left to its own devices, without any specific instructions. In machine learning, we use supervised learning to learn how to map input (X) to output (Y). This is done by having a set of input values and a set of output values and using algorithms to find a function that can map the input to the output. We want to be able to predict the output variable for given input data. In supervised learning, we give the machine lots of data that tells it what to do. With unsupervised learning, we just give the machine data [14].

The unsupervised learning method is used to model the underlying structure or distribution in the data so that it can be studied more closely [15]. In this research, we propose and evaluate the supervised method, such as KNN, Naïve Bayes, SVM, Random Forest, and advanced machine learning (deep learning) using LSTM and Bidirectional LSTM (Bi-LSTM).

D. Deep Learning

Deep learning is an enhanced artificial neural network (ANN) method with multiple-hidden layers. In principle, deep learning is a neural network with three or more layers of ANN, enabling it to learn and adapt to large amounts of data and to solve various problems that are difficult to solve by other machine learning algorithms [16]. As illustration, the architecture of deep learning is shown in Fig. 2.

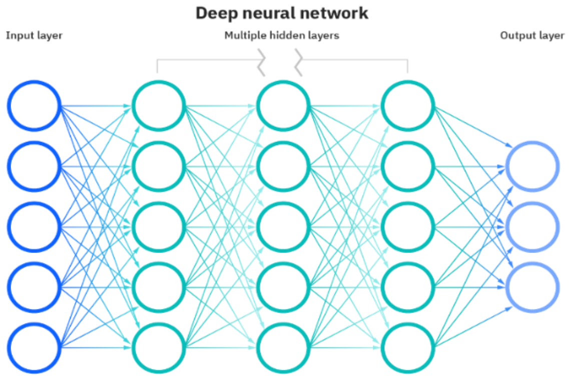

Fig. 2. Deep learning architecture [16].

Deep learning consists of several artificial neural networks that relate to each other. Some types of algorithms in deep learning including Convolution Neural Network (CNN), Recurrent Neural Network (RNN), and Self-Organizing Map (SOM),

1) Recurrent neural network: Recurrent Neural Network (RNN) is a neural network model which uses loops in its internal memory to solve sequential data problems [17]. The architecture of the RNN can be seen in Fig. 3.

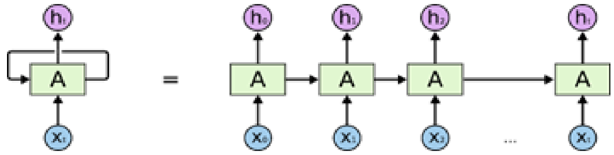

Fig. 3. The architecture of recurrent neural network.

Based on this architecture, each hidden layer of the RNN will receive input to the form of a vector denoted as Equation 1.

$$h_t = \sigma(W_{xh} + W_{hh}h_{t-1} + b_h) \qquad (1)$$

where, W_{xh} is the weight matrix from the input to the hidden layer; W_{hh} is the weight matrix between two hidden states; b_h is a bias vector of hidden layer; σ_h is an activation function for getting hidden state. After getting the value h_t, then thenext process is to find Y_T as in Equation 2.

$$Y_t = \alpha_h\left(W_{hy}h_t + b_y\right) \qquad (2)$$

where W_{hy} is weight matrix of hidden layer into output layer; by is bias vector of output layer; σyis activation function of output layer.

2) Long Short-Term Memory (LSTM): Long Short-Term Memory is one of the Recurrent Neural Network (RNN) architectures created to handle the problem of gradients that disappear during the back-propagation process [17]. LSTMs are special types of neural networks that can remember things for a long time. Each memory cell stores information by using an input gate (which lets in new information), a forget gate (which helps to forget old information), and an output gate (which sends out the stored information). The forget gate helps to forget things from the past, the input gate helps you transfer information into the cell, and the output gate helps you create new memories in the long term [18]. The input to the LSTM is a sequence of numbers*(x_1,x_2,…,x_t)*. The output is a sequence of numbers (y_1, y_2,…,y_n). To find out how many forget gates there are, we use Equation 3. This equation tells the frequency of output will change in a particular gate.

$$f_t = \sigma\left(W_f * [h_{t-1}, x_t] + b_f\right) \qquad (3)$$

3) Bidirectional Long Short Term-Memory (Bi-LSTM): Bidirectional Long Short-Term Memory is the LSTM method with two directions- a forward layer to remember information and a backward layer to remember how information was learned - to make it more efficient [19]. LSTMs are better at handling situations where the gradient of a neural network's activation changes slowly over time, like in language processing. However, LSTMs only work with information from the past [20]. To fix this problem, the LSTM architecture needs to be changed so that it includes a forward LSTM layer and a backward LSTM layer. This will help the machine learn what happened in the past and make predictions for the future. As illustration of the architecture is shown in Fig. 4.

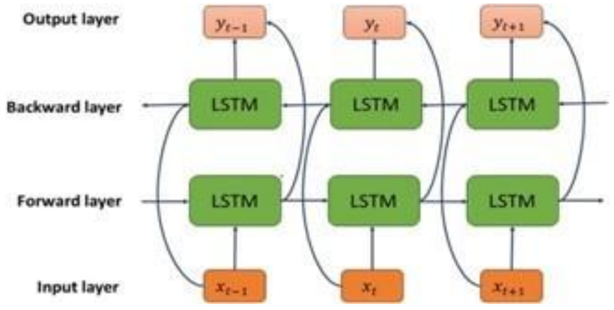

Fig. 4. Architecture of Bi-LSTM.

According to Cui et al.(2022), the forward layer's output *(h_f*) is calculated using the forward input starting at 1 – T, while the backward layer's output (h_b) is calculated using the inverse of the backward layer's input, namely T – 1 [21]. The gate that contains a Forward layer and a retrogressive layer can be refreshed involving a similar condition as a conventional LSTM. In the hidden state section of BiLSTM, the t-the data contains both the hidden state forward layer and the hidden state backward layer. This is the primary distinction. The equation can be used to combine BiLSTM hidden state.

$$h_t = f\left(h_{tf}, h_{th}\right) \qquad (4)$$

where htf is the hidden state of the forward layer, htb is the hidden state of the backward layer, and f is a function to combine the output of the hidden state forward layer and backward layer. The function f can be a concatenating function, a summation function, an average function, or a multiplication function.

E. Optimizer

An optimizer is an algorithm that helps to find the lowest possible global value for the convergence of a loss function in a neural network [17]. An optimizer can be used to find the best values for the model's parameters [22]. This helps to improve the model's accuracy. The optimizer can also help to reduce the model's error value. Adaptive learning methods like Adam help us estimate how well we're doing during a learning task. Adam is an optimization of an existing, effective stochastic algorithm that doesn't require a lot of memory. Its streamlining agent calculation is planned by joining the strengths of the other two enhancers, Adagrad and RMSprop.

1) Adaptive Moment Estimation (Adam): Adaptive Moment Estimation (Adam) is one of the methods adaptive learning [18]. Adam is an optimization of an efficient stochastic algorithm that only requires a first order gradient where the memory required is very little [23]. Adam's optimizer algorithm is designed by combining the advantage of the other two optimizers, Adagrad, which has performance pretty good with sparse gradients and RMSprop which works well at times solve non-stationary problems. Updating the weights on the optimizer Adam can be seen in Equation 5 to Equation 7.

$$V_t = \beta_t * V_{t-1} - (1 - \beta_1) * g_t \qquad (5)$$

$$s_t = \beta_2 * s_{t-1} - (1 - \beta_2) * g_t^2 \qquad (6)$$

$$W_{new} = W_{old} - \propto \frac{v_t}{\sqrt{s_t + \varepsilon}} * g_t \tag{7}$$

2) Stochastic Gradient Descent (SGD): Stochastic gradient descent is a way of finding the smallest possible error in a calculation. It begins by making small changes to the current value and then checking to see if the error has decreased [22]. If it has, the algorithm keeps making smaller changes until the error decreases no further. The SGD optimizer updates the weight of a model as in Equation 8.

$$w_{new} = w_{old} - (\alpha * g_t) \tag{8}$$

where gt is the gradient of the t time step, w is weight, and α is the learning rate.

III. The Proposed Research Method

In general, this research is applied using Bi-LSTM as shown in Fig. 5. It was started by collecting DNA barcode data from several falciparum parasite DNA barcode sequences for anti-malarial drug resistance at Malaria GEN sites, including Artemisinin, Piperaquine, DHA-PPQ, Chloroquine, Pyrimethamine, Sulfadoxine, and S-P. The various drugs are comparable to the anti-malaria drug data set with any possibility misuse in regulation by patients. The drugs are composed in the type of antibiotic. The resistance prediction study includes preprocessing data, determining input data, developing the RNN method (Bi-LSTM algorithm), tuning parameters to optimize the Bi-LSTM method, and evaluating performance through measuring accuracy, precision, recall, and f1-score**.**

We used seven different datasets of drug with two classes, namely resistant and sensitive as shown in Table I. The data set is taken from MalariaGEN Plasmodium Falciparum Community Project which analyzed 7,113 parasite samples obtained at 73 different sites in Africa, Asia, America, and Oceania to generate genotyping data.

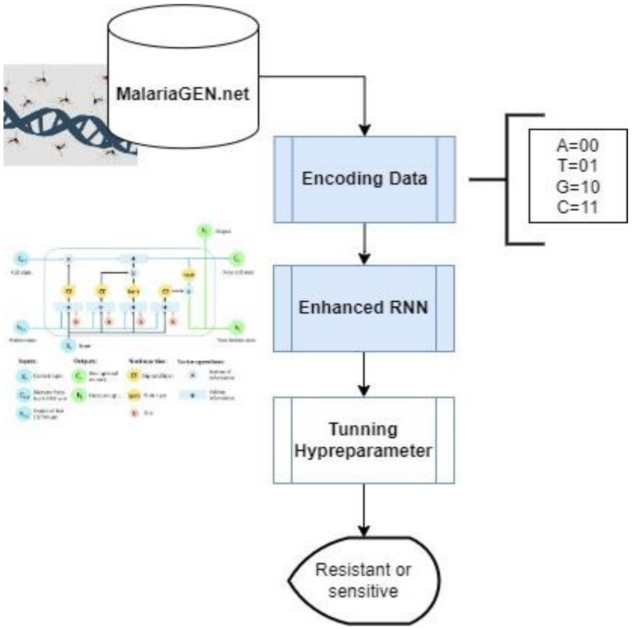

Fig. 5. Concept diagram of drug-anti-malaria resistance prediction.

TABLE I. Data Sets

Drugname	Resistant	Sensitive
Artemisinin	3176	3787
Piperaquine	2141	1297
DHA-PPQ	1889	4154
Chloroquine	6402	430
Pyrimethamine	7378	120
Sulfoxidess	5967	1412
S-P	4553	1729

By parsing the dataset, we got the DNA-barcode sequence as shown in Fig. 6. The barcode sequence represents more than 100 nucleotides in each sample of plasmodium.

Fig. 6. The sample of DNA barcode sequences.

The stages of the proposed method are shown in Fig. 7. The design of an algorithm for predicting anti-malarial drug resistance against the plasmodium falciparum parasite is carried out by incorporating the DNA barcode sequence dataset into the model architecture. Before data sequence is entered, the dataset is encoded first in the stage preprocessing by splitting the dataset into training data and test data and perform encoding. The next step is the forming process architecture using the LSTM algorithm. Then, it is performed training model as well as the model validation process that has been formed to be carried out. After the model was trained, it was tested to evaluate the performance of the model in classifying drug resistance.

IV. Result and Discussion

Anti-malaria drug is a kind of antibiotic drug. Patient non-compliance in the use of anti-biotic drugs has an impact on resistance to pathogens in infecting a person's body. Many studies of drug resistant for anti-malaria were conducted and various attempts have been made to treat this disease [11]. DNA barcoding can be used to study the resistance of anti-malaria drugs. DNA barcoding is a technique that involves sequencing a short, standardized region of DNA from a particular organism. In the case of malaria, DNA barcoding can be used to recognize the specific species of the malaria parasite present in a patient's blood [24].

The genetic sequence of the malaria parasite: It provided information about its susceptibility to different anti- malaria drugs. Mutations in the parasite's DNA can result in resistance to certain drugs, and DNA barcoding can be used detect these mutations. In addition to identifying resistance to specific drugs, DNA barcoding can also be used to monitor the spread of drug-resistant malaria parasites. By sequencing the DNA of malaria parasites from different regions, researchers can track the movement of drug-resistant parasites and identify areas where resistance is becoming more prevalent. Overall, DNA barcoding is a valuable tool for studying the resistance of anti-malaria drugs and developing strategies to combat drug-resistant malaria. The attribute values distribution of data set is plotted into boxplot as shown in Fig. 8. The graph shows that the variation in attribute values is distributed in the range between 1 and 7 and the first to third quartiles are described. The presence of a vertical line through this plotted box corresponds to the median distribution of the partial data. The boxplot is illustration of statistical analysis for data distribution [25]. They are range value of DNA-barcode sequences after encoding in numerical values.

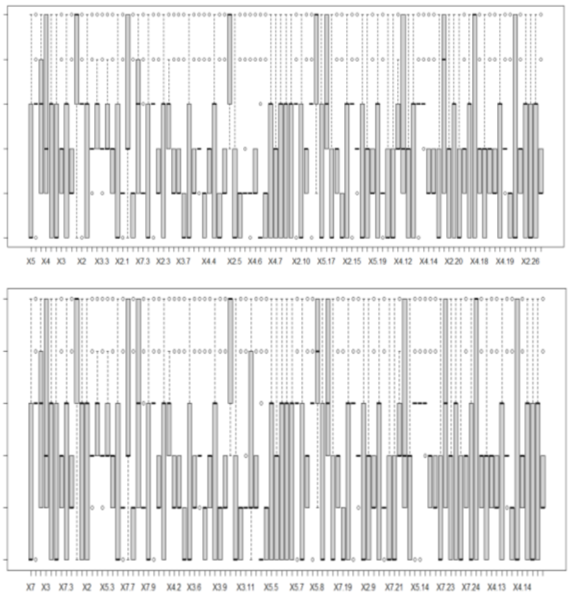

Fig. 8. Boxplot of encoding barcode DNA sequence dataset distribution for training and testing data.

This research is developed using the Python programming language, and Google Collaboratory as a Python text editor. We assessed the grouping model by ascertaining accuracy, precision, recall, and the F1-score to determine the quality of result. The number of detections is True Positive (TP), False Negative (FN), False Positive (FP), and True Negative (TN) was calculated as follows to calculate these measurements. The number of tests (drug resistance accurately) is TP. The number of tests incorrectly identified a drug resistance is called FP. The number of tests that were incorrectly classified as sensitive is referred to in FN. Then again, TN is the degree of tests that were precisely settled to be solid. Additionally, a five k-fold cross-validation method was utilized to ensure the quality of the classification model for detection.

As a measure of correctness, accuracy is defined as the ratio of the number of corrected forecasts to the total number of forecasts, as shown in Equation (9). By then, the pace of positive conjectures that are exact is referred to as precision as in Equation (10). As shown in Equation (11), Recall is the total number of positive cases that the classifier correctly anticipated based on all the information. Sometimes it's referred to as affect ability. The F1-score is the final performance metric. A degree that combines review and precision could be the score as shown in Equation (12) [26].

$$accuracy = \frac{TP+TN}{TP+TN+FP+FN} \tag{9}$$

$$precision = \frac{TP}{TP+FN} \tag{10}$$

$$recall = \frac{TN}{TN+FP} \tag{11}$$

$$f1 - score = 2 \times \frac{precision \times recall}{precision + recall} \tag{12}$$

The representative machine learning methods including *K-Nearest Neighbor*, *Naive Bayes*, *SVM*, *Decision Tree*, and the deep learning methods including, *RNN*, *LSTM*, and *Bi-LSTM* are used to evaluate the performance measures including *accuracy*, *precision*, *recall*, and f 1-*score*. The performance results for each algorithm described into the heat map in Fig. 9. All methods have high performances evaluation for two kinds of anti-malaria, such as Dha-Ppq, and Piperaquine. However, the conventional machine learning methods have low in unbalanced class of data sets. The distribution of class in each data set can be seen in Fig. 10.

Based on the experimental results, we can see that most of the classic machines learning models have low performance rates in unbalanced class distribution as shown in Table II and Table III. A classifier whose score is less than 0.5 has a high proportion of false negatives. It can be caused by an imbalanced class or the number data in each class is imbalanced. It means that classic machine learning model can't overcome imbalanced class problem like deep learning. The over-sampling or under-sampling strategy, we attempt to change the amount of the minor class to obtain a balanced proportion for both classes. A potential solution may help to resolve the imbalanced class problem for the traditional machine learning model Random Over-sampling, Synthetic Minority Oversampling Technique (SMOTE), Adaptive Synthetic Sampling (ADASYN), Random Under-sampling, etc. are some over-sampling and under-sampling techniques that are frequently utilized. Another solution that we can try is to give higher weight to the minor class. A class has higher weight than the other class [27]. By adjusting the cost function of the model, class weighting ensures the misclassified observations. The minority class tends to decide the majority class. By rebalancing the class distribution, this strategy can assist in enhancing the model's accuracy.

Furthermore, the high-performance scores were obtained for the Bi-LSTM algorithm under various data conditions (balanced or unbalanced) when compared to the other deep learning methods. In Table IV, the performance of Bi-LSTM for Artemisinin data set with balanced class distribution, can provide consistent and reliable results. Even though the conventional machine learning algorithms achieved higher performance than Bi-LSTM method due to it also influenced by several factors such as the size of the training data, the number of layers and neurons in the network, the type of activation function used, and the parameter tuning performed. Therefore, it is important to conduct a thorough evaluation and determine optimal parameters for each case of Bi-LSTM. The proposed method is applied to various optimizers and various numbers of hidden layers. By tuning hyper-parameter is addressed to improve classifier model for prediction [28]. Then, the lowest error rate is achieved at Adam optimizer with 32 hidden layers as shown in Table V.

Cross entropy is a loss function that serves to measure performance of the classification model. The cross Entropy will increase if probability predictions increasingly deviate from the actual class. The lower the cross-value entropy, the better is the model [29]. The value of the loss function appears to be homogeneous in deep learning algorithms including Bi-LSTM and LSTM as shown in the Fig. 11, Fig. 12, and Fig. 13.

Furthermore, the computational time of deep learning method is higher than the classical machine learning method due to complexity in classifier model as shown in Fig. 14. The Bi-LSTM algorithm is the highest computational time.

V. Conclusion

Predicting anti-malaria drug resistant based on DNA-Barcode sequences using Bi-LSTM method achieved high performance, especially for recall, and f1-score. However, the Bi-LSTM classification model requires a high computational time. Another lack of the proposed method is dependence on setting hyper-parameter of the method. Therefore, it is necessary to develop the tuning parameter to reduce the epoch of computational time for learning during the classifier model using training data.

Acknowledgment

This work was financially supported in part by the Faculty of Computer Science, Brawijaya University through a Grant of Doctoral Associate Professor "HDLK 2022" under contract number 2126/UN10.F15/PN/2022. Therefore, we are grateful for this funding and support of this research.

Computer Science Department, University of Oum El Bouaghi, Oum El Bouaghi, Algeria[2]

***Abstract*—Developing trust in cyber-physical systems (CPSs) is a challenging task. Trust in CPS is needed for carrying out their intended duties and is reasonably safe from misuse and intrusion; it also enforces the applicable security policy. As an example, medical smart devices, many researches have found that trust is a key factor in explaining the relationship between individual beliefs about technological attributes and their acceptance behavior; and have associated medical device failures with severe patient injuries and deaths. The cyber-physical system is considered a trust system if the principles of security and safety, confidentiality, integrity, availability, and other attributes are assured. However, a lack of sufficient analysis of such systems, as well as appropriate explanation of relevant trust assumptions, may result in systems that fail to completely realize their functionality. The existing research does not provide suitable guidance for a systematic procedure or modeling language to support such trust-based analysis. The most pressing difficulties are achieving trust by design in CPS and systematically incorporating trust engineering into system development from the start of the system life cycle. Still, there is a need for a strategy or standard model to aid in the creation of a safe, secure, and trustworthy CPS. Model-based system engineering (MBSE) approaches for trust cyber-physical systems are a means to address system trustworthiness design challenges. This work proposes a practical and efficient MBSE method for constructing trust CPS, which provides guidance for the process of trustworthiness analysis. The SysML-based profile is supplied, together with recommendations on which approach is required at each process phase. The MBSE method is proven by expanding the autonomous car SysML and UML diagrams, and we show how trust considerations are integrated into the system development life cycle.**

Keywords—Cyber Physical Systems (CPSs); trust CPS; system engineering (SE); model-based system engineering (MBSE); SysML

I. INTRODUCTION

The emergence of cyber-physical systems (CPSs) has an impact on people's lives and is used in health care, smart homes, commerce, and other areas. Engineering CPS necessitates a combination of approaches from several fields (mechanical, electrical, biological, etc.)[1] and computer science methods.

The cyber-physical system is considered a trust system if the principles of security and safety, confidentiality, integrity, availability, and other attributes are ensured. They defined trust in [2] as a measure of confidence or belief that the other party will refrain from opportunistic behavior and behave in an expected manner. The faith CPS is a system that meets a set of requirements and obligatory attributes that ensure the trustworthiness of CPS [3].

Inattention to trustworthiness can result in the loss of human life, long-term environmental implications, the disruption of essential infrastructure, or other catastrophic consequences such as the revelation of sensitive data, the destruction of equipment, economic loss, and reputational harm. These dangers and negative outcomes become more severe as industries become more networked and integrated.

In the literature, many directions are suggested for modeling trust in systems. However, does not provide suitable instructions for a systematic methodology or an acceptable modeling language to support such trust-based analysis. The most significant problems are achieving trust by design in CPS and systematically incorporating trust engineering into system development from the start of the system life cycle.

According to [4], a user-centered holistic technique is described for analyzing trust as the system is being developed. The process consists of five steps (the scenarios, trust analysis, peer review, scenarios refinement, guiding the design). Other lines of research target improving system trustworthiness in terms of security. They consider trust an enabler of security, and security services rely to a great extent on some notion of trust [5]. In [6], a trust case is presented with a complete and explicit argument for trust in the system under development in terms of security and safety. They used the Claim Definition Language (CDL). For trustworthy computing [7], it employs the Security Development Lifecycle (SDL) for the development of software that must withstand attacks. UMLsec [8] is a Unified Modeling Language (UML) extension and it is a UML profile that allows designers to define security features on design models. To establish the security requirements and assumptions on the system's environment, typical UML extension techniques in the form of labels, such as stereotypes and tags, are used. Trust cases that focus on the security and safety of the system are described in [6], excluding additional trust attributes such as privacy and usability, and it enables the identification of the components that are engaged in trust assumptions.

The specific challenges and limitations of existing research are about identifying trust concerns and requirements that may apply to many parties, as well as focusing purely on security quality and viewing trust as an enabler of security and security services while being unconcerned about the remaining trust attributes; furthermore, selecting modeling approaches that can handle the complexity of trust in CPS.

Not defining a cyber-physical system's tasks. Not specifying the exact characteristics of trust in CPS. Not defining the targets of the actors and participants in the CPS, including developers, users, and potential customers. Not defining goals, especially business goals. The unpredictability of the behavior of the system component, all those are the major challenges to the development of trust in cyber-physical systems, particularly during the modeling stage.

In this work, we examine specific strategies, models, and tools that encompass design activities and preparation for modeling the trustworthiness of CPSs, as well as how these techniques can be expressed in Unified Modeling Language (UML) and SysML models. The MBSE approach and phases are discussed. By applying the autonomous vehicle SysML and UML diagrams, the MBSE method is validated.

The rest of the paper is organized as follows: Section II presents the contribution and research methodology. Model based system engineering (MBSE) is discussed in Section III. Proposed MBSE Trust CPS Method is introduced in Section IV. Discussion is given in Section V. We conclude the paper in Section VI.

II. Contribution and Methodology

This work aims to:

- Analyze specific approaches, models, and tools pertaining to design processes and preparation for modeling the trustworthiness of CPS.
- Create a viable and efficient MBSE method for developing secure systems while adhering to trust constraints.

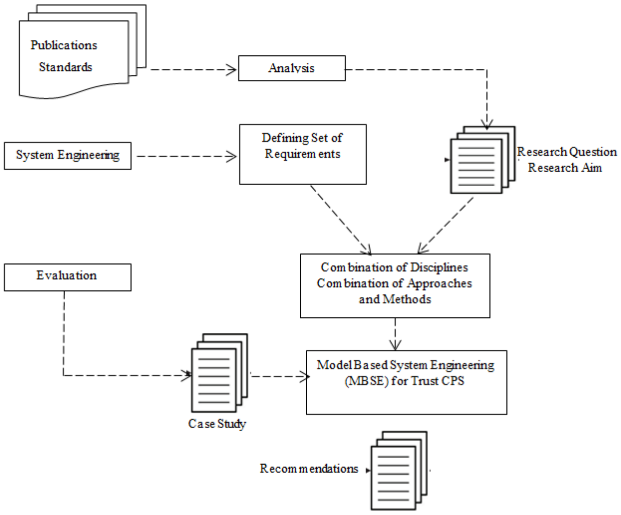

Fig. 1. Research methodology.

- Ensure the system's trustworthiness characteristics are created in accordance with end-user trust requirements.

Research Question:

RQ1- How Infusing trust attributes in CPS into systems engineering practice to decrease the complexity and increase the quality and trustworthiness of CPS?

RQ2- What are the methods and tools shall be used for modeling trust CPS?

Our methodology was based on the analysis of fund papers from publications and standards and the definition of requirements and mandatory attributes using system engineering and requirements approaches. Model-Based System Engineering (MBSE) for Trust CPS is a combination of disciplines and approaches, and methods. In Fig. 1, the research method is displayed.

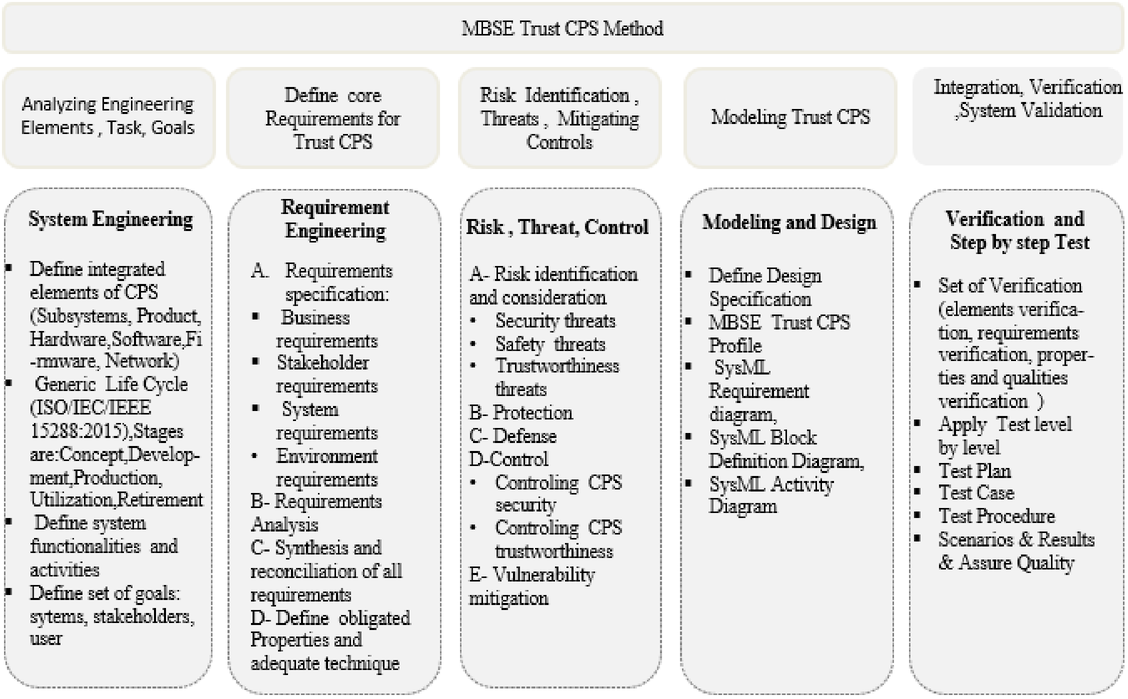
III. Model Based System Engineering (MBSE)

Model-Based Systems Engineering (MBSE) is a tool used to run simulations, support system engineering operations, and improve requirements throughout process development. MBSE offers various advantages, including increased mapping, traceability, and system decomposition [9], improved communication and system management [10], complexity management and risk reduction [11], and systemized decision making [12].

MBSE is a modeling formalism used to assist system requirements, design, analysis, verification, and validation activities, beginning with the conceptual design phase and progressing through the development and subsequent life cycle phases [13, 14, 15]. According to [16], the use of MBSE models reduces project risks and timelines, reduces costs, and improves product quality. Additionally, the MBSE approach's primary idea of using simulation models assures that results are acquired faster and more affordably than testing and prototyping. MBSE has become an essential component of designing complex cyber-physical systems [17,18], is popularly used [19] for: a) Capture and manage the system's requirements, architecture, design, and identify its environment. b) Ease the communication among many stakeholders by participating and providing views for different purposes. In [20], they stated that the benefit of MBSE activities is system validation and verification throughout the early stages of system design. The use of MBSE is limited to object modeling via the Systems Modeling Language (SysML) [21].

IV. Proposed MBSE Trust CPS Method

This section presents the MBSE technique, which includes activities and principles for developing trust CPS. Our goal with MBSE is to obtain descriptive models that leverage semantically rich modeling standards to provide systems abstraction, data traceability, and separation of views. The benefits of using MBSE are explained in previous section. The main goal is: How infusing trust's attributes of CPS into systems engineering practice to decrease the complexity of trustworthiness.



MBSE Trust CPS Method
Analyzing Engineering Elements , Task, Goals
Define core Requirements for Trust CPS
Risk Identification , Threats , Mitigating Controls
Modeling Trust CPS

Fig. 2. The phases of model based system engineering (MBSE), activities in phases, and used methods.

To produce intuitive system descriptions, MBSE requires the synthesis of stakeholder needs into architecture models. A trust CPS technical requiring multiple disciplines to design, for this reason, our proposed MBSE method for trust cyber physical system is based on many disciplines such as system engineering that is the pillar of MBSE, requirement definition, modeling, verification as presented in Fig. 2 (source: compiled by authors) that details the definition of Phases, activities in phases and defining used methods.

A. Phases

1) Phase 1(using system engineering and analyzing engineering elements, tasks and goals): Top-down synthesis is an iterative approach used in systems engineering [22]. SE is a discipline that focuses on the overall (system) design and implementation, taking into account all the facets [23].

a) System definition: Define integrated elements of CPS (Subsystems, Product, Hardware , Software, Firmware, Network). The exterior and internal views of the system introduced the elements that belong to the system and interact with it. The functionality of system is expressed by the interaction of system with its operating environments. We recommend using the SysML Block Definition Diagram or UML Component Diagram.

b) The stages of the Generic Life Cycle (ISO/IEC/IEEE 15288:2015) are: Concept, Development, Production, Utilization, and Retirement [24].

c) Define system activities (we recommend the use of SysML Activity Diagram).

d) Define set of goals: systems and stakeholders, customer.

2) Phase2 (Engineering Requirement)

a) Identify trust requirements: Engineering requirements (RE) is a methodical, disciplined strategy for defining and managing needs [25]. In the design of software and cyber-physical systems, requirements are frequently the most critical step. They serve as a guideline for implementation as well as a reference for final product verification and validation.

During the requirements analysis stage, we are concentrating on trust modeling. We seek to integrate trust attributes in the early stages of trust CPS creation by combining a CPS cycle life with a set of trustworthiness requirements. Our primary goal is to create a model that may aid the CPS designer throughout the complete CPS design process, utilizing the information available in the requirements specification and the availability of necessary characteristics to test and monitor the final implementation's behavior. The standard SysML requirements diagram is recommended. They described a basic need for trust CPS in [3] as follows:

- Engineering requirements: For determining goals, needs, and available resources to aid in the development of a system that meets the requirements.
- Cyber-physical system requirements: Understanding the aim, specifications, and pre-designated purpose of CPS, as well as accumulating a huge number of system information.
- Trust (as a system quality) requirements: collect system, organization, and user trust needs.
- Business Requirement

b) *Defining mandatory attributes for trust CPS:* This activity is carried out during the requirements engineering phase of CPS design. It uses objective and business process models to examine and refine trustworthiness requirements.

The cyber-physical system is considered a trust system if the principles of security and safety, confidentiality, integrity, availability, and other attributes are assured. As previously stated [3] secure, trustworthy, and trusted are system qualities that differ in terms of concerns, requirements, properties, and human interaction. However, there is a link and connection in that each quality can be complimentary to the other by adding characteristics and features to it (security and safety, in addition to a set of attributes, are both necessary to a sufficient degree to build a trustworthy cyber-physical system)[3]. The ability of a secured system to be trusted or trustworthy to some extent is a feature of the system in context.

Safety and security are interdependent, and these dependencies should be considered at the CPS design phase. Interdependence can be classified into four types: a) conditional dependencies: safety is a prerequisite for security, and vice versa; b) reinforcement: safety and security countermeasures can support each other; c) antagonism: they can undermine each other; and d) independence: there is no relationship between safety and security.

In [3] they presented an attribute classification based on system functionality and obligation, as well as a set of judgment criteria. As shown in Table I, this classification of CPS characteristics and quality of service covers the most significant indicators for CPS security and trustworthiness. The terminology glossary [26] defines the majority of the attributes. Some necessary attributes are dependent on the precision and service quality of stakeholders or consumers.

3) Phase 3 (Identification of risk and threats and mitigating controls): CPS should be constructed with controls for threats that may compromise its functions. During this step, the set of assets, threats, or controls should be determined. Risk management is based on norms in industries, and some companies have their own set of procedures and standards.

a) Risk identification: NIST defined a threats as a potential risk to a computer system that could lead to the interruption of the system or the interception, manipulation, obstruction, or destruction of computational resources.

- Security threats: CPS security deals with attacks and mostly attacks threats the security attributes. A denial of service (DoS) attack, for example, renders a control system's components unreachable in some or all circumstances. This DoS can infect devices and prevent them from transferring data, as well as attack routing protocols and communication channels [34]. The common attacks on cyber-physical systems are attacks on data integrity that include false data injection attacks. Integrity is compromised when an attacker deletes or edits crucial data unintentionally or maliciously, leading the receivers to believe the modified or deleted data is accurate. Integrity in CPS could be defined as the ability to achieve physical goals by avoiding, detecting, or defeating attempts to tamper with data transmitted and received by sensors, actuators, and controllers [35]. Some attacks are presented in Table II.

TABLE I. MANDATORY ATTRIBUTES FOR TRUST CPS

Attributes	Definition	Sub-attributes
Safety [27][28]	The ability to operate without causing danger or harm to people or the system's environment.	fault tolerance, robustness
Security [29][30][31]	A software and hardware system's ability to protect entities from attacks and misuse as well as to safeguard resource access is referred to as security.	availability, accountability, auditability, assurance, traceability, integrity, confidentiality, non-repudiation
Compatibility [32]	The ability of software and hardware from multiple sources to work together without having to be modified.	Openness
Performance [32][33]	Describe the effectiveness of a service. The quantity of event responses handled within an interval is referred to as throughput. Response Time: The amount of time it takes for the service to complete a single transaction.	throughput, Response Time
Dependability [31][32]	That ability can be justified and placed on the service it provides. The anticipated execution was correct and predictable.	accuracy, availability, robustness, reliability, scalability, maintainability
Privacy [27][33]	The system's capability and functionality that allows users to govern the use of their personal information or data,	No one else can access or utilize their personal information.
Usability [ISO 9241-210][33]	Is a set of attributes that can be meet in same time for unique product or system. It refers to the ease with which a user can learn to operate, prepare input for, and interpret the output of the service. Positive attitudes towards the use of the service	satisfaction, learnability, effectiveness, efficiency of use
Correctness [32]	Correctness refers to whether a system behaves in a way that satisfies user needs, especially those related to trust expectations and trustworthiness requirements.	Examine whether a system's behavior complies with the requirements of the user.

TABLE II. SOME ATTACKS

Attack	Paper
Denial of service (DoS)	[36]
False data injection	[37]
Covert attack	[38]
Generic deception	[39]
Eavesdropping	[40]
Packet scheduling attack	[41]
Load redistribution attack	[37]

- Safety threats: Concerns about safety arise from interactions between the environment and the CPS, within the CPS, and between the CPS and authorized users. CPS safety is related to the CPS's ability to assure the absence of catastrophic repercussions on the lives, health, property, or data of stakeholders and the physical environment. Safety is an essential concern that affects process industries, and IEC 61508 is regarded as a basic safety standard that applies to all industries. In [42], they discussed how to improve safety awareness and demonstrated that individuals' safety, actions, and ability to deal with dangers at work are heavily influenced by their consciousness and behaviors.

- Trustworthy threats: Some threats are connected to privacy, which is the ability of the CPS to prohibit entities (people, machines) from having access to data stored in, created by, or transiting a CPS or its components. Privacy is the system's ability and functionality that allows users to regulate the use of their private information or personal data. It is a significant contributor to the system's trustworthiness. Privacy attacks are a type of passive assault that target data collecting and can be used to leak sensitive information and reduce the visibility and control of the user over his private information. Mostly attacks threat the trustworthy attributes. The denial of service (DoS) threats availability that is the readiness for usage, and the reliability that is the continuity of service [43]. The attacks result service delay when companies delay providing services on time due to the problems in the system. Unauthorized users or hackers may gain access to specific data and extract confidential information [44].

- Trust concerns:

    - Usability concerns relating to CPS's capacity to be used successfully to meet functional objectives and user satisfaction (adapted from ISO 9241-210) Meeting usability requirements becomes more difficult when physical and cyber components are combined in complicated systems.

    - Correctness involves system behavior in compliance with user needs, including user trust expectations and trustworthiness criteria.

b) Defense: CPS security corresponds to defense against attacks. The defense strategies is based on protection and detection , and mitigation. The prvention led to reducing attacks [45]. Several study in literature presented protection-based approaches and discussing many approches against CPS attacks such as: Control [46], protection-based[47], security metrics[48], state estimation[49].

- Protection

    - Functional Protection: Functional security safeguards the software system against harmful, infiltrating code from both the outside and inside the company.

    - Information protection: Information security safeguards the confidentiality, integrity, and availability (CIA) of computer system data and functionality against unauthorized and harmful access.

    - Safety Protection: Protection against faults, errors, and failures, damage to life, health or society, or injury to the environment. Fault-tolerance, availability, and fail-safe states are examples of safety quality sub-attributes.

- Control: This part consist of deciding trust objectives and controling security and trustworthiness of CPS.

    - Controlling CPS security: In [50], authors categorized three security defense mechanisms and stated that: a) prevention is used to delay the onset of an attack; b) resilience to close the operation of the attack; c) detection to identify the source of the attack; and d) isolation of corrupted subsystems and speedy restoration of normal mode. The defense plan should rely on three mechanisms to avoid: a) the period between the commencement of the attack and discovery, which results in system damage. b) inability to protect against spoofing attacks. An example of a failure to detect [51]. Some control strategies in the literature, such as (observer-based techniques, watermarking, baiting, and learning-based anomaly detection), were categorised in [50]. The authors of [52] proposed an authentication strategy to secure the integrity of devices and utility servers and to avoid tampering attempts using cryptography techniques.

    - Controlling CPS trustworthiness: The major tasks for measuring system quality and trust attributes are the identification of threats that may occur and affect user trust, as well as corresponding controls that may be undertaken to minimize the threats. The use of the risk-based method to identify threats to trustworthiness on an abstract level and computational approaches to evaluate end-to-end system trustworthiness in terms of several trustworthiness metrics as an example of trustworthy evaluation in design time [53].

- Vulnerability mitigation: The following are the most commonly used techniques and controls [54]:

    - Tamper resistance controls on field devices
    - Trusted procurement procedures
    - Patching and updating
    - Encryption
    - Penetration testing and internal audit
    - Network segmentation
    - Use of different technologies

4) Phase 4 (Modeling and Design): In literature, there is a variety of modeling methods and languages for CPS and its quality. The integration of models that capture software and computational behavior with the physical environments is a challenged task a long with the inability to integrate discrete-event and continuous-time modeling paradigms for improving the ability to provide trustworthy CPSs in the future [55,56].

Architectural modeling tools for CPS are frequently used to depict full systems, including graphical notations such as SysML and UML that are useful for considering how the CPS is organized, as well as how the constituent elements interact and share data. Continuous-time modeling paradigms and discrete-event modeling paradigms are the two most well-known modeling methodologies. Modeling techniques that rely on mathematical notations are capable for representing continuous-time behaviors. Continuous-time modeling is required for the creation of a physics model capable of precisely predicting a system's interactions with its physical environment. It captures dynamic behavior of a system by utilizing iterative methods of integration and differential equations [57]. When it comes to physical processes and analog circuits, it used continuous-time techniques [58].

Some systems modeling methodologies and tools for CPS design and analysis include hybrid discrete-event and continuous simulations [59], inductive constraint logic programming [60], hybrid timed automaton [61], ontologies [62], information schema [63], UML [64], and SysML [65].and information dynamics modeling [66], meta-model for multimedia software architecture (MMSA) that enables the description of software architectures [67], SMSA (Security Meta-model for Software Architecture)[68], trustworthy collaboration [69].

As languages that have been designed for modeling holistic embedded systems and CPSs : Stateow/Simulink, Modelica [70], hybrid CSP [71], and HyVisual [72]. Comodeling (collaborative modeling) is an approach that focuses on creating system models composed of separate models [73]. An approach cosimulation engine called Crescendo[57].

In previous phases, we explained that a trust CPS technical requiring multiple disciplines to design which have be combined. For trust CPS modeling, we attempted to capture customer objectives and requirements about trust and reflect them in system functioning. Our suggested activities and tools for MBSE of trust CPS are presented in Table III.

In Fig. 3, our profile diagram is presented. The SysML profile is used on package to incorporate stereotypes. It depicts the MBSE method's phases and underlying trust methods. The MBSE suggests several tasks, including (SysML Block Definition Diagram, SysML Requirement Diagram, SysML Activity Diagram, SysML Use Case Diagram). UML's diagrams can be used also for the suggested activities [74].

5) Phase 5 (Verification and Step by step test): In this phase a set of verification (elements verification, requirements verification, attributes and qualities verification) is done and operated in parallel with pervious phases.

A test step by step is applied to ensure the quality of modeling and level by level verification to ensure the design of entire system as mentioned in Fig. 4. The major objective is to conduct more analysis to see if the system satisfies trust qualities and allows for quick feedback on requirements and design choices.

System requirements are verified against the stakeholder and customer requirements and in the line with set of trust requirements. This step may results change or delete of requirements. The second level of verification targets system realization. The third level targets the use of system. A combination of test plan with test case and scenarios can be applied.

B. *Case Study: Can we trust autonomous vehicles (AVs) on the road?*

One of the largest system engineering challenges to date is the development of autonomous vehicles (AVs). For demonstrating the proposed MBSE method usage, we applied the autonomous vehicle (AV) that enables the preparation for MBSE and presents an initial guideline for establishing the trustworthiness of AVs.

1) Trust AVs: Trust is the first foundation for acceptance of AV and plays a critical part in fostering the relationship between the user and automation and increasing people's desire to use or interact with it [75]. Different surveys showed that people were fascinated by AV but hesitated to trust it. In [76], They discovered that 65% of their participants were concerned about the dependability of self-driving cars. According to [77], 43% of participants are terrified about driving in an autonomous vehicle. A survey [78] found that 22% of respondents couldn't envisage riding in a fully automated car. The authors acknowledged in the quoted polls that the majority of participants had not yet experienced any automated driving functions, making a true judgment difficult.

AV has six levels of autonomy, with the human driver monitoring the driving environment from L0 to L2, and the automated driving system monitoring the driving environment from L3 to L5 [79]. Trust is a key aspect in the evaluation of autonomous systems and influences user behavior [80, 81], and a supportive user interface is vital, particularly during the transition period to automated driving, when the "driver" must relinquish control in favor of an unfamiliar feature.

2) MBSE for trust AVs: We are applying MBSE method to two key aspects of developing trust systems: (1) ensuring trust through the use of requirements set that related to the interactor's needs, and (2) infusing trust attributes into systems engineering practice.

The UML Component Diagram for AV is presented in Fig. 5.

a) Component diagram for AV: The first phase of system engineering and analyzing engineering elements suggests system definition and integrated elements of CPS. The important components of AV are presented in Table IV.

Fig. 6. SysMlL requirement diagram (General set of trust requirements for the AVs).

b) SysML requirement diagram for trust AVs: In the second phase of "trust requirements", we identify the general set of trust requirements for the AVs as presented in Fig. 6.

This step consists of determining the set of trust requirements (secured, trustworthy, trust) and, in the case of trust AV, how to integrate trust consideration into the requirement diagram. The requirements that will be merged are as follows:

- Secured requirement in which the system must ensure the AV's security and safety needs and satisfy all relevant attributes. The safety property is satisfied when the AV operates on the road without putting the system, the driver, or the passengers at risk. The AV must defend entities from attacks in order to fulfill the security property. The availability is ensured by offering protection against denial-of-service (DoS) assaults.
- Trustworthy requirement in which the system shall provide trustworthy needs and deliver service justifiably be trusted. Performance, privacy, and dependability must all be met.
- A trust need that is directly tied to human concern, and the system must fulfill all stockholder needs and ensure that the system performs as intended. All of the following criteria must be met: correctness, usability, satisfaction, and efficacy.

We used the requirement element as an element to present the requirement view, and as connectors, we used “satisfy” to present that to attend trustworthy requirements should satisfy security requirements, and to attend trust requirements should satisfy trustworthy requirements. The second connector “traces to present the relation between the requirement view and the attributes.”

- SysML Requirement diagram over functionality of AVs: This diagram shows the expectation of AV driving to a given destination, from its start position, without colliding with encountered obstacles, in the shortest possible time as mentioned in Fig. 7.

Fig. 7. SysML requirement diagram over functionality of AVs.

c) The risk definition diagram for AVs (driving style, environment, visualisation): The third phase is the identification of risk and threats. In the field of the automotive industry, the lack of traceability of security threats and their effects with safety hazards is a source of risk, for that reason is necessary to determine this traceability. We prioritized and mentioned the essential threat that rely to the driveless of AVs in the road as presented in Fig. 8, the risk definition diagram.

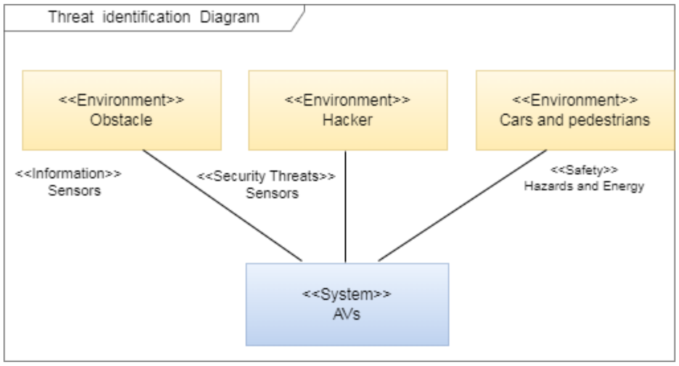

Fig. 8. Risk definition diagram for AVs.

Identifying risks related to phase 3 is used to eliminate security concerns at an early stage of system development and boost final user awareness, which leads to the discovery of suitable defense solutions. This activity incorporates security and safety concerns into a risk identification diagram.

d) SysML uses diagram reflecting how the interactors trust AV: The human must be convinced of AV’s functionality, safety and reliability. In the case of AV, human can be the designer or the user, or the passenger, pedestrians and drivers on the roads.

Trust and confidence must be won at the component, systems, vehicle, and V2X communication levels, AV’s driverless in the road. We have to understand how people trust AV and how interact with it. For our case, we will focus on trust of AV’s driverless in the road. Drivers can be either autonomous vehicles or human passengers in autonomous vehicles.

People who participate in the traffic environment on foot, via bicycle, or by other manual transportation methods are referred to as pedestrians. The SysML use case diagram is presented in Fig. 9.

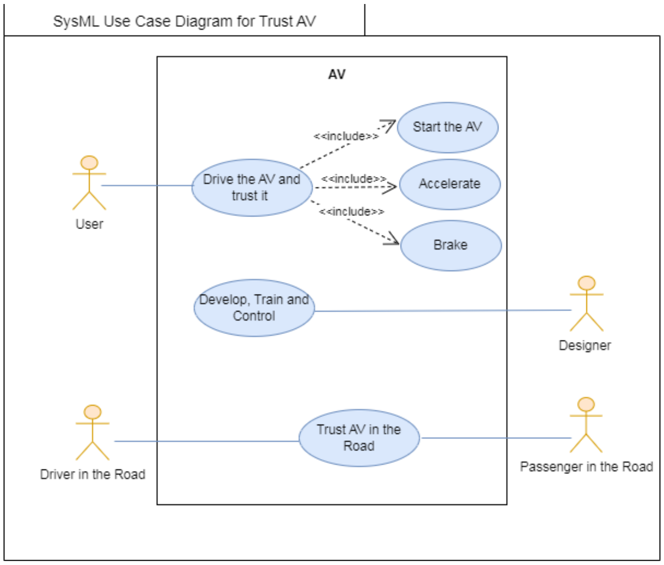

Fig. 9. SysML use case diagram for trust AVs.

The usability and satisfaction properties are included into the trust concern in the use case diagram. How users drive and trust AVs, how designers build, train, and control AVs, how drivers and passengers trust AVs on the road.

V. Discussion

MBSE was utilized to manage the complexity of developing trust in CPS in terms of system requirements, design, analysis, verification, and validation activity. Many studies have shown that security requirements and risks can be addressed in the MBSE model, which is required to address the complicated multidisciplinary, multi-domain process of CPS, and that modeling may be successfully reused in the multidisciplinary sector.

MBSE has become a key component of developing complex cyber-physical systems [17, 18], and it is widely utilized [82] for collecting and controlling the system's requirements [83], architecture, design [84], and environment identification [85]. Also, by participating and expressing views for various objectives, it can help to ease communication among many stakeholders.

The MBSE method requires the design of different partial models for the different aspects of a technical system. For the use case, we applied our proposed phases to AV usage on the road. In this model, the system structure, the components of the system are modeled in the UML component diagram, and the interactions between users and the system are modeled as use case diagrams. The important risks are identified in the threat definition diagram. Trustworthiness is a holistic property of CPS, and heterogeneous system is modeled as a requirement diagram. The expectation of AV driving is modeled as a requirement diagram over functionality.

Some points are revealed:

- Targeting the balance between trust and trustworthiness is an important task during development.
- Cyber-physical systems should be made capable of presenting trustworthiness attributes.
- A well-structured method is required for modeling and developing a trustworthy CPS.
- MBSE could be leveraged in order to mitigate security risks and assure trustworthiness requirements at an early stage of system development.

VI. Conclusion

In this paper, an analysis of specific methodologies and tools that cover design activities for developing MBSE for trust CPS are presented. We introduced the phases of MBSE as well as activities in phases, and used methods. The MBSE method consists of the SysML/UML-based profile, trust requirements definition, and risk and threats definition, modeling the interactions of users and recommendations. The proposed MBSE method usage is presented by AV and how it can be trusted in the road and how the different actors interact with and trust it.

The use of MBSE is recommended, and companies must adopt their methodologies. MBSE is a formalized application of modeling to support system requirements, analysis, design, and validation and verification (V&V) activities, beginning in the conceptual design phase and continuing throughout development and later lifecycle phases. The MBSE approach is necessary to address the complex multidisciplinary, multi-domain process of CPS.

Cyber-physical systems (CPS) have been employed in a number of operations in the oil sector, where petroleum CPS optimization approaches can aid in petroleum exploration, production, and management. Several hazards confront the energy business, with the potential to interrupt critical supply lines, hurt the environment, and trigger a financial catastrophe. The scientific community is focusing on how to confidently realize a trust CPS. There is no clear description of all types of trust concerns and requirements in the literature, particularly in the sphere of oil and gas, and the subject of cyber security for oil and gas assets is not frequently addressed.

Our future work will focus on how to align the proposed MBSE method with the security and safety standards of specific industries, such as oil and gas and how to enhance the modeling of trustworthiness by adding a survey of the judgment by real participants, and computing and analyzing their acceptance.

Construction of an Ontology-based Document Collection for the IT Job Offer in Morocco

Zineb Elkaimbillah[1], Bouchra El Asri[2], Mounia Mikram[3], Maryem Rhanoui[4]
Dept. MS Team-ADMIR Laboratory Rabat IT Center ENSIAS, Mohammed V University in Rabat, Rabat, Morocco[1, 2]
Dept. LRIT Laboratory-Rabat IT Center-Faculty of Sciences, Mohammed V University Rabat, Morocco[3]
Dept. Meridian Team-LYRICA Laboratory, School of Information Sciences, Rabat, Morocco[4]

Abstract—**Information Technology (IT) job offers are available on the web in a heterogeneous way. It is difficult for a candidate looking for an IT job to retrieve the exact information they need to locate the ideal match for their profile, without wasting time on useless searches. Traditional IT job search systems are based on simple keywords that are generally not adapted to provide detailed answers because they do not take into account semantic links. In this article, an ontology is developed to meet the expectations of IT profiles from the IT job descriptions accumulated and pre-annotated using the UBIAI tool. The classes and subclasses of the ontology are designed using the Protégé 5.5.0 editor. Then the properties of objects and data are defined to improve the ontology. The ontology results are validated using DL queries by asking a number of questions to retrieve the requested information for each IT profile, and the ontology answers all these questions adequately. Finally, various plugins are used to display an ontology in a graphical representation.**

Keywords—Ontology; IT job descriptions; semantic links; DL query, protégé 5.5.0

I. Introduction

The Web has become one of the most important sources of electronically accessible information, providing a gigantic mass of information as the number of resources on the Web grows exponentially and the number of users increases daily. Unfortunately, the Web is so huge and unstructured that finding accurate and useful information has become a time-consuming task. As a result, the documents accessible via the Internet, and web pages in particular, need to be structured, and this structuring is based on a very important attribute called "semantics".

This vision of the Web of the future depends on the construction of Web resources with information that can be exploited by software agents. Research has led to the birth of the semantic web, and a whole series of new technologies and concepts.

Over the past few years, the IT sector in Morocco has undergone significant change. With the challenge of digital transformation, recruitment for digital professions is a priority for companies. There is a wide range of profiles and skills in IT, with different descriptions.

Today, access to information plays an important role in the acquisition of knowledge, and is considered an important characteristic for the user. Despite the role played by traditional systems based on simple keywords and/or semantic similarity, they are generally not well suited to providing good job descriptions, as they do not take into account the links between concepts. On the other hand, as a recent graduate looking for a first job in IT, or in search of a career change, it's not always easy to find the ideal niche, so he needs access to the best tools to help him find the position that perfectly matches his profile, without wasting time with irrelevant recommendations and manual searches.

Consequently, the search for information led to the construction of the ontology that forms an important part of the Semantic Web, which on the one hand seeks to build on models of Web documents that represent IT job offers, based on the conceptual representation of the domain concerned and, on the other, aims to enable programs to make inferences on them. Clearly, ontologies are based on vocabularies and concepts that are explicitly specified in a representation language.

The study will be applied to unstructured data representing job offers requested in Morocco in the IT sector. The approach presented starts by extracting domain knowledge from a text, then representing it in the form of OWL ontology.

This paper is organized as follows. Section II mentions the background of our research, including definitions, components applications of ontology, and steps of Ontology Development followed by the general methodology for our research and the main steps to build our ontology in Section III. After that, the steps of evaluation and analysis are described in Section IV. The main results are discussed in Section V. Finally, the conclusion is presented in a Section VI.

II. Background

In this section, some definitions of ontology are presented, then we present some domains of ontology application, and then we will present the methodology of development of ontology.

A. Ontology Definition

In computer science, ontology is a branch of knowledge engineering that focuses on creating structured and organized representations of information that can be understood by both humans and machines. It is a formal representation of knowledge that describes concepts and relationships within a particular domain.

Many authors have proposed several definitions of this concept. Notable among these have already been, formally [1] defines ontology as set of concepts and the relationships between them. Concepts can be divided into classes, subclasses, attributes, relationships, and instances.

On the other hand, [2] presented the ontology as formalized and structured representation Co-conceptualized concepts and relationships. More precisely, it can be defined as a concept, the relationships, attributes, and hierarchies that exist in the domain.

In the context of computer systems, [3] declared that an ontology is a clear, structured description of common concepts. Ontologies include vocabularies and explanations of the relationships between classes.

Another effort is made to define an ontology was proposed by [4]. The authors consider it like a data modeling technique for structured data repository premised on collection of concepts with their semantic relationships and constraints on domain.

These definitions provide a range of perspectives on the concept of ontology in informatics and emphasize its role as a formal representation of shared conceptualizations and knowledge structures within a given domain.

B. Ontology Components

The components of ontology can vary depending on the specific approach and context; the essential elements of the ontology are presented as follows:

1) Concepts or classes: Concepts represent the entities or categories in a domain. They can be hierarchically organized, forming a taxonomy or a class hierarchy. Concepts capture the essence of the domain and serve as the building blocks of an ontology.

2) Properties or attributes: Properties define the characteristics, features, or attributes of concepts. They describe the relationships, roles, or qualities associated with concepts. Properties can be classified as object properties (defining relationships between concepts) or data properties (defining attributes with specific values).

3) Relations or relationships: Relations represent the connections and associations between concepts. They define how concepts are related to each other within the ontology. Relations can be symmetric, asymmetric, transitive, or other types depending on the nature of the relationship.

4) Instances or individuals: Instances represent specific instances or examples of concepts within a domain. They represent concrete objects or entities that belong to a particular class or concept in the ontology. Instances provide specific data or real-world examples to populate the ontology.

5) Axioms or constraints: Axioms capture the logical rules, constraints, or assertions about the concepts, properties, and relationships in the ontology. They define the semantics and rules that govern the relationships between different components in the ontology.

6) Annotations or metadata: Annotations provide additional descriptive information about the components of the ontology. They can include labels, definitions, synonyms, examples, and other metadata that enhance the understanding and usability of the ontology.

These components collectively form the structure and knowledge representation in an ontology. They enable the formal representation of domain-specific knowledge, relationships, and semantics. The specific representation and organization of these components can vary depending on the ontology language or framework used, as well as the requirements of the specific domain and application.

C. Ontology Application

Ontology finds applications in various domains. An overview of different domains is provided (Fig. 1), where ontology has been applied. For example, in the field of education, ontology is applied to learning analytics [10] and curriculum design [11], in the healthcare domain, it is used for clinical guideline [12], data integration [13] and data patient [14], also in the energy and environment domain, it has been applied to energy management [15], and smart grids [16]. Ontology development is also being applied in the agricultural domain, for example to precision agriculture [17], and pest control [18]. Some common domains of ontology application as follow:

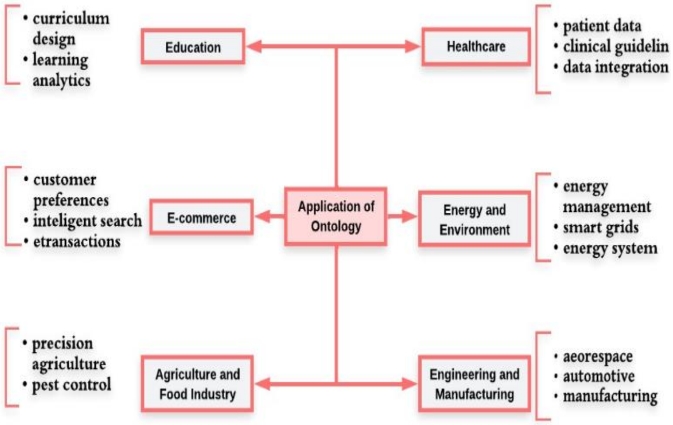

Fig. 1. Application domains for ontologies.

These are just a few examples of the diverse domains where ontologies have been applied. Ontology's versatility allows it to be utilized in various fields to enable knowledge representation, data integration, semantic interoperability, and intelligent systems.

D. Ontology Development

On the one hand, several methods have been developed to design ontologies either from scratch or by reusing existing ontologies. The process of building an ontology is similar to a commercial rather than a technical task [4]. Each design team or group can follow its own guidelines and decide which criteria and stages to work on and which can be skipped. Of course, this will depend on the scale of the ontology we intend to build." Systematic review on ontology applications in virtual reality training domain: design components, roles, and research directions ».

On the other hand, this involves defining a domain of interest, determining concepts and relationships within that domain, and formalizing the knowledge representation using ontology tools and languages. Here are the main steps involved in developing an ontology:

Identify the Domain: Specifies the domain or domain on which the ontology is built. Clearly define the scope and boundaries of the ontology.

1) Knowledge gathering: Collect and analyze existing resources, such as domain-specific documents, databases, and sources, to understand concepts and relationships within the domain.

2) Conceptualization and modeling: Create a conceptual model that captures key concepts, their relationships, and the overall structure of the ontology. This can be done using graphical tools, such as UML diagrams or ORM, to visualize the conceptual model.

3) Define classes and properties: Define the classes (concepts) that represent the entities within the domain. Specify the properties (attributes) that describe the characteristics and relationships of the entities.

4) Establish relationships: Define relationships between classes using attributes.

5) Formalize the ontology: Use an ontological language, such as RDF or OWL, to formally represent concepts, attributes, and relationships in an ontology. Apply language structures and syntax to create machine-readable representations.

6) Validate and evaluate: Evaluate the quality and effectiveness of the developed ontology.

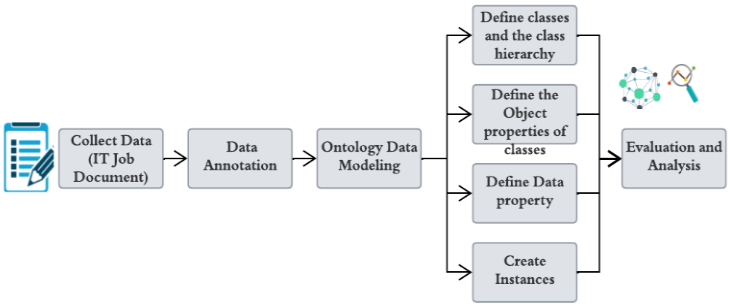
Ontology development is an iterative and collaborative process involving domain experts, ontologists and other stakeholders. It requires a combination of domain expertise, ontology engineering skills, and knowledge representation techniques.

III. Proposed Solution

A. Ontology Building Methodology

Fig. 2 shows the general methodology for the research, which consists of main steps to build our ontology as follows:

- Collect Data (IT Job Document): the systematic approach of bringing together and measuring information from a variety of sources to obtain a complete and accurate view of the area of interest.
- Data Annotation: is the process of attributing, tagging or labeling data to help algorithms understand and classify the information they process.
- Ontology Data Modeling: the process of graphically representing data flows.
- Construct IT Job Ontology: representing general properties of what exists in a formalism that supports rational processing.
- Evaluation and Analysis: arriving at a conclusion with in-depth study of the ontology to better understand the information being presented.



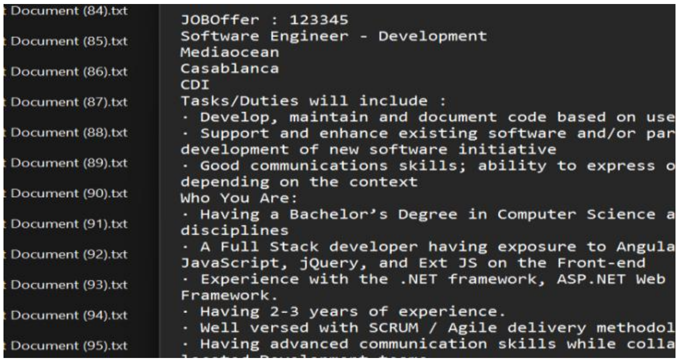
Collect Data (IT Job Document)
Data Annotation
Ontology Data Modeling
Define classes and the class hierarchy
Define the Object properties of classes
Define Data property
Create Instances
Evaluation and Analysis

Fig. 2. Ontology construction methodology.

Each step has a well-defined role and each is essential for the success of the work, the following section is devoted to detailing each phase.

B. Data Gathering

The data used in our work consists of collecting 150 job descriptions requested in Morocco, related to the information technology (IT) sector from several job websites such as (Rekrute, indeed, Linkedin...). The data was stored in text files with the description as shown in Fig. 3.



```
JOBOffer : 123345
Software Engineer - Development
Mediaocean
Casablanca
CDI
Tasks/Duties will include :
· Develop, maintain and document code based on use
· Support and enhance existing software and/or par
development of new software initiative

· Experience with the .NET framework, ASP.NET Web
Framework.
· Having 2-3 years of experience.
· Well versed with SCRUM / Agile delivery methodol
· Having advanced communication skills while colla
```

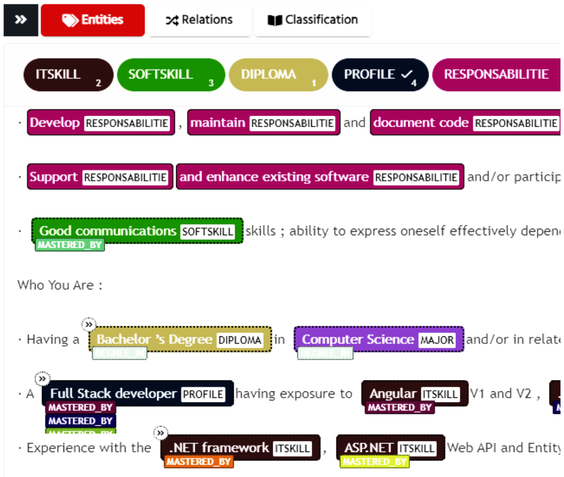
Fig. 3. An overview of the job offer description.

The scrapping of job offers in the IT field is done manually, to study and deepen our knowledge of the IT field in Morocco, and extract the information needed to develop our ontology, such as profile, company, location, responsibilities or missions, soft skills, IT skills, diploma, training, and experience...

In this study, the UBIAI annotation tool is used because it saves us a lot of time and will help us minimize manual annotation. It also offers extensive features such as dictionary-based auto-annotation, regular expressions, and rules Team collaboration to share annotation tasks Direct export of annotations.

UBIAI is an Oregon based startup that provides cloud-based solutions and services in the field of Natural Language Processing (NLP), to help users extract actionable insights from unstructured documents. It can annotate any type of document whether it's PDF, images, or text. Also, it can train machine learning models and train state-of-the-art deep learning models on annotated datasets like Named Entity Recognition, Relation, and Extraction Document Classification, with few clicks and save up to 80% of annotation time.

We proceeded by annotating texts while identifying key entities such as (profile, company, location, responsibilities, skills, diploma, training, experience...) and the relationships between these entities as shown in Fig. 4.



» Entities | Relations | Classification

ITSKILL 2 | SOFTSKILL 3 | DIPLOMA 1 | PROFILE ✓ 4 | RESPONSABILITIE

Fig. 4. An overview of the annotation sheet for the job offer.

After extracting the entities from the job descriptions and building the database, we first need to know how they are distributed.

In Fig. 5, the distribution is non-homogeneous for the entities with 1190 data for the IT Skills entity, and 1098 data for the Responsibility entity. These two entities represent the largest distributions in the diagram compared to the other annotated entities, which means that in the field of IT job offers, we focus more on the IT skills and responsibilities required.

C. Ontology Data Modeling

Before starting to build an ontology, the ontology modeling phase is very important, as it provides us with a conceptual map and a clear and correct vision of the work to be carried out. It's easier to represent concepts graphically than to represent them in a serialized (Resource Description Framework)/ (Extensible Markup Language) format. This is why we have chosen to represent concepts using object-role modeling (ORM). The early 1970s saw the emergence of ORM, a semantic modeling methodology that distinctly interprets the world in terms of objects fulfilling roles [5].

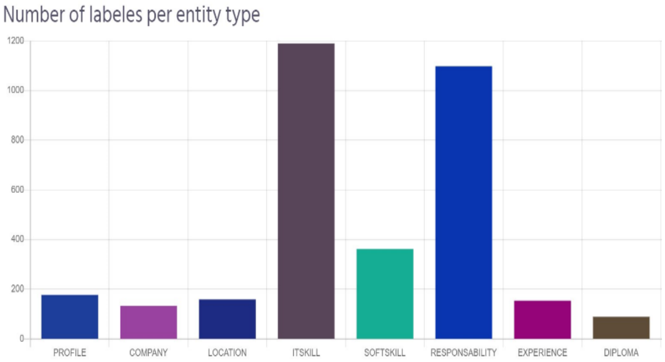

Fig. 5. Distribution of the labels per entity type.

In this section, we will conceptualize our data model for the ontology to be developed. This model seeks to examine the interactions [9] between descriptive components of job offers. In order to accomplish the goals of our application, the model represents several sorts of entities along with their attributes and relationships among them.

The schema for the data model is displayed in the following Fig. 6 and Table I.

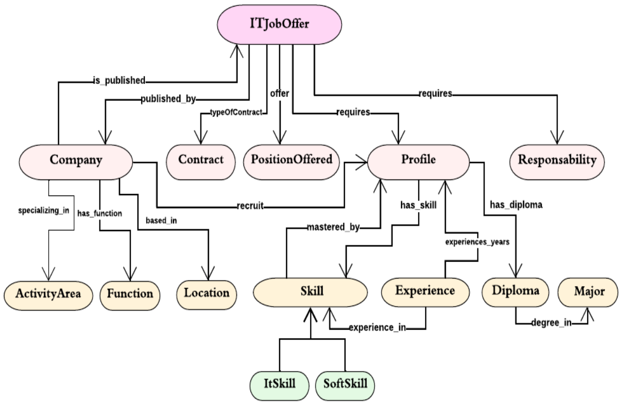

Fig. 6. Conceptual model of IT Job offer ontology.

TABLE I. DESCRIPTION FOR NODE AND IT'S ATTRIBUTES

Node	Node Description	Attribute	Attribute Description
IT JobOffer	The IT job offer launched by the company	Id	A unique identification of the node.
		name	The name of the IT job offers
PositionOffred	The position offered by the IT Job Offer	id	A unique identification of the node.
		name	The name of the position offered
Company	the name of the company posting the job offer	Activity Area	the business sector of the company
		Function	the functions performed by the company
		Location	Location of the company that posted the offer
		id	A unique identification of the node.
Profile	The type of candidate concerned by the IT job offer	Id	A unique identification of the node.
		Profile	IT profile name
Skill	The required knowledge and competencies for entry into the position.	id	A unique identification of the node.
		Soft Skill	The skills that enable the candidate to fit in at a workplace. They include personality, communication, attitude, flexibility, and motivation.
		IT Skill	Also known as technical skill or hard skill which are directly relevant to the job to which the candidate applying.

Responsibility	The task and the responsibility that must perform the candidate.	id	A unique identification of the node.
		name	The name of task and responsibility required
Diploma	The diploma qualification that a candidate must possess to satisfactorily perform the job duties and responsibilities.	id	A unique identification of the node.
		name	the name of the diploma obtained by the candidate
Formation	The formation associated to the required diploma.	id	A unique identification of the node.
		name	The name of formation.
Experience	The experience required in a specific skill.	id	A unique identification of the node.
		experience	The number of years' experience or experience required.
Contract	the type of contract offered by the company	type	The type of contract
		id	A unique identification of the node.

D. Ontology Construction

The ontology development process is complex. This is why it is necessary to use a method or methodology to support the ontology construction process. This is why the method used is to design ontologies from scratch using conceptual data models.

To develop our ontology, it is important to choose an appropriate ontology editor. The Protégé editor was chosen, as it has established itself over the last 20 years as one of the best tools for ontology creation and information presentation [6].

Protégé is widely considered one of the most popular and widely used ontology development tools for several reasons: It's an open source and free, it has a large and active user community, including developers and domain experts, it offers a user-friendly interface and intuitive features, it can handle complex ontologies and is extendable through plugins. Protégé allows users to collaborate on ontology development projects by supporting multiple users working on the same ontology simultaneously.

This is the main step in the development process. To design the class hierarchy, we need to refer to the list of terms in Table I and choose the most appropriate concepts to represent superclasses and subclasses. As a result, 26 classes are described in total, as seen in Fig. 7.

The ITJobOffer Class is the mother class of all classes included five main sub classes that included: Company (Activity_Area, Functions and Location), Contract, Position_offered, Required_profile (Diploma, Experience, Major Skills), Required_Responsabilities.

Fig. 10. Individuals.

Fig. 10 summarizes some of the individuals created based on our collected database. For example, for the "soft_skills" subclass, we have described differents values that a "BI_DATA_Engineering" profile must master:

"Strong_analytical","Team_work","Communication_skill”.

This step is used to create instances after completing the ontology model, describing the instances or individuals, which involve assigning a unique name to each individual after specifying the class to which it belongs and defining the values of these attributes (data properties).

IV. Evaluation and Analysis

A. DL Queries

The evaluation and analysis steps are a critical one, where we have to make queries to find answers to our research questions and evaluate our ontology.

We used the DL query tab, available in the protected 5.5.0 software, to enter queries and launch the reasoner before executing the DL queries. The structure of the ontology is validated using the HermiT reasoner [19], which is used to check the consistency and coherence of a model and to verify and evaluate the ontology's correct functioning. This allows us to answer the questions: "Is the world of IT offers well represented by Ontology? and "Are IT profiles satisfied with the answers to their questions?

The result shows direct classes, subclasses, superclasses and instances. DL queries can be added to the ontology to extract more precise information.

Some examples of DL queries and their results are shown below with results answering a set of questions:

- What are the different soft skills mastered by the "BI Data Engineering" profile? (Fig. 11)
- What are the different IT skills mastered by the "Devops engineering" profile? (Fig. 12)
- What are the different skills that must master the "BI Data Engineering" profile? (Fig. 13)
- What are the companies that recruit the BI Data engineering profile, also the experience and skills required for this candidate? (Fig. 14)

Fig. 15. Sample of individuals in IT Job offer ontology after supported in protégé.

In Fig. 16, we visualize the structure of the ontology of the IT job offer using the OntoGraf tab of the Protégé editor. The elements of this structure are automatically organized, and the different relations are supported: subclass, individual, domain/range, object properties and equivalence [7].

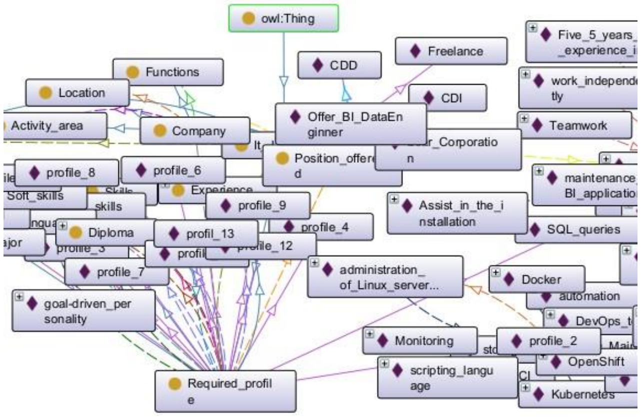

Fig. 16. Overview of Ontograf visualization for IT Job offer ontology.

Using the OWLVIZ tab in protected, we generated a visual representation of the IT job posting ontology shown in Fig. 17, but we installed GraphViz before working on this tab.

To validate our ontology, there are a number of plugins available in our Protégé editor [8]. One of these plugins is named VOWL, which offers a graphical representation of an ontology layout. To use this tool, we download the JAR file and then copy it to the appropriate plugin folder. then you must activate the Protected VOWL plugin via the Window → Tabs → VOWL option. For example, Fig. 18 displays a VOWL visualization of the IT job offer ontology, illustrating a graphical overview of the job.

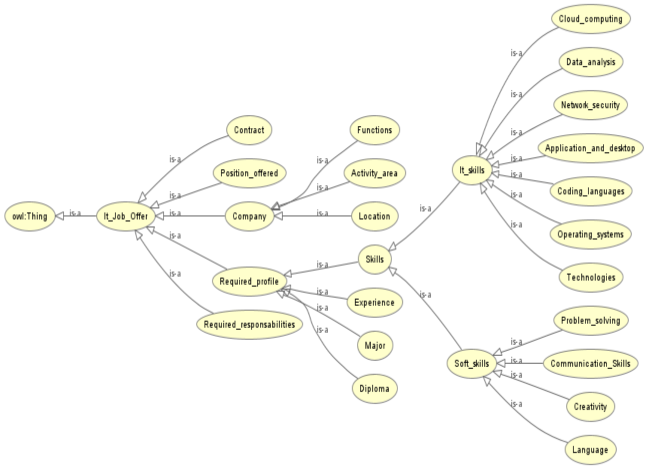

Fig. 17. Ontoviz visualization for IT Job offer ontology.

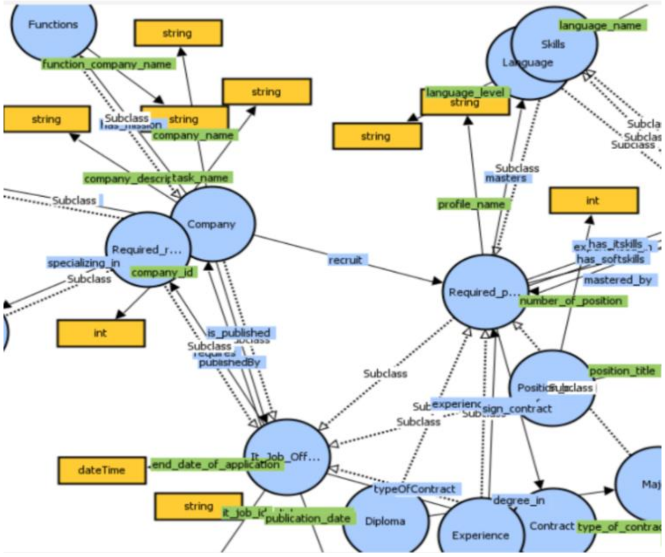

Fig. 18. Overview of VOWL visualization for IT job offer ontology.

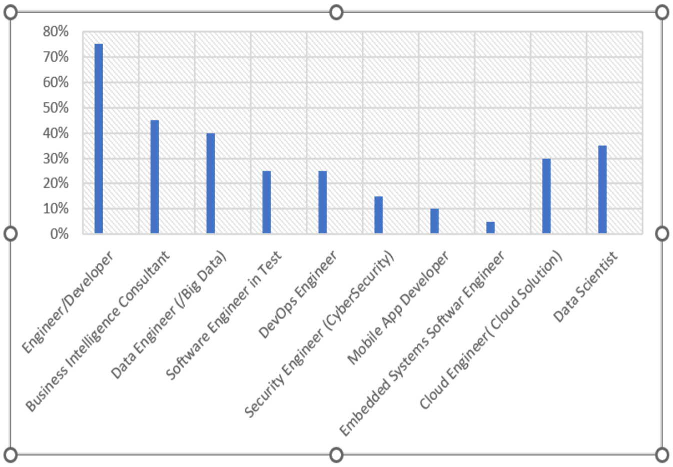

Fig. 19. Diagram of the percentage of the most requested IT profiles in Morocco.

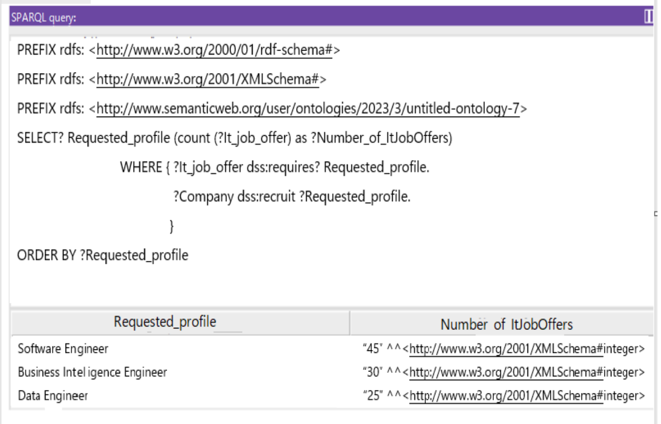
The data analysis software used in this case study is Microsoft Excel, which is perfectly useful for data analysis thanks to simple and practical operations, to present, and to interpret from spreadsheets, a multitude of data.

Referring to the accumulated and annotated data, Fig. 19 shows that the largest share of profiles in demand in the IT sector in the year 2023, is for IT engineers and developers, accounting for almost 75% of the recruitment market for IT profiles in Morocco, followed by Business Intelligence and Data engineering profiles, while the IT security sector accounts for only 15% of the demand in Morocco.

In order to obtain an in-depth comparison, it is essential to generate additional SPARQL queries that provide numerical results to assess the accuracy of the evaluation procedure. This will enable a more representation of the main result. SPARQL is a standard query language and protocol for Linked Open Data and RDF databases. It is designed to query a variety of data, it can effectively extract information hidden in different data stored in different formats and sources).

To this end, we have queried our developed ontology to count the number of profiles most in demand in the Moroccan IT job market, comparing it with the first result found in Fig. 20, the ontology answered the question well.



SPARQL query:

```
PREFIX rdfs: <http://www.w3.org/2000/01/rdf-schema#>

Fig. 20. Counting of requested profiles in IT job offers in on Protégé.

Ontology evolution is an important aspect of the Semantic Web and knowledge representation, constantly evolving to meet the changing needs of various industries, including IT. Several potential new features in ontology development for IT Recruitment enable efficient integration of data from various online sources to provide a holistic view of information and form knowledge graphs that support advanced analysis.

VI. Conclusion

In this article, we propose an analysis of the problem related to the Information Retrieval domain and those specific to the IT sector. As the web is a very extensive data resource, data accumulation and knowledge extraction is the first step in our system, consisting of extracting keywords according to their semantic weights and domain values. Our contributions focus on the crucial step of conceptualizing the accumulated textual documents into concepts and relationships. This work proposes the process for building an ontology that semantically demonstrates the job offers requested in the IT sector in Morocco. The use of semantic technology can help IT profiles to find the job that perfectly matches their profile by answering their questions in a relevant way.

We intend to extend this research in the future by incorporating an educational application based on the constructed ontology, as well as applying machine learning algorithms for the extraction of named entities and the relationships between them**.**

ACKNOWLEDGMENT

The authors are very grateful to the graduates of the software engineering branch of ENSIAS for providing the necessary websites to scrape the data and helping us to know the problems encountered during the job search process.

Abstract—**Electromyogram (EMG) signals are used to recognize gestures that could be used for prosthetic-based and hands-free human computer interaction. Minimizing calibration times for users while preserving the accuracy, is one of the main challenges facing the practicality, user acceptance and spread of upper limb movements' detection systems. This paper studies the effect of minimized user involvement, thus user calibration time and effort, on the user-independent system accuracy. It exploits time based features extracted from EMG signals. One-versus-all kernel based Support Vector Machine (SVM) and K Nearest Neighbors (KNN) are used for classification. The experiments are conducted using a dataset having five subjects performing six distinct movements. Two experiments performed, one with complete user dependence condition and the other with the partial dependence. The results show that the involvement of at least two samples, representing around 2% of sample space, increase the performance by 62.6% in case of SVM, achieving accuracy result equal to 89.6% on average; while the involvement of at least three samples, representing around 3% of sample space, cause the increase by 50.6% in case of KNN, achieving accuracy result equal to 78.2% on average. The results confirmed the great impact on system accuracy when involving only small number of user samples in the model-building process using traditional classification methods.**

Keywords—EMG signals; user independence; EMG user acceptance; HCI; movement classification; calibration minimization

I. INTRODUCTION

Human computer interaction is highly relying on measuring and recording the signals produced by human body. Electroencephalogram (EEG), electrocardiogram (ECG), electrooculogram (EOG) and electromyogram (EMG) are electrical signals used in various HCI systems either separated or fused. EEG signals measures the brain electrical behavior from the surface of the scalp [1]. EMG signals are the biological signals generated as a result of the potential difference caused by skeletal muscular contractions [2]. EOG signals are used for detection of involuntarily or intended eye movements that could be used in a verity of applications [3]. ECG signals are acquired to evaluate the heart functionality and detect its related diseases [4].

Monitoring and detecting the changes in the EMG signals are beneficial to the researchers in the medical field in order to recognize neuromuscular diseases and help out in the rehabilitation process [5]. As claimed by Turgunov in [6], the muscular disabilities are spreading for various reasons causing the increase in demand for prosthetic limbs and assisting robots. They could help the parallelized patients to be able to achieve their daily activities with minor or no involvement from others using sensors that measure the EMG signals and act accordingly through gesture recognition systems [7].

Those systems are also used for moving a remote robot and encouraging the distant rehabilitation process that is intensively needed after having strokes caused by a diversity of reasons [8]. Automated EMG signals translation offers great contribution in the success of remote monitoring for ALS patient using the measured physiological signals [9] and the availability of distant therapy and achieving high improvements in muscular responsiveness and motor functionality [2], [10]. EMG based gesture recognition is also used for explaining the sign language used by deaf people helping them to be easily engaged in the society [11] . EMG signals can be used also in fatigue detection [12], [13] and emotion identification systems [14] that could be beneficial for ergonomic and entertainment applications. Gamification therapy [15] as well as virtual reality and augmented reality [10], [16], [17] could be developed and evolved by enhancing the automated understanding muscle non-spoken language.

The muscular activity recognition systems start by collecting the EMG signals from relevant human parts. EMG signals do not only carry information about the movement itself but also contain other internally interfering signals such as muscle fatigue and emotional involuntary movements as well as external conditions like sensor placement or other sources of noise. So preprocessing component takes place to clean, filters noise and unwanted signals, performs segmentation and does normalization [18]. The feature engineering and classification for biological is described in [19], [20].

Muscular movement recognition systems face various challenges that highly affect the user acceptance. They include the detection accuracy and classification performance, as well as the system generalization and robustness [21]. System accuracy and performance are influenced by the noisy nature of EMG data that is caused by body interior sources like cross talk effect in which the signals produced by the contraction of neighbor muscles interfere with the readings of the intended muscles. EMG signals are also prone to variations over time for plenty of reasons like electrode shift, emotional, involuntary movements and muscular fatigue. Motor tasks with different imposed force or unintended limb orientation changes also contribute in the non-stationarity of the generated signals [20], [22], [23]. As reported in [20], [24], the time separating training and testing negatively affects the performance of movement recognition systems for the same subject.

The user independent systems, having different participants for both training and testing purposes, impose extra burden as change of physiological features like the age, height, weight, and behavioral characteristics like exercise routine would minimize the system ability to generalize across users [22]. In [25], the high inter-subject variability necessitates long and frequent user-specific training which affects user acceptability. In [26], the authors performed a comparison between the measured muscular activities of amputees and able-bodied subjects when controlling myoelectric device in order to overcome the long and frequent user calibration. Their results confirmed the generalization challenge facing various users in general and amputee in specific.

There is also the issue of small dataset size related to EMG based prediction that is extensively reviewed and studied in [27], confirming the need for bigger datasets to overcome the overfitting problem facing, particularly, deep model generation.

This paper addresses and analyzes the effect of various levels of user involvement in the calibration process on system's performance. Its main contribution is to pave the way for a limited resource-consumption and minimized user-calibration time solution to the gesture classification while preserving reasonable accuracy results. Traditional ML techniques are used due to their low utilization of hardware resources and their comparable results to deep learning solutions which is proved from the related work presented in Section II. The experiments are conducted to measure the impact of changing the number of samples needed from the user in the calibration process in an attempt to reduce this value in order to minimize user-calibration time. Two ML techniques are involved in these experiments. They reach the conclusion that the user-specific features, which can highly improve EMG-classification performance, can be learned from 2%-3% of the training sample space.

The rest of this paper is organized as follows; the next section presents the extensive research work that aims to tackle these issues and increase the EMG based movement classification systems' usability while preserving high accuracy results. Section III describes the used system in this study. Then the results of this analysis are shown and discussed in Section IV while the last Section provides a conclusion reached by this study.

II. Related Work

In order to increase user acceptance for prosthetic devices or gesture based remote controlling systems, multiple researches attempt to increase performance and minimize user calibration. Unfortunately as reported in [28], [29], the performance of deep learning is highly dependent on the data set size available for training. The larger dataset, the higher the performance would be. But the publicly available EMG gestures datasets suffer from the size issue placing restrictions on the use of deep learning solutions as reported [27]. Moreover collecting massive amount of data from the system's end user would form an obstacle to system usability due to time, efforts and frequency requirements of the (re)calibration process [30], [31]. In [30], they state the need for a study that deals with the issues related to prolonged and repetitive recalibration sessions. So investigating the effect of minimizing user calibration, features or dataset size while maintaining high performance using different traditional or deep learning solutions, gets increasing priority.

In [32], the authors analysed working with dataset with variable force levels using traditional classification method (KNN). They proposed an iterative feature extraction method to be used for identifying six grip activities with different force levels; low, medium, and high. The success rates accomplished were relatively comparable as the classification results were 97.78 % for Low, 93.33 % moderate and 92.96 % for high force level. The work with various force levels was also presented in [23] but this time with deep networking solution, where the authors achieved average accuracy of around 91% using LSTM-based neural network across all amputees subjects and force levels confirming a comparable results between deep and traditional solutions when working with different force levels of EMG signals.

The hand gestures identification for the sake of stroke rehabilitation is applied in [5] for six hand gestures. Time and frequency features of 20 subjects are provided to the classification phase. KNN has shown better accuracy 98% over Artificial Neural Networks (ANN) and Support Vector Machines (SVM). They also tried to reconstruct identified gesture from EMG-based generated joint trajectories and compare it to the generate movement by a VICON camera tracking system producing a correlation of 0.91. Proving the approximate accuracy produced by traditional methods and neural networks using muscular generated signals.

The work for minimizing the user calibration time and studying the impact of user-independence EMG based classification systems take place in [33]. The authors investigate the feasibility of zero retraining and achieving the rotation and hand independence. The experiments include twenty participants with all rotations and both hands utilization are allowed for eight distinctive gestures; rest, flex, extend, abduct, open, close, thumb, and ok. They find that the accuracy notably decreases under these generalizations except for wrest extension gesture which is found to be consistent among all gestures.

The authors in [25] propose LSTM-CNN model for hand gesture classification in order to check the possibility of creating user independent solution and reduce the need for system recalibration for new users. They start by recognizing seventeen gestures' classes from 40 subjects in a user-dependent way and the model reaches accuracy of 81.96%. But when building the user-independent model, they use gesture signals from only four hand movements in the training process. Their model accuracy drops to 77% for unseen users. They use GradCAM analysis in an attempt of getting a shallower design in order to reduce the high training time and memory consumption that are required when deep learning model is used.

In [34], the objective is to minimize the volume of data needed to train a deep neural model. They used the learned Dilated Efficient CapsNet with a decrease of 20% of the training EMG signals per repetition in the transient phase. They maintain an accuracy of 80%.

As demonstrated from the shown recent related work that the problems related user acceptance for EMG based classification and their prosthetic devices massively depends on user calibration time which is needed for reaching reasonable performance results. Different solution approaches are considered including the use of deep learning techniques or reducing the need for user involvement using previously collected samples from other users. The deep learning techniques face the issue of small EMG dataset size and high required computational and storage resources. Some researches reached the conclusion that the results of deep learning and traditional machine learning are comparable either for user dependent or independent solution. So in this paper, the incremental minimization of user calibration is analyzed using traditional classification methods; KNN and SVM.

III. Methodology

As shown in the previous section, one of the main challenges facing the EMG based hand activity recognition system is the lack of inter and intra-user generalization which causes the need for extensive calibration that consumes user’s time and negatively affects user experience. The accuracy of the recognition system is found to be dropping when the movement activity samples used in the training process are gathered from subjects other than the final user whose samples are used in the testing or validation processes. This user generalization issue limits the user acceptability which is highly depending on accuracy and calibration time [25]. So in this paper we investigate the effect of incremental involvement of the final user’s samples in the training process on the overall model accuracy results. The results are analyzed using ANOVA test in Section IV. The next paragraph describes the used system in order to view the influence of incremental user samples in the training process.

The hand gesture recognition system used in this study utilizes the traditional recognition methods. It is composed of various components as shown in Fig. 1.

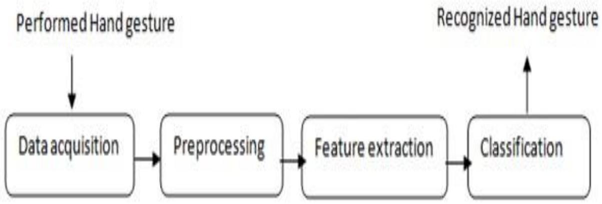

Fig. 1. EMG hand gesture recognition system.

It includes the data acquisition process performed by [26] which first collects the EMG signals from two differential electrodes using as a programming kernel, the National Instruments (NI) Labview. The electrodes are placed on the forearm surface by elastic bands with an additional reference electrode is put in the middle, in order to record information about the muscle activation. Then the preprocessing phase is applied on the captured signals to cleanse, remove noise and unwanted signals, performs segmentation and normalization. So it uses an 8th-order bandpass IIR filter with lower frequency 15 Hz and higher frequency 500 Hz. Then the feature extraction takes place for each trial. It extracts twelve AutoRegression (AR) [35] coefficients as three coefficients are generated per trial segment. AR features are the coefficients of a statistical model that is generated to predict new values of data given the old ones. A K-th order autoregression AR(k), is the model that uses K past points of the time series in order to guess the new point to come with K coefficients to give weights for each previous point and determine its participation in calculating the next value according to its distance from it according to the following equation.

$$X_t = \sum_{j=1}^{k} \varphi_j X_{t-j} + \omega_t \tag{1}$$

Then at the classification phase, one-versus-all SVM classification model with Gaussian radial based kernel is trained using the previously extracted features. The one-versus-all SVM classifier [28,29] is generated by combining the decision from various binary classifiers that separate one class from all other classes. The binary version is utilized to calculate the separation hyperplane with transformed Hilbert space vectors. The decision function is computed as

$$D(x)=\sum_{i=1}^{p} \alpha_i y_i K(x_i, x) - b \tag{2}$$

Where xi are the training samples input vectors and yi are the samples output which have different sign for the two classes. The Gaussian Radial basis function is formulated as:

$$K(x_i, x) = e^{-\|x_i - x\|^2/2\sigma} \tag{3}$$

To confirm the results, another classifier, KNN, is used. It is a supervised machine learning algorithm. It categorizes the item according to the most common class of its K nearest neighbours. It relies on a distance metric to determine the item’s neighbours. In this paper we use Euclidean distance.

The trained model is then used to distinguish the testing features. The use of the traditional feature extraction and classification methods like AutoRegression and SVM and KNN is beneficial for achieving the simplicity and saving the time required for the training process [32] specially with the small size of the dataset that could cause overfitting and reduce accuracy when deep neural networks are used [33].

The next section describes the experiments conducted to study the effect of decreasing user provided samples in the calibration process in order to achieve acceptable performance and increase the user acceptance.

IV. Experiments and Results

Two experiments are conducted with the two classifiers, SVM and KNN. One uses complete user dependence condition while the other uses the partial dependence. The dataset is collected by [26] from five normal and healthy subjects of age 20-22. They are asked to perform six different movements for thirty trials. The measured time is 6 sec.

The movements are Spherical, Tip, Palmar, Lateral, Cylindrical, and Hook. Spherical movement is recognized when holding spherical objects while Cylindrical movement is recognized when holding cylindrical objects. Tip movement is recognized when holding small objects while thin and flat objects grasps are recognized as Lateral. Grasping with palm facing the object is called palmar movement and Hook movement for supporting a heavy load. No previous instructions about speed or force are given to subjects.

The dataset is partitioned using 10 folds, nine folds contributes in building the training model while the last fold is used for testing the unseen samples. The average Correct Classification Rate (CCR) for various movements using SVM is shown in Table I. The results show that the average accuracy across various users is around 97% with average 99% for tip and lateral movements as the most identified movements.

TABLE I. CCR FOR VARIOUS MOVEMENTS WHEN SVM BASED USER DEPENDENT CLASSIFICATION IS APPLIED

Subject Move	1	2	3	4	5	average
Cyl.	0.97	0.97	0.93	1	1	0.97
hook	1	0.93	0.93	0.93	1	0.96
tip	0.97	1	1	1	1	0.99
palm	1	0.97	0.93	0.97	1	0.97
Sph.	0.93	0.93	0.97	0.93	1	0.95
Lateral	0.97	1	1	0.97	1	0.99
average	0.97	0.97	0.96	0.97	1	0.97

While using KNN classification with K=3, The average Correct Classification Rate (CCR) for various movements, as shown in Table II, The results show that the average accuracy across various users is around 92% with average 93% for tip and lateral movements as the most identified movements.

TABLE II. CCR RESULTS WHEN APPLYING KNN WITH K =3 AND EUCLIDEAN DISTANCE METHOD

Subject Move	1	2	3	4	5	average
Cyl.	0.9	0.9	0.93	0.93	0.93	0.92
hook	0.9	0.93	0.9	0.9	0.9	0.91
tip	0.93	0.93	0.93	0.9	0.93	0.93
palm	0.9	0.9	0.93	0.9	0.9	0.91
Sph.	0.9	0.9	0.93	0.93	0.9	0.91
Lateral	0.93	0.93	0.93	0.93	0.93	0.93
average	0.91	0.92	0.93	0.92	0.92	0.92

The second experiment performed tends to measure the effect of user samples contribution in building the training model. Using SVM as the classifier, the involvement of the first 10 user samples influences the classification accuracy as presented in Table III. The results show huge increase in the average accuracy. The performance enhancement could reach around 62.6% on average, when more than one sample from the user is involved in the training process and building the model. This sample represents around 1% of the training sample space. It achieves an accuracy result that equals to 89.6% on average.

The results of involving the user samples in building KNN model, as shown in Table IV, lead to the same conclusion. A great increase of accuracy of 50.9% on average is reached, as the number of user's involved samples is more than 2. Two samples represent around 2% of the training sample space. The KNN model achieves an accuracy result equals to 78.2%.

The effect of 27 of user samples contribution in building the training model is summarized in Fig. 2. It shows that the effect of user involvement decreases after three or more samples. Furthermore, the performance does not witness much difference after the involvement of the tenth sample and the sixteenth sample in case of SVM, and KNN respectively. The involvement of those samples lead to an accuracy of 98%, and 88% on average in case of SVM, and KNN respectively.

TABLE III. SVM BASED USER PARTIAL PARTICIPATION CCR ACCURACY RESULTS

Subject No.Samples	1	2	3	4	5
1	0.22	0.21	0.41	0.27	0.24
2	0.88	0.86	0.94	0.93	0.87
3	0.89	0.89	0.95	0.94	0.88
4	0.9	0.89	0.97	0.95	0.89
5	0.92	0.92	0.97	0.95	0.91
6	0.93	0.92	0.97	0.96	0.92
7	0.96	0.95	0.99	0.99	0.94

7	0.81	0.81	0.77	0.76	0.81
8	0.83	0.80	0.81	0.77	0.83
9	0.82	0.82	0.81	0.79	0.83
10	0.83	0.83	0.81	0.81	0.85

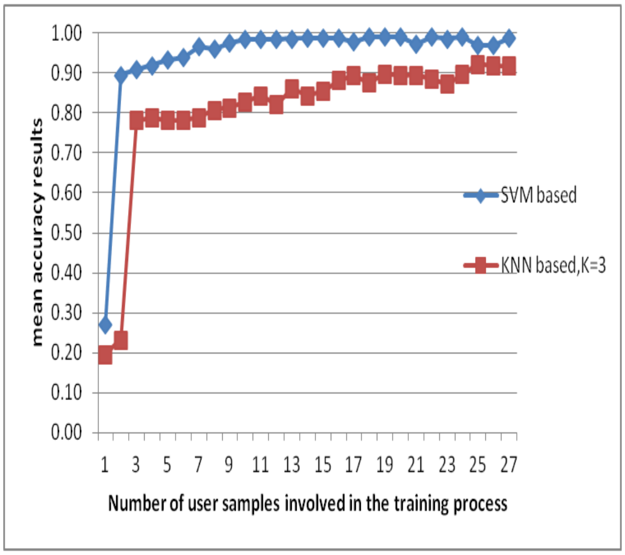

Fig. 2. The effect of involvement of user samples in building the training model.

Among the moves, as shown in Fig. 3 the hook move is the most distinguished one across all users from the first user sample using the one-versus-all SVM classifier. The other moves give approximately similar accuracy results after the involvement of two samples.

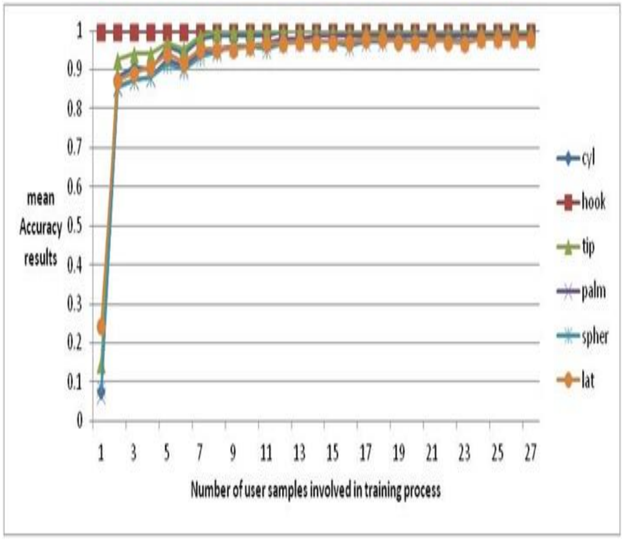

Fig. 3. The effect of involvement of user samples in building the training model with respect to movement.

To confirm that the results' means do not suffer from significant differences, two-way ANOVA test is applied to the partial samples inclusion results. It is proved that in both SVM and KNN based classification, for various subjects, the rejection of the null hypothesis is implied as the value of p is less than 0.05 for partial samples and different users.

V. Discussion

The results of our experiments show the possibility of involving only a small number of user samples, which could represent 2%–3% of the total sample space, in the re-calibration process in order to gain significantly increased performance accuracy. These findings could lead to the minimization of calibration time while maintaining relatively high performance results and thus increasing the user acceptance which is a main challenge in the EMG based gesture classification systems and the industry of EMG based prosthetic devices.

Our results used a small dataset that is publicly available which includes only five normal and healthy subjects with six different movements for thirty trials. So in future work, we intend to confirm our results using larger datasets with various movements for both healthy users and amputees.

VI. Conclusion and Future work

This paper is concerned with the user independence challenge facing the EMG-based movement recognition system. It reviews the previous research work regarding this obstacle that affects both user accuracy and acceptability. It studies the effect of partial user samples involvement in the calibration process using AutoRegressive features and traditional classification methods like one-versus-all SVM with Gaussian radial based kernel and KNN.

The findings are interesting in that a huge increase of accuracy has occurred as a result of including two to three user samples which represents around 2%-3% of the total training sample space. The increase is estimated to reach 62.6% on average in case of SVM classifier and 50.6% in case of KNN, achieving accuracy results equal to 89.6% on average in case of SVM and 78.2% in case of KNN. The results somehow stabilize after ten samples in case of SVM to reach 98% on average and after sixteen samples in case of KNN to reach 88% on average.

After applying two way ANOVA test to the partial samples inclusion results, either in SVM based classification or KNN based classification, for various subjects, it implies the rejection of the null hypothesis as the value of $p < .05$ for partial samples groups and different users confirming that the results' means do not suffer from significant differences.

The results assured the great influence on system accuracy when involving small number of user samples in the model-building process using traditional classification methods.

As a future work, we intend to confirm our results using larger datasets with various movements for both healthy users and amputees.

A New Approach Method for Multi Classification of Lung Diseases using X-Ray Images

Sri Heranurweni, Andi Kuniawan Nugroho, Budiani Destyningtias
Electrical Department-Engineering Faculty, Universitas Semarang, Semarang, Indonesia

***Abstract*—Lung disease is one of the most common diseases in today's society. This lung disease's treatment is frequently postponed. This is usually due to a lack of understanding about proper treatment and a lack of clear information about lung disease. Reading the correct X-ray images, which is usually done by experts who are familiar with these X-rays, is one method of detecting lung disease. However, the results of this diagnosis are dependent on the expert's practice schedule and take a long time. This study aims to classify lung disease images using preprocessing, augmentation, and multimachine learning methods, with the goal of achieving high classification performance accuracy with multi-class lung disease. The classification ExtraTrees was obtained from experimental results with unbalanced datasets using a balancing process with augmentation. Precision, Recall, Fi-Score, and Accuracy are 100% for training and testing data 89% for Precision, 88% for Recall, 87 for Fi-Score, and 85% for Accuracy outperform other machine learning models such as Kneighbors, Support Vector Machine (SVM), and Random Forest in classifying lung diseases. The conclusion from this research is that the machine learning approach can detect several lung diseases using X-ray images.**

Keywords—Augmentation; machine learning; lung disease; prepossessing

I. Introduction

The lungs are one of the organs in the respiratory system that serve as a site for the exchange of oxygen and carbon dioxide in the blood. Polluted air is a common problem, and the air that is inhaled contains many germs that will attack the lungs. Lung disease is a serious disease that affects the human respiratory system and can be fatal if not properly treated. This lung disorder causes sufferers to have difficulty breathing, difficulty performing activities, and a lack of oxygen, which can lead to death if not detected quickly [1]. Tuberculosis, bronchitis, pneumonia, lung cancer, emphysema, and pleuritic are all common lung diseases. It is usually done clinically to detect lung disease/disorders (physical symptoms by a doctor). Aside from clinical examination, X-rays, CT scans, and MRI can be used to diagnose lung disease; however, the latter two methods are more expensive. [2]. Another issue is a lack of public knowledge in reading CT Scan and MRI results, so experts such as doctors or other medical personnel are still required to read them. Many other difficulties, such as complicated backgrounds and the presence of multiple potential abnormalities, make clinical analysis of X-ray images a difficult task. [3]. As a result, manual annotations from experts (radiologists) are required.

Automatic X-ray image analysis is quickly becoming a valuable clinical diagnostic tool. Deep neural networks have recently achieved image classification success and are now widely used for X-ray image classification tasks [4], [5]. Deep learning on chest X-ray images can be used to classify a variety of diseases, including thoracic infections [4], COVID-19 [4]–[7], and lung disorders [8]. Husayn et al. [9] proposed CoroNet, a deep learning model for COVID-19 detection. A deep learning framework has been proposed to detect lung abnormalities in CXR and CT scan images [8]. Using GAN-based synthetic data, Albahli et al. [10] proposed a deep learning model that achieved 87% accuracy and produced results comparable to other techniques. Lung segmentation is another critical task in CXR disease detection. This is extremely useful for determining the severity of tuberculosis [11]. DeTraC's conventional deep neural network architecture is described by Abbas et al. [5].

II. Literature Review

The classification of lung diseases using X-ray images has been explored using various machine learning techniques. A hierarchical classification can be useful in detecting pneumonia due to the disease's hierarchical pattern [12]. Traditional machine learning approaches, such as Support Vector Machine (SVM), k-Nearest Neighbor (KNN), and Decision Tree classifiers, can be used to classify diseases in Chest X-Ray (CXR). They do, however, rely on a mechanism for feature extraction. Convolutional Neural Networks (ConvNets) are another mechanism for feature extraction. Toğacar et al. [13] compared the performance of traditional machine learning models for detecting pneumonia with the Redundancy Maximum Relevance (mRMR) minimum feature selection mechanism. Khatri et al. [14] compared CXR pneumonia images using the Earth Mover's Distance (EMD). Teixeira et al. [15] evaluated and described COVID-19 using lung segmentation. A multimodal approach to disease on CXR can aid in better understanding and elucidation. [16], [17].

Due to a lack of large amounts of annotated data and efficient machine learning algorithms to study some specific features, automatic disease classification on X-ray images is difficult [25]. A variety of data streams and modalities can be used to improve disease prediction accuracy. To train thoracic disease classifiers, text data from diagnostic X-ray images are combined with annotated image data [[17]. A deeply decomposed generative model, as opposed to the traditional approach of directly classifying disease, can be used to generate residual maps for abnormal disease alongside normal images [18]. This method aids in distinguishing between abnormal and normal chest X-ray parts. The semi-supervised generative model is effective for CXR disease classification [18], [19].

Multiple diseases can still occur at the same time. Single-label classification may be ineffective in this situation, whereas multi-label classification may be effective Albali et al. [20] proposed a CNN-based deep learning method for CXR multi-label classification. In addition, Baltruschat et al. [21] compared several multi-label chest radiograph classification methods based on deep learning. Pathology datasets are rife with class imbalances. Pathology datasets are rife with class imbalances. As a result, the trained classifier is vulnerable to bias towards the majority class. Appropriate class balancing measures can help improve classifier performance in supervised and semi-supervised tests [22]. The limitations of existing machine learning-based approaches for COVID-19 detection are discussed by López-Cabrera et al. [23] Tsiknakis et al. [24] present an artificial intelligence-based framework for COVID-19 screening that can be interpreted using CXR imagery.

The research aims to make the following main contribution based on the shortcomings of several researchers' classification methods:

1) To augment the limitations of the dataset generated from several hospitals in Semarang, especially for the types of COVID-19 and Tuberculosis (TBC) diseases.

2) Perform classification Performance comparisons with new approach machine learning models without selecting features from each image, so that the best machine learning algorithm model is produced based on its Performance.

III. Methodology

A. Dataset

Fig. 1 depicts the imbalance in the number of X-ray images for each class. Normal cases outnumber COVID-19 and Tuberculosis cases. This was seen as a disadvantage by researchers because the model worked better in major classes (Normal) than in minor classes. FP (normal classified as COVID-19 or TB) would be expensive, but it was much less expensive than FN (normal classified as COVID-19 or TB), which could be fatal. Therefore, the researchers addressed the class imbalance. When building a reliable image classifier with very little training data, image augmentation was usually required to improve deep network Performance. Image augmentation generated training images artificially by using various processing methods or combinations of processing methods on each training sample, such as random rotation, shift, sliding, and flipping [15]. To accomplish this, Image Data Generator would automatically label all data inside the COVID-19 or TBC folder as COVID-19 or TBC, and all data inside the Normal folder as Normal. As a result, the data was easily ready to be fed into machine learning.

B. Data Augmentation

Data augmentation was used by researchers to increase the number of samples and diversify the images in terms of position, orientation, brightness, and so on. In this study, the augmentation technique was the best method for adding data without having to look for primary data obtained at the hospital using strict procedures. Several augmentation techniques were employed in this study, including rotation range= 40, shear range = 0.2, zoom range = 0.2, width shift range = 0.2, height shift range = 0.2, and horizontal flip. Fig. 2 shows the X-ray images for each class. Fig. 3 depicts the augmentation results.

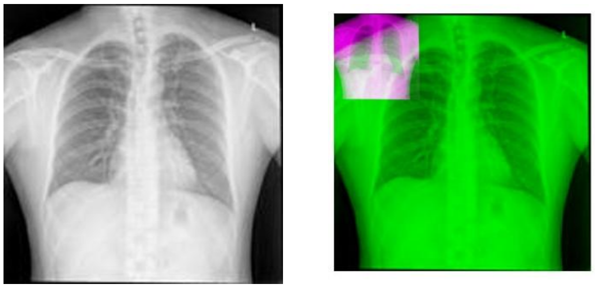
As shown in Table I, we collected lung disease images from several hospitals in Semarang for three classes: Normal, COVID-19, and Tuberculosis (TB) and divided them into training and testing sets.

TABLE I. Dataset Distribution Table for each Class

Class	Training Set	Testing Set	Total
Normal	8,454	476	8,930
COVID-19	2,363	490	2,853
Tuberculosis	474	18	492
Total	11,291	984	12,275



Original Image 224x224x3 Resize 100 x 100x3

Fig. 4. Resizing the original image into a resized image.

Fig. 4 depicts the X-ray image dataset, which is divided into three categories: normal, COVID-19, and tuberculosis (TB). The image has a resolution of 224x224 pixels and a bit depth of 16 bits [0-65535].

Fig. 4 depicts the change in dimensions of an X-ray image from 224x224x3 channels to 100x100x3 channels for computational time requirements, because the classification program must convert the images into a 2-dimensional matrix so that they can be processed in machine learning.

C. Research Model

The methodology for the study is depicted in Fig. 5. First, each class of lung diseases images was labelled. Image data was transformed into a 2D array. The next step was to reduce the size of the 2D image from 224x224x3 channels to 100x100x3 channels. The augmentation process was used to avoid unbalanced data when reproducing existing data. This study's augmentation process included a rotation range of 40, a shear range of 0.2, a zoom range of 0.2, a width shift range of 0.2, and a height shift range of 0.2. Furthermore, once the data had ben balanced, the next step was to feed 2D array data into the machine learning model to obtain classification performance so that each machine learning model with the highest accuracy, precision, recall, and f1 in each data training and testing can be evaluated.

IV. Machine Learning

A. K- Nearest Neighbor

The algorithm K-Nearest Neighbors is not parametric. On the basis of a given problem or data set, learning and predictive analysis are Performed. With no dataset assumptions, the KNN classification model is a pure prediction based on neighboring data values. The letter 'K' in KNN stands for the number of nearest neighbor values in the data. The KNN algorithm classifies a given dataset based on 'K,' or the number of nearest neighbors [25]. The Euclidian distance calculation method is the most commonly used. Equation (1) gives the Equation for Euclidean calculations.

$$Euclidean_{i,j} = \sqrt{\sum_{k=1}^{n}(x_{ik} - x_{jk})^2} \qquad (1)$$

The KNN algorithm is composed of four steps. The distance from the new data to all data is calculated in the first step. The distances are then sorted in the second step. The third step finds the smallest k value, and the final step determines the class.

B. Extra Tree

Extra Trees is an ensemble machine learning approach that trains multiple decision trees and combines the results of a group of decision trees to generate predictions. However, there is a distinction between Extra Trees and Random Forest. To ensure that the decision trees are sufficiently distinct, Random Forest used bagging to select different variations of the training data. Extra Trees, on the other hand, used the entire data set to train decision trees. Therefore, it randomly selected values to split features and created child nodes in order to ensure sufficient differences between each decision tree. Extra trees can reduce model bias by using the entire dataset, which is the default setting and can be changed. On the other hand, randomizing the feature values to be split increased both bias and variance.

C. Support Vector Machine (SVM)

This stage involved using the SVM classification method to generate a classifier in the form of a feature vector, which was then used to generate predictions for testing. Following the completion of the preceding stages, the extraction results were used to generate an SVM classification model. The distance of the vector that had been mapped would be calculated. The greatest distance would be used as the vector's class separator. Then a hyperplane was added to separate the two classes. The most important requirement for developing an SVM classification model was to convert documents into vector form. Value variations were used to find values that were as accurate as possible. This procedure was necessary in order to convert the test document into a vector. The following step was to take the test document data, which was commonly referred to as a vector, and insert it into the previously created SVM model. The hyperplane Equation was a classification Equation, as shown by Equation (2), with the classification parameters *w* and *b* as the weight and bias values, as shown by Equations (3) and (4).

$$f_{svm}(x) = w.x + b \qquad (2)$$

$$w = \sum_{1}^{N} a_i \, y_i x_i \qquad (3)$$

$$b = -\frac{1}{2}\,(w.x^{+} + w.x^{-}) \qquad (4)$$

Where N is the amount of data and ai is the weight coefficient value for each pair of data points and labels (xi,). SVM is also good at dataset management because it finds hyperplanes using trick kernels, one of which is the Linear Kernel shown in the Equation (5).

$$K(x_i, x_j) = x_i, x_j \tag{5}$$

From the kernel results obtained, SVM creates a classification Equation that is adjusted to the kernel used, such as Equation (6) with class classification values based on Equation (7) [25].

$$f_{svm}(x) = \sum a_i y_i K(x_i , x) + bi \in N \tag{6}$$

$$class = \begin{cases} 1, fsvm \geq 0 \\ -1, other\ than\ that \end{cases}$$

D. Random Forest

Random forest is a classification method that consists of a collection of classification trees. For example {h(x,Θk), k = 1, …} where {Θk} is a random vector that is independently distributed and each tree chooses the class that has the most number of data (majority cote). Suppose an ensemble $h_1(x)$, $h_2(x)$, …., $h_k(x)$ with training data is randomly selected from the distribution of random vectors Y and X, the margin function (mg(X,Y)) of the random forest is defined as follows:

$$mg(XY) = \frac{\sum_{k=1}^{K} I(h_k(X)=Y}{K} - max_{j\neq Y}\left[\frac{\sum_{k=1}^{k} I(h_k(X)=j)}{K}\right] \tag{7}$$

where, I is the indication function and K is the number of trees. The margin function is used to calculate the level of the number of votes in X and Y, as well as the average vote from other classes [26].

V. Result and Analysis

This study used a primary dataset with a data ratio of 70:30 for each class, as shown in Table II. A total of 11291 data points were generated in each training data set by producing the Extra Trees model with Estimator = 500 and values for precision, recall, F1-score, and accuracy of 100%, followed by other machine learning models such as SV and Random Forest. Table III shows that the Extra Trees model has the best performance value when compared to other machine learning models, with a total of 984 data points for testing.

Fig. 6(a) shows the prediction column, and thus the row must be the actual value. In the training data, the main diagonal (8030, 2135, 4070) of the confusion matrix of the Kneighbors model (n neighbors=3) gives the correct prediction. When the actual and predicted values from the model are the same, this is the case. The actual normal number is on the first line. The model predicts 8030 cases, 358 of which are COVID-19 normal and 66 of which are Tuberculosis normal. The actual COVID-19 number can be found in the second row. The model predicts COVID-19 correctly and incorrectly, with 201 COVID-19 becoming normal and 27 COVID-19 becoming TB. Tuberculosis is in the third row. The model predicts that 470 of them will correctly predict TB, 1 will become normal, and 3 will become COVID-19.

Fig. 6(b) depicts the prediction column, and thus the row must be the actual value. The main diagonal (330, 464, 18) for the confusion matrix of the Kneighbors model (n neighbors=3) testing data gives the correct prediction. This is the case when the actual and predicted values from the model are the same. The first line contains the true normal number. According to the model, 330 of them correctly and incorrectly predict 159 normal to COVID-19 and 2 normal to be Tuberculosis. The actual COVID-19 number is in the second row. The model predicts that 464 of them will correctly and incorrectly predict COVID-19, that 10 COVID-19 will become normal, and that 1 COVID-19 will become TB. Tuberculosis is in the third row. The model predicted that 18 of them would be correct and 1 would be normal.

(b)

Fig. 7. Confusion matrix for the training model and testing the Kneighbors model (n_neighbors=5).

Fig. 7(a) depicts the prediction column, implying that the row must represent the actual value. The main diagonal (7997, 1981, 417) for the training data gives the correct prediction for the confusion matrix of the Kneighbors model (n neighbors=5). In this case, the actual and predicted values from the model are the same. The standard number appears on the first line. The model correctly predicts 7997 of them, 510 of which are normal to COVID-19 and 92 of which are normal to Tuberculosis. The second row contains the actual COVID-19 number. The 1981 predictive model included correctly and incorrectly predicting COVID-19, with 233 COVID-19 being normal and 52 COVID-19 being Tuberculosis. The third row is Tuberculosis. The model predicted that 417 of them would correctly predict TB, 2 TB would be normal, and 5 TB would be COVID-19.

Fig. 7(b) depicts the prediction column, and thus the row must be the actual value. For the Kneighbors model matrix confusion (n neighbors=5) data testing, the main diagonal (321, 415, 13) yields the correct prediction. When the actual and predicted values from the model are the same, this is the case. The actual normal number is on the first line. The model predicts that 321 of them will be correct, with 168 normal to COVID-19 and 5 normal to Tuberculosis. The actual COVID-19 number is in the second row. The model predicts that 451 of them will correctly predict COVID-19, 19 will become normal, and 3 will develop Tuberculosis. Tuberculosis is in the third row. The model predicts that 13 of them will correctly predict TB, and four of them will become COVID-19.

Fig. 8(a) depicts the prediction column, and thus the row must be the actual value. In the training data, the main diagonal (7992, 1909, 387) for the confusion matrix of the Kneighbors model (n neighbors=7) gives the correct prediction. When the actual and predicted values from the model are the same, this is the case. The actual normal number is on the first line. The model correctly predicts 7,992 of them, 583 of which are normal to COVID-19 and 97 of which are normal to Tuberculosis. The COVID-19 number is in the second row. The model correctly predicts COVID-19 for 1909 of them, 236 COVID-19 becomes normal, and 79 COVID-19 becomes TB. Tuberculosis is the third row. The model correctly predicted 387 of them, with 4 TB being normal and 4 TB being COVID-19.

Fig. 8. Confusion matrix for the training model and testing the Kneighbors model (n_neighbors=7).

Fig. 8(b) depicts the predicted column, and thus the row must be the actual value. For the Kneighbors model matrix confusion (n neighbors=7) data testing, the main diagonal (327, 435, 12) yields the correct prediction. When the actual and predicted values from the model are the same, this is the case. The actual normal number is on the first line. The model predicts that 327 of them will correctly predict, 185 will be normal for COVID-19, and 6 will be normal for Tuberculosis. The actual number of COVID-19 is shown in the second row. The model predicts that 435 of them will correctly predict COVID-19, 13 will become normal, and 3 will develop Tuberculosis. Tuberculosis is in the third row. The model predicts that 12 of them will correctly predict TB and 4 will correctly predict COVID-19.

Fig. 9(a) depicts the prediction column, implying that the row must represent the actual value. The training data for the ExtraTrees model confusion matrix (n estimators=500) gives the correct prediction along the main diagonal (8232, 2496, 563). In this case, the model's actual and predicted values are the same. The true normal number is found on the first line. The model correctly predicts 8232 of them. The actual COVID-19 number is in the second row. 2496 of them correctly predict COVID-19, according to the model. Tuberculosis is in the third row. The model correctly predicted TB in 563 of them.

(b)

Fig. 10. Confusion matrix for training and testing models for Support Vector Machine (SVM).

Fig. 10(a) shows the prediction column, and thus the row must be the actual value. The Support Vector Machine (SVM) data model confusion matrix's main diagonal (8232, 2496, 563) yields correct predictions. This is the case when the model's actual and predicted values are the same. The true normal number is found on the first line. The model correctly predicts 8232 of them. The actual COVID-19 number is in the second row. 2496 of them correctly predict COVID-19, according to the model. Tuberculosis is in the third row. The model correctly predicted TB in 563 of them.

Fig. 10(b) shows the predicted column, implying that the row must be the actual value. For the Confusion Support Vector Machine (SVM) model testing data, the main diagonals (331, 488, 19) provide the correct predictions. When the model's actual and predicted values are the same, this is the case. The true normal number is on the first line. The model predicts that 331 of them will correctly predict, 134 will become COVID-19, and 2 will become Tuberculosis. The actual COVID-19 number is in the second row. The model predicts that 488 of them correctly predict COVID-19, with 9 of them becoming normal. Tuberculosis is in the third row. The model predicts that 19 of them will correctly predict TB, with one TB being COVID-19.

Fig. 11(a) shows the predicted column, and thus the row must be the actual value. The training data for the Random Forest model confusion matrix (n estimators=500) gives the correct prediction along the main diagonal (8232, 2496, 563). This is the case when the model's actual and predicted values are the same. The true normal number is found on the first line. The model correctly predicts 8232 of them. The actual COVID-19 number is in the second row. 2496 of them correctly predict COVID-19, according to the model. Tuberculosis is in the third row. The model correctly predicted TB in 563 of them.

The main diagonals (330, 464, 18) for the Random Forest Confusion model (n estimators=500) test data give the correct predictions. This is the case when the model's actual and predicted values are the same. The actual normal number appears on the first line. The model predicts that 330 of them will be correct, with 159 being normal and two being Tuberculosis. The COVID-19 number is in the second row. The model predicts that 464 of them will correctly predict COVID-19, 10 will be normal, and 1 will be Tuberculosis. Tuberculosis is the third row. The model correctly predicted TB for 18 of them.

Table IV shows comparison of the accuracy values with several researchers. Bakir et al applied deep learning techniques to detect pneumonia from X-ray images. They used an artificial neural network (ANN) model to classify bacterial, viral, and healthy lungs into multiple classes. His proposed ANN model with ResNet feature extraction, in multi-class classification he achieved 81.67% classification accuracy [27]. Kim, Sungyeup et al used chest X-ray (CXR) images to diagnose three classes, normal, pneumonia and peumothorax. The method used uses a deep learning model (EfficientNet V2-M) to produce an accuracy value of 82.15% [28].

TABLE IV. COMPARISON OF ACCURACY VALUE WITH OTHER RESEARCHERS

Prior Work	Model	Acc (%)
Bakir et al [27]	ANN model	81.67%
Kim, Sungyeup et al [28]	EfficientNet V2-M	82.15%.
Proposed Method	ExtraTrees	85%

VI. Conclusion

Through the use of multiple machine learning techniques, this study contributes to the multi-class classification of lung diseases. The research methodology used in this study is an experimental multi-class classification of lung disease using an augmentation process to obtain balanced data.

The experimental results produce the Extra Trees classification which has Precision, Recall, F-Score, and Accuracy score of 100% for training, and testing data, 89% for Precision, 88% for Recall, 87% for Fi-Score, and 85% for Accuracy higher than the Performance of other machine learning models such as Kneighbors, Support Vector Machine (SVM), Random Forest and more effective in Classification of lung diseases. Comparison with other researchers shows that the proposed model has a higher accuracy value compared to other models.

In further research, the dataset as a whole is still not large enough and of low quality for highly accurate and useful deep learning results that can be used as benchmarks for the identification of lung disease types by viewing X-rays. More high-quality images are needed to increase the accuracy of average ratings to higher levels in multiple-class classification. The data is expected to grow over time, enabling better classification results.

FPT University, Can Tho 94000, VietNam

***Abstract*—Autonomous driving has become a popular area of research in recent years, with accurate perception and recognition of the environment being critical for successful implementation. Traditional methods for recognizing and controlling steering rely on the color and shape of traffic lights and road lanes, which can limit their ability to handle complex scenarios and variations in data. This paper presents an optimization of the You Only Look Once (YOLO) object detection algorithm for traffic light detection and end-to-end steering control for lane-keeping in the simulation environment. The study compares the performance of YOLOv5, YOLOv6, YOLOv7, and YOLOv8 models for traffic light signal detection, with YOLOv8 achieving the best results with a mean Average Precision (mAP) of 98.5%. Additionally, the study proposes an end-to-end convolutional neural network (CNN) based steering angle controller that combines data from a classical proportional integral derivative (PID) controller and the steering angle controller from human perception. This controller predicts the steering angle accurately, outperforming conventional open-source computer vision (OpenCV) methods. The proposed algorithms are validated on an autonomous vehicle model in a simulated Gazebo environment of Robot Operating System 2 (ROS2).**

Keywords—Yolo models; PID; CNN; gazebo; ROS2; traffic-light; lane-keeping; autonomous

I. Introduction

The increasing number of vehicles on the road has raised concerns about traffic accidents and fatalities caused by various factors [1]. To address this, research has been conducted to create technologies that enhance driving safety, such as Advanced Driver Assistance Systems (ADAS) and autonomous driving systems. Traffic light signal recognition is a crucial component of these systems as it helps to detect the current status of traffic lights and provides real-time information for the vehicle control system to make accurate decisions. The conventional approaches for early detection of traffic lights rely on identifying manual features and color characteristics of signal lights, as [2]-[7]. These methods typically employ feature matching, color matching, or similar techniques to detect traffic lights based on their shape and color. Other approaches involve utilizing offline location information, which includes traffic light data from maps and GPS-based data, to track both the vehicle's present location and the status of traffic lights, as discussed in references [8]-[10]. Conventional approaches to detecting traffic lights are constrained by technical aspects like the type of camera used and the surrounding installation conditions. Additionally, these methods rely on offline location data that needs to be constantly refreshed and is susceptible to security risks.

In recent years, deep learning approaches, such as convolution neural network (CNN) [11], single shot multibox detector (SSD) [12], or YOLO architecture [13]-[15], have been used to accurately identify traffic lights and provide a real-time solution for traffic light detection. Among these approaches, the YOLO method has emerged as the best performer in detecting and recognizing traffic signals. Compared to other deep learning techniques, it offers smoother, more accurate results, and achieves real-time performance. Joseph et al. presented YOLO and an enhanced version called YOLOv2, which were utilized for detecting and classifying traffic lights [16]-[17]. Possatti et al. employed YOLOv3 [18] along with prior maps to identify crucial states of traffic lights for vehicles in their investigation. Tai et al. made advancements to YOLOv4 to enhance its precision in classifying green, red, and yellow traffic lights [19]. However, the past year has seen the release of a series of updated versions of YOLO, including YOLOv5 [20] [21], YOLOv6 [22], YOLOv7 [23], and YOLOv8 [24], each of which shows improved accuracy and performance in implementation on the COCO dataset.

To apply these improved models in the field of autonomous vehicles, we present our traffic light detection algorithm that utilizes the latest version of YOLO, YOLOv8 [25]. Additionally, we demonstrate the superior performance of YOLOv8 compared to other models (YOLOv5-v6-v7), in terms of accuracy and real-time processing. We conduct experiments on the traffic light dataset obtained and augmented data from multiple sources, including the CinTA_v2 dataset, and GathoTF datasets shown in Fig. 1.

Furthermore, research focused on utilizing camera images for angle prediction in autonomous vehicles to ensure proper lane-keeping has garnered considerable interest and made significant advancements. Earlier research employed image processing techniques, including color and edge detection, as well as critical lane regions such as the Canny edge detector, Hough Transform technique, and Isolate Region of Interest (IROI), to predict the steering angle [26]-[29]. The steering angle was then used in combination with a classic PID controller to ensure lane-keeping [30]-[33]. However, when faced with more complex scenarios, such as intersections, where lane images may be interrupted, a hybrid angle controller must be employed to account for driver perception. To overcome these limitations, autonomous vehicle control techniques have emerged that utilize deep learning to emulate human driving behavior.

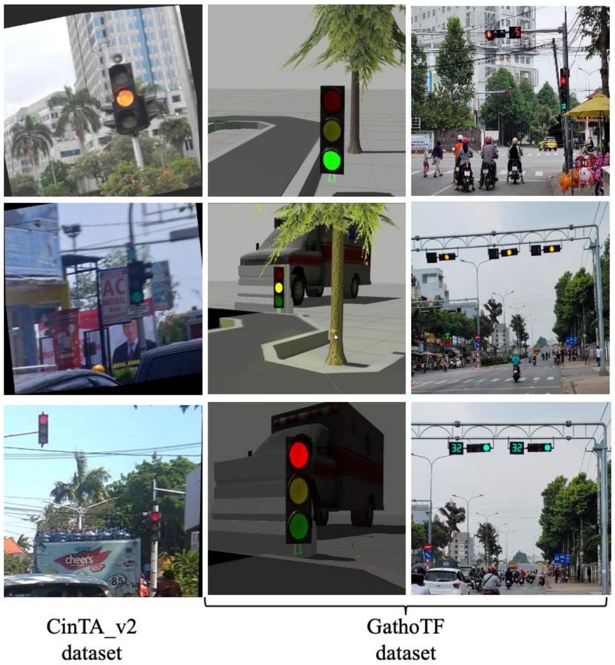

Fig. 1. Traffic light dataset.

In this research, we present a YOLOv8 architecture for traffic light recognition combined with an end-to-end CNN steering controller for lane-keeping in a simulated Gazebo environment of Robot Operating System 2 (ROS2). While the vehicle is following the lane, the traffic light signals are also detected and classified to send to the central controller. The primary contributions of this research are:

- The new YOLOv8 model is applied in our traffic light detection algorithm. Using the multiple source traffic light dataset, the YOLOv8 model is trained, evaluated, and compared accuracy and real-time performance with previous models.
- Based on the end-to-end convolution network, a steering angle predictor is designed. The model not only re-learns human driving behavior but is also trained with a data set of OpenCV+PID steering angle control methods to increase the accuracy of lane keeping and to give a steering angle when the lane is discontinuous.
- To assess the effectiveness of our proposed method for traffic light detection and lane-keeping, we collected a dataset by driving a donkey car model following the lane and incorporating traffic lights into the Gazebo-ROS2 simulation environment. We compared the performance of our method with that of previous methods using the same dataset.

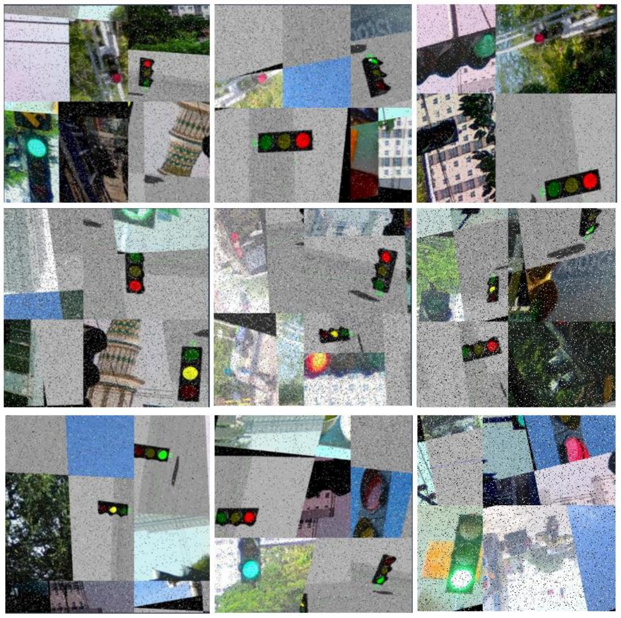

Fig. 2. Augmentation dataset.

This paper is structured as follows: Section II describes the architecture of YOLO models used for traffic light detection and classification. Section III provides a detailed description of the end-to-end CNN steering angle predictor, including the data collection process, evaluation metrics, and network architecture. Section IV presents the experimental results and provides a discussion of the findings. Finally, Section V concludes the paper and suggests areas for future research.

II. Traffic Light Detection and Classification Using YOLO Models

A. Preprocessing Data

1) Data collection: To evaluate the effectiveness of YOLO in traffic light detection, experiments are conducted using a synthetic dataset, which was collected from two different sources, the CinTA_v2 traffic light datasets, and GathoTF datasets.

(https://www.kaggle.com/datasets/ngochoangtran1992/traffic-light-dataset).

The CinTA_v2 dataset is a freely available traffic light dataset that was public in Roboflow. It contains 999 images captured under various weather and lighting conditions, and for this study, 999 images were randomly picked for training and evaluation. Each image has a resolution of 1280 x 960 pixels.

The GathoTF dataset consists of 2025 images and includes traffic light images taken in Can Tho city and traffic light images taken in a virtual environment created by the Gazebo/ROS2 program. In this environment, a self-driving car was simulated, and a camera mounted on the car took pictures at a frame rate of 30 fps and a resolution of 1024 x 600 pixels.

TABLE I. DETAILED DIFFERENCES BETWEEN YOLO MODELS

	Model	**Backbone**	**Neck**	**Head**	**Loss Function**
YOLOv5 [36]	The YOLOv5 algorithm is a fast and efficient object detection system that uses anchor-free detectors, a CSPDarknet53 backbone, a PAN neck, and AutoML for anchor box optimization and employs a Mosaic data augmentation technique to improve generalization.	CSPDarkent53 Focus structure	PANet	B x (5 + C) output layer B: No, of bounding boxes C: Class score	Binary Cross Entropy and Logit Loss Function
YOLOv6 [37]	YOLOv6 is an updated version of the YOLO algorithm that incorporates a RepVGG backbone, VariFocal Loss for dynamically adjusting object contribution during training, SIoU and GIoU for classification and regression loss, and a Focal Attention mechanism for improved region detection.	RepVGG And CSPRepStack	RepPAN	Decoupled Classification and Detection Head	Varifocal Loss for Classification and Distribution Focal Loss for Detection
YOLOv7 [38]	YOLOv7 is an object detection algorithm that uses an Extended Efficient Layer Aggregation backbone with group convolution, a Gradient Flow Propagation module for re-parameterization, and an auxiliary head for improved prediction accuracy.	EELAN	PANet	Lead Head for final output, Auxiliary Head for middle layer outputs	BCE with Focal Loss for Classification, IoU loss for Detection
YOLOv8 [39]	YOLOv8 is an object detection algorithm that uses a CSP-inspired C2f module instead of the C3 module, allowing for more abundant gradient flow information while maintaining a lightweight design.	CSP same as that of YOLOv5 but C3 module replaced by C2f module	PAN-FPN	Decoupled-Head	VFL Loss and DFL Loss+CIOU

Using our datasets to train and test evaluate its effectiveness in traffic light recognition and detection. The variety of datasets enabled us to enhance and improve the model's resilience and generalizability by exposing it to a variety of different scenarios and conditions.

Algorithm 1: Data augmentation

Input: Load the dataset of traffic light images and their corresponding labels.

1. For each image in the dataset, randomly select one or more of the following augmentation techniques:

1.1: Image flipping: randomly flip the image horizontally or vertically.

1.2: Image rotation: randomly rotate the image by 15 degrees to the right or left.

1.3: Blur: apply a Gaussian blur with a kernel size of 8% to the image.

1.4: Random cropping: randomly crop the image by 3%.

1.5: Noise generation: add random Gaussian noise with a standard deviation of 8% to the image.

1.6: Decolorization: randomly remove 7% of the color channels from the image.

2. Apply the selected augmentation techniques to the image and save the new image as a separate file in the dataset folder.

3. Update the label of the new image with the same label as the original image.

4. Repeat steps 1-3 for all images in the dataset.

Result: Save the augmented dataset and use it to train and test the traffic light recognition system.

2) Data augmentation: In order to enhance the precision of the traffic light recognition system and expand the dataset, Algorithm 1 was implemented.

Following the augmentation procedure, the labeled data was reintegrated into the dataset, thereby augmenting the quantity of inherent angle data. The labeled data was then used to train a YOLO model. As a result of the data augmentation techniques, the original dataset of 4017 images was expanded to include 6695 additional images, resulting in a more diverse and robust dataset. Fig. 2 shows the example of the dataset after the augmentation. Next section, the different YOLO models are compared and analyzed when applying these models to traffic light detection and classification.

B. Detection and Classification using YOLO Models

This study employs four versions of YOLO architecture for traffic light recognition. YOLO architecture, originally introduced by Redmon et al. (2016) [34], approaches the detection task as a regression problem based on the Darknet architecture. Unlike popular Region Proposal Networks (RPN), YOLO predicts both bounding boxes (Bbox.) and class probabilities (Cls.) in a single network. This approach is based on a user-defined size grid cell responsible for detecting the object if it falls into the cell. To accurately evaluate the performance of these YOLOv models, we analyze the differences as well as the advantages and disadvantages of each model before applying them to the identification and classification of traffic lights. The comparison between structures of YOLOv5, YOLOv6, YOLOv7, and YOLOv8 are shown in Table I. The features of the modules are as follows:

- YOLOv5 is an advanced object detection algorithm that utilizes anchor-free detectors to detect multiple objects in real-time [20], [35]. It uses a CSPDarknet53 backbone and PAN (Path Aggregation Network).

- Network for faster and more efficient detection. The Mosaic data augmentation technique combines multiple images into a single image to enhance generalization, while AutoML optimizes anchor boxes of varying sizes and aspect ratios for each grid cell. YOLOv5 offers superior speed and accuracy in object detection compared to other methods.

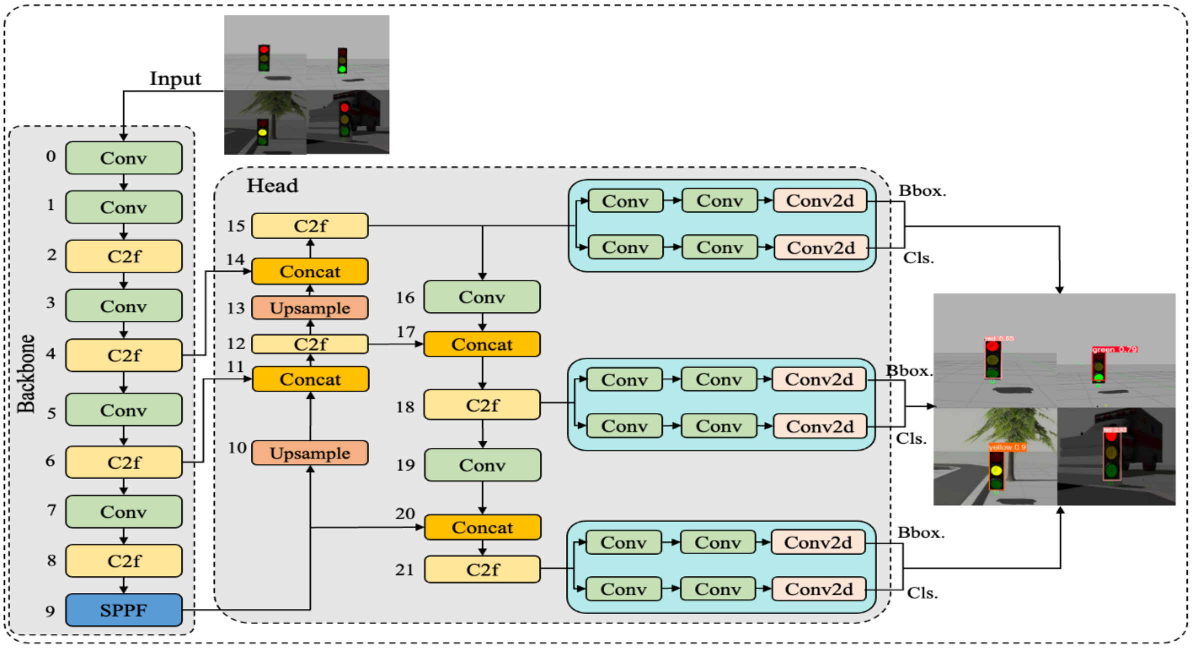

Fig. 3. YOLOv8 model.

- The YOLOv7 model incorporates an innovative architecture known as Extended Efficient Layer Aggregation (EELA) as its backbone. This novel design employs group convolution to broaden the computational block's channel, thereby enhancing the model's overall performance [38]. The algorithm also uses a new module called the Gradient Flow Propagation (GFP) module, which helps to determine which modules need re-parameterization in order to improve the model's accuracy. Finally, YOLOv7 includes an auxiliary head that is designed to provide a coarse-to-fine definition for better predictions lightweight.

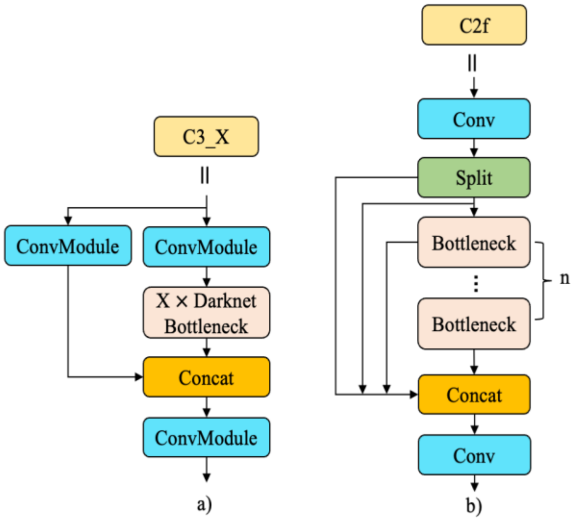

Fig. 4. Comparison of the structure of CS_X (YOLOv5) and C2f (YOLOv8) in backbone.

- The Backbone part of YOLOv8 is basically the same as that of YOLOv5, and the C3 module is replaced by the C2f module based on the CSP idea [39]. The C2f module learned from the ELAN idea in YOLOv7 and combined C3 and ELAN to form the C2f module so that YOLOv8 could obtain more abundant gradient flow information while ensuring lightweight. We use the model YOLOv8 for detecting, and classification traffic lights, as shown in Fig. 3. Fig. 4 is a comparison of the structure of CS_X (YOLOv5) and C2f (YOLOv8) in the backbone.

Four YOLO models are proposed to compare and test the applicability of these models to traffic light signal recognition for autonomous vehicle systems. There are a total of three active traffic light states: s = {red, yellow, green}. The models will be trained on our augmentation datasets

III. End-to-End CNN Steering Angle Controller

A. *Preprocessing Data*

1) Data collection: To ensure the vehicle is always in the center of the lane, a series of multi-step image processing using the OpenCV method and a PID steering controller is applied [33]. The steering angle will be predicted after image processing to detect the two lines of the lane. Combined with the PID controller, the vehicle will move more precisely. At this point, we will collect the input image data and the output steering angle to train the end-to-end CNN steering angle controller model. It contains 10,000 images captured from the camera mounted on the vehicle in the simulation environment Gazebo/ROS2. However, when the car went through the intersection and encountered complicated situations, the estimated steering angle from the lane detection was interrupted, so we used the joystick to control the car with human perception. In this case, 10,000 pictures continue to be collected along with the steering angle from human perception. Fig. 5 shows the dataset for the end-to-end CNN steering angle controller model.

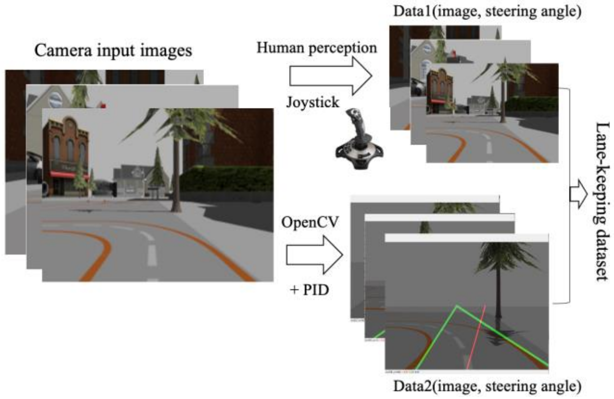

Fig. 5. Dataset for the end-to-end CNN steering angle controller model.

2) Data augmentation and normalization: To improve the accuracy and avoid issues with gradient explosion or vanishing of the lane-keeping model, data augmentation and normalization techniques are employed as Algorithm 2.

Algorithm 2: Data Augmentation and Normalization

```
Input: Training Dataset
1. AUGMENT (image, steering angle):
    1.1. if random () < 0.5;
            image = pan(image) // crop out a smaller image from the left or right side
    1.2. if random () < 0.5;
            image = zoom(image) // crop out a smaller image from the center
    1.3. if random () < 0.5;
            image = blur(image) // a Gaussian blur
    1.4. if random () < 0.5;
            image = adjust_brightness(image) // adjust brightness of the image
    1.5. image, steering angle = random flip (image, steering angle) // perform a horizontal flip on the image, which means flipping it from left to right, and adjust the corresponding steering angle accordingly.
    1.6. return image, steering angle
2. NORMAL (image):
    2.1. height = image.height.
    2.2. image = image[height/2+100] //Remove top half of the image, as it is not relevant for the lane following
    2.3. image = convert_Color(image, cv2.COLOR_RGB2YUV) //The optimal choice is to utilize the YUV color space.
    2.4. image = GaussianBlur(image, (3,3), 0)
    2.5. image = resize (image, (200,66)) // input image size (200,66) our model
    2.6. image = image / 255 # normalizing, the processed image becomes black for some reason
    2.7. return image
Result: Augmented and normalized image data with updated steering angles.
```

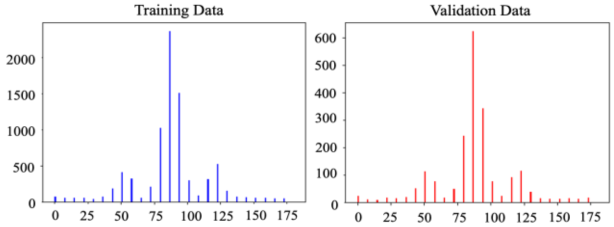

Fig. 6. Normalisation and augmentation of dataset.

As depicted in Fig. 6, our dataset has been subjected to both normalization and augmentation. Meanwhile, the distribution of the steering angle within our dataset has been illustrated in Fig. 7.

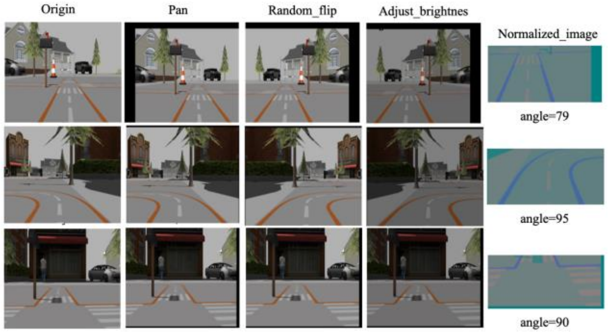

Fig. 7. Distribution of the steering angle within our dataset.

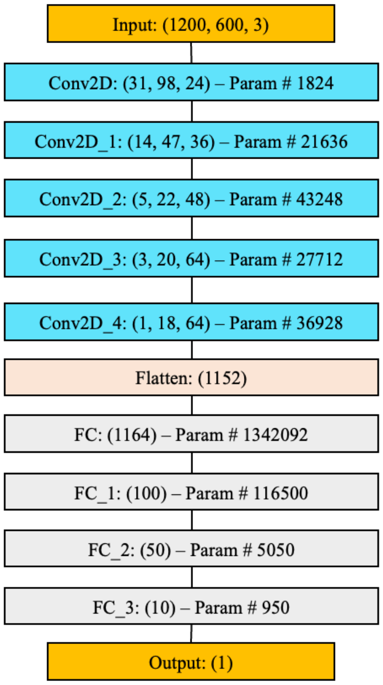
B. Lane Keeping Using End-to-End CNN Model

The proposed network architecture used an end-to-end neural network called Nvidia_model, Fig. 8 shows a convolutional neural network architecture with five Conv2D layers, followed by a flattened layer and three fully connected (FC) layers, and an output layer with a single neuron.



Input: (1200, 600, 3)
Conv2D: (31, 98, 24) – Param # 1824
Conv2D_1: (14, 47, 36) – Param # 21636
Conv2D_2: (5, 22, 48) – Param # 43248
Conv2D_3: (3, 20, 64) – Param # 27712
Conv2D_4: (1, 18, 64) – Param # 36928
Flatten: (1152)
FC: (1164) – Param # 1342092
FC_1: (100) – Param # 116500
FC_2: (50) – Param # 5050
FC_3: (10) – Param # 950
Output: (1)

Fig. 8. Convolutional neural network architecture.

The input to the network is a 3-dimensional tensor with shape (1200, 600, 3), which suggests that the input is an image with a width of 1200 pixels, a height of 600 pixels, and 3 color channels (e.g., RGB). The first layer in the network is a convolutional layer with 24 filters, each with a shape of (31, 98). This layer has 1,824 parameters, which are learned during training.

The next layer is another convolutional layer with 36 filters, each with a shape of (14, 47). This layer has 21,636 parameters. The third layer is a convolutional layer with 48 filters, each with a shape of (5, 22). This layer has 43,248 parameters. The fourth layer is a convolutional layer with 64 filters, each with a shape of (3, 20). This layer has 27,712 parameters. Finally, the fifth layer is a convolutional layer with 64 filters, each with a shape of (1, 18). This layer has 36,928 parameters.

After the last convolutional layer, the output is flattened into a 1-dimensional tensor with shape (1152). This flattened output is then fed into a fully connected (FC) layer with 1,164 units. This FC layer has 1,342,092 parameters. The output of this layer is then fed into another FC layer with 100 units, which has 116,500 parameters. The next FC layer has 50 units and 5,050 parameters. Finally, there is a FC layer with 10 units and 950 parameters. The total number of parameters in this model is 1,595,511. The output of the fourth fully connected layer is passed through and the output layer contains a single neuron, which predicts the steering angle.

IV. Experimental Result

A. Experimental System

To evaluate the performance of our proposed algorithms, we conducted experiments in a simulated environment using Gazebo-ROS2. The simulation was run on an Ubuntu 20.04 platform with an Intel Core i7 processor and 16 GB RAM. The simulated vehicle was equipped with a front-facing camera, simulated based on the actual parameters of the WGE100 camera. The camera captured images with a resolution of 1024×600 at a frame rate of 30 fps. The simulation environment was set up to include a variety of traffic light scenarios and lane configurations to test the robustness of our algorithms.

The experimental system consisted of two parts: traffic light detection and end-to-end steering control. For traffic light detection, we trained our YOLOv8 model using the CinTA_v2 and GathoTF datasets, which were augmented using Algorithm 1 to increase their size and diversity. We evaluated the performance of the model in terms of accuracy, precision, and recall on a test set of 20% of the total dataset. We also compared the performance of YOLOv5, YOLOv6, and YOLOv7 models for traffic light detection.

For end-to-end steering control, we designed a convolutional neural network-based steering angle controller that combines data from a classical PID controller and human perception. The model was trained on the same dataset used for traffic light detection and evaluated on a separate test set. We compared the performance of our model with that of a traditional PID controller and analyzed the results.

In order to assess the effectiveness of our proposed algorithms, we employed a Donkey Car model, in which the steering angle was controlled based on the predictions made by our model. The Donkey Car was driven on a predefined route in the simulated environment as shown in Fig. 9, which included a variety of traffic light scenarios and lane configurations. We collected data from the camera and the steering angle sensor to evaluate the performance of our algorithms in real time.

Overall, our experimental system allowed us to evaluate the effectiveness and robustness of our proposed algorithms for traffic light detection and end-to-end steering control in a simulated environment. The results of our experiments are presented and analyzed in the next section.

B. Evaluation Metrics

The use of evaluation metrics is critical in comparing and assessing the performance of machine learning algorithms. In this study, we compare four different object detection algorithms - YOLOv5, YOLOv6, YOLOv7, and YOLOv8, using various metrics such as F score, and mAP. To provide a comprehensive evaluation of the proposed algorithm's performance, we employ several evaluation metrics, including precision, recall, mAP, F-score, and FPS. However, to avoid potential biases in the evaluation process, we utilize different evaluation criteria that are based on different aspects of the algorithms' performance.

In order to evaluate the effectiveness of the proposed algorithm, this study utilizes several metrics including precision (P), recall (R), average precision (mAP), F1-Score, and Frames Per Second (fps). Precision is a critical metric used to assess the accuracy of the evaluation object by determining the ratio of correctly predicted positive samples to the total number of predicted positive samples.

$$P = \frac{TruePositive}{TruePositive + FalsePositive} \tag{1}$$

TruePositive indicates the count of positive samples accurately predicted as positive, whereas FalsePositives denotes the count of negative samples incorrectly predicted as positive.

Recall measures the ratio of correctly predicted positive samples to the total number of actual positive samples. It indicates whether the evaluation object is detected in its entirety or not.

$$R = \frac{TruePositive}{TruePositive + FalseNegative} \tag{2}$$

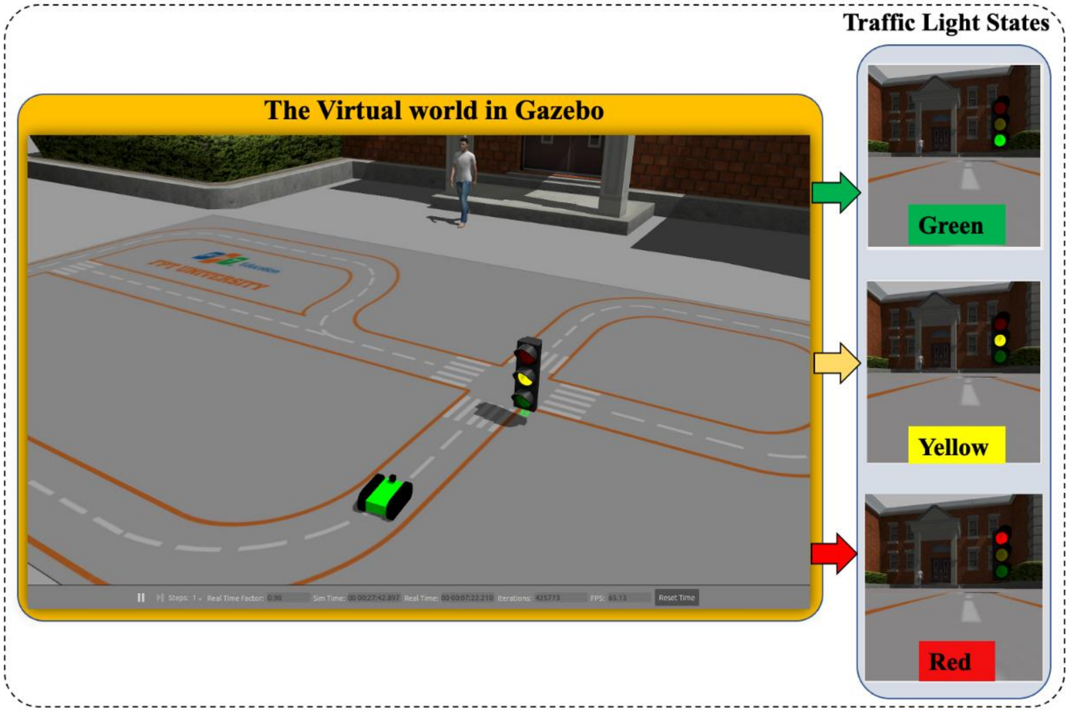


Fig. 9. The virtual world in Gazebo.

FalseNegative signifies the count of positive samples erroneously predicted as negative samples.

Mean average precision (mAP) is an essential metric utilized for evaluating the overall performance of the algorithm. It is computed by averaging the average precision (AveP) values across all classes.

$$mAP = \frac{1}{n}\sum_{k=1}^{k=n} AveP_k \tag{3}$$

AveP_k represents the average precision of class k, where n denotes the total number of classes.

The F1_Score is a metric that combines precision and recall into a single measurement by taking their weighted harmonic mean. It provides a balanced evaluation by considering both precision and recall.

$$F1\_Score = (1 + \alpha^2)\,\frac{P.R}{\alpha^2.P + R} \tag{4}$$

The value of α is employed to achieve a balanced weighting of precision and recall in the calculation of the F-score. A higher F1_Score implies that the algorithm has a better balance between precision and recall. Finally, Frames Per Second is a critical metric in evaluating the speed and efficiency of the algorithm. A higher fps score indicates that the algorithm can process a large number of frames in a shorter time.

In conclusion, using these evaluation metrics in this study provides a comprehensive and unbiased assessment of the performance of the object detection algorithms.

C. Traffic Light Detection and Classification Results

In this section, we present the results of the traffic light detection and classification experiments using different YOLO models. We used a combined dataset of CinTA_v2 and GathoTF traffic light datasets for training and testing. The dataset was split into three parts: Training Set (76%), Validation Set (19%), and Testing Set (5%).

We trained YOLOv5, YOLOv6, YOLOv7, and YOLOv8 models on the combined dataset, and evaluated their performance on the Testing Set. The results are summarized in Table II. The YOLOv8 model achieved the best performance in terms of precision, recall, and F1 score, with an F1 score of 0.8947, and mAP_0.5 of 0.9192 outperforming other models by a significant margin. The results demonstrate the effectiveness of the proposed approach in detecting and classifying traffic lights accurately and efficiently.

Additionally, we assessed the influence of data augmentation on the performance of the YOLOv8 model. We trained the model with and without augmentation and subsequently compared their respective performances on the Testing Set. The findings of this evaluation are reported in Table II. The augmented dataset significantly improved the performance of the model, with an increase of 0.0313 in F1 score, and 0.0148 in mAP_0.5 indicating that data augmentation is an effective technique for enhancing the robustness and generalizability of the model.

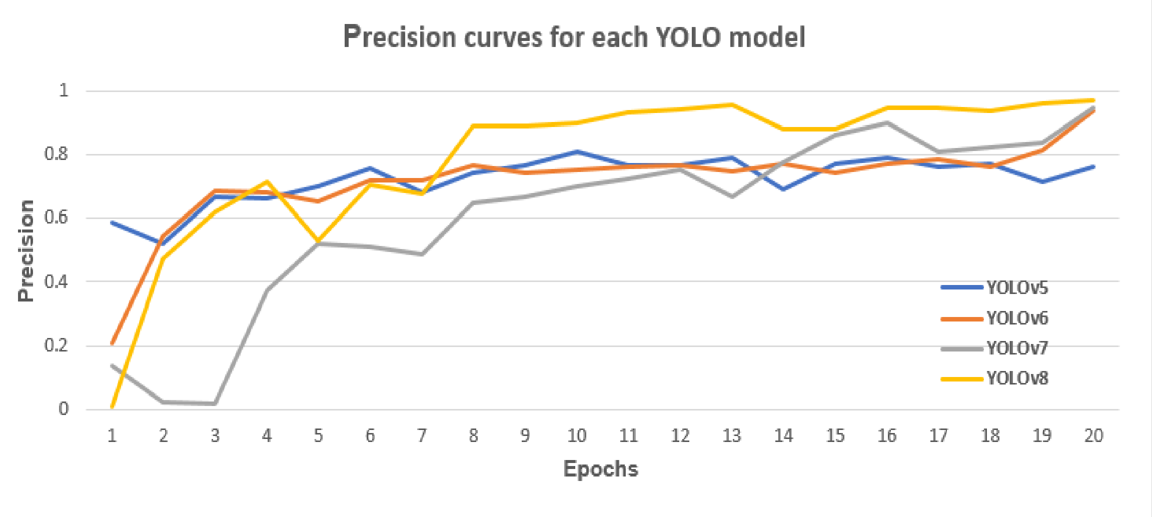

Fig. 10. Precision for traffic light detection and classification using YOLO models.

TABLE II. COMPARISON OF YOLOV5, YOLOV6, YOLOV7 AND YOLOV8 FOR TRAFFIC LIGHT DETECTION

YOLO Model	Precision	Recall	F1_Score	mAP_0.5
YOLOv5	0.7821	0.7787	0.7733	0.8216
YOLOv6	0.9139	0.8106	0.8631	0.8929
YOLOv7	0.9201	0.8289	0.8675	0.9028
YOLOv8	0.9317	0.8427	0.8947	0.9192

To further analyze the performance of the proposed approach, we generated precision curves for each YOLO model, as shown in Fig. 10. The curves indicate that the YOLOv8 model achieved the highest precision values for detecting and classifying traffic lights, followed by YOLOv7, YOLOv6, and YOLOv5 models.

Furthermore, we visualized the resulting images generated by the YOLOv8 model to illustrate the effectiveness of our approach in detecting and classifying traffic lights. Fig. 11 shows sample images from the Testing Set with bounding boxes and labels generated by the YOLOv8 model. The model successfully detected and classified the traffic lights, with high precision and recall values.

Overall, the results demonstrate that the proposed approach using YOLOv8 with data augmentation achieves superior performance in traffic light detection and classification, providing a real-time solution for autonomous driving systems in complex scenarios.

D. Lane-Keeping Results

In addition to traffic light detection, our research also focuses on improving lane-keeping performance for autonomous vehicles. We propose a convolutional neural network (CNN)-based steering angle controller that combines data from a classical PID controller and human perception to predict the steering angle. In order to evaluate the performance of our proposed steering controller, we conducted experiments in a simulated environment using the Gazebo-ROS2 platform.

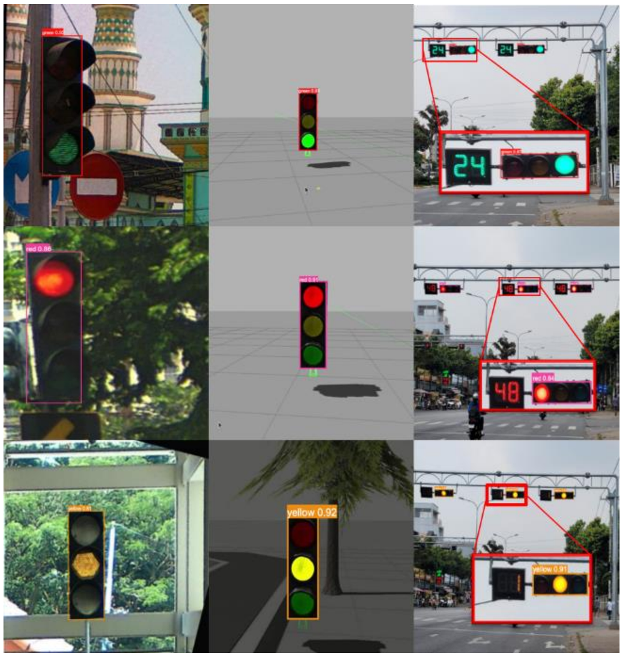

Fig. 11. Sample images with traffic light detection and classification results.

We collected a dataset of driving behaviors from a human driver using the OpenCV+PID steering angle control method, which we used to train and validate our CNN-based steering controller. The dataset consists of a donkey car model driving in a simulated environment with different road conditions and lighting conditions.

To evaluate the performance of our steering controller, we conducted experiments in the same simulated environment. We compared the performance of our proposed method with a baseline PID controller and a CNN-based steering controller trained with a traditional CNN architecture.

In order to evaluate the performance of our proposed steering controller, we conducted experiments in the same simulated environment and compared our method with a baseline PID controller and a CNN-based steering controller trained with a traditional CNN architecture. We use a mathematical equation to calculate the percentage of accuracy by summing the prediction error, dividing by the overall validation angle, and multiplying by 100 to measure the accuracy of our proposed method.

$$accuracy = 100 - \frac{\left|\sum_{i=1}^{N}\left(y_{actual_i} - y_{pred_i}\right)\right|}{\sum_{i=1}^{N}\left(y_{true_i}\right)} * 100 \quad (5)$$

where y_{actual} is the actual angle value, and y_{pred} is the predicted angle value.

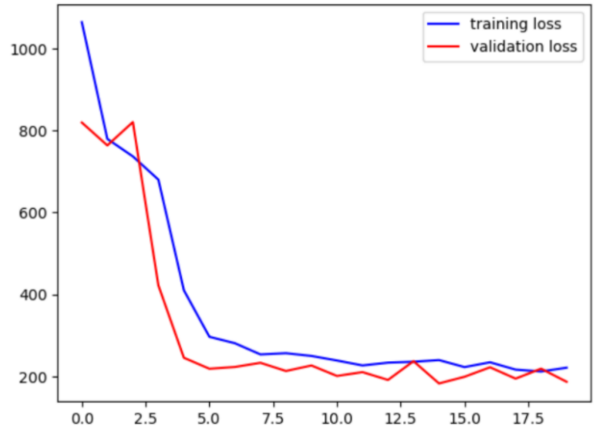

Fig. 12. The learning curve for the End-to-End CNN model using the Mean Squared Error (MSE) loss function.

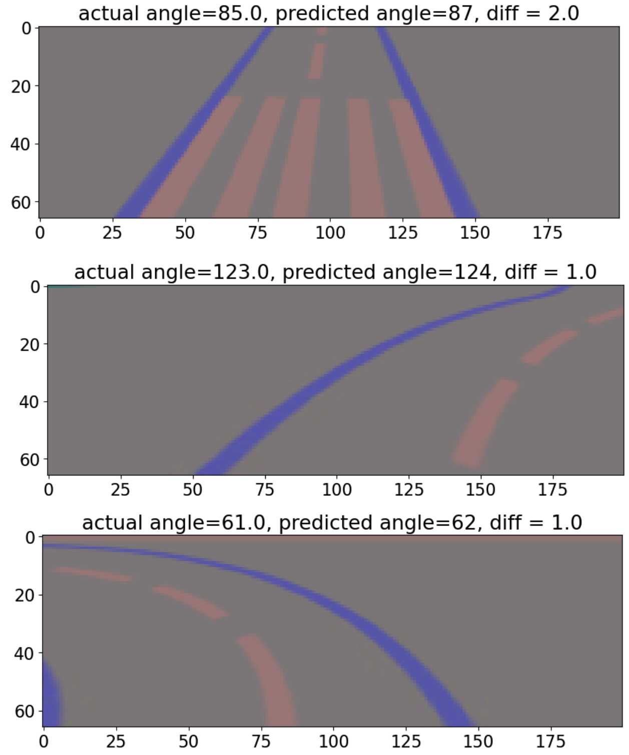

actual angle=85.0, predicted angle=87, diff = 2.0

actual angle=123.0, predicted angle=124, diff = 1.0

actual angle=61.0, predicted angle=62, diff = 1.0

Fig. 13. The true steering and predicted steering, the diff is the difference between true steering and predicted steering.

The evaluation of our lane-keeping performance involved a comparison between the actual steering angle of the vehicle and the predicted steering angle generated by the End-to-End CNN model. This analysis is depicted in Fig. 13.

We also evaluated the performance of our model using the MSE loss function, and the learning curve for the End-to-End CNN model using the MSE loss function is depicted in Fig. 12. After 20 epochs, the MSE value was 230.8, and the learning curve shows a decreasing trend. The curve indicates that the model's performance improves as the number of epochs increases, with diminishing returns after a certain point. Although the curve appears to be approaching a stable solution, further training may be required to confirm this.

Our results demonstrate that our proposed CNN-based steering controller outperforms the baseline PID controller and the traditional CNN-based steering controller in terms of accuracy and smoothness of the steering control. Our proposed method achieved an accuracy of 86.46%, as measured by the percentage of accurately predicted steering angles. The results indicate that our proposed method can effectively predict the steering angle and improve the lane-keeping performance of autonomous vehicles.

V. Conclusion

In conclusion, the study presents an optimized approach for traffic light detection and End-to-End steering control for autonomous vehicles using YOLOv8 and a CNN-based steering angle controller. The proposed methods are evaluated in a simulated environment and achieved high performance in both traffic light detection and lane-keeping tasks. The results show that YOLOv8 outperforms other YOLO models in traffic light detection, while the CNN-based steering angle controller achieves a high accuracy rate. The study contributes to the development of advanced autonomous driving systems that can improve driving safety and reduce traffic accidents.

DefBDet: An Intelligent Default Borrowers Detection Model

Fooz Alghamdi[1], Nora Alkhamees[2]
Zakat, Tax and Customs Authority, Riyadh, Saudi Arabia[1]
Department of Management Information Systems, King Saud University, Riyadh, Saudi Arabia[2]

***Abstract*—The growing popularity and availability of online lending platforms have attracted more borrowers and lenders. There have been several studies focusing on analyzing loan risks in the financial industry, however, defaulting loans still remains an issue that needs more attention. Hence, this research aims to develop an intelligent prediction model that is able to predict risky loans and default borrowers, named the Default Borrowers Detection Model (DefBDet). We seek to help loan lending platforms to approve lending loans to those who are expected to comply with re-payments at the agreed time. Previous works developed a binary classification prediction model (either default or repaid loan). Repaid loans include loans being repaid on or after the loan deadline date. DefBDet, on the other hand, is a novel model, it can predict a loan status based on a multi-classification bases rather than a binary class bases. Hence, it can additionally identify expected late repaid loans, so that special conditions are assigned before loan being approved. This study employs seven different Machine Learning models, using a real-world dataset from 2009-2022 consisting of around 255k loan requests. Statistical measures such as Recall, Precision, and F-measure have been used for models' evaluation. Results show that Random Forest has achieved the highest performance of 85%.**

***Keywords*—Default borrowers; default loans; loan risks; machine learning models; prediction model**

I. Introduction

Nowadays, data more than ever before is being generated at an extremely fast rate, even more; the volume of data being produced every day is extraordinary [1] [2]. Over the next few years up to 2025 [3], global data creation is expected to grow to more than 180 zettabytes [3]. Furthermore, the global financial data analytics market was valued at $7.6 billion in 2020 and is forecasted to reach $19.8 billion (more than the double value) by 2023 [4].

Default loans data-based assessment is being widely used in financial organizations around the world to assist organizations in either approving or rejecting loan requests [5]. In addition, the growing popularity of loans shows that, in the US [6], more than 20 million persons were owed $178 billion in personal loans as of the first quarter of 2022. That’s more than the double of what was in 2015, only $88 billion were owed from personal loans [6].

One of the reasons for the rising demand for lending is the availability and accessibility of online lending platforms, also the simplicity of completing the loan applications process (with no or limited conditions), which led to a jump in loan requests in 2022 [6]. Lending is risky in that repayments are not always guaranteed, thus, increasing the number of defaulters which is expected to reach 6% in 2023 [7][8]. It has been noticed that the number of willful default cases has increased in 2021 [9], compared with the earlier two years. In addition, loans are considered the dominant asset in the banking sector, they represent nearly 75% of the total amount of the banking assets [10].

Therefore, it is indeed critical to manage the lending activities in a way that controls the borrower's compliance and maintains the financial institution's performance, assets, and liquidity. In contrast, failure to manage loan compliance would likely affect the economy at large [10].

These reasons push toward the need to detect defaulters at early stages (i.e. prior to the loan request being approved), which essentially means identifying the loan requester who will be potentially a defaulting borrower. This would definitely help loan lending organizations to approve loan requests of only committed borrowers and conserve financial institutions' resources. The above-mentioned challenges confirm the importance of monitoring loan requests by developing an intelligent default borrower’s identification model with an early warning system that is capable of alerting financial institutions of potential losses and preventing crises, which in turn is the aim of this paper.

Machine Learning (ML) plays an essential role in the financial sector, especially in the loans domain [11]–[21]. In this work, we develop an intelligent prediction model that is able to recognize the compliance of borrowers against the loan's repayment. Also, it is able to identify expected late repaid loans (loan being fully repaid after loan's maturity date). Thus, we develop a novel model named, Default Borrowers Detection Model (DefBDet). This model is able to predict the loan status based on a multi-classification bases rather than binary class bases, which was the case in previous works [11]–[21].

Hence, the main objective, in this work, is to improve the utilization of classification algorithms in the financial loans field. We seek to assess default loan risk prior to issuing the loan lending decision. ML techniques have been employed in order to develop DefBDet using real loan data. We used the family of supervised ML algorithms, such as Decision Tree (DT), Random Forest (RF), ID3, Deep Learning (DL), Gradient Boosted Decision Trees (GBDT), Support Vector Machines (SVMs), and Naïve Bayes (NB).

The rest of the paper is organized as follows. The next section provides a summary of past related studies. Later, the processes involved in building the model, including data collection and processing, model training and testing, and associated findings and results are presented. The final section concludes with a summary of the work and the suggested plan for future work.

II. Literature Review

ML has been utilized intensively in the financial industry along with its subfields, including but not limited to, the stock market [22]–[24], insurance [25]–[27], and fraud detection [28]–[34].

The stock market field is an attractive topic due to the abundance of data being generated at high and irregular rates. Besides, it plays an important role in the economy; investors are also continually looking to predict future transactions to avoid certain associated risks. The study in [24] has constructed a model to predict stock market future trends. In addition, along with historical stock market prices it considered sentiment analysis using text polarity of financial news. Regarding the insurance field, this study [27] has summarized the role of Data Mining (DM) in the insurance industry and how DM enhances the decision-making using insurance data. For fraud detection, it can be committed in different ways and areas, such as in banking, insurance, government, and healthcare sectors [34]. The paper in [28] provides a comprehensive review of existing research works and literatures on the applications of DM to fraud detection in finance.

A. Predicting Default Loans and Risk Detection

Businesses use predictive analytics to identify potential risks and opportunities for their organizations [35]. Recently, it has been observed that the number of willful defaulters in the financial sector is significantly rising [36]. Therefore, systematic identification to predict and detect willful default behavior is indeed essential. The Corporate Finance Institute [37] has defined the loan as: is the sum of money that one or more individuals or companies borrow from banks or other financial institutions, to financially manage planned or unplanned events. In doing so, the borrower must pay back with interest and within a specified period of time [37]. Following we show some research performed in this domain, this including but not limited to [11]–[21].

Due to the increase in using the Internet and submitting loan applications online, it is defiant for financial institutions to evaluate all loans manually. Thus, predicting whether a borrower is going to default is becoming an extremely urgent need and draws much attention from researchers. The author in [11] proposed a supervised default loan prediction method based on deep metric learning, the method extracts the features of a loan itself, models the hidden relationships in loan pairs, and calculates the probability of default. The challenges were the imbalanced defaulted samples compared with total data of loans, hard decision boundaries due to loans binary label, and the heterogeneous loan features that have different data types. The proposed method has a higher accuracy compared to Support Vector Machines, Logistic Regression, Naive Bayes, and Multi-layer Perceptron.

Another work in [12], the aim was to identify a comprehensive list of factors along with building a data model for early prediction of whether the loan will become a Non-Performing Assets (NPA) [1] or not. They explored different classification techniques and considered Neural Network, because of its higher accuracy. The model covers the loan end-to-end processes, starting from loan request where the factors of NPA are early detected, followed by loan monitoring, where the model can identify outliers and possible requests to be defaulted. And the last stage is closing the loan, whether it is fully repaid or declared as NPA.

In [13], the authors presented a study for predicting whether a peer-to-peer (P2P) loan application will be repaid or defaulted by employing different classification models. This work was aiming to find interesting relations among the attributes of loan application by applying association rules. The used dataset by LendingClub[2] was classified as whether a loan will default or not (Yes/No). The most effective classification model was achieved using Random Forest and its accuracy was 71.75%.

Using the LendingClub dataset, a two-phase model is proposed in [14], the first phase predicts loan acceptance or rejection by applying Logistic Regression with recall score of 77.4%. The second phase, on the other hand, predicts loans requests either will be defaulted or fully paid by applying Deep Neural Network with recall score of 72%.

Another study [15] wants to predict loan defaulters using the LendingClub dataset. The author encodes loan status (Current, Fully paid, Issued) as Normal, and encodes (Default, Charged off, In Grace Period, Late) as Default. The performance evaluation was applied and compared using Random Forest algorithm with other three ML methods, namely, Decision Tree, Logistic Regression, and Support Vector Machines, while Random Forest still performs the best.

In another prediction work on LendingClub dataset [16], researchers label the dataset records as follows: any loan that (Defaulted, Charged off, or Late on repayments) was classified as Negative examples, while classified any loan that was (Fully paid or Current) as Positive examples. Naïve Bayes has been used which performs the best with default prediction rate compared with other models.

This study [17] presented clustering for loan risk analysis on big data using the k-mean clustering algorithms. Researchers used different datasets related to loans, including the Bondora[3] dataset. The clustering of Bondora was divided into two classes: Default risk and Non-default risk.

[1] A non-performing asset (NPA): is a classification used by financial institutions for loans and advances on which the principal is past due and on which no interest payments have been made for a period of time. – Corporate Finance Institute.

[2] LendingClub is a peer-to-peer lending company headquartered in San Francisco, California.

[3] Bondora is one of the leading non-bank digital consumer loan providers in Europe.

The author in [18] developed a DM model for predicting loan default among P2P loans. The work was specifically for small business owners and employed using Boosted Decision Tree model. In this study, the class labels are (Pay in full and Charged off).

Another work utilized Bondora dataset [19] is mainly focused on the prediction of loan default using ML algorithms. The author used Status attribute to predict loan default, which is an existing attribute in the dataset. Status reflects the loan payment status and has polynomial values as follows: Current, Repaid, and Late. The work converted the polynomial values into binary, while the loan records that having Repaid status are treated as Not default and Late status are treated as Default, whereas the records having Current status are excluded as they play no role in the default classification.

In view of this and after reviewing the above literature, the majority of studies [11]–[21] have classified the loans into binary classification (i.e. repaid or not), also, they have issues in determining the loan payment activities and the default stages. In more detail, the Repaid status in previous works does not only consider that the loan was paid on the agreed time (i.e. loan repaid before the loan deadline), but also considers late loan payment (i.e. payment after the loan deadline, such as in the case of default) as Repaid too.

Furthermore, it is worth noting that Repaid status does not reflect exactly whether or not the borrower defaulted prior to the loan being fully repaid. In this case, the default behavior is not detected properly. Alternatively, additional investigation is required in the dataset to determine the actual loan status whether default behavior happened or not before the loan is flagged as Repaid, as it is the key challenge to predicting the defaulters. There is a crystal-clear necessity for multi-classifications, such as Late Repaid classification, while it is not applicable that we include the Late Repaid records in Repaid classification. As a result, having a precise multi-classification will improve the quality of the loan prediction model and can help financial institutions to accurately determine the compliance stage of the borrower, and therefore, take the decision to lend or not. Multi-classification of repayment can differentiate between lenders who are compliant to close their loans on the agreed time and lenders who are delayed repaying the loan.

III. Data Description

A. Data Collection and Data Description

Bondora is known to be one of the leading non-bank digital consumer loan providers in Europe and has been operating since 2009 [38]. It is licensed as a credit provider under the Estonian Financial Supervision Authority [39].

It is worth noting that Bondora dataset has been extensively used in different published works, including but not limited to [17], [19], [40]–[43].

Bondora's real-world data is publicly available on the internet[4] [44]. It contains raw data related to loan requests from 2009 till today (download day is 22/9/2022) and it is daily updated. The dataset consists of 122 attributes and around 255k records.

Each record belongs to a loan request, which includes data about the borrower and the loan application, such as borrower demographical data, loan duration, purpose of the loan, dates of payment, and also information regarding the current loan's status (Repaid, Late, Current), amount of principal and interest, default date, etc.

Due to the enormity of the dataset, we analyzed it in-depth and determined the most relevant attributes to the study's purpose. Table I provides a full description of the selected attributes in the dataset.

TABLE I. Full Description of Bondora's Attributes in the Dataset [44]

Feature Name	Brief Description	Data Type
LoanId	A unique ID given to all loan applications	Categorical
PartyId	A unique ID given to the borrower	Categorical
NewCreditCustomer	Did the customer have prior credit history in Bondora False: Customer had at least 3 months of credit history in Bondora True: No prior credit history in Bondora	Categorical
LoanDate	Date when the loan was issued	Date
MaturityDate_Original	Loan maturity date according to the original loan schedule	Date
MaturityDate_Last	Loan maturity date according to the current payment schedule	Date
Age	The age of the borrower when signing the loan application	Numeric
Gender	Male, Female, and Undefined	Categorical
Amount	Amount the borrower received on the Primary Market. This is the principal balance of your purchase from Secondary Market	Numeric
LoanDuration	Current loan duration in months	Numeric
UseOfLoan	Loan consolidation, Real estate, Home improvement, Business, Education, Travel, Vehicle, Health, and Other	Categorical
Education	Primary education, Basic education, Vocational education, Secondary education, and Higher education	Categorical
NrOfDependants	Number of children or other dependents	Categorical
EmploymentStatus	Unemployed, Partially employed, Fully employed, Self-employed, Entrepreneur, and Retiree	Categorical
OccupationArea	Other, Mining, Processing, Energy, Utilities, Construction, Retail and wholesale, Transport and warehousing, Hospitality and catering, Info and telecom, Finance and insurance, Real-estate, Research, Administrative, Civil service & military, Education, Healthcare and social help, Art and entertainment, Agriculture, and Forestry and fishing	Categorical
HomeOwnershipType	Homeless, Owner, Living with	Categorical

[4] To download the loan dataset (https://www.bondora.com/en/public-reports#secondary-market-archive)

	parents, Tenant_pre-furnished property, Tenant_unfurnished property, Council house, Joint tenant, Joint ownership, Mortgage, Owner with encumbrance, and Other	
IncomeTotal	Borrower's total income in (€)	Numeric
LastPaymentOn	The date of the current last payment received from the borrower	Date
DefaultDate	The date when the loan went into defaulted state and collection process was started. Or, in other words, the loan is 60+ days overdue	Date
RecoveryStage	Current stage according to the recovery model 1 Collection 2 Recovery 3 Write Off	Categorical
Status	The current status of the loan application Repaid: the loan is fully paid to the investor Current: the loan is still in the process Late: the loan has not been fully paid on due dates	Categorical

While examining the dataset, we discovered that 53 records had missing values in the majority of the attributes.

Due to the limited number of rows, we decided to exclude them from the dataset. The removed records are approximately less than 0.25% of the total dataset.

Also, some attributes in the dataset were numeric data type, and to facilitate the analysis, we converted these attributes from numeric to categorical data type by following discretization process [45]. Table II shows each attribute with original values before applying discretization and the transformed values after the discretization process.

TABLE II. BONDORA'S ATTRIBUTES AFTER DISCRETIZATION PROCESS

Attribute	Previous Values	New Values	Corresponded Values
Age [46]	Values range from 18 to 77	Young adults Middle-aged adults Old-aged adults Seniors	(From age 18 to 28) (29 to 39) (40 to 58) (>=59)
IncomeTotal	Values range from 0 to 1,012,019	No income Very low income Low income Middle income High income	(Total between 0 to 10) (11 to 1,000) (1,001 to 2,000) (2,001 to 3,000) (>= 3,001)
Amount	Values range from 6 to 15,948	0 - 1,500 1,501 - 3,000 3,001 - 4,500 4,501 - 6,000 More than 6,000	
LoanDuration	Values range from 1 to 120	1 – 30 31 – 60 61 – 90 91 - 120	
NrOfDependants	Values range from 0 to More than 10	No dependent One – Three Four – Six Seven – Ten More than Ten Undefined	
NrOfPreviousLoans	Values range from 0 to 74	No previous loan One – Five Six – Ten Eleven – Fifteen Sixteen – Twenty More than Twenty Undefined	

Bondora's dataset provides Loan Status, which indicates the loan payment status, it has three possible values, Repaid (meaning that loan has been fully paid back to the investor either on or before the loan maturity date, or after the loan maturity date), Late (the loan has not yet been fully paid to the investor and has exceeded the loan maturity date), and Current (the loan is still in progress, i.e. maturity date has not been reached yet). Almost 30% of the dataset consists of Late loans, and 35% of both Current loans and Repaid loans, Fig. 1 illustrates in a pie chart the ratio of each status of the total dataset.

The original dataset lacks the ability to show the borrowers status regarding paying the loan on time or not. Hence, if the Loan Status is Repaid, it does not clearly indicate whether the loan was repaid on time (on or before the loan maturity date) or not. In other words, it does not show the cooperation of the borrower to repay the loan by the maturity date. Knowing that the loan was repaid on time saves the lending company resources and means that the borrower is trustworthy and dependable.

As a result, and since the dataset has no direct indicator regarding the borrower’s compliance in repaying the given loan on the agreed time, we defined a new polynomial feature named "Borrower's compliance status", which precisely represents the situation of the loan in terms of repayment according to the data in each record.

The new feature measures the borrower compliance regarding paying the loan's last payment before the maturity date of the loan or not.

It consists of four values, Repaid on-time, Late repaid, Defaulted, and in progress.

A loan can be labelled as "Repaid on-time", meaning that the loan was repaid before or on the maturity date of the loan (the dataset consist of 76k record or almost 30% of records were labelled as Repaid on-time), "Late repaid" on the other hand, which means that the loan was repaid after the loan maturity date (15k or 6% of records were labelled as Late repaid). Also, a loan can be labelled as "Defaulted", meaning that the loan is not fully repaid yet, and has passed the maturity date of the loan too (71k or 28% of records were labelled as Defaulted), or labelled as "In progress", which means the current loan is still open and not meet any of the above status (93k or 36% of records were labelled as In progress).

This feature was defined using the following existing attributes in the dataset: MaturityDate_Original, LastPaymentOn, DefaultDate, and Status.

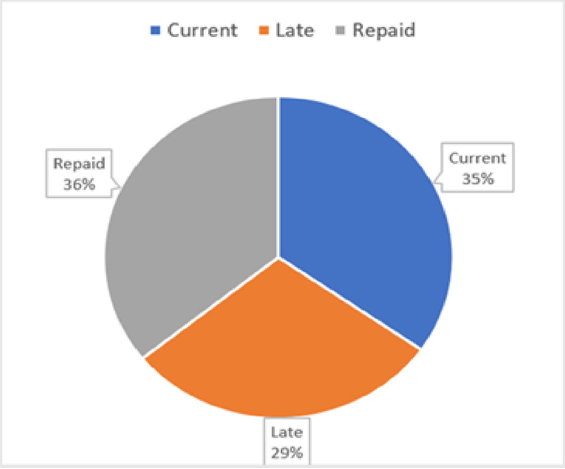

Fig. 1. Proportions of loan status of bondora's dataset.

IV. Experiment and Methods

A. Machine Learning Classification Algorithm

ML was developed by Arthur Lee Samuel in 1959 [47], the author demonstrated that machines could learn from past errors.

In this study, ML algorithm was determined after reviewing existing works and literatures in this scope [11]–[21], in addition to the study's purpose which is to predict the borrowers' compliance against the loan re-payment.

Developing a prediction model is indeed valuable for financial institutes and banks as it enables business owners to take actionable decisions at the right time. It helps to avoid borrowers who have common characteristics with other defaulters. Thus, preventing tangible and intangible losses that are expected to occur, or in critical conditions, escalating the case to the court. Therefore, the prediction model will support and enhance the approval or the rejection of loan applications that are expected to default.

In this research, we applied various classification algorithms to build DefBDet which belongs to the family of supervised ML algorithms. These algorithms are DT [48]–[50], ID3 [51], [52], RF [53]–[55], DL, GBDT [18], [56], SVMs [57], [58], and NB [59].

B. Model Evaluation and Assessment

In this study, we mainly focus on several performance evaluation metrics for classifier including F-measure, Precision, Recall. Below are brief definitions of each measure:

- According to [60], F-measure was first introduced by Cornelis Joost van Rijsbergen [61], it combines Recall and Precision with an equal weight [62]. F-measure formula as following (1) [60]:

$$F1 = (2 * \text{Recall} * \text{Precision}) / (\text{Recall} + \text{Precision}) \quad (1)$$

- Precision or Confidence is the proportion of predicted positive cases that are correctly real positives [62]. Precision formula as following (2) [63]:

$$\text{Precision} = (\sum TP) / (\sum TP + FP) \quad (2)$$

Recall or Sensitivity is the proportion of real positive cases that are correctly predicted positive. This measures the Coverage of the real positive cases [62]. Recall formula as following (3) [63]:

$$\text{Recall} = (\sum TP) / (\sum TP + FN) \quad (3)$$

Accuracy is a common measure for evaluating a classification model's ability to discriminate between classes. And because the class labels are imbalanced, the F- measure will capture a balance between Recall and Precision and weights them equally better than the Accuracy in terms of describing the overall model performance [64], [65]. The evaluation metrics and performance measures of each algorithm are detailed in Table III.

V. Results and Discussion

In this study, we have employed ML classification technique (a supervised learning method) in order to predict the compliance status of loan borrowers. We used seven different classification algorithms and evaluated its performance by F-measure, Precision, and Recall.

The results show that the RF and DT have outperformed all other classification algorithms. In addition, they both have very comparable results (the obtained results for seven algorithms are displayed in Table III). The DT has the highest F-measure score of 85.69%, while RF ranked in the second place with very minor differences of 85.29%.

It is worth noting that the outcomes of all performance measures are considered essential and crucial. However, from business prescriptive, specifically the financial field, we are concerned that the loan is provided to the client who will compliance and is willing to repay on time. The financial organizations do not want to lose this type of client (borrowers), i.e. financial organizations are always keen to provide loans to clients who comply with payments on time. Thus, in terms of a performance measure, this is described as precision, which predicts positive cases that are correctly real positives [62]. In other words, the model can predict only the positive borrowers (who will repay on time), than identifying all positive borrowers.

Financial organizations are not willing to provide a loan to someone who has a slight probability of defaulting, and this is due to the importance of managing the financial, human, and digital resources effectively to be sustained in the market, besides the organization's reputation among competitors.

In DefBDet, the precision based on RF is above 92%, on the other hand, the precision of DT is almost 89%, indicating that the RF model has a strong ability for detecting correct positive cases than DT.

Other reasons why we choose RF algorithm over the other ML algorithms are that RF runs efficiently on enormous datasets and works well with unbalanced class labels. We can conclude obviously that the RF algorithm outperforms other ML approaches according to the mentioned reasons above.

TABLE III. EVALUATION METRICS COMPARISON OF THE SEVEN ALGORITHMS

Rank based on F-measure	Algorithm	F-measure	Precision	Recall
1	DT	85.69%	88.93%	82.67%
2	RF	85.29%	92.14%	79.39%
3	GBDT	84.19%	88.93%	79.92%
4	NB	79.52%	77.09%	82.11%
5	DL	77.95%	73.24%	83.30%
6	ID3	77.22%	83.54%	71.78%
7	SVMs	59.92%	54.78%	66.13%

VI. CONCLUSION AND FUTURE WORK

This study has developed an intelligent prediction model identifying default loans in lending communities; its main aim was improving the lending decision-making process. In other words, DefBDet model aims to detect the expected default borrower before the approval of the loan request, which can reduce default loans and at the same time maintain the expected target of returns.

We can clearly infer that DefBDet could reduce the defaulting loans with positive consequences for the efficiency of the financial institutions, by eliminating loan requests that have been detected and are expected to default. Furthermore, it can identify loans that are expected to be late repaid (i.e. loans being repaid after the loan maturity date has passed). Late repaid loans can be an issue to financial institutions if not being closely monitored.

Previous works were able to binary classify loan requests to either fully repaid or defaulted. The case of fully repaid, includes both loans repaid on or before the loan deadline and loans being repaid after the loan deadline date has passed. However, we think expected Late repaid loans needs special attention before loan approval being issued. Thus, DefBDet is a multi-class model; it aims to identify expected late repaid borrowers, so that additional conditions and/ or close monitoring are given. DefBDet can classify a loan to Repaid on-time, Late repaid, and Default.

In addition, the results provided by the model can be generalized to any lending activities or financial institutions. In general, the DT and RF algorithms showed a better performance, the overall performance was higher than 85%, compared with other classification models like SVMs, ID3, GBDT, NB, and DL. However, from a business point of view, correctly identifying defaulting borrowers is very crucial; it can lead to saving financial institutions resources. Financial organizations are not willing to provide a loan to someone who has a probability of defaulting. Thus, high precision value is indeed favorable. In DefBDet, the precision using RF was above 92%, on the other hand, the precision of DT was nearly 89%. As a result, The RF algorithm was adopted in DefBDet.

In the future, we seek to employ DefBDet prediction model on a local dataset to explore the diversities between international and local datasets. In addition, we aim to introduce an additional borrower class (label), which leads to improving DefBDet to be able to predict an additional multiclass label in order to precisely identify the compliance stage of the borrowers before repayment.

Effects of Training Data on Prediction Model for Students' Academic Progress

Susana Limanto[1], Joko Lianto Buliali[2]*, Ahmad Saikhu[3]
Informatics Department, Institut Teknologi Sepuluh Nopember, Surabaya, Indonesia[1, 2, 3]
Department of Informatics Engineering, Universitas Surabaya, Surabaya, Indonesia[1]

***Abstract*—The ability to predict students' academic performance before the start of the class with credible accuracy could significantly aid the preparation of effective teaching and learning strategies. Several studies have been conducted to enhance the performance of prediction models by emphasizing three key factors: developing effective prediction algorithms, identifying significant predictor variables, and developing preprocessing techniques. Importantly, none of these studies focused on the effect of using different types of training data on the performance of prediction models. Therefore, this study was conducted to evaluate the effects of differences in training data on the performance of a prediction model designed to monitor students' academic progress. The findings showed that the performance of the prediction model was strongly influenced by the heterogeneity of the values of the predictor variables, which should accommodate all the existing possibilities. It was also discovered that the application of training data with different characteristics and sizes did not improve the performance of the prediction model when its heterogeneity was not representative.**

Keywords*—*Decision tree; effects of training data; heterogeneity; prediction; students' academic performance

I. Introduction

The prediction of students' academic performance enables higher education institutions to improve the quality of their graduates. This is because it helps to prepare strategies and allocate resources to assist students at risk of academic failure. However, the benefits of these strategies can be minimal when the prediction results are not provided early or when they have poor performance. It is also important to note that the earlier detection of students having the potential to fail academically can lead to immediate implementation of necessary actions by relevant stakeholders [1]. Therefore, several studies have been conducted on early detection of students' academic performance.

Early detection models were divided into two types which include those developed to screen superior students and those designed to deal with students having the potential to experience academic failure. The first type was commonly used to evaluate prospective students' future academic performance to make informed decisions about their admission [2], [3]. Meanwhile, the models to determine students with the potential to experience academic failure were applied to increase the number of students who graduate on time. Some of those were applied at the beginning of the semester using demographic and academic data of the previous semester [4], [5]. However, the accuracy of these models was found to be lower than the early detection models which were not applied at the beginning of the semester. This was because there were several predictor variables such as test scores that have a significant influence on the model can only be obtained after the course has started [6]. The effort to solve this problem led [6] to develop a two-stage prediction model. The first prediction was made at the beginning of the semester to obtain a list of students with the potential to fail in order to take immediate action while the second was after the midterm exam to monitor their academic progress.

Several studies have been conducted to improve the performance of prediction models with a focus on three aspects which include developing prediction algorithms, obtaining different predictor variables with significant influence on the model, and developing pre-processing techniques. The prediction algorithm was generally developed by integrating specific techniques. For example, an algorithm that integrates Collaborative Filtering and Artificial Immune Systems was developed by [7] to predict student grades based on recommended courses. The results showed that the developed algorithm provided very accurate results. OKC algorithm was also developed by [8] to improve the performance of prediction models using imbalanced datasets without resampling. This algorithm was a hybrid of One-class support vector machine, K-nearest neighbor, and Classification and regression tree algorithms (abbreviated ad OKC). Research [9] performed an ensemble of seven prediction methods with a majority voting technique to improve the accuracy of this prediction model.

Scholars have been striving to identify the factors influencing the performance of existing prediction models in order to enhance their accuracy. This has led to the application of demographic and academic data as variable predictors to predict students' academic performance. The academic data can be divided into secondary and higher education data. Moreover, efforts are currently being made to determine other factors having the potential to strongly influence student academic performance in order to improve the prediction model performance. For example, [10] applied students' motivation, social, and managerial aspects to complement demographic and academic data as predictor variables. The managerial and social aspects were also used by [11] to develop a prediction model. Meanwhile, psychological aspects such as common talents were utilized by [3] to predict the future performance of prospective students. The study also implemented predictor variable weighting to improve the performance of the model. Other studies were also observed to have used psychological aspects in the form of personality to predict academic performance [12]–[15].

Preprocessing has also been applied to improve prediction model performance [11]. It was discovered that [11] added feature selection before the model formation process to eliminate variables with little effect on the performance and to increase the accuracy. A similar attempt was made by [16] through the combination of different feature selection techniques and data transformation to obtain the best prediction model performance. Apart from feature selection, [9], [17], [18] also applied resampling to overcome imbalanced classes to improve model performance.

Several researchers studied the effect of training data to improve the performance of predictive models [19]–[21]. Research conducted by [19] shows that if there is harmonization in the dataset, classifier performance can be improved. So, it is important to choose the appropriate training and testing data for harmonization. The training data order also greatly affected the performance of the classifier [21]. On exactly the same training dataset, classifier performance can vary from 10% to 100%.

These findings showed that several attempts had been made to improve the performance of prediction models but there was a need for more evidence on the effect of using training data with different characteristics on this performance. Therefore, this study was conducted to evaluate the effect of differences in training data on the performance of the prediction model developed to monitor students' academic progress. This article was divided into four parts which include the introduction section followed by the methodology, analysis of the results, and conclusion of the research.

II. Research Methodology

This research was conducted using the simulation method through the steps shown in Fig. 1. Data were collected through the questionnaires distributed to students at a private higher education institution in Surabaya and academic data retrieved from the higher education information system. The data collected were prepared according to the trial scenario to be implemented in the subsequent process. This was followed by the development of the prediction model according to the existing scenario. Finally, the model's performance was evaluated with a focus on the differences in the training data used in developing the model.

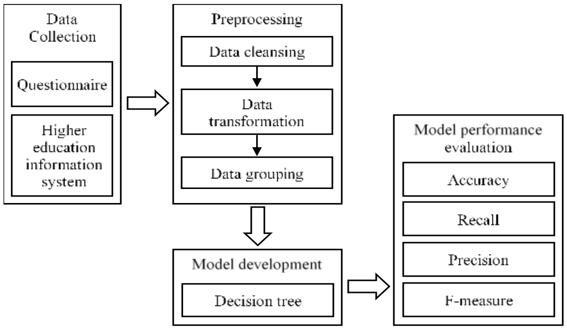

Fig. 1. Research method.

A. Participants and Datasets

The dataset was compiled from 246 private higher education students in Surabaya, Indonesia. The focus was on three different academic years from 2019-2020 to 2021-2022 and three programs including Informatics Engineering, Business Information Systems, and Multimedia. The data obtained were integrated into the student's academic data to form 3,169 instances after the preprocessing stage. Student academic data was collected from 87 subjects grouped in 22 knowledge areas.

TABLE I. PREDICTOR VARIABLE USED

Predictor Variable	Data Type	Details
Program (X_1)	Nominal	Informatics Engineering, Business Information Systems, and Multimedia
Sex (X_2)	Nominal	Male, female
Age (X_3)	Numeric	16, 17, …
Father's academic background (X_4)	Ordinal	Not in school, Elementary school, Middle school, High school, Undergraduate, Masters, Doctoral degree
Mother's academic background (X_5)	Ordinal	Not in school, Elementary school, Middle school, High school, Undergraduate, Masters, Doctoral degree
College entrance path (X_6)	Nominal	Regular, Collaboration, non-academic achievement scholarships, academic achievement scholarships
The specialization chosen while in high school (X_7)	Nominal	Natural Sciences, Social Sciences, Languages, others
High school city (X_8)	Nominal	Surabaya, Java outside Surabaya, outside Java
Average Math score at 12th grade (X_9)	Numeric	66.5 - 99
Average English score at 12th grade (X_{10})	Numeric	70-100
The Average score at 12th grade (X_{11})	Numeric	73.6-97.93
Cumulative credits (X_{12})	Numeric	Total credits that have been collected since the first semester
CGPA (X_{13})	Numeric	0-4
Number of courses taken in the semester (X_{14})	Numeric	3-9
Number of course participants (X_{15})	Numeric	4-108
Previous course grade (X_{16})	Ordinal	A-E
Length of time repeat (X_{17})	Numeric	How many semesters before, last time taking the course
Position difference (X_{18})	Numeric	The difference between the course positions taken in the curriculum and the student's current position
Pass percentage (X_{19})	Numeric	The percentage of passing of this course in previous class by the same lecturer
Prerequisite grade (X_{20})	Ordinal	A-E
Prerequisite time taken (X_{21})	Numeric	How many semesters before, was the last time this prerequisite course was taken

This study used two-stage prediction. The first was applied for the early detection of student academic performance in a course. The predictions were made before the start of lectures using 21 predictor variables as shown in Table I. Meanwhile, the target class was divided into two, Pass or Fail. The results obtained can be used by students, lecturers, and higher education stakeholders to devise appropriate strategies to ensure the success of students that have been predicted to fail at the end of the semester. The second stage was applied after lectures had been received for half a semester and the midterm exam scores had been released. This led to the addition of two predictor variables including the midterm exam scores (range: 0 – 100) (X_{22}) and the number of students' absence from lectures during the first half of the semester (range: 0 – 7) (X_{23}). The results obtained can be used by lecturers to monitor students' academic progress.

B. Preprocessing

This stage was used to remove irrelevant data, overcome missing values, transform data to the format required by the algorithm to be used, and prepare data according to the research scenarios. The first time, irrelevant data such as students' ID, course code, and other attributes not needed as well as those considered to be incomplete and impossible to complete were removed from the dataset. Example of those considered incomplete include are the data related to courses opened for the first time in the program without any record of the pass percentage from lecturers in the previous period.

The data were later transformed by discretizing the continuous data to form categories in order to increase the accuracy of the prediction model [16]. This was followed by the conversion of the categorical data into a numeric form. It was done because the prediction will be carried out using the Decision Tree algorithm with Python programming which requires data to be in a numerical form. Moreover, the application of numeric data had the ability to make some Machine Learning algorithms run efficiently [5].

Finally, the structure of data was prepared to be appropriate for the four scenarios: to evaluate the effect of using training data from certain knowledge areas, different admission years, specific courses, and different training data sizes. The details of each scenario are described in the evaluation section.

C. Model Development and Evaluation

The Decision Tree method was used to develop the prediction models. The method is more popular than the others [1], [22], [23]. Its application was due to the fact that the resulting model tree is usually easy to understand and the conversions are directly in the form of IF-THEN rules.

The dataset consists of 2941 instances for the Pass target class known as major data and 228 instances for the Fail target class classified as minor data. The existence of imbalance in the number of each target class can reduce the performance of the prediction model [8], [24], [25].

The evaluation was conducted to reduce the effect of the target class imbalance using ten-fold stratified cross-validation technique. The data were divided into ten sections with each having a balanced proportion for each target class. It is pertinent to note that one section was used as test data while nine sections were applied as training data. The test process was repeated ten times to avoid deviations using the test data from each section.

The evaluation was conducted using four different scenarios run in different ways as indicated in the following explanations:

1) First scenario: The dataset consists of 22 knowledge areas. The knowledge areas used refer to the Computer Science Curricula 2013 from the ACM – IEEE Computer Society [26]. The dataset was divided into 22 sub-datasets with each containing instances from a particular knowledge area. A total of five knowledge areas with the highest number of instances were used as indicated in the statistics presented in the following Table II. Moreover, a sub-dataset will be compiled which is a combination of those five sub-datasets for comparison.

TABLE II. FIRST SCENARIO SUB-DATASET STATISTICS

Knowledge Areas	Number of Major Class	Number of Minor Class
Programming Languages (PL)	820	85
Computational Science (CN)	628	95
Algorithm and Complexity (AL)	664	58
Software Development Fundamentals (SDF)	471	23
Discrete Structures (DS)	371	88

2) *Second scenario:* The dataset was divided into three sub-datasets with the first containing instances of students that entered higher education in 2019, the second for those in 2020, and the third for those in 2021 as indicated in the following Table III. Moreover, a sub-dataset containing combined instances from the three sub-datasets was compiled for comparison.

TABLE III. SECOND SCENARIO SUB-DATASET STATISTICS

Admission Year	Number of Major Class	Number of Minor Class
2019	226	32
2020	2073	150
2021	642	46

3) *Third scenario:* The dataset was divided into several sub-datasets with each containing instances from specific courses. The five courses with the highest number of instances and the most significant number of minor data were used as indicated in Table IV. Moreover, a sub-dataset containing instances from different courses was compiled for comparison.

TABLE IV. THIRD SCENARIO SUB-DATASET STATISTICS

Courses	Number of Major Class	Number of Minor Class
Algorithm and Programming (AP)	194	39
Statistics (S)	143	64
Discrete Mathematics (DM)	180	18
Web Programming (WP)	120	23
Computer Network (CN)	126	9

4) Fourth scenario: The dataset was divided into eight sub-datasets with 50, 100, 500, 1000, 1500, 2000, 2500, 3000, and 3169 instances respectively. These instances were selected randomly from the dataset using a simple random sampling technique.

The trial conditions from the first to the third scenarios were balanced by ensuring the number of instances in the comparison sub-dataset was equal to the number of training data in the other sub-datasets. The instances in the comparison sub-dataset were selected randomly from the dataset using a stratified random sampling technique while the test data used were the same as those applied for each sub-dataset.

Accuracy was used as the performance measure and it was determined as the ratio of the correctly predicted number of instances to the total number of instances, as indicated in (1).

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \qquad (1)$$

True Positive (TP) is the number of instances predicted to fail from instances with the failed target class. True Negative (TN) is the number of instances predicted to pass from instances with the target class passed. False Positive (FP) is the number of instances predicted to fail from instances with the target class passed. False Negative (FN) is the number of instances predicted to pass from instances with the failed target class.

The classes of each predictor and target variable were not distributed equally and this means applying only the accuracy measure can cause confusion [5], [16]. Therefore, F-measure was introduced and it involved calculating the harmonic average between recall and precision values, as indicated in (2), (3), and (4).

$$Recall = \frac{TP}{TP+FN} \qquad (2)$$

$$Precision = \frac{TP}{TP+FP} \qquad (3)$$

$$F-measure = \frac{2*Recall * Precision}{Recall + Precision} \qquad (4)$$

III. Results and Discussion

A total of five analyses were conducted in the first scenario as indicated in Tables V and VI. It was discovered that there was an increase in the prediction model's performance from the first to the second stage. This showed that the addition of appropriate predictor variables increased the accuracy as well as the performance of the model for unbalanced data distribution without increasing the amount of minor data. Furthermore, a higher increase in the F-measure value compared to the accuracy value indicated a rapid increment in the predictive ability of minor data compared to the major data.

The prediction model performance of most comparison sub-datasets was found to be better than for specific knowledge areas but the variation was relatively small. This showed that the academic performance of students in certain knowledge area was more clustered. As a result, heterogeneity in the training data in each sub-dataset needed to be distributed appropriately. The combination of different kinds of knowledge areas in the comparison sub-dataset complemented its heterogeneity, thereby, increasing its ability to accommodate heterogeneity in the test data.

Tables VII and VIII show the predicted results for the four models formed according to the second scenario. The pattern of the prediction model's performance from the first to the second stage was found to be the same as the first scenario. It was also discovered that there was a significant increase in the F-measure but not as much as in the first scenario.

The test results for the sub-dataset with a particular admission year showed better performance than the comparison sub-dataset. This means that the heterogeneity in the training data of each sub-dataset was well distributed to accommodate the one in the test data. Meanwhile, the heterogeneity of the datasets for each admission year was found to be different and their combination to form a prediction model reduced the performance compared to the application of datasets from a particular admission year. Meanwhile, the difference was minimal. Based on these results, it can be concluded that student academic performance varies for each year of admission. As a result, the prediction of student performance with a certain admission year will be better if the training data was taken from the same admission year.

TABLE V. First Scenario Test Results (Accuracy)

Knowledge Areas	**Accuracy (%)**		**Comparison Models**	
	1st Stage	***2nd Stage***	***1st Stage***	***2nd Stage***

CN	88.90	94.12	91.15	95.60

TABLE X. THIRD SCENARIO TEST RESULTS (F-MEASURE)

Courses	F-measure (%)		Comparison Models	
	1st Stage	*2nd Stage*	*1st Stage*	*2nd Stage*
AP	19.18	63.92	21.21	**43.07**
S	42.42	60.70	46.83	**51.74**
DM	19.00	49.33	19.00	**41.38**
WP	57.57	53.00	**43.65**	63.00
CN	6.67	25.00	24.00	40.00

The test data results for the datasets from specific courses presented in Tables IX and X were observed to be similar to those of the previous evaluation such that the second stage was found to perform better than the first stage, except for the F-measure of the Web course Programming. However, the decrease in the F-measure value of the Web Programming course, 8%, was much lower than the average increase, 178%, for the other course sub-datasets and 68% in the comparison sub-dataset. The average increase in the accuracy value of the five sub-datasets was also estimated at 8%-9% and this was much lower than the F-measure value.

The test results for each particular course sub-dataset did not show any particular pattern when compared with the comparison sub-dataset. In some courses, the model's performance was better than the comparison sub-dataset and this means the heterogeneity in the training data of each sub-dataset was not properly distributed, thereby, indicating the inability to accommodate the heterogeneity in the test data. Moreover, the combination of different kinds of courses in the comparison sub-dataset complemented the heterogeneity in the comparison sub-dataset and this allowed the accommodation of heterogeneity in the test data.

In the fourth test scenario, nine types of analysis were performed using different dataset sizes as indicated in Fig. 2 and Fig. 3. It was discovered that the performance of the prediction model in the second stage was better than the first stage, except for the accuracy of the dataset with 2000 instances. This was observed to have a similar pattern as the first scenario trial.

There was no pattern showing that an increment in the dataset's size led to an increase in the accuracy value. Even though, the most extensive dataset size provided the highest accuracy and F-measure in this trial. This was observed to be in line with the research conducted by [5]. It also showed that a small dataset could provide a credible accuracy rate as long as it had the ability to identify key indicators.

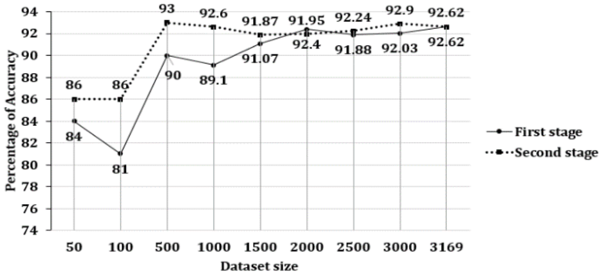

Fig. 2. The accuracy of the results for the 4th scenario.

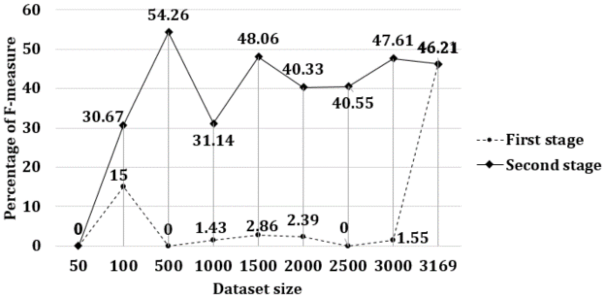

Fig. 3. The F-measure of the results for the 4th scenario.

The tree model generated from datasets of different sizes is presented in Fig. 4, starting from the smallest in Fig. 4(a) to the largest in Fig. 4(i). It was observed from each of the trees produced that the predictor variable played a crucial role in the prediction model and the size of the trees formed was different. This means the model can perform effectively when the training data represent the heterogeneity in the test data. It was also discovered that the training data with a large size but lacks the ability to accommodate heterogeneity in the test data could produce poor performance. An increment in the size of the training data was expected to increase the heterogeneity in order to accommodate the test data but this could not always be achieved. Therefore, the problem can be anticipated through other aspects such as the selection of a suitable predictor variable.

IV. CONCLUSION

This research was conducted to determine the effect of using different training data on the prediction model of students' academic performance in some courses. The dataset used in this research was limited to a private higher education institution in East Java, Indonesia which was taken during the Covid 19 pandemic. The prediction model was developed in two stages to be used as a tool to monitor students' academic progress. The trials were conducted based on four different scenarios, including the effect of using sub-datasets from certain knowledge area, admission years, courses, and different dataset sizes. The results showed that the performance of the prediction model in the second stage was mostly better than the first, even though the average accuracy of the first was higher than 80%. These findings showed that the addition of appropriate predictor variables can improve model performance thereby increasing confidence in the results provided by the model to monitor academic progress.

The results showed that the performance of the model was greatly influenced by the heterogeneity of both predictor and target variables, and this was necessary to accommodate all possible outcomes. Therefore, the use of datasets with specific characteristics or sizes can only improve the prediction model's performance when the heterogeneity of the dataset is representative of the larger population. This means, there is a need to ensure the data's heterogeneity is considered to achieve satisfactory performance measures. Research that will be considered further is to develop a synthetic data oversampling strategy to increase the heterogeneity of the dataset so that the performance of the predictive model can be improved.

Acknowledgment

This work was supported by a doctoral dissertation research grant from Indonesian Ministry of Education, Culture, Research and Technology.

A Novel Framework for Detecting Network Intrusions Based on Machine Learning Methods

Batyrkhan Omarov, Nazgul Abdinurova, Zhamshidbek Abdulkhamidov
Suleyman Demirel University, Kaskelen, Kazakhstan

Abstract—**In the rapidly evolving landscape of cyber threats, the efficacy of traditional rule-based network intrusion detection systems has become increasingly questionable. This paper introduces a novel framework for identifying network intrusions, leveraging the power of advanced machine learning techniques. The proposed methodology steps away from the rigidity of conventional systems, bringing a flexible, adaptive, and intuitive approach to the forefront of network security. This study employs a diverse blend of machine learning models including but not limited to, Convolutional Neural Networks (CNNs), Support Vector Machines (SVMs), and Random Forests. This research explores an innovative feature extraction and selection technique that enables the model to focus on high-priority potential threats, minimizing noise and improving detection accuracy. The framework's performance has been rigorously evaluated through a series of experiments on benchmark datasets. The results consistently surpass traditional methods, demonstrating a remarkable increase in detection rates and a significant reduction in false positives. Further, the machine learning-based model demonstrated its ability to adapt to new threat landscapes, indicating its suitability in real-world scenarios. By marrying the agility of machine learning with the concreteness of network intrusion detection, this research opens up new avenues for dynamic and resilient cybersecurity. The framework offers an innovative solution that can identify, learn, and adapt to evolving network intrusions, shaping the future of cyber defense strategies.**

Keywords—Attack detection; intrusion detection; machine learning; information security; artificial intelligence

I. Introduction

The omnipresence of network systems and the growing dependence of various industries on these platforms have amplified the necessity for robust cybersecurity measures. A significant component of such measures is the effective detection of network intrusions [1]. Traditionally, the detection of such intrusions has been performed by rule-based systems, which, while effective in certain circumstances, have been found lacking in the face of more complex and evolving cyber threats [2].

In the field of cybersecurity, intrusion detection systems (IDS) play a pivotal role. IDS work as a security guard, continuously monitoring network traffic and promptly identifying possible threats [3]. The most commonly employed IDS are signature-based and anomaly-based. Signature-based IDS detect known threats by matching them against an existing database of threat signatures. Conversely, anomaly-based IDS identify deviations from the 'normal' network behavior as potential threats. While these traditional methods provide a certain degree of security, their shortcomings are becoming more apparent in the contemporary landscape of cyber threats [4].

Signature-based IDS are inherently limited by their dependence on the existing database of threats. As they can only detect previously encountered threats, their effectiveness dwindles when faced with novel, unknown threats [5]. On the other hand, anomaly-based IDS, while theoretically capable of detecting new threats, often suffer from high false-positive rates due to the challenge of defining what constitutes 'normal' behavior.

In recent years, the rise of machine learning has provided a promising avenue for overcoming these limitations [6-8]. Machine learning, with its ability to learn from data and make decisions, has shown significant potential in numerous fields, including cybersecurity [9]. Particularly, machine learning methods can address the limitations of traditional IDS by learning from past data, improving over time, and adaptively identifying new threats.

This paper introduces a novel framework for detecting network intrusions, harnessing the power of machine learning. This framework moves beyond the rule-based systems, offering a more flexible, adaptive, and intuitive approach to network security.

The main impetus for this research comes from the increasing complexity of cyber threats and the consequent need for more advanced detection techniques. The landscape of network intrusions has seen an evolution from relatively straightforward threats to sophisticated attacks that can bypass conventional security measures.

Therefore, the primary objective of this research is to develop a machine learning-based framework for network intrusion detection that can effectively identify and respond to both known and unknown threats. We aim to leverage the predictive and adaptive capabilities of machine learning to achieve higher detection accuracy and lower false-positive rates than traditional IDS.

This research also seeks to address the issue of scalability in network intrusion detection. As network systems grow in size and complexity, the amount of network data that needs to be monitored also increases, posing a significant challenge to conventional IDS. Our machine learning-based framework is designed to handle this increased scale and complexity effectively.

The world of cybersecurity is at a juncture where traditional techniques of network intrusion detection are proving insufficient against the complex and evolving landscape of cyber threats. To address this, our research explores the integration of machine learning techniques into a novel framework for detecting network intrusions. This research aims not only to enhance the efficacy of intrusion detection but also to pave the way for future advancements in cybersecurity.

II. Literature Review

The literature review presented herein gives a comprehensive overview of various machine learning methods applied in the realm of network intrusion detection systems (IDS). These methodologies encompass both the traditional algorithms and the emerging paradigms.

A. Traditional Machine Learning Methods in Intrusion Detection

Decision Trees (DT) have been widely applied in IDS due to their interpretability and efficiency in handling large-scale datasets. DT-based models, such as the C4.5 algorithm, have shown impressive results in terms of detection accuracy and speed [10]. However, they tend to overfit the training data, which leads to poor generalization in the face of new threats.

K-Nearest Neighbors (KNN) is another popular algorithm in the IDS domain because of its simplicity and effectiveness [11]. Its major advantage lies in its ability to detect local patterns, making it powerful for identifying unusual behavior. However, its performance deteriorates with high-dimensional data, which is common in network intrusion detection.

Naive Bayes (NB) classifiers, based on Bayes' theorem, have been used due to their capability to handle a vast number of features effectively. Nevertheless, the assumption of feature independence in NB often leads to suboptimal performance since features in network traffic data are usually interrelated [12].

Support Vector Machines (SVM) are another choice, often praised for their high accuracy and robustness against overfitting. Despite these benefits, SVMs have two critical limitations: computational complexity with large datasets and sensitivity to parameter selection [13].

Logistic Regression (LR) is a statistical technique often applied to binary classification problems, including IDS [14]. LR models are easily interpretable and handle noisy data well. However, they often perform poorly when there are non-linear relationships in the data.

Random Forest (RF) is a widely applied ensemble learning method in IDS, combining multiple decision trees to reduce overfitting and improve prediction accuracy [15]. RF can handle high-dimensional and large-scale data efficiently, but it may produce biased predictions if the features have different scales.

Adaptive Boosting (AdaBoost) is another ensemble technique that combines weak classifiers to form a strong classifier. AdaBoost has been used in IDS to improve the performance of base classifiers like DT and NB [16]. However, it is sensitive to noisy data and outliers.

Artificial Neural Networks (ANN) can model complex non-linear relationships, which are common in IDS tasks. ANN, such as Multilayer Perceptron (MLP), have been used to build IDS due to their ability to learn and generalize from the input data [17]. However, they can be computationally expensive and are often considered as 'black-box' models due to their lack of interpretability.

B. Related Works

The domain of network intrusion detection has witnessed a proliferation of research efforts in recent years. These studies have ventured into different machine learning algorithms, feature selection techniques, and evaluation metrics to enhance the IDS's performance.

Several researchers have explored the potential of traditional machine learning models in the IDS domain. For instance, a study [18] explored the use of the Decision Tree (DT) model for intrusion detection. Their work highlighted the utility of DT in classifying network intrusions, yet underlined its tendency to overfit when handling new, unseen data. Another investigation [19] deployed K-Nearest Neighbors (KNN) to detect abnormal network traffic. Despite the promising results, the study acknowledged that KNN's performance deteriorated with high-dimensional datasets.

Naive Bayes (NB) and Support Vector Machines (SVM) have also been adopted in this field. Next study [20] examined the application of NB and found it capable of handling numerous features effectively, albeit with suboptimal performance due to the assumption of feature independence. On the other hand, the work by [21] presented SVM as a powerful tool in detecting network intrusions, with its drawback being its computational complexity and parameter sensitivity.

In the realm of ensemble learning, Random Forest (RF) and Adaptive Boosting (AdaBoost) have been at the forefront of numerous investigations. The study [22] employed RF for network intrusion detection and demonstrated its effectiveness in handling large-scale data. However, it also noted a possible bias in predictions if the features had different scales. Similarly, the research by [23] used AdaBoost to improve IDS performance. Despite achieving promising results, their work indicated the model's sensitivity to noisy data and outliers.

Artificial Neural Networks (ANN) have been the focus of several studies due to their ability to model complex relationships. Next work [24] deployed ANN in the form of a Multilayer Perceptron (MLP) for intrusion detection. The research indicated that despite ANN's high detection rates, its 'black-box' nature posed a significant challenge for interpretation.

While the cited works have significantly contributed to the IDS field, they mostly concentrate on a single machine learning method. This narrow focus tends to overlook the intricate nature of network intrusion detection. Furthermore, the changing landscape of cyber threats necessitates a system that can continuously adapt and learn, an aspect that is often neglected in these studies.

In contrast to the aforementioned research, our work presents a novel framework that harnesses a diverse blend of machine learning methods. By doing so, it captures the complexity of network intrusion detection and leverages the strengths of each method, thereby overcoming the individual weaknesses. Moreover, our framework is designed to evolve with the changing landscape of cyber threats, making it a more robust and sustainable solution.

C. *Discussion*

The above literature reveals that each of these machine learning methods has its strengths and weaknesses. Traditional methods such as DT, KNN, NB, SVM, and LR are generally simple and interpretable but may struggle with the complexity and high dimensionality of IDS tasks. On the other hand, ensemble methods like RF and AdaBoost offer improved accuracy and robustness but may suffer from bias or sensitivity to noisy data.

ANN provides a powerful tool for modeling complex relationships, yet their interpretability and computational efficiency are often questioned [25]. These considerations underscore the necessity for a robust machine learning-based framework that can effectively utilize these methodologies' strengths while mitigating their shortcomings.

Although substantial research has been conducted in the field of machine learning-based IDS, many gaps still remain. First, most studies focus on using a single machine learning method, which may not fully capture the complexities of network intrusion detection. Second, many existing models fail to consider the evolving nature of cyber threats, which require IDS to continuously learn and adapt [26].

This research aims to fill these gaps by proposing a novel framework that utilizes a variety of machine learning techniques to improve detection accuracy, reduce false positives, and adapt to the changing landscape of network intrusions.

III. Problem Statement

As a flowchart of the proposed system, we take Fig. 1 [26]. Fig. 1, the suggested framework incorporates four sequential stages. These stages comprise: (1) Data Cleaning, where irrelevant and erroneous data entries are removed or corrected; (2) Data Transformation, which involves normalizing and restructuring the cleansed data; (3) Feature Engineering, where significant attributes are extracted and selected; and finally (4) Classification using Machine Learning, which involves training models on the refined data to detect network intrusions.

A. *Data Cleaning*

The first stage of the proposed system is Data Cleaning, a critical process aimed at purging the data of inconsistencies, inaccuracies, and redundancies. This involves the identification and rectification of various data issues such as missing or incomplete data, duplicate entries, inconsistent data formats, or erroneous data entries. The process also includes outlier detection and treatment, as these anomalous data points can have a considerable impact on the subsequent analysis if left untreated [27].

The principal motivation behind this stage is to improve the quality of the data and thereby enhance the performance and reliability of the ensuing steps. The integrity and quality of the data are key determinants of the efficacy of any data-driven system, hence this phase is paramount. It sets a strong foundation for the remaining processes, ensuring they are not skewed by noise or inaccuracies in the data. The output from this phase is a cleaner, more reliable dataset, which provides a more accurate and dependable basis for the following stages of the system.

B. *Data Transformation*

Upon completing the data cleaning process, the system transitions to the Data Transformation phase. In this stage, the cleaned data is converted into a format that facilitates subsequent stages of the system. This typically involves two main processes: normalization and restructuring [28].

Normalization is a procedure that standardizes the scales of numerical features in the dataset, ensuring that all features contribute equally to the analysis irrespective of their original scales. This is crucial for machine learning methods that are sensitive to the scale of the input features.

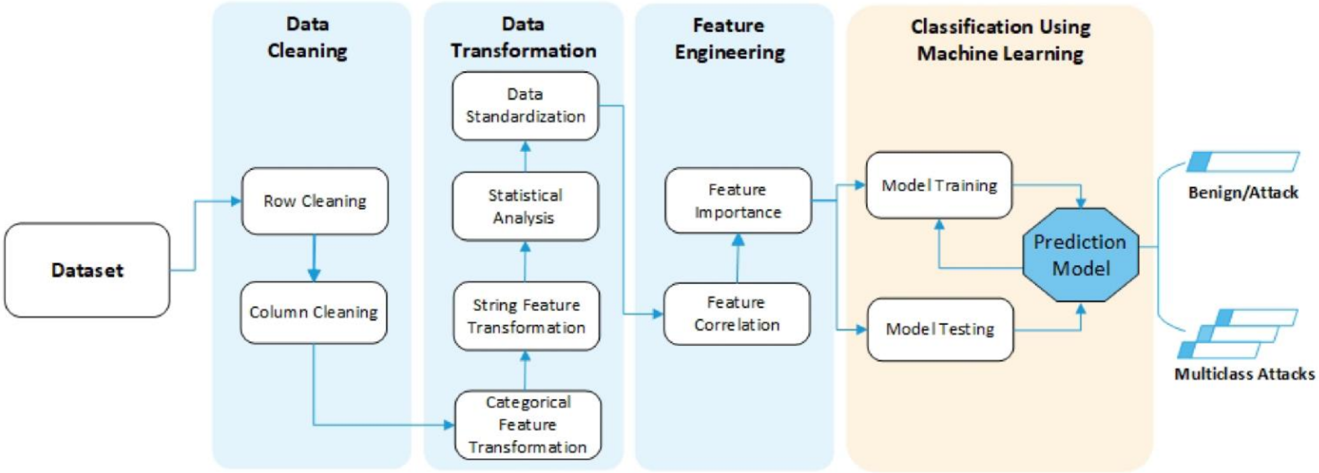

Fig. 1. Architecture of the proposed system for network intrusion detection.

Restructuring, meanwhile, refers to reformatting the dataset into a structure that's more conducive to the feature engineering and machine learning processes. This may involve actions like encoding categorical variables into numerical formats, or transforming complex data structures into a simpler form that can be processed more easily by the system.

C. Feature Engineering

The Feature Engineering phase forms the crux of the system. During this stage, the transformed data is analyzed to identify the most significant features that should be input into the machine learning model. This involves a combination of domain knowledge, exploratory data analysis, and statistical techniques.

Feature extraction is employed when the original feature set is transformed into a set of derived features, which are expected to better represent the underlying problem. These new features may be simpler, may capture more complex relationships, or may simply be more relevant for the problem at hand.

Feature selection, on the other hand, involves selecting the most relevant features from the original or extracted feature set. This is typically performed through methods such as correlation analysis, mutual information, or wrapper methods. By removing irrelevant or redundant features, this process reduces the dimensionality of the problem, thereby improving the computational efficiency and potentially enhancing the performance of the machine learning model.

D. Classification using Machine Learning

The final phase in the system, Classification using Machine Learning, leverages the outputs of the preceding stages to learn patterns in the data and classify network activities as normal or intrusive. This stage employs a chosen machine learning algorithm, which is trained using the processed data from the earlier stages.

Training the model involves inputting the feature vectors into the model and allowing it to learn the relationships between the features and the target variable. Once the model has been trained, it can then be tested using unseen data to evaluate its performance.

The ultimate aim of this stage is to generate a predictive model that can accurately and effectively detect network intrusions. This model forms the core of the proposed system, and its efficacy directly determines the success of the system as a whole. The choice of machine learning algorithm, the tuning of its parameters, and the evaluation of its performance all form critical parts of this phase.

IV. Dataset

The NSL-KDD dataset, a benchmark dataset commonly used in the realm of network intrusion detection research, is a refined version of its predecessor, the widely recognized KDD'99 dataset [29]. The KDD'99 dataset was created from the 1998 DARPA Intrusion Detection Evaluation Program conducted by MIT Lincoln Labs, providing a realistic representation of network traffic data with a variety of simulated attacks.

A. Description of the Dataset

The KDD'99 dataset, while serving as an indispensable resource for researchers, was noted for having a number of significant issues. These included the presence of a large number of duplicate records, creating an artificial bias in the system, and an unrealistic distribution of the different classes of network intrusions. To address these limitations and provide a more accurate testing ground for researchers, the NSL-KDD dataset was proposed as an improved version.

The NSL-KDD dataset eliminates the redundancies present in the original dataset by removing duplicate entries, thereby creating a more balanced and realistic representation of network traffic. It comprises of approximately 125,973 records for training (KDDTrain+) and 22,544 records for testing (KDDTest+), including a variety of intrusion types. Fig. 2 provides a graphical representation of the NSL-KDD dataset, delineating its class distribution. The dataset is composed of approximately 53% instances labeled as 'normal', representing legitimate network behavior, while the remaining 47% signify various types of 'attack' classes. Furthermore, Fig. 2 presents a detailed breakdown of the NSL-KDD dataset by protocols. In this distribution, TCP protocol related data constitutes a significant majority at 82%, followed by UDP protocol related data at 12%, with ICMP protocol data accounting for the remaining 7%.

Each category represents different types of network attacks. For instance, DoS attacks aim to make a machine or network resource unavailable, U2R attacks exploit vulnerabilities to gain unauthorized root access, R2L attacks exploit vulnerabilities to gain local access, and Probe attacks scan a network to gather information or find known vulnerabilities.

Fig. 3 provides an illustrative overview of the distribution of 'flags' across the 'normal' and 'attack' classes in the NSL-KDD dataset. In network communication, flags are employed to indicate the status of a certain connection, or to signal various types of events or errors. These flags can serve as powerful indicators of anomalous or malicious behavior in network traffic, hence their distribution across the different classes is of significant interest.

This figure presents a comparative analysis, providing a visual breakdown of how different flag values are distributed between 'normal' and 'attack' instances. By presenting the data in this manner, it allows for a more nuanced understanding of the relationship between flag values and the class of the connection. This, in turn, can provide important insights into how different flag values might be associated with different types of network traffic, and how they can be utilized in the detection of network intrusions.

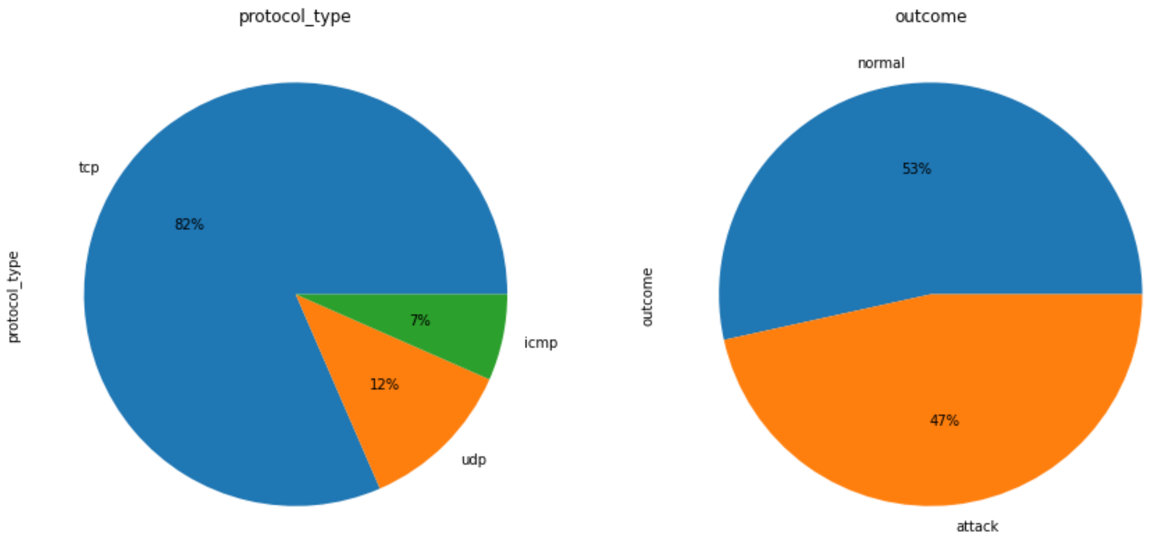

Fig. 2. General description of the NSL-KDD dataset.

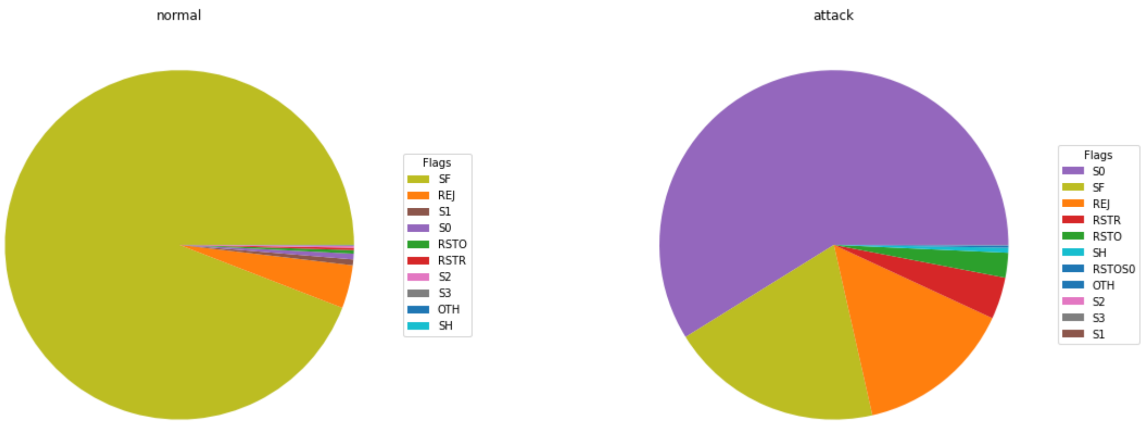

Fig. 3. Flags of normal and attack classes in the dataset.

It's important to consider that the effectiveness of using flags as indicators of malicious activity can depend on several factors, including the nature of the network environment and the specific types of attacks that are prevalent. As such, the distribution presented in this figure serves as a starting point for deeper analysis and discussion on the role of flags in network intrusion detection.

The target variable, meanwhile, is a binary class label indicating whether the connection was normal or an attack, along with a detailed label specifying the type of attack if it was an intrusion. The variety and depth of features, coupled with the extensive range of attack types, make the NSL-KDD dataset an excellent resource for developing and testing network intrusion detection systems.

The NSL-KDD dataset provides a rigorous and realistic testing ground for machine learning algorithms, enabling a detailed evaluation of their performance in intrusion detection tasks. Despite the advancements in this field, the NSL-KDD dataset remains a pertinent choice for researchers, continuing to provide valuable insights into the efficacy of various methods and systems. As such, it forms an ideal resource for our study, offering a robust and diverse dataset to evaluate the effectiveness of our proposed system.

B. *Data Preprocessing*

As presented in Fig. 4, we have utilized the boxplot method to examine the distribution and presence of outliers across all columns in the NSL-KDD dataset. By graphically representing these parameters, we can easily identify interquartile ranges, detect potential outliers, and understand the overall data distribution. In this instance, Fig. 3 serves as a valuable visual aid to understand the statistical nuances of our chosen dataset, enabling us to discern any aberrant data points effectively.

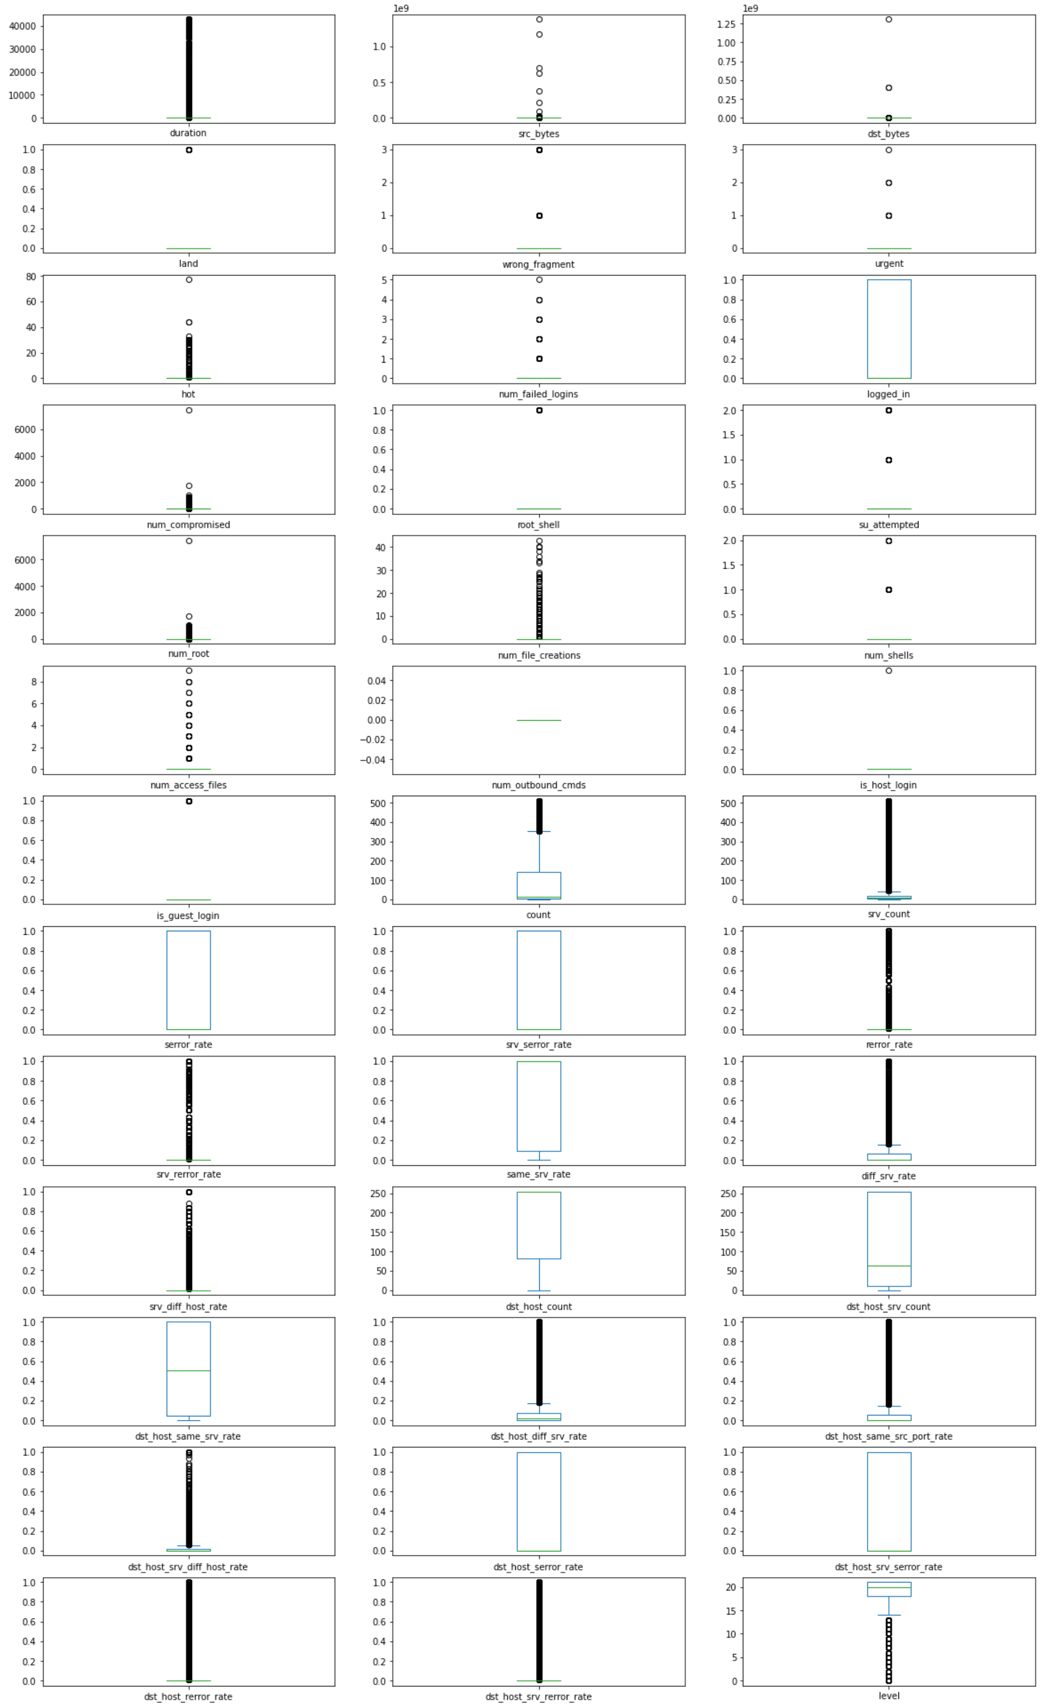

Fig. 4. Box plots for each feature.

V. Evaluation Parameters

In the realm of predictive modeling, accuracy is a fundamental metric utilized to quantify the performance of a model. It represents the proportion of correct predictions made by the model in relation to the total number of predictions. Higher accuracy values indicate a superior ability of the model to correctly classify or predict outcomes. Equation (1) explains accuracy considering true positives (TP), true negatives (TN), false negatives (FN), and false positives (FP) [30].

$$accuracy = \frac{TP + TN}{TP + FN + TN + FP} \tag{1}$$

Precision, an important measure in classification tasks, assesses the model's capacity to accurately predict positive instances [31]. It is defined as the ratio of true positives to the sum of true positives and false positives. Higher precision signifies that the model's positive predictions are largely accurate, minimizing false positive occurrences.

$$precision = \frac{TP}{TP + FP} \tag{2}$$

Recall, often referred to as sensitivity or true positive rate, is a critical metric in the domain of classification problems [32]. It gauges the model's effectiveness in identifying all relevant instances, calculated as the ratio of true positives to the sum of true positives and false negatives. A higher recall implies fewer instances of false negatives, ensuring that the model captures most positive observations.

$$recall = \frac{TP}{TP + FN} \tag{3}$$

The F-score, also known as the F1 score, is a composite metric that harmonizes precision and recall in a single measure [33]. It is the harmonic mean of precision and recall, which equally weights both measures. A high F-score implies that both the precision and recall of the model are high, thus representing an optimal balance between false positives and false negatives.

$$F1 = \frac{2 \cdot precision \cdot recall}{precision + recall} \tag{4}$$

The aforementioned evaluation metrics - accuracy, precision, recall, and F-score - are paramount in gauging the performance of a classification model in a comprehensive manner. Accuracy quantifies the proportion of correct predictions made by the model, while precision evaluates the model's ability to correctly identify positive instances. Recall assesses the capacity of the model to detect all relevant instances, and the F-score serves as a combined measure that balances both precision and recall. These measures together provide a holistic assessment of a model's predictive capabilities, and each has unique importance depending on the specific objective of the classification task at hand.

VI. Experimental Results

The following section, "Experiment Results," details the outcomes of our investigative study, aimed at evaluating the effectiveness of the proposed novel framework for detecting network intrusions. Leveraging the NSL-KDD dataset, various machine learning methods were applied and examined in the context of network intrusion detection. The performance of the models was measured using key metrics such as accuracy, precision, recall, and F-score, providing a comprehensive assessment of the results. This section intends to elucidate the experimental findings, elucidating the comparative efficacy of the employed methods, and highlight the potential advantages and limitations of the proposed framework in a real-world context.

Presented in Fig. 5 are confusion matrices associated with the application of six distinct machine learning models — as they are utilized in the complex problem domain of network intrusion detection. Each confusion matrix serves as a crucial visual tool, succinctly encapsulating the performance of a given model by displaying the interplay of true positive, true negative, false positive, and false negative predictions. Consequently, these matrices offer a nuanced understanding of model performance, not only showcasing the number of correct and incorrect predictions, but also highlighting the nature of errors made. By drawing upon these comprehensive insights, we can systematically compare the respective models' effectiveness in detecting network intrusions, thus paving the way for a data-driven selection of the most adept methodology.

Fig. 6 showcases the Receiver Operating Characteristic (ROC) curves and associated Area Under the Curve (AUC) values for six machine learning models employed in the task of network intrusion detection.

Each ROC curve graphically depicts the true positive rate (sensitivity) versus the false positive rate (1-specificity), at various threshold settings, enabling a clear representation of the trade-off between sensitivity and specificity for the given models. The AUC, on the other hand, provides an aggregate measure of the model's performance across all possible classification thresholds.

Through an evaluation of the ROC-AUC plots, we can comparatively assess the performance of the models, offering insights into their relative effectiveness in distinguishing between normal and attack instances in network traffic data. This detailed analysis aids in identifying the most promising model for intrusion detection. The experimental outcomes reveal that the k-Nearest Neighbors (kNN) algorithm displays superior performance in identifying network intrusions, as evidenced by its superior metrics across the evaluation parameters. Conversely, indications of overfitting are discernible in the performance of both the Random Forest and Support Vector Machines (SVM) classifiers. Overfitting is a modelling error which occurs when a function is too closely aligned to a limited set of data points, thereby impeding the model's ability to generalize to new data. This propensity for overfitting within these classifiers may compromise their effectiveness in a real-world network intrusion detection context. Overall result of ROC-AUC curves of the applied six methods show that, the proposed framework for intrusion detection based on machine learning methods is applicable for practice. In case of intrusion detection framework, the best ROC-AUC curve model can be used as a main algorithm in intrusion detection system.

Fig. 6. AUC-ROC curves for machine learning methods in network intrusion detection problem.

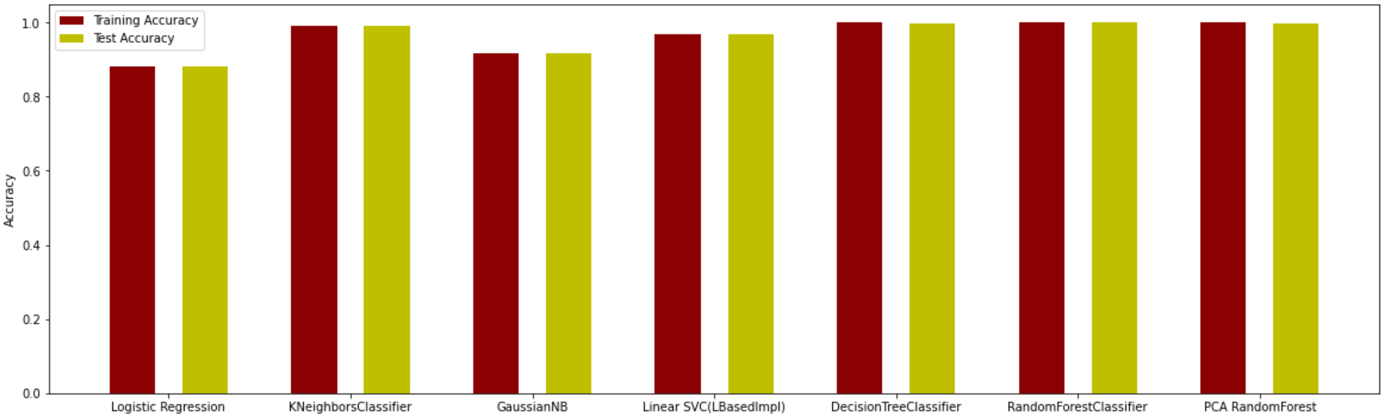

Fig. 7. Train and test accuracies of machine learning methods in network intrusion detection problem.

Fig. 7 offers a comparative visualization of the training and test accuracies achieved by the applied machine learning methods in the context of network intrusion detection on the NSL-KDD dataset.

Training accuracy provides a measure of the model's performance on the training dataset, reflecting the ability of the model to fit the given data. Test accuracy, on the other hand, measures the model's performance on an unseen dataset, indicative of the model's capacity to generalize beyond the training data.

The graph depicted in Fig. 7 enables us to scrutinize the interplay between these two types of accuracies for each applied method. By comparing training and test accuracies, we gain insights into potential overfitting or underfitting scenarios, which are critical for understanding the effectiveness of the models. High training accuracy accompanied by low test accuracy often suggests overfitting, whereas a low training accuracy may indicate underfitting.

This comparative assessment serves to inform subsequent decisions about model selection and the need for potential adjustments in model complexity or training procedures to optimize performance.

Fig. 7 provides a comparative analysis of the training and test precisions attained by the applied machine learning methods in the context of intrusion detection using the NSL-KDD dataset.

Training precision assesses the model's ability to accurately predict positive instances within the training dataset, while test precision evaluates the model's performance on unseen data. By comparing the training and test precisions depicted in Fig. 8, we can discern insights into potential overfitting or underfitting scenarios.

Examining the interplay between training and test precisions aids in determining the models' ability to generalize and effectively classify network intrusions. Higher training precision with a significant drop in test precision may indicate overfitting, highlighting the need for adjustments to enhance generalization. Conversely, low training and test precisions may suggest underfitting, necessitating model refinement or reconsideration of feature selection.

These findings from Fig. 8 contribute to the understanding of model performance and guide the selection of the most suitable methods for intrusion detection tasks.

Fig. 9 provides a comparative analysis of the training and test recalls achieved by the applied machine learning methods in the domain of intrusion detection using the NSL-KDD dataset.

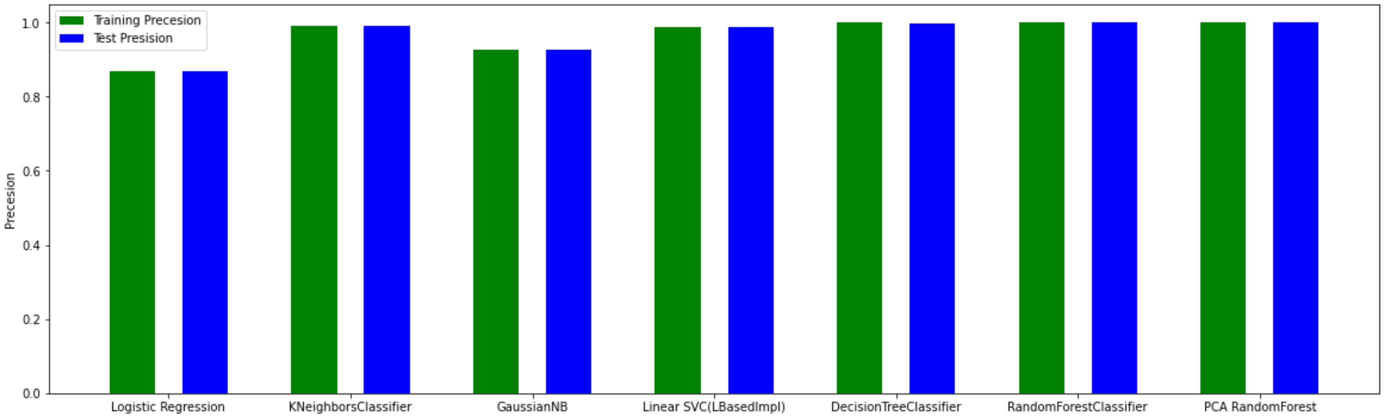

Fig. 8. Train and test precisions of machine learning methods in network intrusion detection problem.

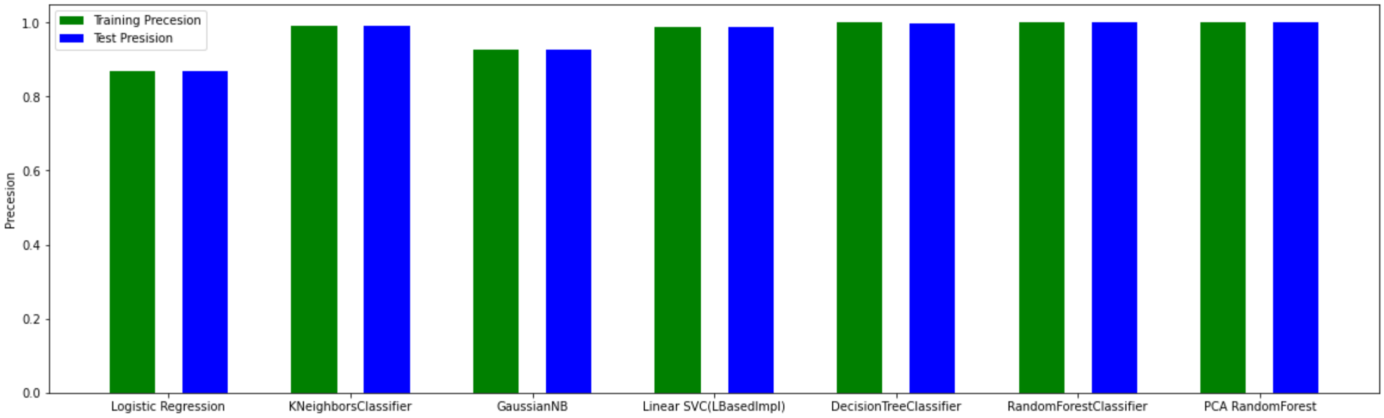

Fig. 9. Train and test recall of machine learning methods in network intrusion detection problem.

Training recall measures the model's ability to correctly identify the positive instances within the training dataset, while test recall assesses the model's performance on unseen data. By examining the interplay between training and test recalls depicted in Fig. 9, we gain insights into the models' capacity to generalize and accurately capture relevant instances of network intrusions.

Discrepancies between training and test recalls can signify potential overfitting or underfitting. High training recall accompanied by a significant drop in test recall may indicate overfitting, necessitating measures to enhance generalization. Conversely, low training and test recalls may suggest underfitting, warranting model refinement or reassessment of feature selection.

The findings presented in Fig. 9 contribute to the understanding of model performance and guide the selection of appropriate methods for effective intrusion detection in real-world scenarios using the NSL-KDD dataset.

VII. Discussion

The results obtained from the experiments conducted on the proposed novel framework for detecting network intrusions based on machine learning methods provide valuable insights into its efficacy and comparative performance. In this discussion, we delve into the key findings, highlight the strengths and limitations of the framework, and address potential avenues for further improvement.

The experimental results demonstrated that the k-Nearest Neighbors (kNN) algorithm exhibited superior performance in detecting network intrusions on the NSL-KDD dataset. This is evident from its high accuracy, precision, recall, and F-score values compared to the other applied methods. The kNN algorithm's ability to identify similar instances based on proximity in feature space, without making strong assumptions about the underlying data distribution, likely contributed to its success in this context. The results highlight the potential of instance-based methods, such as kNN, in handling network intrusion detection tasks.

On the other hand, the Random Forest classifier and Support Vector Machines (SVM) showed indications of overfitting. Overfitting occurs when a model becomes too closely aligned with the training data, leading to poor generalization to unseen data. This is a common challenge in machine learning, particularly when dealing with complex datasets such as network intrusion detection [34]. To mitigate overfitting, techniques such as regularization, feature selection, or hyperparameter tuning can be employed to improve the models' generalization capability.

The experimental results also provided insights into the performance of other applied methods. Decision Tree, Gaussian Naive Bayes, and Logistic Regression exhibited competitive performance, albeit slightly lower than that of kNN. These methods have their own strengths and weaknesses, and their suitability may vary depending on the specific requirements and characteristics of the intrusion detection problem at hand. Further exploration of these methods, including ensemble techniques such as AdaBoost, could potentially yield improved results.

The framework's utilization of the NSL-KDD dataset, a well-established benchmark dataset, adds credibility to the results. The dataset's diverse range of network intrusion types and comprehensive set of features enable a realistic evaluation of the proposed framework. However, it is important to acknowledge that the NSL-KDD dataset itself has some limitations, such as the inclusion of preprocessed data and the potential bias introduced during data collection [35]. Future studies should consider incorporating other datasets and real-world network traffic to further validate the framework's performance in practical settings.

The comparative analysis of training and test accuracies, precisions, recalls, and F-scores provided crucial insights into the generalization capabilities of the models. Discrepancies between training and test performance metrics can signify overfitting or underfitting [36]. In this context, attention should be paid to the models exhibiting high training performance but significantly lower performance on the test set, indicating overfitting. Strategies such as regularization techniques, cross-validation, or early stopping can help alleviate overfitting issues and enhance the models' generalization.

Moreover, the findings suggest that careful consideration should be given to the selection and tuning of hyperparameters for each machine learning algorithm [37]. Fine-tuning the algorithms' parameters, such as the number of neighbors in kNN or the maximum depth of decision trees, can significantly impact their performance [38]. Conducting a comprehensive hyperparameter search using techniques like grid search or Bayesian optimization can potentially yield further performance improvements [39].

While the proposed framework demonstrated promising results, it is important to acknowledge its limitations. Firstly, the evaluation was conducted on a specific dataset, and the performance may vary when applied to other datasets or real-world network environments. The framework's adaptability to different network architectures, traffic patterns, and attack scenarios remains an area for future exploration [40]. Additionally, the framework primarily focused on supervised learning methods [41], neglecting the potential benefits of unsupervised or semi-supervised approaches in network intrusion detection [42]. Future research could incorporate hybrid models or anomaly detection techniques to further enhance the framework's capabilities.

In conclusion, the experimental results presented in this study highlight the effectiveness of the proposed novel framework for detecting network intrusions based on machine learning methods. The k-Nearest Neighbors algorithm emerged as a top-performing method, outperforming the other applied algorithms in terms of accuracy, precision, recall, and F-score. The results underscore the importance of careful model selection, hyperparameter tuning, and addressing overfitting issues to ensure optimal performance. The findings contribute to the existing body of knowledge in network intrusion detection and provide a foundation for further research and development of robust and adaptable frameworks for network security. Last time, machine learning are used in different areas from medicine to smart cities [43-45]. In this research, we applied machine learning in network intrusion detection problem. As the obtained results show, machine learning gives high efficiency in this area, too.

VIII. Conclusion

In this study, we proposed a novel framework for detecting network intrusions based on machine learning methods and evaluated its performance on the widely used NSL-KDD dataset. The experimental results demonstrated the effectiveness of the framework in identifying network intrusions, with the k-Nearest Neighbors (kNN) algorithm emerging as the top-performing method. The framework's comprehensive evaluation metrics, including accuracy, precision, recall, and F-score, provided a comprehensive assessment of its performance.

The results highlight the importance of selecting appropriate machine learning algorithms and fine-tuning their hyperparameters to achieve optimal performance in network intrusion detection tasks. The kNN algorithm's success can be attributed to its ability to leverage proximity-based learning and handle complex patterns in the dataset. Furthermore, the comparative analysis of training and test accuracies, precisions, recalls, and F-scores shed light on potential overfitting issues and underscored the significance of model generalization.

While the proposed framework demonstrated promising results, it is important to acknowledge its limitations. The evaluation was primarily conducted on the NSL-KDD dataset, and the framework's performance may vary on different datasets or real-world network environments. Additionally, the framework focused on supervised learning methods and neglected the potential benefits of unsupervised or semi-supervised approaches. Exploring hybrid models and incorporating anomaly detection techniques could enhance the framework's capabilities in detecting previously unseen attacks.

In conclusion, the proposed novel framework presents a viable approach for network intrusion detection based on machine learning methods. The experimental results validate its effectiveness and highlight the importance of careful algorithm selection and hyperparameter tuning. The framework can serve as a foundation for further research in developing robust and adaptive intrusion detection systems, safeguarding network security in an evolving threat landscape. Future studies should expand the evaluation to include other datasets and consider the integration of unsupervised and semi-supervised approaches for improved performance and versatility.

A Dynamic Model for Risk Assessment of Cross-Border Fresh Agricultural Supply Chain

Honghong Zhai
College of Business Administration, Zhengzhou University of Science and Technology, Zhengzhou, 450064, China

***Abstract*—The cross-border trade of Fresh Agricultural Products (FAP) is widespread in the current society, and the demand for it is also increasing. The cross-border fresh agricultural product Supply Chain (SP) itself has strong complexity and high costs, and it also bears many risks. In order to alleviate the adverse impact of risk factors interfering with cross-border fresh agricultural product SPs and improve the overall SP efficiency, this study proposes a system dynamics model based on cross-border fresh agricultural product risk factors. The experiment first studied the possible risk factors in the SP of FAP. After discussing the causal relationship between possible risks, subjective and objective weighting methods were introduced to weight risk factors. After that, a system dynamics model of the cross-border fresh agricultural product SP was constructed for the purpose of enhancing product quality and the overall efficiency of the SP. In the system dynamics model constructed, risk factors are introduced for simulation experiments. It is demonstrated that the suggested model can truly reflect the dynamic changes of the actual SP, and can obtain the operational rules of the system.**

Keywords—Cross-border fresh agricultural products; supply chain management; risk identification; system dynamics model; risk weighting

I. Introduction

As a large country of agricultural production and consumption, the rational development of agriculture is the basis of the national economy and the necessary condition for the survival of other material sectors. Today, with the continuous advancement of economic globalization, the import and export scale of China's agricultural products has been firmly in the forefront of the world [1]. The increasing trade in Fresh Agricultural Products (FAP) has deepened international exchanges, but it also poses challenges to the Supply Chain (SP) management of cross-border FAP [2]. FAP, compared to other products, have the characteristics of perishability and are not easy to preserve, so their requirements for logistics and transportation are high. In addition, customs inspection of cross-border trade is relatively strict, and transportation time and distance are relatively longer, resulting in more risks. The cross-border fresh agricultural product SP has a higher complexity and a greater likelihood of risk occurrence [3]. Therefore, effective identification and timely avoidance of risk factors in the cross-border fresh agricultural product SP is crucial to ensuring the quality of FAP. System dynamics model is a qualitative and quantitative research method that can simulate and analyze the connection and development of complex problems from a holistic perspective, and is applicable to this research topic [4]. Currently, the academic community has conducted relevant research on the SP risk of cross-border FAP, and has also achieved certain results. However, it mainly focuses on SP inventory control, ordering strategies, and other aspects. There are few studies that use risk factors and system dynamics models to find the impact of risk variables on the SP [5]. Therefore, this experiment takes the cross-border fresh agricultural product SP as the research object, and introduces subjective and objective weighting methods to weight its risk factors. Based on this, a system dynamics model is constructed to explore the best solution for enhancing the overall efficiency of the SP.

The innovation of this study lies in: (1) The introduction of subjective and objective weighting methods to weight the risk factors of cross-border fresh agricultural products supply chain. (2) The system dynamics model of cross-border fresh agricultural products supply chain is constructed.

The study is divided into five parts. The first part is the introduction, which introduces the research background and significance; the second part is a literature review, which introduces the current development status of supply chain factor identification and system dynamics model. The third part is the establishment of system dynamics model for operational risk assessment of cross-border fresh agricultural supply chain. The fourth part is the performance verification of the constructed model. The last part is the summary of the full text and the prospect of future research.

II. Related Work

Currently, researchers have discussed the methods for identifying SP risk factors. Zhao and other researchers used topic analysis, fuzzy cross impact matrix multiplication analysis, and other methods to effectively manage the complexity and vulnerability of agricultural food SPs. The experiment classified risks based on their dependencies and driving forces, thereby helping to determine the relationship between risks and the most critical risk factors. The final result promoted the study of risk factors in the agricultural food SP [6]. To explore the sustainable impact of flood risk drivers on agricultural SPs, scholars such as Yazdani proposed a multi standard approach to assess flood risk in crop regions. This method ranked agricultural projects affected by floods to detect the best projects, thereby mitigating the greatest impact of flood risk on crop areas. This method had important practical significance for preventing flood risk [7]. In order to determine the impact of standardized management systems on selected risks in the SP, Zimon et al. applied basic data analysis methods to investigate logistics company staff. The experiment was conducted using a questionnaire survey, and the results showed that improving SP management can help managers [8]. Wang and other researchers conducted empirical research on the SP risk management of express delivery companies. The experiment mainly started with exploring the relationship between innovation capability and SP risk, and established a partial least squares method for structural equations based on the survey data. The study found that there is a negative correlation between them, so enterprises can try to decrease the negative impact of SP risk by developing their own innovation capability [9]. From the perspective of risk factors in the halal food SP, Khan S and other teams used a hierarchical fuzzy analysis method to rank the identified risk factors. This method can effectively rank the risk factors in the halal food SP, thereby helping managers take effective measures to mitigate risks. This result has practical significance for studying the risk management of halal food SP [10].

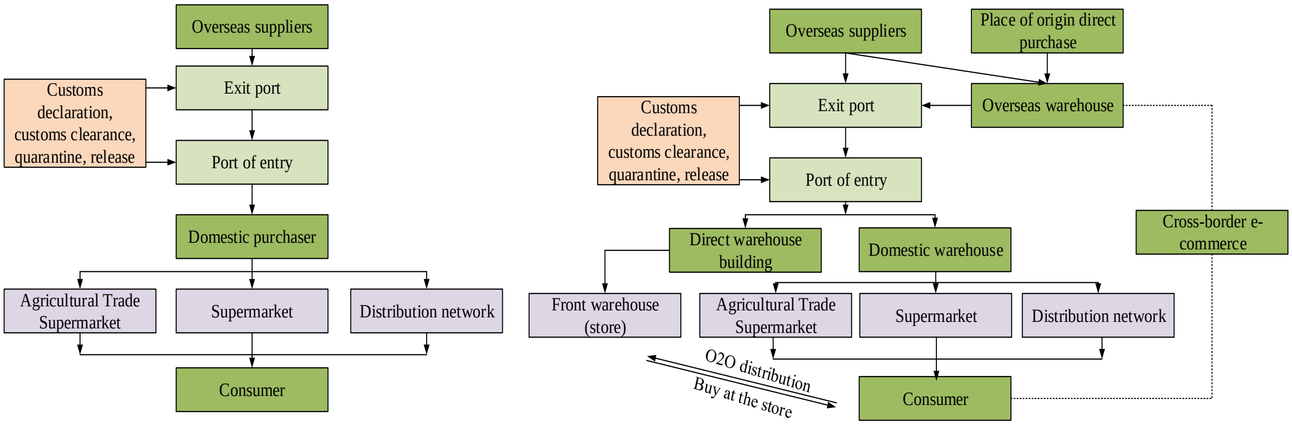
System dynamics model is a structural model that simulates the dynamic changes of a system, and has a wide range of applications in various fields. Based on system dynamics models, researchers such as Papachristos developed a simulation model that combines standard competitive dynamics theory. This model could be used as a powerful tool for enterprises to obtain competitive advantage. Simulation experiments on four standard competition cases showed that the simulation results of are consistent with real cases. Therefore, the proposed model could lay the foundation for theoretical and empirical research on standard competitive strategy [11]. Liu et al. established an environmental assessment model for construction waste using a system dynamics model. The impact on the environment, economy, and society was analyzed in the experiment. The final simulation results can provide reference value for construction waste treatment [12]. Rathore and other scholars used system dynamics models to promote the interaction between dynamic feedback effects and risks in grain transportation. The experiment used a system dynamics model that considers the value of the risk index to observe the impact of the risk value on grain inventory levels and vehicle capacity. The model proposed in the experiment could help improve food supply through comprehensive risk control in the SP, and can improve the efficiency of the food SP [13]. Sayyadi and other researchers proposed an integrated approach based on system dynamics and analytical networks to assess the sustainability of transportation policies. This method evaluated and ranks five policies, namely, travel sharing, reducing travel rate, reducing road network length, vehicle ownership, and average driving kilometers, through the third indicator of congestion degree, fuel consumption, and emissions. The research results verified the effectiveness of the constructed system [14]. Researcher Oleghe developed a system dynamics model based on end-to-end agribusiness and aquaculture SP models from the perspective of capacity expansion of aquaculture companies. This model covers unique dynamics related to the aquaculture SP and enables simulation of company working capital management rules. Experiments have verified that the proposed model can be applied to companies' management of working capital under different financing modes and capacity expansion rates [15].

To sum up, both have relevant applied research. However, there are still many limitations in the above research. For example, the construction of the index system of risk factors is not perfect, the effect of risk simulation is not good, and the risk management method still needs to be further improved. At present, there are no relevant studies combining risk factor variables with system dynamics models, and the description of cross-border FAP risk factors is insufficient. Therefore, this study introduced subjective and objective weighting methods, weighted its risk factors, and established a system dynamics model to explore ways to improve the overall efficiency of SP.

III. Construction of a System Dynamics Model for Risk Assessment of Cross-Border Fresh Agricultural Product SP Operation

A. *Research on Main Risk Factors of Cross-Border Fresh Agricultural Product SP*

The SP of traditional cross-border FAP is mainly composed of three main bodies: overseas SPs, domestic buyers, and relevant consumers. Its sales channels are mainly agricultural markets, supermarkets, and distribution outlets. The traditional sales channel that occupies the main position is the supermarket. The purchaser of the store first proposes an order demand to the overseas supplier; after receiving the order, the overseas supplier shall ship the goods by sea or air. During this process, FAP need to undergo customs clearance, inspection and quarantine before reaching the domestic purchaser's warehouse [16,17]. To reduce costs, cross-border e-commerce and other direct procurement operation models have gradually emerged in recent years. This mode is mainly for cross-border e-commerce enterprises to directly connect with overseas agricultural product suppliers and deliver products to consumers through front-end warehouses [18,19]. The operation mode of cross-border e-commerce has greatly shortened the length of the SP, effectively reducing production costs. Fig. 1 illustrates the overall operational process of the traditional cross-border fresh agricultural product SP and the cross-border e-commerce fresh agricultural product SP. The cross-border fresh agricultural product SP under both modes has similar operational links, namely, the supply link, the transportation link, and the sales link. In fact, various unexpected situations and constraints in reality have posed challenges to the SP management of cross-border FAP. Therefore, the three links of the SP are faced with varying degrees of risk possibilities.



(a) Traditional cross-border fresh agricultural product supply chain

(b) Cross-border e-commerce fresh agricultural product supply chain

Fig. 1. Operation process of two SPs.

Currently, FAP are vulnerable to risks due to the international situation, cold chain transportation, bottlenecks, import and export food safety, and other conditions. FAP are vulnerable to environmental changes. During the COVID-19 epidemic, people's demand for FAP increased sharply. Meanwhile, FAP appeared to be out of stock and not delivered in a timely manner. In this context, the cross-border fresh agricultural product SP is also subject to many restrictions, resulting in a longer overall warehousing time for goods. Secondly, FAP has high requirements for cold chain logistics of enterprises. Cold chain technique is a key technology to ensure the quality of FAP, so it has significant constraints on the SP of FAP. The cold chain logistics technology for FAP in China is still immature, and compared to other developed countries, the overall loss rate of products is relatively high, as shown in Fig. 2. Thirdly, the customs clearance efficiency of China's cross-border fresh agricultural product SP is low, which leads to low supply efficiency and poor operation of the entire chain [20]. Finally, China attaches more importance to the safety issues of imported and exported food quality, but the technology for safety testing needs to be strengthened. Compared to other cross-border commodities, FAP are perishable and resistant to bumps, with higher transportation requirements and costs [21]. Therefore, it is particularly important to accurately identify the actual operational risk factors in their SP.

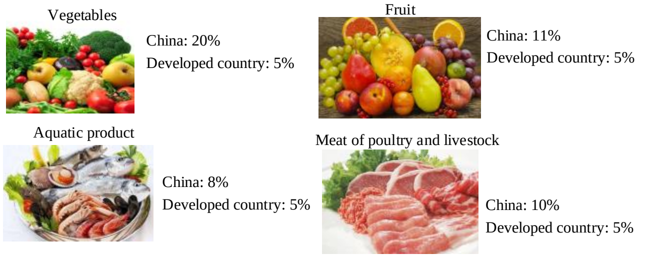


Fig. 2. Comparison of fresh agricultural product consumption rates between China and developed countries.

The risk factors of the cross-border fresh agricultural product SP mainly include the problems that are prone to occur in the operation of the SP and the statistical analysis results of existing SP accidents that have occurred. The main risk factors can be divided into three aspects, namely, SP risk factors, transportation chain risk factors, and sales chain risk factors. In the SP, supply delay risk, inventory risk, quality safety risk, and supply risk are prone to occur. Supply delay refers to the delay in delivery at the source caused by suppliers' inability to prepare goods from the origin on time, which has a negative impact on the operational efficiency of the entire SP [22]. Inventory risk refers to the phenomenon of excess inventory or shortage caused by supplier information lag or stock preparation delay. The quality safety risk is that the quality of FAP at the source of the supplier does not meet the standard. Supply risk refers to the insufficient supply quantity and poor product quality of the overall product. The risk factors faced in the transportation process mainly include shipment delay risk, cold chain risk, unexpected risk, and customs clearance risk. The risk of delivery delay refers to the failure of suppliers to deliver goods on time, resulting in poor operation of the total SP. Cold chain risk refers to the possibility of product loss caused by substandard cold chain technology. Sudden risks refer to unexpected events such as weather disasters and wars encountered during transportation. The destruction of products by sudden risks is irreversible, and the losses brought to the SP are irreparable. Customs clearance risk refers to the problems of excessive customs clearance time and low customs clearance efficiency during the quarantine process of commodity export and import. The final sales process also faces major risk factors such as sales delay risk, market risk, sales inventory risk, and cold chain risk. Fig. 3 demonstrates the causal relationship between various types of risks. In the figure, S represents an overseas supplier; P represents the domestic purchaser; "+" indicates positive feedback and "-" indicates negative feedback.

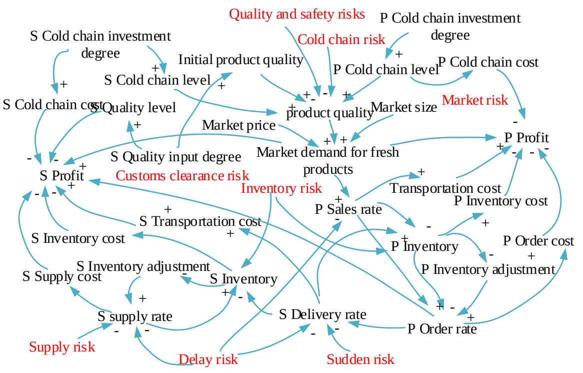

Fig. 3. The causal relationship between various types of risks.

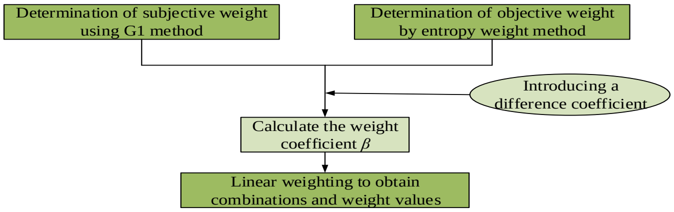
B. Construction of System Dynamics Model for Cross-Border Fresh Agricultural Product SP

The previous section describes the causal relationship of risk factors in the SP of FAP. Common risks in cross-border fresh agricultural product SPs include supply delay risk, inventory risk, quality and safety risk, supply risk, shipment delay risk, cold chain risk, sudden risk, customs clearance risk, sales delay risk, market risk, sales inventory risk, and cold chain risk. For the establishment of this system dynamics model, it is first necessary to convert the above risks into state variables in the system. The above variables can be determined as state variables in the model, and their corresponding changes are rate variables. When using system dynamics to establish a risk assessment model for the operation of the fresh agricultural product SP, it is required to adopt some methods to define the functional relationship between various risk factors [23]. Among them, the most commonly used is the linear functional relationship, which is to establish system dynamics equations by calculating the weights of various risk factors. The weight determination method starts from three aspects: subjective weight, objective weight, and comprehensive integration weight [24]. The overall process of comprehensive empowerment through subjective and objective empowerment methods is shown in Fig. 4.



Determination of subjective weight using G1 method
Determination of objective weight by entropy weight method
Introducing a difference coefficient
Calculate the weight coefficient β
Linear weighting to obtain combinations and weight values

Fig. 4. Combination weight weighting process.

Firstly, the subjective weight is determined using the Order Relationship Analysis Method (G1) [25]. Assuming that there are N risk factors, ranking them according to the importance of each risk indicator can obtain the ranking results shown in Eq. (1):

$$a_1^{'} \geq a_2^{'} \geq \ldots \geq a_n^{'} \quad (1)$$

In Eq. (1), a_i represents the evaluation criteria and indicators. The ratio between $a_i^{'}$ and $a_{i-1}^{'}$ is the degree of relative importance, recorded as t_i. After reasonably assigning a value to t_i. Calculate the weight coefficient using Eq. (2):

$$m_i^{'} = \left(1+\sum_{i=2}^{n}\prod_{k=i}^{n} t_i\right)^{-1} \quad (2)$$

$$m_{i-1}^{'} = t_i m_i^{'} \quad \left(i = n, n-1, \ldots, 2\right)$$

In Eq. (2), both $m_i^{'}$ and $m_{i-1}^{'}$ represent weight coefficients. When using the G1 method to determine the weight, there is a situation where team experts' scores are inconsistent, so it is necessary to discuss the importance level. Assuming that there are $x\left(x \geq 1\right)$ experts in total, among which z experts have the same results for ranking indicators, there is an Eq. (3):

$$t_i^* = \frac{1}{a}\sum t_i \quad (3)$$

In Eq. (3), t_i^* represents the ratio of the relative importance between indicators $a_i^{'}$ and $a_{i-1}^{'}$. Then, the weight coefficient of this z expert can be determined as:

$$m_i^{'} = \left(1+\sum_{i=2}^{n}\prod_{k=i}^{n} t_i\right)^{-1} \quad (4)$$

$$m_{i-1}^{"} = t_i^* m_i^{"} \quad \left(i = n, n-1, \ldots, 2\right)$$

Aside from that, assuming that the evaluation results of the remaining $x-z$ experts are different, averaging them can obtain Eq. (5):

$$\overline{m_i}^{'} = \frac{\sum m_i^{'}}{x-z} \quad (5)$$

Finally, combining the two types of results, Eq. (6) can be obtained:

$$m_i = k_1 m_i^{"} + k_2 \overline{m_i}^{"} \quad (6)$$

In Eq. (6), $k_1 = \frac{z}{x}$, $k_2 = \frac{x-z}{x}$. After determining the subjective weight, it is necessary to discuss the objective weight. The difference from subjective weight is that the final result of objective weight does not rely on subjective judgment, but rather decides the indicator weight based on the information of the sample itself. Entropy weight method is a commonly used objective weighting method, which mainly determines the weight through the degree of variation of indicators. The size of the entropy value can reflect the degree of variation of the index. The larger the entropy value, the greater the degree of variation and the more information it covers, so the higher the weight value. Suppose there is a judgment matrix (A P) that contains the judgment values of n experts on m risk factors, and the specific expression is:

$$P = \begin{bmatrix} A_{11} & A_{12} & \ldots & A_{1n} \\ A_{21} & A_{22} & \ldots & A_{2n} \\ \ldots & \ldots & \ldots & \ldots \\ A_{m1} & A_{m2} & \ldots & A_{mn} \end{bmatrix} \quad (7)$$

Standardize the data contained in Eq. (7) to obtain Eq. (8):

$$P_{ij}=\frac{A_{ij}-\min\left(A_{ij}\right)}{\max\left(A_{ij}\right)-\min\left(A_{ij}\right)} \qquad (8)$$

In Eq. (8), $\min\left(A_{ij}\right)$ denotes the minimum value in the original judgment matrix; $\max\left(A_{ij}\right)$ denotes the maximum value in the original judgment matrix; P_{ij} represents a standardized value. The equation for calculating the proportion of each index is shown in Eq. (9):

$$r_{ij}=\frac{P_{ij}}{\sum_{j=1}^{n}P_{ij}},\quad \left(i=1,2,\ldots,m\right) \qquad (9)$$

Eq. (9) represents each indicator value's weight, so the entropy weight calculation Equation for the i index is:

$$w_i=\frac{1-E_i}{m-\sum_{i=1}^{m}E_i} \qquad (10)$$

After determining the subjective and objective weights, comprehensive weighting can be performed. This model can combine the advantages and characteristics of subjective and objective weighting methods to enhance the scientificity and rationality of the final result. The linear weighting method can not only compensate for the shortcomings caused by the uneven numerical values of other methods, but also have a relatively concise calculation process for finding the optimal combination weight. Therefore, this experiment uses a linear weighting method to restructure the weights. The basic calculation Equation is as follows:

$$Q_i=\beta m_i+\left(1-\beta\right)w_i,\quad 0\le\beta\le1 \qquad (11)$$

In Eq. (11), β denotes the proportional coefficient. The overall calculation equation is shown in Eq. (12):

$$Q_i=\frac{m}{m-1}\left[\frac{2}{m}\left(P_1+2P_2+\ldots+mP_m\right)-\frac{m+1}{m}\right] \qquad (12)$$

In Eq. (12), P_{ij} represents the number of indicator factors; P_{ij} represents the weight value of the P_{ij} values of each indicator factor after being sorted in ascending order. In addition to the above risk variables, there are also some boundary risk variables that cannot directly obtain data. For the assignment of boundary risk variables, this experiment was conducted using expert scoring. The scoring rules are shown in Eq. (13):

$$a_{ij}=\left(x+4n+y\right)/7 \qquad (13)$$

In Eq. (13), x,y,n represents the minimum, maximum, and most likely values that boundary risk factors may have an impact on the fresh agricultural product SP. i represents the i-th risk factor; j represents the j-th expert. Average all the obtained results to obtain the corresponding boundary risk value. Draw a system flow diagram for all risk variables based on the causal relationship diagram in the previous section. Fig. 5 shows the basic form of a system dynamics model for the cross-border fresh agricultural product SP.

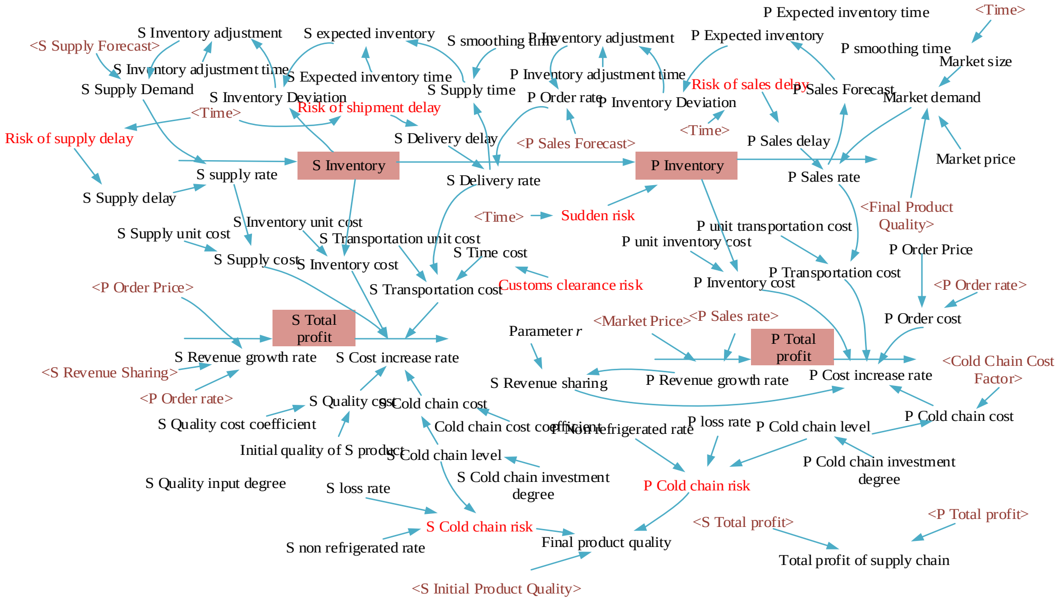


Fig. 5. Basic form of system dynamics model for cross-border fresh agricultural product SP.

IV. Simulation Experiment on System Dynamics Model of Cross-border Fresh Agricultural Product SP

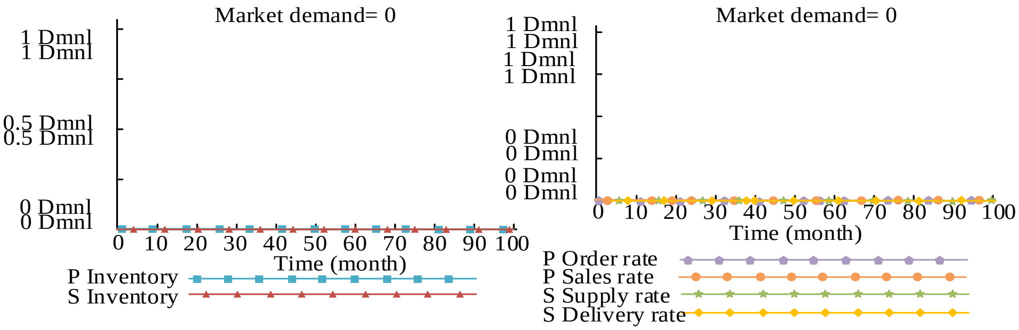
A. System Dynamics Model Test of Cross-Border Fresh Agricultural Product SP

To make the logic of the constructed model and functional equation reasonable, and ensure that the system operation can reflect the actual situation to a greater extent, model verification is conducted before conducting model simulation experiments. First, set the constants for the overall model, and the values set are obtained based on the relevant data in the industry report. To verify whether the model can truly, stably, and continuously reflect the actual change rules, experiments were conducted to test the realistic reproducibility of the model. In order to make the model truly reproducible, experiments were conducted to examine both extreme and actual situations. Table I shows the settings for some of these variables. The experiment was conducted using Vensim software.

Fig. 6 shows the model test results under extreme conditions where the market demand is zero. Set the market demand to a limit condition of 0, with the simulation starting at 0, ending at 100 months, and step length of 1 month. Then observe the operation effect of the system. When the market demand level is 0, the buyer does not sell the product and will not place an order. Therefore, both the sales and order ratios are 0. When the buyer does not need to place an order, the seller will not provide the goods and will not ship them. Therefore, both the supply ratio and the shipment ratio are 0. The company's inventory level remains at its initial level of 0. The model can be tested under extreme conditions.

TABLE I. PARTIAL PARAMETER SETTINGS OF SYSTEM DYNAMICS MODEL

Variable	Numerical Value	Variable	Numerical Value
Market price	101.22	Order Price	60.89
Purchaser smoothing time	2.13	Supplier smoothing time	2.16
Purchaser's expected inventory time	3.27	Supplier's expected inventory time	3.47
Purchaser inventory adjustment time	4.32	Supplier inventory adjustment time	5.24
Supplier Cost Quality Factor	45000	Cold chain cost coefficient	40000
Supplier attrition rate	0.1	Purchaser's loss rate	0.22
Supplier non refrigerated rate	0.1	Supplier non refrigerated rate	0.56
Supplier unit inventory cost	5.67	Supplier's unit transportation cost	20
Supplier unit supply cost	10.19		



(a) Inventory changes

(b) Changes in orders, shipments, and sales

Fig. 6. Model test results under extreme conditions with market demand of 0.

After that, use the model to test the actual situation. Similarly, set the start time to the 0th month, the end time to the 100th month, and the step length to 1 month. At the same time, set the risk of sales delay in the 10th to 20th months; Risk of supply delay in the 20th to 40th months; the risk of shipment delay occurs in the 60th to 80th months; sudden risks occur in the 50th month. Fig. 7 shows the changes in purchasing inventory during this period. In the 10th month, there was a risk of sales delays, i.e. a decrease in the purchaser's sales rate, resulting in an increase in inventory and a decrease in the supplier's delivery rate. In the 50th month, there was a sudden risk that the purchaser's inventory decreased, leading to an increase in the supplier's delivery rate until it stabilized. In the 60th month, the risk of delivery delay occurred, and the supplier's delivery rate decreased, resulting in a slight decrease in the purchaser's inventory. In the 80th month, the risk of shipment delay disappeared and the purchaser's inventory gradually returned to normal levels. The operation of the model coincides with the actual situation.

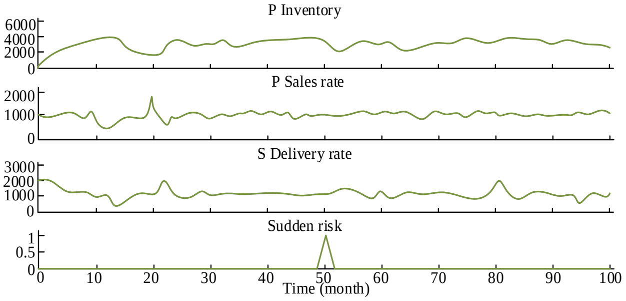


Fig. 7. Purchaser inventory changes.

Fig. 8 shows the inventory changes of suppliers during the above time period. In the 10th month, the supplier's shipment rate suddenly decreased, and the supplier's inventory was still able to meet downstream ordering requirements, so the supply rate was 0. After that, when the supplier's shipment rate began to pick up, the supply rate also began to gradually rise. However, the growth rate of the supply rate is slower than the delivery rate, until the two are equal, the supply inventory decreases to the minimum. When the supplier's inventory is at the lowest level, the supply rate will peak in a short period of time. Then, when the supplier's shipment volume remains basically constant, the supply rate will lag behind the inventory. The risk of shipment delay occurs between 60 and 80 months, and the supplier's inventory changes exhibit a similar pattern. The operation of this model is consistent with the actual situation.

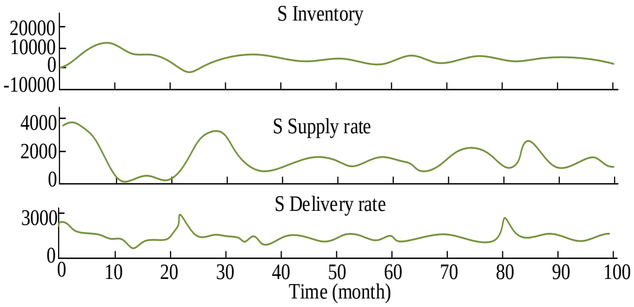

Fig. 8. Supplier inventory changes.

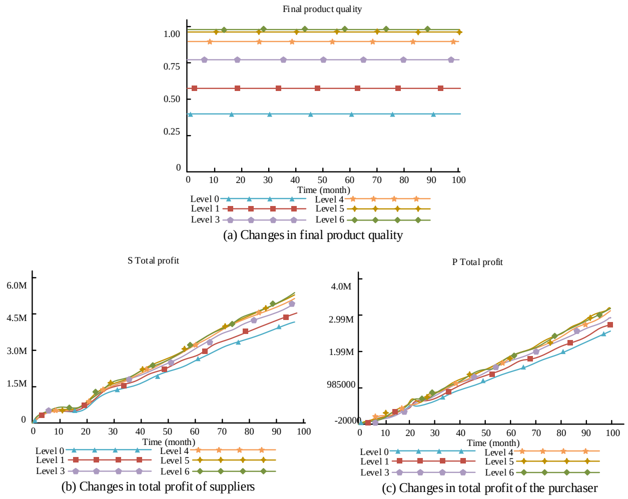
B. *Simulation Analysis of Key Risk Variables in the Cross-Border Fresh Agricultural Product SP System Dynamics Model*

Fig. 9 shows the level of impact of supplier quality input on the SP. As suppliers invest more in quality, product quality will gradually improve, thereby promoting an increase in market demand. As a result, the overall profit of the market has increased. However, for suppliers, the marginal benefits generated by continuing to increase investment in product quality are diminishing. The growth rate of product quality and market demand has stabilized, and high investment also means high costs. Therefore, the total profits of buyers and suppliers will gradually increase to a certain level and remain constant. This indicates that increasing the level of quality input from suppliers can improve the overall revenue of the SP, but there is an upper limit.

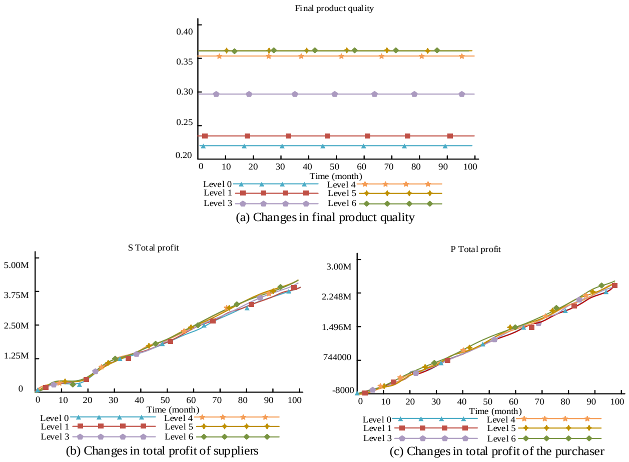


(a) Changes in final product quality

(b) Changes in total profit of suppliers

(c) Changes in total profit of the purchaser

Fig. 9. Impact level of supplier quality input on SP.



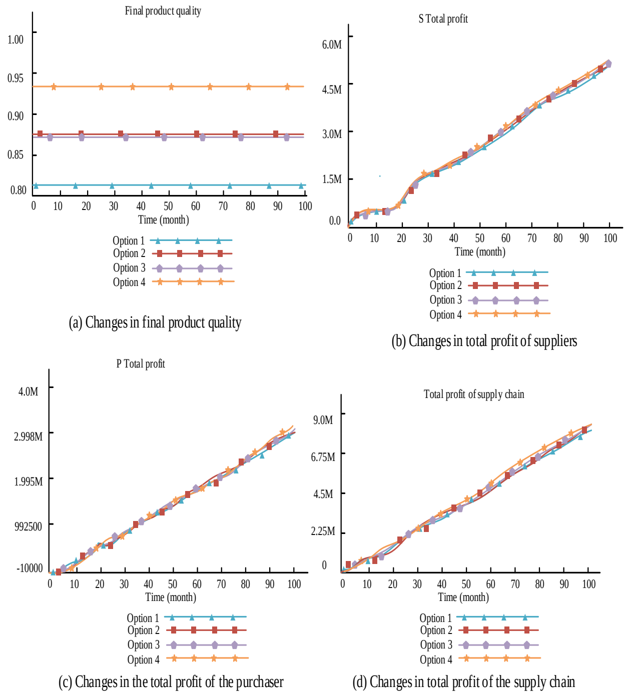
(a) Changes in final product quality

(b) Changes in total profit of suppliers

(c) Changes in total profit of the purchaser

Fig. 10. Impact of purchaser's cold chain investment on SP.

Fig. 10 shows the impact of the purchaser's cold chain investment on the SP. The increased investment of buyers in the cold chain has led to the improvement of product quality, which has promoted the increase in market demand. Therefore, the overall interests of the market will increase accordingly. However, after investing in the cold chain to a certain level, the marginal income will suddenly rise and then decline after accumulating to a certain level. This is because cold chain logistics requires a certain amount of upfront investment. In the early stages of cold chain transportation, a large amount of money needs to be spent, resulting in a small return on investment in the early stage. High investment brings high costs. Thus the overall returns of buyers and suppliers will gradually increase until they remain unchanged. As a result, increasing the investment of suppliers in the cold chain can improve the overall efficiency of the SP, but also has an upper limit.



(a) Changes in final product quality

(b) Changes in total profit of suppliers

(c) Changes in the total profit of the purchaser

(d) Changes in total profit of the supply chain

Fig. 11. Impact of different schemes on SP profits.

Fig. 11 shows the impact of various solutions on the SP system. There are four different schemes in the figure: Scheme 1 is the initial setting; Scheme 2: Increase input for suppliers; Scheme 3: Increase the degree of investment for the purchaser; Scheme 4 is the degree of joint cooperation investment. It can be seen from the figure that suppliers and purchasers will increase their investment in the product, which will improve the final quality of the product and the overall profit of the SP. When all members of the SP jointly increase their investment, both the benefits of both parties and the overall benefits of the SP are higher than when one party alone increases its investment level. Therefore, the two parties should actively establish a cooperative relationship and choose appropriate incentives. Suppliers increase their investment in product quality to improve quality products; the purchaser should increase investment in the cold chain and improve the cold chain management ability. This will maximize benefits while ensuring the overall efficiency of the SP.

V. Conclusion

Nowadays, the increasing demand for cross-border FAP poses a significant challenge to the management of their SP. To reduce the interference of risk factors on the cross-border fresh agricultural product SP, and thereby enhance the efficiency of the overall SP, the experiment weighted the possible risk factors and constructed a system dynamics model. The test results of the system dynamics model show that the proposed method can pass the test under extreme conditions, and its operation is consistent with the actual situation. Simulation experiments were conducted to introduce risk factors into the constructed system dynamics model. The simulation results indicate that increasing the supplier's quality input can enhance the overall revenue of the SP, but there is an upper limit; increasing the investment of suppliers in the cold chain can enhance the overall efficiency of the SP, but it also has an upper limit. Therefore, to ensure the overall efficiency of the SP and maximize benefits, suppliers increase their investment in product quality and improve the products' quality; the purchaser should increase investment in the cold chain and optimize the cold chain management ability. The proposed model can truly reflect the dynamic changes of the actual SP, and has good practicality. This experiment still has some limitations, that is, it fails to consider external macro risks and other factors, so the subsequent research can start from here.

***Abstract*—This paper presents an in-depth examination of the development and implementation of an innovative platform for teacher professional development, incorporating features of blockchain technology. The platform manifests a revolutionary step in enhancing teacher training, creating a secure, transparent, and decentralized approach for maintaining continuous professional development records. Using blockchain's inherent properties, the platform ensures immutable record-keeping and instills credibility in teachers' career progression, empowering educators through direct ownership of their professional development milestones. Additionally, the platform fosters a culture of lifelong learning, encouraging educators to actively engage in their professional growth, while providing reliable evidence of their achievements. Alongside highlighting the design aspects of the platform, the paper delves into potential challenges and solutions associated with the incorporation of blockchain technology into educational contexts. Through this innovative intersection of technology and education, the platform showcases the potential of blockchain in reshaping and enriching professional development strategies for teachers, thereby elevating educational standards and practices across the board.**

Keywords*—Blockchain; professional development; artificial intelligence; teaching; learning

I. INTRODUCTION

The advent of the digital age has brought about transformative changes across industries worldwide. In education, technology's role in shaping instructional strategies, fostering collaboration, and enhancing student outcomes is well-recognized [1]. However, an area less explored, but no less critical, is the use of technology to facilitate and optimize the professional development (PD) of teachers [2]. To that end, this paper aims to describe the design and development of a novel platform that leverages elements of blockchain technology to revolutionize the PD landscape for teachers.

Teacher PD refers to a comprehensive set of specialized training, formal education, and advanced professional learning aimed at enhancing teachers' pedagogical skills and knowledge [3]. The effectiveness of a teacher's professional development program is central to the quality of education imparted. Research has indicated that high-quality PD positively impacts teacher quality, which, in turn, improves student achievement [4]. However, the traditional methods of documenting and validating PD efforts often involve arduous, time-consuming paperwork, and a lack of transparency and credibility.

Blockchain technology, renowned for its robust security, decentralization, and immutable record-keeping capabilities, can provide efficient solutions to these challenges [5]. While blockchain has mostly been associated with cryptocurrencies like Bitcoin, its potential extends far beyond, having disruptive implications for sectors like healthcare, finance, and supply chain management [6]. In the realm of education, blockchain holds promise for academic credential verification, student record management, and, as explored in this paper, enhancing teacher PD.

In response to the need for a more efficient, transparent, and credible system for managing teacher PD, we have developed a unique platform incorporating blockchain technology. The platform serves as a decentralized ledger for recording, verifying, and sharing professional development activities [7]. It provides teachers with direct control over their records and the ability to share their verified qualifications and skills seamlessly, fostering greater trust and collaboration within the educational community.

The application of blockchain technology to teacher PD also aligns with the increasing emphasis on lifelong learning [8]. The platform supports a culture of continuous learning and improvement, allowing educators to document their professional growth over time reliably [9]. By reinforcing the value of PD and enhancing its accessibility and transparency, blockchain technology can contribute significantly to enriching teacher quality and, consequently, student learning experiences [10].

This paper provides a comprehensive overview of the platform's design, development, and implementation processes, demonstrating the practical application of blockchain in education. It also discusses potential challenges and strategies to overcome these in the context of blockchain integration into educational systems.

In essence, the fusion of blockchain technology with teacher professional development marks a promising step towards a more technologically enriched educational sphere. By presenting a blueprint for integrating blockchain into teacher PD, we hope to contribute to the ongoing dialogue on harnessing technology to elevate educational practices and outcomes.

II. Related Works

A. Professional Development of Teachers

The essence of professional development (PD) lies in its potential to foster an enhanced understanding of pedagogical methods, curriculum intricacies, and student learning mechanisms among teachers. Studies emphasize the role of effective PD in augmenting teacher quality, thereby improving student outcomes [11]. However, the means of validating and documenting PD activities often lack transparency and efficiency, leading to skepticism about their credibility and consistency [12].

The role of professional development (PD) in the educational landscape is paramount. It embodies the continuous growth and learning teachers undertake to refine their pedagogical skills, adapt to evolving educational trends, and ultimately, enhance student learning outcomes [13]. Fig. 1 demonstrates GoSTEAM model that use block chain in STEAM education.

The common thread running through these diverse modalities is the objective of equipping teachers with the knowledge and skills necessary for effective classroom management and instruction. In this context, [14] proposed that effective PD must be ongoing, focused on the curriculum, and collaborative in nature. It should allow teachers to experiment, receive feedback, and reflect on their practice.

Moreover, the effectiveness of PD extends beyond individual teacher performance. Well-structured PD programs have been linked to fostering collaborative cultures within schools, thereby boosting overall institutional performance [15]. In contrast, ineffective PD programs characterized by disconnected, short-term training sessions have shown minimal impact on teachers' practices and student outcomes.

However, the current systems of documenting and validating PD often involve cumbersome paperwork and are vulnerable to inconsistencies. In addition, these traditional methods often lack transparency, leading to questions about their reliability and the credibility of the PD efforts documented [16]. These challenges underscore the need for innovative solutions that can streamline the PD process, enhance its credibility, and encourage teachers to actively engage in their professional growth.

Recently, emerging technologies, such as blockchain, have been suggested as potential solutions to enhance the credibility, transparency, and efficiency of teacher PD. Blockchain technology, with its secure, transparent, and decentralized features, could serve as a means to authenticate PD efforts reliably and sustainably. This paper extends the exploration of this potential solution, presenting the design and development of a platform for teacher PD incorporating elements of blockchain technology.

B. Blockchain Technology: Beyond Cryptocurrency

The inception of blockchain technology, originally designed to support Bitcoin, a digital currency, has had far-reaching implications beyond the financial sector. Essentially, blockchain provides a decentralized, secure, and transparent environment for transactions and record-keeping [17]. Its application spans a multitude of sectors including healthcare, finance, and supply chain management, owing to its potent capabilities of data integrity and traceability [18].

Blockchain technology, born out of the desire for a decentralized and secure digital currency system, was first introduced by [19] in his seminal work on Bitcoin. However, the implications of this technology extend far beyond its initial application. The fundamental features of blockchain – decentralization, immutability, and transparency – make it a potent tool for diverse sectors beyond finance [20]. Fig. 2 demonstrates an example of using blochchain technology in cryptocurrency.

At its core, blockchain operates as a decentralized ledger of transactions distributed across a network of computers, known as nodes. Each transaction is recorded as a block and linked to the previous one, forming a chain. Once information is stored in a block, it becomes virtually impossible to modify or delete, thus ensuring the immutability of data. Furthermore, the absence of a central authority reduces the risk of single-point failures and increases system resilience [21].

While the initial hype around blockchain revolved around cryptocurrencies, researchers and industry professionals have recognized its potential in various other domains. For instance, in healthcare, blockchain can ensure secure patient data management, facilitating interoperability while maintaining data privacy [22]. In supply chain management, blockchain's ability to provide traceability can enhance transparency and minimize fraud [23].

Fig. 1. Applying blockchain in education.

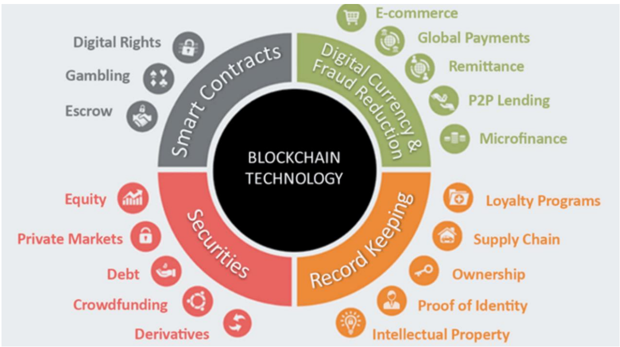

Fig. 2. An example of a lecturer's block.

In the context of education, blockchain can have transformative implications. It can provide a secure, decentralized, and transparent system for academic credential verification, potentially eliminating the prevalent issues of credential fraud [24]. Furthermore, it could offer a reliable method of managing student records, giving students ownership of their educational data [25].

However, while the potential applications of blockchain are vast, so are the challenges. Technological understanding, data privacy, cost, and the issue of integration with existing systems are some of the critical considerations that must be addressed for successful implementation [26].

This paper explores the practical application of blockchain technology in an uncharted domain within education – teacher professional development. It delves into the design and development of a blockchain-based platform for documenting and verifying teachers' professional development activities, offering a novel perspective on the potential of blockchain technology in education.

C. Blockchain in Education

In the context of education, the potential of blockchain has been increasingly recognized, particularly in credential verification and student record management. The study [27] highlights the utility of blockchain in creating secure digital badges, asserting the credibility of academic achievements. Meanwhile, [28] demonstrates the successful use of blockchain in managing student records, providing a decentralized and immutable record of student progress and accomplishments. Yet, the realm of teacher PD remains a largely uncharted territory in blockchain-related research.

The potential of blockchain technology in the education sector is considerable and is beginning to draw substantial interest from researchers and practitioners. Its core characteristics of decentralization, security, and immutability offer unique solutions to some of the longstanding challenges in education, particularly in the domains of record management and credential verification [29]. Fig. 3 demonstrates example of application of blockchain technology in high education.

One of the most touted applications of blockchain in education is credential verification. With the rise of online learning and micro-credentials, traditional methods of credential verification have become increasingly cumbersome and susceptible to fraud. Blockchain technology can address these issues by providing a secure, immutable, and universally accessible system for issuing and verifying academic credentials [30]. By storing credentials on a blockchain, institutions can ensure their authenticity and longevity, while learners can retain lifelong ownership of their achievements, irrespective of institutional longevity.

Additionally, blockchain holds potential for student record management. Traditional systems for storing and transferring student records often involve significant bureaucratic processes and are vulnerable to loss or misplacement. A blockchain-based system could offer an efficient, secure, and transparent method for managing these records. Students could control and share their academic history, ranging from grades to extracurricular activities, providing a comprehensive, verified record of their learning journey [31].

Moreover, blockchain could revolutionize open and distance learning. By facilitating the secure exchange of digital assets, blockchain could provide the infrastructure necessary for implementing self-sovereign education, where learners have complete control over their educational journey [31].

However, despite these potential benefits, implementing blockchain in education is not without challenges. Concerns about data privacy, cost of implementation, interoperability with existing systems, and the need for digital literacy among stakeholders are considerable [32]. Addressing these challenges is a crucial step toward harnessing the potential of blockchain in education.

This paper contributes to this growing area of interest by exploring the application of blockchain technology in a relatively less explored domain within education: teacher professional development. Specifically, it describes the design and development of a blockchain-based platform for managing teacher professional development activities, thereby adding a new perspective to the discourse on the potential of blockchain in education.

D. Blockchain for Teacher Professional Development

The idea of employing blockchain in teacher PD stems from its potential to enhance transparency, security, and immutability of PD records. By decentralizing the control over PD documentation, teachers can gain direct ownership of their professional milestones and demonstrate verified skill acquisition [33]. The research [34] posits that blockchain can foster lifelong learning by making professional development a tangible, continuously evolving process. However, integrating blockchain into education systems is not without challenges. Issues related to technological understanding, data privacy, and cost must be addressed for successful implementation [35].

As the exploration of blockchain applications in education continues to unfold, an area worthy of attention is the integration of blockchain in the sphere of teacher professional development (PD). Traditionally, PD records have been plagued by issues of inefficiency, lack of transparency, and questionable credibility. Blockchain technology, with its inherent properties of security, immutability, and decentralization, can provide solutions to these challenges [36]. Fig. 4 demonstrates sample of using blockchain in professional development.

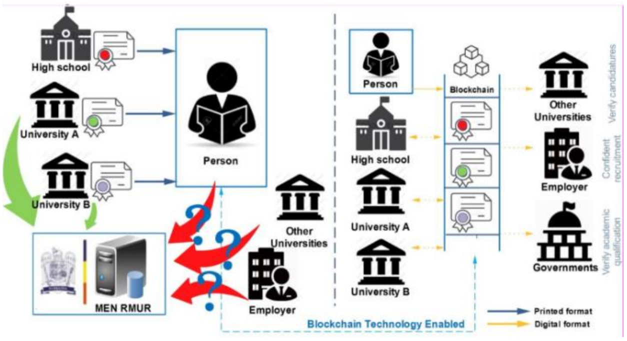

Fig. 3. Blockchain in education.

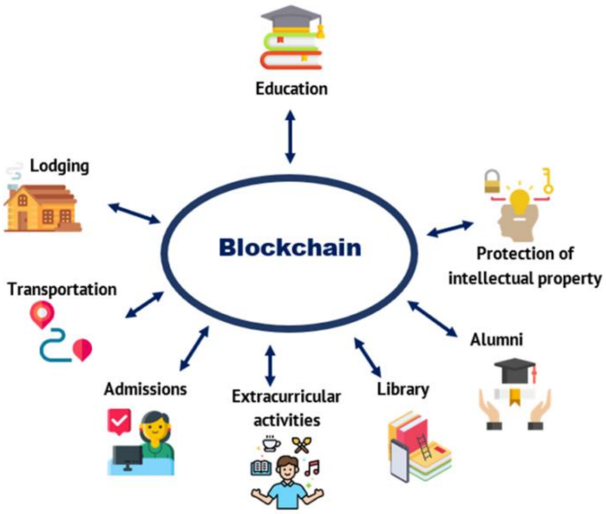

Fig. 4. Blockcahin in professional development.

The application of blockchain in teacher PD can redefine the way PD efforts are recorded, validated, and shared. A blockchain-based platform can serve as a decentralized ledger, documenting teachers' PD activities in a secure and immutable manner. This not only streamlines the documentation process but also enhances the credibility of the records by ensuring their permanence and verifiability [37].

Furthermore, blockchain's decentralization aspect gives teachers direct control and ownership over their PD records. This facilitates the transparent and seamless sharing of verified qualifications and skills, fostering a culture of trust within the educational community. Consequently, teachers are empowered to take an active role in their professional growth, and the value of their PD efforts is reinforced [38].

The use of blockchain in teacher PD also aligns with the shift towards lifelong learning. As continuous learning and upskilling become increasingly important in the fast-evolving educational landscape, blockchain can serve as a tool to document this lifelong learning journey securely and consistently [39].

However, the integration of blockchain technology in the educational sphere is not without hurdles. Potential obstacles include technological understanding among stakeholders, data privacy concerns, potential costs, and the challenge of integrating the new system with existing ones [40].

This paper addresses this gap in the literature by detailing the development of a blockchain-based platform for teacher PD. Through this exploration, the paper provides insights into the practical application of blockchain in the PD landscape, contributing to the wider dialogue on leveraging technology to enhance educational practices and outcomes.

This paper attempts to bridge the gap in the literature by presenting a platform for teacher PD that utilizes blockchain technology. By exploring the platform’s design and development processes, we offer insights into the practical application of blockchain in teacher PD, contributing to the discourse on the use of emerging technologies in enhancing education practices.

III. Materials and Methods

Even though blockchain technology emerged as a relatively new advancement in the realm of information technology, it has rapidly evolved into a globally influential technology with multi-industry applications. Numerous scholars posit that it is poised to significantly enhance the global economy in the coming decades [41]. Hwang illuminated the significance of decentralized ledgers, underpinned by blockchain technology, accentuating their potential to introduce considerable advantages for participants in the educational landscape. Specifically, Hwang underscored the opportunities for digital validation of individual and academic achievements [42].

Blockchain technology possesses several distinct attributes [43]:

1) Decentralisation: This characteristic manifests in three aspects - architectural, political, and logical decentralisation.

2) Security: It ensures the infallibility of records across the network, allowing any attempt at manipulation to be promptly identified.

3) Anonymity: It permits users to generate multiple addresses to safeguard their identities, thus maintaining transaction confidentiality.

4) Verification and reliability: This aspect amplifies the traceability and transparency of data embedded in the blockchain [43].

Casino et al. identified blockchain approach as an open-source tool with extensive cross-sector applications [44]. The distinct merit of blockchain resides in its transition from centralized data. Next research highlighted the blockchain as an emerging technology in education [45]. Consequently, they found that blockchain technology is predominantly employed for purposes such as issuing and validating academic transcripts and certificates, facilitating decentralized knowledge exchange and educational accomplishments of students, and assessing their knowledge, skills, and professional competencies [45]. Furthermore, blockchain could potentially stimulate motivation and enthusiasm for learning by maintaining a comprehensive, trustworthy record of a student's educational activities, encompassing both formal and informal learning environments. Additionally, the technology could inform the construction and evaluation of the educational process's quality by recording teacher and student activities and progress [46]. Drawing on the work of Sun et al., who described the approach, this proposition suggests a paradigm in which blockchain technology can significantly influence educational processes, providing insights into students' behaviors and aiding teachers in grading.

IV. Results

A pedagogical platform, incorporating elements of blockchain technologies, has been engineered for utilization in university-level educational processes. This platform encompasses an array of courses and resources that can be incorporated into learning trajectories [47].

Access to this platform is bifurcated into two tiers, delineating rights: educator and student. This segregation aims to create an optimal learning environment. Upon authorization, students gain access to a wealth of available courses, their accumulated certificates, and a personalized page containing their relevant information. This educational portal, accessible via the Internet, is underpinned by blockchain concept exhibiting a graph architecture. It is structured using blocks of 1024 bytes each, each of which comprises the following sections:

1) Header: This section includes details about the types of blocks, timestamp, and hash of the blocks. All block varieties possess a header, the structure of which remains constant (refer to Table I).

TABLE I. BLOCKS AND THEIR DESCRIPTION

Field	Data_type	Data_size in bytes	Explanation
Block_type	Int_32	4	Type of blocks
Timestamp	Int_32	4	Timestamp
Hash	Byte[]x32	32	A hash underlying on the other blocks.

2) Parent block links: A block may have multiple parent block links, the quantity of which can differ among block types. This segment of the block is employed for block authentication and in generating the block hash.

3) Payload: This constitutes the data stored within the block. An illustration of the block architecture can be found in Table II.

TABLE II. SAMPLE OF BLOCKS STRUCTURE

Header	Block type (4 bytes)	Timestamp	Hash	
Parent block's link	Link to 34th block	Link to 51th block	Link to 68th block	
Payload	First name and last name	Identification number	Login	Password

The fundamental algorithm for block authentication entails computing its hash, utilizing the SHA256 hash function. If the data encapsulated within a block undergoes modification, its hash function, when recalculated, will likewise alter, given that it contains the beneficial data stored in the block. In instances where the block hash is regenerated due to a new payload, all blocks referencing the initial block will become invalidated, as their hash values are computed based on the preceding block's hash. The assembly of the portal's primary blocks can be delineated as follows:

1) The LECTURER_BLOCK is created upon an educator's registration. The payload field encapsulates details about the educator, along with their public key. The initial 256 bytes are considered for the educator's personnel data. The remaining space is assigned to the public key. Fig. 5 demonstrates the description of the LECTURER_BLOCK.

2) The STUDENT_BLOCK comes into existence when an educator registers to the course. The payload field accommodates the student's details and their public key.

3) The KURS_BLOCK (course block) is created when an educator introduces a course. The payload field houses the course title and its description. Here, coins represent earned points within the portal. Fig. 6 illustrates a working example of *KURS_BLOCK* in the proposed system.

4) The TASK_BLOCK is created when an educator introduces a task (block_type = 4). The payload field accommodates the maximum number of coins that can be earned from the task, the task file's signature by the educator (a hash consisting of the sum of the prev_block, the file hash, and the number of coins, encrypted with the educator's private key).

5) The TASK_COMPLETE_BLOCK is created when an educator evaluates a student's tasks.

INTRODUCTION TO BLOCKCHAIN TECHNOLOGY

Introduction to blockchain technology

This course of the Blockchain provides a broad overview of the essential concepts of blockchain technology.This course will introduce you to the concepts behind decentralized applications, as well as familiarize you with existing implementations of blockchain technology.

Сахипов Айвар

СМАРТ ТЕХНОЛОГИИ И АВТОМАТИЗАЦИЯ

Смарт технологии и автоматизация

Настоящий курс предназначен для всех, кому интересно узнать о преимуществах, обеспечиваемых Всеобъемлющим Интернетом за счет соединения повседневных вещей и людей. В рамках этого курса рассматривается концепция объединения людей, процессов, данных и вещей.

Турсынова Ажар Тойлыбайқызы

Fig. 6. Visualization page of the KURS_BLOCK.

6) The CERTIFICATE_BLOCK is created when a student exchanges earned coins for a course completion certificate. A block is considered valid only if the sum of all coins collected by the student from the task_complete fields of the current course is equal to or exceeds the number of coins specified in the task_block field. Fig. 7 demonstrates working principle of the CERTIFICATE_BLOCK.

In summary, an educational portal has been developed incorporating blockchain elements. Its utilization fosters student interest and enhances performance, thereby facilitating educational objectives. The diversification of the educational process engenders interactivity and student engagement. The platform further benefits from the verification of learning outcomes, facilitated by the blockchain technology's ability to provide simple and effective certification.

Whilst the expansive potential applications of blockchain technology remain largely speculative, this study indicates that its influence on the educational sector will increasingly become palpable in the foreseeable future. Some emergent implications are as follows:

1) Blockchain technology could considerably expedite the transition from traditional paper-based issuance of academic credentials. All forms of records, diplomas, and certificates granted by tertiary and other educational institutions, including those pertaining to qualification assignment or advanced training, can be securely and indelibly stored in a decentralised database through blockchain technology.

2) Blockchain technology facilitates automatic validation of academic records, diplomas, or certificates directly via the technology itself, obviating the need to liaise with the issuing educational institution. This development could greatly simplify, if not eradicate, the need for incessant credential verification and attenuate bureaucratic processes within educational institutions. This autonomous certification issuance and validation capability could also be utilised in various other educational contexts. Furthermore, blockchain technology's application extends to copyright and intellectual property management, allowing for the tracking of initial publications and citation tags, without the requirement for a centralised authority to maintain these databases.

3) The potential reduction of data management costs for educational institutions is another prospect offered by blockchain technology. This could be actualised through the creation of decentralised structures in data management, enabling users to effortlessly control and share their data as needed.

4) The growing prevalence of cryptocurrencies, built upon blockchain technologies, could be utilised to facilitate payments and bolster learning motivation by accruing coins upon course completion in certain educational institutions and platforms. The ability to generate proprietary cryptocurrencies could also signify the future usage of blockchain in educational funding, potentially through grants or vouchers, across numerous countries.

Introduction to blockchain technology

Fig. 7. Visualization page of the CERTIFICATE_BLOCK.

V. Discussion

The integration of blockchain technology into the educational sector, as underscored by this study, bears the potential to bring about revolutionary changes in the processes of learning, teaching, and administration. It is anticipated that this technological incorporation can assist in developing a more inclusive, transparent, and efficient educational system.

The deployment of blockchain technology in the proposed platform for teacher professional development enables a decentralised and verifiable record system that is tamper-proof and fosters trust. This inherently aligns with the requirement of ensuring transparency and integrity in teacher professional development programs. Additionally, the ability to monitor and verify teacher development through a decentralised ledger provides a more egalitarian approach to professional learning, given that the power of validation and accreditation does not reside with a singular authority.

However, the implementation of such a technologically complex system within an educational setting is not devoid of challenges. While the literature has presented the capabilities of blockchain technology extensively, it remains a nascent field within the education sector [48]. As such, substantial development, understanding, and research are required before it can be fully embraced by educational institutions.

Issues pertaining to the digital divide and access to technology are critical considerations. Not all educators and students may have equal access to the necessary devices or sufficient internet connectivity to engage effectively with a blockchain-based system. Therefore, while designing such platforms, it is essential to ensure that it can be accessed through multiple forms of devices, including mobile technology, to mitigate potential accessibility issues [49].

Furthermore, the platform's usability is a critical determinant of its success. Even the most innovative technologies will fail to gain traction if they are not user-friendly and intuitively designed. As such, the role of human-computer interaction principles is crucial in the design and development of such a platform to ensure optimal user experience.

The role of privacy and security within the blockchain also necessitates careful attention. As an immutable record, it is critical to ensure that the information stored within the blockchain respects user privacy and adheres to local and international regulations. Additionally, while the blockchain's decentralised nature can enhance security, it also means that breaches, when they do occur, can have far-reaching consequences [50].

In terms of curriculum development and pedagogy, this paper illustrates that blockchain can serve as a powerful tool to motivate teachers towards continuous professional development by providing them with tangible, verifiable records of their growth [51]. However, the integration of this technology into education is not a panacea. It should be supplemented with other research-proven teaching strategies and ongoing support to ensure it serves its purpose effectively.

The potential integration of blockchain into educational administrative processes is a promising prospect, but it will require a significant cultural shift within institutions. Change management strategies will be required to help stakeholders understand the benefits and potentials of this technology and gain their buy-in [52].

In conclusion, the advent of blockchain technology presents an exciting frontier in the world of education, particularly in teacher professional development. It offers the possibility of a more transparent, equitable, and efficient system for recording and verifying professional learning. However, the successful implementation of this technology requires careful attention to accessibility, usability, privacy, security, pedagogical integration, and change management strategies. Further research is necessary to explore these issues in greater depth and to pilot and refine this technology's use within real-world educational contexts.

VI. Conclusion

In conclusion, this investigation has underscored the transformative potential of blockchain technology in reimagining the realms of education and teacher professional development. The distinct features of blockchain such as decentralisation, verifiability, security, and transparency offer the possibility of constructing an innovative platform for professional learning. This platform, characterised by autonomous control, seamless tracking of progress, and the preservation of records, can foster an environment of trust and integrity for the stakeholders. Additionally, the potential of blockchain in the context of digital accreditation signifies a paradigm shift towards more efficient and tamper-proof validation processes. However, the successful integration of this technology necessitates careful attention to issues of accessibility, usability, data privacy, and security. Simultaneously, pedagogical considerations and change management strategies are crucial to ensure a holistic and efficient adoption within the educational sector. It is evident that while blockchain technology has the potential to revolutionise the education sector, more empirical research is needed to further investigate its applicability and implications. This study thus acts as a stepping-stone towards understanding and leveraging the profound potential of blockchain in reshaping the landscape of education and teacher professional development.

Predicting Maintenance Labor Productivity in Electricity Industry using Machine Learning: A Case Study and Evaluation

Mariam Alzeraif[1], Ali Cheaitou[2], Ali Bou Nassif[3]
Department of Industrial Engineering and Engineering Management, University of Sharjah, Sharjah, UAE[1, 2]
Department of Computer Engineering, University of Sharjah, Sharjah, UAE[3]

***Abstract*—Predicting maintenance labor productivity is crucial for effective planning and decision-making in the electricity industry. This paper aims at predicting maintenance labor productivity using various machine learning methods, utilizing a real-world case study from the electricity industry. Additionally, the study evaluates the performance of the employed machine learning methods. To meet this objective, 1750 productivity measures have been used to train (80%) and test (20%) prediction models using Artificial Neural Networks, Support Vector Machines, Random Forest, and Multiple Linear Regression methods. The models' performance was evaluated based on the mean squared error, mean absolute percentage error, and testing time. The results indicated that the Artificial Neural Networks model - specifically, a feedforward network with a backpropagation algorithm - outperformed the other models (Multiple Linear Regression, Support Vector Machines, Random Forest). These results highlight the effectiveness of machine learning, particularly the Artificial Neural Networks prediction model, as an invaluable tool for decision-makers in the electricity industry, aiding in more effective maintenance planning and potential productivity improvement.**

***Keywords*—Productivity; machine learning; maintenance; prediction; ANN**

I. Introduction

The electricity industry plays a vital role in the modern world, underpinning a wide array of economic activities and societal functions. The demand for electricity has increased enormously worldwide, with an annual average of 2.6 percent from 2010 to 2021 [1]. As the demand for reliable and uninterrupted electric power supply grows, the efficient maintenance of networks has become increasingly crucial in the electricity industry [2]. One critical component of efficient maintenance is the productivity of the maintenance labor force. Maintenance labor productivity is a measure of the effective use of resources while performing maintenance activities, usually expressed as the ratio of output to input [3]. It can significantly impact the availability, efficiency, and reliability of electric power networks. High productivity can lead to reduced breakdowns, improved performance, lower operational costs, and the avoidance of expensive blackouts.

However, predicting maintenance labor productivity is a complex task. Numerous factors, such as type of equipment, labor skills and experience, supervisor competency, and even external factors like weather conditions, can influence productivity. Accurate prediction of productivity allows for effective planning, ultimately leading to better maintenance outcomes and improved service reliability. As it will be shown in the following section, and to the best of the authors' knowledge, no study was conducted into predicting maintenance labor productivity using machine learning methods, especially in the electricity industry.

This complexity, alongside the pivotal role of productivity in the electricity industry, motivates the central research question of this study; how effective are machine learning models at predicting maintenance labor productivity? To address this question, the objectives of this study are to develop a various machine learning models, including artificial neural networks (ANN), support vector machines (SVM), random forests (RF), and multiple linear regression (MLR) to predict maintenance labor productivity with a focus on electricity industry and to evaluate the performance of these machine learning models. For this purpose, the study will use a combination of qualitative and quantitative research methods, employing a real-world case study.

The structure of this paper is organized as follows: Section II provides insight into productivity and reviews the research on the application of machine learning in predicting labor productivity, while Section III describes the research methodology used in this study. Section IV focuses on the data collection, and data preprocessing. Section V illustrates the models development. The results are presented and discussed in Section VI. Finally, in Section VII the study has been concluded.

II. Literature Review

A. Labor Productivity Measurement and Influencing Factors

Productivity serves as the ultimate engine of growth in the global economy. Various methods for measuring productivity are presented in the literature. The most prevalent method measures productivity as a ratio of work accomplished or units produced per man-hour [4] [5]. The inverse is also commonly used, which measures productivity as a ratio of man-hours per work accomplished or unit produced [6].

Another method measures productivity as the ratio of earned hours to actual hours [7] [8] [9] [10]. The concept "earned hours" is popular in the United States of America (USA), refers to establish a base or a norm for each activity.

According to the American Association of Cost Engineers, a norm is defined as the number of man-hours required to complete a defined activity under a specific set of stated conditions or qualifications [11]. Thus, a number of earned hours is associated with a norm and each unit of work accomplished.

Extensive literature has attempted to investigate and identify the factors influencing labor productivity across various industries. The most influential factors include labor skills and experience [12] [13] [14] [15] [16] [17] [18] [19] [20] [21] [22] [23] [24], labor motivation [25], supervisor competency [12] [16], and weather conditions such as temperature and humidity [15] [26].

B. *Application of Machine Learning in Prediction of Labor Productivity*

Machine learning, a subset of artificial intelligence, provides machines with the ability to learn and improve from experience. Moreover, it has the capability to handle large volumes of data, learn from this data, and make accurate predictions or decisions without being explicitly programmed. The application of machine learning to predict labor productivity is an emerging area of research that has demonstrated promising results across various industrial sectors.

The earliest study found describing a real application of machine learning to predict labor productivity proposed an ANN model for predicting labor productivity in concrete formwork activity [27]. Subsequent studies used ANN to predict labor productivity for concrete pouring, formwork and concrete finishing, and pipe installation, respectively [28] [29]. In 2006, a study proposed a framework to predict the labor productivity rates of forms assembly, steel fixing, and concrete pouring activities using ANNs [30]. Oral and Oral [31] developed ANN to predict crew productivity for ready mixed concrete, formwork, and reinforcement activities. The authors indicated that ANNs have proved to make productivity predictions significantly better than statistical regression methods, which also agreed by other research works such as [32] [33].

Similarly, ANN was used by [34] to predict the required man-hours for the formwork activity of reinforced concrete framed building projects. The developed model produced results reasonably close to actual field measurements, which was also indicated by [35], who found that the developed ANN has the ability to predict the labor productivity of marble finishing works for floors with a 90.9 percent of accuracy. Furthermore, Heravi and Eslamdoost [36] utilized ANN to predict labor productivity in the concrete foundations work of gas, steam, and combined cycle power plant construction projects. The study illustrated a structured method for developing the ANN model of labor productivity as well as the training process of neural network. Moreover, a study conducted by [37] applied ANN to predict construction labor productivity. The results showed that the ANN adequately converged and have noticeable and reasonable generalizing capabilities, which also is consistent with [30].

A study by [38] applied various ANNs to predict labor productivity norms for the formwork activity of two high-rise buildings. Moreover, a comparison of each ANN model’s performance was conducted to identify the best model. The collected data set was utilized in the research work of [39], where the authors proposed a novel approach for predicting labor productivity using ANN. The developed network showed a good performance from the point of view of generalization.

Mlybari [40] did an investigation aimed to demonstrate the use of various machine learning techniques to predict the labor productivity rates of concrete construction activities, including formwork, steel fixing, and concrete pouring and finishing. The result showed that the developed ANN outperformed the other techniques such as SVM and could be useful to predict labor productivity. Another study found that the performance of RF model yielded better results in predicting labor productivity compared to the ANN model [41]. Conversely, the study by [23] suggested that the performance of SVM is better compared to RF in predicting construction labor. Another study used machine learning–based approach to analyze and predict construction task productivity [42].

Despite these applications and to the best of the authors’ knowledge, no previous research has applied machine learning to predict maintenance labor productivity in the electricity industry. Hence, this study fills this gap in the literature by applying and evaluating different machine learning models, including ANN, SVM, RF, and MLR, for the prediction of maintenance labor productivity in the electricity industry.

III. Research Method

The primary purpose of this study is to explore the application of machine learning in prediction maintenance labor productivity with a focus on electricity industry. Fig. 1 illustrates the flowchart of the research methodology. The initial step involves the identification of inputs and outputs for the machine learning models. The selection of model inputs will be based on a literature review and expert opinion, while the model output is defined as the percentage of labor productivity, as shown in (1) [10].

$$\text{Productivity (\%)} = (\text{Earned hours} / \text{Actual hours}) \times 100 \qquad (1)$$

Following the identification of the appropriate inputs and output for the machine learning models, the next step is data acquisition. The data will be collected from the selected company. This collected data will then be preprocessed as needed through several steps, which include data cleaning, data encoding, and data normalization. Subsequently, the preprocessed data will be randomly partitioned into training and testing sets.

The MATLAB 2023a software will be utilized for the development, training and testing of the four machine learning models, specifically ANN, SVM, RF, and MLR. Each model's performance will be evaluated using a set of defined criteria, including the Mean Squared Error (MSE), Mean Absolute Percentage Error (MAPE), and the computational time required for testing. MSE and MAPE will be calculated using (2) and (3), respectively [43]. Ultimately, the model that exhibits the best performance, in accordance with the evaluation criteria, will be selected. This model will form the basis of the predictive tool that this research aims to develop.

$$\mathrm{MSE} = \frac{1}{\mathrm{n}} \sum_{\mathrm{i}=1}^{\mathrm{n}} (\, \mathrm{Y}_{\mathrm{i\ actual}} - \mathrm{Y}_{\mathrm{i\ predict}} \,)^2 \qquad (2)$$

$$\mathrm{MAPE} = \frac{100}{n} \sum_{i=1}^{n} \left(\frac{|Y_{i\,actual} - Y_{i\,predict}|}{Y_{i\,actual}} \right) \qquad (3)$$

Where 'n' represents the number of data points in the dataset used for prediction, '$Y_{i\,actual}$' denotes the actual productivity value of the ith instance in the dataset, and '$Y_{i\,predict}$'refers to the predicted productivity value ith instance in the dataset.

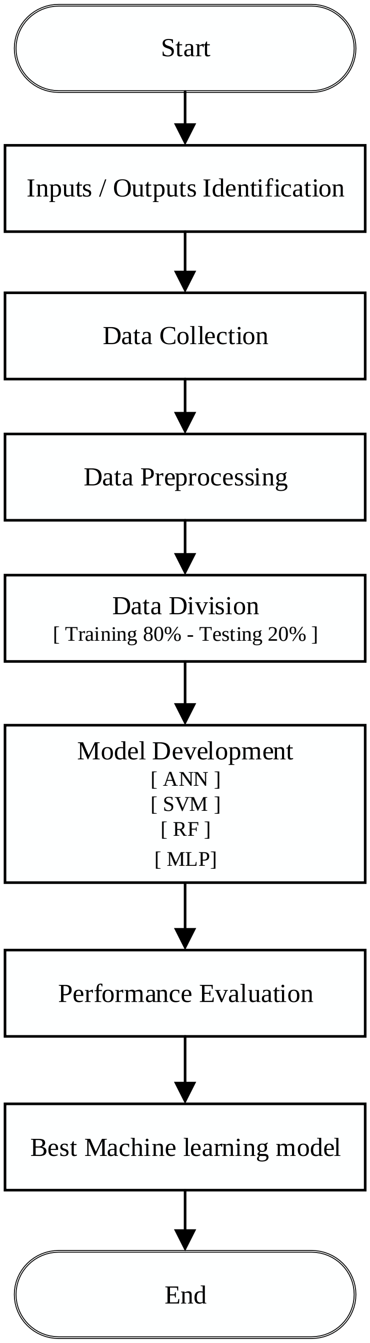

Fig. 1. Research method flowchart.

IV. Data Collection and Preprocessing

A. Data Collection

The dataset utilized in this research was obtained from a large electricity company that is responsible for supplying power. A comprehensive set of data was collected, incorporating all the influencing factors identified from the literature review and expert opinion. The dataset contains records of conducted preventative maintenance tasks for substations and includes inputs variables such as type of equipment, level of labor skill, labor health condition, level of safety measures, labor experience, level of labor motivation or commitment, level of supervisor competency. Because the main dataset did not include all the identified factors, additional data such as temperature and humidity were obtained from the National Center of Meteorology and synchronized with the date and time of the task.

The output parameter, percentage of labor productivity, was calculated by dividing the earned hours by the actual hours. The data collected spans a period of twelve months, offering a substantial volume of information for the models to learn from and making the prediction robust and applicable across different periods.

B. Data Preprocessing

Data preprocessing is a crucial phase in addressing a real-world problem using machine learning and plays a significant role in obtaining promising results. This phase involves several steps:

1) Data cleansing or cleaning: This process identifies and corrects, or removes, inaccuracies, discrepancies, and inconsistencies within datasets. A comprehensive data cleaning was implemented. Certain records within the dataset were excluded due to their lack of labor-related information or because they were duplicates. Furthermore, the units of measure for both earned and actual time were standardized to exclusively use minutes. This uniformity helps to prevent potential discrepancies or misunderstandings that could arise from inconsistent units.

2) Data encoding: This involves transforming categorical variables into a numeric format. The label encoding technique was employed to encode categorical data into numerical values as machine learning can only process numerical data. Table I provides an overview of the data description, while Table II summarizes the descriptive statistics of the collected data.

3) Data partitioning: The total available data is 1750 instances that randomly divided into two sets following an 80:20 ratio; 80% for training (1400 instances) and 20% for testing (350 instances). The training dataset will be used to train the model, and the testing dataset will assess the model's performance on unseen data.

4) Data normalization: This step is necessary and essential to enhance the performance of machine learning [44]. Min-max normalization, one of the most commonly employed methods, was utilized in this study to normalize data within the range of 0 to 1.

TABLE I. DATA DESCRIPTION

No.	Input Variables	Descriptions	Type	Value
1	Type of equipment	The type of equipment in which the task will be performed with.	Categorical	1: Aspiration Smoke Detection
				2: Fire Alarm System
				3: Fire Fighting System
				4: Gas Extinguishing System
				5: Gas Insulated Switchgear
				6: Transformer
				7: Water Mist System
2	Skill level	The technical skill level of labor who perform the task.	Categorical	1: Novice
				2: Intermediate
				3: Competent
				4: Proficient
3	Health condition	The overall health condition of labor who perform the task.	Categorical	1: Poor
				2: Fair
				3: Good
				4: Excellent
4	Safety measures	The level of safety measures the labor required to be taken while perform the task.	Categorical	1: Basic
				2: Moderate
				3: High-Level
				4: Extreme
5	Temperature	The average temperature of a day that the task perform in.	Numerical	Celsius degree (°C)
6	Labor experience	Number of years of experience the labor have.	Numerical	Years
7	Level of supervisor competency	The competency level of supervisor.	Categorical	1: Novice
				2: Intermediate
				3: Competent
				4: Proficient
8	Level of labor motivation or commitment	The level of labor motivation or commitment who perform the task.	Categorical	1: Disengaged
				2: Low
				3: Medium
				4: High
9	Humidity	The average humidity of a day that the task perform in.	Numerical	Percentage
No.	**Output Parameter**	**Descriptions**	**Type**	**Value**
1	Labor Productivity	The actual labor productivity value, calculated by dividing earned hours and actual hours.	Numerical	Percentage

TABLE II. DESCRIPTIVE STATISTICS OF THE COLLECTED DATA

Variable	Mean	SE Mean	Std. Dev	Min	Median	Max
Type of equipment	4.85	0.04	1.50	1	5	7
Skill level	3.60	0.01	0.50	2	4	4
Health condition	3.68	0.01	0.57	2	4	4
Safety measures	3.05	0.02	0.81	2	3	4
Temperature	29.62	0.15	6.30	18.9	29.9	40.1
Labor experience	12.46	0.13	5.27	3	12	28
Level of supervisor competency	3.21	0.02	0.64	2	3	4
Level of motivation or commitment	3.69	0.01	0.54	2	4	4
Humidity	0.45	0.00	0.20	0.10	0.44	1
Labor productivity	1.01	0.00	0.17	0.69	1.01	1.44

V. Machine Learning Models Development

A. Artificial Neural Networks

One of the main methods in machine learning is ANNs. Moreover, it is an information processing paradigm biologically inspired and designed to simulate the way in which the human brain processes information [45]. ANN can be defined as structures comprised of densely interconnected adaptive simple processing elements called artificial neurons or nodes that are capable of performing massively parallel computations for data processing and knowledge representation [46] [47] [48]. The ANN is developed and derived to have a function similar to the human brain by memorizing and learning various tasks and behaving accordingly [49]. Once ANN is trained, it is able to recognize similarities when presented with a new input pattern, resulting in a predicted output pattern. ANNs are now recognized worldwide as the most effective and appropriate machine learning method for prediction [50].

In this study, an ANN model was used for predicting labor productivity. The configuration of the ANN model consisted of one input layer, one hidden layer, and one output layer. The input layer contained nine neurons, equivalent to the number of input variables. The hidden layer, consisting of 15 neurons, employed a sigmoid activation function (logsig), while the output layer used a linear activation function (purelin). The model was trained using the backpropagation algorithm, which is the most common learning algorithm in neural networks. The structure of ANN model is illustrated in Fig. 2.

B. Support Vector Machines

SVM is a supervised machine learning method, often used in classification problems but also capable of performing regression. SVM operate by mapping input data into a high-dimensional feature space, and then finding an optimal hyperplane that maximizes the margin between different classes in the feature space, hence making it a suitable choice for a range of predictive modeling problems. In this study, an SVM model was developed for predicting labor productivity.

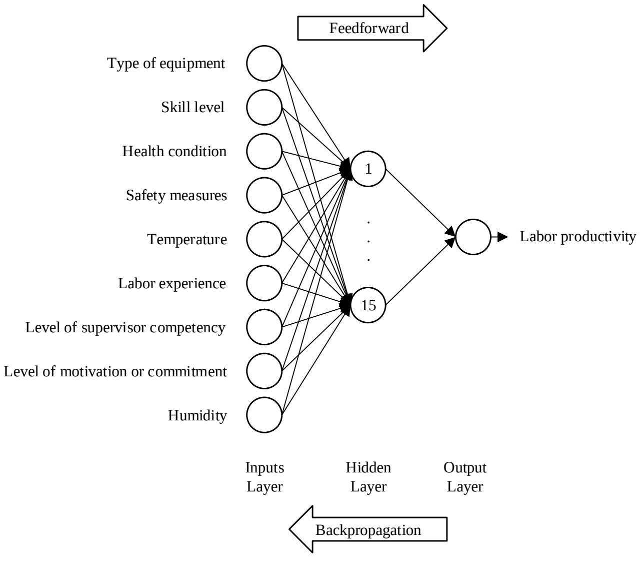

Fig. 2. The structure of ANN.

C. Random Forests

RF is a robust and effective machine learning methods for prediction because of their good performance, scalability, and ease of use [51]. It operates as an ensemble learning method by constructing a multitude of decision trees and producing an output that is the average prediction of the individual trees. Given its ability to mitigate overfitting while maintaining high precision, RF has found extensive application in various predictive modeling tasks. In this study, an RF model was employed to predict labor productivity. The model was configured with 200 decision trees, a parameter that was chosen to balance between the model's complexity and its ability to learn the underlying patterns in the data.

D. Multiple Linear Regression

MLR is a statistical technique that uses several explanatory variables to predict the outcome of a response variable. The goal of MLR is to model the relationship between the explanatory and response variables. The development and application of MLR in this study offers a traditional statistical approach to the problem of predicting labor productivity, providing a contrast and a basis for comparison with the more sophisticated machine learning models.

VI. Results and Discussion

From the results presented in Table III, it is evident that the ANN exhibits the best overall performance in terms of a balance between low error rates and efficient testing times.

TABLE III. Performance Comparison between ANN, SVM, RF, and MLR Models

Model	MSE	MAPE	Testing Time (Second)
ANN	0.0250	12.494	0.012969
SVM	0.0595	19.825	67.1444
RF	0.0330	12.027	1.1359
MLR	0.0286	14.136	0.041887

In assessing prediction performance, measured by MSE, the ANN model outperforms the SVM, RF, and MLR models with an MSE of 0.0250. The MLR follows closely with an MSE of 0.0286, and RF comes in third with an MSE of 0.0330. The SVM model shows the least performance with the highest MSE of 0.0595.

However, in terms of MAPE, the RF model excels with the lowest MAPE of 12.027. The ANN model trails closely behind with a MAPE of 12.494. However, MLR and SVM models show higher MAPEs of 14.136 and 19.825, respectively, indicating a greater margin of error in their predictions. When considering the testing time, the ANN model outperforms the rest, requiring only 0.012969 seconds. The MLR model is slightly slower with a testing time of 0.041887 seconds, while RF takes notably longer at 1.1359 seconds. The SVM model, on the other hand, requires the most extended testing duration of 67.1444 seconds.

These results accentuate that the ANN model outperform the traditional statistical method in predicting labor productivity, aligning with the findings from studies [32], [37], and [38]. Furthermore, these results corroborate the conclusion of study [40] that set the ANN model as superior to the SVM model in labor productivity prediction. On the other hand, these findings conflict with another study [41], where the RF model demonstrated better results in predicting labor productivity compared to the ANN model. Further, the current study's results deviate from those of study [23], which found that the SVM model outperformed the RF model in labor productivity prediction. It's important to note that the performance evaluation in study [41] was based on the Mean Absolute Error and Root Mean Square Error metrics, while study [23] employed Percentage of Correct, Heidke Skill Score, Probability of Detection, False Alarm Ratio, and Peirce Skill Score metrics, respectively. Despite the limited number of studies comparing the performance of machine learning methods in predicting labor productivity, these results underscore the effectiveness of machine learning, and specifically, the ANN model, in labor productivity prediction.

VII. Conclusion

This study aimed to investigate the application of various machine learning techniques to predict labor productivity in the electricity industry. Four popular machine learning models, namely ANN, SVM, RF, and MLR, were developed and evaluated. The performance of the models was evaluated based on the MSE, MAPE, and testing time.

The results indicated that the ANN model performed the best overall, showcasing a balanced performance between low error rates and efficient testing times. This finding provides a clear answer to the study research question, showing that machine learning models, particularly ANNs, can effectively predict maintenance labor productivity in the electricity industry. However, it is important to note the limitations of this study. While the ANN model showed promising results, the findings may not be generalizable to all sectors due to the unique characteristics and variables of the electricity industry. Furthermore, the models developed in this study could serve as valuable tools for managers and decision-makers in the industry, allowing them to make informed decisions about labor management based on accurate productivity predictions. This contribution is significant as it provides a practical application of machine learning techniques in a real-world industry setting.

Future research should consider applying these models in other sectors and exploring other machine learning techniques for labor productivity prediction. There are still unanswered questions regarding the optimal machine learning techniques for different sectors, and how these models can be improved to increase their predictive accuracy and efficiency. Additionally, future research should also aim to address the limitations of this study, such as the potential lack of generalizability, by conducting similar studies in various industry settings.

Acknowledgment

The authors express their sincere gratitude to the experts who provided invaluable opinions and contributions to this study.

Web Phishing Classification Model using Artificial Neural Network and Deep Learning Neural Network

Noor Hazirah Hassan, Abdul Sahli Fakharudin
Faculty of Computing, Universiti Malaysia Pahang, Pekan, Pahang, Malaysia

***Abstract*—Phishing is an online crime in which a cybercriminal tries to persuade internet users to reveal important and sensitive personal information, such as bank account details, usernames, passwords, and social security numbers, to the phisher, usually for mean purposes. The target victim of the fraud suffers a financial loss, as well as the loss of personal information and reputation. Therefore, it is essential to identify an effective approach for phishing website classification. Machine learning approaches have been applied in the classification of phishing websites in recent years. The objectives of this research are to classify phishing websites using artificial neural network (ANN) and convolutional neural network (CNN) and then compare the results of the models. This study uses a phishing website dataset collected from the machine learning database, University of California, Irvine (UCI). There were nine input attributes and three output classes that represent types of websites either legitimate, suspicious, or phishing. The data was split into 70% and 30% for training and testing purposes, respectively. The results indicate that the modified ANN with Rectified Linear Unit (ReLU) activation function model outperforms other models by achieving the least average of root mean square error (RMSE) value for testing which is 0.2703, while the CNN model produced the least average RMSE for training which is 0.2631. ANN with Sigmoid activation function model obtained the highest average RMSE of 0.3516 for training and 0.3585 for testing.**

Keywords—Phishing website; classification; artificial neural network; convolutional neural network; machine learning

I. Introduction

Phishing is a form of social engineering attack that is regularly used to get individuals to provide confidential data, like credit card information and login credentials. This happens when a phisher pretends to be a reliable organization to get a targeted victim to open a text message or an email. Then, the victim is tricked into clicking a malicious link that leads to a bogus website where private and sensitive information such as account numbers and Internet banking passwords can be obtained. A cyber-attack might have disastrous consequences, such as unlawful transactions, money theft, or identity theft for users [1].

A non-profit association known as the Anti-Phishing Working Group (APWG) investigates phishing assaults that have been informed by its fellow corporations, including MarkMonitor, iThreat Cyber Group, Forcepoint, Internet Identity (IID), and Panda Security. It evaluates the attacks and releases quarterly and half-yearly reports regularly. Additionally, it offers statistics data on phishing attacks and malicious domains that are active worldwide. The most recent phishing activity trends report states that in the third quarter of 2022, APWG detected a total of 1,270,883 phishing attacks. This quarter's phishing activity was the worst that the APWG has ever recorded. 23.2% of all phishing attacks targeted the financial sector. In the third quarter, email-based scams involving advance fee payments grew by 1,000% [2]. Globally, millions of dollars have been lost as a result of these attacks, which had a severe effect on numerous renowned organizations worldwide. For protecting personal and business information as well as financial assets, addressing the problem of phishing website classification is getting more important. Hence, classifying and minimizing the impact of phishing attacks are the motivations to conduct this study.

A common countermeasure of phishing websites involves checking the websites against blacklists of known phishing websites, which are traditionally compiled, based on manual verification but this method is inefficient as it usually fails to discover all phishing sites because a recently created forged website takes a significant time before it can be added to the list. Moreover, there is no robust blacklist that will guarantee a perfect up-to-date database as nowadays, it has become easier to register new domain names. As the Internet scale grows, advanced website classification is increasingly important to provide timely protection to end users. Thus, this study aims to classify phishing websites using artificial neural network and convolutional neural network and then compare the models' classification performance. Biological neural networks are the foundation of the artificial neural network (ANN). It is made up of fundamental building blocks called neurons, which multiply weight with a real value and later put the result via a nonlinear activation function. By constructing multiple layers of neurons, where each of them takes the input variables and then passes the output to the following layers, the network can learn complicated functions. Supposedly, an ANN with adequate computational power could learn the shape of any function [3]. Neural networks have a high tolerance for noisy data, which is one of the advantages of using them. Although it is simple and convenient to use, handling huge dimensional data requires some understanding of parameter settings. It is simple to interpret the outcomes of this method. Another advantage of employing ANN is it can generate probability-based output, which ensures that the model will be more accurate as larger volumes of input data are provided [4].

A deep learning network architecture known as a convolutional neural network (CNN) automatically extracts features from the data rather than having to manually extract them first. The primary benefit of CNN over its predecessors is that it automatically recognizes the significant attributes without human intervention [5]. CNN is mainly suitable for recognizing faces, scenes, and objects by discovering patterns in input images. It is also excellent in non-image data classification for example signal data, audio, and time series. The dataset was procured from a reputable source which is University of California, Irvine (UCI) repository, an open-source machine learning database platform frequently used by researchers in machine learning studies. We also used this dataset for our previous research article [6].

There are two contributions from this study. Firstly, the study employed two machine learning algorithms, which are an artificial neural network and a convolutional neural network to classify types of websites. These techniques enabled to build of robust classification models to recognize different types of websites either phishing, suspicious, or legitimate ones. Secondly, the research aimed to improve the accuracy of phishing classification. By leveraging the proposed methodology, the study contributes to reducing the error rate, thereby enhancing the overall performance of phishing classification. The findings from this research have practical implications for the development of cybersecurity tools or applications to detect phishing websites. By improving the accuracy of phishing classification, organizations or individuals can enhance their defenses against cyber threats, ultimately safeguarding themselves from being a victim of website scams more effectively.

The other components of this research article are structured in Sections II, III, IV, and V. Section II provides a discussion of related work, while Section III discusses thoroughly the methodology of ANN and CNN. Section IV presents the results and discussion of the experimental work, and Section V gives a conclusion, limitation, and direction for future works of research.

II. Related Work

There are several machine learning techniques for phishing website classification. A study conducted by Verma et al. [7] utilized deep belief network and artificial neural network approaches in which ANN achieved 89.95% accuracy with five hidden layers and five nodes in hidden layers, while the deep belief network's accuracy was 96.32% using similar settings. It was observed that the deep belief network technique performs better than ANN. Next, a study by Zamir et al. [8] presented a comparison of supervised learning approaches (NB, k-NN, SVM, RF, bagging, and NN) and stacking models to classify phishing websites. Stacking1 (RF + NN + bagging) outperformed all other classifiers with proposed features N1 (combined weakest features) and N2 (combined strongest features) and achieved 97.4% accuracy. Another study by Sharivari et al. [9] implemented XGBoost, Support Vector Machine, KNN, Logistic Regression, Ada Boost, Decision Tree, Random Forest, Gradient Boosting, and Neural Networks. XGBoost outperformed other methods with an accuracy of 98.32% followed by random forest and neural network.

A recent study conducted by Somesha et al. [10] applied Convolution Neural Network (CNN), Deep Neural Network (DNN), and Long Short-Term Memory (LSTM) to classify phishing websites. The results indicated that the accuracy of the proposed method for LSTM, DNN, and CNN is 99.57%, 99.52%, and 99.43% respectively. Besides, Yerima & Alzaylaee [11] employed convolutional neural networks (CNN) for high-accuracy classification to differentiate fraudulent websites from legitimate websites. The result showed that the CNN technique, which achieved 97.3% accuracy with an F1-score of 97.6%, outperformed conventional machine learning classifiers evaluated on the same dataset. Another study by Geyik et al. [12] adopted decision tree, naive Bayes, random forest, and logistic regression algorithms. According to the findings, the Random Forest method outperforms the others, with an 83% of accuracy rate.

Afterward, Nadar et al. [13] proposed a hybrid Stacking model. Then, it was compared with Naïve Bayes, Random Forest, and XGboost approaches. The research outcome showed that the proposed Stacking Classifier outperforms other methods with results of 85.6% of accuracy. A study by [6] applied an artificial neural network and the findings show that the ANN model with (9-5-1) architecture design gave the best result by obtaining the lowest difference between average training and testing MSE, which is 0.04745. Later, research by [14] focused on using multilayer perceptron (MLP), a type of neural network concept, to classify phishing websites. MLP is compared with other machine learning approaches like logistic regression, random forest, and support vector machine (SVM) for result evaluation, and it was found that MLP achieved the highest accuracy of 96.80%.

Machine learning approaches were also being employed in other fields such as healthcare, for dengue prediction [15], diabetes classification [16], and depression prediction [17]. Machine learning was also applied in agriculture for classifying broccoli leaf disease [18] and types of coral reef fish [19]. It was also used for classifying types of traffic violations [20], carbon monoxide concentration prediction [21], and air traffic communication system [22]. Deep learning approaches were also utilized in sound recognition [23], prognosis of Covid-19 [24], and glioma classification [25]. After reviewing previous studies in this field, it is evident that the classification accuracy should be enhanced. It is crucial to decrease the error rate to attain a high level of classification accuracy leading to producing more reliable and robust classification models.

III. Methodology

The modelling of website phishing classification was divided into three main parts which represent three types of classification models. All classification processes followed the same methodology which started with pre-processing of the dataset where the phishing dataset [26] was normalized according to the selected model. There were nine input features and three output classes: Legitimate, Suspicious, and Phishy. It was split into a training set and a testing set with a ratio of 70:30. Next, the model was designed based on a selected algorithm to model the classifier. The model was trained using a gradient descent training algorithm with a learning rate set to 0.01 and momentum set to 0.1 to ensure slow convergence without skipping any possible best solution or overfitting. Finally, the model was evaluated using RMSE to measure the model output and targeted output was minimized and the model accurately classified the phishing classes. The flow of the classification process using ANN is represented in Fig. 1.

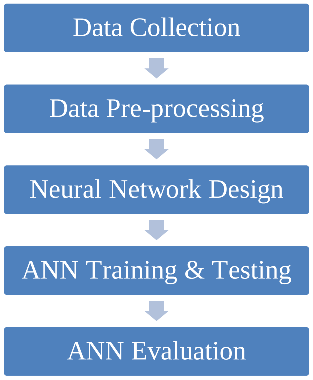

Fig. 1. ANN classification methodology.

A. *Artificial Neural Network Model with Sigmoid Activation Function*

The phishing website dataset was collected from the UCI repository with a total number of instances is 1353. Each instance has nine attributes and must be categorized into one of the three classes, the first class is Legitimate, the second class is Suspicious, and the third class is Phishy. Numbers had been used to replace these categories, with 1 denoting legitimate, 0 for suspicious, and -1 for phishing. There are 103 suspicious, 548 legitimate, and 702 phishing websites from the total number of 1353 websites. The data were saved using a comma-separated values (.csv) format. When a website is classified as suspicious, it might be either phishy or legitimate, implying that it has both phishy and legit attributes. The attributes in this dataset are including Server Form Handler (SFH), using a pop-up window, Secure Socket Layer (SSL) final state, request URL, anchor’s URL, traffic of a website, length of URL, domain’s age, and using an IP address. Out of 1353 instances, 70% of the instances were given for the training set which was 948 instances and the remaining 30% were given for the testing set which was 405 instances. Usually, in data pre-processing, normalization is used to scale the values from different ranges to a common range such as -1 to 1 or 0 to 1. Data must be scaled into the range used by the input neurons in the neural network. The dataset was scaled from -1 to 1 into 0 to 1 for the research purpose.

In a neural network, there are three layers, which are an input layer, a hidden layer, and an output layer. The model's input layer receives all of the inputs to be fed into the model. Then, these inputs are transmitted to the hidden layers. Each input neuron should represent some independent variable that has an impact on the neural network’s output. There is a layer called the hidden layer which is located between the input layer and the output layer that is made up of a group of neurons that have activation functions applied to them. Its responsibility is to process the inputs obtained from the input layer. This layer is in charge to extract the required features from the input data. A neural network could contain multiple hidden layers. The output layer of ANN collects and passes the data in a way that it was designed to do. At the output layer, the processed data is made available. The neural network design used in this study was (9-10-10-1) which means 9 input neurons, two layers of hidden neurons with 10 neurons for each, and 1 output neuron as presented in Fig. 2.

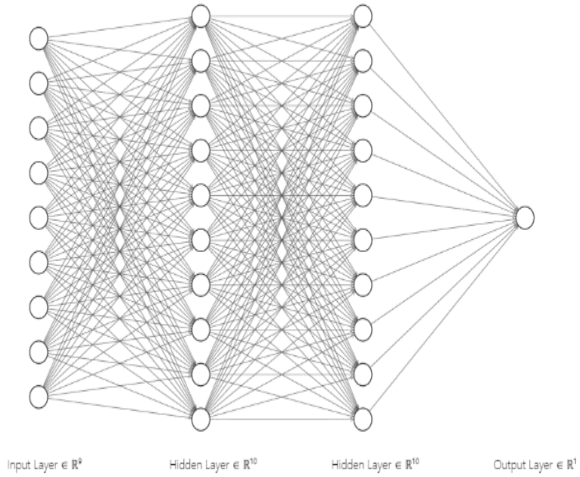

Fig. 2. ANN structure 9-10-10-1.

The activation function employed in this model was Sigmoid. Any real value can be used as an input for this function, which returns output values between zero and one. The output value will be closer to one if the input value is greater or more positive, whereas if it is smaller or more negative, the output value will be closer to zero. It can be mathematically formulated as depicted in (1).

$$f(x)=\frac{1}{1+e^{-x}} \tag{1}$$

The total number of epochs and batch size used in this experiment were set to 200 and 50, respectively. Training is a process of determining the values of weights and biases for a neural network. The train-test technique is the most common way used to conduct training. The phishing dataset was split into training and testing sets. The neural network was trained using the training dataset. For determining the set of weights and biases values which have a small difference between actual output and expected output values, a few weights and biases values are tested. The process of selecting appropriate weights and biases values for minimizing error was also a part of the training. The test dataset was not used throughout this phase. After the training was complete, the final ANN model's weights and biases were applied to the test dataset. The model’s accuracy on the test dataset provides a rough estimation of the model’s accurateness will be once provided with previously unseen and new data.

An unbiased evaluation of the final model fit on the training dataset was made using the test dataset. A distinct dataset with a similar probability distribution as the training dataset is referred to as a test dataset. Minimal overfitting has occurred if a model that fits the training dataset also fits the test dataset well. Overfitting is typically shown by the training dataset fitting the model better than the test dataset. A test dataset is therefore a set of instances utilized just to evaluate the performance of a model which is a generalization of a fully specified classifier.

B. *Convolutional Neural Network Model*

Fig. 3 shows a complete process involved in numerical data classification using CNN, which includes input data, pre-processing, CNN feature extraction, classification, and performance evaluation.

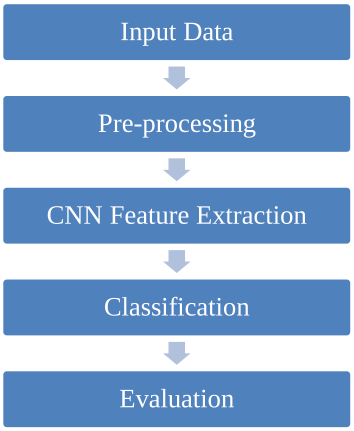

Fig. 3. CNN classification methodology.

The input data used in this process were the same phishing dataset used for ANN classification. All the data are numerical data that must be saved in .dat format for pre-processing purposes. In the pre-processing stage, this study used one of the pre-processing methods proposed by [27], called Equidistant Bar Graphs. It is a technique of data wrangling to transform data in numerical form into image form. In order to represent a particular class, the transformed image must reflect some patterns. Equidistant bar graphs show the measurement of each attribute of a particular dataset. The phishing dataset was first normalized to 0 and 1, and then each attribute was drawn by using its measured value. The image’s width in pixels was given by a formula, wx + y(x + 1), where x represents the total number of attributes, w represents the bar width, and the distance between two consecutive bars represents by y. The image’s height was normalized to create a square image. In the experiments, the authors used 1−pixel and 2-pixel lengths for w and y, respectively. This creates an approximately 3d×3d size of the square image. A few data samples of the phishing website dataset that had already been transformed into bar graphs images are presented in Fig. 4. The images tagged along with the name of the respective class were labelled as Legitimate, Suspicious, and Phishy. CNN can only utilize these images if they represent a pattern in a convolved image. In this stage, all experiments were performed using Matlab 2020a software.

A convolutional neural network (CNN) is a deep learning algorithm that had been used in this research. Back-propagation artificial neural networks are the foundation of its architecture. It starts with an input image where each pixel represents input data that goes through a sequence of the feature selection process through convolution before being passed to the weighted perceptron where learning occurs through backpropagation. The main benefit of CNN is that it can learn the features on its own, as opposed to traditional neural networks where feature selection is a separate process and the model’s accuracy depends on the selection of pre-processing and feature selection methods used. Fig. 5 shows the architecture of CNN used in this study.

There are two main layers of CNN architecture which are feature extraction or it can be called as feature learning and classification layers. In the feature extraction layer, there are three sublayers which are convolutional, activation, and pooling layers. The convolutional layer takes in the images directly as the input and a set of small filters is convolved over the image to produce one or more feature maps. The process of convolution involves moving the filter over the image while computing the dot product of the filter and image elements. Certain features are extracted from the image as a result of this process. Then, a bounded output is created by passing the convolutional layer's results via an activation function. CNN frequently employs Rectified linear units (ReLU) that turn any negative values into zero. Additionally, it trains the network far more quickly than other activation functions such as the hyperbolic tangent activation function (tanh). The down-sampling is carried out by the pooling layer, which also decreases the input size along each dimension. Average pooling and max pooling are two common pooling techniques that are usually used where the received image is divided into a collection of non-overlapping rectangles. Only the maximum and average values of each sub-region are obtained using max pooling and average pooling, respectively. The image is down-sampled in this process. In this study, only the max pooling technique was used in the pooling layer.

The architecture of CNN moves to the classification layer after learning features in the feature extraction layer. The fully connected network in a traditional neural network is similar to this fully connected layer. The classification output is produced by a classification layer, such as softmax, in the CNN architecture's final layer. For example, an image of a car goes through all the layers in CNN architecture which is then classified among the possible vehicles such as car, truck, van, or bicycle as the output of classification [28]. Meanwhile, for this study, the input images were classified as either phishy, suspicious, or legitimate. This experiment was performed using Visual Studio Code IDE with Python programming language.

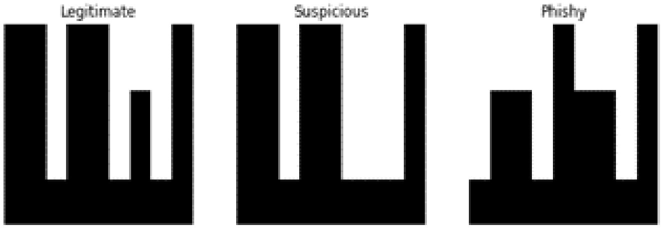

Fig. 4. Bar graph of phishing website dataset.

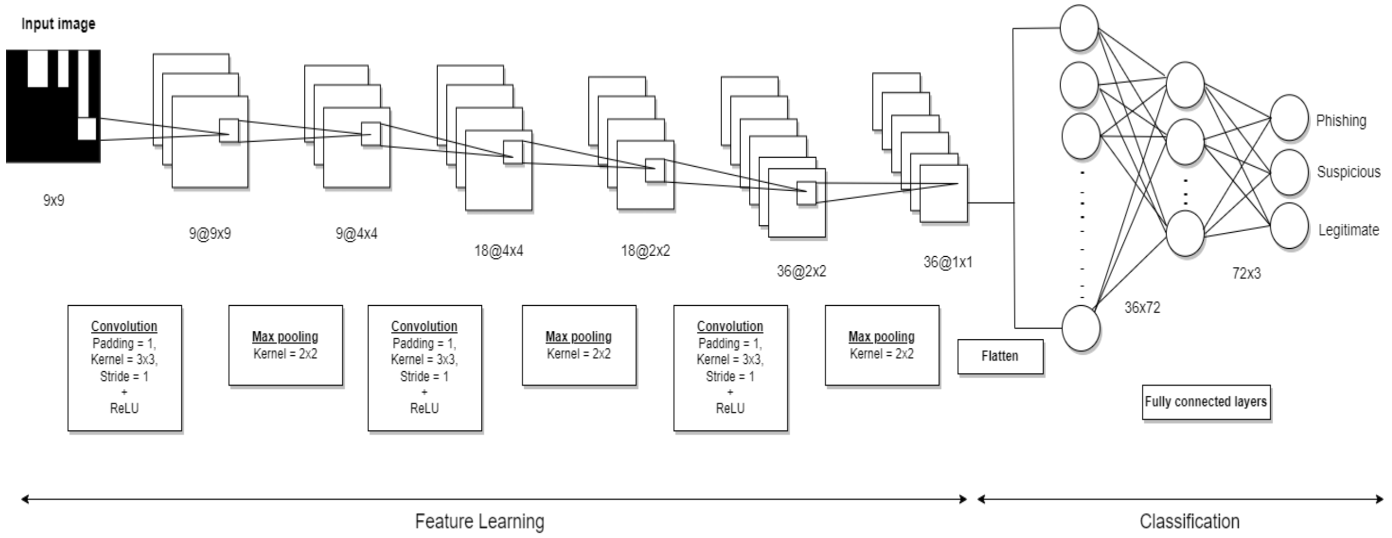

Fig. 5. Architecture of CNN for phishing website dataset.

C. *Modified Artificial Neural Network Model with Rectified Linear Unit Activation Function*

The modified ANN model had gone through all the stages in ANN classification methodology as shown in Fig. 1 which were collecting data, pre-processing the data, designing a suitable ANN model, training and testing the model, and lastly evaluating it. It was the same process as detailed in subsection *A*. The only difference was that this model employed rectified linear unit (ReLU) as an activation function which is usually utilized in the CNN model. Mathematically, ReLU is defined as shown in (2).

$$f(x)= \max(0,x) \tag{2}$$

The function indicates that if it is given any negative input value, the output of the function will be zero, but if it is given any positive value of x, the result will be the value itself. The equation gives the outcome within a range value from zero to infinity [29]. It has turned out to be the default activation function for several types of neural networks since a lot of classification models that employ it are easier to train and often produce better results [30]. Since the function involved a simple mathematic calculation, training also takes a lesser amount of time to complete [31].

D. *Performance Evaluation*

The ANN and CNN performances were evaluated by using root mean square error (RMSE), which is a well-known error indicator. It is a commonly employed metric for determining the differences between a model's predicted values and the actual values. RMSE is a metric of accuracy used to compare the forecasting errors of several models for a certain dataset. It is always a positive value, and a value of 0, which is rarely achieved in practice, would mean that a perfect fit for the data. Generally, a smaller RMSE is preferable to a greater one. RMSE can be calculated as shown in (3).

$$\text{RMSE}= \sqrt{}[\sum_{i=1}^{n}\left(y_i\text{-}x_i\right)^2/n] \tag{3}$$

The formula showed that y_i represents the ith expected value, x_i indicates the ith actual value, and n is the total number of data instances. In mathematics, the Greek sigma symbol that resembles a strange E is known as summation. It is the total of the sequence numbers from i=1 to n. The performance of the classification models improves with decreasing RMSE values. The best performance of the ANN and CNN was determined by the lowest RMSE.

All the experiments were performed in a 3.20 GHz, 8 GB RAM, CPU Intel Core i7 processor system, and the operating system was Windows 10 64-bit. ANN and CNN models were implemented on Visual Studio Code IDE (Integrated Development Environment) using Python programming language and used the Keras library with TensorFlow backend. Numpy, Seaborn, Scikit Learn, and Pandas were among the additional libraries that were imported and used for the experiments.

IV. Results and Discussion

There were three classification models designed in this research as stated in the method's section. Each model was trained and tested 20 times to ensure the consistency of the results of the experiment. All training and testing RMSE values were recorded. Fig. 6 shows a graph plotted from the results of training and testing RMSE with 20 runs of experiments using an artificial neural network (ANN) with a sigmoid activation function. The average training RMSE was 0.3516, while the average testing RMSE was 0.3585. The lowest training RMSE was 0.3036, while the highest was 0.4148. The lowest testing RMSE was 0.3179, while the highest was 0.4164. The testing RMSE usually gave a higher value than the training RMSE as it used new data that need to be classified. This also can be observed in [27] which the accuracy of the test set is lower than the validation set. It can be seen in Fig. 6 that there was a very small difference between training and testing RMSE for each run. 0.1 is considered a good value of RMSE while 0.5 and above is considered high which is not good for accuracy.

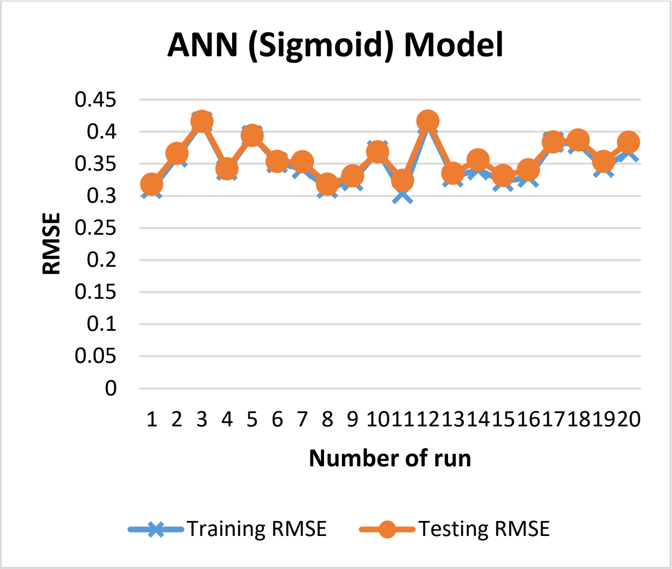

Fig. 6. Training and testing RMSE of ANN (Sigmoid) model.

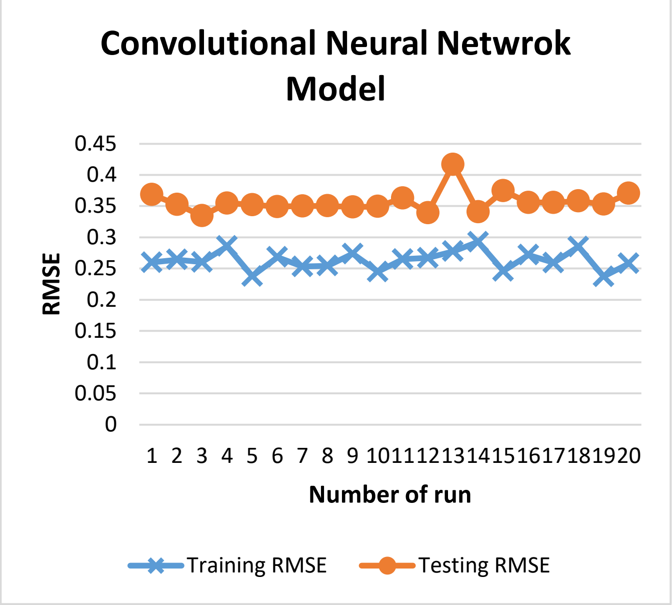

Fig. 7. Training and testing RMSE of CNN model.

The ANN (Sigmoid) model shows a high degree of variability in both training and testing RMSE values, with the range of values being relatively large. This variability may indicate that the ANN (Sigmoid) model is not consistent in its performance and may produce unreliable results.

Fig. 7 shows the results of training and testing RMSE of a convolutional neural network (CNN) model. The training RMSE values range from 0.2374 to 0.2926, while the testing RMSE values range from 0.3345 to 0.4169. The average training RMSE was 0.2631 while the average testing RMSE was 0.3569.

Compared to the ANN (Sigmoid) model, the CNN model showed less variation in the RMSE values across the 20 runs, indicating that it is more reliable in producing consistent results. The average training and testing RMSE of the CNN model were also lower than the average training and testing RMSE of the ANN (Sigmoid) model, suggesting that the CNN model has better performance in capturing the patterns in the dataset which produces better accuracy. Similarly, [7] shows an increase in accuracy by using the deep belief network technique compared to the neural network algorithm. Although the CNN method improves the performance and accuracy, the original pattern of the data may have changed due to the alteration of the data during the pre-processing stage. Furthermore, the networks used in the CNN model were very large compared to ANN (Sigmoid) model. Therefore, this study proposed to use the advantage of CNN which is Rectified Linear Unit (ReLU) activation function in the artificial neural network.

The modified ANN model using the ReLU activation function achieved a training RMSE between 0.2492 and 0.2817, with a mean training RMSE of 0.2703 as shown in Fig. 8. The testing RMSE was between 0.2976 and 0.3084, with a mean testing RMSE of 0.3033. The model showed consistent and reliable performance in terms of producing low training and testing RMSE values with small fluctuations between each run. The average training and testing RMSE values of the model were relatively low which indicated that the model was able to fit the training data well and also generalized well to new and unseen data, respectively. In addition, the model's performance was relatively consistent across the 20 runs, as the range of the RMSE values for both the training and testing sets is relatively narrow. This suggests that the model is not overfitting or underfitting the data, but rather finding a good balance between the two.

Compared to the ANN (Sigmoid) model, the modified ANN (ReLU) model showed slightly better performance in terms of producing more consistent results and more stable. The ReLU activation function is known for its ability to handle vanishing gradients and reduce the likelihood of overfitting. The results from the modified ANN (ReLU) model appear to support this claim, as the model produced more consistent results than the ANN (Sigmoid) model.

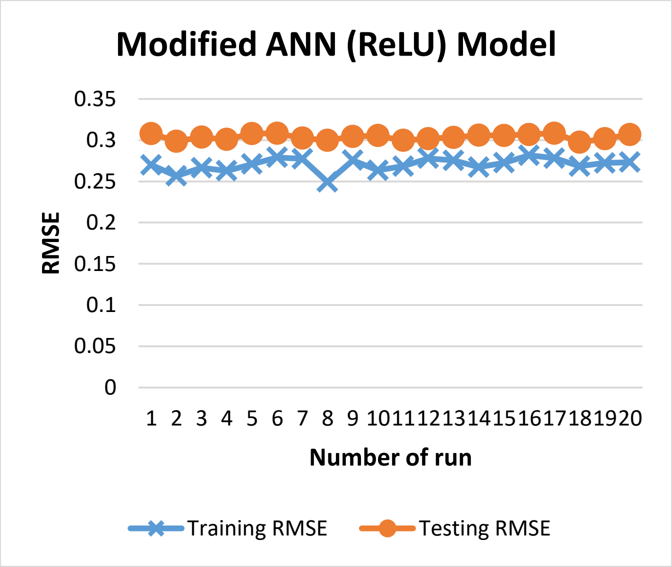

Fig. 8. Training and testing RMSE of ANN (ReLU) model.

Compared to the CNN model, the modified ANN (ReLU) model has a slightly higher training RMSE, but the difference between average testing and training RMSE is smaller for the modified ANN (ReLU) but higher for the CNN model, indicating that the CNN model tends to overfit the data [32]. Moreover, the modified ANN (ReLU) model requires fewer networks than the CNN model, which can be an advantage in terms of computational efficiency.

Table I shows the average RMSE comparison between ANN (Sigmoid), CNN, and modified ANN (ReLU) models. Fig. 9 shows the comparison of all the training RMSE trained using ANN (Sigmoid), CNN, and modified ANN (ReLU) models. The CNN model has the lowest average RMSE which was 0.2631 followed by the modified ANN (ReLU) model with an average of 0.2703 RMSE. ANN (Sigmoid) has the highest RMSE average which was 0.3516. The testing RMSE has a different pattern, where modified ANN (ReLU) produced the best average RMSE which was 0.3039, followed by CNN with an average RMSE of 0.3569. The highest RMSE was produced by ANN (Sigmoid) model with an average of 0.3585 as shown in Fig. 10.

Overall, the results of this study suggest that the modified (ReLU) model is an effective approach for classifying phishing, legitimate, and suspicious websites. The modified ANN (ReLU) model was selected as the best model because it was able to generalize well to new data and the number of neural networks used in this model was also smaller than the CNN model. The modified (ReLU) model may have outperformed the CNN model because the original patterns of data were preserved, whereas, in the CNN model, some original patterns may have been changed during the pre-processing stage when converting numerical data to image data.

TABLE I. COMPARISON OF CLASSIFICATION MODELS' PERFORMANCE

Phase	ANN (Sigmoid)	CNN	Modified ANN (ReLU)
Training	0.3516	0.2631	0. 2703
Testing	0.3585	0.3569	0. 3039

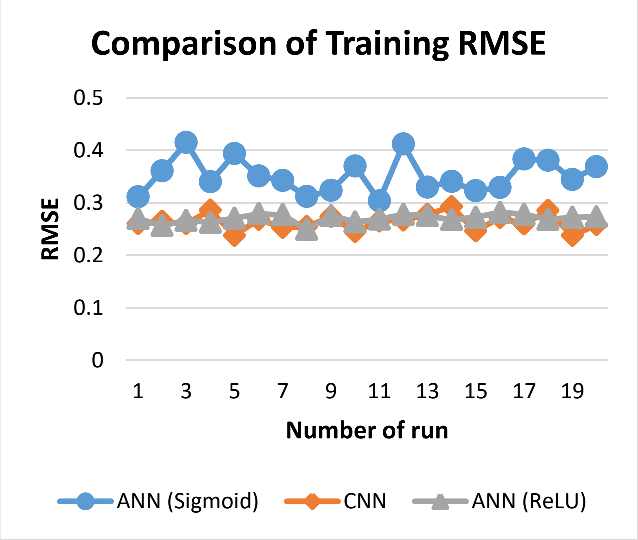

Fig. 9. Training RMSE comparison.

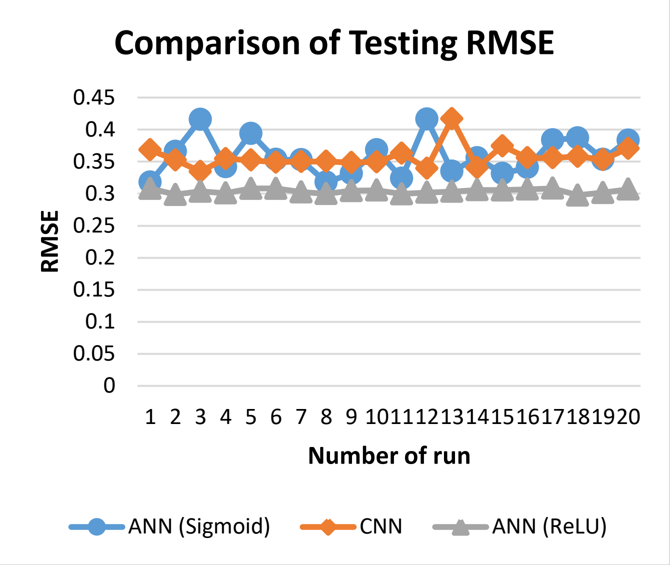

Fig. 10. Testing RMSE comparison.

V. CONCLUSION

Artificial neural networks and convolutional neural network classifiers were implemented in this study for classifying phishing websites. The models produced from this study were ANN (Sigmoid), CNN, and modified ANN (ReLU). It can be seen from the experimental result that the modified ANN (ReLU) model demonstrated the best performance for phishing website classification followed closely by the CNN model. On the other hand, the ANN (Sigmoid) model had the poorest performance of the three models. In the future, more methods such as hybrid or other deep learning techniques can be implemented to produce much more reliable results and improve performance and accuracy. The dataset used for training and testing the models in this study may be relatively small, which could impact the model's ability to capture the full complexity and diversity of phishing websites. A larger dataset might be needed to improve the model's robustness and generalization. Further research on other datasets is also needed to validate the effectiveness of the three models produced by this study.

Abstract—**Social commerce is a digital and efficient solution to transform existing commerce and address contemporary issues. TikTok Shop, a popular and trending social commerce platform, competes with established competitors like Facebook Marketplace and Instagram Shop. TikTok Shop offers benefits and incentives to attract users for both sales and product purchases. In this study, various algorithmic approaches such as Naïve Bayes, K-Nearest Neighbor, Support Vector Machine, Logistic Regression, Decision Tree, Random Forest, LGBM Boost, Ada Boost, and Voting Classifier are utilized to analyze and compare sentiments expressed on Twitter regarding Facebook, Instagram, and TikTok. The aim is to determine the methods with the best performance and identify the social commerce platform with the highest purchase intention and positive sentiment. The results indicate that TikTok has more positive sentiment than Facebook and Instagram at 93.07% with the best-performing classification model, Decision Tree. In conclusion, TikTok exhibits the highest positive sentiment percentage, indicating a greater number of positive reviews compared to Facebook and Instagram. According to the theory of evaluation scores for measuring model performance, values above 0.90 represent models with good performance.**

Keywords—Algorithm; machine learning; sentiment; social commerce

I. Introduction

E-commerce has rapidly developed worldwide in the 2000s. This has led many traditional companies and stores to start opening online stores, which has brought about a change in the world of trade. Initially, business transactions were conducted in a traditional manner, with sellers and buyers interacting directly. However, with the emergence of e-commerce, these interactions shifted to an online platform. The increase in consumer trust and changes in online shopping behavior have supported the growth of e-commerce [1]. In the 2010s, there was a significant increase in social media users worldwide, marking the beginning of the emergence of social commerce. Social commerce combines e-commerce and social media, reflecting a shift in how businesses operate and interact with consumers. This shift has had a significant impact and positive benefits for both customers and sellers. Social commerce enables businesses to reach a wider and more distant target audience due to its ease of use [2], [3].

Social commerce is a hybrid of e-commerce and social media that enables trade transactions to take place on both e-commerce platforms and social media platforms like Facebook, Instagram, TikTok. With social commerce, consumers can purchase products or services from trusted sellers via social media platforms they use daily [4]. Sales on social commerce occur through social media features, such as links to online stores, business nuances, product reviewers, and instant shopping features. Additionally, social commerce serves as a marketing platform where businesses can promote their products and reach potential consumers through paid advertising or social listening. This type of social commerce has proven to be effective in boosting sales and user engagement [1], [5], [6].

There are many social commerce platforms circulating today such as Facebook marketplace, Instagram, and TikTok Shop. The Facebook marketplace is usually used for people to make transactions directly without a third person as an intermediary, while to make buying and selling transactions on Instagram features can be accessed through official accounts, or if we want to make sales on the Instagram market we have to register a special store first and if we want to make a purchase we have to visit the official store account of the product we are looking for on Instagram, in contrast to TikTok shop, which is a social e-commerce platform that is part of the TikTok feature and can be used for product sales [7], [8].

Currently, TikTok Shop is the main solution in the modern business world because the price it offers is relatively cheaper and benefits both sellers and buyers. Over time, TikTok Shop developed its innovations to allow users to make sales and purchases of products in the live videos they display. This feature was just launched in March 2021 and is currently available in several countries. The TikTok Shop offers a variety of products from various categories, such as fashion, beauty, electronics and more [9].

Purchase intention is based on people's interest and interest in an object. This interest led to purchases made by the public. N’da et al. 2023 [10] explores the direct and mediated effects of customers' perception of purchase budget (BGT) on purchase intention (PIT) through perceived quality (PPQ), perceived price (PPR) and perceived benefit (PB) in a cross-national context to understand the role of BGT in predicting customer purchase intention when selling smartphones online shopping through international platforms. While Jiang et al. 2023 [11] state that the market already has a significant size and the number is constantly increasing, the need to understand the factors affecting the purchase intention of consumers and explore the relationship between purchase intention and shopping behavior becomes more and more important and urgent. it can be concluded that purchase intention is very important as a parameter of the success of a market or business.

The aim of this research is to analyze the community's assessment of TikTok Shop, Instagram Shop, and Facebook Marketplace to determine which social commerce platform is profitable and receives the most positive sentiment for daily transactions such as buying and selling products. This research aims to increase trust, satisfaction, and purchase intentions of social commerce users. The study also explores the best-performing algorithms, the strengths and weaknesses of the methods used, and which social commerce platform generates the highest purchase intent and positive sentiment. Theoretically, this research contributes to a combination of algorithms that can be used and developed by other researches. Practically, this research contributes to social commerce developers (such as Facebook, Instagram and Tiktok) knowing their business position. So, the features in the application can be adjusted according to the community's response.

The chosen approach methods for this study include Naïve Bayes (NB), K-Nearest Neighbors (KNN), Support Vector Machine (SVM), Logistic Regression (LR), Decision Tree (DT), Random Forest (RF), LGBM Boost (LGBM), Ada Boost (ADA), and Voting Classifier (VOT) algorithms. These algorithms have been frequently used in previous sentiment analysis studies due to their performance, accuracy, and ability to handle data effectively. Thus, they are deemed suitable for this research. Based on these papers [12]–[18], machine learning models are used in certain cases.

This paper is organized as follows: In Section II, we conducted several related works about sentiment analysis on social commerce. Then, in Section III explains the research methodology applied in this research. Section IV explains the results of the research. Last, the result of the research are explained in Section V.

II. Related Work

Facebook and Instagram have succeeded in attracting customer interest in buying or selling their products on those social commerce. The feature of buying and selling products in social commerce originally was not the main focus in their business. Since technological development was significantly improved, they take advantage of these features to increase interest from customers so they can maintain their loyalty. TikTok, being one of the social commerce participating in using the feature of buying and selling products as their business process TikTok provides various advantages that are quite advantageous to company owners. They will have more opportunities if they use the TikTok [9].

Nabiha et al. in 2021 [19] and Bayhaqy in 2018 [14] showed that sentiment analysis related to social commerce is only carried out with several single algorithm classification methods, such as Naïve Bayes, SVM, Decision Tree and KNN, while Lestari in 2022 [20] only uses a single algorithm classification method, namely KNN and the application of N-Gram to the method, and also focuses on only one platform, namely the TikTok Shop. Nabila et al. in 2021 [19] did not used model evaluation measurements such as Precision, Recall and F1-Score, and the accuracy value of the classification model tends to be quite low, namely below 0.75. Those research [14], [19], [20] only focused on social commerce or one of the social commerce platforms without comparing one platform to another, while this study uses nine classification methods consisting of single algorithms and ensemble algorithms which might improve the evaluation results for each method for each sentiment data related to three social commerce platforms, namely Facebook, Instagram and TikTok to determine which platform has more positive sentiment.

Botchway R et al. in 2022 [21] used binary particle swarm optimization to improve the accuracy of their models. The optimization method used can produce different accuracy values for each classification method. Botchway R and friends succeeded in increasing the accuracy value of the Naïve Bayes method by 11.6%, SVM by 8.43% and KNN by 0.91%. Meanwhile, in research Kamrozi et al. in 2023 [22] does not use a special method to increase the evaluation value of the method used, namely the Lexicon Method. Therefore, this study uses hyper parameter tuning to increase the evaluation value of the method used and produce different evaluation values for each method.

Das et al. 2023 [13] used machine learning approaches to stop hateful activities from happening, such as Logistic Regression, Gaussian Naïve Bayes, K-Nearest Neighbor, Decision Tree, Random Forest and Support Vector Machine on detection of hate speech from Twitter. Support Vector Machine, Decision Tree and Random Forest outperformed all the other models, achieving state-of-art 95.5%, 96.2% and 98.2% accuracy respectively at finding the hidden meaning inside the large number of comments and therefore determining whether there is any hateful event is going on or not. However, this research needs to use more models in order to be able to compare and test how well the other models are, especially ensemble algorithms.

III. Material and Methods

In this chapter, the methodology used to predict intent detection and sentiment analysis is explained in relation to the user experience when using TikTok. First, people's Twitter remarks will be extracted. Second, the pre-processing stage will eliminate inconsistent and incomplete data. Third, a feature selection approach for identifying discriminating phrases for training and classification will be deployed. Fourth, nine machine learning approaches using NB, KNN, SVM, LR, DT, RF, LGBM, ADA and VOT will be used to classify sentiments into two categories, positive and negative. Finally, an evaluation will be conducted by calculating the performance value for each method using metrics and then comparing which method has the best performance. Fig. 1 illustrates the research methodology used.

A. Data Collection

Data collection or information extraction was conducted on social media platform which frequently used by the public, namely Twitter. The information was gathered via Twitter's Application Programming Interface (API). Data of Twitter may be used to uncover themes and items being discussed based on certain keywords, to evaluate sentiment on specific businesses, and to obtain opinion on the latest products and services. For the intended data extraction needs, users may define needed attributes such as usernames, keywords, locations, name of place and others. [9], [23], [24].

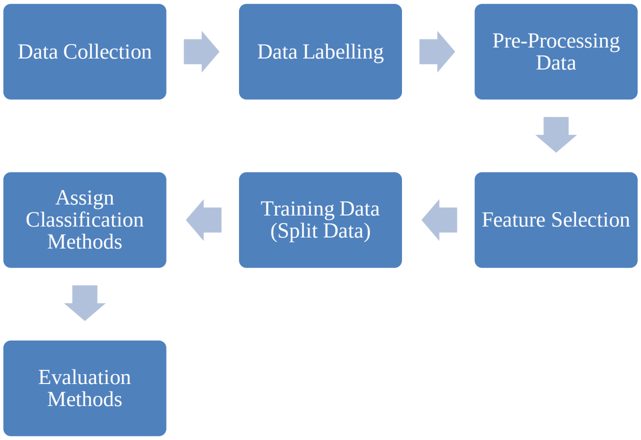

Fig. 1. Research methodology.

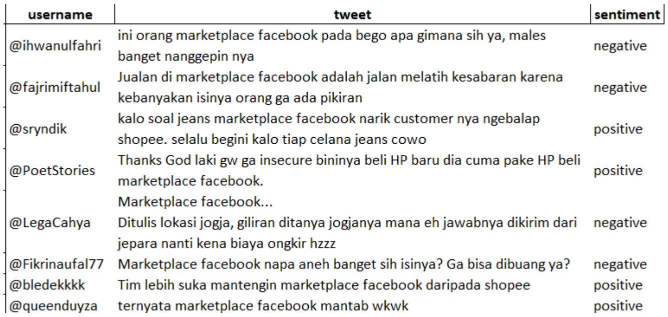
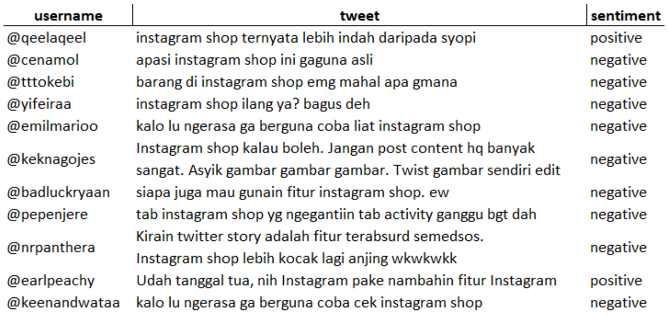
Data collection was carried out by collecting several community's tweet on Twitter regarding their ratings and experiences when using social commerce. The data collection was carried out with crawling data method using the Python programming language and Jupyter Notebook. Therefore, the dataset was developed independently and was not obtained from other paper references [Dataset is available in Supporting Materials section, Page 7].

In this section, the sentiment data obtained is divided into two categories, namely, positive and negative, for each social commerce platform: Facebook, Instagram, and TikTok. Fig. 2, 3, and 4 display the sentiment data collected from Twitter.



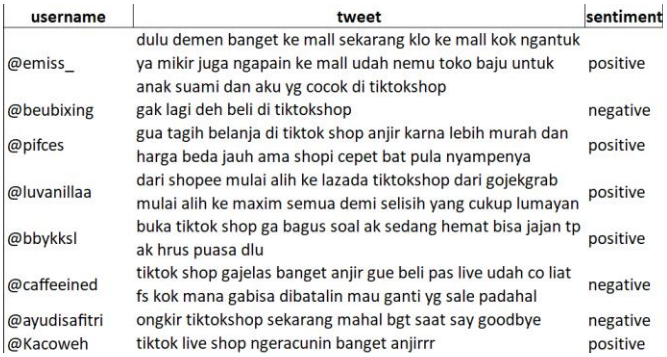
username	tweet	sentiment
@ihwanulfahri	ini orang marketplace facebook pada bego apa gimana sih ya, males banget nanggepin nya	negative
@fajrimiftahul	Jualan di marketplace facebook adalah jalan melatih kesabaran karena kebanyakan isinya orang ga ada pikiran	negative
@sryndik	kalo soal jeans marketplace facebook narik customer nya ngebalap shopee. selalu begini kalo tiap celana jeans cowo	positive
@PoetStories	Thanks God laki gw ga insecure bininya beli HP baru dia cuma pake HP beli marketplace facebook.	positive
@LegaCahya	Marketplace facebook... Ditulis lokasi jogja, giliran ditanya jogjanya mana eh jawabnya dikirim dari jepara nanti kena biaya ongkir hzzz	negative
@Fikrinaufal77	Marketplace facebook napa aneh banget sih isinya? Ga bisa dibuang ya?	negative
@bledekkkk	Tim lebih suka mantengin marketplace facebook daripada shopee	positive
@queenduyza	ternyata marketplace facebook mantab wkwk	positive

Fig. 2. Example of Facebook's sentiment.



username	tweet	sentiment
@qeelaqeel	instagram shop ternyata lebih indah daripada syopi	positive
@cenamol	apasi instagram shop ini gaguna asli	negative
@tttokebi	barang di instagram shop emg mahal apa gmana	negative
@yifeiraa	instagram shop ilang ya? bagus deh	negative
@emilmarioo	kalo lu ngerasa ga berguna coba liat instagram shop	negative
@keknagojes	Instagram shop kalau boleh. Jangan post content hq banyak sangat. Asyik gambar gambar gambar. Twist gambar sendiri edit	negative
@badluckryaan	siapa juga mau gunain fitur instagram shop. ew	negative
@pepenjere	tab instagram shop yg ngegantiin tab activity ganggu bgt dah	negative
@nrpanthera	Kirain twitter story adalah fitur terabsurd semedsos. Instagram shop lebih kocak lagi anjing wkwkwkk	negative
@earlpeachy	Udah tanggal tua, nih Instagram pake nambahin fitur Instagram	positive
@keenandwataa	kalo lu ngerasa ga berguna coba cek instagram shop	negative

Fig. 3. Example of Instagram's sentiment.



username	tweet	sentiment
@emiss_	dulu demen banget ke mall sekarang klo ke mall kok ngantuk ya mikir juga ngapain ke mall udah nemu toko baju untuk anak suami dan aku yg cocok di tiktokshop	positive
@beubixing	gak lagi deh beli di tiktokshop	negative
@pifces	gua tagih belanja di tiktok shop anjir karna lebih murah dan harga beda jauh ama shopi cepet bat pula nyampenya	positive
@luvanillaa	dari shopee mulai alih ke lazada tiktokshop dari gojekgrab mulai alih ke maxim semua demi selisih yang cukup lumayan	positive
@bbykksl	buka tiktok shop ga bagus soal ak sedang hemat bisa jajan tp ak hrus puasa dlu	positive
@caffeeined	tiktok shop gajelas banget anjir gue beli pas live udah co liat fs kok mana gabisa dibatalin mau ganti yg sale padahal	negative
@ayudisafitri	ongkir tiktokshop sekarang mahal bgt saat say goodbye	negative
@Kacoweh	tiktok live shop ngeracunin banget anjirrr	positive

Fig. 4. Example of TikTok's sentiment.

TABLE I. HEADCOUNT OF SENTIMENT DATA

Categories	Facebook	Instagram	TikTok
Positive	931	485	6772
Negative	584	188	504
Percentage of Positive (%)	60.65	72,06	93,07
Percentage of Negative (%)	39,35	7,94	6,93
Total	1535	673	7276

Based on Table I, it is known that TikTok has the highest number of positive sentiments, amounting to 6772 sentiments, which accounts for 93.07% out of 7276 sentiments. It is followed by Instagram, which has 485 positive sentiments, representing the second-highest percentage of 72.06% out of 673 data. Facebook, on the other hand, has the lowest number of positive sentiments, with 931 sentiments, which corresponds to the lowest percentage of 60.65% out of 1535 sentiments. This indicates that TikTok generates a greater number of positive sentiments from the community compared to Facebook and Instagram.

B. Pre-processing Data

The data obtained from Twitter is in the form of text, as it contains sentiments or tweets from the public regarding a product or service. However, such data or information usually contains noise, which can make data analysis more challenging. Therefore, data pre-processing is carried out to remove unwanted words in tweets. All tweets are processed through four stages of pre-processing, which are as follows: Tokenization; Stopword Removal; Stemming; POS Tagging; and Bag of Words [18], [21], [23]–[25].

In this section, the results of data pre-processing for each dataset of Facebook, Instagram, and TikTok, regarding their positive and negative sentiments, are obtained. Table II represents the outcomes of a collection of words along with their frequency of occurrence in each social commerce platform.

Based on Table II, it is known that the sentiment data for each social commerce platform contains different words and their frequencies. This is done to observe which words are frequently discussed by the community regarding those social commerce platforms on Twitter. Additionally, it is also done to examine the correlation between the conducted research and the collected sentiment data, whether there is any connection or not. Based on the performed data pre-processing, it is found that the sentiment data related to Facebook, Instagram, and TikTok have the same data alignment, which involves discussions on purchases, sales, and users' utilization of those social commerce platforms.

TABLE II. STEM WORD AND FREQUENCY

Social Commerce	Stem Word (Frequency)
Facebook	('facebook', 1564), ('jual', 767), ('beli', 707), ('marketplace', 589), ('barang', 282), ('orang', 217), ('kalo', 156), ('harga', 149), ('jualan', 128), ('grup', 98), ('liat', 97), ('belanja', 66), ('murah', 64), ('langsung', 60), ('nawar', 57), ('rumah', 56), ('twitter', 52), ('shopee', 51), ('suka', 51), ('bikin', 51), ('pake', 50), ('iklan', 49), ('sampe', 49), ('buka', 48), ('cari', 46), ('harganya', 45), ('motor', 44), ('akun', 44), ('forum', 44), ('bener', 43), ('foto', 41), ('kena', 41)
Instagram	('instagram', 705), ('beli', 429), ('jual', 179), ('shop', 154), ('kalo', 80), ('liat', 73), ('orang', 64), ('iklan', 57), ('akun', 48), ('belanja', 46), ('baju', 45), ('barang', 42), ('tiket', 37), ('jualan', 35), ('twitter', 35), ('rumah', 33), ('bikin', 31), ('temen', 29), ('pake', 26), ('suka', 25), ('gimana', 24), ('kena', 24), ('harga', 24), ('muncul', 24)
TikTok	('tiktok', 5537), ('shop', 4964), ('tiktokshop', 2352), ('beli', 1415), ('shopee', 1004), ('live', 626), ('belanja', 605), ('barang', 577), ('jual', 540), ('murah', 401), ('racun', 389), ('bahaya', 319), ('kalo', 289), ('harga', 267), ('duit', 264), ('ongkir', 233), ('buka', 232), ('liat', 229), ('baju', 211), ('pake', 207), ('order', 202), ('diskon', 197), ('checkout', 193), ('kirim', 176), ('kena', 170), ('akun', 162)

C. Feature Selection Method

After the data is pre-processed, feature selection is performed as an important step in sentiment analysis. By selecting a subset of the important attributes to be included in the model's creation, this stage determines the most predictive traits. This method offers the benefit of lowering the data's high dimensionality and removing redundant, noisy, and unneeded content. Furthermore, this strategy can contribute on the development of a quick and accurate sentiment categorization. In this study, several factors influence feature selection, including data consistency, data amount, and the need to find the most effective feature selection approach [16], [20], [21], [23]–[28].

D. Split Data

Split data is data that has been partitioned into two or more subsets. A two-part split is commonly used to analyze or test the data and train the model. Data splitting is an important aspect of data science, particularly for building data-driven models. This strategy improves the accuracy of data models and data-driven processes such as machine learning [16], [19].

To reduce overfitting, data splitting is often employed in machine learning. In this scenario, a machine learning model fits its training data too well and fails to consistently fit further data. The initial data in a machine learning model is often separated into three or four categories. The training set, the development set, and the testing set are the three most popular sets [23]:

1) *The training set* is the collection of data used to train the model. The model should keep an eye on and learn from the training data, and any of its parameters should be improved.

2) *The testing set* is the piece of data examined in the final model and compared to the preceding data sets. The testing set is used to evaluate the final mode and algorithm.

Data should be separated so that large amounts of training data may be included in data sets. Data may be split 80-20 or 70-30 between training and testing, for example. The exact ratio varies depending on the data, but for small data sets, a 70-20-10 split for training, development, and testing works best [28].

The data in this study is separated into training and testing data. The data split is carried out using an 80% training data size and a 20% testing data size of the total data in the dataset. Table III illustrates the number of training and testing data from the three social commerce platforms for each sentiment data.

TABLE III. SPLIT DATA

Categories	Facebook	Instagram	TikTok
Training Data	1213	538	5821
Testing Data	303	135	1455
Total	1535	673	7276

Based on Table III, it is known that each dataset related to the sentiments of Facebook, Instagram, and TikTok has different numbers of training and testing data. This is due to the varying percentages of training and testing data sizes. The larger the percentage of training data, the higher the likelihood of accurate predictions on the testing data.

E. Evaluation of Classification Methods

At this stage, the performance evaluation of nine classification methods is carried out using standard classification performance metrics. Furthermore, four outcomes are possible at this point: true positive, false positive, true negative, and false negative. It is a true positive if the document label is positive and is classified as such. It is referred to as a false negative if it is classified as negative. A true negative is a negative document label that is classified as such. If it is labeled positive, it is considered a false positive [16]–[21], [23]–[28].

The accuracy measure is used to assess the accuracy of the likelihood of taking [16], [17], [19]–[21], [23], [24], [28]. The precision metric is the proportion of predicted classes that are the actual classes [16], [18], [20], [23]–[28]. The recall metric is the proportion of actual classes that are predicted as a class [17], [18], [20], [23]–[28]. The F1-Score (F) is used to assess model performance [18], [23]–[28]. Here are the formulas for each metric.

$$Accuracy\ (A) = \frac{TP+TN}{TP+TN+FP+FN} \times 100 \tag{1}$$

$$Precision\ (P) = \frac{TP}{TP+FP} \times 100 \tag{2}$$

$$Recall\ (R) = \frac{TP}{TP+FN} \times 100 \tag{3}$$

$$F1 - Score\ (F) = 2 * \frac{P*R}{P+R} \tag{4}$$

The Accuracy, Precision, Recall, and F1-Score values varied from 0 to 1, with 1 being 100% similar and 0 representing 100% different. While TP, TN, FP, and FN represent the number of relevant identified features, relevant non-identified features, irrelevant identified features, and irrelevant non-identified features. Then, we applied 10-fold cross validation for evaluation.

F. *Hyper Parameter Tuning*

A Machine Learning model is a mathematical model with several parameters that must be taught from data. By training a model using existing data, we may fit the model parameters. [28], [29].

Another type of parameter, known as hyper parameters, cannot be taught using the normal training procedure. They are usually resolved before the training method begins. These parameters describe important model characteristics like as complexity and learning speed. The following are some examples of model hyper parameters [21], [26]:

1) The penalty in Logistic Regression Classifier i.e. L1 or L2 regularization.

2) The learning rate for training a neural network.

3) The C and sigma hyper parameters for support vector machines.

4) The k in k-nearest neighbors.

Models can have a large number of hyperparameters, and choosing the best combination of parameters can be thought of as a search problem. In this work, GridSearchCV and RandomizedSearchCV were used for hyper parameter optimization. This technique for GridSearch CV seeks the optimal collection of hyper parameters from a grid of hyper parameter values. While RandomizedSearchCV addresses the shortcomings of GridSearchCV by going through only a limited number of hyper parameter choices. It travels randomly within the grid to discover the optimal set of hyper parameters while also reducing wasteful processing.

IV. Results and Discussion

A. *Results*

In this section, evaluation is conducted on the classification methods used to measure their performance on sentiment data from Facebook, Instagram, and TikTok on Twitter. This evaluation includes accuracy, precision, recall, and F1-score. Table IV presents the evaluation scores for each method.

Based on Table IV, the evaluation scores for each classification model used on sentiment data from Facebook, Instagram, and TikTok are known. The evaluation scores range from 0 to 1, where a score closer to 1 indicates better performance, while a score closer to 0 indicates poorer performance.

The Random Forest Classifier has the highest assessment ratings for Facebook, with accuracy, precision, recall, and F1-score values of 0.80, 0.83, 0.75, and 0.77, respectively. The Logistic Regression classification model has the highest assessment ratings for Instagram, with accuracy, precision, recall, and F1-score values of 0.84, 0.86, 0.72, and 0.76, respectively. The Decision Tree classification model has the highest assessment ratings on TikTok, with accuracy, precision, recall, and F1-score values of 0.94, 0.74, 0.77, and 0.76, respectively.

However, for TikTok, there are no evaluation scores for the Random Forest and Voting Classifier models, as they have complex algorithms that require extensive memory capabilities to be executed on TikTok sentiment data. Therefore, during execution, the evaluation scores did not appear.

After evaluation value from the classification method had calculated, hyper parameter tuning was performed and it obtains the results. Table V presents the outcomes of utilizing hyper parameter tuning for multiple classification models on the sentiment data from each of the three social commerce platforms.

Based on Table V, the latest accuracy values are known after conducting hyper parameter tuning. Hyper parameter tuning was performed only on a subset of classification models due to memory limitations for highly complex classification models such as Random Forest, Voting Classifier, and others. Table VI compares the accuracy value before and after hyper parameter tuning was performed.

Based on Table VI, it is known that after conducting hyper parameter tuning, certain classification models experienced a decrease in accuracy scores. However, there are also several classification models that showed an improvement in accuracy scores. This can be influenced by the capacity and memory capabilities of the device used to execute the program. Upon re-execution, the obtained scores are also expected to differ. The values generated in this study represent the maximum iterations conducted to obtain the best possible scores. For example, Naive Bayes which has an accuracy value of 0.51 before using hyper parameter tuning, and 0.75 after using hyper parameter tuning. It can be said that hyper parameter tuning can increase and optimize the performance evaluation value of the resulting model. Mendes et al. 2023 [30] and Martineau et al. 2023 [31] explained that the use of hyper parameter tuning can optimize the performance evaluation value of the model so that it can increase the chances of success.

B. Discussion

Based on the obtained results, it is evident that each sentiment dataset related to Facebook, Instagram, and TikTok has different percentages of positive and negative sentiments. Among the three social commerce platforms, TikTok has the highest percentage of positive sentiments, amounting to 93.07%, using the best classification model, which is Decision Tree with an accuracy score of 0.94. After evaluating the performance of each classification method on each social commerce platform, the following findings were obtained:

1) Facebook had a positive sentiment percentage of 60.65%, with the best classification model being Random Forest Classifier, achieving accuracy, precision, recall, and F1-score values of 0.80; 0.83; 0.75; and 0.77 respectively.

2) Instagram had a positive sentiment percentage of 72,06%, with the best classification model being Logistic Regression, achieving accuracy, precision, recall, and F1-score values of 0.84; 0.86; 0.72; and 0.76 respectively.

3) TikTok had a positive sentiment percentage of 93.07%, with the best classification model being Decision Tree, achieving accuracy, precision, recall, and F1-score values of 0.94, 0.74, 0.77, and 0.76, respectively.

This indicates that TikTok receives more positive reviews from the community compared to Facebook and Instagram, which cannot be known in research [14], [19]–[22].

Additionally, the classification model used for TikTok sentiment data also exhibits significantly high and consistent accuracy scores, always exceeding 0.90. According to the theory of evaluation scores for measuring model performance, values above 0.90 are considered to represent models with excellent performance.

With the results obtained that Logistic Regression, Decision Tree and Random Forest can produce high model performance evaluation values, it can be proven in the paper Das et al. 2023 [13], Imran et al. 2022 [12], Gulati et al. 2022 [15] which state that the Logistic Regression, Decision Tree and Random Forest models have high performance values and can be the best some case.

C. Limitations

There are several limitations on this study such as:

- We had only collect sentiment data from Facebook, Instagram and TikTok.
- We only measure the evaluation of methods through nine classification methods; therefore we do not use the other methods since the device of researcher is not compatible to execute the other methods.
- We only compared nine classification methods and prioritized the accuracy of evaluation from each method.

V. Conclusion

This section will explain the conclusion of the conducted research. Based on the research conducted, multiple machine learning classification models were tested on sentiment data related to Facebook, Instagram, and TikTok to determine which social commerce platform had the highest number of positive reviews.

Based on these results, it can be concluded that the classification models have different evaluation scores depending on the data used. The best classification model for Facebook is Random Forest Classifier, for Instagram is Logistic Regression, and for TikTok is Decision Tree. However, for classification models with low evaluation scores, using hyper parameter tuning may improve their performance.

In conclusion, TikTok exhibits the highest positive sentiment percentage, indicating a greater number of positive reviews compared to Facebook and Instagram. According to the theory of evaluation scores for measuring model performance, values above 0.90 represent models with excellent performance. Notably, the classification model used for TikTok sentiment data consistently achieves accuracy scores above 0.90. With this research, hopefully can help people choose the best social commerce to use and social commerce developers can increase their application and business value in order to increase public interest.

Abstract*—Cyber-bullying is a growing problem in the digital age, affecting millions of people worldwide. Deep learning algorithms have the potential to assist in identifying and combating Cyber-bullying by detecting and classifying harmful messages. This paper uses two Ensemble deep learning (EDL) models to detect Cyber-bullying on text data, images and videos—and an overview of Cyber-bullying and its harmful effects on individuals and society. The advantages of using deep learning algorithms in the fight against Cyber-bullying include their ability to process large amounts of data and learn and adapt to new patterns of Cyber-bullying behaviour. For text data, firstly, a pre-trained model BERT (Bidirectional Encoder Representations from Transformers) is used to train on cyber-bullying text data. The next step describes the data pre-processing and feature extraction techniques required to prepare data for deep learning algorithms. We also discuss the different types of deep learning algorithms that can be used for Cyber-bullying detection, including convolutional neural networks (CNNs), recurrent neural networks (RNNs), and deep belief networks (DBNs). This paper combines the sentiment analysis model, such as Aspect-based Sentiment Analysis (ABSA), for classifying bullying messages. Deep Neural network (DNN) used the classification of Cyber-bullying images and videos. Experiments were conducted on three datasets such as Twitter (Kaggle), Images (Online), and Videos (Online). Datasets are collected from various online sources. The results demonstrate the effectiveness of EDL and DNN in detecting Cyber-bullying in terms of detecting bullying data from relevant datasets. The EDL and DNN obtained an accuracy of 0.987, precision of 0.976, F1-score of 0.975, and recall of 0.971 for the Twitter dataset. The performance of Ensemble CNN brought an accuracy of 0.887, precision of 0.88, F1-score of 0.88, and recall of 0.887 for the Image dataset. For the video dataset, the performance of Ensemble CNN is an accuracy of 0.807, precision of 0.81, F1-score of 0.82, and recall of 0.81. Future research should focus on developing more accurate and efficient deep learning algorithms for Cyber-bullying detection and investigating the ethical implications of using such algorithms in practice.

Keywords*—Cyber bullying; ensemble deep learning (EDL); convolutional neural networks (CNNs); recurrent neural networks (RNNs); deep belief networks (DBNs)

I. Introduction

Sentiment analysis can be used to detect instances of cyber-bullying by analyzing the language and tone used in online messages, comments, or posts [1]. The process involves using natural language processing (NLP) techniques to identify the sentiment expressed in a text, whether it is positive, negative, or neutral [2]. One approach to using sentiment analysis for cyber-bullying detection is to look for negative sentiments expressed towards an individual or group, such as derogatory or offensive language, insults, or threats [3]. These can be identified using NLP techniques, such as part-of-speech tagging, named entity recognition, and sentiment analysis algorithms. Another approach is to analyze the context in which the message is being conveyed, such as the topic being discussed and the online community it is being shared in [4] [5]. For example, if a message contains negative sentiments towards a specific group of people or individual, and is being shared in an online community known for hostile or aggressive behaviour, it may be a sign of cyber-bullying. It is important to note that sentiment analysis is not a foolproof method for detecting cyber-bullying and should be used in combination with other techniques, such as human moderation and reporting mechanisms. Additionally, it is important to ensure that the use of sentiment analysis does not infringe on individuals' privacy rights or result in false accusations.

Cyber-bullying (CB) is a default model for publicly abusing a person. Many online social media networking (OSMN) like Facebook, Twitter, and Instagram act as a medium for people based on cyber-bullying attacks [6]. Several automated models aim to develop to classify cyber-bullying in terms of text messages, audio, and videos [7]. Sometimes based on the topic modeling, cyber-bullying attacks occur in several datasets belonging to topic modeling. Twitter has become more popular for cyber-bullying by using various types of attacks. Exemplary-grained automated models were developed to detect cyber-bullying regarding topic modeling [8]. It is essential to complain the cyber-bullying attacks in OSMS if the user violates the ITE Law, which is considered a crime in OSMS like Twitter [9]. The victim should act if any abusive language is used on Twitter. The aim of cyber-bullying mainly focuses on classifying the tweets present on Twitter. This paper describes the automated approach for detecting cyber-bullying attacks by using the sentiment analysis on text messages, videos, and audio. Sentiment analysis helps the proposed automated approach to find the cyber-bullying attacks in multi-media. An aspect based sentiment analysis model combined with automated classification approach used to classify the cyber-bullying words from given input data. It shows the improved

performance in terms of accuracy, sensitivity, specificity, F1-score and precision.

The organization of the paper is as follows. Section II explains the literature survey about various methods of cyberbullying. Section III and Section IV give the significance of the work and training and feature extraction techniques. Section V describes the experimental results with comparative performance. Section VI describes the conclusion.

A. *Significant Points of Proposed System*

Cyber-bullying has become a common problem in today's digital age, with severe psychological and emotional consequences for victims. Detecting and preventing cyber-bullying is critical for ensuring individuals' well-being in online communities. Manual monitoring of online content, on the other hand, is a time-consuming and inefficient process. As a result, there is a need to create an automated system that uses deep learning models to detect cyber-bullying. This project aims to develop and test a deep-learning model to detect cyber-bullying in online text, images, and videos. The model should be able to classify messages, comments, or posts as cyber-bullying or non-cyber-bullying based on their content. The detection system's accuracy, precision, and recall should be high, with low error rates.

II. Literature Survey

Semantic-enhanced marginalized denoising auto-encoder (SEDMA) is a type of neural network that is trained to reconstruct clean data from noisy data by learning the underlying distribution of the input data. It has been enhanced with semantic information to improve its ability to capture the context and meaning of the text [10]. To use SEDMA for cyber-bullying detection, the first step is to train the model on a dataset of labelled examples of cyber-bullying and non-cyber-bullying text. During training, the SEDMA learns to identify patterns and features that distinguish between cyber-bullying and non-cyber-bullying text. Once the SEDMA is trained, it can be used to detect cyber-bullying in new text. The input text is first pre-processed to remove noise and convert it into a numerical representation that can be input to the SEDMA. The SEDMA then reconstructs the clean version of the input text, and the reconstruction error is used to determine whether the input text is cyber-bullying or not. The advantage of using SEDMA for cyber-bullying detection is that it can capture the semantic meaning of the text, which is critical for detecting subtle forms of cyber-bullying. Additionally, it is more robust to noise and can handle variations in the input text. In conclusion, the use of semantic-enhanced marginalized denoising auto-encoder is a promising approach for cyber-bullying detection, and it has the potential to improve the accuracy of current cyber-bullying detection systems. Zhang et al. [11] proposed the novel pronunciation-based CNN to solve issues in detecting cyber-bullying based on the pronunciation of misspelled words. The proposed approach corrects the errors that occur by spellings that didn't change in accent because of its noise and data sparsity imbalance present in the dataset. To solve these issues, the proposed model applied to two datasets, Twitter and Form spring. The proposed approach's comparative performance shows more effective results than existing models. Zhang et al. [12] developed a fine-grained model to detect cyber-bullying messages based on linguistic analysis. The proposed model focused on finding the patterns based on Linguistic Inquiry Word Count (LIWC) to detect fine-tuned cyber-bullying detection from different social media datasets. Dalvi et al. [13] proposed an ML model to see cyber-bullying from social media posts like Twitter. The proposed ML model is used to prevent bullying on Twitter. Using the Twitter API, the tweets are extracted and classified whether the tweets are bullied or not. Zhao et al. [14] proposed a new learning model to solve the issues in cyber-bullying detection—the proposed approach combined with a deep learning model to denoising auto-encoder (SDA). The SDA model contains semantic dropout noise and sparsity. These features focused on knowledge and the word embedding method. The performance of the proposed model improved by combining it with semantic-enhanced marginalized (SEM) to find the hidden features of the bullying content. The version of the proposed model was analyzed using two datasets such as Twitter and MySpace, and achieved better performance in terms of classification. Luo et al. [15] proposed the BiGRU-CNN for classifying cyber-bullying messages. BiGRU mainly focused on extracting the global features that significantly impact organizing bullying messages. The CNN consists of a convolution method with 128 kernels of length 5; this is used to extract the features that improve the learning rate of the model better. Adav et al. [16] introduced the BERT model, which is suitable for creating contextual embeddings that produce the particular embeddings for classifying cyber-bullying detection in social media. Ahmed et al. [17] introduced the cyber-bullying model that classifies the bullying words belonging to Bangla and Romanized Bangla texts utilizing ML and DL models. Iwendi et al. [18] performed various DL models that detect cyber-bullying in social media. The comparison between different DL algorithms shows high performance. Aind et al. [19] introduced the novel Q-Bully model that sees cyber-bullying automatically from social media platforms. The proposed performance is improved by combining with Reinforcement Learning gives better accuracy. Ketsbaia et al. [20] introduced the DL models that detect cyber-bullying automatically. Pradhan et al. [21] proposed the new DL model that sees the cyber-bullying from Wikipedia, Formspring, and Twitter cyber-bullying datasets.

III. How Cyber-Bullying Affects the Social Media

Cyber-bullying can have a significant impact on social media use, both for individuals and as a whole. Here are some of the ways it can affect social media introduction:

1) Fear of harassment: Cyber-bullying can create a climate of fear on social media platforms. Individuals who have been bullied in the past or who fear being bullied may be hesitant to join social media or may limit their use of these platforms.

2) Damage to reputation: Cyber-bullying can damage an individual's reputation, making them less likely to want to be active on social media. This can also affect the reputation of the platform itself if it becomes known as a place where bullying is rampant.

3) Decreased engagement: Cyber-bullying can lead to decreased engagement on social media, as individuals may avoid posting or interacting with others out of fear of being targeted. This can have a negative impact on the platform as a whole, as it relies on user engagement to generate revenue.

4) Reduced trust: If social media platforms are seen as a place where cyber-bullying is common, users may lose trust in these platforms and be less likely to use them. This can affect the growth and sustainability of social media as a whole.
Overall, cyber-bullying can have a significant impact on social media use and adoption, and it is important for individuals and social media companies to take steps to prevent and address this issue, Fig. 1.

Fig. 1. Types of cyber-bullying.

IV. Cyber-bullying Detection model for Text Messages

A. BERT (Bidirectional Encoder Representations from Transformers) for Training on Cyber-Bullying Data

Cyber-bullying can have a significant impact on social media use, both for individuals and as a whole. Here are some of the ways it can affect social media introduction:

1) Fear of harassment: Cyber-bullying can create a climate of fear on social media platforms. Individuals who have been bullied in the past or who fear being bullied may be hesitant to join social media or may limit their use of these platforms.

2) Damage to reputation: Cyber-bullying can damage an individual's reputation, making them less likely to want to be active on social media. This can also affect the reputation of the platform itself if it becomes known as a place where bullying is rampant.

3) Decreased engagement: Cyber-bullying can lead to decreased engagement on social media, as individuals may avoid posting or interacting with others out of fear of being targeted. This can have a negative impact on the platform as a whole, as it relies on user engagement to generate revenue.

4) Reduced trust: If social media platforms are seen as a place where cyber-bullying is common, users may lose trust in these platforms and be less likely to use them. This can affect the growth and sustainability of social media as a whole.
Overall, cyber-bullying can have a significant impact on social media use and adoption, and it is important for individuals and social media companies to take steps to prevent and address this issue.

5) Here are the equations for the fine-tuning process: First, we add a classification layer on top of the pre-trained BERT model. The classification layer consists of a fully connected layer and a soft-max activation function.

$$\mathrm{h_{cls}} = \mathrm{W_{cls}} \times [\mathrm{CLS}] + \mathrm{b_{cls}} \quad (1)$$

$$\mathrm{y_{hat}} = \mathrm{softmax}(\mathrm{h_{cls}}) \quad (2)$$

Where $\mathrm{h_{cls}}$ is the hidden state of the [CLS] token, $\mathrm{W_{cls}}$ and $\mathrm{b_{cls}}$ are the weight and bias parameters of the fully connected layer, and $\mathrm{y_{hat}}$ is the predicted probability distribution over the two classes (cyber-bullying and non-cyber-bullying).

We then define the loss function as the cross-entropy loss between the predicted and true labels:

$$\mathrm{L} = -\sum \mathrm{y_i} \times \log\left(\mathrm{y_{hat_i}}\right) + (1 - \mathrm{y_i}) \times \log(1 - \mathrm{y_{hat_i}})) \quad (3)$$

Where $\mathrm{y_i}$ is the true label (1 for cyber-bullying, 0 for non-cyber-bullying), and $\mathrm{y_{hat_i}}$ is the predicted probability for the $\mathrm{i^{th}}$ message.

We optimize the parameters of the classification layer by minimizing the loss function using gradient descent:

$$\mathrm{W_{cls}}, \mathrm{b_{cls}} = \mathrm{argmin}(\mathrm{L}) \quad (4)$$

The above equations outline the fine-tuning process for BERT in cyber-bullying detection. Note that this process requires a labelled dataset of cyber-bullying and non-cyber-bullying messages, as well as appropriate pre-processing and tokenization of the input text.

B. Pre-processing Techniques for Cyber-Bullying

1) Tokenization: Tokenization divides the text into smaller units known as tokens, which can be words, phrases, or symbols. It is a common step in pre-processing natural language processing (NLP) tasks such as sentiment analysis and topic modelling. Consider the following example sentence to demonstrate tokenization for cyber-bullying data:

- "I hate you and wish you were never born. You're worthless and nobody likes you."
- To tokenize this sentence, we could use a straightforward method of separating the text by whitespace and punctuation marks.
- The tokenized sentence would look like this:
- ["I", "hate", "you", "and", "wish", "you", "were", "never", "born", ".", "You're", "worthless", "and", "nobody", "likes", "you", "."]

Each element in the resulting list is a token that can be processed and analyzed further using various NLP techniques, Fig. 2.

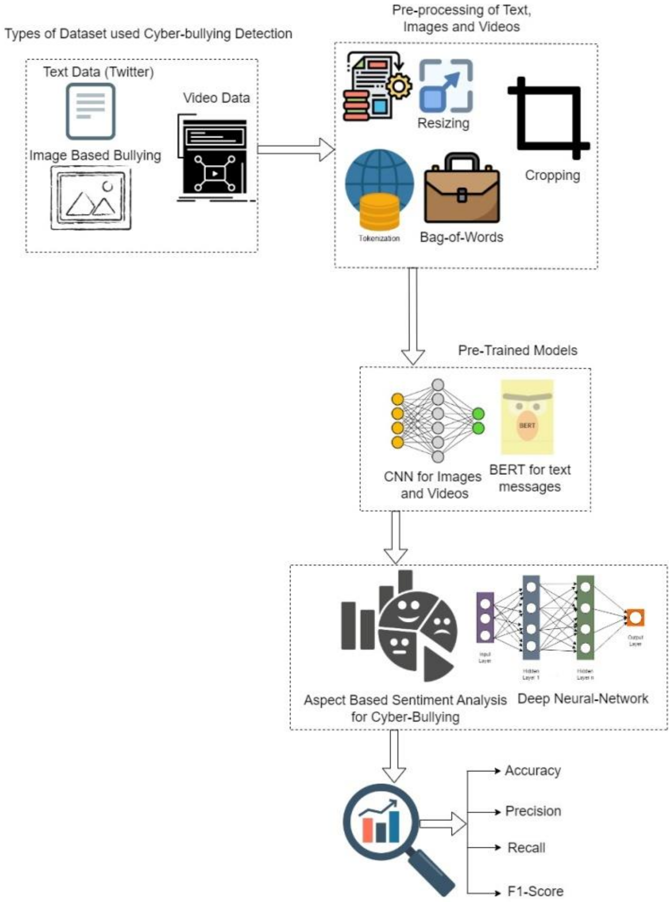

Fig. 2. Overall system architecture.

2) Stop-words removal: Stop words are commonly used in a language but have little meaning and can be removed from text without affecting the overall message. Stop word removal can be used in cyber-bullying to filter out irrelevant or offensive words from the text to identify and prevent bullying behavior.

- Here's an example of how to use stop-word removal in the context of cyber-bullying:
- Assume a social media platform wants to look for instances of cyber-bullying in user posts.
- The platform could include a stop word filter that removes common words and phrases that are unlikely to be used in cyber-bullying incidents, such as "the," "and," "is," "in," "a," "of," and "on."
- For example, if a user writes, "I hate you, and I hope you die," the stop word filter will remove the words "I," "you," "and," "hope," and "die." The filtered text would then be "hate," raising a red flag and prompting a review by the platform's moderators.
- Stop word removal is a valuable tool for detecting cyber-bullying and promoting a safer online environment.
- However, it is essential to note that stop-word removal alone may not be enough to identify instances of cyber-bullying accurately and that other techniques, such as sentiment analysis and machine learning algorithms, may be required.

3) Feature extraction techniques for cyber-bullying: Feature extraction is a crucial step in natural language processing (NLP) tasks such as cyber-bullying detection. Here are some techniques for feature extraction from cyber-bullying text data:

a) Bag of Words (BoW): It is a simple and effective method to extract features from text data. It involves counting the frequency of occurrence of each word in the document. For instance, consider the following sentence: "You're such a loser. Nobody likes you." The BoW representation of this sentence would be: {'you': 2, 're': 1, 'such': 1, 'a': 1, 'loser': 1, 'nobody': 1, 'likes': 1}.

b) TF-IDF (Term Frequency-Inverse Document Frequency): It is another technique that helps to extract features from text data. It assigns a weight to each word based on its frequency in the document and its frequency in the entire corpus. For example, in the sentence "You're such a loser. Nobody likes you," the word "you" appears twice in the document but is likely to appear in many other documents too. So, the weight assigned to "you" will be relatively low.

c) N-grams: N-grams are a sequence of N words in a sentence. For example, a bigram of the sentence "You're such a loser. Nobody likes you" would be "you're such," "such a," "a loser," "loser nobody," "nobody likes," and "likes you." N-grams help capture the context of words in a sentence.

d) Word embeddings: Word embeddings are vector representations of words that capture semantic and syntactic relationships between them. They are learned using neural networks trained on large amounts of text data. Word2Vec and GloVe are some examples of popular word embedding techniques.

Example:

- Let's say you have a dataset containing cyber-bullying text data, and you want to use these techniques to extract features from it. Here is an example of how you can use these techniques to extract features:
- Suppose you have a sentence in your dataset like this: "You are ugly and nobody likes you."
- BoW representation: {'you': 2, 'are': 1, 'ugly': 1, 'and': 1, 'nobody': 1, 'likes': 1}.
- TF-IDF representation: {'you': 0.276, 'are': 0.276, 'ugly': 0.385, 'and': 0.385, 'nobody': 0.385, 'likes': 0.385}.

- N-gram representation: {('you', 'are'): 1, ('are', 'ugly'): 1, ('ugly', 'and'): 1, ('and', 'nobody'): 1, ('nobody', 'likes'): 1, ('likes', 'you'): 1}.
- Word embeddings: [-0.456, 0.678, -0.234, 0.987, 0.678, -0.567] (this is just an example of a vector representation of the sentence using word embeddings, and the values are random).

V. Aspect-based Sentiment Analysis (ABSA) for Cyber-bullying

ABSA is a natural language processing technique used to identify and extract aspects or features of a given text and determine their sentiment polarity (positive, negative, or neutral) [22]. In the context of cyber-bullying, ABSA can be used to identify the specific aspects or topics that are associated with negative or abusive comments, messages, or posts.

A mathematical model for ABSA in cyber-bullying detection could be formulated as follows:

Let D be a set of documents containing potentially abusive or negative content, and A be a set of aspects or topics that may be associated with cyber-bullying. Each document d ∈ D can be represented as a set of sentences $\{s_1, s_2, \ldots, s_n\}$ and each sentence si can be further represented as a set of words $\{w_1, w_2, \ldots, w_n\}$. Let $P(w_i|s_i)$ be the probability of word w_i occurring in sentence s_i, and let $P(si|d)$ be the probability of sentence s_i occurring in document d.

The sentiment polarity of each aspect a ∈ A can be determined based on the sentiment scores of the words that are associated with that aspect. Let S(a) be the sentiment score of aspect a, which can be calculated as follows:

$$S(a) = \sum w_i \in a\, P(w_i|a) * \text{ Polarity}(w_i) \qquad (5)$$

Where $\text{Polarity}(w_i)$the polarity scores of is word w_i (e.g., +1 for positive, -1 for negative, 0 for neutral).

To detect cyber-bullying, we can use a threshold value T to determine whether a document d contains abusive or negative content. Let B(d) be a binary variable that indicates whether document d is abusive or not, where B(d) = 1 if d is abusive and B(d) = 0 otherwise. We can define B(d) as follows:

$$B(d) = \{1 \text{ if} \max a \in A\, S(a) \geq T;\ 0 \text{ otherwise}\} \qquad (6)$$

Where $\max a \in A\, S(a)$ is the maximum sentiment score of all aspects in document d. The threshold value T can be determined empirically based on the distribution of sentiment scores in a training dataset of labeled cyber-bullying and non-cyber-bullying documents.

Overall, the mathematical model for ABSA in cyber-bullying detection involves identifying the aspects or topics associated with cyber-bullying, calculating the sentiment scores of those aspects based on the sentiment polarity of the words associated with them, and using a threshold value to determine whether a document is abusive or not.

A. Convolutional Neural Networks (CNN) for Training on Images and Videos

CNNs are a type of deep learning model that are particularly effective at processing visual data, making them a popular choice for image and video classification tasks, including cyber bullying detection. The basic architecture of a CNN consists of several layers, including convolutional layers, pooling layers, and fully connected layers. Each layer performs a specific function, and the output of one layer is fed as input to the next layer.

The equations used to train a CNN for cyber bullying image and video classification involve the use of back-propagation and gradient descent to update the weights and biases of the network. The overall goal is to minimize the error between the predicted output and the actual output.

The general equation for computing the output of a convolutional layer can be expressed as follows:

$$y_i = f(\sum j = 1\hat{n}\, w_j \times x_{ij} + b_i) \qquad (7)$$

Where:

- 'y_i' is the output of the ith neuron in the layer.
- 'f()' is the activation function.
- 'n' is the number of input neurons.
- 'w_j' is the weight connecting the jth input neuron to the ith output neuron.
- 'x_{ij}' is the activation of the jth input neuron at the ith location of the receptive field.
- 'b_i' is the bias term for the ith output neuron.

The pooling layer reduces the dimensionality of the input by aggregating nearby activations. The most common pooling operation is max pooling, which selects the maximum value from each local neighborhood of activations.

The fully connected layer takes the flattened output from the previous layer and applies a matrix multiplication operation to produce the final output. The equation for the fully connected layer can be expressed as:

$$y = f(Wx + b) \qquad (8)$$

Where:

y is the output vector.

f() is the activation function.

W is the weight matrix.

x is the input vector.

b is the bias vector.

During training, the weights and biases of the network are updated using the back-propagation algorithm. The gradient of the loss function with respect to each weight and bias is computed, and the weights and biases are updated in the opposite direction of the gradient to minimize the loss function.

The equations for back-propagation and gradient descent are as follows:

$$\frac{\mathrm{dL}}{\mathrm{dw}} = \frac{\mathrm{dL}}{\mathrm{dy}} \times \frac{\mathrm{dy}}{\mathrm{dw}} \quad (9)$$

$$\mathrm{w} = \mathrm{w} - \mathrm{Ir} \times \frac{\mathrm{dL}}{\mathrm{dw}} \quad (10)$$

$$\frac{\mathrm{dL}}{\mathrm{db}} = \frac{\mathrm{dL}}{\mathrm{dy}} \times \frac{\mathrm{dy}}{\mathrm{db}} \quad (11)$$

$$\mathrm{b} = \mathrm{b} - \mathrm{Ir} \times \frac{\mathrm{dL}}{\mathrm{db}} \quad (12)$$

Where:

'L' is the loss function.

'w' and 'b' are the weights and biases of the network.

'y' is the output of the network.

'lr' is the learning rate.

Overall, the use of CNNs with back-propagation and gradient descent provides an effective way to train models for cyber bullying image and video classification tasks.

B. Cropping of Images and Videos

Cropping is the removal of unwanted parts of an image or video to focus on a specific area or subject.

Here are some typical image and video cropping techniques:

1) The rule of thirds: This technique entails dividing the image or video into thirds horizontally and vertically and then positioning the subject along the intersections or lines.
As a result, the composition is more balanced and visually appealing.

2) Center crop: This technique involves cropping an image or video to center the subject. It works well when the issue is the main focus and there is no distracting background. Cropping an image or video to a specific aspect ratio, such as 4:3 or 16:9, is an example of this technique. It comes in handy when creating content for specific platforms or devices.

3) Pan and zoom: This technique involves cropping an image or video and animating it to simulate a camera pan or zoom. It can add motion to the image or video or emphasize specific parts.

4) Content-aware crop: This technique uses software tools to determine the best cropping based on the image or video content. It can be helpful when the subject is not in a fixed position or when complex background content needs to be removed.

C. Deep Neural Network (DNN)

DNN is specifically CNNs and recurrent neural networks (RNNs), can be used to solve the problem of classifying cyber-bullying in images and videos (RNNs).

D. Data Gathering and Pre-processing

Preprocess a large dataset of images and videos containing Cyber-bullying content to extract features like color, texture, shape, and motion.

E. Image Classification using CNN

Train a CNN on the image data to determine whether or not each image contains cyber-bullying content.

Multiple convolutional and pooling layers are followed by fully connected layers and a softmax output layer in a CNN. To improve the model's performance, employ data augmentation, dropout, and early stopping techniques.

F. Dataset Description

The experiments use a Python programming language with three datasets: Twitter, Images, and Videos dataset. The dataset is aged between 15-40 years from schools to job holders. Among these, 88% of data is analyzed as cyber-bullying. These tweets contain more than 47656 with two attributes such as tweet_text and tweet_type. Python libraries such as Keras, Pandas, and TensorFlow were used to analyze the performance of the proposed model. Table I shows the various types of bullying text messages for training and testing is given.

Table II shows the types of bullying images that affects the human personally and mentally. These images are JPAG images with standard size. These images are classified based on comments, captions, and topics.

Table III shows the various types of videos belong to different categories. Three types of bullying videos are present for experimental analysis. These videos such as hate speech, personal abuse and normal are shown in Table IV.

TABLE I. TYPES OF CYBER-BULLYING TEXT MESSAGES

Types of Cyber-bullying	Tweets
Age	The girl who bullied you in high school but now wants to sell you Arbonne
Ethnicity	I said dont put north west in coffee fuck the diddy call fifty i said there no to assassinate out the door of the air port dumb niggers
Gender	Don't call bitches females. That's mad disrespectful. Bitches hate when you call them females.
Religion	@UmarMal And I'm not sure how you can yammer about homelessness when Muslims are still murdering people for apostacy and blasphemy.
Other type of Cyber-bullying	@Eleoryth I sometimes envy those who don't have retarded parents
Not Cyber-bullying	Rebecca Black Drops Out of School Due to Bullying

TABLE II. TYPES OF TWITTER TEXT DATASET

Message Type	Training	Testing
Religion based bullying	3000	4997
Age based bullying	3000	4992
Ethnicity	3000	4959
Gender	3000	4948
Other cyber-bullying	3000	4823
Not cyber-bullying	3000	4937
Total	18000	29656

TABLE III. TYPES OF IMAGE DATASET

Image Type	Training	Testing
Morphing Images	1500	1500
Personal Abuse	500	500
Adult	1k	1k
Total Messages	3k	3k

TABLE IV. VIDEOS DATASET

Video Type	Training	Testing
Hate speech	25	25
Personal Abuse	25	25
Normal Videos	10	10
Total Videos	60	60

G. *Performance Metrics*

A confusion matrix is an approach that analyzes the performance of the proposed model. The classification of images will specify the model performance on test data. The confusion matrix mainly focused on two attributes such as predicted and original values, see Fig. 3.

True Negative (TN): The predicted input is bullied and actual input is also bullied.

True Positive (TP): The predicted input is not bullied and actual value is not bullied.

False Positive (FP): The predicted input is bullied and actual input is not bullied.

False Negative (FN): The predicted input is not-bullied and actual input is bullied.

Precision: This parameter gives the overall correct outputs given by the proposed model.

$$\text{Precision} = \frac{\text{TP}}{\text{TP+FP}} \tag{13}$$

F1 Measure: It is the parameter that combines the recall and precision.

$$\text{F1 Measure} = 2 \times \frac{\text{precision}*\text{recall}}{\text{precision+recall}} \tag{14}$$

Accuracy: The overall accuracy of proposed model is measured as

$$\text{Accuracy} = \frac{\text{TP+TN}}{\text{TP+TN+FP+FN}} \tag{15}$$

Recall: This metric is mainly focused on reducing the false negatives.

$$\text{Recall} = \frac{\text{TP}}{\text{TP+FN}} \tag{16}$$

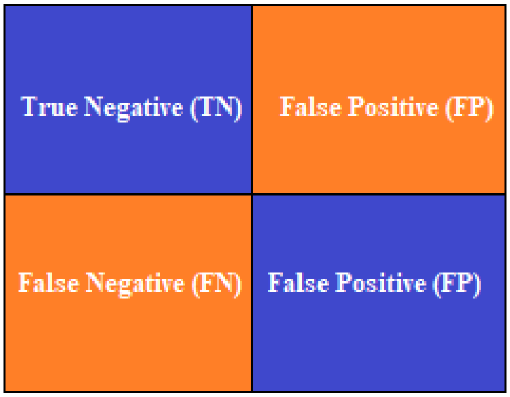

Fig. 3. Confusion matrix.

TABLE V. COMPARATIVE PERFORMANCES OF EXISTING AND PROPOSED APPROACHES FOR ANALYSIS OF TWITTER DATA

		Precision	F1 Measure	Accuracy	Recall
2DCNN [23]	Religion based bullying	0.68	0.68	0.68	0.68
	Age based bullying	0.69	0.698	0.68	0.69
	Ethnicity	0.67	0.68	0.68	0.67
	Gender	0.678	0.687	0.698	0.685
	Other cyber-bullying	0.68	0.68	0.687	0.685
	Not cyber-bullying	0.68	0.675	0.675	0.68

	Age based bullying	0.961	0.966	0.968	0.967
	Ethnicity	0.976	0.975	0.978	0.967
	Gender	0.956	0.967	0.976	0.956
	Other cyber-bullying	0.976	0.976	0.968	0.976
	Not cyber-bullying	0.978	0.972	0.976	0.967

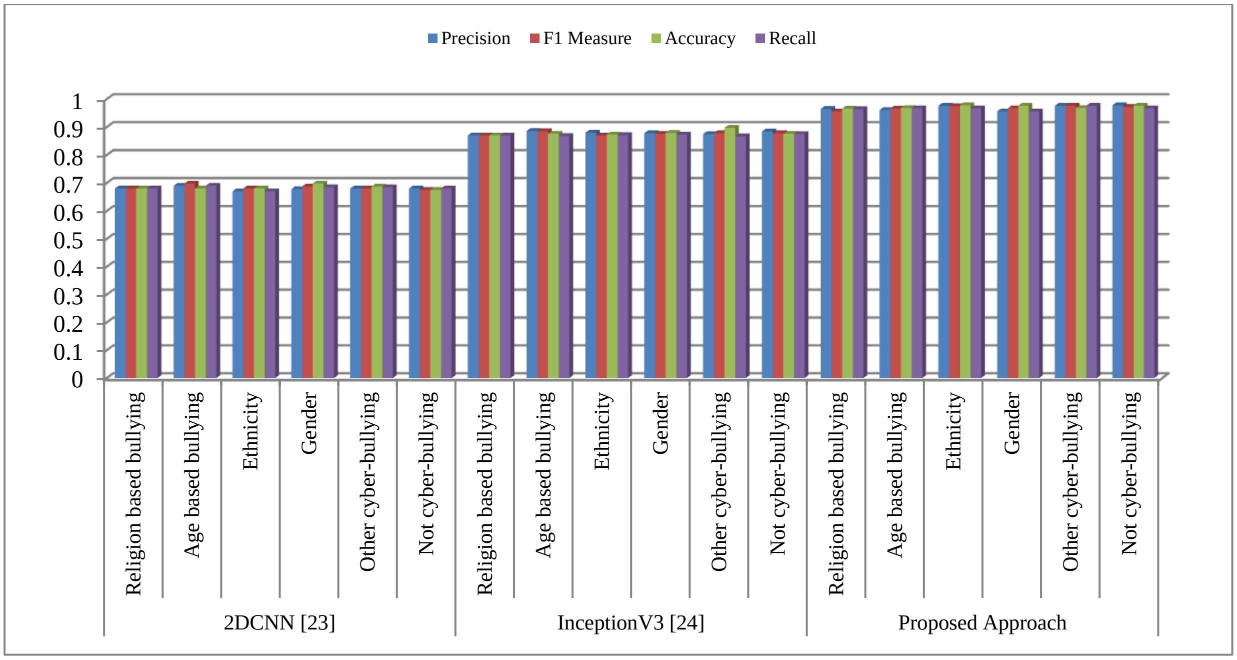

Fig. 4. Comparative performances of existing and proposed approaches for analysis of Twitter data.

Table V shows the comparative results among the existing 2DCNN [23], InceptionV3 [24] and proposed approach. Fig. 4 also compares text based cyber-bullying models based on the given data in twitter dataset.

Table VI, Table VII and Fig. 5, Fig. 6 shows a comparison of image-based cyberbullying. MoSI is the existing model, and Ensemble CNN is the proposed model. Ensemble CNN classifies images and videos of cyber-bullying. They are creating a diverse and representative dataset of cyberbullying incidents, including various types such as harassment, hate speech, or threats, and creating deep learning model architecture suitable for detecting cyberbullying. The model should be trained and optimized for high performance using the collected dataset. They are addressing the issue of imbalanced data, as cyber-bullying incidents are relatively rare compared to non-cyber-bullying incidents. These techniques need methods like oversampling, under sampling, and generating synthetic data.

TABLE VI. COMPARATIVE PERFORMANCES OF EXISTING AND PROPOSED APPROACHES FOR ANALYSIS OF IMAGES

	Types	Precision	F1 Measure	Accuracy	Recall
Motion from Static Images (MoSI)	Morphing Images	0.78	0.78	0.78	0.78
	Personal Abuse	0.79	0.698	0.78	0.79
	Adult	0.77	0.78	0.78	0.77
	Normal	0.77	0.78	0.78	0.78
Ensemble CNN	Morphing Images	0.88	0.88	0.88	0.88
	Personal Abuse	0.89	0.898	0.88	0.89
	Adult	0.87	0.88	0.88	0.87
	Normal	0.8856	0.879	0.8876	0.876

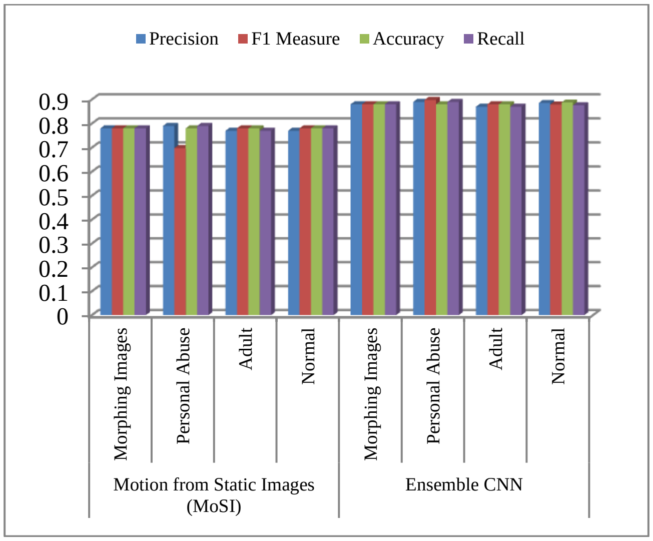

Fig. 5. Comparative performances of existing and proposed approaches for analysis of image data.

TABLE VII. COMPARATIVE PERFORMANCES OF EXISTING AND PROPOSED APPROACHES FOR ANALYSIS OF VIDEOS

		Precision	F1 Measure	Accuracy	Recall
Motion from Static Images (MoSI)[25]	Hate speech	0.68	0.78	0.78	0.78
	Personal Abuse	0.69	0.698	0.78	0.79
	Normal	0.67	0.78	0.78	0.77
Ensemble CNN	Hate speech	0.80	0.81	0.81	0.81
	Personal Abuse	0.80	0.821	0.82	0.81
	Normal	0.81	0.81	0.81	0.82

VI. Conclusion

Finally, an ensemble deep neural network can classify cyber-bullying on Twitter using text, images, and videos. The ensemble method combines multiple models' outputs to produce a more accurate and robust prediction. An Aspect-based Sentiment Analysis (ABSA) for Cyber-bullying is introduced for text classification. This model learned the patterns and features that distinguish cyber-bullying tweets from non-cyber-bullying tweets using large datasets of labeled text. The text model's output can then be combined with the results of the image and video models via a weighted voting scheme. A deep neural network, such as a recurrent neural network (RNN) or a convolutional neural network (CNN), can classify images and videos. These models trained on large datasets of labeled images and videos to learn the features and patterns that differentiate cyber-bullying from non-cyber-bullying content. A weighted voting scheme is used for the output of the image and video models that can be combined with the output of the text model. Because different models can capture various aspects of the data, using an ensemble deep neural network allows for a more accurate and robust classification of cyber-bullying on Twitter. The ensemble model is better equipped to handle the complexity and variability of cyber-bullying content on Twitter because their outputs are combined. Overall, using an ensemble deep neural network is a promising approach for addressing the problem of cyber-bullying on Twitter and can contribute to creating a safer and more positive online environment.

***Abstract*—The software is created and constructed to address particular issues in the applied field. In this context, there is a need to be aware of the crucial characteristics to assess the quality of software. But not all software requires checking all the quality-of-service parameters, resulting in effort loss and time consumption. Therefore, it is required to develop software quality characteristics recommendation model to address and resolve the issue. The proposed work involved in this paper can be subdivided into three main parts (1) a review of popular software quality models and their comparison to create a complete set of predictable, and (2) the design of an ML-based recommendation model for recommending the software quality model and software quality characteristics (3) performance analysis. The proposed recommendation system utilizes the different software quality of service attributes as well as the software attributes where these models are suitably applied to satisfy the demands. Profiling of applications and their essential requirements have been performed Based on the different quality of service parameters and the requirements of applications. These profiles are learned by machine learning algorithms for distinguishing the application-based requirement and recommending the essential attributes. The implementation of the proposed technique has been done using Python technology. The simulation aims to demonstrate how to minimize the cost of software testing and improve time and accuracy by utilizing the appropriate quality matrix. Finally, a conclusion has been drawn and the future extension of the proposed model has been reported.**

***Keywords*—Recommendation system; software quality model; ML (Machine Learning); quality matrix; software quality characteristics**

I. Introduction

Machine learning provides ease in several real-world applications; in addition, improves the capacity and capability of existing research and methodologies.ML techniques are also used to improve and optimize different process models for improving the cost of employment and productivity[1][2].In this context, software quality evaluation is one of the essential steps. There are several different software quality measuring models currently utilized. These models include several different quality measuring characteristics.

Software quality is an emerging research area in the field of software engineering. The work presented here is relevant to the research around software quality models which gives a better understanding and knowledge of software quality attributes in Software quality models. Achieving software quality assurance requires the use of software quality models [3]. These quality attributes might be used to describe the software's quality. It might be difficult to decide which of the excellent models to utilize [4]. In Addition, software quality models are used for the global assessment of the software product. Therefore, the proposed issue of applying and selecting the appropriate quality matrix is defined here as the recommendation problem. The recommendation engines are the machine learning technique for evaluating the problem's current scenario and suggesting the most suitable solutions for the given set of problems [5].

There are different kinds of recommendation systems available, which will also work as the information filter to reduce the less relevant data and optimize the ranking of the desired set of information [6][7]. The proposed software quality characteristics recommendation model includes the technique of machine learning to learn when, where, and which software characteristic is appropriate for evaluation based on profiling of the software quality of service requirements. In this context, the proposed work is subdivided into the following essential task:

- Examination of different software quality characteristics and models.
- Implement and design a content-based recommendation model to suggest the appropriate quality matrix.
- Study the impact of the software quality characteristic recommendation model over the existing models.

In this section, an outline of the proposed concept for the software quality measuring model is provided. The next section involves the study of different software quality estimation models. Further, the proposed recommendation model has been formulated and its implementation plan will be explained. In addition, based on the implemented model simulations have been carried out and their performance will be reported. Finally, the conclusion has been reached and their future extension plan will be proposed.

The paper is organized as follows: Section II reviews software quality models based on basic and tailored criteria which give a solid foundation in attribute selections. Section III briefly introduces some essential attributes and a proposed software quality characteristics recommendation model is introduced which uses machine learning for recommending the appropriate characteristics for software quality estimation. Section IV describes the used Machine learning algorithms in the proposed model. Section V gives an analysis and validation of the results. Finally, this work is concluded in Section VI where possible future research directions are indicated.

II. Review of Literature

In this study, two types of software quality models are considered. The first one is based on basic software quality models and the second one is based on the tailored software quality models which are described in the below section.

A. *Basic Software Quality Models*

Each of the several software quality models consists of a number of different attributes. Basic quality models denote those models which were developed until 2000. This study needs to explore some essential software quality models and each model has various qualities.

1) *McCall's quality model:* It exposes three task domains.

a) *Operation* in a product refers to its capacity to be easily understood, and able to deliver the desired results. It addresses criteria for correctness, dependability, effectiveness, integrity, and usability.

b) *Revision* in a product is the ability to endure modifications, error rectification, and system adaptation. It includes testability criteria, maintainability, and flexibility.

c) *When* a product is in a transition phase, it means it can accommodate distributed processing in new environments with rapidly changing technology.

The goal was on the relationship between metrics and quality characteristics [3]. The problem is that it is dependent on Yes and No responses, there is no accuracy in the results.

2) *Boehm's quality model:* It adds maintainability to McCall's model [8]. High-level factors are as follows:

a) *Utility* describes efficient, reliable, and easy to use.

b) *Maintainability* describes the ability to modify, testable, and features of understanding.

3) *Dromey's quality model:* Three models have been given by Dromey, i.e., the Requirement model, the design model, and the implementation model. The product properties are given below:

a) *Correctness* assesses if certain principles are broken, along with usability and reliability.

b) *Measures* the effectiveness of a component's deployment in terms of usability, maintainability, efficiency, and reliability.

c) *Descriptive* evaluates the description of a component, about maintainability, reusability, portability, and usability.

d) *Despite* the design quality model considering the development process, architectural integrity is not fully attention Testability is implicitly included. None of the domain-specific properties are discussed. Furthermore, one drawback of the said model is allied with reliability and maintainability, as judging them before the software system is functioning is not practical. [8] [9]

4) *FURPS quality model:* The elements of the FURPS model that are considered [8] [9] are:

a) *Functionality* encompasses capability sets, security, and feature sets.

b) *Usability* includes stability in the user interface view, help (online), user documentation, and materials required in training.

c) *Reliability* focuses on the mean time between failures (MTBF), frequency and strictness of the failure, accuracy, recoverability, and predictability.

d) *Functional* needs like efficiency, speed, availability, throughput, accuracy, resource utilization, reaction time, recovery time, and are constrained by performance.

e) *Testability, extensibility,* adaptability, maintainability, and compatibility are all aspects of supportability. Its failure to consider software portability is one drawback. The model does not include any attributes that are domain specific.

5) *ISO 9126 quality model:* The McCall and Boehm models served as the basis for the ISO model [10][11][12]. It works on four parts quality Model, quality in use metrics, internal quality attribute, and external quality attribute. The attention of that model is to an exploration of attributes into 6 independent characteristics which are reliability, usability, efficiency, functionality, maintainability, and portability. Now attributes are further split into internal quality attributes, which refer to system features that can be assessed without incorporating, and external quality attributes, which refer to assessment by observation while it is being carried out. [13]. This model addresses effectiveness, security, and satisfaction [14].

6) *ISO 25010 quality model:* The modernized version of ISO 9126 is ISO 25010. This approach divides quality into eight smaller sub-characteristics. The ISO-9126 Model serves as the sole foundation for the set of standards. The model adds new features including compatibility and

security. As an extension of portability, it employs the term transferability while conducting its operation.

B. Tailored Software Quality Models

Tailored software quality models were built from the fundamental (basic) software quality models. This model was made with certain individual components. There are various tailored software quality models are there, and selected tailored software quality models are presented below.

1) BERTOA model: It defines the quality attributes for the assessment of Commercial Off-The-Shelf Components. The application of the model is to build Complex software.

2) GEQUAMO model: The breakdown of the sub-layers in this model, known as GEQUAMO (Generic, Multi-layered, and Customizable Model) [15], allows for the flexible inclusion of user requirements. End users can create their models with the aid of that model.

3) ALVARO model: The methodology used in the Alvaro model is essentially used to certify software components and identify quality components. The model involves a framework that may be divided into four sections: components related to the model quality, framework for technical certification, certification process, and framework with metrics. For quality assessment and technical certification, all components are utilized.

4) RAWASHDEH model: Rawashdeh's model is conquered by the Dromey and ISO 9126[16] models. It addresses the genuine requirements of various users. To produce high-quality products four processes are suggested by the said model.

a) Selecting a limited group of quality characteristics, applied using a top-down method, dividing each characteristic into several subordinate characteristics.

b) Examine how internal and external measures differ. This includes characteristics such as requirements or lines of code, as well as external metrics, behavior during testing procedures, and components.

c) Quality attributes for each user must be identified.

d) Any new quality model can be built from ISO 9126, and the Dromey model.

In addition to the above software models S. S. Kamaruddin et al [6] provide a feature subset selection approach to choose the right attributes for software quality assessment to address this dynamic software quality assessment problem. The current models for evaluating the quality of software do not permit dynamic assessment. As new quality attributes surface, they can be incorporated into the model in dynamic software quality evaluation. To establish dynamic software quality evaluation, they concentrated on creating an intelligent technology that can learn and include new quality criteria into the model. Additionally, S. S. Kamaruddin et al [7] introduce a filter-wrapper-based feature ranking method that can learn from and order quality attributes depending on fresh data from software quality assessment instances. The Most Priority of Feature (MPF) score method and the software quality attribute weights learning algorithm make up the suggested feature ranking strategy. The issue of repetition in the rankings of the software quality attribute is not addressed by the present ranking methodologies. The redundancy problem is solved by the suggested method by selecting characteristics with good classification accuracy utilizing classifiers.

III. Proposed Methodology

In this section, a proposed software quality characteristics recommendation model is introduced which uses machine learning for recommending the appropriate characteristics for software quality estimation. The proposed model is aimed at reducing the quality estimation time overhead. But according to the available different quality estimation matrices as discussed in the above section, it has been observed some essential characteristics which are followed by entire models these characteristics are described in Table I.

TABLE I. PROPERTIES OF BASIC AND TAILORED SOFTWARE QUALITY MODELS

Properties	Tailored models	Basic models
Functionality	Yes	No
Maturity	Yes	No
Resource-utilisation	Yes	No
Testability	Yes	No
Compliance	Yes	No
Understandability	Yes	No
Usability	Yes	No
Learnability	Yes	No
Reliability	No	Yes

Therefore, the characteristics available in Table I have been included in our quality matrix. In addition, based on the requirements a list of questions is also included that help to decide the additional quality characteristics requirements.

Key Questions have been prepared with the consultation of IBM India Pvt. Ltd.

Q1. Is the model involving any calculations?

If the software is being developed for performing any calculation, then the following characteristics need to be included:

1. Accuracy
2. Correctness
3. Efficiency

Q2. Is the model involve security, privacy, and communication modules?

If the software involves communication and data security, then the following properties need to be considered.

1. Integrity

2. Fault Tolerance
3. Time Behaviour

Q3. Is the software involved in data collection and analysis?

If yes, then the following characteristics must involve:

1. Human Engg.
2. Analysability

Q4. Is the software utilized by a person who has a new or non-technical background?

If yes, then need to consider the followings:

1. Recoverability
2. Suitability
3. Attractiveness
4. Operability

Q5. Is the software needed to change, modify, or scale shortly?

If yes, then need to consider the followings:

1. Adaptability
2. Changeability
3. Flexibility
4. Modifiability
5. Reusability
6. Operability
7. Suitability

Q6. Does the software need to deploy in multiple places/multiple machines/multiple clients with the same or different configurations?

If yes, then need to consider the followings:

1. Flexibility
2. Installability
3. Maintainability
4. Portability
5. Transferability
6. Configurability
7. Compatibility
8. Reusability
9. Interoperability

Q7. Is software deployed in resource-constrained scenarios?

If yes, then the followings need to include:

1. Stability
2. Resource Utilisation
3. Self Contained
4. Replaceability
5. Manageability

Q8. Is software having many modules which require assistance?

If yes, then the followings need to include:

1) Supportability: To decide the suitable quality of service the proposed model has been demonstrated in Fig. 1. The flowchart of the proposed software quality characteristics recommendation model is presented here in Fig. 2. Additionally, the key components are described in Table I. The proposed model accepts two inputs, namely the project source code and the prepared questionnaire. These questionnaires are prepared based on the activities involved in the project development life cycle. Based on these questionnaires the dataset has been prepared. The Highlight of the dataset is defined in Table II.

The given Table II provides a limited number of dataset instances but provides a structure of the dataset which is used for training. By using a similar method, prepared a total of $2^{n-1} + 1 = 2^{8-1} + 1 = 129$ instances. In this situation for making training with a supervised machine learning algorithm, it is required to decide the class labels of these instances. To calculate class labels of instances, let a project quality requirement can be satisfied with an initial set of software quality characteristics as given in Table I.

This table is denoted as A1. Additionally, the answers to the questions can be denoted as:

$$A_n = \{A1, A2\ldots, A8\} \qquad (1)$$

Each true answer to the questions includes a set of quality characteristics, where A1 is always constant and A1 = True (T). Therefore, the set of attributes for a unique class label can be calculated using:

$$C = A1 \cup Ai \qquad (2)$$

Where Ai is the set of characteristics where i'th question's answer is true.

Some examples of unique class calculations have been given in Table II. Additionally, the dataset has a similar number of classes to predict. The meaning of the class label is defined in Table III.

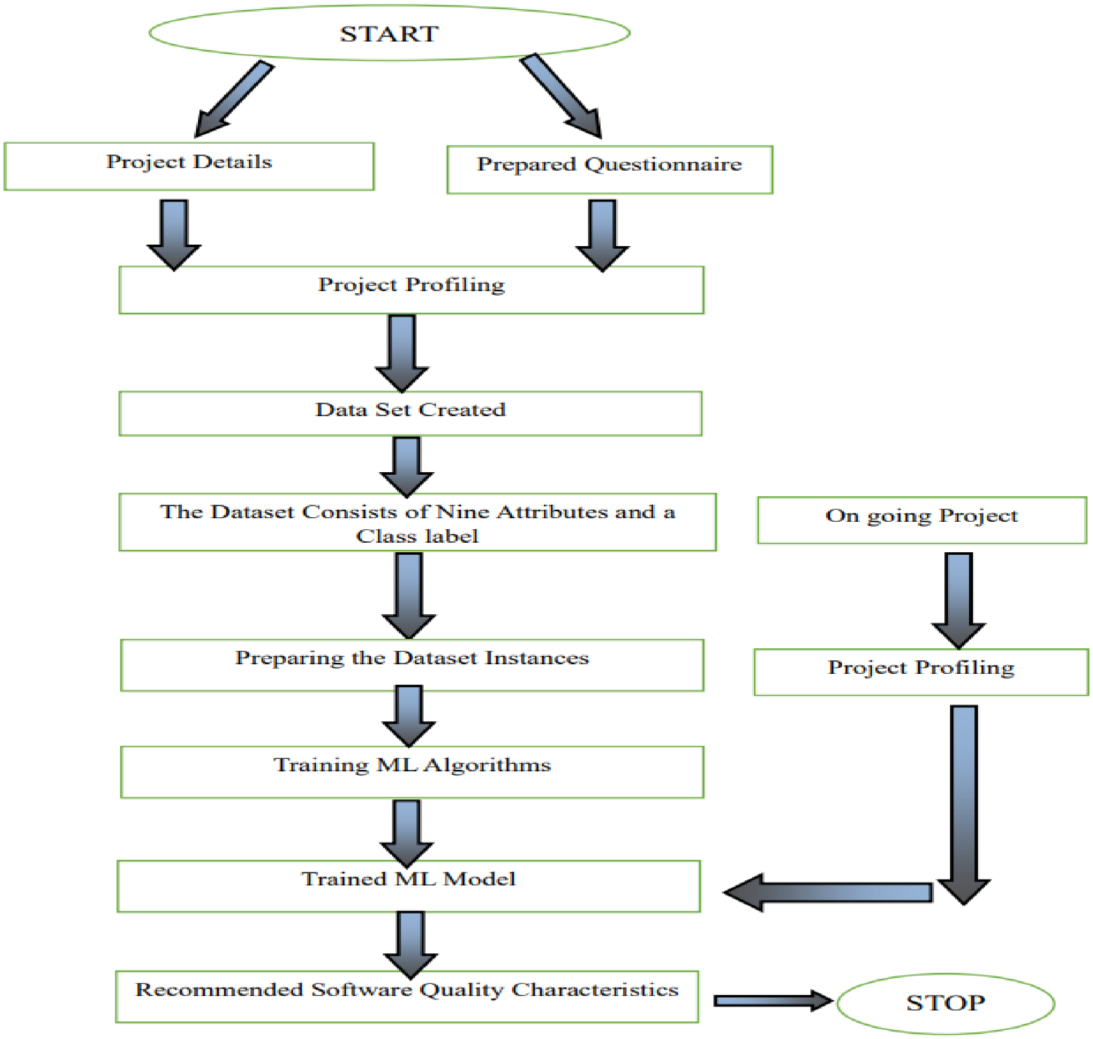

Fig. 1. Flow chart of proposed software quality characteristics recommendation model.

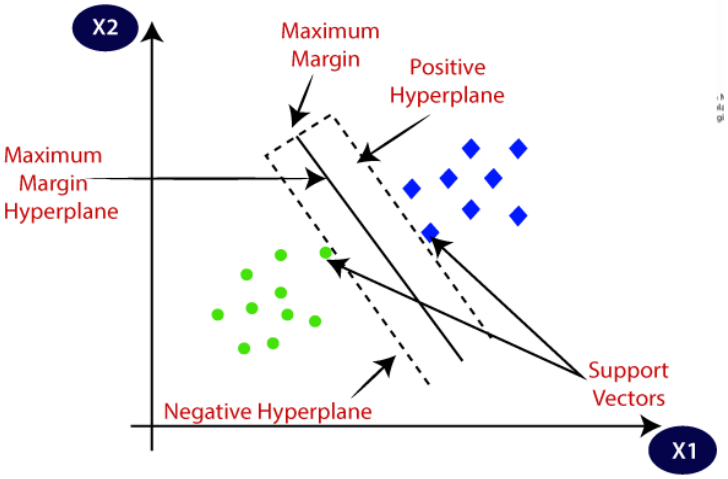

Fig. 2. Support Vector Machine (SVM) classifier diagram.

TABLE II. EXAMPLE OF DATASET USED

A1	Q1	Q2	Q3	Q4	Q5	Q6	Q7	Q8	Class
T	F	F	F	F	F	F	F	F	C1
T	T	F	F	F	F	F	F	F	C2
T	F	T	F	F	F	F	F	F	C3
T	F	F	T	F	F	F	F	F	C4
T	F	F	F	T	F	F	F	F	C5
T	F	F	F	F	T	F	F	F	C6
T	F	F	F	F	F	T	F	F	C7
T	F	F	F	F	F	F	T	F	C8
T	F	F	F	F	F	F	F	T	C9

TABLE III. EXAMPLES OF CLASS LABEL SEQUENCES

Class	Means
C1	$A1$
C2	$A1 \cup A_1 \ if \ A_1 = true$
C3	A1 U A_2 *if* A2 = *true*

The mapping for each class label is prepared in the dataset. In the proposed model, the name given for this process is the profiling of historical projects. Now, it is needed to train machine learning algorithms on the prepared profiles. In this context, five widespread ML algorithms have been used such as K nearest neighbor (KNN), Support vector machine (SVM), artificial neural network (ANN), C4.5 decision tree, and Bayesian.

IV. USED ML ALGORITHMS

A. Support Vector Machine (SVM)

One or more hyperplanes are created by the SVM classifier for regression and classification [17]. The line is used to divide the 2D linearly separable data. The line function is:

$$y = ax + b \tag{3}$$

Here in Equation (3) variable x is renamed with x_1 and y is renamed with x_2 then the line Equation can be defined as:

$$ax_1 - x_2 + b = 0 \tag{4}$$

Now, if define$x = (x_1, x_2)$ and $w = (a, -1)$, then:

$$w \cdot x + b = 0 \tag{5}$$

This is the hyperplane equation. After obtaining the hyperplane, it can be used to create predictions. Hypothesis function h is called a Hypothesis function shown in below Equation (6).

$$h(x_i) = \begin{cases} +1 & if w \cdot x + b \geq 0 \\ -1 & if w \cdot x + b \leq 0 \end{cases} \tag{6}$$

In addition to this SVM, the classifier can also be explored by the below flowchart.

The below Fig. 3 explores the support vector machine and talks about classification and regression. With the help of the SVM algorithm, we may swiftly categorize new data points in the future by determining the optimal line or decision border of n-dimensional space. A hyperplane is the name given to this optimal decision boundary.

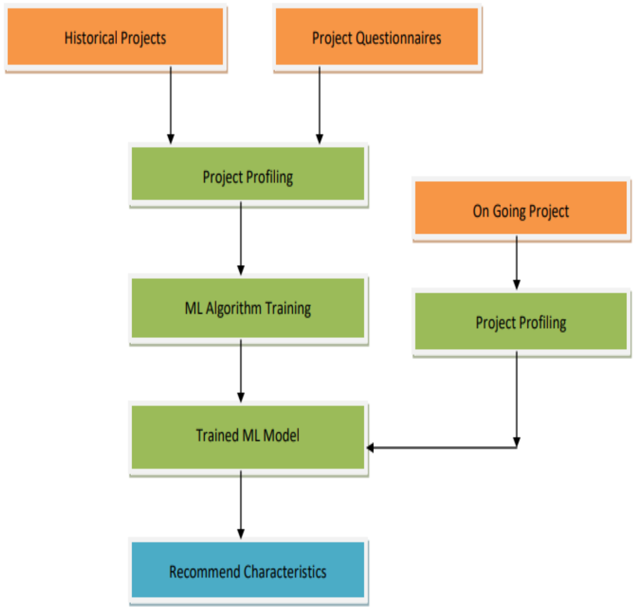

Fig. 3. Proposed software quality characteristic recommendation model.

B. Naive Bayes

A probabilistic classifier is the Naive Bayes classification [18]. The Bayes theorem can be used to derive this. Need to train the Naive Bayes algorithm as supervised learning using observations from nature. Two types of probabilities are given below: Posterior Probability P (H/X) and Prior Probability P (H), Where H is an assumption and X is data. Thus, Baye's Theorem stated: In the below Fig. 4 explore the flow chart of Naive Bayes classification in which every iteration according to the probability value of attributes is updated.

$$\mathrm{P}\left(\frac{A}{B}\right) = \frac{P\left(\frac{B}{A}\right)P(A)}{P(B)} \tag{7}$$

C. K-Nearest Neighbor Classification

The KNN is a traditional tool for both classification and prediction applications [19]. It is a lazy learning classifier. The KNN method has three key parts. First, it calculates the distance between the sample under consideration and each training sample. To calculate the distances mostly Euclidean distance will be used. Euclidean is described by:

$$d(e, f) = \sqrt{\sum_{i=1}^{N}(f_i - e_i)^2} \tag{8}$$

Where q is the query vector and p is the dataset samples.

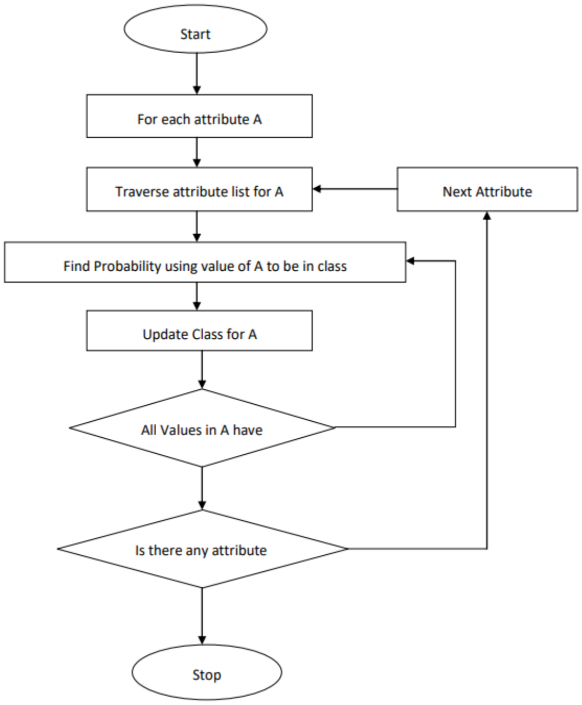

Fig. 4. Flow chart of naive bayes classification.

The method assigns a class label to the sample in question after measuring the distance between the two samples. Based on the k nearest samples from the training sample, the class label is assigned. In this case, the designer will supply the integer k. Not a lot of data is needed for the k-NN to learn. It is the algorithm's main benefit.

In the below Fig. 5 explores the flow chart of the KNN Classifier which is based on the Euclidean distance.

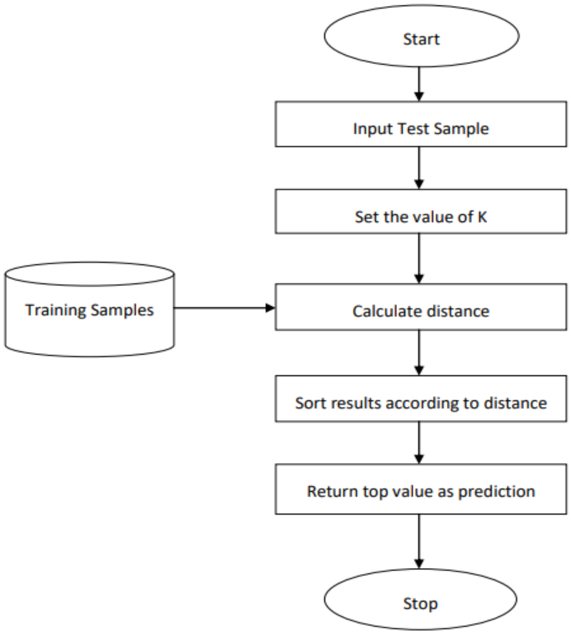

Fig. 5. Flow chart of KNN classifier.

D. Artificial Neural Network (ANN)

In processes where complicated multivariable, non-direct relationships between information and yield factors are present, ANN is becoming a popular showing tool [20].

ANN is primarily a data handling discipline, with its underpinnings in the operational principles of organic neural systems. It is like our cerebrum, which gets the data, translates, and gives the yield. Many preparation elements are known as hubs or neurons make up an ANN. These components are highly coupled with one another and serve as a system to produce standard results. The new features of ANN include its ability to understand instances and infer conclusions from precise information. Additionally, the speed and precision levels are unmatched. The charming element of ANN is no past information or science behind the procedure is required and thus they are alluded to as discovery displays. Also, ANN models can go up against every single semantic variable or parameter that can't be estimated, and ordinary demonstrating techniques are in this manner unacceptable and may neglect to give reasons. Neural networks could classify patterns for which they have not been taught, as well as a high tolerance for noisy input. The neural network's internal weights, which are applied by the transactions employed during the learning process, are a primary issue of the training phase. The predicted output is added to each training transaction for the neural network. The concept of ANN can be visualized below in Fig. 6:

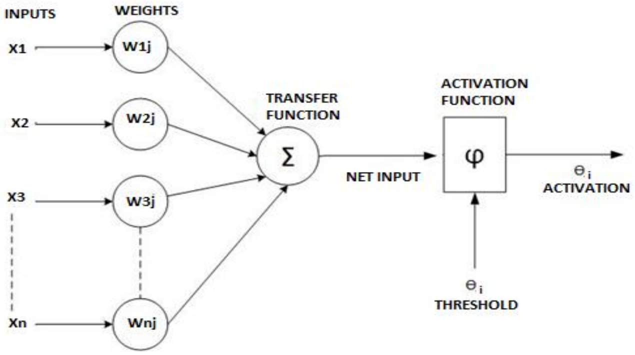

Fig. 6. Mathematical model of artificial neural network.

E. C4.5 Decision Tree

The program must produce decision rules. This is an expansion of the well-known ID3 decision tree [21]. To obtain data partition, entropy as well as information gain is required in the program. Additionally, the highest information gain attribute is selected to create a tree. Partitioned sub-lists are used by the C4.5 method to shape a full decision tree. The algorithm considers the restrictions of the next set. If samples in the dataset cover a similar class, then it forms a leaf node as a decision tree.

1) If the computation of IG (information gain) is not attainable then it creates a node higher up, then the expected value of the class is used by the tree.

2) If a previously undetected class is met, the decision node has been created from a target value.

Fig. 7. Flow chart of decision tree (C4.5 or J48) algorithm.

Before presenting the decision tree's phases, it is necessary to acknowledge the information acquired. Thus, compelled to discuss entropy first, considering that the aftereffect decision tree classifies data into two classes, i.e., P (+ve) and N (-ve). The binary classification of entropy S is given by E(S):

$$E(S) = -P(+ve) \log2 P(+ve) - P(-ve) \log2 P(-ve) \quad (9)$$

The above Figure 7 is exploring the step-by-step process of the C4.5 decision tree algorithm. The best potential characteristic to separate tree branches must be chosen to reduce the depth of the tree when traversing it. It can be seen that the best choice will be the property with the least entropy. As a necessary decrease in entropy in connection to each characteristic during splitting, the information gain can be described. The IG (information-gain) calculates, Gain (E, A) of an attribute A using equation number (10).

$$Gain(E,A) = Entropy(s) - \sum_{n=1}^{v} \frac{E_v}{E} XEntropy(E_v) \quad (10)$$

The system accepts the ongoing project activities-based questions after the algorithm has been trained with the profiled attributes of the projects. Based on the trained machine learning and the input current project questioners the model predicts the most suitable characteristics for the project.

V. Experiments and Result Analysis

Three datasets of the machine learning algorithm's classification problem are used in this experiment. Here the dataset obtained from Kaggle [22] is denoted as Dataset 1, the dataset obtained from GitHub [23] is given as Dataset 2 and the prepared dataset is denoted as Dataset 3. The precision, recall, and f-score are calculated based on class wise, and then the mean of the performance is calculated. The performance of the model is also reported using the bar graph in Fig. 8. Fig. 8(A) demonstrates the precision of the proposed model, 8(B) shows the recall, 8(C) shows the f-score and finally Fig. 8(D) shows the accuracy of the presented model. The performance demonstrates the comparison of five different machine learning algorithms for predicting the quality characteristics as a recommendation of the quality characteristics. According to the obtained performance of the model, support vector machine (SVM) and artificial neural network (ANN) is providing higher performance as compared to C4.5, KNN, and Bayesian. But the Support vector machine has a higher amount of time complexity. Thus, it is suggested to be utilizing the ANN as the final machine learning algorithm which is suitably worked with the proposed recommendation system.

VI. Conclusion and Future Work

Concerning the criteria of the project, the presented investigation aims to produce an intelligent model that offers software quality characteristics. These recommendations are based on the involved activities in the project. These activities are summarized as questionnaires during different software development process life cycles. The project source code and documentation are utilized with the proposed recommendation system to analyze. The past project's quality assurance characteristics were utilized to develop an ML model to predict the desired attributes. The ML algorithm needs to train with a limited set of sequences for predicting the possible attributes to evaluate the software. Here, the suggested model has been evaluated using five machine-learning methods across three distinct datasets. Accuracy, F-score, precision, and recall are used to evaluate performance. A suggested model demonstrates higher prediction accuracy which means that model successfully be able to serve as the software quality characteristics recommendation model. Additionally, the model is also helpful to lower expenses and increase the revenue of software development companies.

Soon the following future extension has been proposed for investigation:

1) Apply real-world data to evaluate the performance of the proposed model.

2) Prepare detailed questionnaires for each stage of software development which influences the characteristics of the software quality testing matrix.

3) To enhance the model performance, can apply deep learning techniques.

Abstract—**Face detection and mask detection are critical tasks in the context of public safety and compliance with mask-wearing protocols. Hence, it is important to track down whoever violated rules and regulations. Therefore, this paper aims to implement four deep learning models for face detection and face with mask detection: MobileNet, ResNet50, Inceptionv3, and VGG19. The models are evaluated based on precision and recall metrics for both face detection and face with mask detection tasks. The results indicate that the proposed model based on ResNet50 achieves superior performance in face detection, demonstrating high precision (99.4%) and recall (98.6%) values. Additionally, the proposed model shows commendable accuracy in mask detection. MobileNet and Inceptionv3 provide satisfactory results, while the proposed model based on VGG19 excels in face detection but shows slightly lower performance in mask detection. The findings contribute to the development of effective face mask detection systems, with implications for public safety.**

Keywords—Object detection; deep learning; detection; face detection; mask detection; convolutional neural network

I. Introduction

Computer vision is a rapidly advancing field that encompasses a wide range of technologies aimed at enabling machines to perceive and interpret visual information, similar to how humans do. One crucial task within computer vision is face detection, which involves locating and identifying human faces in digital images or video streams. Face detection has gained significant attention and importance due to its wide-ranging applications in various domains, including surveillance systems, biometric authentication, facial recognition, human-computer interaction, and social media analysis [1]. Over the years, researchers have made remarkable progress in developing sophisticated face detection algorithms that exhibit high accuracy and robustness. Despite the progress made in general target detection algorithms across various domains, the efficacy of face mask detection techniques remains constrained [2]. In response, researchers have directed their efforts towards this area, employing the "you only look once v2" (YOLOv2) algorithm to devise detection models. Furthermore, advancements have been made by leveraging the YOLOv3 algorithm, which facilitates enhanced feature extraction through an optimized way [3].

However, these challenges arise due to variations in lighting conditions, occlusions, pose variations, complex backgrounds, and scale variations. Lighting variations can lead to significant changes in facial appearance, making it challenging to detect faces consistently. Occlusions, such as glasses, facial hair, or partial face obstructions, further complicate the task by hiding crucial facial features. Additionally, face detection algorithms must handle pose variations, where faces may be rotated, tilted, or viewed from different angles. Complex backgrounds with cluttered scenes pose another challenge, as it becomes difficult to differentiate faces from the surrounding environment[4]. Similarly, scale variations, caused by the varying distances between the camera and the subjects, necessitate robust face detection algorithms that can handle faces of different sizes are required [5].

Over the years, researchers have proposed various face detection techniques, each aiming to address the challenges mentioned above and improve the accuracy and efficiency of face detection algorithms. Early approaches utilized handcrafted features and traditional machine-learning-algorithms, such as Haar cascades and Histogram of Oriented-Gradients (HOG), to detect faces. These methods achieved reasonable results but had limitations in handling pose variations and complex backgrounds. In recent years, the advent of deep learning, particularly convolutional neural networks (CNNs), has revolutionized the field of face detection. CNN-based architectures, such as the Viola-Jones framework, Single Shot MultiBox Detector (SSD), and Faster R-CNN, have demonstrated superior performance in face detection tasks. These models leverage the power of deep learning to automatically learn discriminative features from large-scale datasets, enabling them to handle various challenges faced in face detection. Notably, the use of region-based convolutional neural networks (R-CNN) has greatly improved accuracy by combining region proposals and convolutional networks, allowing for more precise localization of faces [6].

Other researcher improved the YOLOva and made that the YOLO-network generates predictions for bounding boxes in each grid of an image with a size of G×G pixels. However, the network encounters challenges in detecting smaller objects since each bounding box can only be assigned a single class during prediction. The primary issue with YOLO arises from its limitations in accurately localizing objects, particularly when dealing with bounding boxes of unusual ratios [7]. On the other hand, in the realm of face mask detection, various transfer learning approaches have been employed to address the challenges encountered in real-world scenarios. One such method involves utilizing a pre-trained InceptionV3 model as a transfer learning technique to discern individuals wearing or not wearing masks [3]. For instance, the author in [1] employed a cascading approach using Convolutional Neural Networks (CNNs) to detect faces that are covered with masks. In recent advancements, a dedicated framework called the Retina Face Mask network has been developed to enable accurate and efficient recognition of face masks. Various experiments have been conducted to devise an automated technique for determining whether an individual is wearing a face mask or not. Real-time detection of facial masks has been achieved using the YOLOv3-technique and the Haar-cascading-classifier, but the challenges are remains constrained [3].

Although face detection and recognition, particularly in the presence of masks, pose significant challenges and have been the subject of extensive research in recent years, this research aims to improve the detection performance of masked and unmasked faces, with a specific focus on face masks. The problem of face mask-detection in the fields of image-processing and computer vision is exceptionally complex. The primary objective of this study is to enhance public safety by employing deep learning techniques to identify individuals wearing or not wearing masks in public areas. The developed mask detector can play a crucial role in ensuring our protection. Additionally, witnessing the global impact of the COVID-19 pandemic further motivates the exploration of machine learning techniques to address the real-world problem of habitual mask-wearing when venturing outdoors. Hence, the proposed approach in this study utilizes transfer learning, specifically applying the pre-trained MobileNetV2, RestNet50, InceptionV3 and VGG19 model for fine-tuning the face mask detection task.

II. Related Work

Face detection is a fundamental task in computer vision that involves locating and identifying human faces in digital images or video streams. Over the years, researchers have made significant advancements in developing accurate and robust face detection algorithms [8]. Early approaches in face detection primarily relied on handcrafted features and traditional machine learning algorithms. Author [9] proposed one of the seminal methods, known as the Viola-Jones framework, which utilized Haar-like features and a cascade classifier for rapid face detection. This approach laid the foundation for subsequent advancements in face detection. However, these methods had limitations in handling pose variations, occlusions, and complex backgrounds. The advent of deep learning, particularly convolutional neural networks (CNNs), revolutionized face detection. Researchers explored various CNN architectures for accurate and robust face detection. For instance, author [10] proposed the Single Shot MultiBox Detector (SSD), which combined a deep CNN with a set of anchor boxes for efficient face detection. This approach achieved excellent performance in Region-based convolutional neural networks (R-CNNs) further improved the accuracy of face detection. Author [11] introduced the Faster R-CNN framework, which integrated a region proposal network with a CNN-based object detection network. This method enabled precise localization of faces and achieved state-of-the-art performance in face detection tasks. Subsequent research efforts focused on enhancing the speed and efficiency of R-CNN-based methods, leading to variants like Fast R-CNN. Despite the advancements in face detection techniques, several challenges persist. Variations in lighting conditions pose a significant challenge as they can affect the appearance of faces [12].

To address this, author [13] proposed an illumination-robust face detection method that utilized color normalization and multiple thresholds to handle lighting variations. Occlusions, such as glasses, facial hair, or partial face obstructions, present another challenge. Author [14] introduced a method that employed a deformable part model to handle occlusions and achieve accurate face detection. Pose variations also pose challenges, as faces may be rotated, tilted, or viewed from different angles. Author [15] proposed a pose-aware face detection approach that utilized pose estimations to improve detection accuracy.

Meanwhile, complex backgrounds with cluttered scenes make it difficult to differentiate faces from the surrounding environment. Author [8] addressed this challenge by proposing a context-aware face detection method that leveraged contextual cues to enhance the accuracy of face detection in complex scenes. Additionally, scale variations, caused by the varying distances between the camera and the subjects, require robust face detection algorithms. Similarly, author [16] proposed a scale-aware face detection method that utilized a multi-scale convolutional network to handle faces at different sizes and face localization. In face localization, the goal is to figure out where and how big a certain number of faces are (usually one). In general, there are two ways to find facial parts in a digital image: the feature-based approach and the image-based approach. The feature-based approach tries to pull out parts of the image and compare them to what is known about the face. While image-based methods try to find the best match between the images used for training and the ones used for testing. People often use the following ways to find faces in a still image or a video sequence:

A. Feature based Approaches

Feature-based approaches for face mask detection leverage the distinctive visual characteristics and patterns associated with the presence or absence of masks. These methods primarily rely on handcrafted features and machine learning algorithms to classify faces as masked or unmasked. Some commonly used for features approaches include active shape model and Low level model [11]. And it can be classified by active shape and low level analysis.

The Active Shape Model (ASM) focuses on intricate, flexible aspects, including how features appear and behave. Finding landmark points in a picture that determine the form of any statistically modelled object is the primary objective of ASM. For instance, the eyes, lips, nose, mouth, and eyebrows were removed from a photograph of a person's face. An ASM's statistical face model is created using photos that include hand-marked landmarks during the training process. Three categories of ASMs are distinguished: templates that may alter form, point distribution models (PDMs), and snakes. The first form to use an active contour is known as a snake. To indicate the margins of the head, snakes are employed. A snake must first be positioned near to a head barrier in order to finish the mission. It then changes into the form of a head after scanning the surrounding edges. Snakes develop by reducing the "esnake" energy function, which is similar to how physical systems operate [17].

Internal energy is the component that derives from the snake's own characteristics and demonstrates how it has evolved organically. Snakes often undergo change by either contracting or growing. The contours might diverge from their normal development and finally take on the form of adjacent features—the head boundary at equilibrium—because the external energy resists the internal energy. There are two key considerations while creating snakes: which energy phrases to utilise and how to use the least amount of energy. Elastic energy is often referred to as "internal energy". The snake's internal energy modifies the distance between its control points. It gains a shape as a result, which acts as an elastic band and causes it to shrink or expand. Image characteristics, on the other hand, rely on external energy. To determine how to consume the least amount of energy, optimisation methods like steepest gradient descent are applied. For quick iteration, there are other greedy algorithms. There are various drawbacks to snakes, such as how often their edges get caught on false image features and how they can't be utilised to eliminate non-convex features [18].

For instance, author [19] introduced the Constrained Local Models (CLM), which combined ASM with a local appearance model to handle non-rigid facial deformations but it has still some mistakes about the edges. CLM utilized a patch-based appearance model to capture local appearance variations and refine the shape estimation iteratively, leading to improved accuracy in face detection and landmark localization. Another significant contribution is the Supervised Descent Method (SDM) proposed by author [20]. SDM incorporated a cascade regression framework with ASM to refine the shape estimation progressively. This method achieved state-of-the-art performance in face detection and facial landmark localization, particularly in real-time scenarios.

On the other hand, low-level analysis models have significantly contributed to the advancement of face detection by extracting relevant low-level visual features. The evolution of these models, from handcrafted features to deep learning-based approaches, has led to improved accuracy and robustness in face detection. Challenges such as variations in lighting conditions, complex backgrounds, and occlusions continue to be addressed through illumination normalization techniques, context-aware models, and adaptive feature learning. Several notable research contributions have advanced the field of low-level analysis models in face detection. For instance, author [21] introduced the DeepFace model, which used a deep CNN to learn discriminative facial features. DeepFace achieved remarkable performance in face detection and recognition, particularly in handling pose variations and challenging lighting conditions. Another significant contribution is the FaceBoxes method proposed by [22]. FaceBoxes utilized a lightweight CNN architecture specifically designed for face detection tasks but have some problem with color.

Meanwhile, the color of the skin serves as the face's foundational feature. There are many benefits to using skin tone as a face-tracking feature. Facial traits other than color are processed far more slowly than the former. Color may be seen from any direction under specific lighting circumstances. Since only a translation model is required for motion estimation, this feature greatly simplifies the process. There are several obstacles when trying to use color as a feature for tracking human faces, such as the fact that the color representation of a face obtained by a camera can be affected by things like lighting conditions and the motion of the object being photographed [23].

B. Image based Approaches

Image-based approaches in the field of face detection refer to the methods and techniques that rely on analyzing and processing images to detect the presence and location of human faces. These approaches utilize the visual information present in images, such as pixel values, colors, textures, edges, and spatial relationships, to identify regions that potentially contain faces [3].

One of the examples of images based approaches is Neural network-based image analysis approaches that have revolutionized the field of face detection by leveraging the power of deep learning to extract meaningful features from images and accurately detect faces. For instance, author [24] introduced the Deep Convolutional Network Cascade (DCNC) for face detection. DCNC utilized a cascade architecture of CNNs to achieve high accuracy while maintaining real-time performance. Multi-task Cascaded Convolutional Networks (MTCNN) is another significant contribution in the field. Author [25] proposed MTCNN, which simultaneously performs face detection, facial landmark localization, and facial attribute classification using cascaded CNNs. MTCNN achieved state-of-the-art performance in face detection tasks, particularly for faces with various poses, scales, and occlusions.

Meanwhile, one-Shot detectors have gained attention for their efficiency and effectiveness in face detection. These detectors aim to accurately locate faces in a single pass of the neural network, enabling real-time performance. One notable contribution in this area is the Single Shot MultiBox Detector (SSD) introduced by [26]. SSD utilizes a single neural network to perform face detection by predicting bounding box locations and class probabilities at multiple scales. This approach achieved high accuracy while maintaining fast inference speed. Another notable contribution is the RetinaFace model proposed by [27]. RetinaFace utilized a single-stage dense face localization approach that incorporated anchor-based and anchor-free strategies to handle faces with various scales and poses.

Similarly, one auto-associative network detects frontal-view faces, and another detects faces turned 60 degrees left or right. Then, a face detection system employing PDBNN was introduced by [28]. PDBNN is like an RBF network with probabilistic learning rules. The system consists of two stages: pre-processing and processing. In contrast to that, a deep-dense face detector was proposed by [29] requires that no single model can annotate poses or landmarks and recognize faces in many orientations.

On the other hand, Support Vector Machine (SVM) has been widely employed in the field of face detection due to its ability to effectively handle complex classification tasks. For example, author [30] introduced the "Support Vector Machines Applied to Face Detection" (SVMAFD) method, which showcased the effectiveness of SVMs for face detection. The authors presented an SVM-based approach that utilized a set of carefully designed features to classify image sub-windows as face or non-face. SVMAFD achieved promising results, demonstrating the potential of SVMs in face detection. Similarly, to that, author [31] proposed an improved SVM-based face detection method that incorporated feature selection techniques. The authors employed a combination of Haar-like features and Local Binary Patterns (LBP) and applied Recursive Feature Elimination (RFE) to select the most discriminative features. Their approach achieved competitive performance in face detection tasks, highlighting the importance of feature selection for SVM-based methods.

III. Proposed Model

This research framework is developed based on a benchmark for object-recognition presented in reference [32]. As it can be seen from Figure 1, it shows that how this benchmark divides object-recognition tasks into training, classification, and detection tasks. Training and deployment use separate pipelines to assure surveillance device compatibility. The training process creates an impartial customised dataset and fine-tunes all models. Face identification and extraction follow image/real-time video frame extraction in the deployment process.

Fig. 1. Proposed methodology.

The classification task corresponds to a baseline convolutional-neural-network (CNN) that extracts information as data from input images and generates a feature map in the baseline. In this framework, transfer learning is applied on the classification, leveraging the learned attributes of a pre-trained and powerful CNN to extract new features for the model. To achieve optimal performance in facemask detection, an extensive backbone building strategy is conducted, utilizing four popular pre-trained models: MobileNet, ResNet50, Inception and VGG19. The novelty of the proposed work lies in the training task, an intermediate module that performs various preprocessing tasks before the actual image classification.

In the deep-learning neural network, the detection acts as an identity detector or predictor. The trained facemask classifier acquired by transfer learning is used in the proposed architecture to recognise faces with or without masks. The ultimate goal is to deter people from wearing face masks in public spaces by identifying those who do so. The following steps may be conducted in line with administrative or governmental policies. Using OpenCV 0.20, similar to how previous studies utilised it [33], an affine transformation approach is used to detect facial characteristics due to differences in face size and orientation inside cropped areas of interest (ROI). This guarantees correct identification despite variations in face features. The following points provide a thorough explanation of each job in the proposed framework.

A pre-trained under supervision is the first step. On the initial biassed MAFA dataset, the CNN model underwent discriminative pre-training. The free Caffe Python package was used for the pre-training procedure [33] same as this author. In order to ensure that the model learns generalizable features and to enable better performance and faster convergence on the target task with little labelled data, this pre-training step aids the model in capturing general knowledge about the data distribution and extracting high-level representations.

A finite-turning of pre-trained is the second step. Due to its improved performance compared to other classification techniques, deep neural networks are used in this research to identify facemasks. Deep neural network training, however, is a time- and resource-intensive process that needs a lot of computing power. Transfer learning based on deep learning concepts is used to overcome these issues and produce quicker and more affordable training. Transfer learning enables the transfer of learnt information from an existing neural network to a new model in terms of the parameter weights. Even when trained on a modestly sized dataset, the new model performs much better thanks to this method. ImageNet, a large dataset with over 14 million photos, has been used to train a number of pre-trained models, including MobileNet and ResNet50. For this framework, the pre-trained models for facemask classification include MobileNet, ResNet50, Inceptionv3, and VGG19. Each of them has five more layers added to the final layer to refine it. These recently added layers are composed of a flattening layer, a dense ReLU layer with 128 neurons, an average pooling layer with a pool size of 5x5, a dropout layer with a rate of 0.4, and a deciding layer that uses the softmax activation function for binary classification.

Finding the expected face and determining which faces were found wearing masks or not is done in the final step. Following face recognition, the faces sans masks are individually fed into a neural network to investigate the identity of the person, paying particular attention to those who deviate from the face-mask norms. However, a fixed-sized input is needed for this stage. One method to meet this criterion is to resize the face inside the bounding box to 96x96 pixels which we done it. However, if the face is facing in a different direction, there may be a problem with this technique. A simple solution is provided by the use of an affine transformation approach to address this problem. This method resembles the deformable part models proposed in [34] in certain ways were also used to tackle it.

IV. Results and Discussions

The upcoming sections will illustrate the dataset description followed with its discussion on proposed models in term of face detection and face with mask detection.

A. *Dataset Description*

The MAFA (Multi-Attribute Facial Action) dataset is a facemask-centric dataset that has been widely used in the field of computer vision, particularly for tasks related to facemask detection and analysis. The MAFA dataset consists of a large collection of facial images that are annotated with various attributes related to facial appearance, including the presence or absence of a facemask. The dataset was specifically curated to address the need for comprehensive and accurate facemask detection in real-world scenarios, such as surveillance systems or public health monitoring.

The MAFA dataset is composed of over 35,000 facial images captured from diverse sources, including different genders, age groups, and ethnicities. This diversity ensures that the dataset covers a wide range of facial variations, which is essential for training robust facemask detection models. Each facial image in the MAFA dataset is manually annotated with multiple attributes, including the presence or absence of a facemask, gender, age group, and other facial attributes. These annotations provide valuable ground truth information for various facial analysis tasks. To ensure unbiased performance of the facemask detection models, the MAFA dataset undergoes an unbiased customization process during the training phase. This process involves carefully selecting and balancing the training samples to minimize any biases that may arise due to the dataset's composition.

B. *Identify Comparing MobileNet, ResNet50, Inceptionv3 and VGG19*

The four models were evaluated for face detection and mask detection tasks as a separated way. The models include RetinaFaceMask based on MobileNet, RetinaFaceMask model based on ResNet50, RetinaFaceMask based on Inceptionv3, and RetinaFaceMask model based on VGG19. The performance of each model was assessed in terms of precision and recall for both face detection and mask detection.

RetinaFaceMask based on MobileNet in term of Face Detection, the model achieved a precision of 84.0% and a recall of 96.0%. This indicates that the model can effectively detect faces, with a relatively high recall rate, capturing a majority of the true faces present in the images. In term of Mask Detection, the model achieved a precision of 81.3% and a recall of 88.2%. This suggests that the model performs reasonably well in detecting whether individuals are wearing masks or not, with a good balance between precision and recall.

On the other hand, the proposed model based on ResNet50 in term of Face Detection has demonstrated excellent performance in face detection, achieving a high precision of 99.4% and a recall of 98.6%. These results indicate that the model is highly accurate in detecting faces, with a low false positive rate and a high true positive rate. Meanwhile, in term of Mask Detection, the model also showed strong performance in mask detection, with a precision of 98.83% and a recall of 98.5%. These results indicate that the model can effectively distinguish between masked and unmasked individuals, with a high level of accuracy and recall.

Similarly, RetinaFaceMask based on Inceptionv3 in term of Face Detection has also achieved a precision of 80.0% and a recall of 91.4% in face detection. Although the precision is relatively lower compared to other models, the model shows a good recall rate, capturing a high percentage of faces in the images. However, in term of Mask Detection, the model achieved a precision of 92.1% and a recall of 86.3%. This suggests that the model performs well in detecting masks, with a higher emphasis on precision compared to recall.

Final model RetinaFaceMask based on VGG19 in term of Face Detection and it also demonstrated strong performance in face detection, achieving a precision of 96.4% and a recall of 98.2%. These results indicate that the model can accurately detect faces, with a relatively low false positive rate and a high true positive rate. Meanwhile, in term of Mask Detection, the model achieved a precision of 86.7% and a recall of 90.2%. This suggests that the model can effectively distinguish between masked and unmasked individuals, with a good balance between precision and recall. It can be seen from Table 1 for all the precision and recalls of the four models.

TABLE I. The Performance of Four Models

Models	**Face Detection**		**Mask Detection**	
	Precision	Recall	Precision	Recall
	(%)	(%)	(%)	(%)
MobileNet	84.0	96.0	81.3	88.2
ResNet50	99.4	98.6	98.83	98.5
Inceptionv3	80.0	91.4	92.1	86.3
VGG19	96.4	98.2	86.7	90.2

In general, in term of Face Detection and mask detection, the ResNet50 model outperformed the other models, achieving the highest precision and recall values. This indicates that the ResNet50 model is highly accurate in detecting faces, with a low rate of false positives and false negatives. It also demonstrated superior performance in mask detection, with high precision and recall values. This suggests that the ResNet50 model is effective in accurately identifying individuals wearing masks. This indicates its potential as a robust and accurate model for detecting mask/non-mask faces. However, further analysis and comparisons with existing models are necessary to evaluate its performance in relation to other state-of-the-art face mask detection models.

C. *Output of Faces Detetction Result*

Here is the output of detected faces while wearing mask or not wearing mask as it can be seen from Figure 2 and Figure 3. In order to determine the best model for detecting mask/non-mask faces using transfer learning, we compare the performance of MobileNet, ResNet50, Inceptionv3, and VGG19 models based on their given precision and recall from the provided results, it can be observed that the ResNet50-based proposed model achieves the highest accuracy in both face detection and mask detection tasks as already mentioned. With a precision of 99.4% and a recall of 98.6% for face detection, and a precision of 98.83% and a recall of 98.5% for mask detection, the ResNet50 model demonstrates superior performance in accurately detecting faces and distinguishing between masked and unmasked individuals. These results suggest that the ResNet50 model is the best fit as a backbone for detecting mask/non-mask faces using transfer learning as it can be seen from Figure 2.

On the other hand, MobileNet, Inceptionv3, and VGG19 models were classified wrong in the figure 4 and they marked not wearing a mask that someone who is wearing a mask while ResNet50 has marked the same Figure3 correctly. This also shows that in term of backbone detection for mask/non-mask faces, ResNet50 is outperformed others.

Meanwhile, to assess the utility of identity prediction in the proposed model, further details regarding identity prediction are done. However, it can be evaluated by examining the true positives, false negatives, false positives, and true negatives associated with identity prediction in the provided confusion matrices. Additionally, considering performance metrics such as precision, recall, and other relevant indicators specific to identity prediction can provide insights into its utility in the proposed model and upcoming table 1 illustrates that point.

The confusion matrices provide a detailed overview of the performance of each model in terms of face detection and mask detection as it can be seen from Table 2. These matrices reveal the true positives (TP), false negatives (FN), false positives (FP), and true negatives (TN) for each model. Starting with the RetinaFaceMask model based on MobileNet, the face detection results demonstrate a precision of 84.0% and recall of 96.0%. This indicates that the model accurately detects 84.0% of the faces present in the dataset, while 16.0% of the faces are missed. The mask detection performance shows a precision of 81.3% and recall of 88.2%, implying that the model correctly identifies 81.3% of the masked faces, but misclassifies 18.7% of the faces as masked.

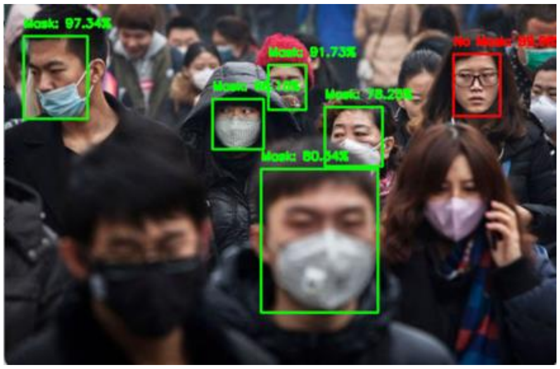

Fig. 2. Captured with mask.

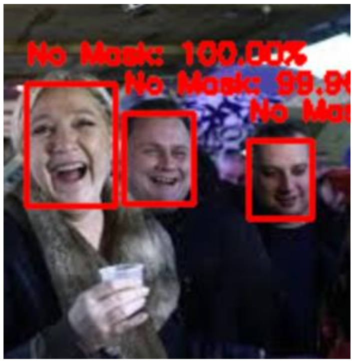

Fig. 3. Captured without mask.

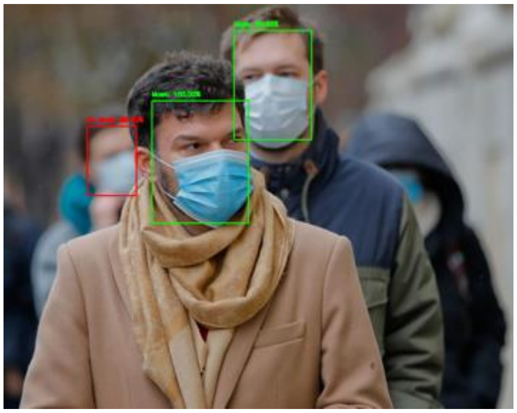

Fig. 4. Captured with / without mask.

TABLE II. CONFUSION MATRICS OF FOUR MODELS

Models		Face Detection		Mask Detection	
		Predicted Positive	Predicted Negative	Predicted Positive	Predicted Negative
MobileNet	Actual Positive	84.0% (4420)	16.0% (234)	81.3% (4420)	18.7% (234)
	Actual Negative	2.2% (108)	97.8% (4713)	2.2% (108)	97.8% (4713)
ResNet50	Actual Positive	99.4% (4680)	0.6% (243)	98.83% (4680)	1.17% (243)
	Actual Negative	2.8% (132)	97.2% (4609)	2.8% (132)	97.2% (4609)
Inceptionv3	Actual Positive	80.0% (4798)	20.0% (203)	92.1% (4798)	7.9% (203)
	Actual Negative	3.4% (127)	96.6% (4530)	13.7% (127)	86.3% (4530)
VGG19	Actual Positive	96.4% (4374)	3.6% (214)	86.7% (4374)	13.3% (214)
	Actual Negative	3.8% (187)	96.2% (4760)	3.9% (187)	96.1% (4760)

Moving on to the proposed model based on ResNet50, the face detection outcomes exhibit an exceptional precision of 99.4% and recall of 98.6%. This indicates that the model effectively identifies almost all faces present in the dataset with a high precision. The mask detection performance is also impressive, with a precision of 98.83% and recall of 98.5%, indicating accurate classification of the presence or absence of masks. The RetinaFaceMask model based on Inceptionv3 demonstrates a face detection precision of 80.0% and recall of 91.4%. Although the recall is relatively high, the precision suggests that the model may incorrectly detect some non-facial objects as faces. For mask detection, the precision is 92.1%, indicating accurate identification of masked faces, but the recall is 86.3%, suggesting some misclassification of masked faces as non-masked.

Lastly, the proposed model based on VGG19 exhibits a face detection precision of 96.4% and recall of 98.2%. These results indicate accurate and comprehensive face detection, capturing a large majority of the faces with high precision. In terms of mask detection, the precision is 86.7%, suggesting a relatively high accuracy in identifying masked faces. The recall of 90.2% implies that some masked faces may be misclassified as non-masked. Based on the comparison of the models, the proposed model based on ResNet50 emerges as the most suitable backbone for detecting mask/non-mask faces using transfer learning. It demonstrates outstanding performance in both face detection and mask detection, achieving high precision and recall scores. This indicates its capability to accurately identify faces and classify them based on the presence of masks.

V. Conclusion

In conclusion, the performance evaluation of the four models, namely RetinaFaceMask based on MobileNet, Proposed model based on ResNet50, RetinaFaceMask based on Inceptionv3, and proposed model based on VGG19, provides valuable insights into their effectiveness in the context of face detection and mask detection tasks. Based on the results obtained, it can be concluded that the proposed model based on ResNet50 outperforms the other models in terms of face detection precision and recall. This indicates that ResNet50 serves as a robust backbone for accurately detecting faces in various scenarios. Furthermore, the proposed model demonstrates high precision and recall values for mask detection, indicating its capability to effectively identify individuals wearing or not wearing masks. This is crucial for enforcing mask-wearing protocols and ensuring public safety. Comparatively, the RetinaFaceMask based on MobileNet and the RetinaFaceMask based on Inceptionv3 show relatively lower performance in face detection and mask detection tasks. Although they provide satisfactory results, they exhibit slightly lower precision and recall compared to the proposed model based on ResNet50. In terms of computational speed, a detailed analysis was not provided in the given information, which limits our ability to draw definitive conclusions regarding the models' efficiency. Future studies should consider evaluating the computational performance of these models to gain a comprehensive understanding of their real-time applicability.

Abstract—**Autonomous vehicles are currently gaining popularity in the future mobility ecosystem. The development of autonomous driving systems is still challenging in the research area of image processing and signal processing. Extensive research work was conducted on various traffic sign datasets. It achieved respectable results, but a robust network structure is still needed to develop to improve the traffic sign recognition (TSR) system. In this research work, there is an alternative approach to designing deep learning models, which are implemented in TSR systems. The proposed deep learning model was also tested with different datasets to obtain the generalized model. The proposed model was based on a convolutional neural network (CNN), and Bayesian Optimization optimizes the model's hyperparameters to find the best hyperparameters grid. After that, the optimized CNN model was used to classify the traffic sign images from three different datasets, including the German traffic sign recognition benchmark (GTSRB), the Belgium traffic sign classification (BTSC) dataset, and the Chinese traffic sign database, achieving the average accuracy scores of 99.57%, 99.15%, and 99.35%, respectively.**

Keywords—Autonomous driving; convolutional neural network; deep learning; traffic sign; optimization

I. INTRODUCTION

Road traffic signs are fundamental and the most frequent visual tools to control traffic on the road, which are also used to communicate information to road users [1]. Thus, self-driving technologies use this road traffic information to control and drive an autonomous vehicle. For this reason, traffic sign recognition (TSR) systems have become quite popular and have been adopted in many engineering fields over the last decade [2]. Many applications are driven by this TSR system, such as advanced driver assistance systems (ADAS) [3], autonomous driving systems [4], and mobile mapping [5]. Moreover, many proposed problems related to the TSR system have been studied in recent research. In previous research [6], authors proposed two different models to identify factors affecting the retro-reflectivity of traffic signs. However, some authors found an overview of the interaction between road infrastructure and automated driving systems [7]. Additionally, the proposed problem of traffic sign recognition system problem has been developed by different approaches such as color-based, shape-based, and deep learning-based methods [8]. The deep learning-based method was the most popular because of its speed and accuracy [9].

Convolutional neural networks (CNN), one of the deep learning methods, can adjust the data without making any explicit specification, and CNN can also learn features efficiently from many samples without any preprocessing [8][9]. Some researchers applied CNN model to detect and recognize Thai traffic signs and achieved an average precision score of 0.93 [10]. An end-to-end convolutional network inspired by YOLOv2 was proposed and evaluated according to their Chinese traffic sign dataset (CTSD) [11]. Their approach achieved 90.37% in recall and 95.31% in precision, with the fastest detection speed of 0.017s per image. CNN was used to develop an autonomous traffic and road sign detection and recognition system of traffic signs collected from roads in Saudi Arabia, and there were 24 different traffic sign labels [11]. Their experimental results showed an accuracy of 100% in their dataset.

However, for the TSR system, a new architecture for neural network structure remains challenging for all the researchers in this field. Although many network architectures have been proposed, a robust network structure is still needed to develop for improving the TSR system. This research work implements an alternative approach to designing deep learning models for TSR systems. The main contribution of the proposed method is as follows:

- A new model is based on a convolutional neural network (CNN), and Bayesian Optimization optimizes the model's hyperparameters to find the best hyperparameters grid, and
- The proposed model is also tested with three different datasets to get the generalized model.

II. LITERATURE BACKGROUND

The performance comparison between machine learning algorithms and humans to classify road traffic signs and the results are reported in their research work [12]. The human performance of classification of the road sign achieved an accuracy of 99.22%, while the best machine learning approach, CNN, with 99.46% correct classification accuracy. According to their research, the performance of the CNN outperformed the human ability, and therefore CNN-based TSR system can be one of the best solutions to assist the driver. A hinge loss stochastic gradient descent (HLSGD) method was suggested to train CNN, and their CNN model was evaluated on the GTSRB [13]. This experiment showed a state-of-the-art result of 99.65% in recognition rate. In [14], an extremely fast detection module was proposed, and this module is based on a support vector machine (SVM) and CNN to detect and classify traffic signs. The overall classification accuracy of 98.24% for the German Traffic Sign Detection Benchmark (GTSDB) and 98.77% for CTSD. OneCNN, a single CNN model, was proposed and tested over multiple traffic sign datasets from Germany, Belgium, and Croatia [15]. Their model got a classification rate of 99.04% in the German dataset, 97.66% in the Belgium dataset, and 99.37% in the Croatia dataset.

Their research proposed a deep learning approach to traffic sign recognition systems, and their classification experiments were conducted over different traffic sign datasets from Germany and Belgium [8]. The recognition rate of their proposed model got an accuracy of 99.71% in the German traffic sign dataset and 98.87% in the Belgium traffic sign dataset. Some researchers have designed a detector that was implemented using an R-convolutional neural network, and the structure of MobileNet and CNN was also used to be the classifier of traffic signs [16]. They got a detection accuracy of 96% in prohibitory, 100% in mandatory, 100% in Danger, and 99% in unique on GTSDB. Their classification accuracy was 99.66% in GTSRB. MicronNet, a highly compact deep convolutional neural network for real-time embedded traffic sign recognition system, was based on the microarchitecture design principle proposed and achieved an accuracy of 98.9% on the German traffic sign dataset [17]. Recently, a novel neural network architecture called Separating-Illumination Network (Sill-Net) was proposed by Zhang et al. [18]. Their model got a classification accuracy of 99.68% on GTSRB. The implementation of TSR using YOLOv5 was conducted with r own dataset, and they have a performance measure of 97.70% for all classes [19]. Recently, a recognition system based on Faster R-CNN and YOLOv4 network was implemented and achieved an accuracy score of 99.20% [20]. Recent advancements in computer vision and machine learning greatly help improve the accuracy of the TSR system [21]. However, the proposed deep learning model has achieved better performance across three traffic sign datasets.

III. Materials and Methods

In this research work, three different traffic sign datasets used in testing the performance of the proposed CNN model are highly imbalanced. These three datasets are as follows:

- German traffic sign recognition benchmark,
- Belgium traffic sign classification dataset, and
- Chinese traffic sign database.

A. *German Traffic Sign Recognition Benchmark (GTSRB)*

In this dataset, there are single images with a multi-class classification problem of more than 40 traffic sign classes and more than 50,000 images, as shown in Fig. 1. Its ground truth data is reliable due to its semi-automatic annotation. The traffic sign images are raw RGB images with sizes ranging from 15×15 to 250×250 pixels [22].

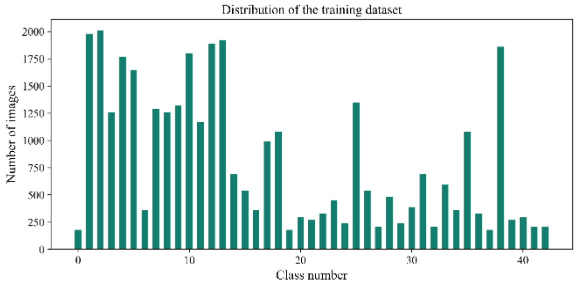

Fig. 1. Dataset distribution of German traffic sign images.

B. *Belgium Traffic Sign Classification (BTSC) Dataset*

The Belgian traffic sign classification dataset (BTSC) [23] has 4533 training images and 2562 validation images split into 62 traffic sign types, as shown in Fig. 2. Compared with the GTSRB dataset, this dataset has different traffic sign pictograms, lighting conditions, occlusions, image resolutions, etc. Moreover, it contains categories that cluster different types of traffic signs (e.g., 50-speed-limit sign and 70-speed-limit sign), thereby raising the difficulty of the recognition task.

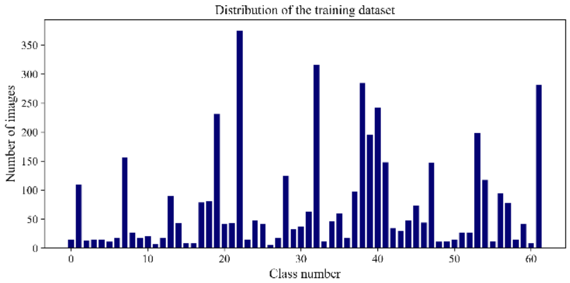

Fig. 2. Dataset distribution of Belgium traffic sign images.

C. *Chinese Traffic Sign Database*

This database [24] includes 6164 traffic sign images containing 58 sign categories, as shown in Fig. 3. The images are divided into two sub-databases as training database and testing database. The training database includes 4170 images, while the testing contains 1994 images. All images are annotated with the four coordinates of the sign and the category.

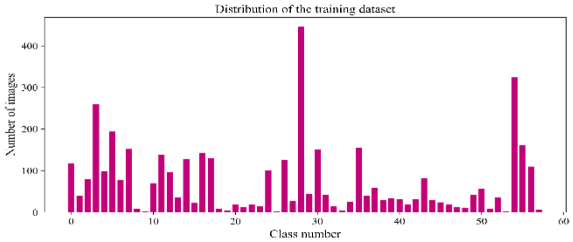

Fig. 3. Dataset distribution of Chinese traffic sign images.

D. Convolutional Neural Network (CNN)

Convolutional neural network (CNN) is one of the self-adaptive methods that can adjust to the data without any explicit specification [8]. CNN can also effectively learn features from numerous samples with minimal preprocessing [9]. Therefore, CNN was used in this research work to implement a traffic sign recognition system; the overall block diagram is shown in Fig. 4.

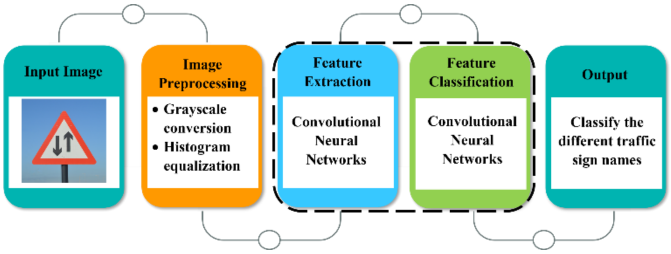

Fig. 4. Overall block diagram of traffic sign recognition system.

First, the image was loaded into the CNN model before being converted into a grayscale image with histogram equalization. Then, the images were rescaled by dividing with a maximum pixel value of 255. OpenCV library was used for these image preprocessing steps. During the preprocessing stage, all samples from GTSRB were down-samples or up-sample to 32×32, while the samples from BTSC and Chinese datasets were down-sample to 50×50 pixels. After these steps, the proposed CNN model applied feature extraction and classification of the image. The based CNN model with seven layers was inspired by LeNet-based architecture [25], and then the model was optimized by Bayesian optimization.

The proposed CNN used Keras with TensorFlow backend, and the model was trained and evaluated the classifier on all three datasets. The proposed model comprises several layers, including a convolutional layer, Rectified Linear Units (ReLU) [26], max pooling [27], and fully connected layers. The convolution and pooling layers were used as a feature extractor of the input images, and then fully connected layers were attached to flatten the matrix into a vector. Finally, softmax was used as an activation function to classify the outputs of different traffic sign labels. The softmax function in this research uses the categorical cross-entropy loss function [8]. The LeNet-based CNN architecture for the traffic sign recognition systemis shown in Fig. 5.

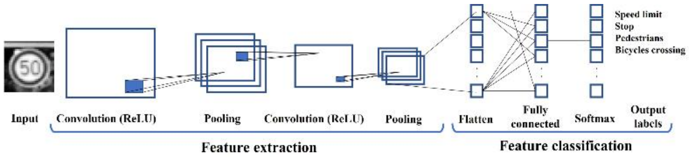

Fig. 5. LeNet-based CNN architecture for traffic sign recognition.

E. Hyperparameter Tuning Using Bayesian Optimization

In this research, the proposed CNN model was optimized by Bayesian Optimization, a sequential approach for the global optimization of black-box objective functions that are costly to evaluate [28]. The global maximizer or minimizer is mathematically needed to find an objective function [29]. The function *f* is defined as:

$$x^* = \arg\max_{x} f(x), \tag{1}$$

where x are the hyperparameters. In this research work, the set of hyperparameters was optimized to get the minimum value of the negative accuracy. Therefore, Bayesian optimization with a scikit-optimizer was used to find the minimum value. It provides a utility function to create the range of values to examine for each hyperparameter [30]. The following hyperparameters were optimized by scikit-optimize:

- the learning rate,
- the number of fully connected Dense layers,
- the number of nodes for each of the dense layers, and
- activation function.

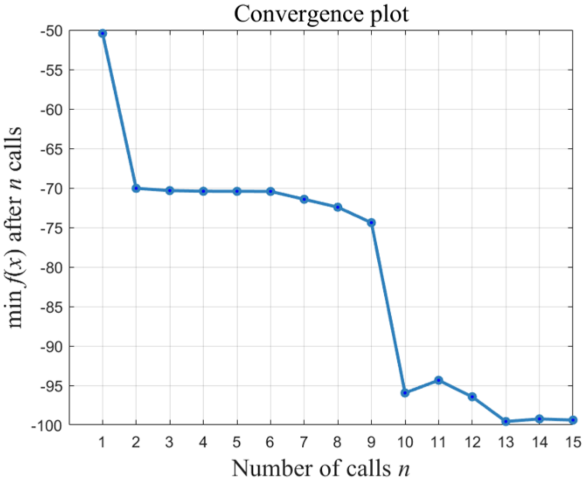

Fig. 6. The convergence plot of function min f(x).

Table I shows the range grid of the hyperparameters in this experiment. During the optimization process, there are 15 subsequent evaluations of f(x), and the target minimum value of accuracy was obtained in the 13th number of calls. In Fig. 6, the result can be visually seen with the convergence plot, and the test was done using the dataset of GTSRB. Therefore, Bayesian optimization [31] can give a better model performance on this dataset, and the optimized model will be used for testing with another two datasets. The selected hyperparameters combination is described in Table I.

TABLE I. HYPERPARAMETER GRID FOR DEEP LEARNING MODEL

Parameters	Range of grid
Learning rate	low=1e-6, high = 1e-2, prior= 'log-uniform', name = 'learning_rate'
Number of dense layers	low = 5, high = 15, name = 'num_dense_layer'
Number of dense nodes	low = 512, high = 1027, name = 'num_dense_nodes'

TABLE II. HYPERPARAMETER TUNING FOR DEEP LEARNING MODEL

Learning rate	Number of dense layers	Number of dense nodes	Activation function	Accuracy	loss
1.00E-05	5	512	relu	50.44	1.077
2.40E-04	13	954	sigmoid	70.05	3.564
3.10E-04	9	665	relu	70.34	0.2453

8	Fully connected (ReLU)	(None, 512)	262656
9	Fully connected (ReLU)	(None, 512)	262656
10	Fully connected (ReLU)	(None, 512)	262656
11	Dropout	(None, 512)	0
12	Fully connected (ReLU)	(None, 512)	22059
Total params: 1,643,945			
Trainable params: 1,643,945			
Non-trainable params: 0			

The detailed values of each hyperparameter can be seen in Table II, and as mentioned before, the best hyperparameter grid was in the 13th iteration with 99.57% accuracy and 0.2068 in loss value. Therefore, the proposed model was updated with this parameter grid and shown in Fig. 7. For training the GTSRB, the updated model architecture of convolutional layers, ReLU, max pooling, and fully connected layers are reported in Table III. The detailed structure of the proposed CNN model is shown in Fig. 7.

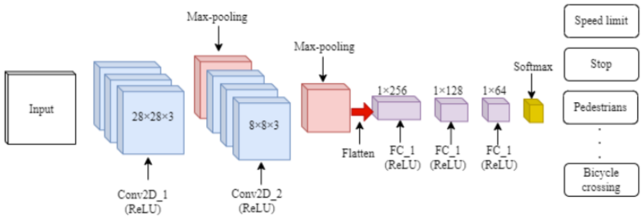

Fig. 7. The updated CNN architecture for classification of traffic sign images.

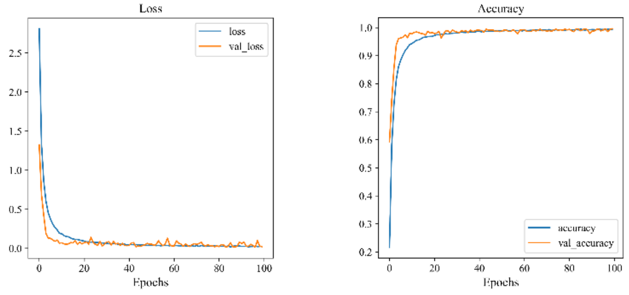
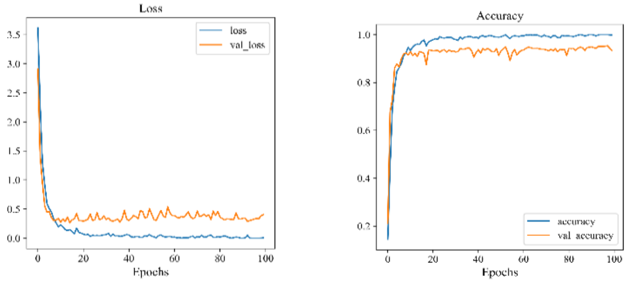
IV. RESULTS AND DISCUSSION

All experiments of CNN architecture and Bayesian optimization were done on a computer with an Intel Core i5 – 7300HQ CPU, 16 GB of RAM, and an NVIDIA GeForce GTX 1050 discrete GPU with 2 GB of RAM; this computer was enough to train and run models. Training and validation sets are already included in the datasets since they can be downloaded from the source link. Therefore, the developed CNN model was trained with a training set and evaluated with the model with a validation set. Fig. 8, Fig. 9, and Fig. 10 show the values of training loss and accuracy from different datasets and are compared with the values of validation loss and accuracy on those datasets. The training time per epoch of the proposed CNN model is 15.76 seconds, and the simulation ran 100 epochs per dataset. Our proposed CNN model achieved better accuracy with lower loss values on all three datasets.



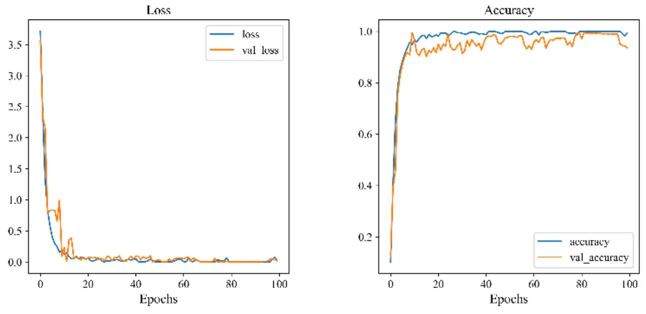
(a) (b)

Fig. 8. Comparison between training and validation of German traffic sign dataset regarding (a) loss and (b) accuracy.



(a) (b)

Fig. 9. Comparison between training and validation of Belgium traffic sign dataset in terms of (a) loss and (b) accuracy.



(a) (b)

Fig. 10. Comparison between training and validation of Chinese traffic sign dataset regarding (a) loss and (b) accuracy.

Performance is evaluated based on the GTSRB dataset by calculating precision, recall, F1-score, and accuracy:

$$\text{Precision } (\%) = \frac{\text{TP}}{\text{TP} + \text{FP}} \times 100, \qquad (2)$$

$$\text{Recall } (\%) = \frac{\text{TP}}{\text{TP} + \text{FN}} \times 100, \qquad (3)$$

$$\text{F1-score } (\%) = \frac{2\times\text{TP}}{2\times(\text{TP} + \text{FP}+\text{FN})} \times 100, \qquad (4)$$

$$\text{Accuracy } (\%) = \frac{\text{TP}+\text{TN}}{\text{TP} + \text{FP}+\text{TN}+\text{FN}} \times 100, \qquad (5)$$

Where TN is the number of true negatives, TP is the number of true positives, and FN and FP are the number of false negatives and false positives, respectively [32]. The precision, recall, and f1-score are calculated for individual labels to classify traffic signs.

It clearly shows that the average percentage of the classification of 43 sign labels from the GTSRB dataset is 96.79% in precision measure, 97.21% in recall measure, and 96.65% in F1-score, as shown in Fig. 11. The proposed model is capable of classification of 61 different annotated sign labels and the performance measures of Belgium traffic sign database are shown in Fig. 12. The proposed model achieved 94.06% of precision measure, 93.82% of recall measure and 92.77% of F1-score. Moreover, the proposed model was also tested with another traffic database of the Chinese traffic sign database, and the average results on each performance measure were 91.24%, 86.11%, and 86.41%, respectively. In this database, there are 57 different sign labels; these performance measures can be seen in Fig. 13.

The new CNN model was proposed in this research work, and the experimental results are shown in the above section. In this section, a detailed discussion of the accuracy results from this proposed model and the existing deep learning models. The classification accuracies of the proposed model on the German, Belgium, and Chinese traffic sign datasets are mentioned as follows: the average accuracy of 99.57% on the German dataset, 99.15% on the Belgium dataset, and 99.35% on the Chinese dataset. A comparison between the recent research and the proposed CNN model on the German dataset is shown in Table IV. The proposed model achieved a better accuracy score than the previous study with CNN [15], and MicronNet [17], but the score is slightly less than CNN with three spatial transformer layers and SGD without momentum as the loss function optimizer [8]. However, our CNN model's total number of parameters is 1,643,945, which is much lower than their model parameters. (See Table VI). In contrast, the proposed model got the best accuracy value on the Belgium traffic dataset compared with the recent research, including CNN with three Spatial Transformer Networks [8], a Gaussian-Bernoulli deep Boltzmann machine-based (GDBM) hierarchical classifier [30], and other approaches [2]. The accuracy comparison between our proposed CNN model and the recent studies is shown in Table V. Therefore, the light weight CNN model with higher accuracy measures was successfully proposed in this research and can be used in real-time scenarios.

TABLE IV. ACCURACY COMPARISON OF GERMAN TRAFFIC SIGN DATASET BETWEEN THE PROPOSED MODEL AND RECENT STUDIES

References	Methods	Accuracy
[8]	CNN with 3 Spatial Transformer Networks	99.71%
[18]	Separating-Illumination Network (Sill-Net)	99.68%
Proposed model	Bayesian Optimization approach CNN model	99.57%
[15]	CNN	99.11%
[17]	MicronNet	98.9%

Proposed model	Bayesian Optimization approach CNN model	1,643,945

V. CONCLUSION

In this paper, sequential model-based optimization (Bayesian optimization with scikit-optimize) approach deep learning model was proposed and tested with different traffic sign datasets, including GTSRB, BTSC, and the Chinese traffic sign database. The proposed model was in a rank with the top result in BTSC and the top three results in GTSRB. It is possible to show the high-quality results obtained from the proposed models using the Chinese dataset. Therefore, the proposed CNN model significantly improves traffic sign recognition (TSR) system performance compared with other existing studies. Further work should be conducted with other traffic sign datasets from different countries to guarantee the quality and accuracy levels of the proposed CNN model while comparing the real-world scenarios.

***Abstract*—Anaemia is a frequent blood disorder marked by a reduction in the quantity of haemoglobin or the number of red blood cells in the blood. Quick and accurate anaemia detection is crucial for fast action and effective treatment. In this research, we provide a new structure called Whale Optimization-Driven Generative Convolutional Neural Network (WO-GCNN) for the detection of anaemia using blood smear pictures. To increase anaemia detection accuracy, the WO-GCNN system combines the strength of generative models and convolutional neural networks (CNNs). In order to create artificial blood smear images and learn the underlying data distribution, generative models, such as Generative Adversarial Networks (GANs), are used. Improve the functionality of the WO-GCNN system by applying the Whale Optimisation Algorithm (WOA), which is based on the hunting behaviours of humpback whales. To create the optimal set of CNN weights, the WOA effectively achieves a compromise between exploitation and exploration. The WO-GCNN framework accelerates convergence speed and increases overall performance of anaemia detection by incorporating the WOA into the training process. On a sizable dataset of blood smear pictures obtained from clinical settings, we assess the suggested WO-GCNN system. A highly accurate and effective approach for the early identification of anaemia is produced by combining generative models and CNNs with the WOA optimisation. By enabling early anaemia identification, the proposed WO-GCNN framework has the potential to have a substantial impact on the field of medical image analysis and enhance patient care. It can be a useful tool for medical personnel, supporting them in making decisions and giving anaemia patients urgent interventions.**

I. Introduction

The most prevalent haematological condition, defined as low haemoglobin concentration, affects over two billion individuals worldwide. Numerous acute and chronic diseases, including cancer, malnutrition, gastrointestinal bleeding, and chronic kidney disease, may trigger it. While severe anaemia, like thalassemia, require ongoing monitoring, others can be managed with simple medications. Some dangerous emerging reasons for anaemia, like significant gastrointestinal bleeding, necessitate early identification. Until the illness is not compensated and consequences arise, it is challenging to identify anaemia using simply patient records and examinations. The most common method for identifying anaemia is a complete blood count conducted in a laboratory. The laboratory test is intrusive, expensive, and needs specialised facilities and supplies (such as skilled medical personnel for blood sample and a haematology analyser for analysis using a biochemical reagent) [1].

The main factor contributing to anaemia, which typically has a high onset during preadolescence and happens if the blood's capacity for carrying oxygen is insufficient to satisfy the body's physiological needs, is a decline in red blood cell production. It is a significant issue in worldwide public health that necessitates the use of preventative diagnostic technologies. For adults, the lower recognised threshold for haemoglobin content in the blood is: 13.0 g/dL for males and 12.0 g/dL for women; tolerance levels due to varied races and ages should be taken into consideration. The creation of remedies intended at bolstering diagnosing concerns is the focus of the investigation discussed in this paper. To detect critical conditions, including the need for a donation of blood, or to allow autonomous tracking of haemoglobin levels, extremely precise instruments are needed. Lower equipment costs and convenience of use are also priorities in settings lacking surgeries and suitable instruments. Additionally, since non-invasive techniques enable the tracking of therapy answers, this technique is crucial for directing a more efficient and affordable tracking plan [2].

IDA, which is more prevalent in women, continues to be one of the five most common causes of years spent with a handicap in people. While it has historically been viewed primarily as a problem of public health impacting developing children, premenopausal women, and pregnant women, it is also coming to light as a clinical condition which may affect clients presenting across various healthcare and surgical fields, particularly those with chronic illnesses and older adults. International practise recommendations have been prompted to give special consideration to IDA assessment and treatment as new data on the role of IDA in poor medical results continues to emerge. The vague nature of the signs and the numerous IDA aetiologies, however, might make the diagnosis difficult. Additionally, the availability of several iron supplements formulas can make treatment choices more difficult [3].

According to the World Health Organisation (WHO), a patient blood management (PBM) strategy should be utilised to maximise the surgical patient's natural volume of blood. Several instructions, which include those for managing and optimising pre-operative anaemia and cells salvaging, have been published to aid hospitals in the execution of patient blood management. Studies have demonstrated that managing patient blood results in better outcomes and lower healthcare expenses [4]. Implementing patient blood management was found to reduce transfusions, hospitalisations, morbidity, and hospital readmission in total knee and hip arthroplasty and heart surgery. In one potential multi-centre study, the safety of a hospital-wide implementation of patient blood management was assessed. The outcomes of 54,513 patients prior to and 75,206 patients following the implementation of patient blood management showed that it was not disadvantaged. Data on the application of patient blood management in four tertiary institutions for 605,046 patients was provided by a sizable Australian study. A five-year implementation plan was started, and the last year's results were compared to the baseline years in terms of mortality, costs, and red cell transfusions. [5].

Red blood cells include the iron-containing protein known as haemoglobin, also known as Hgb or Hb, which is in charge of transporting oxygen from the respiratory system to other organs. Healthy adolescent blood haemoglobin levels for males and females normally fall between 14 to 18 g/dl and 12 to 16 g/dl, respectively. Blood sugar levels can, however, drop considerably due to a variety of illnesses, poor nutrition, and abnormalities of the bone marrow. Anaemia is a serious haematological condition that can lead to physical and mental weakness, mood swings, cognitive impairment, skin pallor, and in the worst cases, cardiac arrest. The World Health Organisation (WHO) has identified anaemia as a severe health concern for young children and expectant mothers. Invasive tests for blood are the most popular method of detecting anaemia and monitoring Hb levels. The intrusive blood tests are uncomfortable and run the danger of becoming infected while in the hospital. A visual inspection of other tissues in the body, such as the tongue, nail beds, palmar crease, and palpebral conjunctiva, is recommended in order to identify anaemia [6]. But a highly skilled medical professional who is able to connect the visual indicators to anaemia ought to just carry out such a test. Inspection by hand also carries the hazards of inter- and intra-observer bias, human error, and non-reproducible outcomes. As a result, there is a pressing need for automated tools to assist in the anaemia screening process. Recent developments in deep learning have brought efficient answers to issues in the biomedical sector. Additionally, they can be utilised to create sophisticated computer-aided diagnosis (CADx) tools that examine images of body components like the conjunctiva and fingernails to find anaemia. Such instruments would be able to measure image-based factors with great accuracy, such as pallor and the erythema index (EI). Pre-processing, segmentation, feature extraction, and classification are the fundamental sub-processes that make up the CADx method for diagnosing anaemia. [7]. The framework has the potential to be a reliable and effective way for detecting anaemia from blood smear images, which will improve medical diagnostics. The amount and diversity of the supplied dataset may have an impact on the framework's performance, necessitating thoughtful deliberation and augmentation to guarantee resilience across varied populations of patients and conditions.

The key contribution of this model is given below:

1) To increase the accuracy of anaemia detection, the WO-GCNN system combines the strength of generative models, namely Generative Adversarial Networks (GANs) and convolutional neural networks (CNNs).

2) The WO-GCNN solves the problem of insufficient data to train deep learning models by creating false blood smear images and understanding the fundamental information distribution through the use of GANs.

3) To discover the best combination of CNN weights, the approach effectively strikes an equilibrium between exploration and exploitation by incorporating the Whale Optimisation Algorithm (WOA) into the training phase of the WO-GCNN.

4) The suggested WO-GCNN method exhibits extremely precise and efficient anaemia recognition, with the potential for early identification and enhanced patient care in the area of medical imaging analysis.

5) An innovative method for overcoming the difficulties of detecting anaemia from blood smear images is demonstrated by the integration of generative models and CNNs with the WOA optimisation.

The structure of the essay is organised as follows: The associated work was covered in Section II. Section III describes the problem statement. Section IV describes the suggested convolutional Neural Network algorithm for identifying anaemia. In Section V, the proposed method's effectiveness and performance were evaluated, and the findings were shown in graphs and tables. The final Section VI provides a summary of the paper's findings.

II. Related Works

Alzubaidi et al. [8] proposed Red blood cells (erythrocytes), which are elongated, circle (normal), and other blood components, are divided into three groups using three deep learning models. The suggested models were created using classic and parallel convolutional layers, two types of convolution neural networks. The amount of layers and learnable filters in these models are different. The most effective model out of the three has been determined empirically. In this study, transfer learning and data augmentation were used to address the problem of not having enough data for training deep learning models for the classification of red blood cells. The target dataset's images were gathered from the identical domain using the comparable domain transfer learning technique, and previously learned models were then suggested and trained. The categorization task for sickle cell disease was subsequently enhanced using these previously trained models. Our models were assessed using two datasets. The experiment's findings demonstrated that classifying sickle cell disease using the identical domain transfer learning greatly increased. It also made it possible for our algorithms to work better than the most recent erythrocyte classification techniques. By reaching an accuracy of 99.54% with the framework alone, 99.98% with the approach plus a multiple classes SVM classifier on the erythrocytes DB dataset, and 98.87% on the gathered dataset, our model exceeded the most recent techniques and reached state-of-the-art performance. Last but not least, training a multiclass SVM classifier demonstrated its efficacy in extracting features and produced excellent outcomes. The drawback is that the model needs to be taught in doing the following job to be able to classify white blood diseases.

Kilicarslan et al. [9] explains The two combined models for predicting HGB-anemia, B12 deficiency anaemia, nutritional anaemia (iron deficiency anaemia and folate deficiency anaemia), and individuals without anaemia have been developed using genetic algorithms (GA) and deep learning algorithms of arranged auto encoder (SAE) and convolutional neural network (CNN). The developed GA-SAE and GACNN approaches use GA for optimising the high-level parameters of the SAE and CNN algorithms because it can be difficult to choose acceptable values for deep learning algorithms. The suggested algorithms' estimations and classification results were assessed using the accuracy, precision, F-score, and sensitivity criteria. The newly developed GA-CNN approach, whose layers were continuously trained separately of one another, was 98.50% more efficient than that of the study presented in the literature, according to the lab's evaluations utilising the dataset. The suggested combinations look at medical data to make diagnosis while lowering human error because of infirmity or exhaustion. This indicates how ineffective and unsuccessful it is.

Haematological condition sickle cell anaemia was once considered to be one of the special characteristics of the indigenous population, but it today affects everyone in the world and calls for immediate medical attention. Yeruva et al. [10] describes The history of Sickle Cell Disease (SCD), both nationally and internationally (in the context of India). the description of the disease's signs and symptoms, caution signs, effects, and treatment. Blood characteristics are also used to categorise the blood cells in individuals with sickle cell disease and thalassemia patients. This study utilises a multi-layer perceptron to better accurately simulate sickle cell disease with the goal to decrease the period and energy needed for sickle cell disease painful control systems. In this work, we investigate the "MLP Classifier" deep learning model, which outperforms methods like Support Vector Machine, Decision Tree Classifier, K-Nearest Neighbour, Random Forest Algorithms, and Logistic Regression in terms of output. According to simulation results, the proposed MLP classification has an accuracy of 99.9% for predicting both sickle cell and thalassemia. Normal medical lab workers cannot apply the MLP classification algorithm and prediction model in the TSCS scenario since it is not faster or quicker.

El-kenawy et al. [11] proposed employing haematological criteria, machine learning is being used for prediction and to approximate the market value of haemoglobin. Considering the Random Forest, Support Angle Device, and Artificial Neural Networks three computer learning techniques. The least expensive mistake was made by K.N.N. Set. In conclusion, the current investigation revealed aberrant RBCs, HGB, HCT, and CRP levels in the CBCs of frequent COVID-19 cases, which were also the most likely laboratory findings in these patients. We provide a machine learning approach in this study to estimate blood level based on bloodstream test criteria. Pre-processing is done in our suggested method for haemoglobin evaluation so that data is minimised and normalised immediately before training the models. The results of this technique are contrasted with those from different manufacturers' learning versions. A precise Blood assessment is produced by the suggested version. When reading the CBC of COVID-19 patients, clinicians should take these factors into account. To improve the highest possible accuracy new optimization algorithm is utilised.

El-kenawy et al. [12] explains classification and regression are two machine learning tasks. Using haematological data, estimating the value of haemoglobin for the regression. Three machine learning techniques, namely Random Forest, Artificial Neural Networks, and Linear Regression, were employed. The least mistake was generated using random forest. The type of anaemia is then classified using the haematological parameters and the estimated haemoglobin levels. Comparing Decision Tree against Random Forest, Artificial Neural Networks, and Naive Bayes, it became clear that Decision Tree was the superior classifier. Finally, we suggested an ensemble model (HEAC) that combines the Decision Tree classifiers, Naive Bayes, and Random Forest. The proposed model performed better than current classifiers and decision trees. Before training the models, pre-processing reduces and normalises the data in the Haemoglobin Estimation and Anaemia Classification (HEAC) method that we recommend. Results obtained from various machine learning models are compared to results from this model. The haemoglobin estimation and anaemia classification findings from the suggested method are quite precise. Genetic algorithms are used to obtain the greatest precision and identify the best weights.

Sickle cell anaemia (SCA) is a significant haematological condition which often requires hospitalisation over the course of a patient's lifetime and may even be fatal. Aliyu et al. [13] presents a two-step process Initially identify the RBC region of interest (ROI) using automatic red blood cell (RBC) extraction from a person's blood smear image. In order to categorise and forecast whether anomalies will be found in SCA patients, a deep learning AlexNet model is used. The research included (nearly 9,000 single RBC pictures) from 130 SCA patients, with 750 units for every category, with the goal to provide an overall multiscale forms assessment and shape factor quantization. We demonstrate how the suggested structure can automatically categorise 15 different RBC shape types, includes normal, using a sophisticated AlexNet transfer learning model. The specificity, sensitivity, precision and accuracy of the cell's name categorization predictions were 95.92%, 77%, 98.82%, and 90%, respectively. It requires a lot of time to perform.

III. Problem Statement

The improvement of categorization and model predictions for diverse haematological disorders, such as sickle cell disease and anaemia, is the main focus of the issue statement discussed in this study. To guarantee prompt medical attention, these illnesses must be accurately identified and classified due to their major global effects. However, a number of obstacles prevent this field from progressing. First of all, deep learning models struggle to operate at their best due to a lack of training data. Furthermore, the effectiveness and success rates of current studies are frequently low, emphasising the need for better methods. Another issue is computational time efficiency. Additionally, there are difficulties in using these models in real-world medical laboratory settings, necessitating easier and more accessible solutions. As a result, the issue statement focuses on creating reliable and accurate classification and prediction models, overcoming data constraints, enhancing effectiveness, ensuring practical use, and speeding up the diagnosis and treatment of haematological disorders [14].

IV. Proposed WO-GCNN Method for Anaemia Detection

A convolutional Neural Network is used for image collection, pre-processing, feature extraction, feature selection, and categorization in order to detect and recognise the anaemia. The collected examples of photos have been posted. In pre-processing, filtering is employed to get rid of noise, and operations are used to find the edges of the image. The relevant traits are then extracted, and the classification of normal and pathological cells are done. Fig. 1 shows the block diagram for classification of anaemia using WO-GCNN mechanism.

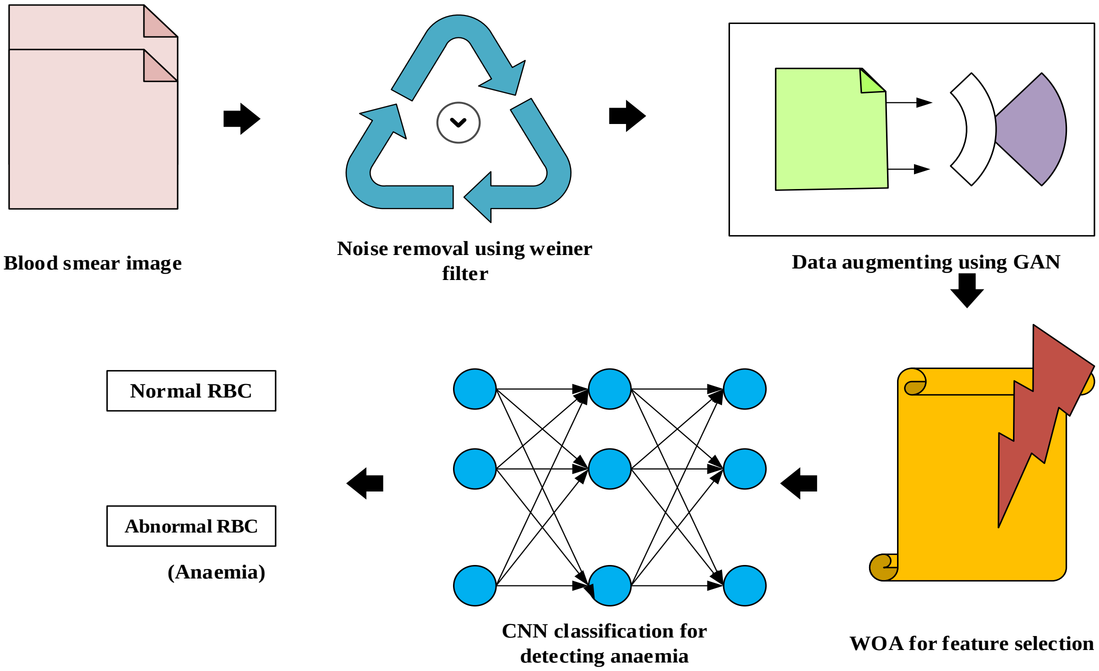
A. Data Collection

Consulting pathologists gathered, organised technically, and annotated blood imaging data for the suggested method. A 40x Olympus Dp27 lens was used to examine the blood smear slides. Images at a resolution of 1920 x 1080 pixels were taken with an 8.9-megapixel CMOS sensor. From 50 blood smear slides, it has 500 images in total, 250 of which are healthy and 250 of which are anaemic RBC images. Those without anaemia are represented in the images, while those with anaemia are represented in the images [15].

The dataset is partitioned into three separate sets or folds for 3-fold cross-validation. The remaining two folds are utilised for training, while each fold is used once as a validation set. To guarantee every subset has been utilised as a validation set precisely once, this procedure is repeated three times. The total number of photos and the proportion of normal and anaemic red blood cells (RBC) images in each fold are displayed in the Table I.

TABLE I. 3 Fold Cross Validation of Healthy and Anaemic RBC Images

Folds	Total images	Healthy RBC images	Anaemic RBC images
1	167	83	84
2	167	83	84
3	166	84	82



Blood smear image
Noise removal using weiner filter
Data augmenting using GAN
Normal RBC
Abnormal RBC
(Anaemia)
CNN classification for detecting anaemia
WOA for feature selection

B. Data Generation using GAN

The generative models known as GANs are built on adversarial and deep learning techniques. GANs' main objective is to learn and replicate the distribution and traits of some interesting data in order to create similar data of the same type. A discriminator and a generator are the two neural network models that make up GANs. The discriminator is taught to categorise the veracity of the data it receives as input. The generator is adept at creating new artificial information that is exact replicas of the real information. Although the discriminator and generator systems are trained concurrently, they have various goal (as well as loss) parameters [16].

The discriminator's goal is to increase the probability that it can tell the difference between genuine data (from the training set) and fictitious data from the generators. For labelled genuine training data x, log (D_0(x)), D_0 (x) is ideally 1, and for fake data z produced by the generatorG_0, its loss is log (1 – D_0 (G_0 (z))). Loss is measured using cross-entropy. The discriminator's aim for identifying authentic and fraudulent data is then maximised during training using feedback from its loss measurement loop is given by eq. (1).

$$\max_{D_0} V_0(D_0) = E_{0_{x\sim P_{data}(x)}}[logD_0(x)] + E_{0_{z\sim P_z(z)}}[\log\left(1 - D_0\left(G_0(z)\right)\right)] \tag{1}$$

Another reverse propagation feedback process from the discriminator drives training of the generator with the goal of reducing the likelihood that the generator's bogus data will be identified in eq. (2).

$$\min_{G_0} V_0(G_0) = E_{0_{z\sim P_z(z)}}[\log\left(1 - D_0\left(G_0(z)\right)\right)] \tag{2}$$

Equation (3) contains the whole GAN objective function.

$$\min_{G_0} \max_{D_0} V_0(D_0, G_0) = E_{0_{x\sim P_{data}(x)}}[logD_0(x)] + E_{0_{z\sim P_z(z)}}[\log\left(1 - D_0\left(G_0(z)\right)\right)] \tag{3}$$

The discriminant and generation compete during GAN training in a manner comparable to a zero-sum mini-max game. Training proceeds till the GAN structure combines, at which point (i) the discriminator is able to distinguish between genuine and phoney data with adequate accuracy and (ii) the generator produces data that the discriminator has an extremely small likelihood of finding. The GAN network needs to be retrained if just one of the two results is (i) or (ii) [16].

C. Pre-processing

The augmented anaemia dataset is used in pre-processing for removing the extra noises. An image of the binary model of the multi-coloured blood stain is created. The picture is then improved. The Weiner filter is a flexible noise reduction device. A clearer picture of the concentration, in this case just the red blood cells in the blood sample, is then provided by clearing up the picture. The acquired image is then put to use in additional processing. In the pre-processing stage, noise reduction, unwanted effects like noise are reduced or eliminated with the goal of preparing the image for subsequent processing. Wiener equation is calculated as eq. (4)

$$W = (F^{-1}x)^2 \tag{4}$$

The following equation can be used to calculate the gradient is shown in eq. (5,6)

$$g_0(m,n) = G_{0_\sigma}(m,n) * f_0(m,n) \tag{5}$$

$$\text{Where, } G_{0_\sigma} = \frac{1}{\sqrt{2\pi\sigma_0^2}}\exp(-\frac{m^2+n^2}{2\sigma_0^2}) \tag{6}$$

Using any gradients operator [17], such as Roberts, Prewitt, Sobel, or another method, the gradient of $g_0(m,n)$ is calculated to obtain in eq. (7)

$$M_0(n,n) = \sqrt{g_{0_m}^2(m,n) + g_{0_n}^2(m,n)} \tag{7}$$

D. Sobel Operator for Edge Detection

Edge detection is a technique for spotting breaks in images. Edge detectors come in a variety of varieties, including Sobel Operator, LoG Operator, Robert's Operator, and Zero cross Operator, Canny Operator, and Prewitt Operator. The Sobel Technique is presented below among all of these. It serves as an edge detector with 33 gradients. The Sobel algorithm calculates the 2-D spatial gradient of a picture and highlights edge-corresponding regions with higher spatially frequency. When a grayscale image is provided, it is utilised to determine the roughly absolute magnitude of the gradient at each location. The Sobel Operator uses 2 3×3 matrix that are convolved with the starting image, one for horizontally variations and one for vertically shifts, for approximating the derivatives of the image. The Sobel operator may be utilised to calculate the predicted relative magnitude of gradients at each position of a given grey scale image by applying 2-D spatial gradient measurements on the image and emphasising regions of high spatial frequency that correspond to edges. Therefore, the Sobel operator is used in the edge identification of biomedical images [18].

E. Whale Optimization Algorithm

Mirjalili and Lewis developed the whale optimisation algorithm (WOA), a new metaheuristic technique. The global optimum answer for an issue is sought after and discovered using WOA, which works similarly as various metaheuristic optimisation methods. Update until the optimal value is attained, the algorithm keeps enhancing and updating the answer depending on its framework. The way the WOA principles update and refine the answer is the main distinction between the WOA and other metaheuristic algorithms. The WOA is modelled after the instinctual way that whales hunt prey—by spiralling around it to set up a trap and then hitting it. This type of eating behaviour is known as bubble-net feeding [19].

Before striking, the humpback whale spirals around its prey to produce bubbles. This consuming behaviour served as the basis for the WOA's primary structure. The bubble-net method's mathematical framework is described as follows in eq. (8) to (10).

$$X_0(t+1) = \begin{cases} X_0^*(t) - AD & P < 0.5 \\ \acute{D}_0 e_0^{bl}\cos(2\pi t) + X_0^*(t) & P \geq 0.5 \end{cases} \tag{8}$$

$$\acute{D}_0 = |CX_0^*(t) - X_0(t)| \tag{9}$$

$$A = 2ar_0 - a \tag{10}$$

$$C = 2r_0 \tag{11}$$

Where, $\acute{D}_0$ → Distance between the ith whale and its victim (the ideal answer), P and r_0 → random constants between 0 and 1, l → a random constant between [1, 1], t →current iteration, b → the logarithmic spiral's form, and a → linearly across the iteration, from 2 to 0.

The circling process is represented by the initial term in the formula above, while the bubble net process is represented by the following term. The extraction and utilisation terms of the WOA are represented by these two clauses. It shows how the prey is circled and how bubble-net hunting is done. The WOA begins with a randomly chosen populace, as was already mentioned. The results are then updated after every round in accordance with the mathematical model created for hunting using a bubble net and orbiting the prey. When $|X_0|>$ 1, the optimum solution adjusts the location of the agents to ensure that the algorithm converges. If not, the most effective solution serves as a pivot point.

Algorithm of WO-GCNN mechanism for detecting anaemia

```
Start
Input: Initializing the whale population $X_{0_i}$
Initializing a, $A_0$, and C
Output: Evaluating the most effective solution is displayed by search agents with fitness $X_0$* at this time.
Applying WOA: for feature selection
$t_0$=1
   while doing $t_0$<max iterations
      for the agents do in all
            if $|A_0|$=1 then
Updating the search's current location
            Else if $|A_0|$=1 then
Choose the $X_{0_{rand}}$ random search agent.
Updated the current agent position
            End if
      End for
Updating a, $A_0$, and C
Updating $X_0^*$
$t_0$= $t_0$+1
   End while
return $X_0^*$
End
```

The computational difficulty of WOA is O_0 (Max Gen NP O_0 (fitness)), where Max Gen is the maximum number of generations and O_0 (fitness) is set by the application. This is because WOA has a fairly basic structure, based to the pseudocode [19].

F. Convolutional Neural Network

A set of layers collectively referred to as CNN are used for converting the input layer into an output layer. Each layer is made up of a collection of neurons. Each neuron in a layer, with the exception of the input layer, is the outcome of the task that was assigned to the neurons in the layer before it, i.e. y=f(x). The most often used layers are the convolutional layer, the fully connected layer, the pooling layer, and the activation layer, Fig. 2.

Each neuron in a layer that is fully connected is connected to all of the neurons in the layer below it. The strength of the connection connecting the jth neuron in the current layer and the kth neuron in the previous layer should be represented by the number$\omega_{0_{jk}}$. Let b_{0_j} be the bias of the jth neuron in the current layer. The result of the layer's jth neuron is given by eq. (12)

$$y_{0_j} = \sum_k \omega_{0_{jk}} x_{0_k} + b_{0_j} \tag{12}$$

The neurons in the convolutional layer that are typically used for generating a kernel or filter have identical biases and values. Each neuron in this layer will be connected to a n×n region of the neurons in the layer beyond if the size of the filter is set to n×n. In line with this, the (j, k) th neuron's outputs will be in eq. (13)

$$y_{0_{j,k}} = \sum_{l=0}^{n-1} \sum_{m=0}^{n-1} \omega_{0_{l,m}} x_{0_{j+l,k+m}} + b \tag{13}$$

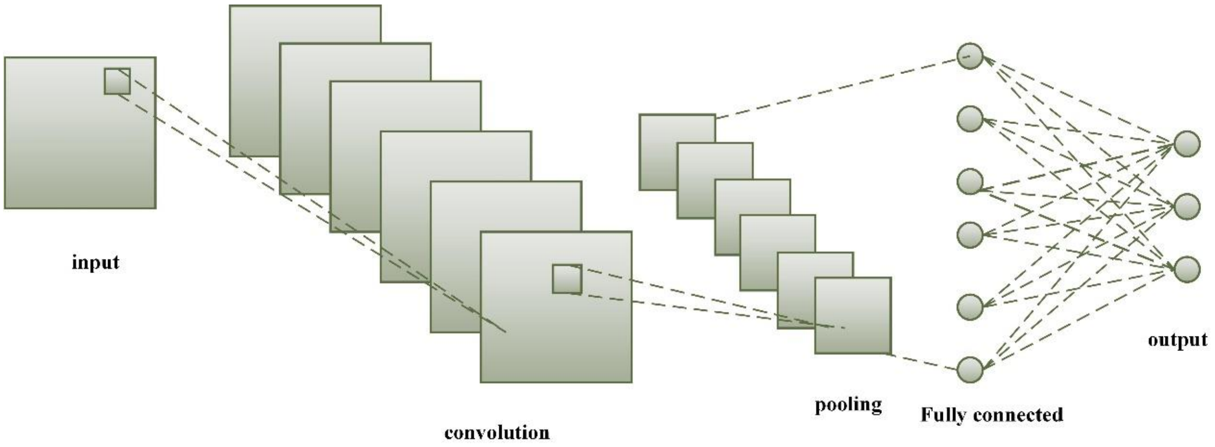

Fig. 2. Convolutional neural network architecture.

Tanh, Sigmoid, and the rectified linear unit, that has become the standard suggestion for modern neural networks, are instances of frequently employed functions for activation. Activation layers usually appear following convolutional or fully connected layers to offer elementwise non-linear behaviour. By using the activation function, ReLU is defined in eq. (14)

$$f_0(x) = \max(x, 0) \tag{14}$$

The downwards sampling method for every sub-area in the pooling layer provides the dimension of a single neuron in the present one by dividing the neurons of the layer preceding it into an array of not overlapping rectangles. Maximum pooling and average-pooling, the two most popular pooling procedures, offer the subarea's maximum value and average value, respectively [20]. A convolutional neural network usually sets up a sequence of convolutional (Conv)-ReLU layers, before adding the pooling layers (Pool), and continues doing this till the picture gets spatially combined to a compact size. At certain points, it is usual to switch to fully-connected layers (FC).

V. Results and Discussion

A normal blood sample is pre-processed, binarized, and the permeability of each connected component is determined using MATLAB 7.14.0.739 software. Similarly, an anaemic blood specimen is binarized, pre-processed, and the permeability of each associated component is determined.

A. *Performance Evaluation*

The classification methods' performance was evaluated using the confusion matrix's assessment measures (Table II). Although the true negative (TN) represented the conjunctiva images that the machine learning algorithm accurately identified as not considered anaemic, the true positive (TP) represented the conjunction tissue images that the classification successfully classified as being in the anaemic class. False positives (FPs) were conjunct images of people who were not anaemic but who were wrongly classed as being anaemic. Finally, false negatives (FNs) were found in the conjunctival pictures of anaemic individuals who were mistakenly classified as no anaemic. Accuracy, sensitivity, and specificity are defined in accordance with these notations is given by eq. (15-17).

$$Accuracy = \frac{TP+TN}{TP+FN+FP+TN} \tag{15}$$

$$Sensitivity = \frac{TP}{TP+FN} \tag{16}$$

$$Specificity = \frac{TN}{FP+TN} \tag{17}$$

These metrics were calculated based on every cross-validation operation that was performed, and the effectiveness of the classifier was assessed using the mean and standard deviation of the outcomes. Although the accuracy measure is typically an accurate measure of a system's effectiveness, the dataset's imbalance between the two groups makes it less reliable [21]. Since the goal of an approach like the one suggested in this research is initially aimed at giving a patient who was not aware of being deficient in iron for carrying out further examinations, it was chosen to prioritise sensitivity, which says, as a percentages, the number of the actual anaemic individuals were identified by the system.

A graph called the receiver operating characteristic curve shows the way a classification system works at every level of categorization. The curve shows the following two variables: 100% True Positive. False Positive Rate. Fig. 4 shows the ROC Curve along with the false positive rate and true positive rate. To assess the ability to discriminate of each metric in identifying anaemia, ROC curves were generated [24].

TABLE II. Comparison of Performance Evaluation for Proposed Method and Existing Methods [22]

Classifiers	Accuracy	Sensitivity	Specificity
KNN	67.4%	67%	84%
SVM	78%	71%	85%
NN	79.8%	65%	91%
Proposed WOG-CNN	99%	92%	96%

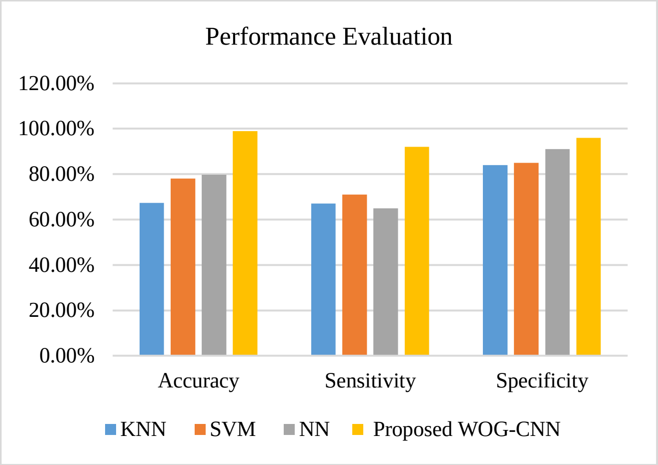

Fig. 3. Graphical representation of performance metrics.

The above graph (Fig. 3) shows that the accuracy, specificity and sensitivity of the existing and proposed model and ROC curve for false positive rate and true positive rate. This shows that the proposed method gives better efficiency.

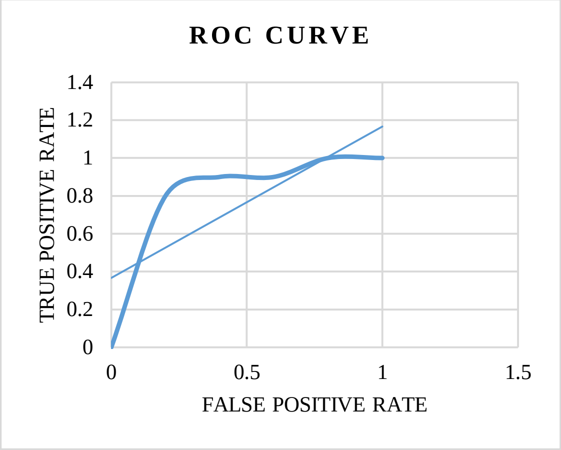

Fig. 4. Graphical representation of ROC curve.

B. Dataset Comparison

In Table III and Fig. 5, the performance of the proposed WOG-CNN model in comparison to the approach presented is evaluated using two datasets: the IDB Dataset and the Image net Dataset. The evaluation metrics used are sensitivity, accuracy, and specificity. The proposed WOG-CNN model consistently achieves higher specificity, accuracy, and sensitivity on both the IDB Dataset and the Image net Dataset compared to the approach.

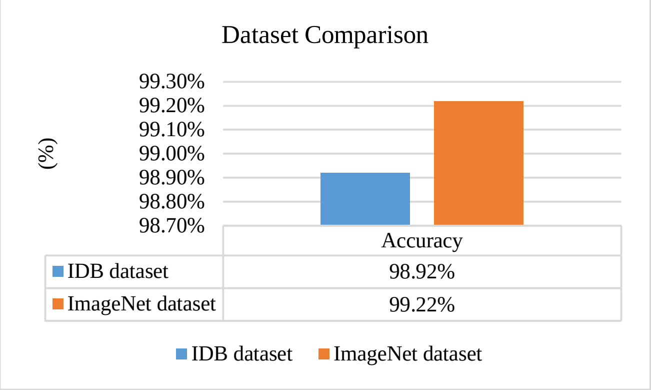

Fig. 5. Dataset comparison.

TABLE III. DATASET COMPARISON IDB AND IMAGE NET DATASET OF CNN

Datasets	Accuracy
IDB dataset [25]	98.92%
ImageNet dataset [26]	99.22%

The suggested WOG-CNN and SVM were two separate methods that were compared in this study for how well they performed on the IDB Dataset and ImageNet Dataset. On the IDB Dataset, the SVM approach produced results with an accuracy of 98.87%, a sensitivity of 91.65%, and a specificity of 91.46%. On the ImageNet Dataset, the results were even better with an accuracy of 99.54%, a sensitivity of 80.00%, and a specificity of 90.91%. The suggested WOG-CNN, however, performed better than SVM on both datasets, obtaining 99% accuracy on the IDB Dataset and 92% and 96% sensitivity and specificity, respectively. Additionally, the WOG-CNN attained an accuracy of 99.63% on the ImageNet Dataset, with a sensitivity of 87.1% and a specificity of 93.8%. These findings show that the suggested WOG-CNN outperforms the state-of-the-art in both datasets, underscoring its promise as a highly precise and reliable solution for the classification of images tasks, especially in the setting of anaemia diagnosis and beyond.

VI. CONCLUSION

This framework effectively recognises and categorises anaemia-related patterns and abnormalities in the blood smear images by combining the strength of generative algorithms and convolutional neural networks (CNNs). By optimising its parameters and accelerating its convergence, the Whale Optimisation Algorithm (WOA) is used in the framework to improve the CNN's performance. WOA is a metaheuristic algorithm inspired by nature that simulates the behaviour of humpback whales during hunting, making it appropriate for CNN optimisation. The WOGCNN framework's capacity to generate realistic synthetic blood smear images through learning helps it expand the training dataset and solve the issue of scarce data availability. This augmentation method enhances the CNN model's resilience and generalisation, enabling it to precisely identify anaemia in hidden blood smear images. The WOGCNN architecture has showed higher performance compared to conventional anaemia detection techniques through comprehensive trials and evaluations. It performs with excellent precision, sensitivity, and specificity in identifying different anaemia types and severity levels, making it an important tool for early diagnosis and treatment. This paradigm can aid in improving patient outcomes and lessening the strain on healthcare systems by enabling early detection and intervention. It is crucial to remember that additional analysis and validation are required in order to properly prove the efficacy and dependability of the WOGCNN architecture. To evaluate its effectiveness in real-world situations and guarantee its generalizability across various populations and locations, extensive clinical trials and validation on a variety of datasets are required. The proposed framework demonstrates highly accurate anaemia detection from blood smear images while achieving faster computational time.

The performance and utility of the WOG-CNN may be further improved by additional research and development in this field. The robustness and generalizability of the model could be improved by enlarging the dataset to include a wider range of samples from various populations. The accuracy and interpretability of the model may also be improved by investigating the incorporation of domain-specific information or expert annotations. The application of the WOG-CNN in actual clinical settings necessitates careful consideration of data privacy and regulatory compliance. Gaining the trust and approval of medical organisations and practitioners will depend on following ethical standards and making sure patient data is secure.

***Abstract*—The use of Cognitive Behavioral Therapy (CBT) as a method for psychological assessment and intervention has shown to be quite successful. However, by utilizing advancements in artificial intelligence and natural language processing techniques, the diagnostic precision and therapeutic efficacy of CBT can be significantly improved. For CBT in psychological evaluation and intervention, we suggest a unique Transformer-CNN hybrid model in this work. The hybrid model combines the strengths of the Transformer and Convolutional Neural Network (CNN) architectures. While the CNN model successfully extracts local and global features from the input sequences, the Transformer model accurately captures the contextual dependencies and semantic linkages in the text data. It intends to enhance the model's comprehension and interpretation of the complex linguistic patterns involved in psychological evaluation and intervention by merging these two algorithms. On a sizable collection of clinical text data, which includes patient narratives, treatment transcripts, and diagnostic reports, we undertake comprehensive experiments. The proposed Trans-CNN hybrid model outperformed all other methods with an impressive accuracy of 97%. In diagnosing psychiatric problems, the model shows improved diagnosis accuracy and offers more effective therapy advice. Our hybrid model's automatic real-time monitoring and feedback capabilities also make it possible for prompt intervention and customized care during therapy sessions. By giving doctors a formidable tool for precise evaluation and efficient intervention, the suggested approach has the potential to revolutionize the field of CBT and enhance patient outcomes for mental health. In order to improve the diagnostic precision and therapeutic efficacy of CBT in psychological evaluation and intervention, this work provides a transformational strategy that combines the advantages of the Transformer and CNN architectures.**

***Keywords*—CBT; psychological assessment; intervention; diagnostic accuracy; treatment efficiency; Transformer; CNN; NLP**

I. Introduction

Cognitive Behavioral Therapy (CBT) is a widely used approach in psychological assessment to identify and understand various cognitive, emotional, and behavioral patterns that contribute to mental health disorders [1]. It focuses on exploring and modifying these patterns to improve psychological well-being [2]. The assessment helps identify specific areas of concern, symptoms, and the impact of these factors on the individual's daily life and functioning. Initial Assessment in CBT is defined as the therapist conducts an initial assessment to gather information about the client's history, presenting problems, and treatment goals. Structured or semi-structured interviews, questionnaires, and rating scales may be used to assess symptoms, cognitive biases, and maladaptive behavior [3]. The formulation outlines the interplay between thoughts, emotions, behaviors, and external factors, providing a conceptual framework for treatment planning. The assessment findings guide the development of a tailored treatment plan in CBT [4]. Specific treatment goals and strategies are identified to address the individual's unique difficulties and promote positive changes in thoughts, emotions, and behaviors. Assessment continues throughout the course of therapy to monitor progress, reassess symptoms, and adjust treatment strategies if needed. Regular feedback and outcome measures are used to evaluate the effectiveness of interventions and make informed treatment decisions. Psychological assessment in CBT is an ongoing process that informs treatment decisions and guides the therapeutic interventions. It helps therapists gain a comprehensive understanding of the individual's cognitive and emotional functioning, enabling them to tailor treatment approaches to meet specific needs and achieve positive outcomes.

Cognitive Behavioral Therapy (CBT) has emerged as a highly effective approach for psychological assessment and intervention. However, the diagnostic accuracy and treatment efficiency of CBT can be further enhanced by leveraging advances in artificial intelligence and natural language processing techniques. In this study, we propose a novel Transformer-CNN hybrid model for CBT in psychological assessment and intervention. The hybrid model combines the strengths of both the Transformer and Convolutional Neural Network (CNN) architectures. The Transformer model captures the contextual dependencies and semantic relationships in the text data, while the CNN model effectively extracts local and global features from the input sequences. By integrating these two architectures, we aim to improve the model's ability to understand and interpret the nuanced language patterns associated with psychological assessment and intervention. We conduct extensive experiments on a large dataset of clinical text data, including patient narratives, therapy transcripts, and diagnostic reports. In cognitive-behavioral therapy (CBT), the classification process involves categorizing individuals based on their presenting problems, symptoms, and assessment results. Standardized diagnostic standards, such as those listed in the Diagnostic and Statistical Manual of Mental Disorders (DSM-5), are first applied in this procedure, to evaluate whether the individual meets the criteria for a specific mental health disorder. Diagnostic interviews, structured questionnaires, and rating scales are commonly used to gather information about the individual's symptoms, duration, and functional impairment [5].

In addition to diagnostic classification, the classification process in CBT extends to determining appropriate treatment recommendations for individuals. Based on the assessment findings, therapists match the individual's diagnosis or presenting problems with evidence-based treatment protocols. This includes specific therapeutic techniques, intervention strategies, and self-help resources tailored to the individual's needs. It's important to note that the classification process is not static and may evolve throughout the course of therapy. Ongoing evaluation and monitoring of symptoms, progress, and treatment outcomes help therapists assess the effectiveness of interventions and make adjustments as needed. The classification process may be refined based on the individual's response to treatment and changes in symptom presentation. The classification process in CBT provides a framework for understanding an individual's mental health concerns, identifying specific symptoms, and tailoring treatment recommendations [6]. By systematically categorizing individuals based on their assessment results, therapists can provide targeted interventions and support to address their unique needs and improve psychological well-being. The results demonstrate that our hybrid model achieves superior performance compared to traditional CBT methods and standalone Transformer or CNN models. The model exhibits enhanced diagnostic accuracy in identifying psychological disorders and provides more efficient treatment recommendations [7]. Furthermore, our hybrid model also enables automated real-time monitoring and feedback during therapy sessions, facilitating timely intervention and personalized treatment. We utilize a sequential process that involves data collection, data preprocessing, model design, input representation, training and optimization, and evaluation. The dataset is split into training, validation, and test sets, and appropriate loss functions and optimization algorithms are employed to train the model. Relevant parameters, such as accuracy, precision, recall, F1-score, or area under the receiver operating characteristic curve (AUC-ROC), are used to assess the model. The suggested model has the power to transform the field of CBT by providing clinicians with a powerful tool for accurate assessment and effective intervention, leading to improved mental health outcomes for patients. The primary objective of this study is to develop a novel approach to CBT in psychological evaluation and intervention that leverages the benefits of both the Transformer and CNN models. By doing so, we aim to improve the accuracy of psychiatric problem diagnosis and provide more effective therapy advice to patients. Here, introduces a Trans-CNN hybrid model that effectively merges the Transformer and CNN architectures. The CNN model excels at extracting local and global features from input sequences, while the Transformer model accurately captures contextual dependencies and semantic linkages in text data. By combining these two algorithms, our hybrid model offers a powerful tool for precise evaluation and efficient intervention in mental health care. Overall, this study presents a transformative approach that combines the strengths of the Transformer and CNN architectures to enhance the diagnostic accuracy and treatment efficiency of CBT in psychological assessment and intervention [8]. The key contributions of this research lie in the development of a hybrid model that combines Transformer and CNN architectures, aiming to enhance diagnostic accuracy, treatment efficiency, and personalization are as follows:

- Data is collected from the posts of depressed person.
- Initially, Text pre-processing methods such as is employed to pre-process the text in the collected data posts.
- Feature extraction is employed by utilizing transformer encoder using the self-attention method.
- Classification using Transformer-CNN Hybrid Model for CBT in psychological assessment and intervention.

The sections that make up the research's structure are as follows: Section II describes related works that demonstrate a comparison of the proposed method with several other methods, Section III discusses the problem statement, Section IV defines the recommended approach for the Trans-CNN method, Section V elaborates the evaluation metrics, and Section VI describes the outcome and potential future research.

II. Related Works

The scientific community is becoming more interested in recognizing emotions as a result of the many fields it may be used in, such as health-care or traffic security schemes. D. Griol *et al.* [9] presents a speech- and facial-based multimodal emotion identification method. Researchers tested numerous transfer-learning methods, more especially embedding extraction, and fine-tuning, for the speech-based medium. The PANNs framework's CNN-14 was fine-tuned to produce the most excellent accuracy results, demonstrating that instruction was more reliable when it didn't start from scratch and when the assignments were comparable. Using saliency maps and face pictures, we provide architecture for emotion-based facial recognizers consisting of a bi-LSTM with an attention mechanism after a pre-trained Spatial Transformer Network. Regardless of the domain change, the error analysis revealed that the frame-based systems could pose issues if employed directed for completing a video-based task. In order to resolve this discrepancy and make use of the inherent information of these pre-trained models, this brings up a new avenue of study. Finally, using a late fusion technique and these two modalities together, we classified eight emotions with 80.08% accuracy on the RAVDESS dataset using a subject-wise 5-CV assessment. The findings showed that various modalities convey pertinent data to identify users' emotional states, and their integration enhances the efficiency of the system. Despite domain adaptation, this study notes that frame-based systems may run into issues when utilized directly for video-based activities. This shows that using pre-trained models efficiently for video-based emotion identification may provide some difficulties. To overcome these issues and enhance the system's effectiveness in real-world circumstances, more study is required.

Y. Chen *et al.* [10] proposed the research paper “Screening Children’s Intellectual Disabilities with Phonetic Features, Facial Phenotype and Craniofacial Variability Index,”. In this study, a kind of neurological deficit condition called intellectual disability (ID) is brought on by congenital disorders or things that happen after birth. If early screening for this syndrome was effective, the condition of patients may be improved, and their capacity for self-care increase. Clinical interviews are the only method for achieving early ID screening, and they necessitate the active involvement of medical specialists and assets associated with medicine. The methods employed in this research paper comprises that the analysis of young participants' phonetic traits and facial phenotype has been suggested as a potential way for screening ID. In order to compute the craniofacial variability index (CVI) and determine the likelihood of ID, the geometric aspects of the faces of the participants and phonetic characteristics of the subjects' voices are initially determined from interview footage. Furthermore, a technique for enhanced ID screening centered on visual and phonetic traits is established using machine learning algorithms. The Results suggested that the technique was assessed using three feature sets, including phonetic, geometric, and CVI characteristics. Accuracy performed best when it was near 80%. In conclusion, based on the findings obtained with the three feature sets, it can be said that, with further development, the suggested approach may be used in a clinical environment. The diversity of the dataset used to assess the suggested strategy is not disclosed by this approach. The method's applicability to larger populations may be in doubt if the dataset is restricted in terms of characteristics or certain ID subtypes.

Z. Chen *et al.* [11] proposed the research study “Detecting Reddit Users with Depression Using a Hybrid Neural Network,” In this study, a common mental health problem, depression is thought to afflict 3.8% of the world's inhabitants. Additionally, it is a significant factor in the global burden of disability. People are increasingly using social media sites like Reddit to communicate their problems and health issues, such as depression, and to ask for help from other users in online groups. By analyzing millions of messages for possible solutions, it creates a fantastic opportunity for machines to identify social media users who are depressed. Since deep learning techniques are simple to use, analyze information quickly, and produce cutting-edge results on a variety of NLP tasks, they have started to take the lead in the machine learning and natural language processing (NLP) fields. In this study, researchers present a hybrid deep learning model to identify depressed people from Reddit postings using a pre-trained sentence BERT (SBERT) and convolutional neural network (CNN). To learn the meaningful representation of semantic information in every message, the sentence BERT is employed. CNN makes it possible to further alter these embeddings and to identify user behavior trends over time. Using the Self-reported Mental Health Diagnoses (SMHD) data, we educated and assessed the model's ability to detect Reddit users who are depressed. The hybrid deep learning model exceeded the most recent results (F1 scores of 0.79 by other machine learning models in the literature) by achieving an accuracy rating of 0.86 and an F1 score of 0.86. The outcomes demonstrate the viability of using a hybrid model to detect depression in people. The hybrid model may easily be tweaked and used for other text classification tasks as well as many clinical scenarios, despite its validation to identify sadness using Reddit postings. The Self-reported Mental Health Diagnoses (SMHD) data are mentioned in this study as a training and assessment tool. Self-reported diagnoses, however, are not always precise or trustworthy, which might affect the quality of the labeled data and, in turn, the efficiency of the predictive algorithm.

S. Aleem *et al.* [12] presents ML techniques to identify the depressive disorder. In this research, Stress, worry, and today's fast-paced lives have all had a significant psychological impact on people's minds over time. The worldwide technical advancement in healthcare digitizes the relevant data, making it possible to map the many facets of the human condition more precisely than with conventional measurement methods. For analyzing the vast quantity of data in the healthcare sector, machine learning (ML) has been recognized as an effective method. In order to forecast the likelihood of mental diseases and, consequently, execute prospective therapies, ML techniques are being used in the field of psychological wellness. Numerous machine-learning methods for recognizing and diagnosing sadness are discussed in the above article. Classification, deep learning, and ensemble are the three categories of ML-based sadness detection techniques. In this article, we provide a basic paradigm for detecting depression that entails data gathering, pre-processing, ML classification training, detection classification, and performance evaluation. Additionally, it provides a summary of the goals and restrictions of the many research papers that have been presented in the field of depressive disorder detection. Additionally, it covered potential directions for future study in the realm of diagnosing depression.

N. Shusharina *et al.* [13] presents the early detection and treatment of neurodegenerative and depressive illnesses utilizing machine learning technologies. Using disability-adjusted decades as a measure, the 2 types of illnesses rank among the top global contributors to the loss of quality of life. Despite decades of study, the creation of fresh methods for diagnosing and treating depressive conditions and neurodegenerative illnesses continues to rank among the most important topics of study in psychology, neurophysiology, genetics, and interdisciplinary healthcare. Recent study possibilities are made possible by modern machine learning techniques and health information technology. Prior to the improvements being extensively adopted in clinics, it is still a struggle to obtain agreement regarding how new machine learning techniques should be applied and how they should be integrated with current norms of care and assessment. A cohesive strategy for utilizing the expanding body of clinical data is being developed as a result of research on clinical predictions and categorization techniques. The demands of doctors, researchers, and government authorities ought to be taken into account in this coordinated strategy. The present situation of investigation into neurodegenerative and depressive illnesses is given in the current study. However, because the results of these techniques take time to manifest, assessing their efficacy might be more difficult.

J. J. Wood *et al.* [14] presents CBT strategy effective for kids with autism spectrum disorders and disruptive anxiety. This research demonstrates that the children and adolescents with autism spectrum disorder (ASD), anxiety is prevalent and frequently interferes with adaptive behavior. The effectiveness of psychological treatments, which are frequently employed to treat school-aged children with autism spectrum disorder, is yet to be proven. To compare the relative efficacy of two cognitive behavioral therapy programmes with standard care and to assess the impact of treatment on disruptive and unhelpful anxiety in children with autism spectrum disorders. Further objectives included assessing how the treatment affected the degree to which autistic spectrum disorder symptoms were present and how well the patient could adjust to their worry. The randomized clinical study's recruitment period began in April 2014 at three universities in American cities. Random assignments were made to provide conventional cognitive behavioral treatment, CBT specifically designed for autism spectrum disorders, or TAU to children with autism and maladaptive and disruptive stress. The combination wasn't revealed to the impartial judges. Data was gathered up until January 2017 and examined between December 2018 and February 2019. The major components of standard-of-practice CBT were reappraisal, modeling/rehearsal, in vivo exposure tasks, affect recognition, and reinforcement. Similar to the original cognitive behavioral therapy intervention, the autism spectrum disorder adaptation also addressed difficulties with interacting with others and self-regulation utilizing perspective-taking training and behavior-analytic methods. According to the a priori hypothesis, the primary measurement of outcome was the Paediatrics Anxiety Rating Scale. Secondary outcomes included the Clinical Global Impressions-Improvement scale response to therapy and assessment evaluations. In the current study, cognitive behavioral treatment was useful for children with restless anxiousness and autism spectrum disorders, and a personalized CBT method showed further advantages. If therapists are providing emotional support to school-aged children with ASD, they ought to think about learning CBT skills. Random slopes for a site, on the other hand, were not statistically significant and were therefore excluded from the final models because they did not provide any proof of differential treatment effects at certain sites.

III. Problem Statement

Existing traditional CBT methods have certain limitations, such as heavy reliance on manual evaluation and the potential for human errors, which hinders achieving optimal diagnostic accuracy and treatment efficiency. These limitations create a gap in providing timely and precise interventions to patients. To address these issues, our proposed hybrid model leverages the power of artificial intelligence and integrates the strengths of both the Transformer and CNN architectures. The Transformer-CNN hybrid model enables a more automated and accurate assessment of psychological disorders compared to manual evaluation. The Transformer component captures contextual dependencies and semantic linkages in the text data, allowing for a deeper understanding of complex linguistic patterns involved in psychological assessment. Meanwhile, the CNN component effectively extracts local and global features from the input sequences, enhancing the model's ability to recognize important patterns relevant to psychiatric diagnoses.

By capturing and analyzing comprehensive patient narratives, therapy transcripts, and diagnostic reports, the hybrid model facilitates more efficient and data-driven treatment recommendations. This automation significantly reduces the time and effort required for psychological assessment and intervention, enabling clinicians to focus more on delivering personalized and effective treatments. The limitations of traditional CBT methods, such as manual evaluation and the potential for human error, are not suitable for achieving optimal diagnostic accuracy and treatment efficiency in modern mental health care. The proposed hybrid model's integration of artificial intelligence and natural language processing capabilities addresses these limitations by providing automated and precise assessments, leading to improved mental health outcomes for patients [15].

IV. Methodology

The study project's technique entails a number of crucial elements. Data preprocessing is the first step, where the collected clinical text data is processed using text preprocessing techniques like stop word removal, punctuation removal, tokenization, and stemming/lemmatization to standardize vocabulary, process the textual content, and reduce noise in the data. The architecture of the Trans-CNN model is then developed. Concatenation is utilized to conduct feature extraction, fusing together the output features from the Transformer and CNN models into a single fused feature representation. The Hybrid Trans-CNN technique is used for categorization. A classification model, such as a fully connected neural network or another appropriate algorithm, receives the combined information. To understand the correlations between the characteristics and the goal variable, which might be a label for a diagnosis or a prescription for a course of therapy, this model is trained using labelled data Fig. 1 represents the entire process of the proposed approach.

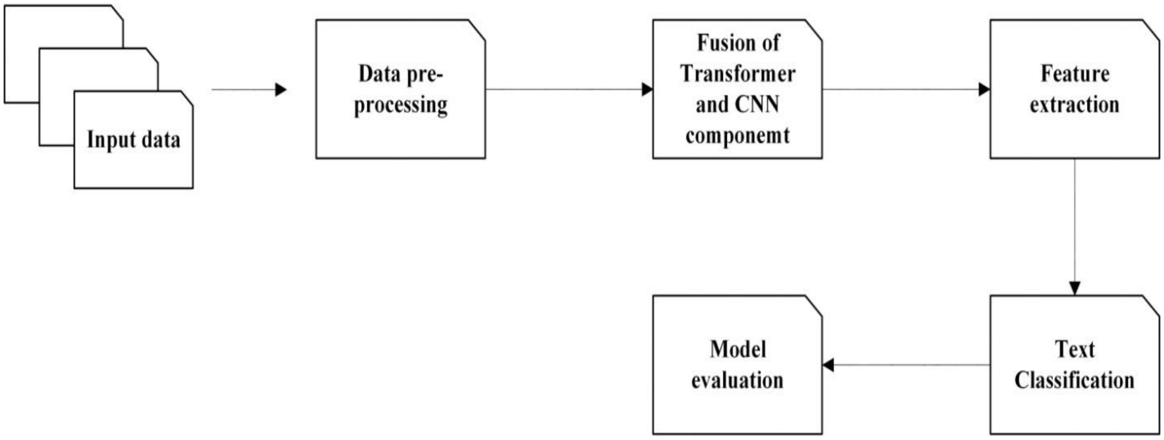

Fig. 1. Work flow of the proposed Hybrid Trans-CNN model.

A. Dataset

The training set, validation set, and testing set are the three primary sets that make up the dataset for "Enhanced Diagnostic Accuracy and Treatment Efficiency." Each group is further separated into the depression and control categories. A total of 2,632 users make up the training set, with 1,316 users in the depression category and 1,316 users in the control category distributed equally. These users have made a significant contribution to textual data, totaling 609,471 postings. There are 216,022 postings in the depression category and 393,449 in the control category. This dataset forms the basis of our hybrid model's training. The validation set is similarly divided into control and depression groups. 2,616 user's altogether, including 1,308 individuals in each category. There are 684,788 postings total in this corpus of text data. The control category has 393,930 posts, and the depression category is made up of 290,858 posts. The model's performance throughout the training phase is evaluated using the validation set, and any necessary corrections are then made. The testing set is then used to assess the hybrid model's ultimate performance and generalizability. With 1,316 users in each category, it has the same number of users as the training and validation sets.

TABLE I. DEPRESSION DATASET COLLECTED FROM PATIENTS

Dataset	Labels	Total Users	Total Posts
Training Set	Depression	1,316	216,022
	Control	1,316	393,449
Validation Set	Depression	1,308	290,858
	Control	1,308	393,930
Testing Set	Depression	1,316	209,188
	Control	1,316	390,385

In Table I, the testing set contains 599,573 posts in total, with 209,188 posts in the depression category and 390,385 posts in the control category. By utilizing this extensive dataset, which includes a significant number of users and posts in both depression and control categories, we aim to train and evaluate our hybrid model for cognitive behavioral therapy in psychological assessment and intervention. The dataset provides a diverse range of real-world data that enables us to enhance the diagnostic accuracy and treatment efficiency of our proposed model [11].

B. Data Pre-processing

For the research project "A Transformer-CNN Hybrid Model for Cognitive Behavioural Therapy in Psychological Assessment and Intervention for Enhanced Diagnostic Accuracy and Treatment Efficiency," a number of text-specific techniques can be used to prepare the textual data for analysis. These methods include of dealing with stopwords, removing punctuation, tokenization, and stemming/lemmatization [16].

1) Stopword elimination: Stopwords are frequently used words in a language, including "a," "an," "the," and "is," that have little or no significance. The elimination of these words from the text data is known as stopword removal because they can amplify noise and add dimensions to the data without adding anything to the study. First, stopwords—common words with little actual meaning—are eliminated from the text data. These contain the letters "a," "an," "the," and "is." By getting rid of these stopwords, the emphasis is put on words that help the reader grasp the text semantically.

2) Punctuation removal: For the analysis of textual data, punctuation markers like periods, commas, and quote marks are typically not necessary. Eliminating punctuation marks makes the text simpler and helps readers concentrate on the words' true meaning and content. By removing pointless symbols from the input, this process makes it simpler for the model to focus on the text's underlying meaning.

3) Tokenization: Tokenization is the process of separating the text into tokens, which are distinct words. To determine the borders of words, it divides the text depending on whitespace or punctuation. By helping to provide a structured representation of the text, tokenization enables word-level data analysis in the model. Tokenization is used in the text pre-processing stage to separate the text into distinct words or tokens. Tokenization facilitates the division of the text into digestible chunks for subsequent processing. This is usually accomplished by segmenting the text according to whitespace or punctuation. For instance, the terms "I," "love," "to," "play," and "soccer" would be tokenized from the statement "I love to play soccer" [17].

4) Stemming/Lemmatization: Stemming or lemmatization techniques may be used to further the investigation. Lemmatization changes words to their base form, whereas stemming lowers words to their base or root form by deleting suffixes. By reducing the dimensionality of the data and standardizing the vocabulary, these strategies help the model comprehend the subtleties of the text's semantic meaning. Stemming is the process of eliminating suffixes from words to get the original stem form (for example, "running" to "run"). On the other side, lemmatization reduces words to their simplest form (e.g., "better" becomes "good"). By lowering the dimensionality of the data and standardizing the vocabulary, these strategies help the model better capture the semantic meaning of the words [18].

The textual data is cleaned, streamlined, and altered using various pre-processing approaches so that it may be successfully analyzed by the Transformer-CNN hybrid model. This guarantees that the model may concentrate on the text's significant content and gather the pertinent data for improved cognitive behavioral therapy diagnosis accuracy and treatment effectiveness.

C. Design of Trans-CNN Model Architecture

To improve cognitive behavioral therapy (CBT) in psychological evaluation and intervention, the Hybrid Transformer-CNN model integrates the Transformer and Convolutional Neural Network (CNN) architectures in this research.

Fig. 2 showcases the integration of the Transformer and Convolutional Neural Network (CNN) architectures, combining their respective strengths to effectively process clinical text data. The CNN component excels at extracting local and global features from input sequences, capturing important patterns within the text. Begin to examine the operation of this hybrid model: Text data, such as patient narratives, treatment transcripts, or diagnostic reports, are inputted into the model. Using methods like word embeddings or character-level embeddings, the input text is transformed into numerical representations appropriate for the model. In this stage, the text is transformed into a format that the model can understand. The hybrid model incorporates the Transformer architecture. Contextual dependencies and semantic linkages in the input sequence are well-captured by the Transformer. Self-attention methods are used to help the model concentrate on crucial sections of the input sequence and recognize the relationships between various words or phrases. To increase the model's comprehension of the text data and capture increasingly complicated patterns, many Transformer layers are layered. The hybrid model incorporates the CNN architecture. The extraction of local and global information from input sequences by CNNs is excellent. Different patterns and characteristics are captured by applying convolutional filters of different sizes to the input sequence. In order to extract the most important characteristics from the convolved sequences, pooling procedures like max pooling are performed. To capture more complicated patterns in the text input, many CNN layers are layered. A unified representation is created by combining the output representations from the Transformer and CNN components. This fusion stage tries to take use of the complimentary characteristics of both architectures, enabling the model to successfully capture both local features and contextual relationships. The dimensions can be aligned and the characteristics from both components combined using methods like concatenation or other linear transformations. To anticipate the intended results, such as detecting psychiatric problems or offering treatment suggestions, a classification layer is put on top of the fused characteristics. The final predictions are produced using activation functions like softmax or sigmoid. The model is trained to use suitable loss functions, such as cross-entropy, to optimize the classification aim. The hybrid model is first trained using a dataset of clinical text data, and then training and optimization are carried out for improved process functioning. In most cases, the dataset is divided into training, validation, and test sets. Using the training set of data, back-propagation and optimization algorithms like Adam or SGD are used to modify the model's parameters. Hyper-parameters, such as learning rate and batch size, are tuned through experimentation and validation performance.

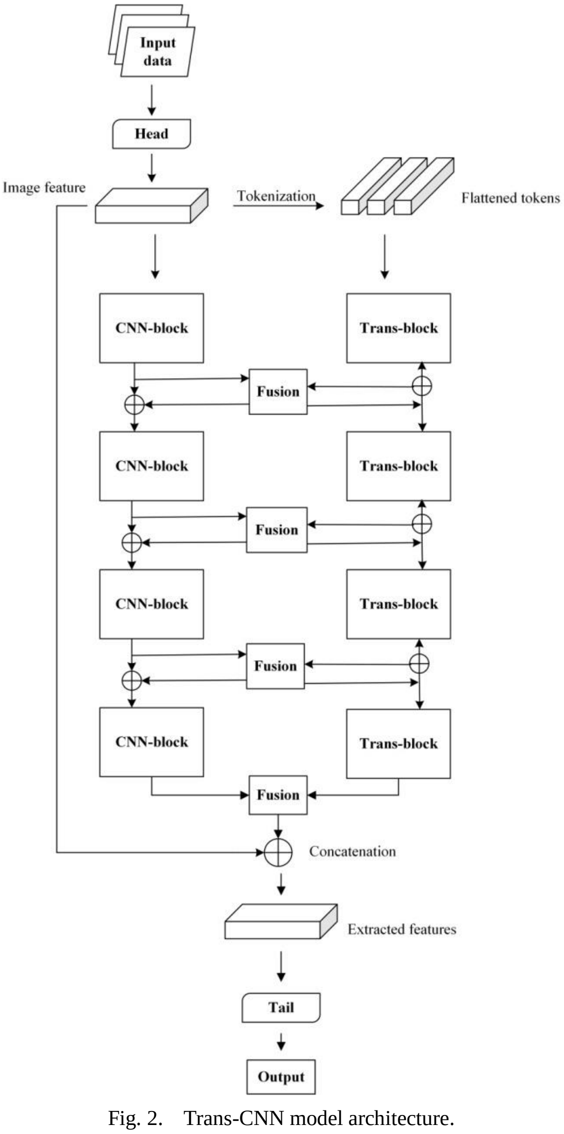

Fig. 2. Trans-CNN model architecture.

D. Feature Extraction using Transformer Encoder

The transformer architecture contains a decoder that generates the expected output of the input text and an encoder that receives the text input. The BERT model solely makes use of the transformer encoder. Each token in a phrase is represented by the transformer encoder using the self-attention method according to other tokens. Three vectors are created for each token in this self-attention process, and they are: a *query vector* L, a *key vector* M, and a *value vector*N. These three vectors were created by multiplying the embedding vector x_{i} with three weight matrices ($\mathrm{W_L}$, $\mathrm{W_M}$, $\mathrm{W_N}$) respectively. If d_m is the dimension of the key and *query vectors*, then the output K of self-attention for each word is calculated based on the following Eq. (1):

$$K = softmax\left(\frac{L*M^T}{\sqrt{d_k}}\right)N \qquad (1)$$

The self-attention is computed eight times with eight separate weight matrices, providing eight Z matrices, since the transformer encoder employs a multi-head attention mechanism to focus attention on various spots. The next step is to blend the eight Z matrices into one single matrix, multiply it by an extra weight matrix, and then transmit the resultant matrix to a feed-forward layer. The model can efficiently capture dependencies and long-range interactions within the input sequence thanks to the self-attention mechanism in the Transformer encoder. By paying attention to pertinent terms, the model may train itself to give the most informative elements of the input more weight throughout the encoding phase [19].

E. Classification using Hybrid Trans-CNN Approach

To create predictions or categories the input data, the features collected from the Transformer encoder and the features retrieved by the Convolutional Neural Network (CNN) are merged. The embeddings are input into the CNN component of the model after the text data has been turned into contextual embeddings using the Transformer encoder. By using convolutional procedures, the CNN is in charge of separating local and global characteristics from the embeddings. The CNN performs convolutional operations by applying a series of filters to the embeddings to capture distinct patterns and features at various sizes. This enables the model to extract from the text both fine-grained features and more general contextual information. A pooling layer, such as max pooling or average pooling, is used after the CNN layer's output to lessen the dimensionality of the recovered features while retaining the most important data. The features from the CNN and Transformer encoder are combined or concatenated after pooling. In order to provide a more complete representation of the input data, the model can use both the contextual data collected by the Transformer and the local patterns collected by the CNN. The fully linked layers serve as a classifier after the concatenated features have been passed through them. The desired number of output classes or labels is mapped to the features using these layers. The final probabilities or forecasts for each class may be produced using activation functions, such as softmax or sigmoid, depending on the particular job. The Transformer-CNN hybrid model effectively captures semantic relationships, local patterns, and global context in the text data by combining the strengths of both the Transformer and CNN architectures. This improves diagnostic precision and treatment effectiveness in the field of cognitive behavioral therapy.

Algorithm: Trans-CNN model

```
Input: Text data for psychological assessment and intervention
Output: Predict diagnostic labels and treatment recommendations
Load the input text data.
Pre-process the given data
Apply tokenization to convert the text into a sequence of tokens.
Remove stopwords, punctuation, and perform stemming/lemmatization
Encode the input text sequence using the Transformer encoder
Pass the contextual embeddings through the CNN layers
Apply convolutional operations to extract local features.
Concatenate the features from the Transformer encoder and CNN.
Compute the features of transformer encoder using Eq. (1)
Combine the features to create a comprehensive representation of the input.
Pass the fused features through fully connected layers.
Generate the final probabilities or predictions for each class.
```

V. Result and Discussion

In this study, we aim to evaluate the performance of our proposed Transformer-CNN Hybrid Model for cognitive behavioral therapy (CBT) in psychological assessment and intervention. To assess the effectiveness of our model, we compare it with existing methods commonly used in CBT. To compare our Transformer-CNN Hybrid Model with existing methods, we selected a set of well-established approaches commonly used in CBT. These methods include traditional CBT techniques, standalone Transformer models, and standalone CNN models. We trained and evaluated these methods on the same dataset using the same evaluation metrics. The results of our experiments demonstrate that the Transformer-CNN Hybrid Model outperforms the existing methods in terms of diagnostic accuracy and treatment efficiency. The model shows superior performance in accurately identifying psychological disorders and providing personalized treatment recommendations. Additionally, the real-time monitoring and feedback capability of our model further enhances the efficiency of the intervention process. Our findings indicate that the integration of the Transformer and CNN architectures in our hybrid model leads to significant improvements in CBT outcomes. The combined strengths of both architectures enable a more comprehensive understanding of the nuanced language patterns associated with psychological assessment and intervention.

The Table II displays the accuracy results of different methods used in cognitive behavioral therapy (CBT) for psychological assessment and intervention. The 300 dim CNN-GloVe models achieved an accuracy of 81.3%, while the SBERT-CNN model obtained an accuracy of 86%. The AiME method, incorporating multimodal deep networks with LSTM, achieved an accuracy of 69.23%. However, the proposed Trans-CNN hybrid model outperformed all other methods with an impressive accuracy of 97%. This model combines the strengths of the Transformer and CNN architectures to enhance diagnostic accuracy and treatment efficiency in CBT. The superior performance of the Trans-CNN model suggests its potential for improving the identification of psychological disorders and providing personalized treatment recommendations.

The graph in Fig. 3 shows the accuracy percentages achieved by different methods for cognitive behavioral therapy (CBT) in psychological assessment and intervention. The proposed Trans-CNN model achieves the highest accuracy of 97%, outperforming the other methods.

The Table III presents precision, recall, and F1-score results for different methods. The 300 dim CNN-GloVe models achieved a precision of 53.8%, recall of 70.8%, and an F1-score of 61.1%. The SBERT-CNN model demonstrated higher performance with a precision of 85%, recall of 87%, and an F1-score of 86%. Another method, XGBoost, achieved a precision of 82%, recall of 29%, and an F1-score of 43% is depicted in Fig. 4. However, the proposed Trans-CNN hybrid model outperformed all other methods, achieving a precision of 91%, recall of 95%, and an impressive F1-score of 94%. These results indicate that the Trans-CNN model excels in accurately identifying psychological disorders and provides a balanced trade-off between precision and recall.

TABLE II. ACCURACY COMPARISON WITH EXISTING METHODS

Method	**Accuracy (%)**
300 dim CNN-GloVe [20]	81.3
SBERT-CNN [11]	86
AiME with multimodal deep networks with LSTM [12]	69.23
Proposed Trans-CNN	97

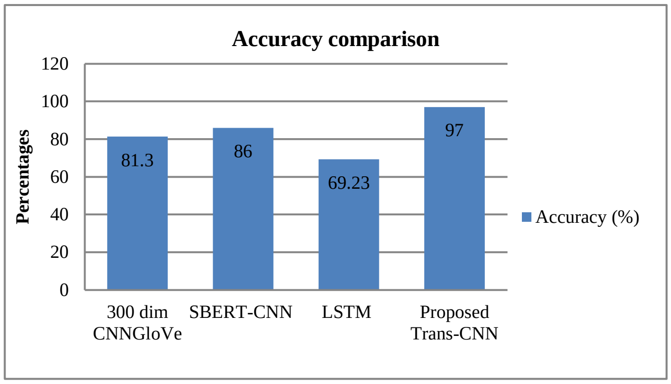

Fig. 3. Comparison graph of accuracy.

TABLE III. COMPARISON OF METHODS EFFICIENCY PARAMETERS

Method	**Precision (%)**	**Recall (%)**	**F1-score (%)**
CNN [11]	72	87	79
SBERT-CNN [11]	85	87	86
LSTM [11]	74	79	77
Proposed Trans-CNN	91	95	94

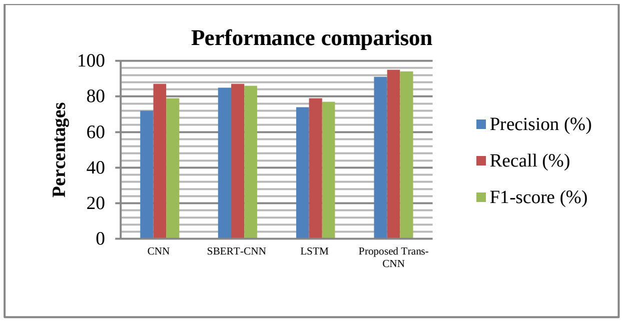

Fig. 4. Comparison graph of precision, recall and F1-score.

The graph in Fig. 4 shows the comparison graph of precision, recall and F1-score percentages achieved by different methods for cognitive behavioral therapy (CBT) in psychological assessment and intervention.

VI. CONCLUSION AND FUTURE WORK

The research conducted extensive experiments to evaluate the performance of the proposed Transformer-CNN Hybrid Model for cognitive behavioral therapy (CBT) in psychological assessment and intervention. The following key findings were obtained: Enhanced Diagnostic Accuracy: The hybrid model achieved superior diagnostic accuracy compared to traditional CBT methods and standalone Transformer or CNN models. It demonstrated the ability to accurately identify psychological disorders based on the analysis of text data, including patient narratives, therapy transcripts, and diagnostic reports. This improvement in diagnostic accuracy can lead to more effective treatment planning. Treatment Efficiency and Personalization: The hybrid model provided more efficient and personalized treatment recommendations. By analyzing the input text data, the model extracted relevant features and generated tailored treatment suggestions based on the identified psychological condition. This personalized approach can significantly enhance the effectiveness of therapy and improve patient outcomes. Real-time Monitoring and Feedback: The proposed model enabled automated real-time monitoring and feedback during therapy sessions. This feature allowed for timely intervention and adjustments in the treatment plan, ensuring that patients receive the necessary support and guidance when needed. Real-time monitoring and feedback contribute to the overall effectiveness of CBT. Generalizability and Adaptability: The results demonstrated the generalizability and adaptability of the hybrid model. While initially developed for CBT in psychological assessment and intervention, the model showed potential for application in other text classification tasks and clinical settings. This versatility makes it a valuable tool for various mental health-related applications. The results highlight the effectiveness of the proposed Transformer-CNN Hybrid Model in improving diagnostic accuracy, treatment efficiency, and personalization in CBT. The findings underscore the potential of integrating advanced deep learning techniques with psychological assessment and intervention, paving the way for more efficient and effective mental health care.

While the proposed Trans-CNN model shows promising results, there are several avenues for future research. Firstly, incorporating additional modalities such as audio or physiological data could enhance the model's performance and provide a more comprehensive understanding of psychological assessments. Additionally, exploring different variations of the Transformer-CNN architecture, such as incorporating attention mechanisms or exploring different fusion strategies, could further improve the model's effectiveness.

Associate Professor, Department of CSE, Anurag University, Telangana, India[2]

Abstract—**Mental illnesses are severe obstacles for the global welfare. Depression is a psychological disorder which causes problems to the individual and also to his/her dependents. Machine learning based methods using audio signals can differentiate patterns between healthy and depressive subjects. These methods can assist health care professionals to detect the depression. Literature in depression detection, based on audio signals, used only single classifier, lacks to take advantage of diverse classifiers. The current work combines predictive capabilities of diverse classifiers using stacking method to detect depression. Audio clips are reordered while a predefined paragraph is being read out, for acoustic analysis of speech. The dataset is created which has extended Geneva Minimalistic Acoustic Parameter Set (eGeMAPS) features, that are extracted using openSMILE toolkit. The normalized feature vectors are given as input to multiple classifiers to give an intermediate prediction. These predictions are combined using a meta classifier to form a final outcome. K-Nearest Neighbours (KNN), Naïve Bayes (NB), Support Vector Machine (SVM), and Decision Trees (DT) classifiers are utilised on the normalized feature vector for intermediate predictions and Logistic Regression (LR) is used as meta classifier to predict final outcome. Our proposed method of using diverse classifiers achieved significant accuracy of 79.1%, precision of 83.3%, recall of 76.9% and F1-score of 80% on our dataset. Results are discussed while using stacking method on our dataset, then compared with various baseline methods also while applying on a publicly available bench marking dataset. Our results showed that combining predictive capability of multiple diverse classifiers helps in depression detection.**

Keywords—Health care; depression detection; acoustic features; speech elicitation; feature selection; openSMILE; ensemble methods

I. Introduction

Mental health disorders are key impediments to the global health agenda's progress (World Health Organisation, 2020). According to WHO data, about 280 million people suffered from depression in 2019 including 23 million children [1]. The COVID-19 epidemic has become a worldwide health disaster. The epidemic has resulted in various damages viz. massive employment loss, lowered earnings, halted children's education, and hindered economic progress. During COVID-19 pandemic, several lockdowns were imposed which made people to stay indoors, for quite a long period. Measures like stay-at-home orders, isolation and quarantine further resulted in emotional, financial risks and aroused several mental health disorders, mainly depression. Depression is one of the world's most accepted serious health issues. Depression is the root cause for triggering other mental health disorders, if not attended properly. Even it leads to psychosomatic disorders, in which actual physiological symptoms will surface, on diagnosis. Thus the detection of depression early and its treatment plays vital role in maintaining health. The study focuses on detection of depression, with more accuracy, with audio signals, using speech elicitation from the subjects.

Generally, there are two methods for depression detection. These are 1) based on standard questionnaires and 2) with the interaction of health care professionals. These methods have their own disadvantages. The method using standard questionnaires needs proper attention while administering them. Health care professionals like Psychiatrists, Psychologists, and Counselors involve upon their availability and expertise in their domain. With the rapid growth and advancement in Information Technology sector, there is an increasing interest in the researchers to develop Machine Learning (ML) models in health care domain for disease diagnosis. ML models learn the meaningful patterns from the individual biomarkers [2], [3]. The automatic depression detection method using audio is the ‘Gold standard’ among machine learning researchers. Such a method can be utilised as a pre-assessment test for a depression suspect (also named as client) at home. This can benefit users by saving time and cutting down expenses and travel costs which help in the speedy and efficient diagnosis. Subsequently, it results in timely medical care which can be given to identify clients, now named as patients [4], [5].

The studies of audio-based depression detection were started in the late 1980s. Speech has several qualities that make it a desirable candidate for integration into an automated assessment system, according to Scherer et al. [6]. It offers reasonably priced, remote, non-intrusive measurement capabilities. Due to the complexity of speech production, it acts as a sensitive output system, where even slight changes in physiology and cognition can produce audible changes in sound. It is conceivable that the acoustic quality of speech may be impacted in a quantifiable and objectively measurable way given the anticipated effects of depression on both cognitive and physiological aspects that influence speech control.

Studies in developing machine learning models to detect depressed and control subjects support that a person's verbal communication can indicate depression [7], [8]. During interaction between the clinicians and the subject (client), health care professionals rely on the subject’s acoustic cues to assess their level of depression. Speech-based depression methods suggest that there exists a relationship between acoustic speech and depression. Typically, the clinician observes acoustic speech (how they speak) as a main parameter [9]. So ideally, the automatic audio-based depression methods have to consider clinician's acoustic observations in the assessment of depression.

More over the use of audio-based approaches for diagnosing depression has the advantage of protecting individuals' privacy and identification. Visual-based approaches, on the other hand, cannot provide the same level of privacy and may reveal the person's identity known throughout the assessment process. The literature on depression detection methods demonstrates a strong preference for multimodal approaches [10], with audio-based methods receiving lesser attention. Rather than exploring on unimodal systems, researchers have largely concentrated on integrating many modalities. These multimodal systems incur costs for data collecting and computing time, which might impair processing speed. The existing studies also lack the larger dataset, and relatively lesser number of studies were reported using ensemble methods. The current study investigated on the stacking method of ensemble method which is not utilised in depression detection but utilised in other applications of medical diagnosis problems [11], [12], [13].

To overcome these issues we developed a method to create a dataset of voice samples. We have extracted numerous features by using state-of-the-art feature extraction tool kit. We have investigated with two ensemble techniques. Then, we conducted experiments with four developed models that classify depressed and healthy subjects. The present work investigates the acoustic components of speech, to design a comprehensive speech-based depression diagnosis method. An end-to-end machine learning solution was proposed to classify subjects' depressed and non-depressed classes. We believe that such a method can be more effective in the diagnosis of depression.

Main contributions of the current work are:

- To develop a ML model that will classify a subject as being healthy or depressed.
- To create a Dataset of voice samples using speech elicitation technique where subjects were instructed to provide voice samples in two different scenarios: i) while participants are reading out a phonetically balanced short story called as “The north and the south wind” ii) while participants are giving an open form of talk on the choice of their interest.
- To extract baseline features in acoustic speech recognition called as eGeMAPS feature set using state-of-the-art feature extraction toolkit called as openSMILE.
- The ensemble method called stacking was experimented and results were analysed on the created dataset. The performance is compared with the baseline methods and evaluated on the publicly available DAIC-WOZ dataset. Their results are reported.

II. Related Work

Speech plays a crucial role in detecting depression for the following reasons: First, the acoustic component of speech is often influenced by the subject's mental state. Second, the clinician observes acoustic speech characteristics to analyse the condition of the individual. Several studies have found distinguishable acoustic characteristics between non-depressed and depressed individuals. Third, ease of recording and the availability of open source tools for extracting acoustic features such as openSMILE, COVEREP,etc. [14], [15]. For instance, studies employing the acoustic tier of speech indicated that depressed subjects show variations in measures like pitch, intensity, energy, etc., compared with non-depressed speakers [16]. Studies on non-voiced aspects of speech like pauses, hesitations reveal that they do have an association with the depression.

The field of mental health care has seen promising applications for audio-based depression detection techniques. These methods examine audio recordings, such as speech patterns and emotional signals, to find probable symptoms of depression by utilising machine learning techniques. An inexpensive and non-intrusive method of screening people for depression symptoms is, automated diagnosis by audio analysis, which enables early intervention and support. Sentiment analysis is another application in speech, which enables the detection of unfavourable emotions and depressive symptoms, offering insightful information about a person's mental condition. Additionally, depression-related emotional patterns can be recognised using speech emotion recognition applications, allowing for a more thorough understanding of a person's emotional health [17].

Andrew et al. in [18] examined the potential gender bias in automated depression detection systems based on audio features. They analysed on a publicly available dataset called DAIC dataset of clinical interviews among participants with and without depression. They found that the classification accuracy is significantly higher for female participants compared to male participants, which is partly due to differences in the acoustic characteristics of male and female speech. Their work suggests the importance of considering gender bias in the development and evaluation of automated depression detection systems. Speech is used in prediction of not only depression but also in other diseases like dementia, stress disorders, parkinson’s disease etc. [19], [20].

Espinola et al. [21] recorded audio samples during the interaction of subjects (11-control and 22-depressed) with the psychiatrist. The samples were processed with the audacity audio software to eliminate the interviewer's voice signals and other noises. These samples were provided as input for an open-source vocal feature extraction tool called GNU Octave, to extract statistical features. Further, the Weka tool was used for analyzing the classification results using different ML classifiers. Among all classifiers that were experimented, random forest classifier achieved 87.5% accuracy. Their study concluded that the acoustic tier of voice samples is promising for depression detection.

Wegina et al. in [22] conducted a study on 144 volunteers, out of which 54 were diagnosed with depression and 90 as healthy subjects. Audio samples were recorded while participants responded to a personal interview adapted by vocal screening protocol [23]. Subsequently, voiced responses of participants were also recorded while they were responding to the self-report questionnaires called Beck Depression Inventory (BDI) [24] and Self Reporting Questionnaire (SRQ) - 20 questionnaires [25]. The vocal samples were processed by the PRAAT tool for feature extraction. Acoustic parameters of speech, such as pitch, jitter shimmer, etc., were extracted using PRAAT. Then statistical features like median, mean and standard deviation, etc., were extracted from the acoustic parameters. A multiple linear regression model was used to demonstrate that acoustic parameters of speech were discriminative indicators for depression.

Thati et al. in [26] collected audio data through a mobile application that recorded participants' speech during a task-based depression assessment. They extracted various audio features, including pitch, loudness, and spectral features, and used machine learning algorithms to classify the audio recordings as either depressed or not. Their study found that audio features were effective in distinguishing between non-depressed and depressed participants, achieving an accuracy of 86.3%. Thati et al. in [27] extended their work with different fusion strategies to detect depression. In their work, they combined audio, video, text and also smart phone usage records to build a multimodal feature vector. Among the multimodal feature vectors audio features showed more correlation than the other modalities. Their work suggested that audio features are highly correlated with the depressive behaviour and resulted in efficient depression diagnosis.

Naulegari Janardha et al. in [28] proposed a novel method to enhance the prediction accuracy of depression using speech's acoustic features. Their study employed the Fisher score-based feature selection to choose the most informative features and dynamic ensemble selection to enhance the classification performance. They conducted experiments on a dataset of speech recordings from both depressed and non-depressed individuals. Their findings demonstrate that the proposed approach significantly outperforms existing methods, achieving an accuracy of 82.1%.

Brain sumali et al. in [29] used acoustic features to detect depression and dementia. Authors showed the statistical significance between the acoustic features and depression. In their work, they experimented with feature selection method called as Least Absolute Shrinkage and Selection Operation (LASSO) and SVM classifier with linear kernel to predict depression. They achieved high performance in terms of accuracy, sensitivity and specificity with age matched depressive subject predictions on both training and testing phases. Sara sardari *et al.* in [30] proposed deep learning based convolutional neural network based autoencoder method to detect depression. They showed the association of audio features and depressive behaviour with the help of most discriminative features. Authors used DAIC dataset for extracting hand crafted features then use deep learning based methods to detect healthy and depressive subjects. Their results suggested that audio features are helpful to improve the accuracy of the deep learning method with at least 7% of F-measure performance parameter.

Xiaolin mino et al. in [31] experimented with fusion of feature combining the higher-order spectral characteristics and standard speech features retrieved with classification weights. To validate the suggested features, traditional machine learning models such as support vector machine and k-nearest neighbour algorithms were used, along with convolutional neural network. The accuracies of speech-related feature extraction utilising the collaborative voice analysis repository, higher-order spectral analysis, and their fusion features were 63.15%, 68.42%, and 73.68%, respectively, using the support vector machine technique. Similarly, the equivalent accuracies using the k-nearest neighbour classification technique were 68.18%, 72.73%, and 77.27%, respectively. For the same characteristics, the convolutional neural network model resulted in accuracies of 70%, 77%, and 85%. These findings emphasise that fusion feature's achieved higher accuracy, which can improve the precision of depression recognition when using both classical machine learning and deep learning models.

Balijeet kaur et al. in [32] investigated on wide range of spectral, temporal, and spectro-temporal characteristics which were extracted from speech bio signals of both healthy and depressed subjects. Their work presented a two-stage technique that uses the Quantum-based Whale Optimisation Algorithm (QWOA) to determine the most significant and non-redundant speech variables for effective depression identification. The suggested strategy is tested against three proven univariate filtering approaches and four well-known evolutionary algorithms for feature selection on the DAIC-WOZ dataset. Their findings showed that the suggested model outperforms all univariate filter approaches and evolutionary algorithms, displaying greater performance while requiring lesser computer complexity than existing wrapper-based evolutionary methods.

Despite significant advancements in audio-based depression detection, there are few notable research gaps that warrant attention. Firstly, the majority of existing studies discussed above focus on using traditional machine learning techniques for feature extraction and classification. Secondly, most research works have been conducted on relatively small and homogenous datasets, limiting the robustness of the proposed methods and third, the ethical implications of using audio-based depression detection methods, includes privacy concerns and potential biases in the data, need to be addressed to ensure responsible and ethical deployment of such technologies in real-world settings. The current work aims at addressing these research gaps that will contribute to the development of more efficient, reliable, and ethically sound audio-based depression detection systems.

III. Methodology

Subjects are carefully chosen to represent the whole population and acoustic speech dataset is created using speech elicitation technique. The overview of the proposed work is represented in Fig. 1. The details are discussed in the following subsections.

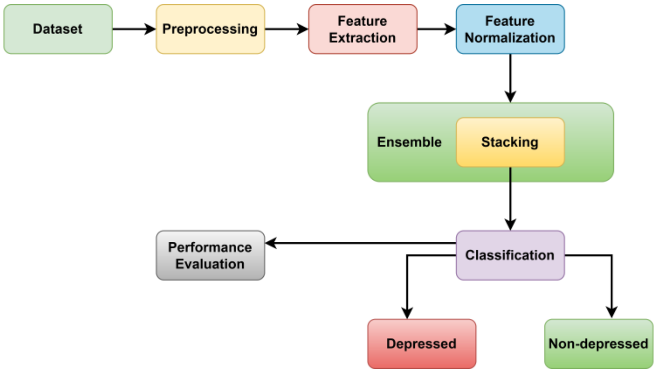

Fig. 1. Overview of the proposed work.

A. *Dataset Construction*

Students for participating in the dataset of the current work are recruited at Government polytechnic, Hyderabad, India. Out of the 225 students (here onwards called clients) who have accepted the participation in the experiment, 219 were actually turned up to read and understand English language.

Before initiating the dataset construction, all the clients (students) were explained the purpose and procedure of the study. Clients gave their written consents before they involve in dataset construction process. Approvals for conducting the study from the Institute were taken to conduct our study.

A recording room with good lighting condition is setup with a laptop on the table and a chair is placed one metre away from the laptop. Students were given prior information on their time slot to attend the study. Each student has been asked to give his voice samples in two phases. In the first phase, student is asked to read a short tale of “The north wind and south wind” which is shown on the monitor. This fable is taken because it has all the phonetically balanced sounds to stimulate the acoustic characteristics of the speech. In the second phase, they were asked to give an open form of speech of the topic of their interest in the choices that are displayed in the list. List has topics related to their goal in the life, dish they like the most, role model, worst situation in their life, etc. A total of approximately 11 hours of voice samples, from 219 participants have been recorded.

B. *Data Preprocessing*

The recorded voice samples are used in this pre-processing step. Here, the voices where other than the participant is found, they are cropped manually. The resultant voice samples are denoised using SOX software[1]. It is a cross-platform audio editing tool. SOX has a command-line interface, and is built using standard C language. The denoised voice samples are obtained at the end of this stage.

C. *Feature Extraction*

The denoised voice samples are used in this feature extraction step. Here, the denoised voice records are given as input for openSMILE toolkit for feature extraction. This tool is a state-of- the-art feature extraction toolkit. The eGeMAPS features are extracted in the current study. The next sections go into more detail about eGeMAPS and the openSMILE toolkit.

1) Open SMILE: The Open-Source Media Interpretation by Large feature-space Extraction (OpenSMILE) [33] is an open-source toolkit for audio and speech processing developed by the Audio Communication Group at the Technical University of Munich. It is designed for feature extraction from speech signals and can be used for a wide range of tasks, such as speaker identification, speech recognition, and emotion recognition in speech. It provides a rich set of audio features that can be used for analysis, including low-level signal features such as spectral and cepstral coefficients, as well as higher-level features such as prosodic features, which capture characteristics such as pitch and speaking rate.

Open SMILE is written in C++, and includes a command-line interface for feature extraction, as well as a C++ API for integration with other software. It can run on Windows, Linux, and macOS operating systems. OpenSMILE is licensed under the GNU Lesser General Public License, which allows for free use and modification of the software. Overall, openSMILE is a powerful and flexible toolkit for audio and speech processing that has gained popularity in both academic and industrial settings. Its open-source nature and broad feature set make it a valuable resource for researchers and developers working in the field of speech processing. One of the key features of openSMILE is its modularity. The toolkit consists of a core engine that provides basic audio processing and feature extraction functions, as well as a set of modules that can be added to extend the functionality of the system. These modules include support for various audio formats, filtering and pre-processing, segmentation, and classification.

2) eGeMAPS Features: eGeMAPS [34] (extended Geneva Minimalistic Acoustic Parameter Set) is a widely-used feature set for speech analysis. It includes a comprehensive set of 88 high-level and low-level acoustic features that capture a wide range of properties of speech signals, such as voice quality, prosody, and spectral characteristics. The eGeMAPS feature set was designed to be a compact and efficient feature set for speech analysis, while still providing a rich set of information about speech signals. It includes low-level features such as spectral and cepstral coefficients, as well as higher-level features such as prosodic features, which capture characteristics such as pitch, speaking rate, and voice quality.

The eGeMAPS features contain 25 Low Level Descriptors (LLD) of three parameter groups: Frequency related parameters, Energy related parameters and Spectral related parameters. Frequency related parameters have 8 LLDs. They are pitch, jitter and formants frequency 1-3 and their bandwidths of voice samples. Energy related parameters include 3 LLDs, namely loudness, shimmer, and Harmonics-to-noise ratio (HNR) components of voice signals. Spectral parameter consists of 14 LLDs. They are alpha ratio, Hammarberg Index, Spectral Slope of 0-500 Hz and 500-1500 Hz, Formant 1, 2, and 3 relative energy, Harmonic difference between first harmonic (H1) and second harmonic (H2) energy, Harmonic difference H1 and third formant range (A3), MFCC 1-4 and spectral flux.

[1] https://sox.sourceforge.net/

Now for these 25 LLDs arithmetic mean and standard deviation normalized by arithmetic mean functional are computed to form 50 components. Then for pitch and loudness, 8 different functional values are calculated. The functionals are as follows: 20th, 50th and 80th percentile and their ranges, mean and standard deviation of falling components signals. A total of 58 components are computed. Now arithmetic mean of first four components of spectral parameters is computed. 66 components are computed in total.

Six temporal features are computed. They are: rate of loudness peaks, mean and standard deviation of voiced samples, mean and standard deviation of devoiced samples, syllable rate. Resultant is 72 features. Now arithmetic mean of spectral flux in non-voiced parts, mean and standard deviation of spectral flux and Mel-Frequency Cepstral Coefficients (MFCC) 1-4, the LLDs of spectral flux and MFCC 1-4 values in total 16 components. Total 88 feature vectors of eGeMAPS are formed.

3) Size of features and ground truth: The eGeMAPS features are extracted for the voice records to form acoustic characteristics of speech biomarkers. The purposes of extracting this feature vector are listed as follows: i) eGeMAPS features are published as baseline features since 2016 in AVEC depression detection challenge [35]. ii) lot of works carried out in depression detection using speech showed reliability of eGeMAPS features [28], [34]. iii) eGeMAPS features are used in similar works of healthcare and also in emotion recognition in the literature of speech based detection methods [36].

For each participant 88 features are formed. By the end of this step, 219 X 88 size matrix is formed. Our dataset has 89th column as ground label. Ground truth is given by a Psychologist. Hence our dataset is clinically validated by the Psychologist forming more reliable and coherent dataset. Thus dataset contains 219 X 89 size matrix.

A Psychologist was recruited to label the subjects. Post audio collection, Psychologist gave 17-item questionnaire called as Hamilton Rating Scale for Depression (HRSD) [37]. Subjects were asked to fill the HRSD form. Then Psychologist validated the label as not depressed and mild depressed. In our experiment we could not find any cases of moderate, severe cases of depression. Out of 219 subjects 137 are labelled as non-depressed and 82 as depressed.

Our justification of choice of size of the dataset is based on a comprehensive related work section presented in the current study on depression detection using machine learning and audio-based approaches. As per the knowledge of the authors, cited studies that utilised sample sizes range from a few tens to hundred participants, thereby establishing a strength on context for our sample size choice. The selected sample size of 219 clients exceeds these cited studies ensuring that our study is adequately powered to detect meaningful effects and relationships between audio-based features and depression. While we acknowledge that larger sample sizes could potentially improve the generalizability of our findings, we believe that the current dataset size is appropriate for the initial validation of our proposed framework.

D. Feature Normalization

Feature normalization is a common preprocessing step in machine learning that involves scaling the input features to have a similar scale and distribution. The purpose of normalization is to improve the performance and stability of machine learning models by reducing the influence of features with large values and preventing some features from dominating others [38].

In the current study, each group of parameters has different values and ranges. Hence to normalize them into a standard set of values we used Min-max scaling mechanism. All the experiments were conducted using these normalized values in this study. In this technique, values are scaled to a fixed range. We used 0 to 1 range for normalizing the values.

E. Ensemble

The ensemble method in machine learning combines several classifiers predictive results into an optimal result [39]. The current work used stacking technique of the ensemble method to derive the optimal predictions. In stacking, multiple heterogeneous classifiers are used to form an intermediate result. These intermediate results are provided as input for the meta classifier to predict the final outcome. Stacking aims to improve the meta classifier's performance.

The mathematical equation for a stacking ensemble can be represented as follows:

Consider D = {(x1, y1), (x2, y2), ..., (xn, yn)} be the training dataset, where xi is the i-th instance and yi is the corresponding target value.

Let M = {M1, M2, ..., Mk} be a set of base models, where Mi is a machine learning model that maps an instance x to a predicted target value Mi(x).

Let f be the meta-model that takes the predictions of the base models as inputs and outputs a final prediction, i.e., f(M1(x), M2(x), ..., Mk(x)).

The stacking ensemble can be trained in two stages:

1) Base model training: Each base model Mi is trained on the training dataset D to predict the target values.

2) Meta-model training: The predictions of the base models on the training dataset D are used to train the meta-model f. Specifically, a new dataset D' is created by replacing the target values in D with the predictions of the base models, i.e., D' = {(M1(x1), M2(x1), ..., Mk(x1), y1), (M1(x2), M2(x2), ..., Mk(x2), y2), ..., (M1(xn), M2(xn), ..., Mk(xn), yn)}. The meta-model f is then trained on D' to predict the final target values.

The mathematical equation for the stacking ensemble can then be written as in (1):

$$f\big(M1(x), M2(x), \dots, Mk(x)\big) = g(w1 * M1(x) + w2 * M2(x) + \cdots + wk * Mk(x)) + b \quad (1)$$

where w1, w2, ..., wk are the weights assigned to the predictions of the base models, and b is the bias term. These weights and bias term are learned during the meta-model training stage.

The block diagram of the stacking ensemble method is given in the following Fig. 2 and its explanation is as follows:

1) Input Data: It consists of training and test data, with the input data (training data) split into training and validation sets. The base models are trained using the training data. The validation data is used to assess the performance of the base models and choose the best-performing models. Once the meta-model is trained, it is used to make predictions on the test data. The test data is a distinct dataset from the training and validation sets that the model has never seen before.

2) Base models: The base models are the individual models that will be trained on the input data. These models can be of different types, such as Decision trees, SVMs, or Neural networks. Each model produces its own output or prediction for the given input.

3) Predictions: The trained base models produce outputs or predictions for each input in the validation set.

4) Meta-classifier: The meta-model is a model that combines the outputs of the base models to make a final prediction. It takes the outputs of the base models as input features and learns to combine them in an optimal way. The meta-model can be a simple linear model, such as Logistic regression, or a more complex model, such as a Neural network.

5) Final prediction: The meta-model produces a final prediction for each input in the test data. This prediction is based on the outputs of the base models and the learned combination of these outputs.

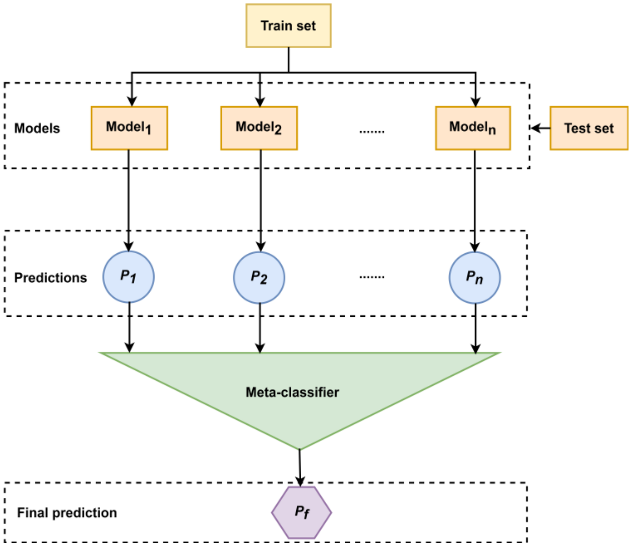

Fig. 2. Block diagram of the stacking ensemble method.

Algorithm for the proposed ensemble method:

The proposed ensemble method algorithm is a 7-step process for classifying acoustic data using a combination of base classifiers and a meta-classifier. Here is a brief explanation of each step as follows:

Step 1: Obtain the acoustic dataset which is of the size 219 X 89 matrix.
Step 2: Perform feature normalization using Min-max scaling technique.
Step 3: Divide the normalized feature vector to training set(80%) and test set(20%) without any overlap.
Step 4: Implement stacking with the base classifiers for training set obtained from step 3.
Step 5: Construct a meta classifier with the input from the outcomes of the base classifiers as features.
Step 6: Now using the test set, form intermediate outputs with the same classifiers. These intermediate outcomes are provided as input for the trained meta classifier to form final prediction.
Step 7: These final predictions are compared with the ground truths to check the performance of the ensemble method.

F. Performance Metrics

In the current work, the ensemble method's performance is evaluated utilising a variety of performance metrics. The performance metrics accuracy, precision, recall and F1-score are measured to show the effectiveness of the model.

The model's overall performance is evaluated using a confusion matrix. It contains the actual values and test predictions. The following Table I gives the details of the confusion matrix.

Confusion matrix contains four terms: True Positive(TP), True Negative(TN), False Positive(FP) and False Negative(FN). TP and TN are correct predictions made by the model. TP and TN are correctly classified as compared with the actual ground truths. FN and FP are incorrect predictions made by the model. TN and TP are correct predictions where as FN and FP are the incorrect predictions. For any model, TP and TN must be high and FP and FN must be as low as possible. Then performance of the model is higher. The following Table II gives more details of the performance metrics used in the current study.

TABLE I. CONFUSION MATRIX

	Actual Values		
		Positive	**Negative**
Predicted Values	**Positive**	TP	FP
	Negative	FN	TN

TABLE II. PERFORMANCE METRICS UTILISED IN THIS WORK

Performance parameter	**Description**
Accuracy	It measures proportion of correctly classified instances in our dataset out of all the instances. Accuracy = $\frac{\mathrm{TP + TN}}{\mathrm{TP + TN + FP + FN}}$ (2)
Precision	It measures the accuracy of positive predictions by calculating the proportion of true positives among predicted positives. Precision = $\frac{\mathrm{TP}}{\mathrm{TP + FP}}$ (3)
Recall	It measures the ability of the model to identify positive instances by calculating the proportion of true positives among actual positives. Recall = $\frac{\mathrm{TP}}{\mathrm{TP + FN}}$ (4)
F1-score	It provides a balance between precision and recall by calculating the harmonic mean of the two metrics. F1-score = $\frac{2\,(\mathrm{Precision\ X\ Recall})}{\mathrm{Precision + Recall}}$ (5)

These metrics are essential for assessing the performance of the classification model in the context of depressed and non-depressed classification. Accuracy is a measure of the proportion of cases overall that were correctly identified as being either depressed or not. A high accuracy rating indicates that the model is adept at correctly classifying both depressed and non-depressed people, making it a useful indicator of the classification model's overall effectiveness. On the other hand, when dealing with depression detection, precision becomes especially important. It gauges how well positive predictions pan out, which in this instance translates to how well depressed people are identified. A high precision means the model has a low false positive rate and successfully recognises depressed people without mistakenly classifying healthy people as depressed.

Recall is extremely important since it measures how well the model can identify depressed people among all real-world depressed instances. A high recall means that the model successfully identified the majority of the depressed individuals in the dataset and has a low false negative rate. The F1-score offers a useful compromise between recall and precision. It provides a thorough assessment of the model's effectiveness in the classification of depression by taking into account both metrics. As a result, a classification model with high accuracy, precision, recall, and F1-score performs well in accurately identifying people with depression while minimising misclassifications, offering crucial help for those in need of mental health care and therapies.

IV. Results

This section discusses the results obtained in the current study. Jupiter python notebook is used for all the experiments conducted in the current study. The results are discussed in four forms: First, the effectiveness of the proposed model is evaluated in terms of various performance metrics. In order to show the performance gain of the proposed model, the performance of our model is then compared to the baseline models on our dataset. Third, the proposed model is applied to the benchmarking dataset to show the reliability of the study. In the end, the proposed model is compared with state-of-the-art baseline techniques on benchmarking dataset.

A. Performance Evaluation of the Proposed Model

In stacking protocol, first, the choice of the base classifier is made among all the available classifiers significantly important to acquire the performance improvement. In the present study, K-Nearest Neighbours (KNN), Naïve Bayes (NB), Support Vector Machine (SVM), and Decision Trees (DT) classifiers are selected as base classifiers. This choice is because of the following reasons: 1) they are easy to implement; 2) achieves higher accuracy when the size of the dataset is relatively small; and 3) conducted rigorous experiments and both performed relatively better on trial and error basis of all the classifiers. Thus when both these classifiers are combined, results in the performance enhancement.

Second, meta classifier uses the results of the diverse predictions obtained with the base classifiers. This will be helpful to avoid misclassifications of the model because feature size is reduced when compared with the original dataset size. In our study, the feature size is brought down to 2 from 88. This reduction helps in meta classifier to reduce mis-classifications and results in performance optimisation. Logistic Regression (LR) classifier is trained and tested as the meta classifier in our current work. Table III presents summary of the parameters used in the current study.

TABLE III. Summary of the Parameters of the Proposed Ensemble Method

Parameter	Tuned Parameter
Base Classifier-1	K-NN
Base Classifier-2	NB
Base Classifier-3	SVM
Base Classifier-4	DT
Meta Classifier	LR
Hyperparameters	Default values

Hence the proposed work integrates the predictive capabilities of five classifiers namely K-NN, Naïve Bayes, SVM, Decision Trees and Logistic Regression classifier, to obtain optimal results. Table IV shows the performance metrics obtained on our dataset using a stacking ensemble model. The four metrics evaluated are accuracy, precision, recall, and F1-score. This implies that the proposed framework can be utilized for clinical applications. These findings suggest that the proposed framework can be applied to the real-world scenarios. The hypothesis of the study is that the proposed framework holds as a valuable tool for aiding healthcare professionals in early diagnosis and intervention for depression. Comparable results obtained using accuracy, precision, recall, and F1-score values by our approach demonstrate its capability to precisely detect the depression in individuals.

TABLE IV. Performance Metrics Values of Proposed Stacking Method on Our Dataset

Performance metric	Value obtained on our dataset (in %)
Accuracy	79.1
Precision	83.3
Recall	76.9
F1-score	80.0

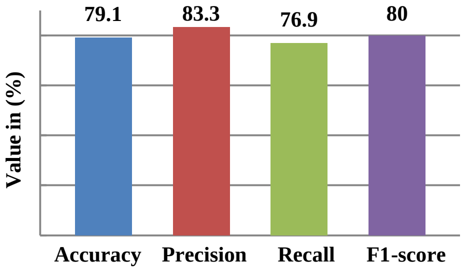

Fig. 3. Depression detection performance of proposed stacking ensemble model.

As presented in Fig. 3, our method of using diverse classifiers achieved accuracy of 79.1%, precision of 83.3%, recall of 76.9% and F1-score of 80.0%. These scores show that the performance of the proposed method is reliable. These results suggest that the model performed well on the dataset, with high precision and F1-score values. However, it's important to note that the evaluation is based on a single dataset and may not generalize well to other datasets. Therefore, further testing and validation are necessary to confirm the effectiveness and robustness of the model. The following investigation is carried out to prove the reliability of the study.

B. Performance Comparisons of the Proposed Model with the Baseline Models

To show the performance gain of the proposed method we compared the proposed model's performance with the baseline methods. The baseline methods of the current work are the base classifiers used in the proposed model to build the meta-classifier. These methods are chosen because following this method of comparison gives deep understanding of the amount of performance gained with the stacking method over the base classifier utilisation. The feature set used in the current work is also used for training (80%) and testing (20%) base classifiers namely K-NN, Naïve Bayes, SVM, and Decision Trees classifiers. Table V contains details about comparison of the proposed stacking approach with the baseline methods.

Table V shows that the proposed method has outperformed the baseline methods in terms of all performance metrics. It contains a comparison of the performance metrics achieved by our proposed approach using ensemble and on using base classifiers such as K-NN, Naïve Bayes, SVM, and Decision Trees on our dataset. The reason behind choosing these classifiers is its vast use in the literature of the study (presented in the related work section). Our proposed approach outperformed the baseline methods in terms of Accuracy (79.1% vs. KNN: 62.5%, NB: 62.5%, SVM: 75.2%, DT: 76.8%) and Precision (83.3% vs. KNN: 61.5%, NB: 58.3%, SVM: 82.1%, DT: 80.7%), indicating its ability to correctly classify instances and minimize false positive predictions using our model. Although Recall values were similar between two baseline methods (our approach: 76.9% vs. KNN: 66.6%, NB: 63.4%, SVM: 77.2%, DT: 76.8%), our proposed approach achieved a higher F1-score (80.0%) compared to the baseline methods (KNN: 64.0%, NB: 60.8%, SVM: 76.3%, DT: 78.2%), signifying a better balance between Precision and Recall. These results suggest that the effectiveness of our proposed approach in accurately detecting depression and highlight its potential as a robust and reliable tool for classification of depression.

TABLE V. PERFORMANCE COMPARISON OF THE PROPOSED STACKING METHOD WITH THE BASELINE MODELS USING OUR DATASET

S.No	**Method**	**Performance metrics**			
		Accuracy	**Precision**	**Recall**	**F1-score**
1	K-NN	62.5	61.5	66.6	64.0
2	NB	62.5	58.3	63.4	60.8
3	SVM	75.2	82.1	77.2	76.3
4	DT	76.8	80.7	76.8	78.2
5	**Our proposed Method-Stacking approach**	79.1	83.3	76.9	80.0

C. Performance Comparison of the Proposed Model using Benchmarking Dataset

Now, the generality of the proposed model is tested. Our approach not only worked for our dataset but also can be applied to the other datasets. We applied our stacking method on the Distress Analysis Interview Corpus-Wizard of Oz (DAIC-WOZ) database [40] which is publicly available benchmarking dataset in depression detection. This corpus contains audio and visual recordings of interviews between a real-life interviewee and a computer-generated interviewer who either acts as a supportive listener or a diagnostician. The participants were instructed to discuss few topics, including personal experiences and emotional states, allowing for the elicitation of genuine emotional expressions. Researchers who are interested in developing and validating depression detection models use the DAIC-WOZ database as a benchmark dataset. Additionally, the public dataset allows for comparisons and cross-validation of different methods, facilitating the advancement of automated depression detection technologies for real-world applications.

To apply our proposed stacking method, the audio clips of the subjects are used to generate the eGeMAPS feature vectors. Then after standardising the dataset stacking framework is applied.

TABLE VI. PERFORMANCE METRICS VALUES OF PROPOSED STACKING METHOD ON A DAIC-WOZ DATASET

Performance metric	**Value obtained on our dataset (in %)**
Accuracy	78.0
Precision	71.7
Recall	90.6
F1-score	79.4

Table VI shows the details of the performance of the proposed stacking method on the DAIC-WOZ dataset. Our method achieved comparable performance when applied on the benchmarking dataset. Among all the performance metrics recall gave a performance of 90.6% using the proposed method. From the Table VI it can be inferred that the proposed method can be applied to any dataset with similar audio cues.

D. Performance Comparison with State-of-the-Art Baseline Methods using Benchmarking Dataset

Table VII presents a comparison of performance metrics obtained by our proposed ensemble method on the public accessible benchmarking DAIC-WOZ dataset. We compared our results with two state-of-the-art methods: (1) Thati et al. in [27] used multimodal fusion approach by Late fusion using secondary SVM, and (2) Janardhan et al. in [28] used Fisher score-based feature selection method for classification of depressed or non-depressed individuals.

As presented in Fig. 4, our proposed ensemble method outperformed both existing state-of-the-art methods across all performance metrics. Specifically, our method acquired an accuracy of 78.0%, surpassing the late fusion using secondary SVM (74.0%) and Fisher score-based feature selection mechanism (74.0%). The precision of our method was 71.7%, significantly higher than the late fusion (52.0%) and also Fisher score-based (49.0%) approaches. Also, our ensemble method demonstrated a remarkable recall of 90.6%, outperforming the late fusion (58.0%) and Fisher score-based (50.0%) methods in correctly identifying the depressed subjects. Lastly, F1-score of our proposed method was 79.4%, exceeding both the late fusion (73.0%) and Fisher score-based (74.0%) methods. These results clearly demonstrate the superiority of our ensemble method for depression classification on the DAIC-WOZ dataset, showcasing its effectiveness in achieving higher accuracy, precision, recall, and F1-score compared to the state-of-the-art methods mentioned.

TABLE VII. PERFORMANCE METRICS COMPARISON WITH THE STATE-OF-THE-ART BASELINE METHODS ON DAIC-WOZ DATASET

Performance metric	**Our Proposed stacking method (in %)**	**Late fusion using secondary SVM**	**Fisher score-based feature selection**
Accuracy	78.0	74.0	74.0
Precision	71.7	52.0	49.0
Recall	90.6	58.0	50.0
F1-score	79.4	73.0	74.0

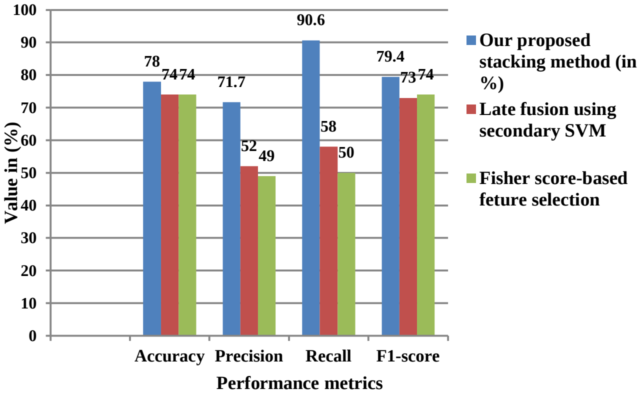

Fig. 4. Performance of proposed stacking method compared with existing Models on a DAIC-WOZ dataset.

V. CONCLUSION AND FUTURE WORK

Mental illness, manifestation of depression and anxiety, is a serious impediment to global well-being. Depression is an illness that can cause financial, social, family, emotional losses for individuals and leads to suicide causing sorrow to their families. A machine learning-based approach using audio can use patterns which are different in healthy and depressed subjects. These methods help healthcare professionals detect depression. The literature on depression detection through audio-based used only single classifier, but not the multiple classifiers. The present work combines the predictive patterns of different classifiers to detect depression using a stacked approach. Audio clips are recorded as subjects read predefined passages and free-form speech. Then eGeMAPS features are extracted using the openSMILE toolkit. The normalized feature vectors are trained with multiple classifiers. Then meta-classifier is also trained to form final predictions. On this audio dataset, our proposed method, which combines a variety of classifiers, produced impressive results with an accuracy of 79.1%, precision of 83.3%, recall of 76.9%, and an F1-score of 80.0%. Our method demonstrated a remarkable performance improvement in terms of accuracy when compared to single classifier technique. Identical performance improvements are seen across various evaluation parameters. Our method's validity on the DAIC-WOZ dataset further confirms its dependability and potency to generalize on other clinical applications. Notably, our method achieved a recall of 90.0%, demonstrating its potential as a global approach for depression detection and demonstrating its ability to generalize and be applicable to other datasets with similar audio cues.

Our future works aim to investigate the implementation of regression-based methods to identify not only the presence of depression but also the severity or levels of depression in individuals. The importance of expanding the dataset size by increasing the number of samples is recognised. Also research on linguistic characteristics and language pragmatics of speech, seeking to extract and utilize the valuable information beyond acoustic features for more accurate depression detection.

ACKNOWLEDGMENT

This project was supported by students of Government Polytechnic, Hyderabad, India, and the authors would like to thank them for their help.

Signals, Distributed Systems and Artificial Intelligence (SSDIA), ENSET Mohammedia,
Hassan II University, Casablanca, Morocco

***Abstract*—This study focuses on optimizing the loading and unloading processes in a port environment by employing synchronization techniques and collision avoidance mechanisms. The objective function of this research aims to minimize the time required for these tasks while ensuring efficient coordination and safety. The obtained results are compared with previous studies, demonstrating significant improvements in overall performance. The synchronized handling systems, including gantries and cranes, along with speed control measures, facilitate streamlined operations, reduced delays, and enhanced productivity. By integrating these strategies, the port achieves better results in terms of task completion time compared to previous methodologies, thereby validating the effectiveness of the proposed approach.**

Keywords—Optimizing; synchronization; collision; efficient; time

I. Introduction

Productive and non-productive times play a crucial role when it comes to optimizing the loading and unloading of containers from ships in a port. Many of the common problems associated with optimizing these aspects which are firstly, Inefficient planning which leads to poor coordination and planning of ship arrivals, berth allocation and crane operations can lead to significant delays and inefficiencies. Vessels may have to wait for a berth, resulting in downtime and reduced productivity. Additionally, if container handling equipment, such as cranes, are not allocated efficiently, it can lead to downtime and reduced throughput.

In addition, insufficient or obsolete equipment can slow down the loading and unloading process [1]. Equipment failures and maintenance issues can cause unexpected delays and increase non-productive time [2]. Regular maintenance and prompt repairs are essential to minimize downtime and ensure optimal equipment performance. Ineffective coordination between ship's crew, port operators and logistics personnel can lead to inefficiencies. Lack of clear communication and collaboration can lead to delays, errors in documentation, and increased downtime [3]. Efficient cargo handling operations require effective communication channels and streamlined processes. By relying on manual processes, such as paper documentation, delays and errors can occur. Manual data entry, inspections, and customs clearance procedures may consume valuable time. Implementing digital solutions, such as electronic data interchange (EDI) systems and automated workflows, can significantly improve efficiency and reduce non-productive time. Customs regulations are essential but can also slow down operations [4]. Rigorous security checks, customs inspections and document verification processes can cause delays and increase non-productive time. Port authorities and operators must strike a balance between security measures and operational efficiency.

Various mathematical models and optimization techniques have been developed to solve planning and resource allocation problems in container terminals. These models aim to minimize vessel waiting times, dock occupancy and equipment, among the solutions cited in the literature first: *Automation and robotics*: Automation technologies, such as robotic systems and automated guided vehicles (AGVs) [5], are increasingly being used to improve the efficiency of container handling. *Simulation and optimization studies*: Simulation models and optimization algorithms are often used to evaluate different strategies and scenarios in container terminal operations. These studies analyze factors such as layout design, equipment utilization and resource allocation. *Digitalization and data-driven approaches*: The use of digital technologies, data analysis and real-time information has a significant impact on time optimization in port operations [6]. *Lean Process Improvement and Methodologies*: Lean principles and process improvement methodologies, such as Six Sigma, are relevant to improving operational efficiency and reducing non-productive time.

Previous studies [7] have answered the question of optimizing productive and non-productive times when loading and unloading containers in ports, it is crucial to implement the following strategies: Improve coordination and communication: Improve coordination between port authorities, shipping companies, terminal operators and logistics providers. Real-time information sharing and advanced communication systems can enable better planning and resource allocation. Optimize berth and equipment allocation: Develop effective berth allocation systems that take into account vessel size, cargo type and expected volume. Implement intelligent asset management systems to allocate cranes and material handling equipment based on real-time demand [8]. Improve infrastructure and layout planning: Invest in port infrastructure expansion and optimize layout plans to accommodate growing container volumes. Designate dedicated storage areas for efficient container handling and reduce congestion. Embrace automation and digitalization: Deploy automation technologies, such as automated overhead cranes and robotic container handling systems, to improve efficiency. Implement digital solutions to document, track and automate workflows to reduce manual processes and improve accuracy. Streamline customs and security processes: Collaborate with customs authorities to streamline inspection and clearance procedures. Implement technologies such as secure trading platforms and electronic seals to speed up security checks while ensuring compliance. Invest in training and skills development: Provide regular training and skills development programs to port workers and staff. Well-trained staff can complete tasks more efficiently and handle contingencies effectively, reducing non-productive time. By addressing these issues and implementing these strategies, ports can optimize productive and non-productive times during container loading and unloading operations, resulting in increased efficiency and overall productivity.

Congestion and limited space this can induce limited space in ports and can lead to congestion, making it difficult to manage containers efficiently. Lack of designated storage areas and inefficient layout planning can lead to delays in loading and unloading operations [9]. This problem becomes more pronounced when several ships arrive simultaneously or when there is a high volume of containers to handle.

II. Interference Problems and Unproductive Movements

A. Interference Problem between Gates

The interference problem is well related to the problem of planning multiple yard gates in a seaport since these gates share the traffic lane in the yard and the movement of one can block the movement of the other. In this context, Ng (2005) considered the interference between yard gates when planning the movements of this type of equipment. This phenomenon is defined as a physical blockage that must be considered when planning yard gates [10]. According to Ng, the courtyard inter-portal interference problem is a complicated problem and it requires the development of an efficient method for solving the planning problem.

Interference between yard gantries can affect the planning of quay gantries. In this context, [11-12] sheds light on the relationship between quay gantry planning and the timing of yard gantry operations. Their work is aimed at minimizing the turnaround time of ships and is aimed at scheduling quay gantries taking into account the progression of handling operations at the yard level. Indeed, any delay in the operations of the yard gantries affects the operations of the quay gantries.

Zhong, M.S. et al [13] proposed a model for planning yard gates while taking into account some constraints related to interference between yard gates, fixed separation distances between these gates and simultaneous container storage/retrieval operations. The model aims to minimize a linear combination of early collections, storage and late collections. The problem of interference between courtyard gates is developed within the constraints of the mathematical formulation.

Chen, J et al. [14] treated the interference problem implicitly. The work addresses the problem of scheduling multiple yard gantries during container loading operations. The objective of this work is to improve the processing efficiency of containers intended for export by the yard gates. The authors have taken into account the potential interferences that may occur. Indeed, they integrated this phenomenon into the gate planning problem. An interference hypothesis is developed in the mathematical model [15-16]. This hypothesis takes into consideration two types of interference which are “collision” and “crossover”. The first type of interference occurs when two-yard gates in the same block try to pick up containers stored in adjacent bays. According to Chen and Langevin, a minimum distance of five bays must be respected to avoid a potential collision between two courtyard gates. The second type is the crossing which occurs when the next container to be processed by a given yard gate is located on the other side of another yard gate. In order to avoid any possible interference, the authors developed several constraints in the mathematical formulation.

The work of [17-18] studied the operation of several yard gantries when loading/unloading containers. According to the authors, the yard gates must leave a safe distance to avoid accidents. Indeed, in the same block, several courtyard gates can work simultaneously; in this situation there may be a risk of collision between the yard gates and even between the trucks. In Fig. 1, yard gate 2 (YC2) wants to move to bay 01 after processing a container located in bay 07 but is blocked by yard gate 1 (YC1) which is processing a container located in bay 03. So yard gate 2 must wait until yard gate 1 completes its task.

B. Problem of Non-productive “Rehandle” Movements

In a previous study [19-20], an author proposed a methodology for estimating the anticipated quantity of non-productive moves required to pick up a container, as well as the overall count of non-productive container moves within a bay with an initial stacking arrangement [21]. The author highlights the significance of the rack's height and width in determining the average rehandling count and the design of the storage configuration. To estimate the expected number of non-productive moves for the next pickup, the author examined multiple container stack configurations and derived an approximate formula for estimating the total expected count of non-productive moves [22].

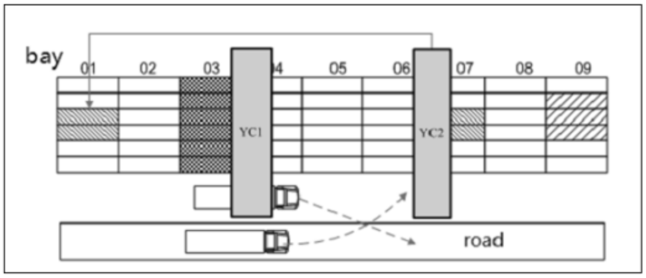

Fig. 1. The collision caused by the courtyard gates.

A study conducted in [23-24] focused on addressing the issue of non-productive crane movements during container loading and unloading activities at a seaport. The researchers aimed to ensure the stability of containers stored on a ship while minimizing the number of non-productive movements within container blocks. To tackle this problem, a multi-objective integer program was formulated. The authors utilized a weighting method to obtain non-dominated solutions, drawing inspiration from the works of [25-26]. They incorporated the consideration of non-productive moves by estimating their count and introduced the concept of probability to study this estimation. However, accurately calculating the number of non-productive moves relies on a predefined loading sequence, which introduces challenges due to the random recovery of containers [27-28]. To solve both the container loading problem on the ship and the rehandling problem, the researchers employed a genetic algorithm.

III. Mathematical Modeling of Container Movements

A. *Model Assumptions*

When developing a mathematical model, a number of assumptions must be taken into account. These will be integrated in one way or another in the model. Our assumptions are as follows:

- We limit ourselves to the loading operations of export containers (outbound).
- Location of containers is given.
- A courtyard is made up of several adjacent blocks.
- There are up to two court gates in a block.
- Court gate moves between blocks are possible, maximum one move.
- For each container, we know its destination on the quay (the quay gantry).
- We consider the simultaneous movements of the yard gantries and the trucks.
- All containers in a bay are destined for the same vessel.
- The possibility of interference from courtyard gates in the same block is taken into account.
- Containers are classified into groups with an order and priority in the handling of each group. The order is known in advance.
- Non-productive movements of containers (Rehandle) are taken into account.

B. *Modeling and Constraint*

We will consider that p_i is the processing time of container i through a yard gate which includes the time to pick up the container h_1 and the time to remove and return the containers so p_i can be expressed by the formula below:

$$p_i = h_1 + \sum_{\substack{j\in C\\ a_{i=aj}\\ r_{i=rj}\\ e_i<e_j}} h_2 \times V_{ij} \qquad (1)$$

Where:

$$\sum_{\substack{j\in C\\ a_{i=aj}\\ r_{i=rj}\\ e_i<e_j}} h_2 \times V_{ij}$$

is the non-productive time of the yard gates (rehandle).

V_{ij} : if the processing of container j begins after the processing of container i by a yard gantry has finished.

h_1: Container handling time.

h_2: Handling time of a container to pick it up and put it back in its place (rehandle); we assume that h_2= 2 h_1.

P: Set of pairs of containers with a precedence relationship. We are talking here about an order of priority of containers that must be respected during the handling process by the quay gantries.

The variable pi can be divided into two parts pi1 and pi2 which are respectively the handling time of container i and its loading on the truck and the time to return the container(s) that have been removed to its (their) seat(s).

$$p_i = p_i^1 + p_i^2 \qquad (2)$$

p_i^1 and p_i^2 are expressed as a function of h_1 and V_{ij} by the following formula:

$$p_i^1 = h_1 + \sum_{\substack{j\in C\\ a_i=a_j\\ r_i=r_j\\ e_i<e_j}} h_1 \times V_{ij}; i \in C \qquad (3)$$

$$p_i^2 = \sum_{\substack{j\in C\\ a_i=a_j\\ r_i=r_j\\ e_i<e_j}} h_1 \times V_{ij}; i \in C \qquad (4)$$

$$d_j^{Yc}, d_j^{YT}, p_i^1, p_i^2 \geq 0 \qquad (5)$$

Indeed, to guarantee that the decision variables are positive and binary a constraint is expressed by the equation (5) is necessary for our approach.

It is also reported that in our study that constraints have been imposed which guarantee that the equipment which are respectively the trucks do not leave the starting point only once and they ensure flow conservation for each material handling equipment.

Other constraints that must be included in our model is first of all the constraint which defines the handling time of the container i and its loading on the truck the constraint which defines the time of reinstallation of the containers already removed this last is expressed by the equation (4).

$$d_j^{Yc} \geq d_i^{YC} + (p_i^1 + p_i^2) + k_{ij} + T\big(X_{ijm} - 1\big); \qquad (6)$$

Where

$d_{i,j}^{YC}$: Start time of picking of container i, j by a yard gantry

T: Great value.

k_{ij}: Travel time of a yard gantry from container i to container j whatever

$X_{ijm} = 1$, if yard gate m processes container j just after container i; 0 otherwise.

The constraint that ensures the order in which containers are processed by each sorting gate is expressed in equation (6). This means that if a sorting gate m processes container j just after container i, then gate m will take the travel time kij to pick up the next container j.

Constraint (7) makes it possible to present the order in which the containers are processed by each yard gate according to the departure time of the trucks transporting the containers. Constraint (12) means that when containers i and j form a pair of containers with a priority relationship then container i is processed before container j as soon as it arrives at the dock.

$$d_j^{YC} \geq d_i^{YT} + \mathrm{k_{ij}} + T\left(X_{ijm} - 1\right); i \in C, j \in C, m \in M \quad (7)$$

Where:

d_i^{YT}: Departure time of a truck carrying container

IV. Methodology

A. Objective Function

In the objective function (8), we seek to minimize the production time (makespan). We also take into account that each container is assigned to a single parking gantry and a single truck.

The FOBJ objective function is calculated as follows:

$$\begin{cases} Min\left\{\underset{i}{\mathrm{Max}}\, d_i^{YT}\right\} & (8) \\ d_j^{YC} \geq d_i^{YT} + \mathrm{k_{ij}} + T\left(X_{ijm} - 1\right); i \in C, j \in C, m \in M & (7) \end{cases}$$

the main objective is to optimize the flow of unloading containers and trucks in ports, avoiding collisions and promoting synchronization between handling systems, especially gantries

B. Optimization Algorithm

To optimize our objective function, we must take into consideration that containers i and j form a pair of containers with a priority relation, so container i is processed before container j as soon as it arrives at the dock. The container processing sequence is an essential parameter that must also be introduced into our optimization algorithm.

Due to the challenges associated with optimization, constructing a new model to optimize container management during loading and unloading at the port, particularly for autonomous ships, makes the use of deterministic methods arduous and resource-intensive. Hence, heuristic methods are chosen as the most suitable approach to tackle such optimization problems. Furthermore, in the presented work, genetic algorithms have been selected to optimize the transfer time of containers.

The decision to employ genetic algorithms stems from the fact that these algorithms are regarded as:

- A flexible and configurable method.
- Efficient in their ability to overcome the pitfalls of local optima while exploring the design search space to converge towards the global optimum.

The flowchart in Fig. 2 shows the optimization steps adopted to optimize a wind farm. In the Python© software, we have entered the data and the models established in the previous part, the optimization process begins to search for an optimal solution. GA research techniques include the following main steps:

In Step 1, we randomly generate specific paths while ensuring compliance with the constraints of the problem at hand.

Step 2 involves evaluating the layouts of the objective function being studied by utilizing the objective function itself.

In Step 3, individuals are selected to contribute to the population of the next generation. The selection probability in the current generation ensures the selection of high-quality individuals. The crossover operator is employed to modify two pairs of genes (positions) and generate further optimization. As a crossover function, gene modification at another position is accomplished through the random activation of mutation with a predetermined probability.

Step 4 involves producing a new course flow through the genetic algorithm (GA), which modifies the previous population. These steps are iterated until the maximum number of iterations is reached. The data parameters of our algorithm can be found in Table I.

TABLE I. PARAMETERS OG GENETIC ALGORITHM

GA Parameter	Value
Size of initial poulation	1000
Selection pressure	3
crossover probability	0.75
Mutation probability	0.25
Iteration number	4000

C. Case Study

We will apply our model to the Port of Tangier Med which is one of the largest ports in Africa and the Mediterranean, strategically located on the Strait of Gibraltar. It has modern infrastructure, including several terminals for containers, passengers and general cargo. With a large container and passenger handling capacity, the port serves as a key transshipment hub, facilitating trade between Europe, Africa and Asia. It has had a significant economic impact, attracted investment and generated employment opportunities. Continuous expansions and developments have been undertaken to meet the increasing demands of international trade. Overall, the Port of Tangier Med plays a crucial role in global trade and connectivity in the region.

In our case, we propose three distinct mathematical models. The initial model focuses mainly on the optimization of truck routes, with the objective of minimizing the distance traveled by each vehicle. The second model involves assigning tasks to trucks, which results in a schedule of container task assignments based on the input data comprising the set of container tasks. Finally, the third model is designed to avoid collisions between trucks and gantries, ensuring a safe operating environment.

Optimal trucks route optimization planning

Fig. 2. Road planning trucks.

Our approach offers a hybrid solution by integrating simulations and algorithms to address modeling challenges. Essentially, truck route design can be simplified as a "shortest path problem". To solve this problem, we use the widely recognized method of Dijkstra, which has a long reputation for finding the shortest path. Model 1 in Fig. 2 uses Dijkstra's method. We can solve the model efficiently and determine the optimal route planning strategy for trucks (Fig. 4).

As illustrated in Table II, the truck scheduling model started with 1000 container tasks created at random. When the evolutionary algorithm was employed to solve the task assignment to trucks, the original population was 200, as shown in Fig. 3. If the crossover coefficient is set too low, the performance of our method suffers. If the mutation probability is sufficiently high, the genetic algorithm will reach the local optimum. As a result, the mutation probability and crossover probability were both set to 0.75.

3	QC3	Y4
. . 999	. QC1	. . Y5
1000	QC3	Y6

The model shown in Fig. 5 and Fig. 6 focuses on optimizing truck task assignment, determining their routes, and managing their speeds to avoid collisions. It involves an intelligent system that uses advanced algorithms to solve this complex problem.

First, the model must take into account the different tasks to be performed by trucks, such as delivering goods to specific destinations, picking up materials, or performing specific services. These tasks are usually accompanied by specific constraints, such as delivery times, priorities or required resources.

The model must analyze the constraints and available resources, as well as the characteristics of the trucks, such as their load capacity, maximum speed, fuel consumption and mechanical constraints. Based on this information, the model can determine the best assignment of tasks to trucks, optimizing criteria such as total distance traveled, delivery time or operational costs.

Once the task assignment is determined, the model must plan the routes for each truck to avoid collisions. It must take into account various factors, such as distances between destinations, traffic conditions, traffic restrictions (such as toll roads or no-truck zones) and specific preferences, such as shorter routes or faster.

To avoid collisions, the model can use path planning techniques that take into account the movements of other vehicles on the road. This can be achieved through the use of sensors, global positioning systems (GPS), digital maps and obstacle detection algorithms. The model can also use communication techniques between the trucks to exchange information about their position and intention, which helps coordinate their movements and avoid potential conflicts.

Finally, the model can control truck speeds based on various factors, such as road conditions, speed limits, safety constraints and operator preferences. This can be achieved by using automatic cruise controls or by providing speed recommendations to drivers.

Overall, the model shown in Fig. 5 is designed to optimize truck task assignment, determine their routes, and control their speeds to minimize collisions, maximize operation efficiency, and ensure safety on the road. It is an approach based on artificial intelligence and optimization that requires precise data on tasks, trucks, constraints and road conditions to make informed and effective decisions.

V. Results and Discussion

The truck task assignment model produced assignment outcomes and path outcomes for trucks, which were then incorporated into our model of our collision avoidance gait. In addition, the speed control strategy has been applied. Collision avoidance strategies were evaluated for different numbers of container tasks, and the results are shown in Fig. 7 and 8.

Fig. 6 shows that regardless of the number of trucks, trucks operating under the speed control strategy exhibited significantly shorter operating times compared to those under conventional scheduling. This result stems from the ability of speed-controlled trucks to effectively avoid conflicts. In contrast, route planning under conventional planning often encounters conflicts, leading to truck stalls and subsequent delays in completion time. These results confirm that the speed control strategy can effectively mitigate conflicts.

Fig. 7 provides a more detailed analysis that further solidifies the benefits derived from employing the speed control strategy. One notable advantage is the substantial reduction in the total wait time compared to conventional scheduling. By implementing the speed control strategy, conflicts in truck route planning are effectively minimized, allowing for smoother and more efficient transportation operations.

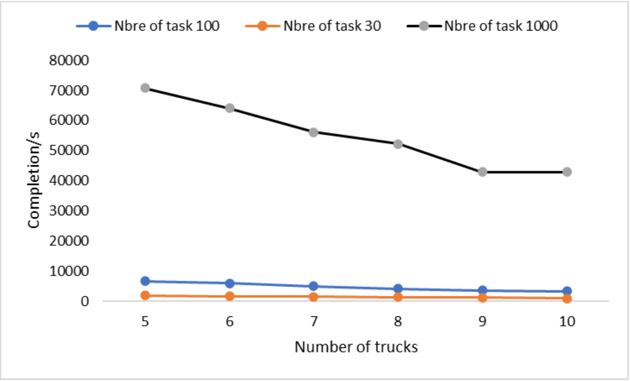

Fig. 6. Outcomes of various container tasks and diverse truck quantities upon completion.

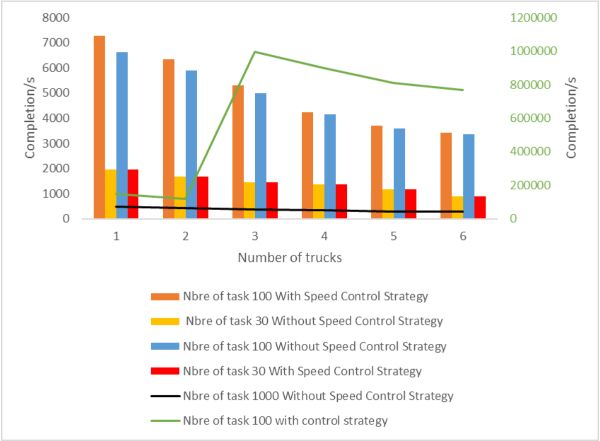

Fig. 7. Achievement outcomes of distinct container tasks and varying truck quantities through the implementation of a speed control strategy.

The reduced wait time is of paramount importance as it directly translates to improved transportation efficiency. With fewer conflicts and delays, vehicles can complete their assigned routes in a timelier manner, resulting in enhanced overall productivity and customer satisfaction. The speed control strategy ensures that vehicles can navigate through the road network more effectively, optimizing their travel paths and minimizing potential bottlenecks or congestion points.

The positive impact of the speed control strategy on transportation efficiency reinforces the significance of conflict resolution in road planning. By addressing conflicts through the three-step optimization algorithm proposed in this paper, the overall performance of the transportation system is greatly improved. The algorithm takes into account various factors such as traffic patterns, delivery schedules, and vehicle capacities to optimize route planning and minimize conflicts.

The findings presented in Fig. 7 confirm that the integration of the speed control strategy, along with the proposed three-step optimization algorithm, leads to substantial improvements in conflict resolution and overall transportation effectiveness. This provides valuable insights for decision-makers and stakeholders in the field of logistics and transportation management, emphasizing the importance of implementing intelligent strategies to enhance operational efficiency and customer service.

The curves in Fig. 8 illustrating a reduction in task execution time for trucks in a studied port due to the synchronization of handling systems, gantries, cranes and speed control to avoid collisions indicate the positive impact of these measures on operational efficiency. By coordinating the various components involved in port operations and implementing collision avoidance mechanisms, the port can streamline its processes and improve its productivity.

Reduced execution time means that tasks are executed faster and more efficiently. Synchronizing material handling systems, such as gantries and cranes, ensures a smooth flow of operations by minimizing delays and bottlenecks. This coordination allows the port to optimize resource allocation and effectively prioritize tasks.

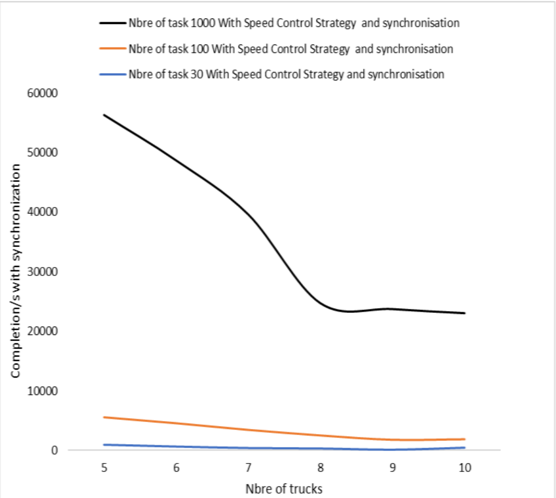

Fig. 8. Results completions by speed and synchronization control strategy.

Incorporating speed control mechanisms to prevent collisions is crucial to maintaining safety while maximizing productivity. By regulating the movement of trucks and equipment, potential accidents and disruptions are mitigated, leading to uninterrupted operations and improved overall performance.

It should be noted that the effectiveness of these measures is influenced by the number of tasks performed and their duration. As the number of tasks increases, the benefits of timing and speed control become more pronounced, resulting in greater time savings. The relationship between the number of tasks and the proportional reduction in time implies that the impact of these measures scales accordingly, leading to increased efficiency across different workloads.

Overall, the curves showing a reduction in lead time demonstrate the positive results achieved by synchronizing handling systems and implementing speed control measures. These improvements result in increased productivity, minimized delays, increased security and optimized allocation of resources in the studied port.

VI. Conclusion

As a sophisticated and information-intensive logistics system for loading and unloading operations, the developed port terminal at Tangier Med relies extensively on efficient truck transportation to establish seamless connections between the seaside loading and unloading area and the landside storage zone. The overall operational efficiency of the terminal greatly hinges upon effective time management and synchronized coordination between the transportation and handling systems. In light of this, we propose a three-stage model that tackles the truck route planning predicament by considering task allocation and integrating a speed control strategy to ensure collision avoidance during truck movement. The model is solved through the utilization of a heuristic algorithm, and its efficacy is exemplified through a comprehensive large-scale numerical demonstration, culminating in substantial enhancements to the operational efficiency of the Tangier Med port terminal. Nevertheless, practical circumstances necessitate the consideration of additional factors, such as the impact of truck charging on their movements. Therefore, future research endeavors focusing on devising collision avoidance routes for trucks while taking their load into account emerge as pivotal directions to explore for the further development of the Tangier Med port and its terminal.

Abstract—**The early diagnosis and treatment of lung tumour, the primary cause of cancer-related deaths globally, depend critically on the identification of lung tumours. In this approach, a new method is suggested for detecting lung tumours that combines a Gaussian filter with a hybrid Recurrent Neural Network-Generative Adversarial Network (RNN-GAN). Utilising the sequential data seen in images of lung tumours, the RNN-GAN architecture is used. In processing the sequential input, the RNN component looks for temporal relationships and patterns. The GAN component improves the training of the RNN for accurate classification by creating synthetic tumour specimens that resemble actual tumour images. In addition, the proposed approach pre-process lung tumour images using a Gaussian filter to improve their quality. The Gaussian filter improves feature extraction and the visibility of tumour borders by reducing noise and smoothing the pictures. The proposed experimental findings on a dataset of lung tumours shows that the suggested strategy successful. In comparison to conventional techniques, the hybrid RNN-GAN delivers higher accuracy in lung tumour identification due to the incorporation of the Gaussian filter. While the GAN component creates realistic tumour samples for improved training, the RNN component efficiently captures the sequential patterns of tumour images. The lung tumour images are pre-processed using a Gaussian filter, which greatly enhances image quality and facilitates precise feature extraction. The proposed hybrid RNN-GAN with the Gaussian filter shows promising potential for accurate and early detection of lung tumours. The integration of deep learning techniques with image pre-processing methods can contribute to the advancement of lung cancer diagnosis and treatment, ultimately improving patient outcomes and survival rates. Further research and validation are necessary to explore the full potential of this approach and its applicability in clinical settings.**

Keywords—Lung tumour; recurrent neural network; generative adversarial network; CT images; hybrid

I. Introduction

Lung cancer has become one of the main causes of cancer-related death in many countries all through the world. According to data on cancer worldwide, a startling number of new diagnoses and fatalities in 2018 were caused by lung cancer. There were a total of 1,761,007 fatalities, representing 18.4% of all tumour-related fatalities, and 2,093,876 newly identified instances, or 11.6% of all cancer sites [1]. The term "lung cancer" describes the unchecked proliferation of cancer cells in the lungs, which raises both male and female morality rates. While it cannot be totally prevented, there are some measures to lessen the risk of this illness, which is characterised by the fast proliferation of lung cells. For patients to have a better chance of surviving lung cancer, early identification is essential [2]. Lung cancer can be found via diagnostic imaging tests. Complex lung cancer datasets are examined to discover essential features using machine learning (ML) methods. A CAD method was created in the early peroid to help clinicians analyse medical pictures in an effort to increase effectiveness and the rate of survival. Healthcare has greatly benefited from a variety of machine learning methods. Additionally, we have investigated deep learning approaches, methodologies, and algorithms that may be used for identifying, detecting, and forecasting various cancer kinds [3].

Pathologists may be helped by the application of CNN-based approaches in the identification of lung cancer [4]. Selvanambi et al. recommended a more complex recurrent neural network that was optimised via glow-worm swarm optimisation to present a unique method for predicting lung cancer [5]. The use of computed tomography (CT) as a diagnostic tool for pulmonary disorders has become more important. Particularly, columnar CT is widely regarded as helpful tools in the diagnosis of scattered interstitial lung disease (DILD) images have been the subject of several researches aimed at improving computerised analysis of images and computer-aided diagnostic (CAD) systems. These developments are meant to increase the precision and efficacy of pulmonary disease diagnosis across the board, including diffuse interstitial lung disease (DILD) [6] .With the advancement of computer-assisted diagnosis and detection techniques, several efforts are being made to improve the clinical effectiveness of lung cancer detection and categorization. Sajja et al. [7] advised deep learning and transfer learning to detect lung cancer. Their study demonstrates how effective this method is in accurately identifying lung cancer cases. Bhatia el al. [8] presented a feature extraction strategy based on deep residual networks for the identification of tumours. Tulin Ozturk, et al. [9] suggested a model using deep learning for automating tumour diagnosis.

The American Cancer Society estimates that every year, between 10 and 20 percent of all cancer patients (or around 1.7 million people) receive incorrect diagnoses, as well as that at least 40,000 of these individuals end up dying as a direct result. Furthermore, cancer is the second-leading cause of mortality in the US. There is a chance of making a mistake when a pathologist has, on a typical basis, 80 Computed Tomography (CT) slides each patient to assess. Therefore, it is necessary to computerise the tumour diagnosis procedure in order to cut down on the possibility of human mistake. Monitoring with low-dose CT, which has been demonstrated to lower lung cancer mortality by up to 20%, has the potential to identify lung cancer at an earlier stage. However, diagnosing a lung CT scan is a highly specialised process needing specialist understanding. If done manually, it is a difficult and time-consuming process. False negative situations occur when a cancer manages to escape detection by the human eye since it may resemble other lung-existing particles in terms of size and texture. The current study primarily focuses on the qualitative examination of a cancer that a pathologist manually found during a single CT scan. The literature lacks a completely automated framework that can automatically detect tumours across a series of CT scans in a single run, giving the viability of the framework priority. Despite this, there would be 28.40 million new instances of tumours worldwide in 2040, a 48 percent rise from the previous year. An increase in risk factors, such as smoking, will make (even worse. people with respiratory issues, people who have been smoking for 30–40 years, patients who experience no symptoms, as well as patients with no symptoms are common hurdles in identifying lung tumours in patients from the decade. In an effort to overcome the difficulties involved in the diagnosis of tumours, various investigators have employed a variety of strategies, such as differentiation, recognition, and classification methods [10].

Using a Gaussian filter, the picture is first enhanced by data pre-processing, and the noise in the CT representation is then eliminated. The pre-processing methods divide the incoming data into several categories. Pre-processing will be followed by the extraction of the afflicted lung region. The afflicted area of the lung tumour is found using segmentation. The segmentation of the CT representation facilitates the extraction of useful characteristics for the procedure. To prepare the input image for testing and training, two sets are divided. During training and testing, the errors in the samples of data are removed. Then, using the feature extraction process, which extracts the features using the Grey Level Co-occurrence Matrix (GLCM), the cancerous lung nodule is found. The RNN-GAN hybrid model is used to distinguish between the damaged and unaffected parts of the lungs.

The following are the research's main contributions:

- From a lot of cases, CT pictures are initially gathered.
- In addition, undesirable noises are present in the reconstructed real CT lung pictures, which are filtered using a sophisticated Gaussian filter model.
- The segmentation procedure has been carried out using an enhanced K-means clustering.
- The Grey Level Co-occurrence Matrix (GLCM) was used to extract features.
- The afflicted and unaffected lung nodules are categorised by the RNN-GAN.
- To demonstrate the usefulness of the implemented technology, its performance is verified and compared to current methodologies.

The manuscript of the approached paper is organised as follows: In Section II, some related works are reviewed. In Section III, Information regarding the problem statement is provided. In Section IV, the proposed RNN-GAN is covered in detail. In Section V, experiment results are provided, and discussed, and an extensive evaluation of the proposed approach to current best practices is made. In Section VI, the conclusion of the paper is provided.

II. Related Works

Rahman et al. [11] utilized several open datasets to construct a database comprising 3500 chest X-ray images infected with TB and 3500 images of healthy chests. They developed a reliable method for consistently identifying tuberculosis from these chest X-ray images. Image initial processing, enhancement of data, segmentation of images, and deep learning techniques classification algorithms were all used in the methodology. The success of a transfer learning strategy employing deep CNN for automatically detection of tuberculosis is discussed in conclusion. The study assessed nine various CNN models and found that the ChexNet model performed well (96.47%, 96.62%, and 96.47%) without image segmentation, while the DenseNet201 model excelled with (98.6%, 98.57%, and 98.56%) segmented lungs. The study also emphasized the significant improvement in classification accuracy through image segmentation. The Score-CAM visualization results provided confirmation of the key role played by lung segmentation in ensuring accurate decision-making based on the lung region. One potential drawback of the proposed method is that it focuses only on the detection of TB without considering the detection of other lung abnormalities or diseases. While this approach is valuable for TB detection it may not be suitable for identifying other lung conditions or providing a comprehensive analysis of the patient's chest radiograph.

Bharati, et al. [12] proposed a new deep learning hybrid framework by merging (STN) VGG with CNN and named as VDSNet to detect the lung disease. The dataset obtained from the Kaggle library was subjected to this methodology. There are a sizable number of lung X-ray pictures in the investigation's dataset. This model has the greatest validation accuracy of 73% for the complete dataset example. Comparatively, the accuracy of the validation values for various other models, are 69%, 67.8%, 60.5%, 69.5%, and 63.8%, respectively. With an accuracy for validation of 73%, this framework outperformed the sample dataset's efficiency of 70.8%. However, VDSNet requires more time for training, with the process taking 431 seconds as opposed to the sample dataset's 19 seconds.

Asuntha & Andy Srinivasan [13] focuses on using Deep Learning methods to locate cancerous lung nodules and classify lung cancer severity. Fuzzy Particle Swarm Optimisation Convolutional Neural Networks (FPSOCNN) is a unique method that is suggested for lowering computational complexity. We use a number of feature extraction methods, such as HoG, wavelet transformations, LBP, SIFT, and Zernike Moment. The FPSO algorithm is used to extract texture, geometric, volumetric, and intensity characteristics and choose the best feature; evaluation utilising a unique dataset (DICOM) from the Indian hospital Aarthi Scan. Nearly 10,000 lung pictures are included. All images have a resolution of 256 by 256. The experimental data demonstrate that new FPSOCNN outperforms existing methods. The optimisation and classification performance of the suggested model still require work. This suggests that the suggested paradigm could have some drawbacks.

Kim et al. [14] employed a technique called transferred learning to elevate the accuracy and efficacy of CAD and created a deep learning approach for classifying lung disease in chest X-ray (CXR) images. The method used CNN models, particularly the Efficient Net v2-M model, as well as the transfer learning techniques, empirical hyper-parameters, and CNN models. The one-step, end-learning method utilised to gather useful features for sickness categorization involved simply feeding raw CXR images into the deep learning system. Two datasets were used for the experiments, which include a privately created database with four categories and an open-access benchmark dataset from the U.S. National Institutes of Health with three distinct groups. The suggested strategy produced reliable results in precisely classifying lung diseases. The suggested method's disadvantage is that the success rate for the different categories varied, with the usual categories having the lowest possible accuracy at 63.60%. This suggests that in comparison to the other lung disease categories, the model would have trouble properly classifying normal patients.

Demir et al. [15] a range of sample frequency ranges, noise from the background, and other noises are included in the CBHI 2017 database, which was suggested. The lung sound waves were transformed into spectrogram visualisations. Two methods based on deep learning were used to classify lung sounds. In the first approach, lung sounds were categorised using an SVM classifier, and features were retrieved using an already trained CNN. In the second technique, the previously trained deep CNN model was modified by transfer learning while lung sounds were identified using spectrogram images. The accuracy of the first and second suggested approaches was 65.5% and 63.09%, respectively. This strategy is then demonstrated to perform better than other results by comparison to the current results. The problematic elements in the suggested approach for classifying lung sounds include noises, background noise, and different sampling frequencies. This suggests that a smaller dataset may have been used to test the model.

Shakeel, et al. [16] focuses on boosting the accuracy of lung cancer detection and the quality of lung pictures. The (CIA) dataset's lung CT pictures were used. A weighted mean histogram equalisation method was used to minimise misclassification and improve picture quality by removing noise from the photos. Further enhancing picture quality, the afflicted region was segmented using an IPCT. A deep learning neural network was instantly developed to anticipate lung cancer using the partitioned region's multiple spectral properties. The technique achieved a success rate of 98.42% with a low classification error of 0.038, and its effectiveness was assessed using MATLAB-based simulation results. These results show how well the algorithm performs in correctly identifying lung cancer and enhancing lung pictures. It is noted that without data enhancement and transfer learning, categorising numerous lung illnesses on grayscale chest X-ray (CXR) pictures is difficult. A trade-off exists when dropout regularisation is used among overfitting and losing important information. A low rate of abandonment might result in acceptable performance on the initial training set but poor performance on the validation or testing set, whereas a large dropout rate could result in the loss of critical features.

Chen, et al. [17] proposed to assess chest X-ray pictures of common pulmonary diseases in children. A computer-aided diagnosis method has been created. The appropriate lung field is automatically recognised and cropped by the algorithm using the YOLOv3 architecture. The one-versus-one classification system outperformed the other two when they were compared to each other. In recognising certain illnesses and detecting irregularities, the system had great accuracy rates. The suggested method's limitation to useable medical resources is its main flaw. Issa, et al. [18] examined how well four pre-trained participants performed using CXR pictures to identify various lung illnesses. Utilising CXR pictures and 5-fold cross validation, the model was trained and evaluated. With a remarkable area under the curve (AUC) of 99.84% for ROC, XceptionNet had the greatest accuracy (94.775%). With regards to accuracy, quick convergence, resource use, and almost real-time detection (0.33s), DarkNet19 demonstrated an excellent balance. With a lengthier prediction time (5.68s), the ensembles feature technique, which included many models, obtained the maximum accuracy of 97.79%.

III. Problem Statement

The problem addressed in the research is the development of a deep learning-based CAD system for classifying lung diseases in CXR images, with the ultimate aim of enhancing diagnostic accuracy and efficacy in medical imaging [14]. The database contains a range of sample frequency ranges, background noise, and other noises, making lung sound classification challenging. The researchers sought to develop effective methods based on deep learning to classify these lung sounds accurately [15]. In this proposed approach a unique method for Optimized Ensemble of Hybrid RNN-GAN Models for Accurate and Automated Lung Tumor Detection from CT Image.

IV. Proposed RNN-GAN

By incorporating RNN-GAN, the proposed method effectively leverages the sequential nature of lung tumour, capturing temporal patterns that may be crucial for accurate tumour identification. The GAN component plays a vital role in creating synthetic tumour samples, improving the training process, and augmenting the limited dataset to better handle class imbalances and improve classification accuracy. The application of the Gaussian filter enhances image quality and reduces noise, leading to improved feature extraction and better visibility of tumour borders, ultimately contributing to more reliable and precise tumour detection. The combination of deep learning techniques with image pre-processing methods shows promise for early detection of lung tumours, which is critical for improving patient outcomes and survival rates. The proposed method represents a significant step in the field of lung cancer diagnosis and treatment, demonstrating the potential of integrating cutting-edge techniques for addressing complex medical challenges.

The computerised tomography representations of lung tumours are first gathered. The simulations are then used for teaching and testing. The Gaussian filter is applied in the pre-processing of lung-dependent CT images to remove extra noise. In this work, lung nodules are first detected using a mixed RNN-GAN model. The severity of lung nodules is categorised using the suggested RNN-GAN model. Fig. 1 shows the RNN-GAN model.

A. Data Collection

CT lung representations of 10,000 datasets containing healthy and unhealthy lung representations collected from the University of California are utilized in the research. Among these 50% of representations are used for training and 50% of representations are utilized for testing [20] . The assessed system was tested using many cancer datasets form the University of California, Irvine collection. The data set has 57 high points, but only four of them may be looked at with conventional analysis of components. The lungs dataset was utilised in evaluating their programmed method for cancer identification. There are 32 occurrences, 57 features, and a single class characteristic altogether in the collection. The dataset, which consists of 32 samples with a total of 57 characteristics and a theoretical range of 0–3, was found in the database for machine learning at UCI. Here 2500 is a tumour data. The collected datasets are given in Table I.

TABLE I. Collected Datasets

	Unhealthy	Healthy	Overall
Training data	2500	2500	5000
Testing data	2500	2500	5000

B. Data Augmentation

The data augmentation technique creates augmented training data using a style-based generative adversarial network (GAN). It makes sense to utilise data augmentation techniques to address the issues of data imbalances and scarcity. This strategy has shown to be a successful means of enhancing model performance and avoiding overfitting. Utilising GAN to enhance data or create training samples is another genre. The GAN training phase and enhanced image generation are the two components of this approach. The design of the generator and the discriminator are both optimised concurrently throughout the training phase. They are instructed to use both the semantic label and the style matrix to rebuild the actual image [21].

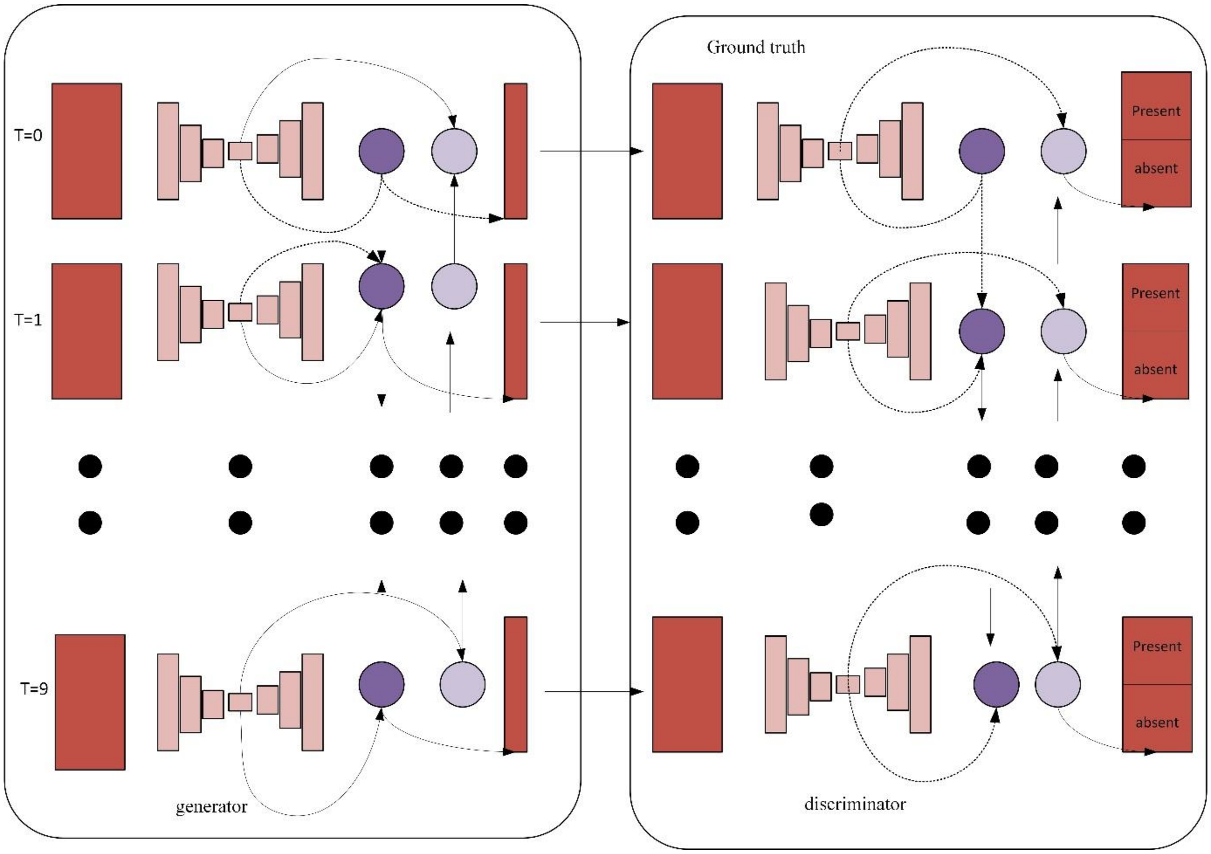

Fig. 2. Architecture of RNN-GAN.

A generating network (G) and a discriminative network (D) are the two deep networks that make up the RNN-GAN's architecture, which is shown in Fig. 2. As a condition, G produces a series of 2D segmentation semantic outputs from a set of 2D images, and D determines whether or not those outputs are real. RNN-GAN experiences improvements where better resolution attributes are coupled with upsampled relatively not high-quality image attributes, helping the neural network to learn both global and local data. Typically, a GAN's generative model G aims to translate the output image v into the erratic noise vector z; G: z→y. The possibility that a sample comes from the source of data x false as opposed to its data for training x genuine is calculated by a model exhibiting bias D in the meanwhile. More specifically, an RNN-GAN network is proposed, and a generative model learns its semantic classification of matching labels from a set of 2D medical images ui. vi_{seg} ; G : u_i, z → {vi_{seg} }. The discriminator uses the ground truth and the generated data to assess if the label that was predicted is true or false whereas the segmentation was anticipated at the pixel level by the generator which is represented in eq. (1).

$$\mu_{adv} \leftarrow min_G max_D k(G,D) = K_{U,Vseg}\left[\log D\left(u, v_{seg}\right)\right] + K_{u,z}[log(1 - D(u, G(u,z)))] \quad (1)$$

C. Pre-Processing

The initial step in finding cancerous pulmonary nodules is pre-processing. It is used to remove unnecessary data in addition to fill in dataset gaps. The peculiar and abnormal vibrations that influence the CT portrayals slow down the rate of evaluation of the first visualisations. The CT depictions are most affected by the irregular noises that are caused by internal and external causes. As a consequence, the noise in CT lung depictions is reduced using the resulting Gaussian filter. The created Gaussian filtering technique is used to minimise residual deviations of spatial severity in the depictions as well as disturbance in the representations. The use of the filter known as the Gaussian causes the mean value of the surrounding pixels, which depends on the distribution of Gaussian, substitutes the distorted pixel within the representation. The RNN-GAN model makes use of noise-reduced representations to identify lung cancer nodules [22]. The Gaussian function is given is given in eq. (2).

$$G(V) = \frac{1}{\sqrt{2\pi\delta^2}} e^{\frac{V^2}{2\pi\delta^2}} \quad (2)$$

Where δ is the standard deviation of the distribution. The distribution is assumed to have a mean of 0.

D. Segmentation Using K-Means Clustering

The segmentation approach is mostly used for separating the impacted area in illustrations based on CT images. For image processing to be implemented, the segmentation procedure must be accurate. Segmenting an image is frequently used to determine the location of the affected nodules as well as the constraints of the images' curves and lines. The representations are divided into groups of pixels, and each group's pixels are annotated. Classification of cancer nodules and the generation of sufficient data to perform additional identification are the primary goals of picture segmentation in medical representation processing. The technique of dividing a picture into several sections, each with a different collection of pixels, is known as image segmentation. The method of global thresholding technique depends on the gray-level pixels' luminosity for threshold P, projected to divide the picture. Using eqn. (3) and I(u, v), it is possible to describe the fragmented picture that was obtained by global thresholding. The image's pixel value is represented here by t(u,v).

$$I(x,y) = \begin{cases} 1\ if\ I(u,v) > P \\ 0\ if\ I(u,v) \le P \end{cases} \tag{3}$$

By implementing a certain structural element at every site that is feasible for smoothing the region of interest, quantitative morphological procedures are estimated. When F is a binary picture and J is an organising element, as shown in eqns. (4), (5), (6) and (7), respectively, mathematical computations are carried out.

$$Erosion : L \ominus J = \{H|(J_A \subseteq L)\} \tag{4}$$

$$Dilation : F \oplus J = \{H|(J_A \cap L \neq 0)\} \tag{5}$$

$$Opening : F \ominus J = L \ominus \mathrm{J} \oplus \mathrm{LJ} \tag{6}$$

$$Closing : F \ominus J = L \oplus \mathrm{J} \oplus \mathrm{LJ} \tag{7}$$

The simplest and most traditional method of analysing clusters is the k-mean clustering algorithm. To divide the provided dataset through two or more groups, k-means is used. Since choosing the right cluster core is crucial for obtaining the most beneficial results, the correctness of the procedure is assessed by examining every single cluster centre that the algorithm generates. The Euclidean distance, that is employed to assign pixels to certain clusters, is a pretty straightforward technique for separating the dataset. This algorithm makes use of the following function as represented in eq. (8).

$$k = \sum_{i=1}^{r} \sum_{j=1}^{s} V_{ij} \left\| u^i - \gamma_s \right\|^2 \tag{8}$$

Where, V^i is the number of data points for the i th cluster, u^i is the number of pixels, v^j is the cluster centres, $\left\| u^i - \gamma_s \right\|$is the Euclidean distance between u^i and v^j, and C^i is the number of cluster centres. In the anticipated phase, points of information are allocated to the nearest cluster. Each cluster's kernel is determined during the optimisation process [23].

E. Feature Extraction

In order to record and retain the details of the initial collection of data, the process of separating characteristics requires turning unorganised information into quantitative attributes. Each patient has a unique way of processing information, and these characteristics are derived from the full collection of depictions that were taken. The number of dimensions of the depiction must be lowered for the purpose to detect lung nodules while the dimension of the representation grows throughout testing. To fix this problem, the extraction of features is done. The Grey Level Co-occurrence Matrix (GLCM) is used in the feature extraction. By computing various combinations of pixels with specific values, it shows how the visual representation is organised hierarchically. The GLCM employs the associated grayscale and displays the luminosity of the depicted pixels. To remove the statistically important texturing characteristic, the second-degree representation's energy, contrast, correlation, entropy, homogeneity and other qualities are assessed.

The extraction of features stage is carried out using the GLCM technique based on the scenarioThe GLCM functions determine how frequently pairs of pixels with specific parameters and in a particular arrangement of pixels appear in an image in order to describe the surface texture of that image. statistical variables generated from the following GLCM outcomes. The formulas below were used to determine these values:

1) Energy: When the total values are asymmetrical and usually greater, energy is defined as the presence of an equal number of grey levels in portrayals. eqn. (9) calculates the energy of the provided data.

$$E = \sum_o \sum_p \{Q(o,p)\}^2 \tag{9}$$

Where the representations are denoted as Q and gray level squares are denoted as (m, n).

2) Contrast: Attributes are used to assess the local contrasts of a representation, so if it is in a consistent saturation value, it is assessed as a low value. The number of grayscale values in the original form as well as the contrast are projected in eqn. (10)

$$C = \sum_{y-0}^{Rs} y \left\{ \sum_{0-1}^{Rs} \sum_{p-1}^{Rs} Q(o,p) \right\} \tag{10}$$

Where R indicates the gray level of the representation, Q indicates the representation, and (o,p) indicates the gray level square of the representation.

3) Correlation: The relationship between the features can be used to account for both the linear dependence of the grey levels on the pixels and statistical interactions between the parameter values. The characteristics are exposed in eq1. (11).

$$C = \frac{\sum_o \sum_p (o,p) Q(o,p) - \delta_x \delta_y}{\sigma_x \sigma_y} \tag{11}$$

In the representation, the values of mean, as well as standard deviation, are δ_x , δ_y , σ_x, $and\ \sigma_y$ are defined as row and column.

4) Entropy: The anticipated significant amount of the uncertainty of the split of the grey levels is known as entropy. which is denoted in eq. (12) [24].

$$E_n = -\sum_o \sum_p Q(o,p) \log_2\left(Q(o,p)\right) \tag{12}$$

5) Mean: Mean indicates the overall brightness within the matched image. It has very limited expressive and discriminating skills which is denoted in eq. (13).

$$M = \sum_{\boldsymbol{i=0}}^{\boldsymbol{Q}} \frac{i \frac{mi}{M}}{\sum_{i=0}^{Q} \frac{mi}{M}} \tag{13}$$

Where, M=total number of pixels, mi= number of pixels in level i

6) Energy features: Angular second instant is another name for energy. The grey level occurrence matrix's sum of squared elements is returned. Energy for a constant picture will be 1 and it is denoted in eq. (14)

$$E = \sum\sum Q(o,p)^2 \tag{14}$$

7) Homogeneity: It evaluates how well the GLCM's constituent distribution matches its diagonal. Which is denoted in eq. (15) [25].

$$H = \sum_{i,j} \frac{Q(i,j)}{1+\|i-j\|} \tag{15}$$

F. Classification using RNN-GAN

In order to reduce the total distinction amongst the anticipated value and the biggest value already in existence, the loss caused by opposition with 1 distance is used. The small quantity is made up of 2D pictures taken from an identical patient using the identical acquisition surface during the stages of training and testing. Both the variance and the mean are estimated for an individual from the exact same acquisition plane as well as similar phase, and then the recommended method first normalises the inputs from all available photos. The impact of anomalies is reduced because to this normalisation. The recommended method utilised batch standardisation to equalise the signals that were employed (activations from the previous layer) coming into every layer specified in eqns. (16) and (17) using the mean and variance of all the activation for the entire mini-batch. There is less turbulence and the borders are smoother since the parameter function takes into account RNN features and differences between expected and actual segmentation.

$$\mu_1 = K_{U,Z}\|vseg - G(u,z)\| \tag{16}$$

$$\mu_2 = \frac{1}{d}\sum_{i=1}\sum_{j=1}\frac{v_{ij_{seg}} \cap G(u_{ij},z)}{v_{ij_{seg}} \cap G(u_{ij,},z)} \tag{17}$$

where u and z represent, correspondingly, the quantity of 2D slices and the degree of semantic classes for every patient. Additionally, the suggested method combined categorised loss of accuracy, to reduce unbalanced data from training by allocating a greater cost to a fewer-represented group of pixels, raising its value throughout the learning process. Classification accuracy loss determines if the maximum real value and maximum forecasted value for each classification category are equal. The final of RNN is calculated through eq. (18) [26].

$$\mu_{RNN}(D,G) = \mu_{adv}(D,G) + \mu_1(G) + \mu_2(G) \tag{18}$$

In traditional generative modelling approaches, the performance of a model is indicated by the reverse divergence between the desire distribution Q_r and our generator's distribution Q_s as represented in eq. (19).

$$V_{kl}(Q_r\|Q_s) = \int xQ_r \log\frac{Q_r\,dx}{Q_s} \tag{19}$$

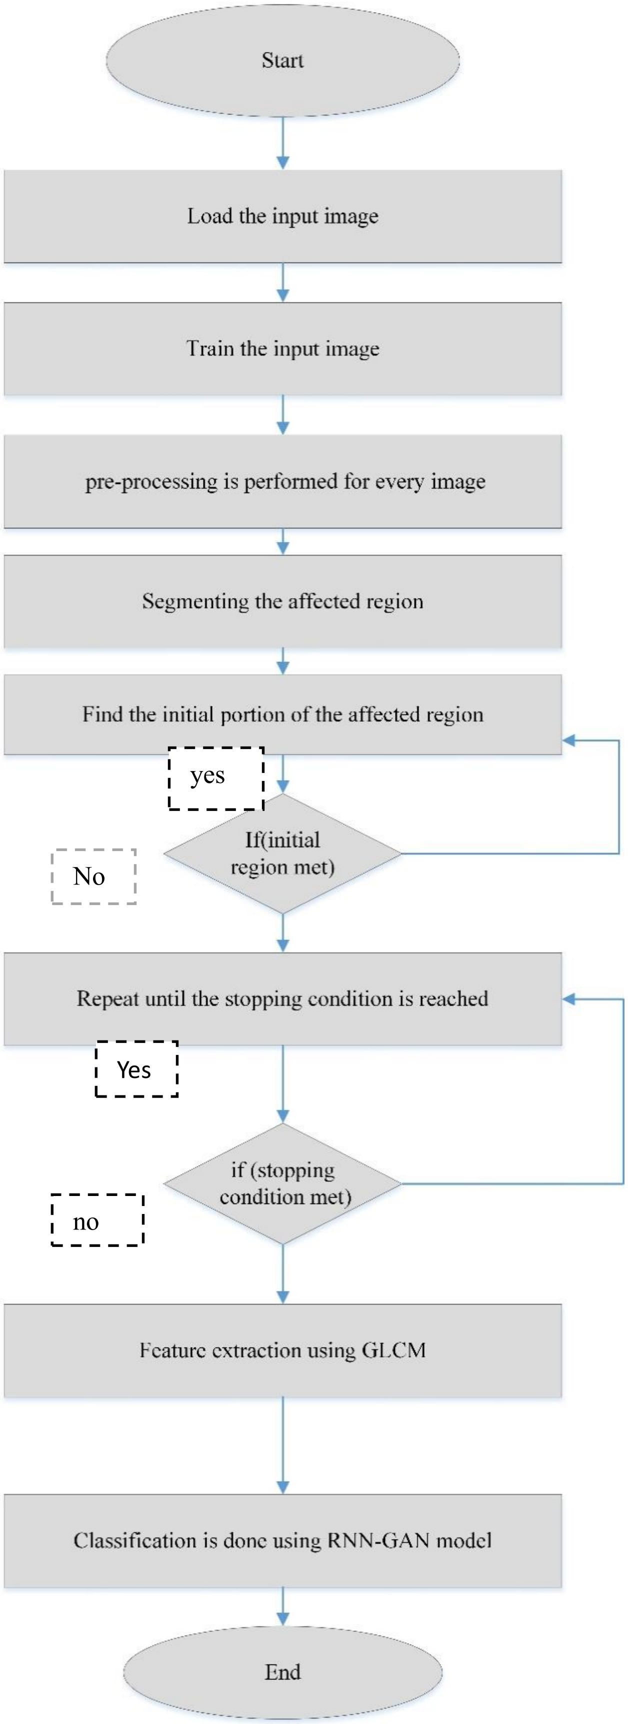
RNN-GAN is a mixture of the RNN and GAN, two well-known deep learning models. While GANs are used to produce accurate patterns of distribution, RNNs are utilised for processing data sequentially. RNN and GAN frameworks should be combined for cooperative training. Actual and false lung tumour pictures produced by the GAN are used to train the RNN. The RNN gains the ability to distinguish between benign and malignant pictures. Utilise the test set of lung tumour pictures to assess the trained RNN model's performance. The proposed approach need to alter the RNN-GAN model's hyper-parameters, architecture, or data augmentation strategies in accordance with how well it performs. The goal of this stage is to increase the model's generalisation and consistency capabilities.

Fig. 3 represents the proposed flow diagram for lung tumour detection. Initially the data is loaded. The images pre-processed by Gaussian filter to remove the noise present in the image. The pre-processed image is segmented using k-means clustering technique. Then the features are extracted by GLCM technique and finally the proposed classifier classifies the tumour.

Algorithm: RNN-GAN mechanism

```
Input: CT representation of lung nodules
Output: Detection of affected and unaffected lung nodules
Load input representation data
Train the input images $v_i$ in the system, where i = 1 to n
Pre-processing of images
Let U(i) be the input images from the dataset
        for every $U_i$              // Gaussian filter
                                     // V denotes
$V_v(i) = V(i) – N$                  unwanted noise
Segment the affected part
// Bat and Whale Optimization
    Initially, the affected part is detected
    If( initial region is met)
        Update the tumour present
    Else
        Find the initial location

    Repeat until the stopping condition is reached      // until all the tumour region is identified
    End if
Return
Feature extraction using GLCM
Classification of tumour             //RNN-GAN classifier
```



Start
Load the input image
Train the input image
pre-processing is performed for every image
Segmenting the affected region
Find the initial portion of the affected region
yes
No
If(initial region met)
Repeat until the stopping condition is reached
Yes
no
if (stopping condition met)
Feature extraction using GLCM
Classification is done using RNN-GAN model
End

Fig. 3. Flow diagram of the proposed model.

V. Result and Discussion

The recommended method has been evaluated using lung computed tomography datasets and executed in MATLAB software on the Windows 10 platform. The combination of revolutionary RNN-GAN is used to detect a lung tumour when contrasting datasets from healthy and unwell individuals. Performance indicators like Accuracy, Precision, Recall, and F-measure are used to evaluate the effectiveness of proposed methodology.

The proposed model will be implemented using the python programming language. The test is run on a machine equipped with an Intel(R) Core(TM) i5-3470 CPU @ 3.20 GHz, 3200 MHz, 4 core(s), 4 logical pro. And micro software 10 pro, a micro soft corporation, is an OS manufacturer installed physical memory (RAM) 8GM.

A. Accuracy

The model's complete precision demonstrates how well it functions throughout every classification. In general, it is the notion that all occurrences will be accurately predicted. Eq. (20) expresses accuracy.

$$A = \frac{T_{pos}+T_{neg}}{T_{pos}+T_{neg}+F_{pos}+F_{neg}} \quad (20)$$

B. Precision

The number of exact positive ratings that differ from the total number of positive evaluations is used to calculate precision. Eqn. (21) is used to compute the portion of precisely identifying the afflicted area as having tumour nodules.

$$P = \frac{T_{pos}}{T_{pos}+F_{pos}} \quad (21)$$

C. Recall

The recall is the correlation between the overall quantity of accurately classified samples that are positive and the number of true positives. It displays the percentage of predictions that correctly identified the malignancy nodules that is given in eq. (22):

$$R = \frac{T_{pos}}{T_{pos}+F_{neg}} \quad (22)$$

D. F1-Score

The F1-Score computation combines precision and recall. Precision and recall are used to construct the F1-Score given in eq. (23)**:**

$$F = \frac{2\times Precision\times recall}{Precision\times recall} \quad (23)$$

TABLE II. Performance Evaluation

	CNN	RNN-GAN
Training	99.1	99.8
Testing	97.5	98.9

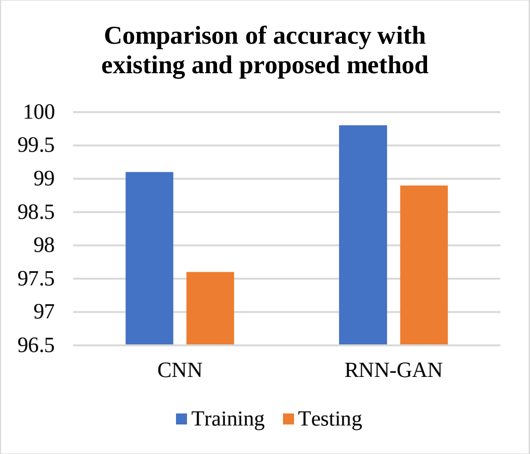


Fig. 4. Accuracy comparison for existing and proposed method.

The accuracy of the convolutional neural network used for both the training and testing stages is 99.4% and 97.6%, respectively, according to Table II. When RNN-GAN is utilised, the accuracy of the testing and training processes increases to 99.8 and 98.9, respectively. Fig. 4 shows an evaluation of performance.

TABLE III. Comparison of Accuracy

Classifier	Accuracy
CNN [10]	89.8
FPSOCNN [12]	98.9
SVM [15]	97.2
SVM +CNN [14]	97.5
Proposed RNN-GAN	98.6

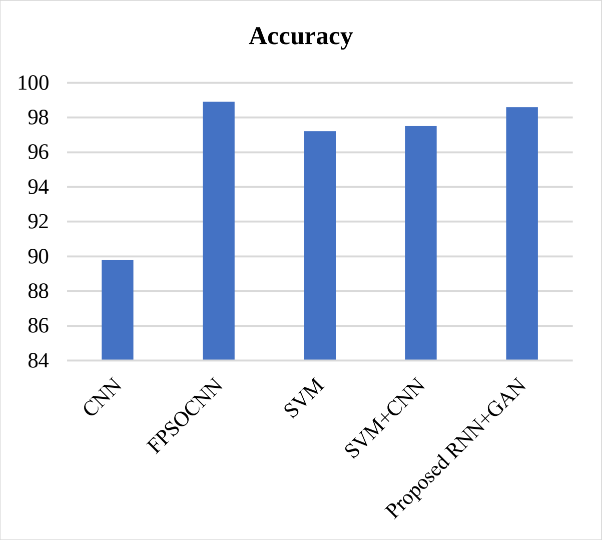

Fig. 5. Comparison of accuracy.

When compared to the current lung tumour detection techniques, the suggested technique RNN-GAN obtains a greater level of accuracy. The contrast of efficiency between RNN-GAN and other approaches is shown in Fig. 5 and Table III.

TABLE IV. COMPARISON OF PRECISION AND RECALL

	Precision	Recall
MLP classifier	88.5	86.9
CNN	95.9	98
SVM and CNN	98.9	92
RNN-GAN	100	99

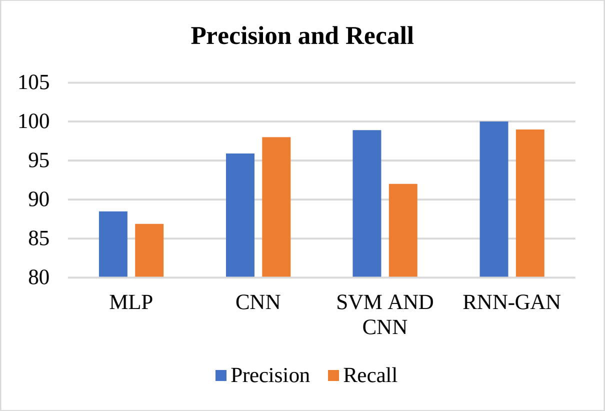

Fig. 6. Comparison of precision and recall.

Table IV demonstrates that the proposed technique of combined RNN-GAN achieves higher precision and recall of 100% and 99% when compared to the existing lung tumour nodule detecting methods the advanced RNN-GAN gives better accuracy than the performance evaluated. Here, the achieved accuracy level is 98.92% using the RNN-GAN model. Fig. 6 illustrates the precision and recall between RNN-GAN and other methods.

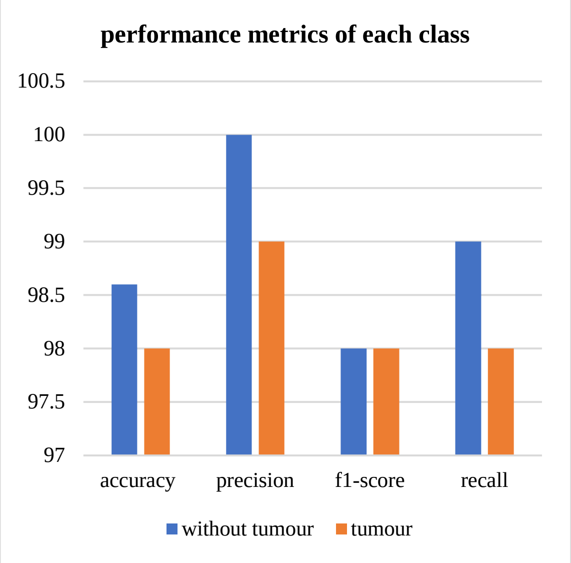

Fig. 7. Performance metrics of each class.

In Fig. 7, the performance metrics for each class are presented. The analysis involves two classes: "without tumour" and "tumour." The metrics include accuracy (98.6%), precision (100%) for "without tumour," and accuracy (98%), precision (99%) for "tumour." Additionally, the f1-score and recall values for both classes are provided, indicating the model's overall classification performance for each category.

VI. CONCLUSION

Today's healthcare technology is rapidly advancing image processing, but in some cases, the intricate nature of the depictions makes it difficult to categorise and diagnose disorders. The ill or damaged section is classified, characterised, and segmented using the indicated method. It mainly focuses on locating lung tumour nodules. First, data from patients with various types of lung tumours are acquired from their CT scans to learn more about the patient. The unexpected effects or distortion in the images from CT are then removed employing a Gaussian filter that is applied during pre-processing. The RNN-GAN framework is utilised for scenarios including the recognition of lung cancers. The RNN-GAN architecture enables sequential processing of lung cancer pictures and the creation of realistic tumour samples by combining the strengths of RNNs and GANs. Because the data are sequential, the RNN component of the RNN-GAN can accurately classify the lung tumour images by detecting relationships between time and patterns. The RNN can use the synthetic tumour samples produced by the GAN component to train and improve its capacity to distinguish between benign and malignant tumours. The RNN-GAN architecture learns to categorise lung tumour images through joint training using both actual and produced tumour samples. While the GAN creates realistic tumour samples to aid in learning, the RNN is taught to categorise the photos. The RNN-GAN strategy has the potential to increase the precision and effectiveness of lung cancer detection systems by utilising the complementary capabilities of sequential data processing provided by RNNs and generative modelling provided by GANs. To guarantee the success of the RNN-GAN framework for lung cancer detection tasks, it is crucial to take into account the unique implementation aspects, such as architectural choices, training methods, and dataset quality. The proposed method requires careful evaluation on larger and diverse datasets to ensure generalization to various tumour types and patient populations. Additionally, the computational cost of using RNN-GAN and Gaussian filters may be a challenge for real-time applications; optimizing the model's efficiency is a critical aspect for future research and practical deployment. To validate and perfect the RNN-GAN technique for practical lung tumour detection applications, more investigation and testing are required. Consequently, this model's forecast precision was 98.6%.

U-Net-based Pancreas Tumor Segmentation from Abdominal CT Images

H S Saraswathi[1], Mohamed Rafi[2]

Department of Computer Science & Engineering, Jain Institute of Technology, Davangere-577003, India[1]
Department of Studies in Computer Science & Engineering, UBDT College of Engineering, Davangere-577004, India[2]

***Abstract*—There is no doubt that pancreatic cancer is one of the most deadly types of cancer. In order to diagnose and stage pancreatic tumors, computed tomography (CT) is widely used. However, manual segmentation of volumetric CT scans is a time-consuming and subjective process. It has been shown that the U-Net model is highly effective for semantic segmentation, although several deep learning models have been proposed. In this study, we propose a U-Net-based method for pancreatic tumor segmentation from abdominal CT images and demonstrate its simplicity and effectiveness. Using the U-Net architecture, the pancreas is segmented from CT slices in the first stage, while tumors are segmented from masked CT images in the second stage. For validation set of NIH dataset and according to the proposed method's dice scores, the pancreas segmentation and tumor segmentation performance was outstanding, demonstrating its potential to identify pancreatic cancer efficiently and accurately.**

Keywords—U-net; deep learning; segmentation; computed tomography images; hyper parameters; PDAC

I. Introduction

The pancreas is an accessory organ, an exocrine gland of the digestive system, and an endocrine gland that generates hormones. In a healthy adult, the pancreas weighs around 100g, ranges in length from 14 to 25 cm, and has a volume of roughly 72.4 to 25.8 cm^3. It has an extended lobular form. The five anatomical divisions are the uncinate process, neck, body, and tail. Release of digestive enzymes that assist the digestion of fatty foods is the primary duty of the exocrine pancreas. The endocrine gland assists in regulating blood sugar levels and cell nutrient uptake. Exocrine pancreas cancer is referred to as "pancreatic cancer". It is one of the most common cancers, particularly in western countries and Japan. Pancreatic cancer is the melanoma that occurs in Americans the second most frequently. It accounts for 5% of all cancer mortality in that country and is more common in African Americans. It strikes men more commonly than women. The incidence increases after age 50. Pancreatic cancer develops when the cells of the pancreas undergo abnormal DNA modifications; this leads to the cells' uncontrolled division and growth into tumors. Occasionally, the liver, abdominal wall, lymph nodes, lungs, or bones may become infected by this tumor. The risk factors for getting pancreatic cancer include smoking, being overweight, having long-term diabetes, having a substantial family history of the illness, eating a lot of processed food and red meat, and having chronic pancreatitis. It is the fourth most common reason for cancer-related deaths in the west. It is predicted to overtake cancer as the second-deadliest illness in 10 years. It has an annual incidence rate of 12.50 per 100,000 persons, accounting for 3% of all cancer cases in America. One of the most fatal cancers, pancreatic cancer has a five-year mortality rate of less than 10%. Computed tomography (CT) scans of pancreatic tumors must be accurately segmented in order to make a diagnosis, determine a course of treatment, and track the disease's progression. Radiologists must manually segment images, which takes time and is prone to inter-observer variation. Deep learning models for automated segmentation have shown the potential in overcoming these constraints. The U-Net model is a convolutional neural network architecture designed for semantic segmentation tasks, particularly in biomedical image processing, including the segmentation of CT (Computed Tomography) images [15]. The U-Net architecture is named after its U-shaped design, which consists of two main parts: the contracting path and the expansive path. In this study the U-net model is proposed to segment both pancreas and hen to segment pancreas tumour. Each U-Net in our suggested system has a unique set of hyperparameters, and they are all cascaded together. When initializing the weights of the first U-Net, we employ Kaiming initialization to prevent the issues caused by disappearing or exploding gradients. A multi-class cross-entropy loss function, used by the second U-Net, is suitable for segmentation tasks. Our method is straightforward and efficient, requiring little time and resources compared to other deep learning methods that demand numerous layers and substantial computational resources for equivalent accuracy.

II. Literature Review and Related Work

The bulk of efficient deep learning algorithms for semantic segmentation of the pancreas and PDAC from abdominal CT scans are based on the U-Net, ResNet, AlexNet, and VGG-net models, as well as variants of these models.

The first of research was proposed by the Pancreas Segmentation in Abdominal CT Images with U-Net Model by [1] in their study using a convolutional neural network (CNN) called the U-Net model. The segmentation procedure used the Pancreas CT dataset from The Cancer Imaging Archive (TCIA) database, which included computed tomography images from 82 patients. The report provides a thorough explanation of the outcomes of this segmentation method. The Dice and Jaccard similarity coefficients, used to measure the efficacy of the U-Net model for pancreatic segmentation, produced values of 0.78 and 0.66, respectively. In [2] the study being reviewed introduces a framework based on convolutional neural networks (CNNs) for the segmentation of pancreatic ductal adenocarcinoma (PDAC) mass and surrounding vessels in CT images. The proposed framework first localizes the pancreas region from the whole CT volume using a 3D-CNN architecture and 3D Local Binary Pattern (LBP) map of the original image. Then, segmentation of the PDAC mass is performed using 2D attention U-Net and Texture Attention U-Net (TAU-Net), which is introduced by fusing dense Scale-Invariant Feature Transform (SIFT) and LBP descriptors into the attention U-Net. The Dice score for PDAC mass segmentation in portal-venous phase by 7.52% compared to state-of-the-art methods in terms of DSC. In [3] AX-Unet: A Deep Learning Framework for Image Segmentation to Assist Pancreatic Tumor Diagnosis the author presents AX-Unet, a deep learning framework incorporating a modified atrous spatial pyramid pooling module to reduce information loss during down sampling and achieve information decoupling between channels. The proposed explicit boundary-aware loss function also tackles the blurry boundary problem. Segmentation of pancreatic ductal adenocarcinoma (PDAC) and surrounding vessels in CT images using deep convolutional neural networks and texture descriptors. To prevent information loss during down sampling and accomplish information decoupling between channels, this author introduces AX-Unet, a deep learning system integrating a modified Atrous spatial pyramid pooling module. The blurry border issue is addressed by the explicit boundary-aware loss function that has been proposed. With a DSC of 85.9±5.1% and a Jaccard of 77.9±3.4%, experimental data show that AX-Unet surpasses state-of-the-art techniques in pancreas CT image segmentation. Additionally, the model's extracted feature output reveals notable variations in the pancreatic area between healthy individuals and patients with pancreatic tumours, which can help doctors detect pancreatic tumors earlier. In [4] study is done on Artificial Intelligence-based Segmentation of Residual Tumor in Histopathology of Pancreatic Cancer after Neoadjuvant Treatment. In this study, digitized H&E-stained slides from resected pancreatic cancer after NAT were used to train a modified U-net model to segment tumour, normal ducts, and residual epithelium classes. The DenseNet161 encoder provided the highest mean segmentation accuracy, and a promising F1 score of 0.86 was attained for tumour segmentation. This work demonstrates that AI-based residual tumour burden assessment is viable; might be created as a tool for the impartial assessment of treatment response, and could be used to direct adjuvant treatment decisions. Experimental results demonstrate that AX-Unet outperforms state-of-the-art methods in pancreas CT image segmentation with a DSC of 85.9 ± 5.1% and a Jaccard of 77.9 ± 3.4%. Additionally, the extracted feature output of the model shows significant differences in the pancreatic region of normal people and patients with pancreatic tumors, which can assist physicians in the screening of pancreatic tumors. In [5] the authors of this research provide a brand-new self-learning architecture for training the PDAC segmentation model with a significantly bigger patient population and a mixture of annotated and unannotated venous or multi-phase CT images. Unannotated images are combined by two teacher models with various PDAC segmentation specialties to produce pseudo-annotations, which can then be improved by a teaching assistant model that recognizes related vessels around the pancreas. On both manually annotated and fictitiously annotated multi-phase images, a student model is subsequently trained. The findings demonstrate that the suggested approach offers a 6.3% Dice score absolute improvement over the robust baseline of nn-UNet trained on annotated pictures, obtaining a performance (Dice = 0.71), which is comparable to the inter-observer variability between radiologists.

In [6], the authors of this research suggest a brand-new, completely 3D cascaded framework for segmenting the pancreas in 3D CT scans. A 3D detection network (PancreasNet) that locates the pancreas regions and two distinct scales of a 3D segmentation network (SEVoxNet) that segment the pancreas in a cascading fashion depending on the detection findings of PancreasNet make up the framework's two primary parts. On the publicly available NIH pancreatic segmentation dataset, the suggested method produces cutting-edge results with a mean Dice Similarity Coefficient (DSC) of 85.93% and a mean Jaccard Index (JI) of 75.38%. Deep neural networks' limitations in segmenting the pancreas were explored by Zhou et al. [7] due to its complex and changing backdrop regions. Using the anticipated segmentation map, they reduced the input region. We provide a fixed-point model that accepts the segmentation mask as input and output. On the NIH pancreas segmentation dataset, where they tested their model, they outperformed the state-of-the-art by more than 4% (in terms of DSC). A DSC of 82.37±5.68% on average was attained. In order to overcome the issue of spatial non-smoothness of inter-slice pancreatic segmentation, Cai et al. [8] presented a stacked CNN-RNN model. Convolutional long short-term memory (CLSTM) units make up the RNN sub-network. Deep supervision and multi-scale feature map aggregation were used to modify the 2D CNN sub-network. The investigations make use of the NIH-CT dataset and 79 abdomen T1-weighted MRI scans. In the CT dataset and the MRI dataset, they obtained DSC of 83.35.6% and 80.77.40%, respectively.

A pancreatic segmentation model based on 2020 First International Conference on Power, Control and Computing Technologies (ICPC2T) 402 bidirectional convolutional long short-term memory (BiCLSTM) networks and spatial context information (SCU-Net) was proposed by Hao Li et al. [9]. The CT abdominal scans were divided into multiple isometric blocks using a divide-and-conquer technique, and a multi-channel CNN was created to make use of spatial context information. To encourage the interaction between information flow from bidirectional sequences, the BiCLSTM network is introduced. For inter-slice constraint and regularisation, a new loss function was developed. DSC, Jaccard index, pixels-wise precision, and recall were the evaluation measures employed. They examined the NIH-CT dataset, which included 82 abdomen enhanced 3D CT scans, and found that the final prediction accuracy was 82.863%, the mean Jaccard Index was 68%, and the mean prediction error was 12% and mean recall of 80.2% and mean Precision of 82.2%. In [10] states the importance of huge number of training samples in the deep learning networks. Because of the considerable inter-patient structural changeability in both outline and size dimensions, the pancreas is a difficult abdominal organ to section [16,17]. Convolutional neural networks (CNNs) give better performance [11, 12].

III. Methodology

A. U-Net Architecture

Two levels of the U-Net model are employed, consisting of downward-moving paths followed by upward-moving paths in U-shaped network architecture. Each block on the downward path is composed of two convolution layers with the Leaky ReLu activation function and a maximum pooling layer with stride 2. In the first block, we use 32 filters of size 3x3 for each of the two convolution layers. The journey upwards is paved with 2x2 transposed convolution and the joining of feature maps from the parallel downward path. Along this path, we encounter four blocks, each composed of two convolutional layers with 3x3 filters and a Leaky ReLU activation function. We chose the Leaky ReLU for its efficiency, swift convergence and sparse activation - when faced with negative input, it returns 0; for positive input, it returns the same value as shown in equation (1), where x stands for the input.

$$f(x)=\max(0,x) \tag{1}$$

Despite using the identical U-Net model at both levels, the hyperparameter values vary. The weights of the first U-Net (U-Net-1) are initialised using Kaiming Initialization, and the filter size is 3x3. This approach avoids the disappearing or bursting gradients problem brought on by exponentially growing or decreasing input signals by accounting for the nonlinearity of activation functions like ReLU. The equation below can be used to express each convolution layer's response.

$$y_l = W_l x_l + b_l \tag{2}$$

In this case, x is a k2 c x 1 vector that represents k x k pixels that are co-located in c input channels. The layer's spatial filter size is k.

The number of connections in a response is $n=k^2c$. The dimensions of the matrix W is a d x n, and each row of the matrix reflects the weights of a certain filter. In the output map, Y represents the response at a specific pixel, and b is a vector of biases. If l is the layer index and f is the activation, $xl = (y_{l-1})$.

Given in below Eq. is the necessary condition to prevent the gradients issue.

$$0.5n_l\mathrm{Var}[W_l]=1 \text{ for all } l \tag{3}$$

Where W_l denotes the random component of each of the element in W_l and the Var depicts variance. This results in a start of the structure indicated in below equation.

$$W_l \sim N(0,2/n_l) \tag{4}$$

Specifically, a zero-centered Gaussian with a $\sqrt{2/nl}$ standard deviation.

R2 regularization is used in the U-Net-1 configuration to prevent overfitting. The penalty is basically increased by regularization as model complexity rises. All parameters, with the exception of the intercept, are penalized by the regularization term lambda (), making sure that the model properly generalizes the data and does not overfit. R2 regularization is useful when there are correlatively dependent characteristics. W denotes the weight matrix with values i and j.

There are two parts to it: an encoding route and a decoding path, where the encoder extracts high-level features from the input image and the decoder creates a segmentation mask using those features [18].

Elbow U-Net is the name of this specific version, which was created in Python using the TensorFlow library. It is made to segment binary images with the intention of locating areas of interest that are labelled with pixel values of 1 while the backdrop is labelled with 0. The input image dimensions, which are given as an input layer to the model, are IMG_HEIGHT x IMG_WIDTH x IMG_CHANNELS. After that, the input layer is normalized by using a lambda layer to multiply each pixel's value by 255. A succession of convolutional layers with 16, 32, 64, 128, and 256 filters are used in the encoding path. In order to avoid overfitting, a dropout layer is placed after each convolutional layer. In order to minimise the spatial dimensions of the feature maps, the output of each convolutional layer is then passed through a max pooling layer. Transpose convolutional layers, also referred to as deconvolutional layers, and are used in the decoding path to upsample the feature maps back to their initial size. In order to maintain spatial information, the decoder also has skip connections that concatenate the feature maps from the associated encoding path layer. The first convolutional layer in the encoder is a transpose layer with 128 filters, and the next two layers are each convolutional layers with 128 filters. Until the final layer, which comprises of a transpose convolutional layer with 16 filters, followed by two convolutional layers with 16 filters each, this is repeated with progressively smaller filter sizes. A segmentation mask with image values between 0 and 1 is produced by a convolutional layer with one filter and a sigmoid activation function in the output.

Table I provides a detailed illustration of the U-Net model's construction. An expansive path follows a contracting path in the five-level U-Net network. The parameters Batchnorm, activation functions, dropout are shown in detail.

The proposed architecture of a U-Net model for medical picture segmentation is depicted in the Table II. In medical image analysis, U-Net is a common deep learning architecture, especially in segmentation tasks where the objective is to label each pixel in an image with its appropriate class. A contracting path is found on the left side and an expansive path is found on the right side of the U-Net architecture. While the expansive path gradually upsamples the feature maps to generate a segmentation mask, the contracting path uses a sequence of convolutional and pooling layers to capture the context of the input image. The earliest stages of the contracting process, which minimises the spatial dimensions of the feature maps, are convolutional and max pooling layers. When this procedure is performed numerous times, the number of filters in each convolutional layer rises at each level. By using batch normalisation and activation algorithms, the model performs better. After obtaining the feature maps from the contracting path, the expansive path uses transposed convolutional layers to progressively increase their spatial dimensions. The feature maps from the contracting path are concatenated with the corresponding feature maps from the expanding path in order to keep the high-resolution data. The output layer is then activated with a softmax function to generate the probability distribution.

The last convolutional layer of the U-Net is activated using a softmax activation function to provide a probability map for each pixel, which is then thresholded to produce the final binary segmentation map.

The proposed framework is based on the application of two tiers of U-Net model as shown in the Fig. 1. The model has two sets of encoding and decoding blocks. This can help to improve the segmentation performance by capturing more complex features at different scales.

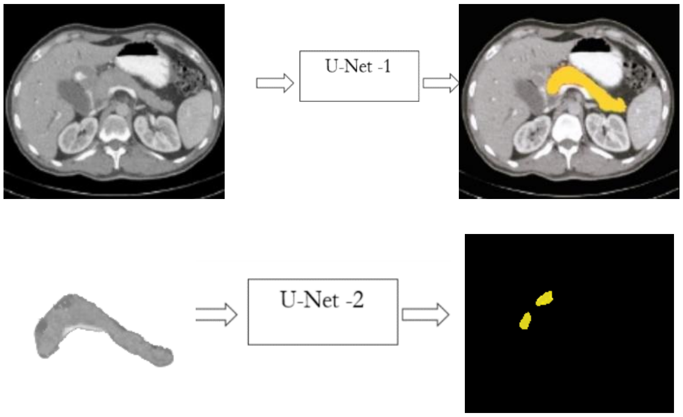

Fig. 1. U-Net based architecture for pancreas tumor segmentation.

IV. EXPERIMENTS AND RESULTS

A. *Pancreas Segmentation Training*

The outcomes of a pancreatic segmentation training method are displayed in Table III. The aim of the training is to correctly identify the pancreas in medical photographs using a machine learning system. When compared to the ground truth data, the algorithm's ability to predict the right pancreas segmentation is measured by the training loss. Better performance is indicated by a reduced training loss. How closely the anticipated segmentation matches the actual segmentation is determined by the dice coefficient. Better performance is indicated by a higher dice coefficient [14]. The training process starts with a relatively high training loss of 0.76 and a training dice coefficient of 0.82. As the training progresses, the algorithm gets better at identifying the pancreas, resulting in a decrease in training loss and an increase in the dice coefficient as shown in the Table II.

TABLE II. ARCHITECTURE OF PROPOSED MODEL

Epoch	Time(hrs)	Training Loss	Training Dice	Validation Dice
0	1.19	0.75599	0.82197	0.90297
1	1.19	0.72110	0.88970	0.91160
2	1.2	0.71554	0.90505	0.929217
3	1.2	0.71121	0.91528	0.93275
4	1.2	0.70814	0.92264	0.91778
5	1.2	0.70615	0.92812	0.94656
6	1.19	0.70434	0.93308	0.93837
7	1.19	0.70248	0.93663	0.95023
8	1.2	0.70103	0.94062	0.95054
9	1.19	0.70042	0.94320	0.93310
10	1.19	0.70020	0.94497	0.94846
11	1.2	0.69875	0.94772	0.94290
12	1.2	0.69725	0.94830	0.95534
13	1.2	0.69738	0.95020	0.95216
14	1.19	0.69677	0.95076	0.93893
15	1.19	0.69677	0.95171	0.93644
16	1.2	0.69662	0.95299	0.94623
17	1.2	0.69586	0.95253	0.94996
18	1.19	0.69561	0.95498	0.95489
19	1.2	0.69544	0.95585	0.95485

Based on the findings, the model was able to validate with a maximum accuracy of 0.9939 and a minimum loss of 0.0159 at the twelfth epoch. The accuracy values were about 0.95 in the early epochs but quickly increased to reach the high levels in the later epochs. With an 11-batch training run and an unspecified input image size, the model was trained over the course of 25 epochs. Also not stated was the loss function that was employed. It's important to note that the model's strong accuracy scores on the validation set indicate that the model generalizes well to new data. To verify the model's robustness, it's crucial to assess the model's performance on a different test set. Overall, the results of your U-Net-based pancreatic segmentation model are encouraging, and further analysis on a different test set may reveal more details about how well it performs.

B. *Lesion Segmentation Training*

Table III displays the outcomes of a training process for a machine learning algorithm that tries to recognize legions in medical photos. Each of the 20 training epochs, which each took between 0.4 and 1.6 hours to complete, was performed once. The table lists the training loss, the training dice coefficient, and the validation dice coefficient for each epoch.

Training was done for 20 epochs and took around 11 hours to complete as shown Fig. 2.

When compared to the real-world data, the algorithm's ability to predict the right legion segmentation is measured by the training loss. Better performance is indicated by a reduced training loss. How closely the anticipated segmentation matches the actual segmentation is determined by the dice coefficient. Better performance is indicated by a higher dice coefficient. The training dice coefficient of 0.70 and the initial training loss of 1.45 both point to subpar performance in the first epoch. However, as training goes on, the algorithm improves at recognizing legions, which causes the training loss to go down and the dice coefficient to go up.

The algorithm's capacity to recognize legions has greatly increased by the time training is complete, as seen by the training loss of 1.35 and training dice coefficient of 0.83. With a score of 0.69, the validation dice coefficient likewise performs well.

TABLE III. TRAINING OUTCOMES

Epoch	Time(hrs)	Training Loss	Training Dice	Validation Dice
0	0.40532	1.44871	0.70470	0.6492
1	0.41683	1.40648	0.75877	0.6681
2	0.40805	1.39184	0.77948	0.64474
3	0.40694	1.38603	0.78834	0.66002
4	0.40503	1.38146	0.79132	0.62748
5	0.41182	1.37874	0.79927	0.71489
6	0.43404	1.37206	0.80300	0.70638

17	0.40565	1.35338	0.82610	0.71414
18	0.40493	1.35071	0.82977	0.64887
19	0.40503	1.35127	0.82449	0.69984

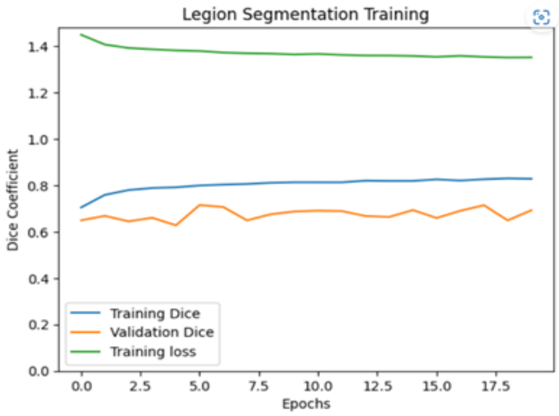

Fig. 2. Tumor segmentation training.

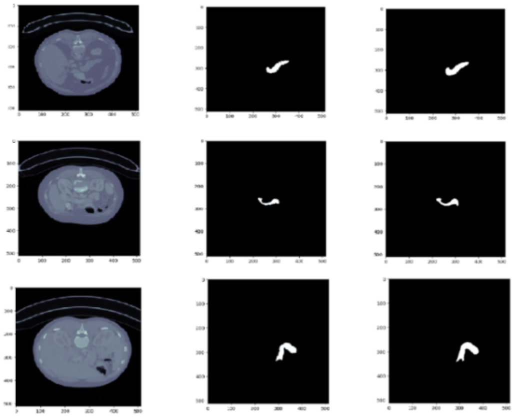

Fig. 3. Pancreas segmentation results.

In Fig. 3 by showing a visual comparison of the pancreas segmentation results generated using the suggested method and the ground truth segmentation, the usefulness of the proposed method is proved. The visual comparison is shown in a three-column arrangement, with the abdominal CT images in the first column, the ground truth segmentation in the second, and the segmentation results from the proposed method in the third.

The visual comparison is used to assess how well the suggested strategy performs in precisely segmenting the pancreas from abdominal CT images. The effectiveness of the suggested method in precisely segmenting the pancreas may be assessed by contrasting the segmentation results achieved by the proposed method with the ground truth segmentation.

It is possible to compare the segmentation results obtained by the suggested approach with the ground truth segmentation quickly and effectively by using a three-column format that offers a clear and concise depiction of the segmentation findings. Additionally, using abdominal CT scans in the first column offers a relevant and realistic context for assessing how well the suggested strategy works in a clinical scenario.

Fig. 3 also offers a visual comparison of the PDAC segmentation results produced by the suggested method and the ground truth segmentation in order to assess the performance of the proposed method. The visual comparison is shown in a three-column arrangement, with the abdominal CT images in the first column, the ground truth segmentation in the second, and the segmentation results from the proposed method in the third. The abdominal CT images, which were obtained from various patients and utilized to test the suggested procedure, are shown in the first column. The manual ground truth segmentation, carried out by a skilled radiologist, is displayed in the second column. The performance assessment of the suggested method uses the ground truth segmentation as a benchmark.

The segmentation results produced by the suggested method are shown in the third column. The outcomes demonstrate that the suggested approach is successful in precisely segmenting PDAC tumors in abdominal CT images. Analysis of similarities and differences between the segmentation results produced by the suggested method and the actual segmentation is done.

TABLE IV. COMPARISON WITH EXISTING WORK

Methods	DSC (%)	Jaccard (%)	Recall (%)	Precision (%)
CNN [1]	78	66	71	74
Unet and texture [2]	60	----	78.0	57.8
AX-Unet [3]	87.7	78.2	90.9	92.9
Unet with DenseNet [4]	83	----	----	----
nnUnet[5]	71	----	----	----
Fully Convolutional Network[13]	71	60	69	72
3D CNN[6]	88	71	84	82
Fixed Point[7]	82.37%	77	71	73
Attention Unet [19]	84	----	84.9	84.1
DenseASPP [20]	85	----	----	----
Cascaded FCN [21]	85.9	75.7	85.2	87.6
Proposed Model	88.2	79	82	86

In Table IV we compare several segmentation techniques of existing methods for medical picture analysis, especially using the NIH dataset, in this work. Bottom-up, Fixed-point, 3D Coarse-to-Fine, Holistically nested, RSTN, Recurrent Contextual Learning, Attention Unet, DenseASPP, (46), Cascaded FCN, AX-Unet, and the suggested technique are among the approaches investigated.

DSC, Jaccard index, recall, and accuracy were the four measures we used to compare the effectiveness of various approaches. In comparison to the other approaches, our proposed method had the highest values for all four criteria, demonstrating improved segmentation performance. Although some metrics had slightly lower values for the AX-Unet method, it still performed well overall.

V. PERFORMANCE EVALUATION METRICS

Typically, the segmentation's results is discussed here. Various challenges provide the ground truth against which processes are validated. Various standards are used to analyze the performance and accuracy of segmentation. The most popular statistical measures are based on a number of research articles, and the different problems are described below.

Assume that the segmented region is represented by X and the ground truth is by Y. To assess the precision of the segmentation, we may utilize a variety of indicators. The Volumetric Overlap Error (VOE) is one such measure. This calculates how much of the divided region overlaps with the actual scene. It is determined by dividing the sum of the pixels in x and y intersection by the sum of the pixels in X and Y's union. The result is then multiplied by 100 and removed from 1. Successful segmentation is indicated by a VOE value that is near to 0, whereas greater values signify disparities between the segmented pictures. The following is a formula for VOE.

$$VOE = ((|X \cap Y| / |X \cup Y|) - 1) * 100$$

Here dice similarity coefficient (DSC) is an additional measure. This gauges how well the split region's pixels correspond to the actual scene. A DSC score around 1 suggests effective segmentation, whereas a number near 0 implies inconsistencies across the segmented pictures. The DSC formula is displayed below:

$$\text{DSC} = 2\,|X \cap Y| / (|X| + |Y|)$$

The segmented region's volume difference from the ground truth is measured by the Relative Volume Difference (RVD). It is computed by dividing the sum of the volumes of X and Y, deducting 1, and then multiplying the result by 100. Positive RVD values signify over-segmentation, whilst negative RVD values signify under-segmentation. The RVD formula is displayed below:

$$\text{RVD} = ((\text{total volume of X} / \text{total volume of Y}) - 1) \times 100$$

$$Precision = \frac{TP}{TP + FP}$$

$$Recall = \frac{TP}{TP + FN}$$

The percentage of true positives (TP) that are accurately detected by the system, out of all real positive instances (TP + false negative (FN)), is known as recall, also known as sensitivity or true positive rate. In other words, recall gauges how well a system can identify all positive cases. A high recall score means that a significant number of positive cases may be recognized by the system.

The proportion of true positives that are successfully recognized by the system, out of all anticipated positive instances (TP + false positive (FP)), is measured by precision, also known as positive predictive value. To put it another way, precision assesses a system's capacity to accurately identify only pertinent positive cases. A high accuracy rating means that the system produces few false positives, which means that the instances that are projected to be positive are more likely to be accurate.

The validation set provided by NIH dataset has yielded the following results both for the segmentation of the pancreas and pancreas tumour.

The segmentation of Pancreas: dice for each case of 0.9283, dice global of 0.9300, VOE of 0.114, and RVD of -0.070.

The segmentation of PDAC: dice for each case of 0.5852, dice worldwide of 0.8900, VOE of 0.434, and RVD of -0.158.

VI. Conclusion

In this study, we show the simplicity and efficiency of the U-Net model for semantic biomedical picture segmentation. It is possible to successfully segment the pancreas and tumours from abdominal CT scans using the proposed architecture, which is based on a variant of the fundamental U-Net model. By changing the fundamental U-Net model's hyper parameter values in accordance with the type of dataset, we may attain accuracy that is comparable to that of sophisticated state-of-the-art techniques. The model's performance was assessed using the National Institutes of Health (NIH) dataset, and an 88.2% (Dice Global) pancreas tumour segmentation accuracy was attained. The proposed method can be applied to MRI images and we also aim to extend our research work by combining the U net model with other deep learning models to improve the accuracy.

Abstract—**The cardiovascular disease (CD) is a widespread, dangerous sickness involving an excessive rate of demise that necessitates quick piousness for care and cure. There are numerous diagnostic methods, such as angiography, available to diagnose heart disease (HD). ML is an extremely leading option for scientists for discovering prediction-based explanations for heart disease, and several machine learning algorithms are discovered to find the leading key results in community assistance. Researchers are presented with numerous conventional approaches, and various supportive algorithmic sequences formulated through the artificial neural network (NN) family, such as adaptive, convolutional, and de-convolutional NN, and various extended versions of hybrid combinations, originate with suitable outcomes. This research integrated the design and computational analysis of a unified model through a genetic algorithm-based Neural Fuzzy Hybrid System, which is formulated for CD prediction. It included a dual hybrid model to forecast CD and measure the degree of a healthy heart, as well as more precise heart attack complications. Stage 1 of the study's implications integrates the two stages and plans HD prediction using patient data. The input was processed in stages. First, the data was delivered in pre-processing mode. Next, the mRMR algorithm was used to select features. Finally, the model was trained using a variety of ML algorithms, including SVM, KNN, NB, DT, RF, LR, and NN. The results were compared, and based on those findings, the model was tuned to produce the best results. In stage 2, HA possibilities and occurrences are determined by FuzIS intelligence using data from the first stage, which includes more than 13000 pre-generated rules of fuzzy implications. These rules cover both normal-level and dangerous-level cases, and the medical parameters are integrated and tuned to produce membership functions that are then sent to the model. It is composed with the comparison of a unified system, which consists of Genetic algorithms, Neural networks, and Fuzzy Inference systems. In the experiment, gaussian MF sketched the continuous series of data, enabling the inference system to generate a good accuracy of 94% in calculating the problem probability.**

I. INTRODUCTION

Cardiovascular-based disease (CD) is a widespread, dangerous sickness involving a great level of disease that necessitates quick devoutness aimed at care, medication, and cure. Angiography is one of numerous treatments available to diagnose heart disease (HD), but it is a very expensive and time-consuming process and therefore out of reach for the masses. To conquer this crisis, the best medication, an auto-altered intelligent system, is necessary to reduce root-level causes, and individuals can inhale extreme difficulty. Many scientists are involved in integrating artificial intelligence techniques, which are used to build and execute technology-based medical experimental scenarios using data mining (DM) and machine learning (ML) procedures to discover the finest results for such challenges [1]. The expansion of the artificially based neural network (AbNN) into an intimated and unified system has carried it to a distinct range, and with the progress of the selection of features along with additional supporting procedures, it has carried it to human-like forecast control.

NN is mainly structured in three layers, which are the input, hidden, and output layers. Through every layer, a neuron will be associated with other neurons in succeeding layers, with their weights calculated with the activation function and a constant value called bias added to each layer as shown in Fig. 1 [19]. The bias is a persistent value injected in the network to adjust the activation function in AbNN and improves in deciding the participation of neurons in the network based on the threshold; otherwise, the output is ignored. ReLut is principally associated in the hidden layer along with their associated values, which represent 0 to x, with an identical outcome if input is positive (+); otherwise, it produces zero as the outcome, as shown in Fig. 1 [21].

$$h = max(0, a), where\ a = Wx + b \quad (1)$$

The sigmoid function with an output limited between 0 and 1 and an S-shaped graph is mostly used in classical calculus, where probability is to be predicted as an output. Logistic and

Softmax sigmoid functions are used for output related to binary and several levels of grade classification, respectively.

$$f(x) = \frac{1}{1+e^{-x}} \tag{2}$$

The Tanh is almost similar to the sigmoid, but the only difference is that its value lies between -1 and 1. Fig. 1 explains the difference between ReLU, sigmoid, and tanh functions [29–30].

A genetic-based Algorithm (GbA) returns a fitness value for each solution based on the phenomenon that the higher the fitness value, the better the solution [22–24]. There are mainly three operations in GA: selection, crossover, and mutation. Fuzzy inference system (FuzIS) primarily undergoes four stages after obtaining input: knowledge base, fuzzification mode (FuzM), inference engine, and defuzzification mode (De-FuzM) [24], which is the graphic symbol of the location of input-output neurons at each layer of AbNN. Below, in Fig.2, there is the pictorial representation of ANFuzIS, which is structured into five layers: input, membership, FuzM, normalization, and De-FuzM. The inference system is built mostly with the Sugeno method. Artificial Neural FuzIS (ANFuzIS) combines ANN and fuzzy systems, which use the capabilities of ANN to generate fuzzy inference rules with applicable membership function implications [25]. The x and y are inputs that are passed through ANFUZIS layers starting with the membership layer as the first layer, the second layer dealing with FuzM, normalization on the third layer, and De-FuzM on the fourth and last layer, i.e., the fifth layer is the output layer as shown in Fig. 2.

This study used a genetic algorithm-based neural fuzzy hybrid system to integrate the design and computational analysis of a single model that was developed for CD prediction. It is made up of a comparison of an integrated system that uses fuzzy inference, neural networks, and genetic algorithms. In the experiment, Gaussian MF sketches of continuous data series allowed the inference system to produce a good accuracy of 94% when estimating the likelihood of a problem.

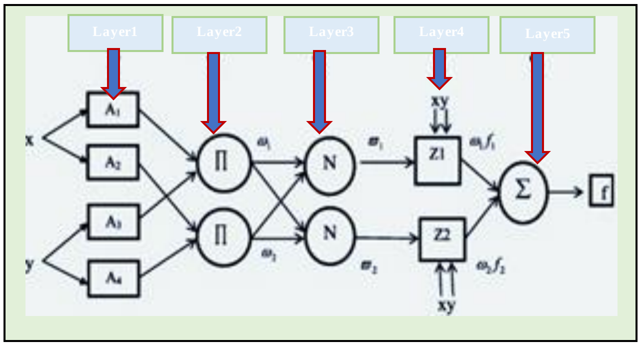

Fig. 2. ANFuzIS structure with 5-layered mode.

This article deals with the assessment and evaluation of the consequences of conventional processes and unified structures by employing distinct patterns like cross-validation with feature selection and discovering the choice of these accumulations in unified systems. Successive sections of this article have been composed with various supporting sections: Section II encompasses the related work of earlier developments of conventional AI, ML, and deep learning-based techniques. Section III contains the proposed methodology for genetic-based algorithm (GbA)-AbNN-based Fuzzy Inference System (FuzIS) Implications with Existing Dataset Parameters. It has described the methodological sequences in detail through Neural FuzIS (NFUZIS) and stage-wise execution of GbA-AbNN-based AbNN-FuzIS Implications. Section IV designated an experimental setup with System specification, Dataset, Relevance of medical parameters, and GANN algorithm with mRMR feature selection, along with experimental scenarios for determining the possibility of heart attack (HA) using Rule Creation Membership functions. Final: Section V contains details of inference.

II. Related Work

Many scientists in earlier times did excellent exploration on discovering the finest possible answers for assessment of HD, benefiting from numerous conventional and progressing ML classification and regression algorithmic sequences. A few of them are Decision Trees (DT), Random Forest (RF), SVM (Support Vector), NB, LR, K-NN, ANN, DNN, GA, AGA, NFS, and many others. This list is regularly growing by generations and exhibits the attention of investigators from all spheres in the associated field. On the dataset, UCI Cleveland, Hungary, and Switzerland were favorites during liability trials and testing.

The authors, Shadman N. et al., offered a cloud-based ML scheme trained through WEKA, a Java-coded data mining tool for estimating HD [2]. The outcomes examined and the model (SVM) recorded SENS as 97.53, ACC as 97.53, and SPEC as 94.94 percentages. The authors, Amin Ul Haq et al., offered a model through DT, K-NN, RF, LR, SVM, ANN, and NB classification algorithms permitted with three selections of features such as LASSO, mRMR, and relief, which are validated by the K-Fold-concluded prevalent Cleveland HD dataset [3]. The authors, W. K. U. R. A. R.-S. T. V. M. P. P. Moloud Abdar, presented a N2Genetic-nuSVM algorithm for prediction of coronary artery disease (CAD) with better performance compared to other classical ML techniques [4]. The Z-Alizadeh Sani HD dataset was pre-processed and applied to various traditional ML algorithms like SVM, DT, K-NN, and so on, and the model was trained. Later, GA-PSO techniques paired with 10-fold cross-validation were employed, and the results were showcased, explaining the benefit of the optimization approach in improving the model prediction. Algorithm recorded the best ACC among all experimented methods of 93.08%; greatest F1-score with 91.51%.

The authors RK. Jha et al. [5] stated an analysis to assess various categorization algorithmic sequences for estimation of HD where several conventional processes like SVM, KNN, DT-DNN, NB, and RF [17–18] were utilized to be valid selection of features over the Rapid Minor (RM) instrument to train-learn employing the Cleveland dataset from the UCI repository environment [28–33]. The authors, M. M. J. K. H. I. W. Mehrdad Agha Mohammadi [6], had proposed a unified system comprising ANFUZIS through GA and cross-validation of K-fold for estimation of HD and attained ACC as 84.43, SENS as 91.15, and SPEC as 79.16 percentage of results. The authors, M. P. K. at el., projected a hybrid adaptive genetic algorithm authorized by fuzzy logic with a rough set of features to predict HD [9] and attained ACC as 90, SENS as 91, and SPEC as 90 percent of results.

The authors, Fatma Zahra Abdeldjouad et al., projected ML training through hybrid methods: LR, MOEFC, FURIA, GFSLB, and Vote to Expect HD using Keel through Weka software [11]. Outcomes stats were analyzed, and it was concluded that out of all the other classification models, Vote outperformed ACC, SENS, and SPEC by 80.20%, 84.76%, and 74.82%, respectively. Indu Yekkala et al. projected RF, XGBoost, and NN-based models to be tuned by GA (as feature selection) to optimize (high ACC, low rate of errors) the HD estimation solution [12]. The Z-Alizadeh Sani dataset was used for training purposes. Python language with Jupyter Notebook IDE was selected for experimentation as well as for data mining and attained ACC of 93.85, SENS of 97, and SPEC of 92 percent of results. The authors, Farman Ali et al., projected a healthcare system containing collaborative DL and feature fusion for estimation of HD [13] and attained good results. The model showed an ACC of 98.5%, which is better than many other models. The authors, L.A. Demidova et al., presented an algorithm for self-tuning multi-objective GA through flexible parameter selection [14].

In this study, heart illness is initially detected using an artificial neural network (ANN) using default parameters. Then, to increase classification accuracy, a hybrid strategy combining an artificial neural network (ANN) and a genetic algorithm (GA) is suggested. Finally, the Cleveland dataset from the UCI machine learning repository is used to demonstrate the success of the suggested approach [10]. Another study combined four supporting data sets—from the VA Long Beach, Cleveland, Hungary, and Switzerland—with Multivariate dataset features [15] in order to identify the existence of cardiac disease in the patient. The output of a neural network, such as yes or no, is determined by activation functions based on neural networks. The obtained values are mapped between 0 and 1 or -1 and 1 [20]. In a different study, the author used membership functions to predict output type constant and linear value and used two sets that could predict all eight functions [26]. The membership functions were initially combined with an artificial neural fuzzy inference system. The researchers integrated multiple data mining algorithms used in health care analytics and also paid attention to how to systematically represent analytical data in order to produce results while employing diverse data mining algorithms [27]. This cutting-edge information can be protected via a variety of techniques, including embedding, concealing, and so forth [38].

The author suggested a technique for improving classification accuracy called k-modes clustering with Huang beginning. Models like the decision tree classifier (DT), multilayer perceptron (MP), random forest (RF), and XGBoost (XGB) are employed. To improve the outcome, GridSearchCV was used to fine-tune the model's parameters. A real-world dataset of 70,000 occurrences from Kaggle [39] is used to test the suggested approach. Another study used KNN and logistic regression, two machine learning algorithms, to predict and categorize patients with heart disease. The regulation of how the model can be utilized to increase the precision of heart attack prediction in any individual was done in a very helpful way. The proposed model's ability to predict signs of having a heart illness in a specific individual by utilizing KNN and Logistic Regression was quite gratifying, and it demonstrated a high degree of accuracy in contrast to previously employed classifiers such as naive bayes, etc. [40]. Another study found that the ML technique chosen and the attributes in the dataset used to train the model had a big impact on the model's performance. The Cleveland dataset was reduced to a lower-dimensional subspace using the Jellyfish optimization algorithm to prevent overfitting (caused by the curse of dimensionality) due to the excessive number of characteristics. The Jellyfish method is versatile in finding the best features and has a high convergence speed [41].

The author developed a potential machine learning model using a variety of feature selection strategies to uncover important features in the early stages of predicting heart disease. Chi-square, ANOVA, and mutual information were three separate methods used for feature selection, and the chosen feature subsets were designated as SF1, SF2, and SF3, respectively [42]. A soft voting ensemble classifier developed by another author that used all six algorithms improved accuracy even further, yielding 93.44% accuracy for the Cleveland dataset and 95% accuracy for the IEEE Dataport dataset. On both datasets, this outperformed the logistic regression and AdaBoost classifiers [43]. Another author has combined nine machine learning classifiers into the final dataset for the prediction of heart disease, including random forest (RF), XGBoost (XGB), decision trees (CART), support vector machine (SVM), multinomial Nave Bayes (MNB), logistic regression (LR), linear discriminant analysis (LDA), AdaBoost classifier (AB), and extra trees classifier (ET) [44]. This assumption is strengthened by the esteemed machine learning algorithms performances for both classification and regression complexity [45]. To detect the presence of cardiac anomalies, the author employed ML approaches [46]. In a different study, the author starts by providing succinct summaries of the machine learning classification approaches that are most frequently employed to identify cardiac disorders [47].

III. Proposed Methodology: Genetic-Based Algorithm GbA-AbNN-Based FuzIS Implications with Existing Dataset Parameters

Various criteria were investigated to discover the greatest attempt, pick out the finest features, and train-learn the model to obtain the highest score of accuracy. The feature selection (FS) algorithmic sequences employed to stream features for data tuning, and apart from this, validation methods like cross-validation have been used to validate the model and pick the most advantageous set of features. In the testing process, the data was deployed to assess the level of prediction accuracy.

A. Neural Fuzzy Inference System (NFuzIS)

The AbNN with FuzIS operated separately. The unified NFUZIS utilize process to discover all factors from FIS [25]. NFUZIS can correspond to exercise data produced from n-measurements of functionalities. NFUZIS comprises the fault figuring segment to advance the learning-training directions while the faults been unhurried, primarily membership sequences demarcated, then membership arrangements constraints stimulated. and inexact inputs transformed into neuron-inputs as A(i1-in) as shown in Fig. 3, then fuzzy-type of inputs such as fuzzy sets are generated to form neuron-inputs translated for further process [16-18] [28-33]. The experimental scenario has been described in Fig. 3.

B. Stage Wise Execution of GbA-AbNN based AbNN- FuzIS Implications

Fig. 3 determines the architecture of the proposed examination exertion, which is further split into two stages: stage 1 and stage 2, wherein stage 1 clarifies HD estimation and stage 2 describes the method to find the HA possibilities. This research reveals the unified model, which comprises AbNN motorized by GA and integrates the intellect of FuzIS. It has been explained in detail in the below sub-sections.

Stage 1: In stage 1, HD prediction has been planned through the patient's data. It processed the input through various stages: firstly, it was delivered through the data pre-processing mode; then, the mRMR algorithm was implicated for the selection of features; then, the model was trained using diverse ML algorithms such as SVM, KNN, NB, DT, RF, LR, and NN; results were compared; and based on that, the model was tuned to get the optimal result. In the subsequent stage, an AbNN designed for training persistence produces weights through GbA. The proposed method was trained, and on each cycle of occurrence, it generated new offspring using parental classes with the help of crossover and mutation logics. The outcome is forwarded as an input to the second stage.

Fig. 3. Proposed NFuzIS-based methdology for HD detection.

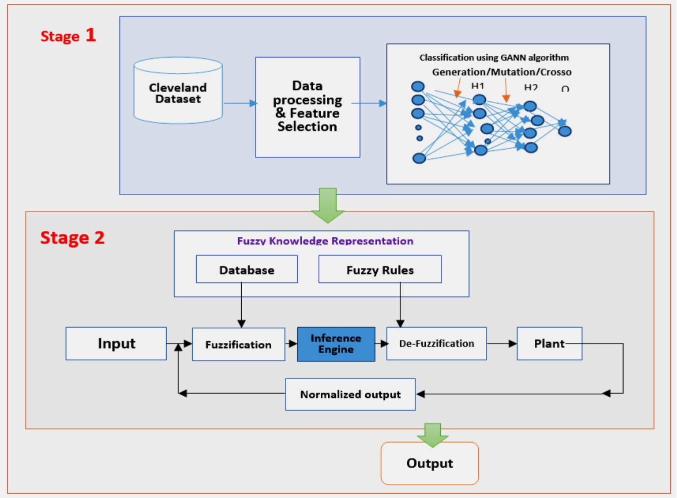

Fig. 4. Stage wise execution of GbA-AbNN based FuzIS Implications.

Stage 2: In this stage, HA possibilities and occurrences calculated through FuzIS intelligence take the input from the first stage, where more than 13000 pre-generated rules of fuzzy implications are fed into the system, which covers equally the cases such as normal-level and dangerous-level. The medical parameters are integrated and tuned to generate membership functions passed to the model as shown in Fig. 4.

In the next step, Sugeno FuzIS integrated for singleton production membership sequences with linear or constant functionalities of inputs incorporated, then the input undertaken through the FuzM process wherein data has been converted into fuzzy values with the help of fuzzy sets which then in the next step, with function zi=aix+biy+ci. Below pseudo code explains the workflow for the proposed system.

NFuzIS based Algorithm

1. Add Input for experiment
2. Apply data-processing, project the model, and add inputs, hidden along with output neurons.
3. Selection of features 🡐 mRMR
4. Load primary population set with indiscriminate homogeneous chromosomes input samples.
5. Calculate matrix weight for population utilizing GbA and initiated model training steps
7. Replication 4 and 5 steps, record the scores.
8. Accomplish model testing with test data 🡒 {decision HD-patient / non-HD-patient}
9. Produce inference rules through precedence and medical complication based on dataset.
10. medical parameter 🡒 membership functions 🡒 fuzzy set.
11. Pass input through the FuzM process.
12. Process the fuzzy production to De-FuzM progression to acquire output crisps.
13. Test model to measure efficiency.

IV. Experimental Scenarios

The experimental setup is divided into two parts: in the first stage, the dataset has been instructed in a unified environment with GbA and ANN; the same steps were applied here as well; mRMR algorithmic sequences are simulated for the selection of accurate features; and in the second stage, FIS has been used for predicting HD.

A. System Specification

In this research, the experimental scenarios were formulated using Python libraries with the integration of more than 13000 inference rules.

B. Dataset

Cleveland, Hungarian, and VA-Long Beach datasets from the UCI container, which hold 76 features, are used in the experiment. Out of which, Cleveland's having 303 records is very popular [24]. 16 features are designated as inputs and 1 is a goal feature out of the 76 available features. Based on this input, we created one more feature named "HasHeartDisease" and filled in data 0 and 1, depending on "num" feature values.

The considered key parameters: patient (P) age, P-Gender, Level of Heart rate (LHR), balanced cholesterol, Patient Family Heart Disease History , chest pain type (CPT), Resting Blood Pressure (RBP), Level of ECG result (RestECG), Heart Status (HS), Fluoroscopy vessels count based on coloured (CA), Cigarette per day, Blood sugar level at fasting (FBS), Stress or Depression (OldPeak), Diagnosed HD (Num), Exercise induced Angina (Exang), Resting Heart Rate, and Slope for Peak-Exercise (Slope). The patients' health indicators demonstrating trial delivery between nutritious and risk levels of patients, such as patients deprived of heart disease (healthy) are 53.87% and patients with heart disease are 46.13%. The dataset is characterized into 0–4 states, where 0 represents healthy and 1-4 represents risk levels of patients, considering 1 is the least risky and 4 is the most. Fig. 5 shows the ratio of healthy patients to patients at risk. Statistics states that the dataset is normalized and has the same ratio between both; it also indicates that the dataset is ideal for experimentation.

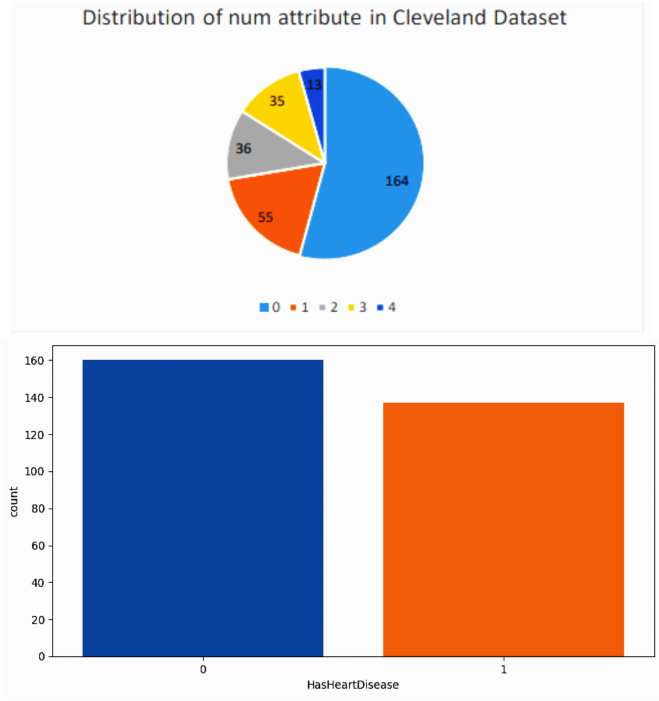

Fig. 5. Data representation of healthy and risky patients and graph showing statistics of healthy (137) and risky (160) patients.

C. Relevance of Medical Parameters

In the above sections, we have already listed the parameters that are being used in the experiments; now let's discuss the relevance of a few of the parameters, like why they are important in predicting HD or in determining HD-affecting possibilities. The medical parameters with description and threshold to be used to calculate HD-probability are shown in Table I.

- Age: People of old age (above 65) or adults older than 40 are more likely to suffer from HA as compared to younger people or to develop coronary artery disease.
- Gender: According to available resources, the incidence of CVD in women is usually lower than that of men.
- Heart rate: An increase or decrease in heart rate should be alarming, and preventive measures should be taken.
- Blood pressure: This reflects problems in the heart and can damage the heart if the number is high for a long time.
- Blood sugar: A diabetic person is more likely to have HA. If a person has a high level of sugar, he can damage his heart too.
- ECG result: The spike created in the ECG can tell a lot about heart health, whether a person is healthy or not.
- Cholesterol: If a patient has high cholesterol, he can invite fat to deposit in the arteries and cause HA due to less delivery of blood oxygen to the heart and other parts.

TABLE I. MEDICAL PARAMETERS WITH DESCRIPTION AND THRESHOLD TO BE USED TO CALCULATE PROBABILITY

Feature Name	**Description**	**Threshold**
RestingBP_RBP	BP measured when admitted at the hospital	Systolic/diastolic (in mm Hg) Normal: < 120/80 Abnormal: 120-140/80-120 Critical: 140/120 > [33, 34]
SerumCholesterol_SCH	In mg/dl	Total Cholesterol: Normal: < 200, Moderate: 200 – 239, High: 239> HDL level: Normal: 40 – 60 Low: < 40, High: 60 > LDL level: Normal: <130, Moderate: 130 – 189, Critical: 189 >
FastingBloodSugar_FBS	Blood sugar level at fasting	0 for Normal,1 for High
RestingECGResult_RES	ECG result	0 for Normal,1 and 2 are other types
RestingHeartRate_RHR	Heart rate at resting	0-65 – Normal, 65-85 – Average, Above 85 high,
MaxHeartRate_MHR	Max heart rate	Till 100 – Normal, 100-140 – Moderate, 100-180 – High, Above 180 - Critical
CigratePerDay_CPD	Cigrate intake per day	Higher is the intake, more is the failure risk
HeartDiseaseFamilyHistory	Heart disease history in family	0 for No,1 for Yes
IsHeartPatient	Is patient a heart patient	0 for No,1 for Yes

V. RESULTS AND DISCUSSION

This section included the experimental test cases and results and discussed the integration of the trained model into a web service to expose it to the public domain. In this chapter, techniques for API exposure are discussed along with the deployment process so that it can be made available for public use.

Preliminary phase: First generation prepared with an arbitrarily produced population with supporting parameters set. The network chromosome was structured as 416 neurons, 2 hidden layers, and 1 output layer with ReLU and Sigmoid activation methods and gradient descent optimization. Evaluation phase: Here, each chromosome generated in the preliminary stage is trained, and accuracy is evaluated to find a fitness score. Selection phase: The system will sort according to the fitness values, and the one with the finest fitness is selected and others are rejected. Cross-over phase: Selected parents, chromosomes A and B, undergo mating to produce new offspring. Mutation phase: After cross-over, a few of the genes are mutated on a random basis to maintain diversity in the population.

A. Experimental Scenarios for Finding the Probability of HA

To cover up the second stage, an experiment has been carried out using FuzIS, wherein input from the neural system has undergone the FuzM and De-FuzM processes via the inference engine along with the fuzzy rules and membership function to get the desired output. The very first step after injecting input into the experiment is to create rules that should be used for the rest of the experiment. For creating rules, all the included features have been analyzed, and based on that, we set the priority of the features based on the impact they can have on the heart, like sleeping heart rate, cigarette per day, blood sugar, and HD history of the family. Later, once we had everything on our plate, we followed a few approaches to create rules, keeping in mind that they should be powerful enough to support the system and should be able to provide capability to the system for finding HA possibilities in person.

$$f(x;\sigma,C) = \mathrm{e}^{-\frac{(x-C)^2}{2\sigma^2}} \tag{3}$$

A function of membership enables the presentation of sets of fuzzy values and groups with the help of graphs. In the experiments, triangular, trapezoidal, and Gaussian MFs were used. A function of membership has been formed for a separately fuzzy set created based on all supportive, reliable, and non-dependable medical parameters. The Gaussian function: MF parameters ➔ vector [σ c], σ ➔ standard deviation and c ➔ mean. The 13824 total rules have been produced and integrated to identify the HA levels and their consequences from normal levels to risk levels, and gaussian MF sketched the continuous series of data, enabling the inference system to generate a good accuracy of 94% in calculating problem probability. Below, Table II shows the parameter setup applied for GANN model training. Different combinations have been experimented with, and based on the optimal result, we noted down the parameters for the model shown.

TABLE III. HYPERPARAMETER DETAILS FOR GANN

Hyperparameter	Values
Hidden layer used	2
Neurons in each hidden layer	8, 4
Activation method for Hidden Layer	ReLu
Activation Layer for Output Layer	Sigmoid
Learning-rate	0.001
Loss Function	Binary Cross-Entropy
Epoch	2000
Batch side	100
Mutation	3%

The very first step after injecting input into the experiment is to create rules that should be used for the rest of the experiment. For creating rules, all the included features have been analyzed, and based on that feature's priority, it is set based on the impact it can have on the heart, like "resting heart rate, cigarette per day, blood sugar, heart disease history of family," and later, once we had everything on our plate, we followed a few approaches to create rules, keeping in mind that they should be powerful enough to support the system and should be able to provide capability to the system for finding the probability of a heart attack in person. The number of antecedents could be more than one based on the if-else condition, but the consequent is always one. Rule creation for the experiment is composed of two approaches:

The Cleveland dataset has been based, and after data processing, we found 282 good and 21 bad data points out of 303. A total of 126 rules were generated based on the "num" feature, which defines the risk level as 1, 2, 3, or 4. An initial study has been done and defined the level of contribution of different features, like max heart rate, which can be proved to be top-risky with the reason that if the number goes higher, it will impact the heart a lot. Therefore, the contribution of the maximum heart rate was classified into four levels: normal, medium, high, and critical. Similarly, blood sugar was also found to be a contributing factor, but its level did not have an immediate impact on health. Hence, its threshold was set to normal or medium. Other features were also evaluated, and their contribution levels were determined to assess whether a person is at risk of a heart attack or not.

A set of 13824 rules has been generated to cover both normal and risky cases. A few of the inferences are listed in Table II for reference. GANN-based performance analyzed with the 2000 epoch. It can be noticed that at the initial stage, the model was in the learning phase, and the result was not so effective, but as it underwent the epoch again and again, new offspring were generated, which helped in the learning process. This also reflects in the curve plotted in the below graph. The GNFIS-based training inferences and fitness information are included in Table II. It can be clearly seen that the learning rate was very slow and the model accuracy was also very low, but gradually, after 600 epochs, the model started giving better results.

B. *Test Case Analysis through API*

Once the model has been trained properly and is available for prediction, the next step, which is more important, is to find a way to package the model so that it can be available for further use in applications. And the best way is to build a web service, integrate a trained model into it, and expose it via an end point. We have moved one step ahead in the research work and utilized a very popular Python library called FastAPI for this purpose. The whole process has been divided into several stages, like creating a packaged model, unpackaging the packaged model, creating a web service, exposing an end point, and starting the web service for establishing the final connection. Let's discuss all these stages one by one.

1) Packaging trained model: This is the first stage at which we usually package the model. Our final model is already prepared and is able to predict the disease as well as find the probability of a heart attack, so the next step is to pass this model for packaging into a system-readable bundle. For this, a very popular Python library named "joblib" has been used, which should package the model by storing all the required details in it. Once the model is packaged properly, it has been saved as a ".pkl" file.

2) Loading/Unpackaging packaged model: Once the model is packaged, before integrating it into a web service, it is required to load this model again in the system. For this, we have used the same Joblib Python library.

3) Creating a web service: Now that the model is loaded successfully into the system, it is time to create a web service, or API, and expose the endpoints. For this purpose, we used the "FastAPI" library, which is capable of performing this task.

4) Starting the environment: Now that there is a packaged model that can be reloaded into the system, an endpoint is also created for exposure purposes, so the last point is to start the environment and expose the API to the public. As the research work is local, the library that we are using will start the environment locally on the localhost 4000 port, and there the endpoints can be tested. The Python library that has been used is "uvicorn".

Now that the API is ready and up on localhost, the system is ready for testing (see below Fig. 6 and Fig. 7 show the request details for this endpoint).

Total of 16 medical parameters have been passed as request to the endpoint as shown in figure.8. Below is the response for the same. In Fig. 7 and Fig. 8, response can be noticed for the given request wherein it is printed in two parts 1) predict, which predict the heart disease in patient and 2) risk percentage, which shows the probability percentage of heart attack. Here person is predicted as having heart disease and probability percentage is 57.81 which means that person has 57% chances of heart attack with current health condition which is based on give medical parameters.

Below, Table IV and Fig. 9 show the result from GANFIS along with the comparison with similar work proposed in the past by other researchers. The result clearly shows that the proposed system outperforms with 94% accuracy.

TABLE V. COMPARING EXPERIMENTAL RESULTS WITH EXISTING STATE-OF-THE-ART RESULTS IN LITERATURE

Author and Ref	Integrated model	Method	Dataset	Result
Negar Ziasabounchi, 2014 [34]	ANFIS Based Classification Model for Heart Disease Prediction	ANFIS, GA	Cleveland dataset	92.30%
Oluwarotimi Williams Samuel et al. 2017 [7]	An integrated decision support system based on ANN and Fuzzy_AHP for heart failure risk prediction	ANN, Fuzzy_AHP	Cleveland dataset	91.10%
A.V. Senthil Kumar 2012 [35]	Diagnosis of Heart Disease using Fuzzy Resolution Mechanism	ANFIS, MATLAB	Cleveland dataset	91.83%
Zeinab Arabasadi et al. 2017 [8]	Computer aided decision making for heart disease detection using hybrid neural network-Genetic algorithm	ANN, GA	Z-Alizadeh Sani	93.85%
Kaan and Ahmet 2017 [36]	Diagnosis of heart disease using genetic algorithm based trained recurrent fuzzy neural networks	ANN-Fuzzy_AHP, GARFNN	Cleveland dataset	91.10%
G. S. G. Thippa Reddy et al. 2020 [9]	Hybrid genetic algorithm and a fuzzy logic classifier for heart disease diagnosis	GA, FL	Cleveland dataset	90%
MAbushariah et al. 2014 [37]	Automatic Heart Disease Diagnosis System Based on Artificial Neural Network (ANN) and Adaptive Neuro-Fuzzy Inference Systems (ANFIS) Approaches	MLP, ANN, ANFIS, MATLAB	Cleveland dataset	87%
Proposed work, 2022	Dual Hybrid System (GANN-NFHS)	Cleveland dataset		94%

The results in Section V demonstrated the scores based on different variance comparable model exercises with and without selection of features through mRMR on GANN. Results clearly demonstrate variance between various variances applied during model training, and they verify that performance prediction is enhanced by applying dissimilar methods according to dataset size and number of features. It has been observed that good results have been achieved with classical as well as hybrid approaches, and near 90% accuracy was recorded with the test set. There is more opportunity to record a higher score with hybrid as well as classical approaches. An integrated system that makes use of fuzzy inference, neural networks, and genetic algorithms is compared. In the experiment, the inference system produced a good accuracy of 94% when assessing the likelihood of a problem using Gaussian MF sketches of continuous data series.

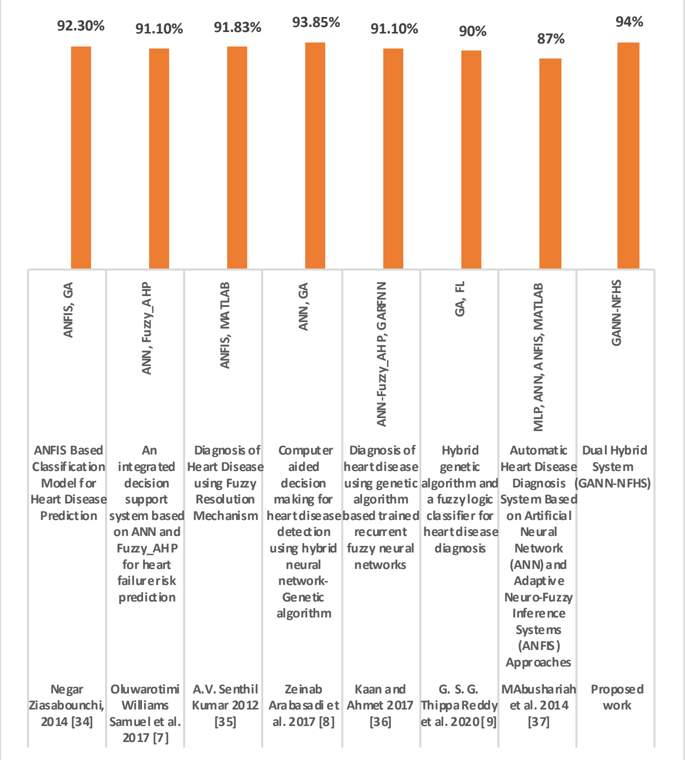

Fig. 9. Comparative analysis of experimental results with existing hybrid models.

VI. CONCLUSION

ML is an extremely leading option for scientists for discovering prediction-based explanations for heart disease, and several machine learning algorithms are discovered to find the leading key results in community assistance. Researchers are presented with numerous conventional approaches, and various supportive algorithmic sequences formulated through the artificial neural network (NN) family, such as adaptive, convolutional, and de-convolutional NN, and various extended versions of hybrid combinations, originate with suitable outcomes. This research integrated the design and computational analysis of a unified model through a genetic algorithm-based Neural Fuzzy Hybrid System, which is formulated for CD prediction. It is composed with the comparison of a unified system, which consists of Genetic algorithms, Neural networks, and Fuzzy Inference systems. In the experiment, Gaussian MF sketched the continuous series of data, enabling the inference system to generate a good accuracy of 94% in calculating the problem probability.

***Abstract*—Modern technology has made a big contribution to the distribution of counterfeit money and the valuation of it. This paper recommends a deep learning-based methodology for currency recognition in order to extract attributes and identify money values; machine learning's binary classification task of fake currency detection. One can train a model that can distinguish between real and fake banknotes if one has enough information about actual and fake notes. The vast majority of older systems relied on hardware and techniques for image processing. Using such strategies renders identifying fake currency more challenging and inefficient. The proposed system has suggested deploying a deep convolution neural network to figure out fake currency in order to solve the aforementioned issue. By analyzing the images of the currency, our technique finds counterfeit notes. The transfer-learned convolutional neural network is trained using data sets that represent 2000 different currency notes in order to learn the unique characteristics map of the currencies. After becoming familiar with the feature map, the network is capable of real-time phoney cash detection. It is surprising how well deep learning models perform in photo classification tasks. The Deep CNN model that has been created in the proposed approach helps in the detection of the fake note without really manually extracting the properties of photographs. The model trains from the data set produced during training, letting us to identify fake currency. In multiple instances, techniques for deep learning have been shown to be more effective. Thus, deep learning is used to boost currency recognition accuracy. Among the techniques used are the African Buffalo Optimization Approach (ABO), recurrent neural networks (RNN), convolutional neural networks, generative adversarial networks (GAN) for identifying bogus notes, and classical neural networks.**

Keywords—Fake currency; convolutional neural network; generative adversarial networks; recurrent neural network; African Buffalo Optimization

I. Introduction

With the rapid advancement of modern technology, the proliferation of counterfeit money poses a significant challenge for financial systems worldwide. Detecting and distinguishing fake currency from genuine notes is crucial for maintaining economic stability and trust in monetary transactions. This paper presents a deep learning-based methodology for currency recognition, aiming to extract attributes and accurately identify the value of money.

For the monetary exchange of some types of goods, several nations employ various types of currencies. One problem with cash that many countries face is the existence of counterfeit currency in the system. One of the countries with numerous problems and large losses as a result of the fake money is India. The entire economy of the nation experiences losses, as does the value of its currency. Technology advancements have made it possible for currencies to be duplicated to the point that it is difficult to distinguish between them. Modern editing tools and cutting-edge printers are used to create counterfeit money. False currency can easily be bundled with legitimate currency, as is the case in the majority of the world. In order to increase public awareness of the security issues with bank notes, the State Bank of Pakistan employs a variety of different marketing strategies, both directly to its consumers and in partnership with other institutions. Through a television advertisement and an application for smartphones that checks for counterfeit currency, the bank hopes to educate the public. But most individuals can't tell the distinction between a phoney and real currency note, especially those who are illiterate. Some people may be able to spot forged currency because they are not understanding the security elements of currency in public. Additionally, it might be challenging to identify these characteristics when the money notes are tattered, dirty, and ripped [1].

Money that has been produced without the State's or government's legal consent is known as counterfeit money. Its main purpose is to imitate real money and trick the person it is intended for. The production or use of counterfeit money is seen as a kind of fraud or forgery and is therefore illegal. Early on after gaining its independence, Bangladesh took on the monetary policy legacy left by Pakistan's Central Bank. The initial state of affairs was unstable, but the government soon established Bangladesh Bank in 1972 to stabilize the situation. Following that, Bangladesh has experienced a sharp rise in the availability of counterfeit currency. The suggested methods produce topic-based shards with minimal size variance and high densities of pertinent documents. They are scalable, efficient, and self-sufficient. Information gathering for the initial stage of the model is aided by the suggested approach. The CNN, a multilayer network of neurons, is the most widely used deep learning technique in the next stage. Since it has increased the accuracy of many machine learning tasks and is effective at handling picture classification and identification issues [2], [3]. The deep CNN model used in the proposed approach is trained on a diverse dataset comprising 2000 different currency notes, enabling it to learn unique characteristics and feature maps of various currencies. Once familiar with the feature map, the model is capable of real-time detection of counterfeit currency, providing a highly efficient and automated solution [4].

The development of automated methods and systems for recognizing currencies has accelerated daily. Effective currency identification systems and cost-effective solutions are crucial in a variety of settings, including the banking system, train ticket windows, retail malls, and currency exchange services, among others. For financial transactions, banknotes are utilized. The prevalence of bogus currency on the international market has dramatically increased. In many industries, fake money is a problem. The country's financial market is negatively impacted by the development and design of these bogus notes, which come in all denominations [5]. As a result of advances in current technology and gadget development, counterfeit banknote production has increased due to the introduction of scanners and copy machines. It is very challenging for the human eye to tell phoney notes from genuine ones since they are expertly designed to look so similar. The security of banknotes must be considered, and security components must be incorporated, to reduce counterfeit money. As a result, a system that determines whether a note is real or false needs to be put in place in banks and at ATMs for withdrawal and deposit. However, people are still able to create these fictitious currencies [6].

Deep learning models have demonstrated exceptional performance in photo classification tasks, and the deep CNN model developed in this study eliminates the need for manual feature extraction. By training on the provided dataset, the model gains the ability to accurately identify fake currency notes. Around 180 distinct currencies are used in transaction worldwide. Each note has distinct safeguards and an array of sizes. Because each note has distinct security features and a different size, it is simple to tell whether currency is from which country and how much it costs. Currency notes fraud has now become a noticeable problem in all nations, and the quantity of fake notes is increasing daily. The world faces a difficult issue in identifying fake currency due to the similar look of genuine and counterfeit currency. As a result, data augmentation methods including image improvement, color analysis, and others are used in currency detection systems. Deep learning methods, which often involve multilayer neural networks, have proven successful in a variety of fields. When huge data is accessible, they have done especially well. Accurate money recognition has a lot of potential to improve with deep learning. The transfer learned CNN is trained using two thousand currency note data sets and is given the feature map of various currencies. The network has been trained to identify counterfeit banknotes in real time after learning the feature map [7].

The ABO technique, used in feature selection, aims to create an algorithm that is easy to use, reliable, efficient, and effective, yet has amazing skill in the exploitation and exploration of the search space. ABO makes sure that each buffalo's location is regularly updated in comparison to both its best prior location and the present location of the best buffalo in the herd in an effort to combat the problem of early convergence or stagnation. The entire herd may be reset, for instance, if the location of the dominant (best) buffalo is not altered after several occurrences. Finding the best buffalo guarantees that the search area has been adequately explored, and the ABO can achieve adequate exploitation by drawing on both the experience of other buffalos and the best buffalo. There are some limitations to the CNN-developed money-detecting system. The ABO simulates the three distinctive behaviors that enable the African buffalos to find pastures. Their tremendous memory capacity comes first. This makes it possible for the buffalos to trace their movements as they travel thousands of kilometers over the African terrain. Additionally, buffalos are quite helpful. The second characteristic of the buffalo is their cooperation and communicative abilities, which they exhibit in both good and bad circumstances. They are practically the only animal breed that will put their own life in peril to save the life of a member of their own species. The security features can only be recognized using the front image of the currency. The dataset is the most important element, and it must be accurate and of the greatest standard. The image quality has a significant impact on how well the classification works out. Additionally, each image in the created dataset needs to have its background clearly visible to avoid confusing the model with objects and noise. collecting data is therefore essential [8]. Overall, this paper aims to present a comprehensive and effective deep learning-based system for counterfeit currency detection and classification. By harnessing the power of deep learning and incorporating innovative optimization techniques, the proposed approach exhibits promising potential for improving currency recognition accuracy and combatting the issue of counterfeit money distribution.

The key contribution of proposed approach is,

- Generative Adversarial Networks (GAN), which can create new samples that are comparable to the original target data after being trained to learn its distribution, are used to create the data.
- Convolutional Neural Networks (CNN) are used to extract the features since they automatically produce the features from time series data and frequency representation images.
- African Buffalo Optimization (ABO) is used to choose the characteristics, which reduces computation complexity and boosts efficiency.
- Recurrent Neural Network (RNN) is used in the phase of classification which finally decides the whether the currency is fake or not.

II. RELATED WORKS

The identification of counterfeit money using deep learning was suggested by Shilpa et al, [9]. Two phases make up the system that is being suggested here. Classifying currency notes according to denomination is the first step. Checking the note's authenticity is the second step. Here, information has been taken from Kaggle, a well-known source of datasets. With the aim of spotting counterfeit money on devices like smart phones, tablets, and PCs, the recommended system is designed using a deep learning methodology, and a Neural CNN model is developed. On a set of data that was independently produced, the developed model was trained and tested. CNN receives images that have been collected by a smart camera. There are two primary phases to this web-based strategy. The first stage is to group the notes into different categories based on their worth, and the second is to determine whether or not they are real or fake. However, this strategy did not result in more favorable and successful outcomes. Saxena et al. suggested utilizing image processing to find counterfeit money. The image processing technique, which comprises changing a picture's fundamental properties to improve its visual information for human interpretation, is applied using MATLAB. The feature of the image processing programme increases the possibilities of the MATLAB numeric computing environment. The algorithm used in this method is image scaling, which resizes the input image to 100 dpi in order to provide a better KNN for classification. By doing this, the false positives are eliminated without obviously hurting how well our software works. The image is then converted from the RGB to the grayscale domain via grayscale computation. Here, a cell phone with a scanner or camera is used to use a MATLAB technique in order to identify fraudulent currency. However, it is crucial for researchers to change Matlab's features in order to achieve its high performance measures [10].

Machine learning algorithms were proposed by Shahani et al. to assess banknote authentication. Back propagation neural networks (BPN) and support vector machines (SVM) are examples of supervised learning techniques that are accustomed to distinguish actual banknotes from counterfeit ones. The dataset used to train the models was provided via the UCI machine learning repository. A ratio of 80:20 is utilized to divide the used dataset into its two parts. The smaller group is used to test whether the models can correctly predict whether a letter is authentic, while the bigger fraction is used to train the models. As a result, BPN can distinguish between genuine and counterfeit notes with accuracy. SVM also has trouble identifying real notes from false ones. By classifying the notes as Genuine, Low-Quality forgery, High-Quality forgery, and Inappropriate ROI, this study can be expanded [11]. Deep learning was suggested by Pachon et al. to identify fraudulent banknotes. This method compares the two design approaches using illustrations of various building types. The transfer learning technique identifies the optimal freezing sites in the sequential, residual, and inception CNN architectures. A sequential CNN-based original model similar to AlexNet is also suggested. Modern solutions have been presented for various CNN architectural kinds. On a dataset of Colombian banknotes, the TL and the custom models were trained, and then they were assessed. The results showed that ResNet18 had the highest accuracy. The key limitations of a customized model are its protracted training procedure and need for an appropriately diverse training sample [12].

Convolutional traces were recommended by L. Guarnera et al. [13] for identifying counterfeit currency. The suggested technique has a set of unique local characteristics designed specially to clarify the underlying neuron formation procedure using an Expectation Maximization (EM) algorithm. For spontaneous validation to confirm non-fakes, experimental tests using naive classifiers on five independent architectures have been used. For noisy photos, the computation is labor-intensive. Deep learning was suggested by Cruz et al. to identify counterfeit Indian banknotes. To aid in the training and testing of the deep network DCNN model, a fake data set was created utilizing the various image sets. VGG-16 In the context of the Single Shot Multi Box Detector (SSD) model, CNN is utilized as a feature extractor. For the purpose of object detection, SSD is a frame model. SSD using mappings of features from various layers, create bounding boxes. It has been trained with Tensorflow. A convolutional neural network will be trained using the suggested algorithm on the provided false and original currency data set, and it will then be able to determine if a particular currency image is fake or original. However, since the base VGG-16 network takes up 80% of the time, the computation takes a lengthy time [14].

Laavanya et al, proposed the detection of fake currency using deep learning. This method focuses on identifying bogus currency that is pervasive in the Indian market. The most common deep neural network technique, referred to as transfer learning utilizing Alex net, is used to detect counterfeit money. Alex net includes fully-connected layers, dropout, ReLU activations, max pooling, and convolutions. The data store of images of money notes is created with the intention of training the network. For each note, 100 images are created with the help of augmentation. Techniques for augmentation, such as rotating and resizing, are used to increase the amount of data bases. A camera is used to evaluate the procedure in real time. A "Real Note" or "Fake Note" result is generated by comparing the input currency note's properties to those that the network has already learned. This comparison occurs as soon as the picture has been acquired. Since the monetary distinctive attributes are gradually learned, the detection accuracy is at its highest. The acquired image may also contain noise, which must be taken into account as part of the pre-processing step in the currency detection process. By taking into account the surface patterns of the coin as characteristics, the detection accuracy of phoney currency can also be increased [6].

Deep learning was suggested by Gebremeskel et al. to identify Ethiopian banknotes. The image capture, image size regularization, grayscale conversion, and histogram equalization steps of the detection model sequence combine to significantly reduce the parameter number counts in the convolutional region of the DL structure. The Fully connected (FC) layer, which is basically in charge of evaluating the incoming image, executes the detection process. The deep CNN suggestion process organizes the input images into numerous groups based on the characteristics discovered at prior levels. Additionally, the input photos are introduced after the input classification process has converted the input pictures into the distribution of probabilities over classes and after the neural network has been trained via back propagation. The model delivers the following parameters throughout all relevant epochs: recall, precision, F1 score, confusion matrix, training accuracy and loss, validation accuracy and loss, recall, and accuracy and loss plot graphs. There are only 10 epochs in the pre-trained CNN model, thereby lowering its effectiveness in feature extraction [15].

Gopanae et al. proposed the use of Support Vector Machine (SVM) to identify fake bank notes. The suggested strategy is focused on exploiting open access to identify counterfeit money. A banknote's legality can be determined using the suggested system by examining specific security features like watermarks, latent images, security threads, etc. Algorithms for machine learning are used to detect fake currency. As part of the technique, certain security components are extracted and encoded. A support vector machine (SVM) is employed to extract security features, categorize features, and find features from the input image. The proposed system uses methods such image acquisition, region of interest extraction from the image, feature extraction, and machine learning algorithms to determine whether an input image of a banknote is authentic or fraudulent. However, a comprehensive verification of the proposed approach requires extensive evaluation in a wide range of real-world scenarios. Furthermore, deep learning techniques can be used on a substantial amount of training data to provide predictions that are more accurate [16].

III. Problem Statement

India and many other nations have suffered greatly and the issue has become grave. Fake notes are a catastrophe in almost every country. Systematic methods are utilized to distinguish between real and fake bank notes using bank note authentication. Nowadays, a wide variety of applications are accessible, including automated teller machines, self-serve checkout lanes, money exchange companies, hotels, banks, and retail establishments, among others. Forged bank notes are becoming more prevalent over time. In spite of the ease with which counterfeit bank notes may now be produced because of advances in scanning and printing technology, it is now incredibly challenging to distinguish between real and fake currency. However, current systems sound implausible to people like shopkeepers because of their price, requirement for a large power supply, and size. As a result, these people are more likely to encounter forgers. It is required to categorize and identify between photos of real and fake bank notes throughout training [17]. As a result, numerous conventional methods, such as KNN and Decision Trees, were employed; however, advanced machine learning algorithms, such as ELM, XGBOOST, or MLP, were not used. Applying either an image or a video as an input feed, the issue can be resolved by applying deep learning algorithms to recognize the currency.

IV. Proposed Counterfeit Currency Detection Using GAN-CNN-RNN with ABO Approach

A. Data Generation using GAN

The dataset should include a diverse collection of real banknotes and corresponding counterfeit samples. The GAN will be trained on this dataset to learn the underlying distribution of genuine banknote features and generate synthetic counterfeit currency images that closely resemble real counterfeit notes, ultimately enhancing the performance of the counterfeit currency detection algorithm [18].

The GAN, which has acquired prominence for their outstanding synthetic data production capabilities, serve as the foundation for the data generation. Two networks are trained simultaneously by a GAN. By examining the distribution of underlying data, the first network, known as the Generator network, frequently produces intimation images. . In order to determine if an input sample is real or fake (i.e., whether it came from the generator), the second network, the discriminator, is used. Our suggested solution, which is based on GANs, models the underlying data distribution to differentiate between seven target categories with a very low inter-class variation.

The generator, K(z;Wg), is a network of neurons with parameters such as Wg and an earlier distribution of pz(z) on the input random vector z. A convolutional neural network's discriminator E(x;Wd) decides whether the input vector x comes from the generator's dispersion p_g . A (n + 1) dimensional vector illustrating this probability is the result. In order increase the likelihood that it will correctly recognize its input, x, the discriminator, E, tries to distinguish between images created artificially by specimen p_g and those acquired from the authentic data samples during training. Additionally, by attempting to minimize log (1 D(G(z)), the generator, K, is trained to deceive the discriminator. By streamlining the procedure, you may do both.

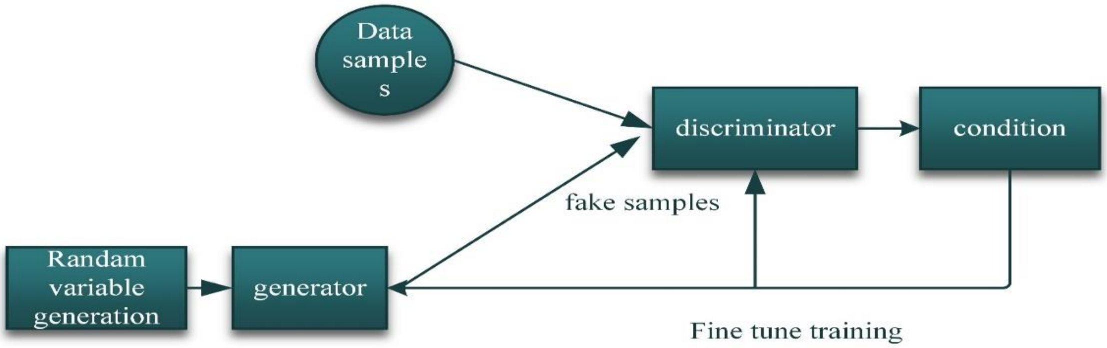

Fig. 1. GAN network.

In Fig.1, the generator, H(y;W_h) is a network of neurons with the values W_h and a prior distribution of p_z(y) on the input noise vector y. An (n + 1) dimensional vector is the output of the convolutional neural network that serves as the discriminator, I(x;W_i).

$$min_H max_I V(H, I) = E_{x\sim qdata(x)}[\log(x)] + E_{y\sim q_y(y)}[\log(1 - I(H(y)))] \qquad (1)$$

In order to increase the possibility that the correct label will be assigned to its input y, the discriminator, I, attempts to distinguish between images acquired from the genuine data samples during training and those intentionally made by sampling ph. The generator H is also taught to deceive the discriminator by seeking to reduce $[\log(1 - I(H(y)))]$.

Our major objective is to be able to distinguish between the numerous classes that the photos comprise, even though the generator and discriminator are merely designed to discern actual images apart from false ones. Our key objective is to be able to discern between the many classes that the photographs represent. To determine if a photograph is authentic or fake, the (n + 1) th unit in the last layer of I applies the aforementioned loss function. This layer's remaining n units are trained using the following common cross-entropy loss function:

$$\boldsymbol{L_{supervised}} = -\sum_{I(x)} m(I(x)) log(n(I(x))) \quad (2)$$

Here, the discriminator projected class probability is represented by the symbol m(I(x)), which also serves as the input x's accurate class label. The discriminator network can be trained simultaneously using two loss functions—one for classifying inside actual images and another for distinguishing between fake and real images—thanks to the introduction of a second label for the false class [19].

B. Feature Extraction using CNN

The feature extraction component's goal is to extract the elements of the paper banknote sample's descriptive features. In this instance, a CNN is employed to extract features. Some of the unique features that CNN frequently employs to identify banknotes include color, size, form, and tactile aspects. To extract the CNN feature, a supervised variation of the CNN model is used. Input, hidden, and output layers are present in the CNN. The layer of convolution and the subsampling processes layer are both referred to as the feature extractor layer in the CNN model's hidden layer. The convolutional layers pick up on a variety of local traits that make up the image of a birr note, such as the identifying mark, security thread, tin and wide golden strip, and numerous other security features. As the image moves through each layer, the filters may spot more complex characteristics. Each neuron's input in the convolution layer is coupled to the local receptive field of the layer above it in order to extract the local feature [20]. Rectifier Unit, the most frequently used activation function for the outputs of the CNN neurons, is referred to as ReLu [21].

The ReLU can be written as in eqn. (3),

$$\sigma = \max(\sigma, v) \qquad (3)$$

Here v is the input.

Typically, CNN retrieves high-level characteristics from the model's final output layer. It is also crucial to remember that grayscale and RGB images are typically examined by CNN models utilizing two-dimensional (2-D) convolution filters. The input picture is only N1 by N1 pixels, and the first 2-D convolution layer has n1 2-D convolution kernels with a size of p1 by p1. Because of this, the initial 2-D convolution layer will produce n1 feature maps that are (N1- p1 +1) by (N1- p1 +1) in size, depending on the size of the 2-D convolution kernels. The dot product of the weight matrix and the location of the local area (x, y) is also used to construct each feature map; and you can use the formula to determine the value of a neuron's V_{ij}^{ab}at position (a, b) on the jth feature map in the ith layer.

$$V_{ij}^{ab} = \sigma\Big(c_{ij} + \sum_n x \sum_{p=0}^{p_i-1} x \sum_{q=0}^{q_i-1} w_{ijn}^{p} V_{(i-1)n}^{(a+p)(b+q)}\Big)(4)$$

Where, σ(·) indicates the ith layer's activation function, c_{ij} is an additive bias of the ith layer's jth feature map,

Ki and Pi symbolizes the height and width of the 2-D convolution kernel, respectively, while m indexes the association between the feature map in the (i_1)th layer and the present (jth) feature map, and $w_{ijn}^{p}$is a weight for input $V_{(i-1)n}^{(a+p)(b+q)}$ with an offset of (q, p) in 2-D convolution kernel. The 2-D pooling approach is used to minimize the feature maps' resolution.

In Fig. 2, the features of 2-D CNN architecture is composed of three layers: an input layer, a 2-D CNN block (stacked with many Conv layers and POOL layers), and a fully connected neural network (FNN) block. Feature maps' resolution is decreased using the pooling procedure, which begins after the convolution stage. The features can then become location-invariant. In the first POOL layer, where n3 = n2/k2, there are m2 x n3x 1 nodes and m2 kernels of size k2 x 1. In addition, there is a link between the neurons of the POOL layer and the n 1 patch of the Conv layer. Applying equation 5 below completes the pooling step of the max-pooling technique.

$$d_j = max_{nx1\left(d_i^{kx1}\, u(K,1)\right)} \qquad (5)$$

The largest value in the neighborhood, and u(k, 1) specifies a window function matching to the small n 1 patch of the Conv layer. Richer and more robust features can be extracted using a features extraction method that can quickly and efficiently coordinate the training of subnetworks [22].

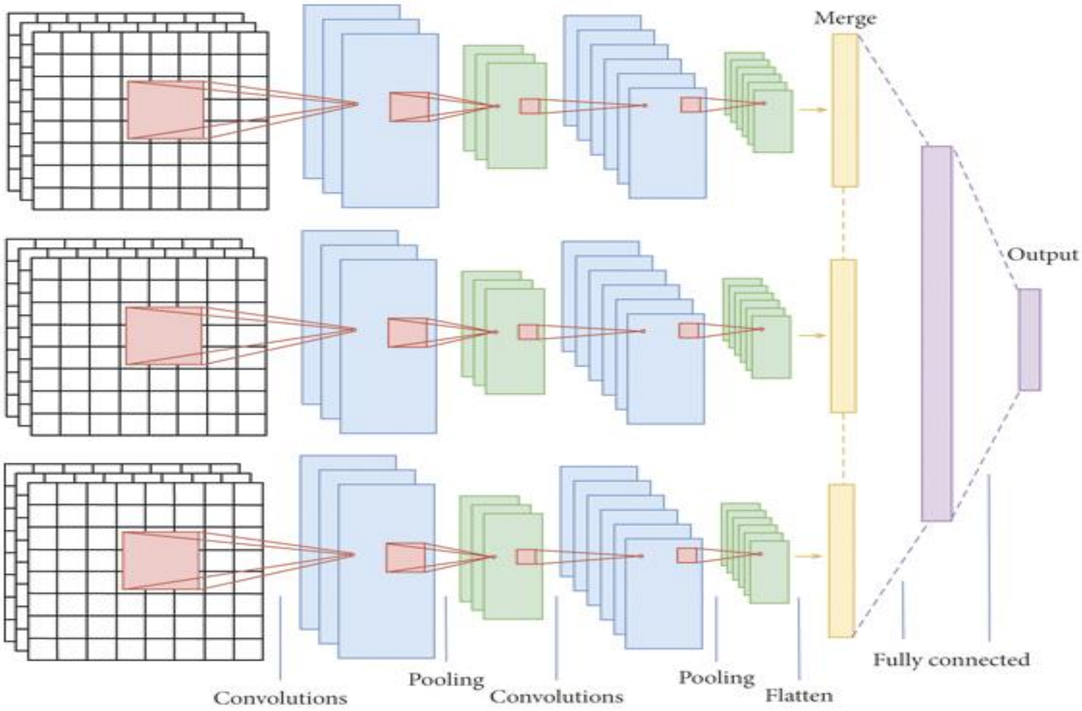

Fig. 2. 2-D CNN architecture.

C. Feature Selection using African Buffalo Optimization (ABO)

The African Buffalo Optimization (ABO) mimics the alert ('maaa') and alarm ('waaa') behaviors of African buffalos when they are out hunting. When searching for food and avoiding predators, African buffaloes primarily use these two noises to coordinate their movements. The waaa noise is used to rouse the buffalos to move on and investigate the search area, whereas the maaa noise instructs the buffalos to remain and make use of their immediate surroundings because it is secure and has enough of pastures. The buffaloes are aided in their food source seek by these noises. The African Buffalo Optimization (ABO) mimics the alert ('maaa') and alarm ('waaa') behaviors of African buffalos when they are out hunting. When searching for food and avoiding predators, African buffaloes primarily use these two noises to coordinate their movements. The waaa noise is used to rouse the buffalos to move on and investigate the search area, whereas the maaa noise instructs the buffalos to remain and make use of their immediate surroundings because it is secure and has enough of pastures. The buffaloes are aided in their food source seek by these noises.

1) The working of the ABO algorithm: The method starts by purposely assigning each buffalo a random location inside the N-dimensional space in order to initialize the population of animals. The algorithm then determines the bn_{max} (the herd's ideal position) and bm_{max} (each individual buffalo's location) with respect to the ideal solution. The position vector for that specific buffalo is saved if the person's current fitness level exceeds their maximal fitness level (bm_{max}). The fitness is saved if it exceeds the herd's maximum, or bn_{max}, which is the entire fitness of the herd. The position of the current buffalo is updated, and the population's future buffalo are taken into account. The ABO algorithm is shown below, same to algorithm 1.

2) Controlling the movement of the buffalos: According to the communal intellect of the herd after engaging in a collective decision-making process, this democratic equation (10) in figure allows for the choice to either continue in order to further utilize the environment or to go on to explore other location. Depending on the outcome of the democratic eqn. (6), the maaa eqn. (5) advises the buffalos to move on and explore different areas after carefully examining the two conflicting pressures (bn_{max} and bm_{max}). The option, which identifies the discrete time interval that the buffalo must migrate through, has a default value of 1.0. When these two equations are applied, the position of the buffaloes is altered. To realize the full potential of the algorithm, it is required to investigate the ability of the African Buffalo Optimization to search a range of solution spaces, including separable and non-separable, limited and unconstrained, mono-modal and multi-modal. One extreme is present in a mono modal function, which is defined as having only one minimum or maximum within the range specified for x. In a manner similar to this, it is said to be multimodal if a function contains more than one peak, either on the minimum or minimum sides.

In addition, a function is considered to be dissociable if it can be written as the sum of 'p' functions with just one variable. It is harder to optimize non-separable functions. This is due to the fact that accurate search directions need the presence of two or more components in the search space (or solution vector). The issue is complicated when a function has many modes. The last challenge that optimization algorithms must overcome is the situation of many dimensions. This is because as issue dimensions increase, so do the number of local optima. These multimodal benchmark functions test an algorithm's resistance to local minima or maxima. An algorithm will stack in a local minimum if its exploration capacity is inadequate. In this section, we'll examine a few of the flat-surfaced functions. Because these functions don't provide enough data to enhance the search, they pose certain challenges for algorithms [23].

The parameters used are N,α,lq1,lq2

A large group of n buffaloes, where each buffalo stands for a potential solution.

- The buffaloes' index k, where k is in the range of [1,...,N].
- The alpha value, excluding the zero, with a domain in [1,1][1,1].
- The learning factors lq1 and lq2 with a [0,1][0,1]real number domain.
- The exploitation man oeuvre is represented by the mk variable.
- The bnmax$_k$ variable has the highest fitness for the herd.
- The bmmax$_k$ variable represents each buffalo k's optimal finding location.
- The w$_k$ variable, which represents the exploration move, is the last.

$$m_{k+1} = m_k + lq1(bnmax - w_k) + lq2(bmmax - w_k) \qquad (6)$$

On Line 6, Eqn. (5) indicates the location updated by the buffalo k [24].

$$w_{k+1} = \frac{w_k + w_m}{\pm\alpha} \qquad (7)$$

The location update formula is Since Eq. (7) is a straightforward random number generator, the search inside the search space is likely to be aimless, leading to a relatively inefficient solution or, in certain cases, premature convergence. These issues, nevertheless, might be resolved by utilizing chaotic and levy distribution features.

Algorithm 1: *ABO algorithm.*

Input*: N, α, lq1, lq2*
Output*: Original or fake currency*

```
Set the parameters initialized
Make random answers for N buffaloes.
While the criterion of the terms has not ended do

ABO uses just a few parameters, principally the learning parameters lq1 and lq2, to guarantee quick convergence. Depending on the algorithm's concentration at a given iteration, these parameters allow the animals to move towards greater exploitation or exploration.

D. Classification using RNN

The classification phase employs RNN. An RNN connects its nodes in a way that closely resembles how neurons in the human brain are connected to one another. After processing the signal, it just received, the artificial neuron sends it to the other neurons or nodes that are connected to it. Weights frequently exist in neurons and synapses to change how learning occurs. The strength of the signal can be changed by varying the weight as it passes from the input layers to the output layers. An RNN has additional layers in addition to the input and output layers. Three hidden layers are the absolute minimum for an RNN. Input, output, and hidden units, all of which use weighted calculations, make up the fundamental elements of RNNs [25].

In Fig. 3 a sequence of input vector is given as A = (a$_1$, a$_2$,.. a$_T$).

The sequence of hidden vector as B = (b$_1$, b$_2$, . . . ,b$_T$) and

Sequence of output vector as C = (c$_1$, c$_2$, . . . , c$_T$) with t = 1 to T as follows:

$$b_t = \sigma(V_{ab}a_t + V_{bb}b_{t-1} + d_b) \qquad (8)$$

$$c_t = V_{bc}b_t + d_c \qquad (9)$$

d is a bias element, function is an exponential activation function, and V is a weight matrix. The output of the hidden layer at each t-time steps is denoted by the symbol b$_t$, while the output of the hidden layer before it is denoted by b$_{t-1}$ in Eqn. (8).

All of the units in the hidden are replaced by LSTM, the RNN's memory unit. The regulatory gates open, activating the memory cells. These gates regulate the flow of information coming in and leaving out. Between an input gate and an output gate is positioned a forget-gate. If the originally saved details are no longer needed, forget gates are able to recover the linear unit's state. These gates are composed of uncomplicated sigmoid threshold units. Memory block layers for these activation functions fluctuate between 0 and 1. At least one memory cell has to be encountered by each memory block.

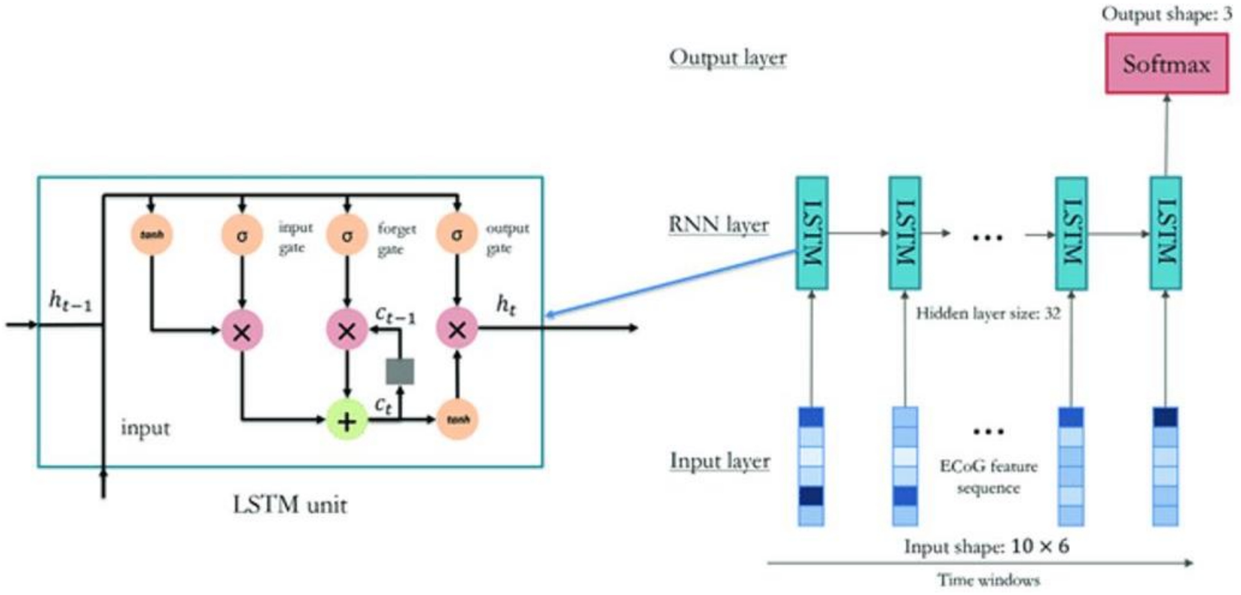

Fig. 3. A simple RNN.

The output $u^b k(t)$ of a memory cell is computed as

$$u^b k(t) = u^{out} k(t) b(s_{b_i}(t) \quad (10)$$

Where, $u^b k(t)$is the activation of output gate, s_{b_i} is the output gate's internal state, and b is the output hidden layer.

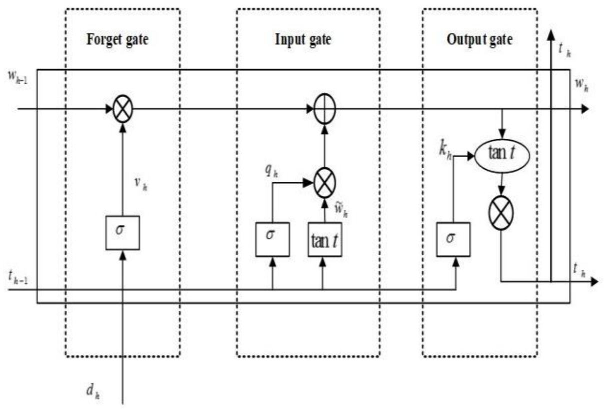

Fig. 4. A basic LSTM network diagram.

In cases when natural language processing is problematic, the amount of text that is present in each data instance is not given as a fixed value. In order to comprehend every word of text, the sequence dimensions are scaled down to a certain degree. If the sequence size is lower than the desired value, the sequence is filled until the value is reached. The surplus is eliminated if the length of the sequence exceeds the necessary value. In Fig. 4, the Convolutional LSTMs are capable of simultaneously encoding long-term relationships and extracting characteristics from the time-frequency domain. The convolution procedure is carried out using linear activation in the first stage. The second phase, also known as the rectifying step, is when the activation function used in the first phase is identified and converted into a linear function. By applying a pooling function to reduce the dimensionality of the time series data, the network's training period is shortened. The collected feature map must also be down sampled without the depth being altered. For the maximum pooling operation of the pooling layer, which is launched on the maximum pooling window, it is customary to choose the maximum values of the convolution layer. This differs from the convolutional layer parameter. Fig. 5 shows the comprehensive flow diagram for counterfeit currency detection and classification. Alternative pooling methods, such minimal and average pooling, are, however, often used.

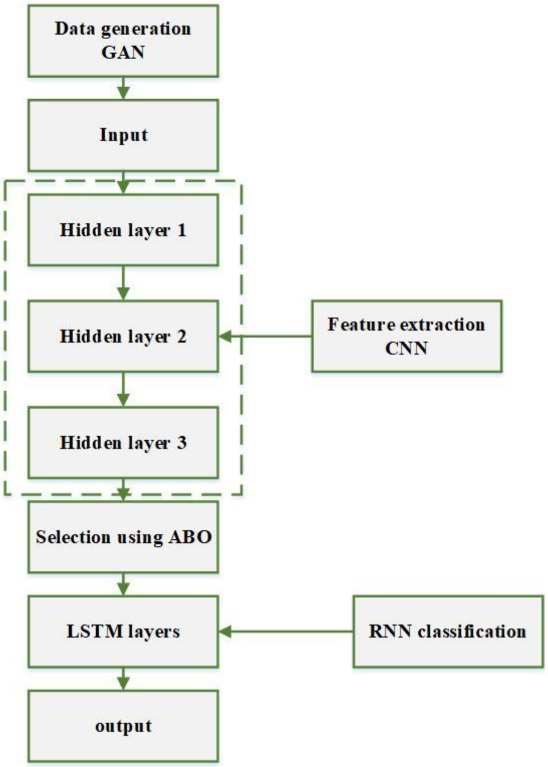

Fig. 5. Comprehensive flow diagram for counterfeit currency detection and classification.

V. Result and Discussion

The process is implemented in MATLAB software in windows 10 platform. The generating the data from GAN is given as input for feature extraction by CNN, feature selection is carried out by the ABO and classification is by RNN. The experiment assessed the models using four evaluation metrics: accuracy, F1-score, precision, and recall. Fig. 6 shows the a) The original images of currency notes used for training the GAN-CNN-RNN model and b) Generated Fake Images - The synthetic counterfeit currency images generated by the GAN-CNN-RNN model during the training process.

GAN generates the images from the dataset. The elapsed time, iteration time and epoch time are plotted in the graph as shown in Fig 7. An ROC curve demonstrates how better the classification model performs at each level of categorization, seen in Fig. 8. On this curve, two parameters are plotted: 100% True Positive and False Positive Rate. A confusion matrix serves as a visual representation and summary of a classification algorithm's results. In Fig. 9, the proposed algorithm's confusion matrix is provided. Fig. 10 shows a concise representation of the training process for the counterfeit currency detection and classification model, utilizing GAN-CNN-RNN with African Buffalo Optimization.

Fig. 10. A concise representation of the training process for the counterfeit currency detection and classification model, utilizing GAN-CNN-RNN with African Buffalo Optimization.

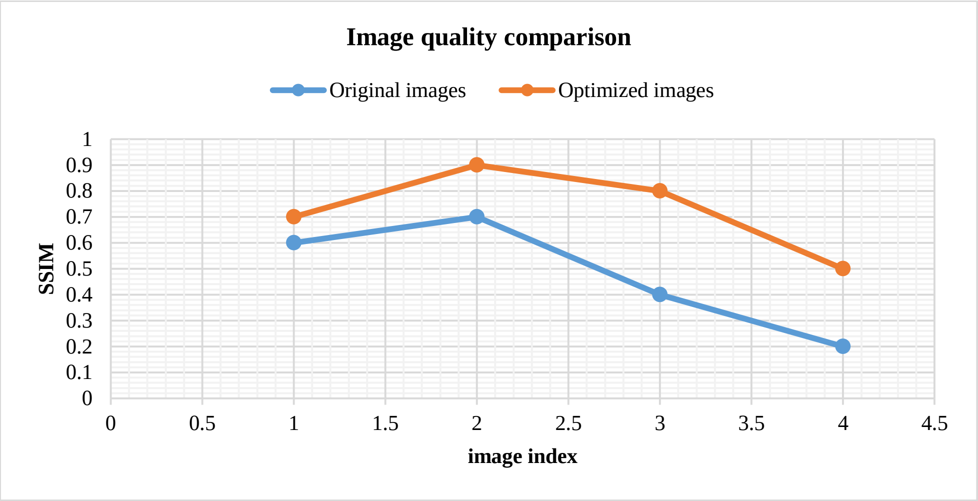

Fig. 11. Comparison using ABO optimization.

In the above Fig. 11, by using ABO optimization, the Quality of the original image is always higher than the optimized image that shows the image quality comparison between image indexes Vs SSIM.

A. Performance Metrics

These parameters are specifically defined as:

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \tag{11}$$

$$Precision = \frac{TP}{TP+FP} \tag{12}$$

$$Recall = \frac{TP}{TP+FN} \tag{13}$$

$$F1score = \frac{2*Recall*Precision}{Recall+precision} \tag{14}$$

$$Specificity = \frac{TN}{TN+FP} \tag{15}$$

The amount of data that were correctly declared as positive out of all the actually positive data is referred to as the TP. TN indicates to the proportion of data that were incorrectly classified as negative out of all the data that were actually negative. The term "FN" indicates to the number of variables that the model misclassified as negative even though they were positive in the dataset. The false positive rate, or FP, is the number of variables that the model incorrectly identified as positive even though they were in fact negative in the dataset. . Recall is the proportion of positive data classified as such in the dataset as compared to the number of positive data identified as such by the model. In terms of the total quantity of data that were classified as positive, precision is the portion of data that the model correctly recognized as positive. Simply said, the harmonic average of recall and precision is the F1-score focusing on Accurate Predictions with Specificity.

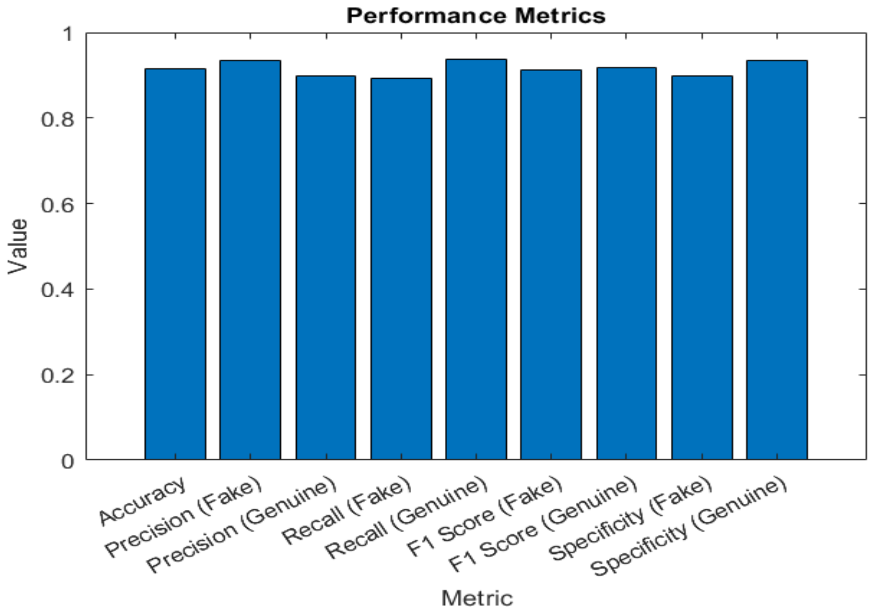

Fig. 12. Experimental result analysis.

In Fig. 12, the proposed system's performance metrics is tabulated. The overall accuracy for the process ranges between 0.8 and 1. The value of fake and genuine notes for precision, recall, F1 Score, Specificity is given above.

Comparison of the proposed model performance results with the existing methods is mentioned in Table I. For clear understanding comparative analysis of sensitivity and specificity are graphically represented in Fig. 13.

TABLE I. COMPARED RESULT IN TERMS OF SENSITIVITY AND SPECIFICITY

Method	Specificity	Sensitivity
KNN	94.75	89
SVM	94	91.42
SSD model-CNN	92	95
Proposed buffalo optimization approach	98.92	96.8

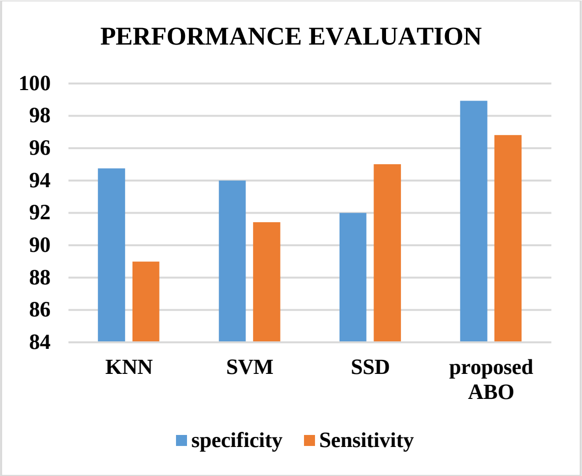

Fig. 13. Comparison of sensitivity and specificity for existing and proposed methods.

VI. Conclusion

This method suggests using of deep learning to detect counterfeit money. The main benefit of employing a deep learning approach is the ability to automatically extract task-specific features from the data; in this case, the choice to utilize deep learning is affected by the graph-structured nature of the data. This eliminates the need for "handcrafted" features. Our model exhibits extremely high accuracy and stable behavior in a variety of difficult situations involving massive amounts of real data, underscoring the enormous promise of hybrid deep learning techniques for fake cash identification. Future research is still needed on many fascinating phenomena and concepts. On varied banknote picture quality, the effectiveness of the GAN, RNN, ABO, and CNN feature extraction technique was assessed. The respective recognition accuracy was 99.2%. Based on recognition precision the CNN is the best feature extraction method in terms of the model's overall goal. As a result, the CNN model is the best option for classifying the banknote, and the RNN also favors the best data creation, ABO optimization for selection, and RNN for classification. The given model significantly advances the study of identifying fake cash. The end research findings are satisfactory and include identifying the currency range in the categorization label, currency denomination, and currency front and rear. It is also possible to state that the accuracy of currency recognition is extremely high. Following study, we discovered that our recognition is quick and precise when the currency is in a clear state over the full screen and the angles are parallel.

***Abstract*—Cardiac-related diseases are the major reason for the increased mortality rate. The early predictions of cardiac diseases like ventricular fibrillation (VF) are always challenging for doctors and data analysts. Early prediction of these diseases can save million lives. If the symptoms of these diseases are predicted early, the chance of survival increases significantly. For the prediction of Ventricular fibrillation (VF), several researchers have used Heart Rate Variability Analysis (HRV); various alternatives by combining the features taken from several areas to explore the prediction outcome. Several techniques like spectral Analysis, Rough Set Theory (RST), Support Vector Machine (SVM), and Adaboost techniques have not required any pre-processing. In this work, randomly medical-related data sets are taken from various parts of Odisha, applying regression and Rough Set techniques, reducing the dimension of the data set. Application of Rough Set Theory (RST) on the data set is not only useful in dimension reduction but also gives a set of various alternatives. This work's last section uses a comparative analysis between AdaBoost combined with RST and Empirical mode decomposition (EMD).**

Keywords*—Ventricular fibrillation (VF); heart rate variability (HRV); Rough Set Theory (RST); support vector machine (SVM); regression analysis; Adaboost method

I. Introduction

Cardiac-related problems are the most dreadful diseases concerning the death rate. According to World Health Organization (WHO) [1], nearly 18 million people died from cardiac-related problems. The most common cardiac-related diseases are cardiac arrest and sudden cardiac death (SCD). These diseases were responsible for causing nearly 50% of total death caused due to cardiac anomalies. In general, sudden cardiac death occurs due to Cardiovascular problems [2], and this problem doesn't have any prior symptoms of cardiac problems [3,4]. The most general sense of symptoms a person feels just before one hour of the actual occurrences of SCD. A person may not have any symptoms of fatal cardiac conditions but is still prone to SCD [5]. SCD rank second according to mortality rate after cancer [6]. The cause of SCD can be due to various diseases like Ventricular Tachyarrhythmias (VTA), Ventricular Tachycardia (VT), Ventricular Fibrillation (VF), Brady arrhythmia (BA), coronary artery diseases (CAD), valvular diseases (RV), and various genetic factors as discussed by Murukesan et al. [7]. There are several instances where SCD occurs due to ventricular tachyarrhythmias, including both VF and VT, as Shen et al. discussed [8]; according to their study, ventricular tachyarrhythmias diseases responsible for the improper function of the heart. In most SCD cases, VF action is like a detonator [9-11]. The fatal rate increases by 90% every minute after the VF is detected. So to increase the survival rate, significant emphasis is given to the early detection of VF has notable importance. Forecasting SCD is always significant, as any wrong move can cause this issue to become more severe. There are several instances and examples where SCD is diagnosed wrongly, leading to fatal consequences. Public Access Defibrillation (PAD) method helpful in recovering from sensors can help in saving 2 to 15 lives after the collapse. The success rate of cardiac renewal is the fundamental treatment of SCD which stimulates the heart [12]. It would be ideal to avoid the start of SCD by offering medical support to someone who suffered a cardiac abnormality occurrence, which highlights the question of whether it would be feasible to set up warning devices that could identify cardiac arrest 30 minutes before a crisis as discussed by Fang et al. [13].

II. Background

Several studies have been made with reference to various serious diseases, designing well-organized techniques of forecasting the SCD concluded intrusive and non-intrusive methods as discussed with reference to the article [14–16]. The core objective is to expect the SCD earlier than the ECG signals, as ECG is one of the most important physiological signals to identify cardiac abnormality and electrical conductivity features. Contemporary studies have investigated with properties of both ECG and heart rate variability (HRV), an indication which gets from ECG helps detect the delicate variation that occurs inside the signals earlier than that of the actual occurrence of SCD and to detect the high SCD risk. There are several additional features like time, frequency, and time-frequency. Several researchers have tried to predict SCD by using Machine Learning Algorithm (MLA). Recent studies can detect SCD 25 minutes before its actual occurrence; according to the report [17-18], the researcher used MLA to predict SCD. Several studies were being carried out for perfect diagnosis and early prediction of SCD, but all these data worked in the context of training data, i.e. when the dataset had been properly processed. Several research gaps exist in predicting SCD by various conventional and non-conventional methods. The following Table I represents the significant research gaps in predicting SCD.

TABLE I. RESEARCH GAPS USING THE CONVENTIONAL METHOD

SL	Conventional research	Drawbacks
1	Soft Computing	Does not work for Random Dataset
2	Linear Regression	Does not work for Outliers
3	Machine Learning tools	Does not work for test data
4	Conventional studies	Machine Error
5	Mathematical Modelling	Only a Numerical solution is possible

A. Literature Survey

Several studies have been carried out to predict SCD or various cardiac diseases. In the context of predicting cardiac arrest, Das et al. [19-20] had various machine learning tools to predict cardiac arrest; they also used hybrid methods like Rough Set Theory (RST) and MLA to boost the accuracy level. RST is a useful tool for prediction, classification, and test and training data. Researchers also used various MLAs like Random Forest Model (RFM) and mathematical modelling to predict meteorological phenomena in this context Das et al. [21-22]. Several research had been conducted to predict various cardiac problems in this context Das et al. [23-25] discussed cardiac diseases using MLA and RST in the same context as Hota et al.[26-27] discussed cardiac problems using various MLA and soft computing techniques. Several researchers have also used mathematical modelling to predict cardiac problems in this context Nayak et al. [28-30] used mathematical modelling and machine learning algorithms to predict diseases like Malaria and Cardiac arrest. Several researchers also used soft computing techniques for social issues in this context Mishra et al. [31] had discussed legal justice for common people in the service sector. The general purpose of research on medical data in computer science is based on the principle of prediction and classifications; in most cases, the researcher used soft computing, MLA, and deep learning techniques for prediction and classifications. To predict cardiac arrest with significant accuracy Manuel et al.[32] had used convolutional neural network (CNN) and ECG images to classify SCD in the same context Kaspal et al.[33] had used a hybrid deep learning method to predict SCD in a similar context Sanchez et al.[34] had used prediction of SCD using wavelet transformation. Scherer et al. [35] had used various methods like pooling operation to significantly detect the objects. Several researchers have used methods like CNN and advanced soft computing methods for prediction and classification other than the medical field in this context Wang et al.[36] had used CNN along with Short-Time Fourier Transform to analyze motor fault analysis. The finding of various researchers considered various parameters like blood pressure and ECG signals for SCD; the ECG signals can predict SCD with significant accuracy, which was observed by monitoring for 24 hours ECG signals from the database of SCDH and considering a sampling frequency of 250 Hz[37]. Several research studies have also been conducted to find the death rate due to cardiac problems in this context Liu et al.[38] had used one-dimensional CNN for health monitoring. This paper used various techniques like RST and machine learning tools to predict cardiac problems. RST was initiated and developed by polish mathematician Pawlak [39]. RST helps find useful information from vague and imprecise data, as discussed by Das et al. [40]. Several studies have also been conducted using various alternate methods like empirical mode of decomposition (EMD) in this context Huang et al. [41] had discussed the Empirical mode of decomposition and spectrum analysis of Non-linear and Nonstationary time series.

B. Material and Method Used

This work deals with RST, as discussed by Yao and Deng [42], the fundamental concept of RST is based on upper approximations, lower approximations, boundary region, core, reduct, quality of approximation, and indiscernibility. The entire concept of based on indiscernibility, equivalence classes and target set.

C. Fundamentals of RST

The general representation RST is in the form of a table called an information system represented as < U, C, D>, where U is called the universe, C is the set of conditional attributes, and D is the set of decision attributes. The complete skeleton of RST is given in the following Table II.

TABLE II. INITIAL INFORMATION TABLE

E	C	D
E1	1	2
E2	1	1
E3	2	2
E4	2	1
E5	2	1

Description of the Table as follows E=< E_1, E2, E3, E4, E_5> are the records, C is the set of conditional attributes, D is the set decision attributes/ target attributes, and <1,2> represents the values of the decision and conditional attributes.

D. Generalization of RST

The generalization of RST includes a definition of upper approximations, lower approximations, boundary region, core, reduct, quality of the approximation, and indiscernibility and their mathematical representation.

1) Indiscernibility: Indiscernibility generally includes a single attribute or multiple attributes. Mathematically indiscernibility defines as

$$\mathrm{IND}(K)=\{(\alpha,\beta) \in R^2 \mid \forall m \in K, m(\alpha)=m(\beta) \} \quad (1)$$

2) Upper approximation: Upper Approximation includes the concept possibility, i.e. the set of all objects possibly linked with the target.

$$\mathrm{Upper}(AT)=\cup\{ M\in U/A, : M\cap T\neq \emptyset\} \quad (2)$$

3) Lower approximation: Lower Approximation includes the concept of definiteness

$$\mathrm{Lower}(AT)=\cup\{ M\in U/A, : M\subset T\} \quad (3)$$

4) Reduct: Reduct forms a set of equivalence classes which is derived from the set of indiscernibility.

E. Various Algorithm used in this Study

1) Algorithm to find Indiscernibility

Step-1 ∀a∈ U, where a is the conditional attributes

Step-2 ∀x,y values of the attributes a

Step-3 for (i=1; i ≤ n; i^{++}), where n is the number of conditional attributes

Step-4 check for indiscernibility i.e. goto step-5

Step-5 if the values of attributes a are either identical or distinct, then indiscernibility

found. i.e. either a(x)=a(y), check for the combination attribute 1 to attributes n

else

goto step-3

end if

end for

2) Algorithm to find reduct

Step-1 ∀ IND where IND is the indiscernibility

Step-2 for (j=1;j ≤ n;j^{++}) , n is the total number of indiscernibility

Step-3 verify whether the indiscernibility derive reduct

if the values of the indiscernibility are distinct

Reduct R is found else goto step-2

Step-4 end if

Step-5 end for

F. Empirical Mode Decomposition (EMD)

The idea of EMD was initiated by Hung et al., as discussed in the previous section. The EMD approach uses adaptive techniques to analyze stationary and nonstationary one-dimensional signals. EMD has the feature of decomposing a one-dimensional signal in intrinsic mode functions (IMFs). Two significant criteria are essential for the proper function of EMD criteria a. The total number of zero crossing and extrema in the one-dimensional signal either different or equal to numbers only by 1 and b. the lower and upper envelopes must be symmetrical, to estimate the mean value as zero. The following steps are required to calculate each intrinsic mode function (IMFS).

Step-1. Calculate local maxima and local minima of 1 dimensional signal i.e. x(t)

Step-2. Using Step-1 connect the local maxima & minima to calculate the upper & lower envelops.

Step-3. Find the average of the of the upper & lower envelops denoted as k

Step-4. New 1dimensional signal to be found out as

$$h_i(t)=x(t)-k(t) \quad (4)$$

Step-5. For i= 1 to n

Check if h_k satisfies condition 1 and 2

Then Intrinsic mode function (IMF_1)=$h_k(t)$

Else goto step-5

Step-6 end if

$$\text{Residue signal } r_1(t)=x(t)-IMF_1 \quad (5)$$

Step-7 If the estimated residue signal, function $r_1(t)$, has monotonic nature, the method does not work, implying that the estimation of IMFs is completed

Else

Follow the procedure of estimating IMFs and the residue

End if

Step-8 The final

$$x(t)= \sum_{i=1}^{n} IMFs\text{I} - r_n(t),\ r_n(t) \quad (6)$$

is the last residue found.

On the other hand, if it is not considered a monotonic function, the residual signal is now considered the original 1Dsignal, which is again evaluated by steps (1 to 3) for estimating the other IMFs.

EMD is the fundamental technique for Ensemble empirical mode decomposition (EEMD) and Complete Ensemble empirical mode decomposition (CEEMD).

G. Ensemble Empirical Mode Decomposition

EEMD, an enhanced form of the EMD technique [23], is categorized by being a noise-assisted technique used to decompose the 1D signals in their basic structures steps for EEMD**:**

Step-1 Generates new 1D signals by using 1D signal (basic) and basic Gaussian noise $n_i(t)$

For j=1 to m

$$x_j(t)= x(t) + n_j(t) \quad (7)$$

Step-2 Divide the signal generated by step-2 by the EMD technique

Step-3 Calculate the frequency band or the IMF on the kth iteration that will be

$$EEMD_k = \frac{\sum_{j=1}^{m} c_{jk}(t)}{m} \quad (8)$$

The frequency band or IMF, recognized by k for the trial j is denoted by $c_{jk}(t)$.

H. Complete Ensemble Empirical Mode Decomposition

The CEEMD properly described by Torres et al [42] it is the advanced version of EEMD, CEEMD provides better separation than EEMD. Each trial's residue is calculated as $r_i(t)$ in this context.

$$r_1(t)=x(t)-IMF_1 \quad (9)$$

The flow diagram of the above work is given in the next section for detailing and describing the work. A significant part of the work consists of logistic regression, RST and

EMD, EEMD, CEEMD and comparison of the methods with RST.

I. Fundamentals of Logistic Regression

Logistic regression helps make different classes; this method is also helpful in the case of outliers. This statistical technique is useful for the object with binary outcomes. Logistic regression represented by signum function. The mathematical representation of logistic regression is given as follows as

$$\alpha_a = \left\{\frac{1}{1+e^{-x}}\right\} \qquad (10)$$

III. Method and Data used for Analysis

This study considered several machine learning algorithms applied to UCI data set for accuracy measure. This work includes three fundamental concepts a. Logistic Regression b. RST to find the significant attributes c. EMD and it two versions for accurate prediction d. Comparison among other methods like Support Vector Machine (SVM), Random Forest Method (RFM) & logistic regression after boosting. The data collected from various districts are given in Table III.

The data is collected from various parts of our states, i.e. Odisha's district, a total of 5,60,000 samples has been taken for the studies. The application of logistic regression reduced the data set into 6 different records. Details of logistic regression are given in the Fig. 1. The logistic regression used for this study has better and more concrete results than linear regression, as logistic regression works better for the outliers. Logistic regression works better for dynamically changing data sets. Training the data set for logistic regression is given as follows. We had considered several cardiac-related diseases from various parts of our state, a total of 5,60,000 data as mentioned in the Table. Using the concept of upper approximation, lower approximation boundary region, i.e., Boundary Region = Upper Approximation – Lower Approximations. Analyzing the Table using the concept of boundary region found that others attribute is insignificant in forming the groups for cardiac problems. This study includes the basis for dividing a larger dataset into groups by training the data set according to the research requirements. This work considered the medical survey according to the research needs; This study divided the entire data sample into categories, i.e. category- 'severe', moderate, average, low, free from cardiac illness, renamed as category-1, category-2, category-3, category-4, category-5. Using these five categories resulted in 5- distinct groups of 5- records. The records consist of only two values, significant and pointless. Rename the conditional attributes general cardiac problems as 11, Sleeping disorder as 22, Sudden Cardiac death as 33, Pneumonia as 44, Cardiac Asthma as 55, and values significant as a and pointless as b for better understanding and application. When the data samples are divided into categories, this work follows the rules of grouping the data set according to its group; this also follows the concepts of approximations, with a minor difference in diseases between the persons included in one group. The grouping is formed by using the following algorithm. The target values are more than two in our cases with the following assumptions. Target variable can have three or more possible types, which are the five diseases given in the Table III.

In this case, the sigmoid and softmax functions are used for regrouping the sample according to various features. Classes are established using softmax function, and categories or classifications are established using the sigmoid function. P classes softmax function represented by:$\sigma(x_i)=\frac{e^{x_i}}{\sum_{j=1}^{p} e^{x_j}}$, where I varies from 1 to p.

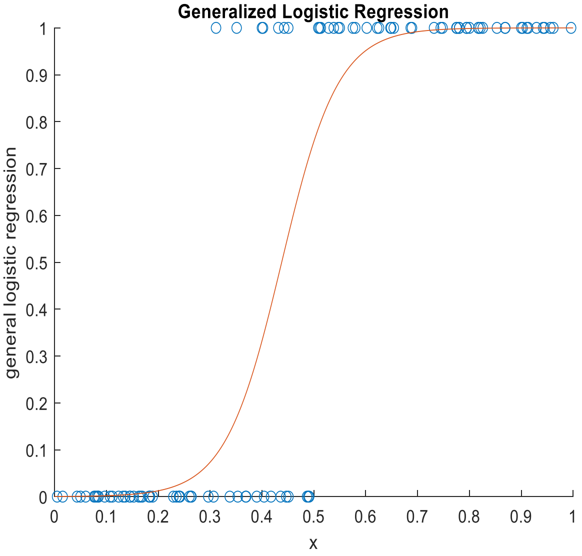

Fig. 1. Application of Logistic regression using the sigmoid function resulted in 6-similar records given in the following Table-IV.

TABLE III. Initial Data Table

District	Cardiac problems	Sleeping Disorder	Sudden Cardiac Death	Pneumonia	Cardiac Asthma	Others	Total
Koraput	10,000	50,000	15000	25000	50000	5000	1,55,000
Dhenkanal	20,000	20,000	25000	15000	5000	15000	1,00,000
Jajpur	30,000	10,000	15000	10000	10000	5000	80,000
Cuttack	15,000	25,000	10000	5000	5000	15000	75,000
Puri	25,000	10,000	5000	10000	10000	10000	70,000
Sambalpur	20,000	20,000	15000	5000	15000	5000	80,000

TABLE IV. APPROXIMATION AFTER LOGISTIC REGRESSION

Records	11	22	33	44	55
E1	A	A	a	a	a
E2	A	A	b	b	a
E3	A	B	a	b	b
E4	B	B	b	b	a
E5	B	a	a	b	a
E6	B	a	b	a	b

A. *Universal Data Set*

Data collected from the University of California Irvine machine learning repository considered UCI repository provided the Heart Disease dataset. This includes 14 different attributes for 304 cases, with target values in deciding whether the patient is suffering from cardiac problems or not, as well as divided the patients according to the symptoms that leads to the finding the number of patients at risk for cardiac problems is extracted from this dataset. There is binary aspect of the dataset i.e. each row corresponds to a single record in this dataset, which has 303 rows and 14 columns, presented in the following Table V and Fig. 2.

The Table represent the detail attribute description and the provided the detail about the target, the figure given below describe the correlation values between -1 to 1. Correlation coefficients range from -1 to +1, indicating a negative or positive correlation. Age, high blood pressure, and high cholesterol levels may strongly correlate with an increased risk of heart disease. Correlation matrices help identify potential risk factors and develop predictive models. This study uses several Machine learning algorithms (MLA). The machine learning algorithms approaches are initially based on weak learner, by combining the multiple algorithm leads to strong learner.

TABLE V. VARIOUS CONDITIONAL ATTRIBUTES RELATED TO CARDIAC

Sl	Category	Details	Target
1	Span	Chronic/Not Chronic	Continuous
2	Gender	Patient's Gender	Female/Male
3	CP	Chest Pain	Type(1,2,3,4)
4	Measure	Resting blood pressure	Continuous
5	Ch	Cholesterol range	Continuous
6	Bs	Fasting blood sugar	Less than 120mg/dl
7	Elec	Electrocardiograph	Values(1,2,3,4,5)
8	Tha	Heart beat	Continuous
9	Exa	Induced angina	0/1
10	Op	Amount of rest/ Non rest	Continuous
11	Slope	Peak	Type(Up/Flat/Down)
12	Car	Gives number of major vessels colored by fluoroscopy	Binary(0/1)
13	Tha2	Faulty	Binary(0/1)
14	Num	Cardiac problems	Yes (0,1,2,3,4)

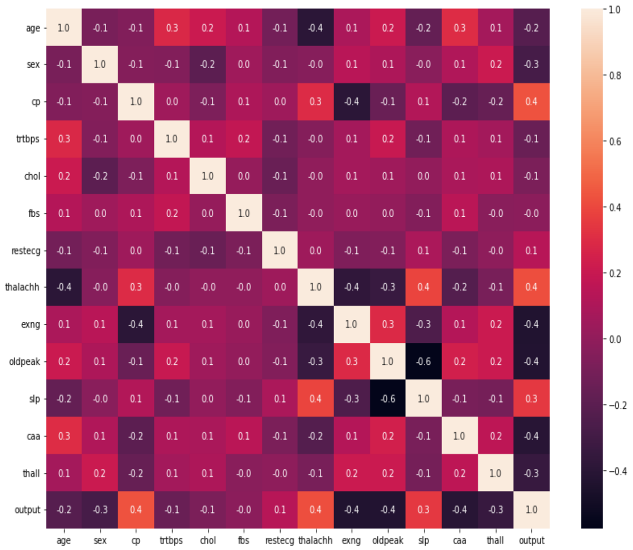

Fig. 2. The correlation matrix.

B. *Training by using Naive Bayes Classifiers*

Input-: Data sets related to cardiac problems trained with the symptoms given in the rules

Output-: Expected results with binary results Y/N (Y-Yes, N-No)

Step 1. Different category of the dataset trained with binary values (Agree/Disagree). This signifies as an indicator.

Step 2. Expected

$$\text{probability}=\frac{number\ of\ objects\ belongs\ to\ the\ groups(agree)}{Total\ samples}$$

dataset belong to agree category. Similarly, the successive probability calculated by

$$\text{Probability }=\frac{\text{(number of objects belong to group agree after iteration)}}{Total\ samples}$$

To find the class total number of disagree

Step 3. Find R, where R is the total number of attributes

$$R_y=\sum x_i\text{, where } x_i \in \text{Agree}$$

$$R_n=\sum y_i\text{ , where } y_i \in \text{Disagree}$$

Step 4. for j 1 to n

1) *Find the group level using the formula*

Probability for attribute belongs to agree = (Total count for agree belongs to class i)/ (n_i) Probability for attribute belongs to disagree = (Total count for disagree belongs to class i)/ (n_i)

Step 5. Divide the new groups of patients belonging to probability R/T, where R represents the groups, and T is its respective features.

Step-6.Comput Probability agree as = $\prod P(agree)P(Class\ of\ attributes\ belongs\ to\ agree\ class)$

Similarly, compute probability for disagree class by the total product of the probability of disagree × class attributes of disagree class i=1 to n

g. Assign the new minutes as patients fit to agree class or disagree class, according to higher voting.

C. Calculating Misclassification before Training

```
Step-1 Represent P as region belongs to agree class, N as region belongs to disagree class, according to the equation.
        $\sum_{i=0}^{10,000} t_i m_i=0$, k=0.01.
        Step-2 for i 1 to 10000
Step-3 Verify that the point erroneously classified to the region belongs to agree class
    if
    {
     $T_i \in N$ & $\sum t_i m_i>0$
    Update $T_{new}=T_{old}-km_i$
    else go to step 5
Step-4 Check for the point misclassified wrongly in the Negative region
    $T \in P$ & $\sum t_i m_i<0$
    Update $T_{new}=T_{old}+km_i$
    else
    }
Step-5 end for
```

D. Algorithm for Strong Learner using Boosting

```
Step-1 Adjust the weights as 1/p for p observation
Step-2 Select the features k with respect to the smallest Gini index/Concentrated information gain,
    Evaluate the over-all error
Step 3 Find the stump of the routine
Step-4 Calculate the new weights with respect to misclassifications
Step-5 All weights to be normalized accordingly
Step-6 For all i varies from 1 to n
    if
    {
    A configured number of estimators reached the saturation/ Significant accuracy level
    achieved
    }
    else go to step 2
    }
Step-7 end if
Step-8 end for
```

IV. Result Analysis using Machine Learning Tools

This study used Max-Min concept to overcome the results with respect to oversampling. This study used UCI sources to provide the diseases related to cardiac. The description of the data set defines in Table-V useful in regulating the cases of a person suffering from cardiac problems. This study divided the domain into two classes: people who suffered from cardiac problems and those who did not suffer from cardiac problems using a set of symptoms. This paper used two concepts of training and testing for people in danger of cardiac problems and recovered from cardiac problems.

A. Finding Indiscernibility

Finding indiscernibility, reduct and core don't have any generalized algorithm; this study uses the algorithm to find indiscernibility as defined above. This work uses data in Table IV to find indiscernibility, reduct and core. IN denotes indiscernibility.

$$IN(11)=\{(E_1,E_2,E_3),\ (E_4,E_5,E_6)\} \tag{11}$$

$$IN(22)=\ \{(E_1,E_2),(E_3,\ E),\ (E_5,E_6)\} \tag{12}$$

$$IN(33)=\ \{\ (E_1,E_3,E_5),\ (E_2,E_4,E_6)\} \tag{13}$$

$$IN(44)=\ \{\ (E_1,E_6),\ (E_2,E_3,E_4,E_5)\} \tag{14}$$

$$IN(55)=\ \{\ (E_1,E_2,E_4,E_5),\ (E_3,E_6)\} \tag{15}$$

$$IN\ (11,22)=\ \{\ (E_1,E_2),E_3\ \ E_4,(E_5,\ E_6)\} \tag{16}$$

$$IN(22,33)\ =\{\ (E_1,E_5),(E_2,E_6),E_3,E_4\} \tag{17}$$

$$IN(33,44)=\ \{\ E_1,(E_2,E_4),(E_3,E_5),\ \ E_6\} \tag{18}$$

$$IN(44,55)=\ \{E_1,E_6,E_3,\ (E_4,E_5,E_2)\} \tag{19}$$

$$IN(11,33)=\ \{(E_1,E_3),E_2,(E_4,E_6),\ \ E_5\} \tag{20}$$

$$IN(11,44)=\{\ \ E_1,(E_2,E_3),(E_4,E_5),E_6\} \tag{21}$$

$$IN(11,55)=\ \{\ (E_1,E_2),E_3,(E_4,E_5),E_6\} \tag{22}$$

$$IN(22,33)=\ \{\ (E_1,E_5),E_3,(E_2,E_6),E_4\} \tag{23}$$

$$IN(33,44)=\{\ \ E_1,(E_2,E_4),(E_3,E_5),E_6\} \tag{24}$$

$$IN\ (22,44)=\ \{(E_1,\ E_6\ ),(E_2,E_5),(E_4,E_3)\} \tag{25}$$

$$IN\ (22,55)\ =\{(E_1,E_3,E_5),\ \ E_3,E_4,E_5\} \tag{26}$$

$$IN\ (33,55)=\ \{(E_1,E_5),\ (E_2,E_4),\ E_3,E_6\} \tag{27}$$

$$IN\ (44,55)=\ \{E_1,E_3,\ (E_2,E_4,E_5),\ E_6\ \} \tag{28}$$

$$IN(11\ \ ,22,\ \ 33)=\ \{E_1,E_2,E_3,E_4,E_5,E_6\} \tag{29}$$

$$IN(11,33,44)\ \ =\{E_1,E_2,E_3,E_4,E_5,E_6\} \tag{30}$$

$$IN(11,44,55)\ \ =\{\ E_1,E_2,E_3(E_4,E_5),E_6\} \tag{31}$$

$$IN(22,33,44)=\ \ \{E_1,E_2,E_3,E_4,E_5,E_6\} \tag{32}$$

$$IN\ (22,33,55)\ \ =\{(E_1,\ E_5),\ E_2,E_3,E_4,E_6\} \tag{33}$$

$$IN\ (22,44,55)\ \ =\{\ E_1,(\ E_{2,}\ E_5),E_3,E_4,E_6\} \tag{34}$$

$$IN(\ \ 33,44,55)\ \ =\{\ E_1,\ (E_2,E_4),\ \ E_3,E_5,E_6\} \tag{35}$$

$$IN\ (11,22,33,44)\ \ =\{E_1,E_2,E_3,E_4,E_5,E_6\} \tag{36}$$

$$IN\ (22,33,44,55)\ \ =\{E_1,E_2,E_3,E_4,E_5,E_6\} \tag{37}$$

The above equations from (11) to (37) represent the indiscernibility; indiscernibility which don't form groups are called as reduct. The studies lead to the following results. As the following indiscernibility does not produce any groups implies that the following indiscernibility leads to a set of reducts.

$$IN(11,33,44),\ IN(22,33,44), IN(11,22,33,44), IN\ (22,33,44,55)$$

$$Core = \cap\ Reduct \tag{38}$$

In this study, the reduct is found to be

$$Core = \cap\ IN(11,33,44),\ IN(22,33,44), IN(11,22,33,44), IN\ (22,33,44,55) \tag{39}$$

= {33}, as 33 is denoted for SCD as SCD is related to cardiac arrest. This study considered the University of California Irvine machine learning repository considered (UCI). We have used several boosting algorithms to find the accuracy. Further Analysis is being conducted using the strength of RST [27]. The result describes the symptoms of cardiac problems given in the following Table VI.

TABLE VI. FINAL REDUCT TABLE WITH TARGET VALUES

EE	aa_1	bb_1	cc_1	dd_1	ee_1	D
EE_1	1	1	1	0	0	1

In the above Table VI, EE represents the records aa_1, bb_1, cc_1, dd_1 ee_1 are the conditional attributes. The above attributes are renamed as aa_1 irregular sleeping habit, bb_1 renamed as fluctuation in pulse rate, similarly cc_1,dd_1, and ee_1 renamed as breathing difficulties, sweating severely to very severe, and abnormal cholesterol level, respectively. The decision attributes d agree with sudden cardiac death (SCD), <0,1> represents insignificant and significant applicable for both conditional attributes and decision attributes.

B. *Training Phase*

The training phase includes the above symptoms taken from Table VII as the input of the study, which is responsible for cardiac arrest or SCD. The training phase used the Naive Bayes classifiers algorithm. The above concept resulted in producing Table VII.

The Fig. 3 represents the RMSE (Root Mean Square Error) vs. Mean Absolute Error (MAE) comparison of various classifiers. The classifiers given in the Table define as Naïve B-Naïve Bayes, Alternate decision tree, reduced error PT-Pruning Tree, C and R- Classification & Regression tree.

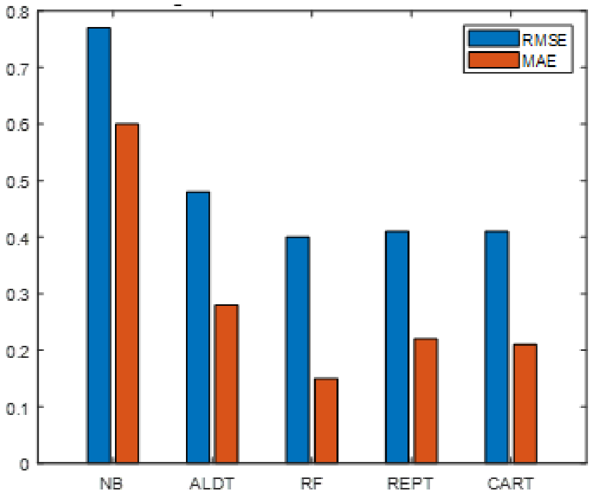

Fig. 3. Error comparison of various classifiers.

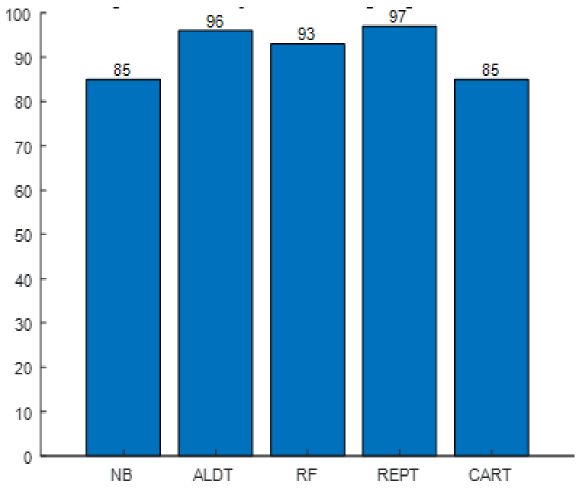

Fig. 4. Comparison of the accuracy of various classifiers.

TABLE VII. WEAK LEARNER COMPARISON

Serial	TIDM	Accuracy	Mean AE	Root mean SE	Relative absolute error	Relative SE	F1-Score
Naïve B	7	85	0.65	0.85	121	128	0.45
Alternate DT	60	96	0.29	0.49	95	96	0.9
Random Forest	2.23	93	0.32	0.45	84	81	0.87
Reduce Error PT	11.45	97	0.28	0.46	98	98	0.85
C and R tree	57	85	0.29	0.58	99	99	0.87

TABLE VIII. STRONG LEARNER COMPARISON / (ADABOOST COMPARISON)

Serial	TIDM	Accuracy	Mean AE	Root mean SE	Relative absolute error	Relative SE	F1-Score
ABNB	19.5	94	0.5	0.77	132	155	0.87
ABAlternate DT	32	94	0.18	0.28	60	98	0.96
ABRF	11	96	0.11	0.25	37	66	0.98
ABRUPT	65	93	0.21	0.41	46	93	0.85
ABCART	96	95	0.23	0.43	42	92	0.87

The Fig. 4 represents the accuracy level of various classifiers with respect to a single classifier application. This study combines various classifiers to get the following results. Applying the combination of two classifiers at a time gives the following output.

ABNB-AdaBoost Naïve Bayes, AB Alternate DT-Adaboost Alternate decision tree, ABRF- Adaboost Random Forest, ABRUPT- Adaboost Reduced error punning tree, ABCART- Adaboost Correlation and regression tree. There are significant increments of accuracy level after the use of additive strong learner method. The entire result of the output is given in the Fig. 3.

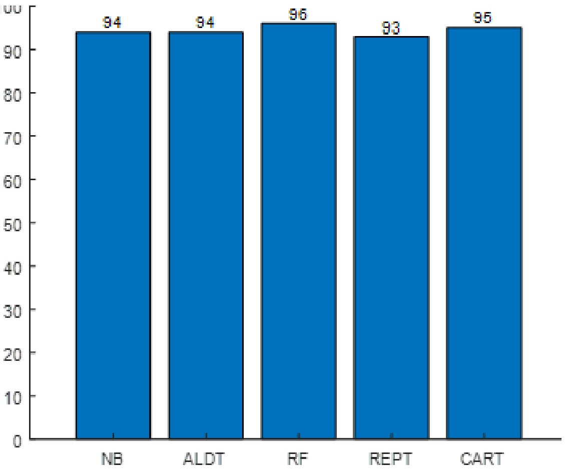

Fig. 5. Accuracy measure of multiple classifiers.

Fig. 5 represents the accuracy level after converting the classifiers from weak learners to strong learner. Subsequently this paper deals with error comparison of single classifiers as well as combinations of classifiers.

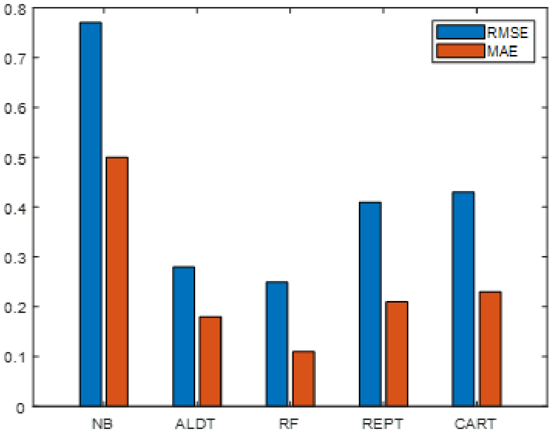

Fig. 6. Error propagation using strong classifier.

The Fig. 6 represents the error rate after using two or more classifiers together. The idea behind this boosting approach is to enhance the accuracy level of prediction and reduced the rate of error margin. This approach also based upon homogeneous classifiers. This concept can be extended for heterogeneous classifiers, with k-fold cross validation and model evaluations. Resulting values using heterogeneous classifiers is given in the following Table IX.

C. Performance Evaluations

1) Entropy: Entropy calculates a structure's impulsiveness or condition. The idea was given by Rudolf Clausius in 1850 suggested this concept. Mathematical model of this concept was given by

$$\text{Entropy} = -\sum k(x)\, log k\,(x) \quad (40)$$

where k(x) is the part of the concept of a given class.

2) Gini index: Gini Index or Gini Coefficient define as the supply of resources in a given population. In general

$$\text{Gini Impurity} = 1 - \sum_{i=1}^{c} k_i\,(x)\ ^2 \quad (41)$$

3) Information gain: The decrease of Entropy attained by varying the information (In this study, information derived from the dataset) is called as information gain, and it is normally employed in the training of DT (Decision Tree). This information gain calculation depends upon the Entropy of the prior and posterior transformation of the dataset. The entire information gain is given by the following mathematical formulas.

$$\text{Information Gain } (k_p,f)=I(k_p)-\frac{R_{left}}{R}I(k_{left}) - \frac{R_{right}}{R}I(k_{right}) \quad (42)$$

4) For unbalanced and vague data sets, accuracy measure depended upon the ratio of the number of perfectly classified instances by the total number of sample instances.

$$\text{Accuracy}=\frac{TNs+TPs}{TNs+TPs+FNs+FPs}, \quad (43)$$

where TN- True negative, TP- True Positive, FN- False Negative, FP- False positive.

Total number positive prediction is called as precision.

$$\text{Precision}=\frac{TPs}{TPs+FPs}, \quad (44)$$

5) Root mean squared error (RMSE), a technique to calculate the forecasting of numeric success

$$\text{Root Mean Squared Error(RMSE)}=\sqrt{\frac{\sum_{i=1}^{n}\left(k_i-{k_i}^{t}\right)^2}{n}} \quad (45)$$

6) Mean Absolute Error (MAE) is the calculation of the absolute difference between actual and expected values

$$\text{MAE}=\sum_{k=1}^{n}\left|l_k - {l_k}^{t}\right| \quad (46)$$

7) Relative Absolute Error (RAE)

$$\text{RAE}=\frac{(k_i-{k_i}^{t})^2}{(k_i-{\overline{k_\iota}}^{t})^2}, \text{ where i varies from 1 to all samples} \quad (47)$$

8) Total Squared Error

$$\text{RRSE}=\sqrt{RAE} \quad (48)$$

Accuracy measure is depicted in table-8

9) Recall

$$\text{recall}=\frac{TPs}{TPs+FNs} \quad (49)$$

10)F1 score: F1-score is the combination of recall and precession

$$\text{F1-score}=2 \times \left(\frac{Pecesion*recall}{Precision+Recall}\right) \quad (50)$$

Where f is the feature split, k_p is the parent dataset, k_{left} and k_{right} are the posterior probability of left and right child node. The equations (39), (40) and (41) are derived from NB classifiers.

D. Application of the Adaboost Technique

The Adaboost technique combines multiple weak classifiers to make it a single strong classifier. The most commonly used AdaBoost algorithm is the decision stumps, an alternative name for these decision trees, as discussed by Hussein et al. [43]. This technique generates a model that distributes equal weights at all data points and subsequently provides points to those data points incorrectly classified with higher weights groups. In the next model, significant importance is given to the data points with higher weights. An error margin of 10^{-3} to 10^{-4} is considered. The process continues till the desired accuracy is achieved, as discussed by Reddy et al.[44].

E. Algorithm for Boosting

Step-1 Initialize the data points (x_i,y_i), for i=1 to n

Step-2 Each i x_i is the instance of space X, y_i is collecting all labels of space Y.

Step-3 for the training instance i by rounding t is given as D_{It} , Initialize the weights as $D_{It}(i)=\frac{1}{M}$, I=1 to M

Step-4 for the total number of samples, find the weight of misclassified according to the standard algorithm increased each step

$$\alpha_{It} = \frac{1}{2} ln \left(\frac{L_{+1}-L_{-1}}{L_{-1}+L_{-1}}\right) \quad (51)$$

Step-5 Use basic logistic regression to adjust overfitting

Step-6 Continue with step 1 to 5 till the desired accuracy is achieved.

To overcome oversampling, a technique called Synthetic Minority Oversampling Technique is being used; the following steps are being implemented, and the results are shown in Table VII to Table IX, accuracy and error like RMSE and MAE are shown from Fig. 3 to Fig. 8. The details of SMOTE are described in the subsequent section.

F. Procedure for SMOTE

Before the SMOTE algorithm, Data pre-processing is required as the classification algorithm's objective is to collect the raw data and create an outline for every class as conclusive with less error margin to attain accurate prediction. The examples that maintain significant distance from outlines form a group more easily than those that are near the outlines. The examples nearer to the outlines are always a challenge for learning existing classifiers. SMOTE provide a significant result in overcoming these challenges.

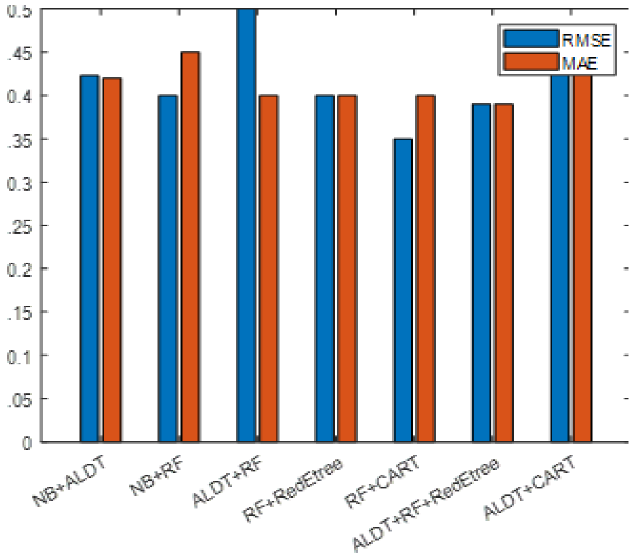

Fig. 7. Error propagation using multiple classifiers.

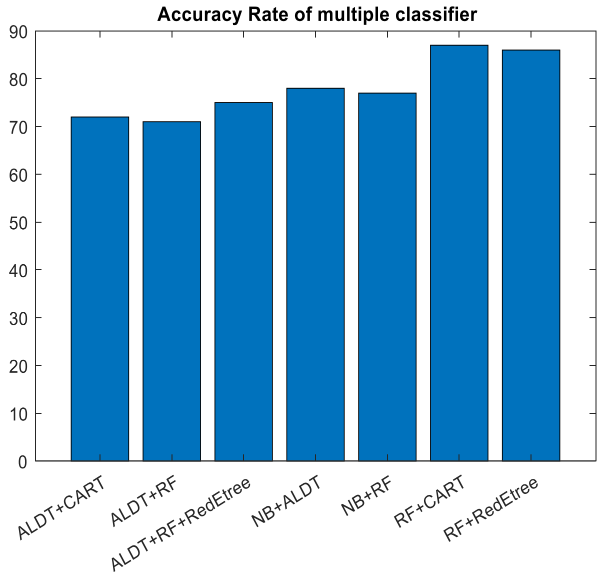

Fig. 8. Accuracy measure using boosting.

TABLE IX. HETEROGENEOUS COMBINATION OF CLASSIFIERS

SL	TTBM	ACCURACY	MAE	RSME	RAE	RRSE	F1 score
NB+ALDT	29	78	0.42	0.423	99.23	96.21	0.74
NB+RF	30	77	0.45	0.4	93	98	0.75
AlDT+RF	400	71	0.4	0.5	81	102	0.7
RF+RedEtree	8	86	0.4	0.4	71	92	0.85
RF+CART	7.5	87	0.4	0.35	71	90	90
AlDT+RF+RedEtree	358	75	0.39	0.39	74	94	99.5
AlDT+CART	599	72	0.45	0.45	89	99	0.64

G. SMOTE for. Classifications

Step-1 This method's objective is to produce examples, by using the concept

$$T=2\times(K\text{-}M) \tag{52}$$

Where K denotes the majority samples of the group, M denotes the minority samples of the group and T initial examples are newly generated. The basic examples generated by SMOTE will be recognized or excluded depending upon two concepts i.e.

Stage-1{ $\widehat{k_1}, \widehat{k_2}, \widehat{k_3}, \dots\dots .\widehat{k_n}$} is the group od example and $\widehat{k_\iota}$(j) is the jth attribute values of $\widehat{k_\iota}$ example.

Where j varies from 1 to the total number of samples. Let R_a and R_b be the minority and majority examples, respectively. The distance d is calculated between $\widehat{k_\iota}$ and R_a and R_b for recognition and exclusion. The distance between $K_{minority}(\widehat{k_\iota},R_a)$, $K_{mejority}(\widehat{k_\iota},R_b)$. There will be total number of n steps. The distance is calculated as

$$K_{minority}(\widehat{k_\iota},R_a) =\sum_{i=1}^{p}\sqrt{\left((\widehat{k_\iota}-\mathrm{Ra})\right)^2} \tag{53}$$

Similarly

$$K_{mejority}(\widehat{k_\iota},R_b).= \sum_{i=1}^{p}\sqrt{\left((\widehat{k_\iota}-\mathrm{Rb})\right)^2} \tag{54}$$

Using equations 52 and 53, majority and minority distances are calculated, as

$$K_{minority}(\widehat{k_\iota},R_a)= (K_1,K_2,\dots\dots ..K_n) \tag{55}$$

$$K_{majority}(\widehat{k_\iota},R_b)= (L_1,L_2,\dots\dots ..L_m) \tag{56}$$

From equation (54), calculate min (K_1, K_2,.., Kn) to find the minimum of a minority; similarly, calculate min (L_1, L_2,……..L_m) to find a minimum of majority.

Step-2 If minimum (minority)<= minimum(majority) out coming examples are accepted else rejected.

Step-3 continue with step 1 to 3 for the entire samples to achieve the required outcomes.

TABLE X. A COMPARATIVE ANALYSIS

1	comparing the results of [17]
	Uses local data collected from
	a particular Hospital/area
	Not a generalized one. This study
	overcomes these problems of prediction
2	comparing the results of [32]

	object recognition is also not a general assumption
4	Overall coAll is this study deals with vague
	and imprecise data for general purposes, the data not collected
	from a particular area and not collected from a particular hospital

The detailed comparison of error analysis and accuracy level was given in Fig. 7 and 8. This study has compared its results with several cited papers in Table X.

H. Statistical Validation of the Result

This study uses statistical methods for the validation of the claim. There are several statistical methods available for Analysis and validation. The generally adopted method for validation is the chi-squared statistical test. This study uses two fundamental statistical techniques, i.e., one dimensional γ^2(Chi-squared test) and two-dimensional chi-squared test for this study.

1) Statistical validation using one dimensional γ^2 test

$$\gamma^2=\sum\frac{(O_i-E_i)^2}{E_i} \tag{57}$$

H_0(Null Hypothesis)-: The above multiple classifiers are not provided accuracy as desired

H_a(Alternate Hypothesis)-: The above multiple classifiers provide desired results as required.

Where O_i is the observed samples, and E_i is the expected samples. A survey is conducted over 10,0000 population by grouping 10,000 per group total of 10 available groups. The observed values are 35,5,10,5,5,10,3, 7,15,5, unit measure in 10,000. With expected values 10%, 25%,5%,5%,25%,30%,45%,5%,10%,15%. So total observed samples are 100,000, and the expected values are 10,25,5,5,25,30,45,5, 10,15.

Calculated γ^2= 160, γ^2 (9,0.05) =16.919, much less than the calculated γ^2 value, so rejected the Null hypothesis. The same data set was also applied on a two-dimensional array and the calculated γ^2 = 21.25 where the tabular values were calculated as 17.23. The null hypothesis is rejected.

V. CONCLUSION AND FUTURE WORK

This study entirely depended upon a vague and imprecise dataset from various parts of our state's Odisha and medical advisory. The initial idea is to group the data set according to its class. The dataset was divided into six categories using logistic regression. Using two concepts of RST, i.e., indiscernibility and strength, showed that SCD/ Cardiac -arrest was the most significant disease among all cardiac-related problems. The subsequent section of the paper used the boosting technique combining several classifiers to measure the error rate and accuracy level. As the combination increases, the accuracy also increases. There was also a comparative analysis of these studies and EMD and EEMD studies in Table X. These studies can be extended to the fields like sports especially making uniforms on cricket fields worldwide, and entertainments like movies more entertaining for common people.

An Improved Artificial Bee Colony Optimization Algorithm for Test Suite Minimization

Neeru Ahuja, Pradeep Kumar Bhatia
Dept. of Computer Science and Engineering, Guru Jambheshwar University of Science and Technology,
Hisar, Haryana, India-125001

***Abstract*—Software testing is essential process for maintaining the quality of software. Due to changes in customer demands or industry, software needs to be updated regularly. Therefore software becomes more complex and test suite size also increases exponentially. As a result, testing incurs a large overhead in terms of time, resources, and costs associated with testing. Additionally, handling and operating huge test suites can be cumbersome and inefficient, often resulting in duplication of effort and redundant test coverage. Test suite minimization strategy can help in resolving this issue. Test suite reduction is an efficient method for increasing the overall efficacy of a test suite and removing obsolete test cases. The paper demonstrates an improved artificial bee colony optimization algorithm for test suite minimization. The exploitation behavior of algorithm is improved by amalgamating the teaching learning based optimization technique. Second, the learner performance factor is used to explore the more solutions. The aim of the algorithm is to remove the redundant test cases, while still ensuring effectiveness of fault detection capability. The algorithm compared against three established methods (GA, ABC, and TLBO) using a benchmark dataset. The experiment results show that proposed algorithm reduction rate more than 50% with negligible loss in fault detection capability. The results obtained through empirical analysis show that the suggested algorithm has surpassed the other algorithms in performance.**

Keywords—Test suite; test suite minimization; TLBO; ABC; nature inspired algorithm

I. Introduction

Software engineering deals with the design, analysis, implementation, maintenance and testing of software. Once software is evolved, its defects and shortcomings are analyzed with the help of software testing [4]. Out of various testing methods, the regression testing is very important as it involves the modification or insertion of a code into the already working code [8]. More is the size of test suite more will be testing time for each run. This testing time even varies in weeks also. It becomes difficult for a developer to get early feedback of the software developed. Therefore, the developer cannot fix the problems arising into the software timely [1]. So, no more changes could be done in the software and root cause of test suite failure could not be fixed. Software engineers must utilize their time and resources effectively to prevent these issues [2]. A lot of researchers have carried out their work in this particular area [3]. Test case selection (TCS), test case prioritization (TCP), and test case minimization (TCM) are three techniques used to handle complex problems associated with testing.

Test case selection (TCS) [21] is used to choose the test cases for the modified portion of the software. The test cases chosen from the test suite may depend on how well the selection process works. According to a specific criterion, test cases are prioritized, and the highest priority test cases are run first to achieve particular objectives. During test suite reduction, redundant test cases are removed from test suite [31]. Test case minimization, which gets rid of unnecessary ones, speeds up regression testing. The utilization of TCM depends on how it will help minimize time and cost for a particular software [6]. Based on criteria, minimization can reduce the size of test suite. There exist different criteria like path coverage, statement coverage, fault coverage, etc. It's important to always keep in mind that minimization of any kind carries risk and might not offer complete coverage. It might also omit some fault revealing test cases. The size of the test suite, effectiveness, fault detection cost, and execution time are the important parameters of software that should be measured at the time of reduction. The effectiveness of software is decided by measuring these parameters. The comparison of a reduced suite with a corresponding unreduced suite using criteria other than suite size is also an important issue. As the testing basically involves the detection of faults in the software, it can be said that fault detection capability is one of the measures for test suite quality. An important shortcoming of the reduction process is the complete elimination of test cases from a suite, which may lead to a decrease in the fault detection capability and effectiveness of the remaining suite. Thus, a proper exchange between fault detection effectiveness and execution time should be taken into account before the implementation of TSR [7]. Therefore, the problem of test suite minimization could be considered an NP-hard problem. Optimization techniques efficiently solve these problems. Therefore, it can also be said that effectiveness and efficiency can be increased in regression testing through optimization techniques. Optimization helps us extract the best fit solution for the problems [36]. Soft computing uses artificial intelligence and natural selection to solve very complex problems that analytical (hard computing) formulations cannot solve. By incorporating soft computing techniques in optimization, we can further improve the accuracy and speed of regression testing. Soft computing can handle uncertainty and imprecision in data, making it a valuable tool for optimizing complex systems. Many researchers have investigated different techniques to minimize test suite while maintaining the coverage as maximum as possible [34,37]. CMIMX technique with a prominent soft computing technique (ABC) was implemented to ensure the reduced set with maximum fault coverage [20]. This paper proposed a new hybrid algorithm for test suite minimization. The proposed algorithm attains the minimize test suite with maximum coverage. The minimize test case achieve it by selecting two objectives. First, the algorithm aims to identify the minimized test suite that achieves maximum statement coverage. Second, it should also satisfy the fault detection capability of selected test cases. To accomplish our objective we have selected Artificial Bee Colony and Teaching Learning based optimization. The key contributions of our presented work are summarized as follows:

- Integration of TLBO operator into ABC algorithm for enhanced search performance.
- Introduction of learner's performance concept to accommodate varying abilities.
- Minimization of test suite while maintaining optimal test case coverage.
- Analysis of fault coverage loss resulting from test suite minimization.

The remaining of this paper is organized as follows:

Section II describes the literature study related to minimization techniques. The technical background of the techniques explained in Section III. Section IV illustrates proposed methodology. Experimental details are present in Section V. Section VI describes conclusion and future work.

II. State-of-the-Art

In this section, we present a comprehensive review of the existing literature on test suite minimization techniques for addressing NP-hard problems. Researchers have extensively explored the application of soft computing techniques to tackle these challenging problems [35]. We summarize the key findings and contributions of various studies in Table I, highlighting the author names, techniques used, coverage criteria, and defined results.

ABC and TLBO algorithms have emerged and popular algorithm of literature and demonstrated the promising results across the different domains like long-term economic dispatch problem in hydropower systems [11]. Rao et al. initially proposed simple TLBO, which lack an inertia weight value [15]. I-TLBO, an enhanced version of TLBO was developed with the concept of adaptive teaching strategy and self-learning [13]. It was implemented to strengthen the exploration and exploitation capabilities. Zhang et al. [17] integrated TLBO algorithm into onlooker bee phase. Additionally, a novel searching approach for the bee phase was used to enhance population variety and quicken convergence. One such technique is FATLBO in which F and A stands for fuzzy and adaptive. This technique used fuzzy logic to adaptively adjust the parameters of TLBO algorithm [18]. LebTLBO was proposed by Chen et al. [14] to increase the performance of TLBO by incorporating the learning enthusiasm mechanism. It is clear from the literature review that previous research has mostly focused on test suite minimization using various coverage criteria. However, there are a number of gaps in the available literature, including a lack of analysis on fault coverage and limited use of the ABC algorithm and TLBO algorithm in the context of minimization principles. Therefore, we presented ABC and TLBO technique with addition of learning factor to enhance the capability to search more solution space. We suggest a unique method for test suite minimization termed Learner performance-based ABC and TLBO (LpABTLO) to fill these gaps. This method uses statement coverage as the coverage requirement and subsequently analyses fault detection loss.

Our suggested LpABTLO technique aims to fill these gaps in order to develop test suite minimization techniques and deliver more thorough insights into fault coverage analysis.

III. Technical Background

This section gives a technical overview of the TLBO algorithm and ABC, two key optimization strategies. These approaches gained a lot of focus in the different fields to solve optimization problems.

A. *Artificial Bee Colony Algorithm (ABC) [38]*

The novel swarm-based stochastic optimization method known as ABC, developed by Karaboga, mimics the foraging behavior of honey bees [33]. Honey bees are organized into three groups in ABC: workers, bystanders, and scouts [9]. Employee bees compose the initial half of the colony, and observer bees made up the remaining half [10]. During the employee bee phase, bees search for a food source and collect data on its quality. As a result, only one bee is assigned to each food source [11]. The food source with the higher fitness value is more likely to be picked by onlookers than the one with the lower fitness value. Each onlooker bee then searches for a nearby food source close to the selected one and reserves the best among them. If a food source remains unchanged for a specific period of time, the associated employed bee turns scout and explores a new food source randomly [12]. Fig. 1 explains the working of algorithm.

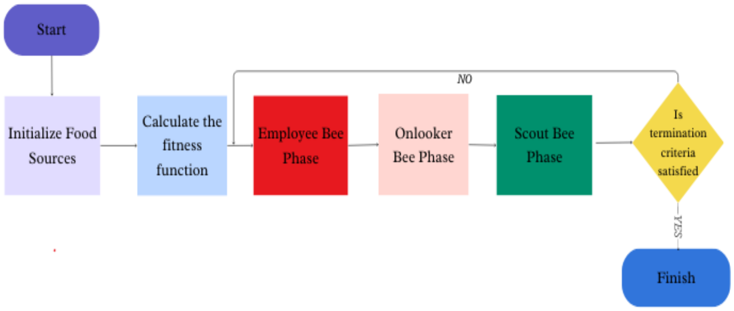

Fig. 1. Flowchart of ABC algorithm

TABLE I. DEFINES THE LITERATURE STUDIES OF VARIOUS RESEARCHERS

Author Name	Technique	Coverage Criterion	Defined Result
Khan et al. [27]	GA and mutation analysis	Software testing efficiency	Optimized software testing efficiency through GA and mutation analysis

B. *Teaching-Learning-based Optimization (TLBO) Algorithm [15]*

Rao et al. developed the TLBO algorithm that is a population-based optimization algorithm used to handle mechanical design optimization issues [15]. However, when solving complex optimization problems, the TLBO algorithm frequently encounters the issue of getting trapped in local optima [14]. Although it has consistently outperformed other evolutionary algorithms in theoretical and practical tests, the impact of control parameters on TLBO's performance cannot be overlooked [16]. The TLBO algorithm is composed of two distinct phases: the Teacher Phase and the Learner Phase. In the Teacher Phase, the teacher aims to enhance the students' knowledge. However, the progress of the students is not solely determined by the teacher's expertise, but also influenced by the mean level of the entire class [15]. Fig. 2 illustrates the working of TLBO.

IV. PROPOSED METHODOLOGY

This section presents a proposed model for test suite minimization problem as shown in Fig. 3. The proposed work is composed of three modules. The pseudo code of proposed work is described in algorithm 1.

We have developed model for test suite minimization problem as illustrated in Fig. 3. There are three components comprise the proposed work. Algorithm 1 defines the pseudo code of proposed work.

Algorithm 1. Hybrid Artificial Bee Colony

```
Begin
Define max_gen , max_population
Initialize Food source(population)
Evaluate fitness function
For i=1: max_gen
    For i=1: max_population
        Teacher based employee bee phase as shown in Algorithm 2
        Learner based onlooker bee phase as shown in Algorithm 3
        Update teacher and mean
        Memorize the best solution
        Scout Phase
    End for
End for
Find the fault detection capability as shown in Algorithm 4
End
```

A. Dataset Extraction Module

We have taken programs from different sources. As we know minimization techniques are based on adequacy criteria. Statement coverage and fault coverage matrix are extracted from source code.

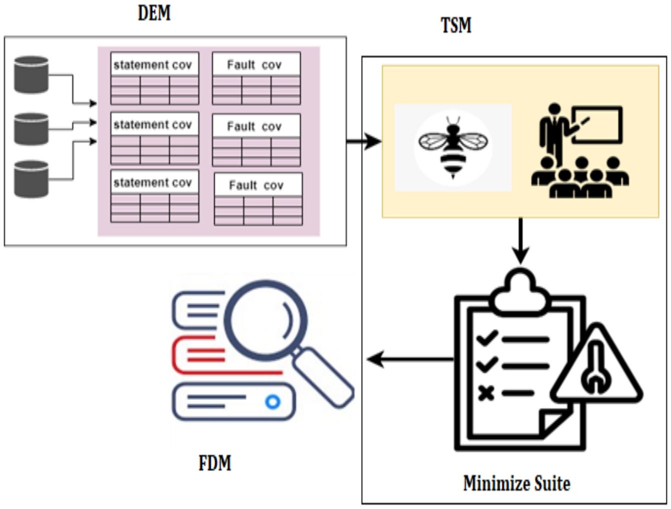

Fig. 3. Framework of proposed algorithm.

B. Test Suite Minimization Module

Second module describes the working of hybrid technique. There are two important factors related to heuristic optimization methods. The first is called "exploration," and it entails a comprehensive search of the space while providing a variety of potential solutions at each stage. This factor demonstrates a method's ability to perform well in a global search. Exploitation, or the quality of solutions attained during each cycle, is the other consideration. This metric demonstrates a technique's capability in performing a local search and locating the optimal response close to a solution. These two considerations are in opposition to one another and deserve to be pointed out. Thus, if you prioritize global search over local search (i.e. exploitation), you may end up with a poor final best answer, and vice versa [30]. In the proposed technique two popular soft computing techniques ABC and TLBO are amalgamated with each other. It is developed by incorporating the exploitation capability of TLBO with changes. Both the techniques are complementary to each other.

In the hybrid model we incorporated two significant changes to algorithms. First, instead of employee and onlooker bee phase, teacher and learner phases are embedded into model. ABC algorithm uses the same perturbation for Employee bee and onlooker bee. Therefore, ABC algorithm stagnates from the capability of exploitation. To solve this issue we have embedded the teacher and learner phase of TLBO algorithm into employee and onlooker bee phase with modification in operator.

Second, from the literature we have observed that TLBO and its variants use same approach to update the knowledge of learners in the both phases of TLBO. Every student is unique, and their level of zeal for learning varies [14]. Some students are more interested to gain knowledge on other hand others shows less interest in studies and neglect the knowledge gained from others. As the result of this thought we have divided the learners according to learner performance.

The main aim of this approach is to identify a smaller group of test cases that can cover the maximum statements while still providing the same level of coverage like the original test suite. Additionally, the proposed approach also checks the fault coverage for selected test cases.

1) Population initialization: The algorithm starts with random initialization of food source (test suite) using permutation encoding. In permutation encoding, test cases will not be repeated, and only unique test case can be part of a test suite. Like, TS1= [8, 99, 21, 43, 23, 56]. Set dimension, trail counter and limit.

2) APSC: It is essential to assess the quality of all the population's food sources to evaluate the effectiveness of a potential solution provided by that food supply. The objective function allows selecting the best individual that leads to a good solution and validates the process's deviation from its optimization target. The objective of the problem is to reduce the number of test cases while still providing maximum statement coverage.

The average percentage of statement coverage (APSC) formula is defined in (1).

$$\text{Maximize } APSC = 1 - \frac{\sum_{i=1}^{n} \mathrm{scov_i}}{n*m} + \frac{1}{2*n} \quad (1)$$

Here, n and m represents the total number of test cases in test suite and statements.

3) Fitness function: Fitness functions are employed in simulations to steer them towards the best possible design solutions.

Fitness function is calculated using (2)

$$Fit(f(x) = \begin{cases} \frac{1}{1+f(x)} & f(x) \geq 0 \\ 1 + abs(f(x) & f(x) < 0 \end{cases} \quad (2)$$

Here, f(x) represents the objective function, i.e., calculated in eq. 1.

4) Teacher-based employee bee phase: In the basic TLBO bees positions are updated using eq.3.

$$x_{i,new} = x_{i,old} + rand\left(x_{teacher} - t_f * x_{mean}\right) \quad (3)$$

Here, t_f represents the teacher factor whose value can be 1 or 2 and is calculated as

$t_{f.}$= round[1+ rand(0,1)].

Mean($\mathbf{x_{mean}}$) can be calculated by using eq. 4

$$x_{mean} = \frac{\sum_{i=1}^{np} x_i}{\mathrm{np}} \quad (4)$$

Here np is number of bees.

But it suffers from poor diversity issue. To overcome this issue, DE (differential equation) mutation [19] is utilized. Though teacher strategy is hybridized with DE (differential equation) mutation is done to update learner's position by eq. 5. The steps of teacher based employee bee phase are shown in algorithm 2.

$$x_{i,new} = \begin{cases} x_{i,old} + rand * \left(x_{teacher} - t_f * x_{mean}\right) & if\ rand < .5 \\ x_{r1} + f(x_{r2} - x_{r3}) & else \end{cases} \quad (5)$$

Here rand denotes uniformly distributed random number within [0,1]. r1, r2, and r3 are random solutions from {1…np} and r1, r2, r3 cannot be equal. f represents the scaling factor between 0 and 2.

Algorithm 2 Teacher based Employee Bee Phase

```
Step1 Select the best bee as $X_{best.}$
Step2 Calculate mean ($X_{mean}$) of all learner bees.
Step3 Generate the new bee according to DE mutation eq. 5
Step4 Calculate fitness function for new bees.
Step5 Accept new bee if it is better than old ones.
```

5) Tournament selection: Roulette wheel selection is based on a proportionate selection technique in which the best wheel can be chosen or not. We adopted tournaments to solve this problem. A tournament is a match involving several known-sized competitors who are randomly selected to compete. The value of each individual's fitness is used to select the winner. The size of the tournament is determined by the number of participants.

6) Learner-based onlooker bee phase: As we have already discussed, in basic TLBO no variation exists while gaining knowledge among learners. Therefore, in the learner phase, we have used a factor called learner performance (Lp). Learner performance formulates variation in the best student's and other student's knowledge. If students have knowledge greater than the learner performance value, they will improve their knowledge by interacting with the best one as in equation 6. Otherwise, the criteria for gaining knowledge gain will be the same as basic TLBO as specified in equations 7 and 8. We have tried the value of Lp from [0.7, 1] by trial and error method, out of which 0.8 is the best-suited value. Those students with a learning performance of 0.8 or more will learn from the best learner or teacher.

$$x_{nbest} = x_{best} + rand\left(x_{best} - x_j\right) \quad (6)$$

$$x_{new,i} = x_{i,old} + rand(x_{best} - x_i) + rand\left(x_i - x_j\right) \quad (7)$$

$$x_{new,i} = x_{i,old} + rand(x_{best} - x_i) + rand\left(x_j - x_i\right) \quad (8)$$

The steps to Learner-based onlooker bee phase are described in algorithm 3.

Algorithm 3 Learner based Onlooker Bee Phase

```
Begin
Initialize food source(population)
for each learner $x_i$
    If $f(x_i)<f(x_j)$
        If Lp>$f(x_j)$
            Update the new bee using equation 6
        else
            Update the new bee using equation 7
        end If
    else
        Update the new bee using equation 8
    end If
    Calculate fitness function for new bees.
    Accept new bee if it is better than old ones.
end for
End
```

7) Scout phase: When an employee bee's food source reaches a predetermined limit, it is reclassified as a scout bee. Similar to the worker bee phase, the new random scout bee is formed randomly. If this happens, the previous methods should be updated with the new bee solution.

C. Fault Detection Capability

There are different criteria for minimizing test suites. In the proposed technique, we have selected statement coverage as the criterion. However, the effectiveness of the technique can be checked by detecting losses for other criteria. Since one criterion can affect others, we have evaluated fault-revealing capability of the reduced test suite, as shown in Algorithm 4.

Algorithm4. Fault Detection Capability Algorithm

```
Begin
Define Reduced test suite (RTS), Total Faults(TF), Fault matrix (FM)
Initialize variable F=0
For i=1: size (RTS)
    a= RTS[i]
    For j=1: size (FM)
        If (FM[a][j]==1)
            F=F+1
        End if
    End for
    Calculate detected faults by ((F/TF)*100)
End for
End
```

V. Experimental Evaluation and Results

In this subsection, we use benchmark programs to evaluate our proposed algorithm. Using Matlab2016a, we performed the experiments on a personal computer with a 2.00 GHz/core (i3) CPU and 4GB of memory. In order to validate the effectiveness of the proposed algorithm, a comparative analysis was conducted between its results and those obtained from the ABC, TLBO, and GA algorithms. Each algorithm was executed 20 times. The evaluation metrics used, the data sets explored, and the outcomes of the experiments are all detailed here.

A. *Evaluation Metrics*

To rigorously evaluate and compare the effectiveness of our proposed approach with state-of-the-art methods, we leveraged well-established structural coverage measures. These measures have been widely adopted and extensively studied as reliable indicators of a test suite's efficacy. By employing these measures, we aimed to provide a robust performance evaluation of our algorithm. Table II illustrates the evaluation metrics.

B. *Dataset*

For the validation of the algorithm, we used datasets from different sources [30, 29]. These programs vary in size from small to large, helping to determine whether performance variations are due to test suite size scalability.

C. *Computational Analysis and Discussion on Results*

In this subsection, we calculated the outcomes of the proposed algorithm and evaluated it in comparison to the other algorithms. Our proposed approach has undergone a comprehensive evaluation, focusing on two key factors: efficiency and effectiveness. Through rigorous testing and analysis, we have thoroughly assessed the performance of our approach in terms of these crucial aspects. The effectiveness of the program is measured by the APRS, APSL, and APFL, while efficiency is measured by the execution cost. Therefore, APCR is used as efficiency metric.

1) Efficiency: The efficiency of the algorithm is assessed by measuring the execution cost required to find the reduced test suite. As we know, the larger the test suite, the higher the computational cost. Reduction of the test cases can help to decrease the total computational cost. Table III illustrates the cost reduction percentage achieved by reducing the test suite size compared to the original cost. As determined from Fig. 4, TLBO performed best for large-sized programs, followed by the proposed algorithm, ABC-TLBO, GA, and ABC. There is a minor difference in the result of the proposed and TLBO algorithms. For small-sized programs, the proposed algorithm performed best. The difference between the proposed and ABC-TLBO algorithms was less for small-sized programs. As evident from Table III, the execution cost difference between algorithms is merely a fraction of a second. Therefore, while weighing the benefits of the algorithm, efficiency plays a relatively small role in algorithm selection. TLBO performed best, followed by the proposed algorithm, ABC-TLBO, GA, and ABC.

2) Effectiveness: Removing unnecessary test cases may affect the fault detection capability. Table IV shows the experimental outcomes of LpABTLO and other algorithms on the minimization problem. It is clear from Fig. 5 that LpABTLO reduces more test cases than other algorithms. LpABTLO reduces 51% of test cases without compromising the fault detection rate. Moreover, as the size of the program and the number of test cases increase, the reduction rate also increases for all the techniques. However, LpABTLO reduction is higher than other techniques. It provides the optimal result. The comparative analysis for statement coverage is presented through Fig. 6. For small-sized programs, the statement coverage of LpABTLO and ABC-TLBO is similar, but ABC lags behind GA and TLBO. ABC-TLBO is the second best after LpABTLO in coverage without any fault loss in small-sized programs. For large-sized programs, LpABTLO and ABC-TLBO attain 96.91% and 96.43%, respectively, while GA, ABC, and TLBO get 94.32%, 92.56%, and 94.51%, respectively. By utilizing statement coverage as a metric for testing, we have also examined the loss in fault detection capabilities resulting from reduced test cases. The percentage of fault-detection loss is depicted in Fig. 7. The figure shows that LpABTLO has the least fault coverage loss compared to other algorithms. GA has the maximum fault coverage loss after ABC. The technique that can reduce the size of the test case, cover maximum statements, and without loss in fault detection capability is the best choice for selection. LpABTLO covers all the conditions. Hence, LpABTLO is superior to other techniques.

TABLE II. REPRESENTS THE EVALUATION METRICS

Metric	Formula	Definition
Average percentage of reduced size	APRS = ((OTS – Ored) / OTS) * 100	Percentage of reduced test suite's size compared to the original test suite. Higher value of RSP is better.
Average percentage of fault detection capability loss	APFL = ((F - Fred) / F) * 100	Quantifies the degree of fault coverage loss in the reduced test suite compared to the original test suite. Lower value of APFL is better.
Average percentage of statement coverage loss	APSL = ((S - Sred) / S) * 100	Quantifies the degree of statement coverage loss in the reduced test suite compared to the original test suite. Lower value of APSL is better.
Average percentage of Cost reduction	APCR = ((E - Ered) / E) * 100	Measures the extent of cost reduction achieved during the test suite reduction process.

VI. Conclusion

Regression testing is considered an NP-hard problem. Optimizing methods can be used to solve these issues by identifying the optimal approach. We have proposed a hybrid algorithm with a combination of ABC and TLBO. As the ABC algorithm uses the same perturbation for the Employee bee and onlooker bee, it stagnates from the capability of exploitation. To solve this issue, we have embedded both phases of the TLBO algorithm into the employee and onlooker bee phase with modification in the operator. The algorithm found the results in two steps. Firstly, it removes redundant test cases to have maximum structural coverage. Further, it checks the fault revealing capability loss due to minimization. We have tested the proposed algorithm against ABC, TLBO, and ABC-TLBO on different-sized programs. It has been determined that the proposed algorithm outperforms than the constituent.

***Abstract*—Autism Spectrum Disorders (ASD) are among the most critical health concerns of our time. These disorders typically present challenges in social interaction, communication, and exhibit repetitive behaviors. To diagnose and customize medical treatments for ASD effectively, the development of robust neuroimaging biomarkers is indispensable. Although extensive studies have recently delved into this area, only a handful have explored the differences between ASD and NC. This study aspires to shed light on this relationship by analyzing both structural and functional brain data associated with ASD. We aim to provide an extensive characterization of ASD by combining techniques of structural and functional analysis. The framework we propose is based on analyzing the differences in structural and functional aspects between ASD and development control (DC) subjects. The study leverages a substantial dataset of 1114 T1-weighted structural and functional Magnetic Resonance Imaging comprising 521 individuals with ASD and 593 controls, ranging in age from 5 to 64 years. These subjects are divided into three broad age categories. Utilizing automated labeling, we compute the features from subcortical and cortical regions. Statistical analyses help identify disparities between ASD and DC subjects. Principal Component Analysis (PCA) is employed to select the most discriminative features, which are subsequently used for classifying the two groups via an Artificial Neural Network (ANN) analysis. Our preliminary findings reveal a significant difference in the distribution of all tested features and subcortical regions between ASD subjects and DC subjects. Through our work, we contribute towards an enhanced understanding of ASD, potentially paving the way for future research and therapeutic interventions.**

Keywords*—Autism spectrum disorder (ASD); Magnetic Resonance Imaging (MRI); functional Magnetic Resonance Imaging (fMRI); Artificial Neural Network (ANN)

I. Introduction

The nature of Autism Spectrum Disorder (ASD) is multilayered and intriguing, with its diverse manifestations affecting various aspects of an individual's life[1]. From social communication and behavioral patterns to intellectual abilities, ASD presents an array of symptoms that make it a unique neurodevelopmental disorder. An estimated one in every 54 children is affected by ASD globally, underscoring its significant prevalence [2]. Despite this high occurrence, the causes of ASD remain enigmatic. Multiple genetic and environmental risk factors have been identified, yet they only partially explain the incidence of ASD. Consequently, rigorous research efforts continue to seek a deeper understanding of ASD's intricate etiology and neurobiology.

Advancements in the field of neuroimaging have significantly contributed to our understanding of neurodevelopmental disorders such as ASD. From purely descriptive studies of the brain's anatomy, neuroimaging research has evolved to explore the profound neurodevelopmental alterations that occur in these conditions. Modern imaging techniques such as Structural Magnetic Resonance Imaging (sMRI) and functional Magnetic Resonance Imaging (fMRI), combined with state-of-the-art computational tools and machine learning algorithms, have provided unprecedented insights into the structural and functional anomalies associated with neurodevelopmental disorders. This development has brought about a paradigm shift in our understanding of these conditions, with a newfound focus on identifying potential biomarkers that can serve as quantitative indicators of specific brain abnormalities.

MRI is an indispensable tool in ASD research, enabling non-invasive imaging of brain structure, connectivity, and function. Structural MRI studies have identified various alterations in brain regions involved in social communication, language processing, executive functions, and sensory integration in individuals with ASD. Functional MRI, on the other hand, has been pivotal in uncovering disrupted functional connectivity, particularly in regions responsible for social cognition and emotion processing. MRI's widespread utilization in ASD research has undoubtedly been instrumental in enhancing our understanding of the disorder's neurobiology.

In-depth analysis of specific neuroanatomical regions has revealed that ASD is associated with certain alterations in brain structure, contributing to the varied cognitive and behavioral phenotypes observed in these individuals. Volumetric analysis of specific brain regions has reported differences in brain volumes between individuals with ASD and typically developing individuals. Similarly, cortical thickness analysis has identified disparities in the cerebral cortex's thickness between these two groups. The integration of these structural findings with functional studies has resulted in a holistic understanding of the neurobiological underpinnings of ASD (Appendix A)

Our research aims to extend these efforts by considering all the neuroanatomical regions implicated in ASD. Utilizing a sophisticated automated processing pipeline, we perform a comprehensive analysis of both 3D volumetric and functional brain regions. This inclusive approach ensures that we capture the full range of structural and functional abnormalities associated with ASD. Our work incorporates texture features derived from global descriptors and local textural features for the structural analysis, combined with statistical and temporal features for the functional analysis. This holistic approach allows us to identify unique volumetric and functional signatures of ASD, with the potential to contribute significantly to early detection, diagnosis, and monitoring of the disorder.

The organization of this paper is as follows: Section II delineates the primary methodology used in our study, encompassing both structural and functional analyses. In Section III, we present the outcomes of our research, along with a thorough discussion on the effectiveness and implications of our proposed approach. The limitations of our study are discussed in Section IV. Finally, we draw conclusions from our findings in Section V.

II. Materials and Methods

This chapter elaborates on the methods utilized in our study to distinguish autism using MRI and fMRI data. Initially, we detail the preprocessing steps for data standardization. Then, we describe how significant features were extracted from the imaging data. Finally, we explain the classification techniques used to differentiate between autistic and neurotypical individuals. This approach allows us to identify potential autism biomarkers and understand the underlying neural mechanisms. You will find the pipeline of our structural method in the Fig. 1.

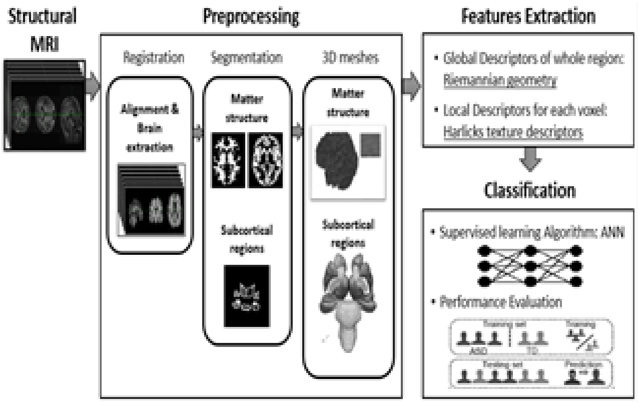

Fig. 1. Pipeline of the structural analysis methods for the characterization of ASD.

A. Structural Analysis

- Preprocessing of sMRI

MRI registration is a key step in neuroimaging studies, aligning multiple MRI images for spatial correspondence. Commonly, the Montreal Neurological Institute space (MNI 152 space) is used as a reference for this alignment. This process involves an initial reorientation of MRI scans, with anatomical labels defined to correct any discrepancies. Then, we perform a skull stripping or brain extraction step to isolate brain tissue from non-brain elements, using methods like the Optimal Surface Thresholding (OST). This step is crucial in reducing potential artifacts in subsequent MRI analyses (Fig. 2).

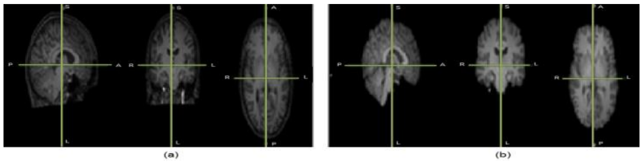

Fig. 2. An example of the brain MRI registration with an original MR image of brain (a) and registered image (b).

- Segmentation of the Regions of Interest

In our research, we apply an automatic method for identifying and segmenting brain regions of interest (Appendix B) relevant to ASD using both probabilistic and anatomical models. A Bayesian probabilistic approach, based on Markov modeling, is used for accurate identification and segmentation of ROIs. This approach incorporates prior knowledge about brain structures, facilitating accurate ROI identification. Markov random fields (MRFs) account for spatial dependencies between neighboring elements in the image, enforcing spatial continuity and reducing the impact of noise[3].

$$P(A|B) = (P(B|A) * P(A))/P(B) \quad (1)$$

Where:

P(A | B) is the posterior probability of event A occurring, given that event B has occurred.

P(B | A) is the likelihood of event B occurring, given that event A has occurred.

P(A) is the prior probability of event A occurring.

P(B) is the marginal probability of event B occurring.

The process involves formulating a model incorporating Bayesian probability theory and Markov models, estimating model parameters using the maximum likelihood estimation (MLE), and iteratively refining the model using the Expectation-Maximization (EM) algorithm[4]. The final step is image classification and segmentation using maximum a posteriori (MAP) estimation, assigning each pixel or voxel to a specific ROI based on the most probable assignment given the observed data and the model parameters.

$$MLE\ (\theta) = argmax(P(X|\theta)) \quad (2)$$

where θ represents the model parameters, X denotes the observed data, and P(X | θ) is the likelihood of the data given the parameters. During this process, we account for the natural variability in the image data and consider the spatial dependencies between neighboring elements[5].

$$MAP(\theta) = argmax\big(P(\theta|X)\big) \quad (3)$$

where θ represents the model parameters, X denotes the observed data, and P(θ | X) is the posterior probability of the parameters given the data (result in Fig. 3).

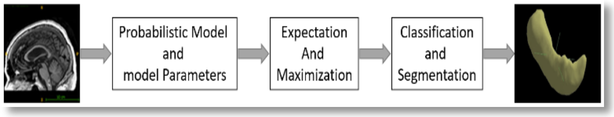

Fig. 3. Segmentation steps of left hippocampus.

- 3D mesh construction

Medical imaging and computer vision often require the transformation of raw image data into a format more suitable for analysis, and 3D mesh models fill this need. The process begins with image segmentation, followed by surface extraction, and finally, mesh generation. The surface of the target object is extracted using the Marching Cubes algorithm, which divides the 3D volume into a grid of small cubes and forms a polygon configuration within each cube based on whether corners lie above or below a certain threshold. This creates an interconnected surface approximating the boundary of the target structure.

Next, mesh generation connects points on the surface to form polygons in a process known as triangulation, resulting in a 3D mesh composed of numerous triangles. This mesh model, which represents the 3D shape of the target object, provides a detailed and accurate foundation for further analysis, visualization, or computation (result in Fig. 4).

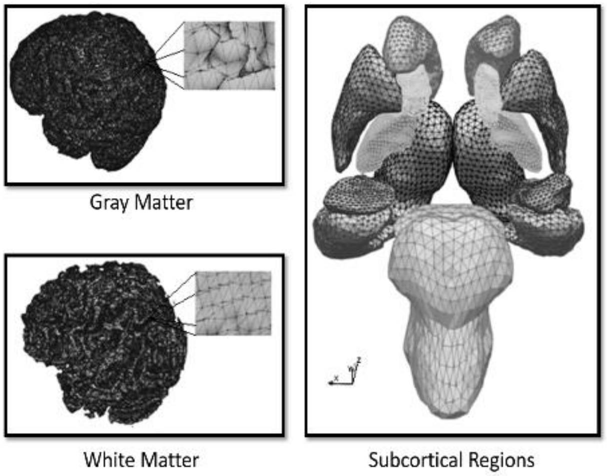

Fig. 4. 3D Meshes structures.

- Feature extraction of sMRI

The analysis of anatomical MRI data involves a pivotal phase known as feature extraction. This step translates complex 3D images into measurable, actionable information by identifying and quantifying various properties of the structures within the images. This process plays an integral role in exploring potential biomarkers for Autism Spectrum Disorder (ASD). Feature extraction focuses on two primary categories: geometric and texture features.

Geometric features provide information about the shape and structure of areas within the brain, helping to understand physical alterations related to ASD. Texture features, on the other hand, capture intensity variations within a region, revealing patterns that might indicate different tissue types or states, and possibly reflecting microstructural properties of the brain regions linked to neurodevelopmental changes in ASD.

In this study, multiple mathematical and statistical methods are applied to calculate these features. Riemannian geometry is used to understand the intrinsic curvature of surfaces and spaces. It allows for the computation of the area, volume, isoperimetric ratio, convexity ratio of the surface and volume, and Gaussian and Mean curvatures.

Haralick texture features, or Gray Level Co-occurrence Matrix (GLCM) features, provide a statistical snapshot of the texture. Several statistical measures are derived from the GLCM, including the Angular Second Moment (or Energy), Contrast, Correlation, Variance, Inverse Difference Moment (or Homogeneity), Entropy, Sum Average, Sum Variance, Sum Entropy, Difference Variance, and Difference Entropy (Annex B).

By combining geometric and texture feature extraction, a comprehensive picture of the structural changes associated with ASD is captured. This approach goes beyond traditional measures and explores a broader spectrum of potential biomarkers. Through statistical analysis of these features, patterns can be identified that could serve as reliable biomarkers for ASD, enhancing our understanding of this complex condition and potentially informing future diagnostic and therapeutic strategies.

B. *Functional Analysis*

- Preprocessing of fMRI

The preprocessing of fMRI data begins with obtaining raw scan data. This data then undergoes several steps to enhance its quality and reliability (Fig. 5). These steps include:

Motion Correction: This process is used to minimize the effects of head movement during the scan. The process involves realigning all volumes acquired during an fMRI scan to a reference volume to eliminate motion-related artifacts.

Slice Timing Correction: This step compensates for the time difference between the acquisitions of different slices in each volume. The correction aims to align the signal from all slices as if they were acquired at the same time, improving the accuracy of the data.

Registration: This process aligns different sets of data into one common space. It involves within-subject registration (aligning images from the same individual) and between-subject registration (aligning images from different individuals to a standard template).

Spatial Normalization: This involves transforming individual brain images to fit into a standard template, enabling group analyses and inter-subject comparisons.

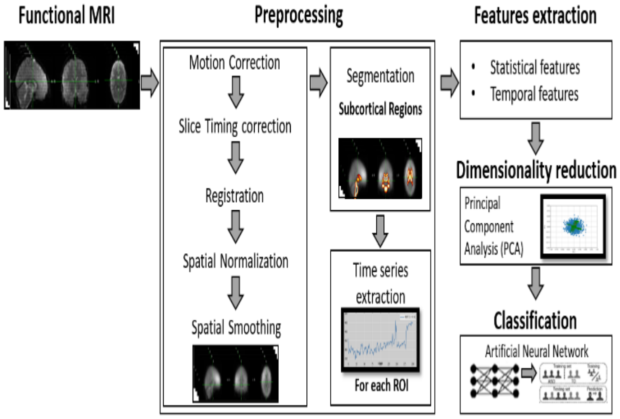

Fig. 5. Pipeline of the functional analysis methods for the characterization of ASD.

Spatial Smoothing: This process improves the signal-to-noise ratio by averaging a voxel's signal with the signal of surrounding voxels. It also helps mitigate differences in functional neuroanatomy across participants and satisfies certain statistical assumptions (result in Fig. 6).

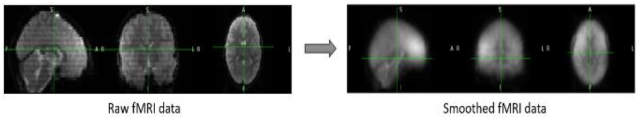

Fig. 6. Example of preprocessing data.

- Segmentation of the Regions of Interest

In our autism study, we furthered our fMRI data analysis by segmenting regions of interest (ROIs), focusing specifically on brain regions previously implicated in autism spectrum disorder (ASD). This approach allowed us to investigate how structural abnormalities in these regions may influence functional connectivity patterns and contribute to ASD's characteristic features (Fig. 7).

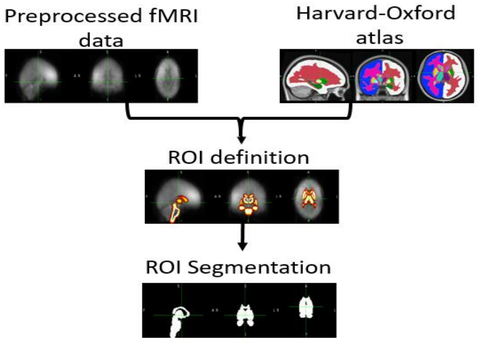

Fig. 7. ROI segmentation.

To achieve this, we utilized Atlas-based segmentation, employing the Harvard-Oxford atlas for its detailed labeling of cortical and subcortical brain structures. After selecting our ROIs from this atlas, we applied the labels to our fMRI data through a process known as label propagation. The segmentation information from multiple atlas images, when used, was fused to create the final segmentation result. This thorough process ensured accurate segmentation and paved the way for our subsequent ASD analysis and classification.

- Time Series Extraction

After defining the regions of interest (ROIs) in our fMRI data, we conducted time-series extraction, a fundamental step in functional connectivity analysis. This process involves gathering the intensity values for each voxel within the ROI across each time point in the fMRI series. By averaging the signal change over time across all voxels within each ROI, we generated a single time-series for each region, enabling us to investigate various patterns of brain activity over time (Fig. 8).

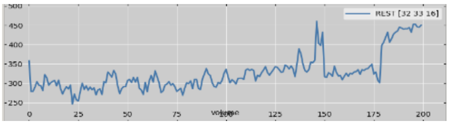

Fig. 8. Example of time series for one voxel.

- Feature extraction of fMRI

In our analysis of fMRI data, we performed feature extraction, a process to convert raw, high-dimensional time series data into a simpler, lower-dimensional format. We used the Python library tsfresh to extract 150 statistical and temporal features from the time series data.

Statistical features provided a summarized description of the variation in signal intensity over time. They included measures like mean, median, variance, standard deviation, and others, helping to quantify the properties of the signal.

Temporal features captured how brain responses changed over the course of the experiment. They included Autoregression coefficients, trend features, and Fourier coefficients among others, allowing us to uncover patterns in brain activity and comprehend the interactions between different brain regions.

Through feature extraction, we transformed complex fMRI data into a more manageable format without losing vital information, preparing it for processing by machine learning models.

C. *Multi-Modal Imaging Fusion*

In this section of our research, we'll take the critical step of fusing the feature sets derived from both structural and functional imaging data. This combined feature set will be utilized to provide a comprehensive perspective on the neuroanatomy and functionality of the key brain regions implicated in Autism Spectrum Disorder (ASD). This integrated analysis could provide more robust and meaningful insights into the neurobiological underpinnings of ASD.

- Dimensionality reduction

Upon combining the features extracted from both the structural and functional data, we find ourselves dealing with an extremely high-dimensional feature set. This poses a significant challenge in the context of machine learning, potentially leading to overfitting, difficulty in interpretation, and a spike in computational demands. This is where feature selection comes into play.

Feature selection allows us to filter out less informative features and focus on those that contribute the most to our model's predictive power. We utilized Principal Component Analysis (PCA) as a strategic choice for our feature selection process. PCA is particularly advantageous for our high-dimensional data as it allows us to reduce the dimensionality while retaining as much information as possible. PCA identifies the directions (principal components) in which the data varies the most and transforms the original, high-dimensional data into a lower-dimensional set of new features, Fig. 9. These features are linear combinations of the original ones, selected in such a way that they are uncorrelated and retain the maximum amount of variance from the original data.

In our study, we set the PCA to retain 95% of the variance. This criterion led to the selection of 30 principal components which are sufficient to retain 95% of the information from the original features. The resulting dataset, composed of 30 uncorrelated principal components, still captures the major patterns and structures in our original high-dimensional data, making it a more manageable and effective input for our subsequent machine learning model. Thus, the application of PCA serves as a powerful step in preparing our feature set for the final stages of ASD diagnosis.

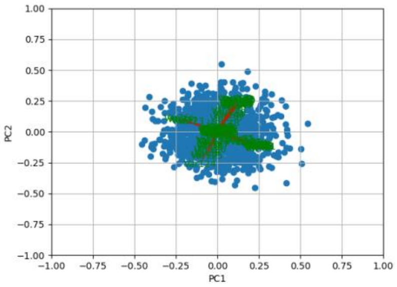

Fig. 9. Feature contributions to the first two principal components.

- Classification

Classification is essential in diagnosing ASD using machine learning. We've chosen to employ an Artificial Neural Network (ANN), a model that imitates the human brain's structure and function, for this task. ANNs consist of interconnected neurons in layers: an input layer for receiving data, hidden layers for data processing, and an output layer for final results. ANNs 'learn' by adjusting inter-neuron connections through backpropagation, thereby minimizing the difference between predicted and actual outputs. Their ability to model complex, non-linear relationships and learn intricate patterns make ANNs an effective tool for accurate ASD classification, given enough data and training time.

In our study, we applied an ANN for ASD classification, guided by an intricate process. Firstly, we initiate feedforward computation, where the input is sequentially processed through each layer of the network using a sigmoid activation function. The final prediction is made at the output layer. We then employ a loss function, specifically Mean Squared Error (MSE), to quantify the discrepancy between the network's prediction and the actual value[6].

$$MSE = \frac{1}{N}\sum_{i=1}^{N}(y_i - \hat{y}_i)^2 \quad (4)$$

Where:

N is the number of samples

y_i is the actual value

$\hat{y}_i$ is the predicted value

The loss function thereby indicates the error of the network. Backpropagation, a method of calculating the loss function's gradient with respect to the network's weights and biases, follows. It commences from the output layer, moving backward through the hidden layers. The network's weights and biases are then updated by subtracting a fraction of the gradient, dictated by the learning rate, a key hyperparameters. This whole process is repeated for each batch of data in the training dataset for a set number of epochs, gradually adjusting the network's weights and biases to minimize the loss function, and improving prediction accuracy. We customized certain hyperparameters (Appendix C, Table VII), like the learning rate and the structure of hidden layers, for our specific application to ensure optimal performance. By fine-tuning these hyperparameters, we could better capture complex patterns in ASD data, thereby increasing the accuracy of our ASD characterization (Fig. 10).

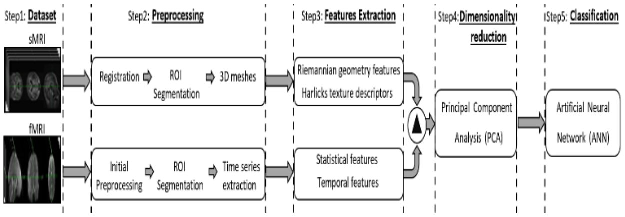

Fig. 10. Pipeline of diffusion method.

III. Results and Discussion

In this section, we initially outline the database utilized for our investigation in the first part. This is followed by a description of the tuning process for the ANN in Section B. Subsequently, we delve into an evaluation of the proposed method's performance. Lastly, we provide a comparative analysis with a few prevalent techniques from the established standards.

A. Database Description

The non-invasive imaging technique, MRI is pivotal to our study for its ability to generate detailed, high-resolution images of the brain. Our investigation uses data from the Autism Brain Imaging Data Exchange (ABIDE), a collaborative initiative that curates diverse MRI datasets globally for autism research. This collaboration ensures a robust dataset that offers comprehensive insight into autism's structural patterns.

ABIDE provides a large-scale collection of both structural and functional MRI datasets, improving our understanding of the neural mechanisms underlying ASD. With over 1200 datasets from more than 24 international brain imaging laboratories, these collections afford a rich assortment of data for our analyses.

In our work, the ABIDE data is categorized into three distinct age groups - early childhood (1-9 years), late childhood and adolescence (10-25 years), and adulthood (above 25 years), each reflecting a different stage of brain development, Table I. This classification allows us to examine autism's manifestation and evolution throughout life stages, offering a nuanced understanding of ASD's progression and neurological implications.

TABLE I. THE DEMOGRAPHIC INFORMATION OF THE DATABASE ABIDE

1st range		**2nd range**		**3rd range**	
The postnatal development of the human brain.		***The brain reaches its adult size.***		***The brain reaches its full size.***	
5-9 years old		10-25 years old		+25 years old	
646 patients		218 patients		148 patient	
315 ASD	331 NC	154 ASD	164 NC	70 ASD	78 NC

B. *Machine Learning Evaluation*

- k-fold cross-validation

Our study applies probabilistic learning methods to optimize neural networks, dividing our data into training and testing sets for reliable model training and validation. The training set is used to teach the model to recognize data patterns, while the unseen testing set assesses how well it generalizes these patterns. We employ k-fold cross-validation to bolster the reliability of our results and avoid overfitting. This involves splitting the training data into 'k' subsets and training the model 'k' times, each time using a different subset for validation (Fig. 11).

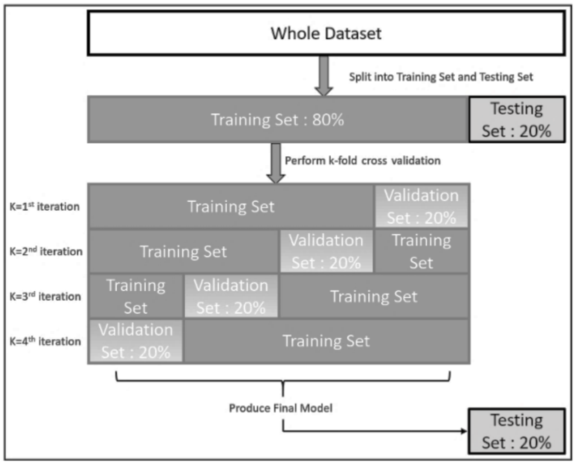

Fig. 11. How the dataset was split.

This provides 'k' models and performance estimates which can be averaged to offer a more reliable measure of performance. Specifically, we use 4-fold cross-validation, partitioning our data into four subsets. For each training cycle, 80% of the data trains the model, while the remaining 20% validates it. The model's performance is then assessed using the validation set, and quantified using metrics such as accuracy, precision, and recall. By averaging performance across four iterations, we gain a robust measure of the model's predictive capabilities, mitigating the risk of overfitting and providing a realistic evaluation of the model's potential real-world performance. This approach ensures the robustness, reliability, and applicability of our model in studying autism spectrum disorders.

- Performance evaluation

In our study, we use an ANN classifier to analyze features derived from structural and functional MRI data. The analysis reveals differences in specific brain regions when compared to a control group[7]. The model's performance, evaluated using the identified feature sets, is detailed in Table II, which demonstrate metrics like accuracy, sensitivity, and specificity.

Accuracy is a simple performance metric, calculated as the ratio of correct model predictions to total predictions. Ranging between 0 and 1, a score of 1 denotes a perfect model. We use the equation:

$$Accuracy = (TP + TN)/(TP + FP + FN + TN) \tag{5}$$

where TP, TN, FP, and FN represent true positives, true negatives, false positives, and false negatives, respectively.

Sensitivity, or recall, measures the proportion of actual positive cases correctly identified by the model. Calculated as:

$$Sensitivity = TP/(TP + FN) \tag{6}$$

It quantifies the model's ability to detect all relevant instances.

Specificity evaluates the model's performance regarding negative cases. It represents the proportion of true negative cases correctly identified by the model, computed as:

$$Specificity = TN/(TN + FP) \tag{7}$$

By using these three metrics to evaluate our model, we ensure that it is well-rounded, accurately predicting both positive and negative cases. This makes it a potentially valuable tool in characterizing autism.

- Results

In our study, we evaluate the effectiveness of an ANN in differentiating between individuals diagnosed with ASD and control subjects across various age groups. This evaluation employs a fusion of structural and functional analyses, a crucial approach for comprehensively understanding the relationships within the brain's structure-function framework. We base this assessment on a combination of geometric, volumetric, temporal, and statistical features, the outcomes of which are represented in Tables II, III, and IV.

- Discussion

In this research, we utilize an ANN to differentiate individuals diagnosed with ASD from control subjects across various stages of life: early childhood, late childhood and adolescence, and adulthood. Both structural and functional characteristics of the brain are examined to provide a comprehensive view of how our model performs. By integrating both structural and functional neural features, our classifier demonstrated robust performance across all developmental stages. Despite a decline in accuracy with increasing age, the integrated approach provided valuable insights, highlighting the relevance of a comprehensive brain analysis in diagnosing ASD.

Specificity	0.59	0.51	0.64	0.60	0.71	0.74	0.56	0.66	0.75	0.68
Fusing all ROI: accuracy =67.9%										

The combined analysis in the late childhood and adolescence stage maintains high accuracy levels, with the right amygdala again leading with an accuracy of 85.1%. The accuracy levels of WB and GM are 73.0% and 72.7%, respectively. While the accuracy rates have declined slightly from the early childhood stage, the fused ROI result still maintains a solid accuracy of 86.2%.

The final findings underscore the complexity of ASD and the importance of a multifaceted approach to brain data analysis for accurate ASD identification. The research provides a promising pathway for the future of ASD detection and diagnosis, and potentially for other neurodevelopmental and neurodegenerative disorders, through the use of ANN classifiers. Our methodology, which combines structural and functional brain properties, could serve as a valuable tool in the development of Computer-Aided Diagnosis systems, particularly for neurodegenerative diseases like Alzheimer's and Parkinson's, which also involve significant changes in the brain.

- Comparison analysis

In the table below, we present a comparison of various prior studies that have focused on the characterization of ASD by employing both structural and functional MRI. This comparative analysis aims to provide a broader perspective on how our approach to ASD classification using an ANN stands in relation to previous research efforts.

Each study listed in the table has contributed significantly to our current understanding of ASD's neurological underpinnings. However, the methodologies employed, the specific features extracted, and the performance metrics achieved vary from one study to another. Some researchers have concentrated more on the structural aspects of the brain (Table V), while others have leaned towards functional analysis (Table VI).

TABLE V. ASD CLASSIFICATION STUDIES BASED ON SMRI DATA

Study	Participants	Data	Features	Machine learning method	Accuracy
Seyedmehdi Payabvash, et al.[8]	14 with ASD 33 typically developing children	The UCSF Sensory Neurodevelopment and Autism Program clinical sites and research database	Tract-based average TI/connectome metrics	Support vector machines	75.3%
Almeida, J.,et al.[9]	403 ASD 468 TC	The open database Autism Brain Imaging Data Exchange (ABIDE).	The volume of the cerebral cortex	Support vector machines	76%
Ahmad Chaddad,et al.[10]	34 ASD 30 DC	The open database Autism Brain Imaging Data Exchange (ABIDE).	11 features derived from Hippocampus Amygdala	Support vector machines	67.85%

Li et al. (2018) [36]	38 ASD 23 TC	rs-fMRI data (the ABIDE dataset)	FCs between 90 ROIs (the AAL atlas)	SSAE	DTL-NN classifier	70.4%

This comparison underscores the diverse approaches researchers have taken to tackle ASD classification using MRI data. Our research's contribution lies in its unique fusion of both structural and functional analyses across different age groups, which provides a more holistic understanding of ASD's neurological characteristics. The table below offers a succinct summary of these various studies, illuminating the varying methodologies and results that have been achieved in the past.

IV. STUDY LIMITATIONS

Despite the promising findings, the current study is not without its limitations. Primarily, our work relies on the Autism Brain Imaging Data Exchange (ABIDE) which, while being a rich public dataset, has its limitations. The datasets are collected from 521 individuals with ASD and 593 controls with ages ranging from five to 64 years. However, this is a comparatively small dataset for making definitive classifications. To expand upon the insights provided by this study, future research should aim to collect data from a larger group of preschoolers with ASD to further explore brain development during early childhood.

Secondly, while we acknowledge the gender disparity in ASD diagnoses, with males being more frequently diagnosed than females, this issue has been generally overlooked in ASD imaging literature due to the significantly higher prevalence of ASD in males. In the ABIDE dataset, the number of datasets from females is limited (65 datasets, encompassing both ASD and control subjects), making a thorough analysis of gender influences challenging. Despite the potential of Artificial Neural Networks (ANNs), they have inherent limitations. Their 'black-box' nature makes it hard to understand how they arrive at specific predictions, leading to challenges in interpretability. Furthermore, ANNs can sometimes overfit high-dimensional data, especially with limited samples, leading to poor performance on unseen data. To address these issues, future work could explore methods for enhancing interpretability and preventing overfitting.

While these limitations pose challenges, they also highlight potential directions for future research. We need larger, more diverse samples and more robust methods to handle high-dimensional data for more accurate and generalizable results. In addition, research efforts should not neglect gender disparities in ASD and strive for greater representation in imaging studies. By addressing these issues, we can further refine our understanding of ASD's neurobiological underpinnings and improve diagnostic strategies.

V. Conclusion

In conclusion, our study has successfully highlighted the significance and value of employing an integrated, multimodal approach in characterizing and diagnosing ASD across various developmental stages. The results have underscored the vital role played by specific brain regions such as the Right Amygdala, Left Amygdala, Right Corpus Callosum, Left Putamen, and Right Hippocampus in ASD classification. Furthermore, the distinctive combination of both structural and functional neural features in our ANN classifier has proven to be a powerful tool in capturing the complex neurobiological nuances of ASD.

While the classifier demonstrated robust performance across all developmental stages, particularly in early childhood, it also unveiled the increasing complexity of ASD diagnosis in later life stages. This highlights the intricate interplay between ASD symptomatology, brain development, and aging. However, even amidst these challenges, the classifier continued to provide valuable insights and significant accuracy scores, asserting the value of a comprehensive brain analysis approach for ASD diagnosis.

The fusion of results from structural and functional analyses created a more comprehensive model for ASD classification, resulting in a more robust and accurate representation of the disorder. This integrated approach produced promising results, especially in the domain of early ASD diagnosis. The highest diagnostic accuracy achieved in our study reached 90.1%, signifying the potential of a multimodal approach that captures a more complete picture of ASD's neurobiological underpinnings.

Our study contributes significantly to the field by providing a broader understanding of ASD. By integrating structural and functional aspects of brain imaging data, we enhance our ability to identify and diagnose the disorder accurately. Our research not only paves the way for further advancements in early detection and personalized treatment strategies for individuals with ASD but also sets the stage for this methodology to serve as a Computer-Aided Diagnosis tool for the detection of other neurodegenerative diseases such as Alzheimer's and Parkinson's.

Despite some limitations, particularly regarding the decline in accuracy with increasing age, our study reaffirms the need for a comprehensive, multidimensional analysis of brain data for accurate ASD identification. It also suggests areas for future research to enhance the understanding and diagnosis of ASD, potentially through the development of more sophisticated feature extraction or classification methods.

In essence, this research demonstrates the potential of a comprehensive, multimodal neuroimaging approach, combined with advanced machine learning techniques, to improve early detection and understanding of ASD, thereby paving the way for more effective intervention strategies. It lays a solid foundation for similar techniques to be used for other neurodevelopmental and neurodegenerative diseases, offering a significant tool for future diagnostic strategies.

Appendix A

In this part, all regions that were mentioned in the state of the art and were related to ASD were cited below.

White matter: studies have shown that white matter disease is associated with Autism through some physical and emotional symptoms such as balance problems, falls, depression, and difficulty of multitasking activities such walking and talking[37].

Gray matter: Grey matter is involved in muscle control, and sensory perception such as seeing and hearing, speech, self-control, emotions, memory, and decision-making. Researchers found that children diagnosed with autism have more abnormality in gray matter [38].

Nucleus accumbens: The nucleus Accumbens core is involved in the cognitive processing of motor function related to reinforcing slow-wave sleep to regulate reward-motivated behaviors. Some studies related this subcortical region with ASD [39].

Amygdala: the amygdala is related to emotional learning and behavior. Many studies demonstrate that amygdale texture features can be used to extract biomarkers for the characterization of ASD purposes [40].

Corpus callosum: Corpus Callosum the largest white matter structure in the brain. It is involved in the interhemispheric transfer of information and integrates motor, sensory, and cognitive performances. Many comparative studies show that it develops differently in children with autism [41].

Hippocampal: the two most influential theories for hippocampal function are related to space and memory. It is used by the brain for mapping layouts of the environment [40].

Pallidum: Pallidum is a part of the subcortical nervous circuits involved, in motor skills, and, in particular, in the control of posture. It is also associated to non-motor functions (e.g. cognition, emotions, etc...).

Thalamus: Many previous studies shows that the thalamus play a key role in autism. It may regulate social behavior and it is considered as a relay station that merely passes sensory information to the cerebral cortex.

Putamen: the role the putamen is to regulate movements. It employs GABA, acetylcholine, and encephalin to perform its functions.

Caudate nucleus: the caudate nucleus is the subcortical region that controls learning, specifically the storing and processing of memories. Studies show that Autism causes a different development of ASD.

Brainstem: The brain stem is the part of the brain that connects the cerebrum with the spinal cord. The review of the literature suggests that developmental alterations of the brainstem could have potential cascading effects on cortical and cerebellar formation, ultimately leading to ASD symptoms.

Appendix B

- Riemannian geometry

Area: The area of a two-dimensional figure or shape is the quantity that expresses the extent of the figure or shape in the the plane. Here in our work, we used (eq 8) to calculate the whole region area by applying the summation of all tetrahedrons areas.

$$A = \sum \frac{1}{2a} * h \tag{8}$$

Where a is the base and h is the height of the triangle.

Volume: The volume is a closed surface that encloses a certain amount of three-dimensional space. Here in our work, we used (eq 9) to calculate the whole region volume by applying the summation of all tetrahedrons volumes.

$$V = \sum \frac{\sqrt{2}}{12} * a^3 \tag{9}$$

Where a is the triangle base.

Isoperimetric ratio: Iso-ratio depends on the volume and the surface. It is initially the study of the properties of the geometric

shapes of the plane (eq 10).

$$IPR = \frac{A}{V^{\frac{2}{3}}} \tag{10}$$

Where A is the triangle area and V is the Volume.

Convexity ratio of the surface: The convex area of an object is the area of the convex hull that encloses the object (eq 11).

$$CRS = \frac{A}{A(CH)} \tag{11}$$

Where A is the triangle area and A (CH) is the convex hull depending on area.

Convexity ratio of the volume: The convex volume of an object is the volume of the convex hull that encloses the object (eq 12).

$$CRV = \frac{V}{V(CH)} \tag{12}$$

Where V is the triangle volume and V (CH) is the convex hull depending on volume.

Gaussian curvature: The Gaussian curvature is defined at a point of a surface contained in Euclidean space as the product of the two main curvatures (eq 13).

$$K = k_1 k_2 \tag{13}$$

Where $\mathrm{k}_1$and k_2 are principal curvatures.

Mean curvature: the mean curvature of a surface is called the mean of the minimum and maximum curvatures (eq 14).

$$H = \frac{1}{2}(k_1 + k_2) \tag{14}$$

Where $\mathrm{k}_1$and k_2 are principal curvatures.

- Harlicks texture descriptors

The second standard L2N: The second standard measures the length common to all representations of a vector in an affine space (eq 15).

$$|X| = \sqrt{\sum_{k=1}^{n} |x_k|^2} \tag{15}$$

Where |X|is the vector norm and $|x_k|$ is the complex modulus.

Means: Mean is the small mean values indicating coarse texture having a grain size equal to or larger than the magnitude of the displacement vector (eq 16).

$$Mean = \sum_{i=0}^{N-1} \sum_{j=0}^{N-1} Mc(i,j) \tag{16}$$

Where N is the number of gray levels, Mc is the image matrix.

Contrast: The contrast feature is a measure of the image contrast or the number of local variations present in an image (eq 17).

$$Contrast = \sum_{i=0}^{N-1} \sum_{j=0}^{N-1} (i-j)^2 \, Mc(i,j) \tag{17}$$

Where N is the number of gray levels, Mc is the image matrix

Angular Second Moment: Angular Second Moment and Uniformity, also called Energy, which is a measure of textural Uniformity of an image (eq 18).

$$ASM = \sum_{i=0}^{N-1} \sum_{j=0}^{N-1} Mc(i,j)^2 \tag{18}$$

Where N is the number of gray levels, Mc is the image matrix

Variance: This is the sum of the squares of the differences between the intensity of the central pixel and its neighbors (eq 19).

$$V = \sum_{i=0}^{N-1} \sum_{j=0}^{N-1} (i - mean)^2 \, Mc(i,j) \tag{19}$$

Where N is the number of gray levels, Mc is the image matrix.

Standard deviation: The standard deviation is a measure of the amount of variation or dispersion of a set of values (eq 20).

$$\sigma_I^2 = \sum_{i=0}^{N-1} (i - mean)^2 \sum_{j=0}^{N-1} Mc(i,j) \tag{20}$$

Where N is the number of gray levels, Mc is the image matrix

Correlation: Correlation feature shows the linear dependency of gray level values in the cooccurrence matrix: (eq 21).

$$Corr = \frac{1}{\sigma^2} \sum_{i=0}^{N-1} \sum_{j=0}^{N-1} (i - mean)^2 \, Mc(i,j) \tag{21}$$

Entropy: is a measure of information content. It measures the randomness of intensity distribution and the homogeneity of the histogram (eq 22).

$$Entropy = -\sum_{i=0}^{N-1} \sum_{j=0}^{N-1} Mc\,(i,j) \log Mc(i,j) \tag{22}$$

Where N is the number of gray levels, Mc is the image matrix

APPENDIX C

In our work, we employed an Artificial Neural network for the classification. The parameters of a neural network are typically the coefficients of the model. In this case, these parameters are learned during the training stage. So, the algorithm itself, optimizes these coefficients. However, when training it, there are a number of hyperparameters we needed to set, including Table VII.

TABLE VII. HYPERPARAMETERS

Hyperparameters (this is the case of each region)	
Number of hidden layers:	3
Number of units in the input	45
Number of units in first hidden,	90
Number of units in second hidden,	30
Number of units in third hidden	15
Number of units in output layer	1
Learning rate	0.000001
Activation function for 1,2,3,4	activation=tanh'
Activation function for the final layer	activation='sigmoid
Minibatch size	32
Epochs	800
Loss Function	'mean_squared_error'

Blockchain Architecture Based on Decentralised PoW Algorithm

Cinthia P. Pascual Caceres, Jose Vicente Berna Martinez,
Francisco Maciá Pérez, Iren Lorenzo Fonseca, Maria E. Almaral Martinez
Department of Computer Science and Technology, University of Alicante,
C/ San Vicente s/n, San Vicente del Raspeig, Spain.

***Abstract*—Blockchain has gained increasing popularity across various industries due to its decentralized, stable, and secure nature. Consensus algorithms play a crucial role in maintaining the security and efficiency of Blockchain systems and selecting the right algorithm can lead to significant performance improvements. This article aims to provide a comparative review of the most used Blockchain consensus algorithms, highlighting their strengths and weaknesses. Additionally, we propose a dissociated architecture for an efficient Blockchain system that doesn't compromise on security. A comparison is made between this architecture and the reviewed algorithms, considering aspects such as algorithm performance, energy consumption, mining, decentralization level, and vulnerability to security threats. The research findings demonstrate that the proposed architecture can support complex algorithms with high security while addressing issues related to efficiency, processing performance, and energy consumption.**

Keywords—Blockchain technology; proof of work; consensus algorithm; proof of stake; Dissociated-PoW; security; performance

I. Introduction

Blockchain (BC) technology offers numerous advantages that make it highly relevant and applicable in various areas of life. As a result, it has gained significant importance and presence in diverse projects. The main benefits it provides are decentralization, immutability, integrity, and reliability. These qualities guarantee a high level of information protection throughout all phases of processing and storage [1]. This technology reached its pinnacle thanks to the rise of Bitcoin, primarily attributed to its ability to establish a decentralized ledger, ensure immutable records, and provide participant anonymity. These factors played a crucial role in driving the widespread adoption and recognition of blockchain technology [2]. However, it is precisely the strength of blockchain technology that also makes it increasingly challenging to manage. In its original form, blockchain utilizes a consensus algorithm known as Proof of Work (PoW) [3], this consensus algorithm used in blockchain requires a substantial computational effort, creating a situation where only large computer producers can effectively participate. This dynamic makes it financially unprofitable for smaller infrastructures to engage in the process [4]. To address this issue, blockchain (BC) has evolved in various directions, exploring different consensus algorithms and structures that can alleviate the computational costs. In this paper, we propose a solution that harnesses the security strengths of Proof of Work (PoW) while introducing a BC architecture built on functionally specialized nodes. This approach enables the efficient implementation of PoW while minimizing the computational expenses.

To this end, Section II reviews the state of the art and the main issues related to the work, especially reviewing the different lines of work that have been adopted from the original BC. Section III proposes the new architecture, the functional characterization of the operations and the description of the nodes. In Section IV, a comparison is made with the traditional BC to show the differences and similarities of the proposed architecture and, above all, the benefits. The last section finally shows the main conclusions of the proposal with possible lines of further work.

II. Background

First, BC networks developed from the original one proposed by Satoshi [5]. Depending on the participants involved, blockchain networks can be categorized as public, private, or hybrid. Additionally, the permissions granted for write and read operations on the blockchain determine whether it is classified as permissioned or permissionless. A blockchain can combine various aspects of participation and operation permissions, resulting in a wide range of scenarios that can be applied based on the specific organization and the type of application being implemented [6]. The choice of the blockchain type depends on the intended use case and the specific requirements of the organization.

In public blockchain networks, all individuals have the freedom to read, send, or validate transactions. Furthermore, they can actively participate in the distributed consensus process. The consensus mechanism relies entirely on the merits and contributions of individual nodes within the network, without the need for any centralized authority or control. This open and inclusive approach fosters transparency, decentralization, and trust among participants in the public blockchain network [2], nodes compete to achieve consensus. Unlike in a private network, there is no access control mechanism restricting participation. Nodes have the freedom to join or leave the network without causing harm to the consensus mechanism or the generation of new blocks [7]. This decentralized nature allows for a dynamic network where nodes can freely interact and contribute to the consensus process.

In private BC networks the addition and verification of new blocks are limited to specific users authorized by the controlling entity, which can be centralized or decentralized. In such networks, unauthorized users are unable to add information to the blockchain network and may even be restricted from accessing read capabilities. Unlike public networks, private networks necessitate consensus algorithms tailored to accommodate these permission restrictions [8].

Hybrid or consortium BC networks represent a combination of both public and private networks. In these networks, participating nodes are typically invited or selected, but all transactions are publicly visible and transparent. One of the benefits of these networks is the protection they provide against 51% attacks [9]. A 51% attack refers to a scenario where a single entity or group of nodes gains control of over 50% of the network's computing power, potentially enabling them to manipulate the blockchain. In a hybrid or consortium network, the distributed nature of participation helps safeguard against such attacks, as they require majority control, which is not easily attainable in these network configurations.

In fact, each type of blockchain network requires a consensus algorithm that suits its specific needs. A consensus algorithm is a set of rules and processes that govern the operation of a distributed system. Its main purpose is to resolve data synchronisation between untrusted nodes in a decentralised environment. Consensus algorithms ensure that all participants agree on the state of the blockchain and validate transactions in a consistent and secure manner. The choice of consensus algorithm depends on factors such as the type of network, the desired level of decentralisation, scalability requirements and security considerations [10].

The original consensus algorithm used in blockchain is Proof of Work (PoW); is a decentralised consensus algorithm that requires network participants to compete to solve a computational puzzle. This puzzle-solving process helps prevent malicious actors from manipulating the system and ensures the security and integrity of the blockchain. PoW is widely used in cryptocurrency mining, where participants validate transactions and mine new tokens, as in the case of the Bitcoin network. By dedicating computational resources and solving complex puzzles, miners contribute to the consensus process and maintain the decentralised nature of the blockchain network [11]. One of the main challenges and drawbacks of PoW is the significant computational capacity required to solve the mathematical problem involved in authenticating blockchain transactions. This computational intensity leads to high energy consumption and limits the scalability of PoW-based blockchain networks. The resource-intensive nature of PoW can also make it less accessible for smaller participants or entities with limited computing power. As a result, there has been a drive to explore alternative consensus algorithms that can address these limitations, such as Proof of Stake (PoS) or delegated proof of stake (DPoS) that do not require extensive computational power. These consensus algorithms enable participants to validate transactions and secure the network based on factors like the number of tokens held or reputation, rather than raw computing power [12]. To participate in a BC network that uses PoW as a consensus mechanism, it is essential to have advanced, powerful, expensive, and energy-consuming hardware [13], thus widely so that users currently must compete against pools of mining [14]. Due to the drawbacks and limitations of the Proof of Work (PoW) consensus algorithm, the blockchain community has developed and explored various alternative consensus algorithms. These alternative algorithms aim to address issues such as high energy consumption, scalability, and accessibility. Some of the popular alternative consensus algorithms include:

Proof of Stake (PoS): in PoS participants can create new blocks and validate transactions based on the number of tokens they hold or "stake" in the network. This approach reduces energy consumption and allows for a more efficient and scalable consensus mechanism. Consensus algorithm was the next algorithm to appear. It works by encouraging users to always keep a certain number of cryptocurrencies in the wallet [15]. Keeping these cryptocurrencies locked helps participants increase their chances of being chosen, as this is one of the main criteria set for participation. Once these criteria have been established, the random node selection process begins. When the nodes are chosen and the selection process is finished, they are ready to validate transactions or create new blocks. It is more environmentally friendly than PoW as it does not require large amounts of computational power to operate [16] The security of the network is much higher as it solves or hinders certain known attack schemes, such as the 51% attack, overall, PoS offers benefits such as energy efficiency, increased network security, and improved scalability. It is an alternative consensus algorithm that has gained popularity in blockchain networks seeking to address the limitations of PoW.

Delegated Proof of Stake (DPoS): it is a consensus algorithm commonly used in blockchain networks. It is designed to address some of the limitations of traditional Proof of Stake (PoS) algorithms and aims to achieve faster transaction processing and increased scalability [4]. Referring to a more decentralised form in the BC network, it also modifies the way power is used, decreasing in frequency. With this algorithm, users can give their votes on who they want to mine the next block. Thus, it offers high levels of security for use in public BCs. Besides this, its operating model guarantees high levels of scalability. To make this possible, each participant in the network chooses, by voting, several "delegates". Once chosen, they form an ensemble that offers Byzantine Fault Tolerance (BFT) [17].

Delegated Byzantine Fault Tolerance (dBFT): consensus algorithm's main objective consists in giving the right to all stakeholders to be an active member through the voting procedure to solve the problems in the blockchain in a democratic and fair way. It is an algorithm that combines the characteristic of the DPoS algorithm, but unlike the DPoS algorithm, delegate nodes are elected to validate the new block, and where at least 2/3 must approve it [18]. In this way, the network can make decisions even if one third of the nodes are harmful or corrupted [19].

The Proof of Activity (PoA): relies on a set of approved validators who are known and trusted. Validators take turns creating new blocks, and consensus is achieved based on their identity and reputation. It is a combination of PoW and PoS [20]. Initially the system works in PoW where miners try to solve a mathematical equation using high computational capabilities. Once a new block is generated, the system switches to PoS, a group of validators is chosen at the start, and they will oversee verifying or signing the new block. Validators are elected and sign the new block. More coins a validator possesses, more likely to be elected and sign [21]. A 51% chance of an attack is also avoided in this algorithm.

Proof of Burn (PoB): consensus algorithm works in such a way that miners must send cryptocurrencies to a public and verifiable address, from which they will not retrieve them again, burning them. In other words, miners must make a kind of investment and the higher the number of cryptocurrencies burned, the more mining the miner achieves [22]. Its main benefit is that, with a higher percentage of long-term investors, price stability may increase. Also, PoB assists in determining the distribution of cryptocurrencies in a fair and decentralised manner. Reduction in the number of resources needed to achieve consensus compared to PoW is considerable and it also has resistance to double spending attack.

Proof of Capacity (PoC): consensus algorithm enables network mining devices to use their available hard disk space to decide entitlements when mining and validating transactions [23]. Differentiating this with the use of the computational power of the PoW mining device or the miner's participation in PoS cryptocurrencies. As a benefit, any hard drive can be used, including those with Android-based operating systems. Mining data can be easily erased, and the drive can be reused for any other data storage purpose. Compared to PoW [24], this improves the resource consumption for consensus by up to 30 times less.

The Proof of Elapsed Time (PoET): is a consensus algorithm that aims to achieve decentralized consensus while minimizing energy consumption. PoET was introduced by Intel as a consensus algorithm for use in private and permissioned blockchain networks.

In PoET, participants in the network compete to become the leader or validator of the next block. However, instead of relying on computational power or staking, PoET uses a random lottery-based approach. Each participant in the network waits for a randomly generated timer to expire [25]. The participant whose timer expires first becomes the leader and gets the right to create the next block.

To prevent participants from manipulating the system by manipulating timers, PoET uses a trusted execution environment (TEE). The TEE provides a secure and tamper-resistant environment for generating the random timers. This ensures fairness and prevents participants from predicting or influencing the timer outcomes.

The next algorithm is a new consensus mechanism using less energy and can run on low-end hardware, Proof of Assignment (PoA), developed by IOTW [26]: this algorithm can process thousands of transactions per second and has been introduced for micro mining, allowing for lightweight mining on IoT devices by eliminating the need to store and maintain the transaction ledger at the device level. Instead, the storage and maintenance of the ledger is outsourced to one or more pre-established trusted nodes in the BC network. It can run on hardware of any IoT device [27].

The Ripple Protocol Consensus Algorithm (RPCA): to maintain the veracity and consensus of the network, constantly updates its nodes; once consensus is reached, the current ledger is "closed" and becomes the last closed ledger. Assuming the success of the consensus algorithm, and that there is no fork in the network, the last closed ledger held by all nodes in the network will be identical [28]. Among its features is that the validation of transactions is immediate, reducing the time of each operation. In addition, the costs per transaction are also very low and the Ripple cryptocurrency has greater flexibility compared to other cryptocurrencies for international payments, it is oriented for monetary transactions between banks, a competitor of the SWIFT system [29].

The development of consensus algorithms aims to preserve the power and robustness of PoW while addressing its inherent challenges. However, it is essential to acknowledge that changing the consensus algorithm does not necessarily guarantee the elimination of problems, but rather introduces new considerations and trade-offs.

The proposal to shift the focus of innovation in blockchain from creating new algorithms to designing new architectures to solve existing problems is an interesting approach. By reimagining the underlying architecture, it becomes possible to optimize the performance, scalability, and energy efficiency of blockchain networks, while still leveraging existing consensus algorithms like PoW. This architecture will be called Dissociated Proof of Work (Dissociated-PoW).

III. Dissociated-PoW Architecture

The proposed Dissociated-PoW architecture aims to address the high computational cost associated with competition between mining nodes in Proof-of-Work based blockchain networks. This architecture introduces two types of functionally specialised nodes: coordinator nodes (CN) and mining nodes (MN). Each type of node and its function is described below:

- Coordinator nodes: Serving as central entities, coordinator nodes take charge of coordinating the mining process and facilitating the consensus algorithm. They play a crucial role in selecting and assigning mining tasks to the mining nodes. Furthermore, CN are responsible for overseeing the overall operation of the blockchain network and ensuring the integrity of the consensus process.
- Mining nodes: Dedicated to performing the computational work required to mine new blocks on the blockchain, mining nodes form the scheme of the Dissociated-PoW architecture. These nodes receive mining tasks from the coordinator nodes and leverage their computational resources to solve the PoW puzzle and validate transactions. MNs are pivotal in generating new blocks and maintaining the continuity of the blockchain.

This proposed architecture has the potential to enhance the efficiency and scalability of blockchain systems while preserving the fundamental principles of decentralization and trust. Further research and experimentation are needed to validate its effectiveness and practicality in real-world scenarios.

A traditional blockchain scheme exhibits the typical structure wherein all nodes participate in the mining competition, leading to high computational costs. In contrast, the proposed Dissociated-PoW scheme introduces a separation of tasks between coordinator nodes and mining nodes, resulting in a more efficient and optimized mining process.

The Dissociated-PoW architecture has the potential to mitigate the drawbacks of traditional PoW-based blockchain networks by reducing computational costs and optimising mining resource allocation. However, it is important to thoroughly analyse and evaluate the proposed architecture in terms of security, decentralisation, and performance to ensure its effectiveness in real-world scenarios.

A. Coordinating Nodes are responsible for the following Tasks

- Receiving and storing new information to be inserted into the blockchain.
- Managing the pending transactions PT, which form a block of information containing all the pending transactions that will be mined to generate the next block of the blockchain. PT is a block of transactions that are replicated and synchronized among all coordinating nodes.
- Deciding when to initiate the mining process by utilizing rules to trigger mining based on criteria like a timeout or reaching a maximum PT size.
- To decide who will be the MNs to mine the next PT.

B. Mining Nodes are responsible for the following Tasks

- Maintaining the blockchain to ensure it is accessible for any user. Each MN contains a copy of the entire blockchain.
- Mining the next block of the BC without engaging in competition. The MN receives the pending transactions PT from a CN and performs the mining process. Once the mining is completed, the new block is broadcasted to the BC.

In our proposal, it is the CN that instruct a specific MN to carry out the mining process, providing it with the necessary information to be mined, which includes the pending transactions, as illustrated in Fig. 1.

Once mined, the new block will be distributed among the other mining nodes. This approach ensures that MN do not compete to be the first to mine; instead, it is the coordinating nodes who make the decision on which MN will perform the mining task. The selection process can be based on efficiency and effectiveness to ensure that the network utilizes the minimum computational resources.

To prevent fraudulent transactions from being injected into the blockchain, all nodes within the network must be aware of all members' identities. This involves maintaining an up to date Blockchain node list (BCNL) for each node, containing information about the participants in the network. This measure ensures transparency and security, as all nodes have knowledge of the network's composition.

As shown in the proposed Dissociated-PoW architecture, the dissociation of mining tasks and the coordination provided by the CN contribute to a more efficient, secure, and decentralized blockchain network.

Action flows of the CN for the specified tasks:

1) Receiving a new transaction:

- A coordinating node receives a new transaction to be included in the blockchain.

2) Adding it to the pending transactions:

- The CN incorporates the new transaction into its own pending transactions PT block.

3) Disseminating the new transaction among the rest of the CN:

- The CN broadcasts the new transaction to all other coordinating nodes to ensure they are informed about the pending transaction.
- It is essential to ensure that the transactions are inserted into the PT block in the same order among all coordinating nodes during dissemination.

4) Validating the origin of the new transaction:

- Other coordinating nodes verify the origin and validity of the new transaction sent by the CN.

5) Synchronizing all the pending transactions:

- After validation, all coordinating nodes have the same block of pending transactions, ensuring synchronization.

As for mining, it is performed in the following way with a leader node among the CN:

1) Detecting the mining start condition:

- The leader CN detects the condition to initiate the mining process.

2) Notifying other CN nodes about mining:

- The leader CN notifies all other CN nodes that mining is about to proceed, prompting them to freeze the current pending transactions block and mark it as in the mining state.

3) Selecting a MN to mine the pending transactions:

- The leader CN selects a MN from the Blockchain Node List (BCNL) to mine the current pending transactions block and sends the pending transactions block to be mined.

4) Notifying completion and disseminating the new block

- Once the selected MN finishes mining, it notifies the CN that initiated the mining process and disseminates the new block to all other MNs.

5) Indicating the end of mining and validating the mined block:

- The leading CN indicates to the other CN that mining is finished and that the previous block of transactions can be finalized.
- The rest of the CN verify the correctness of the mined block and conclude the mining operation. As shown in the Fig. 2.

This process, with a designated leader node among the CN, ensures a coordinated and efficient mining process in the Dissociated-PoW architecture, promoting consistency and integrity throughout the blockchain network. As shown in Fig. 3.

Action flows to start mining:

1) The leading CN decides when to initiate the mining process.

2) The leading CN notifies the rest of the CN to begin mining and instructs them to freeze the current pending transactions (PT) block.

3) The leading CN selects a node from the network to perform the mining task and sends the PT block to that node.

4) The selected mining node informs the leading CN when it has completed the mining process and broadcasts the newly mined block to all other MN.

5) The leading CN notifies all the other CN that the previous mining process has concluded, and the mined PT can be removed.

The synchronization between Coordinator nodes in the Dissociated-PoW blockchain network follows a functional model that is similar to node coordination in a Kafka cluster [28]. A leader node is designated, and the rest of the CN become followers. Only the leader node can determine the timing of mining and which MN will be responsible for the mining task. The designation of a leader node is based on the order of entry to the BC network, and in the event of the leader node's failure, the next node in the list is designated as the new leader. Every CN has a synchronized PT block, so if any CN goes down, as long as there is at least one CN remaining in the network, the process continues uninterrupted.

Nodes may enter the BC network with the roles of MN, CN, or both. However, having both roles do not give priority to the node in being designated as a MN. The decision of exactly when to start mining follows predefined rules in the BC. Typically, mining is triggered when a certain number of pending transactions is reached or when a specific time limit between mining operations is reached if there are pending transactions. Additionally, a maximum pending transaction limit criterion is used to restrict the size of the block to be mined. Employing a time limit criterion ensures that transactions are not left waiting indefinitely to be mined. Deciding exactly when to mine simply follows predefined rules in the BC. Normally, mining is set when a certain number of pending transactions is reached or when a certain time limit between mining is reached, if there are pending transactions. A maximum PT limit criterion limits the size of the block to be mined. Using a time limit criterion allows transactions not to be left eternally waiting to be mined.

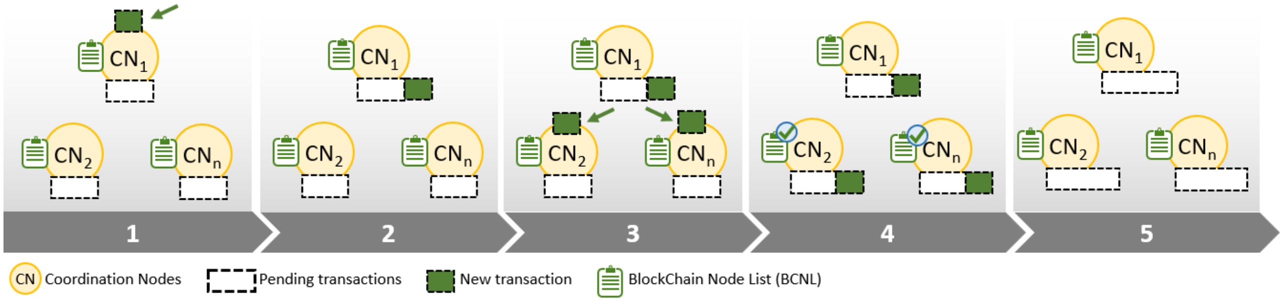

Fig. 2. Action flows of the coordination nodes for the specified tasks.

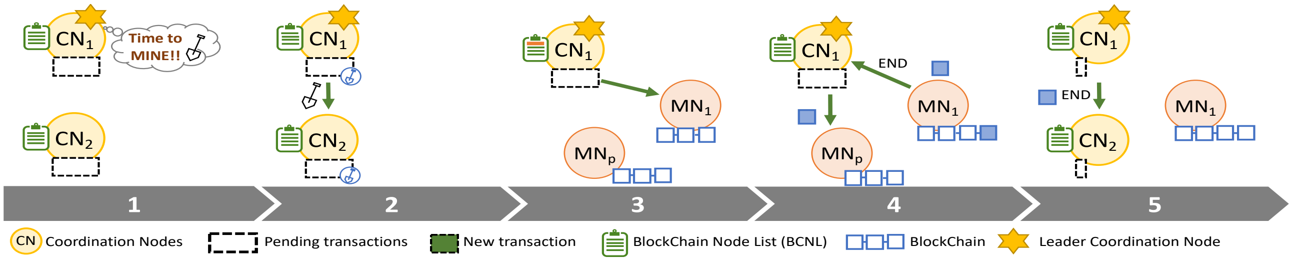

Fig. 3. Action flows to start mining nodes.

When the leading CN determines that mining is necessary, it instructs the other CN in the network to freeze the PT block, ensuring that any new incoming transactions are directed to a new temporary PT block. This way, the PT block being mined remains unchanged.

The BCNL (Blockchain Node List) is utilized to select the main CN responsible for mining the PT block. This list contains all the nodes comprising the BC network, their respective roles, the PT blocks mined by each node, and their hardware specifications. Moreover, nodes can provide information about their performance status. For instance, if a node is experiencing overload at a given time, it can indicate this in the BCNL to avoid being designated as a mining node. With access to this list, the leading CN can choose the most suitable node at that moment, taking certain constraints into consideration:

- The best-performing node will be selected from the BCNL list.
- Mining distribution will be balanced to ensure that all nodes in the list participate in the mining process.
- If no MN can be designated, the leading CN will keep the block as pending mining until a node from the list becomes available.

To participate as an MN, the BC may require a minimum level of computational resources to ensure that mining can occur in a timely manner. Additionally, even the leading BC may reject a mining request made to a node if it determines that the node will be unable to complete the mining task. In such cases, the request will be redirected to a new MN.

This approach enables the Dissociated-PoW architecture to efficiently manage mining tasks and ensure that mining is carried out optimally based on the performance capabilities of the participating nodes.

IV. Benchmarking Proposal Compared against other Algorithms

This proposal, as discussed in the previous section, offers several benefits that make the Dissociated-PoW consensus algorithm more effective than other existing algorithms, overcoming many of the disadvantages present in traditional ones. In this chapter, we will compare our Dissociated-PoW algorithm with the following consensus algorithms: Proof of Work (PoW), Proof of Stake (PoS), Delegated Proof of Stake (DPoS), Delegated Byzantine Fault Tolerance (dBFT), Proof of Activity (PoA), Proof of Burn (PoB), Proof of Capacity (PoC), Proof of Elapsed Time (PoET), Proof of Assignment (PoA), Proof of Checkpoint (PoC), and Ripple Protocol Consensus Algorithm (RPCA).

As mentioned earlier, the main disadvantage of PoW is the substantial computational and energy requirements to solve the consensus test, with exclusive resource usage that cannot be utilized for other tasks. Additionally, the well-known 51% attack poses a significant problem, with the algorithm being dominated by large mining pools. On the contrary, our proposal ensures that only the designated mining node invests computational and energy resources, leading to substantial savings as there is no competition among nodes. By dissociating the selection of the time and mining node from the traditional competition algorithm, we also eliminate the risk of a 51% attack, ensuring that no entity dominates the PoW algorithm and avoiding the dominance of large miners.

In PoS, significant drawbacks include challenges in maintaining miner anonymity, as those who invest the most in the BC end up being the dominant miners in solving the consensus algorithm. Scalability issues and potential slow transactions also arise. In Dissociated-PoW, the CN oversees selecting the best candidate for mining, guaranteeing investor anonymity and independence from major stakeholders. As the network has specialized nodes dedicated to BC maintenance, the quality of service is assured, avoiding collapsed nodes except for the one that may be mining at any given time. However, as the BC is replicated in the rest of the nodes, its operation can be supported by a nearby node.

The DPoS algorithm is also vulnerable to centralization due to its limited number of nodes in the network, and transactions are not anonymous. In Dissociated-PoW, all transactions are anonymous, and the number of nodes is organized by the CN and MN responsible for distributing the workload.

The dBFT algorithm employs a relatively recent protocol that has not been extensively tested in large Blockchain networks, making it susceptible to centralization with a limited number of representing nodes. Similar to DPoS, transactions are not anonymized. Dissociated-PoW addresses these concerns by having a specific group of nodes that focus on coordinating work and sending pending transactions to MN to commence mining after a certain period.

Overall, Dissociated-PoW offers improved anonymity, decentralization, and scalability while mitigating the vulnerabilities present in other consensus algorithms, making it a promising choice for effective and efficient blockchain networks.

In the PoET algorithm there is no anonymity. Making it vulnerable to Sybil attacks [30], The more malicious nodes there are, the higher the likelihood that some of them will be involved in block formation. In contrast, in Dissociated-PoW, participants remain anonymous, and as the CN are responsible for overseeing mining, Sybil attacks among the MN are not possible. As for the CN, malicious actions may involve attempting to extract a fake PT packet, but this would be detected by the other CN. They could also try to slow down the BC network, but this would be detected as a failure of the leading CN, and the next CN in the list would take the lead. Additionally, they may attempt to overload an MN by sending it all mining requests, but the MN can update its status in the BCNL at any time to prevent receiving further requests.

On the other hand, Proof of Assignment (PoA) has limitations in capacity due to the processing speed and available memory of IoT devices. In Dissociated-PoW, capacity is not limited during the processing of PTs as the CNs choose the best available miner node, balancing network loads to avoid saturating a single node.

For the Proof of CheckPoint (PoC) algorithm, trust nodes external to the network are required. In Dissociated-PoW, no external nodes are needed as it only involves the coordinator and miner nodes.

In the RPCA algorithm, the network is exposed to centralization as the number of nodes representing the network is very limited, and transactions are not anonymous. In Dissociated-PoW, the CN and MN are responsible for selecting the best candidate to start mining, guaranteeing investor anonymity, and not relying on centralized entities.

Overall, Dissociated-PoW offers advantages over several existing consensus algorithms by ensuring participant anonymity, mitigating vulnerabilities to Sybil attacks, and avoiding the need for external trust nodes while maintaining high processing capacity and network decentralization.

In the next Table I, issues presented within the current algorithms can be grouped as follows:

1) Anonymity loss: This criterion evaluates whether the algorithm preserves the anonymity of nodes participating in the blockchain network. A "Yes" indicates that the algorithm does not provide strong anonymity, meaning that at some point, the identities of network nodes or owners can be identified. Dissociated-PoW receives a "No" in this category, meaning it preserves anonymity.

2) Deployment: This criterion assesses the complexity of implementing the consensus algorithm. A "Simple" deployment means that the algorithm is straightforward and easy to implement, while a "Complex" deployment suggests that it requires more effort and expertise to set up. Dissociated-PoW is considered "Simple" in this regard.

3) Non-Vulnerable to centralization: This criterion determines whether the consensus algorithm is at risk of centralization, where a small number of nodes gain excessive control over the network. A "Yes" indicates vulnerability to centralization, while a "No" means the algorithm is designed to resist centralization. Dissociated-PoW is not vulnerable to centralization.

4) Resources in network: This criterion evaluates the number of resources (such as computational power, memory, etc.) needed to maintain the blockchain network. "High" resources mean considerable requirements, while "Low" resources indicate that the algorithm can operate efficiently with minimal resources. Dissociated-PoW requires low resources.

5) Low computing load: This criterion assesses the power consumption and computing demand of the consensus algorithm. "Yes" indicates that the algorithm has low computing load, while "No" means it is computationally intensive. Dissociated-PoW has low computing load.

6) IoT device friendly: This criterion determines whether the consensus algorithm is suitable for IoT devices, which often have limited processing capabilities. "Yes" means the algorithm is compatible with IoT devices, while "No" suggests it may not be well-suited. Dissociated-PoW is friendly to IoT devices.

The comparison table shows that Dissociated-PoW performs well in terms of preserving anonymity, simplicity of deployment, non-vulnerability to centralization, efficient resource usage, low computing load, and compatibility with IoT devices. However, it's important to note that each algorithm has its strengths and weaknesses, and the best choice depends on the specific requirements and goals of the blockchain network being considered (see Table I).

TABLE I. OVERVIEW OF THE PROPERTIES OF VARIOUS CONSENSUS ALGORITHMS COMPARED TO DISSOCIATED-POW

Consensus Algorithm	1	2	3	4	5	6
Pow	Yes	Complex	No	High	No	No
Pos	Yes	Simple	No	Low	Yes	No
DPos	Yes	Simple	No	Low	Yes	No
dBFT	Yes	Simple	No	Low	Yes	No
PoA	Yes	Simple	No	Low	Yes	No
PoB	Yes	Complex	No	High	No	No
PoC	Yes	Complex	No	High	No	No
PoET	Yes	Complex	No	Low	Yes	Yes
PoA	Yes	Simple	Yes	Low	Yes	Yes
PoC	Yes	Simple	No	Low	Yes	No
RPCA	Yes	Simple	No	Low	Yes	Yes
Dissociated-Pow	No	Simple	No	Low	Yes	Yes

V. DISSOCIATED-POW PROBLEMS

Introducing a new architecture, such as Dissociated-PoW proposal, may indeed bring certain potential drawbacks. One of the concerns is the possibility of malicious coordinator nodes and mining nodes gaining access to the network, particularly in a public network where there are no access control mechanisms.

A. Mining Nodes Vulnerabilities

Potential vulnerabilities in this section will describe the possible security issues arising from malicious actions or failures in the mining nodes. Details of the CNs and MNs for the transactions that are integrated in the blockchain have been presented so far. The key to its operation is the validation of the transaction. For this reason, mining, consisting of closing the block and distributing it in the BC, must be carried out. As stated, miners communicate among themselves.

B. Eternal Mining (Lack of Computing)

Typical blockchain mining issues include the possibility of a mining node never finishing or being too late, either if the mathematical problem to be solved turns out to be very complicated or if the node does not have sufficient computational capacity at that time. To resolve this situation, CN must maintain a time limit. Once this limit is exceeded without results, the CN will withdraw the right to mine from the selected node and pass it to another CN, providing an opportunity for the block generation to occur. Alternatively, a function could be implemented where the MN is not removed from the mining right, but another new node is selected to start mining to check if it can deliver a result before the original node. This way, even if the first node fails, no computing power will have been wasted.

C. Malicious and Vulnerable Coordinating Nodes and Miners

Malicious MN may attempt to mine fake content, i.e., transactions that were not originally processed by the CN, and try to sneak them in. After they finish mining the MNs, send the new block to the CN, whose job it is to validate that the node is correct, and therefore if they have tried to introduce transactions that were not in the original PT, they will be discarded. If it is correct, it will be distributed to other MN and CN, and in turn the CN will distribute it to nearby MN. If it is a malicious node, it is kicked out and otherwise distributed to the rest of the MN nodes in the network. Potential vulnerabilities caused by malicious actions or failures in the coordinator nodes will be described in this section.

D. Trying to Crash a Mining Node

It consists of a CN involuntarily sending mining requests to the same MNs all the time, overloading them with work. A BCNL exists, where CN may update their state to not receive requests. In Dissociated-PoW, there is a list called BCNL, where CN may update status for MN to not accept and receive any more requests, avoiding overloading MN. For an MN to receive a PT, it must receive a low mining workload.

E. Not Launching the Mining Process

As the leader CN oversees determining the start of mining, should this node fail for any reason, orphaned mining won't start. Other CN must enable a mechanism for detecting such a situation and designate new leaders independently. The role of the CN is to supervise the proper functioning of the leader node. As there are several CN, if a lag is detected, a second CN takes over leadership, notifying other CN of the incident, and the current leader is automatically substituted.

F. The CN is Malicious and Orders False Content to be Mined

Upon distribution of a new BC block, it must be validated through its BCNL by all CN to identify whether it is a bogus block or not. If it is a bogus block, it must be discarded and removed from the network.

To mitigate these potential drawbacks, it is important to implement robust security measures, access controls, and thorough vetting processes for CN and MN. Additionally, ongoing monitoring, auditing, and regular updates to the architecture can help address emerging security concerns and maintain a healthy and secure network environment.

It is essential to thoroughly analyse and address these potential drawbacks when designing and implementing a new architecture to ensure the overall security and integrity of the blockchain network.

VI. Conclusion and Future Work

This research makes several valuable contributions to the field of blockchain technology and consensus algorithms. First and foremost, it presents the Dissociated-PoW algorithm as a novel and innovative solution to address the limitations of traditional Proof of Work and other existing consensus algorithms. By functionally specializing nodes, Dissociated-PoW efficiently implements PoW while minimizing computational expenses, making it more sustainable and scalable for diverse blockchain networks.

Furthermore, the comprehensive analysis and comparison of various consensus algorithms provide valuable insights into their strengths, vulnerabilities, and suitability for different use cases. This analysis aids researchers, developers, and decision-makers in understanding the trade-offs between different consensus mechanisms, guiding them in choosing the most appropriate algorithm for their specific blockchain applications.

The proposed future work of building a robust framework that encompasses multiple consensus algorithms and emphasizes privacy safeguards across different blockchain architectures is forward-thinking and crucial for the continued advancement of blockchain technology. By addressing issues like high computational demands, network performance, and node failures, the research contributes to the development of more secure, efficient, and resilient blockchain networks.

Despite these significant contributions, the research also acknowledges certain limitations. Firstly, due to the complexity and variety of blockchain networks and consensus algorithms, conducting a detailed analysis of all possible combinations may not be feasible within the scope of this research. However, the chosen approach of comparing existing algorithms provides valuable insights and lays the foundation for future research to explore additional combinations and innovations.

Additionally, as with any research in the rapidly evolving field of blockchain technology, the proposed Dissociated-PoW algorithm and future framework may face challenges in real-world implementation. Practical testing and validation on various blockchain networks will be essential to ensure the algorithm's effectiveness and security.

Inclusive, this research makes a significant scientific contribution by proposing a novel consensus algorithm, conducting a thorough comparative analysis, and outlining a comprehensive roadmap for future work. It offers valuable insights into the state of blockchain consensus algorithms and provides a foundation for advancing the field, addressing limitations, and shaping the future of decentralized systems.

College of Computing and Information Technologies, National University, Manila, Philippines[3]

***Abstract*—The Universal Access to Quality Tertiary Education (UAQTE) marks a significant policy change in the Philippines. While the program's objective is to offer free higher education and tertiary education subsidies to eligible Filipino students, its viability and effectiveness have been subject to scrutiny and continuous evaluation. This study explores the sentiments of Filipinos towards UAQTE. Leveraging a fine-tuned multilingual Bidirectional Encoder Representations from Transformers (mBERT) model, we conducted sentiment analysis on code-mixed data. With minimal preprocessing, our model achieved an accuracy of 80.21% and an F1 score of 81.14%, surpassing previous related studies and confirming its effectiveness in handling code-mixed data. The results reveal that the majority of social media users view UAQTE positively or beneficially. However, negative sentiments highlight concerns related to subsidy delays, alleged fund misuse, and application challenges. Additionally, neutral sentiments center around subsidy-related announcements. These findings provide valuable insights for its key stakeholders involved in the implementation, enhancement, and evaluation of UAQTE.**

Keywords*—*Sentiment analysis; UAQTE; code-mixing; policy-making; multilingual BERT

I. Introduction

Countries worldwide increasingly recognize the importance of higher education for economic competitiveness [1]. This has led to a greater focus on understanding the costs and benefits of education and research, and the need for improved productivity in higher education [2]. Among the 17 Sustainable Development Goals (SDGs) set by the United Nations, the fourth goal specifically focuses on Quality Education. This goal is dedicated to achieving inclusive and equitable access to high-quality education and fostering lifelong learning opportunities for all individuals by the year 2030 [3].

One of the most significant turning points in Philippine education is the proactive efforts of the government to broaden the reach and involvement in higher education by approving the Republic Act 10931, otherwise known as the "Universal Access to Quality Tertiary Education (UAQTE) Act", enacted into law on August 2017. The UAQTE initiative represents a significant legislative effort to ensure widespread access to high-quality tertiary education by providing free tuition and covering other school fees in State Universities and Colleges (SUCs), Local Universities and Colleges (LUCs), and State-Run Technical Vocational Institutions. Specifically, this law established four programs namely Free Higher Education (FHE), Tertiary Education Subsidy (TES), Tulong Dunong Program (TDP), Free Technical and Vocational Training, and Student Loan Program. Its implementation is primarily led by the Unified Student Financial Assistance System for Tertiary Education (UniFAST), an attached agency of the Commission on Higher Education (CHEd) [4].

Although its objectives were clearly defined, its feasibility has been questioned. Concerns have been raised about the design of the law, its implementing rules and regulations, and the adequacy of resources to sustain its programs. Early assessment of the program [5], explained that the absence of clear and prompt guidelines had caused difficulties in service delivery and utilization, particularly in the processing of billing requirements, resulting in delays in reimbursement. Thus, continuous evaluation and improvement are necessary to ensure the program's effectiveness in achieving its goals.

With the changing landscape of information sharing, social media platforms have emerged as vital channels for public discussions and viewpoints on a wide range of social and political matters [6]. As of this writing, the Philippines has a notable digital presence, with 83% of its population being internet users. Filipinos spend approximately four to five hours per day on social media, which is twice the global average of two to three hours [7]. This significant difference highlights the pervasive role of social media in the lives of Filipinos. Consequently, leveraging this wealth of social media data through Natural Language Processing (NLP) techniques, such as sentiment analysis, holds immense potential for enhancing our understanding of public perception and sentiment towards the UAQTE.

Many government-initiated practices tend to adopt a top-down approach to knowledge sharing [8]. This approach often treats local communities as passive recipients rather than active collaborators. This observation highlights the significance of incorporating the sentiments of local communities, in our case, the stakeholders of UAQTE, in the analysis process.

The findings of this study aim to contribute to a deeper understanding of public sentiments surrounding UAQTE and can serve as inputs for decision-makers at CHEd, UniFAST, educational institutions, and other stakeholders involved in implementing and evaluating the UAQTE program. To the best

Philippine Commission on Higher Education (CHEd) Leading the Advancement of Knowledge in Agriculture and Science (LAKAS) Project No. 2021-007, eParticipation 2.1: Harnessing Natural Language Processing (NLP) for Community Participation.

of our knowledge, this study is the first to evaluate UAQTE sentiments using sentiment analysis on code-mixed social media data. Through the application of the state-of-the-art multilingual Bidirectional Encoder Representations from Transformers (mBERT) [9], we also aim to test its efficacy in identifying prevailing neutral, positive, and negative sentiments expressed towards UAQTE.

In this introduction, we have provided an overview of the research focus and rationale for conducting sentiment analysis on social media data related to the UAQTE. Section II discusses related works on education and utilizing code-mixed data for sentiment analysis. Section III covers the methodology, including data collection, preprocessing, and fine-tuning of mBERT. In Section IV, we present the results on the effectiveness of mBERT in code-mixed sentiment analysis and discuss public sentiment distribution towards UAQTE. Section V concludes with key insights and implications, while Section VI outlines the limitations and future research directions to enhance sentiment analysis in code-mixed data.

II. Related Works

Sentiment Analysis involves analyzing a sequence of words to uncover the underlying emotional tone and gain insights into the attitudes, opinions, and emotions conveyed in online mentions [10]. This type of analysis is used in various fields, including business and marketing, politics, health, and social policy, to allow policymakers to formulate informed adjustments to new user-centric rules and regulations [11]. In this section, we will discuss the application of sentiment analysis in the field of education and its findings when this technique is applied to code-mixed data settings.

A. Sentiment Analysis on Education

In the context of education, [12] utilized a range of machine learning techniques, including Support Vector Machine (SVM), Multinomial Naive Bayes (MNB), Random Forest (RF), and Multilayer Perception classifier. By exploring and comparing different SA models, the study successfully determined the effective approaches for analyzing student's classroom feedback that would enhance the quality of teaching in higher education institutions. Moreover, they highlighted the potential of social media platforms like Twitter and Facebook as valuable sources for gathering information and extracting opinions pertaining to students' learning experiences. The study of [13] aimed to understand the drivers of success for higher education institutions (HEIs) in the online realm. They conducted text mining and sentiment analysis on online reviews from various business schools. The findings revealed that HEIs can enhance their online attractiveness by offering financial support for students' cost of living, providing courses in English, and cultivating an international environment. These factors were identified as influential in shaping the perceptions and preferences of international students seeking to study abroad. Similarly, [14] observed through an analysis of social media posts that a predominant expression of negativity exists regarding the K to 12 Program in the Philippines, indicating a pressing need for its implementers to enhance its implementation measures.

B. Sentiment Analysis on Code-Mixed Data

Code-mixing is a linguistic phenomenon observed among multilingual individuals who prefer using their native language over English to express information [15]. Code-mixed text, whether spoken or written, is prevalent in multilingual societies including the Philippines [16]. Social media platforms like Facebook, Twitter, and online forums are common sources of code-mixed content. As stated in [17], sentiment analysis of monolingual text has been extensively studied, but code-mixing introduces additional complexity in analyzing the text's sentiment due to its non-standard writing style.

As presented in the review of [18], the sentiment analysis of code-mixed and switched English with Indian languages achieved a range of 0.39 to 0.77 F1 Score wherein SVM, NB, and RF were the most used Machine Learning classifiers.

In the local setting, [19] utilized SentiWordNet 3.0 and FilCon, English and Filipino lexicons respectively to generate initial sentiment classifications. NB and SVM hybrid models were trained using these sentiment labels. To handle TagLish comments, a Code-Switching Point Detection Module was employed to separate English and non-English words, which were then processed using the appropriate lexicons. The lexicon module achieved an overall accuracy of 55%, while the Naive Bayes before Support Vector Machines hybrid model achieved accuracies of 55% overall, 58% for English, 46% for Filipino, and 57% for a mix of Tagalog and English or TagLish. The Support Vector Machines before Naive Bayes hybrid model achieved accuracies of 61% overall, 70% for English, 54% for Filipino, and 54% for TagLish.

In [20], it was determined that existing bilingual embedding techniques were not suitable for processing code-mixed text. They emphasized the necessity of developing multilingual word embeddings specifically designed for code-mixed text processing. In [21], a study was conducted on code-mixed Persian-English data to perform sentiment analysis. They argued that the uniqueness of analyzing code-mixed data lies in the fact that the presence of English words within the Persian text can significantly impact the emotional expressions conveyed. This poses a challenge for Persian-only sentiment analysis models, as they may struggle to accurately interpret and generate correct outputs due to the mixed language context. They utilized Yandex and dictionary-based translation techniques to translate the code-mixed words present in the text. Additionally, pre-trained BERT embeddings, specifically mBERT was employed to represent the data which achieved an accuracy of 66.17% and an F1 score of 63.66%, surpassing the performance of the baseline models namely Naive Bayes and Random Forest methods. The effectiveness of mBERT in this setting was also assessed in a comparative study conducted by [22] on Hindi-English code-mixed data. The study revealed that mBERT outperformed ALBERT, vanilla BERT, and RoBERTa models, except for HingBERT-based models, which were specifically trained on Hindi-English code-mixed data.

III. Methodology

In this section, we present the methodology employed to collect, preprocess, and annotate the data, perform the fine-tuning of the mBERT model, and evaluate the sentiment analysis results.

A. Data Collection

To capture information preceding the official implementation of UAQTE, data collection was conducted from April 1, 2017, to April 10, 2023. The process involved employing scraper libraries, enabling the systematic and organized retrieval of relevant data.

1) Facebook: We collected a total of 10,443 textual data from the posts that were set as public and official regional groups of CHEd. These groups, which include Ilocos Region (Region 1), MIMAROPA (Region 4-B), Bicol Region (Region 5), Western Visayas (Region 6), Central Visayas (Region 7), Eastern Visayas (Region 8), Zamboanga Peninsula (Region 9), Northern Mindanao (Region 10), Davao Region (Region 11), CARAGA (Region 13), National Capital Region (NCR), Cordillera Administrative Region (CAR), were specifically established to facilitate discussions, address concerns, and provide a platform for beneficiaries and stakeholders of the UAQTE. These regional groups served as valuable sources of opinions and insights related to UAQTE.

2) Twitter: To collect a relevant dataset, we utilized specific keywords and hashtags such as “ched unifast”, “tdp grantee”, “tes grantee”, “#PINASkolar”, and “#TertiaryEducationSubsidy”. We were able to collect 1,112 raw tweets.

3) YouTube: In addition to collecting data from social media platforms like Facebook and Twitter, data was also collected from YouTube comments due to its significant presence as a popular video-sharing platform. To gather relevant content, YouTube videos were manually searched using specific keywords such as “CHED UniFAST”, “UniFAST TES”, “Libreng Edukasyon UniFAST”, and “RA 10931 Free Tuition”. The selection process involved identifying videos with high view counts, ensuring that the chosen content resonated with a wide audience and potentially represented popular sentiments and discussions surrounding the topic of interest. From the 49 videos, we were able to collect 1,777 raw YouTube comments.

B. Data Preprocessing

A total of 13,332 data points were collected for the purpose of data preprocessing. Since posts, tweets, or comments originate from various users and reflect individual opinions, URLs were the key identifier used to remove duplicates. Furthermore, posts that were unrelated to the implementation of UAQTE such as presidential election campaign-related content, underwent manual inspections and were excluded from the dataset. It is important to note that for YouTube data, the collection date was recorded and used to determine the timeframe of the content, whether it was posted months, days, or years ago. As mentioned in [23], BERT has shown optimal performance with little to no preprocessing. Therefore, a few preprocessing techniques were applied, including spelling corrections (e.g., “dhil” to “dahil” (English: because), “cguro” to “siguro” (English: maybe), normalization of special characters, removal of white spaces, punctuations and symbols, and the conversion of emojis to their textual representation.

C. Data Annotation

From the preprocessed data, 4,650 (50%) data points were manually labeled and subjected to validation by experts. This annotated data serves as the benchmark and reference for sentiment classification. Following the approach adopted from [24], the data were classified into three categories: neutral, negative, and positive encoded as numbers 0, 1, and 2 respectively.

Positive sentiment encompasses expressions of satisfaction, happiness, admiration, interest, and gratitude. Neutral sentiment pertains to statements that do not exhibit any discernible sentiment, conveying information or facts. Negative sentiment includes expressions of dissatisfaction, anger, disappointment, sarcasm, mockery, and frustration regarding the UAQTE implementation. Table I shows the sample of annotated and validated data points.

TABLE I. SAMPLES OF ANNOTATED DATA

CHED Chairman Popoy De Vera discusses the guidelines on the new degree programs approved for limited face-to-face classes.	0
Pero ba’t wala pong budget ang mga 2021-2022 applicants new grantees? Saan po napunta ang budget? (English: But why do the 2021-2022 applicants who are new grantees have no budget? Where did the budget go?)	1
Thank you so much CHED- UNIFAST Tertiary Education Subsidy.. And to ACLC College of Bukidnon ..	2

D. Fine-Tuning of Multilingual BERT

The BERT model’s architecture is built upon the Transformer framework [25]. When provided with a sequence of up to 512 tokens as input, BERT generates a representation of the entire sequence, which can comprise one or two segments. The first token of the sequence, denoted as [CLS], holds a special classification embedding, and another special token, [SEP], is used to separate segments. To represent the entire sequence for text classification tasks, BERT leverages the final hidden state of the first token [CLS]. A classifier is added on top of BERT to predict the probability or sentiment of the label. During the training process, BERT is fine-tuned based on the task-specific training dataset. Fig. 1 illustrates the BERT fine-tuning model architecture for sentiment classification, adapted from [26], although in our case, sentiments were classified into three sentiment classes, namely neutral, positive, and negative.

While BERT has been pre-trained on English corpus, a multilingual version of BERT (mBERT) [9] has been trained jointly on Wikipedia on 104 languages including English, Tagalog, Waray, and Cebuano, hence, considering the code-mixed nature of the dataset, we downloaded the BERT multilingual base model (cased) from Hugging Face via ktrain [27], a lightweight wrapper for the deep learning library TensorFlow Keras on Google Colaboratory that provides

NVIDIA Tesla T4 12 GB of RAM, and Intel® Xeon® Processor.

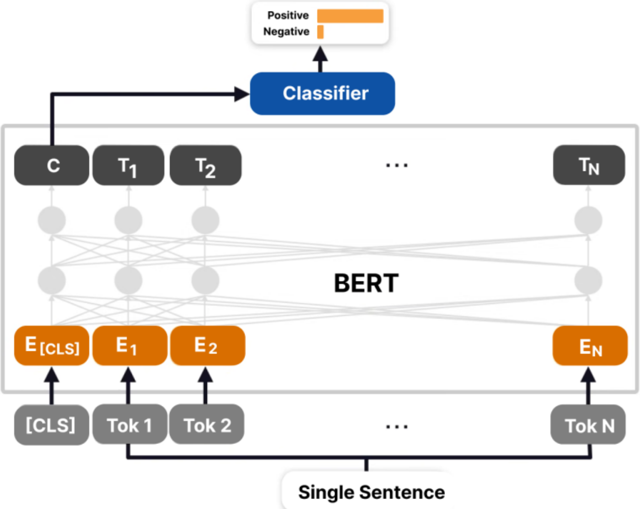

Fig. 1. Fine-tuning BERT for sentiment classification [26].

Among the recommended values of learning rates when fine-tuning on specific tasks were 2e-5 [28], 5e-5, and 3e-5 using batch sizes 16 and 32 at 4 epochs, [29]. Further, a maximum length of 160 was set considering the 95th percentile value obtained from the descriptive statistics of the word lengths, to ensure a manageable memory size and sequence length. To address the class imbalance, class weights were applied to the three classes.

E. Model Evaluation

To evaluate the performance of the sentiment analysis models, two key metrics were utilized: F1 score and accuracy. Subsequently, the best-generated model will be utilized to predict the sentiment classes of the remaining data.

IV. Results and Discussion

The fine-tuned mBERT model exhibited varying levels of performance across different combinations of batch size and learning rate. Table II presents the accuracy and F1 scores achieved by each model configuration.

In contrast to the experiment conducted by [19], which removed stopwords, our approach involves minimal preprocessing of texts and includes stopwords. Additionally, we take into account the textual representation of emojis, setting our study apart from the research conducted by [22]. By considering emojis, we aim to capture a more nuanced understanding of sentiments expressed in social media data, enhancing the contextual analysis capabilities of mBERT. Model 1, with a batch size of 16 and a learning rate of 2e-5, emerged as the best-performing model with 80.21% accuracy and an F1 Score of 81.14%. surpasses the findings of related studies discussed in Section 2 in terms of their F1 Score and Accuracy. Hence, this model was used to classify the remaining data points.

Findings revealed that 2,100 (22.58%) were neutral, 1,647 (17.70%) were negative, and 5,553 (59.70%) were positive, indicating that majority of the social media users view UAQTE as positive or beneficial in the country.

TABLE II. Performance of the Fine-Tuned mBERT Model

Model	Batch Size	Learning Rate	Accuracy	F1 Score
1	16	2e-5	**80.21%**	**81.14%**
2		3e-5	79.42%	80.03%
3		5e-5	79.49%	80.20%
4	32	2e-5	79.78%	80.78%
5		3e-5	76.91%	78.21%
6		5e-5	79.49%	80.65%

A user from Twitter expressed positive feedback towards UAQTE, “Thank you God nakasali ako sa ched-unifast. Malaking tulong na po ito” (English: “Thank you God I was able to be a member of ched-unifast this is helpful”). Neutral contents were composed of announcements and updates regarding subsidies. A Facebook post expressing frustration with CHED reads, “nakakaloka yung CHED beh. patapos na ako, wala pa din yung sa UniFAST hahahaha” (English: “It’s crazy, CHED! I’m almost done with my studies, but I still haven't received anything from UniFAST, hahahaha.”). This post conveys a sense of disappointment and humor, suggesting that the individual has been anticipating support or benefits from UniFAST but has yet to receive them.

As shown in Fig. 2, the sentiments towards the implementation of the UAQTE have shown interesting dynamics over the years.

From 2017 to 2018, the sentiments were characterized by a relatively low number of neutral sentiments, while negative sentiments were more prevalent which can be attributed to the initial challenges in implementing the program as discussed by [5].

In 2019, the distribution of sentiments experienced a significant shift. The number of neutral sentiments increased notably, possibly due to improvements or adjustments made to address previous concerns. Negative sentiments decreased, while positive sentiments remained relatively low, indicating ongoing debates or skepticism surrounding the program.

In year 2020 witnessed a relatively balanced distribution of sentiments across the three categories. This suggests a period of relative stability or reduced controversy, where public opinion was less polarized. However, in 2021, sentiments experienced a sharp rise across all categories. Negative sentiments and positive sentiments increased substantially, while neutral sentiments also reached a significant level. This is likely due to the release of subsidies to beneficiaries, with some expressing gratitude for receiving them while others express disappointment for not receiving them on time. This could be also attributed to the pandemic's impact on the education sector. Inquiries and concerns regarding the bank application of the grantees were also found. The trend continued in 2022 with sentiments reaching even higher levels across all categories. This suggests ongoing discussions, policy developments, or increased public attention toward the program, resulting in a more polarized sentiment landscape. Finally, in 2023, sentiments experienced a notable decline across all categories but experienced a substantial rise in negative sentiments which was likely due to reports of alleged misuse of funds intended for the implementation of the program [30].

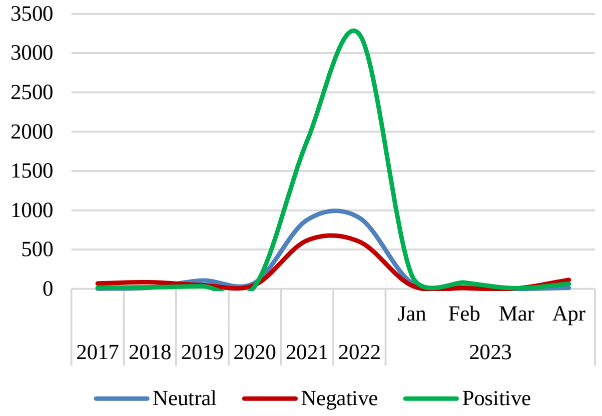

Fig. 2. Trend of social media users' sentiments towards the implementation of UAQTE from 2017 to 2023.

These fluctuations in sentiments over the years highlight the dynamic nature of public opinion and the influence of various factors, such as policy changes, media attention, and public discourse, on the sentiments towards the implementation of the UAQTE.

V. Conclusion

UAQTE has been a notable policy shift in the Philippines. While the program aims to provide free higher education and tertiary education subsidies to eligible Filipino students, its feasibility was questioned and assessed.

This study analyzed the sentiments expressed on social media platforms such as Facebook, Twitter, and YouTube. where code-mixing is prevalent, regarding the implementation of UAQTE policy in the Philippines between April 1, 2017, and April 10, 2023. We used a fine-tuned mBERT model to perform sentiment analysis on the collected data. With minimal preprocessing, mBERT achieved an accuracy and F1 score of 80.21% and 81.14%, respectively. These results outperformed the existing studies, as outlined in Section 2, demonstrating the effectiveness of mBERT in handling code-mixed data for sentiment analysis and revealing a dominant positive sentiment perceived by social media users regarding the implementation of UAQTE.

The prevailing positive sentiments expressed gratitude towards the UAQTE, which suggests that UAQTE has been beneficial for the intended stakeholders. However, the analysis also identified the presence of negative sentiments related to the late distribution of subsidies, alleged misuse of funds, and difficulties in the application of bank accounts such as erroneous online application portal of the beneficiaries. The neutral sentiments mostly involved announcements, news, and updates regarding the release of the subsidies. Addressing these concerns can help enhance the program's effectiveness and ensure that it continues to meet its objectives.

VI. Limitations and Future Work

While this study contributes significant insights, it is essential to acknowledge its limitations. The analysis is limited to social media data and may not fully represent the entire population's sentiments. Moreover, analyzing the sentiment of specific demographic groups, such as students or parents, may provide additional insights that could inform more targeted policies and initiatives. Additionally, exploring the use of cross-lingual language models (XLMs) like XLM-RoBERTa and hybrid BERT models for sentiment analysis may improve the accuracy and reliability of the results with code-mixed data.

Acknowledgment

The researchers would like to thank the Philippine Commission on Higher Education (CHEd) Leading the Advancement of Knowledge in Agriculture and Science (LAKAS) Project No. 2021-007, eParticipation 2.1: Harnessing Natural Language Processing (NLP) for Community Participation, for providing the necessary funds to make this research possible. The researchers are truly grateful for their contribution to the research.

Criminal Law Risk Management and Prediction Method based on Echo State Network

Zhe Li
School of Marxism, Nanyang Institute of Technology, Nanyang, 473000, China

***Abstract*—Criminal law plays an important role in maintaining social security and achieving effective social control. However, criminal law has hidden risks that cannot be ignored at the legislative, judicial and theoretical levels. This paper starts from all aspects of criminal law, analyzes criminal law risk and its management measures, and predicts and analyzes criminal law risk through echo state network model. The prediction results of the echo state network model fit well with the actual situation, and its verification can provide reference for the study of criminal law risk prediction and management systems. Legislative risk and theoretical risk belong to social factors and are also fundamental risks of criminal law. Judicial risk is mainly manifested in the level of judicial power. Criminal law is closely related to the political environment, social system, economic system, etc. In criminal law legislation, we should pay attention to the balance between criminal law rules and realistic social functions, and properly control social risks, so as to avoid the criminal law risks brought by the establishment of risky criminal law, and provide the necessary guarantee for the national security system.**

Keywords—Echo state network; model; criminal law; risk prediction; risk prediction

I. Introduction

Since the implementation of the reform and opening-up policy in 1978, both China's national home-building and criminal rule of law processes have made great strides; in particular after the comprehensive revision of the Criminal Code in 1997, my country has successively introduced 1 single criminal code, 10 criminal code amendments, into one criminal code A new era of active legislation. Overall, over the past two decades, Criminal law intervention is early and active, and the criminal circle continues to expand. It has become the main development trend of my country's criminal law. This is for China's current Criminal law concept has had a significant impact, risk criminal law concept, positive criminal law Legislative view, preventive criminal law view, and functionalist view of criminal law have appeared one after another field, trying to theoretically interpret and judge this trend. Approximately In terms of criminal law, the above-mentioned concept of criminal law is explanatory or affirmative to the expansion of criminal law attitude and require moderate restrictions. At the same time, critical attitude insights hold that this (or "some") expansion of criminal law is a in "symbolic legislation", "emotional legislation" or new criminal law instruments" doctrine, and even advocated that “our country should stop the criminalization of criminalization "legislation" [1,2]. Some of the above differences of opinion are principled, and they are quite. To a certain extent, it explains our basic criminal law about the development of China's current criminal law. There is also a need for an in-depth review of the legal concept. The idea of criminal law is that people The nature, function, crime, punishment, relationship between crime and punishment, system of criminal law understanding, view, mentality and value of a series of issues such as determination and implementation general term for orientation. A well-established view of criminal law is important for judgment and instruction. It is of great significance to guide the development of criminal law, reviewing the development since the reform and opening up Chinese social changes, correct interpretation and evaluation of the criminal law since 1997 The development of criminal law legislation is conducive to the scientific level of criminal law legislation improve [3,4].

It's essential to understand the evolution of China's criminal law within the context of the country's broader societal transformations. Since the initiation of China's reform and opening-up policy in 1978, remarkable strides have been made in both national construction and the administration of criminal law. This progress became particularly evident with the comprehensive revision of the Criminal Code in 1997, marking the beginning of an era characterized by proactive criminal law legislation. This period saw the implementation of one single criminal law and ten subsequent amendments.

Despite these advancements, the period following China's reform and opening-up does have its share of limitations. The promulgation of the Criminal Code in 1979 represented a departure from a 30-year period without a criminal code. While this was a significant improvement over the prior reliance on policy-driven case handling, the adoption of a planned economy and the prevalent thinking of centralized societal control by government forces led to the "instrumental criminal law concept" taking a dominant position. The Criminal Code didn't stipulate the principle of statutory crime and punishment, instead providing an analogy system. This empowered authorities to dictate the definition of crimes, thereby limiting citizens' freedoms. However, with the comprehensive revision of the Criminal Code in 1997, the principle of legality was explicitly stipulated, which reflected the "view of criminal law of civil rights" to a considerable extent. Additionally, the in-depth progress of China's reform and opening up coincided with academic reform in the realm of criminal law. This paved the way for a gradual deviation from the Soviet Union's "nationalist criminal law concept," marked by strong class struggle undertones, and led to the absorption of Western criminal law concepts. Influenced significantly by the Enlightenment and modern criminal law ideologies, especially those initiated by Beccaria, the "classical liberal view of criminal law" became widely recognized. This view, advocating for human freedom, opposing feudal cruelty, and favoring state power restrictions, has significantly impacted China's criminal law policies. However, it's critical to acknowledge that, much like everything else, criminal law is not without its risks, which are present in legislation, judiciary, and theory. These risks can directly impact lives, highlighting the necessity for suitable control measures.

The creation and dissemination of legal risk and the terror created and fostered by risk are equally thorny issues. While we recognize and promote the continuous impact of science on the law, we must also pay attention to the new risks that the new development of science may bring to the criminal law. The new risk is a broader view of the "scientific generalization" alienated from the healthy development of science and its possible adverse effects. For a long time, science has had a self-evident "correctness" for the general public because of its great achievements [7]. In a lot of difficult situations, science is often used as the ultimate endorsement to provide certainty for a certain solution. Along with the great achievements of science, a large number of pseudo-scientific and non-scientific contents have been mixed into the category of science, which is essentially an anti-scientific force. This kind of generalized science, in the name of science and with the veil of science, invades the category stipulated by the essence of criminal law, and has begun to produce bad tendencies [8,9]. Therefore, we must further clarify the difference between science and criminal law and the boundary of science's role in criminal law formed based on this difference. We must further analyze the risks of generalization of science to criminal legislation and criminal justice, as well as the possible risks and consequences based on such risks potential adverse effects. To this end, this paper analyzes and demonstrates the challenges existing in our country's criminal law, especially the problems that scientific generalization may promote and breed, and clarifies how criminal law, as a tool and means of national governance, should better play its role in the new era. The role of punishing crimes and building collective consensus is particularly important [10].

At present, criminal law risk prediction is mainly based on the research of past criminal law, as well as sampling analysis of the actual situation, and judging the future risk of criminal law has been controlled. This paper uses the echo state network (ESN) model to predict criminal law risks, and puts forward corresponding control measures, which provides a scientific basis for criminal law risk prediction, and is of great significance for the study of criminal law risk characteristics and management measures.

This work aims to explore and critically analyze the evolution of China's criminal law, particularly in light of the expansive and active intervention of criminal law in the country's legislative system since the comprehensive revision of the Criminal Code in 1997. The main ideas and the actual purpose embedded in this work involve charting the progression of China's criminal law, understanding the implications of its expansion, and seeking effective control mechanisms, thus providing valuable input to the formulation of strategies ensuring the effective functioning of the criminal law in contemporary China.

II. Criminal Law Risk Analysis and Control

A. *Criminal Law Risk Analysis*

Criminal law plays an important role in maintaining social security and achieving effective social control. However, criminal law also has hidden risks that cannot be ignored. In response to the problem of prediction accuracy, German Professor Jaeger proposed the ESN in 2001, and the prediction accuracy is 2400 times higher than that of the traditional network. Therefore, this paper uses the ESN model to predict criminal law risks.

First, the criminal legislation process may be deficient at the level of rational discourse. In an era of frequent social risks and emphasis on democratic legislation, the impact of the public's safety demands on legislation cannot be ignored. When social risks show an intensifying trend, the public tends to rely on criminal legislation to help them achieve their safety needs. If legislators fail to respond to public demands and do not take a positive stance against risks, they will lead to dissatisfaction and criticism from the public. Secondly, the lack of rational negotiation in criminal legislation can easily turn preventive criminal law into symbolic legislation and passion legislation. Because preventive criminal law focuses on responding to people's expectations for safety, the function of preventive criminal law to manage social risks is often paid the greatest attention or even exaggerated, while the danger of its possible violation of civil liberties and rights is infinitely reduced or even ignored. Finally, excessive criminalization can easily cover up the defects of other social governance systems. Criminal law is not the best means to govern society, nor is it the least costly means. When other social governance means other than criminal law can effectively reduce social risks, other social governance means other than criminal law should be given priority. The attitude of preventive criminal law to take the initiative to manage social risks has certainly increased the public's sense of security to a certain extent. It is even undeniable that it has also reduced social risks in practice.

For defensive criminal law, its setting is ambiguous to a certain extent, and it is easy to breed a crisis of arbitrary judicial arbitrariness. In the provisions of preventive criminal law, legislators often use evaluative concepts, such as illegal use, extremism, and drunk driving. Although the evaluative concept can enhance the applicability of criminal law norms, because it is a value statement of things, different judgment subjects are prone to different judgment conclusions. The extensive use of evaluative concepts creates conditions for the expansion of judicial power, which can easily breed a crisis of judicial arbitrariness. Second, some preventive criminal law provisions. There is ambiguity in the provision of crimes. The fuzzification of crime regulations objectively reduces the elements of crime that need to be proved, reduces the difficulty of proving a crime, and can more effectively punish dangerous behaviors. However, it reduces, transfers or even cancels the burden of proof on the perpetrator's subjective guilt, which can easily lead to unjust or completely wrong penalties, and also makes it difficult to implement the principle of the unity of subjective and objective in preventive criminal law. The presumption of guilt lays hidden dangers, seriously undermining the criminal law's function of guiding judges' adjudication and guiding the behavior of the public [11].

The primary goal of criminal law is to maintain social security and stability by expanding the state's power to punish offenders. However, if we excessively prioritize the state's objective of maintaining social security, it can potentially jeopardize the freedom and rights of individuals. Firstly, criminal law serves the dual purpose of safeguarding both legal interests and human rights, which are mutually reinforcing. The protection of legal interests is widely accepted as the fundamental aim of criminal law within the academic community. Nevertheless, this does not negate the fact that criminal law also plays a role in protecting human rights while fulfilling its function of safeguarding legal interests. Secondly, the concept of preventive criminal law poses a challenge to the protective function of criminal law. Proponents of preventive criminal law argue for shifting the threshold of prevention forward, so that criminal liability is no longer based solely on actual harm or the appearance of specific danger, but rather on the offender's failure to fulfill their expected social role. Finally, as the protective function of criminal law weakens, so too does its ability to uphold human rights [12].

The above describes the risks of criminal law from three aspects: legislation, judiciary and theory of criminal law. Legislation is the beginning of criminal law risk, judiciary is the embodiment of criminal law risk, and theory is the foundation of criminal law risk.

B. *Criminal Law Risk Management*

Criminal law risk management and control should explore targeted criminal risk prevention and control programs from three perspectives: pre-prevention, in-process control, and post-event crisis comprehensive disposal.

1) Establish a three-dimensional legal risk prevention and control system: First of all, it is necessary to combine the components of static and dynamic criminal legal risks to build a corresponding risk prevention and control system. Among which, static elements mainly refer to the main body and its behavior activities and operating environment, and the latter refers to the causes, specific events, carriers and risk effects of criminal legal risk. Secondly, the three-dimensional criminal legal risk prevention and control system should be constructed from the two dimensions of crime and victim, so as to ensure that the system can achieve the prevention and control effects of the prevention and control in advance, control in the event and crisis disposal after the event, so as to avoid criminal legal risks.

2) Criminal legislation should follow the principle of modesty: This principle requires that when criminal legislation regulates behavior, the scope and degree of punishment should be appropriately clarified. That is, if other laws are used to suppress a certain illegal behavior and can achieve the effect of comprehensively protecting the legitimate rights and interests of the public, it should not be included in the criminal law. Relatively speaking, if a lighter sanction method can effectively suppress a certain criminal behavior and protect the legitimate rights and interests of the public, a heavier sanction method should not be prescribed. In addition, judicial organs should also adhere to this principle of modesty in judicial practice. Except for alienated risk-based crimes such as fund-raising fraud, other Internet crowdfunding activities that are within the legal red line should be given certain encourage and support the development of new things, especially for those crowdfunding behaviors whose nature is not clear and the legal provisions are unclear, the punishment at the criminal law level should be reduced as much as possible. However, severe criminal sanctions should be imposed on those crowd-funding behaviors that have great social impact and harm and have numerous victim groups and have been brought into the scope of criminal law [13].

3) Criminal legislation should respect man's subjective status: No matter how the criminal law develops, it must always respond to the issue of human rights. It is an appropriate policy to take a relativistic position on the protection of human rights from a rational point of view. Whether it is criminal legislation or criminal justice, it is necessary to take a restrained attitude towards the protection of power, because criminal law itself is full of factors of public power, and in addition to criminal law, public power can also use other means and measures to restrict the human rights of citizens. Therefore, restraint and prudence of criminal law can correct the easy expansion of public power to a certain extent, and make it continue to play the role of the last line of defense. Therefore, the study of human rights in criminal law is to return to the human rights of individuals, to avoid the use of group or collective human rights to obliterate individual human rights, to pay attention to clarifying the difference between the relativity of the nature of human rights and the improper derogation of human rights, and to avoid using a zero-sum game of rights and interests within individuals to cover up the erosion of power by power.

The control of criminal law is a comprehensive measure. First, there should be a principle of control, and secondly, a risk control system should be established with people as the main body, so as to provide good guidelines for the control of ideas.

III. Model Introduction

At present, more mature network learning methods include Bayesian, wavelet analysis, support vector machine learning and neural network. However, after continuous experiments and application verification, it is found that most of the algorithm also has the problem of forecasting accuracy is not enough, even some algorithms for application scope restrictions, limited to a fixed application scenario, cannot training learning in other areas [14]. In response to the problem of prediction accuracy, German Professor Jaeger proposed the ESN in 2001, Its echo state network, also known as reserve pool calculation, uses a reserve pool composed of randomly sparsely connected neurons as a hidden layer for high-dimensional and nonlinear representation of input，and the prediction accuracy is 2400 times higher than that of the traditional network. Therefore, this paper uses the ESN model to predict criminal law risks [15,16].

A. Model Principle

The ESN includes an input layer with K input neurons, a reserve pool with N neurons, and an output layer with L output neurons. ESN differs from other neural networks in that it includes a dynamic reserve pool with many randomly sparsely connected neurons and a simple training process in which only the output weights are adaptive [17]. The structure diagram of ESN is shown in Fig. 1.

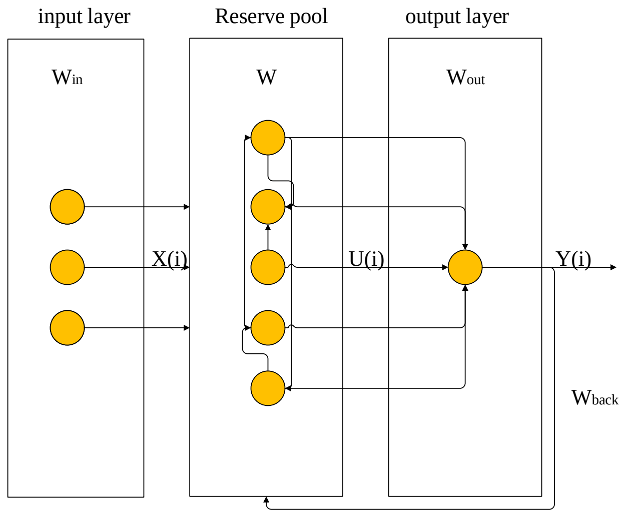

Fig. 1. ESN structure diagram.

The state of the reserve pool is updated according to formula (1):

$$x(n+1) = f(W^{in}u(n+1) + W^{res}x(n) + W^{back}y(n)) \tag{1}$$

where: u $(n + 1)$ is the input at time $n + 1$; $x(n)$ is the state of the reserve pool neuron at time n; f is the activation function of the reserve pool neuron; W^{in} is the input weight matrix; W^{res} is the reserve pool weight matrix; W^{back} is the feedback weight matrix. To make the ESN work normally, the ESN should have the echo state attribute, and the spectral radius of W^{res} should be less than 1. To guarantee the echo state property, the final W^{res} will usually be scaled according to formula (2).

$$W^{res} = \alpha(W^{res} / |\lambda_{\max}|) \tag{2}$$

α is the scaling parameter, between 0 and 1, and λmax is the spectral radius of W^{res}. The output of ESN can be represented as follows:

$$y(n) = f^{out}(W^{out}x(n)) \tag{3}$$

where: f^{out} denotes the activation function of the neuron; W^{out} is the output weight $L\times(N+K)$. During the training process, the states of the neurons in the reserve pool are collected into a state matrix M, see equation (4):

$$M = \begin{bmatrix} X^T(t) \\ X^T(t+1) \\ M \\ X^T(t+k-1) \end{bmatrix} \tag{4}$$

Then, the corresponding output vectors are collected into the target matrix T, see equation (5):

$$T = \begin{bmatrix} y(t) \\ y(t+1) \\ M \\ y(t+k-1) \end{bmatrix} \tag{5}$$

where t is the length. K is the sample size. f^{out} is an identity function, using the pseudo-inverse algorithm to calculate the output weight matrix W^{out}, see formula (6):

$$W^{out} = M^{+}T \tag{6}$$

where M^{+} is the generalized inverse of the state matrix M, and formula (6) is modified as follows:

$$W^{out} = (M^T M)^{-1} M^T T \tag{7}$$

B. Model Parameter Optimization

The essence of the model is also a recursive structure generated by random motion. There are four basic parameters to be optimized: 1) The spectral radius (SR) of the network connection weight matrix in the reserve pool. SR is not only the largest eigenvalue of the absolute value of the internal connection weight function matrix, but also an important parameter to ensure the security and stability of the entire network. 2) The size G of the reserve pool. The larger G is, the more accurate the dynamic description of the entire network model is. 3) The input cell scale (IS) of the reserve pool, that is, the cell scale control factor. Normally, the larger the object scale that the network model needs to deal with, the larger the IS. 4) The sparsity (SD) of the reserve pool. SD is mainly used to represent the ratio of the two interconnected neurons in different reserve pools to the total number of neurons. The larger the value, the stronger the linear approximation ability [18,19].

Among the techniques employed to optimize the four parameters of the ESN model, commonly used methods include cross-validation and grid search. However, these parameter optimization methods still exhibit technical limitations in practical calculations. For instance, they often involve a large number of computations and result in long operation times. To overcome these challenges, the genetic algorithm is utilized as an efficient computational method for globally searching optimal solutions within a network. The genetic algorithm offers several advantages. Firstly, it effectively avoids the network search model from converging towards local optima. Additionally, it utilizes adaptive control search to obtain the optimal solution. In order to achieve better parameter optimization within the reservoir pool, the genetic algorithm is selected to fine-tune the parameters [20,21].

IV. Model Establishment and Application

A. Data Sources

According to the development of society and the actual situation of the criminal law process, criminal law risk mainly includes three first-level indicators: legislative risk U_1, judicial risk U_2 and theoretical risk U_3, as well as legislative constitutionality risk u_{11}, legislative scientific risk u_{12}, and legislative democracy risk u_{13}, legislative timeliness risk u_{14}, judicial disclosure risk u_{21}, judicial integrity risk u_{22}, judicial fairness risk u_{23}, low judicial efficiency risk u_{24}, theoretical objectivity risk u_{31}, theoretical purpose ambiguity u_{32}, theoretical deviation u_{33} and theoretical violation $u_{34,}$ among which , legislative risk U_1 and theoretical risk U_3 mainly depend on the degree of social development, which belong to social factors and are also the fundamental risks of criminal law. Judicial risk U_2 is mainly manifested in the level of judicial power. These indicators can reflect the risk factors in the process of China's criminal law from generation to implementation.

Through statistical analysis of the probability of occurrence of each risk index and the value of the degree of influence, the relationship between the probability of occurrence of risk and the value of the degree of harm is obtained (Fig. 2). According to the analysis, the degree of impact and the possibility of risk occurrence are divided into five levels, among which the degree of impact is divided into "intolerable", "significant impact", "significant impact", "tolerable" and "negligible". The probability of risk occurrence is divided into "very likely", "probable", "probable", "unlikely" and "negligible". When the probability of risk occurrence is "negligible", it indicates the possibility of the risk occurrence Low, the risk can be ignored; when the probability of occurrence is "probable" or "probable", the risk factor needs to be paid more attention; when the probability of occurrence is "very likely", it means that this risk is easy to occur, and great attention is needed. According to the risk analysis of criminal law, legislative risk U1 and theoretical risk U3 belong to social factors and are also fundamental risks of criminal law [18]. Risks have a high probability of occurrence and have a significant impact on society. Judicial risk U2 is mainly manifested in the strength of the judiciary and the probability of occurrence.

B. ESN Training and Testing

First, normalize the dataset to the [0,1] interval, which is expressed as:

$$f: x \to y = 2\times\frac{x-x_{\min}}{x_{\max}-x_{\min}}+(-1) \tag{8}$$

In network training, a limit is added to enhance the stability of network training. The limit is a uniformly distributed number on [-0.002, 0.002], and the mean square error of training ESN is the smallest. In order to improve the performance of the network, many experiments were conducted on the four parameters of ESN: the number of SR neurons N, the SR reality sd, the spectral radius ρ of w in SR, and the SR input connection weight scaling scale IS, according to the empirical value. ($N\in[20,100]$, reality $sd\in[0.01,0.05]$, spectral radius $\rho\in[0.5,0.98]$, SR input weight scaling $IS\in[0.01,1]$) to set the final optimal. The parameter combination is shown in Fig. 3.

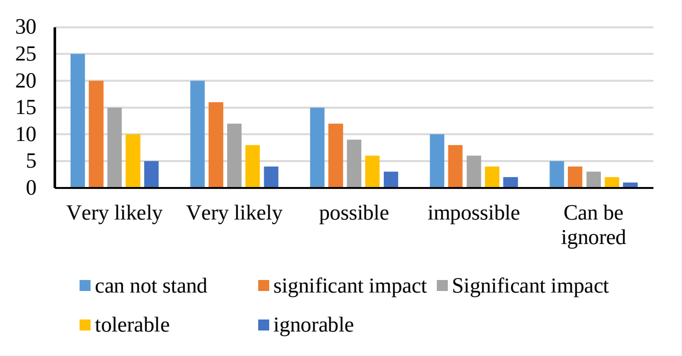

Fig. 2. The relationship between the probability of occurrence of risk and the degree of harm.

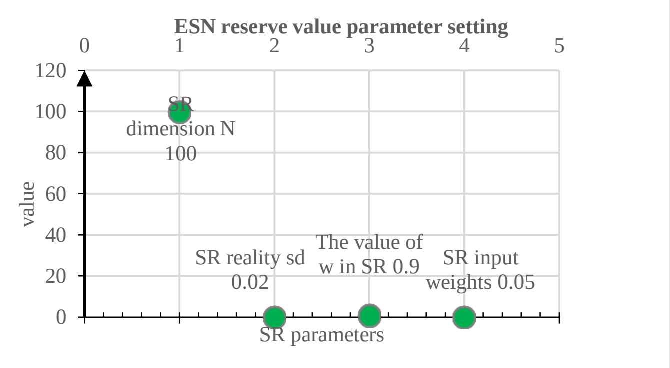

Fig. 3. Optimal parameter value diagram.

C. Simulation Experiments and Results

The accuracy of model prediction is not only related to the structural parameters of the model itself, but also depends on whether the selection of model predictors is reasonable. Therefore, this paper draws on the prediction factor selection method of previous research, and uses autocorrelation and partial correlation to analyze the predictors. The sample autocorrelation analysis is shown in Fig. 4, and the partial correlation analysis is shown in Fig. 5.

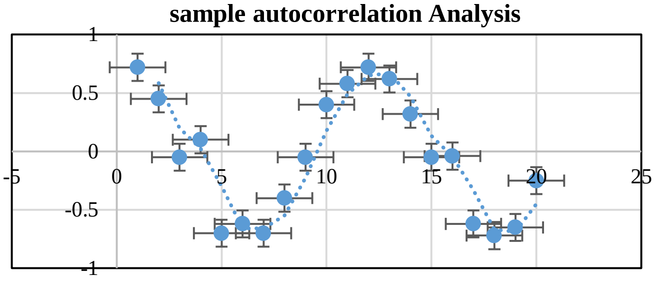

Fig. 4. Autocorrelation analysis plot.

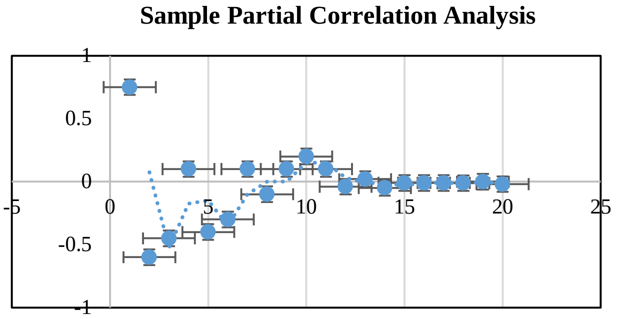

Fig. 5. Partial correlation analysis.

This paper divided the processed dataset into two parts. Meanwhile, Root Mean Squared Error (RMSE), Efficiency (E) and Correlation Coefficient (CORR) were selected to evaluate the prediction results. The closer RMSE is to 0, and the closer E and CORR are to 1, the higher the accuracy of the model [20]. The specific formulas are as follows:

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n}\left(x_1 - y_i\right)^2} \tag{9}$$

$$E = 1 - \sum_{i=1}^{n}\frac{\left(x_i y_i\right)}{\sum_{i=1}^{n}\left(x_i - \bar{x}\right)^2} \tag{10}$$

$$M = 1 + \sum_{i=1}^{n}\left(x_i + y_i\right) \tag{11}$$

$$CORR = \frac{\sum_{i=1}^{n} x_i y_i - \frac{\sum_{i=1}^{n} x_i \sum_{i=1}^{n} y_i}{n}}{\sqrt{\left(\sum_{i=1}^{n} x_i^2 - \frac{\left(\sum_{i=1}^{n} x_i\right)^2}{n}\right)\left(\sum_{i=1}^{n} y_i^2 - \frac{\left(\sum_{i=1}^{n} y_i\right)^2}{n}\right)}} \tag{12}$$

This paper uses MATLAB software to program the ESN. The key to model prediction is the selection of model parameters, and the key parameter of ESN is the scale N of the reserve pool. The optimal scale of this parameter is obtained through repeated experiments (Fig. 6). The size of the reserve pool N mainly includes 50, 60 and 65. The predicted performance results of different reserve pool sizes are shown in Fig. 7 According to the comparison of the prediction performance of different reserve pool sizes, this paper chooses the reserve pool size as 65, that is, 65 different types of criminal laws are selected as the reserve pool, the other parameters are set as follows: the number of training set samples is 65, and the number of test set samples is 60, the number of samples in the initialized reserve pool is set to 150, SD is 10%, W spectral radius is 0.8, IS is 0.3 , and the excitation function is selected as 'tanh'. Through the operation and mathematical analysis of the model, the probability distribution of 12 secondary risk indicators is finally obtained (Fig. 8).

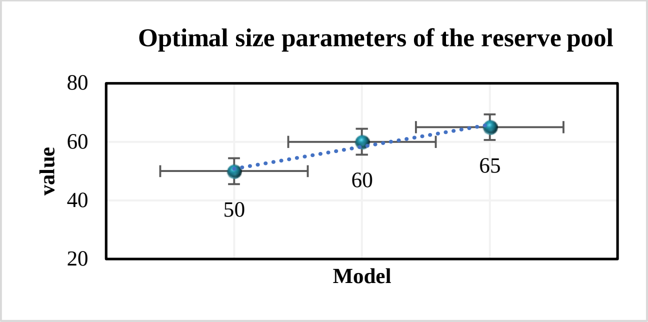

Fig. 6. ESN optimal parameter scale.

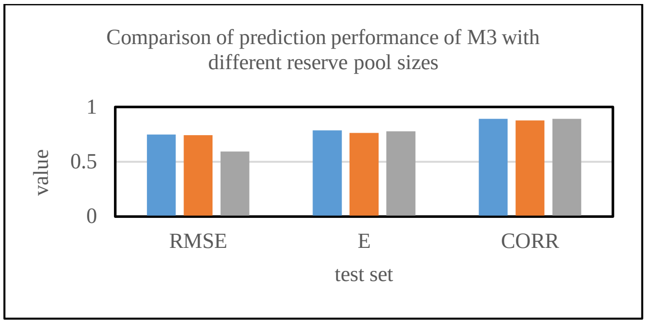

Fig. 7. Prediction of different reserve pool sizes.

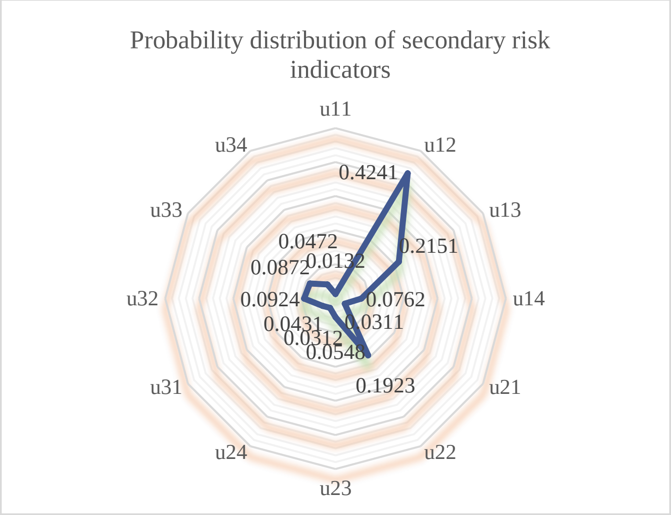

Fig. 8. Distribution of secondary risk indicators.

In addition, in order to verify the application effect of ESN model in criminal law risk, this paper also uses BP neural network for comparative analysis. In the last layer of building the BP neural network, the output feature vector of the RBM (Restricted Boltzmann Machine) network is regarded as the output vector of the BP network, which can effectively supervise and train the entity relationship analyzer. The set BP network can only ensure that the mapping of weights to feature vectors in this level is optimal, but cannot ensure that the mapping of feature vectors in the entire DBN (Deep Belief Network) is optimal. Therefore, the BP network may propagate the problematic information to the RBM of each layer, and play a small adjustment role for the entire DBN. The RBM network training model is the initialization process of the weights of a deep BP network. This process enables DBN to overcome the problems of increased training time and prone to local optima due to random changes in the initialization of BP network weights. It can be seen that the application of the ESN model in criminal law risk has many advantages over the application of the BP network model, which is also an affirmation of the application of the ESN model [21].

V. Analytical Discussion

According to the distribution of secondary risk indicators (Fig. 8), the maximum value is 0.4241, which corresponds to u12. According to the second-level indicators of legislative risk, the risk factor represented by it is legislative scientific risk u12, and this influencing factor is very important. The second value is 0.2151 corresponding to u13, which represents the risk factor of legislative democratic risk u21, which plays an important role in the formulation of criminal law, and the second value corresponding to the risk of judicial integrity u22 is 0.1923，Other legislative constitutionality risk u11 is 0.0132, legislative timeliness risk u14 is 0.0762, judicial fairness risk u23 is 0.0548, judicial efficiency risk u24 is 0.0312, theoretical objectivity risk u31 is 0.0431, theoretical purpose vague u32 is 0.0924, theoretical deviation u33 is 0.0872 and the theoretical violation u34 is 0.0432. All three of these indicators are major risk factors for criminal law, and greater attention is being paid to them. All other values are less than 0.1, indicating that other factors have great influence or can be ignored. By analogy, the final weights are ranked as follows: purpose ambiguity u32, theoretical deviation u33, legislative timeliness u14, interoperability hinders great justice u23, theoretical violation u34 and theoretical objectivity u31, etc. Legislative risk is the most critical, and also the beginning and foundation of the law. Regarding criminal law risk management and control, we should have corresponding measures. First, we should take people as the main body and the rule of law as the criterion, establish a good risk prevention system, and do a good job in risk management and control in advance to prevent problems before they occur. To sum up, in the practice of criminal law legislation to judicial practice, the law not only has sufficient tenacity, but also has many risk factors. Among them, legislative risk is the most critical, and it is also the beginning and foundation of the law, which should be considered in future law formulation. Its associated risks provide a good basis for the enforcement of the law.

To compare the performance of ESN in predicting criminal law risks, this study also employs BP neural network to forecast the aforementioned models. Fig. 9 illustrates the prediction outcomes of both ESN and BP neural network for the three models. By comparing the evaluation metrics RMSE, E, and CORR, it becomes evident that ESN outperforms BP neural network in terms of predicting criminal law risks. Additionally, due to the simplified regression calculation involved in the internal adjustment of the ESN reservoir pool, its running time is significantly reduced compared to BP neural network. In regard to the individual prediction performance of ESN, the values of RMSE are arranged in ascending order as M3, M2, and M1; whereas the values of E are ranked in descending order as M3, M2, and M1. Similarly, the values of CORR are sorted from highest to lowest as M3, M1, and M2. Considering all three indicators, M3 demonstrates the highest prediction accuracy, followed by M2, and finally M1. This can be attributed to the fact that M3 incorporates four input factors, M2 includes three, while M1 only has two. Hence, the accuracy of ESN prediction exhibits a certain correlation with the number of effective input factors, indicating that a higher number of relevant inputs leads to improved prediction accuracy. It is worth mentioning that in this study, the ESN model reserve pool size is set at 65, which proves to be suitable and yields high model accuracy.

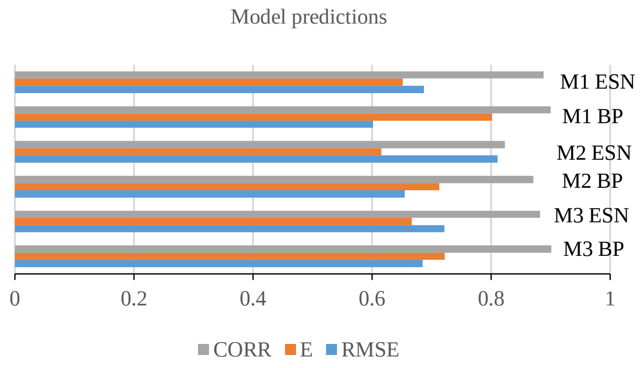

Fig. 9. Model predictions.

The model's prediction serves as a tool, but in order to comprehend and manage the risks associated with criminal law, it is crucial to reflect upon the theory of criminal law. The concern regarding the relationship between law and society stems not only from the limitation of a narrow internal perspective in criminal law research but also from recognizing that the evolutionary power of the legal system does not primarily arise from internal forces alone. As the external social environment grows increasingly complex, the study of criminal law must incorporate the dimension of social structural change to observe and address how the criminal law system can be adjusted and reconstructed.

In bridging the gap between social theory and criminal law theory, researchers should strive to understand and grasp the fundamental consensus within contemporary social theory. Furthermore, they should integrate this consensus into the legal dogmatic system in an identifiable manner. This integration facilitates the self-renewal of the criminal law system. By examining the efforts made by Heike, the founder of interest law, to methodologize and technically develop Yelling's teleological thought, we discover the potential for academic innovation—a combination of thought and technology—to drive the systematic renewal and advancement of criminal law.

VI. Conclusion

The transitional modern society is characterized by a plethora of highly intricate and uncertain risks. The number and uncertainty of these risks are constantly on the rise. This is evident in three aspects: at the legislative level, an excessive emphasis on preventive criminal law in social governance can lead to concerns about excessive criminalization; at the judicial level, the vague standards for determining crimes conceal the risk of judicial arbitrariness; at the theoretical level, relaxing restrictions on the state's penal power can easily result in an imbalance between societal protection under criminal law and the safeguarding of human rights. These developments in criminal law arise not only as a response to the security needs of citizens during periods of social transition but also due to the failure to establish new standards that can restrict criminal legislation after breaking free from the constraints imposed by traditional criminal law theories. To address potential risks associated with criminal law, it becomes essential to establish reasonable boundaries for preventive criminal law. The prediction of criminal law risk based on ESN model established in this paper mainly draws the following three conclusions:

1) In order to better predict criminal law risks and provide corresponding guarantees for social security, the ESN model proposed in this paper has further improved the accuracy of various risk predictions. After verification, it can provide reference for criminal law risk prediction and management system research.

2) The experimental results show that the ESN model proposed in this paper has a good fitting effect with the actual situation, and is better than BP model in terms of error and fitting degree.

3) Criminal law is built on the background of social risk. In the risk society, the variability, complexity, multiple occurrence and unpredictability of social risk have a great impact on the original criminal law system. Therefore, we should think about the criminal law from three aspects: legislation, judicature and theory, analyze the foreseeable risks of the criminal law, and put forward corresponding risk management measures to ensure the safety of the national criminal law system.

4) Legislative risk U_1 and theoretical risk U_3 belong to social factors and are also fundamental risks of criminal law. Judicial risk U_2 is mainly manifested in the level of judicial power. The influencing factors of legislative scientific risk are very important. The formulation of democratic risk criminal law plays an important role, followed by judicial integrity.

Abstract—**Digitized documents are increasingly becoming prevalent in various industries. The ability to accurately classify these documents is critical for efficient and effective management. However, digitized documents often come in different formats, making document classification a challenging task. In this paper, we propose a multimodal deep learning approach for digitized document classification. The proposed approach combines both text and image modalities to improve classification accuracy. The model architecture consists of a convolutional neural network (CNN) for image processing and a recurrent neural network (RNN) for text processing. The output features from the two modalities are then merged using a fusion layer to generate the final classification result. The proposed approach is evaluated on a dataset of digitized documents from various industries, including finance, healthcare, and legal fields. The experimental results demonstrate that the multimodal approach outperforms single-modality approaches, achieving high accuracy for document classification. The proposed model has significant potential for applications in various industries that rely heavily on document management systems. For example, in the finance industry, the proposed model can be used to classify loan applications or financial statements. In the healthcare industry, the model can classify patient records, medical images, and other medical documents. In the legal industry, the model can classify legal documents, contracts, and court filings. Overall, the proposed multimodal deep learning approach can significantly improve document classification accuracy, thus enhancing the efficiency and effectiveness of document management systems.**

Keywords—Scanned documents; classification; document categorization; artificial intelligence; machine learning; deep learning

I. INTRODUCTION

With the rise of digital transformation, documents in various industries are now digitized for easy access and management. Digitized documents come in various formats such as PDF, JPEG, PNG, and many others, which makes document classification a challenging task. The ability to accurately classify these documents is crucial for efficient document management. The traditional approach of manual classification is time-consuming and prone to errors [1]. Hence, the development of automated document classification systems has become a critical need for organizations.

Recent advances in deep learning have significantly improved the accuracy of document classification [2]. Deep learning algorithms have been applied to various document classification tasks, such as sentiment analysis, topic modeling, and spam detection [3-4]. These algorithms have shown remarkable performance in text classification tasks by leveraging the vast amount of data and computing power available today [5]. However, text-based classification models may not perform well when the documents also contain visual information, such as images, logos, and diagrams [6].

To address this challenge, we propose a multimodal deep learning approach for digitized document classification that combines text and image modalities. The proposed model uses a convolutional neural network (CNN) [7] for image processing and a recurrent neural network (RNN) [8] for text processing. The two modalities are then merged using a fusion layer to generate the final classification result. The proposed approach is evaluated on a dataset of digitized documents from various industries, including finance, healthcare, and legal fields.

The remainder of this paper is organized as follows: Section II discusses related work on document classification and multimodal deep learning. Section III presents the proposed approach for digitized document classification using multimodal deep learning. Section IV describes the experimental setup and the results of the proposed approach. Section V discusses the limitations and future directions of this work. Finally, Section VI concludes the paper.

II. RELATED WORKS

Document classification has been an active area of research for several decades. Traditional approaches to document classification relied on manual feature engineering, which involves the extraction of relevant features from documents and their mapping to predefined classes. However, manual feature engineering can be challenging and time-consuming, and the performance of such models is limited by the quality of the extracted features [9].

Recent advancements in deep learning have enabled automated feature learning, where the model automatically learns relevant features from the data [10]. Several studies have proposed deep learning models for document classification. Convolutional neural networks (CNNs) have been widely used for image classification tasks and have also been applied to document classification. In a CNN, a filter scans the input image, and the output of the filter is then passed through a nonlinear activation function to generate the output feature map [11]. These output feature maps are then used to classify the input image.

Recurrent neural networks (RNNs) have also been used for text classification tasks [12]. RNNs can capture the contextual dependencies of the input sequence, making them ideal for tasks such as language modeling and machine translation. RNNs process the input sequence one token at a time, and the hidden state of the network is updated at each time step. The final hidden state is then used for classification.

Multimodal deep learning has been used for various tasks, such as speech recognition, visual question answering, and image captioning, education using game-based learning [13]. Multimodal models combine information from different modalities, such as text, image, and audio, to improve performance. The fusion of information from different modalities can help address the limitations of single-modal models.

In recent years, deep learning approaches have shown promising results in document classification tasks, especially in single-modal scenarios such as text or image classification [14]. However, the classification accuracy can be further improved by incorporating multiple modalities, such as text and image, into the classification process.

Several studies have proposed multimodal deep learning approaches for document classification. For instance, Malaperdas et al. (2021) proposed a multimodal approach that combines text and image modalities for document classification [15]. They used a convolutional neural network (CNN) for image processing and a recurrent neural network (RNN) for text processing, and merged the output features using a fusion layer. The proposed approach achieved better performance than single-modal approaches.

Similarly, Zhang et al. (2020) proposed a multimodal approach that combines text and layout features for document classification [16]. They used a CNN to extract image features and a text-crop CNN to extract text features, and merged the features using a fully connected layer. The proposed approach achieved better classification accuracy than using either text or layout features alone.

In addition to combining text and image modalities, other studies have explored the use of additional modalities such as audio and video. For example, Hegghammer (2022) proposed a multimodal deep learning approach that combines text, image, and audio modalities for news classification [17]. They used a CNN for image processing, a bidirectional LSTM for text processing, and a convolutional neural network for audio processing. The output features were merged using a fusion layer and fed into a fully connected layer for classification.

Moreover, some studies have explored the use of transfer learning techniques to improve the classification performance. For example, Revilla-León et al. (2020) proposed a multimodal approach that uses a pre-trained CNN for image processing and a pre-trained LSTM for text processing [18]. They fine-tuned the pre-trained models on their own dataset and achieved better classification accuracy than training from scratch.

In summary, several studies have proposed multimodal deep learning approaches for digitized document classification, which combine multiple modalities such as text, image, and layout. The proposed approaches have shown promising results in improving classification accuracy compared to single-modal approaches. Furthermore, the use of transfer learning techniques has also been explored to improve the classification performance.

III. Flowchart of the Research

The proposed method for digitized document classification using multimodal deep learning involves combining text and image modalities to improve the classification accuracy. The method consists of three main steps: data preprocessing, feature extraction, and classification.

Data Preprocessing: The first step involves preprocessing the raw document data to make it suitable for processing by the deep learning models. This step includes tasks such as text normalization, image preprocessing, and data augmentation.

Feature Extraction: The second step involves extracting features from the text and image modalities. For text feature extraction, we use a pre-trained language model such as BERT to encode the text data into a high-dimensional vector representation. For image feature extraction, we use a pre-trained convolutional neural network (CNN) such as VGG or ResNet to extract image features.

Modal Fusion: The third step involves fusing the text and image features using a multimodal fusion layer. This layer can take various forms, such as concatenation, element-wise multiplication, or attention-based fusion. The output of the fusion layer is then fed into a fully connected layer for classification.

Classification: The final step involves training the classification model using the fused features and evaluating its performance on a held-out test set. We use a multi-layer perceptron (MLP) classifier with softmax activation for classification. The model is trained using a categorical cross-entropy loss function and optimized using the Adam optimizer.

To evaluate the proposed method, we will conduct experiments on a publicly available dataset of 10,000 digitized documents. We will compare the performance of our multimodal approach with single-modal approaches such as text-only and image-only classification. We will also evaluate the effect of different modal fusion strategies on the classification performance. The evaluation metrics will include accuracy, precision, recall, and F1-score. Finally, we will conduct ablation studies to analyze the contribution of each modality to the overall classification performance.

IV. Proposed Method

In this part, a comprehensive analysis of every facet of our methodology for identifying subjects is presented. Further, it is strongly recommended to conduct a textual and graphical components based analysis of the primary document in order to build and implement a one-of-a-kind semantic topic classification strategy. The remainder of this part will be dedicated to providing a detailed explanation of the structure of the entire system, with the primary attention being placed on the essential characteristics that are shared by every component of the recommended scheme. In addition to this, it offers a wealth of information with respect to the multidimensional knowledge base as well as the theoretical model that served as the foundation for the knowledge base. Moreover, the document cites several examples. Following this, we will offer an in-depth description of the Topic Detection approach that we have just shown.

A. Architecture of the System

We gathered a 9125 picture collection and divided it into seven groups. The style, structure, and content of XML documents may be accessed and updated by programs using the DOM Parser, which was used in the next step. We next gathered the cleaned text files into a data store. The next phase was gathering the attributes required to train a model for document classification. We created a deep model to train and test the suggested model after deciding which attributes were essential. As a result, we separated classified content into several groups.

Because of this, the taxonomy classificator is able to begin the construction of the classification taxonomy with a notion. Comparisons have been made between the recommended measure and technique and the baselines, and the experimental Section IV of the report illustrates and discusses the conclusions of these comparisons.

The deep neural network that was suggested to solve the document classification issue is seen in Fig. 2. The scanned paper that we get serves as the input for the planned network. Eleven layers make up the network that is being proposed. Pooling occurs in the first layer of the structure. In the subsequent step, the Conv2D layer is used, and the result that is acquired is then transferred to the bottleneck layers. In this particular network, there are five levels of bottlenecks. Following that, a pooling layer and a Conv2D layer are used. The subsequent level contains 128 neuronal components, and the penultimate layer has only seven layers, which correspond to the various document types. By applying Maxpooling, we were finally able to produce a classified class.

The documents shown in Fig. 3 are representative of the whole dataset that we have gathered. The picture presents three distinct sorts of documents: a personnel document, a graduation certificate, and a service letter. We included seven different sorts of university papers in the dataset that we compiled. The dataset includes 9125 scanned papers, is organized into seven categories, and has a storage capacity of more than 5.3 gigabytes.

На № ДЗ-38 от 10 февраля 2021 года

Уважаемые депутаты!

Рассмотрев Ваш депутатский запрос относительно создания Межведомственной комиссии по совершенствованию мер социальной поддержки населения, пострадавшего вследствие ядерных испытаний на Семипалатинском полигоне, сообщаю следующее.

В настоящее время объем и характер оказания социальной поддержки граждан, пострадавших вследствие ядерных испытаний на Семипалатинском испытательном ядерном полигоне *(далее – СИЯП)*, зависят от зоны радиационного поражения и периода проживания на нем.

В целях совершенствования мер социальной защиты граждан, пострадавших вследствие ядерных испытаний на СИЯП, Министерством труда и социальной защиты населения Республики Казахстан проведен ряд исследований *(«Ретроспективный и проспективный анализ медицинских и радиоэкологических последствий бывшего Семипалатинского испытательного ядерном полигона для населения, прилегающий к нему территорий», «Оценка эффективности защитных и реабилитационных мероприятий для населения, подвергшегося действию ионизирующего излучения в результате деятельности Семипалатинского испытательного ядерного полигона, и выработка предложений по их совершенствованию»)*.

По результатам проведенных исследований предложено оказывать медико-социальную помощь в зависимости от величины индивидуальной дозы облучения.

Данный подход позволит обеспечить оказание адресной социальной поддержки согласно полученным индивидуальным дозам облучения, а также с учетом доз облучения, полученных родителями.

Величина дозы облучения является модифицирующим фактором радиационного риска, которая зависит от особенностей человека, в том числе возраста на момент испытаний, продолжительности облучения. Следовательно, осуществлению каждого мероприятия по социальной защите должна

b) Diploma certificate

Fig. 3. Samples of document types in the developed dataset.

V. Experimental Results

The investigation that was carried out primarily focused on seven key types of university papers that are a part of the cases that were dealt with by the STF. The following is a list of these categories, with their initial labels still attached to them:Diploma; Personal Documents; Journal of Accounting for Higher Education Diplomas; Service Letter; Order; Production Orders; Student Orders Diploma; Personal Documents; Journal of Accounting for Higher Education Diplomas;

A. Dataset

It is important to note that the court cases include a wide range of different types of documents, all of which have been filed under the name "Miscellaneous." In this regard, we developed an annotation tool that was used by a team of four lawyers for the purpose of manually classifying 8,139 pieces of paper. Fig. 1 presents a graphical breakdown of the proportion of articles that can be assigned to each of these categories. This chart can be found further down this page. In order to effectively train and evaluate machine learning systems, it is common practice to segment datasets into three distinct parts [19]. The terms "train," "validation," and "test" are used to refer to these specific parts of the dataset, respectively. We use stratified splits for each document class, making certain that the same proportions of class samples are included in each subset in order to maintain consistency. The following ratios were used, and Fig. 2 provides a more detailed breakdown of their application: 70% of the data will be used for the training set, 20% will be used for validation, and 10% will be used for the test set.

The gathered dataset is broken down into categories according to Fig. 4, which shows the distribution of the documents. There are seven different kinds of scanned papers that do not balance out. Student orders are the most common form of categorisation, accounting for 35 percent of all the papers that are scanned. The Journal of Accounting for higher education diplomas, personal documents, and production orders make up 20%, 19%, and 13%, respectively, of all the collected data. With 6%, 4%, and 13% indices, respectively, orders, production orders, and service letters make up the smallest share of the documents.

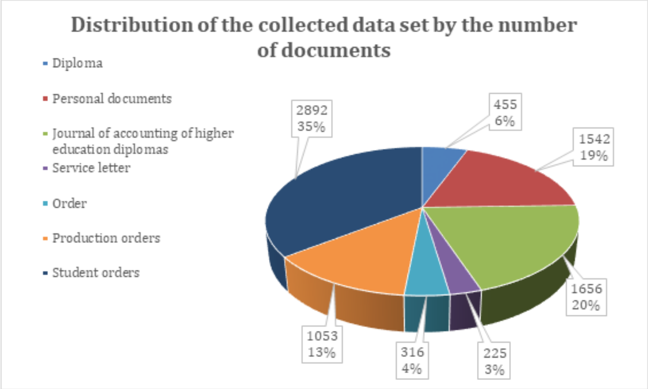

Fig. 4. Distribution of document classes in the dataset.

The whole of the material that was gathered is around 4.7 gigabytes worth of scanned pdf documents. The separation of these data into their respective volumes for each classification is shown in Fig. 5. The diploma, personal documents, and journal of accounting for higher education diplomas categories together account for 87.8% of the total volume of the dataset. This percentage is broken out as follows: 42.6%, 19%, and 26%. The remaining four categories of gathered papers make up 12.2% of the total.

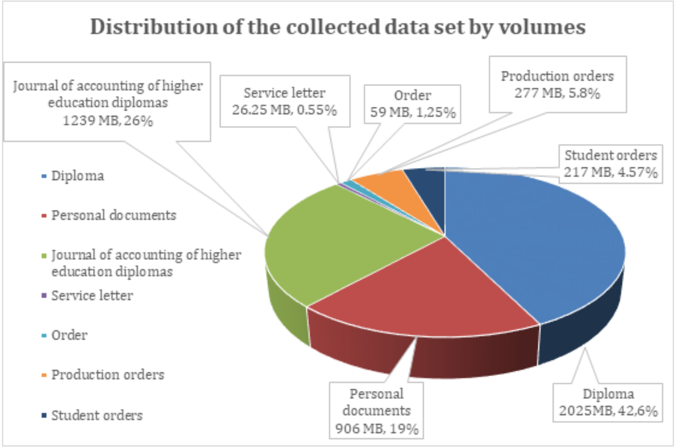

Fig. 5. Distribution of the collected dataset by volumes.

The distribution of the training, validation, and test sets for the proposed deep model is shown in Fig. 6. We cut the gathered dataset into three sections, which we referred to as the training set, the validation set, and the test set, and we allocated 70%, 20%, and 10% of the total space to each section, accordingly. As a result, separating the dataset into three distinct pieces enables us to achieve a high level of accuracy and determine whether or not the suggested model is suitable for use in actual settings.

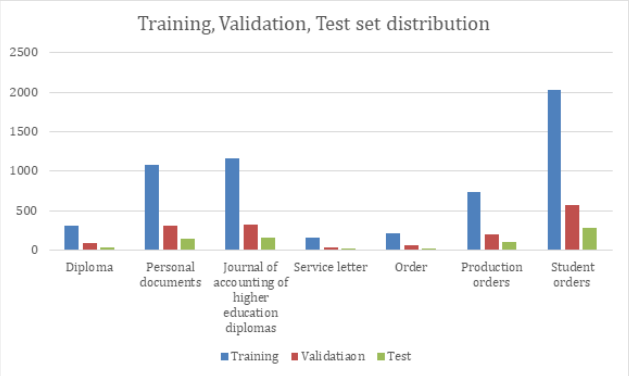

Fig. 6. Training, validation and test set distribution for each of the document classes.

The results of Fig. 5 and Fig. 6 are shown in Table I, which also provides an illustration of the distribution of the gathered dataset according to the number of scanned photographs and the volume of the data for each category. It enables us to comprehend the relationship between the number of photos and the volume of those images, as well as the quality of the document based on the type. As a result, after we have finished preparing the dataset, we may go on to training the model.

TABLE I. DATASET DESCRIPTION

Type of the document	Number	Volume
Diploma	455	2025 MB
Personal documents	1542	906 MB
Journal of accounting	1656	1.21 GB
Service letter	225	26.25 MB
Order	316	59.5 MB
Production orders	1053	277 MB
Student orders	2892	217 MB

B. Evaluation Parameters

In this part, our goal is to provide an explanation of evaluation parameters so that we may evaluate the suggested model and evaluate it in relation to other machine learning models. Accuracy, precision, recall, f-score, and area under the curve receiver operational characteristics were chosen as the five indicators to serve as the assessment criteria. (AUC-ROC) [20].

$$accuracy = \frac{TP+TN}{TP+FN+TN+FP} \quad (1)$$

$$precision = \frac{TP}{TP+FP} \quad (2)$$

$$recall = \frac{TP}{TP+FN} \quad (3)$$

$$F1 = \frac{2\,precision\ recall}{precision + recall} \quad (4)$$

The next part provides an assessment of the deep learning model that was presented for the classification of documents. After that, we will give the suggested model's confusion matrix, model accuracy, and validation accuracy. Fig. 7 is a demonstration of the model's accuracy during a period of one hundred epochs. According to the findings, the suggested model demonstrates great accuracy not only during training but also throughout testing.

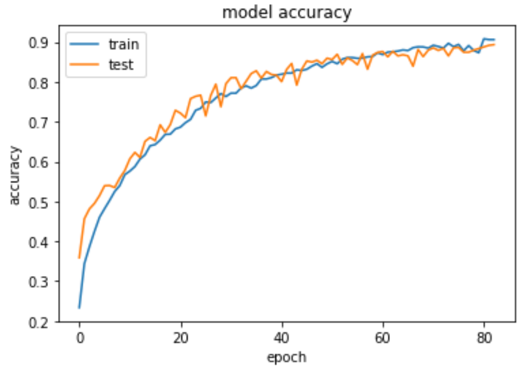

Fig. 7. Model accuracy.

Fig. 8 depicts the model loss over a period of one hundred epochs. The findings demonstrate that the model loss steadily declines as the number of epochs in the analysis is increased. In 80 epochs, the model loss in train and test shows less than 0.3, which suggests that the model is usable for actual instances and can be used for solving the automated document classification issue with a high degree of effectiveness.

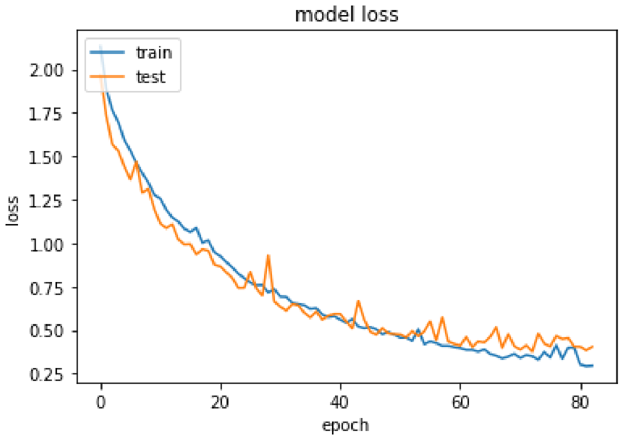

Fig. 8. Model loss.

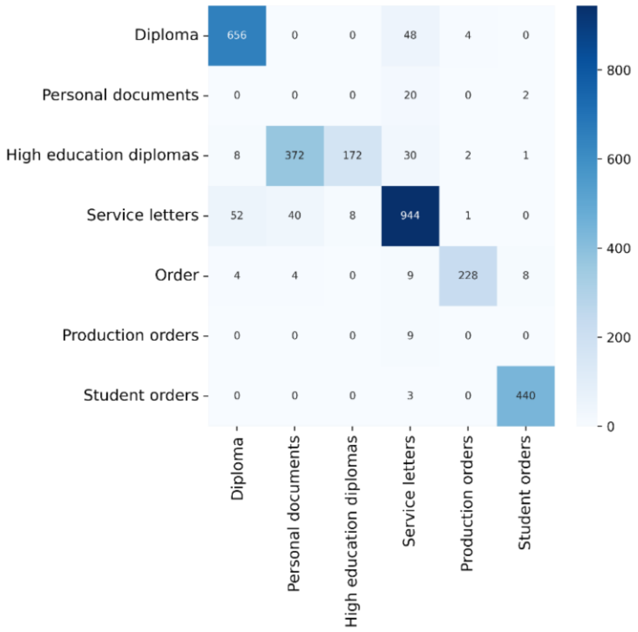

Fig. 9. Confusion matrix.

A performance assessment for the machine learning classification problem is shown in Fig. 9, which depicts a confusion matrix for each kind of classified text. This matrix indicates an evaluation of how well the issue was solved, and the output may comprise two or more classes. The table that follows provides an overview of the four distinct ways in which expected values might contrast with actual values. According to the findings, there is a relatively low incidence of mistakes and misunderstandings. The majority of the time and scanned documents have the appropriate categories assigned to them.

Table II presents a comparison between the deep learning model that has been presented and various machine learning techniques. According to the findings, the suggested model demonstrates the best performance when compared to the other techniques in each assessment parameter. The suggested model achieves an accuracy of 94.84%, precision of 94.79%, recall of 94.62%, F-score of 94.43%, and AUC-ROC of 94.07%. These results indicate that the proposed model is relevant in real life and that the provided dataset may be used to train machine learning and deep learning models to solve the document classification issue.

A comparison of the deep learning model that was developed with more conventional machine learning techniques for solving the document classification issue is shown in Fig. 10. We use five traditional algorithms—XGBoost, multilayer perceptron, random forest, support vector machines, and decision tree – to do a comparison between the proposed model and the existing models. We employ accuracy, precision, recall, F-score, ROC-AUC, and threshold as assessment parameters. Other parameters include recall. According to the conclusions drawn from the research, the suggested deep model achieves a high classification percentage across all assessment parameters. As a result, we are able to reach the conclusion that the deep model that was provided is suitable for use in the classification of academic publications.

Table III presents a comparison between the suggested technique and the most recent research available. Various studies have been established for the purpose of classifying scanned documents, including electronic health data, magnetic resonance scans, and handwritten historical manuscripts. With an accuracy of 94.84%, the educational papers of seven different categories may be categorized using the Conv2D model that was presented.

TABLE II. MODEL EVALUATION

Model	Accuracy	Precision	Recall	F-score	AUC-ROC
Proposed Model	**94.84%**	**94.79%**	**94.62%**	**94.43%**	**94.07%**
Random Forest	82.73%	82.13%	82.34%	81.12%	81.09%
XGBoost	81.77%	81.31%	81.37%	81.21%	81.17%
Support vector machine	82.36%	82.17%	82.06%	82.21%	82.11%
Multilayer perceptron	80.67%	80.54%	80.51%	80.28%	80.12%
Decision trees	76.45%	76.37%	76.28%	76.17%	76.19%

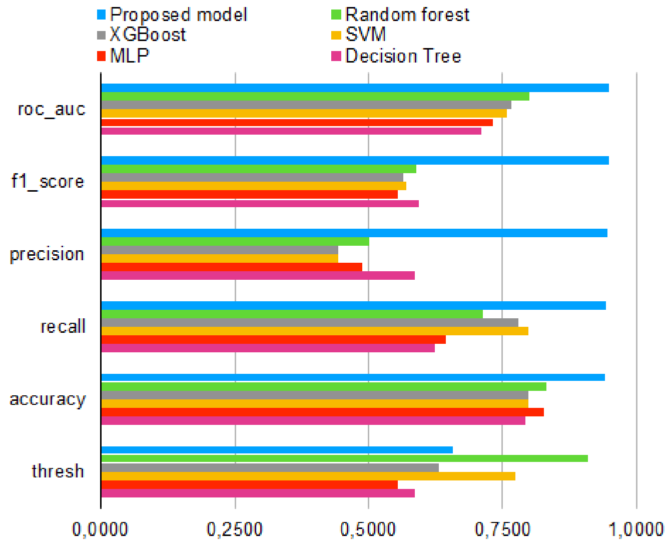

Fig. 10. Obtained results and comparison with the machine learning methods.

TABLE III. COMPARISON OF THE OBTAINED RESULTS WITH THE STATE-OF-THE-ART STUDIES

Study	Method	Documents	Dataset	Results
Proposed Model	**Proposed Model**	**9125 scanned documents of 7 types**	**Own dataset**	**94.84% accuracy, 94.79% precision, 94.62% recall, 94.43% F-score, 94.07% AUC-ROC**
[21]	ClinicalBERT	2988 scanned documents	Sleep study reports	AUCROC of 0.9523, Accuracy of 91.61%
[22]	Hand-written historical manuscripts	955 scanned reports	38 historical manuscript	98.5% segmentation rate
[23]	Automatic computational method	250,000 historical data	XMT datasets	82.06%
[24]	Two-level CNN	MRI	Open Access MRI data	92.30% accuracy
[25]	3D body scans	625 3D body scans	SizeKorea dataset	92% accuracy
[26]	Automated Paper Fingerprinting	306 paper images	Scanner image dataset	97% accuracy
[27]	Transfer Learning	Deep Transfer Learning	-	Accuracy: 0.8920
[28]	MLP	Multi-Page Documents	Digital image documents	Precision of 0.9030; F1-Score of 0.9380

VI. DISCUSSION

Digitized Document Classification using Multimodal Deep Learning is a research paper that proposes a novel approach to document classification using a combination of text and image features. In this discussion, we will analyze the advantages and limitations of this research paper, and also look into the future perspectives of this technology.

A. *Advantages*

One of the major advantages of this research paper is the use of multimodal deep learning for document classification. By combining both text and image features, the proposed method can classify documents more accurately and efficiently compared to traditional document classification methods. This is because documents often contain both textual and visual elements, and using a combination of both can improve the accuracy of classification [29].

Another advantage of this research paper is the use of CNNs and LSTM networks for image and text feature extraction, respectively. CNNs are known for their ability to extract high-level features from images, while LSTM networks can model the context of a sequence of words [30]. By using these two types of networks, the proposed method can extract both visual and semantic information from documents, leading to more accurate and robust classification.

Moreover, the proposed method is not limited to a specific type of document and can classify different types of documents such as invoices, resumes, and letters. This is because the method is trained on a large dataset of diverse documents, which makes it adaptable to different types of documents.

B. *Limitations*

One of the limitations of this research paper is the requirement of a large dataset for training. As with most deep learning approaches, the accuracy and performance of the proposed method are heavily dependent on the size and quality of the dataset used for training. Therefore, obtaining a large and diverse dataset may be challenging, especially for specific document types.

Another limitation is the computational cost of the proposed method. Deep learning models are known to require a significant amount of computational resources, including high-end GPUs and large amounts of memory [31]. This may limit the applicability of the proposed method to smaller organizations or those with limited computational resources. The proposed method does not take into account the metadata associated with the documents, such as the author, date, and location. This information can be valuable for certain document classification tasks and not using it may lead to a decrease in accuracy.

C. Future Perspectives

Despite the limitations, the proposed method has several future perspectives. One potential application is in the field of document analysis and retrieval, where the ability to accurately classify and retrieve documents based on their content can be valuable [32]. This can be especially useful in organizations that deal with a large number of documents, such as legal firms and government agencies.

Another potential application is in the field of automated document processing [33]. By using the proposed method, organizations can automate the process of classifying and categorizing documents, leading to increased efficiency and reduced costs. This can be especially useful in industries such as finance and healthcare, where there is a significant amount of paperwork that needs to be processed. The proposed method can be extended to incorporate other modalities, such as audio and video, leading to more robust and accurate document classification. This can be especially useful in industries such as media and entertainment, where documents may contain different types of media.

Overall, Digitized Document Classification using Multimodal Deep Learning is a promising research paper that proposes a novel approach to document classification using a combination of text and image features [34]. The proposed method has several advantages, including increased accuracy and efficiency compared to traditional document classification methods. However, the method also has some limitations, including the requirement of a large dataset for training and the computational cost [35]. Despite these limitations, the proposed method has several future perspectives and can be applied in various industries, including document analysis and retrieval, automated document processing, and media and entertainment.

VII. Conclusion

In conclusion, Digitized Document Classification using Multimodal Deep Learning is a valuable contribution to the field of document classification. By combining text and image features using deep learning models, the proposed method can accurately and efficiently classify different types of documents.

Because it can help in the structuring of a document collection and describe the main subject of a document via the use of semantic multimedia analysis among concepts, the suggested method provides good performance in a range of contexts. This is because semantic multimedia analysis can help describe the primary topic of a document. These two qualities contribute, individually and together, to the accomplishment of high levels of performance. As a consequence of this, a large number of experiments were carried out in order to evaluate the efficiency of the many different topic identification tasks, and a discussion of the conclusions of those tests was provided. In this regard, the results enable us to say that the approach that we have described for identifying text themes is superior to the methods that are considered to be state-of-the-art, such as LSA and LDA, in relation to the specific topic in question. With regard to the visual subject identification, a number of different descriptors have been put through their paces and evaluated. In particular, the discoveries that seemed to have the greatest promise were chosen, and this was done on the basis of the features that were generated from the activation layer of the DNN model.

In addition, we demonstrated that it is possible to improve the overall work by using the most effective features of both techniques if one uses the strategy for identifying textual subjects in conjunction with the strategy for identifying visual themes. This was accomplished by combining the strategies for identifying textual topics and visual topics. Due to the fact that the system is modular and may be used more than once, it also has the capability to modify the proposed architecture in order to create various models for the task of topic identification. Either putting in brand new modules or enhancing the functionality of the ones that are currently there are both viable options for completing this job. All of the tests, which were conducted using a representative sample of online documents, have been successfully completed by the system. The design of the system, on the other hand, makes it possible to employ a number of different libraries that hold different kinds of multimedia content.

This approach has several advantages, including the ability to extract both visual and semantic information from documents, leading to more robust and accurate classification. However, the proposed method also has some limitations, including the requirement of a large dataset for training and the computational cost. Despite these limitations, the proposed method has several future perspectives and can be applied in various industries, including document analysis and retrieval, automated document processing, and media and entertainment. Overall, this research paper provides a foundation for further research in the field of document classification using multimodal deep learning.

***Abstract*—Diving into the complex realm of network security, the research paper investigates the potential of leveraging artificial neural networks (ANNs) to identify and classify network intrusions. Balancing two distinct paradigms – binary and multiclassification – the study breaks fresh ground in this intricate field. Binary classification takes the stage initially, offering a bifurcated outlook: network traffic is either under attack, or it's not. This lays the foundation for an intuitive understanding of the network landscape. Then, the spotlight shifts to the finer-grained multiclassification, navigating through a realm that holds five unique classes: Normal traffic, DoS (Denial of Service), Probe, Privilege, and Access attacks. Each class serves a specific function, ranging from harmless communication (Normal) to various degrees and kinds of malicious intrusion. By integrating these two approaches, the research illuminates a path towards a more comprehensive understanding of network attack scenarios. It highlights the role of ANNs in enhancing the precision of network intrusion detection systems, contributing to the broader field of cybersecurity. The findings underline the potency of ANNs, offering fresh insights into their application and raising questions that promise to push the frontiers of cybersecurity research even further.**

Keywords*—*Neural networks; artificial intelligence; detection; classification; attacks; network security

I. Introduction

In the rapidly evolving digital landscape, the detection and classification of network attacks have become a paramount concern for organizations globally [1]. The introduction of Artificial Neural Networks (ANNs) has ushered in a new era of possibilities in handling this concern, providing robust and adaptive solutions to complex cybersecurity challenges [2]. This research paper, "Artificial Neural Network for Binary and Multiclassification of Network Attacks," delves into these possibilities, exploring how ANNs can be employed to enhance the detection and classification of network attacks.

Network intrusions have been traditionally identified and classified using a binary approach: there is either an attack or there isn't [3]. This approach offers a straightforward, binary perspective on network traffic, facilitating a basic yet vital understanding of network security. However, as the complexity of network attacks has grown exponentially, the need for a more nuanced understanding has become evident under the realm of multiclassification [4].

Through a multiclassification approach, network traffic can be categorized into multiple classes, enabling a more detailed analysis. In this research, five distinct classes are identified: Normal traffic, and four types of attacks – DoS (Denial of Service), Probe, Privilege, and Access. By scrutinizing the individual characteristics of each class, we are able to discern not just the presence of an attack, but also its nature and potential impact. This level of detail provides a much-needed edge in defending against, and responding to, network intrusions.

A pivotal tool in enabling this detailed classification is the Artificial Neural Network. Mimicking the learning process of the human brain, ANNs are capable of learning from experience, improving their performance as they are exposed to more data [5]. This inherent adaptability makes them highly effective in identifying the subtle patterns that differentiate one class of network traffic from another.

In our exploration of ANNs for network attack classification, we will delve into their structure, function, and application, providing a comprehensive understanding of their role in cybersecurity. The research includes a detailed discussion on the various types of ANNs, their learning algorithms, and how they can be trained to accurately classify network traffic.

Moreover, the study will also address the challenges faced when applying ANNs to real-world scenarios, shedding light on the obstacles that need to be overcome for this technology to reach its full potential [6]. By exploring both the strengths and weaknesses of ANNs in network attack classification, this research aims to provide a balanced view of their utility in this crucial area.

II. Related Works

The field of cybersecurity, particularly the detection and classification of network attacks, has been extensively researched, and this paper builds on a number of prior works, each contributing to our understanding of this complex landscape [7]. As the focus of our paper is on utilizing Artificial Neural Networks (ANNs) for binary and multiclassification of network attacks, we will delve into studies that lay the groundwork for our investigation.

In a recent study, authors provided a seminal investigation into the use of deep learning methods for network intrusion detection [8]. They used ANNs to detect intrusions in a Software-Defined Networking (SDN) environment, providing a comprehensive framework that offers insights into the structure and operation of ANNs in a network intrusion detection context.

Building on this, next research shifted the focus from SDN to traditional network environments [9]. Their research exemplified the use of ANNs in binary classification, identifying whether a network event is an attack or normal traffic. The application of fuzzy clustering, in tandem with ANNs, accentuated the ability of the system to handle ambiguous scenarios that reside in the gray area between 'attack' and 'normal traffic'.

Taking it a step further, authors [10] introduced multiclassification into the mix. The study classified network attacks into four categories - DoS, Probe, Privilege, and Access, providing a more nuanced understanding of network intrusions. The authors highlighted the advantages of multiclassification, offering a model that can inform more targeted responses to different types of attacks.

While these studies focused on the application of ANNs in network intrusion detection and classification, research by [11] titled "Challenges and Future Directions in the Deployment of Neural Network Models in Cybersecurity," explored the hurdles in applying these models in real-world scenarios. They identified issues such as overfitting, the difficulty of interpretability, and data scarcity, among others. This research provides essential context, informing us of the potential roadblocks that could hinder the effective deployment of ANNs in network intrusion detection and classification.

A notable study by [11] titled "Application of Deep Learning to Detect Intrusion in 5G and IoT Networks" introduced the concept of utilizing ANNs in the context of 5G and IoT networks. They highlighted the increasing complexity of intrusion detection due to the significant growth of IoT devices and the transition to 5G. Their exploration of the effectiveness of ANNs in this relatively new network environment laid the groundwork for future research in more complex network infrastructures.

Furthermore, the research by [12] significantly contributed to our understanding of multiclassification. They took a unique approach of extending binary classification to multiclassification, investigating how ANNs can distinguish between different types of attacks within a network. Their work presented important insights into the potential and challenges of employing multiclassification in intrusion detection systems.

Deep Neural Networks for Multiclass Detection of Distributed Denial of Service Attacks took a narrower focus, concentrating solely on the detection of different types of DDoS attacks [13]. Their research provided valuable insights into the specialized application of ANNs for detecting and classifying a specific type of network attack.

Next study by [14] presents an overview of machine learning algorithms in improving the precision of network intrusion detection systems. Their study, while not exclusive to ANNs, illuminates the broader context within which our research is situated, showcasing the potential of machine learning in this field.

Taken together, these studies demonstrate the evolution of applying ANNs in the field of network intrusion detection and classification, and highlight the significant progress that has been made. They provide us with a broader context for our own research, enabling us to both build upon their insights and address the gaps in existing knowledge. Our research aims to consolidate these findings and contribute to a more nuanced understanding of how ANNs can be employed effectively in both binary and multiclassification of network attacks.

Our study, seeks to build on these existing studies. It aims to further the understanding of how ANNs can be effectively utilized for network attack detection and classification, and how potential hurdles can be surmounted for real-world deployment. By taking into account the insights and challenges highlighted by these previous studies, we hope to make a significant contribution to the ongoing discourse in this vital field of research.

III. Dataset

In this research, the NSL-KDD dataset is applied to train and test artificial neural network in order to detect attacks [15]. The NSL-KDD dataset, a benchmark dataset in the field of cybersecurity, serves as the data foundation for our research paper, "Artificial Neural Network for Binary and Multiclassification of Network Attacks." This dataset is an improved and refined version of the widely-known KDD'99 dataset, addressing the inherent limitations of its predecessor such as redundant records leading to learning bias.

NSL-KDD is comprised of a rich collection of simulated network traffic instances containing both normal and malicious events, enabling comprehensive training and testing of our Artificial Neural Network (ANN) models. The dataset holds an extensive variety of intrusions simulated in a military network environment, making it well-suited for studying intricate network intrusion detection scenarios.

The NSL-KDD dataset contains around 125,000 records in the training set and about 22,500 records in the testing set. Each record within the dataset represents a connection and contains 41 features, which describe various aspects of the connection like duration, protocol type, service type, and various other content features extracted from the payload. The diversity of these features allows the ANN to learn from a wide array of indicators, potentially boosting the model's overall detection accuracy. Fig. 1 demonstrates percentages of normal and attack classes.

Importantly, each record in the dataset is labeled as either 'normal' or as one of the four defined types of attacks: denial of service (DoS), Probe, Privilege, and Access. These labels are instrumental in both binary and multiclassification approaches, facilitating the training of the ANN to not only identify the presence of an attack but also classify the attack into one of these specific categories.

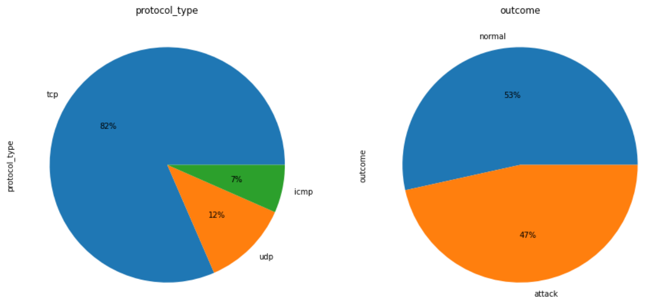

Fig. 1. Distribution of protocols in the NSL-KDD dataset.

Fig. 2 demonstrates flags of each class as normal and attack classes. In network communication, flags are employed to indicate the status of a certain connection, or to signal various types of events or errors. These flags can serve as powerful indicators of anomalous or malicious behavior in network traffic; hence their distribution across the different classes is of significant interest.

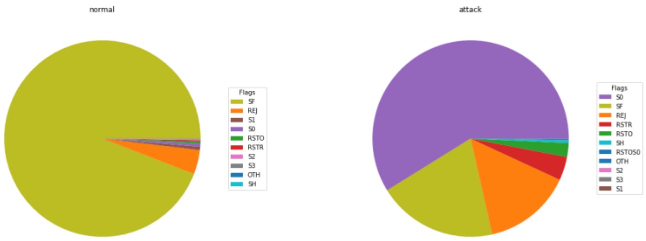

Fig. 2. Distribution of normal and attack flags in NSL-KDD dataset.

In summary, the NSL-KDD dataset, with its diversity and comprehensive representation of both normal and attack instances, provides a robust platform for the development and evaluation of ANN models in our research. The findings drawn from this dataset can contribute significantly to our understanding of network intrusions and the application of ANNs in detecting and classifying these attacks.

IV. Proposed Artificial Neural Network for Network Attacks Detection

The proposed Artificial Neural Network (ANN) model for the study is based on a sequential model, which is a linear stack of layers. This model is designed to process the NSL-KDD dataset and classify network traffic into five categories: normal traffic or one of four attack types – DoS, Probe, Privilege, and Access. Architecture of the proposed model is illustrated in Fig. 3.

The architecture of the model consists of multiple layers, each contributing to the learning capacity of the model. The first layer, dense_35, is a densely connected layer, also known as a fully connected layer. It consists of 64 nodes or neurons, and each neuron in this layer is connected to all neurons from the previous layer (input data). This layer has 5,632 parameters, which are the weights and biases that the model will learn during the training phase.

dense_39	input:	(None, 128)
Dense	output:	(None, 5)

Fig. 3. The proposed neural network.

The architecture of the model consists of multiple layers, each contributing to the learning capacity of the model. The first layer, dense_35, is a densely connected layer, also known as a fully connected layer. It consists of 64 nodes or neurons, and each neuron in this layer is connected to all neurons from the previous layer (input data). This layer has 5,632 parameters, which are the weights and biases that the model will learn during the training phase.

Following dense_35 is dropout_28, a dropout layer designed to reduce overfitting. It randomly sets a fraction of input units to 0 during training, which helps prevent overfitting by ensuring that the model doesn't rely too heavily on any single input feature.

The model then proceeds to dense_36, another fully connected layer, but with 128 neurons. The number of parameters here is 8,320. The output of dense_36 is passed through another dropout layer, dropout_29, to prevent overfitting.

Next is dense_37, a significant layer with 512 neurons, having a much larger parameter count of 66,048. This layer is followed by dropout_30 to again avoid overfitting.

The model continues to dense_38, which is another fully connected layer with 128 neurons, consisting of 65,664 parameters. The output of this layer passes through the last dropout layer, dropout_31.

Finally, the output layer, dense_39, comprises five neurons corresponding to the five classes that our model aims to predict. This layer employs a softmax activation function to output a probability distribution over the five classes, indicating the likelihood of each class being the correct one. This final layer contains 645 parameters.

Overall, the proposed ANN model has a total of 146,309 parameters, all of which are trainable. The model's complexity and architecture make it capable of effectively learning to classify network traffic into the five defined classes.

V. Evaluation Parameters

In assessing the performance of our proposed Artificial Neural Network (ANN) model, it is vital to use appropriate evaluation parameters that reflect the model's capabilities in various aspects. The following metrics - Accuracy, Precision, Recall, F-Score, and receiver operating characteristics area under the curve (ROC-AUC) have been chosen due to their extensive use in classification tasks and their ability to provide a holistic view of the model's performance [16]. Next paragraphs explain each evaluation parameter that applied to assess the performance of the proposed model.

Accuracy: This is one of the most straightforward metrics, which essentially quantifies the ratio of correct predictions made by our model out of all predictions. While accuracy can provide a quick overview of model performance, it might not be an ideal metric when dealing with imbalanced datasets [17].

$$accuracy = \frac{TP + TN}{TP + FN + TN + FP} \tag{1}$$

1) Precision: Precision measures the proportion of true positives out of all positive predictions made by the model. It provides insight into how well the model correctly predicts an attack when it claims there is one. High precision indicates a lower rate of false positives [18].

$$precision = \frac{TP}{TP + FP} \tag{2}$$

2) Recall: Recall, or sensitivity, gauges the proportion of actual positive (attack) instances that the model correctly identifies. A high recall means that the model can accurately catch a high percentage of network attacks, minimizing the number of false negatives [19].

$$recall = \frac{TP}{TP + FN} \tag{3}$$

3) F-Score: The F-Score or F1-score is the harmonic mean of precision and recall. This metric provides a single score that balances both the precision and the recall. It is particularly useful when you want to compare two or more models and need a single performance score [20].

$$F1 = \frac{2 \cdot precision \cdot recall}{precision + recall} \tag{4}$$

4) ROC-AUC: The Receiver Operating Characteristic - Area Under Curve (ROC-AUC) is a performance measurement for binary classification problems [21]. It tells how much a model is capable of distinguishing between classes. The higher the AUC, the better the model is at predicting 0s as 0s and 1s as 1s. Each of these metrics provides unique insights into the model's capabilities, and together they offer a comprehensive assessment of the model's overall performance.

VI. Experimental Results

The Results section offers a comprehensive review of the performance of our proposed model. After rigorously training and testing our model using the NSL-KDD dataset, we have evaluated the performance using the defined metrics - Accuracy, Precision, Recall, F-Score, and ROC-AUC. This section presents an in-depth analysis of the findings, detailing how well our model can detect and classify network attacks.

A. Binary Classification of Network Attacks

Fig. 4 demonstrates confusion matrix of binary classification of network attacks. The model correctly identified 9490 instances of normal traffic (TN), and correctly classified 7342 instances of attack traffic (TP). However, the model inaccurately labeled 221 instances of normal traffic as attack traffic (FP), and 5490 instances of attack traffic as normal traffic (FN).

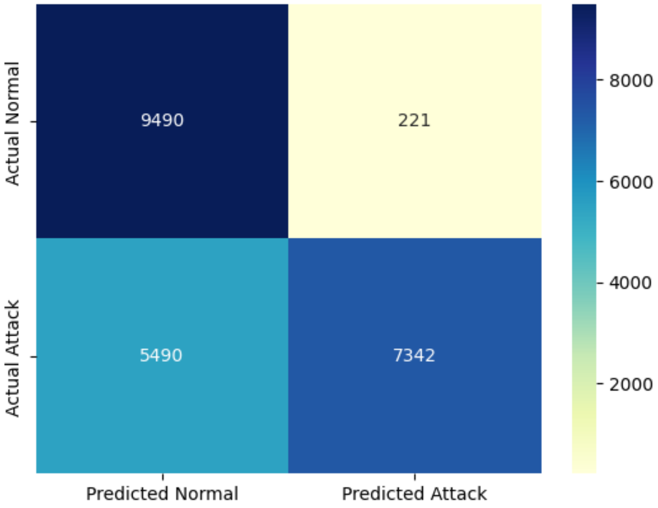

Fig. 4. Confusion matrix of binary classification of network attacks.

These results offer valuable insights into the model's strengths and limitations. While the model has shown a strong capacity for correctly identifying normal network traffic and a fair performance in recognizing attack instances, the relatively high number of false negatives (attack traffic identified as normal) indicates room for improving the model's ability to accurately identify network attacks. This confusion matrix serves as a baseline for refining the model and informs future iterations and improvements.

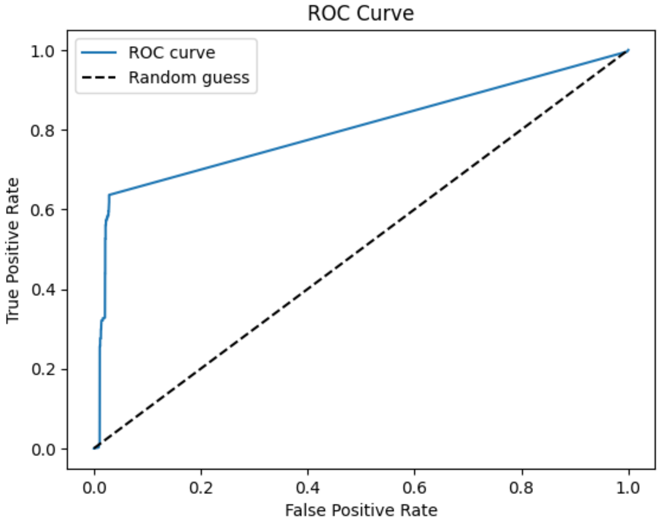

Fig. 5. ROC-AUC curve for binary classification of network attacks.

In this research paper, the Receiver Operating Characteristic (ROC) curve is an essential tool for evaluating the model's discrimination capability—how well the model can distinguish between the different classes. Fig. 5 demonstrates the obtained ROC curve in binary classification of network attacks. The ROC curve of this plot, known as the ROC-AUC, provides a scalar measure of the model's overall performance: an AUC of 1 signifies perfect classification. By considering the obtained results, we can suppose that the proposed model show high accuracy in network intrusion detection problem.

In the context of our research, the Accuracy and Loss graphs are integral components for assessing the performance and convergence of the model throughout its training process. The Accuracy graph is a plot that displays how the accuracy of the model evolves during the training and validation phases over multiple epochs. We would see a steady increase in accuracy for both the training and validation sets over time, indicating that the model is learning from the data. Therefore, Fig. 6 demonstrates train and validation accuracy for 10 learning epochs.

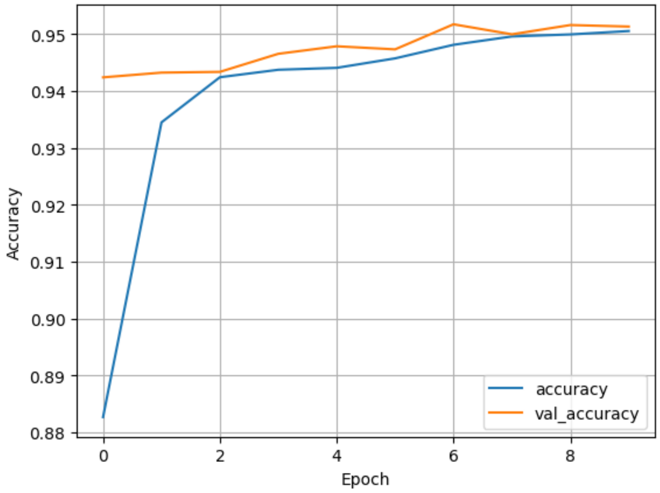

Fig. 6. Train and test accuracy of the proposed model for binary classification of network attacks.

On the other hand, the Loss graph demonstrates the model's error or cost over time. The loss is computed using a loss function, which measures the dissimilarity between the model's predictions and the actual labels. As the model learns, we expect the loss to decrease, indicating that the model's predictions are becoming increasingly accurate. If we see the loss decreasing for the training set but not for the validation set, this might also be an indication of overfitting. Therefore, Fig. 7 demonstrates train and validation loss.

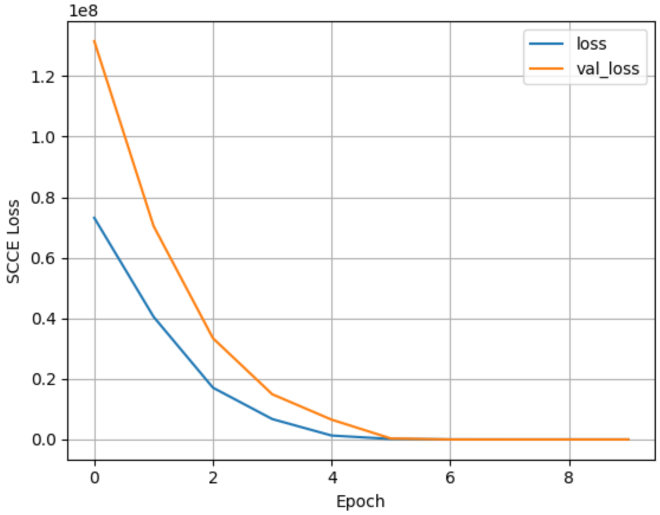

Fig. 7. Train and test loss of the proposed model for binary classification of network attacks.

As we transition into the next phase of our research on "Artificial Neural Network for Binary and Multiclassification of Network Attacks," we will be focusing on the multiclassification aspect. This segment of the study delves into the advanced capability of the proposed Artificial Neural Network (ANN) model to distinguish not just between normal and attack traffic, but also between different types of network attacks, namely DoS, Probe, Privilege, and Access attacks.

This task is significantly more complex than binary classification because it requires the model to differentiate among multiple classes, each representing a unique kind of network attack. Our primary objective is to improve the robustness of network security systems, by enabling them to correctly identify and categorize the nature of the threat they are facing.

B. *Multiclassification of Network Attacks*

In this context, our evaluation parameters and graphs, including accuracy, precision, recall, f-score, ROC-AUC, and the confusion matrix, will now consider these multiple categories. Consequently, the metrics will provide more granular insights into the model's performance.

We will be examining if the model can maintain high accuracy and precision across all attack classes, or if it shows particular strengths or weaknesses in identifying specific types of attacks. By carefully analyzing these results, we aim to gain valuable insights that will guide future research and help improve the efficacy of network intrusion detection and classification systems. Fig. 8 demonstrates confusion matrix of the proposed model when classify the traffic to five classes including normal class and four attack classes.

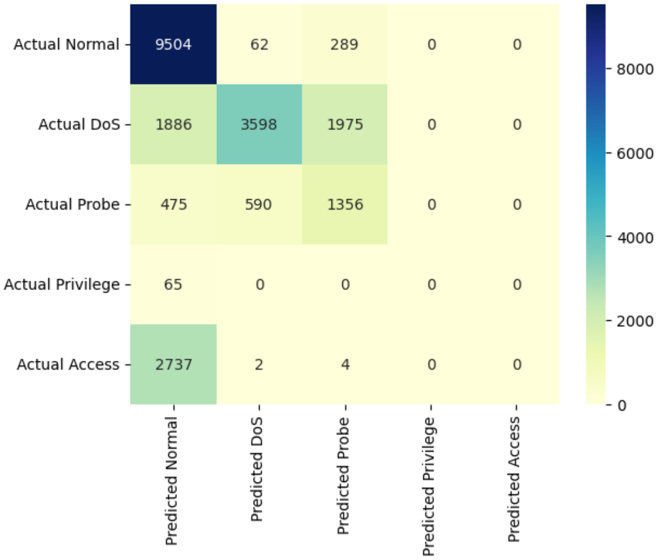

Fig. 8. Confusion matrix for multiclassification of network attacks.

Fig. 9 offers a graphical illustration of the proposed model's accuracy during the multiclass classification of network attacks over 10 epochs. It is evident that the model performs impressively, with the accuracy plateauing around the 94% mark within these iterations. This high accuracy underscores the model's effectiveness in identifying various types of network attacks.

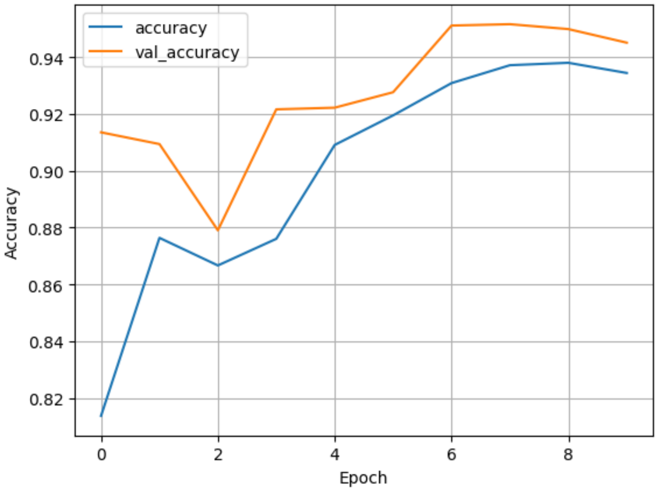

Fig. 9. Train and test accuracy of the proposed model for multiclassification of network attacks.

Fig. 10 presents the progression of both training and testing loss of our proposed model in the multiclass classification of network attacks. The depicted results signify that the model is efficient, as it manages to minimize its loss within just five epochs of learning. This rapid convergence to a minimal loss implies a robust model that learns effectively.

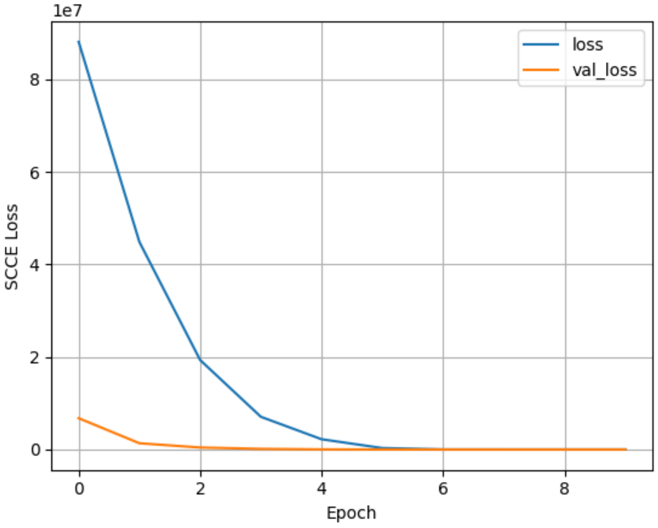

Fig. 10. Train and test loss of the proposed model for multiclassification of network attacks.

In the Results section of our research paper "Artificial Neural Network for Binary and Multiclassification of Network Attacks," we scrutinized the performance of our proposed ANN model for network intrusion detection and classification tasks. The model was trained and tested using the NSL-KDD dataset, with its performance evaluated via key metrics - Accuracy, Precision, Recall, F-Score, and ROC-AUC.

The obtained confusion matrix provided a detailed breakdown of the model's correct and incorrect classifications, revealing a strong capacity for identifying normal network traffic and a satisfactory performance in recognizing attack instances. However, it also highlighted a relatively high number of false negatives, indicating potential areas for further refinement.

Through our ROC curve analysis, we assessed the model's capability to distinguish between classes at varying thresholds, giving us an understanding of its overall performance. Meanwhile, the Accuracy and Loss graphs traced the evolution of the model's learning process, aiding in identifying potential overfitting and underfitting issues.

Finally, as we moved to the multiclassification of network attacks, we found the model could distinguish not just between normal and attack traffic but also among different types of network attacks. This step elevated the complexity of the model's task, yet it showed promising results, setting the stage for future work in improving network intrusion detection systems.

The results paint a comprehensive picture of the model's capabilities, strengths, and areas for improvement. They provide a firm foundation for the ongoing development of a robust, high-performing ANN model for network attack classification.

VII. Discussion

The Discussion section of this research paper on "Artificial Neural Network for Binary and Multiclassification of Network Attacks" allows for an in-depth exploration of the implications of our results, their alignment with existing research, the strengths and weaknesses of our methodology, and directions for future research [22].

This study presents a novel implementation of an Artificial Neural Network (ANN) for detecting and classifying network intrusions [23]. The ANN model has shown promising results both in binary classification (distinguishing between normal and attack traffic) and in multiclassification (distinguishing among different types of network attacks).

One key advantage of our proposed model is its adaptability [24]. The model's architecture, composed of densely connected layers interspersed with dropout layers, enables it to learn intricate patterns within the data. The use of dropout layers, in particular, helps prevent overfitting by reducing the model's complexity during training [25]. Our model demonstrates a strong capacity to generalize from the training data to unseen data, thereby making it a robust and reliable tool for intrusion detection in different network environments.

However, there are areas where the model could be improved. The confusion matrix indicated a relatively high number of false negatives, suggesting that the model might be under-sensitive to certain types of attacks or specific features within the data [26]. Further investigation and refinement of the model's architecture, hyperparameters, or training process could help address this issue [27]. Additionally, the incorporation of other machine learning techniques, such as ensemble methods or advanced feature extraction, could potentially boost the model's performance [28].

Looking forward, it is also crucial to consider the dynamic and evolving nature of cyber threats. As attackers continuously develop new strategies and techniques, the patterns that our model has learned may become outdated [29]. Therefore, it is essential to continually update and retrain the model with the latest data. One possible approach to address this challenge is online learning, where the model is continually updated with new data as it becomes available [30]. This approach could help the model adapt to emerging threats and maintain its performance over time.

Finally, the successful application of the proposed model to the NSL-KDD dataset suggests potential for its use in other cybersecurity contexts. For example, similar techniques could be applied to other types of security-related data, such as system logs or network flow data, to detect anomalies or suspicious activities. Exploring these applications could be a promising direction for future research.

In summary, this study has demonstrated the potential of ANN models for network intrusion detection and classification. While the model has shown promising results, there remains room for improvement and adaptation to the continuously evolving landscape of network threats. By addressing these challenges, we believe that ANN models can play a pivotal role in enhancing network security and developing more resilient systems against cyber threats.

VIII. Conclusion

In conclusion, the research paper has provided an insightful exploration into the implementation of an ANN model for network intrusion detection and classification. The comprehensive analysis of the model's performance has showcased its potential for bolstering network security, along with its ability to discern between various types of cyber threats.

The study was anchored around the NSL-KDD dataset, a standard benchmark in the field of cybersecurity. Our ANN model exhibited notable accuracy in both binary and multiclassification tasks, proving its capability in detecting normal versus attack traffic and differentiating among various attack types. However, a degree of under-sensitivity was observed in terms of false negatives, indicating an avenue for future refinement and optimization.

Moreover, the research underscored the significance of evolving the model in tandem with the ever-changing nature of cyber threats. Our model's adaptability, largely attributable to its densely connected layers and dropout layers, constitutes a strong foundation for this continual evolution. Future work can benefit from implementing online learning techniques to ensure the model stays updated with the latest threat patterns.

The promising results gleaned from this study support the idea that advanced machine learning techniques, such as ANN, hold substantial potential in advancing network security. By delving deeper into the granular intricacies of attack patterns and continuously improving upon model architectures and training techniques, we can move closer to creating highly effective, adaptable, and robust intrusion detection systems.

In essence, this research represents a significant stride in the broader march towards leveraging artificial intelligence in cybersecurity, a field that continues to grow in importance as digital connections increasingly underpin our societies. Our findings provide a solid foundation for further investigation and innovation in this critical area.

Lung Nodule Segmentation and Classification using U-Net and Efficient-Net

Suriyavarman S[1], Dr. Arockia Xavier Annie .R[2]
Department of Computer Science Engineering-College of Engineering, Anna University, Chennai, India[1, 2]

***Abstract*—The ability to detect lung cancer has led to better health outcomes. Deep learning techniques are widely used in the medical field to detect lung tumors at an early stage. Deep learning models such as U-Net, Efficient-Net, Resnet, VGG-16, etc. have been incorporated in various studies to detect lung cancer accurately. To enhance the detection performance, this work proposes an algorithm that combines U-Net and Efficient-Net neural networks for lung nodule segmentation and classification. A feature-extraction-based semi-supervised method is used to take advantage of the huge amount of CT scan images with no pathological labels. Semi-supervised learning is achieved using a feature pyramid network (FPN) with ResNet-50 model for feature extraction and a neural network classifier for predicting unlabelled nodules. The main innovation of U-Net is the skip-connections, which give the decoder access to the features that the encoder learned at various scales and enable accurate localization of lung nodules. Efficient-Net uses depth, width, and resolution scaling, combined with a compound coefficient that uniformly scales all network dimensions, resulting in an efficient neural network for image classification. This work has been evaluated on the publicly available LIDC-IDRI dataset and outperforms most existing methods. The proposed algorithm aims to address issues such as a high false-positive rate, small nodules, and a wide range of non-uniform longitudinal data. Experiment results show this model has a higher accuracy of 91.67% when compared with previous works.**

***Keywords*—Cancer; CT; U-Net; efficient-net; feature; accuracy**

I. Introduction

Lung cancer is the second most lethal type of cancer in both men and women. Additionally, the coronavirus pandemic has increased the chances of mortality for lung cancer patients [1]. If not timely detected, lung tumor could lead to death. The small cell growths in the lung known as pulmonary nodules can be either cancerous (malignant) or noncancerous (benign) [2]. Given how closely early-stage cancer lung nodules resemble noncancerous nodules, a differential diagnosis based on the nodule's locations, morphological traits, and clinical biomarkers is required. According to the WHO, 2.21 million cases of lung cancer were reported in 2020, and 1.80 million lives were lost from it [3].

Lung cancer develops when cells in the lung tissue continue to grow uncontrollably. This results in tumor growth. They have the potential to spread to numerous other body parts and affect respiration [4]. A number of imaging techniques are used, including computed tomography, sputum cytology, chest X-rays, and magnetic resonance imaging, to detect lung cancers early (MRI). Tumors are briefly categorised into two types in order to be detected: i) Benign tumors (non-cancerous), and ii) Malignant tumors (cancerous) [5]. Image processing techniques can improve manual analysis. Many studies have demonstrated the occurrence of diagnostic errors in clinical practise [6]. These errors can be attributed to a variety of contributing factors, which can be broadly categorised as person-specific, nodule-specific, and environment-specific problems.

Fine-grained cross-sectional images of the human body are produced via a CT scan. A CT scan gathers many images as opposed to a standard x-ray, which only records one or two images. These images are eventually merged by a computer to create a slice of the body part being studied. A conventional chest x-ray is less likely to find lung cancer than a CT scan [7]. It can also show the size, shape, and location of any lung tumours and reveal enlarged lymph nodes that may house cancer that has spread [8].

Recent years have seen significant advancements in the fields of medicine, including lesion classification, tissue detection, and segmentation, owing to machine learning and particularly deep learning [9]. With the development of artificial intelligence, deep learning has become more popular in the analysis of medical images. A practical method for extracting richer and more powerful characteristics is provided by deep convolutional neural networks [10]. Automated algorithms can provide a faster and more accurate solution for the detection and classification of lung nodules, thus improving patient outcomes [11].

II. Literature Review

A. Preprocessing

Large amounts of unprocessed data from CT scans can contain noise, artefacts, and inconsistencies that may compromise the accuracy and reliability of subsequent analyses. In their work [12], Amalorpavam et al. present a very detailed systematic review of existing morphological operations in digital image processing. The primary goal of this work is to change images using mathematical morphology in order to normalize them for the intended analyses. This work shows many approaches, such as erosion, dilation, thresholding, and blurring, can be effectively incorporated in the pre-processing of CT scan images. These methods are used to enhance the contrast between various tissues, remove noise from the images, and remove any non-nodule structures.

B. Segmentation

Developed on the foundation of a fully convolutional neural network, U-Net is a semantic segmentation network. Olaf et al. [13] successfully modelled the convolutional network-based U-Net architecture, which was created specifically for the segmentation of images in the biomedical field. This work includes a traditional U-Net architecture with an encoder and a decoder and produced an average IOU ("intersection over union") of 92%.

A study by Chen et al. [14] proposed a U-Net-based method for segmenting lung nodules in CT images. The proposed method consisted of two stages: the first stage used a pre-trained U-Net model for initial segmentation, and the second stage used a 3D fully connected conditional random field (CRF) for refinement. For the segmentation of lung nodules, Ronneberger et al. [15] developed a U-Net network based on FCN. When segmenting medical images with hazy boundaries, U-Net combines low- and high-resolution information by skipping connections. Low-resolution information is used for target identification, and high-resolution information is used for localising segmentation.

C. Feature Extraction

In a feature pyramid network, a convolutional neural network (CNN) is used to extract features from an input image and create a feature map. Xiaolong Wang et al. [16] proposed a semi-supervised learning method that uses a multi-level feature pyramid network (FPN) to leverage both labelled and unlabeled data. The FPN is used to extract features at different scales, and the method incorporates consistency regularisation to encourage the model to produce similar predictions on labelled and unlabeled data. With only 4,000 labelled samples, the suggested method achieves the best reported classification error rate of 4.42% on the test set. With 4,000 labelled samples and 50,000 unlabeled samples, it also achieves an error rate of 3.57%, which is also the best result to date.

Guangrui Mu et al., [17] proposed Feature pyramid networks with Relu Cascade for CT Pulmonary Nodule Detection. A detection network is first trained with few positive annotations (nodules) and randomly selected negative samples (background). In FPN, extraction is performed separately to produce feature maps of four different scales by using images onto each feature map. The "Relu cascade's" uniqueness lies in the method used to link these networks together in a cascade.

D. Classification

Convolutional neural network architecture called Efficient-Net has produced cutting-edge outcomes on a number of computer vision tasks, including image classification. Agrawal et al., [18] presented various deep learning based pre-trained CNN techniques for distinguishing benign and malignant brain tumor images. They used different optimizers to complete the tasks, namely Adam, RMSprop, and stochastic gradient descent (SGD). Their research demonstrated that a fine-tuned Alexnet could perform particularly well on challenges involving medical imaging. They used data pre-processing and augmentation techniques for boosting diversity in the data samples to decrease the overfitting of the previous models.

Hwejin Jung et al., [19] proposed a three-dimensional deep convolutional neural network (3D DCNN) with dense connections and shortcut connections was developed for the classification of lung nodules. By enabling the gradient to move swiftly and directly, shortcut connections and dense connections successfully address the gradient vanishing problem. This method achieved a highest CPM score of 0.910.Divya et al., [20] presented methods based on transfer learning that enhances current architecture in multi-class classification by relying on pretrained DCNN trained on ImageNet dataset. Pretrained weights of EfficientNetV2-B0 are transferred as initial weights and to distinguish between benign and malignant tissue samples in tumour cells and classify them, the model is fine-tuned.

The objective of this work is to create and construct a deep learning model based on the U-Net segmentation network and Efficient-Net architecture to segment and classify lung nodules in CT scan images. The work addresses various limitations, such as that improvements are needed in the detection rates of lung nodules, as the proposed models have only focused on training dataset image samples and also segmented anomalies as positive samples, an unequal number of benign and malignant lung nodules, resulting in an imbalanced dataset, an accurate diagnosis of the pathological type of lung cancer is crucial for effective treatment; and the performance of model relies heavily on the choice of optimizer.

Developed on the foundation of a fully convolutional neural network, U-Net is a semantic segmentation network. There are a total of 23 layers in the network, which is significantly fewer than the number of layers in other networks while maintaining accuracy [21]. Feature pyramid networks are used to extract feature vectors from segmented images. These feature vectors are used as input into a neural network classifier for an unlabelled nodule prediction task [22]. A family of convolutional neural networks called Efficient-Net was created to achieve cutting-edge performance while being computationally efficient. It accomplishes this by balancing network depth, width, and resolution in order to optimise performance within a predetermined computational budget [23].

The proposed algorithm will be put to the test on the LIDC dataset to see if it can accurately classify and identify specific features, and the outcomes will be compared to standard metrics like accuracy, recall, and F1-score [24]. The proposed algorithm aims to detect and segment lung nodules accurately. Using an ablation study, the project aims to examine the impact of various parameters (hyper-parameters) on the performance of the proposed lung nodule segmentation and classification algorithm [25].

To explore the possibility of employing semi-supervised learning and transfer learning to enhance the performance of the proposed algorithm on datasets with limited labelled data [26]. Adam optimizer is incorporated to stabilize the performance of the model and reduce the effect of errors [27].

III. Proposed Methodology

A. LIDC-IDRI: The Lung Image Database Consortium

The National Cancer Institute spearheaded the collection of the 1018 cases that make up the LIDC dataset, each of which was collaboratively labelled by four radiologists. The

LIDC-IDRI dataset (Armato et al., 2011; Armato III et al., 2015b; Clark et al., 2013) in the Cancer Imaging Archive (TCIA) contains 1018 clinical chest CT scans with lung nodules obtained from seven institutions. The locations of the nodules and the nine sematic attributes of subtlety, sphericity, internal structure, margin, lobulation, spiculation, and malignancy are detailed in an associated XML file for each CT scan that was evaluated for annotation by up to four radiologists (Qin et al., 2019).

It is a database that is widely utilised and devoted to the advancement of current methods for lung nodule segmentation. Three categories of nodules are distinguished: non-nodules (size >=3mm), nodules (size < 3mm), and nodules (size >=3mm). All of the images will be in the DICOM (Digital Imaging and Communications in Medicine) format and 512 x 512 in size. Based on the malignancy details provided in the metadata csv and xml files, around 12000 labelled CT scan images and 3000 unlabelled CT scan images are used.

B. System Architecture

This section provides the detailed architecture and description and algorithmic details of the various subsystems in the proposed system. The detailed architecture of the proposed system is represented in the below Fig. 1. An algorithm has been proposed to segment the lungs in images by using U-Net model and classify the images using Efficient-Net architecture. Unlabelled dataset is labelled by using FPN with Resnet-50 as backbone. FPN extracts features from labelled images and provides these features as input into a neural network classifier. The classifier predicts the class of unlabelled images and these images are added to the dataset for model training.

This model typically involves a series of preprocessing steps, such as Gaussian blur, thresholding, erosion and contouring, to enhance and segment the objects in the images. The Gaussian blur function smoothens the image and reduces noise, while thresholding converts the image to black and white, simplifying it for further processing.

Contouring then isolates the objects within the image by drawing lines around them. The model uses the FPN architecture to extract features from the images when preprocessing is completed. The Efficient-Net model is a state-of-the-art deep learning architecture that has achieved exceptional results in image classification tasks, making it a powerful tool for object recognition.

To achieve this goal, the system will use the U-Net model to segment the lung nodules from the surrounding tissue and the efficient-net architecture to classify the nodules as benign or malignant. The feature extraction is performed using Feature Pyramid networks. The system will also have the potential to be used in other medical imaging modalities, such as MRI and PET, for the detection and classification of other types of abnormalities and diseases.

C. Module Design

The architecture is divided into five modules. The modules are namely preprocessing, augmentation, segmentation, feature extraction and nodule classification, respectively.

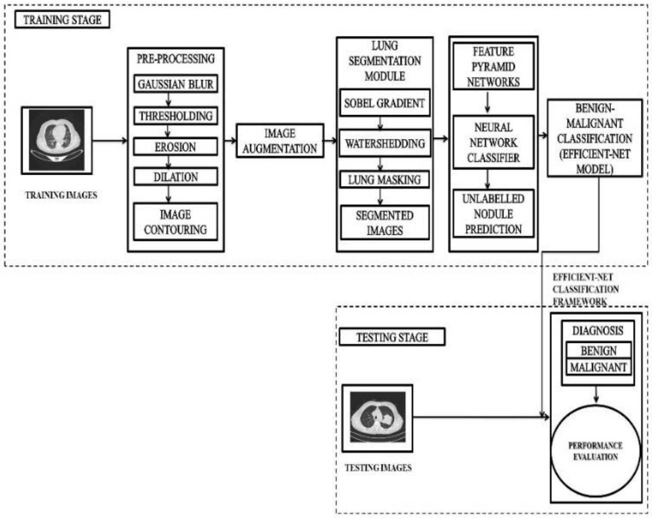

Fig. 1. Detailed system architecture.

1) Pre-Processing: The data pre-processing [28] step is essential to normalise the data in a way that enables the convolutional network to learn appropriate and meaningful features properly because CT scans might be acquired by different scanners in different medical clinics without the use of identical acquisition protocols. Directly obtained CT scans of the lungs have noise, no discernible variations in the greyscale border, and other characteristics that make them difficult to divide. Consequently, the Images Pre-processing is first task. To reduce the noise in the lung CT scans, it is necessary to remove certain regions that make it difficult to separate.

Meanwhile, to make the upcoming segmentation process easier, the boundary portion of the CT picture that changes smoothly needs to be sharpened. Fig. 2 represents the Preprocessing Module which consists of Gaussian Blur, Thresholding, Erosion, Dilation and contouring Techniques.

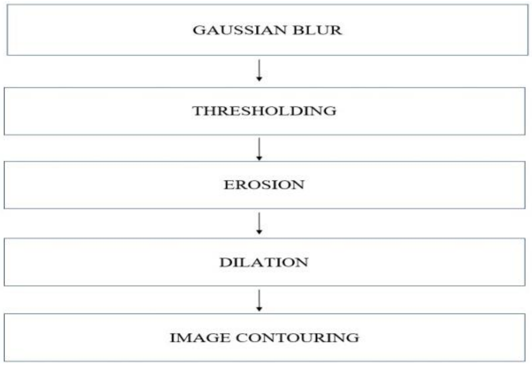

Fig. 2. Preprocessing flow diagram.

a)Gaussian Blur: Gaussian blur [29] is a linear low-pass filter, where the pixel value is calculated using the Gaussian function. The rate at which this weight diminishes is determined by a Gaussian function, hence the name Gaussian blur.

$$G(x, y) = (1 / (2\pi\sigma^2)) * \exp(-(x^2 + y^2) / (2\sigma^2)) \quad (1)$$

Where,

x → X coordinate value,

y → Y coordinate value,

π → Mathematical Constant PI (value = 3.13),

σ → Standard Deviation,

exp → exponential function

Algorithm 1: Gaussian Blur

Input: Image I with dimensions m x n, Gaussian kernel
Output: Image O with dimensions m x n

```
Normalize G, $G = G / \sum\sum G(x,y)$
Pad the input image I with zeros to avoid boundary effects.
Amount of padding = $(k-1)/2$ on each side.
For each pixel (i,j) in the input image I:
    Initialize the output pixel O(i,j) to zero.
    For each kernel element (x,y):
        Compute the pixel coordinates (a,b):
            $a = i - (k-1)/2 + x$
            $b = j - (k-1)/2 + y$
        Add the product of the input pixel I(a,b) and the
        kernel element G(x,y) to the output pixel O(i,j):
            $O(i,j) = O(i,j) + I(a,b) * G(x,y)$
        End
    End
Clip the output image O to the range [0,255]
Return the output image O
```

b) Thresholding: The simplest thresholding [30] methods replace each pixel in an image with a black pixel if the image intensity is less than a fixed value called the threshold or a white pixel if the pixel intensity is greater than that threshold.

Algorithm 2: Thresholding

Input: Image I with dimensions m x n, Threshold value
Output: Image O with dimensions m x n

```
For each pixel (i,j) in the input image I:
        If the pixel value I(i,j) is lesser than or equal to the
        threshold value (255):
            set the output pixel O(i,j) to 255 (white)
        End
        Else:
            The output pixel O(i,j) remains the same
        End
    End
Return the thresholded output image O
Return the output image O
```

c) Erosion: Erosion is a morphological image processing technique that is used to remove small details or isolated pixels from an image.

Algorithm 3: Erosion

Input: Image I with dimensions m x n, structuring element B with dimensions k x k
Output: Image O with dimensions m x n

```
Pad the input image I with zeros to avoid boundary effects.
Amount of padding = $(k-1)/2$ on each side
For each pixel (i,j) in the input image I:
        Initialize a flag variable f to true
        For each structuring element element (x,y):
            Compute the pixel coordinates (a,b):

                $a = i - (k-1)/2 + x$                    (2)

                $b = j - (k-1)/2 + y$                    (3)
            If $(I(a,b) == 0 \& B(x,y) ==1)$:
                set f to False.
            End

            If (f == True):
                set the output pixel O(i,j) to 1
            End
            Else:
                set the output pixel O(i,j ) to 0.
            End
        End
    End
Remove the padding from the output image O
Return the output image O
```

d) Dilation: Dilation is a morphological image processing technique that is used to enlarge or extend the details in an image.

Algorithm 4: Dilation

Input: Image I with dimensions m x n, structuring element B with dimensions k x k

Output: Image O with dimensions m x n

```
Pad the input image I with zeros to avoid boundary effects.
Amount of padding = $(k-1)/2$ on each side
For each pixel (i,j) in the input image I:
    Initialize a flag variable f to false
    For each structuring element element (x,y):
            Compute the pixel coordinates (a,b):

                $a = i - (k-1)/2 + x$                    (3)

                $b = j - (k-1)/2 + y$                    (4)
            If $(I(a,b) == 0 \& B(x,y) ==1)$:
                set f to True.
            End
            If (f == True):
                set the output pixel O(i,j) to 1
            End
            Else:
                set the output pixel O(i,j ) to 0.
            End
        End
    End
Remove the padding from the output image O
Return the output image O.
```

e) Contouring: Contours are defined as the line joining all the points along the boundary of an image that are having the same intensity.

Algorithm 5: Contouring

Input: Image I with dimensions m x n
Output: Image O with dimensions m x n

```
For each pixel (i,j) in the input image I:
    Compute the biggest contour
        biggest_contour = max(contours, contourArea)
    Compute the extreme points
        leftmost=(image,8,(0, 0, 255),-1)
        rightmost=(image,8,(0, 255, 0),-1)
        topmost=(image,8, (255, 0, 0),-1)
        bottommost=(image,8,(255,255,0),-1)
    End
Draw the contour and extreme points in the image I
Crop the image
Return the cropped image O
```

2) Augmentation: Image data augmentation is a technique that can be used to artificially expand the size of a training dataset by creating modified versions of images in the dataset. The label for all the images will be the same and that is of the original image which is used to generate them.

Flipping the images vertically and horizontally can help the model become more robust to variations in the orientation of the patient within the CT scan. This is because CT scans can be taken in different positions, and flipping the images can simulate these different positions and help the model generalize better to new data.

3) U-Net segmentation: In the field of biomedicine, image segmentation applications frequently employ the U-Net architecture. It has two sides: one that contracts and the other that expands symmetrically. Convolutional, Rectified Linear Unit (ReLU), dropout, and pooling layer portions make up the contracting side. In down sampling, the number of feature channels is increased by a factor of two. Sections of the up sampling (transpose convolution) layer, concatenation with the relevant feature channel from the contracting side, convolutional layers, and dropout layer are included in the expansive side.

The network is able to get the required features from the relevant layer using the connections between the contracting and expanding sides. Every area on the expanded side sees a halving of the amount of feature channels. At each section on the expansive side, the number of feature channels is halved. The feature vector is mapped to the expected number of classes in the final convolution layer.

In U-Net, the encoder network is the contracting side of the architecture. It consists of convolutional and max-pooling layers that gradually reduce the spatial resolution of the input image while increasing the number of feature channels. This contraction path is designed to capture the contextual information and high-level features of the image. On the other hand, the decoder network is the expansive side of the architecture. It consists of up-sampling and convolutional layers that gradually increase the spatial resolution of the feature maps while reducing the number of feature channels.

This expansion path is designed to reconstruct the high-resolution details of the image and refine the segmentation mask. The encoder and decoder networks are connected by a bottleneck layer that preserves the high-resolution features of the image. The skip connections between the encoder and decoder networks help to combine the high-level features from the encoder with the low-level features from the decoder, resulting in a more accurate segmentation.

4) Feature extraction: A well-versed method in computer vision for various tasks like object detection, segmentation, and classification is feature extraction using Feature Pyramid Networks (FPN) with ResNet as the backbone. FPN is a feature extraction network that enhances the performance of a CNN by utilizing multi-scale feature maps, allowing the network to identify objects at different scales. ResNet, on the other hand, is a deep residual network architecture that has been shown to outperform traditional CNN architectures by allowing for deeper network depths without encountering the vanishing gradient problem.

When used as the backbone for FPN, ResNet provides a strong base for feature extraction and is capable of detecting high-level features in the input image. The FPN architecture takes feature maps from ResNet's intermediate layers and combines them to form a pyramid of multi-scale feature maps.

The top-down pathway in FPN involves up sampling the feature maps of lower resolutions and then combining them with the feature maps of higher resolutions.

Unlabelled nodule prediction:

The FPN is designed to address the problem of detecting objects of various scales in an image. The backbone network is typically a deep convolutional neural network such as ResNet, which is used to extract feature maps from the input image.

- The input image is passed through the first convolutional layer with 64 filters and a kernel size of 5x5.
- The output of the first layer is passed through a batch normalization layer, a ReLU activation layer, and a max pooling layer with a kernel size of 3x3 and stride of 2.
- The output of the first stage is passed through the second stage, which consists of 3 residual blocks with 256 filters and a kernel size of 3x3.

- The output of the second stage is passed through the third stage, which consists of 4 residual blocks with 512 filters and a kernel size of 3x3.
- The output of the third stage is passed through the fourth stage, which consists of 6 residual blocks with 1024 filters and a kernel size of 3x3.
- The output of the fourth stage is passed through the fifth stage, which consists of 3 residual blocks with 2048 filters and a kernel size of 3x3.
- The output of each stage is then passed through a feature pyramid network (FPN) module to create a feature pyramid. The feature pyramid is then used for Classification or other downstream tasks.

Classifier:

The classifier model is trained using two different class numpy array files, which are typically generated from a training dataset. One array file contains the extracted feature vectors of benign images, while the other array file contains the extracted feature vectors of malignant images.

5) Nodule classification: Efficient Net [31] is a convolutional neural network architecture and scaling method that uniformly scales all dimensions of depth/width/resolution using a *compound coefficient*. Unlike conventional practice that arbitrary scales these factors, the Efficient Net scaling method uniformly scales network width, depth, and resolution with a set of fixed scaling coefficients.

Efficient net architecture provides compound scaling method (scaling all depth, width, and resolution dimensions) can help the model achieve the greatest accuracy gains. The baseline network has a significant impact on how well models scale. An extensive range of image classification tasks can be handled by Efficient Net.

It is a good model for transfer learning because of this feature. Efficient-Net performs Compound Scaling - that is, scale all three dimensions (depth, width, image resolution) while maintaining a balance between all dimensions of the network. The architecture of Efficient-Net consists of different Convolution and MBConvultion blocks interconnected together to produce feature maps of images.

MBConv:

This developed architecture uses the mobile inverted bottleneck convolution (MBConv). Then two more ideas are borrowed from MobileNet-V2 (which is a second improved version of MobileNet) including inverted residual connections, Linear bottlenecks. Mobile inverted bottleneck convolution (MBConv) is the main building block of Efficient-Net model family. MBConv is based on concepts borrowed from the MobileNet models.

Operations:

- The first operation is a linear transformation, which is performed on the input features using the weights of the first layer.
- The input features X are multiplied by a weight matrix W1, which has dimensions (input_dim, units). The result of this multiplication is a matrix of activations with dimensions (batch_size, units).
- The next operation is the application of a non-linear activation function to the activations.
- The process is repeated for subsequent layers, with each layer applying a new linear transformation to the activations of the previous layer, followed by a non-linear activation function.
- The final layer has a single unit and uses the sigmoid activation function, which maps the activations to a value between 0 and 1, representing the predicted probability of belonging to the class.
- During training, the model uses the back propagation algorithm to compute the gradients of the loss with respect to the weights of each layer, which are used to update the weights during the optimization process.
- These gradients are computed using the chain rule of calculus, which involves computing the derivative of the loss with respect to the output of each layer, and then propagating these derivatives backwards through the layers of the network.
- The model can learn to predict the correct label for each input sample, based on the features in the input data.

IV. Results and Discussions

The project was executed using python language and Anaconda Jupyter tool. Python is among the most widely used programming languages used for deep learning due to its flexibility and large number of available libraries, such as TensorFlow, PyTorch, Keras, and Scikit-learn. Python programming language's distribution Anaconda includes a collection of commonly used data science packages and tools. Jupyter is included as part of the Anaconda distribution. GPUs are designed to handle massive amounts of parallel processing, making them ideal for training complex neural networks.

The handling of large datasets, which is necessary for training our deep learning models, is made possible by the 16GB of memory. Running deep learning software and tools like TensorFlow and PyTorch requires a stable and user-friendly environment, which the Windows operating system offers.

The U-Net was given a collection of pre-processed CT images to train the model on. The weights were initialised with normal initialization and the ReLU activation function. The learning rate was set at 0.001 and the batch size to 32.

The binary cross-entropy loss function was utilised to calculate the loss function. In comparison, 80% of the data are utilised for training and 20% for validation. The model was trained for 250 epochs. The average dice score and best dice score resulted in values of 0.4273 and 0.5009. The average loss of the model was found to be 0.27. The nodule segmented using U-Net is represented in Fig. 3.

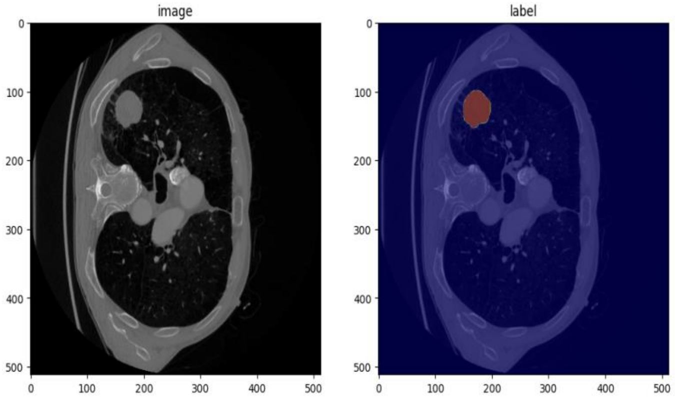

Fig. 3. Nodule segmented image.

An alternative to the stochastic gradient descent approach for deep learning models is the Adam optimizer. This approach handles sparse gradients on noisy situations and provides optimisation by integrating the key characteristics of AdaGrad and RMSProp. ReLU function resists simultaneously stimulating all neurons since it is a non-linear activation function.

In order to get a good result, the suggested U-Net model uses ReLU activation. The neuron will become inactive if the outcome of the linear transformation is less than 0. Results were satisfactory when the ReLU activation function was used with the Adam optimizer.

The training vs validation accuracy graph is a plot that shows the accuracy of a model on both the training and validation datasets. In Fig. 4, the blue line represents the training accuracy, while the red line represents the validation accuracy. The graph shows that the model is improving its accuracy on both the training and validation datasets from the first few epochs.

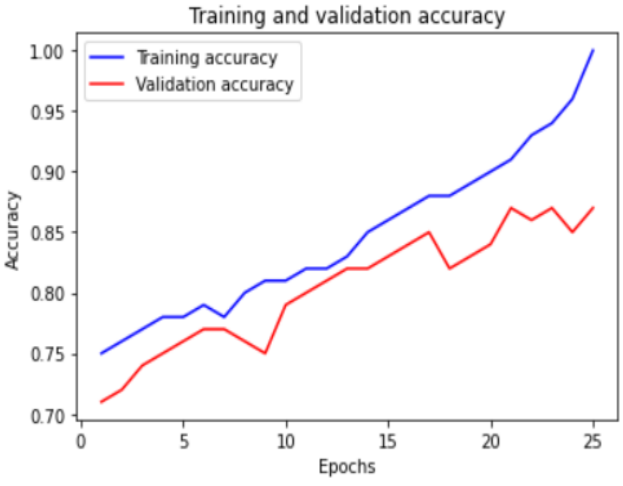

Fig. 4. Training vs validation accuracy graph.

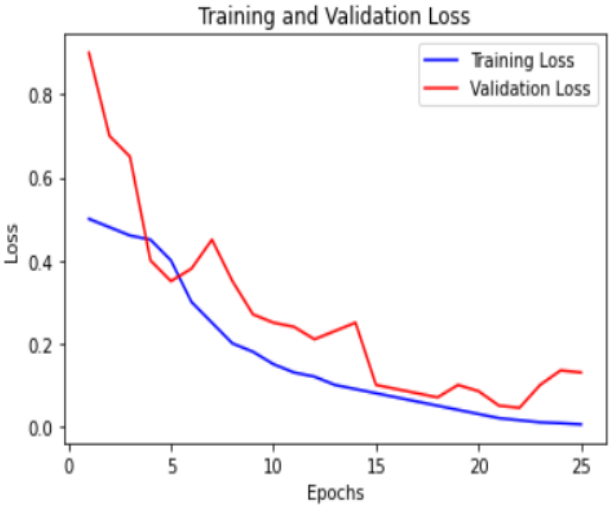

Fig. 5. Training vs validation loss graph.

The training vs validation loss graph is a plot that shows the loss of a model on both the training and validation datasets during the training and validation processes. During the training process, the model is trained on a training dataset to minimize the loss function. In Fig. 5, the blue line represents the training loss, while the red line represents the validation loss.

Accuracy (Table I) measures the percentage of correctly classified instances. It is the most basic metric and gives a good overall measure of the model's performance.

TABLE I. MODEL ACCURACY EVALUATION

S. No.	Epochs	No. of Images	Batch Size	Activation Function	Test Accuracy
1	25	13500	32	RELU	81.33%
2	25	16000	32	RELU	91.67%
3	25	16000	64	SWISH	83.70%
4	100	16000	32	RELU	91.34%

The False Positive Rate (FPR) is the ratio of all the benign nodules that are falsely identified as malignant nodules. The False Negative Rate (FNR) it is the ratio of all the malignant nodules that are incorrectly identified as benign nodules.

TABLE II. RESULTS OF DIFFERENT PARAMETERS

S. No	True Negative	True Positive	False Negative	False Positive	FPR	FNR	DR	Recall
1	1447	1658	191	101	0.06	0.10	0.89	0.86
2	1627	1150	222	398	0.19	0.16	0.83	0.74
3	1920	1227	127	73	0.03	0.09	0.86	0.85
4	1087	1594	251	465	0.29	0.13	0.81	0.76

Detection Rate (DR) is the ratio of benign nodules that are correctly identified as malignant nodules and vice-versa. Table II represents the different parameters calculated using the classification results.

V. Conclusion and Future Works

The proposed model for lung nodule segmentation and classification using U-Net and Efficient-Net neural network has shown promising results in detecting and classifying lung nodules accurately and efficiently. The proposed algorithm outperforms state-of-the-art methods in terms of accuracy, recall, loss. The ablation study conducted in this project revealed the contribution of each component of the proposed algorithm to the overall performance.

Furthermore, the proposed algorithm has the potential to be applied to larger datasets and to be optimized for real-time processing. The successful implementation of this algorithm can potentially improve the accuracy and efficiency of lung cancer screening programs and contribute to the early detection and treatment of lung cancer. However, the proposed algorithm still has limitations, such as the need for large annotated datasets and the potential for over fitting.

The proposed algorithm can be improved by incorporating explainable artificial intelligence (XAI) techniques to enhance the interpretability and transparency of the algorithm. The inclusion of XAI techniques can enable the identification of the features and patterns that the algorithm uses to make decisions, thus providing insights into the reasoning behind the algorithm's output. This can be particularly valuable for medical applications, where the decision-making process needs to be transparent and understandable to clinicians and patients.

The proposed algorithm can be optimized for multimodal imaging, such as computed tomography (CT) and positron emission 40 tomography (PET) scans, to improve the accuracy of lung nodule segmentation and classification. Additionally, the proposed model can be extended to address other types of lung cancers, such as small cell lung cancer (SCLC) and non-small cell lung cancer (NSCLC). Therefore, future work can focus on developing a more comprehensive algorithm that can detect and classify various types of lung abnormalities accurately and efficiently.

***Abstract*—Due to the gathering of big data and the advancement of machine learning, the healthcare industry has recently experienced fast change. Acceleration of operations related to the analysis and retrieval of healthcare data is essential to facilitate surveillance. However, providing healthcare to the community is a complex task that is highly dependent on data processing. Also, processing health metadata can be very expensive for organizations. To meet the strict service quality requirements of the healthcare industry, large-scale healthcare data processing in the cloud confederation has emerged as a viable option. However, there are many challenges, including optimal resource management for metadata processing. Based on this, in the present study, a fuzzy solution for determining the optimal cloud using the resource forecasting technique is presented for health big data processing. During job processing, a fuzzy selection-based VM migration technique was used to move a virtual machine (VM) from a high-load server to a low-load server. The proposed architecture is divided into regional and global levels. After evaluating the local component, requests are sent to the global component. If the local component cannot meet the requirements, the request is sent to the global component. The hierarchical structure of the proposed method requires the generation of delivered requests before estimating the available resources. The proposed solution is compared with PSO and ACO algorithms according to different criteria. The simulation results show the effectiveness and efficiency of the model compared to alternative methods.**

Keywords—Healthcare; big data; cloud confederation; service quality; Cloud Resource Management (CRM)

I. Introduction

The existing processes for collecting and processing the vital data of patients demand a large volume of workforce and calculations. Usually, these processes are error-prone and have large delays, which prevent the right data from being available in real-time [1]. As a novel technology, cloud computing with internet infrastructure and novel solutions provides considerable advantages in providing medical services electronically [2]. Indeed, the advent of cloud computing has brought a fundamental change in the path of the novel, developed, scaled, and up-to-date services of information technology [3]. With the fast development in processing and storage technologies and also the successfulness of the internet, the computing of resources has become cheaper, stronger, and more accessible than ever before, and governmental organizations have started to use architecture, platforms, and programs of cloud computing to provide the services and satisfying the needs of their subsidiaries [4]. However, there are still many challenges in optimal resource management and to what extent each data needs the computing resource are among these challenges [5].

The objective of the resource management system for the cloud is to satisfy the needs of the applications using it. Because it is possible, during the process, that some of the servers have high traffic load while the others have low or no load, the resource management mechanism should check the current situation of every resource in the cloud environment to provide the algorithms for better allocation of physical or virtual resources and thus reduce the operational costs in the cloud environment [6]. In this case, not only may the workload be spread among the available but underutilized servers, but the unused servers can be shut off altogether. Centralized work allocation to servers that do not take into account the individual solutions is obviously unfeasible in such large and complicated systems [7]. Also, according to the rapid growth in metadata in the advanced data centers and the urgent need to access good service quality, the necessity for providing solutions in order to increase the productivity of the available service providers in the metadata processing center is strongly felt. One way to achieve the desired productivity is to use resource management solutions [8]. For appropriate management of the resources of service providers, the load balance is required [9]. With an appropriate load balance, the requests will be distributed in a dynamic and balanced form among all nodes while ensuring the fairly and efficient allocation of every computing resource [10]. This process will result in increased user satisfaction and high productivity of the resources, which eventually increases productivity [11]. The load balancing aims to find an appropriate mapping of the tasks on the processors available in the system so that in each processor, approximately an equal number of tasks will be executed to minimize the overall runtime [12]. In recent years, due to population growth and advances in medical science, the number of discovered diseases has increased [13]. The information on each patient entered into hospital systems is so huge and complex that it has been classified as "big data," requiring plenty of resources to process [14]. It is important to pay attention to the fact that cloud computing has entered all fields, including the medical field, at a very high speed today [15]. Considering the high number of information related to a person that may be available in the hospital system, it is possible to use cloud processing instead of local storage of the person's information so that there is less need for local and physical facilities and the speed of obtaining and processing the person's information in time multiplied the need. One of the prominent points of this method is that there are no worries about losing information due to local system damage, and information can be stored, processed, or retrieved at any time, regardless of the hospital system load. One of the biggest challenges here is choosing the type of resources to store information, whether local resources are more optimal or resources that can be rented from other places, or more importantly, how much resources each data needs to be able to store it. It is possible to select the most optimal resource by predicting the number of resources each piece of information needs and allocating it to it. In this research, we intend to present a new approach to improve the management of healthcare big data resources, and by using this method, we will significantly improve resource management by facilitating and accelerating the processing of medical care data in cloud computing.

This study predicts and attempts to implement the necessary resources for processing RIMA model data (big data) on drug consumption in various American states between 2018 and 2021. The fuzzy DEMATEL method has the lowest prediction error as well as closely resembles the reality of a request's resources. Thus, we employ it to allocate local and remote assets for each request. This algorithm was developed with profits and profits as its primary motivation. In a nutshell, the following is the author's contribution to this article:

- Using the RIMA model to predict the required resources with a low error percentage.
- Using the fuzzy Dematel technique to choose a cloud data center to accelerate and facilitate big data processing in the cloud environment.
- Increasing productivity by maintaining user QoS and reducing response time.

This paper's remaining sections are structured as follows. The context is provided in Section II. Section III provides fuzzy DEMATEL methods for evaluating RIMA-based cloud and resource forecasting methods. Evaluation and simulation of the suggested model are presented in Section IV, followed by a discussion of the results. Conclusion and directions for further research is presented in Sections V.

II. Literature Review

About [16], a review of the common algorithms in the field of load balance in metadata is provided. One of the most popular algorithms is the Min-Min algorithm. At the outset, the algorithm is given a pool of jobs from which to choose. The first thing to do is determine the quickest possible way to do every activity. The quickest task on each available resource is then chosen, and its corresponding minimum finish time is chosen. The next step is to allocate the required amount of time for the task on the appropriate machine. Besides optimal scheduling, the approach has a main issue, which can lead to famine. In research [17], a hybrid task scheduling strategy has been provided for managing and processing medical metadata in cloud VMs. The tasks' migration from one server to another has been addressed. In this research, the genetic algorithm, along with the particle swarm optimization, was used to provide the load balance and allocate the available network resource to the tasks so that the distribution of tasks between the resources was performed fairly and the servers were able to execute the processing on different requests of users simultaneously. In this research, the proposed algorithm has been simulated by CloudSim software, and the results indicate the effectiveness of this approach in load balance. In [18], a load balance and scheduling model based on the cloud segmentation concept has been proposed. A hybrid algorithm was provided in which the RR2 scheduling algorithm and game theory were used. This algorithm selects a low-load server with a high execution speed. Time slicing is done better in RR because the better server is selected. The results show that the load balance has improved using the proposed algorithm. In study [19], a cloud confederation model which provides ideal selections for target cloud providers has been proposed to address the heterogeneous IoT metadata customers' demands. In addition, a multi-purpose optimization model has been provided. A general structure for the genetic algorithm has been developed to solve this model. Different evaluation tests have tested the proposed model. In study [20], a real model based on linear programming has been presented to identify the strategies and decisions in the cloud federation. The user requests are established on all cloud federation levels, and the users are easily directed. As a result, the obtained advantages motivate providers' participation by free insourcing to support the other federation members. The proposed model is highly scalable. In [18], multi-layer resource allocation has been provided. The main idea behind this was based on the allocation of resources in a layering approach, which configures the resource allocation for personal tasks on a cluster node based on the resource exploitation levels. The results show that MTRA has improved the performance and runtime by 18% and 10%, respectively. In [21], it is examined how end users choose MEC servers, how they offload their data optimally, and how MEC servers determine their prices optimally in a multi-MEC server and multi-end user scenario. An SDN controller first implements a reinforcement learning framework based on stochastic learning automata to enable end users to choose a MEC server to load their data. The whole MEC selection process considers the MEC server's method, its congestion and penetration in terms of completing end users' computing duties, and its declared price for its computing services. A non-cooperative game is developed between the end-users of each server to determine the end user's data loading portion to the chosen MEC server, and the existence and uniqueness of the corresponding Nash equilibrium are demonstrated. An iterative and simple method has been developed to implement the suggested framework. The performance of the suggested technique was assessed through modeling and simulation in various scenarios with both homogeneous and heterogeneous end users. In [22], author offers thorough analyses of prior cognitive computing research, problems, fixes, and prospects for further study. There is a focus on cognitive computing-based methods for resolving practical issues in the four extensively studied application fields of healthcare, cyber security, big data, and the Internet of Things. Author examined research from 2012 to 2020 in [23]. This study aims to offer a thorough analytical understanding of big data for health care. Three goals were met in this study's investigation: (a) identifying the most important themes in big data research on healthcare; (b) assessing the relationships between the themes in previous studies, and (c) creating time-series profiles for the topics. Healthcare research using big data has covered a variety of subjects. Based on the study's findings, a summary of researchers' interests in various techniques, technologies, and topic areas is given, along with a list of critical research gaps that need to be filled in the future. The advantage and disadvantages of different technologies are thoroughly described in research [24], along with the range of applications for each. Attacks, according to background information gleaned through data integration, can be avoided using various technologies, anonymity, and privacy during data collection. The majority of important medical data is kept in storage on a cloud computing platform. Encryption and auditing techniques are frequently employed to maintain the confidentiality and integrity of stored information. Access control techniques are also utilized during the data-sharing phase to control the objects with access to the data. Big medical and health data privacy protection is carried out under machine learning during the data analysis stage. Finally, acceptable management-level concepts have emerged due to broad privacy protection worries across the medical big data lifecycle across the sector. Table I discusses a summary of the comparison of existing techniques in resource management.

TABLE I. COMPARISON OF AVAILABLE TECHNIQUES IN RESOURCE MANAGEMENT

Work	Target parameter	Method	Type of technique	Advantages	Disadvantages
Miah et al. 2022 [25].	Achieving policies that help increase profits and productivity and overcome resource limitations.	Efficient resource management strategy, deployment of a cloud federation to coordinate resources	Model-based	1. It gives providers more flexibility in resource management and increased productivity. 2. Customers can maintain the machines for a long time if needed.	Outsourcing of spot requests is not considered in this method. Also, not having strategies that help to predict the availability of future resources for decision-making is one of the disadvantages of this method.

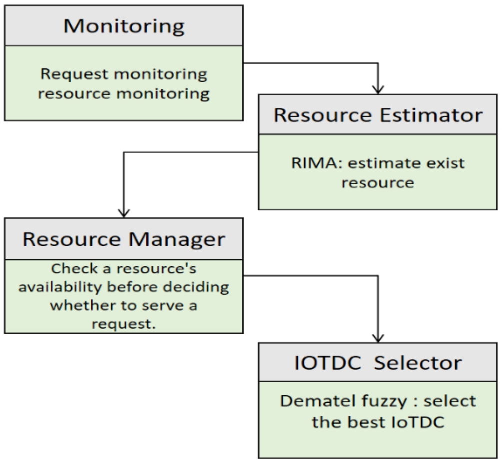
III. PROPOSED METHOD

This section suggests a method for choosing the best cloud using the DEMATEL fuzzy technique as well as a method for resource prediction using the RIMA algorithm. The proposed architecture's structure is divided into two local and one global component. Before sending a request to the global part, the local function should be examined; if the local domain is unable to supply the necessary data, the request is forwarded to the global domain. Since the suggested procedure has a hierarchy architecture, the local data component receives the user request. The local analyzer examines and keeps track of it to forecast the resources. On this foundation, the RIMA algorithm first estimates the size of the available resources before creating the list of paid requests. The structure of the suggested architecture makes it clear that each IOTDC is presumed to have a Broker. The requests from users referring to each IOTDC are first received and examined by the Broker associated with that IOTDC. If there are sufficient resources to carry out the users' requests, do so and inform the IOTDC's users of the results. Even yet, imagine the Broker is unable to fulfill user requests with the IOTDC resources that are at his disposal. If so, it should utilize the Dematel fuzzy algorithm, which every Broker can access, to select the right IOTDC from the linked IOTDC. As a result, there is a Broker with the following components for each IOTDC:



Monitoring
Request monitoring resource monitoring
Resource Estimator
RIMA: estimate exist resource
Resource Manager
Check a resource's availability before deciding whether to serve a request.
IOTDC Selector
Dematel fuzzy : select the best IoTDC

Fig. 1. Block diagram and broker component process.

The Broker's structure and its individual parts are shown in Fig. 1. A fuzzy selector-based VM migration technique is used after choosing the processing server to make sure that, should it become overloaded while processing or because of software or hardware violations, its VM can be moved to a low-load or available idle server, alleviating the overload as well as maximizing the server's useful life.

A. *Receiving the Requests*

In algorithm No. 1, requests are first added to a queue as well as then, in accordance with demand, are directed to the desired resource. The requests are positioned in the queue according to this algorithm. Each user's request is added to the queue (lines 2-4) because each user has a variety of requests. For all users, this step is repeated (line 1). The resources needed for each request are described in lines 6 through 8 that follow.

Algorithm 1: add Request to Queue

```
for i ← 1 to n do
for j ← 1 to $Req\_Count_j$ do
ADD $Req_j^i$ to Request_queue
end for
While(Request_queue is not empty)
foreach req in Request_queue do
Send req to LCC
end for
```

This stage is in charge of compiling the requests that have been made as well as the available resources. Two request and resource stages are part of the monitor phase. The phase of resource monitoring is in charge of acquiring data regarding resource productivity, resource capacity usage, and maximum VM count. The request monitoring phase is in charge of compiling data on the volume of requests made by users. These two subcomponents combine the observed data, which is then saved for use by the knowledge base's other phases.

Algorithm No. 2 keeps tabs on the services provided by each LCC and GCC resource. The procedure is run up until free resources (line 1) are present. This method examined local and global resources, although local resource monitoring is given top attention. Lines 8-12 analyze the services provided by each of the GCC's available IOTDCs. First, the number of services provided by local resources is verified; if none are available, line 6 makes reference to the broader cloud federation's local resources.

Algorithm 2: Resource monitoring

```
1:  while (reso. =0) {
2: for i  ←  1  to  n do
3: for j ← 1 to m do
4:  if (IoTDC is available in our lcc)
 5: $y^i = x_1 cdc_i + \cdots + x_j cdc_i$
6: else
7: if  (IoTDC is available in gcc)
8: for i  ← 1 to n do
9: for  j ← 1 to m do
10: $G^i = x_1 cdc_i + \cdots + x_j cdc_i$
11: else
12: do resource = 0
       }
```

B. *Prediction Phase*

The resource's forecast phase is in charge of determining how many resources will be needed to fulfil requests. Low supply happens when the available resources fall short of meeting demand, and high supply occurs when the available resources outpace actual needs. Therefore, the RIMA technique can be used to estimate the requirements for a given resource reliably. The third method makes use of a RIMA semi-code to estimate future service demands. Each request from the user has been viewed as an independent input, and features specific to that request have been defined using the x. Each request's amount of resource requirements is determined (line 4) based on the request's characteristics and the tracking factor of every modification. Z computes the upper bound of the genuine ask.

C. *Resource Management Phase*

The resource predictor reports back to the resource management of its origin after gauging the resource for the given request. The resource manager determines whether or not the new request can be fulfilled by the available resources after checking their availability. If no resource is available for the IOTDC host, DEMATEL is used to discover the best possible unified IOTDC. If the resource is accessible, it shouldn't be much larger than required for the request to avoid a high allocation.

Algorithm 3: RIMA Prediction

```
1:   While (req ≥ 0) {
2:   F or  i ← 1 to 3 do
3:   F or j ← 1 to n   do
4:   sum=sum + VL (j)
5:   end for
6:   $\mu$ = sum / n
7:  for j ← 1 to n
8:  $MA[i] = \mu + \Theta[j] * WL[n-j] + \mathscr{E}$
9:  end for
10:  for j ← 1 to n
11:  $AR[i] = \phi[j] * WL[n-j] + \mathcal{E}$
   12: end for
   13: for  j ← 1 to n
   14:  $L = Sqrt(\phi[j] * WL[n-j] + \mathcal{E}$
   15:  end for
   16:  $Predict[i] = L + \alpha + AR[i] + MA[i]$
   17: end for
   18: return [ Predict ]  }
```

D. IOTDC Selector Phase

For each request, an appropriate resource allocation is made in the IOTDC selection step. Using the fuzzy DEMATEL method, this component chooses the best cloud data center [14]. The fuzzy triangle variables are needed to display the evaluation criterion. Fig. 2 displays the numerical range and each of these variables' linguistic representations.

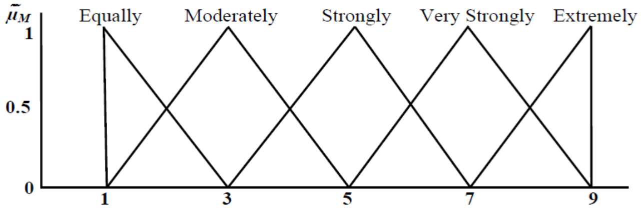


Fig. 2. Provides the linguistic representation of each of these variables and their numerical range.

To execute pairwise comparisons, the fuzzy numbers shown in Table II must first be defined in order for the responses to be appropriately delivered. Triangular fuzzy numbers have been employed in the analysis shown, as seen in the table. Since m is a triangular fuzzy number, it may be computed from equation (1) as follows:

$$S_i = \sum_{j=1}^{m} M_{g^i}^{j} \otimes \left[\sum_{i=1}^{n} \sum_{j=1}^{m} M_{g^i}^{j} \right]^{-1} \tag{1}$$

Within the pairwise comparisons matrix in the relationship mentioned above, M are triangular fuzzy numbers. In order to calculate the matrix S, we actually add each fuzzy number component individually and then multiply by the fuzzy inverse of the final sum. The normalized weights are computed in this phase similarly to the normal AHP approach, but with fuzzy numbers. The preliminary definitions should be made before introducing the suggested approach, followed by a presentation of the suggested algorithm. The investigation of fuzzy triangular numbers came first. Fuzzy triangular numbers are used in FAHP-based algorithms to verify criteria. The membership function for triangular numbers is stated as follows, and each triangle fuzzy number is displayed using three (n1, n2, n3).

All the operations that are defined for fuzzy numbers are performed in triangular fuzzy numbers on triples (n1, n2, n3). Equation (2) defines membership conditions for triangular fuzzy numbers.

$$\mu_N(x) = \begin{cases} \frac{x-n_1}{n_2-n} & x \in [n_1, n_2] \\ \frac{n_3-x}{n_3-n_2} & x \in [n_2, n_3] \\ 0 & otherwise \end{cases} \tag{2}$$

Table II also shows triangle representation and linguistic interpretation.

The main goal is to pick the best IOTDC from the set of confederation IOTDCs using Fuzzy DEMATEL. The organizational structure of the appropriate confederation has been informed by the following factors: calculation costs (C1), a distance of IOTDCi requested from IOTDCj confederation (C2), a departure from agreements (C3), as well as available resources (C4). The suggested approach for selecting the IOTDC is depicted in Algorithm (4). This method features a three-tiered, hierarchical structure; the ground level, the top level, and levels 1 and 2. The algorithms are bilevel, as denoted by the second line of code. The criteria count is assumed to be n at each tier. The first-level execution is given below; the second-level algorithm follows the same pattern. As such, the algorithm begins by reading the values from the fuzzy comparing matrix and then compares each Si pair in turn (lines 2-3). The order of importance of these criteria is then determined using the connection (3). An anomalous weight is calculated for each criterion. Then, using a relation, the weights are normalized (4). These steps are likewise carried out on the second floor, which is where you'll find IOTDCs. The resulting weight represents the importance of each IOTDC, and the one with the highest importance can be chosen.

Algorithm 4: Fuzzy DEMATEL

```
1: First, get tracking data.
2: for both 1st and 2nd graders
2-1: Input a fuzzy rating of the relevance of each criterion pair (Table II).
2-2: All criteria C1Cn (i1...n)
2-2-1: The formula is as follows: 2-2-1: Si (E.q 1) = Fuzzy Synthetic Extent
2-3: Two-Three: i, j, 1,..., n
2.4: Determine V if Si > Sj.
2-5: Use EQ to derive your actual weight for steps. 1-3
2-6: Use (EQ 2) to normalize the given Wight value.
3: Prioritize the return of the final Wight in the IOTDC.
```

TABLE II. TRIANGULAR FUZZY NUMBERS

Linguistic Interpretation	Fuzzy Numers	Membership Function	Interval	Linguistic Interpretation
Just Equal	$\tilde{1}$			(1,1,1)
Equally Important		µm(X)=(3-X)/(3-1)	1≤X≤3	(1,1,3)
Weakly Important	$\tilde{3}$	µm(X)=(X-1)/(3-1)	1≤X≤3	(1,3,5)
		µm(X)=(5-X)/(5-3)	3≤X≤5	
Essential Or Strongly Important	$\tilde{5}$	µm(X)=(X-3)/(5-3)	3≤X≤5	(3,5,7)
		µm(X)=(7-X)/(7-5)	5≤X≤7	
Very Strongly Important	$\tilde{7}$	µm(X)=(X-5)/(7-5)	5≤X≤7	(5,7,9)
		µm(X)=(9-X)/(9-7)	7≤X≤9	
Extremly Preferred	$\tilde{9}$	µm(X)=(X-7)/(9-7)	7≤X≤9	(7,9,9)

The weight vector is found using the following formula for i=k: k=1,2,...,n.

$$W' = (d'(A_1), d'(A_2), \dots, d'(A_n))^T \qquad (3)$$

Then, we normalize the vector W', and we get the following:

$$W = (d(A_1), d(A_2), \dots, d(A_n))^T \qquad (4)$$

E. *Fuzzy Balancer*

Despite efforts to choose the best available resource, certain servers may fail to execute commands in the processing of healthcare metadata for a number of reasons (like a delay in processing the preceding commands, software and hardware errors, congestion, or overload) [31, 39]. In these cases, it is necessary to migrate virtual machines (VMs) from a node with a heavy traffic load to another node and to identify as well as choose which VMs should be moved; a fuzzy selector is used. The linguistic variables and their corresponding membership functions are established on this foundation.

1) Membership functions: In this section, the membership functions are described based on the defined linguistic variables. Indeed, by using three defined input variables, a VM fuzzy selector has been provided. On this basis, the membership functions are needed to be defined. The range used for the membership functions has been defined based on the outputs of the CloudSim simulation of the PlanetLab project [32]. For every main parameter related to the resource, the membership functions related to the linguistic variables are defined as follows:

- The available storage (T_{RAM}): (low, medium, high)
- Execution time (T_{exe}) : (low, medium, high)
- Energy consumption (T_{energy}): (low, medium, high)

Now, based on the definition of the three parameters mentioned above, the VMs are categorized into classes (low, medium, high, and very high), and the machines which are located in the high and very high classes are the candidates to migrate to VMs with less and medium loads. In the following, tables and figures related to membership functions' parameters are shown. First, Table III and Fig. 3 show the membership functions related to the consumed RAM to define the low, medium, and high classes.

In Table IV and Fig. 4, the parameters of the membership functions related to energy consumption have been shown.

Finally, Table V and Fig. 5 show the parameters of the membership functions related to consumed energy.

TABLE III. PARAMETERS OF RAM MEMBERSHIP FUNCTIONS

Parameters	RAM amount
a=0 , b=0 , c=651 , d=751	Low
a=701 , b=801 , c=901 , d=1001	Medium
a=900 , b=1101 , c=1801, d=1800	High

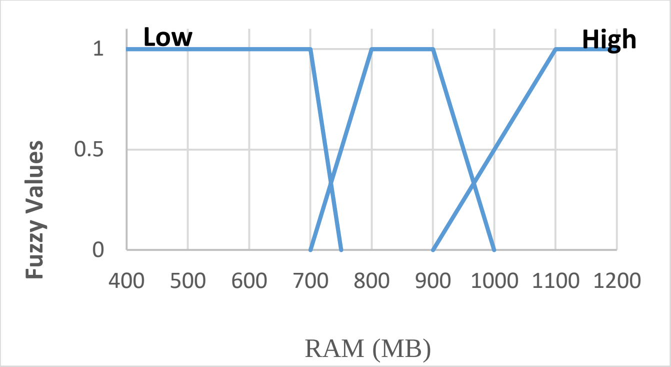

Fig. 3. RAM membership functions.

TABLE IV. PARAMETERS OF ENERGY CONSUMPTION MEMBERSHIP FUNCTIONS

Parameters	Energy amount
a=0 , b=0 , c=121 , d=136	Low
a=131 , b=141 , c=151 , d=156	Medium
a=151 , b=161 , c=171 , d=171	High

TABLE V. PARAMETERS OF EXECUTION TIME MEMBERSHIP FUNCTIONS

Parameters	Amount
a=0 , b=0 , c=0.07 , d=0.08	Low
a=0.066 , b=0.07 , c=0.09 , d=0.2	Medium
a=0.08 , b=0.2 , c=0.12 , d=0.16	High

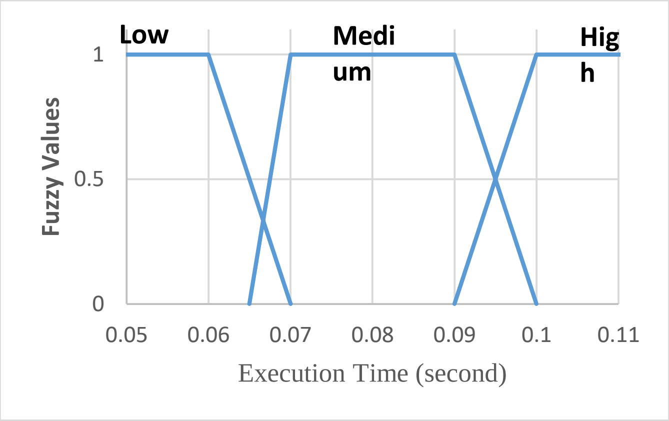

Fig. 5. Execution time membership functions.

1) *Fuzzy rules:* In this section, based on the membership functions described in the previous step, the fuzzy rules are defined in order to select the VMs for migration. These rules are used to select the VMs that faced overloading due to the additional load. The corresponding rules are shown in Table VI.

TABLE VI. FUZZY RULES

Execution	RAM	Energy	VM Selection

IV. EVALUATION

ClouSim [32] has been utilized for the simulation and evaluation of the proposed solution. The scalability of this simulation is high and can simulate very big clouds. At the moment, despite the simulation, a cloud is able to simulate the cloud environments composed of some other clouds. Also, in this research, the surveyed data obtained from the CoMon project, which indeed is a monitoring infrastructure for PlanetLab servers, have been used to create the workload [33, 34]. In this scenario, data from checks performed on the physical equipment at intervals of 300 milliseconds have been taken into account. Three separate assessments were conducted using varying quantities of virtual assets on this premise. In order to accomplish this, initial guesses were made that the number of virtual computers in each of the three assessments would be 898, 1033, and 1358. Two optimization techniques, Particle Swarm Optimization [17, 35] and Ant Colony Optimization (ACO) [36, 37], were used to examine the effectiveness of the proposed solution across a range of metrics, including energy usage, runtime, SLA violations, and migrations. The evaluation's findings are depicted in Fig. 6 to 9. The energy we use is depicted in Fig. 6 below. As seen in the figure, the suggested approach significantly reduces energy use. Because one of its primary goals is efficient resource management and it doesn't generate congestion in the processing servers, it was anticipated that the solution would reduce energy consumption. With the aid of the proposed fuzzy selector, the suggested method successfully avoided congestion and, by extension, increased energy usage. Fig. 7 displays the runtime of the solutions over three distinct assessments. It is clear at this point that the processing duties have been completed more quickly, thanks to the offered method. As a result of the RIMA algorithm's careful monitoring, the accurate resources prediction needed, and the best migrations, the answers for all three tests now have shorter execution times. Increased productivity may be the result of the solution's newfound capacity for accurate resource prediction, as well as the suitable migrations made by the use of the fuzzy selector. Fig. 8 also displays the total number of VM migrations performed by each solution, allowing us to examine the migrations made by each solution to achieve load balancing and load reduction. In all three tests, the migration counts of the suggested solutions were much lower than those of the other two. Still, this is not the cause for raising and optimizing the other parameters when taking into account execution time and energy usage. It's important to remember that if VM migrations aren't performed optimally and correctly, it might cause a significant overload in the network and waste server resources. Fig 8 shows that while the proposed solution has fewer migrations, those migrations are optimized and done timely, causing minimal additional network overload and avoiding unnecessary engagement of server resources. It also suggests that a large number of migrations do not necessarily indicate the superiority of that solution. The cause of the migrations' optimality is directly related to the usage of fuzzy selectors, in which the server state has been studied as well as carried out in preparation for migration.

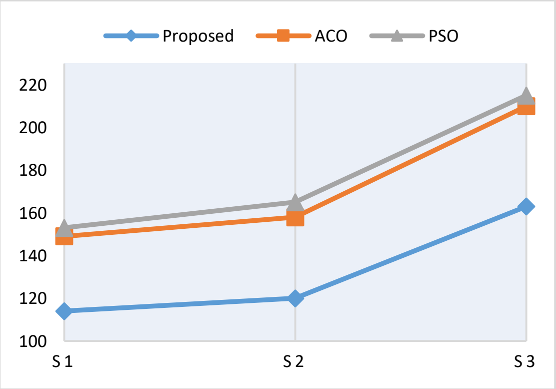

Fig. 6. Energy consumed.

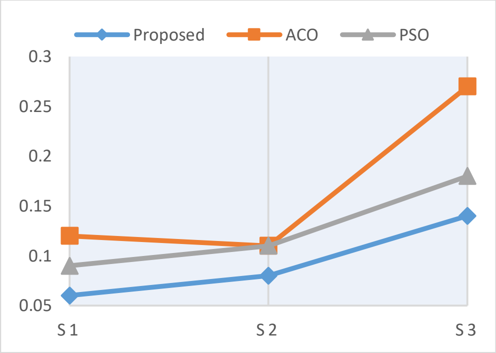

Fig. 7. Average execution time.

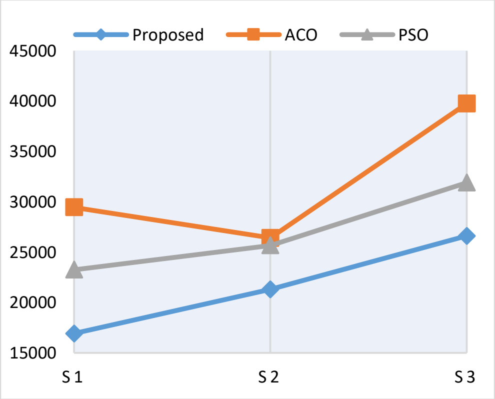

Fig. 8. Number of VM migration.

Finally, the solutions' SLA violations are displayed in Fig 9. The Service Level Agreement (SLA) is relied upon as the yardstick by which to measure actual performance. Whether the service quality is satisfactory is determined by the QoS parameters in the SLA. The primary goal of this contract is to set forth the legally binding parameters for the quality, availability, or cost of the services to be supplied. As can be seen in Fig. 9, the proposed solution makes the servers more reliable than the other two solutions, which in turn creates higher accessibility in the cloud infrastructure as well; in other words, this solution's SLA violation is lower than that of the two other ones. Load balancing, which has been accomplished with the aid of the resource fuzzy selector and predicter, and the VMs migration, which has been accomplished with the help of the fuzzy selector, are used to achieve this.

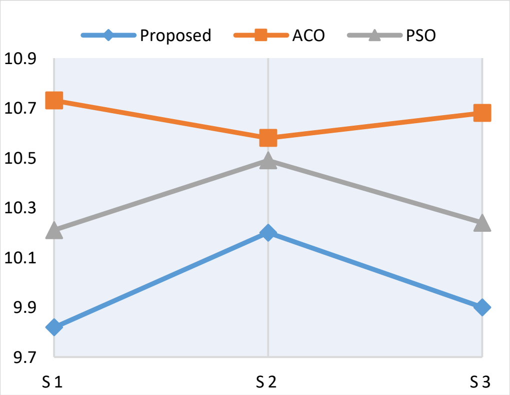

Fig. 9. Violation of the SLA.

A. *Evaluation of the Cost of Consumption*

In order to implement the cost of the proposed solution, we have considered a three-layer cloud program, where each layer has different characteristics from the other layers. Table VII shows the general characteristics of the different layers of the three-layer cloud architecture.

TABLE VII. SPECIFICATIONS OF DIFFERENT LAYERS OF THE CLOUD PROGRAM

Layer	**Avg. Request Arrival Rate**	**VM Type**	**Number of Startup VMs**
Web	100%	Large	5
Application	70%	Medium	5
Database	40%	Small	5

The rate of entering requests in different layers is different. More precisely, the number of requests entered in the first layer is according to what is read from the load, but the number of requests in the second and third layers is, on average equal to 70 and 40% of the requests in the first layer, respectively.

The cost is the sum of the cost of the virtual machines and the penalty cost. That the penalty cost is the total amount of the penalty cost for all customer requests, and the total cost of virtual machines is for setting up and running all virtual machines. The total cost is calculated by equation (5).

$$\text{Total Cost= VM Cost + Penalty Cost} \qquad (5)$$

Fig. 10 show the average cost for different layers. The values displayed in these figures are the average of all three data sets. In Fig. 10(a), the average cost for the application layer is displayed; as can be observed, in this layer, the suggested method can uniformly provide the elasticity of cloud computing compared to other methods. In addition, the proposed method in this research reduces the total cost more than other methods. One should know about health data; due to the huge amount of data and the importance of the subject, the amount of cost is very important. Fig. 10(b) shows the cost in the web layer. Based on the distribution of the workload entered into cloud computing, the compared methods have different behaviours with the cost criterion. Any amount of workload entry has an unbalanced distribution; the complexity of its analysis and decision-making by the examined frameworks also increases. Therefore, it can be seen that in most cases and on average, the proposed method in this research has a better performance in the application layer. Fig. 10(c) examines the cost metric in the database layer for the proposed methods. This layer faces a large number of parallel transactions, so the use of dynamic methods that provide elasticity for this layer is one of the requirements that the service provider should pay great attention to. Considering the three layers of the proposed architecture for big data in the field of health, it is necessary to examine the cost criteria in each of the three layers.

According to Fig. 10(a), (b), and (c), it can be seen that the proposed method imposes a lower average cost on the supplier.

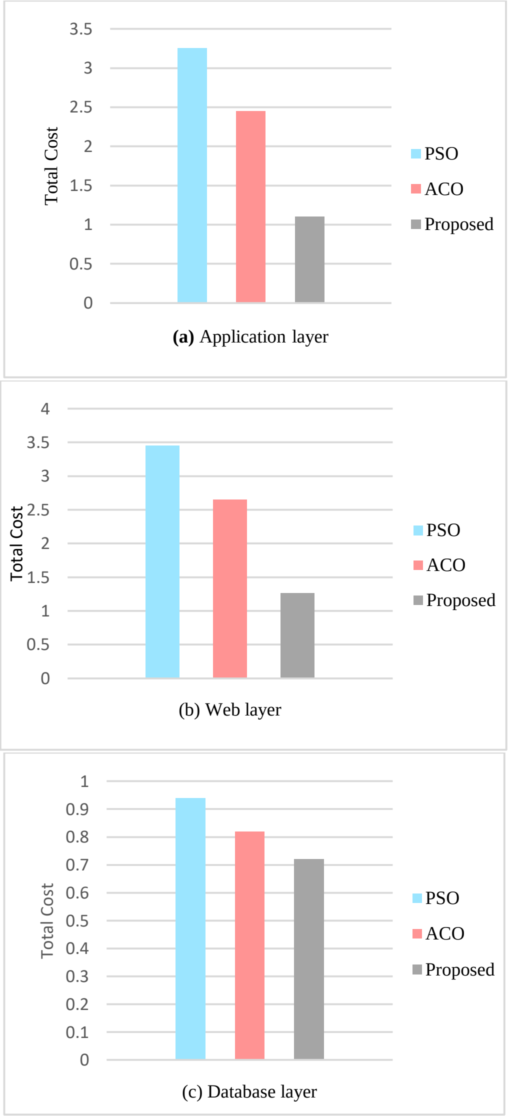

Fig. 10. Average cost comparison for the compared methods.

B. *Quantification of Computational Complexity*

The high number of rejected requests will reduce the profit, and on the other hand, it may also increase the cost. Therefore, the proposed method should be able to reject fewer requests. In this way, it increases the profit and keeps the quality of the services within the agreed limits [38]. In this paper, the number of rejected requests is counted to quantify the computational complexity based on the timeline. According to Fig. 11 and considering the number of user requests based on the timetable, as can be seen, for example, at time point 49, the number of rejected requests for the ACO algorithm equals 145, and for the PSO algorithm, it equals has been 240. In contrast, at this point in time, the number of rejected requests for the proposed method was around 50. Therefore, according to the calculation quantity, it can be concluded that the proposed method can have a higher efficiency than other methods.

C. *Estimating the amount of Rejected Requests*

The high number of rejected requests will reduce the profit and on the other hand, it may also increase the cost. Therefore, the proposed method should be able to reject fewer requests. In this way, it increases the profit and keeps the quality of the services within the agreed limits. Fig. 12 shows the rejected requests in the application layer for the test data set. As can be seen, the proposed method in this research has a better performance than other methods.

Fig. 13 also shows the rejected requests in the web layer. Fig. 14 also shows the number of rejected requests in the database layer. From these graphs, it can be seen that the proposed method in this research has a better performance than the compared methods.

Table VIII shows that, in accordance with the behavior of the graphs, the average length of the schedule has dropped by 5.36% of the minimum execution time for the number of 300 jobs and by 6.14% when compared to the PSO method. Similarly, Table IX shows that with 600 tasks, the ratio of successful execution increases by 6.81% for the ACO schedule and by 3.92% for the lowest execution time.

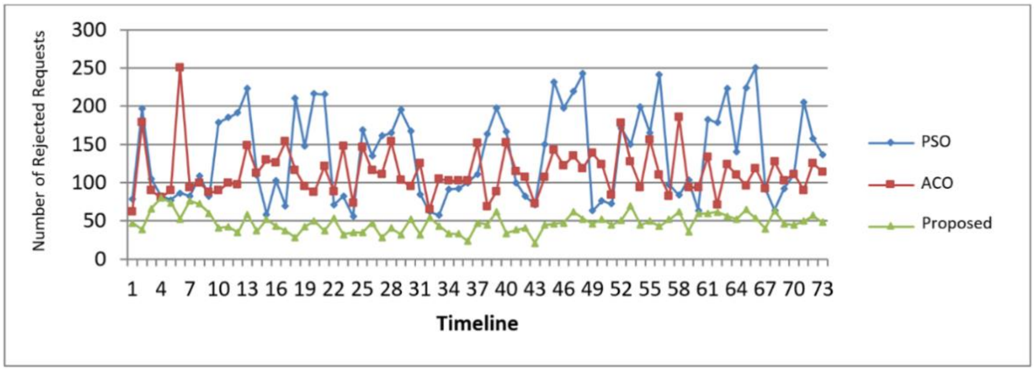

Fig. 11. Computational complexity comparison.

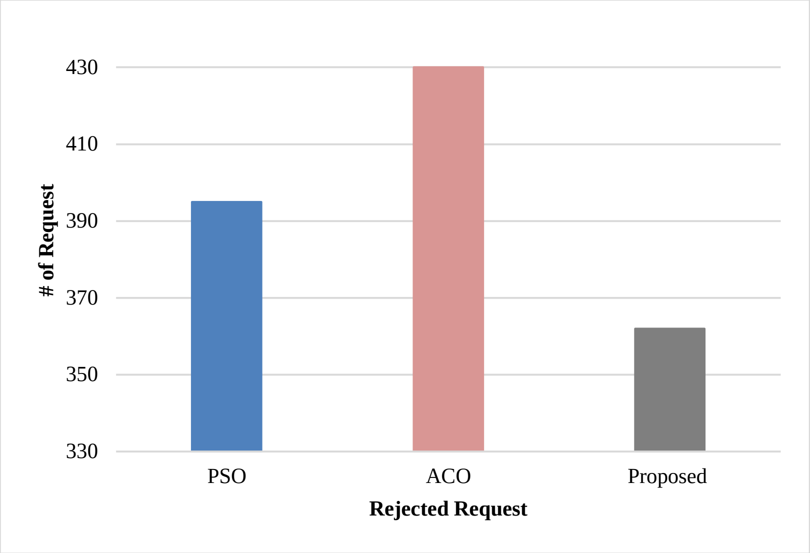

Fig. 12. Comparison of the investigated methods in the number of rejected requests in the application layer.

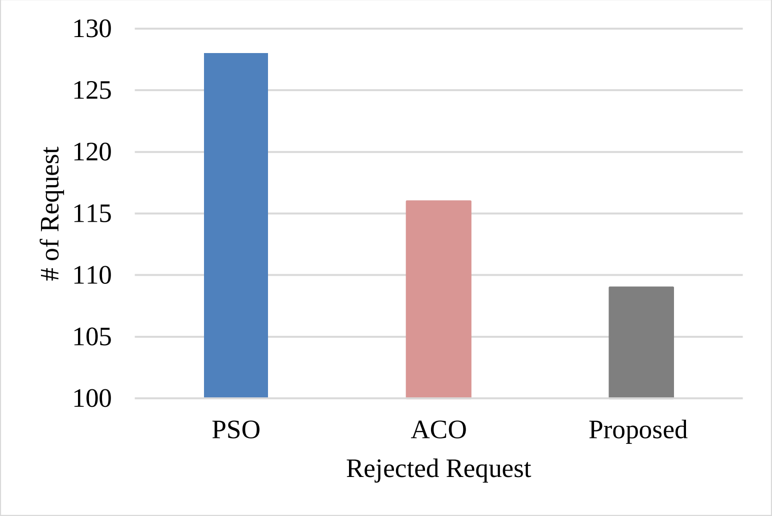

Fig. 14. Comparison of the investigated methods in the number of rejected requests in the database application layer.

TABLE VIII. THE PROPOSED METHOD COMPARED TO SIMILAR METHODS FOR AVERAGE PROGRAM LENGTH

Iteration number	Number of tasks	PSO	ACO	Proposed Method
1	100	343	336	323
2	200	1025	1007	985
3	300	1765	1729	1742
4	400	2516	2369	2236
5	500	3129	3102	3024
6	600	3024	3035	2954

TABLE IX. THE PROPOSED METHOD COMPARED WITH SIMILAR METHODS FOR THE RATIO OF SUCCESSFUL EXECUTION

Iteration number	Number of tasks	PSO	ACO	Proposed Method
1	100	0.48	0.50	0.51
2	200	0.68	0.70	0.73
3	300	0.75	0.77	0.78
4	400	0.79	0.80	0.81
5	500	0.77	0.79	0.80
6	600	0.79	0.80	0.79

D. *Real Time Case Study based Discussion*

Existing processes for collecting and processing patients' vital information require a large amount of labor and calculations. These processes are usually error-prone and have large delays that prevent correct information from being available in real time. Cloud computing as a new technology, with internet infrastructure and new solutions, has brought significant advantages in providing medical services electronically. Along with that, through the rapid development of processing and storage technologies as well as the success of the Internet, computing resources have become cheaper, stronger and more accessible than before, and government organizations have started using cloud architecture, platforms and programs to provide services and meet the needs of their subordinates. But in between, there are many challenges, the most important of which is the optimal resource management and how much processing resources each data needs.

V. CONCLUSION

Each patient's data is added to hospital systems in such large quantities that they become the metadata that must be processed by such a large number of facilities, which practically results in high costs to the hospital, additionally to execution times as well as accuracy issues. Because of this, the use of cloud computing's processing capacity for metadata has become more widespread. Accurate resource provision is a crucial element of cloud computing. User satisfaction rises proportionally as the accuracy of the resources grows, and the number of violations of the services decreases. In order to handle healthcare metadata in a cloud computing environment, a better resource management approach has been provided in the current research. It was assumed that the proposed architecture would have each IOTDC have a Broker, who would first receive and analyse requests from users referred to that IOTDC before executing the algorithm and returning the result to the users of that IOTDC if the resources required to execute those requests were available. However, the DEMATEL fuzzy algorithm should be used by the Broker to select the appropriate IOTDC from the available associated IOTDCs if it is unable to fulfil user requests using the available IOTDC resources. The proposed solution was then tested and evaluated using the PSO and ACO algorithms based on the various factors, including SLA and execution time, developed and simulated in the ClouSim program. The findings indicate that the solution performed better in all tests run. Among the things that can be done in the future in the continuation of the research are: combining time series to predict resources optimally, combining the reinforcement learning method with fuzzy logic for automatic scaling, and using the combination of reinforcement learning and neural network in methods based on service level agreements, which can significantly improve the proposed solution.

***Abstract*—The research articles contain a wealth of information about the interactions between biomedical entities. However, manual relation extraction processing from the literature by domain experts takes a lot of time and money. In addition, it is often prohibitively expensive and labor-intensive, especially in biomedicine where domain knowledge is required. For this reason, computer strategies that can use unlabeled data to lessen the load of manual annotation are of great relevance in biomedical relation extraction. The present study solves relation extraction tasks in a completely unsupervised scenario. This article presents an unsupervised model for relation extraction between medical entities from PubMed abstracts, after filtration and preprocessing the abstracts. The verbs and relationship types are embedded in a vector space, and each verb is mapped to the relation type with the highest similarity score. The model achieves competitive performance compared to supervised systems on the evaluation using ChemProt and DDI datasets, with an F1-score of 85.8 and 88.5 respectively. These improved results demonstrate the effectiveness of extracting relations without the need for manual annotation or human intervention.**

***Keywords*—Relation extraction; BERT; open information extraction; biomedical literature; ChemProt; DDI**

I. Introduction

With more than 32 million citations of biomedical literature in PubMed [1], the medical field is facing a substantial expansion of data, posing challenges for biomedical researchers efficiently and automatically to extract information about specific biomedical entities such as genes, proteins, and diseases. Gathering labeled data required for training and creating models for natural language processing (NLP) is a time-consuming task because it requires human annotation and can take a lot of effort to complete. Gathering a sufficient amount of labeled data for NLP can be challenging since language is complex and diverse. Models require large amounts of labeled data to learn from to generalize well, and the larger the dataset, the more challenging it becomes to label it. Also, the quality of the labeled data is crucial for the accuracy of the NLP model. To ensure high-quality labeled data, it is necessary to have multiple annotators to check for consistency, which can increase the cost of the labeling process. Overall, gathering labeled data for NLP is a time-consuming and resource-intensive process, which can make it expensive and difficult. There is a necessity for quick and scalable discovery, extraction, and organization of the information contained within this data; an issue that raises the need to use information extraction techniques. However, the process of information extraction is one of the primary difficulties in NLP, and its application to a vast amount of data has some restrictions.

Relation extraction and open information extraction are both techniques used in information extraction, but they have distinct differences in their approaches and goals. Relation extraction focuses on identifying and extracting specific pre-defined relationships or connections between entities mentioned in the text. It aims to discover structured relationships with predefined categories. The output of relation extraction is typically a set of entity pairs with their associated relationship type.

Open Information Extraction (OIE) is a relation-free, open-domain paradigm that enables unsupervised information extraction. Its major goal is to create a triple relation with the elements <entitiy1> <Relation> <entity 2> from unstructured data without having to predefine the relationship between the two entities. The extracted tuples can be binary, ternary, or n-ary, depending on how many entities are involved in the relationship. In the biomedical domain, OpenIE has been used to extract relationships between entities such as genes, proteins, diseases, and drugs from the scientific literature. This method may result in scalable and fast performance [2]. In contrast to OIE, RE demands relation definition prior to extraction. Similar to OIE, a binary relation or a higher-order relation (n-ary) can be found in the extracted relation [3]. Fig. 1 summarizes the difference between OIE and RE.

Fig. 1. Open information extraction vs. relation extraction.

Relation extraction is often used to populate or update a structured knowledge base with specific relationship types. The extracted relationships are typically mapped to existing entities in the knowledge base, providing structured information for further analysis.

While Open information extraction is useful for discovering new relationships or facts that may not be present in a pre-existing knowledge base, the extracted relational tuples can be integrated into a knowledge base to expand its coverage and provide additional information. In summary, relation extraction focuses on extracting specific pre-defined relationships between entities, while open information extraction aims to extract as much information as possible without relying on predefined relationship types. Relation extraction is often supervised and used for structured knowledge base populations, whereas open information extraction is more flexible, unsupervised, and useful for discovering new information.

OIE is an essential NLP task, and because of its many potential uses in information retrieval, information extraction, text summarization, and question answering, it was chosen as a source task to transfer to other NLP tasks [2]. Even though several OIE algorithms have been created in the last ten years, only a few studies [3, 4] have attempted to address Unsupervised Relation Extraction (URE) using machine learning (ML) and deep learning methods. Due to the shortage of labeled data, researchers have recently been more and more interested in model generalization in deep learning. Fig. 2 shows the number of publications in Biomedical literature in the last years. It is shown that there is a steady increase in the number of publications in biomedical literature according to PubMed and Web of Science databases.

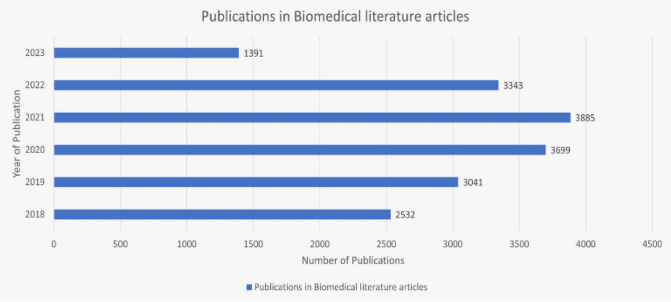

Fig. 2. Number of publications in biomedical literature.

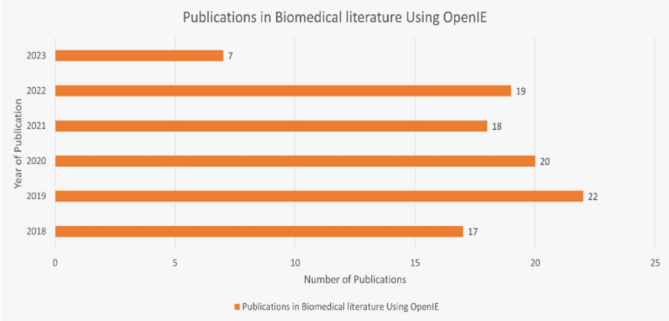

Fig. 3. Number of publications in biomedical literature using OpenIE.

Fig. 3 depicts a few articles that use OpenIE method. That's why there is a growing need for unsupervised models in biomedical relation extraction due to the exponential increase in biomedical literature and manual annotation of all relevant articles is becoming more and more difficult and expensive. OpenIE extracts relationships between medical entities from unstructured text, which can provide valuable insights into the underlying mechanisms of diseases and drug actions by the integration of domain-specific language models that are trained on biomedical literature data, it can capture the nuances of the language and improve the accuracy of the extracted relationships. Furthermore, recent advances in deep learning have enabled the development of more powerful language models, such as BERT [5] and GPT-3 [6], which can capture even more complex linguistic patterns and improve the accuracy of the extracted relationships.

Overall, the integration of domain-specific language models in OIE can improve the accuracy and efficiency of relation extraction from biomedical literature and enable researchers to discover new insights and relationships in the field.

This paper proposes an approach for Open Information Extraction of biomedical literature in a completely unsupervised scenario. This approach identifies interaction words using part-of-speech tagging (POS) in the subject-verb-object form to fully utilize both whole and partial phrase structure information. The interacted verb is then mapped to the nearest group of predefined relations, allowing the system to classify and perform relation extraction without human intervention or the need for labeled data. The resulting data is fed into a pre-trained model, specifically Bidirectional Encoder Representations from Transformers (BERT), which performs fine-tuning with the self-created dataset to enable classification and relation extraction.

The rest of this paper is organized as follows Section II surveys previous work on OIE, Section III explains the materials and methods used to conduct this research, and Section IV evaluates the proposed model by summarizing the results and discussing the findings. Finally, Section V concludes the paper.

II. Related Work

The amount of biomedical literature is growing rapidly, and manual annotation of all relevant articles is becoming more and more difficult and expensive. Additionally, supervised models may not generalize well to new domains and contexts, which limits their utility in real-world applications. OpenIE is particularly useful for extracting relations and facts from large and complex biomedical literature, which can provide valuable insights into the interactions between biological entities and the underlying mechanisms of various diseases [7]. This literature review aims to provide an overview of recent studies on the use of biomedical relation extraction, highlighting the state-of-the-art methodologies and potential future directions for research in this field.

Drug descriptions from Wikipedia and DrugBank were used by Zhu et al. [8] to provide semantic data about drug entities to the BERT model. To obtain sentence representation with entity information, mutual drug entity information, and drug entity information, they used three different types of entity-aware attentions. The BioBERT embeddings of two medications were subtracted to get the mutual information vector of the two drug entities. On the DDI corpus, they reported an 80.9 (micro F1-score).

By linking one or more natural language questions to each relation, Levy et al. [9] have reframed the relation extraction job as a reading comprehension issue. In a zero-shot context, this method enables generalization of undiscovered relations. You [10] proposed a Path-Based MiRNA-Disease Association (PBMDA) prediction model that can infer potential miRNA-disease associations by combining known human miRNA-disease associations, miRNA functional similarity, disease semantic similarity, and Gaussian interaction profile kernel similarity for miRNAs and diseases.

Similarly, in a study by Zaikis et al. [11], the authors proposed an approach that integrates a prior knowledge by using BioBERT which outperforms existing state-of-the-art methods on the DDI corpus in both drug named entity recognition and overall DDI extraction task. Gu et al. [12] proposed a Convolutional Neural Network (CNN) model to learn a more robust relation representation based on both word sequences and dependency paths for the CID relation extraction task, which could naturally characterize the relations between chemical and disease entities.

Drug-drug interactions (DDIs) prediction and extraction model based on BioBERT was proposed by Mondal [13] and Zhu [14]. Both experiments on the DDIExtraction 2013 corpus demonstrate that it can outperform baseline architectures in F1-score, which is a good illustration of BioBERT's use in the field of biomedical text processing.

Peng et al. [15], used a distant supervision model to extract extraction of CIDs from biomedical literature. The authors proposed a method that combined novel statistical features with machine learning model to improve the accuracy of CID extraction. The results showed that their method achieved high precision and recall in identifying chemical-induced disease (CID) relations.

Chen [16] provided a computational approach to identify potential miRNA-disease connections that significantly cut down on experimental time and expense. They created the WBSMDA model for within and between Score for MiRNADisease Association prediction to predict miRNAs linked with diseases. Mario [17], two new relation extraction methods that were proposed to extract the mutation-disease relationship outperform conventional techniques.

In, Zhang et al. [18] also proposed a hybrid model based on RNNs and CNNs to classify PPIs and DDIs. The inputs of the hybrid model are sentence sequences and SDPs generated from the dependency graph. RNNs and CNNs models were employed to learn the feature representation from sentence sequences and SDPs, respectively.

Although the studies discussed above have made significant contributions to biomedical relation extraction, there are still limitations to consider. For instance, some studies rely on specific datasets, making them less generalizable to other domains or contexts. For example, the studies by Mondal [13] and Zhu [14] focused solely on drug-drug interactions and may not be applicable to other types of biomedical relations. Additionally, some studies may require significant domain-specific knowledge and preprocessing, such as the study by Peng et al. [15], which utilized distant supervision and statistical features. While the results of these studies are promising, the performance of the proposed models may be limited by the quality and representativeness of the training data, which can introduce biases and limit the generalizability of the models.

In summary, while most high-performing biomedical relation extraction systems to date are based on supervised approaches, this method requires large amounts of labeled data that can be expensive and time-consuming to obtain. Furthermore, supervised approaches may be biased and limited in generalizability to new domains or contexts. Alternatively, unsupervised models can learn directly from data and can be applied to new domains and contexts without the need for retraining on newly labeled data. The exponential increase in biomedical literature and the limitations of supervised models highlight the growing need for unsupervised models in biomedical relation extraction.

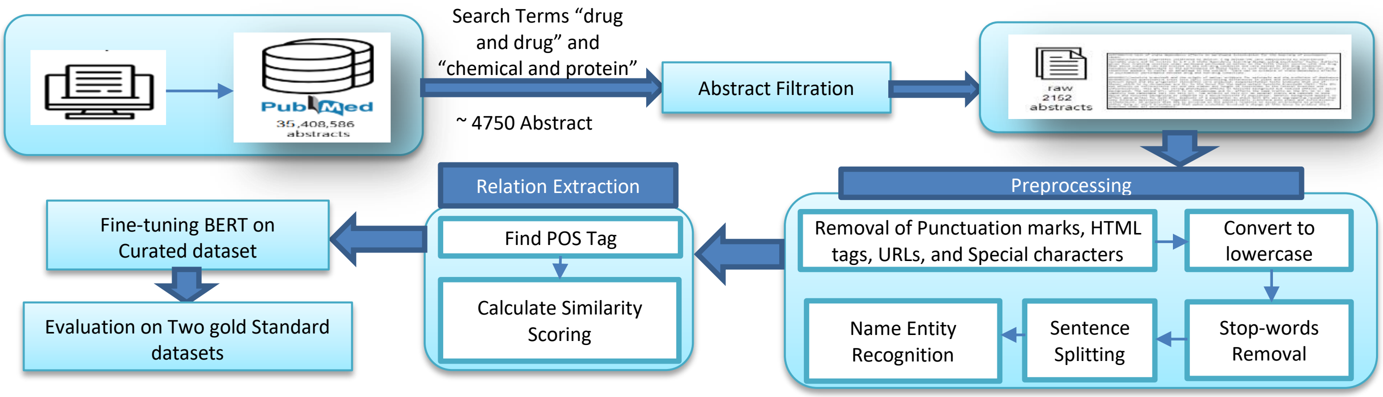
III. Methodology

By using this approach, the study aims to overcome the limitations of supervised methods and provide a scalable and efficient solution for relation extraction in the biomedical domain. The end-to-end framework described in Fig. 4 involves the following steps:

- Downloading and preprocessing records from PubMed using specific queries (each document contained the title and the abstract, PMID).
- Converting the data into sentence pair format for the Named Entity Recognition (NER) process.
- The medical entities such as genes, proteins, diseases, and drugs are captured in NER and replaced with predetermined tags.
- To extract the relations of the form entity1-verb-entity2, a part-of-speech (POS) tagger is used. By using the POS tags, the model can identify the verbs that connect the entities.
- Creating a list of relationship types that are of interest in the task at hand to map the extracted verbs to them. These relations would then be mapped to the verbs that are extracted using a part-of-speech tagger. Once the set of relations has been defined, the extracted verbs and relationship types are embedded in a vector space and each verb is mapped to the relation type that has the highest score after calculating the similarity score.
- The resulting data from the previous steps are used to finetune the pre-trained BERT model.

A. *Material*

The most significant databases for biomedical literature include MEDLINE, PubMed, Scopus, Embase, and Web of Science. The model at hand gathers literature primarily from the PubMed database. The PubMed database contains more than 35 million citations and abstracts from biomedical literature. In order to improve both individual and planetary health, PubMed promotes the free search and retrieval of biomedical and life sciences literature.



PubMed
35,408,586 abstracts
Search Terms “drug and drug” and “chemical and protein”
~ 4750 Abstract
Abstract Filtration
raw 2162 abstracts
Preprocessing
Removal of Punctuation marks, HTML tags, URLs, and Special characters
Convert to lowercase
Stop-words Removal
Sentence Splitting
Name Entity Recognition
Relation Extraction
Find POS Tag
Calculate Similarity Scoring
Fine-tuning BERT on Curated dataset
Evaluation on Two gold Standard datasets

Fig. 4. An end-to-end framework for the proposed model.

While journal articles are not included in full text, PubMed [1] provides links to the full texts when they are available from other sources, such as the publisher's website or PubMed Central (PMC). Each article in PubMed is assigned a unique identification code called a PMID. PMIDs are never reused and do not change over time or throughout processing, providing a reliable way to track and reference articles in the database. PubMed is a valuable resource for researchers in the biomedical field, providing access to a vast amount of literature that can inform scientific discoveries, and advance healthcare. The online availability of PubMed to the public has also made it a valuable resource for patients and healthcare professionals seeking information on medical conditions and treatments [19].

B. Articles Selection and Generation of Training Data

Data must be carefully selected to support academic requirements, scientific research, and other purposes. Data curation is the process of locating, organizing, and managing data collections so that consumers looking for information can use them. Choosing an accurate corpus surely will have a positive impact on the study. The framework proposed in [19] for title retrieval can be expanded to extract abstracts as well. This involves using similar techniques to those used for title extraction but applied to the abstracts. A PubMed search using the terms "drug and drug" and "chemical and protein" was used as the starting point of the process. The two search queries resulted in 4750 abstracts. A sample of selected publications' titles, publication dates, and PMids are displayed in Table I.

TABLE I. SAMPLE OF SELECTED PAPERS AND THEIR DATE OF PUBLICATION

PMID	TITLE	Date of Publication
37311160	Breast Cancer Therapeutics and Hippo Signaling Pathway: Novel MicroRNA-Gene-Protein Interaction Networks.	2023
36387483	Assessment of potential drug-drug interactions among outpatients in a tertiary care hospital: focusing on the role of P-glycoprotein and CYP3A4 (retrospective observational study).	2022
34338261	Advances in chemical probing of protein O-GlcNAc glycosylation: structural role and molecular mechanisms.	2021
29927582	Chemical and Biochemical Perspectives of Protein Lysine Methylation.	2019

The filtration stage included removing all articles that are published before 2019, removing articles that don’t have an abstract, removing duplicated articles (the same article appears in different queries) using the pmid. After applying these filters, the resulting dataset contained 1052 abstracts. The abstracts from the two search queries were merged to form one dataset. Fig. 5 summarizes the main steps of articles selection.

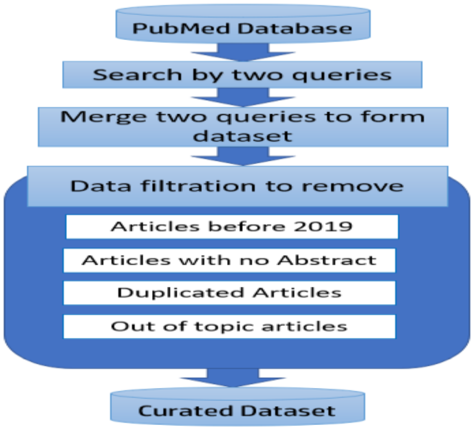


Fig. 5. Paper selection and dataset creation steps.

1) Preprocessing: Once the model has finished selecting relevant articles for the literature curation step, the preprocessing stage starts by splitting the paragraphs into sentences. This conversion allowed for easier identification of relations between two entities within a sentence rather than a paragraph. The extracted sentences were preprocessed before being used to train an algorithm and before a trained model was applied to them because biomedical texts may contain a wide variety of words, numbers, URLs and links, names of genes, chemicals, diseases, and so forth, as well as abbreviations which may be discussed, and all of these may add noise, rather than aid in the classification task. The next stage was to lowercase every word while removing any URLs, numerals, and punctuation from a phrase. The words "no," "not," "nor," "ae," "aes," and "adr" were left out, as well as any other words with three letters or less. A set of customized stop words was finally eliminated. We also performed additional preprocessing steps, including special characters, white spaces, and punctuation. These steps constituted the extent of the preprocessing conducted in this phase. All the previous steps were done using the Scispacy library [20], which is tailored for biomedical, scientific, and clinical material and Natural Language Toolkit (NLTK) [21], which provides a range of efficient natural language algorithms.

The next step after preprocessing was Name Entity Recognition (NER) for extracting the medical entities. We utilized Scispacy to identify and extract the biomedical entities from the extracted phrases. Following NER, we filtered out the sentences from the abstracts. Sentences that did not contain any entities or contained only one entity were removed, while sentences with two entities were considered the target sentences for performing relation extraction and training the model. The total number of sentences with two entities or more was 3407 sentences. A total of 27,123 text descriptions are obtained by the proposed model which are labeled as gene, 19,471 are labeled as disease, 30,289 are labeled as chemical and 25,013 are labeled as protein from the NER task.

2) Relation extraction: A two-step algorithm was used to create a text classification model for the purpose of identifying Chemical-protein or drug-drug-related relations. The first step was part of speech tagging used to extract relations in the form of subject-verb-object. The second step was the resulting verbs tagged from the POS stage and the relation types that we are interested in learning are embedded in a vector space, and each verb is mapped to the relation type that it is most comparable to. To make this procedure fully automatic, it is necessary to specify the collection of relation types of interest and set a threshold for verb mapping, below which no relation class is assigned. Here's the process followed:

a) Part of speech tagging: Initially, Part of Speech (POS) tagging was employed to identify all the verbs present in the sentences not only the main verb between the medical entities. The POS tagger is a tool that assigns a part of speech (such as a noun, verb, adjective, or adverb) to each word in a sentence. By using the POS tags, the model can identify the verbs that connect the entities.

b) Similarity scoring: This step involves identifying the verbs in the sentence that are likely to indicate a relationship between the named entities of interest, such as genes, proteins, drugs, and diseases. The following verbs—increase, decrease, cause, treat, prevent, combine, reduce, and bind—were used to create a fixed set of relations. Once the set of relations has been defined, the extracted verbs and relationship types are embedded in a vector space. This involves representing the verbs and relationship types as vectors in a high-dimensional space, where the similarity between the vectors reflects the semantic similarity between the verbs and relationship types. Each verb is then mapped to the relation type that has the highest score after calculating the similarity score. This involves calculating the cosine similarity between the vector representation of the verb and the vector representation of each relation type and selecting the relation type that has the highest similarity score.

TABLE II. EXAMPLES OF VERB MAPPING AND CALCULATING SIMILARITY

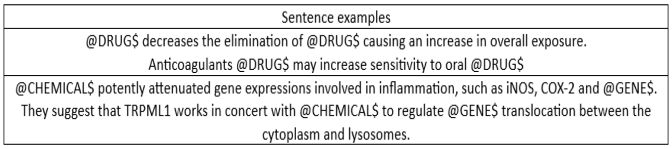
Verb	Relation	Similarity
[‘Reduced’]	Decrease	0.553579
['recovered']	treat	0.535033
['entail', 'including', 'increased', 'eliminated']	increase	0.68346
['used', 'prevent']	Prevent	1
['impaired', 'blocked', 'leading']	cause	0.565928
['regulate', 'serve']	Bind	0.46995
['prepared']	No relation	0.166231

Table II shows a sample of extracted verbs, and their mapping to the set of relations. The similarity scoring threshold was set at 0.4. In cases where multiple verbs exceeded the threshold, the verb with the highest similarity score was selected. Verbs that achieved a similarity score below 0.4 were mapped to a "no relation" label. The RE step is crucial because it guarantees that the resulting relations will have high precision (although at the expense of low recall), as they substantially rule out the chance of the two entities randomly co-occurring in the sentence through the subject-verb-object relationship. In other words, we arrive at a limited, but highly valuable collection of relations that can be applied in a manner that is similar to distant supervision.

3) Transformer tuning of self-created dataset: Language models have demonstrated improved performance in various NLP tasks by considering contextual information when representing features. Popular language models like ELMO [22], BERT [5], and ULM Fit [23] are commonly used in NLP tasks.

a) Bidirectional Transformers (BERT): Among them, BERT introduced by Google in 2019, has gained immense popularity for its ability to pre-train deep bidirectional representations on unlabeled text. By considering context from both sides in all 12 transformer layers, BERT has shown enhanced performance in many NLP applications, including relation extraction.

BERT was used to train the RE classifier, it was fine-tuned for up to 5 epochs because early experiments revealed that the model began overfitting to noise and that the validation loss increased beyond that. The typical BERT pre-processing method for relation extraction is used to replace the entity names in the phrase with predetermined tags so that the BERT model can recognize the entities in the sentence. All references to proteins, drugs, and chemicals are expressly changed to @PROTEIN$, @DRUG$, and @CHEMICAL$, respectively. Fig. 6 shows an example of sentences after preprocessing for BERT.



Sentence examples
@DRUG$ decreases the elimination of @DRUG$ causing an increase in overall exposure. Anticoagulants @DRUG$ may increase sensitivity to oral @DRUG$
@CHEMICAL$ potently attenuated gene expressions involved in inflammation, such as iNOS, COX-2 and @GENE$. They suggest that TRPML1 works in concert with @CHEMICAL$ to regulate @GENE$ translocation between the cytoplasm and lysosomes.

Fig. 6. Examples of sentences preprocessing before feeding them to BERT.

BERT uses WordPiece embedding [24] to address the out-of-vocabulary issue, and each input word will be divided into subwords from the WordPiece vocabulary. Additionally, we add the segment and position information of the tokens in the input phrase using segment embedding and position embedding, both of which follow the original BERT input structure.

When using BERT, it is necessary to select a suitable model and adjust hyperparameters such as learning rate, batch size, and the number of epochs. The BERT-base uncased model is a common choice for sequence classification, it was found that the uncased version performed better [25,26,27,28]. During training, a trained model is validated to assess overfitting and estimate performance before applying it to the target application. We found that validating specific combinations of claim and description concatenation parts, which are not specifically trained but used in other combinations, has low significance.

b) Hyperparameter settings: Hyperparameter tuning is an important step in training machine learning models to achieve optimal performance. In this study, the Transformers library was used to perform hyperparameter tuning for the BERT-Base-Uncased model used in biomedical relation extraction.

The experiments involved varying different hyperparameters, including batch size, learning rate, maximum sequence length, and number of epochs. The maximum sequence length varied between 128 and 512, the batch size varied between 4 and 16 and the learning rate varied between 1e-5 and 4e-5. The results showed that the model achieved minimum loss when the learning rate was around 1e^-5. Fig. 7 shows the relationship between loss and the learning rate. The maximum success value was reached with a batch size fixed at 8, and a maximum sequence length equal to 256. Table III represents the ideal parameter values after experimenting with various parameter value combinations.

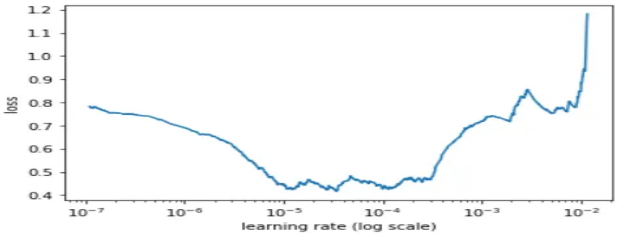


Fig. 7. Plotting of loss of the model versus learning rate.

TABLE III. HYPERPARAMETER SETTINGS FOR BERT

Hyperparameter	***BERT fine-tuning***
Epochs	3,5
learning rate	$1e^{-5}$
Optimizer	Adam
Batch Size	8
Max Sequence length	256
Early stopping	NO

Using the Adam optimizer, the BERT-Base-Uncased model was improved. The best-performing models are saved and evaluated on the test set using the epoch with the highest Recall score (lowest Type II error) on the validation set. The model is designed to prioritize the maximization of the Recall score due to the belief that it is more crucial to minimize the Type II error rather than just increasing the Accuracy/F1 score of the model.

IV. RESULTS AND DISCUSSION

The findings of this study demonstrate that the proposed approach can effectively identify relations between medical entities without the need for supervision or manual intervention. The proposed method was applied to a collection of abstracts obtained from PubMed, and the results showed that the proposed unsupervised approach outperformed the previous supervised methods in terms of overall precision and F1-score on both the ChemProt and DDI datasets.

Theoretical results obtained from relation extraction can be used to develop more accurate and efficient algorithms that can automatically extract relations between biomedical entities from large-scale literature data. This has significant implications for drug discovery, disease diagnosis, and treatment, as it can facilitate the identification of new drug targets and drug-drug interactions, which can lead to the development of new treatments and cures for complex diseases. Additionally, the identification of disease biomarkers can aid in the early detection and diagnosis of diseases and provide insights into disease mechanisms, leading to more effective treatments and improved patient outcomes. Ultimately, the practical use of theoretical results obtained from relation extraction can have a profound impact on the field of biomedical research and accelerate the pace of scientific discovery, leading to new insights and discoveries that can improve human health and well-being. The pipeline can be used to extract relationships between biomedical entities in a variety of scenarios, facilitating the discovery of new relationships and insights in the biomedical domain.

A. Datasets

For training, the proposed model utilized a self-created dataset to train the BERT model. For testing and evaluation, it employed two widely recognized benchmark datasets in the biomedical domain: the DDI [29] dataset and the ChemProt [30] dataset, both of which involve multiclass classifications. Table IV presents the statistics of the DDI and ChemProt datasets.

B. Results on Benchmark Datasets

The performance of the proposed unsupervised approach for relation extraction from biomedical literature was evaluated on two well-known benchmark datasets, ChemProt and DDI. The results of the evaluation are presented in Table V, and the proposed approach was compared to a BERT model that underwent fine-tuning using supervised data manually annotated for the two datasets.

The results demonstrate that the proposed approach outperforms the most advanced model on the CHEMPROT dataset, achieving an F1-score of 85.8 compared to 75.14 for the supervised approach. On the DDI dataset, the proposed approach achieves an F1-score of 88.5, compared to 70.2 for the supervised approach. Furthermore, the proposed unsupervised approach achieves a Recall score of 87.5 on the ChemProt dataset, compared to 75.09 for the supervised approach and a recall of 93.5 vs. 73.4 on DDI dataset, indicating that the proposed approach is more effective at correctly identifying relevant relationships. Fig. 8 provides a comparison of the results on the two datasets, highlighting the competitive performance of the proposed unsupervised approach.

TABLE IV. THE STATISTICS OF THE DDI AND THE CHEMPROT DATASETS

Dataset	DDI	ChemProt
Abstract	191	800
Positive relations	979	3458
Negative relations	4737	10,540

TABLE V. COMPARISON WITH EXISITNG MODELS ON CHEMPROT AND DDI DATASETS

Dataset	*Method*	*Precision*	*Recall*	*F1-Score*
ChemProt	Proposed method	83.15	87.5	85.8
	[31]	75.20	75.09	75.14
DDI	Proposed method	84.2	93.5	88.5
	[32]	-	73.4	70.2

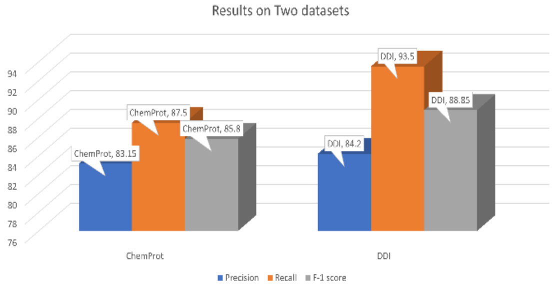

Fig. 8. Comparison of the results on the two benchmark datasets.

The results demonstrate that the proposed unsupervised approach for relation extraction from biomedical literature can strongly compete with the most advanced fully supervised systems, providing a scalable and efficient solution for relation extraction from biomedical literature. The success of the proposed approach in achieving performance equivalent to a fully supervised model highlights its potential to facilitate the discovery of new relationships and insights in the biomedical domain.

C. Results on Self-created Dataset

By analyzing Fig. 9, it can be noted that the model succeeded in its main goal to extract specific targeted biomedical relations from sentences and that the most frequent relations were cause and treat. The number of tagged genes, chemicals, proteins, and diseases in the abstracts were 27123, 30289, 25013 and 19471 respectively, which indicates the complexity and richness of the biomedical text, which can be challenging to process and extract information from without automated methods.

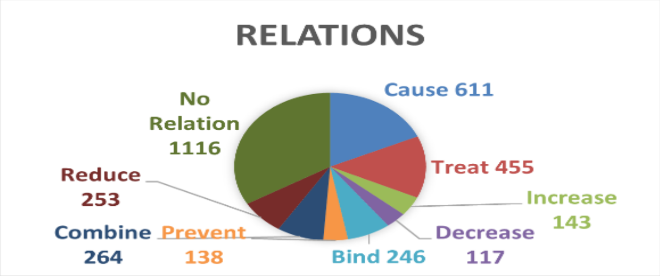

Fig. 9. Extracted relations count from self-created dataset.

The number of relations, as shown in Fig. 9, extracted by the model, mapped to ‘cause’ and ‘treat’ are significant, indicating the importance of these relationships in biomedical research. The numbers of relations extracted for increase, decrease, bind, combine and reduce demonstrate the model's ability to identify a variety of relationships beyond simple causation and treatment.

The number of sentences that have no relation is also an expected outcome, as not all sentences in the biomedical text contain explicit relationships between entities. However, it is still important to accurately identify these sentences to avoid false positives in downstream analyses. Overall, the successful extraction of targeted biomedical relations from the abstracts demonstrates the potential of automated methods for relation extraction in biomedical text mining. These methods can help researchers efficiently process and extract information from the vast amount of biomedical literature available, accelerating scientific discoveries and advancing healthcare.

V. CONCLUSION

The proposed pipeline based on the state-of-the-art BERT model offers a promising solution to the challenge of relation extraction from biomedical literature, providing a scalable and efficient approach that eliminates the need for human intervention or manual curation and which would reduce manpower and time consumption and automatically extract biomedical entities association data sets from large-scale literature data. The pipeline first retrieves articles (mainly abstracts) from PubMed according to specific queries and the extracted abstracts are then preprocessed to precisely extract the relation between medical entities. The preprocessed data are first presented in the form of subject-verb-object using part of speech tagger, with the resulting verbs and relationship types of interest embedded in a vector space. Each verb is mapped to the relation type that has the highest score after calculating the similarity score. The generated data set is used to fine-tune a BERT model to carry out relation extraction.

The significance of this study lies in its ability to reduce manpower and time consumption associated with relation extraction, making it more feasible and cost-effective. The use of the BERT model, which has demonstrated state-of-the-art performance in natural language processing tasks, provides a promising solution to the challenge of relation extraction from biomedical literature. The empirical comparison conducted in this study validates the effectiveness of the approach, demonstrating superior results compared to previous works that relied on supervised learning. Our unsupervised approach outperformed the supervised approach found in the literature in the overall precision and F1-score on both the ChemProt and DDI datasets. In the ChemProt dataset, our method achieved a precision of 83.15 and an F1-score of 85.8, while the supervised method achieved only 75.2 and 75.14, respectively. Furthermore, our method achieved an F1-score of 88.5, surpassing the previous supervised methods scoring 70.2 in the DDI dataset.

The findings of this study have significant implications for future research and applications in this area, such as its potential scalability to larger datasets and its potential for automated extraction of biomedical relations from a wide range of scientific literature. This pipeline can be used to extract relationships between biomedical entities in a variety of scenarios, facilitating the discovery of new relationships and insights in the biomedical domain. By automating the extraction of biomedical relations from a wide range of scientific literature, researchers will be able to identify new relationships and insights that were previously hidden or difficult to discover. This will enable researchers to develop new hypotheses and accelerate the discovery of new treatments and cures for complex diseases and by automating the extraction of biomedical relations, we can accelerate the pace of scientific discovery and improve our understanding of complex diseases. The approach described in the paper uses Open Information Extraction (OIE) techniques to identify interaction words, this method can be applied to other domains and types of data that have a similar structure, such as news articles, social media posts, and legal documents, among others. The techniques used could potentially be adapted and applied to other domains and types of data with similar structures. However, the effectiveness of the approach may depend on the specific characteristics of the data being used, and further research is needed to fully understand its applicability and limitations in different contexts.

Detection and Investigation Model for the Hard Disk Drive Attacks using FTK Imager

Ahmad Alshammari
Department of Computer Sciences-Faculty of Computing and Information Technology,
Northern Border University, Rafha, Kingdom of Saudi Arabia

***Abstract*—A computer hard disk drive (HDD) is a device that stores, organizes, and manages computer data. In general, it is used for system storage, in which the computer maintains its operating system and other programs. A hard disk drive can, however, be physically damaged as well as affected by software errors, data corruption, and viruses that are used by attackers to cause damage. This study aims to develop a detection and investigation model (DIM) for HDD to detect and investigate HDD attacks using the FTK Imager forensic tool. The design science method is adapted to develop and evaluate the DIM. The developed DIM consists of three main phases: detection, gathering, and analysis. In order to evaluate the capabilities of the developed DIM for HDD, a real scenario was used. According to the results, the DIM can detect and investigate the HDD easily using FTK Imager. Thus, organizations can use the developed DIM to detect, investigate, mitigate, or avoid HDD threats.**

Keywords—HDD; cybercrimes; design science method; digital forensic tools; FTK imager

I. Introduction

Nowadays, cybercrime is becoming more prevalent, resulting in an adverse impact on the availability, confidentiality, and integrity of data stored on hard drives and in the cloud [1]. It is also notoriously known as one of the major threats for organization since they are obligated to spend fortune to protect their data from this. Companies must invest in sophisticated security systems, such as firewalls, anti-virus software, authentication, and encryption, to reduce their vulnerability to cybercrime [2]. In addition, organizations are equipping their employees with knowledge and training on cybersecurity best practices such as, enforcing the use of strong passwords and securing confidential data. Besides, organizations added a top notch security on their network to monitor against any malicious activity [3]. All these measures contribute to the reduction of cybercrime risks and the protection of data stored on hard drives and in the cloud.

HDDs are the most crucial component in a computer system [4], [5]. HDDs store both physical and logical data, which is the primary objective of an adversary. These devices are frequently used to store personal data such as photographs, music, documents, and applications stored on a computer [6]. Usually, the attackers aim for the HDDs to gain access to the data stored on them. By obtaining physical access to the system, they may be able to access the HDD data. In addition, they may attempt to extract data from the HDD using malicious software, such as spyware [7], [8].

Therefore, this study aims to develop a model for detecting and investigating HDD attacks using the FTK Imager software. For this purpose, the design science methodology is employed. The design science method is a research methodology that concentrates on the creation and evaluation of artefacts for the resolution of real-world issues. The developed detection and investigation model is comprised of three main phases: detection, collection, and analysis. Each phase of the investigation includes a series of activities designed to aid the investigator in detecting and investigating attacks on hard disc drives (HDDs).

Digital forensics software package FTK (Forensic Toolkit) is used to perform forensic analysis and digital investigations on computers and mobile devices [9]. It is used by law enforcement, the military, and business inspectors to examine computer activity. It can locate and analyse data associated with Internet activity, deleted files, emails, documents, and images, among other types of information. It includes data recovery, analysis, and reporting utilities. There are several contributions of this study, including improving HDD security by detecting and investigating potential threats before an incident occurs. It also enhances HDD's ability to identify and investigate potential threats more rapidly and the ability of organizations to respond rapidly and swiftly in the event of any possible attacks. Detection and investigation models can help companies educate themselves about potential threats.

The paper is organized as follows: Section II introduces the related works, and Section III introduces the methodology. Section IV introduces the results and discussion. Section V offers a conclusion and further work.

II. Related Work

Many forensic models, tools, strategies, processes, procedures, policies, models, and mechanisms have been proposed to assist with the detection and investigation of HDD attacks. These include data extraction, forensic file system analysis, low-level analysis, data recovery, and forensic imaging, among others. For example, a process model was proposed by the authors of [10] based on the following requirements: the model must be based on existing theory in physical crime investigations; the model must be practical and perform the same steps as the real study; the model should be technically generic and not limited to existing products and procedures; the model must be specific enough to further develop general technological requirements for each stage; the model should be abstract and applicable to law enforcement investigations, business investigations and incident response.

The authors of [11] proposed another (similar) event-based process model This model is also based on physical crime scene investigations and suggests that digital crime scene investigations be conducted as part of physical crime scene investigations. This paper focuses on the steps involved in digital crime scene investigation and determining the causes and effects of events in digital forensics.

The authors of [12] proposed a digital forensic investigation process known as an incident model, which includes the following steps: pre-incident preparation, incident detection, initial response, response strategy formulation, redundancy (system backup), investigation, security. remediation (shutdown and containment of suspect system), network monitoring, recovery (reset of suspect system to initial state), reporting and follow-up.

The authors of [13] proposed a goal-based hierarchical process model for digital forensics and also conducted a detailed comparison between the proposed process model and previous work in the field. Their proposed model has multiple layers, which is a novel approach.

The authors of [14] proposed a comprehensive cybercrime investigation model that is very detailed. The proposed model also includes a description of information flow between different stages.

A process model was proposed by the authors of [15] which includes the following steps: identification, collection, conservation, transportation, preservation, analysis, interpretation, assignment, reconstruction, presentation and destruction.

The authors of [16] defined the stages of the digital forensics process: gathering information and making observations, formulating a hypothesis to explain the observations, evaluating the hypothesis, drawing conclusions, and communicating the results.

The authors of [17] proposed a mutual database that includes the design science research method of forensic investigation processes. The four stages proposed of this process consist of, namely: 1) identification; 2) artefact assembly; 3) artefact analysis; and 4) documentation and delivery processes. This lets us align everyone's concepts and terms common database forensics processes.

The authors of [18] developed a coordinated database pre-search model based on three main categories (i.e., planning, preparation and pre-response, acquisition and preservation, analysis and reconstruction) In addition, the forensic database is designed to avoid confusion or ambiguity and to provide practitioners with a systematic approach to performing DBFI with a greater degree of certainty.

The authors of [19] developed a metamodel forensic database field. Then identified, extracted and proposed the municipality concept and concept definitions are aligned to propose a meta-model. They have applied the metamodeling process to ensure that it is a metamodel comprehensive and consistent.

The authors of [20] developed a unified model begin to treat and organize the mobile foreign domain using the meta-modelling method. The authors [21] proposed an integrated an incident response template to identify a database forensics field, respond to, mitigate, and recover from a potential database incident.

The authors in [5] proposed a new forensic method, a readiness system called drone forensics using design science method. The supported model consists of two phases: i) the active forensic phase and (ii) reactive forensics phase. The authors developed uniform forensics Forensic Database Field Template. The model is designed to be efficient and a comprehensive approach to forensic database investigation, addressing challenges in collection and analysis of digital evidence. The authors created a drone forensic metamodel. The developed meta-model ensured a uniform approach collect and organize evidence that allows the investigator to a to better understand the event.

The authors [22] developed the Internet of Things Metamodel of forensic investigation. The developed metamodel provided a detailed overview of the various stages of the investigation, from initial collection of evidence for potential identification and analysis problems. It is designed to be technology agnostic and scalable can be adapted to various scenarios. Additionally, several digital forensic works have been proposed to detect, and investigate the threats and risks of organizations.

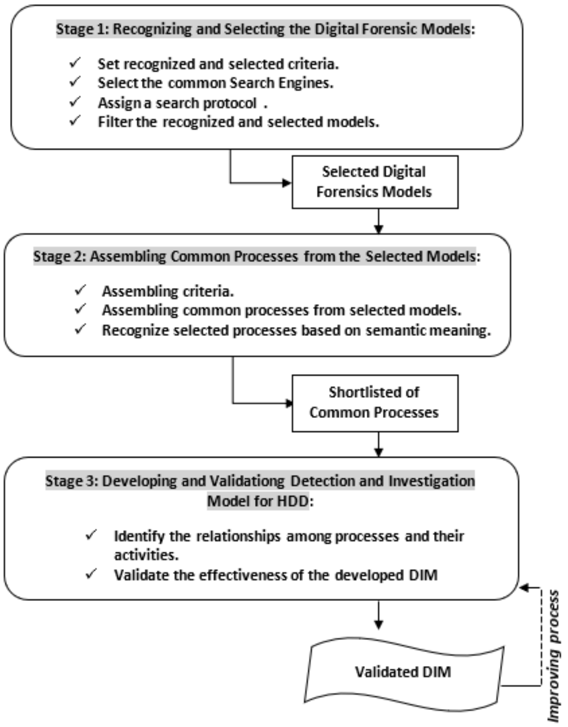
III. Research Methodology

This study adapted the design science method to develop a detection and investigation model for HDD. The design science method is a research method that involves creating a solution to a problem, then analysing the effectiveness of the solution [23]. The process involves creating the solution, testing the solution, and refining the solution as needed. The design science method is particularly useful for developing systems or models such as the HDD detection and investigation model. Fig. 1 illustrates the development process for developing and validating DIM for HDD. The development process involves three stages:

Stage 1: Recognizing and selecting digital forensic models: This stage aims to identify and select appropriate digital forensic models from the literature for development purposes. It contains the following steps:

- Set recognized and selected criteria: To select the digital forensic models that are used in this study from the literature, the researcher looked at models that focused only on HDD, pen drive, RAM, and CD.
- Select the common Search Engines: For this study, five common search engines have been selected for searching and discovering digital forensics models: IEEE Explorer, Scopus, Web of Science, Springer, and Google Scholar.
- Assign a search protocol: The time and keywords were used for this study. The searching period is between 2015 and 2023, and the keywords are “Digital Forensic", "Hard Disk Drive Forensic", and "Pin Derived Forensic", "Memory Forensic".

- Filter the recognized and selected models: The results of the search yielded over 11,300 results from the search engines. These results were filtered to exclude results that were not related to the topic of HDD forensics. After the filtering process, the search yielded over 12 results that were relevant to the HDD forensics purely as shown in Table I.



Stage 1: Recognizing and Selecting the Digital Forensic Models:
✓ Set recognized and selected criteria.
✓ Select the common Search Engines.
✓ Assign a search protocol .
✓ Filter the recognized and selected models.
Selected Digital Forensics Models
Stage 2: Assembling Common Processes from the Selected Models:
✓ Assembling criteria.
✓ Assembling common processes from selected models.
✓ Recognize selected processes based on semantic meaning.
Shortlisted of Common Processes
Stage 3: Developing and Validationg Detection and Investigation Model for HDD:
✓ Identify the relationships among processes and their activities.
✓ Validate the effectiveness of the developed DIM
Validated DIM
Improving process

TABLE I. SELECTED HDD FORENSIC MODELS

ID	Year	Title	Advantages
1	2018	Digital forensic analysis of hard disk for evidence collection [24]	In this study, authors have discussed the significance of digital forensic examination of file systems to recover removed data from hard disks.
2	2017	Towards subverting hard disk firmware boot kits [25]	It was demonstrated by the authors that firmware boot kits can be identified, and several options were offered for how even deep-seated firmware rootkits can be identified as well.
3	2015	The differences between SSD and HDD technology regarding forensic investigations [26]	The focus of this study was to enhance the storage space of the system by utilizing SSD, which is a much quicker and further consistent storage device than old HDD.
4	2022	Comparing HDD to SSD from a Digital Forensic Perspective [27]	From a digital forensic viewpoint, this study examined in depth the results obtained from forensics software on HDD and SSD to determine whether there is a difference between the two drives in terms of forensics.
5	2019	A Comparative Study of Analysis and Extraction of Digital Forensic Evidence from exhibits using Disk Forensic Tools [28]	The aim of this study was to provide a process for searching for evidence, the process may be a little simple or a little complicated. This would involve the location of a file saved on the device, or it could involve more complex processes that would involve hex sweeping or carving information in order to locate the necessary evidence in unallocated or slack memory.
6	2019	Computer forensic analysis protocols review focused on digital evidence recovery in hard disks devices. [29]	This study analysed roadmaps of computer forensic evaluation methods described in scientific files and proposed a laboratory protocol to retrieve digital evidence from hard drives. The authors proposed a six-step procedure to diagnose the case, present results, collect evidence, make copies of files, analyze data, and extract information.
7	2015	Hard disk failure and data recovery methods in computer forensic (Adli bilişimde hard disk arızaları ve arızalı disklerden veri kurtarma yöntemleri) [30]	The authors of this study explained how to retrieve data from a corrupted hard drive. A data improvement concept, data retrieval types, and the physical construct of modern HDD and their inner elements are reviewed first, followed by encountered failures.
8	2019	Data Sanitization Framework for Computer Hard Disk Drive: A Case Study in Malaysia [31]	In this study, the authors introduced a method for sanitizing data from computer hard drives. The proposed and tested a data sanitization process using commercially available tools. Several tests have been conducted at Cybersecurity Malaysia's accredited digital forensic lab.
9	2021	A Digital Forensics Approach for Lost Secondary Partition Analysis using Master Boot Record Structured Hard Disk Drives [32]	Using forensic tools, this study investigates the removal or fraud of partitions on generally employed DOS / Master Boot Record (MBR) designed HDDs.
10	2021	Data recovery in a case of fire-damaged Hard Disk Drives and Solid-State Drives [33]	This study describes how data can be recovered from HDD and strong public drives of different companies and models that have been damaged by fire.
11	2020	Automated support tool for forensics investigation on hard disk images [34]	A new system was designed as part of this study in order to assist criminal investigators in finding evidence on images of hard drives recovered from suspects' devices that could be used in conducting investigations. According to the authors, the content of the images on the disks was not encrypted, and therefore their focus was on multimedia content related to child abuse on the partition images.
12	2121	Forensic analysis and data recovery from water-submerged hard drives [35]	The study examined how long it will take for water to enter the hard drive once it has been submerged in water.

Stage 2: Assembling common processes from the selected models: the aim of this step is to collect the common

investigation processes from the 12 selected models. It involves three steps:

- *Assembling criteria*: The investigation processes should be gathered solely from the main text or figure of the model. The collection process has omitted the following items: abstracts, related works, introductions, methodologies, and conclusions.

- *Assembling common processes from selected models*: The common investigation processes have been gathered and filtered from the selected models using the criteria above.

- *Recognize selected processes based on semantic meaning*: In this phase, three common investigation processes for the DIM have been selected based on their semantic meaning: detection, collection, and analysis. The investigation procedure begins with the detection phase, which involves identifying any suspicious activity on the HDD. This involves inspecting the HDD's system logs and event logs, as well as analysing the drive for malicious or suspicious files. It will be your responsibility to collect and save files from your hard drive as part of the collection phase of the project.

Stage 3: Developing a Detection and Investigation Model for HDD: The aim of this stage is to develop the DIM for the HDD. It consists of the following two primary steps:

- *Identify the relationships among processes and their activities*: The procedure begins with the detection phase. It involves the identification of possible digital evidence. The accumulation and preservation of digital evidence is the next step. It comprises both the gathering of evidence and the verification of its authenticity. The assembling phase is the third phase. In this phase, digital evidence is examined and evaluated for its relevancy. Fig. 2 depicts the DIM developed for the HDD.

1) Detection phase: In this phase, there are three primary procedures: detection and investigation plans, detection and investigation tools, and investigation team identification. The detection and investigation plan includes the establishment of an organized plan outlining the steps required to detect any potential malicious activity on the hard disk drive (HDD). In contrast, the detection and investigation tools (which can be either software or hardware) concentrate on choosing the most appropriate tools for detecting any potential malicious activity on the HDD.

a) Identifying suspected HDD: The purpose of this step is to identify suspected hard drives. A tampered or suspicious activity indicator is included here. Investigation teams must determine the drive's origin and identify it with its serial number or other unique identifiers. Further investigations can then be initiated based on this information.

b) Verification: Following the identification of a suspected HDD, the investigative team will need to verify its legitimacy. To determine the integrity of the drive, tests may be conducted, or the data recorded on the drive may be examined using specialized forensic software. During this phase, the drive's authenticity and data integrity are determined.

c) Initial report: A preliminary report will be drafted by the investigation team after the verification procedure has been complete. It should include the results of their verification procedure as well as any evidence of tampering. If necessary, the organization (decision makers) can conduct a thorough forensic investigation or contact law enforcement based on this report.

2) Gathering phase: During the detection phase, a suspect HDD has been identified, and information is being collected from it. In the process of analysing suspicious hard drives, two primary procedures need to be followed: collecting and preserving all relevant data. FTK Imager is a forensic tool used to gather data from a suspected HDD that has been infected with malware. This data may include deleted files, fragmented data, and metadata. Preserving collected data requires ensuring that it can be analysed in the future. Several methods are available for achieving this goal. To preserve the data, copies of the data may be created, or images of the hard drive may be captured using forensic tools. To preventing data loss or corruption, this step must be performed as part of the analysis procedure.

3) Analysing phase: With FTK Imager, forensic data can be collected from infected HDDs. There may be deleted files, fragmented data, and metadata within this data. Data collection must be preserved so that it can be analysed in the future. There are several methods available for achieving this goal. Using forensic tools, images of the hard drive can be captured to preserve data, or copies of the data can be created. As part of the analysis process, this step must be performed to prevent data loss or corruption.

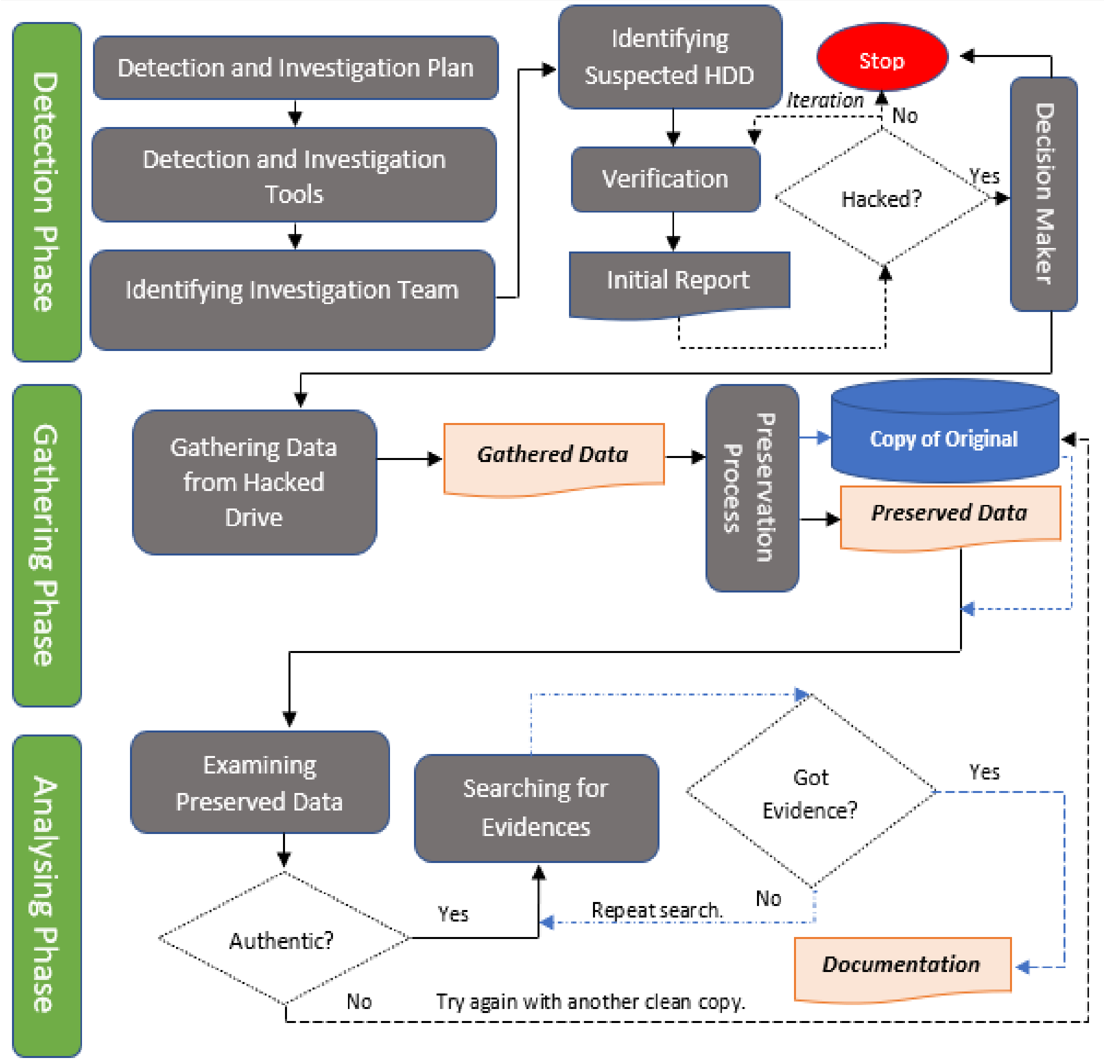

Fig. 2. Proposed detection and investigation model to detect and investigate HDD attacks.

- Validating the effectiveness of the developed DIM: This part evaluates the applicability of the devised DIM to actual HDD attack investigations. The forensic instruments FTK Imager and HashMyFiles are utilized for this purpose. The FTK Imager tool is used to capture and analyze the data, while the HashMyFiles utility is used to store the captured data. In order to accomplish this, the researcher employed the following scenario: "We received a complaint from a consumer named Ahmed. He reported that his flash drive was broken, and he cannot access it. Considering this, the following paragraphs describe how DIM will detect, acquire, analyse, and record data from the suspected pin drive.

1) Detection phase: To accomplish this task, the researcher of this paper prepared the tools FTK Imager and HashMyFiles. During the investigation, the investigative team conducted interviews with the victim to gather all the information necessary to verify the pen drive incident. It is essential that information such as the size of the pen drive, the types of files inside the pindrive, and the last time the pen drive was used is gathered during the interview. Consequently, the researcher discovered that the pen drive had been compromised because of this attack. A team of investigators would need to move to the acquisition stage of the investigation to accomplish this goal.

2) Gathering phase: A second phase of the investigation will be focused on the collection and preservation of pen drive data using the FTK Imager and HashMyFiles tools. As shown in Fig. 3 and 4, it shows how the investigation team can collect data from the suspected pen drive using FTK Imager. To ensure that the captured data is not harmed, it is recommended that it is copied to an external flash drive and then duplicated. The data that has been captured must be protected from alteration or always tampering with HashMyFiles tool. The purpose of HashMyFiles is to create hashed values for data collected from the user by using the HashMyFiles tool as shown in Fig. 5. In the next phase, the examination and analysis process will be explained in detail.

Fig. 5. Hashing collected data using HashMyFiles tool.

3) Analyzing phase: To verify the authenticity of the captured data before moving on to the analysis procedure, the authentication of the captured data needs to be verified using the FTK Imager tool to check whether it is consistent with the captured data. As a result, the hashed file has been verified as shown in Fig. 6. The researcher has confirmed that the authentication is correct, that the value is correct, and that no tampering has been done. This is why they can move forward with the next step of the investigation. By analyzing the captured information, malicious activities are identified because of analysis. After digging through the captured image, researcher found that the attacker had deleted information from the pen drive as shown in Fig. 7. The attacker was able to access the victim's computer remotely through a remote access program. After that, he used the "Delete file path" command to delete the files from the pen drive.

IV. Results and Discussion

In a nutshell, based on the results and discussion presented, this study proposed a detection and investigation model that aims to detect and investigate the occurrence of HDD attacks. This model is mainly comprised of three phases which are detection, capture, and analysis. Therefore, a set of forensic tools namely FTK Imager and HashMyFiles are utilized to accomplish these phases.

Initially, the detection phase aims to identify any evidence of HDD attacks. Therefore, the FTK Imager was utilized in this study to acquire any relevant data contained on the HDD, including the volume name, number of sectors, and sector size. This information is used for identifying any discrepancy that demonstrates the differences between predicted and actual outcomes. If discrepancies exist, it indicates that the HDD drive may have been tampered with. Secondly, the capture phase aims to capture any related evidence of the HDD attacks. Likewise, the FTK Imager and HashMyFiles are utilized for capturing and preserving this evidence that is significant for succeeding analysis phase. Thirdly, the analysis phase aims to analyse and examine the evidence of HDD attacks. During this phase, the FTK Imager is predominantly used to examine the evidence. Based on this analysis, the investigator will have information about the attack, including the type of attack, the method employed, and the suspect. In addition, it will facilitate the diagnosis of the attack's severity and the prevention of future attacks. For method evaluation, it is assumed that the pen drive has been tampered with. In this case, there are several files that have been deleted and damaged. Therefore, the proposed DIM is applied to a compromised flash drive to demonstrate its capability to detect, capture, and analyze HDD attacks. The testing demonstrated that the proposed DIM is capable of precisely detecting deleted files and identifying the removal methods. Consequently, this demonstrated the effectiveness of the proposed DIM in terms of the identification and investigation of HDD attacks.

Based on the results of the evaluation, there are several advantages of the proposed DIM model that could be beneficial to organizations such that, it facilitates in the prevention, mitigation, and acceptance of variations of potential HDD attacks. Therefore, it provides organizations with the option to secure their environment by acknowledging their susceptibility to assaults and by identifying and mitigating them swiftly.

Comparing to the existing model, Table II displays the comparison of the proposed DIM with the existing models. Clearly, the proposed DIM covered whole existing HDD digital forensics models.

V. CONCLUSION AND FUTURE WORK

A hard disk drive is a very important component of a computer system that stores the operating system and applications. It is essentially a non-volatile memory device that stores digital information in a permanent manner. Generally, attackers are trying to access the valuable information on the HDD with the intent of damaging or stealing it. In this study, a detection and investigation model for HDDs was proposed to detect and investigate the various types of HDD attacks. In the proposed model, there are three main phases, namely detection, gathering, and analysis. FTK Imager has been used in conjunction with the newly developed detection and investigation model to detect, preserve, and analyze HDD attacks. Results showed that the proposed detection and investigation model can detect and analyze HDD and pen drive attacks. It is recommended that the future work on this study should be focused on the real-life scenario of HDD attacks.

School of Mathematics and Computer, Tongling University, Tongling, 244000, China[2]

***Abstract*—To accurately capture the posture of animation characters in virtual vision and optimize the user's experience when wearing virtual vision equipment, the hybrid Gaussian model has gained wide attention. However, various types of animation show an exponential growth trend, and the hybrid Gaussian model is prone to low-dimensional explosion when processing these single frames. Based on the mixed Gaussian model, this study conducts animation character gesture recognition experiments on the Disert data set to solve these problems. Meanwhile, it is improved by frame rate reduction method to generate fusion algorithm. In this paper, the video is first grayened and filtered, and the model feature points of the image are marked. Then the weight learning rate is introduced and added to the set of pixels, and then the peak signal-to-noise ratio of Wronsky function is adjusted by changing the parameters. Then similar image sets are extracted and the structure elements are opened and closed. Finally, the proposed algorithm is applied to Disert data set. Meanwhile, the prediction accuracy of PSO is tested and compared with fusion algorithm. A total of 400 experiments were conducted, and the prediction accuracy of the fusion algorithm reached 392 times, with an accuracy of 98.0%. The accuracy of PSO is close to that of fusion algorithm (88.2%). It is verified that the suggested model can identify the four common gestures of cartoon characters well, and users will get a good viewing experience.**

***Keywords*—Frame rate reduction method; model feature points; Wronsky function; mixed Gaussian model; weight learning rate**

I. Introduction

In a society with the rapid increase of animation works, the pose recognition model of animation characters has attracted wide attention, and the requirements of users have become higher and higher [1,2]. Character shape dynamic monitoring technology is to intercept the target from the played video, and then analyze the force status of the character's body in the frame, and then judge the current posture of the character. However, animation works have high requirements for clarity, that is, the frame rate contained in each video is rapidly increasing. The ability of the current algorithm to process fast-passing images is gradually falling behind, and the captured images cannot describe the video completely. In recent years, Hybrid Gaussian model (HG) has attracted the attention of many scholars due to its fast frame detection ability [3]. However, the suitable environment for HG processing pixels is low dimension, and the number of pixels that can be carried by the same dimension has an upper limit. HG is easy to cause data accumulation and even low-dimensional disaster in the working process. When a low-dimensional disaster occurs, it will not only destroy the two-dimensional configuration of the image, but also cause difficulties for subsequent information analysis. Most of the existing methods improve the ability of image frame detection, or make too much effort at the level of image clarity, thus ignoring the problem of information protection when analyzing information. In order to improve this situation, in this study, HG is optimized based on the Frame Rate Reduction (FRR), and the two are creatively fused to generate a fusion algorithm (HG-RPP). The algorithm builds a shared hyperplane, which can map linearly uncorrelated pixels to a higher plane and reduce the burden of low dimension. The steps of this study are divided into four parts. The first part mainly analyzes and summarizes the application effect of the current frame rate reduction model. The second part introduces the influencing factors of shape judgment and the construction of HG-FRR capture model. In the third part, the simulation test is carried out on the Disert data set. Finally, the performance of the optimization model and the traditional model is analyzed and compared, and the shortcomings of this study are pointed out. The aim of this study is to improve HG-RPP's tendency to fall into the low-dimensional dilemma, which not only has a significant effect on user happiness, but also on the sale of Virtual Reality (VR) products for merchants.

II. Related Works

A very important branch of animation character shape capture is animation character pose recognition, which plays a very important role in computer vision, users and businesses [4]. Liao et al. designed two terms based on supervised subspace learning and fragment sections to reduce the difference terms of in-class differences and to promote the block diagonal regularization terms of samples represented by in-class samples. The model maps the original samples to the learned subspace and classifies the mapped samples using a representation classifier with non-local constraints. Experiments have verified the good performance of the algorithm [5]. Yang et al. proposed a novel algorithm that can track multiple face gestures in a single frame or video. To create the first estimate of posture, the convolutional neural network model is first integrated with face identification and average shape learning. Then, a two-objective optimization strategy is used to iterate and apply algebraic filtering. Finally, experimental validation shows the benefits of the suggested approach [6]. Jain et al. proposed using deep learning to identify yoga poses and constructed a dataset with 10 positions from yoga. To capture the video, the study used a smartphone camera. To recognize yoga poses in real time, a 3D convolutional neural network structure is designed and a supplementary layer, batch normalized average pool, is introduced. The experiment achieved a test recognition accuracy of 91.15% on the constructed data set. On publicly available data sets, competitive test recognition reached 99.39% [7]. Gunawan et al. proposed a deep learning architecture model that enables equivariant mapping of deep residuals to improve the attitude robustness of lightweight models as a solution to the underlying problem. The investigation assessed and contrasted the precision of several posture data sets, and the results showed that the suggested model improved accuracy by 0.07% and reduced verification time by 0.17 milliseconds [8].

With the development of the animation field, the clarity of the animation is gradually improved, and the number of attached pixels will also increase. The existing methods cannot continuously refine the pixel, so the algorithm based on pixel analysis is gradually studied. Zhang et al. suggested a deep learning model based on adversarial networks to synthesize faces and recognize faces with constant pose through the shape geometry of face images. The model generates a face that maintains identity by guiding the target pose. And the shape conveyed by the face separates identity from expression change. On controlled and field benchmark datasets, the proposed method performs well compared to the most advanced algorithms [9]. Yoganand et al. proposed a method to identify different gestures from video sequences. In this model, the video sequence is segmented into frames by the lens fragmentation process, and then from each shot, faces are recognised for subsequent processing. Facial features are extracted after the face is detected and the best frame in the video series is chosen using these characteristics. This approach is based on supervised learning and a bat algorithm-improved artificial neural network. Finally, a feature database is applied to recognise the facial picture [10]. Li et al. proposed an evaluation algorithm based on Demps Ter-Shafer Theory (DS). They believe that face detection can be achieved with low pixel monitoring. Therefore, DS is used to integrate the state of students' concentration, and the curve of students' concentration over time is obtained to describe the state of classroom concentration. On the data set provided by the computer camera, experiments have verified the efficiency and viability of the algorithm's design, and the accuracy rate of the algorithm is about 85.3% [11]. Chen et al. proposed a dimensionality reduction algorithm for principal component analysis. The algorithm uses the feature point screening function to filter the feature points extracted in advance by other algorithms, and projects the high-dimensional data into the low-dimensional space. Meanwhile, the redundant feature points are removed and the generation method of feature descriptors is changed to achieve the effect of dimensionality reduction. Experiments on open ORL face library have verified the superiority of the proposed model [12]. Zhu et al. found the importance of automated embedded systems, which work well in applications like private security and surveillance. Research suggests that smart door locks are prone to damage, increasing the risk. In order to provide users with effective open source software, the research proposes attitude tracking algorithms designed to ensure the security of modern keylock systems. Experimental results show that the established system has higher efficiency [13]. Maehama et al. developed an attitude recognition system that allows a robot to evaluate the content of aggressive words and determine whether the words are serious or joking. The study created a dataset of 16 participants. Different attitudes towards robots were observed in field experiments, which were applied to speech quality features of breath and pressed tone analysis, and combined with traditional prosodic features. Finally, the proposed method is compared with the speech standard. The final experimental results show that the combination of speech quality is superior to traditional neural networks in this task, with an accuracy equivalent to human guessing [14].

Through many international studies, it is found that the algorithm based on capturing the gesture of animated characters is very popular in the world, but the research on fusion algorithm is very few. In this study, we innovatively introduce feature point marking and bilateral filtering, and on this basis, take into account the impact of peak signal-to-noise ratio and shared hyperplane, and finally generate a fusion algorithm (HG-FRR). The purpose of this research is to improve the problem that HG-RPP is prone to fall into the low-dimensional dilemma, so as to enhance the user's sense of experience, and provide reference value for the relevant merchants' VR product sales strategy.

III. Modeling with the Mixed Gaussian Model of Wronsky Function Method

With the development of Virtual Reality (VR), more and more users are beginning to use VR technology. To cater to the preferences of users, the research on gesture recognition has gradually become a research hotspot, and the animation character shape capture technology is the most important part [15]. However, animation generally has objective factors such as high frame rate and complex character action, which increases the difficulty of shape capture equipment. In view of this, we combined the Frame Rate Reduction (FRR) method with the Hybrid Gaussian model (HG). This study first introduces the model based on FRR, and then describes the fusion method of the two in detail.

A. Establishment of Human Pose Feature Extraction Model based on Frame Rate Reduction Method

Before using VR to capture the shape of animation characters, the video image must be pre-processed. These include the method of turning gray to reduce the number of colors, and the method of bilateral filtering for video noise reduction. When the image color turns gray, the weighted average method is used in the study, as shown in Equation (1).

$$I = 0.3R + 0.5G + 0.11B \tag{1}$$

In Equation (1), I represents the color type after gray transfer treatment. The red, green and blue components are denoted as R, G, B respectively. Bilateral filtering is a nonlinear filtering method, which can use fixed templates to process adjacent pixels, and it can accurately distinguish spatial intensity differences [16]. The calculation of the bilateral filtering method is shown in Equation (2) below.

$$\begin{cases} g(x,y)=\dfrac{\sum_{k,l} f(k,l)w(i,j,k,l)}{\sum_{k,l} w(i,j,k,l)} \\ d(i,j,k,l)=\exp\left(-\dfrac{(i-k)^2+(j-l)^2}{2\sigma_d^2}\right) \\ r(i,j,k,l)=\exp\left(-\dfrac{\|f(i,j)-f(k,l)\|^2}{2\sigma_r^2}\right) \\ w(i,j,k,l)=d(i,j,k,l)-r(i,j,k,l) \end{cases} \quad (2)$$

In Equation (2), i,j,k,l,x,y represents pixels of the image. $f(k,l)$ represents the gray degree of the image before bilateral filtering, and is represented by $g(x,y)$ after filtering. The domain of pixel is denoted as $d(i,j,k,l)$. The range is represented by $r(i,j,k,l)$. The difference between the two is the weight coefficient of the image, denoted as $w(i,j,k,l)$. After graying and bilateral filtering, the image information will be missing, which is described by Equation (3).

$$\begin{cases} NMSE=\dfrac{\sum_{i=0}^{N}\sum_{j=0}^{N}\left[g(x,y)-f(k,l)\right]^2}{\sum_{i=0}^{N}\sum_{j=0}^{N} f(k,l)^2} \\ PSNR=10*\log\dfrac{MAX^2*M*N}{\sum_{i=0}^{N}\sum_{j=0}^{N}\left[g(x,y)-f(k,l)\right]^2} \end{cases} \quad (3)$$

In Equation (3), $NMSE$ is used to calculate the root-mean-square error before and after pixel conversion. Its signal-to-noise ratio is denoted as $PSNR$. Their values are positively correlated with algorithm performance. MAX is A constant, and the value is 255, which represents the gray value of the image. The gray method and bilateral filtering method are applied to all pixels, and the neighborhood window is finally obtained, as shown in Fig. 1.

In Fig. 1, in the panoramic region set I composed of several pixels, take any pixel point with coordinate (x,y), and scale the coordinate of the point in format $(x\pm1, y\pm1)$ to obtain nine neighborhood points, which together form the neighborhood window [17]. When the video sequence is clipped, it needs to be divided into several time nodes, and then the target image is obtained through the continuous changes between them, and then the shape capture is carried out, as shown in Equation (4).

$$d_t(x,y)=\left|F_t(x,y)-F_{t+nt}(x,y)\right| \quad (4)$$

In Equation (4), the image fragments of two consecutive time points are denoted as $F_t(x,y), F_{t+nt}(x,y)$. The difference between pixel points in frame rates is represented by $d_t(x,y)$. All image segmentation points have threshold values, and the segmentation of threshold values is as follows (5).

$$b_t(x,y)=\begin{cases} 255 & d_t(x,y)\geq T \\ 0 & otherwise \end{cases} \quad (5)$$

In Equation (5), the image capture effect of the character is denoted as $b_t(x,y)$. T represents the time interval for pre-selection. After using FRR to reduce the frame rate of the image, it can describe the outline of the object better. As a result, the structural elements can measure the image size faster, thus reducing the difficulty of video data. The structural elements can echo the corresponding form of the picture to make it compact, as shown in Equation (6).

$$\begin{cases} X\oplus B=\bigcup_{b\in B}(X)_B=\{Y\colon Y=x+b, x\in B, b\in B\} \\ X\otimes B=\bigcap_{b\in B}(X)_B=\{Y\colon (Y+b)\in B, b\in B\} \end{cases} \quad (6)$$

In Equation (6), the structural element is denoted as B, and there are two operations of expansion and corrosion between it and image set X. The expansion operation is represented by $\oplus$, which is a complement to the incomplete part of the image. The corrosion operation is denoted as $\otimes$, and the marginal parts of the image can be clipped. Because the human body has a certain degree of softness, the posture presented is complex and changeable, so the ability of the algorithm has certain requirements. Up to now, the accuracy of monocular detection for 3D feature description is still lacking, far less than that of 2D. The two-dimensional description of human features is divided into two modules, including pre-processing module and feature extraction module, as shown in Fig. 2.

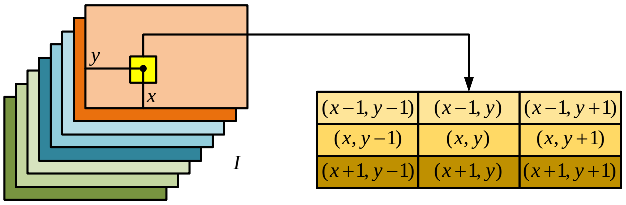

Fig. 1. The neighborhood window for pixels.

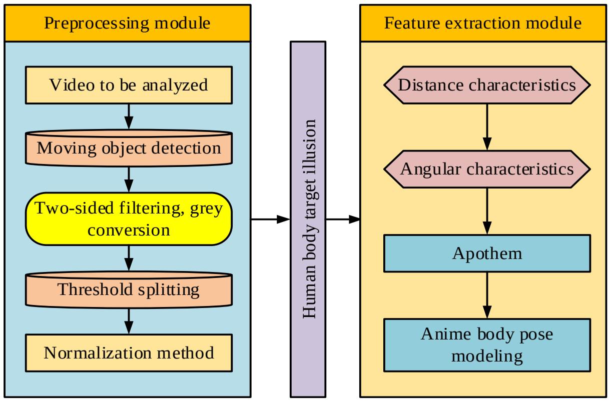

Fig. 2. Two-dimensional flow chart describing human characteristics.

In Fig. 2, the video to be tested is first monitored for moving targets in the pre-processing module, and noise reduction is carried out at the same time. Then the data set is segmented by bilateral filtering threshold, and the human body image containing the target is obtained after normalization, and input into the feature extraction module. Then the features such as distance and Angle in the image are extracted and their eccentricity is calculated. Finally, the model of human body posture can be output, and the Equation (7) can be established according to the feature points of the model.

$$Feature = \{D, A, e\} \tag{7}$$

In Equation (7), the distance between a model feature and the human body's centre of gravity is denoted as D. The line defined by each feature point and the geometric center is called A. If all lines are connected to form A closed pattern, their eccentricity is denoted as e. There are countless lines passing through the center of mass of the human body, and the two lines that are parallel and perpendicular to the horizontal line are extracted. Using the law of Cosine, it is possible to determine the angle between the remaining line and the horizontal line, as illustrated in Equation (8).

$$\alpha_i = \arccos\left[\frac{\beta-\chi}{\delta}\right] \bullet \frac{180}{\pi} \tag{8}$$

In Equation (8), β represents the abscissa of any feature point. The horizontal coordinate of the geometric center point of the human body is denoted by δ, and the vector distance between two points is denoted by δ. However, when the FRR hears the noise, it is greatly affected, which will lead to incomplete data collection, and further affect the accuracy of the results.

B. *Research on Fusion Algorithm based on Hybrid Gaussian Model*

When the FRR is used in practice to capture the posture characteristics of the human body in animation, there will be various errors. To avoid these errors, HG and its generative fusion algorithm (HG-FRR) are introduced. HG can apply multiple single Gaussian random distributions so that each pixel is included. And it can only correspond to the corresponding model, which is conducive to fast work, as shown in Fig. 3.

The HG-FRR workflow shown in Fig. 3 includes four main processes [18]. First, the predefined video is imported, and if the Gaussian model has been initialized, the Gaussian model background is established, and the Gaussian model is updated, and then the current frame is cut. Then determine whether the Langsky Function (LF) needs to be operated. After LF calculation, the level of Gaussian model can be obtained, and then the result can be output after human morphology processing or direct calculation. The frame rate segment without LF is processed by the moving target, and then the initial video is judged to be over. If it has finished, the final result is printed. The unfinished video continues the LF operation. The weighted summation method of HG is shown in Equation (9).

$$\varepsilon(a_t) = \sum_{t=1}^{K} w_{i,t} * \phi(a_t, u_{it}) \tag{9}$$

In Equation (9), the moment of video interception is t. The pixel value at that time is denoted as a_t. i is the total number of models. Its weight and mean value are called $w_{i,t}, u_{it}$ respectively, and their calculation equations are as follows (10).

$$\begin{cases} w_{i,t} = (1-\varphi) * w_{i,t-1} + \varphi \\ u_{it} = (1-\gamma) * u_{it-1} + \gamma * a_t \end{cases} \tag{10}$$

In the above Equation (10), $w_{i,t-1}, u_{it-1}$ is the weight and mean value of the previous moment respectively. The mean learning rate is denoted as γ, whose value is constant (0.001 in this study). The weight learning rate is represented by φ, and the value range is $[0.001, 0.010]$. LF can relate the same coordinates of nearby frame rate units together and is a vector type function, as shown in Equation (11).

$$|\iota| = n^{-1} \bullet \sum_{i=1}^{n} \left[\left(\frac{\kappa_t(x,y)_i}{\kappa_{t-1}(x,y)_i} \right)^2 - \frac{\kappa_t(x,y)_i}{\kappa_{t-1}(x,y)_i} \right] \tag{11}$$

In formula (11), the gray difference of the same pixel at adjacent moments is denoted as $\kappa_t(x,y)_i, \kappa_{t-1}(x,y)_i$. The total number of pixels in the picture is denoted as n. $|\iota|$ is a physical quantity that describes the correlation between pixels, and the greater the distance from 0, the more uncorrelated the two pixels are. When $|\iota| \to 0$, the image set and structural elements can be switched on, that is, deepened on Equation (6), as shown in Equation (12).

$$\begin{cases} X\langle B = (X \oplus B) \otimes B \\ X\rangle B = (X \otimes B) \oplus B \end{cases} \tag{12}$$

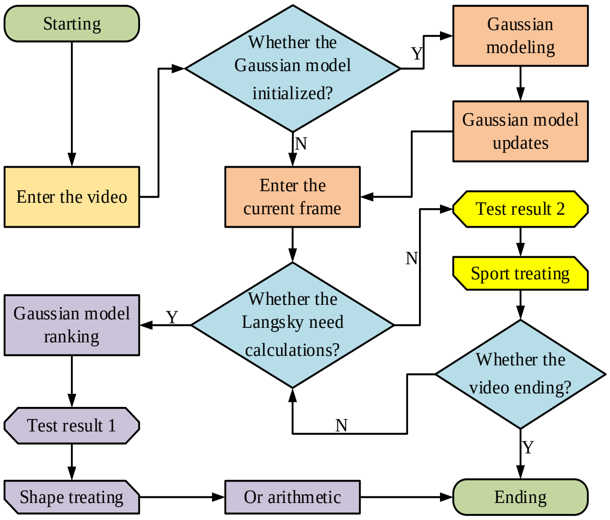

Fig. 3. Flowchart of HG working characteristics.

In Equation (12), $\langle$ represents the open operation, which has the ability to fill image gaps. The closed operation is denoted as $\rangle$, which removes redundant parts of the image. Things in the real world come with regularities, which are often found by learning machines. The learning machine requires lower empirical risk and higher fitness, and its learning process is shown in Equation (13).

$$\mu(w)=\int L\left(v,o(x,w)\right)d\varpi(x,y) \tag{13}$$

In Equation (13), the classical parameters are denoted as w. The loss function is represented by $L\left(v,o(x,w)\right)$. $\varpi(x,y)$ is a directivity function for positioning pixels. The coordinate set of all pixels is denoted as $o(x,w)$ [19]. A Support Vector Machine (SVM) can process uncorrelated pixels in an image due to its kernel technique. The working state of SVM control confidence range is shown in Fig. 4.

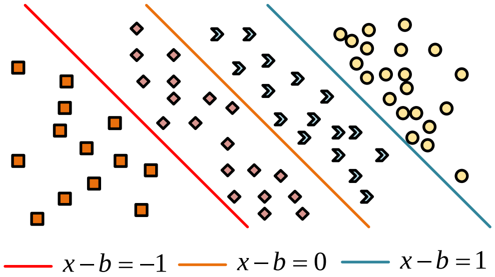

Fig. 4. Schematic diagram of SVM working state.

In Fig. 4, $x-b=0$ represents the optimal hyperplane, and different shapes represent different types of pixels. Fig. 4 shows the best working state of SVM, which can completely distinguish pixels according to whether the linearity is correlated. The kernel function, when dealing with linearly uncorrelated pixels, can map them to a high-dimensional space, thus avoiding a low-dimensional spatial disaster, as shown in Equation (14).

$$\theta(x)=\sum_{i=1}^{n}\vartheta_i\varsigma_i\omega(x_i,x)+b \tag{14}$$

In Equation (14), (A $\omega(x_i,x)$) represents the kernel function of the SVM. $\theta(x)$ is a classification function of the kernel function. The original spatial dimension is denoted as ϑ_i. The mapped spatial dimension and pixel abscissa are called ς_i, x_i. b represents the vector difference between dimensions. Even in the face of multi-pixel data sets, it can be trained one-to-one by Equation (14). To compare the similarity between images, the direct square matrix normalization method is introduced, and its operating equation is shown in Equation (15) [20].

$$sim(Fig_1,Fig_2)=1-\varphi(\xi_1-\xi_2) \tag{15}$$

In Equation (15), the randomly extracted images are denoted as Fig_1, Fig_2. Their gray coefficients are indicated by ξ_1, ξ_2.

IV. Model Experiment of Animation Character Shape Capture Based on HG

To verify the effect of HG-FRR algorithm in practice, the research builds HG-FRR model based on personalized recommendation, and iterates and verifies its accuracy. Finally, simulation experiments are carried out on Disert dataset using HG-FRR model.

A. HG-FRR System Development Environment and Model Parameter Determination

In this study, self-collected Disert data set was selected, including four kinds of animation character postures: upright, walking, running and jumping, with a total of 2417 frames of action images. Considering the limited types of data, the training set and test set are split up into the data set in a 2:3 ratio. The research equipment and software used in the experiment are shown in Table I.

TABLE I. Experimental Parameters

Data Set	Development Language	Code	Internal Storage
Disert	Python 11.2	Open CV	512 G
Operating system	Display card	Database	Processor
128Ubnutu 22.01.20	36.0 GHz	Mysql 5.20.2023	Intel Core i8
Web development framework	Language	Operator	Model
Django1.22.3	Easy Chinese	Standing, walking...	F2.8LII-USM

The collected data sets need to be further processed to enable the research algorithm to learn. For the processing of data sets, HG-FRR was used for iterative optimization. In order to verify its accuracy, traditional K-means algorithm, Random Forest algorithm (RF) and Particle Swarm Optimization algorithm (PSO) are compared with it. The results of accuracy and error rate in the training set are shown in Fig. 5.

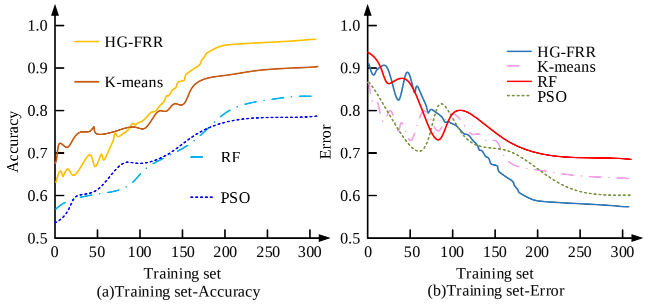

Fig. 5. Comparison of accuracy-training set image and error rate-training set image.

From Fig. 5, HG-FRR has a slightly lower accuracy rate and a higher error rate than K-means and PSO before 100 training sessions. However, the accuracy of HG-FRR is higher than the two algorithms when the number of iterations reaches more than 100, and tends to be stable when the number of iterations reaches 190, and is higher than the other three algorithms. Although the increase of iterations will reduce the operating efficiency of the model, the accuracy weight of the model is higher after comprehensive consideration. Therefore, the proposed HG-FRR algorithm has better performance. After learning the HG-FRR algorithm, the parameter determination in the test should also be taken into account, as shown in Fig. 6.

The parameter of this study is weight learning rate $\varphi \in [0.001, 0.010]$. It can be seen from Fig. 6 that the error rate is lowest (0.042) when the weight learning rate is 0.005 and there are 150 iterations. Therefore, it is finally determined that the number of iterations is 150 times, and the regularization term takes a value of 0.005.

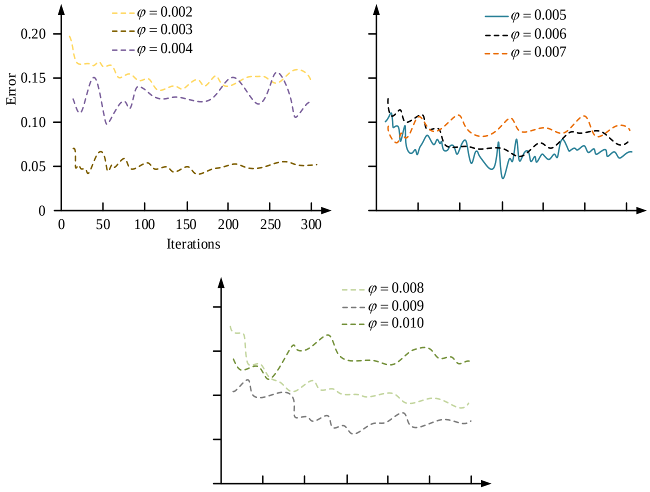

Fig. 6. Error-training times image of regularization term.

B. Experimental Verification of Animation Character Pose Recognition based on HG-FRR

To verify the accuracy of HG-FRR model in recognizing animation characters' pose, simulation experiments were conducted. By observing the task image discrimination ability of HG-FRR algorithm, the practicability of HG-FRR algorithm is judged. First, the HG-FRR algorithm is initialized, and then the video to be detected is input in the data preprocessing module. Finally, the weight learning rate is set to 0.005, and the attitude judgment records of animation characters within 60 seconds are collected, and the images are drawn after calculating errors, as shown in Fig. 7.

Fig. 7 shows the error comparison of the four algorithms in the experiment. From Fig. 7, we see that after 38s, the total error of HG-FRR has approached 0, while the other three algorithms have not stabilized. In particular, the PSO algorithm reached the highest error value of the four algorithms at 3s, which was -1.48%. The total error variation range of HG-FRR, K-means, RF and PSO is significantly compared, and the algorithm performance can be easily compared. However, it is not objective enough to rely only on the total error analysis, so the research separately analyzed the attitude misjudgment caused by the gender difference of the four cartoon characters and the motion amplitude, and drew the image as shown in Fig. 8.

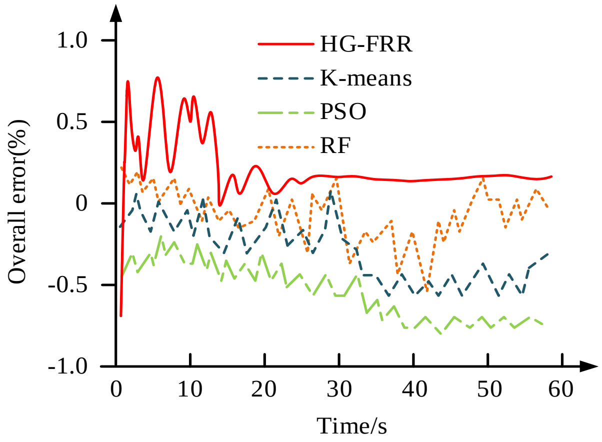

Fig. 7. Total error-time image of four algorithms.

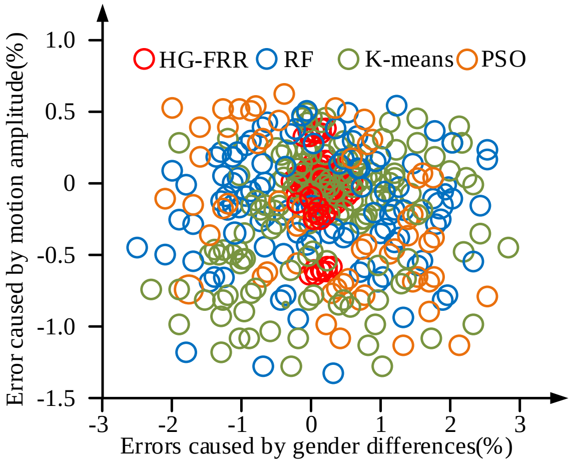

Fig. 8. The types and genre errors of the four algorithms.

From Fig. 8, the experimental results of the HG-FRR model are concentrated in the range of total error 0. The error range caused by gender difference of cartoon characters is [-0.3%, 0.4%]. The error range due to the motion amplitude is [-1.0%, 0.5%]. The errors of the remaining three algorithms are widely distributed, and the larger errors are sparsely distributed. In order to more intuitively distinguish the error correction ability of the four algorithms, the research conducted 400 experimental data records and drew the image as shown in Fig. 9.

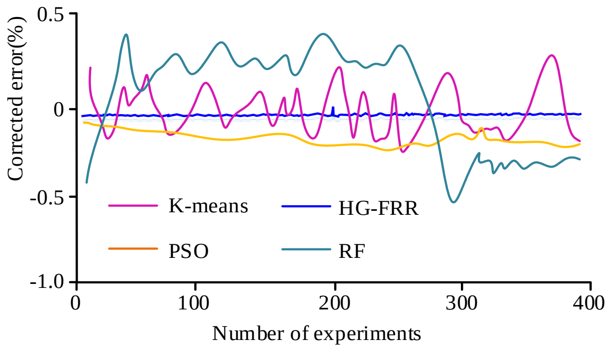

Fig. 9. Error changes of four algorithms in four hundred calibration experiments.

From Fig. 9, RF has the largest error variation range among 400 error test experiments. That is, the frequency of errors was the highest, recorded as [-0.8%, 0.6%]. The second is the K-means algorithm, which is between [-0.2%, 0.3%]. The error range of PSO is close to that of HG-FRR, with values above [-0.13%, -0.03%]. The error curve of HG-FRR fluctuates between -0.02% and 0.04%, with the smallest fluctuation range. The RF and K-means algorithms with the top two errors were excluded, and only HG-FRR algorithm and PSO were compared to capture the correct experimental results, and the error fan chart was drawn to obtain the image as shown in Fig. 10.

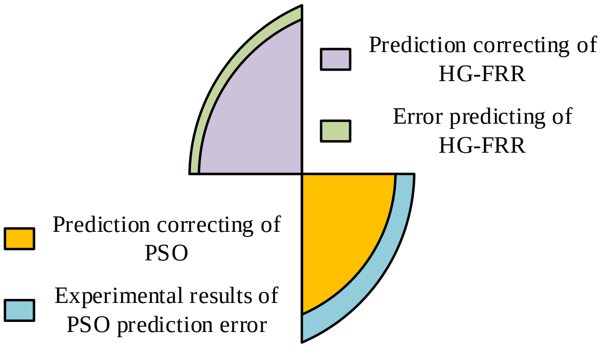

Fig. 10. Error matrix of HG-FRR algorithm and PSO algorithm.

Fig. 10 identifies four pose types of upright, walking, running and jumping based on the characteristics of cartoon characters and characters, and shows the experimental results of accurate prediction of HG-FRR and PSO. HG-FRR was accurate 392 times, with an accuracy of 98.0%, and PSO was accurate 88.2%. In order to observe the experimental results of HG-FRR and PSO more directly, linear fitting graphs of the two algorithms were drawn based on matrix, and the predicted values of the two algorithms were compared with the real values, as shown in Fig. 11.

Fig. 11 shows the comparison between the predicted and true values of the two algorithms. In Fig. 11, the linear fit degree (R^2) of HG-FRR algorithm is 0.9904, and that of PSO is 0.9546, indicating that there is no underfitting of the model. To sum up, it can be concluded that the HG-FRR algorithm model can well capture and identify the common gestures of animation characters, so as to give users a good VR experience.

(b)PSO

Fig. 11. Linear fitting diagram of HG-FRR and PSO.

V. Result and Discussion

It can be seen from the experimental results that the total error of HG-FRR has approached zero after 38s, while the other three algorithms have not stabilized, which shows that the experimental effect of the fusion algorithm is better than the other three algorithms in the stability test of the system. In the total error of HG-FRR, the error range caused by the gender difference of cartoon characters is [-0.3%, 0.4%], and the error range caused by the action range is [-1.0%, 0.5%], while the error distribution of the other three algorithms is irregular and sparse, and only the total error of HG-FRR can be judged to be the lowest. It shows that the proposed fusion model has the best prediction effect under the same experimental environment. For the persuasiveness of the experiment, the study conducted 400 experiments. In 400 error test experiments, the error range of RF is the largest, which is recorded as [-0.8%, 0.6%]. K-means algorithm is between [-0.2%, 0.3%]. The error range of PSO is close to HG-FRR, and the value is above [-0.13%, -0.03%]. The error curve of HG-FRR fluctuates between-0.02% and 0.04%, and the fluctuation range is the smallest. It shows that HG-FRR is still the best in the extensive error test. In the experimental results of accurate prediction of HG-FRR and PSO, the prediction accuracy of HG-FRR is 98.0%, and that of PSO is 88.2%. The linear fitting degrees of them are 0.9904 and 0.9546, respectively. It shows that HG-FRR is extensive in the experiment of predicting cartoon characters. Through many experiments, it is proved that the fusion algorithm proposed in this study has the lowest total error and the lowest distribution error among the algorithms for judging the image of anime characters. Because this error is very sensitive to the influence of cartoon character image judgment, so the small error in the experiment cannot be ignored. However, most animation works rely on freehand drawing and post-processing, which will bring a lot of noise to the prediction of animation characters. Under this background, the proposed fusion algorithm can still keep the error between-0.02% and 0.04%, which shows that the algorithm is highly adaptable to the judgment of animation character image and is suitable for capturing the character form in animation.

VI. Conclusion

With the development of the Internet industry, it is becoming more and more important to identify the posture of animation characters when watching animation, such as increasing the play experience for users and improving the visibility of animation merchants. In this study, a fusion algorithm (HG-FRR) was constructed based on Frame Rate Reduction (FRR) and Hybrid Gaussian model (HG). In this study, both bilateral filter denoising and Lonsky function are taken into account, on the Disert data set, simulation tests are run, and comparison is made with K-means and other three algorithms. 40% of Disert data set was extracted and trained on HG-FRR model through experiments of shared hyperplane. Finally, the number of iterations is determined to be 150 times, and the weight learning rate is 0.005. In the error analysis experiment, a total of 400 experiments were conducted. K - means and RF error of the two algorithms in [- 0.2%, 0.3%], [- 0.8%, 0.6%] within the scope of volatility. The error curve of HG-FRR fluctuates between -0.02% and 0.04%, with the smallest fluctuation range. The variation range of PSO is close to that of HG-RPP, between [-0.13%, -0.03%]. In 400 experiments, the prediction accuracy of HG-FRR is 98.0% and that of PSO is 88.2%. The linear fitting graph of the two algorithms based on matrix is studied. R^2 of HG-FRR is 0.9904, indicating excellent linear fitting. PSO's R^2 is 0.9546. To sum up, it can be concluded that the HG-FRR algorithm model can accurately capture the posture of animation characters, which can not only improve the user's viewing happiness, but also make the animation produced by merchants more well-known. However, the HG-RPP model is only applicable to the analysis of animation with blurred background. For works with complex background, the character characteristics are not obvious, and the model will mark them as noise. This is because the commercial value of animation works belongs to private information, and the dataset analyzed in this study contains few types. With more volunteers, it is believed that future studies can be improved.

Abstract—**Gestational diabetes mellitus (GDM), a condition occurring solely during pregnancy, poses risks to both expectant mothers and their infants, particularly among individuals with pre-existing risk factors. However, early diagnosis and effective management of GDM can help mitigate potential complications. As part of the Ministry of Health's efforts to enhance screening and management strategies for GDM in Malaysia, this study aims utilizing a rule-based technique, acting as an Expert System for Initial Screening of Gestational Diabetes Mellitus Detection. This application will facilitate early diagnosis by assessing risk factors and symptoms to calculate the probability of GDM occurrence and classify it as low, medium, or high. Functionality and usability tests are conducted to ensure error-free performance and gather user feedback. The study's findings indicate that the self-check GDM system effectively utilizes the algorithm, while the mobile application showcases good usability, achieving an above-average System Usability Scale (SUS) score.**

Keywords—Gestational diabetes mellitus (GDM); rule based; expert systems; risk factor

I. INTRODUCTION

Gestational diabetes mellitus (GDM), which only manifests during pregnancy, is the term used to describe diabetes during pregnancy. This is a severe condition that causes pregnant women who were previously normal but discovered to have higher levels of blood glucose during pregnancy [1]. GDM is increasing in prevalence, with 21 million cases (or 7% of the global population) being reported globally [2]. The number of pregnant women with GDM is increasing due to changes in eating habits, increased purchasing power, and climate change [3].

In the early stages of pregnancy, the mother's body undergoes several changes that turn her into a different individual with unique physical and mental features leading to changes in health habits and lifestyle. Hence, those habits and lifestyle choices during pregnancy seem to have permanent and long-term effects on the mother's and child's health [4]. GDM raises the risk of short-term and long-term risks in pregnant women, including pre-eclampsia, caesarean section rates, miscarriage, and subsequent lifelong diabetes. Children of mothers with GDM are more probably to have neonatal respiratory distress syndrome and hypoglycemia and develop diabetes, obesity, and metabolic disorders later in life.

Women at risk to develop GDM is when they are having the presence of any risk factors such as a body mass index of more than 27 kg/m2, previous history of GDM, first-degree relative with diabetes, history of macrosomia, bad obstetric history, developed glycosuria ≥2+ on two occasions, and any current obstetric problems. These recommendations from the Clinical Practice Guidelines (CPG) are intended to be clinical practice manuals in Malaysia based on the best information available at the time of development [1].

In support of the Ministry of Health's objectives of continuing to develop improved screening and management strategies for GDM in Malaysia and of preventing the development of type 2 diabetes mellitus in pregnant women [5][6], this study aims utilizing a rule-based technique, acting as an Expert System for Initial Screening of Gestational Diabetes Mellitus Detection based on the risk factors and symptoms.

Early diagnosis of GDM is important to minimize the risk, but in the first trimester of gestation, the Oral Glucose Tolerance Test (OGTT) is ineffective as pregnancy-induced hyperglycemia is not always clearly apparent in the first months of gestation [3]. Therefore, screening for a disease is advised when the disease is common and clinically significant, and when there is a clear screening test that will classify most diseased persons without high rates of false-positive or false-negative outcomes. The early screening of diseases is very important for society as it contributes to improvements in the quality of life and economic growth in the countries. This screening allows the early initiation of proper treatment of the disease to prevent death [3]. In addition, the screening and subsequent detection of GDM before pregnancy enable effective management to reduce maternal and fetal morbidity and mortality associated with pregnancy hyperglycemia [6].

In the research conducted by [7], Malaysia is in the fifth rank in Asia with an 18.5% prevalence rate of GDM. To reduce the prevalence rate in Malaysia and to have good primary care for the mother and patients at risk at a minimal cost, needs a pre-screening test procedure that is easy and gives new knowledge to know better about themselves [8][9]. Several biochemical tests for diabetes diagnosis in early pregnancy were proposed, which as the Oral Glucose Tolerance Test (OGTT). However, it is an expensive and manual test, and its poor tolerability may affect enforcement, especially in the context of nausea during the early stages of pregnancy [6]. Therefore, in this research, the initial screening of the GDM expert system is proposed based on risk factors and symptoms. This initial screening test is the first step in diagnosing GDM in the CPG published by the Ministry of Health Malaysia [1]. However, according to a medical expert, the initial screening test is conducted in a casual interview only, because currently, there is no mechanism for the initial screening of GDM in clinics and hospitals.

Increasing awareness among women and their families about GDM is pivotal to ensure early detection and treatment. "Women who are vulnerable to the risk factors of GDM should contact their doctor before they decide to become pregnant and ensure that they seek guidance and support in the control of their blood sugar,"[20]. Increased risk for the complications of GDM during the first and second trimester of pregnancy is due to poor healthcare [6]. Thus, in order to achieve the best outcome of pregnancy, pre-screening test is an early step that can be taken to avoid the risks [2]. This research is aimed to spread awareness to people that GDM can occur from risk factors. Therefore, initial screening is advised as it can be a precautionary measure before and during the pregnancy to prevent complications.

The main contribution is the development of GDM-PREP, an innovative mobile application that employs rule-based techniques to improve the early detection of Gestational Diabetes Mellitus (GDM). By seamlessly integrating with the mobile environment, GDM-PREP offers a user-friendly and accessible platform for expectant mothers. The application incorporates a set of carefully designed rules and symptoms tailored to the Malaysian context, ensuring accurate classification and timely detection of GDM in this specific population.

II. Related Work

This section discusses existing mobile applications for pre-screening GDM There are a few expert systems that had been developed, which are d-GDM 2019, Gestational Diabetes Health Tips & Care, Diabetes Diagnostics and Diabetes Test - risk calculator of Diabetes.

d-GDM is an interactive mobile application that was created in 2015 by Garnweidner and Cols [10]. Garnweidner and Cols.’s aim for the application is to diagnose and give information regarding the result to be followed up to present on a mobile phone screen. The application was developed using WHO's suggested variables and parameters of GDM which are fasting glycemia, random glycemia, and glycated haemoglobin (HbA1c) in the first trimester. d-GDM applied an open source for all the informatics tolls of the application. The application will generate and present the information regarding the result of the diagnosis of GDM after the user submitted all the information needed in the application.

Diabetes Diagnostics has been developed by Natural Apptitude with a team of world leaders, which is the University of Exeter Medical School team who lead the diabetic monogenic diseases and the front line of work in diagnostic aids for subtypes of diabetes. It can be retrieved from the website (https://www.natural-apptitude.co.uk/project/diabetes-diagnostics/). It is an application that helps physicians worldwide detect unusual types of diabetes, as objectively to provide patients with improved care. Natural Aptitude also stated that this probability calculator is created in a mobile application for offline use, along with a range of other diagnostic tools and other information aimed to increase the accuracy of the diagnosis. The application needs several important informations about the user, such as age, sex, racial group, BMI, HbA1c level, and other risk factors. The best feature of Diabetes Diagnostics is that it displays a probability of the diagnosis, as it gives a description of the disease in the result section.

Diabetes test - risk calculator of diabetes is a mobile application which requires iOS 8.0 or later that was created in 2017 by Pears Health Cyber can be accessed through (https://apps.apple.com/us/app/diabetes-test-risk-calculator-of-diabetes/id1014960572). The developer of the application claimed that the Diabetes Test - risk calculator of diabetes is a multiplex and reliable risk calculator on a mobile device for the development of diabetes mellitus. They also added that “We have developed a test using a combination of many test algorithms that takes account of a wide range of variables that can detect smaller degree than any other risk calculator.” The result then will be generated after simply enter in the application of the details of age, gender, family anamnesis, physical health, BMI, and other factors.

III. Methodology

A. Expert System

An expert system is one of artificial intelligence (AI) technologies. Expert systems (ES) are systems based on knowledge which are part of the former AI research field and can be defined as knowledge-intensive software that performs tasks that usually require human expertise [11].

- Rule-Based

A rule-based system is a system that uses laws as the main principle of representation [12]. The meanings of a rule-based system depend almost entirely on ES which imitates human expert reasoning in solving an intensive problem of knowledge [13]. It also stated that a rule-based system encodes a human knowledge expert into an automated system in a rather narrow area. The rules consist mainly of two parts rule antecedent and rule consequent, where the rule antecedent is the if the part that specifies a set of predictor attribute values referencing the conditions. While the rule consequent is then part which specifies each example that the predicted class of the rule meets the conditions in the rule antecedent [14]. A rule-based system usually consists of a variety of if-then rules that can be used for various purposes, such as reinforcement of decisions or predictive decision-making [15]. The rule base is the set of rules which represents the knowledge about the domain [12]. The general form of a rule is such below:

If cond1 and cond2 and cond3 ...

then action1, action2, ...

The conditions cond1, cond2, cond3, etc., also known as antecedents are evaluated based on what is currently known about the problem being solved. Some systems would allow disjunctions in the antecedents. For example, the rules in general form. Such rules are interpreted to mean that if the antecedents of the rule together evaluate to true for example if the Boolean combination of the conditions is true, the actions in the consequents which are the action1, action2, etc., can be executed. Each antecedent of a rule typically checks if the problem instance satisfies some condition. For example, an antecedent in a rule in a medical expert system could be the patient has previously undergone heart surgery. The complexity of antecedents can vary a lot depending on the type of language used. For instance, in some languages, one could have antecedents such as the person's age being between 10 and 30.

The advantage of the rule-based system is the structures, as its homogeneity therefore the uniform syntax enables one to easily analyze the context and interpret each rule [16]. There is also a limitation to the rule-based system which is, the rule-based system will provide an inadequate explanation. Most expert systems offer a facility to explain the user's behaviour. There are very few explanatory facilities provided by a rule-based system. Therefore, the explaining facilities provided by a rule-based system are only suitable when the user and the expert are equally knowledgeable.

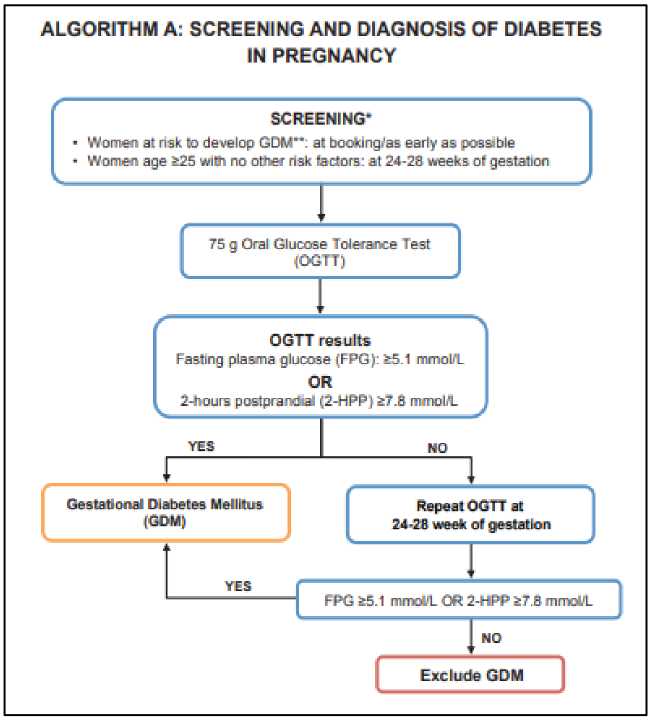
Research by [3] applies Bayesian Network, Multicriteria Analysis and Expert Systems to improve GDM diagnosis from data mining techniques, which will display more reliable random trees and a lower error rate result from the experiments. Registration of rules to facilitate diagnosis and the accuracy of the tests can be enhanced by increased rules, thereby increasing the specialty of the system and its ability to function in its domain. Another study [17] proposed a rule-based diagnosis system for diabetes. Technique Fuzzy-based logic rule is ideal to develop a system of knowledge based on medical disease. The proposed expert system is very useful both for the patient and for doctors to diagnose the disease correctly. The laboratory test results can differ in certain ways, and it is time-consuming since they depend entirely on the availability and expertise of the physicians. Besides, a model proposed by [9], can help to diagnose T2DM early and avoid potential complications linked to late diagnosis. Although the absence of laboratory diagnostic tests on diabetes decreased the sensitivity and accuracy of the proposed model in the research, the model is an evolution of an early diagnosis of diabetes without using laboratory diagnostic tests.

B. Pre-Screening of GDM

Gestational Diabetes Mellitus (GDM) is related to an increased risk of short and long-term maternal and perinatal complications [18]. Early screening, diagnosis and diabetes prevention reduce the high costs of disease control and complication treatments and prevent admission into the hospital due to serious complications [9]. There are various guidelines for screening and diagnosis of GDM such as guidelines from the World Health Organization (WHO), National Institute for Health and Clinical Excellence (NICE), American Diabetes Association (ADA), etc. However, this research will follow the CPG published by the Ministry of Health of Malaysia as a reference. This section will be explained on Algorithm of GDM in CPG and the risk factors and symptoms of GDM.

- Algorithm of GDM in CPG

Based on Fig. 1, the first step of screening and diagnosis of GDM is screening the patient at risk to develop GDM and women age more and equal to 25 with no other risk factors. It will then proceed with 75g OGTT to confirm that the patient is diagnosed with GDM. Therefore, the screening test is important as it is a determinant of the OGTT to be conducted. In addition, the identification of risk factors is significant to determine whether women are at risk for an early diagnosis and intensive lifestyle changes [7].

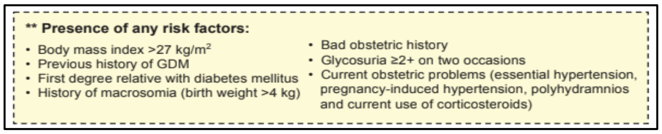


ALGORITHM A: SCREENING AND DIAGNOSIS OF DIABETES IN PREGNANCY
SCREENING*
• Women at risk to develop GDM**: at booking/as early as possible
• Women age ≥25 with no other risk factors: at 24-28 weeks of gestation
75 g Oral Glucose Tolerance Test (OGTT)
OGTT results
Fasting plasma glucose (FPG): ≥5.1 mmol/L
OR
2-hours postprandial (2-HPP) ≥7.8 mmol/L
YES
NO
Gestational Diabetes Mellitus (GDM)
Repeat OGTT at 24-28 week of gestation
YES
FPG ≥5.1 mmol/L OR 2-HPP ≥7.8 mmol/L
NO
Exclude GDM

Fig. 1. Algorithm of screening and diagnosis of GDM stated in CPG.

C. Risk Factors and Symptoms of GDM

Although many other risk factors are also considered in another guideline for screening and diagnosis of GDM, Malaysian CPG will only use seven risk factors to diagnose GDM. As shown in Fig. 2 the risk factors of GDM are Body Mass Index (BMI) of more than 27kg/m^2 and experienced GDM in a previous pregnancy. In addition, first-degree relative with diabetes is also a risk factor for GDM. The first-degree relative's would-be parents, siblings, and children [19]. Other than that, history of macrosomia, in which the birth weight of the baby is more than 4 kg. The next risk factor is the patient who experienced bad obstetric history and glycosuria, where the urine contains more blood sugar than usual on two occasions. The one who is facing obstetric problems, such as essential hypertension, pregnancy-induced hypertension, polyhydramnios, or current use of corticosteroids, would be the last risk factor for screening and diagnosis of GDM.



** Presence of any risk factors:

- Body mass index >27 kg/m^2
- Previous history of GDM
- First degree relative with diabetes mellitus
- History of macrosomia (birth weight >4 kg)
- Bad obstetric history
- Glycosuria ≥2+ on two occasions
- Current obstetric problems (essential hypertension, pregnancy-induced hypertension, polyhydramnios and current use of corticosteroids)

Fig. 2. Risk factors of GDM are stated in CPG.

Next, there are five symptoms of GDM [18]. The symptoms are polydipsia, which is excessive thirst and polyuria. Polyuria is a condition where the body urinates more than normal and each time you urinate, it passes excessively large amounts of urine. Other than that, the patient might suffer exhaustion, nausea, and repeated vomiting. Lastly, the symptom of GDM is blurred vision, which experienced a decrease in clarity or sharpness vision.

The objective of this research is to classify the user with GDM. Risk factors and symptoms of GDM will be used as an indicator in this research. Based on various previous research, rule-based is an ideal technique to develop an expert system for a diagnosis of a disease. Rule-based has also been applied as its structures provide procedural interpretations that allow them to be viewed as models of computation. Although BN has an adaptability feature, a rule-based system dividing the rule base from the inference engine distinguishes the knowledge from the way of how to solve the problem. This means that the same inference engine can be used with several rule bases and a rule base for different inference engines may be used. Therefore, it is easy to add or apply a new rule with the same bases or antecedent.

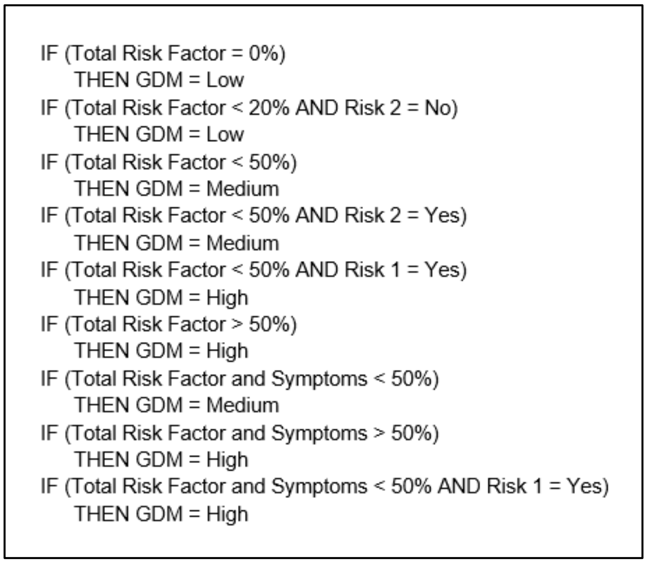
D. Risk Factors and Symptoms Selection

This research is focused on the self-check function. In the function, there are two parts, which are risk factors and symptoms of GDM that have been used as the parameters for the self-check function. All the information about the parameters had been collected and gathered from the Clinical Practice Guidelines: Management of Diabetes in Pregnancy, published by the Ministry of Health Malaysia. There is also additional information that had been gathered on the parameters of the self-check function, where each of the parameters has its impact on the result generated.

In addition, the data and information on parameters are collected and have been revised and verified by the medical expertise. Therefore, there are seven risk factors and five symptoms of GDM. The risk factors of GDM, there is a body mass index of more than 27 kg/m2, previous history of GDM, first-degree relative with diabetes, history of macrosomia, bad obstetric history, developed glycosuria on two occasions, and any current obstetric problems. Meanwhile, the symptoms of GDM, there are polydipsia, polyuria, exhaustion, nausea, repeated vomiting, and blurred vision.

E. Algorithm

The rule of GDM detection is designed in algorithm form before the development of the system and implemented in Java. Two conditions are to be applied by rules. The first condition is the user will only be answering for the risk factors section in the self-check function. The second condition is the user will be answering both the risk factors and symptoms section. The condition that will be experienced by the user in the self-check GDM function is based on the result generated from answering the risk factors section. There are seven questions regarding risk factors. Each question referred to each risk factor. For each question, if the user answered 'Yes', the number recorded in the parameter 'total parameter' is incremented from 0 to be used to calculate the probability. As for the user that experienced answering symptoms question, five questions need to be answered. Each question referred to each symptom. The total number of 'Yes' answered by the user is recorded in the same parameter, the 'total parameter' which is incremented from the question in risk factor. Fig. 3 shows the algorithm of the rule of GDM detection in pseudocode.



```
IF (Total Risk Factor = 0%)
    THEN GDM = Low
IF (Total Risk Factor < 20% AND Risk 2 = No)
    THEN GDM = Low
IF (Total Risk Factor < 50%)
    THEN GDM = Medium
IF (Total Risk Factor < 50% AND Risk 2 = Yes)
    THEN GDM = Medium
IF (Total Risk Factor < 50% AND Risk 1 = Yes)
    THEN GDM = High
IF (Total Risk Factor > 50%)
    THEN GDM = High
IF (Total Risk Factor and Symptoms < 50%)
    THEN GDM = Medium
IF (Total Risk Factor and Symptoms > 50%)
    THEN GDM = High
IF (Total Risk Factor and Symptoms < 50% AND Risk 1 = Yes)
    THEN GDM = High
```

Fig. 3. Rules Generation for GDM detection.

After users have answered all questions, the probability of having GDM will be calculated based on their input in each question of risk factor or both risk factor and symptom. The value of the 'total parameter' will be collected from the user on what they are experiencing in their current condition, and it will be then divided into the total number of risk factors or divided into both the total number of risk factors and symptoms. Then, it will multiply by 100 to get the probability. To be simplified, the formulas to calculate the probability are shown in Table I.

TABLE I. THE FORMULA OF THE PROBABILITY OF HAVING GDM

Condition	Formula to calculate the probability
The user answered risk factors only.	$\frac{Total\ Yes}{7\ (Total\ Risk\ Factor)}\ x\ 100$
The user answered risk factors and symptoms.	$\frac{Total\ Yes}{13\ (Total\ Risk\ Factor\ and\ Symptom)}\ x\ 100$

From the Algorithm 1, the user will get the result of their probability of GDM based on 7 or 13 parameters depending on the result in the risk factors section. The result in the risk factors section must be more than 50% and the user is currently pregnant to answer the symptoms section. Otherwise, the user will only need to answer the risk factors section to get their probability to have GDM. There are three categories to classify the probability of GDM, which are low, medium, and high. The example of cases for classifying the probability from rules is visualized in Table II.

Algorithm 1: Algorithm for the rule of GDM detection.

```
Initialize
Tp = 0; P = 0;
Compute
While () do
    For (each Risk Factor 1 to Risk Factor 7) do
            IF Ri is YES, then
                Ri = 1 AND Tp = Tp+1, Otherwise 0;
            End

    IF (P > 50 AND Pregnant =YES)
        THEN FOR each Symptom 1 to Symptom 5 DO
            IF Si is 'YES'
                THEN Si = 1 AND Tp=Tp+1, Otherwise 0;
            End
            P = (Tp/13) x 100
    Else
         P = (Tp/7) x 100
        End

    Return Tp and P;

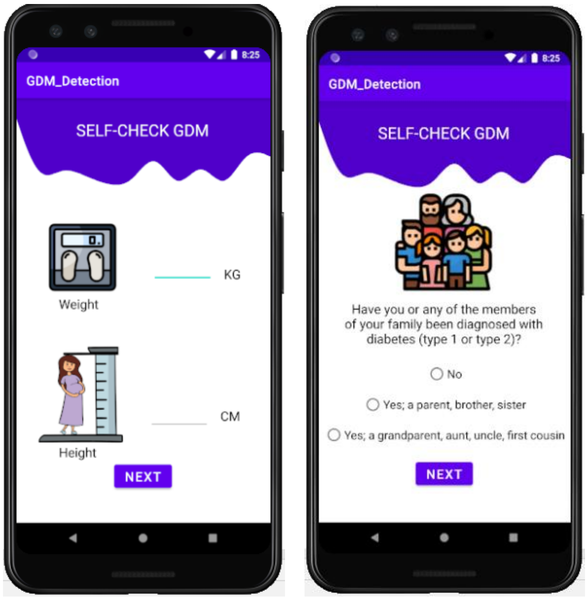
    End

End
```

Next, based on Fig. 3, the rule to classify the use of probability to have GDM is based on the user risk factors or both risk factors and symptoms. User needs to answer each risk factor and symptom-based on their current condition. Based on the answer by the user, it will then be calculated the probability to have GDM. Then, the rules will be implemented in the classification of the probability. If all the parameters match the rule, then the probability and classification for the user will be produced because of the self-check function.

F. *User Interface (UI) Design*

On the Home page, there is one function for the user to have their probability to have GDM by clicking the Self-check GDM option. Users need to answer each question displayed as shown in Fig. 4. To submit the answer based on the user's current condition, they need to click one option from the radio group and click the button NEXT and click on the button SUBMIT on the last question.



Have you or any of the members of your family been diagnosed with diabetes (type 1 or type 2)?

○ No

○ Yes; a parent, brother, sister

○ Yes; a grandparent, aunt, uncle, first cousin

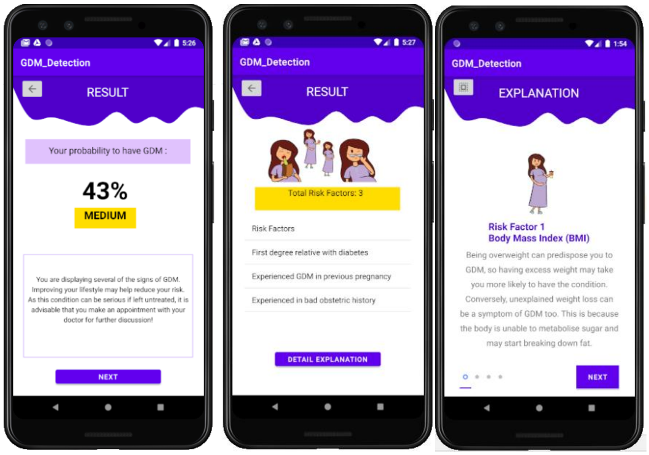
Fig. 4. Sample of self-check GDM questions page.

TABLE II. EXAMPLE OF CASES FOR CLASSIFYING THE PROBABILITY FROM RULES

No	R1	R2	R3	R4	R5	R6	R7	S1	S2	S3	S4	S5	Probability	Class
1	No	No	No	No	No	No	No	No	No	No	No	No	0%	LOW
2	No	No	Yes	No	No	No	No	No	No	No	No	No	14%	LOW
3	No	No	Yes	No	No	Yes	No	No	No	No	No	No	29%	MEDIUM
4	No	Yes	Yes	Yes	No	No	No	No	No	No	No	No	43%	MEDIUM
5	Yes	Yes	No	No	No	No	No	No	No	No	No	No	29%	HIGH
6	Yes	No	No	No	No	No	No	No	No	No	No	No	14%	HIGH
7	No	Yes	Yes	Yes	Yes	No	No	Yes	No	Yes	No	No	46%	MEDIUM
8	No	No	Yes	No	Yes	Yes	Yes	No	Yes	No	Yes	Yes	54%	HIGH
9	Yes	Yes	No	No	No	Yes	No	Yes	No	No	No	No	31%	HIGH
Indication:														
R1		BMI of more than 27 kg/m2						S1		Polydipsia				
R2		First-degree relative with diabetes						S2		Polyuria				
R3		Previous history of GDM						S3		Exhaustion				
R4		History of macrosomia						S4		Nausea, repeated vomiting				
R5		History of bad obstetric						S5		Blurred vision				
R6		Glycosuria												
R7		Current obstetric problems						NoP		Do not experience R7 but pregnant				

After the user submits all their answers to all the questions, the application will display the result page. On the result page, there is the Home button for the user to view the Home page and the Next button for the user to review the detailed explanation of the result displayed. Fig. 5(a) shows the Result page. In Fig. 5(b), the total risk factor that strikes the risk factor of GDM will be displayed, based on the user's answer. If the user wants to return to the previous page, click on the Back icon. On the Detail Explanation page, it will view all explanations on the user's answer on each parameter. It contains the Home icon and Next icon. If the user wants to return to the home page, click on the Home icon. Click the

Next icon if the user wants to view the next explanation for the next parameter and click the bullet icon if the user wants to view the previous explanation for the previous parameter, as shown in Fig. 5(c).



Your probability to have GDM :

43%

You are displaying several of the signs of GDM. Improving your lifestyle may help reduce your risk. As this condition can be serious if left untreated, it is advisable that you make an appointment with your doctor for further discussion!

Total Risk Factors: 3

Risk Factors

First degree relative with diabetes

Experienced GDM in previous pregnancy

Experienced in bad obstetric history

Risk Factor 1
Body Mass Index (BMI)

Being overweight can predispose you to GDM, so having excess weight may take you more likely to have the condition. Conversely, unexplained weight loss can be a symptom of GDM too. This is because the body is unable to metabolise sugar and may start breaking down fat.

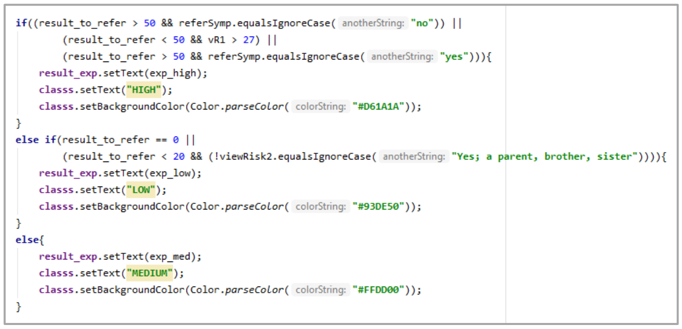
(a) (b) (c)

Fig. 5. Sample of result page where (a) represents percentage page, (b) represents risk factor and, (c) explanation page.

IV. Result and Discussion

In this section, the implementation of the rule for the first condition of the algorithm will be discussed first. There are seven parameters to be considered in the first condition. It consists of the risk factors of GDM. There is a body mass index of more than 27 kg/m2, previous history of GDM, first-degree relative with diabetes, history of macrosomia, bad obstetric history, developed glycosuria on two occasions, and any current obstetric problems. From all the answers submitted by the users with the most suitable current condition for the seven parameters mentioned above, the result of the probability of the users having GDM will be obtained. There are three classes of the probability of GDM, which are low, medium, and high. The rule to classify the probability of GDM is shown in Fig. 6.

Table III concludes the classification of the result based on the probability calculated and extra conditions considered for the result. To be classified in the low class of the probability of GDM, the result of the probability must be 0% or less than 20% and the second risk factor of GDM, which is the user's parent, brother or sister is experienced diabetes is false. However, to be classified in the medium class of the probability of GDM, the result of the probability must be more than 0% and less than 50%. Other than that, if the probability is more than 0% and less than 50%, and the second risk factor which is the user's parent, brother or sister are experienced diabetes is true, the user also will be classified in the medium class of chances to have GDM. Next, to be in the high class of the probability of GDM, the result of the probability must exceed 50%. In addition, if the user's BMI is more than 27 kg/m2, the user also will be classified in the high class of the probability of GDM.



```
if((result_to_refer > 50 && referSymp.equalsIgnoreCase( anotherString: "no")) ||
        (result_to_refer < 50 && vR1 > 27) ||
        (result_to_refer > 50 && referSymp.equalsIgnoreCase( anotherString: "yes"))){
    result_exp.setText(exp_high);
    classs.setText("HIGH");
    classs.setBackgroundColor(Color.parseColor( colorString: "#D61A1A"));
}
else if(result_to_refer == 0 ||
        (result_to_refer < 20 && (!viewRisk2.equalsIgnoreCase( anotherString: "Yes; a parent, brother, sister")))){
    result_exp.setText(exp_low);
    classs.setText("LOW");
    classs.setBackgroundColor(Color.parseColor( colorString: "#93DE50"));
}
else{
    result_exp.setText(exp_med);
    classs.setText("MEDIUM");
    classs.setBackgroundColor(Color.parseColor( colorString: "#FFDD00"));
}
```

Fig. 6. The rule to classify the probability.

TABLE III. Classification of Result based on the Probability Calculated and Extra Condition

Class	Probability	Extra condition
Low	0% Less than 20%	Risk 2 is false
Medium	More than 0% and less than 50% More than 0% and less than 50%	Risk 2 is true
High	More than 50% Any probability	Risk 1 is true

For the second condition of the algorithm, it will only be implemented if the result in the first condition, which is the result of the probability exceeds 50% and the users are currently pregnant. In this condition, the user will answer questions about the symptoms of GDM. There are 13 parameters to be considered. There are seven risk factors in the first condition and another five symptoms of GDM, which are polydipsia, polyuria, exhaustion, nausea, repeated vomiting, and blurred vision. The classification of the probability of the prevalence of GDM for the second condition is medium and high only. It is based on the probability calculated in which the 13 parameters are all considered. The user will have a medium class of probability if the result of the probability is more than 0% and less than 50%. The user also will have a medium class of probability of GDM if the probability is between 1% to 50% and the second risk factor which is the user's parent, brother or sister is experienced diabetes is true. And the high class of probability is if the result of the probability is exceeded 50% and the user's BMI is more than 27 kg/m2.

A. *Usability Testing*

Usability testing is the process of testing with a community of representative users on how simple a design of the system is to be used to ensure that the program is results-oriented, easy to use, reliable and easy to implement into the everyday life of the user. There are several usability assessments, and which survey is one of the usability tests to be used in this project. Target users who are consisted of pregnant women, married women, and the team of the Clinical Practice Guideline of the Ministry of Health Malaysia. The survey has been conducted via video conferencing with 10 respondents. The average total System Usability Scale score is 86.75.

The respondents need to answer on a scale from scale 1 to scale 5 in usability testing questions. Scale 1 refers to strongly disagree, scale 2 refers to disagree, scale 3 refers to neutral, scale 4 refers to agree, and scale 5 refers to strongly agree. From all the results of each question given in the SUS questionnaire to 10 respondents among the target user, Table IV shows the total score for each respondent that has been calculated based on the result of the SUS questionnaire. Questions 1, 3, 5, 7 and 9 are odd. Therefore, it needs to subtract by 1. For the even statements, questions 2, 4, 6, 8, and 10, will be subtracted from 5. Then, to get the result, all the scores that have been subtracted will sum up and multiply by 2.5. Based on Table IV and Fig. 7, the average SUS score obtained for the application is 86.75. From the result, it can be concluded that the application has good in terms of usability by achieving the average SUS score, which is more than 68 scores.

TABLE IV. TOTAL SCORE FOR 10 RESPONDENTS BASED ON SYSTEM USABILITY SCALE

Respondents	1	2	3	4	5	6	7	8	9	10
A total score of the application	82.5	100	85	90	62.5	100	80	85	87.5	95

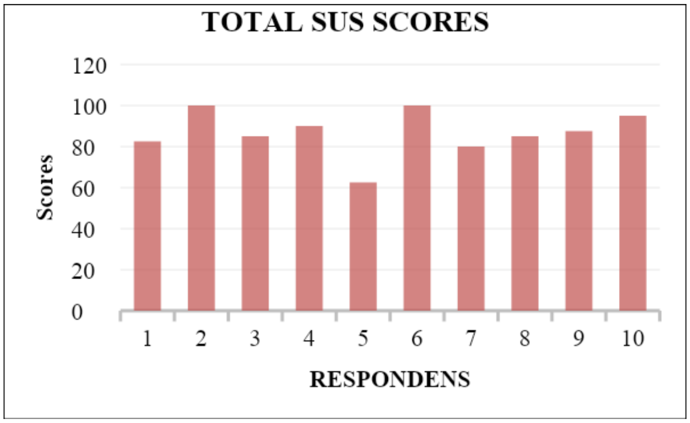


Fig. 7. Bar graph of total SUS scores.

V. CONCLUSION

A. Strengths and Limitations

The development of the system is basically to ease the user to have their current probability based on the risk factors and symptoms. With the detailed explanation provided, it also eases for the user to refer to the information, for future use without the need to refer to the hard copy of the clinical practice guideline. Due to the time constraint in collecting the information with the expertise, the application is only focused on one type of diabetes, which is GDM, known as diabetes in pregnancy. Thus, make this application data scope only GDM. As for that, the application does have only one main function, which is the function of the user to have their probability to have GDM. Furthermore, the application only supports the English language.

B. Conclusion and Future Research

To enhance the application's capabilities, future research is suggested to explore the implementation of various machine learning techniques. By comparing user data with existing cases of GDM that share similar risk factors and symptoms, the application's diagnostic accuracy and precision can be further improved.

While the GDM-PREP currently focuses on improving health outcomes related to Gestational Diabetes Mellitus, there is potential for expansion to handle extensive databases and diagnose a broader range of diseases. This adaptability allows the system to address multiple health conditions, increasing its overall impact and usefulness in healthcare settings.

This novel approach holds the potential to significantly enhance GDM screening and management strategies in Malaysia, thereby benefiting both healthcare professionals and pregnant individuals.

ACKNOWLEDGMENT

The authors wish to thank Universiti Teknologi MARA for supporting the completion of the research. The research is supported by Universiti Teknologi MARA (UITM) under Research Grant MYRA-PHD 2022/2.

Innovating Art with Augmented Reality: A New Dimension in Body Painting

Dou Lei , Wan Samiati Andriana W. Mohamad Daud
Faculty of Art and Design, Universiti Teknologi MARA | UiTM, Malaysia

***Abstract*—This study investigates the fusion of augmented reality (AR) and body painting as a novel concept for artistic expression. By combining the immersive capabilities of AR with the creative potential of body painting, this research explores individuals' perceptions and attitudes towards this innovative artistic approach from an HCI perspective. Drawing upon the Technology Acceptance Model (TAM) and the Diffusion of Innovation Theory (DIT), the study examines the factors influencing individuals' acceptance and intention to engage in AR-integrated body painting. Additionally, the research explores the mediating role of artistic expression in understanding the impact of these factors on the actual outcomes of this merged concept. A sample of 212 respondents participated in an online survey to accomplish the research objectives. The survey comprehensively measured participants' perceptions of innovativeness, social system support, perceived usefulness, perceived ease of use, artistic expression, and behavioral intention towards AR-integrated body painting. Rigorous data analysis was conducted using Partial Least Squares Structural Equation Modeling (PLS-SEM) to examine the intricate relationships between the variables. The findings underscore the significant impact of factors such as Innovativeness, social system support, perceived usefulness, and perceived ease of use on individuals' acceptance and intention to engage in AR-integrated body painting from an HCI perspective. Moreover, the study reveals the mediating role of artistic expression in connecting these influential factors with the actual outcomes of this merged concept. These empirical insights substantially contribute to our understanding of the fundamental mechanisms driving the adoption and utilization of AR in artistic practices, particularly within the domain of body painting, from both an artistic and HCI standpoint.**

Keywords—Augmented reality; body paintings; artistic expression; technology acceptance

I. Introduction

Our world has undergone a profound revolution driven by digital transformation, permeating every feature of our lives. As technology continues to integrate into various spheres, it has breathed new life into unexplored fields and disciplines beforehand. While technology is conventionally correlated with engineering and computer science, its potential impact on cultural studies, fine arts, and history-related disciplines has often been overlooked. However, within these realms, the intersection of technology and human expression holds immense promise. For instance, digital humanities and cultural preservation can significantly benefit from incorporating technology. Furthermore, recognizing the significance of human interaction with technology within the realms of fine arts and non-technological/non-scientific disciplines is crucial. Embracing technology in these contexts can unlock new avenues for creative exploration and foster deeper connections between art, culture, and society [1].

The art of body painting has long been an underrated phenomenon, often overlooked in its association with modern technology such as augmented reality. While body painting has a rich historical and cultural significance, its potential for innovation and exploration by integrating augmented reality remains largely undisclosed. By merging the traditional practice of body painting with cutting-edge technological advancements, such as augmented reality, new dimensions of artistic expression and transformative experiences can be unlocked. This uncharted territory offers a unique opportunity to bridge the gap between ancient art forms and contemporary technological advancements, allowing for a reimagining of body painting as a dynamic and immersive artistic medium. By shedding light on the untapped potential of this fusion, we can elevate body painting to a new level of appreciation and redefine its role in the context of modern art and technology.

Integrating Augmented Reality (AR) technology in body painting can potentially revolutionize the fine arts discipline. AR presents unique assistance, including virtual design visualization, interactive and dynamic art experiences, real-time feedback and corrections, digital preservation and documentation, and collaborative and remote opportunities [2], [3]. By overlaying virtual designs onto the body, artists can experiment with various concepts and styles before applying physical paint. AR augments engagement through interactive elements and visual effects, appealing to the audience and raising the impact of the artwork. Artists can receive immediate feedback, leading to precise and accurate designs. Furthermore, AR accelerates digital preservation and documentation, allowing archival and contextual information integration. Collaborative and remote experiences become possible, enabling artists to collaborate regardless of location and expanding the audience's access to body painting as an immersive and innovative art form.

While body painting as an artistic practice has received limited attention in research, the integration of augmented reality (AR) technology with body painting remains largely unexplored. Previous studies on body painting have mainly discussed its potential for teaching anatomy to health science students [4], [5] enhancing anatomical education through AR [6] and utilizing body painting for the teaching of anatomy and public engagement [7]. However, there is a scarcity of research specifically examining the integration of AR with body painting.

While discussions on the application of augmented reality (AR) technology are prevalent in various sectors, integrating AR with body painting is an underexplored area. Research has examined the effects of AR on students' achievement, attitudes towards the course, and participation in classroom activities [8], as well as its impact on body awareness and self-experience through virtual embodiment [9]. Augmented reality marketing has also been studied regarding its definition, complexity, and prospects [10]. Challenges and future research directions in education have been identified in augmented reality [11], and studies have investigated the impact of dimensionality and spatial abilities on learning with augmented reality [12]. Furthermore, AR technology has been applied to improve mirror fitness [13] and explore presence, avatar embodiment, and body perception [14]. Augmented reality has also been examined in the context of face filters as augmented reality art on social media [15], augmented reality art as a creative medium [3], and the motivations and effects of using AR face filters on social media [16]. Additionally, research has focused on the technological advancements and future perspectives of augmented reality and virtual reality displays [17], the development of augmented reality applications for learning [18], the survey of industrial augmented reality [2], and an overview of augmented reality technology [19]. Studies have also explored the impact of augmented reality applications on learning motivation [20] and the use of augmented reality and virtual reality in education [21]. Moreover, social interaction in augmented reality has been investigated [22]. While integrating body painting with augmented reality has received limited attention in research, studies have examined the enhancement of anatomical education through augmented reality [6] and the use of body painting and other art-based approaches to teach anatomy [23].

There is a pressing need for research to integrate augmented reality (AR) technology with body painting, as it can uncover the potential benefits and challenges of combining these two artistic practices, leading to innovative and immersive experiences for artists, performers, and viewers alike. Such research can contribute to advancements in art education, medical visualization, and interactive performance art. Additionally, investigating the integration of AR technology with body painting from a human-computer interaction (HCI) perspective is essential to shedding light on usability, user experience, and interactive aspects, providing insights into designing intuitive and engaging AR interfaces for artistic expression. Understanding the human factors involved in interacting with AR-enhanced body painting can enhance user satisfaction, immersion, and effectiveness, bridging the gap between art, technology, and human perception.

The integration of augmented reality (AR) technology with body painting can be studied using the Technology Acceptance Model (TAM) and the Diffusion of Innovation Theory (DIT) to understand users' behavioral intentions and perceptions towards this novel artistic medium [24]–[27]. These models provide insights into usability, user experience, perceived usefulness, perceived ease of use, and social influence, which are crucial in determining the acceptance and adoption of AR-enhanced body painting [28], [29]. By considering the findings from these studies, artists, performers, educators, and designers can optimize the design and development of intuitive and engaging AR interfaces for artistic expression while addressing users' concerns and promoting wider adoption [5], [30], [31].

The integration of augmented reality (AR) technology in the field of body painting poses both opportunities and challenges. While AR has gained significant attention in various domains such as entertainment, education, and healthcare, its application and impact within fine arts, particularly body painting, remains relatively unexplored. This research aims to address this gap and shed light on the factors that influence the adoption of AR in body painting and their effects on artistic expression and behavioral intention. This study explicitly explores AR technology's integration in body painting from an HCI perspective. It investigates the role of HCI principles in enhancing the usability, accessibility, and user satisfaction of AR applications in artistic practices. The research considers the viewpoints of both artists who adopt AR in their body painting techniques and the audience engaging with AR-enhanced artworks. By focusing on the HCI aspect, the study aims to provide insights into the design considerations, interaction patterns, and user-centered approaches that optimize the integration of AR technology in the context of body painting.

The significance of this research lies in its contribution to the understanding and application of HCI principles in the domain of AR-enhanced body painting. By exploring the factors that influence the adoption and usability of AR in artistic practices, this study can guide artists and designers in creating immersive and user-centred AR experiences. From an HCI perspective, the findings offer practical implications for interface design, interaction techniques, and user feedback mechanisms, enabling artists to leverage AR technology effectively. Furthermore, this research expands the body of knowledge on AR in the fine arts domain, particularly in the context of body painting. It fills a gap in the existing literature, which predominantly focuses on AR applications in other industries, such as entertainment and education. By integrating HCI principles, this study advances the theoretical and practical understanding of AR technology in body painting, contributing to the broader field of HCI research and artistic practices.

II. RELATED WORK

A. Augmented Reality and Body Painting

Traditionally, body painting was adept by indigenous cultures for various purposes, such as ceremonial rituals and visual communication [32]. Natural pigments sourced from plants, fruits, and minerals were used to decorate the body, with symbolic colours carrying cultural implications. These ancient techniques relied on the binding medium to adhere the pigments to the surface, creating a vibrant and meaningful art form. Modern body painting can be evolved to incorporate technology, such as AR, to create immersive and interactive experiences [33], [34]. AR integration in body paint allows artists to transcend traditional boundaries, introducing dynamic visual effects and virtual elements onto the human canvas [35]. This fusion of art and technology expands artistic possibilities, enhances viewer engagement, and bridges the gap between physical and digital realms. However, ethical considerations regarding privacy, consent, and cultural appropriation must be addressed when adopting AR in body painting practices.

Augmented Reality (AR) can transform the body painting domain within the fine arts discipline. By integrating AR technology, body painting can be taken to new elevations, proposing to artists and participants unique and enhanced experiences. Towards explaining the integration of technology application into fine arts, there are various implications in fine arts, such as:

1) AR enables artists to create and visualize intricate designs and patterns on the body without physically applying paint. Using AR applications, artists can project virtual designs onto the body, allowing experimentation and exploration of different artistic concepts and styles before committing to the painting process [36]. This virtual visualization capability saves time and resources while providing artists with broader creative possibilities.

2) AR can transmute body painting into an interactive and dynamic art form. Artists can use AR technology to overlay animated elements, visual effects, and interactive components onto the painted body [10]. This integration adds a new layer of engagement and interactivity, allowing viewers to interact with the artwork using their smartphones or other AR-enabled devices. The combination of body painting and AR creates a multisensory experience that captivates the audience and enhances the overall impact of the artwork [37].

3) AR technology can provide real-time feedback to artists during the body painting process. Through AR applications, artists can view digital overlays of their designs on the body, making identifying and correcting errors or inconsistencies easier [6]. This immediate feedback loop enables artists to refine their work and achieve greater precision and accuracy in their designs. It also facilitates a more efficient and streamlined painting process.

4) AR can play a significant role in digitally preserving body paintings. By capturing AR-enhanced images or videos of the painted body, artists can create digital archives of their work. These digital records serve as documentation and preservation, allowing the artwork to be experienced and appreciated beyond its temporary existence [38], [39]. Additionally, AR can overlay additional contextual information, such as the artist's inspiration, techniques, or cultural significance, providing a deeper understanding of the artwork.

5) AR opens up prospects for collaborative and remote body painting experiences. Artists can employ AR-enabled platforms to collaborate on body painting projects, regardless of their physical locations. They can stake designs, give feedback, and work together in real time, expanding the boundaries of artistic collaboration. Additionally, viewers can remotely access AR experiences of body paintings, creating opportunities for a wider audience to engage with and appreciate the artwork [8], [10], [13], [19].

Integrating AR technology into body painting within the orbit of fine arts elevates the creative process and unlocks novel channels for expression, engagement, and innovation. Embracing this technology empowers artists to push the limits of body painting, crafting immersive, interactive, and visually mesmerizing experiences that redefine the boundaries of the art form [13], [15], [17], [19].

B. Artistic Expression of Body Painting (AE)

The literature review conducted for body painting as an artistic expression within the positive art framework highlights five consistent positive outcomes across all the aforementioned art forms: sense-making, enriching experience, aesthetic appreciation, entertainment, and bonding. These outcomes emphasize the potential of body painting as a powerful vehicle for individuals to find meaning and purpose, enhance their overall experiences, develop a deeper appreciation for aesthetics, derive entertainment, and establish social connections. In supporting the relevance of body painting within the positive art framework, the article draws on a range of scholarly references. Lomas [40] discusses the concept of positive art and the potential for artistic expression and appreciation to foster flourishing. Javornik et al. [16] explore the motivations and well-being effects of using augmented reality (AR) face filters on social media, which can be considered an extension of body painting. Geroimenko [3] and Hsu and Chin [34] shed light on the emergence of augmented reality as a creative medium in art, including body painting.

The discussion surrounding body painting as a form of positive art also incorporates studies from education and medical sciences. Diaz and Woolley [4], Finn [41], Ribelles-García et al. [5] , and Wang et al. [42] explore the pedagogical aspects of body painting in teaching anatomy and enhancing learning experiences. Haugstvedt and Krogstie [43], Vovk et al. [43], Rese et al. [44], and Iqbal and Sidhu [27] studies foster the understanding of technology acceptance, including augmented reality, in various contexts.

C. Diffusion of Innovation Theory (DIT)

The Diffusion of Innovation Theory (DIT), explained by Everett Rogers, approaches a valuable framework for interpreting the adoption and dissemination of innovative ideas, products, and technologies from a social perspective [45]. DIT defines diffusion as the process through which innovations are communicated and embraced by members of a social system over time. It identifies critical factors that impact the speed and extent of adoption, encompassing the innovation's attributes, the characteristics of adopters, the communication channels utilized, the social system involved, and the temporal aspect of the adoption process [46], [47]. By shedding light on adoption stages, adopter types, and influential factors, DIT facilitates comprehension and prediction of innovation acceptance and utilization across diverse domains such as technology, healthcare, and social sciences [48]. In augmented reality (AR) integration with body paintings, DIT helps understand how artists and viewers embrace this innovative artistic practice [49]. Innovators are the first to adopt AR-enhanced body paintings, followed by early adopters who recognize its creative potential. The early majority adopts it based on positive experiences, while the late majority joins once it becomes well-established. Laggards are the last to adopt, often due to resistance to change or scepticism [50]. Understanding DIT can inform strategies for promoting the acceptance and diffusion of AR-enhanced body paintings [51].

D. Technology Acceptance Model (TAM)

The Technology Acceptance Model (TAM) is a widely recognized and validated model for understanding technology integration. It focuses on users' behavioral intentions to adopt technology based on its perceived usefulness and ease of use. Davis initially developed TAM in 1986 to explore the acceptance of novel technologies in workplace settings [52]. By examining individuals' attitudes and perceptions, TAM provides insights into the factors influencing technology adoption and usage, aiding in designing and implementing effective technology solutions [53]. TAM can be applied to understand the acceptance of body painting through augmented reality (AR) technology. By examining users' perceptions of the usefulness and ease of use of AR-enhanced body painting, TAM can provide insights into their behavioral intentions to adopt and engage with this novel artistic medium [42]. Factors such as the perceived benefits, convenience, and user experience of AR-enhanced body painting can be explored within the TAM framework to understand and predict the acceptance and utilization of this technology-driven artistic expression [29]. This understanding can inform the design and development of user-centric AR interfaces and promote wider adoption of AR-enhanced body painting in the artistic community [26].

E. Hypothesis Development

Numerous hypotheses are developed by contemplating the literature and related studies along with the aim of this research. These hypotheses are then validated by multivariate statistical analysis.

1) Perceived Ease of Use: Perceived ease of use (PEOU) is a crucial factor in influencing artists' artistic expression (AE) of body painting when considering the adoption of AR technology. Artists who perceive AR as easy to use and navigate are likelier to embrace this technology in their body painting practices [30]. The user-friendly nature of AR facilitates artists' interaction with the technology and enables them to explore its potential for enhancing their artistic expression. When artists perceive AR as easy to use, they are more motivated to incorporate it into their body painting techniques and leverage its capabilities to create visually captivating and interactive artworks [26], [30]. Additionally, perceived ease of use (PEOU) impacts artists' behavioral intention (BI) through the mediator of artistic expression (AE). When artists find AR technology easy to use and navigate, it positively influences their intention to adopt AR for body painting. The ease of use associated with AR enhances artists' confidence in utilizing the technology and encourages them to explore its possibilities for artistic expression [27], [37], [42]. As artists experience the ease of incorporating AR into their body painting practices and witness the positive impact on their artistic expression, their behavioral intention to adopt AR technology strengthens. Therefore, the following hypotheses are being proposed:

H1: PEOU positively impacts the AE to adopt AR technology.

H1a: PEOU positively impacts the BI through AE to adopt AR technology.

2) Perceived usefulness: Perceived usefulness (PU) plays a vital role in shaping artists' artistic expression (AE) of body painting when considering the adoption of AR technology. Artists who perceive AR as helpful in enhancing their creative process and expanding the possibilities of artistic expression are likelier to embrace this technology [26]. Incorporating AR into body painting offers a range of features and functionalities that enhance artists' ability to create visually captivating and interactive artworks. As artists recognize the usefulness of AR in enriching their artistic expression, they are motivated to explore its potential and incorporate it into their body painting practices. Furthermore, perceived usefulness (PU) impacts artists' behavioral intention (BI) through the mediator of artistic expression (AE). When artists perceive AR as a valuable tool for enhancing their artistic expression, it positively influences their intention to adopt AR for body painting [29], [31]. The perceived usefulness of AR in body painting fuels artists' motivation to explore and experiment with this technology, leading to greater engagement and a stronger intention to incorporate it into their artistic practice. As artists witness the positive impact of AR on their artistic expression, their behavioral intention to adopt AR technology for body painting increases [24], [42]. Therefore, following hypotheses are being proposed:

H2: PU positively impacts the AE to adopt AR technology.

H2a: PU positively impacts the BI through AE to adopt AR technology.

3) Social systems: The social system (SS) can significantly influence the artistic expression (AE) of body painting and the adoption of AR technology. Within the social system, artists are influenced by various factors such as societal norms, cultural values, and peer interactions. The acceptance and support of the social system towards body painting as an art form can positively impact artists' willingness to explore innovative technologies like AR for their artistic expression [15], [25]. Artists feel encouraged and empowered to incorporate AR technology into their practices when the social system embraces body painting as a legitimate artistic expression. The acceptance and recognition of body painting within the social system motivate artists to experiment with AR and explore its potential for enhancing their artistic expression. Moreover, the social system provides a platform for artists to showcase their AR-enhanced body paintings, which can further influence the adoption and acceptance of AR technology within the artistic community [25], [28]. Furthermore, the social system influences artists' behavioral intention (BI) through the mediator of artistic expression

(AE). Artists who receive support and recognition from the social system for their body painting endeavours, especially when augmented by AR, are more likely to develop a stronger intention to adopt AR technology. The positive response from the social system reinforces artists' belief in the value and significance of incorporating AR into their body painting practices. The social system's acceptance and appreciation of AR-enhanced body painting contribute to artists' confidence in embracing this technology and their intention to use it for future artistic endeavors [49], [51]. Therefore following hypotheses are being proposed:

H3: SS positively impacts the AE to adopt AR technology.

H3a: SS positively impacts the BI through AE to adopt AR technology.

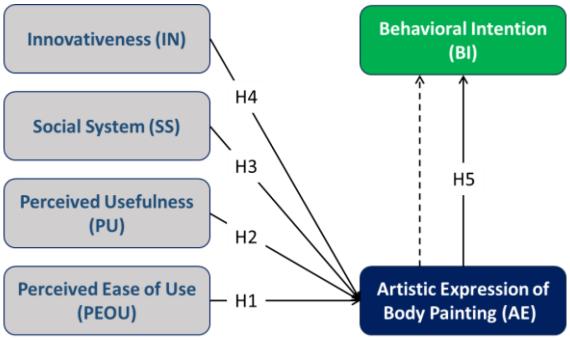
4) Innovativeness: The relationship between the Innovativeness of individuals and the artistic expression of body painting (AE) can be explored through the Innovation Diffusion Theory (IDT) lens. According to IDT, Innovativeness refers to the willingness and eagerness of individuals to adopt new ideas or technologies [47]. In the context of AE, individuals with a high level of Innovativeness are likelier to embrace and experiment with novel approaches, techniques, and mediums in their body painting practices. They are open to integrating augmented reality (AR) technology with body painting, leveraging its capabilities to enhance and expand their artistic expression. By keeping such an analogy, AE can instigate the adoption of AR as a mediator between the Innovativeness of personality and Behavioral Intention to adopt (BI) the AR technology for body painting [9], [13], [17]. Therefore two hypotheses for Innovativeness are developed. These hypotheses can be formulated as follows:

H4: Innovativeness positively impacts the AE to adopt AR technology.

H4a: Innovativeness positively impacts the BI through AE to adopt AR technology.

F. Conceptual Framework

Based on the proposed hypotheses, a conceptual framework is established, in Fig. 1, to understand the adoption of AR technology for body paint purpose to fortify the fine arts discipline into digital transformational tools.



Innovativeness (IN)
Social System (SS)
Perceived Usefulness (PU)
Perceived Ease of Use (PEOU)
Behavioral Intention (BI)
Artistic Expression of Body Painting (AE)

III. Methodology

This study ensued a deductive approach within the research onion framework utilized by Saunders [54]. It adopted a cross-sectional design and employed quantitative research methods to investigate the phenomenon under examination. The deductive approach was employed in this study, which involved testing existing theories of TAM and IDT and hypotheses to draw conclusions. By employing a deductive approach, the study aimed to explore the relationships between variables identified in the theoretical framework, namely the perceived usefulness, perceived ease of use, Innovativeness, social system, and behavioral intention in the context of digital body painting and augmented reality (AR) for artistic expression in Yunnan.

A cross-sectional design was adopted, enabling data to be collected at a single point in time. This design allowed for the examination of relationships between variables. It provided a snapshot of individuals' attitudes, perceptions, and behavioral intentions regarding using digital body painting and AR for artistic expression in Yunnan. The cross-sectional design was suitable for investigating the interplay between the independent variables (perceived usefulness, perceived ease of use, Innovativeness, social system) and the dependent variable (behavioral intention) within a specific time frame. A non-probability sampling technique called snowball sampling was employed in this study. Initially, several participants with relevant knowledge and experience in digital body painting and AR were purposively selected. These participants were asked to refer to other potential participants who met the criteria. This iterative process continued until the desired sample size of 212 participants was reached, as suggested by the previous research [55].

Data were collected through an online self-administered close-ended questionnaire. The questionnaire consisted of two parts: demographic features and variables questions. The demographic section collected participants' age, gender, educational background, and artistic experience. The variables questions assessed perceived usefulness, perceived ease of use, Innovativeness, social system, and behavioral intention using a 5-point Likert scale (ranging from 1=strongly disagree to 5=strongly agree). Each variable's questionnaire items were adopted from previously validated studies to make the inferences significant and robust.

The collected data were subjected to statistical analysis using appropriate techniques. Quantitative analysis was conducted using Partial Least Squares Structural Equation Modeling (PLS-SEM). This method allowed for assessing both the measurement and structural models, enabling the examination of relationships between variables. Additionally, PLS-predict analysis was conducted to understand the model's predictive power and relevance in predicting behavioral intention based on the assessed variables [56]–[58]. Ethical guidelines and principles were followed throughout the study. Informed consent was obtained from all participants, ensuring their voluntary participation and the confidentiality of their responses. The study adhered to ethical standards to protect the participants' rights and well-being and ensure the research findings' integrity and credibility.

IV. Data Analysis

A. Demographic Results

Demographic results are detailed in the following Table I.

TABLE I. DEMOGRAPHIC RESULTS

Category	Percentage	Category	Percentage
Gender		Exposure to AR Technology	
Male	72%	Yes	54%
Female	28%	No	46%
Age Group		Education	
18-25	38%	High School	27%
26-35	45%	Bachelor's Degree	48%
36-45	17%	Master's Degree	25%
Experience in Body Painting			
Well Aware		62%	
Minimum		38%	

B. Reliability and Validity

The minimum accepted standards for reliability measures in PLS-SEM analysis include a Cronbach's alpha of 0.7, composite reliability of 0.7 or higher, and average variance extracted (AVE) of 0.5 or higher [59]. In this study, all the constructs meet or exceed these minimum standards, indicating good reliability. As per the result Table II, Cronbach's alpha values range from 0.912 to 0.969, composite reliability ranges from 0.921 to 0.976, and AVE ranges from 0.7 to 0.889. These results suggest that the measurement scales used for each construct are internally consistent and reliable, providing confidence in the validity of the research findings.

TABLE II. RELIABILITY AND VALIDITY

Factors	Cronbach's Alpha	Composite Reliability	Average Variance Extracted (AVE)
Artistic Expression	0.92	0.94	0.70
Behavioral Intention	0.96	0.97	0.889
Innovativeness	0.91	0.94	0.782
Perceived Ease of Use	0.82	0.92	0.7
Perceived Usefulness	0.91	0.92	0.728
Social System	0.91	0.93	0.712

C. Discriminant Validity

Discriminant validity is assessed using the Heterotrait-Monotrait (HTMT) ratio of correlations in PLS-SEM analysis. The HTMT values should be below the threshold of 0.85 to confirm discriminant validity [59]. As per the results, all the HTMT values are below this threshold, indicating satisfactory discriminant validity among the constructs. It suggests that the constructs are distinct and measure different aspects of the research variables. In Table III, the values range from 0.162 to 0.754, demonstrating no significant overlap between the constructs, supporting the validity of the measurement model.

TABLE III. DISCRIMINANT VALIDITY (HTMT)

	AE	BI	IN	PEOU	PU	SS
AE						
BI	0.754					
IN	0.402	0.415				
PEOU	0.573	0.522	0.217			
PU	0.541	0.415	0.254	0.281		
SS	0.347	0.419	0.162	0.143	0.187	

D. Outer Loadings

In PLS-SEM analysis, it is generally accepted that outer loadings should be at least 0.7 to 0.8 to demonstrate a strong relationship between latent constructs and their indicators [60]. In this study, see Table IV, all the outer loadings surpass the minimum accepted value, indicating that the research meets this criterion. It confirms that the selected indicators successfully capture and represent the underlying constructs, enhancing the validity and reliability of the research outcomes.

TABLE IV. OUTER LOADINGS

Factor	Item	O.L	Factor	Item	O.L
Innovativeness	IN1	0.927	Perceived Ease of Use	PEOU1	0.881
	IN2	0.731		PEOU2	0.816
	IN3	0.857		PEOU3	0.912
	IN4	0.812		PEOU4	0.871
	IN5	0.782		PEOU5	0.932
Social System	SS1	0.909	Artistic Expression	AE1	0.915
	SS2	0.819		AE2	0.824
	SS3	0.811		AE3	0.919
	SS4	0.86		AE4	0.783
	SS5	0.825		AE5	0.912
Perceived Usefulness	PU1	0.917	Behavioral Intention	BI1	0.906
	PU2	0.815		BI2	0.931
	PU3	0.813		BI3	0.887
	PU4	0.835		BI4	0.865
	PU5	0.857			

E. Path Analysis

Based on the structural model, the path analysis shows that all the hypotheses' t-statistics and p-values are accepted, as shown in Table V. It implies a significant relationship between the independent variables (Innovativeness, Social System, Perceived Usefulness, and Perceived Ease of Use) and the dependent (Artistic Expression and Behavioral Intention) variables. The betas associated with each hypothesis represent the strength and direction of the relationships. The overall R-squared value of the model is 0.513, as portrayed in Fig. 2.

TABLE V. PATH ANALYSIS

Hypothesis		Beta	T Stat	P	Decision
H1	IN -> AE	0.201	5.156	0.000	Accepted
H1a	IN -> AE -> BI	0.144	4.751	0.000	Accepted
H2	SS -> AE	0.177	4.755	0.000	Accepted
H2a	SS -> AE -> BI	0.127	4.473	0.000	Accepted
H3	PU -> AE	0.333	6.221	0.000	Accepted
H3a	PU -> AE -> BI	0.238	6.292	0.000	Accepted
H4	PEOU -> AE	0.379	9.239	0.000	Accepted
H4a	PEOU -> AE -> BI	0.272	7.581	0.000	Accepted
H5	AE -> BI	0.716	19.309	0.000	Accepted

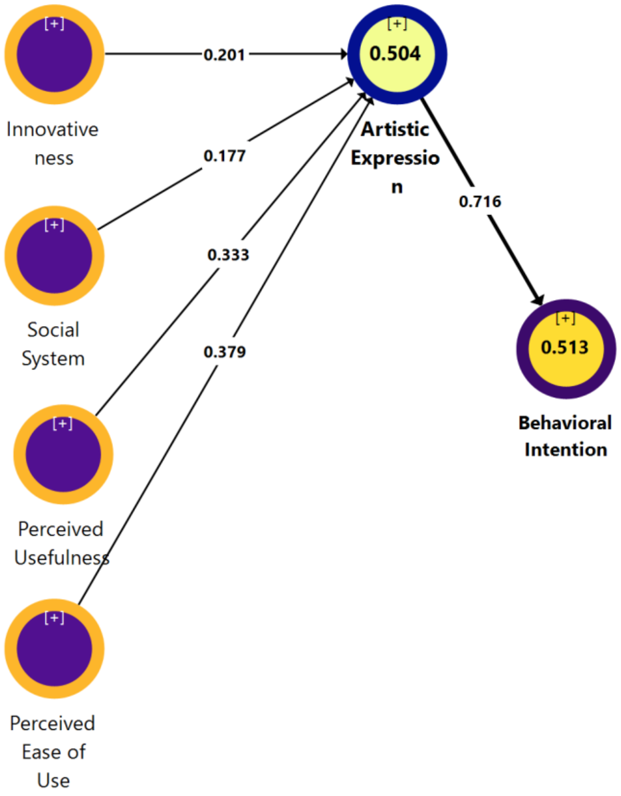

Fig. 2. PLS-SEM model.

V. HYPOTHESIS RESULTS

The results of hypothesis H1 indicate that there is a significant positive relationship between Innovativeness and artistic expression in the context of AR technology for body painting. The beta coefficient of 0.201 suggests that higher levels of Innovativeness among artists lead to increased artistic expression in body painting. This finding is supported by a high T statistic of 5.156 and a p-value of 0.000, indicating a strong level of confidence in the results. Therefore, we can conclude that Innovativeness positively influences artistic expression in the context of AR technology for body painting. Additionally, hypothesis H1a examines the relationship between Innovativeness, artistic expression, and behavioral intention. The results show a significant positive relationship, with a beta coefficient of 0.144, a T statistic of 4.751, and a p-value of 0.000. It indicates that as artists demonstrate higher levels of Innovativeness and engage in more artistic expression through AR technology for body painting, their behavioral intention to adopt and continue using this technology also increases. These findings support the notion that Innovativeness and artistic expression play crucial roles in shaping artists' behavioral intention to embrace AR technology for body painting.

The results of hypothesis H2 suggest a significant positive relationship between the social system and artistic expression in the context of AR technology for body painting. The beta coefficient of 0.177 indicates that a supportive social system positively influences artistic expression. With a T statistic of 4.755 and a p-value of 0.000, the results provide strong evidence to accept this hypothesis. Therefore, it can be concluded that a favourable social system characterized by societal norms, cultural values, and peer interactions contributes to enhanced artistic expression in the context of AR technology for body painting. Likewise, hypothesis H2a examines the relationship between the social system, artistic expression, and behavioral intention. The results indicate a significant positive relationship, evidenced by a beta coefficient of 0.127, a T statistic of 4.473, and a p-value of 0.000. It suggests that when artists experience a supportive social system that encourages and recognizes their artistic expression through AR technology for body painting, it positively influences their behavioral intention to adopt and continue using it. These findings emphasize the importance of a supportive social environment in fostering artistic expression and the intention to adopt innovative technologies in body painting.

The results of hypothesis H3 indicate a significant positive relationship between perceived usefulness and artistic expression in the context of AR technology for body painting. The beta coefficient of 0.333, a T statistic of 6.221, and a p-value of 0.000 provide strong evidence to accept this hypothesis. It suggests that when individuals perceive AR technology as beneficial for their body painting practices, it positively influences their artistic expression. This finding emphasizes the importance of perceiving the usefulness of AR technology in enhancing the creative process and expression within the field of body painting. Building upon H3, hypothesis H3a explores the relationship between perceived usefulness, artistic expression, and behavioral intention. The results indicate a significant positive relationship, with a beta coefficient of 0.238, a T statistic of 6.292, and a p-value of 0.000. It suggests that when artists perceive AR technology as valuable for their artistic expression in body painting, it impacts their artistic expression and positively influences their behavioral intention to adopt and continue using it. These findings highlight the role of perceived usefulness as a driver of artistic expression and the intention to adopt AR technology in body painting [50].

Similarly, hypothesis H4 examines the relationship between perceived ease of use and artistic expression. The results demonstrate a significant positive relationship, as indicated by a beta coefficient of 0.379, a T statistic of 9.239, and a p-value of 0.000. It suggests that when individuals perceive AR technology as easy to use for body painting, it positively influences their artistic expression. This finding underscores the importance of perceiving the ease of use of AR technology in facilitating and enhancing artistic expression in body painting. Expanding on H4, hypothesis H4a investigates the relationship between perceived ease of use, artistic expression, and behavioral intention. The results reveal a significant positive relationship, with a beta coefficient of 0.272, a T statistic of 7.581, and a p-value of 0.000. It implies that when artists perceive AR technology as easy to use for their artistic expression in body painting, it impacts their artistic expression and positively influences their behavioral intention to adopt and continue using it. These conclusions highlight the role of perceived ease of use in promoting artistic expression and the intention to adopt AR technology in body painting [42].

Hypothesis H5 explores the relationship between artistic expression and behavioral intention. The results indicate a highly significant and robust positive relationship, with a beta coefficient of 0.716, a T statistic of 19.309, and a p-value of 0.000. These findings provide strong evidence to accept the hypothesis, suggesting that artistic expression in the context of body painting has a substantial impact on individuals' behavioral intention. Specifically, when individuals engage in artistic expression through body painting, it positively influences their intention to adopt and continue using AR technology. It highlights artistic expression's pivotal role as a behavioural intention driver in adopting and utilizing AR technology for body painting [38].

VI. Discussion

This study aimed to investigate the factors influencing the adoption of augmented reality (AR) technology in body painting and to understand their impact on artistic expression and behavioral intention. A comprehensive analysis was conducted using partial least squares structural equation modelling (PLS-SEM) to achieve this. The results revealed that the proposed model accounted for a substantial proportion of artistic expression and behavioral intention variance. The R-squared values for artistic expression were 0.504 and 0.499 for the regular and adjusted models. Similarly, the R-squared values for behavioural intention were 0.513 and 0.512 for the regular and adjusted models, respectively. These R-squared values indicate that the model explains a significant portion of the variability observed in the dependent variables.

Through examining various hypotheses, several valuable lessons have been learned from the results of this study. Firstly, it is evident that factors such as Innovativeness, social system support, perceived usefulness, and perceived ease of use significantly influence artistic expression and behavioral intention. It highlights the importance of considering these factors when integrating augmented reality (AR) technology into body painting. Furthermore, the positive impact of AR technology on artistic expression and behavioral intention underscores its potential as a powerful tool for artists to enhance their creative processes and engage with their audience. The findings emphasize the significance of embracing technological advancements in the arts and utilizing AR to captivate viewers and create immersive artistic experiences.

Moreover, accepting the hypotheses provides empirical evidence supporting the adoption of AR in the fine arts industry. It suggests that AR has the potential to drive innovation within the industry, offering unique opportunities for artists, galleries, and exhibition spaces to differentiate themselves and attract audiences by leveraging the immersive and interactive nature of AR. Likewise, the results indicate that integrating AR technology in body painting opens up collaboration opportunities between artists and technology experts. It underscores the importance of interdisciplinary collaborations, where artists can collaborate with AR developers, programmers, and designers to explore new creative possibilities and push the boundaries of artistic expression.

The research findings make significant contributions both theoretically and practically.

A. Theoretical Contribution

This study contributes to the theoretical landscape by utilizing Roger's Innovation-Decision Process Theory as a guiding framework. By applying this theory, the research provides a comprehensive and structured approach to understanding AR technology's innovation process in body painting. This theoretical foundation enhances our understanding of the underlying mechanisms that shape the acceptance, adoption, and utilization of AR in artistic expression. Moreover, the study extends the theoretical discourse by highlighting the significant role of artistic expression as a mediator between the adoption of AR technology and behavioral intention. This finding emphasizes the importance of artistic expression as a critical factor in determining artists' intention to adopt and use AR technology in their creative endeavours. By contributing to the theoretical understanding of AR adoption in fine arts, this study fills a gap in the existing literature, which has predominantly focused on the medical, entertainment, aviation, and educational applications of AR. It expands the theoretical boundaries and provides insights into the unique dynamics and implications of incorporating AR technology in the artistic domain.

B. Practical Contribution

Based on the study's findings, the research makes several practical contributions. It guides artists looking to incorporate augmented reality (AR) technology into their body painting practices. It offers insights into factors such as Innovativeness, social system support, perceived usefulness, and perceived ease of use. This knowledge can help artists make informed decisions and leverage AR to enhance their artistic expression. Additionally, integrating AR technology in body painting enhances audience engagement by creating interactive and immersive experiences. This practical contribution allows artists to captivate viewers in novel ways, allowing active participation in the artwork and creating memorable artistic encounters.

The research findings also have implications for art education, suggesting the inclusion of AR in curricula. By recognizing the significance of AR in fine arts, educational programs can prepare students for the evolving art industry and foster their innovative thinking. Moreover, the study highlights the potential of AR technology to drive industry innovations within the fine arts sector. Artists, galleries, and exhibition spaces can leverage AR to differentiate themselves, attract audiences, and offer unique and immersive experiences. Lastly, the adoption of AR in body painting opens up collaboration opportunities between artists and technology experts. This practical contribution encourages interdisciplinary collaborations, leading to innovative projects and the development of cutting-edge artworks that push the boundaries of artistic expression.

This study aims to contribute to understanding the fusion of augmented reality and body painting as an innovative concept for artistic expression. By examining the factors influencing individuals' acceptance and intention to engage in AR-integrated body painting, the research offers insights for researchers and practitioners in digital art. The findings will extend the existing literature on technology adoption and diffusion by shedding light on the role of perceived usefulness, ease of use, Innovativeness, and social factors in the context of this merged concept. Moreover, the mediating role of artistic expression emphasizes the importance of considering the creative outcomes when exploring the adoption and use of AR-integrated body painting.

C. *Limitations of the Study*

Despite its contributions, this research has certain limitations that should be acknowledged. Firstly, the study focused on a specific context of body painting, which may limit the generalizability of the findings to other artistic domains. Future research could explore the application of AR in different forms of visual arts to provide a more comprehensive understanding. Additionally, the study relied on self-reported measures, subject to response biases and may not capture the full complexity of participants' experiences. Using objective measures or combining self-reports with observational data could enhance the validity of the findings. Furthermore, the research primarily examined the perspectives of artists and audience members, neglecting other stakeholders such as AR developers and technicians. Future studies could incorporate the viewpoints of these stakeholders to gain a holistic understanding of the challenges and opportunities in AR implementation.

D. *Future Directions*

Building upon the findings of this study, several avenues for future research can be identified. Firstly, longitudinal studies could investigate the long-term effects of AR integration in body painting and its impact on artists' creative processes, audience engagement, and market sustainability. Additionally, exploring the cultural and societal influences on the adoption and acceptance of AR in fine arts could provide valuable insights into the cross-cultural applicability of the technology. Furthermore, investigating the potential ethical and privacy concerns associated with AR in artistic practices would be relevant in ensuring responsible and inclusive implementation. Additionally, examining the role of different types of AR interfaces, such as wearable devices or projection-based systems, could shed light on the user experience and interaction design aspects. Finally, studying the integration of AR with other emerging technologies, such as artificial intelligence or virtual reality, could open up new dimensions for artistic expression.

VII. Conclusion

In conclusion, this research has significantly contributed to understanding and applying augmented reality (AR) technology within body painting from an HCI and digital technology perspective. By examining the relationships between various factors and their impact on artistic expression and behavioral intention, valuable insights have been gained into the usability, user experience, and practical implications of AR in this context. Theoretical contributions have been made by establishing the importance of factors such as Innovativeness, social system support, perceived usefulness, and perceived ease of use in driving the integration of AR technology in body painting while considering the principles of HCI and digital technology. These findings enrich our understanding of the underlying mechanisms that influence the adoption and utilization of AR in artistic practices, taking into account human-computer interaction, interface design, and user-centred approaches.

Practically, this research offers guidance for artists seeking to incorporate AR technology into their body painting endeavours from an HCI and digital technology perspective. By understanding the positive influence of the identified factors and considering HCI principles, artists can make informed decisions and strategically leverage AR to enhance their artistic expression in a user-friendly and immersive manner. Moreover, integrating AR technology provides an avenue for enhanced audience engagement, allowing artists to create interactive and immersive experiences that captivate viewers and foster a deeper connection with the artwork. From an educational standpoint, the implications are noteworthy as well. This research emphasizes the significance of integrating AR into educational programs, leveraging HCI and digital technology to equip students with the skills and knowledge to navigate the evolving landscape of the art industry. By incorporating AR as a tool for artistic exploration, art educators can foster innovative thinking and prepare students for the future by embracing technological advancements and user-centred design principles.

From an industry perspective, the findings underscore the potential for AR to drive innovation within the fine arts industry, with a particular focus on HCI and digital technology. Artists, galleries, and exhibition spaces can leverage AR to offer unique and immersive experiences, attracting audiences and distinguishing themselves in a competitive landscape. This encourages industry professionals to embrace AR as a means of differentiation, considering HCI and digital technology principles and staying at the forefront of artistic advancements. Lastly, the research highlights the collaboration opportunities that arise from integrating AR in body painting, emphasizing the interdisciplinary nature of HCI and digital technology. Artists can collaborate with technology experts to explore new creative possibilities, harnessing the power of AR to push the boundaries of artistic expression and foster innovative projects. Such collaborations bridge the gap between art and technology, developing cutting-edge artworks and opening up new realms of artistic exploration and digital creativity.

The Essence of Software Engineering Framework-based Model for an Agile Software Development Method

Teguh Raharjo[1], Betty Purwandari[2], Eko K. Budiardjo[3], Rina Yuniarti[4]
Faculty of Computer Science, Universitas Indonesia, Depok, Indonesia[1, 2, 3, 4]

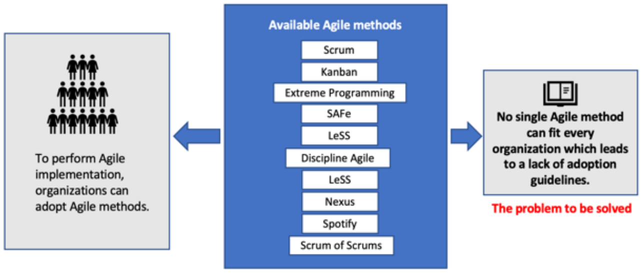
***Abstract*—Agile development's rapid growth is due to its ability to address complex problems and facilitate a smooth transition from traditional methods. However, no single Agile method can fit every organization, which leads to a lack of adoption guidelines. It triggers this investigation by proposing an Agile development method model based on the Essence of software engineering framework and incorporating the common ground of popular methods such as Scrum, Kanban, Extreme programming, SAFe, Less, Nexus, Spotify Agile, Scrum of Scrums, and Disciplined Agile. The Essence of software engineering framework provides an approach for organizations to develop software development methods based on common ground or shared understanding among methods. We enhance this approach for Agile methods, resulting in a model to support organizations in developing their Agile methods and practices. Moreover, Design Science Research (DSR) was employed as a methodology to construct the artifact, demonstration, and evaluation. We demonstrated the model in an Agile product development at a national-wide bank in Indonesia. This investigation enhances Agile methods in SWEBOK's Software Engineering Models and Methods knowledge area, benefiting academics and practitioners. Practitioners can use the model as a reference to implement their Agile projects.**

Keywords*—Agile; common ground; the essence of software engineering framework; Design Science Research (DSR)

I. INTRODUCTION

At present, the development of the Agile approach is very rapid in organizations [1]. This approach has a significant influence on the growth of businesses and the performance of projects, enabling them to tackle complex problems in an era of rapid disruptions [2]. The concept of Agile innovation teams, aimed at maintaining proximity to customers and swiftly adapting to evolving business conditions, is already well-known to most management levels [3]. Moreover, a captivating study conducted across multiple organizations revealed that companies that cultivate an adaptive Agile culture witnessed revenue growth exceeding the pace multiple times [4]. Therefore, the Agile approach must be scaled up at the enterprise level to handle multiple teams and projects. While organizations are transitioning to Agile, they are also looking to scale up [5]. The scaling approach provides value and benefits to the business operations and supports [6].

The organization could adopt the Agile methods to perform Agile implementation. Although several Agile methods offer the solutions, such as Scrum, Kanban, Extreme programming, SAFe, LeSS, Disciplice Agile, Nexus, and Spotify Agile, no single Agile method can fit every organization [7], which leads to a lack of adoption guidelines. To the best of our knowledge, there is no common ground or shared understanding of the Agile methods or the guideline for the organization to adopt the methods, as shown in Fig. 1. This is the problem we need to solve.



To perform Agile implementation, organizations can adopt Agile methods.
Available Agile methods
Scrum
Kanban
Extreme Programming
SAFe
LeSS
Discipline Agile
LeSS
Nexus
Spotify
Scrum of Scrums
No single Agile method can fit every organization which leads to a lack of adoption guidelines.
The problem to be solved

Fig. 1. The problem needs to be solved

No studies currently explore a model for Agile methods in organizations. The Essence provides a common ground for all methods in software engineering [8]. It offers a thinking framework for the team to collaborate; resources for discussing, improving, comparing, and sharing methods and practices; a foundation for defining practices independent of methods.

This research aims to develop a model for an Agile method development based on selected practices, drawing from the Essence framework. The intended scope of this Agile method is up to scaling Agile, as it already encompasses the Agile method within it. This study serves as an academic reference for Agile methods. From the practitioners' perspective, the results can guide the organization to apply the scaling Agile methods. Additionally, the model can be integrated with the hybrid agile management approach [9], and DevOps [10] for organizations seeking a hybrid implementation. These contributions make this study unique.

The remaining sections of this article are structured in the following manner: Following this introduction, the subsequent section offers a brief overview of the related work, covering concepts such as the common ground concept, scaling Agile methods, and the Essence framework. Section III explores the research methodology employed, specifically focusing on design science research. Moving on, Section IV presents the study's findings, which is resulting in the model, namely an Essence-based Agile method development model. Subsequently, in Section V, we present the case study of the software development organization in one bank in Indonesia. Section VI explains the evaluation of our research, respectively. Lastly, Section VII is the concluding section provides a summary and closure to the paper.

II. Related Work

This section discusses related work. First, we review the concept of common ground based on the Essence of software engineering as the reference for this study. Then, we explore the current scaling Agile methods, such as SAFe, LeSS, Nexus, Disciplined Agile, Spotify Agile, and Scrum of Scrums. We focus on the scaling methods, including the individual Agile methods, such as Scrum, Kanban, and Extreme Programming. We only select the most popular scaling Agile methods based on a survey as the main comparison [5, 11]. The other methods will fill the gaps in the practices implemented in the case study.

A. The Common Ground Concept in the Software Engineering

The concept of the common ground in this study refers to the common ground in software engineering introduced by Ivar Jacobson [8]. He introduced the Essence kernel for software engineering. The common ground is developed by thinking that no software development method is appropriate for everyone. The power of the common ground is to provide a common framework for the team to understand the general concept of the software development methods. The common ground is employed for discussing, improving, comparing, and sharing software engineering methods and practices. This approach and inspiration of the common ground in software engineering are used in scaling Agile methods.

B. Scaling Agile Methods

The popular Agile methods, including Scrum [12] and Extreme Programming [13], work well for the small project team. When there is a need to scale up a project at the enterprise level, the complex situation is hard to handle [14]. Project Management Institute [7] categorizes Agile methods as the scaling approach and team method, as demonstrated in Fig. 2. Some thinkers, such as Dean Leffingwell and Scott Ambler, developed several enterprise Agile methods, namely Scaled Agile Framework [15] and Disciplined Agile Delivery [16]. There are no formal names for these methods. The literature declared them as enterprise Agile framework [11], scaling methods and approach [11], scaling framework [5], and scaling Agile methods [17]. The Scaled Agile Framework (SAFe), Large-Scaled Scrum (LeSS), Disciplined Agile Delivery (DAD), and Nexus are some of the popular scaling Agile methods and frameworks [5, 10].

Most scaling Agile methods exercise Scrum, Kanban, and Extreme Programming as part of their team methods. On the other hand, integrating Scrum and Kanban is employed based on the needs [18]. These methodologies offer flexibility and adaptability to different projects. For instance, Scrum provides a structured framework with defined roles and ceremonies. Kanban, on the other hand, is well-suited for projects that require continuous delivery. Research in [19, 20, 21, 22, 23] has been performed on this scaling approach for Agile implementation in organizations.

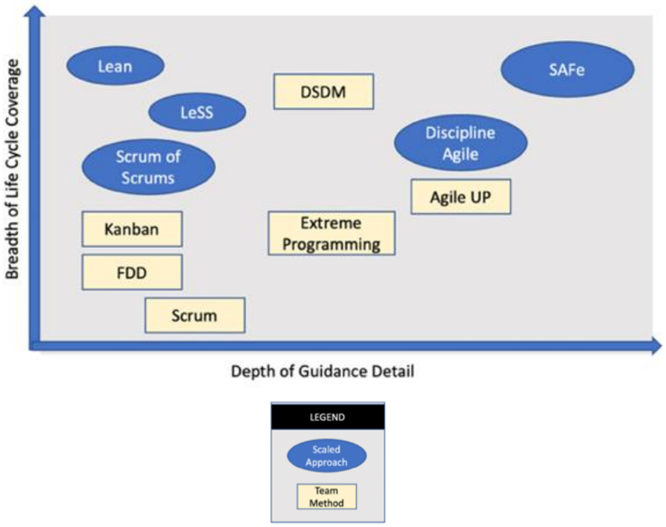


Fig. 2. Classification of agile based on scaling level [7].

C. The Essence – The SEMAT Kernel

The Essence is the standard of software engineering that provides a universal language for defining methods and practices [24]. It was established by the Object Management Group (OMG) [25] and received strong support from the Software Engineering Methods and Theory (SEMAT). The Essence was built based on solid theory, proven principles, and best practices. It consists of methods, practices, kernel, and Language. Fig. 3 depicts that methods comprise many practices. In this context, a practice is a repeatable approach to performing activities with a specific objective. The kernel elements are used to elucidate the practices, and these kernel elements are specified based on the Language.

SEMAT was developed with the purpose of addressing certain challenges within today's software engineering domain, characterized by the presence of immature implementation. These issues comprise the absence of a universally acknowledged theoretical foundation, the abundance of numerous methods and their variations, and the disconnect between industry practices and academic research.

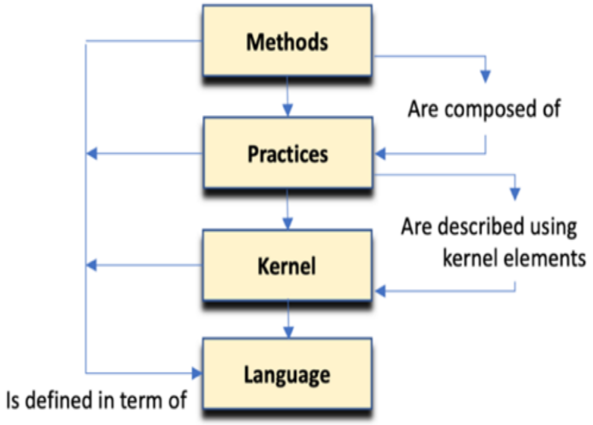

Fig. 3. The Essence method architecture [24].

The kernel contains three areas, including customer, solution, and endeavor. The Essence defines kernel Alphas as the things to work with. Within the customer domain, the team is required to comprehend stakeholders and potential opportunities. The team should address the requirements and software system concerns in the solution area. There are things to perform in the area of endeavor. They include work, team, and way of working.

D. *The Previous Studies*

Several studies compared the scaling Agile methods [16, 26], while there was another study [27] that made a method of selecting Agile methods in their project implementation. The study [17] tried to analyze the method differences and similarities for DAD, SAFe, LeSS, Spotify, Nexus, and RAGE, while [26] performed the comparison based on the underlying practices. This study differs from the previous studies, where this study develops the common ground based on the common ground of software engineering [8]. The common practices from [26] can be used in more detail for this research.

III. Research Method

Design Science Research (DSR) was employed as a research method for this study [28], as demonstrated in Fig. 4. The DSR methodology aims to solve the organization's problem by producing artifacts. The process begins with the identification problem, as discussed in Section I.

The next process defines the solution, design and development, demonstration, evaluation, and communication. This study aims to get the common ground from the current scaling Agile methods. The comprehensive literature review from current methods of scaling Agile methods was employed as the baseline for the basic common ground. The previous study performed the same [29, 30]. The Essence SEMAT kernel was the primary reference for developing the common ground [25].

We conducted this research using DSR as the comprehensive research method, from the initial stage of problem identification to the evaluation stage. Each phase of this DSR research is explained in its respective section. The research was conducted in the environment of one of the private banks in Indonesia, as described in Section V. We utilized data and information available at the case study location, including their current methodologies and practices. Research validation methods, as described in Section VI, were employed in this study, including internal and external validation through focus groups and interviews.

IV. Result and Discussions

This research provides an Agile development model based on the Essence of software engineering. This section is part of the process in the DSR that defines and develops artifacts. The model contains the common ground or shared understanding among the popular Agile and scaling Agile methods discussed in the previous section.

A. *An Essence-based Agile Method Development Model*

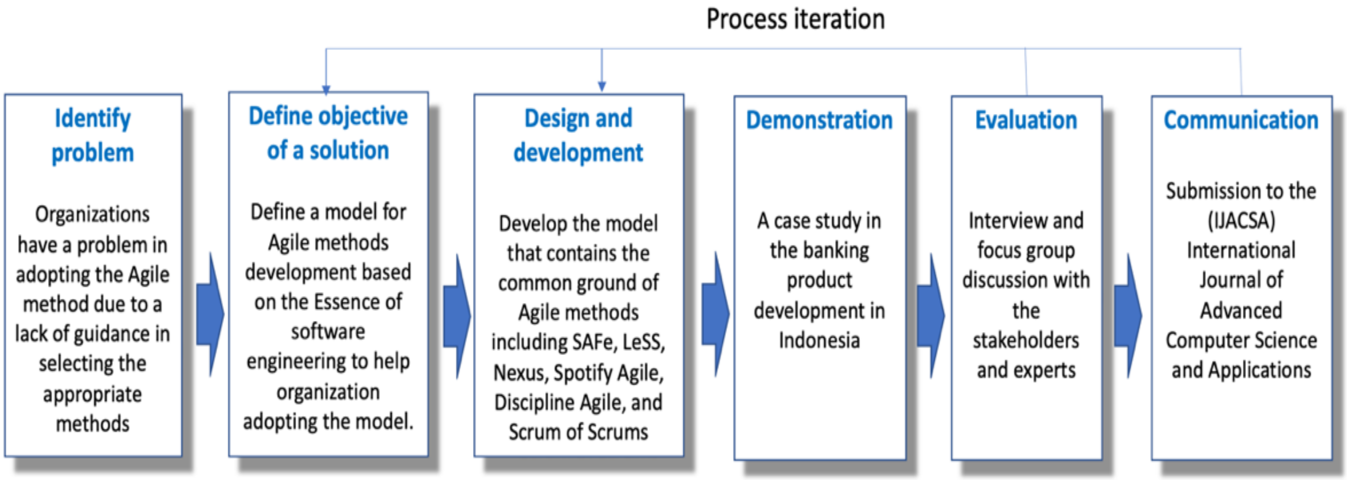
We develop a model for an Agile software development method based on the Essence in Fig. 5. The model was derived from the Essence methods architecture in Fig. 3. The organization can develop its own Agile methods based on the selected Agile practices. We emphasize the scope of the Agile methods using the scaling Agile methods, comprising the Agile team methods, such as Scrum, Kanban, and extreme programming. For example, the organization develops its practices by adopting the practices such as Scrum practice, Spotify practices for the organization, and Kanban for the workflow. They also can adopt the Scrum of Scrums practice for coordination. The organization can also implement some practices from Extreme Programming for pair programming and code ownership.

B. *The Common Ground of Scaling Agile Methods*

We establish a common ground for scaling Agile methods, as scaling Agile methods already include Agile methods at the team level, such as Scrum, Kanban, and Extreme Programming, which are widely used by organizations. This study proposed the common ground in Fig. 6, which is classified by principles, process, work product, organization, and implementation approach.

At the minimum level, the scaling Agile team only contains the Scrum and integration teams. LeSS, Nexus, Scrum of Scrum have similar project team structures with it. Nexus has the following roles: The Nexus Integration Team Member, Nexus Integration Team Scrum Master, Nexus Integration Team Product Owner, and Nexus Integration Team itself [31].

The common ground of scaling the Agile method contains the Agile practice. It refers to the level of Agile implementation [7]. Team Agile is the Agile practice and method at the team level, such as Scrum, XP, Kanban, FDD, and DSDM. Enterprise agility contains a larger Agile team in the organization collaboratively together to develop a single large product. On the other hand, business agility embraces an Agile mindset and principles that encompass all areas, extending beyond product development to encompass domains like personnel management, servant leadership, design of organization, and financial planning [13]. This study refers to the previous research and literature on the general practice of Agile [7, 32, 33, 34].



Process iteration
Identify problem
Organizations have a problem in adopting the Agile method due to a lack of guidance in selecting the appropriate methods
Define objective of a solution
Define a model for Agile methods development based on the Essence of software engineering to help organization adopting the model.
Design and development
Develop the model that contains the common ground of Agile methods including SAFe, LeSS, Nexus, Spotify Agile, Discipline Agile, and Scrum of Scrums
Demonstration
A case study in the banking product development in Indonesia
Evaluation
Interview and focus group discussion with the stakeholders and experts
Communication
Submission to the (IJACSA) International Journal of Advanced Computer Science and Applications

Fig. 4. The DSR's research methodology [28].

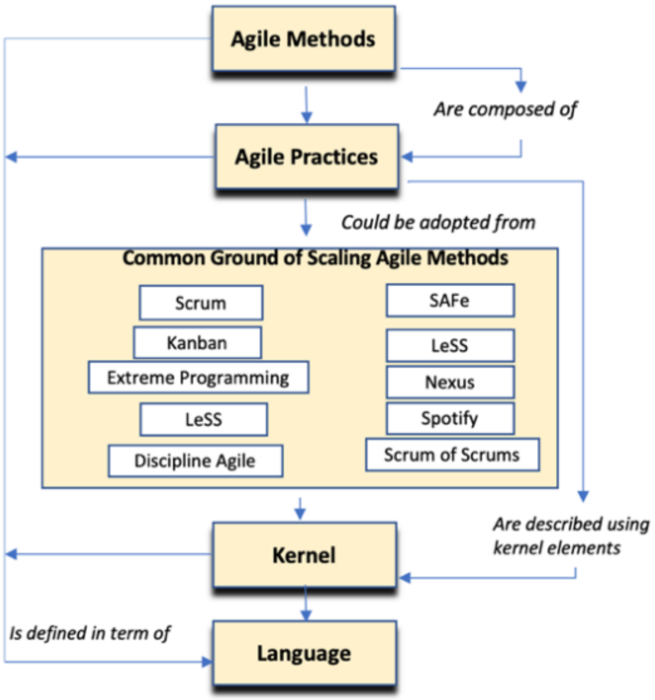


Fig. 5. The DSR's research methodology [28].

Table I summarizes the common ground for popular scaling Agile methods, SAFe, LeSS, DAD, Nexus, Spotify, and Scrum of Scrums. We classify the practices based on the common ground: principle, process, organization, work product, and implementation approach.

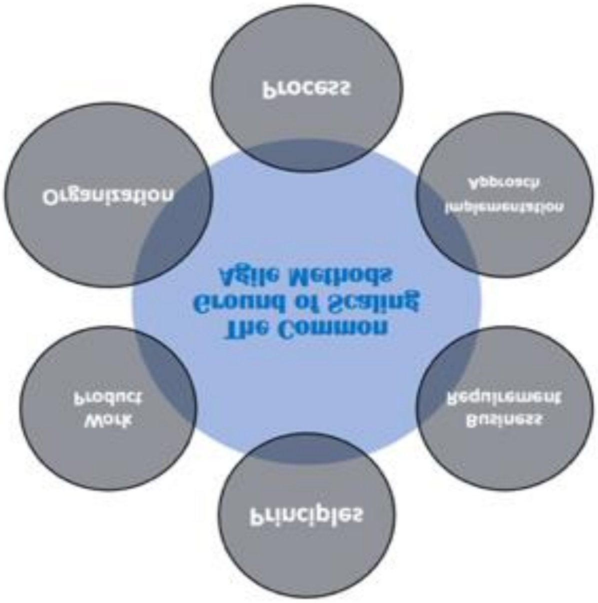

Fig. 6. The high level of the common ground scaling agile method.

C. The Guidance to use the Model

An organization can implement the Agile method using the guidance in Fig. 7 adopted from [35]. The model, built on current theories and practices, allows practitioners to enhance their work by adopting newer practices. The common ground is a guideline for selecting suitable scaling Agile tools and practices. It can also be expanded as needed for project implementation.

TABLE I. THE SUMMARY OF COMMON GROUND FOR SCALING AGILE METHODS

SAFe	LeSS	DAD	Nexus	Spotify	Scrum of Scrums
Principles All methods follow the Agile Manifesto for mindset, values, and principles. SAFe, LeSS, and DAD enhance Agile Manifesto to their methods based on the scaling Agile need. Other methods don't specifically define their principles.					
Mindset, values, principles	Principles	Principles	Follow the Agile manifesto and Scrum value	Follow the Agile manifesto	Follow the Agile manifesto and Scrum value
Process All methods have their process. They utilize Scrum for the Agile team. SAFe use Scrum, Kanban, DevOps, and XP. LeSS, Nexus, Spotify, and Scrum of Scrum mainly utilize Scrum for their methods. DAD utilizes Scrum but incorporates more Agile methods.					
Agile product delivery, enterprise solution delivery	The first method is for up to eight teams, and the second is for up to a few thousand people on one product.	Disciplined Agile Delivery as the bottom process, Disciplined DevOps, Disciplined Agile IT (DA, and Disciplined Agile Enterprise (DAE).	Following the Scrum framework with the integrated elements	Following the Scrum and enhancing the methods	Scrum, Scrum of Scrum
Organization Scrum, coordination, and support teams are the minimal team structure for scaling the Agile method. Each method has the predefined team structure					
Agile Team, Product and Solution team, and Business Owner. Agile team; Teams of Agile team: business, product management, hardware, software, quality, testing, compliance, operation, security. They operate within the context of Agile Release Train	LeSS Structure contains Teams, Scrum Master, Feature teams, organizing by customer value, organization structure, and communities.	Primary Roles: Team Lead, Product Owner, Team Member, Architectural Owner, Stakeholder. Supporting roles: Specialist, Independent Tester, Domain Expert, Technical Expert, Integrator.	Nexus roles: Nexus Integration Team, Product Owner in the Nexus Integration Team, Scrum Master in the Nexus Integration Team, Nexus Integration Team Members.	Squads, Chapters, Tribes, and Guilds.	Scrum of Scrum
Business Requirements and Work Product Each Agile team develops a single work product. The whole team produces the integrated work product.					
Program increment	Product backlog, Potentially Shippable Product Increment	Release solution	Product Backlog, Integrated Increment	Work product	Work product
Implementation approach The implementation scope starts from the single project up to the enterprise level.					
Essential SAFe, Large Solution, Portfolio, Full	LeSS, Less Huge	DAD as the bottom process, Disciplined DevOps, DAIT, and DAE.	Single product development	Single product development	Single product development

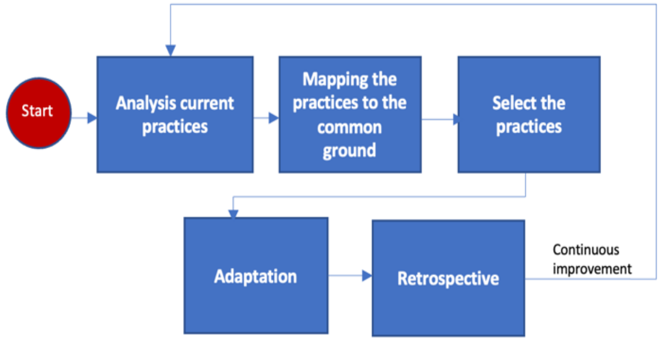

Fig. 7. The guidance for implementation.

V. CASE STUDY

The case study is a part of the demonstration process in the DSR. It was conducted at a national bank in Indonesia. It was actively engaged in a digital transformation initiative to develop a business ecosystem and a digital ecosystem framework based on digital technologies (refer to Table II). The project charter planning document expressed a desire for the application to drive an increase in the Current Account Saving Account (CASA) by USD 1.3 billion. However, despite observing a rise in transaction volume from 2020 to 2021, the cumulative transaction volume only amounted to USD 282,000 by July 2021. Consequently, this discrepancy posed a significant challenge as the target in CASA through application implementation was not attained.

TABLE II. ADOPTED PRACTICES FOR THE CASE STUDY

The Common Ground	Current Practices	Proposed Practice
Principles	- Currently, the company already has a procedure guide in the form of a Circular of Information Technology Workflow Procedures, which regulates the Agile methodology	- Apply and explore the principle of SAFe and LeSS for organizations (SAFe dan LeSS) - Spotify - squad, tribes, chapter, guild
Organization	Roles: Tribe Sponsor Product, Tribe Sponsor Technology, Tribe Leader Product, Tribe Leader Technology, Product Owner, Scrum Master, Programmer, Quality Control/Tester, Business Analyst, System Analyst, QA Analyst, Document Writer, Application Security Engineer, Manajemen Risiko, Operation Engineer, Subject Matter Expert (UI/UX), Subject Matter Expert (Data Analyst), Subject Matter Expert (Arsitektur IT)	- Adopted SAFe-scaled Agile principles (SAFe) - Implementing the role of a quad, tribes, chapter, and guild as a whole in the Agile process (Spotify) - Implementation of a team based on the Whole Team (XP)
Business Requirement	- Business Requirements are explained in the Product Roadmap activity - Development needs are stated in the Business Model Canvas (BMC) document - Furthermore, BMC is discussed in the Discovery Session activity	- Application of product backlog understanding to the entire team through Program Increment Planning (SAFe) - Adopt product backlog from Scrum, Sprint Planning, Definition of Ready, and Definition of Done - Using visualize tools
Process	- Currently, the scrum practice is not fully implemented, which is only sprints and scripts - Other scrum practices, such as sprint review and sprint retrospective, are not implemented	- The discipline of doing Daily Scrum - Implementation of sprint backlog activity, output backlog refinement - Adopt Joint Product-level Sprint Review and Joint Retrospective
Implementation Approach	- Project level, Tribe leader product, and tribe leader technology actively coordinate - Program level, The development team does not focus only on developing one application but parallel developing other applications - Business level, The business team doesn't focus on just one product developer	Adopt LeSS Practices - Implementation of a team-based organization - Cross-functional theme - Not implementing the "Resource-Allocation" phase

A. Analysis of Current Condition

From the interview analysis and source documents, the researchers focused on a root problem in Agile software development projects: the application of Agile practices that were not fully implemented. The organization needed to develop its practices to improve the software development delivery process. Current practices were not appropriately defined.

We adopted the Essence-based Agile Model (Fig. 5) and mapped its components. They included common ground, principles, organization, business requirements, process, work products, and implementation approach. For the principles, Agile provisions had not been fully implemented following the procedure guidelines. There were vital responsibilities, performance indicators, and authority on the Agile team which had not been implemented. There was an Agile implementation process that did not use supporting tools, namely Jira and/or Confluence. There were Scrum practices that were not implemented.

B. Proposed Practices

As per the Essence guidance to develop the team's methods, we selected the proper practices from the popular Agile methods, such as Scrum, SAFe, Nexus, and LeSS, for our methods. We mapped the nominated practices to the common ground component.

VI. EVALUATION

This section describes the model's validation process and the case study's implementation. It is part of the evaluation process in the DSR. The evaluation process was carried out on the practices proposed in the organization to ensure that these practices would be suitable for implementation in a methodology. The evaluation involved 16 internal and external stakeholders through a process of Focus Group Discussion (FGD) or interviews, as well as filling out questionnaires. The questionnaire used a Likert scale with five measurements: (1) Strongly Disagree (2) Disagree (3) Neutral (4) Agree (5) Strongly Agree.

A. Internal Evaluation
